PREFACE.

THE march of mechanical improvement, in the five years that have elapsed since the publication of the AMERICAN MECHANICAL DICTIONARY, renders it necessary to issue another volume, to keep the work abreast of the time.

The two great Exhibitions, at Philadelphia and Paris, — with each of which the author was officially connected as Delegate or Commissioner, and as a member of the respective juries, — have brought forward a world of new matter; and the records of our own Patent Office, as well as the testimony of our technical journals, bear witness to the fact that at no period has invention been more fertile, more brilliant, or more important.

The difficulty is not in filling a book, but in selecting the more important subjects to fill given bounds; and the lavish abundance of the material has been such that it has necessitated the introduction of a new feature into the work — that of copious references to the technical journals of the period 1876–1880, inclusive, — for fuller statement of the subject matters involved.

The author cherishes most confidently the belief that this feature will meet the approbation of readers and inquirers, and hopes that it may prove to the student in machinery, what William of Malmesbury said of a cognate subject, — the introduction of the Arabic [Indian] numerals into Europe by Gerbert of Auvergne, — "A great blessing to the sweating calculators."

EDWARD H. KNIGHT.

WASHINGTON, D. C., *June 1, 1881.*

POSTSCRIPT.

DR. KNIGHT, whose name is so honorably connected with the AMERICAN MECHANICAL DICTIONARY, did not live to see the final publication of this volume. He was engaged upon the final section when he was taken ill, and died January 22, 1883. It was found, after his death, that he had left the remainder of the work in such a forward state of preparation that the task of editing was confined chiefly to such arrangement of his material as would bring it into the order which Dr. Knight was following. While, therefore, the Publishers share with the patrons of the work the regret that its accomplished editor could not give the final touches to his Dictionary, they take satisfaction in knowing that the work was wholly his.

HOUGHTON, MIFFLIN AND COMPANY.

BOSTON, *November 1, 1883.*

LIST OF SPECIFIC INDEXES.

The Specific Indexes in the following List are to be found in their alphabetical places in the body of the work. Each Index embraces the technical appliances, etc., appertaining to its subject.

LIST OF FULL-PAGE PLATES.

KNIGHT'S NEW AMERICAN

MECHANICAL DICTIONARY.

[An asterisk (*) indicates that an article or description referred to is illustrated.]

A.

A-ba'ting. Properly, *bating*. A steeping process in tanning. See BATING.

A-bat-toir'. A city slaughter-house, where are assembled all the conveniences for butchering the animals and putting the offal into merchantable form. The plans usually involve humane, rapid operations and relatively cleanly and wholesome surroundings. See notices of the abattoirs of

Philadelphia . . . * "*Scientific American Sup.*," 1375.
Brighton. *Lawson* . . "*Scientific American Sup.*," 1939.

Ab'scess Knife. A pocket instrument with a curved blade, the edge on the concave, and contained in a tortoise-shell or ivory handle.

The abscess lancet is a pointed thumb lancet in tortoise-shell scales.

Ab-sor'bent Stra'ta Wa'ter-pow'er. An invention of M. G. Hanrian, of Meaux, France, for utilizing the descent of water in a tube leading from a water-bearing to an absorbent stratum as a source of power. The water passing downward in a vertical well-tube acts upon the buckets of an endless chain, which passes over a wheel above and rotates it.

The invention is described and illustrated in the "*Bulletin du Société d'Encouragement pour l'Industrie Nationale*," and is reproduced in "*Scientific American*," * xxxiv. 159.

Ab-sorb'ing Well. A well or deep pit sunk into an absorbent stratum, and used to carry off drainage.

These wells are used in certain localities in the United States where a retentive stratum of clay rests upon gravel or sand, as in Alexandria, Va., where the drainage of the town is mostly obtained in this way, by well or cesspools dug into the substratum.

Ab-sorp'ti-om'e-ter. An instrument invented by Bunsen for measuring the absorptive power of gases.

A-but'ment. (*Add.*) 7. (*Carpentry.*) The shoulder on a joiner's plane between which and the plane-bit the wedge is driven.

A-but'ment Crane. A crane mounted upon an abutment or pier, of a viaduct, for instance, and ascending with the elevation of the structure.

Figure 1 represents a small crane of this nature, used at the Viaduc de l'Indre. It was fixed on the piles, and then upon the masonry, being readily raised step by step as the structure advanced. In the instance cited two horses were attached to the rope by which the material was drawn up.

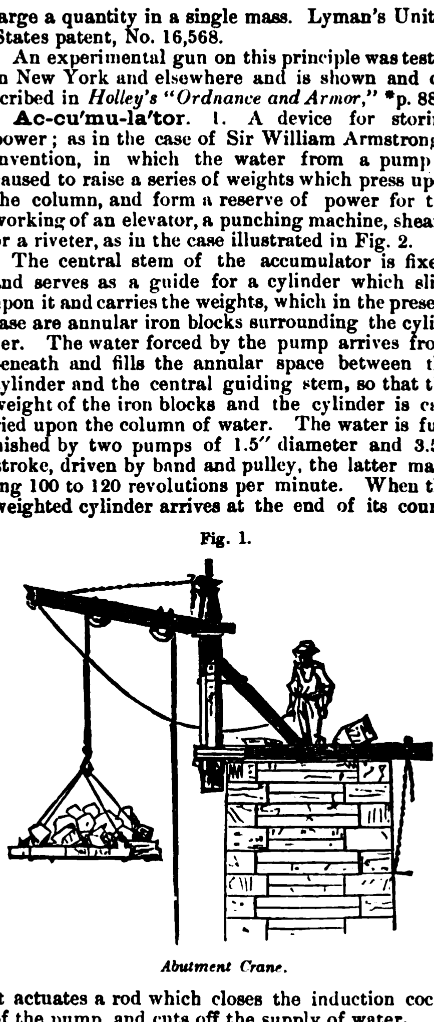
Ac-cel'er-a'tor. (*Ordnance.*) A cannon with additional charge chambers, exploded consecutively in the rear of the shot, in order to give the ball the additional force due to the consumption of a large charge without the strain incident to exploding too large a quantity in a single mass. Lyman's United States patent, No. 16,568.

An experimental gun on this principle was tested in New York and elsewhere and is shown and described in *Holley's "Ordnance and Armor,"* *p. 885.

Ac-cu'mu-la'tor. 1. A device for storing power; as in the case of Sir William Armstrong's invention, in which the water from a pump is caused to raise a series of weights which press upon the column, and form a reserve of power for the working of an elevator, a punching machine, shears, or a riveter, as in the case illustrated in Fig. 2.

The central stem of the accumulator is fixed, and serves as a guide for a cylinder which slips upon it and carries the weights, which in the present case are annular iron blocks surrounding the cylinder. The water forced by the pump arrives from beneath and fills the annular space between the cylinder and the central guiding stem, so that the weight of the iron blocks and the cylinder is carried upon the column of water. The water is furnished by two pumps of 1.5″ diameter and 3.5″ stroke, driven by band and pulley, the latter making 100 to 120 revolutions per minute. When the weighted cylinder arrives at the end of its course

Fig. 1.



Abutment Crane.

it actuates a rod which closes the induction cocks of the pump, and cuts off the supply of water.

The water from the accumulator enters the working cylinder of the riveting machine by one opening and leaves by another, each being provided with valves. A hand lever admits the water to make the effective stroke, the water exit being closed either by the pressure of water or by a spring. The induction valve remains open until the rivet is finished, or for any length of stroke required, as the case may be, and when it is desired to arrest the motion the induction valve is closed.

To make the reverse motion, the water-exit valve is opened by a motion of the hand lever in the contrary direction from that to admit the water; the water runs out of the cylinder, and the piston is driven backward by the action of a small cylinder placed in the piston and which is put in communication with the accumulator by a special pipe and valve.

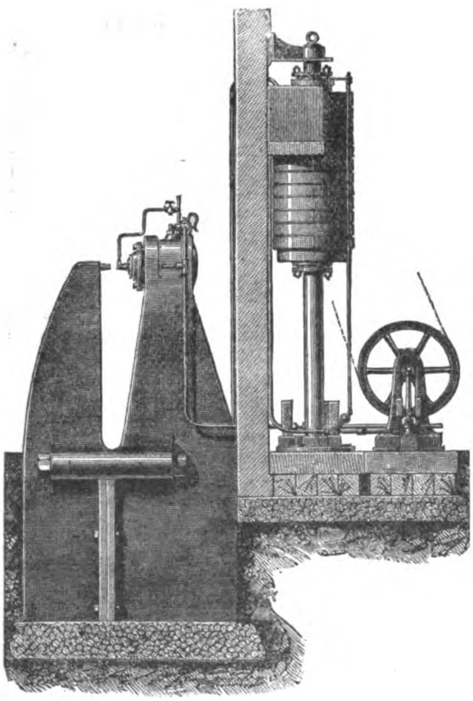
The machine is designed to place 900 to 1,000 rivets of 30 millimeters, in sheet iron of 20 millimeters, in 10 hours: and in smaller works to place 6 to 7 rivets per minute.

Machines in which the suspended swage cylinder is capable of presentation to rivet in any direction are noticed under RIVETING MACHINE, and one is shown in Fig. 4351, page 1949, "*Mech. Dict.*"

The weight-case accumulator is shown in Fig. 4, page 9, vol. i.

A hydraulic riveting machine, with two movable jaws, but without accumulator, is shown in Fig. 4354, page 1949, "*Mech. Dict.*"

Fig. 2.



Sir William Armstrong's Accumulator as applied to a Riveting Machine.

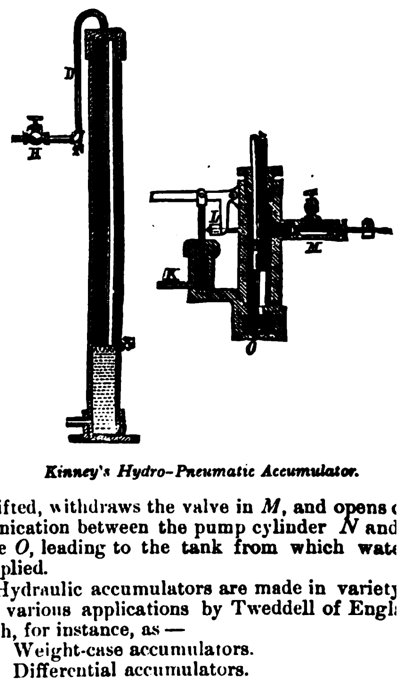
In Kinney's hydro-pneumatic accumulator, compressed air is made the reservoir of power. Like other familiar applications of the accumulator it is designed to be used in connection with the hydraulic press, but the pumps force water into and compress air in vertical cylinders. The pumps work continuously until a stated pressure is attained, when, by automatic mechanism, valves are opened which prevent any further delivery; the pumps merely working the water to and fro till a remission of pressure by the use of some of stored force puts them in service again.

A number of these vertical cylinders are (nected in series by pipes above (*D H*) and belov as to have communication, by which the pressur them is equalized, and for use in charging tl with air at the desired normal tension. See v of a battery of accumulators, page 121, vol. xxx\ "*Sc. American.*"

The cut shows a section of one of the accum tors, and a sectional view of the apparatus for : dering the pump ineffective when the maxin stated pressure is attained.

Proceeding from the gage pipe is a tube *K*, (necting with a small chamber, in which is a plu with a weighted lever whose arm *L*, when the l

Fig. 3.



Kinney's Hydro-Pneumatic Accumulator.

is lifted, withdraws the valve in *M*, and opens (munication between the pump cylinder *N* and pipe *O*, leading to the tank from which wat supplied.

Hydraulic accumulators are made in variety der various applications by Tweddell of Engl such, for instance, as —

Weight-case accumulators.
Differential accumulators.
Basement accumulators.

Morane, of Paris, makes them specifically fo stearine and other chemical industries.

Sellers & Co., of Philadelphia, for riveting chines, etc.

An excellent and compact arrangement is sl in figures 8, 9, 10, 11, article "Presse," Prof. (Laboulaye's "*Dictionnaire des Arts et Manufactu* edition of 1877.

The portable hydraulic accumulator used in works at the St. Gothard tunnel consisted of a tical cylinder, in which a piston traveled, and w had to be loaded to a weight equivalent to 450 per square inch. When the lift was not in o tion, the piston was raised to an extent proporti to the quantity of water introduced, which i turned to the lift when the ingress cock of the l was opened. The diameter of the piston was 11 diameter, and the stroke was 66.93″. The vol of water contained was 26.2 gallons, and the sure on the piston 21.18 tons; the piston and c head weighed 1.18 tons. A load of 20 tons of ingots was suspended to the cross-head at the t the piston. These could be removed at will t cilitate the moving of the apparatus from place to place on the works.

Views of the accumulator and the hydraulic pumps are reproduced in the "*Scientific American Supplement*," * pages 104, 105.

2. (*Electricity.*) *a.* In dynamo-electric machines, one in which the residual magnetism of the field magnets generates in the armature coil a feeble initial current which increases the magnetism of the field of force magnets, thus producing a stronger current, and so on reciprocally to the maximum.

The first patent in which this feature is present is S. Hjorth's English patent No. 2,198, October 14, 1854. The Dane is evidently entitled to the credit of the invention of this most important feature in dynamo-electric machines.

"This principle, of which we discover the application in almost all dynamo-electric machines, is that of the gradual successive increase of power in an electro-magnetic system under the influence of the currents of induction which it develops. It is sufficient for the purpose that a trace of magnetism remains in the armature to produce the amerçage and augmentation of the strength of the armature until the maximum is reached, dependent upon the strength, the resistance of the circuit, and the saturation of the armatures." — "*La Lumière Electrique.*"

The presentation of the memoirs of Wheatstone and Siemens on this subject at the Royal Society Meeting, February 4, 1867, was more than 12 years subsequent to the patent of S. Hjorth, of Copenhagen. See DYNAMO-ELECTRIC MACHINE.

b. See SECONDARY BATTERY. *Faure.*

3. A resilient section, in a chain or rope, usually a drum of caoutchouc, used in British dredge-lines; whereby a certain amount of elasticity is given to the towing rope, preventing the parting of the rope, and giving the man on watch a chance to cast-off, to prevent losing the dredge, which has become fouled or full.

Beardslee's method is to have a certain amount of slack rope held in reserve by a check rope, which breaks when a given strain is brought upon the main rope. See CHECK-ROPE.

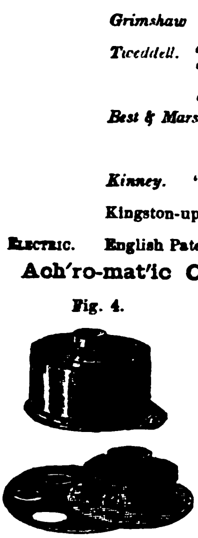
ELECTRIC. English Patent. No. 2198, October 14, 1854.

Ach'ro-mat'ic Con-den'ser. (*Optics.*) An attachment to the microscope, used when the light from the concave mirror proves insufficient for any object requiring an intense transmitted light. The condenser slides, by its tube, into the fitting under the stage of the instrument, in which it has to be moved up or down until the focus of its lenses falls upon the object, the light having been previously reflected in the proper direction by the mirror.

Fig. 4.



Achromatic Condenser.

The upper figure shows a simple form; the lower is Webster's form of Crouch's achromatic condenser, provided with a revolving diaphragm having various forms of apertures.

Ach'ro-mat'ic Right'-an'gle Prism. An achromatic form of the right-angle prism, which is an attachment to the microscope designed for throwing rays of light at right-angles, giving more perfect reflection. See RIGHT-ANGLE PRISM.

Ac'id Pump. A pump constructed for drawing off corrosive liquids, emptying carboys, etc.

It is a portable pump, made of glass, and convertible into a siphon by the addition of an extension tube of caoutchouc to the nozzle. A large India-rubber air-bulb produces the vacuum and expulsion, but does not receive any of the liquid. The valves are glass poppets, riveted, while hot, into their seats. The joints in the pump are of accurately ground glass. The nozzle is also so jointed as to be flexible.

See *Nichols'* pump. "*Scientific American*," * xliii. 232.

Also the air-forcing pump of Wyllie, of Hebburn-on-Tyne, England, used for pumping acid to cisterns at a height of 80'. The air-pressure registers from 70 to 100 lbs.

"*Engineering*," 1876.
"*Scientific American Supplement*," * 524.

A'cier-age. A mode of coating a metallic plate with a surface of iron or steel; used to enable stereotype and copper plates to print a larger number of impressions. Invented by Garnier of Paris. See *Photographic Journal*, vol. vi., p. 31 *et seq.*, September 15, 1859.

A'corn-head'ed Bolt. A carriage-bolt with an ornamental head finished in silver, oroide, or gold, and in shape resembling an acorn.

A-cou'me-ter. (*Surgical.*) An instrument for measuring the degree of hearing. *Acoumeter, Acoëmeter, Acousimeter.*

The instrument affords a source of sound of constant intensity and pitch, and is a substitute for the whisper and the watch, each of which has its difficulties. The voice is a complicated sound, the intensity of which it is difficult to regulate, and consonant sounds vary greatly in their audibility at given intensity. The watch has two tones with slight intensity, both audible when close, and but one at a greater distance.

The first acoumeter was made by Schafhäutl, who made use of a ball falling from a certain height as a source of sound. Wolke invented a pendulum acoumeter. He employed an upright sounding-board of fir, against which an oaken mallet was allowed to fall through a given space. Itard had a freely suspended copper ring which was struck by a pendulous metallic ball. The elevation of the pendulum was measured on a graduated quadrant, and the intensity of the tone thereby determined.

Politzer's acoumeter gives a sound of unvarying character, and the estimate of the degree of hearing of the patient is obtained by making the clicks of the instrument more or less remote from the ear. It consists of a steel cylinder 4 millimeters in diameter and 28 millimeters long, set in vibration by the blow of a small steel hammer, and applied in the vicinity of the external ear. The cylinder is fastened to a small column of vulcanite, the hammer being freely suspended from a slot in this column by means of a pin. The tail end of the hammer shaft, projecting behind and beyond the column can be depressed to a certain point, and, when liberated, allows the hammer to strike the cylinder from a certain height, thereby insuring a certain intensity of tone. Half rings being fastened at either end of the vulcanite column, the instrument may be held between the thumb and forefinger, the middle finger being free to set the hammer in motion.

Fig. 5.

Politzer's Acoumeter.

A small disk is fastened to the column by means of a pin, and is used for testing perception for tone conduction from the mastoid. The illustration shows this application of the instrument.

The determination of the hearing distance is usually conducted by approaching the instrument to the ear until the patient announces that he begins to hear its tone, and it is well to require him to count the number of blows.

"*Archives of Ophthalmology and Otology,*" vi., 603 *et seq.*

A'cou-sim'e-ter. A synonym for acoumeter. *Itard.* See ACOUMETER.

A-cous'tic Tel'e-graph. One which transmits sonorous vibrations. The articulating telegraph known as a telephone, is at present the acme of the art. The United States patent of Lancelot H. Everitt, of New Orleans, dated March 24, 1868, and No. 75,886, is a curious item in the history of the art. See, also, his patent No. 40,616, dated November 17, 1863. The summation states that "sounds produced at one end of the telegraph are transmitted to the other end along a wire."

The first claim (of four) may be inserted (Patent of 1868): —

"*Claim.* — 1. An acoustic battery for telegraphing, a machine which creates and modulates sounds, that, when arranged and sounded under symbolic formulæ, they are made to represent and express all the letters of the English alphabet and all Arabic notations, and when thus evoked into existence the machine reflects these sounds and transmits them through naked wire, buried in the land or water, to their destination, where they impart their various interpretations with such distinctness and order to the auditor who receives them as to become the most important and efficient commissioners of intelligence."

Ac'ti-nom'e-ter. An instrument for measuring the power of the sun's rays.

Herschel's actinometer (described on page 11, "*Mech. Dict.*"), consisted in a small open receptacle, attached to a fixed standard.

Pouillet's pyrheliometer (described and illustrated on p. 1837, "*Mech. Dict.*") was of polished silver. The vessel exposed to the solar rays contained 100 grams of water, was 100 millimeters in diameter, and 15 millimeters in thickness. It was covered on the exterior with lampblack. This instrument could not, however, be used in winter when the temperature fell below 32° Fah.

To avoid the various defects of the instrument and to obtain exact measurement of the intensity of solar heat, Capt. John Ericsson invented the actinometer, or solar calorimeter. The instrument is fixed on a movable table within a rotary observatory. It consists of a copper receptacle, filled with water, and covered with lampblack on the exterior exposed to the sun. A thermometer placed in the liquid indicates variations of temperature, and an agitator, moved by a belt passing over a little pulley, keeps the water in motion and insures its equable temperature. The water-vessel is placed in the bottom of a chamber, the flaring mouth of which receives a plano-convex lens whereby the rays are concentrated upon the calorimeter. In this chamber as nearly a perfect vacuum as is possible is maintained, and a water jacket is provided so that the interior temperature may be constant.

See "*Scientific American Supplement,*" * p. 1103, where is also shown a modified form of instrument, also by Ericsson, for obtaining the measure of the intensity of the solar radiation at a given moment.

An apparatus to measure and record the variations of daylight throughout the day, has been invented by Herr Kreusler, of Bonn.

The apparatus has a special bearing upon plant physiology, and consists of a drum, fixed with its axis in the plane of the meridian, and adjustable so as to be at right angles to the sun's rays. This drum has its border divided into 24 hours, — 12 noon and 12 midnight being in the meridian plane. A strip of paper, sensitized with solution of bichromate of potassium, and having divisions which correspond to those on the drum, is placed round this. A second drum closely surrounds the first, and is turned by clock-work (from which it can be detached) once in 24 hours, in the direction of the sun's apparent course. The second drum has a slit for admitting light to the paper; its width is such that any point on the paper is exposed 20 seconds as the slit passes over. The whole apparatus is placed in the open air under a glass bell jar. The paper strip is placed in its right position at night or under artificial shade (to avoid coloration), and the outer drum slid over and so attached to the rotating axis that the "insolation slit" is opposite the hour then present. The slit then begins to move round the inner drum correspondingly to the sun's course. The impressed slip, when removed in the evening, may be *fixed* by dipping in water and drying between blotting paper, and shows a mostly continuous succession of bands of various shades of brown. For comparison, Herr Kreusler made a scale of 10 degrees of darkening, exposing strips of the paper a given time under different angles of incidence of light. Bands of the experimental strip that appear homogeneous are then measured with reference to breadth and intensity, and the sum of the products of those quantities is taken as a measure of the action of light rays falling on the instrument in a given time.

Ac'tion. (*Fire-arms.*) Used generally, in reference to the position or some characteristic of the firing mechanism; as *side action, snap action,* etc.

Specifically — the iron body which lies between the barrels and the stock.

Back action when the locks are bedded into the stock alone.

Bar action when the locks are bedded partly into the stock and partly into the action. Also called *fore* action.

Ac'tu-al Cau'te-ry. The application of actual heat, as of the searing iron or galvanic wire, for searing or excision, as distinct from moxas or caustics. The latter are included under the terms *potential* or *virtual* cautery. See CAUTERY.

Ac'u-press'ure Pin. A needle for arresting surgical hemorrhage by insertion and torsion.

Fig. 114*b*, p. 38, Part I., * *Tiemann's "Armamentarium Chirurgicum."*

A'cus. A needle. The term is especially used in reference to surgical needles. A number are mentioned on p. 12, "*Mech. Dict.*" To these may be added the

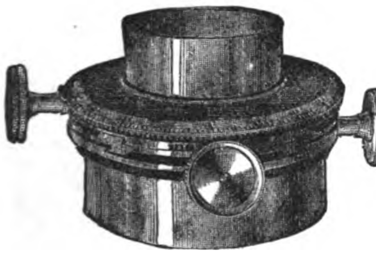
> *Acus capitata* — a pin ;
> *Acus invaginata ;*
> *Acus paracentica*, or *acus paracentelica ;*

synonyms for the *a. triquetra.*

See also ACUPUNCTURATOR ; DERMOPATHIC INSTRUMENTS ; HYPODERMIC SYRINGE, etc., "*Mech. Dict.*"

A-dapt'er. 1. (*Optics*). *a.* An attachment to the microscope for centering or throwing out of center the illuminating apparatus ; it is moved by rack and pinion. In the form shown it is specially contrived for Beck's "International" microscope.

Fig. 6.



Adapter.

b. In the case of object glasses made by different makers, and having different screws, a means for enabling such to be fitted to a body not specially adapted to receive them.

c. An arrangement on a stand to facilitate the use of the object-glass as a condenser.

2. In physical and chemical apparatus, a tube of varying sized ends for uniting apparatus of different sizes. Made of glass or rubber.

Add'ing Pen'cil. A small pencil-shaped adding device or arithmometer, usually having a metallic case and longitudinal slot with graduations and a traveling pointer, and a numbered disk.

Smith & Potts, * "*Sc. American Sup.*," page 542.
* "*Scientific American*," xxxv. 86.
October 21, 1876.
Leuner, Ger., * ('*Deutsche Gewerbe Zeitung*," reproduced in "*Sc. Am. Supplement*," * pp. 2701-2.
Pascal's Adding Machine, "*Sc. Am. Supplement*," p. 742.

Ad'it. (*Mining.*) A level. A horizontal drift or passage from the surface into a mine.

The Joseph II. mining adit, at Schemnitz, Hungary, begun in 1782, was finished October, 1878. Its length is 16,538 meters, a little over $10\frac{1}{4}$ miles; that of the St. Gothard tunnel being 14,920, and the Mont Cenis tunnel 12,233 meters.

The object of the adit is the drainage of the important gold and silver mines at Schemnitz. It furnishes a geological section more than ten miles in length, and gives not only valuable information as to the downward prolongation of the lodes known in the upper levels, but some new ones have been traversed, and the entire series of rocks, with their mutual limits as well as modifications and occasional transitions, are disclosed without interruption.

The entire cost of the tunnel was 4,599,000 florins, — about $2,300,000. Its height is 3 meters ; width, 1.6 meter. By the methods of working employed during the last three years it would have taken but 27 years to do the entire work.

"There are 19 shafts at Pribram, which are connected at various levels. The deepest is at Adalbert, which has reached the depth of 1,020.1 meters and has thirty levels. It is the deepest perpendicular shaft in the world. At the thousand-meter level a station for magnetic observations is established. The underground workings also communicate with one another through the great drainage tunnel "Joseph II.," which is 21,906 meters long. All the water of the mines is raised to the level of this tunnel, which is 445 meters above sea-level. The total length of the galleries is 245,089 meters." — *Prof. James D. Hague*, "*Report on Mining Industries*," "*Paris Exposition Reports*," iv. 297.

The length in excess of the former statement is due to the inclusion of some branch adits.

The Rothschonberger water-adit at the Freiberg mines was completed in 1877. It conducts the water of the mines to the Elbe. The tunnel is ventilated by eight air-shafts, and lies about 400 feet below the deepest previous Freiberger water-adit. It has a uniform height of 9.84 feet, with a somewhat smaller breadth. The present length of the adit with its ramifications is 43,000 meters (all of which length is now in use), and will be when completed over 51,000 meters, or $31\frac{1}{2}$ miles. The cost of the tunnel is estimated at 12,000,000 marks or $4,000,000, and will be paid for by a tax on all the mines which it directly benefits. The gradient of the floor is only 0.03m. in 100 meters.

Ad-just'a-ble-Beam' Plow. One which has a beam adjustable on a pivot upon the standard so as to throw the nose of the beam in or out of land, to adapt the implement to two or to three horses.

In one instance the beam has a pivotal connection above the standard, its rear end being adjustably attached to a heavy rod that connects the handles. The beam has what may fairly be called a *center connection*, the pivotal point being *in the middle of the work*, or center of resistance.

Ad-just'a-ble-bed' Press. A stamping, cutting or drawing press, for sheet-metal work, which can be set with level or inclined bed, to suit the requirements of special work ; notably, the making sheet-metal pans, box covers and bottoms, and similar ware.

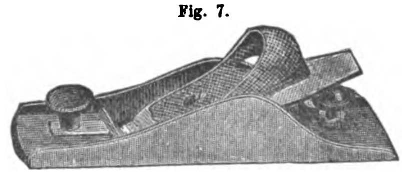
Ad-just'a-ble Plane. A joiner's plane, so arranged that the angle of the bit relative to the bed is adjustable to suit the kind of wood being worked.

The angle of the bit varies with the work : the harder the wood the steeper should be the pitch ; which may vary from 43° to 60° ; indeed, if the spokeshave be included, it may be said from 25° to 60°. The usual angle of the ground plane-iron is a bevel of 25° ; in the spokeshave the usual *back* of the bit becomes the *bed*.

The pitch of planes is considered under PITCH, 6, *Planes*, p. 1793, "*Mech. Dict.*"

See, also, *Holtzapffel's* "*Turning and Mechanical Manipulation*," vol. ii.

Fig. 7.



Adjustable Plane.

Ad-just'a-ble Vise. One the jaws of which may be inclined, being pivoted on the horizontal axis, so as to secure any desired presentation of the work.

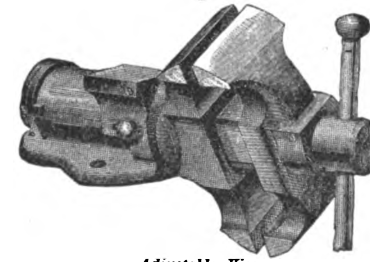
Fig. 8 shows a form of vise, the jaws of which maintain their parallelism, and are concertedly adjustable in a vertical circle to give an inclined presentation, or to bring either of the respective pairs of jaws into position for work.

Ad-jus'ter. (*Surgical.*) An instrument for bringing into coaptation the parts in case of ruptured perineum.

Dr. Agnew's, Fig. 537, p. 115, Part III., *Tiemann's "Armamentarium Chirurgicum,"*

Ad-just'ing Cone. An oculist's instrument for measuring the distance between the axes of the eyes.

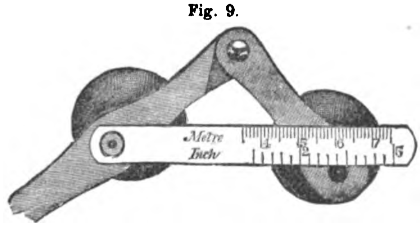
Fig. 8.



Adjustable Vise.

The instrument is shown in Fig. 9. Being held in the right hand, a distant object should be looked at with the right eye through the hole in the right hand cone; the other cone, fixed to an adjusting

Fig. 9.



Adjusting Cone.

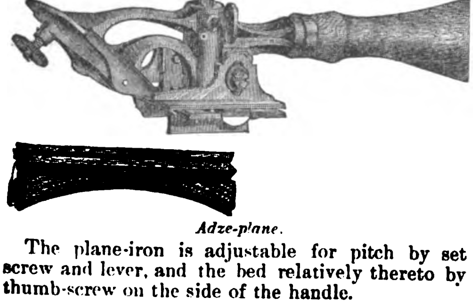
arm, should then be moved backwards and forwards until the left eye sees the same object through the aperture in the left cone, and the two holes appear as one. The distance between the eyes is then indicated on the cross bar, one side of which is divided to inches and tenths, the other to millimeters.

Adze. A wood-cutting tool used with a sweeping blow, and with a blade at right angles to the length of the handle.

Some memoranda of history and principles are given on pp. 16, 17, "*Mech. Dict.*" Fig. 10 shows strictly modern varieties of American patterns.

Adze-plane. A rabbeting and molding tool, especially adapted to solid paneling and used by coach and pattern makers. It has gage adjustments for depth and width of cut and for sweep in circular or crooked work.

Fig. 11.



Adze-plane.

The plane-iron is adjustable for pitch by set screw and lever, and the bed relatively thereto by thumb-screw on the side of the handle.

Fig. 10.

4. Railroad pattern.	10. Stirrup pattern.
5. Round eye pattern.	11. Special pattern.
6. Ship carpenter's pattern.	12. Special pattern.

The small slotted arms attached to the sid the adjustable fulcrum are gages for depth, a slotted piece on the bottom regulates horiz distance from a guiding edge.

The cut shows an adze-plane and specime work.

The tool is perhaps well named as partakii the characteristics of the adze and plane ; b is also nearly related to the spokeshave, th handled in a different manner.

A'er-a-ted Bat'ter-y. (*Electricity.*) O which the exciting liquid is constantly agitate air injected into the bath in order to depolariz negative element.

Byrne, * "*Scientific American Sup.*," Fig. 36, page 252 * "*Telegr. Jour.*," vi. 222, 269, particularly us galvano-cautery.

Air as a depolarizer in a single fluid cell is f in *Pulvermacher's* battery, "*Teleg. Jour.*," vi. 3

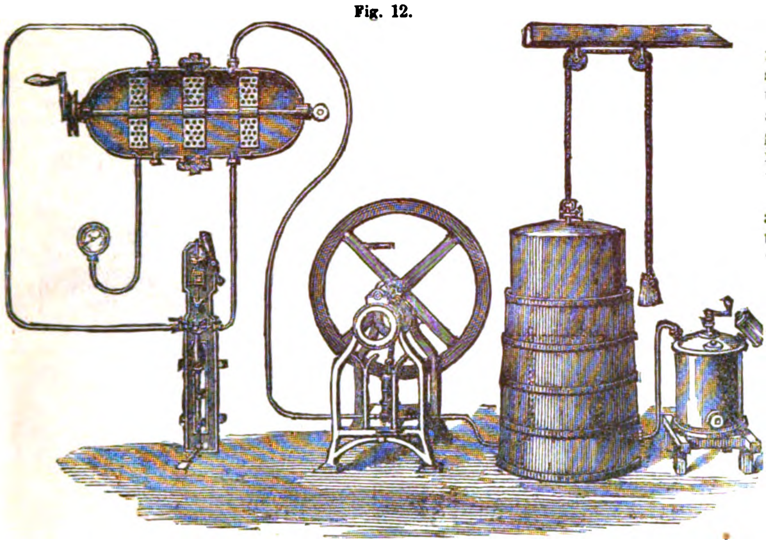
A'er-a-ted Wa'ter Ma-chin'er-y. Var ly known as "Soda-water apparatus," or "Ma ery for making carbonated waters," the latter l the preferable title.

The subject has been considered under the mer title on pp. 18–20 and 2236, 2237, "M *Dict.*" Some improvements will be noticed u CARBONATED WATER MACHINERY (which and certain specific heads.

Hayward, Tyler & Co.'s (British) aërated v machinery, shown at the Paris Exposition, 18 described in "*Engineering*," * xxvi. 287, 288, 349–352.

The principle of an apparatus intended for i ing sparkling liquids, such as sparkling wines, c ginger-ale, etc., is readily seen in Fig. 12, whi a hand-worked apparatus capable of produ

Fig. 12.



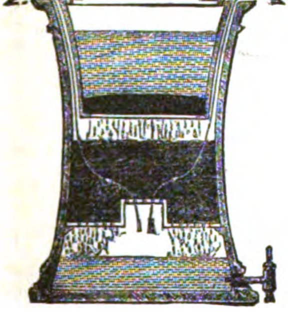
Non-continuous Aërating Machine.

sixty dozen quart bottles per day. It is on the non-continuous principle, the agitator chamber on the left being charged from time to time with the liquid. This is charged by means of the gas-pump, which receives the carbonic acid from the gas-holder, and that in turn from the generator on the extreme right.

The wine or other liquor to be charged with carbonic acid gas is poured through the gun-metal cap on top, into the cylinder, which should be filled about three-fourths full; the gas is then drawn from the gasometer by the gas pump, and forced into the cylinder containing the wine; when the indicator shows the requisite pressure, the working of the pump is stopped, and the agitator in the cylinder turned a few times, which will cause the wine or other liquor to take up the gas; a further quantity of gas is then supplied by means of the pump, and the gas must be renewed as the liquor is drawn off into the bottles.

The bottling apparatus, shown beneath the cylinder, has two cocks fitted into the cone or carriage, through which the cork is driven; one is for supplying the liquor from the bottom of the cylinder, the other takes the surplus gas and foam or froth; it is connected by a pipe to the top of the cylinder, and by this means none of the liquor or gas is wasted.

Fig. 13.



British Aërating Filter.

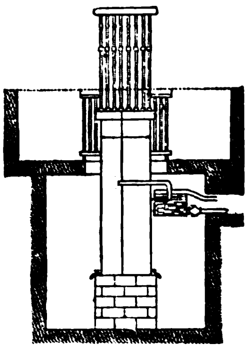
A'er-a-ting Fil'ter. One in which a current of air is conducted through the descending water.

That made by the Sanitary Engineering Co., of London, is of earthenware (Fig. 13). The upper chamber has a movable pan with a block of mineral carbon. The lower has granulated carbon. The water chamber beneath being closed, the descent of water displaces the air, which ascends through the granulated material in contact with the water.

A'er-a'tor. The apparatus for aërating the water for the fish-tanks at the Aquarium of the Trocadéro, shown in Paris, is the invention of M. Gauckler, who was also the author of the original plan of the aquarium. See AQUARIUM.

The water is that of the Vanne aqueduct, and as it is obtained very near the source of the river it is deficient in oxygen, which is essential to the life of the fish, and is supplied by the apparatus shown in Fig. 14. It is placed in the center of the system of tanks in the aquarium, and consists of an application of the principle of the Catalan trumpet (*trompe*) used to operate the bellows in the iron smelting furnaces of Spain, Elba, and elsewhere. It has a number of glass tubes into which water is forced by hydraulic pressure, carrying with it bubbles of air.

Fig. 14.



Gauckler's Apparatus for Aërating the Water of the Trocadéro Aquarium. (*Vertical Section.*)

Apparatus for aërating distilled water on board ship, belongs under DISTILLING APPARATUS.

A-e'ri-al Light Ap'-pa-ra'tus. A balloon, kite, or parachute light, used, in a military sense, for discovering the position, etc., of an enemy's camp at night. As used in recent experiments at Chatham, Britain, it consists of a kite covered with loose canvas, having a parachute provided with an arrangement for exploding the fire-balls which are sent up the line holding the kite. The fire-balls being thus discharged, illuminate the surrounding country for a considerable distance.

A-e'ri-al Pho'to-graph'ic Ap'pa-ra'tus. An apparatus for taking negatives from elevated positions. The camera is supported by a balloon steadied by guys, and the slides operated by cords from the ground. It is especially designed for mapping out an enemy's position, reconnoitering, etc. — "*Photographic News.*"

A-e'ri-al Te-leg'ra-phy. (*Electricity.*) A method of telegraphing between points, dispensing with wires, and using the aërial currents. The current is reached by flying kites to a certain height at each point, the strings being copper wires connected to instruments at the ground ends of the wire. Professor Loomis states that messages have been thus sent by him between points twelve miles apart, using the atmospheric currents only in the interval between the kites.

A'e-ro-hy'dric Blow'pipe. A blow-pipe for burning a mixture of hydrogen and air, giving an intense heat, and used for various metallurgic works, such, for instance, as soldering platinum with gold, the brazing of copper, and the autogenous soldering of lead, without the use of an alloy of tin. The latter use is especially called for in the production of leaden vessels to be used in the making of sulphuric acid. One form of the apparatus is shown in Fig. 738, p. 309, "*Mech. Dict.*" The compound blow-pipe is the invention of Dr. Hare, of Philadelphia; he used the combination of oxygen and hydrogen. The aëro-hydric was invented by the Count de Richmont, of France. It is elaborately shown in Figs. 395–398, article "CHALUMEAU," *Laboulaye's* "*Dictionnaire des Arts et Sciences*," vol. i., edition of 1877.

A'er-o-phone. 1. An invention of Edison for amplifying sound.

Its object is to increase the loudness of spoken words without impairing the distinctness of the articulation. The working of the instrument is as follows: —

The magnified sound proceeds from a large diaphragm, which is vibrated by steam or compressed air. The source of power is controlled by the motion of a second diaphragm vibrating under the influence of the sound to be magnified.

There are three distinct parts to the instrument:

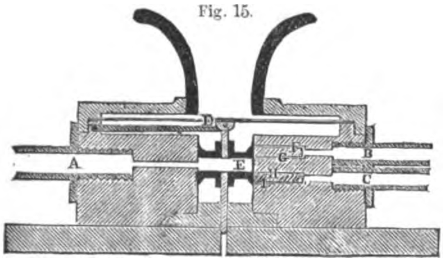
A source of power.

An instrument to control the power.

A diaphragm vibrating under the influence of the power.

The first of these is usually compressed air, supplied under constant pressure from a tank.

Fig. 15.



Edison's Aërophone.

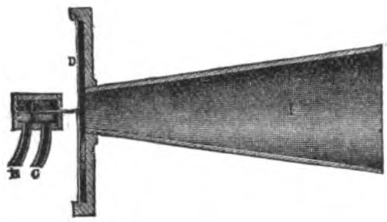
The instrument is shown in section in Fig. 15, and consists of a diaphragm and mouth-piece similar to those of a telephone. A hollow cylinder is attached by a rod to the center of the diaphragm. The cylinder and its chamber, E, will therefore vibrate with the diaphragm. A downward movement lets the chamber communicate with the outlet H, an upward movement with the outlet G. The compressed air enters at A and fills the chamber, which in its normal position has no outlet. Every downward vibration of the diaphragm will thus condense the air in the pipe C, at the same time allowing the air in B to escape *viâ* F. An upward movement condenses the air in B, but opens I.

The diaphragm D is shown in section in Fig. 16. Its center is attached by a rod to a piston, P, moving in a cylinder. The pipes C and B are continuations of those designated by the same letters in the preceding figure.

The pipe C communicates with one chamber of the cylinder, and B with the other. The piston, moving under the influence of the compressed air, moves also the diaphragm, its vibrations being in number and duration identical with those of the diaphragm in the mouth-piece.

The loudness of the sound emitted through the directing tube F is dependent on the size of the diaphragm and the power which moves it. The former

Fig. 16.



Aërophone.

of them is made very large, and the latter can be increased to many hundred pounds pressure. — *G. B. Prescott.*

"*Engineer*," * xlvi., 425, Figs. 32, 33.

2. An invention of Edison's, better known as a *megaphone*. It consists of a horn for talking, and a pair of horns communicating by elastic tubes with the ear, for listening. See MEGAPHONE.

An apparatus by Prof. Mayer for ascertaining the direction of sound is known as a *topophone*, and may be referred to in this connection. See TOPOPHONE.

A'er-o-phore. A respiratory apparatus containing a reservoir of vital air or revivifying composition.

Fig. 17.

Schultz's Aërophore.

The aërophore devised by Herr Schultz, captain of the fire brigade at Aschaffenburg, Bavaria, depends upon the regeneration of the exhaled air, the oxygen being reproduced as it is consumed. It consists of a simple reservoir of sheet-iron, into which the products of respiration are returned. The respired air is led from the mouth by a flexible pipe to a cylindrical tube containing a layer of wadding to intercept dust, and pieces of pumice-stone saturated with caustic potash absorb the carbonic acid. This tube is in direct communication with the reservoir, as is also another tube on the other side containing pumice-stone saturated with dilute acetic acid and sprinkled with crysta of permanganate of potassium. This latter is f(replacing the oxygen absorbed in respiration, and f(adding a certain amount of humidity to the ai which makes it fresher for breathing. Fig. 1 shows a German fireman provided with the appar tus. The flexible tubes for inhalation and exhal tion are connected with the bottom of the reservoi The apparatus only weighs about 10 lbs., and ma be used for half an hour together.

The *Galibert* and the *Rouquayrol & Denayrouze* respirators are shown on p. 1923, * "*Mech. Dict.*"

See, also, "*Scientific American*," * xxxviii. 99.

A'er-o-steam En'gine. See theory of the engine by Henderson, quoted by Thurston, "*Vienna Expos. Rep'ts.*," ii. 151–160.

"*Engineer*" contains a description and illustration of *Wenham's* "heated air engine," the details being taken from a paper read by C. W. Cooke before the "Institute of Mechanical Engineers," in London. It belongs to that class in which the fire is inclosed, and fed by air pumped in beneath the grate to maintain the combustion, the whole, together with the gaseous products of combustion, being made to act upon the piston.

In addition to the British and United States patents cited on pp. 20–23, "*Mech. Dict.*," the following British patents may be noted: —

Clark, 1,449 of 1863. Air is driven into the furnace, is heated, rises with the products of combustion, meets a fine spray of water, which is instantly converted into superheated steam, and the whole passes to the cylinder.

Miller, 932 of 1864. Steam and air combined.

Boulton, 1,291 of 1864. Steam and air combined; mingles gas also.

De Rosen, 5,398 of 1826. Volatile products of combustion mingled with steam.

Vrooman, 3,083 of 1861. Charges air with moisture, and then heats it in spiral passages.

James, 1,445 of 1864. High-pressure steam and compressed air. The air is compressed by the piston in the lower part of the cylinder, and the steam then admitted to it.

Stevens, 1864. Vapor of oil is added to air, steam, and volatile products of combustion.

Cruickshanks, Eng. Pat., No. 8,141, of 1839. Expands air (previously condensed) by heat obtained from liquid fuel injected upon red-hot clay balls.

Hall, 4,935 of 1824, decomposes steam by passing it through red hot fuel, whence the gases, together with those resulting from the fuel, pass to the working cylinder.

A'er-o-ther'a-py Ap'pa-ra'tus. An apparatus in which a patient is inclosed in a chamber of compressed air as a therapeutic.

It is the opposite of the *depurator*, described on p. 687, "*Mech. Dict.*," in which the expulsion of morbid matter from the excretory ducts of the skin is expedited by withdrawing the pressure of the atmosphere from the surface.

The aërotherapy apparatus is the invention of Dr. Carlo Forlanini, of Milan, Italy. It is claimed that by increasing the pressure, the air is forced into the minutest passages of the lungs, and a much greater oxygenation of the blood is secured. This is realized by those who descend into the deep caissons used in laying subaqueous foundations. Fire and lamps also burn with great energy under these circumstances.

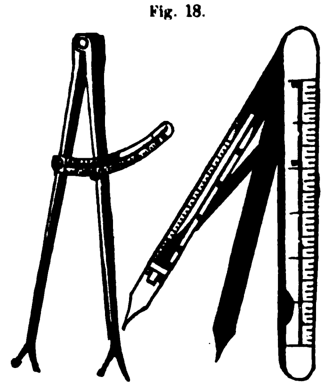
A view of the Forlanini apparatus is reproduced in the "*Scientific American*," * xxxv. 63.

See, also, *Ware's* compressed-air bath shown at Fig. 67, page 31, "*Mech. Dict.*"

Æs'the-si-om'e-ter. (*Surgical.*) An instrument for the determination of the cutaneous sensibility. Invented by Dr. Sieveking, of London, 1858. In the original form it was simply a modification of the common beam-compass. See Fig. 279, page 87, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

The "*Medical Record*," 1872, gives a drawing and description of an instrument by Dr. Alfred L. Carroll, constructed on the general plan of the two-legged compass, but with each free extremity divided into two points, one blunt and the other sharp. (Left-hand instrument in Fig. 18.) This arrangement enables the observer to determine the comparative sensibility to contact and pain at different distances by simply substituting the one pair of points for the other. Dr. Clymer provides himself with two pieces of cork or two small shot, and accomplishes the same result by placing them upon the sharp points of the ordinary instrument when he desires to test the sense of contact without danger of exciting that of pain.

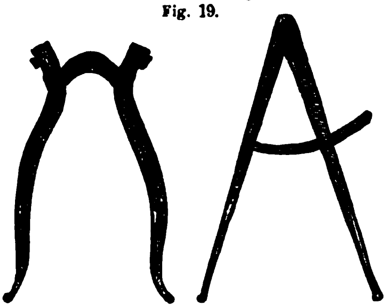
Fig. 18.



Æsthesiometer.

The right hand instrument, by Dr. Vance, exhibits a completely portable instrument. When closed, the points are in coaptation, and are received in the case the same as the blades of a knife shut into its handle. When opened and the points separated, the distance between the points is denoted by the position of the slide, which is so arranged as to move over a scale engraved on one arm of the æsthesiometer. The scale is divided into inches and twelfths of an inch. The points can be separated to the extent of 6″. When closed, the instrument is $4\frac{1}{2}''$ in length.

Fig. 19.



Dr. Elberg's Æsthesiometer.

Fig. 19 shows Dr. Elberg's Æsthesiometer with electrode points.

See description of the principles and application of the instrument, under ESTHESIOMETER, p. 809, "*Mech. Dict.*" Also, article by Dr. Reuben A. Vance in "*Canada Lancet*," iv., Feb. 1872; and "*Medical World*" of the same year.

Af'ter Wale. (*Saddlery.*) The body of a collar; the portion against which the hames bear, and which rests upon the shoulders of the horse. The forward part of the collar is the *roll*.

Aft'gate. The tail-gate of a sluice or lock.

Ag'ate. A burnisher. So called because frequently made of that hard material. Blood-stones and dog's teeth are also used for burnishers.

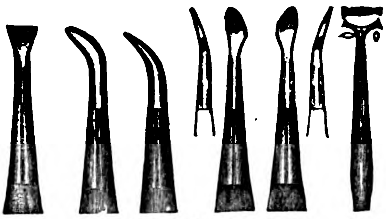
Ag'ate Bur'nish-er. A burnisher specially used in dental operations and bookbinding; in the former for surface-finishing cement or oxychloride fillings; in the latter for smoothing the surface of gold leaf on book edges and covers.

Fig. 20 shows some forms of dentists' burnishers.

A-ga've. Nets of agave fiber were shown in the Agricultural Hall, Centennial Exhibition, from the Argentine Republic.

"The *pita* (Mexican *Itle*) is a variety of the agave, very prolific and yielding fibres varying in quality from the coarsest hemp to the finest flax. It is used for the manufacture of thread, cordage, hammocks, paper." — *Squier's* "*States of Central America*," New York, 1858. See, also, his "*Notes on Central America*," 1855.

Fig. 20.



Dentists' Agate Burnishers.

Age'ing. Imparting the characteristics of flavor of ripeness or age, as of clay, wine, whiskey, calico, etc. See p. 23, "*Mech. Dict.*"

Sweet's appara'tus for ageing distilled spirits is shown in "*Scientific American Supplement*," * p. 181.

Ag-glom'er-a'ted Bat'te-ry. (*Electricity.*) One in which the deploarizing salt is united by a cement and pressure so as to form a solid block with and around the negative, the porous cup being dispensed with. The improved Leclanché is an instance.

Niaudet (American Translation), * 189.
"*Telegraphic Journal*" . . . * vii. 3.

Beaufils' sulphate of mercury battery has a solid depolarizer. "*Telegraphic Journal*," * vi. 397.

Ag'gry. Glass beads found in Ashantee and Fantee countries, and very highly valued.

They are supposed to be of ancient Egyptian manufacture. They are of many colors and patterns, the shades well marked or delicately blended, many of them resembling agates, for which they have been mistaken. The *glain neidyr*, or holy snake-beads of the Druids, found in Wales, may have had a similar origin, as the Phœnicians traded to both places, and carried Egyptian products. There are abundant evidences in the museums to prove the capability of the ancient Egyptian glass-workers to produce these objects of art. See list of Egyptian glass in Museum of "New York Historical Society," on p. 973, "*Mech. Dict.*"

Ag'i-ta'tor. 1. A stirring device used in the petroleum refining process for mixing the oil with the refining and deodorizing materials. It was formerly a series of revolving scoops, but the work is now done by blowing in air which bubbles up through the oil.

A pump used for this purpose is shown in "*Manufacturer and Builder*," * x. 128.

The oil is treated with one and one half per cent. of sulphuric acid, by which it is bleached. It is then washed with a solution of caustic soda, followed by a little ammonia, by which the acid is neutralized.

2. A device in the carbonated water apparatus to stir the gas and water together and cause the absorption of the former by the latter. See CARBONATED WATER APPARATUS; see also cuts on p. 2236, "*Mech. Dict.*"

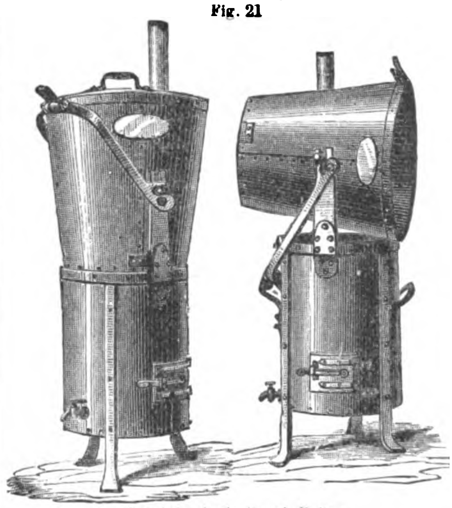
A-graffe'. (Fr. *Agrafe.*) A clasp. A hook, eyelet, or wire, by which a piano wire is firmly held, so as to prevent the translation of vertical vibration to the portion of the string between the bridge and the pin.

Decker's agraffe is a stud secured directly to the wrest-plank.

Ag'ri-cul'tu-ral Boil'er. A boiler or caldron for cooking food for animals.

The cooking apparatus made by Fouché, of Paris is shown in Fig. 21. It is made in copper or iron and is adapted to burn all species of fuel. One

Fig. 21

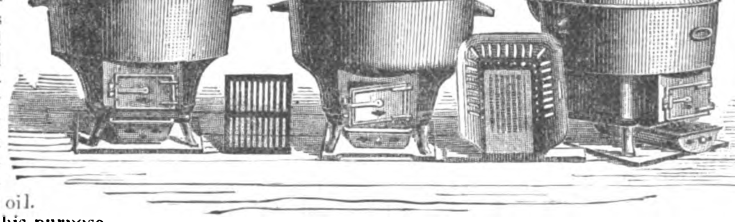


Fouché's Agricultural Boilers.

figure shows it closed for cooking, and the other position for discharging its contents.

The caldron is suspended on posts rising fr

Fig. 22.



Bodin's Agricultural Boiler.

the sides of the furnace. When at work, the tom of the caldron fits within the top of the nace, cleats on the vessel resting on the rim of lower section.

When the caldron is to be discharged, it has to be lifted clear of the furnace so that it may swing clear. This is done by means of the bail, cams on which raise the axis of suspension of the kettle, and it may then be tipped, as shown in the figure.

Bodin's agricultural boiler is made in several forms, and is of cast-iron.

It is provided with grates for wood or for coal, and has additional steaming chambers, which may be fitted on when required to increase the capacity, the contents of each being kept distinct.

It is easily transported in sections, economical of fuel, and ready for immediate use in any place without setting in masonry.

The agricultural boiler of *Tritschler*, of Limoges, France, is portable, and has a circulation of water from the water-bath to the interior caldron, and

FIG. 23.

Tritschler's Circulating Boiler.

vice versa. The water flows over the edge into the inner vessel, and out again at holes in the bottom. The flame courses twice around the caldron, following a helical flue.

Beard's hog scalding kettle and food-boiler is an oblong sheet metal tub with a fire under one end, like some species of evaporators.

Banks' farmers' boiler is circular, of sheet-metal, hung on trunnions in a furnace, the front part of which is hinged, and is moved aside when the caldron is to be tipped to discharge the contents.

The last two mentioned are made in Chicago.

Ag′ri-cul′tu-ral En′gine. A steam-engine for farm work. Used especially in this country for threshing, but having a very much wider use in Britain and France. It is specially constructed when designed for traction, and for plowing. See PORTABLE ENGINE STEAM PLOW.

Air and Cir′cu-la′ting Pump. A ste[am] engine, which in addition to the duty of the pump in condensing engines, pumps the water fr[om] the hot well into the boiler. See, for instance, *Blake* combined air and circulating pump, "*M[an]ufacturer and Builder*." * xii. 4.

Air Bag. 1. Air bags for raising sunken sh[ips] were tried by Captain Gowan on the wreck of U. S. steamer "Missouri," in 1851, and again sunken Russian men-of-war at Sevastopol. In 1864 air bags were applied for raising a steamer sunk in the Lake of Boden; in this case the bags, owing to some defect, gave way. The Alexandrovsky system has rendered good service to the Government and commerce of Russia on several occasions.

"The bags adopted in the Russian navy are, when inflated, of cylindrical form, measuring 12′ in diameter and 20′ in length. They are composed of three layers of the thickest canvas saturated with India-rubber. Their lifting power averages sixty tons. In order to lift a vessel, several chains are drawn by divers under her bottom, and air bags attached to the ends of each of them as near the ship's bottom as possible: the bags, being inflated by means of air-pumps, cause the ship to rise. Before pumping air into the bags, all the chains are connected in a transverse direction, so as to form one system, thus preventing the pairs of bags from sliding off from beneath the hull of the ship. As the vessel rises the surrounding water-pressure decreases, and the excess of air passes out through safety-valves." — "*Engineering.*"

See, also, Fig. 4148, p. 1847, "*Mech. Dict.*"

2. (*Surgical.*) Specifically, Politzer's air bag for inflating the Eustachian canal and treating diseases of the middle ear. See *f*, Fig. 2678, p. 1185, "*Mech. Dict.;*" Fig. 1814, p. 869, *ibid.*

See, also, Figs. 179–182, 184, pp. 39, 41, Part II., *Tiemann's "Armamentarium Chirurgicum."*

Air Box. (*Mining.*) A wooden tube used for ventilation in a mine when there is only one shaft.

Air Brake. (*Railway.*) A railway brake operated by air, either by the *compression* or *vacuum* method.

In the former, the air is compressed by a pump on the locomotive, and conveyed by pipes, and by flexible tubes between the cars, to cylinders under each car. Each cylinder has a piston which operates the brake levers.

The *Westinghouse* brake is an instance, and is described and represented on p. 356, "*Mech. Dict.*"

The *Loughridge* brake is similarly actuated.

In the latter form (vacuum), the air is exhausted from the device beneath the car, and the pressure of the atmosphere operates the brake-levers.

The *Eames* and *Smith* brakes are of this class.

See RAILWAY CAR BRAKE.

Air Bridge. An arrangement for injecting air at the bridge of a furnace, in the rear of the grate surface. Examples of bridges are numerous in Plate LXI., and page 2327, "*Mech. Dict.*"

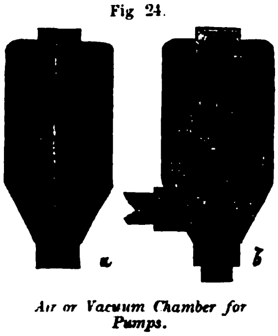
McMurray's corrugated-iron air bridge and fuel economizer, is shown in "*Scientific American,*" * xxxvii. 374.

Air Cam'el. A lightering device, consisting of a caisson placed beneath a vessel to diminish its draft of water to enable it to pass a relatively shallow channel.

The early use of the camel in Holland is referred to on p. 1874, "*Mech. Dict.,*" under the caption, RAISING SUNKEN VESSELS. See also AIR CUSHION.

Air Cham'ber. In Fig. 24, *a* is an air chamber to be placed over the suction cylinder in deep wells, the pump rod working through it.

Fig 24.



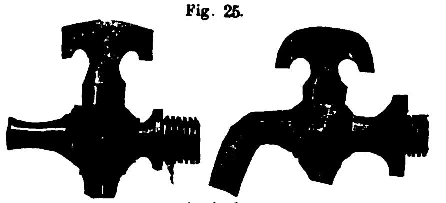
Air or Vacuum Chamber for Pumps.

Also used as a vacuum chamber under a suction pump. With a force pump two may be used with advantage; one as an air chamber above, and the other as a vacuum chamber beneath the pump cylinder.

In the same Fig., *b* is a chamber to be placed where the elbow would be in the angle of the ascending suction pipe and the horizontal water pipe, or placed alongside of the pump when the situation should require it.

Air′-cock. A faucet to allow escape of air: as in the case of the air-cock, otherwise known as a pet-cock, to allow escape of air from the steam cylinder when starting the piston.

Fig. 25.



Air Cocks.

The figure shows the ordinary straight nose air-cock, and the bibb-nozzle air-cock.

See also CYLINDER COCK.

Air Com-press'or. Applications of compressed air: —

Static: Employed in a condition of permanent elasticity.

1. Air reservoir in pumps. Regulators. Diving bells.
2. Pneumatic piles and caissons. Tubular foundations.

Dynamic: Employed in movement.

3. Elevation of liquids; ejectors.
4. Displacement of liquids.
5. Blowers: rotary, collapsible, and piston.
6. Air-guns.
7. Air-pumps and compressors.
8. Ventilation by chimney draft (vacuum).
9. Compression, and transport of compressed gas.
10. Compressed air locomotives.
11. Pneumatic railway brakes, tubular dispatch, and telegraph.
12. Ventilation by injection of compressed air (plenum).

The air compressors at Mont Cenis, and Hoosac Mountain, are referred to on pp. 27, 28, "*Mech. Dict.*"

Under the caption "AIR AS A WATER ELEVATOR," various devices of the nature of ejectors are shown to the number of nine illustrations, embracing the famous device at Chemnitz, and many novel devices growing out of the deep oil-wells. See also Calles' AËRO-HYDRO-DYNAMIC WHEEL.

AIR-COMPRESSING MACHINES are shown on pp. 31–33, "*Mech. Dict.,*" both simple and compound.

Under COMPRESSED-AIR ENGINES, are shown the Gowan colliery engine of Glasgow and the Sommeilleur apparatus at the Bardonneche end of the Mont Cenis tunnel. The latter form of apparatus, depending upon the compression of air by the body of descending water, is maintained in the Colladon apparatus, yet in much favor on the Continent of Europe, in positions where water is abundant and fall sufficient.

The tendency, however, is to the steam-driven air-pump, of which one or two examples will be offered.

The Gowan colliery engine is also shown on p. 10, article *Air comprimé*, Laboulaye's "*Dictionnaire des Arts et Manufactures,*" Fig. 3321, Tome iv., edition of 1877.

The Modane air compressors of the Mont Cenis tunnel are shown and described in the last-mentioned work, Figs. 3322, 3323, and accompanying text.

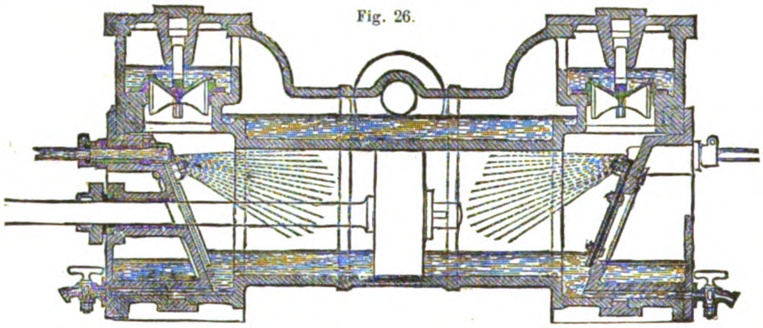
The compresseur Colladon is shown in the same work at Fig. 3324, article "*Air comprimé*," Tome iv., edition 1877. It was used at the St. Gothard tunnel.

Brunnin's water column, or air-compressor, is described in the "*Revue Universelle des Mines*," 1879, the article being reproduced in "*Van Nostrand's Engineering Magazine*," * xxi. 9.

The action of the machine is in two periods: the first consists in compressing the air in a closed cylinder by direct pressure of the water; the second, during which the water, having done its work, flows out. The compressor has a cylindrical reservoir with double seal valves of unequal diameter, one to admit the water, and the other to subsequently discharge it. Two other valves serve severally to admit fresh air and to discharge compressed air to a special holder.

The air-compressor designed by MM. Dubois and François, to drive drills for sinking shafts, is shown in Fig. 26.

Fig. 26.



Dubois & François' Air Compressor for Driving Shaft-sinking Drills.

"The arrangement consists of an air reservoir of 280 cubic feet capacity, of which from one fourth to three eighths is occupied by the injection water, and the remainder by the compressed air. Two iron pipes, 2″ in diameter, conduct the air to the drills, which are four in number, and on the Dubois and François system. The diameter of the cylinder is $3\frac{1}{2}''$, and the stroke $7\frac{7}{8}''$. The frame is formed of wood and iron, and has two vertical iron standards 3.9375″ in diameter; each standard carries a horizontal screw, and the drill is mounted on a nut moving on the screw, and having a range of half a circle. During the period of blasting and extraction of the spoil, the frame and drills are lifted, and when at work it rests upon a timber substructure. The compressor is intended to deliver air at a pressure of $3\frac{1}{2}$ atmospheres. It is actuated by a steam cylinder $29\frac{1}{2}''$ stroke and $13\frac{3}{4}''$ in diameter, and the piston-rod is attached direct to the piston of the compressor. The compressor cylinder has the same stroke and diameter as the steam cylinder, and the ends are inclined as shown in the section; they are fitted with two valves for the admission of the air, and at each end there are two gun-metal valves arranged as shown. Into each end of the cylinder there penetrates the perforated extremity of a pipe, and through these, at every stroke, water is injected against the piston and the sides of the cylinder to prevent the heating due to compression. The water is not allowed to accumulate beyond the level shown in the section, an overflow being provided, operating automatically. The following advantages are claimed for the arrangement: 1. The area of the inlet valves is very large. 2. The water injection ceases at the moment when it becomes unnecessary, that is to say, when the air reaches in the cylinder the same pressure that it has in the reservoir. 3. The compressor may be worked at a speed from 40 to 50 strokes per minute. At the coal mines of Wérister it was used in sinking two shafts, each 656 ft. deep, and the results of working with this system have been highly satisfactory." — *Revue Industrielle.*

The Clayton duplex air compressor, shown in Plate I., has two horizontal steam cylinders and two air cylinders, securely bolted on a very strong frame, the steam pistons communicating most of the power through the yokes to the compression pistons. The fly-wheel is placed between the two compressors, and on each end of the fly-wheel shaft is a crank, which cranks are set at right angles to each other, so that when the full compression of the air is attained in one compressor the opposite crank exerts its full force to complete the strokes, thus giving an even and uniform motion without any danger of the machine sticking on the center.

In the later form shown in the plate, a connecting rod is substituted for the former sliding journal boxes (shown in Fig. 1524, p. 650, "*Mech. Dict.*"); the yokes are connected at top by a rod, and at the bottom by a distance piece which serves as a slide, working on a long slipper guide which is adjustable and is placed inside the frame to relieve the cylinders from the wear incident to the weight of the pistons, rods, and connections.

The steam and air cylinders are united by tension rods above. The engine is duplex, the two portions acting upon the same crank shaft, the fly-wheel on which occupies the center of the machine. The air cylinders are cooled by the application of water in jackets so arranged that the cold water is first brought in contact with a portion of the top, and then forced around the extreme ends of the cylinders where the heat is greatest, the water then traveling upward around the center or cooler portion of the cylinders.

The adjustable tripping device can be set to lift the discharge valves at any point in the stroke, affording free escape for air in the cylinder as soon as it has reached the working pressure. The air governor can be set to any pressure desired, and will not allow the pressure on the rock drills or other machinery to vary, notwithstanding the pressure of steam or the number of drills at work. See Fig. 27.

The lubricating valve supplies the air cylinders at each stroke with a fixed amount of lubricating fluid.

The engines are disconnectable, so that one only may be worked when necessary for repairs or for other reason.

The "*Mining Journal*" (British), 1877, has a discussion on the respective constructions and uses of several air compressors; the article is in part reproduced in "*Scientific American Supplement*," * p. 1491.

It describes the "Moonta," * named from mines in South Australia, and in use in the Isle of Man, and in Cornwall; the "Flower" compressor, used at the Powell Duffryn Colliery, South Wales, and the "Festiniog"-tunnel compressor. It also refers to the cost, and some points in connection with the following air-compressors: —

Sommeiller. Colladon.
Cockerill Foundry.

Pernolet's "*L'Air Comprimé.*" Paris, 1876.
Drinker's "*Tunneling, Explosive Compounds, and Rock Drills.*" New York, 1878.

Air'-cool'ing Ap'pa-ra'tus. See Air-refrigerating Apparatus; Ice-machine.

Air'-cross'ing. (*Mining.*) An arch built over a horse-way or other road, with a passage or airway above it.

Air Cush'ion. Air cushions, distended, serving to support a vessel upon a camel or shallow-water ship-float, are shown in "*Engineering*," * vol. xxiii., p. 369; and the same device applied to graving-docks, * on p. 511 of the same volume. The invention of the engineers Clark and Standfield.

The cushions are composed of layers of canvas and rubber, capable of resisting a strain of about 40 lbs. to the inch, and they are inflated by means of air compressors worked by engines at the side of the dock. They are protected outside with rope matting. The form of the bag when inflated resembles a bellows with a cushioned top, and the lower expanding section has inlet and relief pipes, the latter employed to allow the air to escape after a given pressure has been exceeded. Access to any part of the ship's bottom can be gained by allowing the air to escape from one or more bags, and so making it clear of the ship, while the latter is supported by the adjacent cushions.

Air Cyl'in-der. One in which air is the moving power to operate a piston, or is acted upon by the moving piston.

Such are found in various engines and devices: —

Air engines.	Air cylinders of car-brakes.
Air compressors.	Compressed-air engines.
Caloric engines.	Air-pumps.
Hot-air engines.	

Some of which names are synonyms.

Air'-drain. (*Add.*) 2. (*Molding.*) A large passage, often of considerable length, to conduct the gases safely from heavy castings deeply bedded in the floor of a foundry.

Air En'gine. An engine driven by heated air.

The air engine of Woodbury, Merrill, Patten & Woodbury, patents June 8, 1880, heats and cools the same air alternately. It has two working cylinders, 10″ diameter × 24″ stroke, and two reversers, 20″ diameter × 12″ stroke. The essential features of the engine are a heater, regenerator, and cooler, which three in combination are termed a *reverser*, and, in conjunction with a *working cylinder*, constitute a single acting engine. The rapid heating and cooling of the air is necessary with each stroke, and the rapidity with which this is accomplished is one of the peculiar excellences of this machine. The heating is by fuel in the furnace; the cooling by the circulation of water around small, thin copper tubes through which the air passes. See Hot-air Engine.

The term *air engine* has become somewhat general, and instances of one class are given under

Caloric engine,
Compression engine,
Hot-air engine,

and of another under

Compressed-air engine,
Air compressor, etc.

See list under Air Apparatus.

Air E'qual-i-zer. A device to distribute a blast of air equally throughout the working space in a machine, to prevent its tendency to establish a central current and prove inefficient at the sides of the chamber.

See, for instance, *Shaver's* device in middlings-purifiers, * "*American Miller*," viii. 2.

Air Fil'ter. A protective ventilator consisting of a cloth interwoven with thin brass wire to act as a filter for the air. It is to be attached to the upper and lower sashes so as to close the openings.

Gaston Tissandier has made some investigations into the quantity of dust contained in 35.3 cubic feet of air, by causing that quantity of air to pass through a tube packed with gun-cotton, which filters out the particles. He then dissolved the gun-cotton in ether, and was thus enabled to obtain the particles in a separated condition. After a heavy rain, M. Tissandier has collected 0.09 of a grain of dust in the above-mentioned quantity of air, but in dry weather this proportion rose to 0.3 of a grain. With regard to the nature of the material, he found that about one third was organic, one third silicious, and the rest composed of various substances.

"*Iron Age*," xxi., January 24, p. 19.
See instances, Figs. 95–100, pp. 46, 47, "*Mech. Dict.*"

Air Fur'nace. (*Metallurgy.*) One depending upon the draft of a chimney, as distinct from a *blast* furnace. A *wind* furnace.

Air Gage. A manometer to indicate the pressure of air or gas in a vessel or chamber.

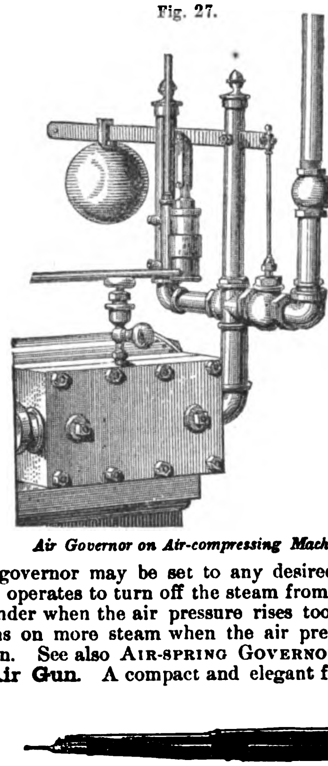
It is sometimes similar to a steam gage, but in other instances, such as the piezometer, it serves to register enormous pressures of gas in the explosion of charges of powder. See list under "Measuring and Recording Apparatus," *infra*.

Air′-gas Ap′pa-ra′tus. Another name for the Carburetor, in which coal-gas or air is passed through a volatile hydro-carbon to increase or confer the illuminating power. See CARBURETOR, p. 464, "*Mech. Dict.*"

Air Gate. (*Molding.*) An opening direct from a large mold, through which the displaced air escapes at the time of pouring, and in which the metal afterward rises. A *riser.*

Air Gov′er-nor. An instrument attached to an air-compressor, or blowing engine, to regulate the pressure of air in rock drills, blast furnaces, etc., where a uniform pressure of air is desirable. The

Fig. 27.



Air Governor on Air-compressing Machine.

air governor may be set to any desired pressure, and operates to turn off the steam from the steam cylinder when the air pressure rises too high, and turns on more steam when the air pressure goes down. See also AIR-SPRING GOVERNOR.

Air Gun. A compact and elegant form of the air gun, in which the whole of the hollow sheet-metal butt is utilized as an air reservoir, charged by a piston in the barrel, may be seen in *Laboulaye's* "*Dictionnaire des Arts et Sciences,*" Article "*Air Comprimé,*" Tome iv., Figs. 3317–3319, edition of 1877.

In the same article is the device by M. Bourdon for testing the force of the blow delivered by the bullet from an air gun, Fig. 3320.

Hyde's Air Gun, "*Scientific American,*" * xliii. 134.

Air′-head. (*Mining.*) A channel driven on a level with the top of the gate road, about four yards distant therefrom.

Air Heat′er. Generally: a device to heat air, as in a HEATING STOVE or HEATING FURNACE, which see.

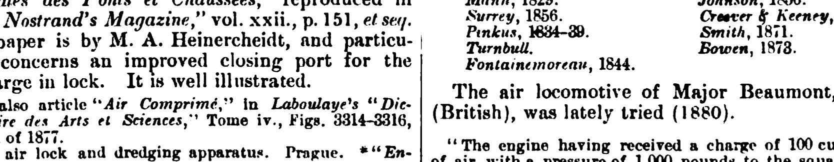
Specifically: a device to heat air to feed furnaces, whether heating or metallurgic. The Siemens, Ponsard, Bicheroux, and other furnaces of the class, have regenerators to heat the incoming air. See GAS-GENERATING FURNACE, REGENERATOR, AIR ENGINE, etc.

Thonger's air heater, for locomotive furnaces, is shown in "*Scientific American,*" * xxxv. 102.
The *Boswell* air heater, for stoves, furnaces, laundries, fruit dryers, etc., is shown in "*Mining and Scientific Press,*" * xxxvii. 281.
Air heater by waste gases, * "*Engineer,*" xlviii. 321.

Air In-ject′or. A blowing device to throw a jet of air. Such are found in atomizers, in some classes of fine sawing machines, to blow away the dust, and, as in the instance shown, in connection with dentists' burring engines.

A rubber bulb is compressed automatically by means of a simple mechanism, which is connected with and worked by the driven pulley. The air is forced from the bulb through the connecting rubber tube to a fixed nozzle at the hand-piece, whence it is thrown into the cavity of the tooth. The air thus driven out of the bulb leaves a vacuum which is instantly filled again with air from the patient's mouth. This alternate exhaustion and supply is kept up so rapidly, even at the ordinary speed of the pulley, that the air is injected in a continuous stream into the cavity. This appliance operates to keep the cavity clear of bur-dust and cuttings, and also to keep the bit cool while in use.

Fig. 28.



Dr. Hickman's Air Injector for Dental Engines.

Air Lock. An intermediate chamber between the outer air and the compressed-air chamber of a pneumatic caisson. See Plate II., op. page 49, "*Mech. Dict.,*" and Figure 1021, page 421, *ibid.*

The air lock is the subject of a paper in the "*Annales des Ponts et Chaussées,*" reproduced in "*Van Nostrand's Magazine,*" vol. xxii., p. 151, *et seq.* The paper is by M. A. Heinercheidt, and particularly concerns an improved closing port for the discharge in lock. It is well illustrated.

See also article "*Air Comprimé,*" in *Laboulaye's* "*Dictionnaire des Arts et Sciences,*" Tome iv., Figs. 3314–3316, edition of 1877.
Also air lock and dredging apparatus. Prague. * "*Engineering,*" xxix. 14.

Air Lo′co-mo′tive. A locomotive driven by heated air or compressed air, usually the latter.

See COMPRESSED-AIR ENGINES; STREET CAR MOTORS, etc.

See notices on p. 603, "*Mech. Dict.,*" of

Bompas, 1828.	*Parsey*, 1847.

Fontainemoreau, 1844.	

The air locomotive of Major Beaumont, R. E. (British), was lately tried (1880).

"The engine having received a charge of 100 cubic feet of air, with a pressure of 1,000 pounds to the square inch, left the Royal Arsenal station, on October 6th, at 12.22 P. M., for a run to Dartford and back, about 16 miles. In order to increase the energy of the air, it was heated, on being admitted to the cylinder, by a very small quantity of steam. The indications on the pressure-gage, as different stations were passed, were 940 pounds at 12.27 P. M.; 860 pounds at 12.33; and 760 pounds at 12.40; 540 pressure being the store of energy on arriving at Dartford at 12.50. Waste having been occasioned by shunting, the return journey began with a pressure of 510 pounds at 1.35 P. M., and Plumstead station was again reached at 2.10. This locomotive, not so large as one of our common street-cars, weighs about 10 tons, and draws a load of 16 tons up a moderate incline. It can be charged with air in fifteen minutes, does not send out any rush of steam or noxious gases, and makes only a trifling noise. Its sanitary advantages for underground work are obvious, and it can also be used for surface roads." — *British Paper*.

The compressed-air locomotive (model) of the "Polytechnic College of Philadelphia," is noticed in "*Scientific American Supplement*," p. 624.

See, also, Official Reports of Paris Exposition of 1878, vol. iv., p. 461, Commissioner Anderson's Report, for

* *Mekarski's* compressed-air motor.

See, also, for *Mekarski's*, "*Scientific American*," *xxxv. 82.

Air Me'ter. An instrument for measuring the rate of motion of an air current; used in mines, hospitals, etc.

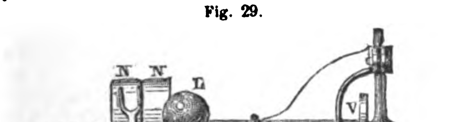
Casella's air meter is shown under ANEMOMETER, which see.

Air Mois'ten-er. An evaporator exposed to the heat of a stove, heating pipes, or radiator, to impart moisture to the atmosphere. See EVAPORATOR.

Air Pis'tol. A small weapon differing in no substantial respect but size and portability from the air gun.

Air-press'ure Reg'u-la'tor. An instrument for preserving an even pressure in pneumatic apparatus.

Fig. 29.



Air-pressure Regulator.

A, Chamber filled with air at the desired pressure.
B, Space filled with water.
C, Caoutchouc membrane separating the air from the water, and lifted by the levers *H I* by means of the rod *T*.
D, Pressure pump, with its supply and discharge-pipes *F E* respectively.
G, Water-pipe leading to the machines in communication with the chamber.

H, Two-branched exterior lever. *I*, Single interior lever.	In prolongation on the same axis, the journals of which are packed in the box *S*.

J, Rod terminating in a cap-piece *R*, and connecting the slotted sector-guide *P* to the lever *H*.
K, Regulation cock, moving automatically by means of its lever and a link connecting it to the rod *J*. Its purpose is to prevent overstrain of the caoutchouc diaphragm when the latter is at its farthest depression.
L, Counterpoise on the belt-shipping lever axis *V*.
O, Levers fixed on the axis *V*, and connected at their ends by a gudgeon traversing the slot of the sector *P*.
P, Sector-guide loose on the axis *V*.
Q, Forks loose on the arbor *V*, jointed to the piece *M*, which limits their movement.
N N', Fast and loose pulleys on the axis of the eccentric *V*, which works the pump rod.

The cut represents the diaphragm near the end of its downward extension. The cock, *K*, is nearly closed, and allows passage to the minimum quantity of water.

In the disposition of parts exhibited in the cut, the pump is about to start; the ball *L*, in consequence of the position given to the levers, *O*, by the sector *P*, has passed the vertical, and is about to draw on the belt fork, and bring the belt upon the fast pulley *N*.

The pump continues to work until the raising of the diaphragm by excess of water shall act inversely, by the connections already cited, upon the ball *L*, and shift back the belt to the loose pulley, *N'*.

Air'-pump. The uses of the air-pump have largely multiplied since its invention by Otto von Guericke.

Fig. 30.

Otto von Guericke's Air-pump, and the Magdeburg Hemispheres. (From a recent photograph.)

The original pump, lately brought to light at a loan collection, is 5′ high; the hemispheres are 26″ diameter; two receivers form a part of the group.

See Father Schott's "*Technica Curiosa.*"

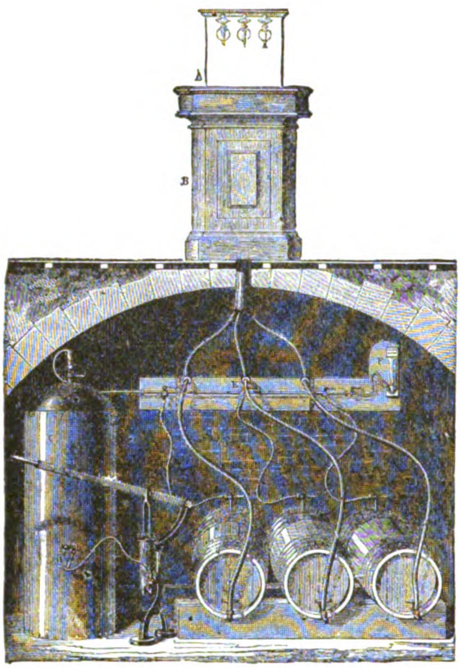
1. The air-pump used by divers has usually three cylinders and three single-acting pistons, operated by a three-throw crank. A form manufactured in Boston is shown under SUBMARINE AIR-PUMP. See AIR COMPRESSOR, DIVING-BELL, RESPIRATOR, etc., "*Mech. Dict.*"

2. The air-compression pump of the Westinghouse air-brake has a steam cylinder and air cylinder placed in line, and with piston-rod connecting the two pistons. The steam and air admission and exhaust of the respective cylinders are governed by valves in the passages. See RAILWAY-CAR BRAKE.

3. The air-pump used in carburetors is usually a form of meter wheel, or a device like the tympanum. See pp. 464 *et seq.*, "*Mech. Dict.*"

4. An air-pump used for beer fountains is shown in Fig. 31. It is somewhat of a refinement upon the mere lift-pump leading from each cask to the dispensing tap at the counter.

Fig. 31.



Compressed-air Beer-pump.

A single pump, *D*, condenses air in a cylinder, *C*, which connects by pipes to the spile-hole of each cask. From the faucet of each cask proceeds upwardly a pipe through the case *B*, to the dispensing table *A*. *F* is a manometer, to indicate the pressure.

Arrangements on similar principles are used in France in cellars and wine-vaults for transferring and racking wines; for heating them on the new process, to give the quality of age, etc.

Air-pumps of this class are largely used in the United States in breweries and other factories, where quantities of liquids are to be moved. For this purpose direct pressure of air is more manageable and convenient than the ordinary liquid pump of whatever class. They are classed as *air-pumps* up to a pressure of thirty pounds.

5. Air-pumps for a pressure exceeding thirty pounds per square inch are known as *air-compressing machines*, which see. The air locomotive of Colonel Beaumont, of Woolwich, England, is said to start with a reservoir filled at a pressure of 66 atmospheres, while the Dubois and François air-compressor delivers air to the rock drills at 3½ atmospheres.

6. Blowers may be classed as air-pumps, but whether for urging fires or for ventilation, their force is usually far inferior to that of the ordinary air-compressing engines, for the service of rock drills, for instance.

7. *Geissler's* air-pump without valve, as improved by MM. Alvergniat Frères, of Paris, and which suppresses *l'espace nuisible*, is shown with illustration on p. 491, vol. iii., of the "*Reports of Paris Exhibition*" of 1867. Succeeding pages describe

* *Kravogl's* mercurial air-pump.
* *Richards'* valveless air-pump (Plate VIII.).
* *Deleuils'* free-piston air pump.
The *Sprengel* air-pump is shown at Fig. 398, p. 170, "*Mech. Dict.*"

8. The independent air-pump is one driven by another motor, in place of being actuated by a crank on the main shaft. Such an air-pump is sometimes used in connection with a condenser, and being independent, a vacuum may be formed for the engine before it is started.

Otherwise the air-pump is combined with a circulating pump which takes the water from the hot-well and sends it to the boiler.

9. (*Surgical.*) Air-pump for cupping; Fig. 195, p. 64, Part I., *Tiemann's "Armamentarium Chirurgicum."*

Junod's boot and arm for dry cupping. *Ibid.* Figs. 176, 177, pp. 112, 113, Part IV.

Air-pump for spray producer and atomizer. *Ibid.* Fig. 364 *b*, p. 89, Part II.

See also AIR-PUMP, p. 50, *et seq.*, "*Mech. Dict.*" ASPIRATOR, pp. 169, 170, *Ibid.*

Air-re-frig′er-a′ting Ma-chine′. A machine constructed by Hall, of Dartford, England, for refrigerating the hold of an Australian meat-ship, has a pair of horizontal trunk-engines mounted on top of a condenser. To one side is bolted a compressing cylinder, 27″ diameter and 18″ stroke; to the other side is bolted the expansion cylinder, 22″ diameter and 18″ stroke. Both these cylinders are open-topped. The valves are placed in the bottoms of the cylinders, and are worked by cams on the crank-shaft and levers. Air is drawn into the compressing cylinder on the up-stroke, and delivered on the down-stroke into the surface condenser, at a pressure of about 50 lbs. to 55 lbs. on the square inch. The air here parts with its heat in the condenser, and it is then delivered into the expansion cylinder, the valve of which cuts off at about one fourth stroke. The expanded air is then delivered through a pipe into the room to be cooled. About fifty per cent. of the work expended in the compressing cylinder is returned in the expansion cylinder, the difference being made up by the engine. In the form recommended for ordinary use, the height is kept down to render it specially suitable for the space between decks; but the machine can be made to take almost any form, and can be made of any dimensions to suit particular requirements. The condenser or refrigerator consists of nests of brass tubes, through which the water circulates. The tubes have an outside diameter of ½″, and are accessible through man-holes.

See illustration in "*Sc. Am. Supplement*," p. 4039. See also *ibid.*, 4011. See also * "*Engineer*," l. 248. See REFRIGERATOR.

The apparatus of MM. Nezereaux and Garlandat has a perforated plate, over which a body of cold water runs, while a body of air, driven by a fan, courses through the holes, and acquires within a few degrees the temperature of the water. "*La Nature.*"

See also "*Scientific American*," xxxiv. 82.

By the use of an air-compressor, with tanks and cisterns, the temperature of a given space may be readily reduced nearly to the freezing point, if desired. Many processes, primarily intended for producing ice, are available for air-refrigerating purposes.

See AIR-COOLING APPARATUS; ICE-MACHINE; in former volumes.

The following United States patents may be examined: —

Nos.	Nos.	Nos.	Nos.
89,456	211,700	162,920	138,411
198,830	226,908	102,660	14,510
164,421	191,232	195,374	184,291
229,374	87,041	44,731	175,291
149,980	161,515	227,796	168,654
233,072	209,892	140,375	139,470

Air Res'er-voir. The reservoirs constructed by Dr. C. W. Siemens, for Colonel Beaumont, of Woolwich, Britain, to be used in his air locomotive, and withstand a pressure of 1,000 lbs. to the square inch, are made of cylindrical rings of steel rolled out of solid ingots in a tire-mill, and hemispherical ends beaten out of steel boiler-plate.—*Paper before "Institution of Mechanical Engineers"* (Br.), 1878. Reproduced in "*Scientific American Supplement,*" * 2033.

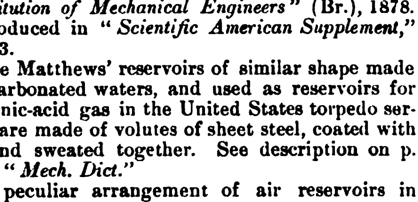
The Matthews' reservoirs of similar shape made for carbonated waters, and used as reservoirs for carbonic-acid gas in the United States torpedo service, are made of volutes of sheet steel, coated with tin, and sweated together. See description on p. 2237, "*Mech. Dict.*"

A peculiar arrangement of air reservoirs in pumps, to totally exclude the shock, is shown in "*Dinglers' Journal,*" and reproduced in "*Scientific American,*" xxxvii. 329.

Air'-spring. A spring in which the elasticity of air is utilized in place of metallic or other material.

1. The air-spring used in a reciprocating flat bed printing-press, to stop and reverse the movement of the bed, is a very important improvement over the wire spring, being almost indispensable for high rates of speed. To overcome the momentum of the bed of a 32″ × 46″ drum cylinder press with a full form of type running at the rate of 1,600 impressions per hour, is calculated to require about 2,550 pounds of resistance on each center.

Fig. 32.



Air-spring for Bed of Printing Press.

The air-spring is used on the presses of several of the superior makers. The press-spring shown in Fig. 32 has a governor attachment, by which, when the press is started, the air-spring is automatically put on, according as the feed progresses, and in stopping the spring power is decreased as the feed declines. The bed is provided with two cylinders to engage with as many plungers at the ends of the frame, and the hollow rods of these plungers are connected by a pipe running along the lower part of the frame; which pipe is opened or closed by the valve of the governor. (See next article.)

The plunger has a hollow rod and an automatic valve at its extremity. This valve rises on the return motion of the bed, and prevents a vacuum forming in the cylinder. Fig. 32 shows a longitudinal section of the device.

2. Air-springs are also used in gun earriages to arrest the recoil of the gun; or to utilize the recoil of the gun to assist in elevating the gun in battery, after being depressed for loading.

Notices are given on p. 1035, "*Mech. Dict.,*" of the invention of Eads (1865–1871).

Moncrieff has another form. See HYDRO-PNEUMATIC GUN-CARRIAGE.

3. The use of the air-spring in car-springs is shown in Figs. 3852, 3853, p. 1755, "*Mech. Dict.*"

4. The air-spring is used in the spring hammer of Hotchkiss, air being used as the elastic medium, holes in the reciprocating cylinder allowing free ingress and egress of air, insuring a perfect cushion at each stroke.

U. S. PATENTS FOR AIR AND PNEUMATIC SPRINGS.

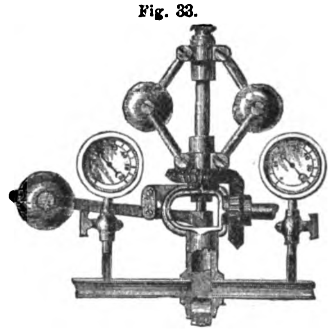
139,346	Automatic Vent-opener for Air-springs.

Air'-spring Gov'er-nor. An attachment to an air-spring arrangement to regulate the pressure.

The instance illustrated represents the governor attached to an improved form of flat-bed printing press, to regulate the pressure of the air in the recoil spring. Fig. 33 shows the governor attached to the connecting pipe, with the plug valve, which it operates, and two spring gages to indicate the amount of condensation in the cylinders. The valve is shut by the motion of the press when running at speed, and is open when the press is at rest. This enables the press to be started at any point without helping it over the centers by hand. The spring gages indicate the pressure in the air cylinders, and this is determined by setting the plungers backward or forward on their rods, readily adjusting the amount of spring to the speed of the press. The press is furnished with a table showing the gage pressures indicating the amount of spring required for the different speeds run. The workman simply adjusts the plungers until the gages indicate the pressure laid down on the table.

Fig. 33.



Air-spring Governor.

Air Strain'er. A gauze or perforated plate to prevent ingress with the air, of dirt, dust, or insects. Such are used with the pump of the railway air-brake, in filtering the air for ventilation, etc.

See also AIR FILTER.

Air Tel'e-graph. A mode of communication known in France under the name of Sonnerie télégraphique, système Sparre. The principle is, that a compression of air produced by the pressure on or squeezing of an India-rubber ball at one end of a long tube (generally a leaden pipe) is immediately transmitted to the other, and there makes audible signals. This mode of telegraphing is used in hotels, manufactories, vessels, etc., for limited distances.

Generally known as *Pneumatic telegraph*, and illustrated by Fig. 3854, on p. 1755, "*Mech. Dict.*"

Air Test'ing. To detect the presence of miner's fire-damp, various instruments have been employed. See FIRE-DAMP DETECTOR; GRISOUMETER.

Professor Wanklyn and W. J. Cooper have brought before the Sanitary Institute of England a new process for testing air. A strongly alkaline solution of permanganate of potassium is prepared, the strength of which is determined accurately. They allow a known volume of this solution to act on a given volume of air heated nearly to the temperature of boiling water. After allowing the solution to act on the air they again determine the strength; the loss of strength represents the amount of oxygen consumed by a known volume of air. The purer the air the less the consumption of oxygen.

Air Ther-mom'e-ter. In a loan collection of scientific apparatus lately exhibited at the "South Kensington Museum," London, the air thermometer of Galileo was shown. It was substantially like that of Santorio, of Padua, shown at Fig. 116, p. 53, "*Mech. Dict.*" The illustration in the "*Illustrated London News*" of the period is reproduced in "*Scientific American Supplement*," p. 742.

The same work, at p. 8929, gives an account of Witz's air thermometer.

For Winstanley's air thermometer, see "*Engineering*," * xxx., 459.

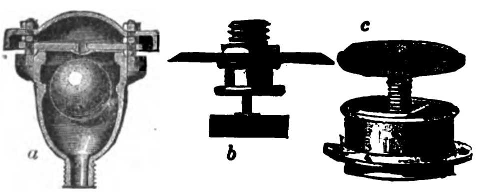
Air Trap. A device in a conduit to allow air to escape at the more elevated portions where it passes over summits.

A stop-cock, to be used as occasion may require, is the simplest form, but automatic appliances have been invented. That of Felix (French), used on the pipe-lines for the conveyance of beet-juice, is an iron bell tested to 15 atmospheres, placed at an elevated point on the pipe, where it is adjusted by two opposite tubulures soldered to its lower part. In the center is a pump cylinder in which slides a piston, the rod of which passes through the summit of the bell and communicates motion to a safety-valve. The air rises to the summit of this, passes into the cylinder, and gradually exercises a sufficiently strong pressure upon the piston to cause it to descend and open the escape-valve. A large portion of the air is ejected, the piston rises and closes the valve, and so on.

Air Valve. A valve to regulate the admission or egress of air.

1. Such are used in bends and traps of water-pipes to allow escape of accumulated air; as in *a* of Fig. 34.

Fig. 34.



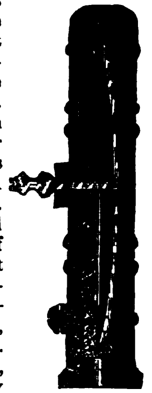
Air Valves.

2. A valve to be operated by a float to close a pipe communicating with a cistern (*b*).

3. A screw valve, *c*, to close the opening of an air reservoir; such as an air cushion, for instance.

4. An automatic air valve is shown in Fig. 35. It consists of an oblate spheroidal disk placed in a chamber, and having attached to its radial axis a valve, which has its seat in the passage to be guarded. Changes in the heat of the disk chamber affect the oblateness of the disk and move the valve toward or from its seat. Expansion by heat acting in greater degree upon the exterior surface decreases the oblateness and shuts the valve opening. A curved plate would act similarly. A plate of two metals of unequal expansibility by a given degree of heat would do the same without being normally curved. See instances of thermostatic arrangement in LOW-WATER ALARMS (2), *D E* of Fig. 3008, p. 1359, "*Mech. Dict.*" See, also, THERMOSTAT, pp. 2551, 2552, *Ibid.*, especially Fig. 6374, p. 2552.

Fig. 35.



Self-acting Air Valve.

Al'a-bas'ter Im'i-ta'tion. Coat a statue of plaster-of-paris, or of papier-maché, with thick white damar varnish, and then dust with a pulverized glass.

To give it the appearance of Carrara marble, varnish it a second time, and dust it with coarsely pulverized white glass or mica. If the marble veins be first traced on it with some delicate blue pigment, the imitation will be enhanced.

Paraffine wax makes a fine imitation of alabaster.

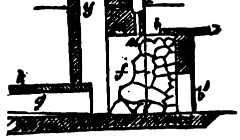
Another recipe for imitating alabaster ornaments prescribes brushing over plaster-of-paris models with spermaceti, white wax, or a mixture of the two, or steeping the models in the warm mixture. Or instead of this process, they may be brushed over several times with white of egg, allowing each coating sufficient time to dry.

A-lan'dier. (*Ceramics, French.*) A species of fire-place, of which several are placed around the base of a porcelain kiln, fed from the outside. Some of them have a downward draft on to the fire, from which the flames are conducted into the body of the kiln; others are ordinary furnaces at the base of the kiln.

The porcelain kilns of Sèvres, and the fine faïence kilns of Staffordshire, have furnaces of this kind.

In the figure: —

Fig. 36.



Furnace à Alandier.

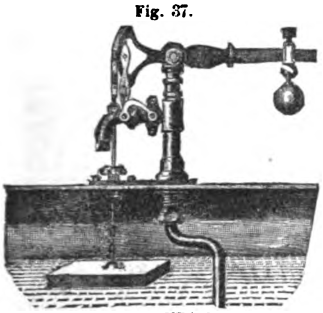
f, Is the fire.
b', Entrance of air.
b, Opening used only in starting the fire.
y, Chimney leading into the kiln.
g, Duct for flame below the kiln floor *k*.
x, *v*, Openings to examine contents of kiln.
u, Duct for cold air when required.

A-larm' Whis'tle. (*Steam.*) One constructed to be automatically sounded when water in the boiler sinks below a certain level.

In Fig. 37, the sinking of the float moves the counter-weighted lever and opens the valve, which permits steam to escape to the whistle.

Alarm whistles have also been constructed, to be sounded when the abnormal heat of a chamber, acting upon a thermostat, gives an alarm of fire. Tampering with a lock or a safe may, by electric connection, produce the same effect.

Fig. 37.



Alarm Whistle.

The alarm water-gage of *Ledent*, of Liége, is shown in "*Scientific American Supplement*," * 3899.

Al'bert-type. A printing process from films of bichromated gelatine exposed in a camera. See p. 57, "*Mech. Dict.*"

A modified Albert-type process, to produce colored pictures, was described in the New York "*World*," and the article reproduced in the "*Scientific American Supplement*," p. 2079.

The Albert process is described at length on p. 18 of the Report of Dr. C. A. Doremus, "*Vienna Exposition Reports*," vol. ii., section D.

Al'bo-car'bon Light. One in which the ordinary illuminating gas is enriched by the volatilization of so-called *albo-carbon*, the solid residuum of creosote, placed in the form of cylinders in a reservoir adjoining the burner, and heated thereby.

"*Engineering*"	xxvii., p. 157
"*Scientific American*"	xl., p. 201.

Al-bu'men-ized Pa'per. Paper prepared for photographic uses by dipping in a bath of white of egg, drying, and pressing.

Al'co-hol En'gine. In this connection the following items may be considered, in addition to the notices on pp. 58, 59, "*Mech. Dict.*"

Abbé d'Hauteville (1682) describes an engine, the action of which was produced by alternately evaporating and condensing, without allowing it to escape. — "*Reflexions sur quelques Machines à elever des Eaux*," p. 9. Paris, 1682.

See, also, English patent, No. 5,262 of 1825.

See, also, No. 9,118 of 1841. Tubes of alcohol or ether in a steam boiler, and connecting with a cylinder, the latter with a condenser. Vapor re-used.

Also, W. Ketland, Eng. Patent, No. 7,526 of 1838. Applies alcohol to condense steam that has worked an engine and uses the vapor generated to work another engine. Saves the condensed spirit vapor.

Al'co-hol'me-ter. The alcoholmeter of Dr. Siemens is an instrument by which a stream of alcohol and water mixed in any proportion is measured in such a manner that one train of counter wheels records the volume of the mixed liquor, while a second counter gives a true record of the amount of alcohol contained in it.

"The volume of liquid is passed through a revolving drum, divided into three compartments by radial divisions, and not dissimilar in appearance to an ordinary wet gasmeter; the revolutions of this drum produce a record of the total volume of passing liquid. The liquid, on its way to the measuring-drum, passes through a receiver containing a float of thin metal filled with proof-spirit, which float is partially supported by means of a carefully adjusted spring, and its position determines that of a lever, the angular position of which causes the alcohol counter to rotate more or less for every revolution of the measuring-drum. Thus, if water only passes through the apparatus, the lever in question stands at its lowest position, when the rotation motion of the drum will not be communicated to the alcohol counter, but in proportion as the lever ascends a greater proportion of the motion of the drum will be communicated to the alcohol counter, and this motion is rendered strictly proportionate to the alcohol contained in the liquid, allowance being made in the instrument for the change of volume due to chemical affinity between the two liquids." — *Nature*.

Ale Re-frig'er-a'tor. 1. An apparatus in which malt liquor is cooled either by surface exposure; in pipes exposed to a cool bath; or in a vessel traversed by pipes containing a refrigerating liquid. See Fig. 631, p. 264, "*Mech. Dict.*;" see, also, devices in CONDENSER, *Ibid.*

2. A case or box in which barreled beer is kept for dispensing. See Fig. 632, p. 265, "*Mech. Dict.*"

Al'eu-rom'e-ter. An instrument invented by M. Boland to measure the elasticity of the gluten of flour, when submitted to the temperature required to bake bread. Described, without cut, on p. 60, "*Mech. Dict.*"

The apparatus has a bath, *K*, of neat's-foot oil, beneath which is a lamp. The bath being heated to 318 F. (150 C.), the cover *E*, with the tube *F*, are lowered and then the aleurometer proper is put in. This is a brass tube, *D*, with a movable base-piece, *B*, and a cap, *A*, in which is a piston, *C*, the upper part of which has a scale graduated from 25 to 50. The piston being down, half the space beneath it is filled with a ball of gluten, prepared by kneading and working flour. The effect of the heat is to evaporate the water of the gluten (66 per cent.) and the gluten swells. Until it has doubled its volume the piston is not moved. Beyond this it registers from 25 to 50. Gluten which does not more than double in volume is not fit for bread, and the best has not exceeded 50.

Fig. 38.

Al'ge-rine'. (*Fabric.*) An all-wool French goods.

Al'i-dade. 1. The movable arm of a graduated instrument carrying sights, or a telescope.

2. A theodolite, or telemeter, provided with such an arm.

Two Viennese alidades shown in the Austrian Exhibition may be noticed: —

"Kraft & Son, of Vienna, had on exhibition an alidade, of which the pillar carrying the telescope was swung on a joint, so that both pillar and telescope could be lowered and made to lie flat and parallel with the rule. The object of this rather hazardous variation from the ordinary construction was to make the instrument more portable by reducing the size of its packing-box.

"Starke & Kammerer, instrument-makers for the Austrian Polytechnic Bureau, exhibited an alidade, with a telemeter attached to and parallel with the telescope, by which the distance of the instrument from the divided staff was determined by the angle subtended by two fixed points on the staff. In other cases, the distance was obtained by observing the vertical distance on the staff subtended by a known angle or two fixed wires in the diaphragm of the telescope." — Report of R. D. Cutts, "*Instruments of Precision*," Vienna Exposition Reports, vol. ii.; § II, p. 8.

Al'i-ment'a-ry Ap'pa-ra'tus. (*Surgical.*) Devices for feeding the helpless or refractory, such are: —

Nasal, esophageal, rectal. See Figs. 403–405, p. 101, Part II., *Tiemann's "Armamentarium Chirurgicum."*

Masticator, Fig. 406, *Ibid.;* and Fig. 3087, p. 1407, "*Mech. Dict.*"

A-liz'a-rine. The coloring principle of madder. It is made artificially from anthracine, a white crystalline substance obtained from coal-tar, which contains about 0.63 per cent. of anthracine.

Paper by Johnson	"*Sc. American Sup.*," 2128.
Alizarine. *Rumpff*	"*Sc. American Sup.*," 620.
Alizarine Blue. *Prud'hommé* .	"*Sc. American Sup.*," 2080.
Alizarine, Printing with . .	"*Sc. American Sup.*," 619.
Alizarine	"*Sc. American*," xli. 232.

Al'li-ga'tor For'ceps. (*Surgical.*) Forceps with long jaws toothed throughout their length.

Such are Thompson's urethral forceps for lithotrity; Figs. 169–171, p. 45, Part III., *Tiemann's "Armamentarium Chirurgicum."*

Farabeuf's and *Hamilton's* Osteophors, Figs. 53 *b*, 53 *c*, p. 12, Part I., *Ibid.*

And numerous other instances.

Al'li-ga'tor Leath'er. The tanning of alligator skins was commenced about 1855, and now from 17,000 to 20,000 are tanned yearly, which are consumed by boot and shoe manufacturers in the United States, as well as exported to London and Hamburg.

Al-loy'. Tellurium has been proposed as a substitute for copper as an alloy for gold and silver in coinage. "*Engineer*," San Francisco.

The Japanese alloys are mostly used for ornamental castings, statues, musical instruments, and bells. The name given to an alloy generally corresponds to the color produced by the treatment which the objects have to undergo before they are finished; thus some of the alloys are named *green copper, violet copper, black copper*, etc. This color depends both upon the composition of the alloy and the chemicals used in coloring the metal. There are many different means used to produce one and the same color, and it so happens that almost every manufacturer uses particular compositions of his own; generally it is only the proportions that differ, but sometimes even the constituent elements are different, although the alloy is called by the same name.

Green copper (*Sei-Do*) is composed of copper and lead, or copper, lead, and tin.

Sentoku-do of copper, lead, and spelter — similar to the old Corinthian alloy — is said to have been first produced by a large conflagration which took place in China during the earlier part of the fifteenth century.

Black alloy called *U-do*, of copper, lead, and tin; the brass, of copper and spelter, sometimes with a slight addition of lead, as, for instance, in Yechiu, one of the chief places of production of ornamental castings inlaid with gold and silver; the purple alloy is composed of copper and lead.

Gin-shibu-ichi is generally composed of four parts of copper or alloy and six parts of silver.

Shaku-do, copper with a small percentage (two to five per cent.) of gold, which produces a beautiful dark blue color, and is mostly used for articles formed by hammering, or for *repoussé* work, generally inlaid with gold and silver, and producing designs somewhat similar to *Niello*.

Bronze for locomotive whistles: —

Copper	80
Tin	18
Antimony	2
	100

Bronze for ball valves and pieces to be brazed: —

Copper	87
Tin	12
Antimony	1
	100

For working models; easily wrought: —

Copper	4
Tin	1
Zinc	0.25

Phosphor-tin for journal boxes: —

Tin with from 2.5 to 5 per cent. of phosphorus.

Ravenue & Co., of Berlin, Ger., "*Sc. Am.*," xl. 118.

Professor Silliman's process of making articles of metallic alloys resonant consists in exposing them for a determinate time to a temperature just short (say within 10° Fah.) of their melting point. This is claimed to endow them with a musical quality. — "*Scientific American Supplement*," 182.

An alloy by Matthey, of London: —

Platinum	80.660
Iridium	19.079
Rhodium	.122
Iron	.098
Ruthenium	.046

Density at 32° Fah., 21.6139.

This is so malleable and ductile, that it may be drawn to a wire a few hundredths of a mm. in diameter.

Organ pipe metal: —

Tin and lead in equal parts, cast into sheets and smoothed with a *planer;* that is, with a flat block beaten by a hammer.

White alloy, by Beirman & Clodius, of Hanover: —

Copper	72.25
Manganese	16.25
Zinc	8.75
Iron	2.50

This alloy is malleable, does not change when immersed in water for forty days, takes the silver plating well, but is a little yellowish.

White alloy, by Le Marquand, of Paris. It is not liable to oxidation: —

Copper	750 parts.
Nickel	140
Oxide of cobalt	20
Tin	18
Zinc	72
	1,000

Alloy, for jewelry, having the appearance of red gold $\frac{750}{1000}$ fine. By Meiffren & Co., Marseilles: —

Copper	800
Platinum	25
Tungstic acid	10
Gold	170

The three former are melted together in a crucible, and then granulated in —

Water	1 cubic meter.
Slaked lime	500 grams.
Carb. potassa	500 grams.

The granulated metal is dried, remelted, and the gold added.

The flux consists of boric acid, nitrate of sodium, and chloride sodium in equal proportions.

Alloy for jewelry, in imitation of silver — sideraphthite — (unchangeable iron), by Meiffren & Co., Marseilles: —

Iron	65
Nickel	23
Tungsten	4
Aluminum	5
Copper	5

The first two are melted together and granulated in a bath of —

Water	1 cub. meter.
Slaked lime	1 kilo.
Carb. potassa	1 kilo.

The latter three ingredients are similarly treated. The flux is one part boric acid to one of nitrate of potassium. Sodium and charcoal are added in melting the last-mentioned batch. The separate batches of granulated metal are then melted together.

Al'lu-mette'. A match or taper for lighting a lamp or candle.

Al-lu'vi-um. (*Mining.*) A deposit of loose gravel between the superficial covering of vegetable mould and subjacent rock.

Al'man-riv'et. (From *Allemand.*) A form of joint in German armor in which the plates were slotted to slide on rivets to give flexibility to the armor.

Al-pac'a. (*Fabric.*) 1. A taffeta woven goods made of alpaca wool.

2. A dress goods of cotton chain and long luster wool weft.

3. Figured fancy weaving makes *fancy alpaca.*

Al-pa'ga. (*Fabric.*) A French dress goods made in a taffeta loom. It has a cotton warp and Lincoln wool weft.

Al'pine. (*Fabric.*) A French goods, made on a "serge 2 and 1" loom; silk warp and merino wool weft.

Alt-az'i-muth In'stru-ment. A theodolite with adjustments for altitude and azimuth.

Al'ter-na'ting Cur'rent Ma-chine'. (*Electricity.*) One in which the current traverses in opposite directions alternately, as in the Gramme machine used with the Jablochkoff light.

* "*Telegraphic Journal,*" vi. 491.

Al'ti-tude Meas'u-rer. Pickering's altitude instrument is designed for measuring the distances and heights of mountains. It consists of a common telescope, with a level attached, a scale of equal parts in the eye-piece, and with a mirror of plate-glass fastened to the object-glass, so that it can be set at any angle. Two images are seen, one through the glass, and the other by reflection from its surface, and any two objects may be made apparently to coincide by turning the mirror through the proper angle. Selecting as our object the mountain whose distance is to be measured, and as the other any convenient, well-defined point, the telescope is moved through a known distance, and the apparent change of position of the two images is measured by the scale. The altitude is then determined by leveling the telescope and reading the apparent elevation from the graduated scale, which is now turned round. By a second inclined level higher mountains may be measured.

Al'um Bat'te-ry. (*Electricity.*) Useful in operating open circuit. It consists of zinc and copper, or zinc and carbon, without porous cups, immersed in a concentrated solution of alum.

Sabine, "*Electric Telegraph,*" 1867, p. 228.
Niaudet, American Translation, New York, p. 78.

Al u-min'i-um. The metallic base of clay. A white, sonorous metal of increasing importance.

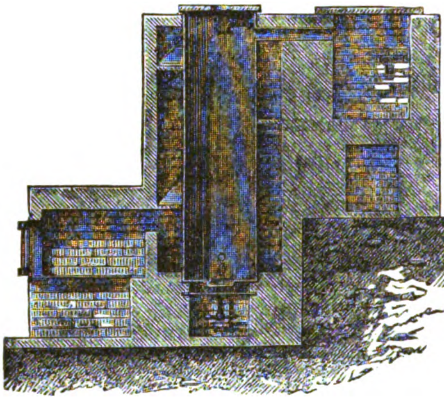
The history of the production of the chloride of aluminium from alumina, by Oerstedt, the segregation of a gray metallic powder, by Wöhler, in 1827, and the production of metallic globules of aluminium by the last named in 1845, are mentioned on p. 70 of "*Mech. Dict.*" The modification of the Wöhler method, by M. H. Deville, in his works at Javelle, near Paris, under the patronage of Napoleon III., about 1857, are also referred to. The Deville process of that time is described with more detail in *Laboulaye's* "*Dictionnaire des Arts et Manufactures,*" tome iv., article "*Aluminium*" (edition of 1877), but more recent improvements have rendered it unnecessary to redescribe it.

Very important in this connection are the successes of M. Deville in the production of sodium, so necessary in the aluminium process. Starting with the foothold acquired by MM. Mareska and Donny, who published a work on the extraction of sodium in 1852, "M. Deville has arrived at the production of sodium with a facility and in such abundance as but a short time ago would have been regarded as impossible." — *Laboulaye.* See the Dictionary above referred to for details of the sodium process.

"It is now certain that the fabrication of sodium is at least as easy as that of zinc, with which it has, for that matter, a very strong analogy." — *Dumas.*

Aluminium (by the later Deville process) is manufactured by decomposing the double chloride of aluminium and sodium (cryolite), with the aid of metallic sodium. The sodium is obtained by heating to redness a mixture of 100 parts of calcined soda, 15 parts of chalk, and 45 parts of coal. The chloride of aluminium is prepared by passing chlorine gas over a moderately heated mixture of pure alumina (obtained either from alum or the mineral bauxite), common salt and coal tar. The idea of this mode of producing the chloride of aluminium is attributed to Thénard, and its first execution to Oerstedt, but it passed from a laboratory expedient to a practical use in the hands of M. Deville.

Fig. 39.



Deville's Chloride of Aluminium Apparatus.

The operation is conducted in an iron gas-retort, and the result of the interaction of the several substances present is the combination of the coal tar with the oxygen of the alumina, and the production of aluminium chloride, which unites with the chloride of sodium (common salt), forming a double salt, which volatilizes and is passed off into a separate chamber, where it condenses. From this method of obtaining the chloride, it is impossible to keep it free from chloride of iron, for which reason the Parisian aluminium is invariably adulterated therewith. From this double chloride of aluminium and sodium the metallic aluminium is obtained, either by passing it in the form of vapor over a heated surface of metallic sodium, in a simply constructed and connected system of iron cylinders appropriately heated, or the materials are at once mixed and heated.

The apparatus of M. Deville is shown in Fig. 36. The principal feature is a retort of fire-clay, like those used in gas-works, but set upright in the furnace. The retort has a capacity of 300 liters, and is heated by an envelope of flame, which follows a spiral course around it. It is pierced with three openings, two near the bottom, and two at and near the top. The opening *O*, near the bottom, is for a tuyere of porcelain, which reaches to the axis of the retort and introduces the chlorine gas into the charge. A second opening, opposite the former, is for cleaning out the debris of the exhausted charge.

Of the openings above, one on top is for the introduction of the charge, and the other at the side leads the volatile choride of aluminium into a condenser chamber, L, of masonry; or it may be made of boiler iron, and lined with glazed faïence tiles. The condensing chamber itself has a conduit for the escape of waste gaseous products.

The alumina employed is the result of the calcination of ammoniacal alum or sulphate of alumina. In place of adding to the alumina, first the pulverized coal, and then the oil, to render the mixture plastic, Deville employed simply coal tar, the refuse of the gas-works, which is very cheap and replaces the oil and coal. This mélange is calcined in earthen pots in a reverberatory, heated from the waste heat of the chloride furnace.

The mixture, being calcined, is charged into the retort, and the heat is gradually raised to a red. The current of chlorine gas is then introduced by the tuyere previously referred to, the production of gas being in stoneware pots containing peroxide of manganese and hydrochloric acid, heated in a sand-bath.

The chlorine does not attack the retort, but follows its axis in an upward direction, not extending laterally more than two decimeters, so that the sides of the retort are protected by a thickness of the charge not attacked by the gas. The chlorine is totally absorbed, and does not even show a trace in the condenser.

Rousseau has a substitute process, in the heating of a mélange of sea-salt, alumina, and coal, producing a liquid chloride which condenses continuously.

The employment of Greenland cryolite, which is a double fluoride of aluminium and sodium, is attributed to Rose, of Berlin. The cryolite is heated with an excess of sodium, when metallic aluminium and fluoride of sodium are produced, and the latter compound gotten rid of by treatment of the mass with caustic lime.

Of late, the metal has been manufactured from the mineral *bauxite*, especially at the factory in Salindres, near Alais (*Gard*), France. There the *bauxite* is heated with soda in a reverberatory furnace, the resulting aluminate of soda is extracted by means of water, and alumina precipitated by a stream of carbonic acid; this is then formed into balls, with salt and coal, and heated to a white heat in vertical retorts during the introduction of chlorine gas. The double chloride of sodium and aluminium, which distills over, is fused with the addition of 35 per cent. of sodium and 40 per cent. of cryolite as a flux, and the metal which settles at the bottom of the crucible is poured into molds. The cost of producing one kilog. of aluminium is stated to be 80 f., while the selling price is 100 f.

The employment of *bauxite* (*l'argile des Baux*) has served as a new point of departure in the aluminium industry, having more than any other increased the scale of production and the diminution of price of the metal. This may now be said, in round numbers, to cost but half as much as silver, and as it is but one quarter the weight of the latter, the metal for an object of a certain size in aluminium costs but one eighth of the same dimensions in silver.

Wilde's process has attained some notoriety.

Lead or sulphide of lead melted is poured on dried or burned alum; the result is crucibled with fluxes, the resulting metallic mass contains aluminium, which is separated, or the alloy can be used for some purposes.

Aluminium resists the action of the air, sulphurous gas from coal, weak acids, but is attacked by alkalies. It molds well. Its appearance resembles oxidized silver and makes it suitable for statuettes and vases; it is useful for culinary vessels, bottoms of sirup pans, and in many cases where its extreme lightness is an important consideration.

The difficult problem of soldering aluminium, seems to be resolved by the use of the alloys of that metal with zinc. See also ALUMINIUM SOLDER.

At present there are three aluminium works in France and one in England. Their total production amounts to about $17,500 yearly, of which $10,000 are produced in France, and $7,500 in England.

Manufacture of Alloys	*Howard.*	220,149	Sept. 30, 1879.
English Patent	*Thompson.*	2,101	Mar. 27, 1879.

Al'u-min'i-um Al-loy'. Aluminium now enters as an ingredient into various alloys; that with copper is perhaps the most notable. See ALUMINIUM BRONZE.

Alloyed with 10 per cent. of copper, the alloy remains ductile.

Alloyed with small quantities of zinc, tin, gold, or silver, it remains ductile, but is rendered harder and more brilliant.

Alloyed with 3 per cent. of zinc, is a superior metal. — *Débray.*

Alloyed with 7 per cent. of tin, can be worked, does not take a fine polish, but is rendered non-homogeneous by fusion.

Does not alloy with lead.

Alloyed with 3 per cent. of silver, is of beautiful color.

With 50 per cent. of silver, is hard as bronze.

With 1 per cent. of gold, is hard, ductile, and greenish.

With 10 per cent. of gold, is crystalline.

With 5 per cent. of silver, can be worked like pure aluminium, but is harder, takes a fine polish. See also p. 71, *"Mech. Dict."*

With 4 per cent. of silver, it is used by Sartorius, of Göttingen, for the beams of analytical balances.

One per cent. of aluminium with copper makes the latter more ductile, more fusible, enables it to fill the mold better, harder, more capable of resisting chemical re-agents.

Copper, with 2 per cent. of aluminium, is used by Christofle, in Paris, for works of art, and numerous " Articles de Paris."

True aluminium bronze has from 5 to 10 per cent. of aluminium. See ALUMINIUM BRONZE.

Silver, with 5 per cent. of aluminium, is hard as coin-silver, and is excellent for coinage.

Al'u-min'i-um Bat'te-ry. (*Electricity.*) One in which one or both of the elements consists of a plate of aluminium.

Al'u-min'i-um Bronze. An alloy credited to M. Débray, in which aluminium takes the place of tin or zinc, in combination with copper, to form a bronze.

This application of aluminium is at present the most important use of the metal. Even so small an addition as 1 per cent. of aluminium to copper considerably increases its ductility and fusibility, and imparts to it the property of completely filling the mold, making a dense casting free from air-bubbles. At the same time the copper becomes more resistant of chemical re-agents, increases in hardness without losing in malleability, and unites in itself the most valuable qualities of bronze and brass. The " alloy formed of copper 9 and alluminium 1, constitutes a new precious metal for industrial uses, which will find still more numerous applications when its price, still rather high (15 fr. the kilo), shall be reduced." — *Laboulaye.*

On account of its grain, it is especially suitable for parts subjected to friction, and slides of locomotives lined with aluminium bronze have outlasted more than twofold those of ordinary bronze. Besides its great tenacity, which much extends its applicability, it can, like iron, — and it is the only alloy which possesses that property, — be welded and hammered hot, at a distance sufficiently remote from its point of fusion.

The true aluminium bronzes, according to Rudolph Wagner, were first made by John Percy, in 1856. They are alloys containing 90 to 95 per cent. of copper, with 10 to 5 per cent. of aluminium. The direct mixture, by first fusion, of 10 parts of aluminium and 90 of copper, gives a brittle alloy, which, however, increases in strength and tenacity by several successive fusions. At each operation a little aluminium is lost. After the compound has been melted three or four times, however, the proportion of aluminium does not appear to change, and the alloy may be again re-melted several times without alteration. These fusions are effected in crucibles. The aluminium bronze is homogeneous, and possesses sufficient expansion to fill the remotest parts of the mold. It affords sharp castings that can be worked more readily than steel. Aluminium bronze may be forged at a dull-red heat, and hammered until cooled off without presenting any flaws or cracks. Like copper, it is rendered milder and more ductile by being plunged into cold water when hot. The bronze polishes beautifully, and possesses great strength — according to Anderson's experiments, an average of 75,618½ lbs. per square inch. The resistance to compression is feeble. From the experiments of Col. Strange on the relative rigidity of brass, ordinary and aluminium bronze, it appears that the last named is four times as rigid as brass, and three times as rigid as ordinary bronze.

According to M. Morin, the director of the manufactory of Nanterre, very homogeneous alloys are obtained with copper and 5, 7½, and 10 per cent. of aluminium. The alloys with 5 and 10 per cent. of aluminium are both of a golden color, whilst that with 7½ per cent. has a greenish tint. A copper alloy with 2 per cent. of aluminium is said to be used in the Parisian ateliers, for works of art. It works well under the chisel and graver.

It is considered excellent for organ reeds, giving a better tone than brass or German silver. Also used for piano strings, and vibrating bars of music-boxes.

The uses of aluminium bronze in making various articles, such as cutlery, hardware, works of art, etc., and by M. Hulot, of the Postage Stamp Factory in Paris, are mentioned on pp. 70, 71, "*Mech. Dict.*;" and the series of Farmer's aluminium alloys is given on p. 71, *Ibid.*

The popularity of aluminium bronze is due to its beautiful golden color, which has enabled it to replace silver-gilt to a considerable extent. Its luster is very durable, which M. Debray explains by the great quantity of heat liberated when aluminium is combined with copper, showing that the alliance is very energetic and complete.

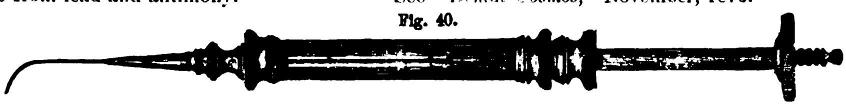
In England, kettles made of aluminium bronze are employed for making preserves and ices from acid fruits.

Morin & Co., of Nanterre, manufacture weavers' shuttles of bronze, which, of course, do not oxidize so readily as steel.

Cambrien recommends this alloy for type casting. Type made of it can be used fifty times as long as those from lead and antimony.

The alloy is largely used in the making of mathematical, optical, surgical, and scientific instruments.

Fig. 40.



Alveolar Abscess Syringe.

" Aluminium bronze is used in France for making the large preserving pans used by wholesale confectioners, and is recommended as an alloy in type metal. Lange, in Glashütte (Saxony), employs an aluminium in the manufacture of watch-springs. The new springs have the advantage over the old in not being subject to rust, in not being magnetic, and in possessing greater hardness and elasticity. An alloy of 100 parts aluminium and 5 silver can be worked like pure aluminium, but is harder, and takes a beautiful polish. An alloy of 5 parts aluminium and 100 silver is almost as hard as ordinary silver, but has the advantage over it of containing no metal which is of a poisonous nature, or which can effect a discoloration of the silver." — "*Engineering and Mining Journal*," xxiii. 157.

Farmer's series of aluminium bronzes are given on p. 71, second column. "*Mech. Dict.*" They are hard, tenacious, laminable, and ductile.

See United States Patents: —

Al′u-min′i-um Gold. A substitute for gold.

Copper	90
Aluminium	10
	100

Has a color like 14-carat gold.

Copper	85
Aluminium	10
Gold	5
	100

Has a color like 18-carat gold, and is an excellent alloy for jewelry, and should be soldered with brass, silver, or gold solders. Avoid all potash for cleansing or as flux for soldering.

See, also, four of Farmer's formulas for *chrysoid* (Cu. Al. Ag.; Cu. Al. Zn.; Cu. Al. Fe.; Cu. Al. Ni.), giving alloys which in color and texture resemble gold. Page 71, "*Mech. Dict.*"

Al′u-min′i-um Gun-met′al. Two per cent. of aluminium added to the usual gun-metal.

Declared by Schulter to be equal to steel for guns. Good for statues, and bells also.

Al′u-min′i-um Sil′ver.

Silver	1
Aluminium	4
	5

Melted together. Valuable in instruments in which lightness is an object, such as sextants, octants, etc., which will weigh in this alloy but about one quarter as much as if made of silver. Aluminium pure is too soft for such purposes and works with difficulty.

Al′u-min′i-um Sol′der.

	Gold.	Silver.	Copper.	Brass.
Hard . .	88	6	6	–
Medium .	54	28	18	–
Soft . . .	14	57	15	14

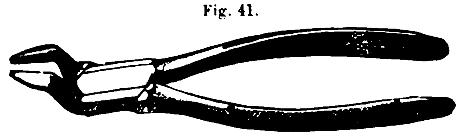
Bottone recommends in preference to coat the surfaces to be soldered with a layer of copper in electro bath, and then use ordinary solder.

Al′ve-o-lar Ab′scess Syr′inge. A syringe for injecting abscesses in the alveolar ridge or processes. It has straight or curved canulas for more convenient access to the parts.

See "*Dental Cosmos*," November, 1876.

Al′ve-o-lar For′ceps. (*Dentistry.*) Forceps for gnawing away portions of the alveolar process, or for extraction of fragment of roots beneath the summit of the alveolar ridge. They have variously shaped beaks: bayonet, straight, curved.

Fig. 41.



Bayonet-shaped Alveolar Forceps.

A-mal′ga-ma′tion. (*Galvanic Battery.*) Coating the zinc plate with mercury so as to present to the liquid a surface of metal which shall be equally affected by the excitant, in order to prevent the establishing of local currents, which the impurities of the zinc would otherwise occasion.

Ganot, "*Physics*," N. Y., 1877, pp. 684, 692.

It is usually done by cleansing the zinc plate with dilute sulphuric acid, and then rubbing over the surface a small quantity of mercury.

A-mal′ga-ma′tor. The amalgamating machinery exhibited by the Republic of Chili at Philadelphia, 1876, was a facsimile of the apparatus in use at Autofagosta, on a scale of ⅙th. It is under the system of Kröhnke. The series of machines and operations is as follows: —

The *washing and reduction* of the ore is accomplished by means of two vertical iron rollers, resting on an iron plate, and kept in motion, thereby producing the necessary friction. The rollers sit in an iron cup, into which the ores to be ground are received by means of a self-feeder. The water necessary is conducted to the cups by means of pipes, and is kept running continually. The reduced ore is carried with the water through gutters into the open, flat tanks below, and there allowed to settle; the water is then run off, and the ore carried to the drying shed.

In the *amalgamating* section are 12 large and 2 small revolving casks; 4 upright tanks, wherein the chemical solution is mixed: one washer; one centrifugal machine.

The powdered and dried ore is placed in the large casks, and mixed with sufficient cold water to saturate the whole thoroughly. The necessary quantity of the chemical solution from the tanks is then added, previously mixed with boiling salt water. After revolving the cask a sufficient length of time to transform the silver ore from a sulphite into a chloride, the quicksilver is added, and the whole subjected to the action of the amalgam. Thence the contents of the casks are run into the washer and there freed from the remaining impurities, acids, chemicals, etc., etc., leaving the pure silver and quicksilver. This then goes into the centrifugal machine, where the quicksilver is separated from the silver as much as this can be done by mechanical action. In case there should still be left some impurities, which may be easily detected by a dark color, the whole is returned to the two smaller casks, and there washed with boiling salt water, until its appearance shows the true silver color. It is then discharged and stamped into molds, to be ready for section three.

The *condensing and smelting* apparatus comprises four condensers and one smelting furnace.

The condenser consists of a cylindrical body closed hermetically at the upper end, while the lower end is open.

The cylinder or retort rests upon an iron plate, one third of which is below and two thirds is above the plate, this retort is surrounded by a furnace made of fire-brick. Below the retort is a mechanical apparatus, part of the machinery to be used to raise the silver into the retort. This apparatus is connected with a railway on which is placed a car fitted with an iron water-bucket, in which is an iron stand whereon the mold containing the silver and the residue of quicksilver not separated by the centrifugal machine is placed by the aid of a derrick. The mold, which is made of two equal pieces fitted and held together by means of iron pins, is then taken off, the car is run on the mechanical apparatus and the bucket filled with water, and the whole wound up, so that the silver column enters the open aperture in the retort and with the water-bucket closes this hermetically. The bucket being so much larger the retort stands from five to six inches in the water. After heating the silver column a proper length of time the quicksilver begins to evaporate, the vapors of which are so heavy that being brought into contact with the water they will soon condense and appear as metallic quicksilver at the bottom of the water-bucket. After all the quicksilver has been evaporated and condensed, the silver column is taken to the smelting furnace and there molded into bricks and bars.

Thirty-nine tons of silver ore are worked daily, and the loss is stated not to exceed 2 oz. of silver to 3 tons of ore, whatever the quality of the latter. The machinery cost $230,500.

Amalgamators involving electrical action are: —

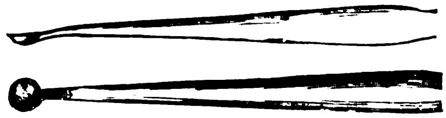
A-mal'gam Car'rier. A scoop for carrying a small quantity of amalgam to fill a cavity in a

Fig. 42.



Amalgam Carrier and Burnisher.

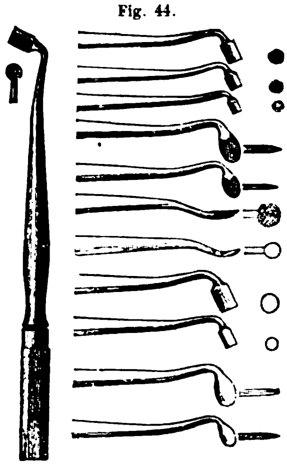
tooth. In the form shown, the back of the bowl serves as a burnisher.

A-mal'gam Ma-nip'u-la'tor. An instrument designed to facilitate the preparation of amalgam for fillings, having a cup at one end for taking up the desired amount of filings or powder, and a curved spatula at the other end for combining the mercury with the filings and packing it in the cavity.

Fig. 43.

Amalgam Manipulator.

Fig. 44.



Amalgam Pluggers.

A-mal'gam Plug'ger. A dentist's instrument for packing and condensing amalgam or allied stopping material in the cavities of teeth. Used with a mallet.

FIG. 45.

Amalgam Retort.

A-mal'gam Re-tort'. An iron retort with a luted and keyed lid, with a hollow inside the latter for expansion.

Am'a-to'ri-i. (*Ceramics.*) Dishes in majolica with portraits of the ladies to whom they were presented. An Italian device.

Am'ber. A fossil resin, noted as being the first electric substance known. It is largely found on the shores of the Baltic, which was formerly the only source of supply.

The word electricity is derived from the Greek name of this substance, ἤλεκτρον. Amber is largely used as mouth-pieces for pipes, etc. In the London Exhibition of 1851 there were four of these mouth-pieces, valued collectively at £1,000.

The Baltic is the principal source of amber, as it was perhaps in the time of Nero, but it is also found in Roumania, the latter the product of a different tree, and assuming various colors, red, pink, brown, blue, green, and black. These colors are frequently found mixed in a single piece, and lumps also occur with silver-colored veins and gold specks. On account of this variety of colors, the Roumanian amber is highly esteemed, and the darker and more beautiful pieces are more costly than yellow amber, especially as they are more rare.

German amber is found in the sea or in alluvial earth; the Roumanian amber is only found in mountainous places and highlands, where it is sought and dug out by the peasants.

On Amber. *Reboux* . . "*Scientific American Sup.*," 1847.
Sources of Amber . . . "*Scientific American Sup.*," 168.

Am'ber, Ar'ti-fi'cial. True amber is the fossil resin of a pine.

Artificial amber is principally colophony, a resin obtained by the decomposition of turpentine.

The detection is by means of heat or solution.

True amber melts at 545°–550° Fah.; the spurious at a much lower temperature.

True amber is slightly attacked by ether and alcohol; the spurious very readily.

Am'ber Bronze. A mode of coloring iron.

An artificial bronze surface upon iron, obtained by rubbing brass upon the smooth iron surface, and protecting with varnish.

U. S. Patent, 197,572, November 27, 1877.

Am'ber Ce-ment'. A solution of hard copal in pure ether, of the consistency of castor oil. — *Rust.*

The carefully-cleaned surfaces of fracture, coated with the solution, should be pressed together, and retained in contact by a band. A few days are required for complete hardening.

Small pieces of amber may be united to form a much larger one by moistening the surfaces to be united with caustic potash, and pressing them together.

Am'ber Var'nish. Yellow amber is bleached by being treated with a hot solution of salt; 1 lb. of the white product is dried, powdered, and melted over a fire in a clean iron pot. 1 lb. of fine nut-oil is then added, after which the whole is well stirred until thoroughly mixed. The pot is then removed from the fire, and when the heat is sufficie moderated, 2 lbs. of the essence of turpentii added to form a composition of the proper cor ency for use.

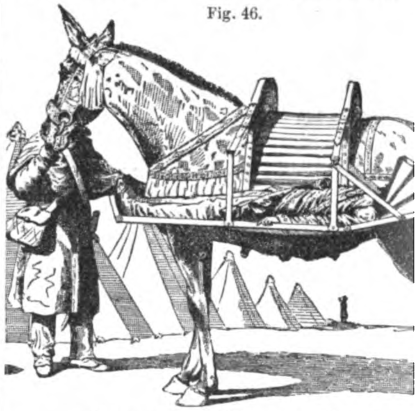
Am'bu-lance. Fig. 46 shows one style of bulance used in various semi-Asiatic armies.

Fig. 46.



Transport of the Wounded. Crimea.

The Turkish ambulance, on porter-back, is in a picture from the London "*Graphic*," repro in "*Scientific American*," *xxxvi., 151. S cular No. 6, Surgeon General's Office, U. S 81–86.

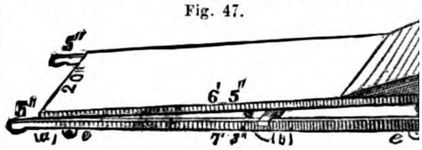
Am'bu-lance Cot. A cot adapted to be (or at least, as to the legs) to fit in an amb for transportation, or to stand on its legs wl field-hospital service.

See "*Art of War in Europe*," Official Rep General McClellan, War Department Series 80, where a French ambulance cot is shown.

Am'bu-lance Stretch'er. A litter cupy a place in an ambulance wagon. U convey a soldier from the spot on which he l the ambulance depot, and then to form his the wagon.

It is composed of two wooden frames, the one with handles, carrying an upper one, s at one end with a hinge (*a*), and rising sligl wards the other, retained in the inclined p by India-rubber springs at *b* and *c*, which a

Fig. 47.



Ambulance Stretcher.

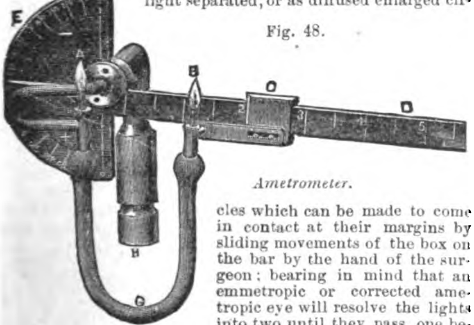
cased with spiral steel cases. The bottom stretcher is formed of leather, and stuffed elevated end of the wooden frame to form a Rollers are attached to the under part of th frame at *e e*, to facilitate its being shoved i ambulance wagon from the rear.

A'me-trom'e-ter. An instrument inve Dr. Thomson for the diagnosis of refractio examination for defects in the human eye.

"It consists of a small fixed gas-jet *A*, a second o tached to a box *C*, which slides upon a bar *D*, the nected by a flexible rubber tube *G*; the end of tl forms a pointer, which, by elevating or depressing end of the bar, can be placed at any part of the g half-circle *E*, which is fixed firmly to the thimb which means the entire instrument can be attached to a common gas-burner, and the lights regulated by its stop-cock.

"The jets having been lighted and turned down into two small flames about 5 mm. in diameter, the patient, placed 5 meters away, is directed to observe the flames, and to say whether he sees them as small points of light separated, or as diffused enlarged circles which can be made to come in contact at their margins by sliding movements of the box on the bar by the hand of the surgeon; bearing in mind that an emmetropic or corrected ametropic eye will resolve the lights into two until they pass, one behind the other, and become fused, whilst in ametropia the circles will seem to touch; whilst a distance, depending upon the degree of ametropia, remains between the small light points. To determine the kind of ametropia, the patient is directed to pass slowly in front of the eye under examination a slip of red glass in such a manner as to color half of each diffused circle, and if the red half seems to be on the same side with the red glass, myopia is recognized, and if on the other side, hypermetropia; this may be as well done by passing before the eye a card or paper in such manner as to exclude from view one half of each circle.

Fig. 48.

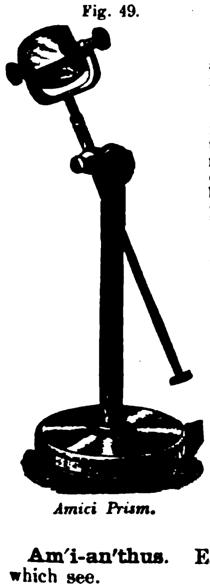


Ametrometer.

"To determine the degree of ametropia, the bar has been divided on one side into spaces of 2.5 cm. with a half space between, and on the other into English inch and half-inches, and it will be found that each space of 2.5 cm. will indicate an ametropia of one dioptric, metric system, and each inch $\frac{1}{40}$ of the old system. The cut represents the two flames as apart 2 dioptrics, and they would appear to a person having myopia or hypermetropia of 2 dioptrics or $\frac{1}{20}$ as two circles of light, with their margins in contact at one point, separating on the removal of light *B*, and overlapping when it is placed nearer to light *A*.

"For those who prefer the old system to the metric, it will be remembered that the old glasses are not based upon their exact powers of refraction, but are ground on *radii* of Paris inches, and that, owing to the index of refraction of the glass commonly used, they by a happy chance correspond in focal length almost exactly with the English inch; hence each inch of distance between the test-lights as determined by the use of the inch scale on the bar, will indicate an ametropia of very nearly $\frac{1}{40}$; and the higher degrees can be found instantly by dividing 40 by the number of inches between the lights when their margins seem to have come into contact." — "*Beck.*"

Fig. 49.



Amici Prism.

A-mi'ci Prism. A device adopted by Amici, for throwing an oblique pencil of condensed light upon an object. See Fig. 49.

Am-mo'ni-a En'gine. The ammonia engine, which utilizes the expansion of liquefied ammonia, is described and represented on p. 90, "*Mech. Dict.*" and references made to Dr. Lamm, and to the dissertation of Dr. Barnard on the subject.

Gamjee's engine, U. S. Patent, No. 240,000, and dated April 19, 1881, uses the vapor or gas of ammonia expansively to the extent of more or less complete liquefaction, and then reconverts it from the liquid to the vaporous condition by means of heat, which restores it to its original tension. See THERMO-DYNAMIC ENGINE.

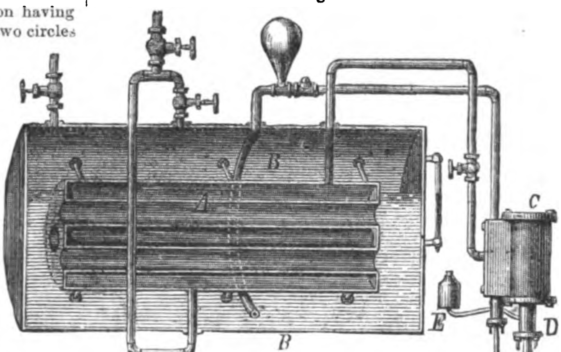
Seyforth's Ammonia Engine, "*Scientific American*," * xxxix. 333.

M. Frot's machine is described in article "*Air Chaud*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," edition of 1877.

The principle upon which the theoretical utility of ammonia, as a motor, is based, may be thus stated: As the gas is absorbed by water its latent heat becomes sensible, and the temperature of the solution consequently rises. This heat may again be used for the expansion of liquid ammonia into a gas, under great pressure — the pressure thus generated being converted into work behind the piston of an engine. The heat thus transformed into work cannot be recovered and utilized as heat, and, consequently, to maintain the efficiency of the combination, additional increments of heat must be supplied, from external sources, to be again converted into work, and so on.

In the apparatus of Dr. Emile Lamm (Fig. 50), the liquefied ammonia, which parted with its latent heat during condensation by pressure, is placed in the inner shell *A*, through which tubes traverse, the whole being inclosed in an outer shell, *B*. The fountain communicates with the valve chest of the cylinder *C*, in the same way as the steam induction pipe of a steam-engine connects the boiler and the

Fig. 50.



Lamm's Ammonia Engine.

cylinder. In the outer shell *B* is placed some of the water, or weak solution of ammonia that was left in the boiler of the still, of a suitable temperature to generate the required pressure at starting. This heat exists, then, in the liquefied ammonia as expansive force, and passes out with the gas to the cylinder, where, a portion having been converted into work, the remainder passes, with the exhaust gas, back to the weak solution in the shell *B*, where, the latter becoming instantly condensed, the heat is again rendered sensible and passes through the walls of the tubes, to generate expansive force, and so on, the total loss of heat for a given amount of work being the equivalent of the work performed, *plus* that which may have radiated from the shell during the performance of the work; while the loss of the material itself is only that due to whatever leakage has taken place.

An oil-packed stuffing-box is shown at *D*. An annular chamber surrounding the piston-rod is kept supplied with oil from the chamber E, through a suitable pipe; this forms a practically impassable barrier to the escape of free ammonia. The oil becomes more or less saponified by the action of the ammonia; but this does not interfere with the usefulness of the packing, or the proper lubrication of the moving parts.

Am-mo'ni-a Me'ter. An instrument by Griffin, for testing liquid ammonia; one spindle, with 125°, which includes the strongest ammonia that can exist at the temperature of 62° F., and extends to all weak solutions: sp. gr. .875 to 1.000.

Every degree shows seventeen grains of dry ammonia in a decigallon of liquor. In "*Chemical Recreations*," p. 329, a table is given which shows every particular respecting solutions of ammonia; the strength in atoms, the percentage of ammonia, its weight per decigallon in grains, the comparative money value of different solutions per lb., etc.

Am-mo'ni-a Ore Pro'cess. The copper and silver salts, after calcination of the ore, are dissolved by means of ammonia and ammoniacal salts; this solution is then passed through a galvanic tank, formed by a suitable and economical arrangement of sheets of platinum and copper, by which means the whole of the silver is deposited in practically a pure state, whilst the copper passes on — still in ammoniacal solution — and is precipitated as oxide, by passing steam into the solution, with the simultaneous addition of a very small amount of caustic alkali. This not only precipitates the copper as oxide, but drives off the ammonia, which may be collected for re-use. The special advantages claimed for the ammonia process are chiefly its economy and simplicity, and the purity of the products obtained.

Am-mo'ni-a So'da Pro'cess. A process of soda manufacture, the success of which is mainly due to the ingenuity and perseverance of M. E. Solvay, of Couillet, Belgium. See p. 2234, "*Mech. Dict.*"

The fundamental reaction in the manufacture — the decomposition of common salt in solution by bicarbonate of ammonium into insoluble bicarbonate of sodium and chloride of ammonium, and the regeneration of the ammonia by treatment with lime — as contrasted with the cycle of reactions involved in Leblanc's process, attracted the attention of technical chemists long since. As early as 1838, the method was patented in England by Dyar, Gray, Harrison, and Hemming.

The subject is fully and lucidly treated in the Report of Dr. Jenkins, "*Paris Exposition Reports*" (1878), vol. iv., pp. 44 *et seq.*

See also "*Scientific American Supplement*," * 2707, 2719, * 3969, * 4112.
"*Scientific Amer.*," June 24, 1876; and vol. * xxxvi. 405.

Am-mo'ni-a Test Ap'pa-ra'tus. W. W. Goodwin's ammonia and sulphur test apparatus, for gas works.

"*American Gas-light Journal*," * July 3, 1876.

Am'o-ri'ni Vase. A vase to be presented as a love-token. For instance, one at the Paris Exposition, by Solon, in the style of Louis XVI., the body in céladon, and an upper zone in blue with cupids in white. The vase supported by cupids (amorini), molded in oxydized silver.

Am'pli-fi'er. (*Microscope.*) A plan for increasing the magnifying power by means of a double concave lens placed in the body tube of the microscope, between the object-glass and the eye-piece.

The *Tolles* amplifier is discussed in the "*American Journal of Microscopy*," February, 1878. The remarks are reproduced in part in "*Scientific American*," xxxviii., 152, 202.

The Rev. J. H. Wythe, M. D., describes two amplifiers used by himself, as follows: —

"Either of them is used in a sliding tube between the eye-piece and objective, and the proper position is found by trial. The first consists of a cylindrical lens, conical in shape, with the smaller end concave, toward the object-glass, and the larger end convex. This gives a large increase of magnifying power and excellent definition when used with the strongest eye-piece of Gundlach, or other makers. The second form is better still, and consists of a double concave lens, having a virtual focus of about 1¼", at the end of a tube about 6" long, at the other end of which is the ordinary negative eye-piece. In both these forms the extent and flatness of the field is quite remarkable, as well as the amount of light, while the amplification is very great. With a periscopic eye-piece of Gundlach, or the No. 3 of the same maker, or with the strongest eye-piece of Crouch, my ⅛th objective defines the semi-lenses on the frustule of *Pleurosigma angulatum*, the markings on *S. gemma*, or *Grammatophora subtilissima*, with a power of 4,000 diameters."

See also "*Carpenter on Microscope*," 1875 ed.

An'a-cos'ti-a. (*Fabric.*) A French goods made on a serge loom, and having a worsted warp and merino wool weft.

An'æs-thet'ic In-ha'ler. An instrument for the administration of ether, chloroform, nitrous oxide, etc. See pp. 92, 93, "*Mech. Dict.*"

In the illustration is a metallic inhaler consisting of —

A, A metallic hood containing
B, A flexible rubber hood covering both mouth and nose.
C, Exhaling valve.
D, Two-way stop-cock.
I, Packing through which passes a silken cord attached to a mouth-gag.
J, Contains the inhaling valve.
F, Hollow sphere containing sponge saturated with the anæsthetic liquid through the opening *G*.
H, Cover to close it when out of use.

A'nal Di-la'tor. (*Surgical.*) Instruments f[illegible] distending the *sphincter ani* to permit examinati[illegible] of the mucous wall of the rectum, are shown [illegible] *Tiemann's* "*Armamentarium Chirurgicum*," as f[illegible] lows: —

Anal Dilator, Fig. 563, p. 119, Part III.
Thebaud's Sphincter Ani Dilator, Fig. 534, p. 119, Part III.

Called also Rectal Dilator.

A'nal Spec'u-lum. (*Surgical.*) *Speculum ani.* An instrument for exposing to view the interior of the rectum. The references are to *Tiemann's* "*Armamentarium Chirurgicum*": —

Gorget-formed Speculum, Fig. 549, p. 117, Part III.
Trivalve Trellis Anal Speculum, Fig. 547. *Ibid.*
Ashton's Fenestrated Anal Speculum, Fig. 546. *Ibid.*
Bodenhamer's Recto-colonic endoscope, Fig. 548. *Ibid.*
Bivalve Speculum Ani, Figs. 534, 559. *Ibid.*
Williams's Rectal Speculum, Fig. 623. *Ibid.*

See also Anal Dilator; Hemorrhoid Instruments, etc.

A'nal Sup-port'er. (*Surgical.*) A pad of similar application to a truss, for supporting the part in cases of *prolapsus ani. Matthieu's, Tiemann's* "*Armamentarium Chirurgicum,*" Part IV., p. 134, Fig. 207; and p. 19, Fig. 46.

An'a-lyz'er. (*Optics.*) The upper one of the two Nichols' prisms in the polariscope; the lower one being the polarizer. See Polariscope.

An-a-mor'pho-scope'. A device to illustrate certain optical effects.

The object has distorted figures, which become perfect on being looked at in the mirror.

Fig. 52.

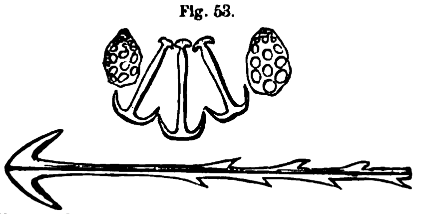
Anamorphoscope.

An'a-tom'ic-al Syr'inge. For injecting the arteries of the human body with an embalming fluid, or, in subjects for demonstrating anatomy, with a colored fluid which solidifies *in situ.*

An'chor. 1. The analogues in nature of the mariner's anchor are amusingly like the grapnel.

The upper one in Fig. 53 is from a relative of the sea-cucumber (*Leptosynapta Girardii*). It is covered with the symbol of the deep. The skin is filled with minute perforated oval plates, to each of which is attached by the shank a perfect little anchor. Doubtless the flukes of these anchors give it the means of keeping itself in place. The lower specimen is the *Pheronema*, which has its threads near the extremities marked by projecting notches, while at the very extremity it is actually anchor-shaped, as shown by a thread greatly magnified.

Fig. 53.

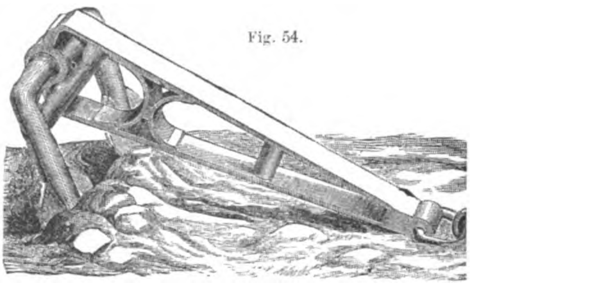


Natural Grapnels of a Holothurian. Anchor and Barbed Threads of a Pheronema.

Rosella, also, has a great outlay of mooring-threads, with frequently a line quadrate-barbed at its extremity. These lines have actually at the bottom a four-hooked grapnel.

Williams's "Reliance" anchor is without a stock, and is designed to be non-fouling and self-canting. It holds by both flukes at once, and has no stock

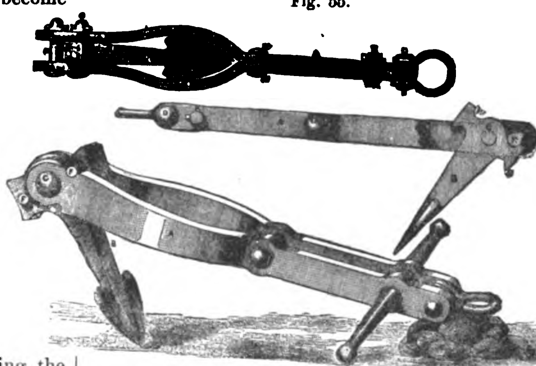
Fig. 54.



"Reliance" Anchor.

to foul the cable, like the Latham anchor, Fig. 190, p. 95, "*Mech. Dict.*" The pair of flukes hinged in the head are also like the Latham and the Morgan (Fig. 188, *Ibid.*). The Marshall (Fig. 189, *Ibid.*), has also hinged flukes, but they are independent.

Fig. 55.



Tyzack's Anchor.

In the celebrated Trotman anchor (Fig. 182), the arms are hinged to the shank.

Tyzack's anchor (Fig. 55, British) has a shank, *A*, made in two parallel parts secured together by pins, and a single arm with a fluke *B*, fitted with a *T*-head, which rests against a pin *H*. The advantages of this form are similar to those just recited: Relative lightness, absence of stock, ready assumption of holding position, ease of handling, etc.

This anchor was tested to destruction at the Lloyd's proving-house, Netherton, England, finally giving way at 250 per cent. overproof.

"*Engineer*," * xliii. 355.

The Martin self-canting anchor is in much favor with the British admiralty, all the turret-ships being provided with it, has no stock, nor steadying arms. Admiral Inglefield's modification of the Martin resembles the latter in the special feature that the arms are on parallel lines, and so grip the ground simultaneously. It differs from it, however, in the very important characteristic, that instead of the arms being made of one forging, and working through the crown, they are formed of separate forgings, and are attached to the shank by a swivel pin. The advantages gained for the anchor are greater holding power and less liability to foul.

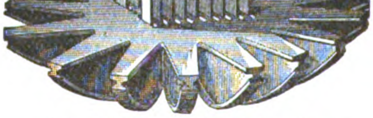
Fig. 57.



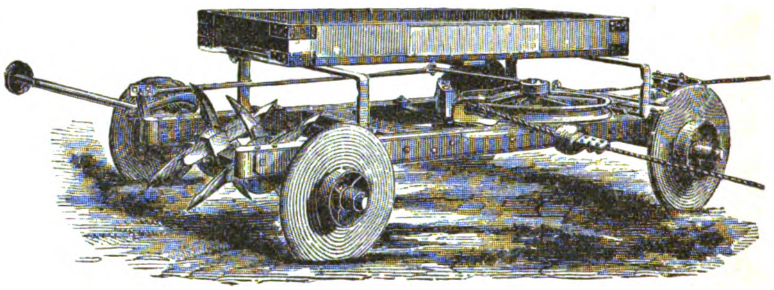
Anchor-plate, East River Bridge, N. Y.

2. The anchors for the suspension cables of the East River bridge are shown in Figs. 56 and 57. In the former the cable and anchor are shown in position, and in the latter figure an anchor-plate is shown separately.

Each anchor-plate weighs 23 tons, and is made with 16 radiated arms. Four of these anchors are required at each end of the bridge, two meeting on the central longitudinal line, and the others disposed one at each side. Each is imbedded in concrete in the third row of stone. Through apertures left in the centers of the plates the first set of bars for the chains is placed. Each chain has 10 sets of links and two sets lead from each plate. The section Fig. 56 exhibits the arrangement. To each pair of bars a strand of the cable is attached so that 19 strands in all will be fastened to the ends of two chains of bars leading from each anchor-plate. The strain on each of the four cables is estimated at 1,833 tons, or 7,332 tons on the collected four cables. Against this is the dead weight of the masonry structure, amounting to 44,000 tons. There is besides a pressure on the joints of the imbedded links which has been considered and provided for.

"*Scientific American*" . . . . * xxxiv. 15.
See also "*Scientific American Supplement*," * 754, 755.

Fig. 58.



Traction Rope Anchor for Steam Plow.

3. A movable pulley carriage to which the traction wire-rope of a steam plow passes at the headlands.

The frame carries a horizontal sheave and rests on thin disk wheels, which cut into the ground, and resist the side strain of the engine and implement. It is moved along the headland by the motion of the sheave or pulley, which is turned by the rope: the sheave is connected by gear to a drum, which winds up a rope stretched along the headland, and keeps the anchor opposite its work. The apparatus is provided with a steerage, which enables it to be worked along a crooked headland, and is managed by a boy, who also attends to shifting rope-porters. The box is to hold stones, intended as a counterpoise, to prevent the anchor from being pulled over when doing very heavy work.

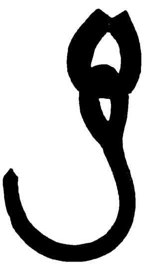
The particular form shown is designed for the roundabout system. Two anchors are employed, occupying positions opposite to each other on the headlands, and proceeding at a right angle to the course of the plow. This form of anchor is automatically moved the regulated distance, equal to the width of cultivation of the implement at one passage, and this without the draw-rope reaching to a claw-anchor at the other end of the field.

See STEAM PLOW, "*Mech. Dict.*"

An'chored Net. (*Fishing.*) One secured by sunken anchors or stones, as with some seines. In contradistinction to *drifting* or *staked* nets.

An'chor Fish'-hook. An anchoring hook for fish-nets or lines. The line is bent around the grommet and lashed.

Fig. 59.



Anchor Fish-hook.

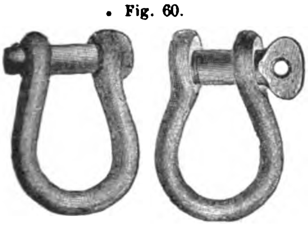
An'chor Lift. A device to lift the pile or pole wherewith a dredge or lighter is anchored. Such a pile is known — in Mississippi River parlance, at least — as a *grouser*, which see.

Canan's anchor-lift is a device on the dredge operated by hydraulic power to grip the anchoring pile during its upward movement, and slacken from it on the return motion, and so by a succession of movements to raise it from the mud or sandy bottom into which it had been driven.

"*Scientific American*," * xxxv. 70.

An'chor Shack'le. (*Nautical.*) The bow or clevis, with two eyes and a screw bolt, or bolt and key, for securing the cable to the ring of the anchor. Also used for coupling lengths of chain cable.

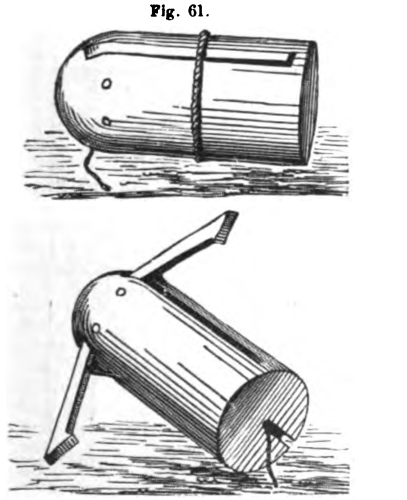
Fig. 60.



Anchor Shackles.

An'chor Shot. (*Life-saving Apparatus.*) A three-fluked anchor, with cord attached, fired from a gun on shore or aboard: in the first case, to afford communication with a stranded vessel; in the second case, to get a rope ashore, to enable boats to land through the surf. A *grapple-shot*; or *barbed shot*, which see.

Fig. 61.



Chandler's Anchor Shot. Before firing and after firing.

The invention of Capt. Ralph Chandler, U. S. Navy; the shot has hinged anchor flukes projecting from its sides, and folding back into slots, so as not to interfere with the entrance of the shot into the gun; but expanding when fired, to catch in the rigging. To the rear of the shot a chain or wire rope is attached, and carried to the front of the shot through another slot.

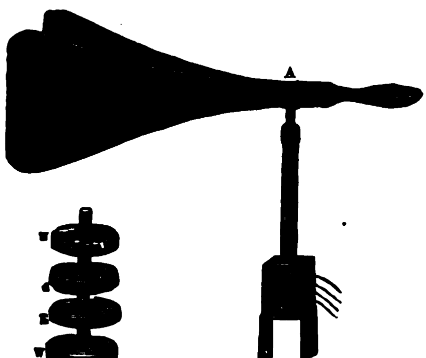
An'der-son Bat'te-ry. (*Electricity.*) The ordinary zinc and carbon elements are employed; the zinc being placed in the porous cell and immersed in a solution of muriate of ammonium, and the carbon in oxalate of chromium and potassium, in combination with free bichromate of potassium and hydro-chloric acid.

"*Scientific American*," * xliii. 115.

A-ne'mi-us. A small chemical smelting furnace.

A-nem'o-graph. The vane for recording the direction of the wind, used in the observatories of France, consists of two connected strips of thin copper, about 2′ in length, attached to an axis at *A*, and having a counterpoise, which enables the vane with its axis to turn with great readiness.

Fig. 62.



Wind Vane of French Anemograph.

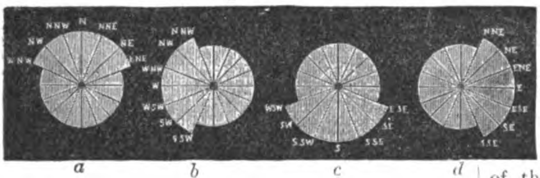
The axis has four copper disks attached. These are shown detached to the left of the cut, Fig. 62, and also in Fig. 63. Each disk is so cut that only $\frac{6}{16}$ths of its circumference has the full size; this portion only comes in contact with a metallic spring, of which there is one for each disk, and this wire connects with electric apparatus in the office of the observer. But two of the disks can be in electric connection at the same time.

Take the left-hand disk (Fig. 63), for instance, Its surface has the 16 divisions, but only the 6, from E. N. E. to W. N. W., are on the extended portion of the perimeter, so as to touch the spring belonging to this disk. The other disks have each also the same proportionate parts of extended perimeters: the second disk from N. N. W. to S. S. W., and so on.

To illustrate, by tracing the action through a portion of a revolution, — at the compass point N. N. E. the North disk (*a*, Fig. 63) alone touches a wire, and but one pencil records upon the traveling paper ribbon until N. N. W. is reached, when the West disk (*b*) closes the electric circuit, and two pencils record until W. N. W. is reached, when the circuit of the N. disk is broken, and the W. disk alone records. So on of the other portion of the circuit.

It will be noticed that at the cardinal points, N., W., S., E., and two points on each side (32 points

Fig. 63



French Anemograph Disks on turning axis.

to the compass), only one telegraphic pencil is at work; at intermediate points two pencils record. Thus the direction of the air current is read within a point or two. Greater accuracy might be attained by multiplying the number of disks. The French observatories have four recording cylinders moved by clock-work. In the United States instruments one cylinder receives the four traces.

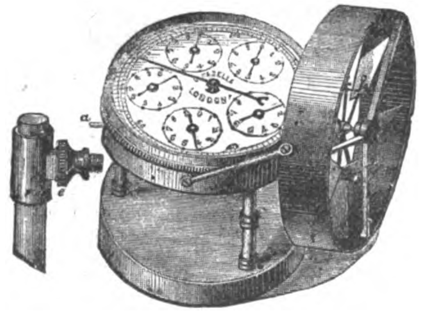
The anemograph of M. Redier, of Lyons, has a vane supported on a wheeled tripod revolving on a circular rail. The axis prolonged downward has a paper-carrying cylinder upon it; this is graduated vertically and horizontally, and a pencil applied to the paper is moved vertically by clockwork. The tracing gives wind direction and time.

An′e-mom′e-ter. An instrument for ascertaining the rate of the wind.

Casella's anemometer is a portable instrument, and is especially intended for measuring the velocity of currents of air passing through coal-mines, and the ventilating spaces of hospitals and other public buildings.

The indications are shown by a large dial and hand, and five smaller ones. The large dial is divided into 100 parts, and represents the number of

Fig. 64.



Casella's Anemometer.

feet up to 100 traversed by the current of air. The five smaller dials represent 1,000, and so on, multiplying successively by 10, to 10,000,000 = 1,893 miles. By means of the large dial, as low a motion as 50 feet per minute may be measured. By means of the catch, *a*, the work is put out of gear. A handle and universal joint, *e*, allow the apparatus to be lifted to a higher level, or thrust into an aperture.

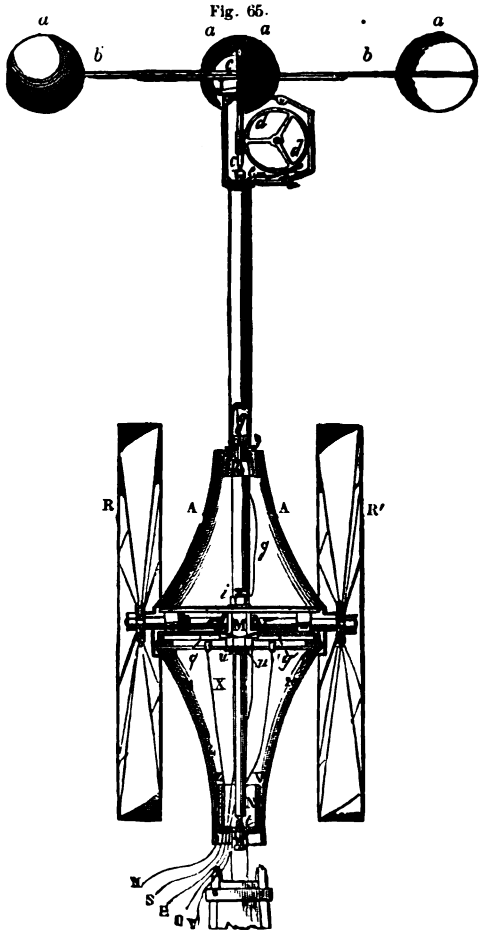
An′e-mo-met′ro-graph. An instrument for recording the rate and direction of the wind.

The anemometrograph of *l'Ecole des Ponts et Chaussées* of France, is composed of two parts which may be regarded as distinct: the *anemometer* proper and the *register*.

The anemometer is on the principle of that invented forty years since by Dr. Robinson, of the Armagh Observatory, Ireland. It is composed of a hollow vertical shaft, of which the lower portion is secured on a mast of any convenient height. The upper end carries four radial horizontal spokes, *b*, at angles of 90°, each terminated

Fig. 65.



Anemometrograph of the Ponts et Chaussées, France. (*Elevation.*)

by a light hemispherical metallic cup *a*, so disposed that the concavity of each is presented towards the convexity of the next one.

When this windwheel — as it may be called — is exposed to a current of air, the wind strikes in the hollow of that cup, the concavity of which is favorably presented, but glides from the convexity of the others. Thus the windwheel assumes a rotary motion on its axis. It was demonstrated by Dr. Robinson that the number of turns in a given time are proportioned to the rate — that is force — of the wind, and it has been found that the number 3 expresses the relation between the speed of the wind and the space traversed by the wings. Thus an anemometer, of which the circle described by the center of the wings is equal to 1.67 meter, will give for each turn of the wings an indication of 5.01 m. as the distance traversed by the wind.

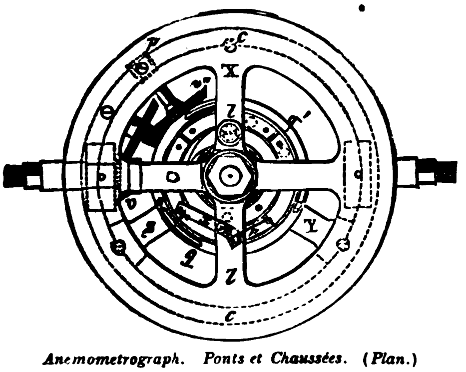
Below the windwheel is a counter, which, by means of an electric wire (*V* in Fig. 65), transmits to the register (Fig. 67), the indications of speed.

Farther beneath, on a horizontal arbor, are fixed two large wheels *R R′*, with inclined vanes, which are driven by the slightest current of air.

The spokes of the wind-cups *a a* are mounted on a small vertical axis, *c* (Fig. 65), the pointed foot of which reposes upon an agate plate in a socket. A worm-wheel on the axis rotates a wheel, *d*, which has 200 teeth, and which carries on its side face two metallic pins which successively touch in passing a spring, *e e*. A wire *g* connects this spring with a binding-post, *i*, to which it is secured.

The shaft which supports the windwheel and the counter is hollow to permit passage to the insulated wire *g*, and is united by a screw-joint to the portion beneath, in which the axis of the windwheels *R R′* is journaled. *J* is a cap to protect from rain and dust.

Fig. 66.



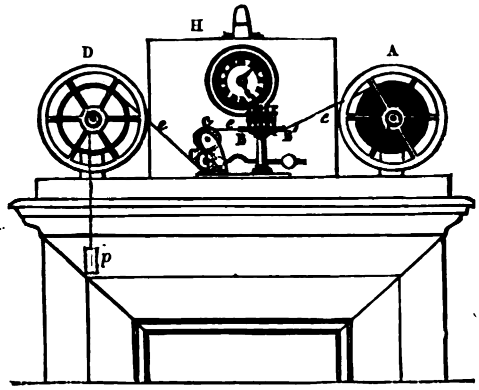
Anemometrograph. Ponts et Chaussées. (Plan.)

The horizontal arbor of the wheels *R R′* operates by means of the wheels and pinions *v v″* (Fig. 66), and a pinion meshing into a fixed crown wheel, *c c*, attached to the body *X Y Z*, which supports the whole instrument. Owing to this arrangement, when the wheels commence to turn under the influence of the wind, the pinion *p* turns also, but, in virtue of the reaction which it receives from the fixed teeth of the crown-wheel *c c*, it is displaced, and the wheels take a movement of translation around the vertical axis *M N* (Fig. 65), until the plane of their wings becomes parallel to the direction of the wind. The axis *M N* rests in a socket, *t*. A brass ring, *u*, secured by a screw, *u′*, holds it in the socket, and at the same time preserves the necessary connection between the moving and fixed portions of the instrument.

A cross-piece, *l l*, attached to the moving portion of the instrument, carries two springs, *x r*, which, drawn by the movement of translation, strike successively on four metallic sectors, separated one from the other, and inlaid in an insulated disk. From these four sectors, which correspond to the cardinal points, N., S., E., W., proceed four electric wires, *N S E O* (Fr.) as seen in Fig. 65. The binding post *i* communicates with another spring, which strikes in all positions upon a metallic circle, also imbedded in the insulated disk. The metallic contacts of the springs on the sectors, or on the circle, suffice to establish electric connection with the register, which remains to be described.

The registration is effected on a paper ribbon, *e e* (Fig. 67), which is unrolled from a bobbin, *A*, and which, having passed over an anvil, *B B′*, envel-

Fig. 67.

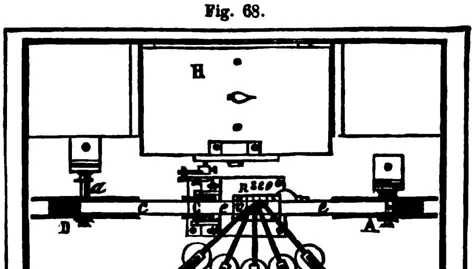


Anemometrographic Register. Ponts et Chaussées. (Elevation.)

ops in part the engine-turned cylinder *C′*, on its way, in turn to be again wound on the wooden drum of a pulley, *D*, which is turned by a weight, *p*, suspended by a silken cord from its axis.

The cylinder *C′* is governed by a clock movement inclosed in the box *H*, which gives the paper a uniform rate of motion. The inscription of the meteorological indications derived from the apparatus formerly described, takes place upon the paper ribbon by means of 5 steel points, *v, n, s, e, o,* put in

Fig. 68.



Anemometrographic Register. Ponts et Chaussées. (Plan.)

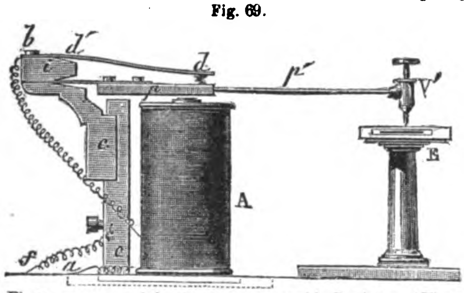
movement by the passage of an electric current in the electro-magnet corresponding to each point.

The 5 electro-magnets are identical with the pulsating armature electric bells; an improvement due to M. Hervé Mangon, now Director of the *Conservatoire des Arts et Métiers.*

The following is M. Hervé Mangon's arrangement of the electro-magnet in the registering apparatus of the Anemometrograph of *l'Ecole des Ponts et Chaussées* of France.

One of the poles of the battery communicates with the extremity a (Fig. 69), of the wire of the bobbin A. The other extremity of the wire of the bobbin is fixed by the screw b to the steel spring

Fig. 69.



Electro-magnet of the Anemometrographic Register. (Elevation.)

d' d. The other pole of the battery connects by the wire f, with a metallic piece, c c, which supports by a steel spring the soft iron armaturé p, the rod p', and the tracing point V'. An insulator block, i, separates the spring b d' d from the piece c.

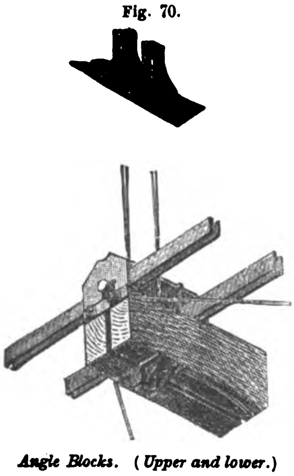
It will be seen that the electric current entering at a, follows the wire of the bobbin, arrives at b d' d, passes by the contact d, in the palette p, arrives at the piece c, and passes off by the wire f. As soon as a current is thus established the soft iron core of the electric coil attracts the palette p; the point V' descends, and strikes the paper placed beneath it on the anvil E. This descent destroys the contact between d and p, and breaks the circuit, consequently the palette p, obeying the spring which sustains it, rises to resume its former position and elevates the point V'. The contact is re-established in d and the preceding phenomena are repeated.

The point V' thus receives a rapid vertical vibration as long as the current is maintained.

It will thus be understood, referring to Fig. 65, that the point v will strike every time that the current shall be closed by the contact of the pin on the wheel d d, and the spring e e; that is to say, each time that the windwheel makes 100 turns.

As to the matter of the direction of the wind, it will be recalled that the striking springs are always in contact with one, or, at most, two of the four sectors answering to the winds of the cardinal points. It results from this that the electric current will pass by one, or at most by two, of the electro-magnets N S E O. The traces left then on the paper ribbon indicate the successive directions of the wind. If the two springs are in simultaneous contact with two opposite sectors, the two electro-magnets corresponding thereto will operate together, and will indicate

Fig. 70.



Angle Blocks. (*Upper and lower.*)

that the direction of the wind is comprised b the two cardinal points to which the two appertain.

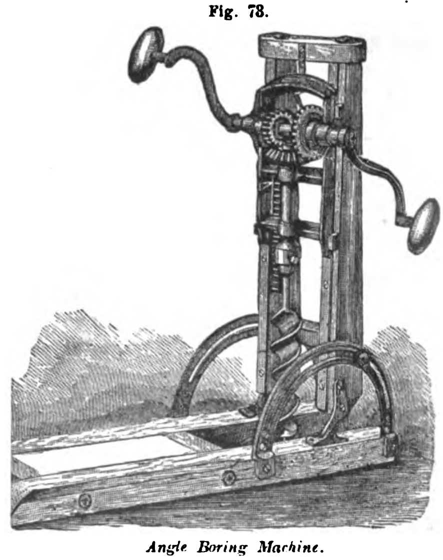
Fig.

Angle Blo

It has usually an iron frame and sheave, an anchored to a stake, or lashed to a ring-bolt.

An'gle Bor'ing Ma-chine'. A carpent machine for boring mortises. The semi-circu guides allow the standard to be set at any an with the base which lies flatly upon the timber, order to allow the holes to be bored at any desi angle.

Fig. 73.

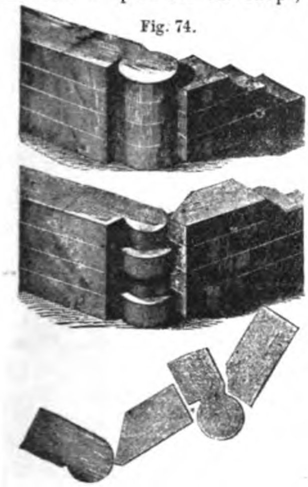


Angle Boring Machine.

An'gle Brick. Bricks specially formed to enable other than square angles to be turned; either to make acute or obtuse angles, or to make the quoin ornamental. The angle bricks, shown in Fig. 74, are of the latter character, admitting of a molding in the corner, either cylindrical or with assizes of varying diameter.

An'gle Car-bor'ing Ma-chine'. A framing machine adapted for car shops, bridge work, etc. being capable of straight, angle, and end boring, saving the moving of the timber by being itself adjustable. (See Fig. 75.) Especially useful in boring holes in truck and body bolsters for truss-rods. The spindle has a horizontal movement of 24″. The head has a horizontal movement in planed slides in the frame, which permits it to be brought close up to the stuff when doing angle-work. The head is adjusted vertically by the hand-wheel, obviating the necessity for movement of the timber. The overhead belt is kept at a proper tension by a weighted pulley, which is hung in a slack loop of the belt.

Fig. 74.



Angle Bricks.

Fig. 76.

Angle Check Valve.

Fig. 77.

Angle Cock for Sugar-house use.

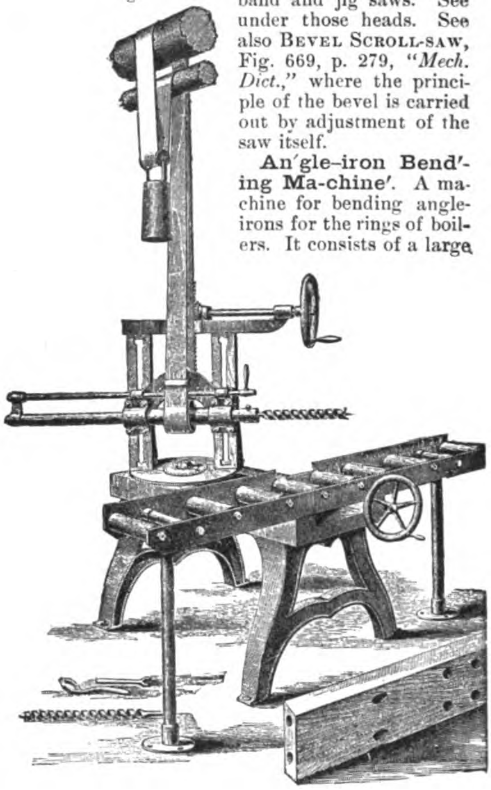
An'gle Check Valve. A valve in a pipe meeting another at an angle.

An'gle Cock. One occupying a position at a turn or bend of a pipe, as in the instance shown, Fig. 77, which is one adapted to sugar-house use.

An'gle-cut'ting Cir'cu-lar Saw. One adapted by adjustable bed and fences to rip, groove, or cross-cut, on any line oblique to the general working-line of the piece.

Angle cutting adjustments are found on other classes of saws, such as band and jig saws. See under those heads. See also BEVEL SCROLL-SAW, Fig. 669, p. 279, "*Mech. Dict.*," where the principle of the bevel is carried out by adjustment of the saw itself.

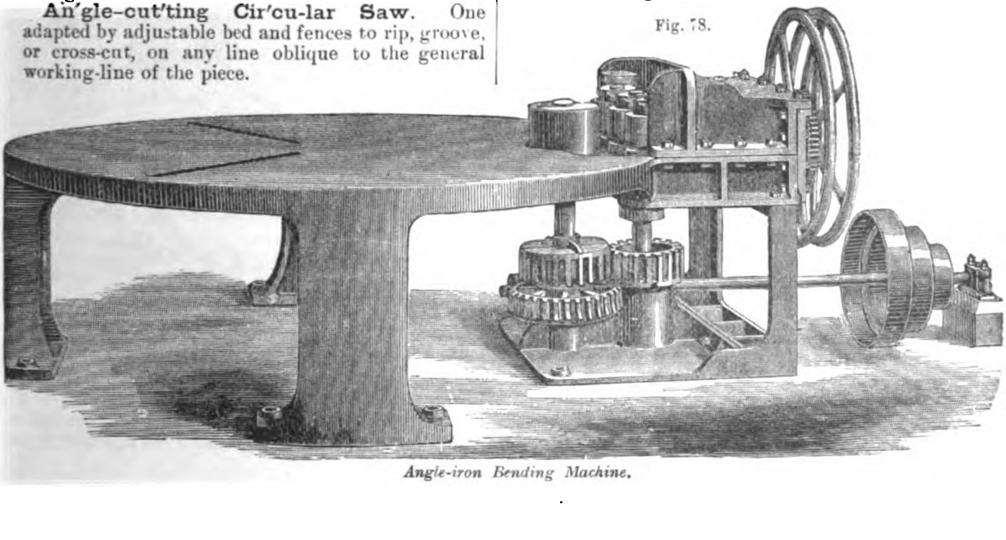
Fig. 75.



Angle Car-boring Machine.

An'gle-iron Bend'ing Ma-chine'. A machine for bending angle-irons for the rings of boilers. It consists of a large circular cast-iron table, to one side of which the bending mechanism is attached. There are one large and three small vertical rolls. The larger one revolves upon a fixed spindle, while the spindles of the others can be traversed by means of screws. The angle iron to be bent is gripped between the fixed and the middle traversing roll, and the two outer ones are then moved forward simultaneously to bend the bar to the curves required. One of the large hand-wheels is used for moving

Fig. 78.



Angle-iron Bending Machine.

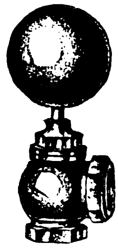
the gripping roller, and the other for traversing the bending rolls, the screws employed for this being geared together. The two gripping rolls are driven by the gearing shown in the drawing, the moving roll being connected to the gearing by universal clutches, which allow a free motion to be given to the sliding bearings. The two bending rolls are free on the spindles, and are not driven. For carrying the angle-irons upon the table, rollers may be recessed into its face.

The machine illustrated in Fig. 78, was made for bending angle-irons for boilers 8′ in diameter.

"*Engineering*," * xxiii. 421.

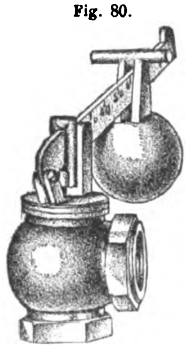
An'gle Meas'u-rer. Rutherford's glass scale, for the mensuration of angles of astronomical photographs, is about 10″ in diameter, divided to 10 minutes of arc, and adapted to a spectrometer similar to the one used by Mascart, and described in his paper on the measurement of wave lengths. The measurements are read by two microscopes, each magnifying 75 diameters. — "*Scientific American*," xxxv. 133.

Fig. 79.



Angle Pressure Valve.

Fig. 80.

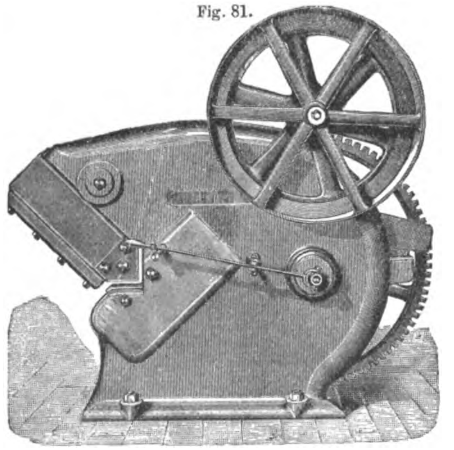


Angle Safety-valve.

An'gle Press'ure-valve. A weighted valve at the bend of a pipe. Fig. 79.

An'gle Safe'ty-valve. One placed at the bend or angle of a steam-pipe. Fig. 80.

Fig. 81.



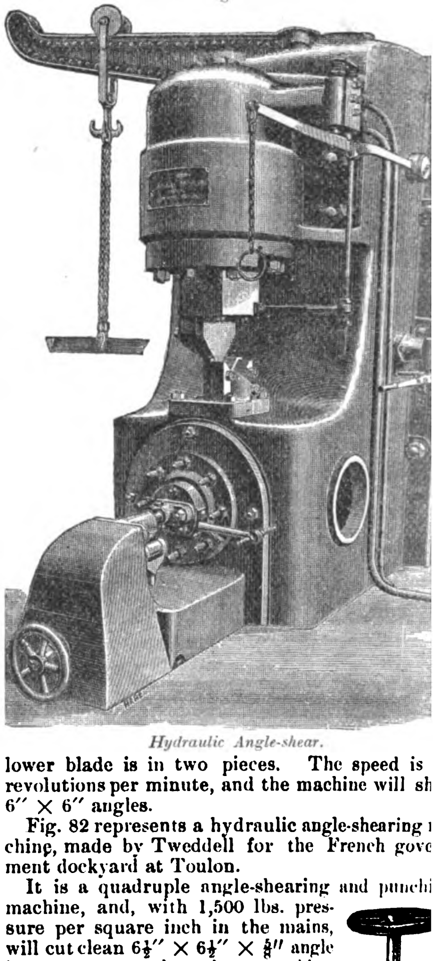
Angle-shearing Machine.

An'gle-shear'ing Ma-chine'. A shear adapted for cutting angle-iron while resting on trestles. Fig. 81.

The blades have no shear given to their edges; but by punching the angle off with a cut extending over all parts of the iron with uniform pressure, the piece cut off is not bent out of shape.

The shear is operated by a heavy wrou lever within the housing. An independe motion will permit the blades to rest open

Fig. 82.



Hydraulic Angle-shear.

lower blade is in two pieces. The speed is revolutions per minute, and the machine will sh 6″ × 6″ angles.

Fig. 82 represents a hydraulic angle-shearing chine, made by Tweddell for the French gove ment dockyard at Toulon.

It is a quadruple angle-shearing and punchi machine, and, with 1,500 lbs. pressure per square inch in the mains, will cut clean $6\frac{1}{2}'' \times 6\frac{1}{2}'' \times \frac{5}{8}''$ angle iron or any equal section, punching 1-inch holes in the same. The machine is really composed of four distinct tools, having independent connections to the main. In the shop the machine is partly sunk below the ground line.

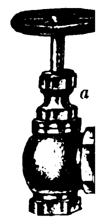


Fig. 83.

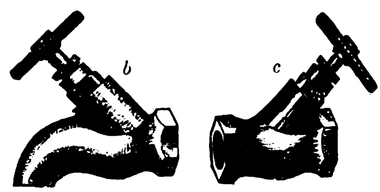
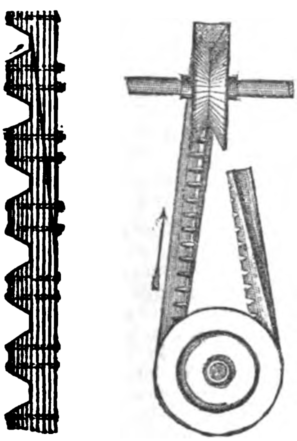


Angle Valves.

a. Angle valve in bend.
b. Full-way angle bib-valve.
c. Full-way angle stop-valve.

An'gle Valve. 1. One placed at a bend of a pipe or tube. In *a*, Fig. 83, it is operated by a screw and hand-wheel, and has screw connection sockets.

Fig. 84.



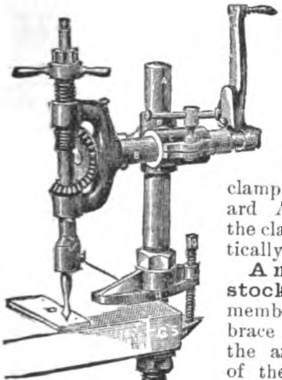
Angular Belting.

2. One having an angular presentation relatively to the line of direction of the pipe, as in *b*, *c*, Fig. 83.

An'gu-lar Belt'ing. A belting made of truncated wedging pyramids of leather of many plies, cemented and riveted together, the whole strongly riveted to a conveying strap of leather. (See Fig. 84.) The belt fits into the angular peripheral channel of the belt pulley, and has great adhesion.

An'gu-lar Bench Drill. A portable drill attachable to a bench, and capable of angular presentation relatively to the surface of the latter. Fig. 85.

Fig. 85.

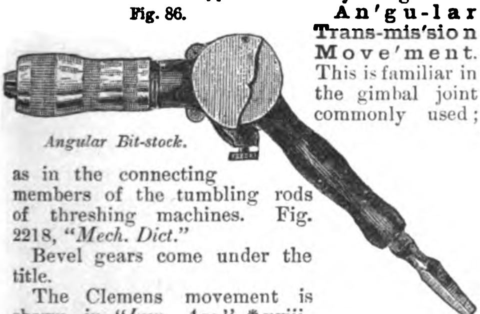


Angular Bench Drill.

The clamp *H* attaches it to the bench. The hollow shaft, *B*, may be slipped, or it may be rotated in the clamp *C* on the standard A, upon which the clamp itself is vertically adjustable.

An'gu-lar Bit'-stock. An extension member to the ordinary brace having a joint for the angular transmission of the movement to the bit so that the latter may reach an object to which the brace cannot be applied vertically. Fig. 86.

Fig. 86.



Angular Bit-stock.

An'gu-lar Trans-mis'sion Move'ment. This is familiar in the gimbal joint commonly used; as in the connecting members of the tumbling rods of threshing machines. Fig. 2218, "*Mech. Dict.*"

Bevel gears come under the title.

The Clemens movement is shown in "*Iron Age*," *xviii., September 28, p. 1.

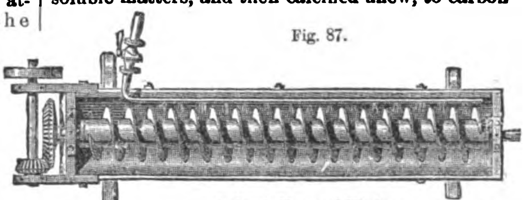
An'i-line Pen'cil. From Portuguese *anil*, derived from *nil*, the Sanskrit name of indigo, the *indicum* of Pliny.

French aniline pencils are made in grades, according to the hardness, very much like common lead pencils. The materials used are aniline, graphite, and kaolin, in different proportions. Made into a paste in cold water, the material is pressed through a screen that divides the mass into the slender sticks used in filling the pencils. When dry, the sticks are fitted to the wooden parts, and these are glued together in the usual way. They may be used in copying, marking in permanent color, and in reproducing writing or designs. In copying, a thin sheet of moistened paper is laid over the letter, design, or document, and the lines are traced with the pencils. The action of the water on the aniline gives a deep, fast tracing, resembling ink in color. On ordinary dry paper they give a well-defined mark that cannot be removed by India-rubber. When the paper is dampened with water, the markings assume the appearance of ink. Moistened sheets laid over the writing, under a slight pressure, will transfer good impressions, that do not blur, and that resemble the original in every respect.

An'i-mal Char'coal Re-viv'i-fi-er. The fabrication of bone-black, employed in sugar-houses as a decolorant and absorbent, consists in the carbonization of bones in a closed retort; the bones having previously been broken, and deprived, by boiling, of their fatty components. Green bones give a maximum of organic substance rather than those long exposed to the air, and give by calcination a more active decolorant.

The revivification of the charcoal consists in the processes employed to restore the decoloring property. For this purpose it is first washed to remove soluble matters, and then calcined anew, to carbon-

Fig. 87.



Animal Charcoal Washer.

ize the organic matters absorbed. This may be done twenty to twenty-five times, as the loss is from 4 to 5 per. cent. at each operation. This loss represents the diminution in weight, but the loss in value is greater, as the quality also deteriorates.

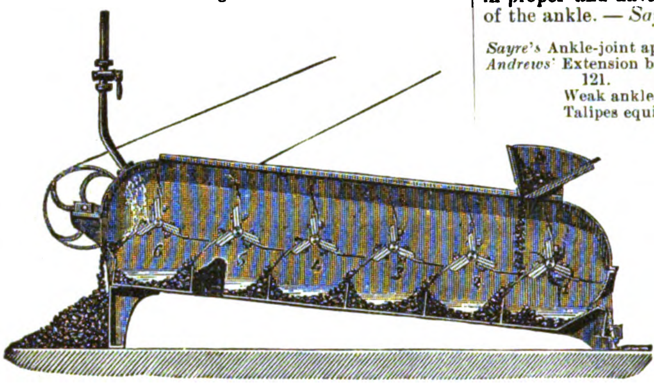
The washing may take place in water or in an alkaline liquor; but the preference is given to a weak solution of hydrochloric or acetic acid. Following the washing in the acidulated solution, which has, in the beet sugar process, for its special object, the separation of the carbonate of lime absorbed, it is necessary to wash in clear water to remove the lime and traces of acid not neutralized. The washing takes place in the apparatus, Fig. 87, or Fig. 88; the former being customary in France, and the latter — the Klusemann washer — being used principally in Germany.

The action of the French machine is evident, the bone-black, fed in at one end, is passed to the other by means of the endless screw, being subjected to jets of water from the horizontal pipes throughout its whole course.

The German machine receives the charcoal from the hopper *A*, at the lower end of the machine. A stream of water is introduced at the other end, and the charcoal is advanced against the stream by successive liftings from one partition to another, until it is dumped at the upper end.

Furnaces, for recalcination of the bone-black, are shown in Figs. 786, 787, p. 328, "*Mech. Dict.*" The usual French charcoal revivifying furnace is that

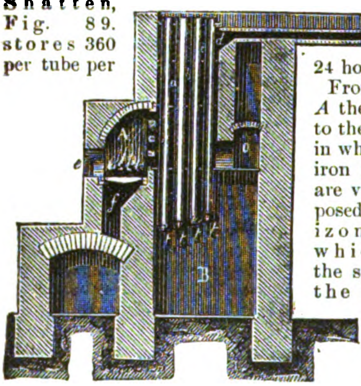
Fig. 88.



Klusemann's Animal Charcoal Washer.

of Blaise, mentioned in most books treating of the Beet-root industry (which see). A favorite German furnace is that of Shatten, shown in Fig. 89. This restores 360 kilograms per tube per 24 hours.

Fig. 89.



Animal Charcoal Furnace.

From the hearth *A* the gas passes to the furnace *B*, in which the cast-iron retort tubes are vertically disposed, having horizontal plates which separate the space around the retorts into four divisions. The upper and second quarters of the tubes are exposed to moderate and increasing heat respectively. In the third is the full heat of the fire, and the lower extends beneath the furnace bottom and allows the bone-black to cool before being discharged by the withdrawal of the register, which closes the lower end. The upper end of the retort is open, and the bone-black, somewhat dried upon the platform over the chimney, is shoveled into the tubes, the production being at the rate, say, of 11 pounds per 20 minutes, that quantity being retired below, and additional charge shoveled in above. The temperature is about 275° C., and the material augments in density in varying proportions, ranging from 77–80, up to 90–115.

It has been proposed by MM. Laurent and Thomas to revivify charcoal by superheated steam at a heat of 300° C., but it has not, according to M. C. Laboulaye, been reduced to practice.

An'kle Boot. (*Manége.*) A covering for the ankle of a horse, to protect it from injury when struck by the other feet; made of leather or heavy felt, with a small piece, called a shield, placed over the part to be protected.

An'kle Com-press'or. (*Surgical.*) An application of the nature of a bandage, consisting of a rubber sac around the joint, with tubes, by which hot or cold water can be passed through. — *Dr. Sayre.*

An'kle-joint Ap'pa-ra'tus. (*Surgical.*) An apparatus for maintaining the leg, foot, and ankle in proper and unvarying adjustment, for treatment of the ankle. — *Sayre.*

Penrose and Richards' Anthracite Coke Furnace.

c is the supply hopper.

An'thra-cite Dust Fur'nace. A furnace for burning the dust or slack of anthracite coal. This accumulates by millions of tons in the anthracite regions of Pennsylvania and Wales, and is a material addition to the cost and waste of mining operations in those regions. See Waste Coal Burning Locomotive, for description of J. E. Wooten's locomotive.

An'ti-clink'er Grate. A stove grate placed below the fire-pot so as to leave an annular opening between the two through which the clinkers can be raked out from the fire.

An'ti-fric'tion-ate. A name given by the inventors to a combination of materials welded into a solid mass, for machinery bearings, or bearing linings. Patents July 6, and July 27, 1875.

An'ti-fric'tion Bear'ing. This subject has been considered under many heads: —

Anti-friction bearing.	Anti-friction pulley.
Palier glissant.	Anti-friction step.
Anti-friction box.	Anti-friction wheel, etc.
Anti-friction metals.	

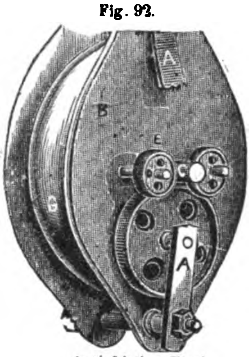
See pp. 118, 119, etc., "*Mech. Dict.*"
Avery's anti-friction has a circle of partially imbedded rollers in the journal. "*Scientific American*," * xl., 278; article "*Rouleaux*," * *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," iv., ed. 1877, where *Chauffour's* and *Brussaut's* (*) systems are described.

An'ti-fric'tion Block. One with roller bearings.

Such are seen in the "Climax" door-hanger, and in Fig. 263, p. 119, "*Mech. Dict.*"

In the illustration, Fig. 92, the pin *C* is keyed fast into the hub of the sheave *G*, and rests and turns on the roller bearings, one on each side of the block. The sheave *G* turns 5 times while *H* turns once. The smaller rollers, *E*, *F*, are to keep the axis *C* in place. The strap *A* is broken, to expose the parts.

Fig. 92.



Anti-friction Block.

An'ti-fric'tion Met'al. Belgian anti-friction metal is composed of —

Copper	20
Tin	4
Antimony	0.5
Lead	0.25

Mix all the other ingredients before adding the copper.
Doubleday's consists of cast-iron, copper, glass, antimony, tin, spelter, and lead. U. S. Patent, 178,841.
Coline. (*French*) Asbestos and graphite in equal parts; mix, and reduce to a paste by addition of silicate of soda or potash. Pressed to shape in a hydraulic press, or pressed to a block and turned to shape when solid. When the bearing is shaped, steep in hot melted paraffine or wax; in solution of paraffine, benzole, or other mineral oil.
See U. S. Patents: —

189,684	*Behrens*	April 17, 1877.
162,065	*Harrington*	April 13, 1875.
157,509	*Guile*	December 8, 1874.
154,317	*Campbell*	August 25, 1874.

234,482	*Hunt*	November 16, 1880
175,841	*Doubleday*	June 20, 1876
217,946	*Jackson*	July 29, 1879.
153,154	*Campbell.*	

An'ti-fric'tion Plow. One with rollers on sole, land side, or mold-board, to avoid friction of the passing soil. A doubtful expedient.

Such were shown at the Centennial by two Swedish exhibitors: Catherineholm's Foundry, and L. P. Eklundh.

It is, however, an old device. See *d*, *e*, *f*, Fig. 3823, p. 1745, "*Mech. Dict.*" Wilkie's plow of this class dates from 1825.

An'ti-in-crus'ta-tor. A material, process, or device to prevent the incrustation of steam boilers resulting from the adherence of a scale of salts of lime, etc. See list on p. 1177, "*Mech. Dict.*"

Vigier Process	"*Manufacturer and Builder*," x. 124.
Zinc	"*Scientific American*," xxxv. 158.
	"*Scientific American Supplement*," 518.
Morehouse	"*Scientific American*," xlii. 374.
Holden's Alloy	"*Scientific American Supplement*," 468.

An'ti-mo-ny Pho'to-graph. A process invented by F. Jones (Br.).

The process is based upon the reaction which takes place between sulphur and antimoniated hydrogen or stibine in the presence of light, by which sulphide of antimony results as the product of decomposition. "*British Journal of Photography*," 1876. Reproduced in "*Scientific American Supplement*," 352.

An-tique' Bronz'ing. A process designed to give the *patina* or surface effect seen on ancient bronze, and due to exposure and the effect of time. Also known as ORUGO, which see.

The repeated applications on copper or brass of alternate washes of dilute acetic acid, and exposure to the fumes of ammonia, will give a very antique-looking green bronze, but a quick mode of producing a similar appearance is often desirable. To this end the articles may be immersed in a solution of one part of perchloride of iron in two parts of water. The tone assumed darkens with the length of immersion.

Or, the articles may be boiled in a strong solution of nitrate of copper.

Or, they may be immersed in a solution of two ounces nitrate of iron, and two ounces hyposulphite of soda in one pint of water. Washing, drying, and burnishing complete the process. See also BRONZE COLORING.

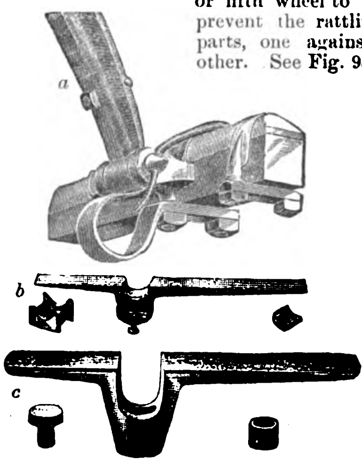
An'ti-ra'cer. A governor for propeller engines to prevent the *racing* of the screw when the ship pitches and throws the propeller out of the water.

Durham, Br. . "*Engineer*" . . . . * 1878.
"*Scientific American Supplement*" * 2397.

See MARINE ENGINE GOVERNOR.

An'ti-rat'tler. An attachment to a carriage coupling or fifth wheel to prevent the rattling of parts, one against the other. See Fig. 93.

Fig. 93.



Anti-rattlers.

a. Represents Ladd's anti-rattler for shaft or pole couplings. A spring presses against the thimble to keep it from chattering on the bolt.
b. Is a fifth wheel anti-rattler. A caoutchouc pad rests in the bearing.
c. Wilcox's fifth wheel anti-rattler. A rubber sleeve is placed in the recess, and the rivet fastens down upon it.

Fig. 94.

Antiseptic Spray Apparatus.

An'ti-sep'tic Spray Ap'pa-ra'tus. (*Surgical.*) An atomizing apparatus for suffus atmosphere with vapor of an antiseptic solı the vicinity of a wound while being dres upon a cut surface during an operation. M ter is the principal authority in the matter, practice is most observed.

The apparatus is generally a steam atomi alcohol lamp making a jet of steam which c the antiseptic liquid into spray. The appara *Hank*, *Weir*, *Head*, *Little*, and *Tiemann*, are in *Tiemann's* "*Armamentarium Chirurgicum*," I., Figs. 408–412, pp. 119–123.

Figure 94 shows that of Dr. Weir, of New See "*New York Medical Journal*," December,

A somewhat similar apparatus is that o Louis Sass, of New York, described in "*Sci. American Supplement*," * 1164.

An'trum Tre-phine'. A small crown used by dentists when it is desired to ente antrum through a tooth socket.

Antrum Drill, *Pope's*, Fig. 50, p. 12, Part I., *Tien* "*Armamentarium Chirurgi*

An'vil. A plate or cup inside the head

Fig. 95.

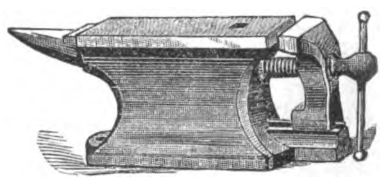
Antrum Trephine.

cartridge to strengthen it. See CUP ANVIL; I ANVIL.

Anvil for Paper Cartridge Shells, *Saget*, * "*Sc. Americ* xxxv. 53

An'vil Cup'per. (*Cartridge.*) A machine making the inside cup or case of the cartri which holds the fulminate; the stamp cuts tl out, and by a die working inside the stamp, dr them to the required length.

Fig. 96.

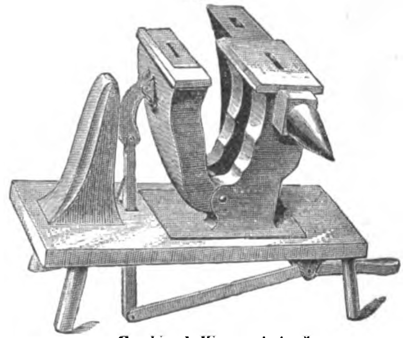


Anvil and Vise Combined.

An'vil Vise. A compound tool in which tl anvil forms one jaw of the vise.

Two forms are shown, in Figs. 96 and 97. On has a screw jaw at the square end of the anvil, an

Fig. 97.



Combined Vise and Anvil.

the other has a long jaw worked by treadle against the side of the anvil.

Ap'a-re'jo. A pack-saddle, or the whole apparatus necessary for loading pack animals. It is one of a number of terms such as "sinch" (Spanish *cincho*, a girth) and "cabresto" (Sp. *cabestro*, a halter), which are working into our language from our Mexico-Spanish frontier.

Ap'er-ture Sight. (*Rifle.*) Another name for the *open bead sight.*

See Bead Sight.

A'pex. (*Mining.*) The top or highest point of the mineral.

Aph'lo-gis'tic Lamp. A flameless lamp; one with platinum sponge and glass wick-holders. Also known as the *Dobereiner lamp*, and *Hydrogen lamp*.

A-phon'go-scope. See Megascope.

Ap'la-nat'ic Search'er. (*Optics.*) Another name for the amplifying lens. See Amplifier. That of Dr. Royston Pigott is described in "*Microscopic Journal.*"

A-plat'is-seur. A name from the French. A grain-flattening mill. Used for the rough crushing of grain for feeding stock. It has a pair of rollers between which the grain is fed from a hopper.

See Grain-crusher.

Ap'o-neu'ro-tome. (*Surgical.*) A blunt pointed curved knife, the blade on the concave edge, used in supra-pubic lithotomy in cutting the tendinous membranes, *aponeuroses.*

Fig. 155, p. 42, Part III., *Tiemann's* "*Armamentarium Chirurgicum.*"

Ap-par'i-tor Au'ris. A species of ear-cornet in which the canal is elongated and overbridged so

Fig. 99.

Apple Corer and Slicer.

Fig. 98.

Apparitor Auris.

that sound entering the aperture A (Fig. 98), cannot diffuse, but is conducted within the tunnel through the meatus auditorius B to the tympanum.

The instrument is of silver, with flesh-colored enamel, is so shaped as to be worn within the concha, and is sold in pairs, one for each ear.

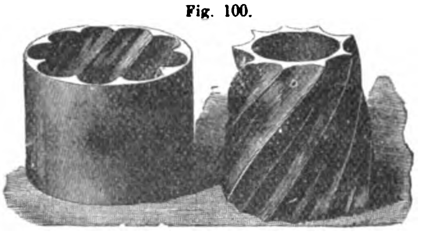
Ap'ple Co'rer and Sli'cer. An implement, Fig. 99, which acts by a simple downward thrust, removing a cylinder of apple containing the core, and cutting the apple into eight pieces.

Ap'ple Gra'ter. The Boomer & Boschert apple grater has an iron cylinder with planed grooves to receive the knives (8) which are adjustable by set screws above and below at each end, and held in their places by a heavy wrought iron band shrunk on at each end of the cylinder. The concaves consist of five iron levers with movable weights.

"*Scientific American*," * xlii. 242.

Ap'ple Grin'der. A mill for grinding apples previous to pressing the pomace.

Fig. 100.



Nut of the Apple Grinder.

Fig. 100 shows the galvanized cast iron nut and concave of the "Peekskill" apple grinder.

Fig. 101.

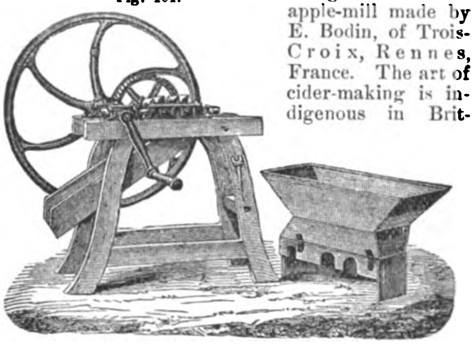


Fig. 101 shows an apple-mill made by E. Bodin, of Trois-Croix, Rennes, France. The art of cider-making is indigenous in Brit-

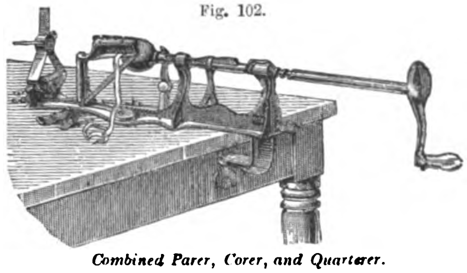
Bodin's Apple Grinder, Rennes, France.

tany, and it is considered that the crushing-mill is superior to the grater, giving a pomace which affords a clearer juice, with less pulp, and consequently less tendency to ferment. The *nuts*, or toothed cylinders, have six teeth, and can be approached or parted by means of two screws.

The duty is from 175 to 200 gallons per hour, by the moderate work of two men.

Ap'ple Par'er. The "Missouri" combined apple parer, corer, and slicer, works by a horizontal motion, the circular movement of the shaft rotating the apple, and the endwise movement of the shaft giving the sweep to the knife; after which a simple thrust delivers the apple to the corer and quarterer, the quarters dropping to the table while the fork withdraws with the core. See Fig. 102.

Fig. 102.



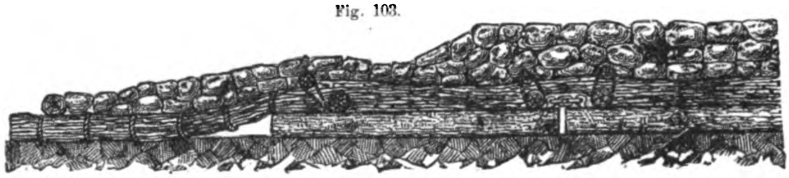
Combined Parer, Corer, and Quarterer.

Ap'pli-ca'tor. (*Surgical.*) Uterine and urethral applicators, for introducing medicaments, caustic, sponge tents, etc.; pp. 21, 65, 73, 77, 82, 83, Part III., *Tiemann's "Armamentarium Chirurgicum."*

Ap-plique'. 1. (*Fine Art Metal Working.*) Ornaments produced by affixing portions to the surface of the object. The metal is previously rolled or stamped into figures, scrolls, braids, etc., and these are soldered on to the object to be ornamented. The result resembles *repoussé*, which is, however, produced by indenting the metal from the interior.

2. In cloth work, also known as *opus consutum*, or cut cloth work, the patterns are cut out and then sewed on.

Fig. 103.



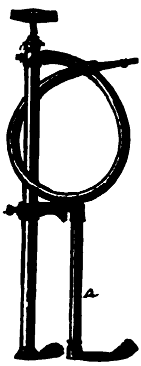
Apron.

A'pron. (*Hydraulic Engineering.*) A protecting surface of logs and brush anchored by rip-rap (or similar contrivances), to protect or to form revetment for river sides, or to form a jetty.

See instance of apron in Charleston Harbor improvements. "*Report of Chief of Engineers U. S. Army,*" 1879, * i. 734.

Savannah River. *Ibid.*, * i. 742.

Fig. 104.



Douglass' Aquapult.

Fig. 103 shows a portion of a cross-section of an apron. It consists of rip-rap, lying on brush anchored by poles and founded on logs.

A'pron Fas'ten-er. A species of catch, resembling a buckle, used for fastening the apron cover on the dash-board of a vehicle. It consists of an apron hook and an apron ring.

A'qua-me'ter. A name for the pulsometer, a vacuum steam-pump. See AQUOMETER.

A'qua-pult'. A portable force-pump. The foot of the barrel stands in a bucket of water and the foot of the operator is on the step of the post *a*, Fig. 104. The pump being thus steadied, the handle is worked up and down, and the stream of water may be directed upon plants, fire, carriage, or what not.

A-qua'ri-um. The aquarium of Brighton is described in some detail, on p. 127, "*Mech. Dict.,*" and reference made to parlor aquaria.

The late Exposition at Paris has furnished a most admirable work of the kind, shown in Plate II.

The aquarium is upon the hill of the Trocadéro, and is for fresh-water fish only. The site was quarried out of the hill, the natural rock being left to form the sides of the tanks and galleries. It covers a surface of 3,200 square meters.

The surface of the water is exposed to the rays of the sun, and light is admitted through the water to the grotto.

These tanks, 24 in number, are connected with each other in a gradually descending series, and the water overflowing each in succession is received into the one next below, the whole presenting, when viewed above ground, the pleasing appearance of a rivulet spanned by numerous rustic bridges and skirted by artistically planned and well-arranged walks. From these walks the visitor can observe the motions of the fish in the tanks below him, but a more accurate survey and closer observation can be had from the interior and lower level, where the fish are rendered plainly visible by reason of the effects of the light passing through the water.

The area of the walks on either side of the tanks is sufficient for the accommodation of 2,000 visitors at a time. The basins which contain the water are formed by the original excavations and artificial rock-work, made to imitate stalactites. These sustain the frames holding the glass plates, which are $\frac{86}{100}''$ in thickness, and number about 250 in all. The water used is the same as that supplied to the city of Paris, from the headwaters of the Vanne, and has a temperature during the summer of from 12° to 15° C. A supply can also be obtained from the Seine if necessary.

As the water is obtained very near the source of the river, it is deficient in oxygen, and in order to supply this element, so essential to the existence of the fish, an apparatus for aërating the water was introduced, the invention of M. Gauckler, chief engineer of roads and bridges, who was, in fact, the author of the original plan of the aquarium.

Some of the basins are 15′ in depth, and the total capacity of the tanks is about 2,000 cubic yards. Forty-six different species and varieties of fish are contained in the tanks, and one peculiarly interesting operation was performed in this aquarium in 1878: the hatching of 35,000 eggs of California salmon, sent by Prof. Spencer F. Baird to the French *Société d'Acclimatation*. Twenty-six thousand were hatched under the care of M. Carbonnier.

When it is remembered that the eggs were taken (artificially) from fish caught on the McCloud River, California, and thence transported across the American continent by rail, and across the Atlantic Ocean by steamship, the loss of only 10,000 eggs was a great triumph for American and French fish culture. The young fish were distributed as follows: —

To the Sarthe	5,000
To the Vienne	5,000
To the Yonne	5,000
To the Adour	5,000
To the Gave de Pau	5,000

The remaining 1,000 were placed in Tank No. 18 of the aquarium. The safe deposit of these fish in the above-named streams was a matter of great rejoicing to the French.

The cost of the aquarium was 50,000 francs.

The London Crystal Palace aquarium is 400′ long and 70′ broad, and the total capacity of all the tanks is 200,000 gallons of water, weighing 1,000,000 pounds. Of sea-anemones alone there are already in the aquarium over 3,000 specimens. These flower-like animals, being deprived in their captivity of the ocean currents which bring them their food, have to be fed at frequent intervals, each having given to it a morsel of food suited to its size.

A'quo-me'ter. Prall & Burr's aquometer steam-pump acts by the direct pressure of the steam upon the water. It has two working chambers, and an intermediate pressure chamber. A double acting balanced valve alternately admits the steam to each working chamber where its pressure closes the water induction valve, opens the water eduction valve on that side, and forces the water contained in the chamber out into the discharge pipe. During this time the induction valve of the other chamber being open, and the eduction valve closed, that chamber becomes filled with water. The steam having expelled all the water from the other chamber, through the rapidity of its exhaust and condensation, a vacuum is formed in the chamber, the unequal pressure on the ends of the steam valve shifts that valve so that the steam passes into the other chamber which has now been filled with water by atmospheric pressure, and at the same time, the water valves in the one chamber are thrown into their proper positions to admit and retain the water ascending through the suction tube, and in the other to permit the water to be expelled therefrom by the steam pressure.

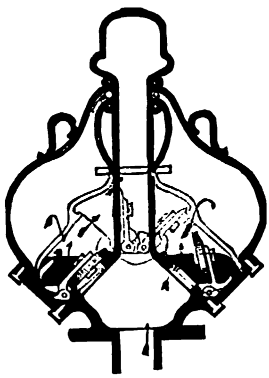
Fig. 105.

Aquometer. (*Elevation.*)

Burdon's vacuum steam-pump has been described under that caption on p. 2687, *"Mech. Dict."* See also early forms, page 2336, *Ibid.*

Van Dusen's and Nye's are also forms of the same kind of apparatus.

Fig. 106.

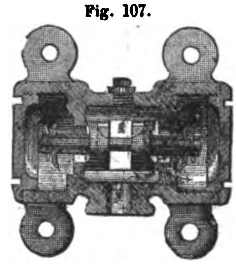


Aquometer. (*Vertical Section.*)

Ar'bor, Ex-pand'-ing. A mandrel having a wedge-shaped feather, capable of being slipped so as to grip interiorly the hollow of a piece of work, or of a circular cutter.

In Fig. 108, *C* is the steel mandrel; *B B* are two of the three keys that are drawn up and pushed down by the nut; a groove is turned inside the nut *A*, which catches the heads of the keys *B*, and thus draws them up to tighten the work; in the outside of the nut *A* is a taper hole which the pin *D* fits, and which answers for a wrench. *F* represents the tool operating on a piece of work.

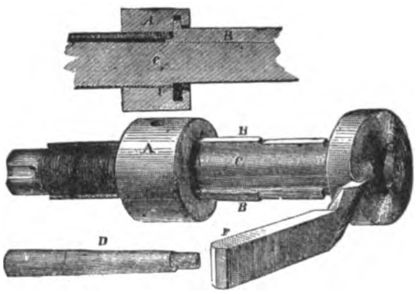
Fig. 107.



Aquometer Valve. (*Section.*)

Arch. (*Add.*) 2. (*Mining.*) A piece of ground left unworked near a shaft.

Fig. 108.



Expanding Mandrel.

3. The fire-chamber of a furnace. The term is used especially in glass-furnaces.

4. The front opening of the ash pit beneath a furnace grate.

Arch Bar. 1. A bar forming a lintel to the mouth of an ash-pit; taking the place of the ordinary brick arch.

Fire-place arch bar, *Wickersham,* * *"Scientific American,"* xxxv. 22.

2. The curved upper member of a round-topped truss.

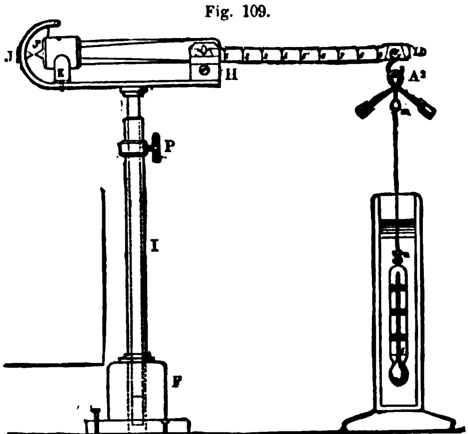
3. A curved bar in a frame depending upon its camber for its stiffness.

Arch Screw Press. One in which the punch and its slide are supported on a frame arched above the die-bed; in contradistinction to one with an over-hang arm or bracket support for the punch-slide.

A're-o-therm'ic Bal'ance. An invention of M. Blondeau for determining the density of liquids. Its advantages are the facility with which the operations may be performed, and the readings taken, the approximation of the specific weight up to the fourth decimal, and its adaptation to liquids either heavier or lighter than water.

The instrument has a base, *F*, and leveling screw, *G*, and a hollow column, *I*, in which the stem of the upper part, *K H*, moves up and down, being held at any vertical adjustment by the binding screw *P*. *H* is a bearing for the knife edges that

Fig. 109.



Blondeau's Areothermic Balance.

support the beam; *K*, the scale-beam guide; *J J'* points to show the equilibrium of the beam. *A 2*, a weight which is suspended from the hook of the 10th division when the specific weight of a liquid heavier than water is sought. *M n*, hooks for suspension of the plunger with its thermometer, from the hook of the balance so that it may dip into the liquid whose density is sought, and which contains the test-glass. One of the arms of the beam carries at its extremity a cylindrical counterpoise, in the center of which is the point, *J'*; and the other is divided into ten equal parts, numbered from 1 to 10. At each division there is an angular notch for receiving a weight. The method of regulating and using is described in a French paper translated and reproduced in "*Scientific American Supplement*," * 3773.

Ar'gen-tif'er-ous. (*Mining.*) Containing silver.

Ar'gen-ti'na. (*Ceramics.*) A name given by M. Hausen, of Stockholm, to his method of covering unglazed porcelain with a coating of gold, silver, or copper. The process is supposed to be as follows: The porcelain articles are dipped in a solution of the metal, similar to that used for electro-plating, and then, by a peculiar process of reduction (perhaps by means of phosphorus vapors), the salt is decomposed, and the metal is deposited within the pores of the earthenware. Articles covered with a metallic coating according to this process, present every appearance of being entirely composed of the metal.

Ar'ith-mom'e-ter. A calculating machine. A number of forms are shown in Figs. 325–329, pp. 143, 144, "*Mech. Dict.*"

Staffel's arithmometer is provided with an attachment, which, if an impossible operation, such as dividing a number by another larger than itself be attempted, stops the machine and rings a bell.

Ar'ith-mo-pla-nim'e-ter. An invention of M. Lalanne; an extension of the principles of the planimeter for calculating certain formulas.

Reference is made at page 1728, "*Mech. Dict.*," to the planimeter of Oppikoffer, and the polar planimeter of Amsler is shown there in Fig. 3794.

The conical planimeter of Lalanne is furnished with longitudinal and transverse scales for calculations, and is shown in Fig. 353, Article "*Calculer*," tome i., *Laboulaye's* "*Dictionnaire des Arts*," etc., edition 1877.

Arm. (*Surgical.*) A dry cupping chamber, inclosing the arm. See DEPURATOR, p. 687, "*Mech. Dict.*"

The apparatus is known as "*Junod's Arm*," from the name of the introducer in Parisian medical practice, about 1855; but it was patented in England by Smith, in 1802. It is a metallic receiver with an elastic band, to exclude access of air, the atmosphere being exhausted from the interior by an air-pump.

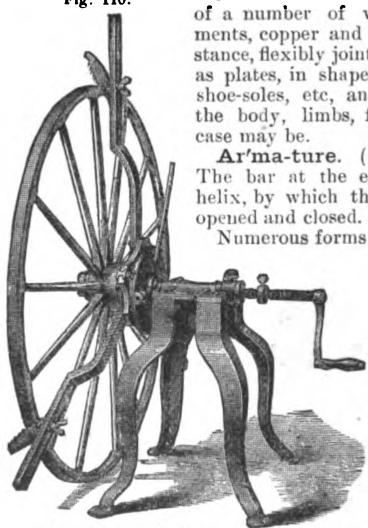
See, also, AËROTHERAPY APPARATUS.

Ar'ma-dil'lo. An electro-magnetic remedy for nervous diseases. It consists of a number of voltaic elements, copper and zinc for instance, flexibly jointed together as plates, in shapes for belts, shoe-soles, etc, and worn on the body, limbs, feet, as the case may be.

Ar'ma-ture. (*Electricity.*) The bar at the end of the helix, by which the circuit is opened and closed.

Numerous forms are shown in treatises on electricity. A compend is given in "*Scientific American Supplement*," * 2,900. See, also DYNAMO-ELECTRIC MACHINE, and list under ELECTRICITY.

Fig. 110.



Arm Boxing Machine.

Arm Box'ing Ma-chine'. A machine for boring the hubs of wheels for the reception of the box for the arm of the axle. The wheel is held, chucked as it were, by three equidistant points on the rim, and the boring device thus presented at the exact center, at right angles to the plane of the wheel.

Ar'mor Com'pound. Ship's armor, having a steel face and iron backing. Made under English Patents to Ellis and Wilson, by Messrs. Brown and Cammell, of Sheffield, England, respectively. See "*Iron*," 1879.

The steel does its work in preventing penetration by causing the shot to break up on impact, and the more tenacious and ductile iron performs its part in preventing the destruction of the steel by being shivered.

In making the compound armor, the liquid steel is poured upon the hot iron plate, the heat of the former being in excess of the welding heat of the latter, and a semi-steel is formed between the two by fusion. Steel-faced iron plates are the latest improvement in the art.

The iron plates are placed horizontally in a furnace when a steel plate is to be cast on to a single iron one, but when a steel plate is to be sandwiched between two of wrought iron, the latter are fixed vertically and the steel run in between them. This is Wilson's plan; that of Sir Joseph Whitworth proceeds on quite a different principle, that of plugging a shield of soft steel with pins of harder quality.

Ar'mor Plate. An iron or steel skin for a vessel of war. See Figs. 337–358, and Plate IV., pp. 150–155, "*Mech. Dict.*" See, also: —

Ar'mure. (*Fabric.*) 1. The character of the weave.

The system of harnesses with which the loom is *armed*, or provided, to produce a definite tissue.

There are four fundamental or classical forms, from which all the varieties of simple tissues are derived.

(*a.*) *Taffeta*, having 2 harnesses, forming a single interlacement.

(*b.*) *Twilled*, or *Batavia Weave*, 4 harnesses.

(*c.*) *Serge*, having 3 harnesses.

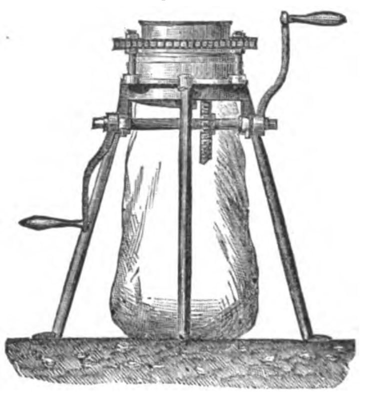
(*d.*) *Satin*, 5 or more harnesses.

See under those heads. See also FABRIC.

2. A silk and wool French dress goods.

Ar'my Mill. A portable mill standing on a tripod, driven by two men at the hand cranks, and grinding into a sack suspended beneath. It is a French invention, costs $40, grinds 44 pounds per

Fig. 111.



Army Mill.

hour, and four of them, packed in two boxes, are a load for a mule on the march.

Ar'my Scales. A portable form of scales which closes up in a box compact for transportation; such scales have a capacity from 600 to 1,200 pounds. When closed, the working parts are entirely protected.

Ar'rage. (*Mining.*) A sharp edge or corner in an adit or drift. — *Arris.*

Ar'row-head For'ceps. (*Surgical.*) An instrument for the extraction of the heads of Indian

As-bes'tos. A curious fibrous mineral; a variety of hornblende and pyroxene. It is found in many parts of the world, is of very various qualities, and requires careful preparation for some of the uses to which it is applied. See p. 167, "*Mech. Dict.*"

In the application of asbestos, it is used loose, or is made into sheets, felt, boards, braid, or rope, sometimes with a cementing substance, such as paper pulp, cement, mortar; or as a covering or lining to hair-felt, to prevent the charring of the latter when used as a covering to steam boilers and pipes.

For steam-packing the fibres are covered with braid, and made in coils of convenient length.

As a paint, it is mixed with metallic pigments, and used on wooden structures, roofs, ceilings, and partitions.

The best asbestos is found in Italy. An exhibition of asbestos has recently been held at the Simonetti Palace in Rome; the material in numerous different crude forms being exhibited, as also all the known applications of it in the useful arts. The cabinet of Mr. C. A. Wilson, of Genoa, is said to contain one hundred distinct varieties from the Alps. It is largely exported from Italy to the United States.

See "*Waste Products and Undeveloped Substances*," by Simmons. London, 1876.

The uses of Asbestos are recited on pp. 167, 168, "*Mech. Dict.*": —

Absorbent in lamps.
Boiler covering.
Coffins.
Cremation shrouds.
Electric insulators.
Fire brick and crucibles.
Firemen's clothes.
Flooring cement.
Fuel bed for petroleum.
Ink.
Journal bearings, Ingredient in.
Lamp-wicks.
Molded articles.
Paper.
Piston and rod packing, either in rope or loose form.
Porcelain.
Refrigerators.
Roofing cement.
Ropes.
Safes.
Wrapper for articles to be consumed.
Yarn.

To these may be added: —
Cellar ceilings, to prevent radiation of heat.
Sheathing paper, for walls and ceilings.
Fire-proof boxes, for shelves, etc.
Theatrical scenery.
Converting hydro-carbon into gas fuel.
Packing and lubricant, Jennings', U. S. Patent, 1828.
Mill boards, for steam joints.
Gaskets, for man-hole plates.
Filtering acids.

It is used in the shape of trays of cardboard, for containing molten metals at high temperature.

As a sponge, to contain concentrated sulphuric acid in that form of lighting apparatus known as *oxygénés*, No. 18 of the series of *lighting devices* recited on p. 1315, "*Mech. Dict.*"

Asbestos is used in Italy as a fire-bed in a furnace, petroleum being poured thereon and burned beneath the steam boiler. — *Scientific American*, xxxvi., 217. Modifications of this form the subjects of many patents in England and the United States.

See, also, Asbestos Stove, p. 168, "*Mech. Dict.*"

As a coating for metals in a furnace: —

Fire Clay, Soap-stone, Asbestos } *Nes* . . . . Patent 104,878, June 28, 1870.

See, also, *"Munsell on Paper,"* pp. 20, 25, 102.

As-bes'tos Pa'per. *Rosenthal's* method of disintegration of asbestos, for paper-making, is as follows: —

The asbestos is put into wooden tanks lined with lead, covered with water, and chemicals added. Steam is introduced, and it is boiled four to six hours. When disintegrated it is passed through a pair of rolls, the top one covered with rubber, and a rubber apron running on the lower one, by means of which the water is driven from the fiber. It is then dried, and manufactured into board on a special machine.

The Italian asbestos paper costs 40 cents per pound. The paper mills are at Tivoli, where Victoria made his successful attempt to manufacture this paper, which is specially adapted for valuable documents, etc. It has recently undergone most conclusive tests by the Marquis de Bariera at an exhibition of objects made of this substance, held in Rome. Two card-board boxes containing papers, one made of ordinary material and the other of asbestos, were thrown into the fire. The former was entirely consumed, while the latter remained intact, together with the papers it contained. It is also made into theatrical hangings. This is an excellent use of it. — *"La France Nouvelle."*

As-bes'tos Felt. Mr. F. A. Gooch, of Cambridge, Mass., describes a mode of preparing a felt of anhydrous asbestos for filtering material.

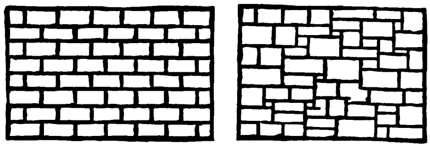
The felt is prepared by scraping white silky asbestos to a fine, short down, boiling it with hydrochloric acid, and washing it by decantation. It is then deposited, by the aid of the Bunsen pump, on the bottom of a platinum crucible perforated with fine holes; or, better, the bottom may be made of fine platinum gauze. The process is described in the proceedings of the American Academy.

As-cen'sion. (*Mining.*) The theory that the matter filling fissures was introduced from below.

Ash'lar. (*Masonry.*) Cut stone masonry.

When regular, it is *ashlar;* but when smaller cut stones break the regularity, it is called *broken ashlar*, as in the right hand illustration.

Fig. 115.



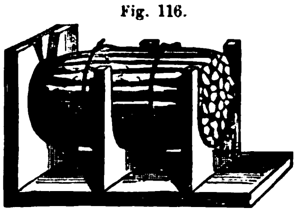
Ashlar.

Small ashlar, when the assizes are less than a foot in height.

Rough ashlar, squared, when the face is only quarry-faced or pitch-faced.

As-par'a-gus Bunch'er. The Sartrouville buncher, shown in Fig. 116, has two U-shaped frames in which the sprouts are laid, the tips symmetrically gathered in the contracted space, and the bunches tied.

Fig. 116.



Asparagus Buncher.

As-phalt' Pave'ment. Asphalt is limestone saturated with bituminous matter. — *Léon Malo.*

The first quarry opened and worked was the famous bed of Val de Travers, on the Neufchâtel Pontarlier Railroad, Switzerland. The bed extends over a distance of six miles, and is 1.75 miles wide. The thickness of the bed varies from 3 to 16 feet, the annual production of the mine fluctuating between 40,000 and 50,000 tons, occasionally exceeding the latter figure. The deposit was first discovered in 1712 by Eirinus, a Grecian physician, who obtained mineral rights from the King of Prussia, at that time in possession of Neufchâtel. Eirinus sold the product obtained by him chiefly as a cement for woodwork, masonry, etc., exposed to water.

Eirinus finally abandoned Val de Travers and went to Alsace, where he opened new mines. After his death the asphalt industry collapsed entirely, other parties who obtained control of the mines using them for distilling oils which were sold as wonderful remedies. It was not till 1802, when asphalt beds were discovered at Seyssel, on the banks of the Rhône, France, that a new impetus was given to an industry which has since steadily grown in importance.

Natural asphalt must contain nothing else but carbonate of lime and bitumen, and the latter must thoroughly impregnate the rock, the grain of which must be as fine as possible. It must not contain less than 7 per cent., and not more than 11 per cent., of bitumen, and the latter itself must not, when warmed for a long time, lose more than 2 per cent. by weight. Greater loss indicates that bitumen is not wholly tarry matter. The following analyses show the composition of the asphalt from the most important mines of the Continent, No. I. being from Val de Travers, No. II. from Seyssel, and No. III. from Lobsann, in Alsace: —

	I.	II.	III.
Water and other substances evaporating below 90° C	0.50	1.90	3.40
Bitumen	10.10	8.00	11.90

Carbonate of lime	87.95	89.55	69.00
Carbonate of magnesia	0.30	0.10	0.30
Mineral matter insoluble in acids	0.45	0.10	3.05
Other substances	0.70	0.35	2.90
Sulphur			5.00
Sulphuret of iron			4.45
Total	100.00	100.00	100.00

The **asphalt rock** is blasted with the aid of powder, dynamite having proved inefficient, probably owing to the elasticity of the rock. It is ground, or, rather, torn to pieces between two rollers rotating at different velocities and provided with steel teeth, a 10 to 12 horse-power mill being capable of reducing to suitable size from 8 to 12 tons of rock per hour. The grinding is completed in a 22 to 25 horse-power Carr disintegrator, running at a speed of 500 revolutions per minute, and turning out 5 tons of powdered rock per hour. The fine asphalt is then melted in a cast-iron semi-cylindrical vessel, provided with a system of mixing knives attached to a shaft. During the operation a varying quantity of mineral pitch is added. For a 3-ton vessel this operation lasts about 3½ hours, the greatest care being taken not to allow the temperature to fall below 175° C., or go above 230° C. The product thus obtained is called "mastic," which possesses the valuable property of rendering the asphalt capable of being melted, while the asphalt rock alone would only be converted into a powder even by the application of the highest temperatures. As soon as the mastic is thoroughly mixed, it is run into molds. For use, the bricks are broken up and melted with a small quantity (from 2 to 3 per cent.) of pure pitch, and from 30 to 40 per cent. of clean gravel.

As-phalt′, Ar′ti-fi′cial. The "Lyons" asphalt, introduced by M. Gobin into Belgium, is composed of 15 parts of bitumen, 35 parte of coal slack, 10 parts by weight of coke powder, 130 parts of lime, and 160 parts of fine gravel. The bitumen and coal slack are mixed together in a boiler, and skimmed until the formation of a scum ceases. The coke powder and lime are mixed, heated to about 300° C. in order to dry them, and then they are added to the material in the boiler. The gravel is embodied in the mixture as the last ingredient.—"*Moniteur Industriel.*"

As-phalt′ Tiles. In a Bavarian method of making flooring tiles from asphalt, the drawing of the intended design is first made on coarse, heavy paper. This is then covered with bits of china and glass, so as to form a mosaic. Lastly, a border is made to the sheet, and liquid asphalt is poured upon it. After the whole has been covered, the paper is taken away with cold water, and the tile is finished.

As-phalt′o-type. (*Photography.*) The process of Niepce; producing the image on a plate covered with bitumen of Judea. See pp. 673, 1683, "*Mech. Dict.*"

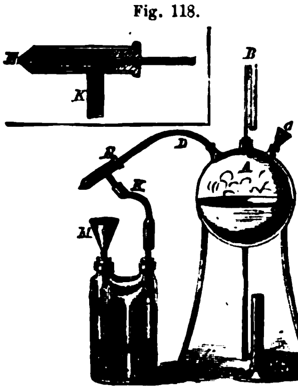
As′pi-ra′ting Fil′ter. One in which the action is expedited by the withdrawal of air from beneath the filtering material.

Fig. 117.

Aspirating Filter.

By compressing the rubber ball in the hand, the slit in the India-rubber tube, which acts as a valve at *B*, closes, and the air it contains is ejected through the valve at *C*. On removing the pressure from the ball, valve *C* closes by atmospheric pressure, leaving a partial vacuum in the ball; air passes from the flask through valve *B* into the ball, to restore the equilibrium, and a partial vacuum is created in the flask which is increased by a second squeezing of the ball. The liquid material in the filter, in consequence, will be rapidly forced into the flask by atmospheric pressure on its surface. — *Partridge.*

Fig. 118.

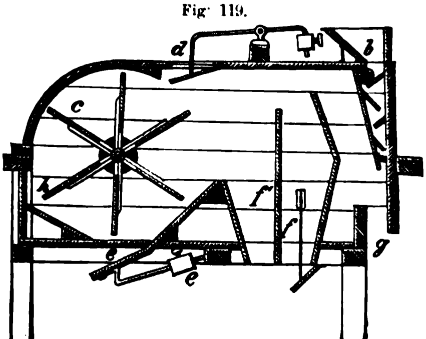


Steam Aspirating Filter.

The aspirating filter apparatus, Fig. 118, operates by steam generated in the globe *A*, which passing by *D* into *E*, issues at the point of the latter, drawing with it through *K* the air from the bottle *L*. *M* is the supply funnel; B, the steam-gage; *C*, water supply.

As′pi-ra′ting Win′now-ing Ma-chine′. One which draws air through the grain instead of blowing it. Action by suction instead of blast. This is very common in the United States in smut mills and machines of that class, but the principle is more commonly adopted with winnowers in France than with us. Fig. 119 is a French machine. The fan *c* draws air in the direction of the arrow. The grain, falling from the hopper *b*, meets the

Fig. 119.

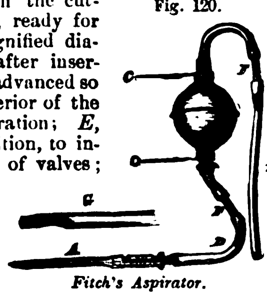


Aspirating Winnower.

blast entering at g, and, according to the comparative levity of the grain, seeds, chaff, dust, etc., each falls or issues at compartments f, f', e h. d is a counterbalanced valve, by which the force of the in-draft is regulated. e is another regulator.

As'pi-ra'tor. An apparatus or instrument for drawing air. In Fig. 120, A represents the dome aspirator-needle, with the cutting point projected, ready for puncture; G, a magnified diagram of the same, after insertion, with the dome advanced so as to protect the interior of the cavity during aspiration; E, bulb in upright position, to insure the best action of valves; C C, valves; D, entrance tube; E, exit tube; F F, bits of glass tubing, through which to observe the presence or absence of fluid. — "*New York Medical Journal*," November, 1877.

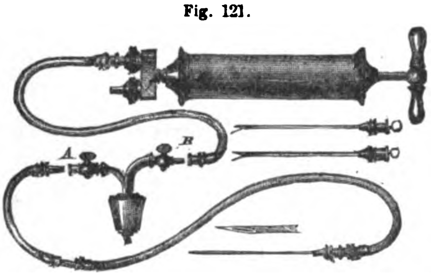
Fig. 120.



Fitch's Aspirator.

Fig. 121 is an aspirator which can also be used as an injector. The instrument consists of three

Fig. 121.



Aspirator.

needles of assorted sizes, a rubber stopper which fits into a jar, and through which passes a double-current tube provided with stop-cocks. This communicates by an elastic hose, at B, with a pump, and at A, by another hose, with the needle or capillary tube to be used.

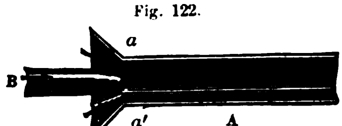
By putting the stopper in the bottle, closing the cock A, opening B, and giving 25 or 30 strokes of the pump, the air is exhausted from the bottle; then close B, and the apparatus is ready for use. The tube is introduced, and cock A being opened, aspiration commences.

To inject with the same instrument, connect the air-tube with the outward flow of the pump; put the desired liquid in the bottle, and, while holding the latter in reversed position, pump air into it. After having obtained the desired pressure in the bottle, close B, and detach the pump; introduce the tube into the object to be injected, and open A.

The rotating aspirator point for use as a trocar is a flat blade twisted. — *Dr. Warren.*

Aspirators are used in trades which produce deleterious dust, also to remove shavings and sawdust from wood-working machinery.

Fig. 122.



Aspirator for Dry Grinding. *Châtellerault.*

Various principles are used. The Sturtevant suction fan is employed. At the works of Châtellerault, in France, the jet of compressed air is used. A is a cylindrical tube, having a length at least five times its diameter. B is a tube throwing a jet of compressed air into the tube, the air at the rear being drawn forcibly through the passage a a^1 by the suction produced.

Another form of aspirator is that used in ventilation; in fact, any exhaust pump or suction fan comes within the definition. Such are used in buildings of importance, hospitals, public buildings, and halls; also in mines.

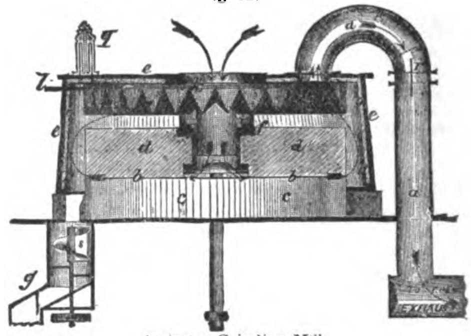
Such machines operate on various principles: the piston, revolving fan, inverted caisson resembling a gas-holder. The former two are shown in Figs. 5, 6, *Laboulaye's* "*Dictionnaire des Arts et Sciences*," tome iii, article "*Ventilation.*"

The hydro-pneumatic aspirator of M. Legat has been applied to paper-making machinery, to replace the air-pumps, which serve to make a vacuum beneath the web, on which the pulp collects to form paper. The effect of the withdrawal of the air from beneath the web is to drain out the water of the pulp, which becomes solidified sufficiently to take off and pass to the calenders.

The hydro-pneumatic aspirator is on the principle of the Giffard injector, and a view and description of it are given in Fig. 3,237, *Laboulaye's* "*Dictionnaire des Arts et Sciences*," tome i., article "*Aspirateur.*"

Fig. 123 shows the aspirating principle applied to grinding-mills, to prevent the accumulation of

Fig. 123.



Aspirator Grinding Mill.

flour dust in the husk. It is the invention of MM. Jaacks and Behrns, of Lubeck, Germany.

A fan exhausts air through the pipe a, from the mill-stone hoop, and fresh air enters with the wheat at the eye of the stone and passes between the buhrs, dd, cc. The hoop is air-tight, and has but the one inlet, k, and two outlets: one at g for the chop, and the other at a, for the warm and damp air. Leakage of air at the eye is prevented by an arrangement of two rings, h, i, one fast to the stone, and the other suspended by a leathern cylinder from the hoop e. The screw s, in the chop tube, presses out the meal, which is sufficiently tightly packed therein to prevent passage of air.

In order to retain the flour-dust within the hoop a cloth of long-haired flannel is stretched and laced up in zig-zag shape over a frame, m, which is suspended by hooks under the top of the curb, and the flannel is tacked loosely, but dust tight, against the top, at the outer and inner diameters of the frame. The flannel detains the flour-dust, but allows the warm air and vapor to pass. The dust gathers on the cloth, and is removed by occasionally striking the pin l, which causes it to drop, and go out with the chop. The valve r governs the force of the air current; q is a vacuum gage; o is a felt non-conducting lining.

As-sem′bling. For account of the parts and methods used in the manufacture of fire-arms on this principle, see RIFLE.

As-tat′ic Gal′va-nom′e-ter. One the magnetized needle of which is balanced so as to make it normally quiescescent in any position.

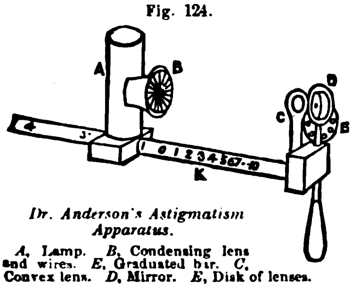
"*Manufacturer and Builder*," * xi. 276.

A-stig′ma-tism Ap′pa-ra′tus.

"Astigmatism is that condition of the eye in which the refraction is different in different meridians of the eye, owing to the refractive media not being perfectly symmetrical. An eye with a cornea shaped like the bowl of a spoon, instead of like a portion of a sphere, would be astigmatic. Dr. Anderson's instrument was exhibited at the meeting of the British Association at Swansea. In it the observations and measurements are made by the observer, and are entirely independent of the patient's sensations. The image thrown on the retina being used as an object, the error arising from the vessels or optic nerve being before or behind the retina is avoided. The refraction and accommodation of the observer does not affect the result: it is only necessary that he should be able to see whether certain lines are sharply defined.

"A lamp (A, in the engraving) is provided with a condensing lens, which has a screen of radiating wires, B, across its front, thus giving a bright field with black lines. This slides on a graduated bar, K, at the other end of which is a convex lens, C. It is better to have two of these of different powers, *4* and *10* dioptrics being convenient. Close to the lens, and at an angle of 45° to it, is a plane silvered mirror D, which reflects the rays at right angles to their former path. The instrument is held so that this pencil of rays enters the observed eye and when the screen is at the proper distance an image of it is formed on the retina. The mirror has its center left unsilvered, and has an ordinary disk of lenses, E, behind it to render the retina and the image on it visible to the observer by the ordinary direct method. The bar is so graduated that when an image of the whole or part of the screen is sharp on the retina, the figure opposite the screen expresses the refractive error of the meridian by which the image is produced. Hence, if the image of the whole screen is seen to be equally sharp, the eye is known to be not astigmatic, and the graduation gives the number of dioptrics by which it is myopic or hypermetropic. If the lines be not all sharp at once, then the most distant point at which any of them is distinct gives the refraction of the meridian of minimum refraction, and the point at which that at right angles to the former is distinct, gives that of maximum refraction. The least of these gives the spherical element of the correcting spectacle required, and their difference that of the cylindrical element. The meridian of maximum refraction is that in which the line appears distinct when the screen is at the greatest distance. If the cylindrical lens be convex its axis must be in this meridian; if concave, then at right angles to it. The makers are Cook & Sons, York. — *Lancet.*

Fig. 124.



Dr. Anderson's Astigmatism Apparatus.

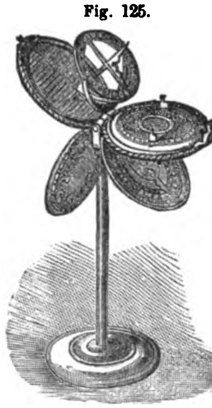
A, Lamp. *B*, Condensing lens and wires. *E*, Graduated bar. *C*, Convex lens. *D*, Mirror. *E*, Disk of lenses.

The ametrometer is also capable of being used to detect the existence or extent of astigmatism. See AMETROMETER, pp. 28, 29.

Referring to the ametrometer, it may be stated that when astigmatism is suspected, the patient should be directed to observe whether the flames are longer in one direction than the other, and if so, by the rotation of the bar on a pivot opposite to the fixed light, the two lights being placed some distance apart so that they do not appear to touch, the apparatus affords one of the most accurate means of ascertaining the meridians of greatest and least refraction, since it will become easy for the patient to say when two elongated points or ovals of light are placed so as to have the same direction; and when this has been fixed, the pointer on the instrument will indicate on the half-circle the exact angle at which the lights are placed, and hence the position of the meridian of greatest ametropia.

On bringing the flames into contact at this angle, the real distance of the lights apart will indicate the degree of ametropia, and having thus found one meridian, the lights can be placed at right angles to it, and the refraction of the second be ascertained.

Fig. 125.

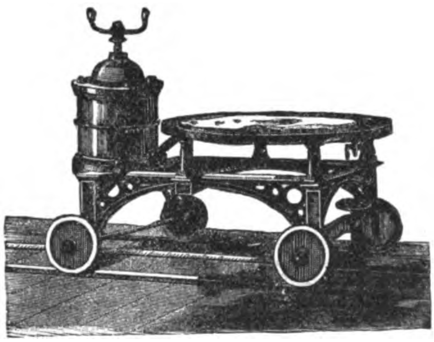


Astrolabe of Sir Francis Drake.

As′tro-labe. Several astrolabes of antiquity, and of the fifteenth and sixteenth centuries, are referred to on p. 172, "*Mech. Dict.*" The astrolabe of Sir Francis Drake is shown in Fig. 125. It was recently shown at a loan collection. It was constructed for him previous to his first expedition to the West Indies, in 1570, and was preserved in the Stanhope family till 1783, when it was presented to the Duke of Clarence, who, in 1833, deposited it in Greenwich Hospital. It is about 9″ high.

As′tro-nom′i-cal Mir′ror. An instrument devised by M. Collin to obtain a fresh reflecting surface of mercury to reflect the image of stars under observation. To obviate the necessity of removing the film from the surface of the mercury, the metal becomes cleaned during its escape from the reservoir in which it is kept hermetically inclosed. It is thus always pure and brilliant. The reservoir shown on the left is a pump cylinder, in which a piston is operated by means of the screw represented above. This forces the metal out upon a large circular shallow vessel through a connecting tube. In order to operate the apparatus conveniently, it is mounted on a carriage on rails. Between the latter is a graduated scale, so that the mirror can be readjusted at any desired point. The vertical screw shown on the right serves to fix it in place.

Fig. 126.



Astronomical Mirror.

As'tro-nom'i-cal Time Mark'er. An instrument for indicating fractions of a second by means of a sliding vernier attached to a graduated scale, which it traverses second by second. A species of metronome.

Invented by E. K. Horn, and shown in the "*Engineer,*" 1876. Reproduced in "*Scientific American Supplement,*" * 204.

As'tro-pho-tom'e-ter. An instrument designed by Zollner to measure the *brightness* of the stars by comparing them with an artificial star of standard brightness.

"The telescope is directed to the natural star, and the light of the artificial star is introduced through a lateral tube. A petroleum lamp serves for this object, the lateral tube carrying a diaphragm with a minute perforation in the center. In the interior of the principal tube, a plane glass mirror with parallel surfaces, placed at an angle of forty-five degrees, reflects the light of the artificial star to the eye; and as the mirror has a sensible thickness, two images are perceived with a small space intervening between them. The image of the natural star is brought to occupy this intermediate space. The lateral tube contains a polarization apparatus, by means of which the light of the artificial star may be modified both for color and for brilliancy. The first adjustment is for color. By rotating the polarization system the tint which corresponds to that of the real star observed is easily obtained, as in the saccharimeter. Then by turning one of the prisms of the system, the brightness of the artificial star, which is always at first superior to that of the real object, is gradually subdued until the two intensities are sensibly equal. As the image reflected from the first surface of the mirror is necessarily the brighter of the two, this one is selected as the standard of comparison. The other serves as a lower limit, and between the two the determination can be very accurately made." — *Barnard.*

Ath'a-nor. The alchemist's base-burning furnace. It is described on p. 175, "*Mech. Dict.,*" and is to be found in —

At-tri'tion Mill. One operating by impact and mutual attrition of the material under treatment. A flouring mill in New York working on this principle has a wheel of some 3′ in diameter and 3″ thick, inclosed in a box of about 4′ in diameter and 8″ thick. The wheel makes 2,000 revolutions per minute, receives the wheat in its center, and whirls it around with such violence that by rolling friction against the sides, but especially by mutual friction or attrition, it becomes pulverized.

A *disintegrator.* See Fig. 1565, p. 707, "*Mech. Dict.*" Cited in "*Manufacturer and Builder,*" May, 1877.

At'wood Steel. (*Metallurgy.*) Steel made by a process in which iodide of potassium is used to take up the phosphorus existing in the iron.

Van Nostrand's "*Engineering Magazine,*" xvi. 280.

Au'di-om'e-ter. An instrument invented by Professor Hughes. It is a combination of the telephone, a new form of microphonic key, and a Leclanché battery. By its means the power of hearing sounds can be accurately gaged and recorded on a suitable arbitrary scale. The one in use is divided into 200 degrees, the zero being the point of positive silence, the absence of recognizable sound produced by the instrument through the telephone, and the maximum being audible to every one not actually deaf. The first point ob-

Atomizers.

a. Dr. *Knight's* atomizer. The vial is connected with the tube by a metallic cup, which is screwed on, and may be so turned as to nearly exclude air and render the spray exceedingly fine.
b. Dr. *Clark's* atomizer, with the addition of a shield.
c. The "Constant" atomizer.
d. The Boston atomizer, with single bulb.
e, f. Other forms.
g. Steam atomizer. It has a brass boiler, steam outlet tube, rubber packing, through which the atomizing tube passes; a safety valve; a suspended medicine-cup; a flaring face shield, and the waste cup to catch the drops.

served with the instrument is that the power of hearing sound is very sharply defined. The sound is abruptly lost within a range of one hundredth part of the entire scale, both when the person can hear audibly and when he is more or less deaf. If the sound be suddenly moved from 15° to 5° on the scale, the weaker sound is inaudible, though if the scale had been gradually moved the sound at 5° would have been easily heard. Filling the chest and holding the breath increases the capacity for hearing for a few seconds. Holding the breath with the chest not full does not produce the same result. Most persons hear better with the right ear than with the left, but physicians who have accustomed themselves to use the stethoscope with the left ear hear better with it than with the right; and four persons who habitually listened to public discourses from the left side also heard better with the left ear. See also SPHYGMOPHONE.

"*Telegraphic Journal*"	vii. 213.
"*Scientific American Sup.*" . . .	2960.

Au'di-phone. An instrument accredited to R. S. Rhodes, of Chicago, for conveying sound through the medium of the teeth.

The instrument is simply a thin plate of vulcanized rubber shaped like a Japanese fan. When in use, it is curved to give it the requisite tension by means of cords attached to the outer edge of the fan and fastened at the junction of the handle. When the top of the fan is placed against the upper teeth the impinging sound waves create a sensible vibration which is conveyed through the teeth and the bones of the face (or possibly by the dental nerves) to the auditory nerve. With a little practice, the sounds thus received are interpreted the same as if they reached the nerves of hearing through the ear; and thus the deaf are made to hear more or less distinctly, provided, of course, that the auditory nerve itself is not defective.

Newspapers, pamphlets, card-board, answer the same purpose in certain degrees.

A rod of wood, with its ends placed against the teeth or bony structure of the heads of the speaker and hearer respectively, has been used, and is a natural suggestion from Wheatstone's contrivance, mentioned on p. 2515, "*Mech. Dict.*"

The writer recollects as a boy, trading two pocket musical boxes to an old and deaf naval officer, turned portrait-painter, and watching the pleasure he derived from hearing them play when placed against his teeth.

Resting the head against the piano or harpsichord is as old as the instruments.

The head of the violinist, or of the harper, resting against his instrument, conveys the musical vibration through the bony structure to the brain. The old Egyptian who swept the strings of his standing harp in the time of Rameses the Great, laid his head against the instrument, as the paintings discovered by Bruce clearly show. Au'ral In'stru-ments. (*Surgical.*) These include those for exploration, diagnosis, prothesis, operation: for the external meatus, the membrana tympani, the Eustachian canal. The list includes the following: —

Air bag.	Eyelet forceps.
Angular forceps.	Forceps.
Basin.	Furuncle knife.
Bistoury.	Gorgeret.
Catheter.	Gouge.
Catheter holder.	Hook.
Caustic holder.	Inhaler.
Conversation tube.	Manometer.
Cotton holder.	Maryngotome.
Curette.	Mastoid process knife.
Diagnostic tube.	Meatus knife.
Director.	Mirror.
Douche.	Otoscope.
Drill.	Polypus forceps.
Eustachian canal inflator.	Polypus knife
Explorer.	Polypus snare.

Port-acid glass.	Spout.
Probe.	Spray apparatus.
Rongeur.	Syringe.
Scissors.	Tensor-tympani instrument.
Scoop.	Trumpet.
Screw hook.	Tuning fork.
Speculum.	Tympanum, artificial.
Spoon.	Tympanum, perforator.

Au-rif'e-rous. (*Mining.*) Containing gold.

Au-ro'ra Tube. A tube, of uranium glass preferably, through which discharges from an induction coil are transmitted to produce the optical effect of aurora.

Au'ro-type. (*Photography.*) Hunt's process upon paper, produced by a preparation of gold.

Aus'cul-ta'tor. (*Surgical.*) An instrument for diagnosis of diseases of the chest by listening to the sounds within the thorax. The *stethoscope* is the principal instrument; see STETHOSCOPE. The word is from the act of listening, but the diagnosis by *pleximeter* and *percussor* is not held to be strictly within the term.

Camann's cylindrical and intercostal auscultators, Figs. 254, 255, p. 82, Part I., *Tiemann's "Armamentarium Chirurgicum."*

Aus-tra'li-an Crape. (*Fabric.*) A cotton and wool French goods.

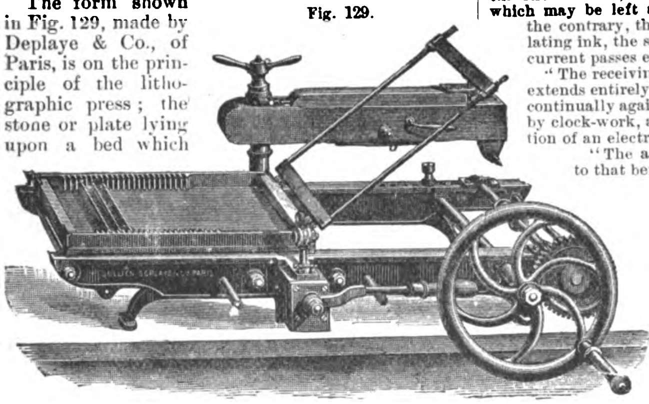
Au-tog'e-nous Sol'der-ing. Soldering by melting the adjacent surfaces of the material itself, without the intervention of solder.

The application of autogenous soldering to the making of perfect platinum stills for sulphuric acid, by Johnson, Matthey & Co, of London, is described in Professor Jenkins' Report on Chemical Industries, "*Paris Exposition* (1878) *Reports*," vol. iv., p. 65.

Au'to-graph'ic Press. A press for making copies of autographic documents, letters, etc., either upon stone or a bichromated-gelatine pad.

The form shown in Fig. 129, made by Deplaye & Co., of Paris, is on the principle of the lithographic press; the stone or plate lying upon a bed which travels beneath a pressure bar, the latter being shown in the cut as detached and swung aside.

Fig. 129.



Autographic Press.

The press is intended for lithography and chromolithography, as well as phototypy, and some other gelatine processes of reproduction.

Au'to-graph'ic Pro'cess. A mode by which a manuscript or drawing made with a peculiar ink may be transferred to stone and then printed.

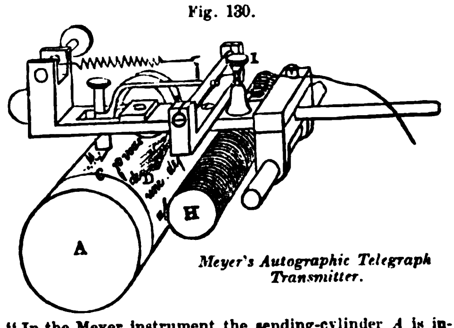
The definition may be somewhat extended, now that a variety of processes operating with gelatine, with gelatine films, bichromated gelatine, etc., have been devised. As mechanical copying processes, the HECTOGRAPH, COPYGRAPH, etc., are familiar.

Two autographic litho-processes may be mentioned: —

Hannot, Belgium .	"*Scientific American*," xxxvii. 259.
Sars, Norway . . .	"*Scientific American*," xxxvii. 326.

Au'to-graph'ic Tel'e-graph. The *Meyer* apparatus has substituted the Caselli on the French lines served by that form of apparatus. The Caselli system is described on p. 191, "*Mech. Dict.*"

Fig. 130.



Meyer's Autographic Telegraph Transmitter.

"In the Meyer instrument the sending-cylinder *A* is insulated, and upon it is wound the message written with an insulating ink upon a sheet of metallic paper. An endless screw, *H*, is moved by clock-work, and carries a car armed with a brush of metallic wires, *D*, and a metallic point, *C*. The brush and point are insulated from each other, and rub constantly against the surface of the paper.

"For each turn of the cylinder *A*, the car moves forward one thread of the screw, or a distance of ¼ millimeter, so that each point of the surface of the cylinder is brought successively in contact with the point *C*. This point is connected permanently with the ground.

"At the transmitting station, the positive pole of the battery is connected constantly on the one hand with the brush *D*, and on the other with the line-wire. The battery is therefore continually in action, but the distribution of its current depends upon the position of the stylus *C*. When the latter touches the metallic surface of the paper, the circuit is closed by the way of the brush *D*, the paper, the stylus, and the ground. Almost the entire current passes into this short circuit, and the line receives only a small portion, which may be left altogether out of account. When, on the contrary, the stylus *C* touches a part of the insulating ink, the short circuit is broken, and the battery current passes entirely over the line.

"The receiving cylinder carries a spiral thread which extends entirely around the cylinder. This thread rubs continually against an ink-roller. The paper is unrolled by clock-work, and brought up to the spiral by the action of an electro-magnet

"The apparatus for synchronism is also similar to that before described.

"If the circuit is closed and the paper is brought in contact with the spiral during a whole turn of the latter, a straight line is drawn across it: at the commencement of another turn a new line is begun, and so on. It will thus be seen that whenever the transmitting stylus touches the ink, permitting a current to pass over the line, the paper receives an impression corresponding to the length of the emission. The writing on the metallic paper is thus reproduced at the receiving end." — *Lines.*

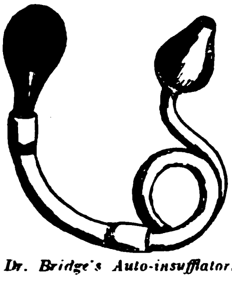
Au'to-la-ryn'go-scope. An instrument by which one may inspect his own larynx. See "*Treatise on the Laryngoscope,*" by Dr. Sieveking, "*Lancet,*" April 8, 1865, p. 360.

Fig. 131.



Dr. Bridge's Auto-insufflator.

Au'to-mat'ic Air'-brake. (*Railway.*) *Westinghouse.* The air is compressed by a steam-pump on the engine, and is stored in tanks on the engine, and under the tender and cars, connection being made by pipes and flexible hose.

"When the brakes are to be applied, compressed air is admitted from the tank on the engine to a valve called a *triple valve* under each car, which releases the compressed air stored up in the tank under that car and admits it to a cylinder provided with a piston which is connected with a system of brake-levers, and the pressure of the air is thus transmitted to the brake-shoes. In this brake the air for operating the brakes on each car is stored up in a tank on that car, whereas in other systems of air-brakes the compressed air to operate the pistons under each car must all flow from the tank on the engine, and in vacuum-brakes the air from the appliances on the car used to operate the brakes must flow forward to the engine before the brakes can be applied. This consumes an appreciable amount of time, whereas the application of the automatic brake is almost instantaneous. The triple-valve is so arranged that the brakes can be applied from each car by pulling a cord, and they will also be applied to the rear part of a train in case it should break in two parts, if one or more cars should be separated from the rest of the train." — *Forney.*

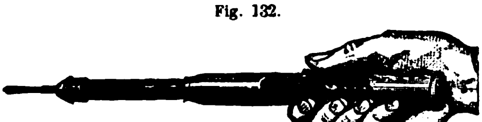
"*Engineering,*" * xxv. 203.

Au'to-mat'ic Bor'ing Tool. An instrument on the principle of what is known as the Persian drill. See Fig. 3650, p. 1671, "*Mech. Dict.*"

Fig. 132.



Automatic Boring Tool.

A spiral on the stem is rotated by endwise pressure on the handle, and when the pressure is withdrawn the case is restored by a spring to its former position. Used for small drilling, such as dentists' and jewelers' work, etc.

Au'to-mat'ic Car'-brake. See RAILWAY CAR-BRAKE.

Au'to-mat'ic Clock. One that will continually or recurrently wind itself. Such have frequently been suggested. Two are mentioned on p. 576, "*Mech. Dict.*" Another is described in the "*Journal of German Engineers,*" as the invention of F. Hellig.

The power winding it up is change of temperature, which expands or contracts glycerine contained in a cylinder and supporting a piston; the piston-rod is connected by means of a toothed rack to ratchet wheels, so arranged that the motion of the piston will wind up the clock whether this motion is upward or downward. The clock may have a weight or a spring. It is evident that such a clock must not be placed in a room where the temperature is equal, but will act best when exposed to extremes, such as are found on the top of meteorological observatories, for which the inventor especially recommends it.

Au'to-mat'ic Cut'-off En'gine. One self-operating, cutting off steam at such portion of the stroke as shall maintain a regular rate of motion. The cut-off device is usually operated through the governor. See CUT-OFF.

Au'to-mat'ic Print'ing Tel'e-graph. An instrument or system which transmits a message, previously prepared, on a paper strip, which is simply drawn through the instrument. The message is usually punched in the strip, the dots or dashes signifying letters.

It is used in connection with a *printer*, which, in ordinary cases, is a puncher.

*Edison's, Phelps', Meyer's,** described by Lines, in his "*Report from the Vienna Exposition,*" 1873, p. 37 *et seq.*

Little's Automatic Telegraph, * *Lines'* "*Report on Vienna Exposition*" of 1873, vol. ii., Section I.

Au'to-mat'ic Re-peat'er. (*Electricity.*) One which is thrown into action by the current itself.

Au'to-mat'ic Sig'nal Tel'e-graph. One set in action by an original impulse derived from —

A thermostat, in case of fire.

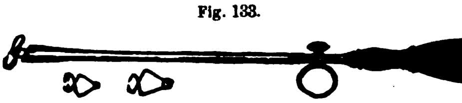
Tampering with a safe, for instance, by a robber.

The turning of a handle, as that of a fire-alarm box, etc.

Au'to-mat'ic Steam En'gine. One having a cut-off self-adjusted from the governor. See CUT-OFF.

Au'to-mat'ic Su'ture. A spring claw, for

Fig. 133.



Hoff's Automatic Suture.

holding together the lips of a wound. Used in vesico-vaginal operations, etc. The clasp is held on the end of an applicator, and thus applied, a slide pin releases it, and it is then self-holding.

Au'to-mat'ic Switch. 1. (*Electricity.*) A device used in many forms of electric apparatus to turn the current in another direction, to reverse it, etc.

An automatic device, to reverse the current in the electric candle of the Jablochkoff light. See "*Scientific American Sup.,*" * 2574.

2. (*Railways.*) A self-setting switch, or one operated by agencies set in motion by the train, for instance.

Au'to-mat'ic Ven'ti-la'tor. (*Railway.*) A car ventilator arranged so as to be self-adjusted, according to the direction in which the car is moving.

Au'to-oph-thal'mo-scope. An instrument by which one may inspect the interior of his own eye. Fig. 3403, p. 1563, "*Mech. Dict.*"

See "*Treatise on the Use of the Ophthalmoscope,*" by Dr. Hutchinson, "*Clinical Reports of the London Hospital,*" 1867, 1868, p. 182.

Au'to-phone. An accordeon or organ, in which a music-sheet of Bristol board, perforated for the notes, is passed through the instrument; the notes sounded are as air passing through the respective perforations is admitted to the appropriate reeds or pipes.

Invented by Merritt Gally. See —

"*Manufac. and Builder*" * xi. 124.
"*Scientific American*" . * xl. 351; xli. 342.

Au'to-pol'y-graph. An autographic printing process. See *Hectograph*, etc.

Bauer's Process, "*English Mechanic*," xxvi. 46, 74.

A-ven'tu-rine. (*Glass.*) 1. *Aventurinus lapis.* A variety of translucent quartz or feldspar spangled throughout with scales of yellow mica. — Dana.

2. A precious quartz spangled with crystals or flakes of gold, giving it a brilliant appearance.

3. *Artificial aventurine* is an imitation of the natural, and consists of glass intermingled with little flakes of copper which look like grains of gold. — *Gold-stone.*

Menage says that the mode of making artificial aventurine being discovered by *accident* among the Murano glass-workers, the stone was called *avventurino*, that is, *pierre d'aventure*, and that this name was eventually applied to the natural stone, which the artificial gem resembles.

Artificial aventurine is made in Murano, Venice, by a secret process. It is yellow, and in the mass are to be seen imbedded numerous small brilliant crystals of copper, or, according to some chemists, of silicate of protoxide of copper. When polished, this glass affords a brilliant object for mounting by jewelers.

It is evident that the crystals are produced in the body of the glass while the latter is in a state of fusion. Among the elements which compose the glass are found the oxides of iron and tin, and M. Peligot deems it probable that it is due to the reduction of the bioxide of copper by these metals that the production of the crystals of copper is to be attributed.

M. Hautefeuille has made aventurine, the recipe for the ingredients being as follows: —

Glass (St. Gobain)	2,000 gr.
Nitre	200 gr.
Flakes of copper	125 gr.
Peroxide of iron	60 gr.

When the glass is completely melted, and while yet in the crucible, add 86 gr. of fine iron turnings wrapped in paper, and mix by means of a red-hot iron rod. The glass becomes blood-colored, opaque, and at the same time doughy and bubbly. Stop the draft of the furnace, put the cover on the crucible and cover with cinders; allow the furnace and crucible to cool very slowly. The following day break the crucible and the glass will be found permeated with crystals, regularly disseminated in parts, in others stratified and irregular, according to the success in mixing the materials.

It has been suggested to add the filings to the pounded glass or frit, in order to obtain more complete dissemination.

Green aventurine or *aventurine de chrome*, as termed by its inventor, M. Pelouze, is compounded of the following: —

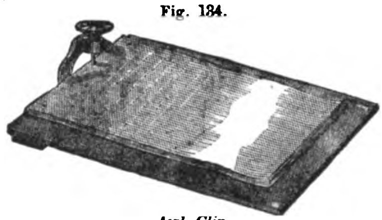
Sand	250 gr.
Carbonate of soda	100 gr.
Carbonate of lime	50 gr.
Bichromate of potassa	40 gr.

The glass which results from this combination contains from 6 to 7 per cent. of oxide of chrome, of which about half is combined with the glass, and the remainder assumes the form of brilliant crystals or flakes.

The color of the *aventurine de chrome* is that of the third yellow-green, the thirteenth tone in the chromatic circle of M. Chevreul. It is very brilliant and its radiant power is stated by M. Pelouze to be second to the diamond only. It is harder than window glass, which it cuts easily, and is much harder than the aventurine of Venice.

Awl Clip. A board and clip pin, to hold blanks, message, or memorandum paper, etc. The pin penetrates the pile of papers, which are removed from time to time with a slight tear in the edge.

Fig. 134.



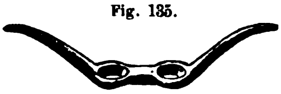
Awl Clip.

Awn'ing Block. A small wooden block for suspending or stretching an awning over the quarter-deck, or elsewhere.

Made plain or rope strapped, and with an eye.

Awn'ing Cleat. A small becket on which to belay an awning rope.

Fig. 135.



Curved Horn Awning Cleat.

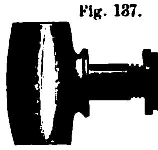
Awn'ing Hinge. One to which an awning rod is journaled. See Fig. 136.

Awn'ing Slide. A holder with a tube through which the rod of the awning slides.

Fig. 136.

Awning Hinge.

Fig. 137.



Awning Slide.

Axe. The poll is formed from a solid bar of iron by a machine that operates two punches simultaneously to form the eye for the reception of the handle. The heated bar is placed under shears that cut off a piece sufficient for the poll, which piece is placed in the machine, the two punches working from either edge, a supplementary punch finishing the eye and a set of dies forming the sides, when the poll drops, still red hot, ready to receive the bit. The after insertion of the steel bit and shaping the axe are done by ordinary forging.

The axes are then sent to the hardening and tempering room, which is partially darkened. The hardening ovens are circular, having a vertical shaft in the center to which are attached rotating tables, on which the axes are laid with the bits toward the outside. The table turns slowly but continually, bringing the axes over furnaces of anthracite coal alternating with spaces. When brought to the proper redness by heat, the axes are hung on hooks on a revolving frame, the bits dipping into a tank of brine, which is kept in constant circulation by a pump. When cool, the axes are tempered, which is done by heating them in a rotary oven like that used for the hardening, except that the fuel used is charcoal. One of the batch of perhaps 200 which are tempered, or drawn, at one time is brightened, and serves as a test of all the others, the rotary action of the shelves insuring equal heating. When the brightened axe shows the right color, the entire batch is removed, and the axes are then ready for the subsequent finishing operations of grinding and polishing.

Several kinds of axes are used among fishermen and whalemen.

Boat hatchet: For cutting the harpoon line at the bow, if it become tangled in "paying out."

Head axe: For cutting off the head of the whale; opening the skull to obtain the spermaceti; cutting off the baleen, etc.

See also SPADE.

Rollins's axe, with detachable bits, is described in "*Scientific American*," * xxxvi. 355.

(*Stone Working.*) Stone axes are of several kinds; their distinguishing peculiarity is having an edge, while the *hammer* has a *face* and a *pick* has a point.

The *cavil* has a face at one end and a point at the other.

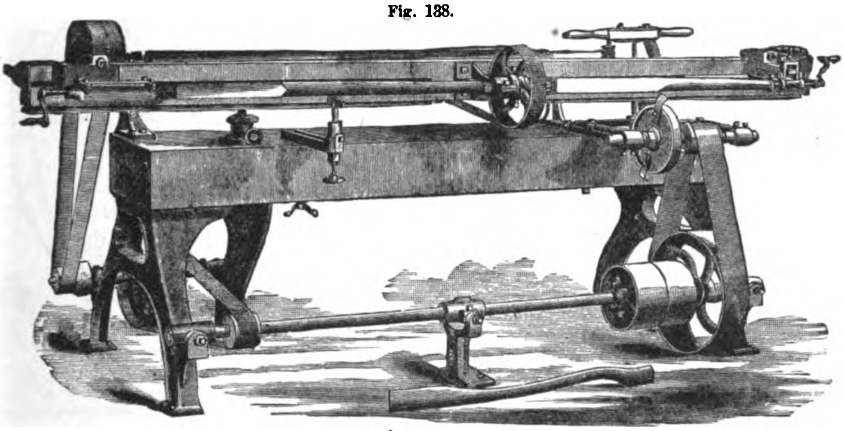
See list under HAMMERS AND STRIKING TOOLS.

Axe Wedge. A small iron wedge driven into the end of the axe-handle, within the eye, in order to expand the wood, and prevent the head flying from the helve.

Axe-han'dle Lathe. This is a machine on the Blanchard spoke-lathe principle, and is adapted to work by pattern. It is shown, Fig. 138, as making a spoke. The pattern spoke is at the left, and rotates against a guide-piece, so that the swinging frame in which the pattern spoke and the blank are chucked moves back and forth as the pattern traverses against the guide. The frame has a motion endwise, and the revolving cutter dresses the blank in accordance with the governing piece against the pattern.

It will turn out 20 to 25 dozen 3 feet axe-handles, or 150 to 300 spokes per day, according to size. The machine feeds itself after the work is in, working by a pattern, and is so arranged that the same pattern will make several sizes, and stops feeding when the end of the stick is reached by the cutter. It is also arranged with adjusting screws to level up the tilting frame for different sizes of work.

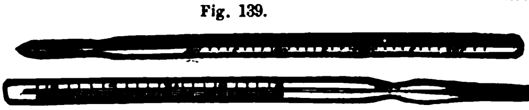
Fig. 138.



Axe-handle Lathe.

Ax-il'la Ther-mom'e-ter. A thermometer, so named from the axilla affording a convenient place for the instrument in the observation of personal temperature. See also CLINICAL THERMOMETER.

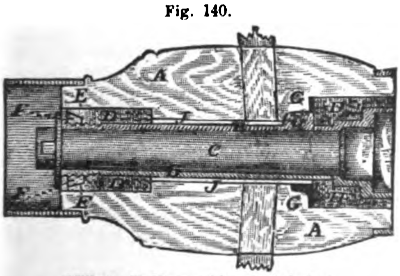
Fig. 139.



Axilla Thermometer.

Ax'le. The rubber-cushioned carriage axle is shown in the hub, Fig. 140, and detached, but with the cushions in place, in Fig. 141.

Fig. 140.



Miller's Rubber-cushioned Axle-box.

A, Hub. *B*, Axle-box. *C*, Axle arm. *D*, Rubber cushions. *E*, Compression nut. *F*, Cavities in compression nut admitting points of the wrench when compressing cushions. *G*, Slotted retaining sleeve. *H*, Spur on axle-box. *J*, Space between axle-box and hub.

It consists of a vulcanized rubber cushion in the form of a thick band interposed between the axle-box and the wood of the hub, as shown by Fig. 140, giving a sectional view of an ordinary hub, to which the cushioned axle is applied.

Adjustable axles to regulate height, are common in reapers, and their adjustment at the divider, on the grain end of the cutter bar, is one of the points of regulation in fitting the machine to cut to a certain height of stubble.

The axles of wheeled cultivators have also an adjustability to raise or lower the machines, according to the required depth of tillage.

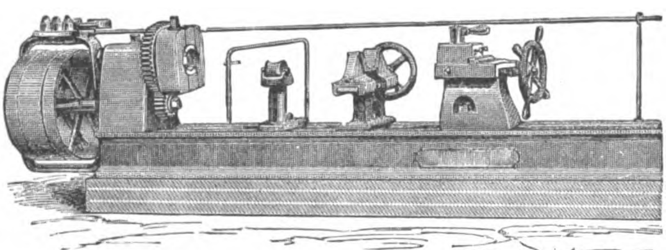
Ax'le Box Guides. (*Railway.*) Slips on the inner faces of the pedestals of a railway truck, to guide the axle brasses as they move up and down.

Ax'le Cen'ter-ing and Siz'ing Ma-chine. A machine tool, to be used in connection with an axle lathe, to center the rough axle, and after it has been turned to size in its journals and rough-turned in the *fit*, to finish this part accurately, and to dress off the ends as well as to re-center. This machine is provided with a powerful chuck lined with brass to clamp the axle by its outer collar. It is arranged with fast and slow motions on the driving gear.

Fig. 144.



Axle Centering and Sizing Machine.

The axle rests in an adjustable V-guide at its end farthest away from the driving head; a squaring-up tool finishes the end of the axle, and at the same time re-centers it. The *fit* part of the axle is brought to size by a hollow reamer provided with adjustable cutting blades.

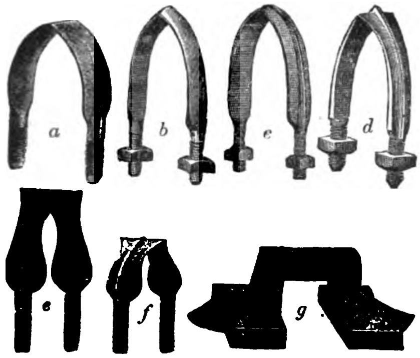
Ax'le Clip. A saddle-shaped clamp which binds a spring to its axle, a spring bar to its spring, etc., etc. Various forms of axle clips are shown in Fig. 145.

Ax'le Col'lar. An enlargement on an axle to form a butting ring, that is, to receive a thrust.

The collar is ordinarily on the shoulder of the axle arm in road vehicles, but is also placed on the outer end in car axles. Examples of each are given on pp. 198–203, and Figs. 1091–1093, p. 459, "*Mech. Dict.*"

Ax'le Lathe. 1. A lathe, Fig. 146, for turning car axles. The shears or bed is in the form of a continuous cylinder of requisite strength, with flat surfaces added to the cylinder for attachment of heads and bearing of slide-rest. The live-head or driving-head is simple and powerful. The face plate is fitted with the Clement driver, which insures rotation of the axle with no lateral strain on the centers. The back-head has a very large spindle

Fig. 145.



Axle Clips.

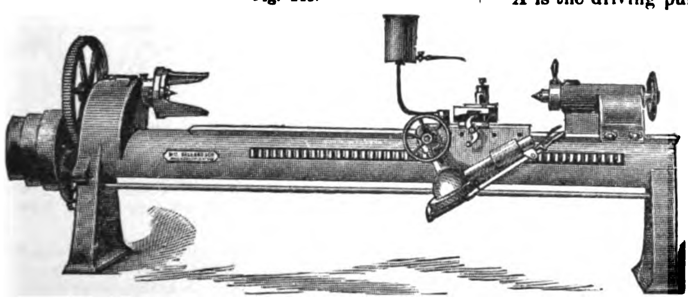
b. Sharp center bent axle clip for spring bars.
c. Sharp center-ribbed, bent axle clip for spring bars.
d. Sharp, wide center, ribbed, bent axle clip for spring bars.
e. Sharp center, O. G., bent axle clip for spring bars.
f. New pattern, sharp center, O. G., bent axle clip for buggy perch-plates and sleigh work.
g. Coach axle clip.

with large center, and a clamping arrangement, which insures the spindle being held central and at the point nearest to the work. It has a rack-

Fig. 146.

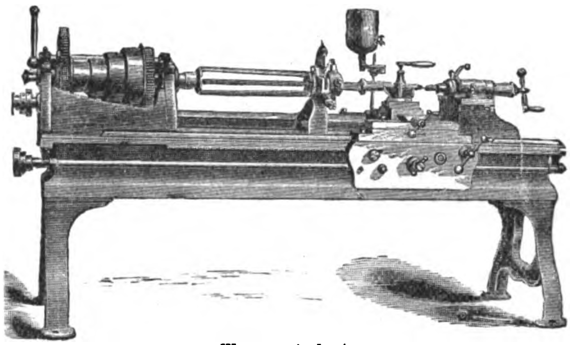


Car-axle Lathe.

feed with quick hand traverse to bottom rest; patent adjustable tool holders, automatic feed motion, which can be started instantly; rate of feed, 15 to the inch.

2. A machine, Fig. 147, for turning the spindles of wagon and carriage axles. It swings over ways

Fig. 147.



Wagon-axle Lathe.

18″; the bed is 8′ long; with plain head, especially adapted for turning wagon axles, with taper attachment to carriage. This lathe can also be used for turning any regular tapers or irregular shapes, by guide or pattern, which can be fastened to a rail on back side of the bed-piece.

3. A machine for turning spindles of wooden axles for the reception of thimble-skeins. The machine, Fig. 148, turns the axle to a pattern, making the wooden spindle fit any inequality in the thimble skein, filling it throughout.

A is the driving pulley, which rotates the mechanism supporting the knife in the standard *G*. *B* is a curved cutter bar, to the outer end of which is secured the knife *C*, and which enters the sliding block *D*, as a fulcrum. Block *D* travels in the ways *F*, and is actuated therein by the feed gearing shown at *E*. At *H* is the clamp which holds the axle while it is operated upon, and at *I* is the pattern, just below which is shown the end of the bar *B*, projecting, which, terminating in a friction roller, enters the skein, and is held against the inside surface of the same, thereby guiding the knife in its revolution, thus necessarily causing the axle to be turned to an accurate fit.

Fetu & Deliège, Liège . . * "*Engineering*," xxix. 418.
Axle-lathe Hoist. *Thomas*. * "*Railroad Gazette*," viii. 289.

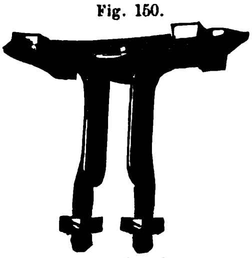
of the arm, and wick protruding up through it, and extending downward into an oil reservoir. See, also, AXLE-BOX, "*Mech. Dict.*"

Ax′le Pack′ing. (*Railway.*) A dust guard around a car axle, to prevent access of dirt to the interior of the axle-box. Figs. 1091, 1092, p. 459, "*Mech. Dict.*"

Ax′le Sad′dle. A saddle-shaped clip, for securing a spring to an axle. A plate or yoke slips over the screwed ends, and is secured by burs.

Fig. 150.



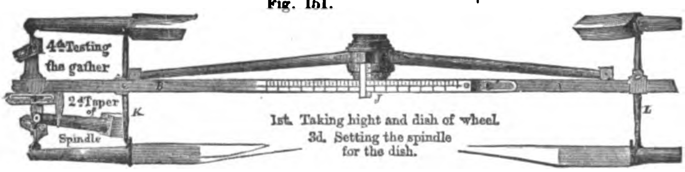
Axle Saddle.

Ax′le Seat. (*Railway.*) The opening in a wheel, fitted to receive the axle arm.

Ax′le Set and Gage. An apparatus, Fig. 151, for enabling the wheelwright to get the height and dish of wheel: the taper of spindle: to set the spindle for the dish: to obtain the gather.

The apparatus consists of a steel bar, *A*, 6′ 3″ long, and an index and gage bar, *B*, 3′ 9″ long, which slides against the former, and has a scale cut upon it to adapt the apparatus to any sized wheel. The bar *B* is attached to the main bar, 13″ from the end, by a straight standard, *K*, projecting 4″ from one edge and 3″ from the other. A screw, passing through the center of this standard, serves as a pivot for the index and gage-bar *B*. A

Fig. 151.



Carleton's Axle Set and Gage.

vertical sliding rule, *J*, on the bar *B*, is designed to show the dish, while the graduated scale on the bar shows the height of wheel. A movable arm-rest, *L*, is attached to the bar *A*, to support the gage horizontally over the center of the axle, the rest *L* and standard *K* resting on opposite shoulders of the spindles, while the taper-taker is placed over the end of the spindle to be set. The taper-taker, or graduated double caliper, is fitted with a movable arm, scale, and graduated sliding gage. It is moved on the index bar *B*, through a socket, and held in place by a set screw. The short caliper, and the short ends of standards, 3″ long each, are placed on the opposite ends of the bar *A*, on the "gather side."

Bex's axle setter, patented December 21, 1875, is for straightening bent axle arms. It is of the type of Fig. 507, p. 200, "*Mech. Dict.*"

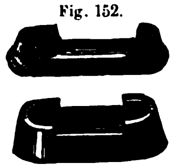
See "*Scientific American*" . . . . * xxxv. 18.
"*Mining and Scientific Press*" . . . * xxiv. 289.

Ax′le Stop′-key. (*Railway.*) A plate abutting upon the end of the car-axle, to resist excessive lateral motion and take the wear.

Ax′le-turn′ing Ma-chine′. See AXLE LATHE.

Ax′le Yoke. A plate beneath the axle; a cross-bar through which the ends of the spring saddle clip are passed, and beneath which they are secured by nuts. Fig. 152.

Fig. 152.

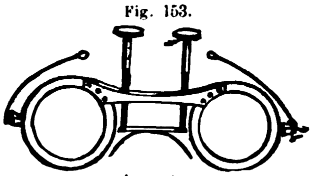


Axle Yokes.

Ax-om′e-ter. An instrument to determine the proper height of the bridge of the spectacles, in order that the lenses may be properly centered vertically with regard to the pupils. Fig. 153.

The patient having put on the spectacles, the movable bridge of the instrument is raised or lowered until the pupils are seen in the center of the circle. This done, the axometer is placed on a sheet of paper, and the bridge, along with the lower half circles, is traced thereon with a pencil.

Fig. 153.



Axometer.

Az′i-muth In′stru-ment. Sir William Thomson's instrument for taking azimuths, which he terms the "azimuth mirror," was patented Nov. 19, 1878, No. 210,068.

In it the axis, on which the mirror is pivoted, is above the plane of the lens, which is contained within the inclined tubular leg, which arrangement allows of the interval of no vision between mirror and lens to be reduced to a minimum, by reason of the inner straight edge of the mirror cutting out of sight with a sharp or fine line that portion of the lens which it hides, whereby the image of the object is seen distinctly on the degree scale of the compass-card.

The azimuth, circle and azimuth compass are considered on pages 203, 204, "*Mech. Dict.*" The brass azimuth of Benares, India, is shown in Fig. 571, page 204, *Ibid.* It was built by Jay-Singh, Rajah of Jayanagar, in the 17th century. The equatorial and equinoctial dials of the same holy city of the Ganges are shown on page 692, Figures 1624, 1625, *Ibid.* The subject is discussed in Dr. Hooker's "*Himalayan Journals,*" "*Transactions American Oriental Society,*" vol. vi., Dr. Hooker's "*Notes on Bengal, Nepaul, etc.*"

Az′o-tine. An explosive: Saltpeter, 69.05; carbon, 15.23; sulphur, 11.43; petroleum, 4.29 per cent.

B.

Bab'bit-ing La'dle. An iron ladle for holding and pouring the melted alloy known as babbit-metal, and used for bearings.

Ba-biche'. (*Fishing.*) Properly *barbiche.* A common name in France for the *nigelle de Damas;* called also *araignée* (spider), *barbe de capucin,* and *cheveux de Venus.* Used in net-making.

Back Band. (*Manége.*) That portion of the harness attached to the gig-saddle under the jockey, and used as a support for the shaft-tug.

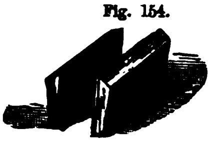
Back Board. (*Boat.*) The board across the stern-sheets of a boat for supporting the backs of the passengers.

Back Cyl'in-der-head. (*Steam.*) That head of a cylinder through which the piston-rod passes.

Back End. (*Mining.*) That part of a judd (an undermined mass of coal) which is left after the lump is brought down.

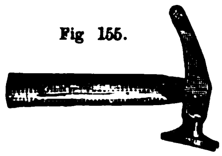
Back'ing Boards. A pair of wooden jaws, Fig. 154, to grip a book in the book-binder's vise.

Fig. 154.



Backing Boards.

Fig 155.

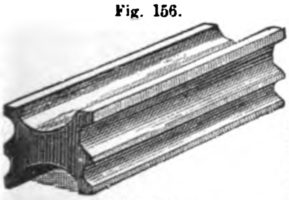


Backing Hammer.

Back'ing Deals. (*Mining.*) Timbers placed behind cribs to keep back loose strata.

Back'ing Ham'mer. (*Bookbinding.*) The hammer, Fig. 155, used in beating the backs of books in condensing and rounding them.

Fig. 156.

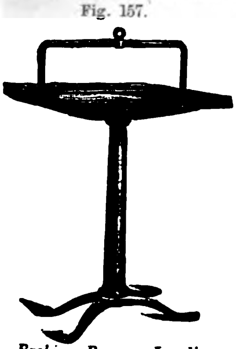


Backing Iron

Back'ing I'ron. (*Bookbinding.*) An appliance used in giving the rounded shape to the backs of books. On its face it has depressions of varying depth and width.

Back'ing Ma-chine'. (*Bookbinding.*) A machine used in rounding the backs of books. That shown in Fig. 160 is adapted to back blank books from ½″ to 4″ wide, and 30″ long and under. The revolving backing-iron is hollow, and is heated from the center by gas or steam. On the right of the cylinder is the adjusting screw, and at the same end is the device which secures the cylinder on the groove desired.

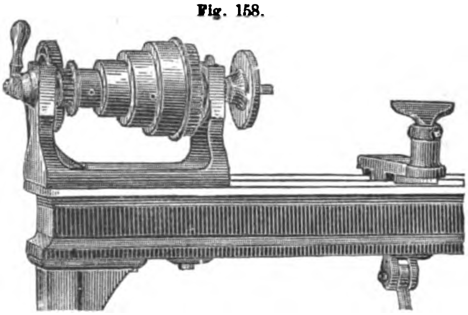
Fig. 157.



Backing Pan on Leveling Stand.

Back'ing Pan. (*Stereotyping.*) A pan, Fig. 157, in which the electrotype shell is placed, face downward, while the melted metal is poured on its back. The table being perfectly level, the stand is secured to the floor by its feet. The pan is swung on to the stand, and the metal poured on to

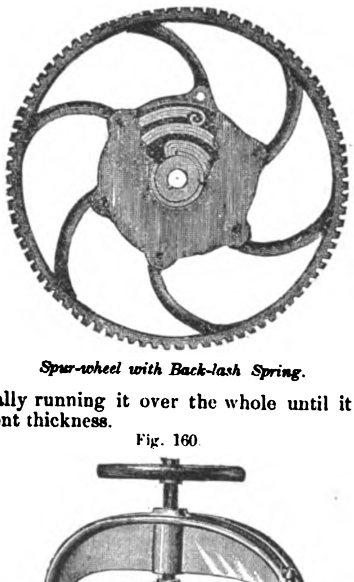
Fig. 158.



Back-geared Lathe-head.

the shell, commencing at one of the corners and

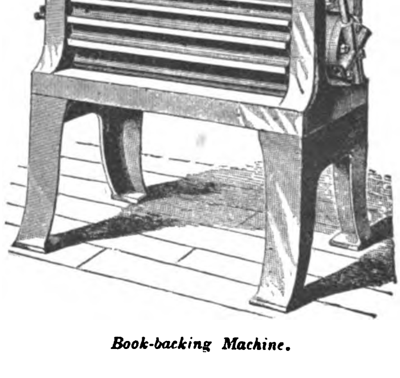
Fig. 159.



Spur-wheel with Back-lash Spring.

gradually running it over the whole until it is of sufficient thickness.

Fig. 160.



Book-backing Machine.

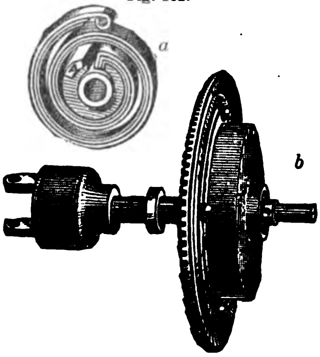
Back′-geared Lathe. One having a set of variable gears in the head-stock.

Back′-lash Spring. A spring interposed between an engine or horse-power and the machinery driven, to prevent a jerking motion in transmission. The spring is wound upon the shaft, its ends connected to the driver and driven portion respectively, so as to absorb a sudden jerk.

Fig. 159 represents the spur-wheel of a thresher, with a casing for the spring cast in its center.

Fig. 161, *a*, represents a spring and hub detached

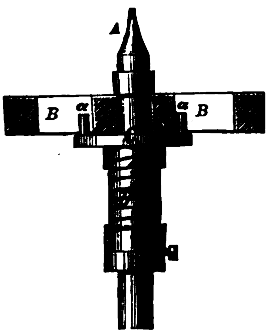
Fig. 161.



Heffner's Back-lash Springs.

from the casing. The hub is keyed to the shaft; the inner end of the spring is connected to the hub, and the outer end to the wheel. Fig. 161, *b*, is a bevel-wheel of a side-gear, forming a casing for the spring.

Fig. 162.



Alsop's Back-lash Spring.

Fig. 162 is Alsop's spring wound upon the shaft, and having a similar function to the above described.

In Fig. 162, *A* is a mill-spindle; *D* the spiral spring, one end clamped to the spindle, and the other end to the driver *C*, which presses by its pins *a a* upon the spokes of the pinion *B*.

Back-lash Spring, applied to Tumbling-rod Coupling.

Fig. 163 shows a bevel-wheel with spring in a case.

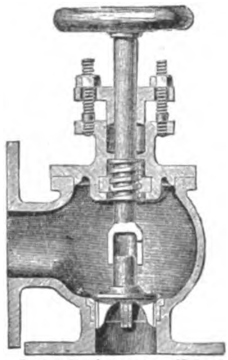
Fig. 164 shows a spring in a case to form part of line-shaft of a horse-power.

See also BACK-LASH, p. 206, "*Mech. Dict.*"

Back′-log. A casting or a work in earthenware in semblance of a back-log or pile of wood, and hollow to admit gas from the service-pipe. The surface of the back-log has minute perforations at which gas is emitted and burned, resembling a log on fire.

Back-press′ure Valve. A valve which is free in the normal direction of the flow, but closes automatically against back-pressure.

Fig. 165.



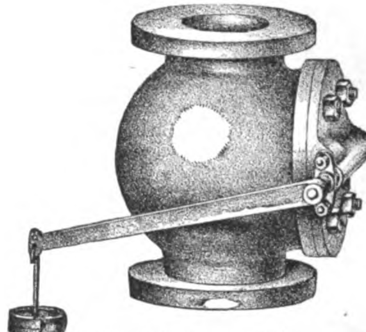
Globe Back-pressure Valve.

In the sectional view, Fig. 165, the valve can be screwed down tightly, but normally yields to upward flow, and is closed at any time against downward flow.

In Fig. 166 the valve is normally closed by a weighted lever, but yields to direct pressure of a given tension while always opposed to any return current.

Back Saw. One with a stiffening bar at the back. That shown in Fig. 167 has a back less than the full length of the saw, and has a recess in the handle for the thumb.

Fig. 166.



Weighted Back-pressure Valve.

Back Skin. (*Mining.*) A leathern covering worn by miners when working in wet places.

Back Spring. (*Vehicle.*) A spring at the rear of a vehicle body, but more especially a C-spring which rides up in the rear of the carriage, and from the forward pendent end of which the body is suspended. A pair of C-springs is shown in Fig. 1541, page 655, "*Mech. Dict.*"

Fig. 167.

Back-saw.

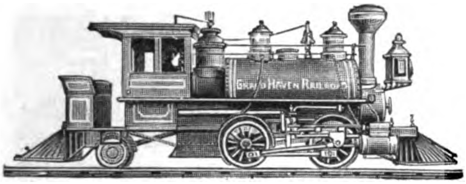
Back Stay. In a carriage: (1), one of the rods extending from the reach or perch to the outer end of the hind axle. The *stay-end* is the end-piece, which is fitted to the axle, and is sometimes sold separately as a piece of carriage hardware, the lengthening-rod being added by the blacksmith.

2. One of the standing flaps on the back of the carriage-top, on each side of the curtain.

Back Strap. (*Manège.*) A broad strap used instead of a pad on common harness. In some sections of the country the strap that extends from the hames back to the hip-straps is more generally known as the *turn-back*.

Back′-truck Lo′co-mo′tive. One having a truck with a pair of wheels under the rear of the locomotive, as distinct from the usual truck in front of the drivers. The engine is intended to run equally well in either direction, being, in fact, a double-ender, adapted for sharp curves and steep grades. The 9 × 16 and 10 × 16 engines of this style are well adapted to suburban roads and special service on wide or narrow-gage roads, and light shifting on wide gage.

Fig. 168.



H. K. Porter & Co.'s Back-truck Locomotive.

A 4-wheel truck is sometimes substituted for the 2-wheel, the tank being placed over the rear truck.

Baf'fle Plate. (*Steam.*) A plate in a steam-furnace, to direct or divert the course of flame and gases. Placed in a space traversed by water-tubes, it will determine the course of the heated gases toward portions of the boiler which would not otherwise be as fully exposed to the heated current.

Bag. (*Fishing.*) The middle portion of a large haul-seine, the last to come ashore. The portions on each side of the bag are the *wings*.

Ba-gasse' Dry'er. An apparatus for drying the refuse cane-stalk from the mill. Page 208, "*Mech. Dict.*"

Berry, Br. . . . . . * "*Engineering*," xxix. 204.
* "*Engineering*," xxx. 482.

Bag Ear-syr'inge. An ear douche, with elastic rubber bag for ejecting the liquid.

Bag Fill'er. A funnel used in filling bags. See also Bag-holding Truck. Machines on a larger scale for filling flour-bags of various dimensions are shown under Flour Packer.

Fig. 169.

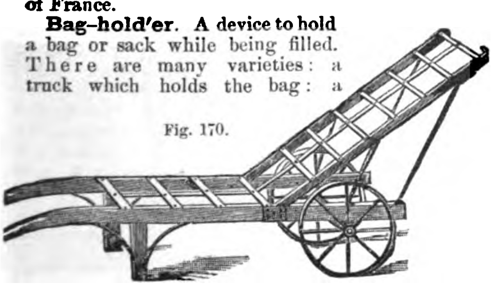
Bag Filler.

Bag'gage Bar'row. A two-wheel hand-vehicle for conveying trunks. See Fig. 170.

Bag'gage Truck. A hand-truck adapted to receive trunks. Fig. 171 shows the pattern used on the Eastern Railway of France.

Bag-hold'er. A device to hold a bag or sack while being filled. There are many varieties: a truck which holds the bag: a

Fig. 170.



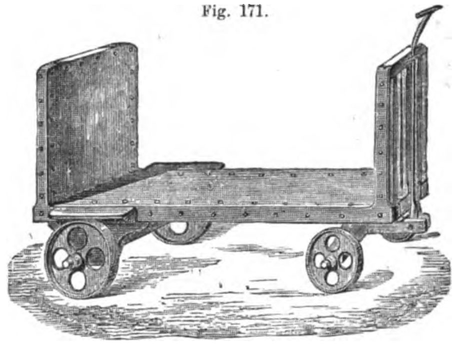
Baggage Barrow.

funnel held upon a tripod, or on the end of a weighing beam, etc. See Bag-holding Truck; Sack Lifter; Sack Filler, etc.

Fairchild's bag-holder has a metallic funnel attached to a standard, and to the funnel are attached four steel hooks which hold the mouth of the bag distended while being filled.

Mosher's bag-holder has two telescopic standards, with curved flanges to hold the bag.

Fig. 171.



Baggage Truck.

Bag-hold'ing Truck. The bag-holding truck of Bodin of Rennes, France, is shown in Fig. 172. It has a slanting frame, supported by a strut, and a clip-ring at top to hold the distended mouth of the bag.

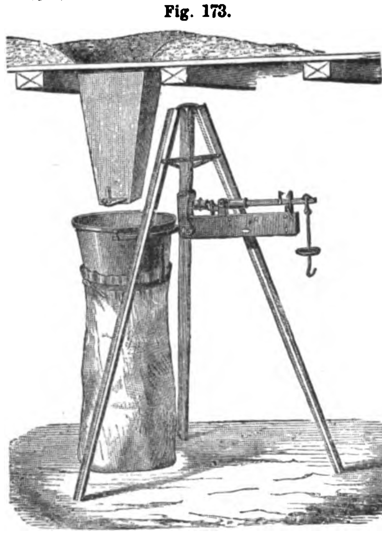
A similar device is made by Pitner of Chicago.

Fig. 172.

Bag-holding Truck.

Bag'-net. (*Fishing.*) A purse-shaped net, or part of a net. In some cases a sort of dip net, like Fig. 3318, p. 1522, "*Mech. Dict.*;" sometimes a portion of a net into which fish collected by the wings are driven or led. See list under Net.

Fig. 173.



Romaine's Sack-filler and Weigher.

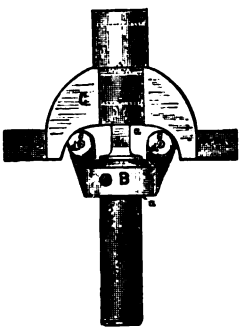
Ba-gra'tion Bat'te-ry. (*Electricity.*) One in which the zinc and copper elements are immersed in a jar filled with earth, sprinkled with chloride of ammonium. — *De la Rive.*

Bag Weigh'er. Fig. 173 shows a French device.

A tripod supporting a scale-beam, on one end of which is a funnel to which the open mouth of a bag is clamped. The bag hangs beneath a spout, and when a prescribed weight of grain has passed from the spout into the sack, the shutter is closed, the bag removed and tied, and an empty sack substituted. The bag is clipped by a ring to the funnel, which is suspended by a notch on the end of the weigh-beam. The scale is centessimal, — the scale-weight being one-hundredth of the weight of grain which makes its equipoise.

Bail. (*Milling.*) The arch-shaped support of a mill-stone. The *balance-rynd.*

Fig. 174.



Bacon's Cushioned Bail and Driver.

In the figure, *C* is the bail resting upon the cock-head *a* of the spindle. *B* is the driver, with two cushioned horns, *c d,* which in the figure are exposed to view by the lifting of the bail out of place, but in operation occupy recesses in the bail.

The cushions, being yielding, allow the stone to be self-balancing.

Bain-Ma'rie. A water-bath; used in perfumery manufacture. See for particulars p. 398, vol. vii., "*Chambers' Encyclopedia,*" article "*Perfumery,*" where is given an interesting account of the flower-farms and processes of the Var, France.

"*Art of Perfumery,*" *Septimus Presse.* London, 1855.
"*British Perfumer,*" *C. Lilly.* London, 1822.
"*Libraire Roret,*" *Mme. Celnart.* Translated by Morfit of Philadelphia.
"*Treatise on Perfumery,*" *Pradal & Malepeyre.* Translated by Dussauce.
"*A Practical Guide for the Perfumer,*" *Dussauce.*

Bait, Ar'ti-fic'ial. (*Fishing.*) Tin minnows, roach, dace, and gudgeon.

Gutta-percha minnows.

Tin blue-fish squids.

White bone blue-fish squids.

Insects: Imitations of grasshoppers, hornets, beetles, spiders, wasps, May-grubs, grubs, etc.

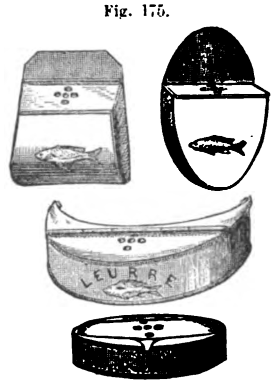
Kellogg's patent, No. 74,378, is for an ice-chest for bait, for fishing-vessels.

Burnham, No. 84,855, uses a saturated solution of lime to preserve bait.

Thorp's fish-bait, No. 96,288, is a baked cracker, made of equal parts of coarsely-ground wheat, oats, rye, and corn.

Goodman, No. 135,-113, uses to make bait more attractive, oils of anise, asafœtida, and cardamons; black root and buzzard-flesh (!) a few drops on the bait.

Fig. 175.



Bait Boxes.

Bait Box. 1. The cistern or tank in which bait of fish or clams is carried to the fishing-grounds.

2. On a smaller scale, the angler's bait-can for worms or what-not.

Kepner's can for live bait, No. 163,498, has a perforated false bottom and openings at the sides, to allow circulation of water when the can is set therein.

Hitchcock's bait-kettle, No. 181,844, has ice-cooler, minnow-bucket, and trays.

Lasater, No 194,258, has a combined minnow-trap and can.

Bait Cut'ter. A bait-cutting machine. See Bait Mill.

Bait Mill. A grinding mill to mince bait, frequently on the principle of a sausage-cutter.

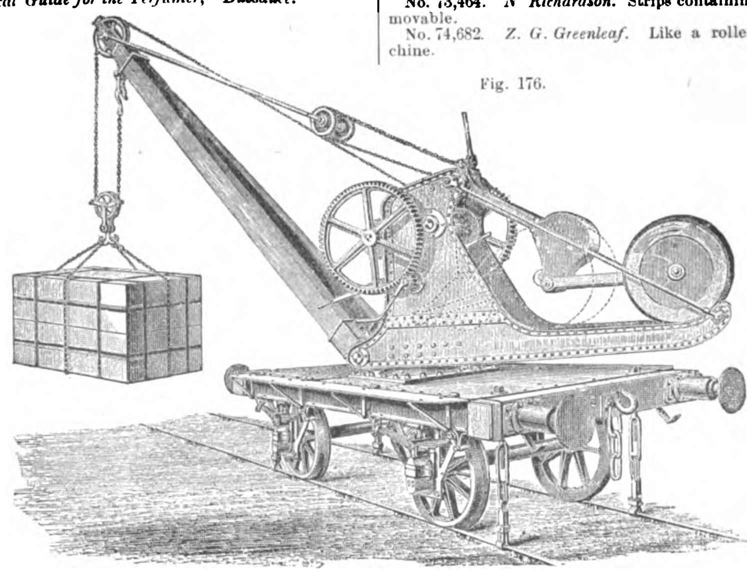
UNITED STATES PATENTS.

No. 35,472. *N. Richardson.* Triangular teeth on each of two rollers, working together.

No. 73,464. *N Richardson.* Strips containing teeth are removable.

No. 74,682. *Z. G. Greenleaf.* Like a roller sausage-machine.

Fig. 176.



Self-acting Balance Permanent-way Crane.

No. 83,048. *V. Doane.* Roller-knives and stationary blades.
No. 101,260. *S. Hamblin.* Knives spirally arranged on roller.
No. 129,576. *W. M'Kay.* Circular saws on roller.
No. 172,777. *N. Richardson.* A roller cutter-mill.
Voss, 1876. Like a sausage-cutter.

Bal. (*Mining.*) Cornish — a mine.

Balance Crane. One in which the load is in part or entirely balanced by a counterpoise on the crane-frame extension.

The manner in which the load on the lifting-chain acts on the counter-balance weights will be readily understood from the engraving, Fig. 176. The rigid rods which tie the jib-head to the side-frames in ordinary railway-track cranes are here replaced by two short tie-rods, each with a chain-sheave at its lower end. One end of each of the chains passing over these sheaves is attached to a chain-barrel fitted with worm and wheel-gear, while the other ends are coupled to the short arms of two bell-crank levers, having a fulcrum in the top of the side-frames; the lower ends of the long limbs of the bell-crank levers are fitted with weights connected by strong wrought-iron links to the axis of a cylindrical balance weight, which is free to roll on the tail-pieces of the crane framing. When the load is being lifted the strain due to the weight of the load passes through the tie-bars and chains to the short arms of the bell-cranks, and the strain thus applied causes the long arms and weights to rise out of the vertical position and to draw the cylindrical weights into the position shown, or until they are at a distance from the center sufficient to counterbalance the load being lifted. When the load is released, the levers resume the vertical position shown in the dotted lines.

The action is therefore entirely automatic, there are few parts, none of them liable to derangement, and all so strong and simple in construction that these cranes have never been known to fail in securing the safety and certainty which they were designed to afford.

The chain-barrel is fitted with a tangent wheel and worm which serve to adjust the jib to any angle or radius required, as well as to lower it down for traveling.

The under carriage and side-frames are of wrought iron.

Bal'anced Draw'bridge. A counter-weighted bascule or lifting drawbridge. Instances are to be found in the drawbridges of fortifications, of counterpoising by means of suspended weights from chains passing over pulleys.

Burdon's drawbridge balanced by hydraulic pressure is shown in

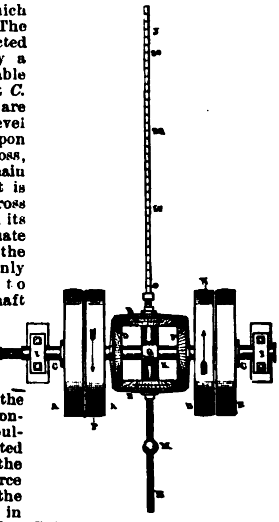
"*Manufacturer and Builder*," * xi. 29.

Bal'ance Dy'na-mom'e-ter. An invention of Samuel Batchelder of Boston. It is placed in the line of communication between the motor and the machinery to be moved, the power exerted on the machinery being measured by the steelyard and weight which form a part of the machine.

A A and *B B* are two pairs of belt pulleys, each pair consisting of a fast and loose pulley. *A* is driven by a belt from the prime motor, and a belt from *B* communicates motion to the machine to be driven.

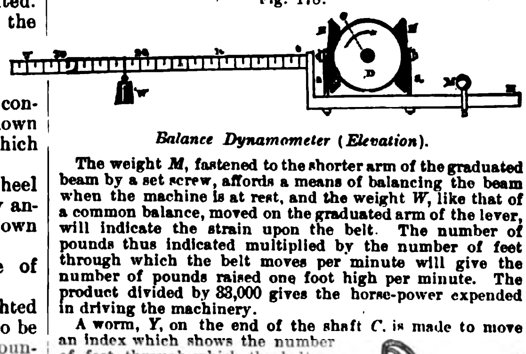
The first pulley, *A*, and the bevel wheel *D*, are fast upon the shaft *C*, which revolves in bearings *I*. The bevel wheel *F* is connected with the pulley *B* by a sleeve, *K*, which is capable of turning on the shaft *C*. The bevel wheels *D F* are geared together by the bevel wheels *E E*, which run upon a cross shaft having a boss, *G*, through which the main shaft passes freely. It is evident that if this cross shaft is not retained in its place by some adequate force, the motion of the bevel wheel *D* will only cause the cross-shaft to move round upon the shaft *C*, and the wheels *E* will roll upon the wheel *F*, without communicating motion to it or to the pulley *B*; but if the wheels *E* and the cross-shaft are held stationary, the motion of the pulley *A* will be communicated to the pulley *B* through the bevel wheels, and the force there applied to retain the shaft *G* and wheels *E* in place will indicate the power transmitted through the dynamometer. The amount of power is ascertained by means of a graduated scale beam, *H J*, connected with the shaft of the wheels *E* by straps, *a*.

Fig. 177.



Balance Dynamometer (Plan.)

Fig. 178.

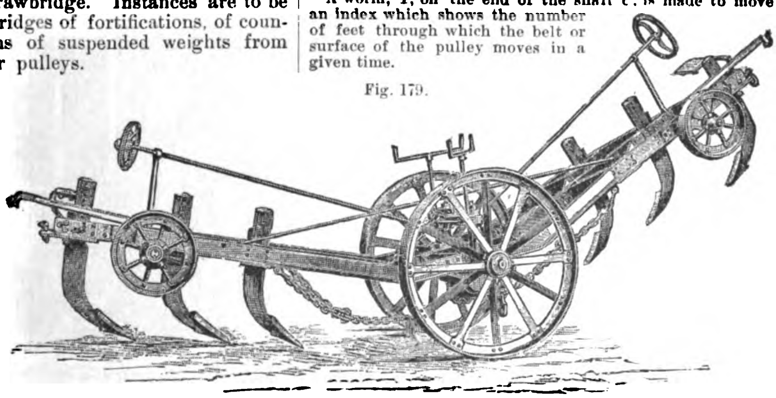


Balance Dynamometer (Elevation).

The weight *M*, fastened to the shorter arm of the graduated beam by a set screw, affords a means of balancing the beam when the machine is at rest, and the weight *W*, like that of a common balance, moved on the graduated arm of the lever, will indicate the strain upon the belt. The number of pounds thus indicated multiplied by the number of feet through which the belt moves per minute will give the number of pounds raised one foot high per minute. The product divided by 33,000 gives the horse-power expended in driving the machinery.

A worm, *Y*, on the end of the shaft *C*, is made to move an index which shows the number of feet through which the belt or surface of the pulley moves in a given time.

Fig. 179.



Balance Plow.

Bal'ance En'gine. A name applied to a form of steam-engine which has two pistons acting in opposite directions in the same cylinder. For instance: —

Wells . . "*Engineer*," * xlvii. 332.
"*Scientific American*," xxxv. 281.
"*Engineering and Mining Journal*," xxvii. 237.

Bal'ance Plow. A plow used in steam culture. The ends are duplicates, one balancing the other, as shown in Fig. 179. The implement is drawn across the field, back and forth, without being turned at the ends. When it reaches the end of its course the plows are lifted from the ground and the other set lowered to do the plowing on the return trip. See STEAM PLOW, pp. 2354–2356, "*Mech. Dict.*," *et infra*, for installation and method of working.

Bal'ance-wheel Turn'ing Ma-chine'. A machine-tool for the automatic turning of the circular rims of balance wheels, such as are used upon sewing-machines and other light machinery. The work is performed by two tools operating upon opposite sides of the wheel at the same time. These tools are automatically revolved in a horizontal plane, about the rim of the wheel, in opposite directions, so that one-quarter revolution of each tool-post completes the half-circle, and then both spindle and tool-posts cease revolving.

The centers around which the tool-posts revolve are adjustable, and allow a variation in the size of wheel to be turned, of from 6″ to 7″ in diameter. This adjustment is made by simply turning a screw. The feed-works are inclosed in the base of the machine, and are readily accessible for oiling, etc. The cone has two speeds.

See "*Scientific American*," * xxxviii. 271.

Balance-wheel adjusting apparatus.
Ide . . . . . . * "*Scientific American*," xlii. 307.

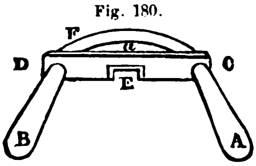
Ba-la'ta. The gum of the *Achras dissecta* of the family Sapoteæ (Mex. Zapotl) found in Guiana, and having properties similar to gutta percha. It may be vulcanized by digesting with sulphur.

Bald'win Bit. (*Manége.*) A bit having two mouth-pieces, the inner one working on levers; claimed to possess superior advantages over others for driving horses that are hard to control or have bad or vicious habits.

Ba-leen'. Views and diagrams showing the manner in which the baleen (whalebone) is arranged in the head of the whale (*Balæna mysticetus*) were given in "*Land and Water*," 1877, and republished in "*Scientific American*," xxxviii. 88.

The house of Meyer, in Hamburg, is probably the largest manufacturer of whalebone wares and walking-sticks in the world. The value of the produce of the former in 1871 was £362,000, and the number of sticks and whips was 175,000 dozen, valued at £65,000.

Fig. 180.



Baleen Splitting-knife.

Ba-leen' Knife. A knife used in splitting the baleen into rods of the required size.

The baleen is held in a bench-vise and split in the direction of its fibers. The knife, Fig. 180, has a curved blade, *F*, in a metallic plate, *C D*, with handles *A B*. The knife-edge is parallel with the upper edge of the directing notch *E*.

Bale Hooks. 1. Large lifting-hooks suspended in pairs from the chain of a crane or winch. See Fig. 181.

2. Small hand-hooks, Fig. 182, used by 'longshoremen in handling bales.

Fig. 181.

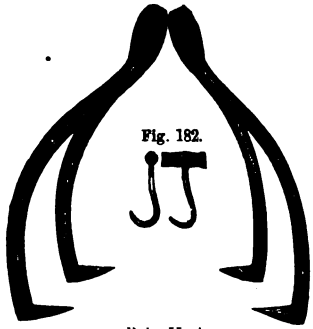


Fig. 182.

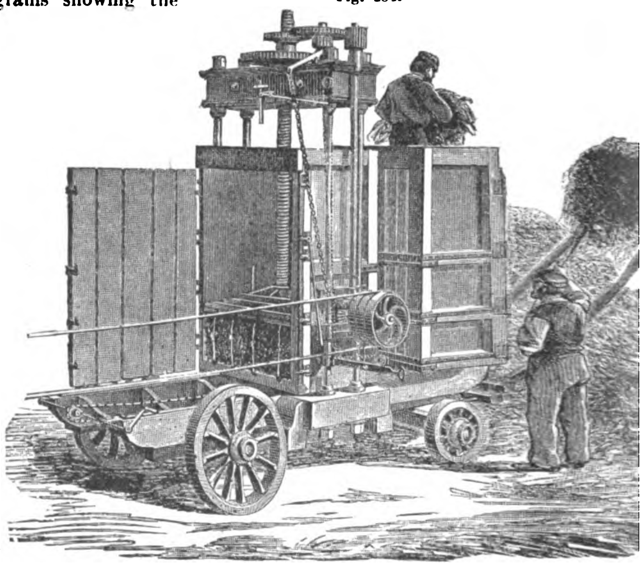
Bale Hooks.

Bal'ing Press. Two continuous baling press took high honors in Paris in 1878, — those of De erick and Dodge.

The former has a plunger or piston in connection wit reciprocating feeder, which drives a bunch of hay wit the range of the plunger before each stroke of the lat A certain quantity being thus compressed into a comp ment at the end of the chamber, is tied with wire dropped from the machine.

In the Dodge machine the hay is thrown loosely on feed-table or troughs in front of the press, whence teeth carry it right into the open mouth of the mac when it is seized by the revolving cones in the head- and drawn in from the feed-table in two continuous str and built up into a bale 26″ in diameter. The diamet the bale is never increased, but the bale grows long layer after layer is built up. In doing this the dens the bale is regulated by the friction-clutch, which has previously made tight. After the bale is built such

Fig. 183.



Mabille Frères' Hay Press.

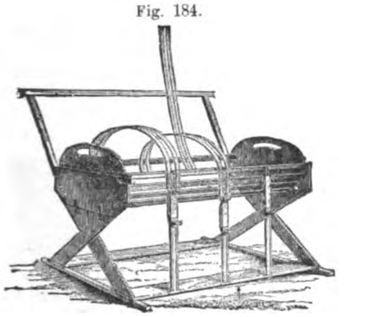
as desired, the action of the compress-screw is b play by simply shifting one cog-wheel, and in a the bale is compressed endwise and shortened about one-fourth or one-fifth its length without increasing its diameter. While the compression is going on, the man attending the press is passing around and fastening the two wires. When this is done, the pressure is released, the bale dropped out, and the press set for another bale.

Fig. 183 represents a baling press, made by Mabille Frères of Amboise, and worked by horse-power. The rotation of the band-wheel is transferred by bevel gearing to the vertical shaft, and that by spur pinion to the system of gearing on top of the machine, which is of different speeds and powers for rapid work at the first of the pressing, followed by slower and more powerful condensation as the truss approaches its final dimensions.

A multitude of small baling presses are used in France, both for packing rations for cavalry and for stowing away in convenient form for handling, the straw or hay of a farm.

One of the smaller kind is that made by Guitton of Corbeil, France. It has three pliable steel bands, which are

Fig. 184.



Guitton's Ration Press.

laid back against the bar (one is shown in this position) while the crate is being filled. The bands are then laid over, the ends brought down in front, and secured to hooks. These are forcibly drawn down by pressing the foot on the treadle, each band being in turn attached, a catch holding each firmly until the encircling cord is placed and tied. Each steel band being then released, the bundle is thrown out.

The machines make bundles from 30″ to 40″ long. A larger size, made on the same principle, but mounted on wheels, makes bundles of from 60 to 80 lbs. weight.

See baling presses, etc.: —

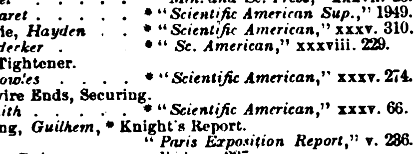
Balk. (*Agriculture.*) The space between rows of plants in a field, as of corn or cotton.

Bal'land. (*Mining.*) Derbyshire: Dusty lead ore.

Ball and Sock'et Coup'ling. A coupling which, by affording a joint, permits flexure.

Fig. 185.



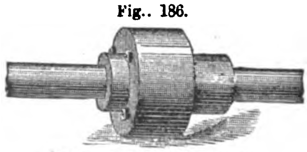
Ball and Socket Coupling. (Parts Detached.)

Figs. 185, 186, show a ball and socket coupling for line shafting, — a more compact device than the gimbal joint of the tumbling shaft.

It has not a perfect ball, but the leaves are the equivalent, and operate against plates in the case. The rounded edges of the leaves allow flexure without cramping. A divergence from the straight of 5″ in 12′ is readily permitted.

Ball and Sock'et Hang'er. One the axis of the opening in which is adjustable so as to be capable of being brought in line with a shaft.

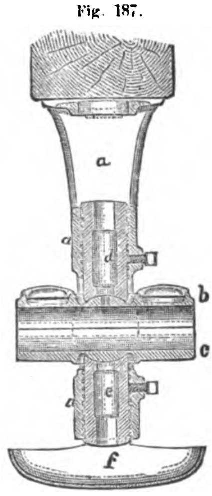
Fig.. 186.



Ball and Socket Coupling. (Parts Connected.)

In Fig. 187, *a* is the frame or hanger; *b*, the upper, and *c*, the lower portion of the box. This box is provided, top and bottom, with spherical surfaces, so placed as to be, in reality, portions of a sphere which has its center in the center of the axis of the box; *d* and *e* are what are called the plungers. These are screwed into the frame, and are provided with cup-shaped ends to clasp the spherical parts of the box. The box can rock to a limited extent in every direction in these cup-shaped ends. The plungers serve a double purpose: 1st, of providing the socket for the sphere to roll in; 2d, to permit of a vertical adjustment of the entire box to bring them in line one with another; *f* is an oil dish to catch the drippings from the box.

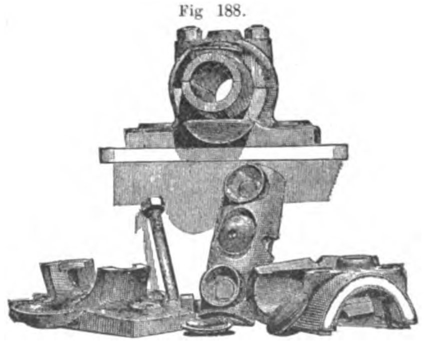
Fig. 187.



Ball and Socket Hanger.

Ball and Sock'et Pil'low-block. One which is capable, within certain limits, of accommodating itself to the line of direction of the shafting.

Fig 188.

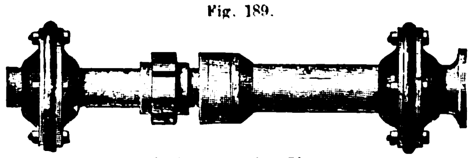


Ball and Socket Pillow-block.

Fig. 188 shows a ball and socket pillow-block, and beneath it are all the parts, detached.

Ball and Sock'et Pipe. One having a flexible joint which permits the sections to be laid out of mutual line.

Fig. 189.



Ball and Socket Pipe.

The illustration shows a pipe with two such joints, each inclosed with casing plates bolted together. The ball at the end of one section rolls in a spherical cavity in the other, as shown in section in Fig. 541, p. 219, "*Mech. Dict.*"; but in the present, each section is tubular.

Ball and Sock'et Truss. (*Surgical.*) One, the pad of which is attached to the strap by a ball and socket joint which allows the pad to adjust itself to the surface of the body.

Bal'last Ham'mer. A track-layer's hammer, having two rounded faces, and used in packing the ballast beneath ties, and also, on occasion, in driving spikes.

Fig. 190.

Ballast Hammer.

Ball-cock.

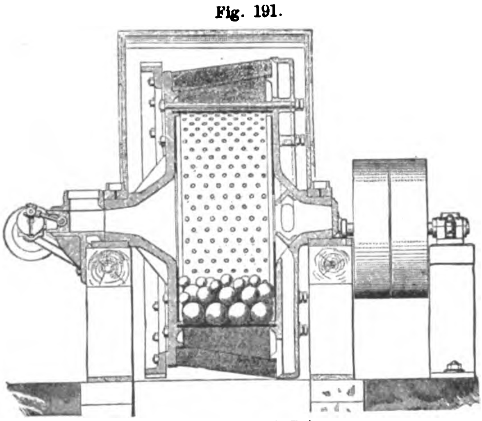
1. One in which a globular valve takes the place of a disk, spigot, sliding plate, etc., which are other forms of devices for closing an aperture in a pipe.

2. One opened or closed by a lever attached to a floating ball. See Fig. 234. See also p. 220, "*Mech. Dict.*"

Ball valve, Br. *Jefferies* . . . * "*Engineer,*" xlvi. 377.

Ball Grind'er. A pulverizer for minerals. It depends upon the attrition of spheres rolling inside a rotating cylinder, the periphery of which is provided with a cast-steel ring, perforated with

Fig. 191.



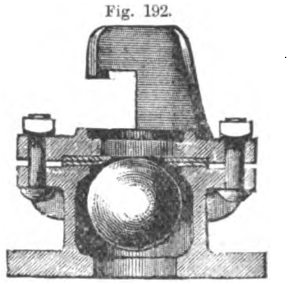
Brueckner's Ball Grinder.

small holes. The heads of the cylinder are made of heavy cast iron, lined with steel. It is filled with steel balls from 2″ to 5″ in diameter, in quantities of 1,000 to 1,200 lbs for a 48″ cylinder. The steel ring is the crushing plate upon which the balls, by a combined stamping and grinding action, break up the material to a size varying from a powder to the size of the holes of the ring. The broken material which has passed through the holes of the steel plate, is sorted by the first wire-screen, all that are larger than the mesh being returned to the grinding chamber by the passage shown on the right hand. This process is repeated on the second outer screen, which regulates the size of the final product, all stuff not coming up to the required degree of comminution also being returned to the grinding chamber.

"*Iron Age,*" February 20, * xxiii., p. 1.

Ball Hy'drant. One having a metallic box containing a self-acting globular valve of gutta-percha or material relatively lighter than water, so as to be normally closed against its seat by its levity, and more firmly by the pressure beneath it. The top of the box has two L lugs so as to form a bayonet-joint with the portable stand-pipe to which it is attached.

Fig. 192.

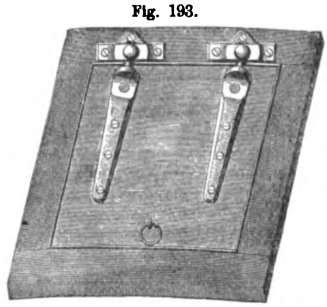


Ball Hydrant.

Ball'-joint Hinge. One having a flexible knuckle. In the form illustrated it is a hinge for a stern-post shutter; when made on this principle each can be adjusted, in fixing, to the bevel of the post, so that hinges from one pattern will answer for all the different rakes and bevels of the various posts. See Fig. 193.

Ball Mount'ing. (*Manége.*) A pattern of harness mountings having a ball at the point where the ring is attached to the base.

Fig. 193.



Ball-joint Hinge.

Bal-loon'. *Hartness's* sectional balloon, the parts resembling the lobes of an orange, was patented May, 1874. This is a substitute for the gores of which the balloon is ordinarily made, and prevents the puncturing of a section from being fatal to the whole. It is like making a ship's hull or a life-preserver in compartments.

Ball-peen Hammer.
a. Hand-hammer.
b. Riveting Hammer.

Ball Probe. (*Surgical.*) A urethral sound; a slight staff with a ball on the end. The *olivary bougie* or *bougie à boule* are of similar character but different proportions. Page ii., Part III., *Tiemann's Armamentarium Chirurgicum.*"

Ball Seat'er. A tool used in loading metallic shells, to place the axis of the ball accurately in line in its seat in the shell. See RELOADING TOOLS.

Ball Trim'mer. (*Cartridge-making.*) The balls after they come from the bullet machine are trimmed both side and end by this machine, working on the principle of the lathe.

Bal'us-ter Lathe. A lathe for turning articles of wood which have to be frequently repeated, such as ornamental stair-balusters, the legs of tables or chairs, bed-posts, etc. Between the headstocks a sliding-frame is arranged and fixed to suit the dimensions; this slide contains two knives, both the entire length of the article, the one knife to rough-out nearly to size in advance of the one to finish; both are set on the skew in order to take the work in detail; the first blade merely brings the piece of wood approximately to form, while the other blade is cut out exactly to pattern with all the irregularities of the required article. One passage of the slide with its two instruments in moving past the revolving article finishes the work.

Bam-boo'. A plant of the grass family. The tubular stem is of great use in the mechanic arts, and the splits therefrom are used in making mats, baskets, etc.

Bamboo, uses of . . " *Scientific American*," xl. 279.
" *Scientific American*," xlii. 240.

Band. The metallic cap on the outside of the hub or nave of a vehicle. Made of many fancy patterns for carriages of luxury.

Ban'dage. (*Surgical.*) A wrapping, support, or dressing of various kinds and uses. For instance (the figures refer to " *Tiemann's Armamentarium Chirurgicum*," Part IV.): —

Abdominal bandage, for supporting the abdomen after parturition, etc. Figs. 40–44.

Suspensory, for the scrotum. Fig. 46.

Umbilical, a truss for the umbilicus. Fig. 16.

Fracture, various in kind, material, and mode of application. Figs. 122, 123, 125–127.

Esmarch's tourniquet. Fig. 184.

Rubber, vulcanized gum cloth.

Roller, cloth in strips.

Plaster-of-Paris, cloth saturated with a thin paste of gypsum, placed on a part of the body to harden *in situ*.

Carbolized, saturated with solution of carbolic acid. See also p. 225, "*Mech. Dict.*"

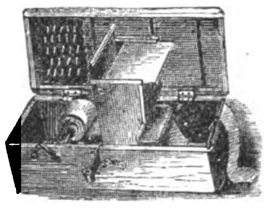
Ban'dage Shears. Curved-tip shears for trimming and cutting bandage cloth; or in cutting away portions of a plaster-of-Paris fracture bandage for inspection.

Figs. 165, 189, 202, 203, 204, Part IV., *Tiemann's* "*Armamentarium Chirurgicum.*"

Ban'dages, Plas'ter Spread'er for. The device, Fig. 195, is for simply rolling bandages, or to apply silicate of soda, dextrine, or plaster simultaneously with the winding process.

" *Medical Record*," October 13, 1877.

Fig. 195.



Dr. Greene's Bandage Winder and Plaster Spreader.

Band Cut'ter. A tool for cutting the bands of sheaves, when feeding to the threshing machine.

In the latest practice the band is of wire or string.

Graham and Haines . * "*Iron Age*," xxv., April 8, 9.
Chadbourne . . . . * "*Iron Age*," xxii., July 11, 20.

In some British threshing machines, the band is cut by a revolving knife in the floor of the hopper down which the sheaf slides into the throat of the threshing concave.

Ban'de-role. The flag formerly known by that name was a company color.

Band'ing Ma-chine'. (*Hat Making.*) A form of hat-body blocking machine specially adapted to make the *band*, the term used in the trade for the sharp angle at the junction of the side-crown and brim. See BLOCKING MACHINE.

Band'ing Ring. (*Hat Making.*) The circular band which grips the hat at the band; the angle formed by the side-crown and brim. It is used in hat-blocking machines.

Band In'stru-ments. See report on band instruments by *H. K. Oliver* on Group XXV., in vol. vii., " *Centennial Exhibition Reports*," p. 50.

Band Mount'ing. (*Manége.*) A pattern of harness the ring of which is broad and flat, with square edges.

Ban'do-leer'. A case containing a musket charge and fastened to the shoulder belt.

Band and Jig Saw Combined. (*Wood Working.*) A machine by Western & Co., of London, in which are provided alternative band and jig saws, each furnished with its own pulleys fixed and loose. The band is adapted to saw wood up to 10″ thick, and the jig up to 6″.

Band Saw. The band saw, consisting of an endless steel ribbon with serrated edge, is the invention of William Newberry, of London, England, and was patented in 1807.

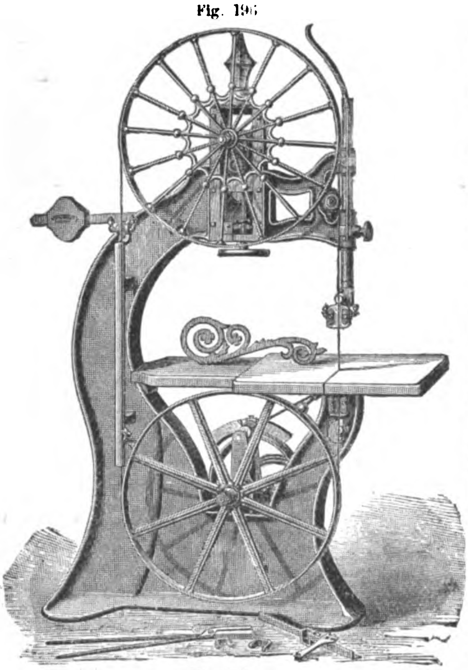
M. J. L. Perin, of Paris, France, overcame the difficulty which long prevented the invention from becoming of general utility, and his celebrated blades are yet unsurpassed.

" Analyzing the peculiar principles of action of the band saw, it may be said to have a blade of superior thinness, capable of tension in varying degrees, moving in right lines through the material, at a speed that is almost unlimited, and capable of exceeding that of circular saws; operating too by machinery consisting only of rotating parts, and of the most simple construction, the sawdust all carried down through the timber, offering no obstruction in following lines.

" Add to this the peculiar adaptation of the band saw to curved lines, and its advantages cannot be over-estimated. The speed of sawing, or the cost of sawing, which is much the same thing as the movement of the teeth, is with the band saw almost unlimited. Its performance, contrasted with reciprocating saws for cutting plain sweeps or scroll work, shows a gain of time, or cost, of three or four to one, with the important advantage of being easier to operate." — *Richards*.

The latest form of band saw is shown in Fig. 196. The machine has a planed iron table pivoted for bevel sawing; a shipper with frictional brake, for arresting the motion of the saw; a vertical guide bar with retracting spring, for instantly adjusting it to the desired height; an elastic steel upper wheel; cast steel shafts, with self-oiling boxes and adjustments to take up the wear; and methods of

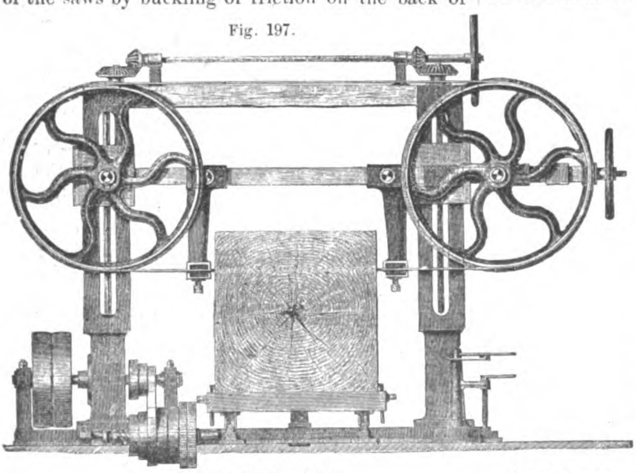
Fig. 196.



Band Saw.

keeping the saw at its proper tension, allowing at the same time flexibility to the parts, to compensate for any sudden impact, and prevent breakage of the saws by buckling or friction on the back or

Fig. 197.



Horizontal Band Saw.

sides. The weighting device gives positiveness to the amount of tension the saw is receiving, at the same time compensating for any variation in the length of the saw by change in temperature, or strain. Friction guide-wheels receive the back thrust of the saw, and wooden guides are provided at the side.

Band Saw′-mill. The band saw has been applied to the sawing of logs into boards, and the resawing of timbers. Three illustrations are given of English, French, and American machines respectively.

The horizontal band saw of Western & Co., of London, is shown in Fig. 197. It is shown as splitting into heavy balks a log already squared and mounted on a horizontally moving carriage. The saw wheels are simultaneously adjusted for height by a single wheel: for tension, by adjustment of the right-hand wheel. The saw guides are separately adjustable to the vicinity of the log.

Plate III. shows the band saw-mill of Arbey, of Paris. It has a continuous roller feed, pivotal table for bevel sawing, and the various adjustments for tension of the blade, elevation of the guide, approach of the feed rollers, etc.

Fig. 198 shows by side and end elevations the band-saw mill of Richards, London & Kelly.

It has wrought iron wheels 72″ in diameter, receives blades 45′ long to 5″ wide, and is shown operating upon a small round log. The wheels are covered with wood and faced with leather or gum: the upper one has an adjustment of 18″, the supports resting on springs which equalize the tension of the blades. The Perin saw blades are used. The wheel is carried on a steel shaft 3½″ in diameter, with brass bearings.

The guide stem is 3½″ diameter, of wrought iron, counter-balanced, and supported in iron brackets bolted to the main column. The lower guide is also mounted on an iron bracket, connected to the main column, and has no attachments to the floor. The lower or main shaft is 4½″ diameter, with bearings 12″ long. The tight and loose driving pulleys are 30″ in diameter, 10″ face. Thermatic oilers are applied to the bearings.

Band′-saw Hold′er. An apparatus (Fig. 199) used in brazing band saws. It consists of a holding device and brazing tongs.

File a taper for, say ½″ on each end of the blade, so that when brought together the ends will be of even thickness with the rest of the saw. When adjusted properly, so that the teeth will match, clamp in the scarfing frame, so that the ends will be pressed together. Wash the saw and solder with acid, place a slip of solder between the laps of the saw, heat the welding tongs, grasp the joint, and when the solder is melted allow the saw to cool gradually.

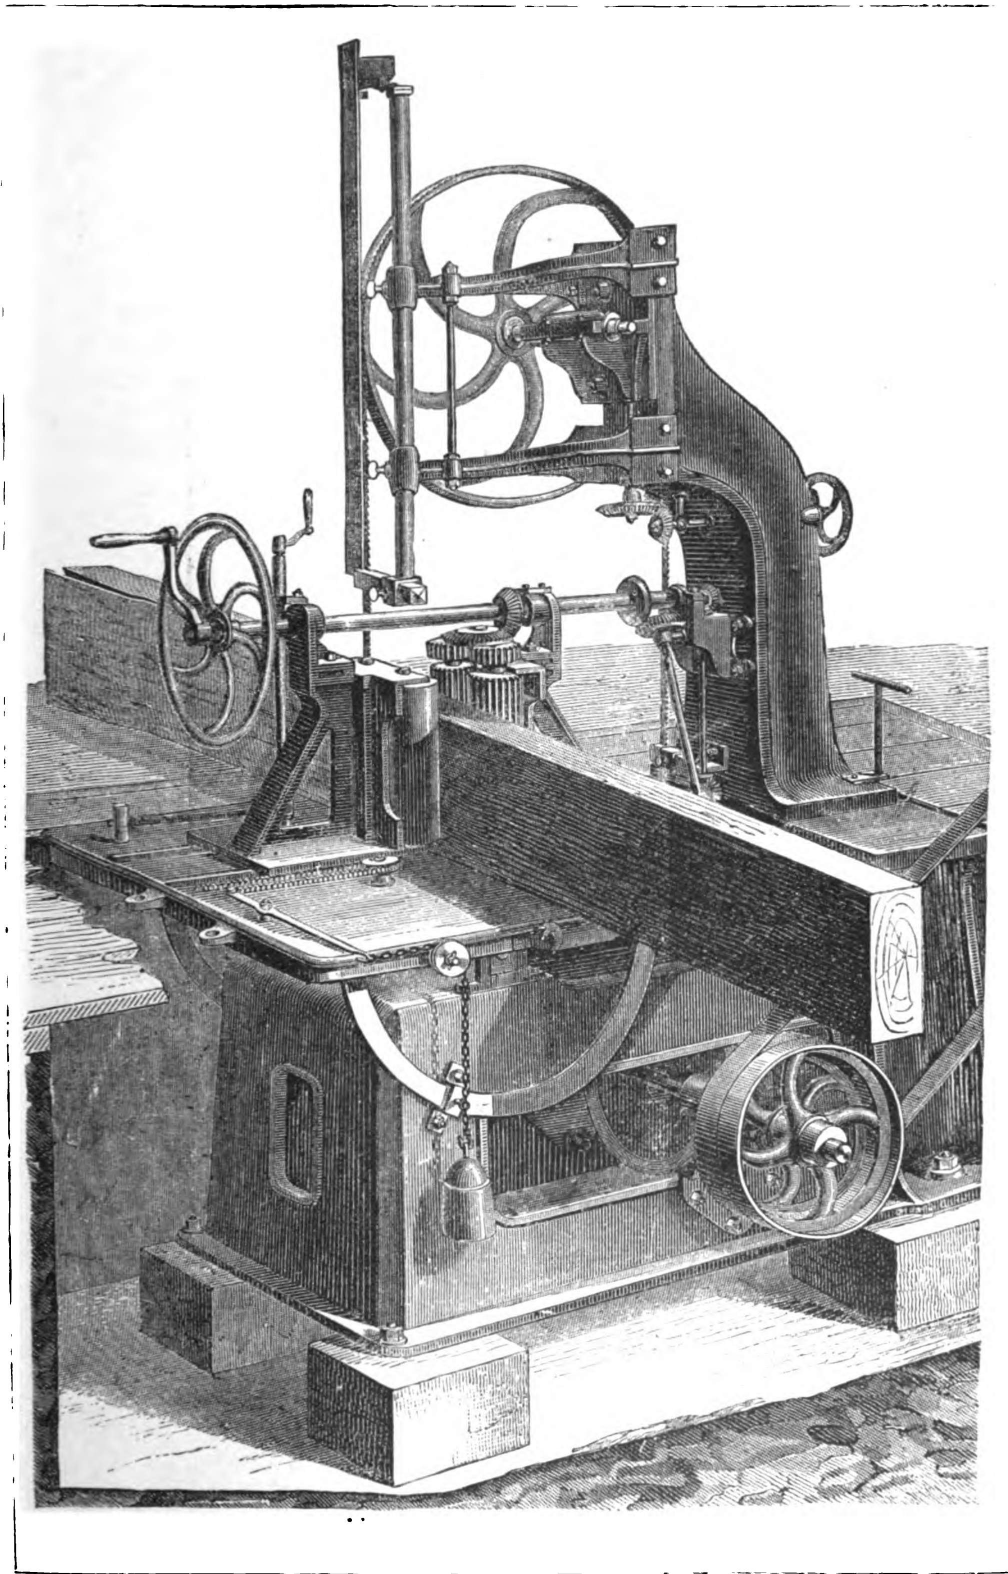

PLATE III. BAND SAW-MILL, BY ARBEY OF PARIS. See page 72.

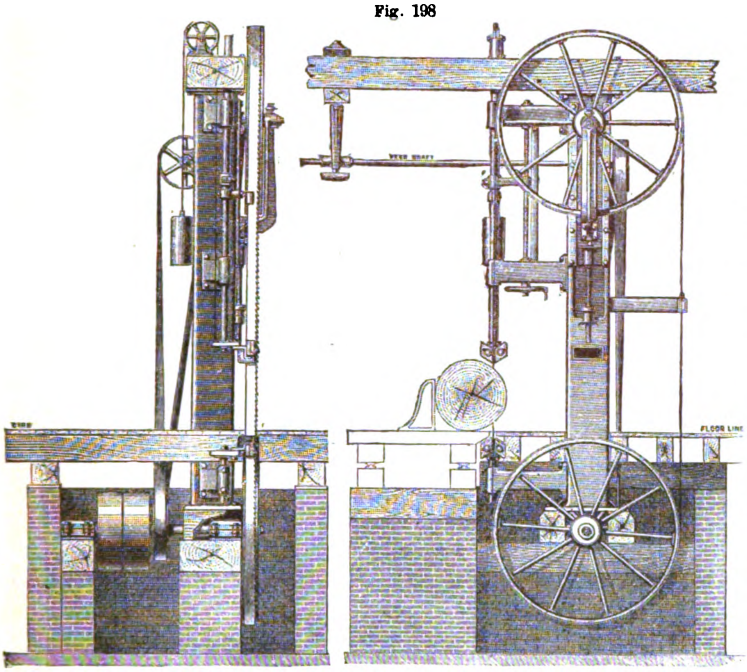
Fig. 198



Band Saw-mill.

Band'-saw Set'ter. Fig. 200 is Richards' band-saw setting machine and filing frame.

The setting is done by a hammer in the hand of the operator. The saw is strained and passes between two steel blocks, feed is imparted to the saw by a pawl, operated by the hammer handle. Every blow of the hammer sets a tooth, and the setting can be done at the rate of about 6′ per minute. The feed is adjustable to any pitch of tooth in an instant.

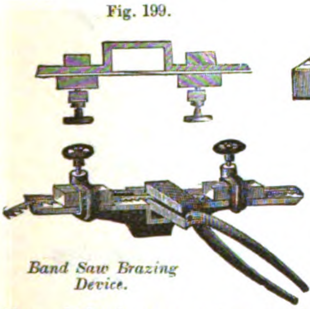
The machine is wholly of metal, except the rims of the wheels. The vise is arranged to close instantly for a length of 24″, by means of cams on the front.

Fay & Co.'s band-saw setter is a machine of similar character, the saw being strained upon the wheels and passing between the jaws of the setting machine. The feed pawl feeds two teeth at a time.

Band'-saw Sharp'en-ing Frame. A frame in which band-saws are stretched, and each portion of the blade clamped in turn, in order that it may be sharpened. When the clamp is slackened, the rotation of the crank brings a new portion of the blade within the loosened jaws of the clamp. See Fig. 201.

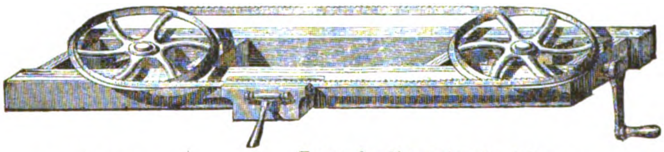
Band'-saw Tongs. A pair of flat-lipped tongs which are heated sufficiently to melt silver solder, and then clasped over the scarfed and matched ends of a band saw, to melt the film of solder placed between the lapping edges. Shown in BAND-SAW HOLDER, Fig. 199.

Fig. 199.



Band Saw Brazing Device.

Fig. 201.



Frame for Sharpening Band Saws.

Band Set'ter. A tool for setting bands on carriage wheels.

It operates as a plane. Cutter *B*, Fig. 202, pares off the surface on which the band is driven; *A* cuts the shoulder.

The end of the axle should be raised so that the wheel can be made to revolve rapidly, and then, while the wheel is in motion, hold the plane to the hub until it is shaved off sufficiently to drive on the band.

Band-saw Setter and Filing Frame.

Fig. 202.

Band Setter.

Bank'-note En-grav'ing. The subject is considered on pp. 228, 2368, 2369, "*Mech. Dict.*"

Mr. George W. Casilear, Superintendent of Engraving in the United States Treasury, Bureau of Engraving and Printing, describes an improved method for engraving denominations or lettering upon lathe-work counters, used on bonds, bank notes, and other securities, by the transfer process: —

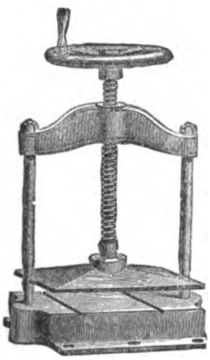
"Instead of proceeding as heretofore by hardening the die laid down from the shell, and taking up a roll for cutting out the white figures or letters, and then hardening the roll and laying down a second bed-piece for finishing with the graver, then in turn taking up a second roll called the finished roll. My improvement consists as follows, in taking the original die as made from the shell, and transferring with my numeral or alphabet rolls directly upon the face of the lathe work the required denomination or lettering. The parts of the lathe-work appearing over the face of the figures is then scraped and burnished away and a new surface gained, by having the die or plate set up from the back in the usual manner known by engravers and transferrers, using the precaution to have a bit of paper between the anvil and plate to protect the lathe-work, the paper only to cover those parts of the lathe-work which are to appear intact.

By this improved process a roll is saved, also a bed-piece, and the lathe work is purer and sharper, being transferred direct from the shell while there is no engraving of the denomination or figures on the die or plate, as the work is all done by the transferrer. The result being more perfect, and a great saving of cost."

Bank'-note Pa'per. See SAFETY PAPER.

Bank'-note Press. One for pressing and packaging bank notes. It has grooves for cords in the bed and follower, so that the notes may be tied up before the platen of the press is raised.

Fig. 203.



Bank-note Press.

Ban'ner. Formerly, the small, square flag of a knight, and charged with his arms.

Ban'ner Net'ting. For painted signs or banners to be hung across a street. The open work avoids injury by the wind.

Bar. Bars of furnaces are *bearer* bars, and *grate* bars; the former hold up the latter, and these the fuel.

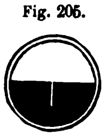
Bar and Open Bead Sight. (*Rifle.*) A form of sight in which the *aperture* is supported on a segment plate in the ring. Fig. 204.

Fig. 204.

Bar and Open Bead Sight.

Bar and Slit Sight. (*Rifle.*) A form of sight having a plate with a vertical slit. Also called a *slit-bar sight*. See Fig. 205.

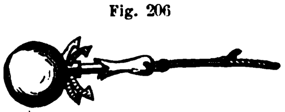
Fig. 205.



Bar and Slit Sight.

Barbed Shot. (*Life-saving Apparatus.*) A ball having grapnels attached and intended to be fired from a mortar to carry a line between a shore and a stranded vessel, or *vice versa.*

Fig. 206

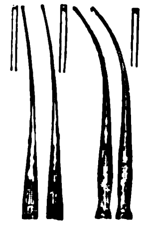


Barbed Shot.

Otherwise known as an ANCHOR-SHOT, or GRAPPLE-SHOT, which see.

Barbed Sca'ler. An instrument, Fig. 207, designed to pass between and around the necks of teeth which are loosened by old deposits of tartar. Being in pairs, with the barbed edges on opposite faces, they admit of application right and left, and on proximate surfaces. While holding the tooth with the finger upon it firmly in the socket, they can be used either by pushing to scale with the chisel edge, or by making the draw-cut with the barbed edge.

Fig. 207.



Dentist's Scalers.

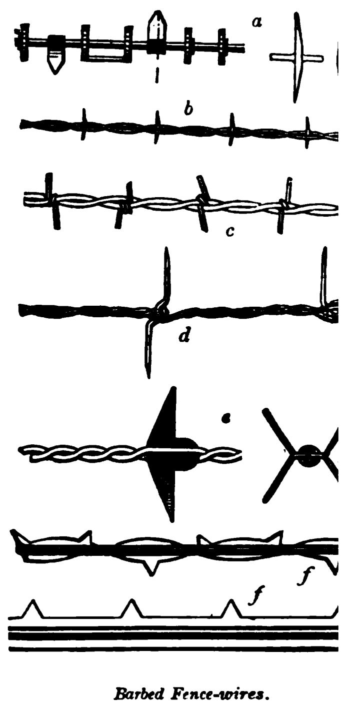
Fig 208.

Barbing Pinc[h'ers.]

Barb'ing Pinch'ers. A tool especially adapted for closing and clinching wire staples upon fence-wire.

Barb Wire. Wire with iron spikes [...] clinched upon it, to prevent breaking [...] when strung between posts as a fence.

Fig. 209.



Barbed Fence-wires.

Fig. 209 shows the prominent feat[...] history of the barb wire.

The upper illustration, *a*, shows the H[...] rough and incomplete invention, but in[...] bottom idea, *i. e.*, a fence wire provided[...] or barbs. Spur wheels or single spurs [...] attached to the wire.

b. Shows the next step, Kelly's pate[...] pointed spurs are strung on the wires [...] place by twisting a second wire around [...]

Glidden, *c*, substituted for the sheet-[...] a barb of wire twisted about one strand [...] place by the pressure of the other. [...] of modifications of this idea is extremel[...]

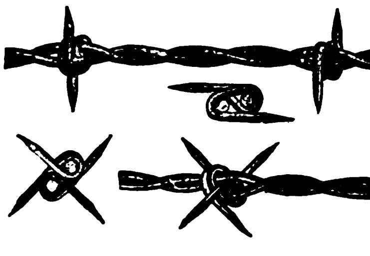
Haish, *d*, is the pioneer in that for[...]

with specially wrapped wires, the conjoined ends are hooked together and form projecting spikes.

Frentress, *e*, is probably the pioneer in that class in which separate sheet-metal plates, so cut as to have projecting barbs, are wholly fastened to the rod by twisting the wire.

In *f*, Allis's, the material is a rod with two flanges, one of which is cut into spurs and spaces, and the whole, being twisted, presents the barbs on all sides.

Fig. 210.



Two-spur and Four-spur Barb Wire.

Fig. 210 shows the barb wire in two forms, two-pointed and four-pointed. Each is shown in perspective and in cross-section. The cable consists of two strands twisted together, and the barbs are fastened between and around both strands, and their points stand out at right angles to the cable. The wire is painted, galvanized, or japanned.

Bar'-cut'ting Ma-chine'. A heavy shears for cutting bar-iron.

Ba-rege'. (*Fabric.*) A French worsted dress goods, woven on a gauze or open taffeta loom, and having a cotton warp and an English wool weft. Usually printed.

Bar'-i-ron Test'er. A form of machine for testing bar-iron. See TESTING MACHINE.

Bark'ing Ma-chine'. Forsaith's barking machine for rossing logs for the making of wood pulp is an annular plate, set with plane bits, and revolving in a vertical plane.

Ba-rom'e-ter Flow'ers. Artificial flowers colored with chloride of cobalt. When exposed to sun and dry air the leaves become deep blue; when the air is saturated with moisture they become pinky. Intermediate shades are easily observed.

Ba-ro-met'ric Bal'ance. An invention of M. Redier, of Paris. It has a long index-needle having an arc of vibration of large amplitude, 30 to 60 centimeters, which makes it visible at a considerable distance.

B B B are three aneroid barometer cases. To the first case to the left is attached a frame which carries the counterpoises M and E. On the same frame is fixed the large index needle. The whole apparatus pivots on a knife blade, T, and the counterpoises M and E being movable, the apparatus can be balanced in such a way as to cause the index to point to any division desired. The cases are attached to a second frame, V. When the pressure increases, these cases are expanded and the two counterpoises move toward the right. The equilibrium is thus broken and the needle moves toward the same side. When the pressure diminishes the contrary effect is produced, and the needle moves to the left.

Ba′ro-mo′tor. A portable hand and foot power invented by Bozerain (France). It has two treadles connecting with cranks on a fly shaft.

Bar′rage. A movable dam. Views of the barrages used in the river improvements between Paris and Auxerre, and a description of the substitution of a continuous navigation upon the upper Seine and Yonne by the aid of movable dams, for the intermittent navigation by flashes, are to be found in the report of Dr. Watson, "*Civil Engineering, Public Works and Architecture;*" "*Vienna Exposition Reports,*" vol. iii., section C, chapter V.

Poirée's movable dam or barrage, at Basseville, at the crossing of the Yonne over by the Nivernais canal, is shown in Plate IV.

"It consists of a succession of iron frames called *fermettes*, placed parallel with the current, and turning around their bases in bearings which are firmly attached to a carefully-prepared bed. The *fermettes* are united above by bars, having jaws or catches at their extremities. Against these *fermettes*, thus united, rests a screen, placed vertically, and composed of a number of wooden battens about 0.075 meters square and 2 meters long, called needles; the bottoms of these needles are placed against the sill, and their tops rest against the *fermette* bars placed near the level of the water, which the *barrage* is intended to maintain. Each *fermette* is trapezoidal; the two bases are horizontal. The lower base is terminated by gudgeons, which are received by two cast-iron bearings. The upper bases support a foot-bridge, used by the lock keeper to work the *barrage*. The details of the hooks, bars, washers, etc., which serve to unite the *fermettes*, are shown in the lower portion of the plate. When it is required to open the *barrage*, the lock-keeper and his assistant remove the needles one by one; the bars, planks, hooks, etc., are removed, and the *fermettes*, turning on gudgeons at their bases, fall into a recess prepared for them below the level of the sill. When it is required to raise the *barrage*, the lock-keeper lifts the *fermettes* by grappling for them under the water, reconstructs his foot-bridge, and replaces the needles. The time required to raise the *fermettes* and place the needles, is about one and a half minutes per running meter; and the time to open the *barrage* thirty seconds; for the complete opening and lowering of the waters fifty seconds." — *Poirée.*

Formerly, during the low water season on the Yonne, the navigation was intermittent, and took place by a system of flashing, which may be thus described: In the upper parts of the river, the water was accumulated by movable dams; a part of one of these dams being suddenly removed, an artificial flood called an *éclusée*, or flash, was formed. Barges and rafts, previously collected above the dam, were carried by the flood down the river with a velocity of from 0.50 m. to 1.50 m. per second.

In Plate IV. the upper figure shows the plan of the crossing of the Yonne River by the canal at Basseville.

Next beneath is an elevation of the barrage, showing half the barrage close fermettes raised, and the other half close fermettes lowered.

Next, a plan of the same.

Next, a transverse section on a mucl scale, showing the needle, the fermette an ings.

On the left, at the bottom of the plate tion and plan of the details for unitin fermettes.

On the right, beneath, transverse se plan of the gudgeons and bearings of a f

Holmes's Barrel-chamfering, Crozing, and Machine.

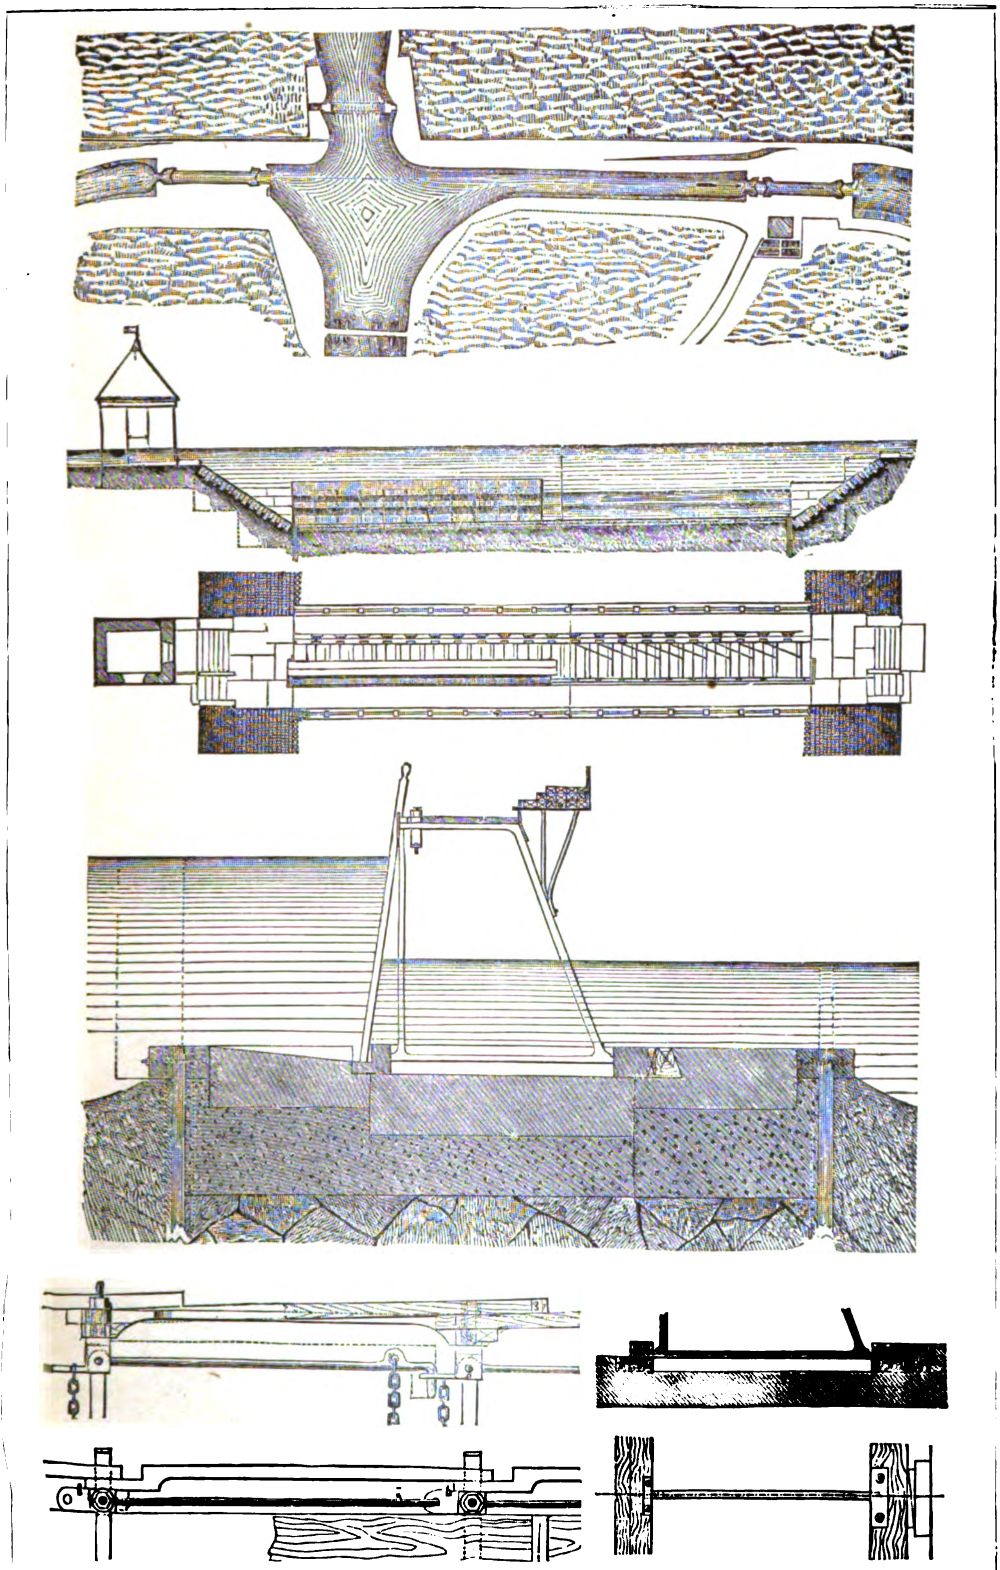

PLATE IV. POIRÉE'S BARRAGE, AT BASSEVILLE, RIVER YONNE, FRANCE. See page 76

lathe specially adapted to boring out gun-barrels. See RIFLING MACHINE.

Bar'rel-cham'fer-ing, etc., Ma-chine'. This machine is designed to chamfer, howel, level, and croze a cask of imperfect periphery, and to finish both ends of the cask at once. See Fig. 213.

To accomplish this, the three tools are placed in one revolving head, which, while revolving with high speed inside of the cask, is controlled by the rest upon the outside, compelling a uniform thickness and depth of chine, while it levels the same in a perfect manner; the rest and cutting head oscillating to conform to the outside irregular form of the cask while the latter makes one revolution; it having been placed within the chuck rings for that purpose.

All kinds of barrels, such as turpentine, oil, whiskey, pork, syrup, cement, sugar, flour, and other barrels, are made upon this machine, and it will finish any size desired by using the proper sized chuck rings. Rings for different sized barrels will fit the machine. The performance is 1,200 tight or 2,000 slack barrels per diem.

"*Engineer*," *xli. 431.

Bar'rel Clamp. A hoisting clutch or sling for barrels. The Yale barrel-clamp, "*American Miller*," vii. 275.

Bar'rel Cock. A faucet. The one shown is for racking, or drawing off the contents by pipe, the outer end of the faucet having a screw coupling.

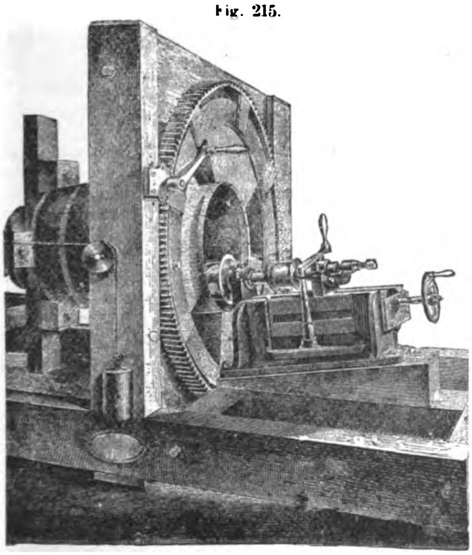
Fig. 214.

Barrel Cock, with coupling.

Bar'rel-cro'zing Ma-chine'. A machine for making the *croze* in the heads of casks. The *croze* is the groove in which the edge of the head is inserted and held. See BARREL-CHAMFERING MACHINE.

Bar'rel-fa'cing, Cro'zing, and Cham'fer-ing Ma-chine'. A machine for dressing the ends of casks, and making the head croze.

Fig. 215.

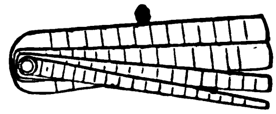


Barrel-facing, Crozing, and Chamfering Machine.

The machine shown is that of Arbey, of Paris. The cask is chucked in a revolving head, and each portion of the end circumference brought in turn against a rotating tool which planes and rounds the interior near the end, makes the croze groove, and chamfers the chine. The tool has all the requisite longitudinal and lateral adjustments.

Bar'rel Gage. A gage for testing the diameter of gun-barrels according to a standard; the instrument has several tapered slips, each graduated, and having a certain range of sizes, the diameter of the barrel being determined by slipping the gage into the muzzle.

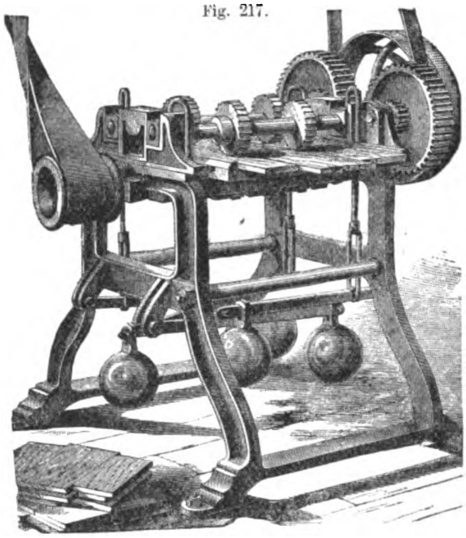
Fig. 216.



Gun-barrel Gage.

Bar'rel-head Dress'ing Ma-chine'. A machine for leveling, facing and dressing on one side the rough barrel-head, made of staves doweled together.

Fig. 217.



Barrel-head Dressing Machine.

The prepared head is laid on the table, is fed by four corrugated feed-rolls above, and its under side dressed by a planer cylinder rotated by a belt shown on the left hand. The pulleys on the right actuate the feed-rolls, which are held against the head by weighted levers acting upon the bearings. The revolution of the feed-rolls carries the head over the planer knives which smooth off the heads at the rate of 20 per minute, feeding rapidly in succession.

Bar'rel-head Joint'ing and Dow'el-ing Ma-chine'. A machine which dresses the edges of staves for heads, and bores the holes for the dowel-pins which hold the head-staves together.

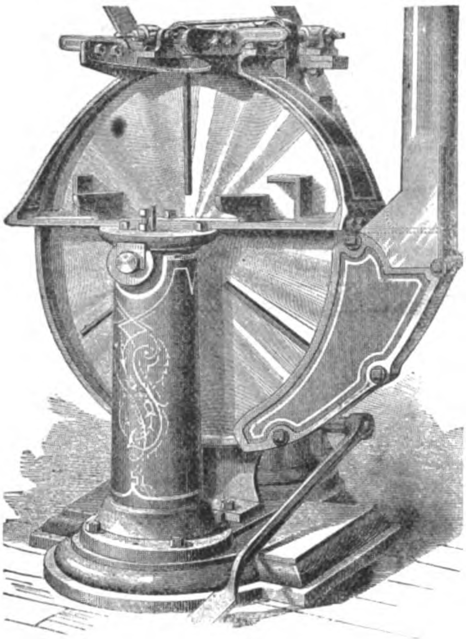
The machine, Fig. 218, has a metallic disk with three radial cutters which act upon the edge of a stave presented to them while lying upon the side-rest diametrically of the rotating disk.

The stave is then removed to the upper rest, and the two rotating augers which bore the dowel-holes are brought against it by pressing the foot upon the treadle.

Bar'rel-head Round'er. A machine (Fig. 219) which works upon the head-blank, rounding it and beveling the edge to fit the croze of the cask.

The head-staves, being jointed and doweled to-

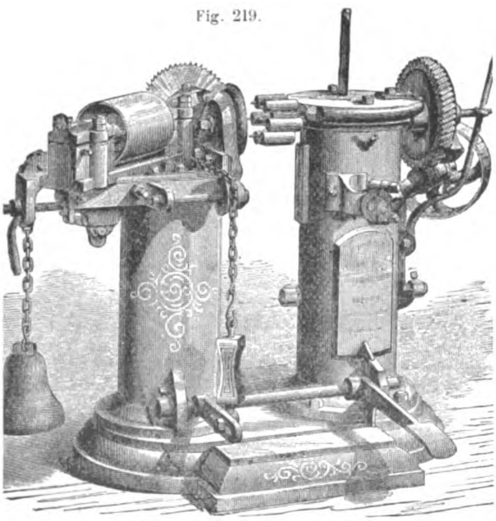
Fig. 218.



Barrel-head Jointing and Doweling Machine.

gether, are placed between the two clamps, one of which is on each side of the posts, so that the head, being in a vertical plane, revolves between them. This clamping is done by treadle, the head with pins being made to approach the round disk on the left. A circular saw brings the head to a round shape, and cutters chamfer the edge. This machine follows Fig. 217, the head dresser.

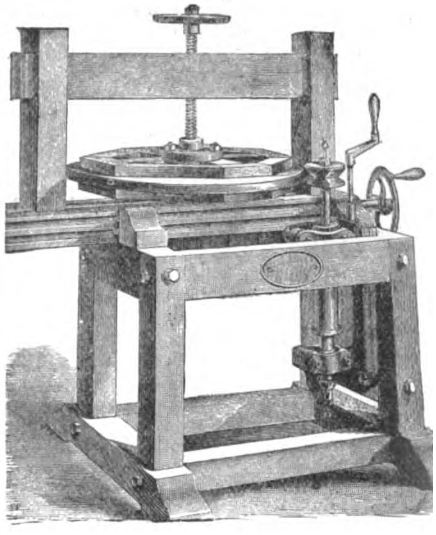
Fig. 219.



Barrel-head Rounder.

Bar'rel-head Turn'ing and Bev'el-ing Ma-chine'. Fig. 220 is a French machine for this purpose, made by Arbey of Paris. The head is carried in a frame, which has a horizontal adjustment to bring it in relation to the concave-faced revolving cutter, and is rotated, to bring each part of its periphery to the tool.

Fig. 220.



Arbey's Barrel-head Turner.

Bar'rel Hooks. Suspension hooks in pı for hoisting casks by the chines.

Fig. 221.

Barrel Hoo

Bar'rel Lev'el-ing Ma-chine'. A machine (Fig. 223) which brings the end of a cask or barrel to a level, that is, to a plane at right angles to the axis of the cask, so that it will stand squarely and vertically upon the floor.

Two end truss hoops are put on to the cask, which is then rolled into the press, the power applied, and the movable disk driven up against one end of it, bringing it into shape, leveling it and driving the truss hooŗ instant.

The machine has an iron frame, upon wh placed two leveling plates upon slides or and operated by cams. Two other plates ‹ are worked by cranks. Upon the latter aı drivers. The leveling plates are first m their cams, and then, while the cask is iı the hoop drivers advance and force all tl hoops to their places. The leveling plates ; ers then recede, and one barrel is discharged from the machine by the introduction of another. The capacity is from 4,000 to 5,000 barrels per day.

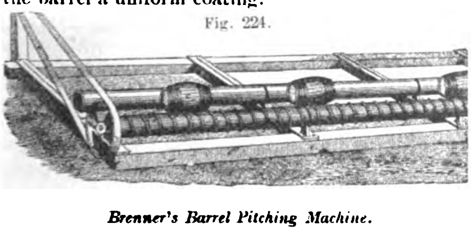
Bar'rel Pitch'ing Ap'pa-ra'tus. An apparatus for pitching the interior of casks.

The machine (Fig. 224) is provided with two lines of rollers, one of which has a screw thread upon its periphery which imparts a lateral as well as rotary motion to the cask, which is placed upon and between the two rollers, and thus passed from one end of the machine to the other, the liquid pitch being distributed over its whole interior.

In Vollmer's apparatus for pitching barrels, the pitching material is placed in the barrel, which is made to rotate; a blast of hot air being forced in melts the pitch, and spreaders give to the inside of the barrel a uniform coating.

Fig. 224.



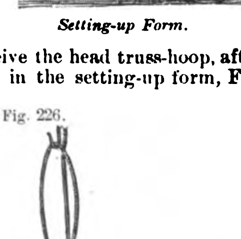
Brenner's Barrel Pitching Machine.

Bar'rel Saw. An annular or cylindrical saw for curved work.

See *Avrillon*, 2d Series French *Brevets*, vol. xxiv., pl. 2.

Bar'rel Set'ting-up' Form. An annular tray and elevated hoop for holding a set of staves while being placed in position to form a cask, shown in Fig. 225. The form is made adjustable, to suit the size and kind of barrel.

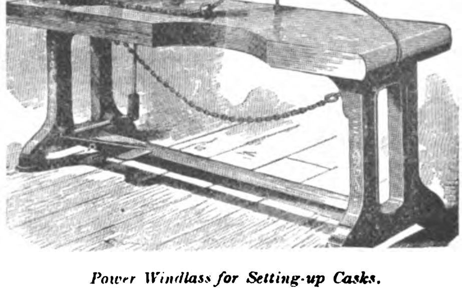
Fig. 225.



Setting-up Form.

Bar'rel Set'ting-up' Ma-chine'. A machine (Fig. 226) by which the ends of staves are drawn together, ready to receive the head truss-hoop, after they have been set up in the setting-up form, Fig. 225.

Fig. 226.



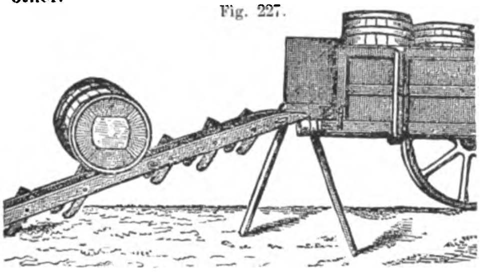
Power Windlass for Setting-up Casks.

The machine has a frame, upon which is planted a windlass operated by friction wheels and supplied with a rope.

The cask, having been set up with the ends of the staves in one head truss-hoop, is placed in the machine, and the rope wound around the flaring ends of the staves. The friction wheels are brought in contact, which starts the windlass and draws in the ends of the staves ready to receive the other truss hoop.

Bar'rel Skid. Fig. 227 shows a skid with pawls, which yield to the pressure of the cask in ascending, but oppose its return. The pivoted stops swing in one direction, but are locked in the other.

Fig. 227.

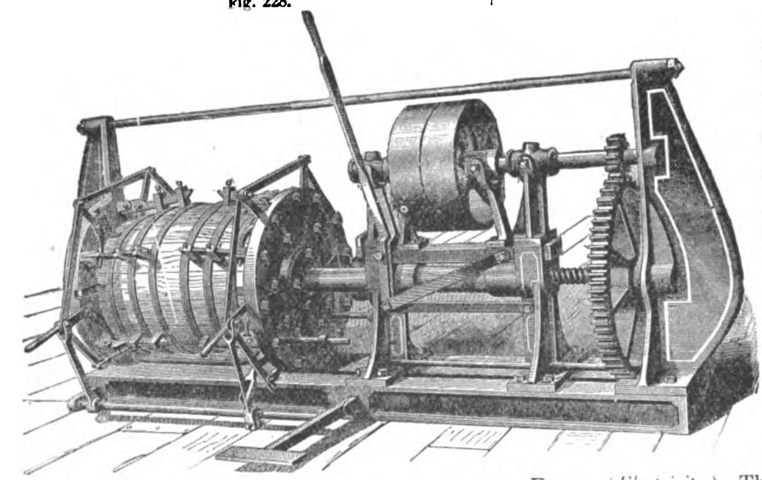


German Barrel-skid.

Bar'rel Stand. See CASK STAND.

Bar'rel Truss'ing Ma-chine.' A machine (Fig. 228) for operating upon slack barrels; compressing a barrel endwise to make it symmetrical and enable it to stand vertically when placed upon end, at the same time driving all the truss-hoops. The machine receives the barrel with all the truss-hoops upon it, but not driven; by placing the foot on the treadle and the hand on the lever, the machine being in motion, the drivers are brought in contact with all the truss-hoops, forcing them to their proper places and at the same time leveling the cask.

Fig. 228.

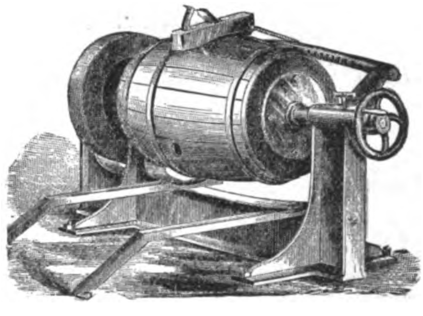


Combined Leveling and Truss-hoop Driving Machine for Slack Barrels.

Bar'rel Turn'ing Lathe. (*Fire Arms.*) See MILLING MACHINE.

Bar'rel Turn'ing Ma-chine'. A machine (Fig. 229) in which a barrel is chucked and revolved while the plane is kept in line by the back arm of the machine, the operator having only to guide it.

Fig. 229.



Barrel Turning Machine.

Bar'rel Wash'er. The barrel is placed on four adjustable supports and rinsed by jets of water from the pipe extending in at the bung-hole. (Fig. 230.) It is so arranged that when the barrel is placed on the supports the water-supply valve is opened; and is closed by means of a spring when the barrel is removed.

A more pretentious machine is that shown in Fig. 231, in which each barrel receives two motions, one on the axis of the chucks which hold it, and the other by the revolution in a vertical plane of the whole frame in which the barrels are held. The former motion throws the water from end to end and the latter from bilge to bilge.

Bar'ri-er. (*Mining.*) A strong pillar of mineral left between two mines, or between two distinct drifts or workings.

Bar'row. See —

Baggage barrow.	Dumping barrow.
Baggage truck.	Pump barrow.
Bloom truck.	Railway barrow.
Box barrow.	Sack truck.
Carboy barrow.	Stone truck.
Coke barrow.	Tub barrow.

See 24 varieties of French wheelbarrows in "*Scientific American Supplement*," * 2622–24.

Bar'row-way. (*Mining.*) An old term for a way in a working. Now *tram-way*.

Bar Shear. A heavy shearing machine for cutting bar iron.

Bar Weir. (*Fishing.*) A weir which is raised as the tide flows into a pond, estuary, or inclosed space; and drops automatically when the tide commences to ebb, thus preventing the return seaward of the fish.

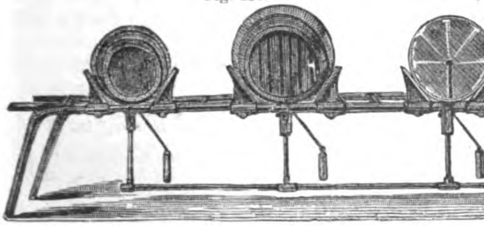
Base. (*Electricity.*) The part of an electro-magnetic instrument containing the helix, switch, primary and secondary binding posts, etc.

Base'-line In'stru-ments. For the measurement of the foundation line of a trigonometrical survey.

See p. 2461, "*Mech. Dict.*," and "*Report of Secretary of War*," 1878, vol. ii., Part III., p. 1401, *et seq.*, and Fig. 4.

Base Rock'er. A chair which rocks upon a base piece, having supporting casters.

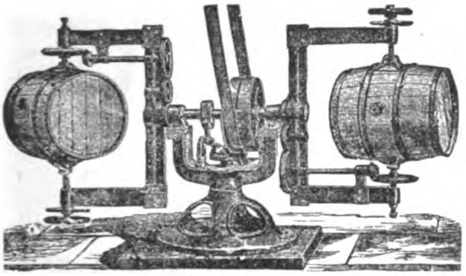
Fig. 230.



Zoller's Machine for Washing (Rinsing) Kegs.

Bas'ic Lin'ing. As applied in convertors or boshes of metallurgic furnaces; a lining which has a tendency to absorb the phosphorus present in the iron.

Fig. 231.



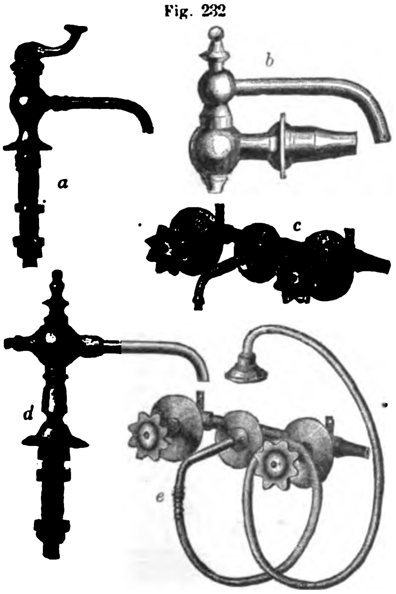
Barrel Washer.

In the Thomas furnace a basic calcareous or magnesian lining is used in the convertor, and lime, or lime and oxide of iron, is added to the charge of metal to insure a highly basic and calcareous slag, in which phosphorus is retained and by which it is removed.

Jacob Reese's Patent, 1866.

Thomas's British Patent, and United States Patent 216,910, June 24, 1879.

Fig. 232



Basin Cocks.

a. Telegraph basin-cock; on account of the shape of the trigger, resembling the key of the telegraph instrument.
b. Bracket basin-cock.
c. Combination basin-cock; for hot and cold water.
d. Ground basin-cock.
e. Combination basin-cock, with rubber tube and sprinkler, for shower-bath or shampooing.

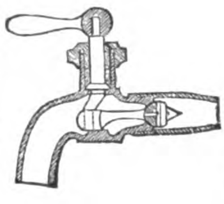
Ba'sin Cock. A faucet to a wash-basin. See Fig. 232.

Fig. 233 shows the positive self-closing cock, which has a spring to force the disk on to its seat, and is removable by pressing together the two horns. The pressure withdrawn, the spring recloses the valve-way.

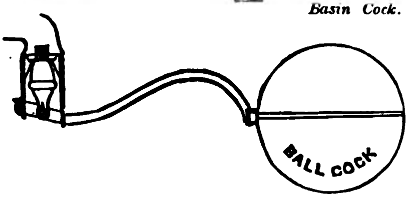
Fig. 233.

Fig. 234 shows the Fuller-Meyer basin cock, in which a conoidal plug of caoutchouc is forced into a conical opening while the pressure of the water tends to confirm the joint. Fig. 234 also shows a Fuller-Meyer ball cock, similar to the basin cock in the special feature mentioned.

Fig. 234.

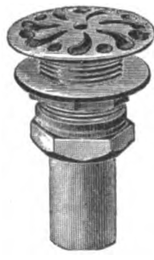


Basin Cock.



Basin Cock and Ball Cock.

Fig. 235.



Basin Grate.

Fig. 236.

Basin Plug.

Fig. 237

Basin Stopper.

Ba'sin Grate. A grated opening to the waste-pipe of a basin or bath-tub, opened by screwing up, and closed by the reverse motion. Fig. 235.

Ba'sin Plug. The stopper of a standing wash-bowl. Fig. 236.

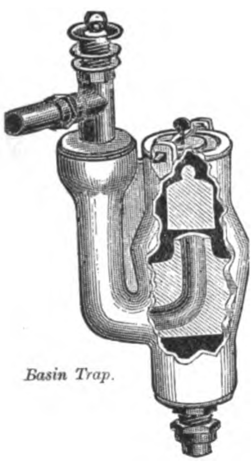
Ba'sin Stop'-per. A plug, Fig. 237, for the waste-pipe of a standing wash-bowl.

Ba'sin Trap. A seal against sewer-gas in the waste-way of a standing wash-bowl.

The arrangement shown in Fig. 238 excludes sewer-gas, whether water is in the trap or not, —

the porcelain valve seating itself upon the upturned end of the pipe.

Fig. 238.



Basin Trap.

Ba'sin Valve. A plug for the aperture at the bottom of a standing wash-basin.

See Basin Stopper.

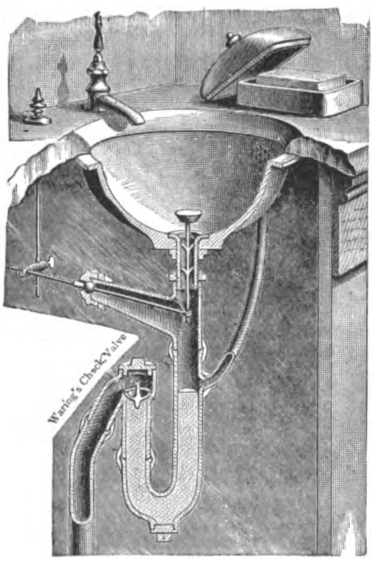
Ba'sin Waste. A pipe at the bottom of a standing wash-basin for the discharge of water. Stopped by a valve.

Fig. 239 is a substitute for the usual chain and plug for stopping the waste of wash-basins. Touching the knob on one side of the bowl opens or closes the valve.

The figure also shows a trap provided with check-valve to prevent passage of sewer-gas.

Ba'sin Wrench. A plumber's wrench with the nipper-jaws presented laterally to enable screws, nuts, and collars to be reached in peculiar situations.

Fig. 239.



Weaver's Basin Waste.

Bas'ket. (*Add.*) 2. (*Fabric.*) An all-wool fancy French coating.

Fig. 240.

Basin Wrench.

Bas'ket-rack. (*Railway.*) A receptacle in a passenger car for holding baskets, shawls, etc.

Bass Clar'i-net. (*Music.*) An instrument an octave below the clarinet, in B flat.

Bas'si-net. (*Fr., dim. of bassin.*) A light basin-shaped helmet without a vizor.

Bas'son-Quinte. (*Music.*) A double-strument, the diminutive of the bassoon, it being one fifth higher.

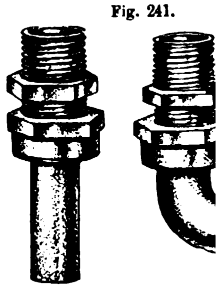
Ba-ta'vi-a Weave. (*Weaving.*) See Tw Armure.

Bath. 1. For bathing the person. See "*Mech. Dict.*"

Arrangement of building for Turkish baths. * "*Manufacturer and Builder*," ix.
Swimming Bath, London. * "*Scientific American Supplement*
Roman Bath. * "*Plumber and Sanitary Engineer*,'

2. Used in laboratories and factories fo ing the objects plunged therein. The reservoir may be a sand-bath, water-bath, oil-bath, mercury-bath, lead-bath, bain-marie, etc., according to circumstances.

Fig. 241.



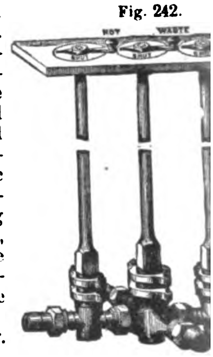
Bath-boiler Union.

Bath'-boil'er Un'ion. A coupling in the pipe uniting the boiler and the bath reservoir.

It is made straight or goose-neck, acco convenience.

Bath Cock. A faucet for bath use. In superior instances the arrangement has separate cocks for hot and cold water, and waste, with engraved labels. The cocks have gun-metal stuffing boxes, brass levers, union-joints, the water cock 1″ diameter, and the waste 1¼″.

Fig. 242.



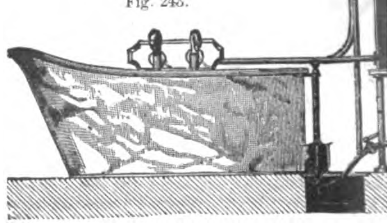
Bath Cocks.

Bath Heat'er. A special arrangement for heating baths, when it is not convenient to connec usual house service of hot and cold water

A small stove is surmounted by a flue, *A B*, Fig. 243, leading to the chimney. Surrounding the flue fire-chamber is a water reservoir, *M N*, which communicates with the bath-tub faucets. Cold water enters in the direction of the arrows.

Fig. 244 shows a portable bath-

Fig. 243.

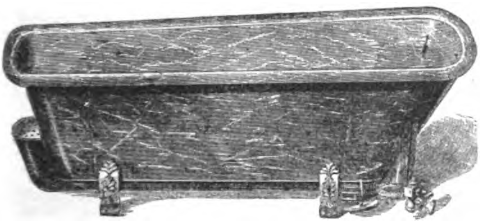


Stove Bath-heater.

tub heated by gas, which requires but an elastic tubular connection with a burner in the room. A ring of gas-jets burns beneath the tub, and at the foot end the exhaust gases pass out at a grated opening.

Bath heater. "*Manufacturer & Builder,*" viii. 43.

Fig. 244.



Gas Bath-heater.

Bath'ing Car. A car fitted up to contain the apparatus of a Turkish bath. The invention of C. H. Cooper.

The internal arrangement is a parlor or drawing-room, 10′ by 15′; Russian and plunge bath, 8′ by 7½′; three shampooing rooms, 6′ by 7½′; tepidarium, 10′ by 23′; movable closets, 2½′ by 10′; passages 18″ wide. The temperature in the various rooms will vary from 80° to 160°. The whole is lighted by blue glass. The car may be used on trains or side-tracked at towns where no such establishments are in operation.

Bath-om'e-ter. The name given by Dr. C. W. Siemens to his instrument for sounding the depth of the sea without the use of a line. The principle upon which the action of this instrument depends is the diminution of the influence of gravitation upon a weighty body, produced by a decrease in the density of the strata immediately below it; thus the density of sea-water being about 1.026 and that of the solid constituents which form the crust of the earth about 2.75, it follows that an intervening depth of sea-water must exercise a sensible influence upon total gravitation if measured on the surface of the sea.

Fol's Bathometer, * "*Scientific American,*" * xxxvi. 260.

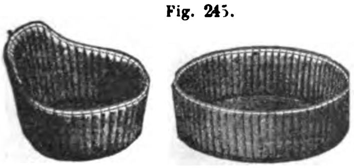
See also Sounding Apparatus, p. 2247, *et seq.*, "*Mech. Dict.*"

See also Flying Sounder, *infra.*

Bath Stove. A stove with circulating pipes connecting with and designed to heat a bath. See Bath Heater.

Bath Tub. Fig. 245 shows a tub of flexible

Fig. 245.



Portable Bath Tub.

material with braces sufficiently strong to preserve the outline of the upper edge of the tub when arranged for use, but sufficiently flexible to admit of their being bent so as to be inclosed in the tub when it is folded. There are also vertical props for supporting the sides and an air-cushion for the head.

Bath'-tub Strain'er. A perforated plug or plug-cover in the waste of a bath to keep soap, linen, or what not from entering the waste-pipe.

Ba'ting. (*Tanning.*) Steeping hides in a lixivium of hen manure, after coming out of the lime-vats.

The process tends to separate the lime, oil, and glutinous principle, and to make the skins pliant, porous, and ready to imbibe the tanning principle.

Ba'tiste. A fine, thin French cassimere made for use in tropical countries in place of cotton and linen fabrics.

Bat Print'ing. (*Ceramics.*) An adaptation of the transfer-printing process as applied to pottery.

An impression in glue (instead of ink) from a copper plate, is transferred to the biscuit, and on this viscous surface metallic color in powder is dusted. The ware is subsequently glazed and baked.

Ba-to're-om'e-ter. An instrument invented by Professor Giordano of Naples, for measuring minute variations of thickness, as, for instance, the increased thickness of a pane of glass due to heat derived from a finger resting upon it.

A vertical tripod is traversed by a very fine micrometer screw, and surmounted by a dial, the border of which is marked off into divisions according to a certain scale.

The object is laid upon the table and the micrometer screw caused to approach it. As soon as contact takes place an electric current, shown by a galvanometer, passes between the point of the screw and the table. If the object to be measured be a poor conductor, it is coated with gold-leaf.

Bat'te-ry. (*Electricity.*) An electro-magnetic instrument taken as a whole.

The part of the machine composed of the jars containing the plates and exciting fluids.

See Galvanic Battery; and list under Electrical Apparatus.

(*Naval.*) See Iron-clad, Armor, etc.

Stevens's Battery, "*Iron Age,*" xix., April 19, p. 1.

(*Military.*) See Battery Gun, Machine Gun, "*Mech. Dict.*"

(*Mining.*) An embankment.

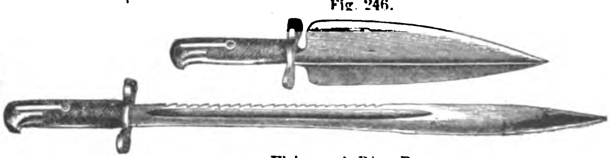
Bat'tle-dore. (*Glass-making.*) The wooden paddle used in shaping articles while blowing. For instance, it is held against the inside of a tumbler to render it circular in shape while the article is revolved.

Bau'de-kin. (*Fabric.*) An English brocade.

Name derived from Baldachini, from Baudas, Baldac, *i. e.*, Baghdad. From the use of the stuff in canopies, the word has been transferred to the latter. — Col. Yule's "*Marco Polo.*"

Bay'o-net. The Rice trowel-bayonet, the invention of Col. Edmund Rice, and the Elcho saw bayonet, invention of Lord Elcho, are shown in

Fig. 246.



Elcho and Rice Bayonets.

Fig. 246. It has been proposed to issue them in certain proportions to troops. See "*Ordnance Report,*" 1872, 1873.

The Snider bayonets for the British Government, triangular in section, are forged from $1\frac{1}{16}''$ round steel bar, which is drawn down under a power hammer, about 4″ remaining untouched to form the socket. The bar is next bent or "broken down," as the term is, in two places. After being cut off from the bar, sufficient metal being left for the blade, it is stamped in a pair of dies; the blade is then drawn out by the hammer. The rolling is performed by Barnes' patent rolling machines, in which there are two horizontal spindles, each carrying four cams, in which the dies are fixed. These cams occupy about one third of a circle; and the dies, which are cut on the periphery, are set so as to give the required thickness to the bayonet blade. After the bayonet has been trimmed, it is hardened and ground. The socket is next drilled and milled, the slot for forming the attachment to the rifle being afterwards cut; and after the further operation of "blueing" and polishing, the bayonet is complete.

See also "*Ordnance Report*," 1877, appendix L, p. 565, and Fig. 99.

Bay′on-et-tooth For′ceps. (*Surgical.*) A tooth forceps, the prongs of which are set off from the side though parallel with the general trend of the instrument, in a manner similar to the position of the bayonet relatively to the barrel of the musket.

Bay Win′dow. A projecting window with angular corners. A compass window.

Beach Com′bi-na′tion Sight. A sight for near or distant shooting: in the former case with the globe down, exposing the fin; and for distance, with the globe and its protecting ring erected.

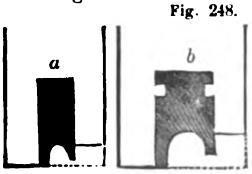
Fig. 247.

(As Open.) (As Globe.)
Beach Combination Sight.

Bea′con. A mode of illuminating sea beacons by gas from a position on shore is described in a paper by *J. Wigham*, "*British Association*," Mechanical Section, 1878. "*New Applications of Gas for Lighthouses.*" Reported in "*Scientific American Supplement*," * 2339.

A small light is kept by day by means of a by-pass connection, and full gas turned on at night.

Fig. 248.



Bead Planes.
(*a.*) Full boxed bead. (*b.*) Dovetail boxed bead. (*c.*) Double-boxed bead.

Bead. 1. (*Planes.*) An inserted guide in the sole of a molding plane. Fig. 248.

2. (*Glass.*) Glass beads are made from glass tubes.

See also BEAD, BEAD-FURNACE, pp. 253, 254, "*Mech. Dict.*"

3. (*Architecture.*) Globular ornaments carved on moldings.

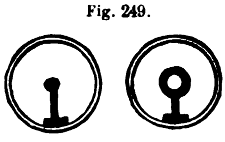
Bead′er. (*Sheet-metal Working.*) A machine for making beads on round boxes, such as blacking boxes, for instance.

Bead Sight. (*Rifles.*) One form of sight; a small circular object elevated on a thin stem and placed in the line of sight. Also called *pin-ball* sight.

An *open bead* has a circular opening through a bead somewhat larger than a solid one. Also called *Aperture* sight.

Combined sometimes with a *bar*. See BAR AND BEAD SIGHT.

Fig. 249.



Bead. *Open Bead.*

Beam. 1. Curved wooden beams are of four kinds: *scarfed, bent, flitched, laminated*, which see.

See also pp. 254-257, "*Mech. Dict.*"

Curved beam. * "*Scientific American Supplement*," 2035.

2. A weighing scale, or the main member of a lever scale.

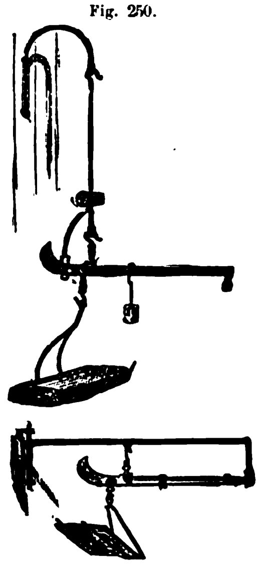
An *even-beam*; one hung by the middle, as in the regular balance.

A *cloth-beam* is for determining the weight per yard by weighing the piece of cloth.

A *paper-beam* is for determining the number of pounds to the ream by weighing one sheet of paper.

A *cotton-beam* (Fig. 251) is for weighing bales. All these are applications of the *Statera*, the *balance-Romaine*.

Fig. 250.



Cloth and Paper Beams.

3. (*Leather.*) An inclined block at which a currier stands to shave the leather with a knife, which agrees in the shape of its edge with the plate of mahogany or *lignum vitæ* which forms the face of the beam.

Fig. 251.

Beat'ing Ham'mer. (*Bookbinding.*) A hammer with two round faces; used in condensing and shaping backs of books in the process of binding.

Fig. 253.

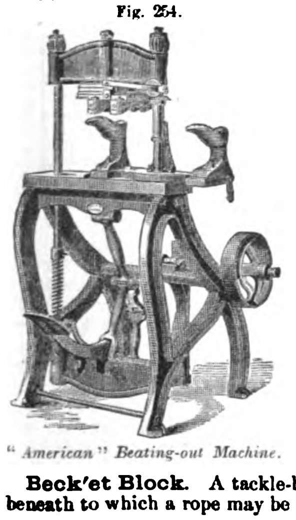
Beating Hammer.

Beat'ing-out' Ma-chine'. A machine for shaping shoe-soles which are presented on a last to a form above, being lifted by a toggle, operated by foot or by power. Fig. 254. It is a machine forming a substitute for the hammer.

Beat'-away. (*Mining.*) To excavate. Usually applied to hard ground.

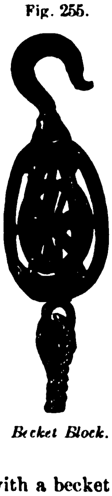
Beat'er. (*Add.*) 6. (*Mining.*) An instrument for packing stemming on a charge of powder in a blast-hole.

Fig. 254.



"*American*" *Beating-out Machine.*

Fig. 255.



Becket Block.

Beck'et Block. A tackle-block with a becket beneath to which a rope may be bent. Fig. 255.

Beck'et Hitch. Another name for the FISHERMAN'S KNOT, which see.

Becque-rel' Bat'tery. (*Electricity.*) 1. The sulphate of lead battery, consisting of zinc in sulphate of zinc and lead in sulphate of lead.

2. The oxygen-gas battery. A glass tube containing solution of potash, closed at the bottom by a porous partition, is placed in a flask containing nitric acid. In each liquid is placed a bar of platinum, which being put in metallic connection, a current is produced, the water is decomposed, the hydrogen goes to the nitric acid, which it reduces, and consequently there is no polarization. The oxygen goes to the potash which surrounds the platinum plate. This was the first battery employing two liquids or a porous diaphragm, and consequently the first one to give a constant current.

"*Niaudet*," American translation, 239.

Bed. 1. Fracture beds with limb elevators and suspenders, counter-extension apparatus, splints, cradles, etc., are shown in *Tiemann's* "*Armamentarium Chirurgicum*," Part IV., pp. 57, 97, 104.

2. (*Mining.*) A horizontal seam or deposit of mineral.

Bed-mor'tis-ing Ma-chine'. A large mortising machine for working on beds and frames of railway cars, etc.

Fay & Co., * *Thurston's* "*Vienna Report*," iii. 260.

Bed'stead Joint. The mode of connecting the side-rails to the head and foot portions respectively, so as to be detachable.

The patents on this subject are numerous. Two modes are shown in Figs. 625, 626, p. 262, "*Mech. Dict.*"

Beef Sha'ver. 1. A knife set in a stock in manner of a spoke-shave or slaw-cutter, for slicing dried beef.

2. A swinging knife pivoted on a frame so as to make a draw-cut on the beef which is advanced in the trough beneath. Fig. 256.

"*Champion*" *Dried Beef Shaver.*

Beer, Con-densed′. Beer reduced in a copper vacuum pan to $\frac{1}{18}$th its bulk in solids, and an equal quantity of alcohol: 36 gallons of beer making 2 gallons of solids and 2 of alcohol, to be remixed.

Dr. Bartlett in "*Scientific American Supplement*," 191.

Beer Cool′er. The devices are numerous. Two are shown at Figs. 631, 632, pps. 264, 265, "*Mech. Dict.*" They take the form shown in other industries, and various shapes; the same in principle may be found under "*Condenser*," "*Evaporator*," *Ibid.*

The "*Refrigerant Dubuc*," made at Carignan (*Ardennes*) is a favorite in France. It is on the method of trickling over pipes, — the Derosne principle. Fig. 1421, p. 609, *Ibid.*

The *Roos* refrigerator follows the same idea.

The *Trageser* cooler also.

The Austrian beer cooler, by *Raimond Metsche*, at Olmutz, has a system of circulating pipes in the wort or beer back.

Weinhagen's beer cooler is for quickly cooling a small quantity of beer for testing the strength of the wort.

Woerle's cooler consists of tin vessels freighted with ice swimming in the vat.

An elaborate apparatus, *Patent-gegenstrom Bierkühlapparat*, on the system of Brüder, Noback, and Fritze, of Prague, was shown at Paris. It consists of convolutions of double pipes, one carrying the beer and the other the cold water, circulating continuously in different directions.

Beer Pre-serv′er. An arrangement by which the space in the barrel above the beer is filled with carbonic acid gas from a reservoir alongside. Wiesebrock's.

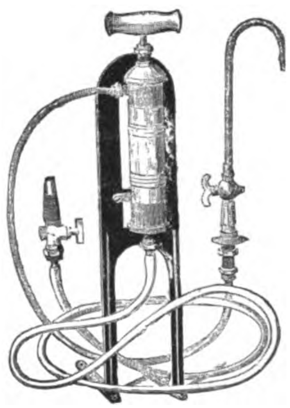
Fig. 257.

Beer Preserver.

The apparatus of Otto Zwietusch, of Milwaukee, is a regular carbonic acid gas generator, with marble-dust and acid chambers, gas washer, holder, etc., with connecting pipes and valves, to serve a row of barrels or kegs under draft. Patents, May 19, and July 2, 1874.

Beer Pump. A hand-pump, forming a connection between a counter in a saloon and the barrel in the cellar. The pump has two tubes, with a barrel cock at one end and a dispensing goose-neck at the other.

Fig. 258.



Beer Pump.

Bees. (*Nautical.*) Of a bowsprit: *bee-blocks.* Pieces of wood bolted to the outer end of a bowsprit to reeve the foretopmast stays through.

Bees′wax. A fraudulent imitation of beeswax is made of a mixture of paraffine and common resin. It resembles the genuine article very closely in color, fracture, and adhesiveness.

The cakes are generally covered with a thin coat of genuine beeswax.

Beet Gra′ter. A machine for grating beetroot for obtaining the juice by expression or diffusion in the manufacture of sugar.

"In the California machine, of the Union Iron Works, San Francisco, the beets are fed continuously into a hopper, which is at the top of the machine. Directly under the hopper are two ways, or sluices, in which the feeding plungers slide. The plungers are actuated by the revolution of a cranked shaft, through the medium of slotted levers and connecting links. The turning and sliding of the cranks in the slotted levers gives a quick return motion to the plungers, and causes their forward motion to be almost constant. The forward motion of the plungers presses the beets, which have fallen into the sluices, while they are drawn back, against a quick revolving drum, which makes about 600 or 800 revolutions in a minute. The drum consists of three grooved flanges, about 22″ diameter, mounted on a shaft, and having 8″ space between them. The grooves are in the inside faces of the flanges, and near their circumferences. They are filled with strips of steel saws, with a strip of wood setting back from the points of the teeth between each two of the blades. About 400 saws are necessary to fill a double drum of these dimensions. The drum, revolving at a high speed, grates the beets which are pressed against it, and discharges the pulp into a chute which leads it into movable hoppers, by which it is transported to the centrifugal machines."

See BEET-RASPING MACHINE.

Beet-juice Def′e-ca′tion Pan. The purifying process formerly adopted with beets was as follows: The juice in the defecating pan was rapidly heated to 185° F. At this moment milk of lime was poured into the juice and well stirred in. When a thin layer of scum had formed on the top of the juice, the supply of steam was gradually shut off, so that at the moment of ebullition the supply of steam was one fourth the original quantity. The steam was suddenly cut off when ebullition was fully developed, indicated by an eruption of clear juice on the surface.

The juice was then filtered through animal char-

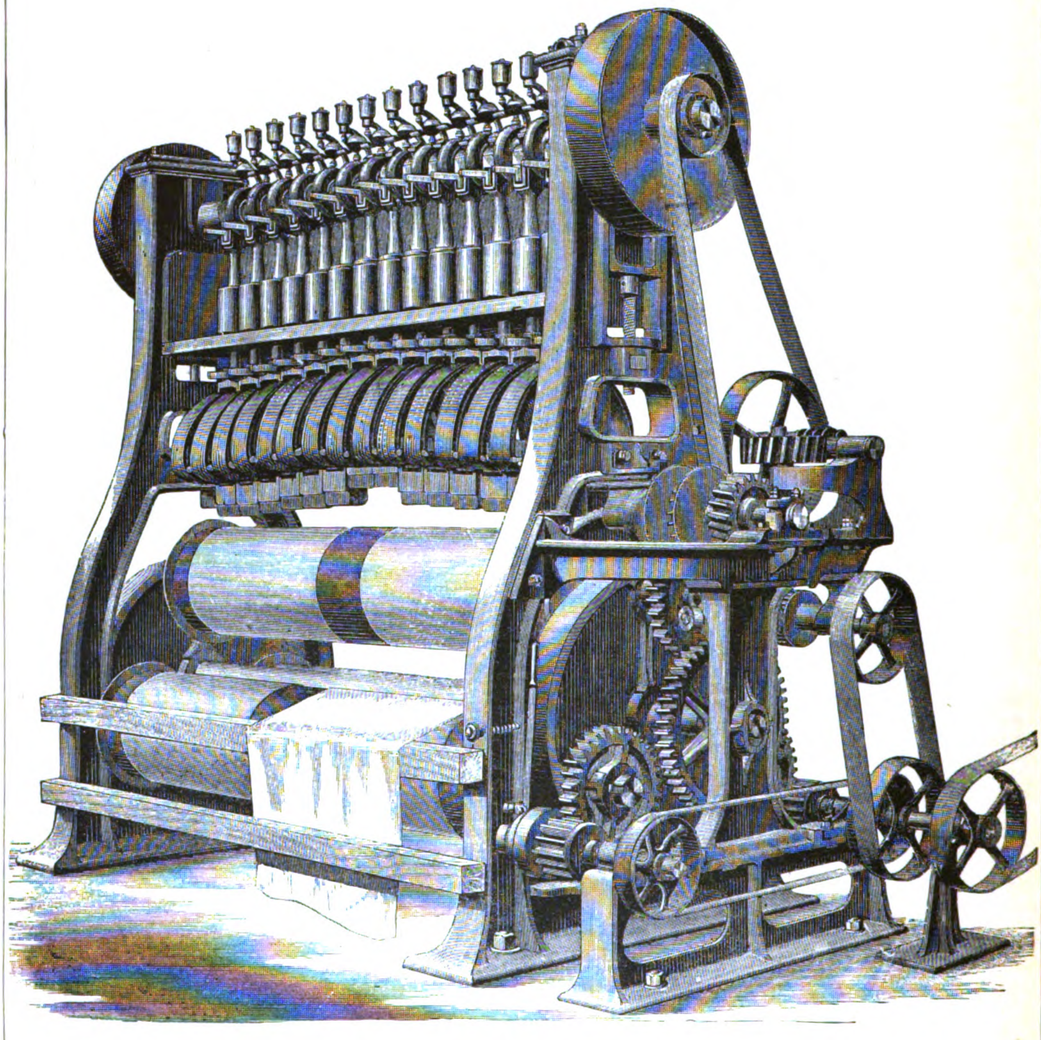


PLATE V PATTERSON'S BEETLING MACHINE. (MATHER & PLATT, MANCHESTER, ENGLAND.) See page 87

coal. CARBONATATION (which see) has been largely substituted for the above process.

Bee'tle De-stroy'er. An implement or machine for killing the potato bug. Numerous kinds are noted under INSECT DESTROYER, which see.

Bee'tling Ma-chine'. A machine for finishing linen or cotton goods by a hammering process. The beetling machine referred to on p. 265 of "*Mech. Dict.*," had a series of vertical stamps lifted by pins or cams in manner of an ore-stamping mill, but the Patterson beetling machine made by Mather & Platt, of Manchester, England, and shown in Plate V., has a series of spring-hammers worked at high speed. These hammers are worked by eccentrics on a shaft which extends along the top of the machine, there being interposed between the eccentric rods and the hammers a spring connection which relieves the working parts from the recoil of the blows, and materially reduces wear and tear. The spring connection is made by suspending each hammer from a leathern belt attached to a semicircular steel spring.

In the old-fashioned beetling machines the hammers or *fallers* were lifted by cams, and allowed to drop by gravity, while the utmost speed at which they could be run was about sixty blows per minute. In the Patterson machine the hammers each give 420 blows per minute, while the striking effect of each blow is the same as in the old machine. The hardness of the blow can, however, be varied by altering the speed.

The cloth being operated upon is carried by one of three rollers which revolve in bearings carried by disks, as shown, these disks being themselves capable of revolving. The three cloth rollers can thus be brought successively under the action of the hammers, and the operation of the machine is thereby rendered continuous, the filling and stripping of the rolls not interfering with the beetling.

"*Engineering*," * xxvi. 91.

Beet Press. One for pressing the juice from the grated pulp of the sugar beet.

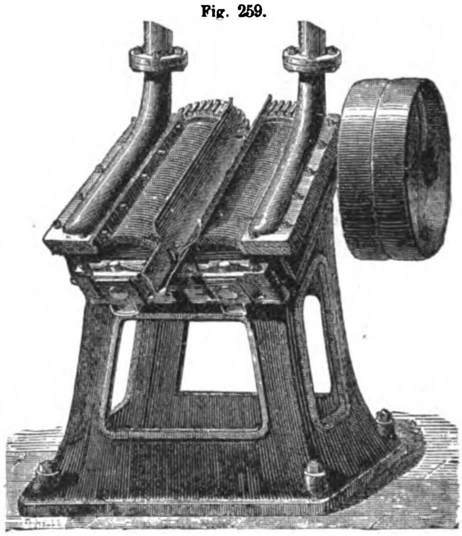
The beet industry has attained its great proportions since the hydraulic press has been in common use, and this description of press in various modified forms is well adapted to this industry.

Lalouette introduced the arrangement which dispensed with the use of sacks which were and are used in the stearine and flaxseed-oil works. He made a chest with strong iron bars lined within with a perforated copper sheet. Sheets or cloths divided the marc into layers. A second pressing was necessary, the first was frequently done in a filter-press (which see), and the pulp fell from that into the chest of the Lalouette press. Sixty per cent. of the juice was obtained.

The direction now seems to be in the line of continuous presses, which so much reduce labor in handling. They usually depend upon rollers.

The cylinders of continuous presses are, (1) constructed with apertures perforating their rolling surface, so that the juice is caused to pour into the interior, from which it is allowed to escape, as in the presses of Pecquer, Champonnois, and Lebée; or (2) the pulp is carried, by means of endless belts of linen or jute, between a series of solid

Fig. 259.

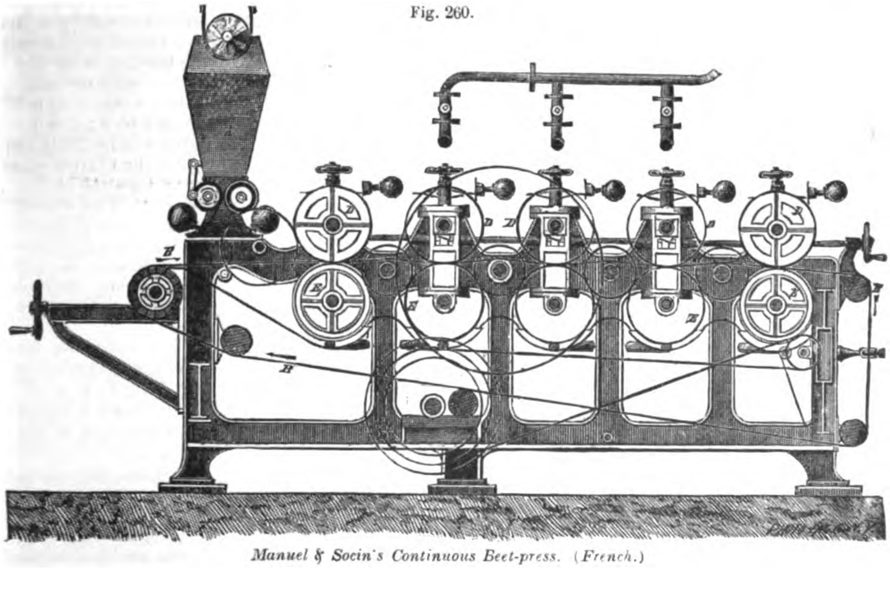


Champonnois' Continuous Press.

rollers, effecting a gradually increasing pressure, as in the presses of Poizot and Manuel & Socin.

1. Pecquer commenced with cylinders perforated

Fig. 260.



Manuel & Socin's Continuous Beet-press. (French.)

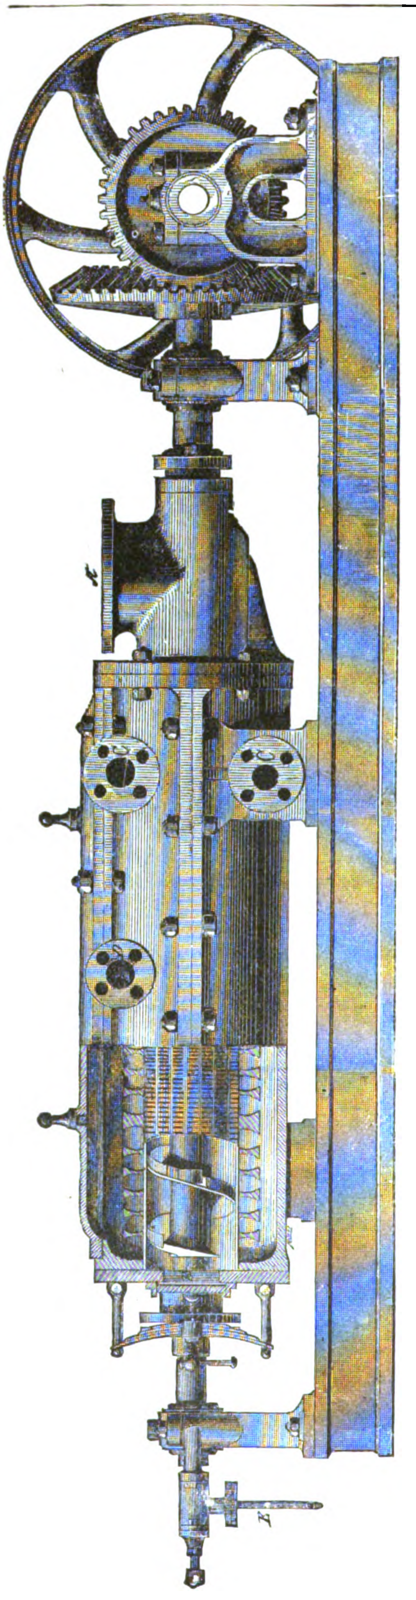


Fig. 261. V. Pierron's Continuous-screw Beet-press. (French.)

A Entry of pomace. B. Exit of pulp. C C. Exits of juice. D. Entry of water for washing. E. Supply of water for injection through center of screw.

with round holes, but Champonnois improved upon this by making longitudinal slits in the cylinder and adding a spiral wire covering, which gives an infinitude of extremely narrow exits for the juice. Fig. 259.

The Lebée press has cylinders whose peripheries consist of movable frames made of narrow bars and intervals respectively 0.05″ and 0.004″ wide. These are soldered in sets to be replaced readily. The pulp requires several pressings. After passing between the first set of filtering cylinders, the pulp passes under a solid cylinder, rolling upon one of the filtering cylinders, after which it is treated with a spray of water, and again passed under solid cylinders, rolling upon another filtering cylinder.

In the Collette press the filtering surfaces consist of sheets of finely perforated copper.

In the Dujardin press the cylinders are covered with heavy brass sheeting about .08″ in thickness. The openings made in this metallic sheet are cylindrical for a short distance, after which they expand conically toward the under side, and by this means the difficulty of choking the holes is largely avoided.

The difficulty encountered in these presses by the escape of pulp with the liquid is somewhat obviated by the addition of milk of lime to the juice, which seems to solidify the pulp.

2. The continuous presses which have an endless cloth filtering surface, depend upon the principle of subjecting the pomace to a gradually increasing pressure by passing between different series of rollers, the pomace being carried between endless belts of the material mentioned above. The first of these presses is stated by Basset to have been devised in 1812, but Poizot seems to have been the first to make an effective one, and to apply it in industrial work.

That described by Basset consisted simply of an endless sheet carried between two rollers held in contact with each other by means of levers to the farther end of which weights are attached. The material was distributed upon this belt and by it carried between the rollers.

Poizot's press, according to his first design, had two belts between which the pulp was carried around a large cylinder, against which smaller rollers were forced with a gradually increasing pressure in the course of the series, followed by a pressure between two large rollers. Poizot now uses a single web of cloth, the pulp passing over the small rollers and in contact with the large cylinder. The pulp falls from the web into a tank, is subjected to a spray of water and passes to a second press.

The Manuel & Socin press (Fig. 260) depends upon the same principle, but the system of rollers is arranged horizontally, and consists of five pairs of cylinders of the same size. The distance between the cylinders of each pair varies respectively, according to its distance from the point of supply. The pressure exerted by each pair of rollers is governed by a strong steel spring, the power of which may be increased or diminished at will by means of a screw regulator.

The pomace from *A* falls between the feed-rollers upon the endless belt *B*, and is carried between the solid rollers *D D D D D* and *E E E E E*. The pressure exerted by the rollers is adjusted by means of screws and springs attached to the journals.

The Leroy press, constructed by Messrs. Mariolle Brothers, of Saint Quentin, is provided with rollers and an endless sheet upon which pulp is distributed by means of a special apparatus called the *préparateur*, founded upon the same principle as the press properly so called; that is to say, in the *préparateur* the material coming directly from the trough of the rasp and equally distributed upon an endless sheet is submitted to an energetic preparatory pressing by means of a series of rollers, gradually approaching each other more and more, in such a manner as to distribute upon the press only pulp partially exhausted of its juice.

The endless sheet is here a thin sheet of steel pierced with a large number of small holes, forming the filtering surface for the juice. In the press the endless sheet is of the same nature, but it is doubled, as it were, by a woolen sheet, upon which the pulp to be pressed is distributed. Good filtration of the juice is thus assured, and at the same time almost all the fatigue is referred to the metallic sheet. — *La Sucrerie Indigène*, xii. 367.

The Pièron press (Fig. 261) is more simple in construction. It consists of a screw arranged horizontally within a perforated cylinder of copper, and the whole hermetically inclosed in an envelope of cast iron provided with internal channels for flow of the juice. The blades of the screw are of copper, and the axis of bronze. The blades are in sections, and may readily be removed and cleaned. The pulp to be pressed is forced into the cylinder by means of a strong pump, and is carried by the revolving screw toward the other end. When it first enters the press, the pulp is submitted to very slight pressure, but the pressure increases as the pulp approaches the other end, where it is forced out through a valve so arranged that the discharge of pulp may be regulated at will. A portion of the axis of the screw is hollow, and the portion beyond the discharge orifice connects with the water supply, so that a small quantity of water may be continuously added to the pulp at the latter part of the pressing to effect a saving in the sugar that would otherwise be left in the pulp.

To secure effective work with this as with other continuous presses, the method of double pressing must be employed, and for ordinary working six presses are used for the first pressing, and two for the second pressing. For the first pressing the motive force required by each press is one and a half horse-power, and for the second two horse-power. The advantages claimed for the press are its solidity, slight liability to accident and repairs, and small amount of labor required in its management. The work of grinding and pressing being altogether automatic, one man can attend to both operations. There is no opportunity for the juice to come in contact with the air between the press and the liming-vat, and there is consequently little or no change. The pulp of the first pressing contains 80 to 83 per cent. moisture, and 7 to 9 per cent. of sugar; and that of the second pressing contains 4 to 5 per cent. of sugar. The final pulp represents 26 per cent. of the beets worked.

See report by Dr. W. McMurtrie, "*On the Sugar Beet and the Manufacture of Sugar therefrom.*" Special Report, No. 28, Department of Agriculture, Washington, 1880.

Beet-rasp'ing Ma-chine'. The machines for rasping beets are of several forms, three of which, of different constructions, are presented.

It is necessary that the cellular structure of the beet shall be entirely degraded in order that there shall be as little loss as possible in the subsequent operation of pressing, which requires to be very carefully performed, and is, in fact, repeated to express the last attainable quantity of saccharine juice from the pulp. See BEET PRESS.

In the greater number of *sucreries* on the Continent of Europe, the rasping machine forms the first of the series of apparatus in the establishment; but of late another system has come into extensive use, and is increasing in popularity. It is to have the *râperies* in the villages or communes, or on farms of extensive area, and to convey the juice by underground pipe-lines to a central *sucrerie* where the subsequent operations are conducted. This enables a single sugar factory to work up the beets of a much larger area than would be possible were the roots to be carted to the central factory.

The system is the invention of Linard, and some data in reference to it are given under PIPE-LINE, which see.

Its advantages are in —

Placing the heavier portion of the work, and that in which the larger number of workmen are employed, in the villages in which they reside.

Increasing the area of the profitable cultivation of beet in the neighborhood of a *sucrerie*.

The decreased weight to be transported.

The transference of the transport from the roads, which are injured by the heavy carts.

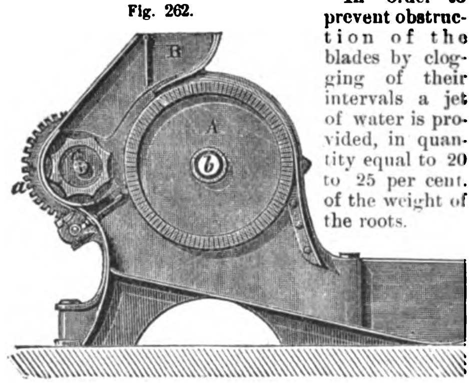
Leaving the residual pulp in the communities where it is needed for cattle and sheep feed.

The opportunity of purchasing the juice by the saccharometer tests instead of by the weight of the roots.

The Lampadius and Kluseman rasps have cylindrical drums furnished with knives, acting upon the roots placed in a hopper, which partially incloses the circumference of the rasping cylinder. The *râpe* of Lampadius is shown at Plate XI. of Dr. McMurtrie's Report on the Culture, etc., of the Sugar Beet, Special Report, No. 28, of the Department of Agriculture, 1880.

The calculation for effectiveness is that a machine which has 70 square decimeters of rasping surface, and 650 turns per minute, which answers to a developed surface of 27,300 meters, will produce 1,000 kilograms of pulp per hour. One horse-power is estimated for each 450 kilograms per hour. In order to prevent obstruction of the blades by clogging of their intervals a jet of water is provided, in quantity equal to 20 to 25 per cent. of the weight of the roots.

Fig. 262.

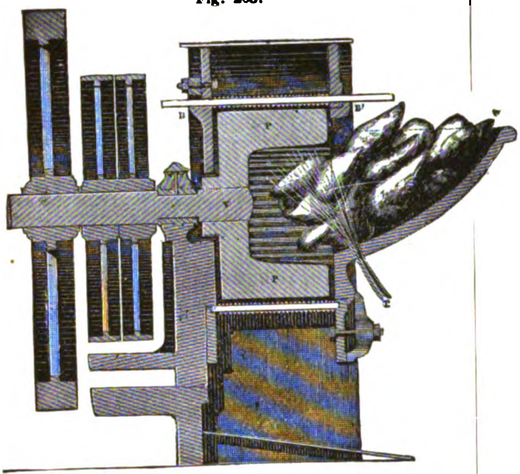


Kluseman's Beet-rasping Machine.

Kluseman's rasping machine, Fig. 262, has a drum *A*, whose perimeter is furnished with radial blades. The roots are put into the hopper *B*, and passing downward, are caught in the flutes of the roller *c*, which makes one turn — towards the rasp — for every 25 revolutions of the rasp. Its duty is to hold the roots against the rasp, and these escape into the box beneath when they are grated sufficiently fine to pass the throat piece which is adjustable from beneath. *a* is the cog-wheel which turns the roller *c*; the gearing of the rasp cylinder on the axis *b* is hidden by the machine.

The Champonnois rasp, Fig. 263, has an axis *V*,

Fig. 263.



Champonnois' Beet-rasping Machine.

with heavy cast-iron arms, *P*, which revolve at a rapid rate, and by centrifugal force and actual grinding action force the roots delivered in the hopper *V* against a series of rasps which are arranged circumferentially as at *B B′*, tearing them into fragments, and pushing them through the interstices between the rasps, whence they fall into the box below.

The series of marks, looking like bars, appearing beyond the roots, are the rasps which are set thus close together. At *T* is shown the pipe for the injection of water into the interior of the rasp.

The rasp of Champonnois is powerful, and produces from 6,000 to 7,000 kilograms of pulp per hour, if it be actively fed, and is one of the most efficient root graters.

Another form of *coupe-racine* is that shown in Fig. 264, which consists of a cast-iron vase of a frusto-conical shape mounted on a vertical shaft which receives from 200 to 400 turns per minute. The vase has 6 straight openings like the throats of a plane, and each of these has a toothed blade which grates the roots, and the fragments pass out at the openings.

A fixed metallic plate descends into the interior of the vase, acting as an abutment for the roots, to prevent their revolving with the vase, and is distant from the surface of the blades 4 or 5 mm. The size of the pieces is from 0.005 to 0.010 m. × 0.003 to 0.004 m. They are expelled by centrifugal action, and the apparatus requires a casing, which is not shown in the cut.

Fig. 264.

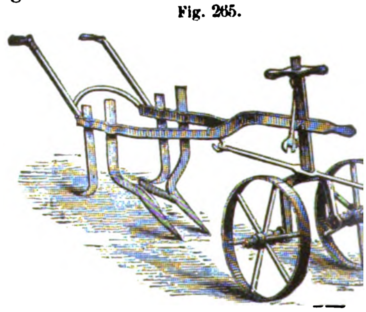
Champonnois, "*Dept. Agric. Sp. Report*," No. 28, Pl. XII., XIII.

Beet′-root Dig′ger. This generally consists of a sort of fork mounted on a wheeled frame and slanting downward so as to include the root between its prongs, and lift it upward and forward. It injures the beet to bruise it or to break the tap-root, as it bleeds and wastes the sweet juice. Following the fork are prongs which lift the roots clear of the soil in which they are more or less imbedded, as they are simply upset and drag the ground.

Fig. 265.

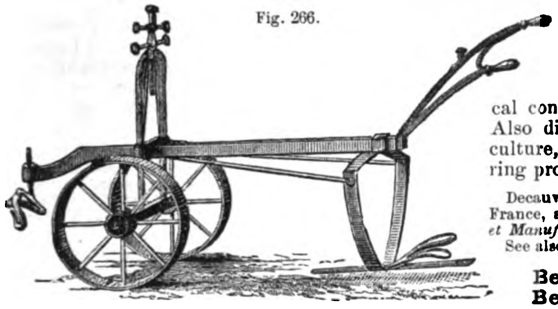


Beet-root Digger.

Figs. 266 and 267 are other forms, made by Delahaie-Tailleur & Bajac, Liancourt, France.

The former has a bow-shaped standard, having

Fig. 266.

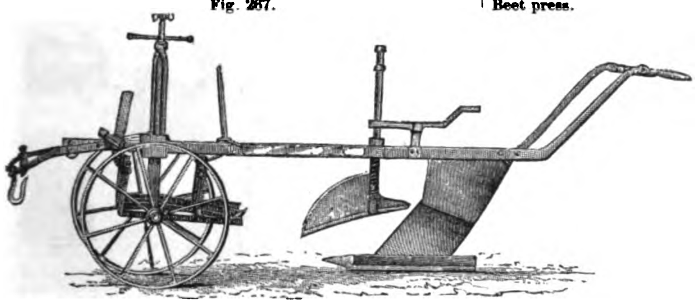


Beet-root Puller.

a lifting share in front and several prongs behind, to raise the beets and leave them on the surface of the ground.

The latter example has a precedent share (*coupe collet*) for cutting off the leaves of the beet simultaneously with the pulling of the root. Several forms of interchangeable shares are furnished with the implement: shares without branches, or with two or three branches, according to the kind of beet and the nature of the soil. The work performed is 1 hectare (2½ acres) per diem.

Fig. 267.



Beet-root Digger.

French beet-root pullers are shown in *Knight's* "*Report on Agricultural Implements*," *Paris Exposition Reports*, * vol. v., pp. 51, 52.
See also "*Scientific American*," * xxxix. 165.

Beet'-root Sli'cer.

The centrifugal root cutter of the "Union Iron Works," San Francisco, "is composed of a stationary drum, in the form of a truncated cone, provided with six grooves, into which are fastened as many grooved-toothed knives. To this drum is attached the feed hopper. A horizontal shaft which is keyed to the head pulley, carries at one of its ends a cast iron disk, armed with two flyers, turning in the stationary drum, and leaving a working space between the edge of each and the inner wall of the drum. The beets come from the washing machine through a channel into the hopper, and thence to the drum. Here the flyers of the disk drive them violently against the blades of the stationary drum, where they are cut into slices of a uniform thickness of one sixteenth of an inch, and a width of about three eighths of an inch. The stationary drum is surrounded by a thin casing of sheet iron, the object of which is to direct the slices thrown out of the machine, downward. This casing is movable, so as to give access to the knives, and allow them to be taken out.

This machine can cut three tons of beet-root in half an hour, with the shaft moving at the rate of 350 revolutions per minute. A single horse power is all that is necessary to actuate it. The blades are fastened into the grooves by screw bolts, and can be adjusted and set at any desired distance apart within given limits."

Beet'-root Su'gar Ap'pa-ra'tus. For a recent timely and excellent treatise on the inception, progress, and success of the beet-root sugar industry in Europe, see Dr. McMurtrie's Report, "*U. S. Department of Agriculture, Special Report, No. 28,*" 1880.

It includes also tables and maps, indicating the regions in the United States included in the belt, where the meteorological conditions favorable to beet culture prevail. Also dissertation on varieties of beet, analyses, culture, manuring, harvesting, and manufacturing processes and apparatus.

Decauville's beet-root machinery and still, at Petit Bourg, France, are described in *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," vol. iv., ed. 1877, Article "*Distillation*."

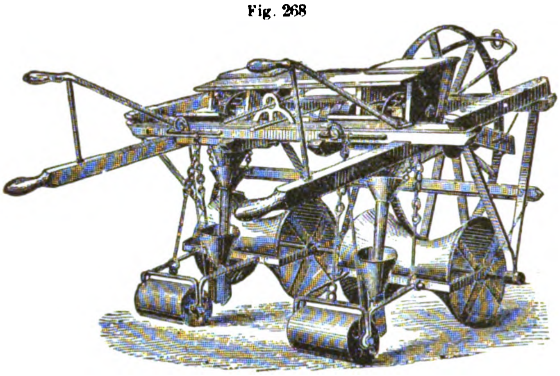
Beet-seed' Drill. A machine for drilling beets, usually upon a ridge listed up.

Fig. 268 is a drill for beet-seed or turnips, made by Corbett & Peele, of Shrewsbury, England. It is specially adapted for sowing on the summits of ridges. The machine drills two parallel rows. On each side of the machine is a concave ridging-roller, a hollow share which receives seed from the box above, and an iron roller for covering the seed. The seed-wheels are of the usual English form, having little hemispherical cups which dip up seed and drop it into hoppers, from which conductors lead to the hollow shares which open the furrows.

The beet-seed drill of Smyth & Sons, of Peasenhall (Suffolk), England, has a range of 5 hoes with a distance apart of 0.45 meter, but the machines vary in the number and interval distance of the hoes and in price.

The seeding is performed by its own set of conductors and hoes, in such manner that the fertilizer is covered with earth in advance of the deposit of the seed, which is not placed in contact with the fertilizer, so that the special nourishment to the roots of the young plant is not furnished until they

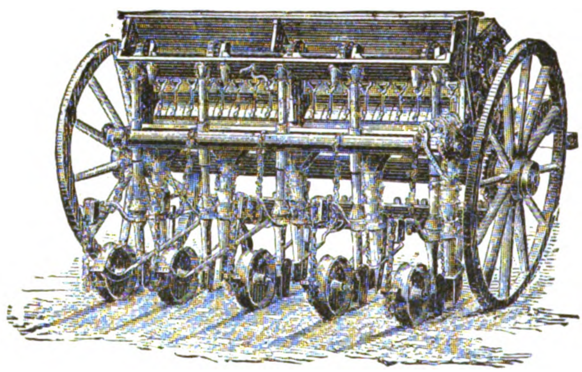
Fig. 268



Beet-seed or Turnip Drill.

have attained a certain development. The concave-faced rollers, which are independent of the hoes, follow in the rear and make a little ridge over the seed and fertilizer, which compacts the soil and makes the row of plants more conspicuous in the earlier stages of their growth.

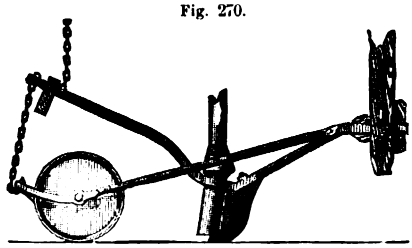
Fig. 269.



Beet-seed Drill.

The device shown in Fig. 270 is for attachment to the ordinary drills of this firm to adapt them to drilling beet seed. The roller has flat, concave, or convex face, as may be ordered.

Fig. 270.



Beet-seed Planter.

English and French beet-drills are shown in Dr. McMurtrie's Report No. 28, Special, Dep. of Agriculture; and in Dr. Knight's report, "*Paris Exposition Reports*," * v., 115-117.

Bell. (*Music.*) 1. An instrument in an orchestra, used for dramatic effects. According to *tone* they are known as *high* bells or *low* bells. Berlioz quotes the use of the former in the graceful chorus in the second act of "*Guillaume Tell*," of which the burden is "*voici la nuit;*" and of the bell in low F, in the 4th act of Meyerbeer's opera, the "*Huguenots*," to give the signal for the mas The bell refrain in "*Les Cloches d nouailles*" is familiar to most of us.

Sets of bells are used in military i a number being fixed one above ai on a frame of iron, and ranged di cally in the order of their sizes. Th made to vibrate by a little hammer. GLOCKENSPEIL, GONG, PAVILLON NOIS, "*Mech. Dict.*"

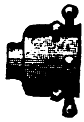
the hopper called a bell, which is lowere able distance when feeding the stock to nace. *D* is an apron or fender, attache mouth-piece *B*, to prevent the stock from striking the walls of the furnace. The apron is secured to the hopper by straps *d d*.

Bell Chuck. Whitworth's lathe chuck, made bell-shaped, with set-screws by which the object is clamped.

Fig. 273.



Bell Chuck.

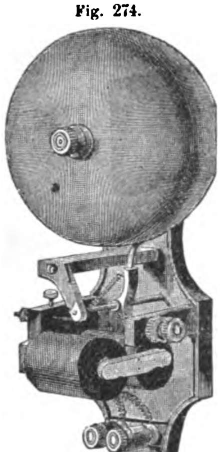
Bell Cord. (*Railway.*) A cord running continuously through the cars, and leading to a signal bell on the engine. It forms a means of communication between the conductor and engineer.

For all the parts and fittings, see "*Car Builders' Dictionary*," pp. 8-10, and illustrations cited, pp. 392 *et seq.*

The inventor of the bell cord on cars was Capt. Ayres, who, in 1842, introduced it on the train of which he was conductor. — *Paterson (N. J.) Press.*

Bell Mag'net. An audible alarm. A clapper is caused to strike the bell by completing the electric circuit, the connecting wire leading from the apartment whence the call proceeds.

Fig. 274.



Bell Magnet.

Electric bells are now extremely common in departments, offices, manufactories; placing a proprietor or superintendent in connection with any office or department in his building or abroad.

Bell Met'al. An alloy which does not tarnish nor crack, has a good sound, and relatively moderate weight, is prepared as follows: —

Nickel 1 pound, copper 6 pounds, are melted and cooled.

Add zinc 1 pound, aluminum ½ ounce. Melt and cool.

Melt and add ½ ounce quicksilver and 6 pounds melted copper.

Other recipes: —

	Copper.	Tin.	Lead.	Iron.	Zinc.

An imitation silver, having sonorous quality: —

Take one part of pure pulverized manganese, one part of copper filings, and two parts of animal charcoal. Intimately mix these substances and expose the mixture to a high temperature in a graphite crucible. After cooling, will be found at the bottom of the crucible, a substance having the appearance and sound of silver. This substance is ductile, malleable, and easily takes the finish of silver.

Bel'lows Steam-en'gine. A form of engine invented by Reilley, in which steam extends longitudinally an expansible bellows-sided chamber, the head of which carries gudgeons which connect by rods to the crank shaft. The moving head, the equivalent of a piston, is in fact placed between two such chambers, which act upon it in succession.

"*Scientific American Supplement*," * 181.

Bell Pump. A bell-shaped pump; used in cleaning gas and service pipes.

Harris, Griffin & Co., in "*American Gas-light Journal*," * July 3, 1876, p. 9.

Bell Punch. A hand-punch, for perforating a ticket or trip slip. It secures the piece punched out, and rings a bell; in some instruments it also registers the fares collected.

Bell Ring'er. Reese's bell-ringer, for ringing the bells of locomotives, is an application of steam to a small piston, which acts upon a sliding bar connected to the bell crank.

"*Railroad Gazette*," * xxiv. 415.

Bell Rope. See BELL-CORD.

Bell Strap. A signal strap in a street car, reaching along the ceiling to a bell at the forward end. It forms the means of communication between the conductor and the driver; or, in some cars, the passengers and the driver.

Bell Tel'e-graph. An indicator for hotels, steamers, etc. A series of plates inscribed with the numbers of the rooms; the ordinary wants of the guests, etc., are connected by wires with the various apartments, and are displaced so as to attract the attention of the clerk in waiting, by touching appropriate knobs in the various rooms.

Fig. 275.

Bell Telegraph.

In the illustration the apparatus is an alarm telegraph, in which an indicator for each of six apartments may show where the entrance of unauthorized persons has taken place.

Bell Tel'e-phone. The articulating telephone of Alexander G. Bell. See TELEPHONE, TRANSMITTER, etc.

Bel'ly-pipe. A flaring blast-pipe nozzle for blast furnaces. In Vielhaber's patent, 182,621, — the belly-pipe nozzle is hollow, and has inlet and outlet pipes for the circulation of water there through. See, also, WATER BREAST.

Belt. (*Mining.*) 1. A body strap with chain attached by which miners draw corves in the workings.

2. A strap for transmitting motion.

The following dimensions and weights of large belts are given in the journals: —

New Jersey Zinc Co., Newark, N. J., 102′ long, 4′ wide, 2,200 lbs. weight.

J. B. Hoyt, New York, 186½′ long, 5′ wide, 2,212 lbs. weight.

P. Jewell & Sons, Hartford, Conn., 147½′ long, 3′ wide, 1,130 lbs. weight.

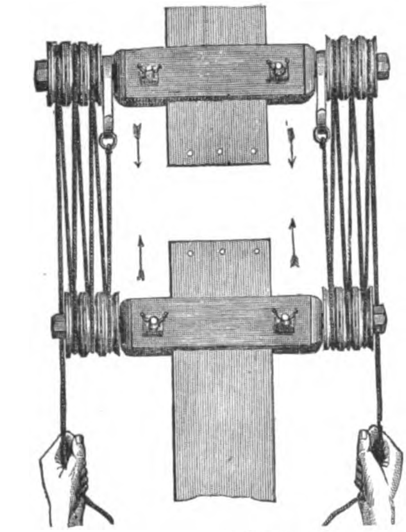
N. Y. Belting and Packing Co. (Makers), 331′ long, 4′ wide, 4,000 lbs. weight. For use in N. Y. Central and Hudson River Railroad Elevator, Sixtieth Street, New York.

Sampson & Co., Manchester, England, 90′ long, 38″ wide. Said by "*British Trade Journal*" to be "the largest ever made in England."

Belt Clamp. A device for approaching the ends of belts in position in order to lace or otherwise attach them.

Fig. 276 has two wooden vises clamped fast to the respective belt-ends, and drawn together by cords and pulleys in order to approach the ends of the belt and hold them while being laced.

Fig 276.



Spiers's Belt Clamp.

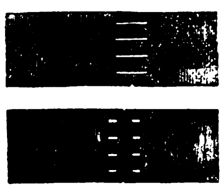
Belt Coup'ling. A device for attaching the ends of a belt. See Belt Fastener.

Belt Fast'en-er. In addition to the examples of means for attaching the ends of belts, and shown in Fig. 649, "*Mech. Dict.*," several others are here shown. See also Belt Screw.

Fig. 277.

Lincolne's Belt Fastener.

Fig. 278.



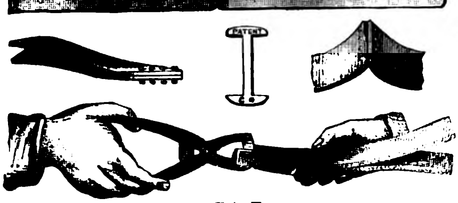
Clinched Staple Belt Fastener.

In Fig. 278 a row of holes being made in each end of the belt, the staples are inserted therein, and the ends turned down and clinched.

Fig. 279 shows Greene's belt-fastener and the tool for inserting the headed pins.

In Fig. 280, in addition to the security of the usual method of attaching the cord to the coupling, — by screwing it in and then riveting, — a gimlet-pointed screw, of the same pitch as the threads in the coupling, penetrates the center of the cord.

Fig 279.



Greene's Belt Fastener.

Harris's belt fastener is a shield-shaped piece with hooking studs. It is applied as follows: Lay the casting, teeth uppermost, on something solid, place one end of the strap on one of the sets of teeth and hammer it on. Repeat the with the other end of the strap on the set of teeth. The curve of the plate gives the hooking position to the teeth.

Jewells' factory	* "*Scientific American*," xlii. 95.

Belt'ing Ce-ment'. For leathern belting. Take common glue and American isinglass, equal parts, place them in a boiler and add water sufficient to just cover the whole. Let it soak ten hours, then bring the whole to a boiling heat, and add pure tannin until the whole becomes ropy or appears like the white of eggs. Apply it warm. Buff the grain off the leather where it is to be cemented; rub the joint surfaces solidly together, let it dry for a few hours, and it is ready for practical use; it is said that, if properly put together, it will not need riveting.

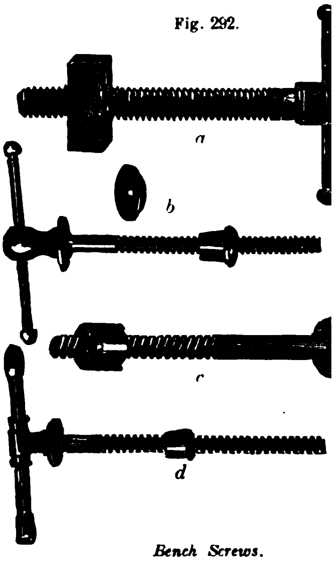
Sailmakers' Bench Hook.

ing. The loop being passed over a nail or other object, the sail is caught upon the hook and held against the pulling of the sailmaker a his canvas taut to make a straight seam.

Bench Screw. The screw for fas vise jaw of a carpenter's bench.

Fig. 292.



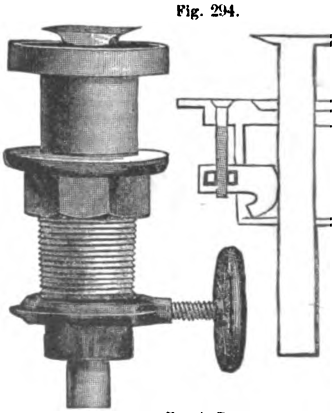
Bench Screws.

a, is the ordinary wooden bench scre
b, is an iron screw with iron handle.
c, *d*, are iron screws with wooden ha

Bench Stop. A device on a carpenter's bench which can be raised to hold a piece which is being worked, against the thrust of a plane. In the ordinary form it is a square prism which is lifted above the general level of the bench, but in the superior forms shown in Fig. 294 the piece is of iron, has a talon and is adjustable. The bench stop on the left in Fig. 294 has a screw socket in which the stop is raised and held by a screw. The other bench stop in the figure is held by a cam-piece which is controlled by a screw.

Br

Fig. 294.



Bench Stops.

Bend. A flexed pipe, changing If it be angular, it becomes a ***branch***.

Bend'ing and Straight'en-ing Ma-chine'. A machine for bending or straightening iron bars or plates.

Fig. 295.

Pipe Bends.

a. Eighth bend.	*e.* Offset bend.
b. Flanged eighth bend.	*f.* Flanged offset bend.
c. L or quarter bend.	*g.* Return bend.
d. Flanged L bend.	*h.* Double hub bend.

Bement's machine is capable of bending plates of any length up to 10½'. Both lower rolls have a positive motion by gearing and are driven by two belts, by which they can be run in either direction. Each of the rolls is cast upon a large wrought iron shaft forming the journal bearings, the upper one being extended at one end to receive the pressure of a screw, which supports the upper roll when a circle or flue is to be removed at the other end, the jointed bearing being movable for that purpose. The two ends of the upper roll have a vertical adjustment, together, or separately, by hand-wheels at the end of the machine. The usual diameter of the lower rolls is 10″, upper roll 11″.

Tweddell's hydraulic bending and straightening machine for angle-iron, beams, pipes, etc., has no gearing, and the pressure cannot exceed that due to the accumulator. The machines are generally made to work at a pressure of 1,500 lbs. per square inch, this being the pressure at which Tweddell's riveting, punching, and shearing machines work; but they can be made to work at any other pressure if desired. The position of the abutting blocks is altered by means of a right and left-handed screw, thus ensuring exact work and saving much labor.

The stroke of the machine can be varied from *nil* to the maximum travel; this is an advantage over a geared machine, or when a cam is used, since the cam must either complete its revolution, or else a break-down occurs, should too large a piece of work be put in. By means of the tappet-gear exact uniformity of stroke can be obtained for consecutive operations; the valve can be worked by the man's foot if desired, leaving his hand free; and the pressure can be kept on as long as desired.

Several of these machines of different powers are found in the British and French government dock-yards.

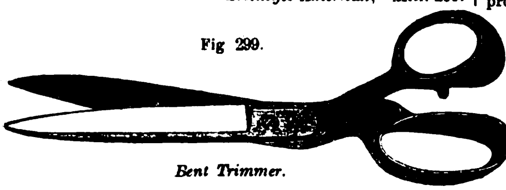
Fig 299.



Bent Trimmer.

Bent Trim'mer. A tailor's shears, bent in the handle so as to make the scissors run more readily upon the board on which the cutting is being done.

Bent Wood Fur'ni-ture. A Vienna industry which has been widely extended of late.

The wood employed is Carpathian mountain beech. The practice in Kohn's factory, in Vienna, is about as follows: —

"The wood to be utilized is cut in the forest, by means of easily transportable steam saw-mills, directly into strips of the dimensions that the separate pieces of the furniture have in the rough. These strips are then conveyed to the factory, where a considerable quantity is simultaneously subjected to the action of steam, until it is both thoroughly saturated therewith, and the vegetable juices largely removed. In this condition the wood is extremely flexible, and when dried is far more durable than when in its natural state, inasmuch as the operation washes out all the soluble constituents and leaves the unalterable cellulose, or woody fibre, behind.

"After steaming, each of the pieces is forced into an iron form, having the shape which the stock is finally destined to possess, and allowed to remain there until quite dry. The several subsequent processes of joining and finishing, involved in the union of the bent sticks into the completed article of furniture, need not be described.

"The advantages possessed by furniture constructed of bent instead of sawed pieces may be briefly summarized as follows: The bent wood furniture possesses superior strength and durability, with the smallest quantity of material, which permits of that admirable combination of lightness with elegance of design which characterizes this class of furniture. The widest scope is allowed for the exercise of artistic talent since the bending process permits of the production of the most varied and intricate patterns." — *Official Report.*

Ber'lin I'ron Work. Very fine cast-iron work such as jewelry, chains, etc., made in Berlin. The art is said to have originated in 1813, when the people of Prussia generally gave their jewelry to the government to assist in resisting Napoleon, and received in exchange similar articles made of cast iron. Some of the separate pieces of which these articles are made up are so small that it is said that there are nearly 10,000 in a pound weight.

Bé'ton. The aqueduct from La Paris, 135 miles long, is nearly entir *Coignet.* The Fontainebleau section over dry quicksand, is composed of arches, some of them 50' high. Ei bridges of span from 75′ to 90′ are also of *béton*. For foundation and gravel walls, the composition is, sand 2½, gravel 2½, hydraulic lime 1, Portland cement ½. For pillars, abutments, etc., sand 4, hydraulic lime 1. The other portions, sand 4, hydraulic lime 1, Portland cement ¼ to ½.

The ingredients are mixed in a dry state, then slightly moistened and ground in a mill that transforms it into a paste almost dry, which is then directly put into the molds. The latter are made of wood lined with sheet iron on the inside. The material is thrown into them by hand and stamped. As soon as the mold is filled it is turned out and left to dry for a few days, as it is only then that it will bear transportation. Compressed *béton* pipe is hard, compact, homogeneous, and resists a very high pressure. It has a smooth surface, so that the flow of the water is greatly facilitated. As this pipe is absolutely tight, filtration of noxious matter is impossible.

The Santorin *béton* used at Pola, was composed of Santorin earth — a volcanic product from the Greek island of Santorino — and common lime paste, in the proportion of 7 cubic feet of the former to 2 cubic feet of the latter, forming the hydraulic mortar; and to this was added 7 cubic feet of broken stone of the size usually employed in making concrete. The whole yielded a batch containing 9 cubic feet, was made into a conical heap, and tempered by open air exposure for a period varying from one day to three days, when the heaps were ready to be used under water.

General Q. A. Gillmore's Report on *Béton agglomèré*, or Coignet Béton, is the subject of a Report of the Corps of Engineers, U. S. Army, Washington, 1871, and contains full and detailed information on the subject.

Fig. 304.

Bevel-head Bolt.

Bev′el Hub. A form of bent pipe connection. See HUB, BEND.

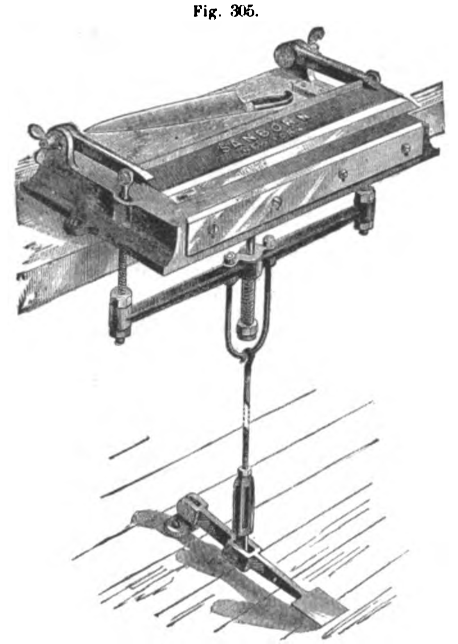
Bev′el-ing Ma-chine′. 1. (*Stereotyping.*) A machine for dressing off and beveling the edges of stereotype and electrotype plates equally on all sides, and parallel to the matter. The edge of the printing matter is placed against an adjustable side gage, secured in this position by clamps, and passed quickly before the revolving cutter, a stationary cutter at the same time taking off the sharp corner from the under edge of the plate. The table can be adjusted in height and also inclined to give a bevel more or less acute, and the revolving cutter-head is adjustable horizontally to suit the position of the table. A brass cover over the cutter prevents the chips from flying, and drops them into a box below.

2. (*Bookbinding.*) A clamp for holding binders' boards while being beveled by the knife.

In Sanborn's machine, Fig. 305, the board is placed between the jaws, and the upper jaw brought down by the treadle to clamp and hold the board. The board is adjusted by back and front gages. The paring knife has the two metallic edges to guide it.

Fig. 306 is Hoe's machine for the same purpose.

Fig. 305.



Foot Beveling Machine.

It is of metal. The plane runs in an oblique channel so as to use the whole edge of the knife, and give a shearing cut to the board. The table is

Fig. 306.

Bi'cy-cle. A two-wheeled vehicle, the *ultima ratio* of the old velocipede.

The "Paragon" may serve as an example. The spokes are of wire, and on the spider-web principle, each spoke having an independent tension. The fellies are of angle iron, the angle holding the round hoop of caoutchouc, ⅞" diameter, which is secured by cement. The backbone is tubular; the front wheel runs on conical bearings.

The pedals are of two kinds: wooden blocks with steel bushes and pins, and oval or triangular pedals composed of steel pins, mounted in brass, and covered with India-rubber.

The handles are of rosewood, ebony, or ivory, upon a steel rod, the support of polished gun-metal, level with the top of the socket, an arrangement found to render it easier to mount and dismount, and giving more command over the machine generally, both in ascending hills and on the level.

Leg-rests are of two kinds, one of which is fixed to the front fork, folding up when not in use, and the other over the front wheel.

The saddle is placed as near the wheel as practicable, to enable a rider to use a machine with wheels as high as possible.

focus. The square form permits the eye-pieces to be brought to the same distance apart as the axes of the eyes of the observer.

Binocular microscope.
Molera & Cebrian . . . *"*Sc. American Sup.*," 3869.
Binocular vision . . . . . "*Sc. American*," xxxvi. 20.

Bi'o-scope. A double-vision instrument. In a recent invention of M. Eugène Simmonar, a portrait is shown with the eyes sometimes open, sometimes shut. The illusion of the same person alternately awake and asleep is very perfect. To obtain this effect, the inventor takes a double photograph of a sitter in exactly the same position, only in the first the eyes are open, in the second closed. From these two negatives prints are taken, one on the right side, the other on the reversed side of the same sheet of paper, in such a way that the two images, when viewed by transmitted light, accurately coincide; this can easily be done by the carbon process. By means of a small instrument arranged for the purpose, the light and reversed sides of the paper are alternately illuminated, and the face is seen with the eyes successively open and shut. Thus the illusion of a person rapidly winking can be perfectly produced.

Bird Foun'tain. A drinking vessel for birds, on the principle of the fountain inkstand.

Bis'cuit Ma-chine'. A machine for making crackers, biscuit, etc. See CRACKER MACHINE.

Bi-sec'tor. (*Surgical.*) A lithotomic instrument used in connection with a grooved staff in cutting the prostate gland in operating for stone in the bladder.

Bit. (*Manége.*) The variety of bits used in England much exceeds our knowledge of the manége. The following are those on sale: —

Breaking bits.
Van and cab bits.
Wilson snaffles.
Snaffles and bits, polished, tinned, or galvanized.
Hackney bits and bradoons.
Pelhams.
Gig bits.
Buckstone, or fancy-cheek carriage bits.
Carriage swivel bradoons.
Stallion bars and chains.
Spring hooks and snaffles.
Regulation officers' tee padroons.
Slabbering bits.
Ladies' riding bits.
Hanoverian bits.
Australian ring snaffles.
Indian snaffles and bits.
Hackney curbs.
Carriage curbs.
Gig curbs.

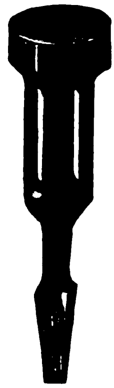
A French electric bit is thus arranged: The coachman has under his seat an electro-magnetic apparatus, which he works by a little handle. One wire is passed through the rein to the bit and carried to the crupper, so that a current once set up goes the entire length of the animal along the spine. A sudden shock will, it is stated, stop the most violent runaway.

Bit Brace. A crank handle for working a bit. Figs. 856–858, p. 353, "*Mech. Dict.*"

Bit-stock . . *De Bert* . . * "*Sc. American,*" xli. 18.

Bit'-brace Die. A screw-cutting die set in the end of a bit to be worked by a brace. Fig. 316. The tool is useful for re-dressing bolts, clips, staples, etc., that have lost nuts, when set in wood-work where it is desirable to cut them without removal or marring paint; also, for cutting stove rods and small bolts, in tin-shops and elsewhere. The collets, of malleable, iron, measure in their largest diameter 1½". The dies are made of one piece of steel, split on one side, held in position in the collet and adjusted by three screws.

Fig. 316.



Bit-brace Die.

Bit Stand. A turned piece of wood with perforations in which bits may be stuck to keep them in order and ready for use. For dentists' purposes principally.

Bit Strap. (*Manége*). A short strap used to attach the bit to a short cheek bridle, or to a halter.

Bit'ting Har'ness. (*Manége.*) A harness consisting of a plain halter, a girth with wooden uprights placed in the center of the pad and set at an angle, and leather reins with rubber web ends. Rings are attached to the uprights and sides of the girth, into which the ends of the reins are buckled after being passed through the ring of the bit. Used for breaking colts to the bit. Also called breaking harness.

Bi'valve Spec'u-lum. (*Surgical.*) One having two leaves or flaps.

The figures refer to *Tiemann's* "*Armamentarium Chirurgicum.*"

Bivalvular Anal Speculum, p. 118, Part III.
Bivalvular Ear Speculum, p. 34, Part II.

Bivalvular Vaginal Speculum, pp. 60, 66, Part III.

Black-ba'salt Ware. (*Ceramics.*) One of the contributions of the admirable Wedgwood to the Ceramic art. Invented by him in 1766. It is a fine black ware, choice, and an *article de luxe.*

Black Brick. Bricks colored by heating red-hot, and dipping the exposed surface into a pan containing half an inch or so of melted coal-tar. Soft bricks are the best. "*American Architect.*"

Black Flux. Composed of 7 parts of crude tartar, 6 parts of saltpeter, 2 parts of common bottle glass, and by some a small amount of calcined borax is added. These ingredients are first finely pounded and mixed, and then gradually heated in an iron pot or ladle so as to burn them together. Care should be taken to not overheat the mixture, and as soon as it is thoroughly melted and mixed together it should be removed from the fire and allowed to cool. After it has cooled it is finely pulverized and sifted, and is then ready for use.

Black Glass. The black glass made in Venice is famous for the intensity of its color. M. Kayser, a Nuremberg chemist, has ascertained by analysis that manganese is the substance used. To confirm this result, he melted in a small furnace a mixture of sand and sulphur, in which he introduced 15 per cent. of peroxide of manganese. He thus obtained a glass of a deep black color; in very fine threads or thin splinters it was of a sombre violet.

Black'ing. 1. For Iron Castings: —

Common. — Coal tar.
Finer. — Japan varnish.
Work exposed to heat. — Graphite.
Work exposed to weather. — Black varnish, dusted with dry graphite, and brushed.
Ornamental Castings. — Heat to blue annealing heat, coat with black copal varnish, and dry at same heat. To polish, give another light coat, and heat moderately.
Mantels. — Enamel varnish.
Lead-color Paint. — Oxide of lead heated in a pot, and flower of sulphur and oil stirred in.

2. For Leather: —

Harness and Bridle Leather. — A decoction of iron-rust and vinegar, or iron-rust and sour wine or sour beer, applied to the grain side of the leather after it has been stained. The vinegar solution is the best. After this application the leather is said to be *blacked on the grain.*
Wax Leather. A compound of lampblack and soft soap, laid on the flesh side with a brush. The skin is now said to be *blacked on the flesh*, or *waxed.*

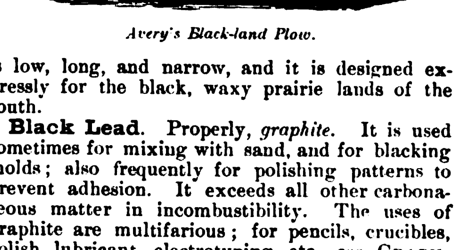
3. (*Founding.*) Charcoal in fine powder dusted from a bag on the mold or applied as black wash.

Black'ing Bag. (*Founding.*) A linen bag from which ground charcoal is dusted on to the surface of a mold.

Black'ing-box Press. A sheet-metal press expressly for cutting and drawing blacking-boxes and covers. See STAMPING PRESS.

Black'-land Plow. A light, one-horse, 7" cut, steel plow. The model of its mold and share

Fig. 317.



Avery's Black-land Plow.

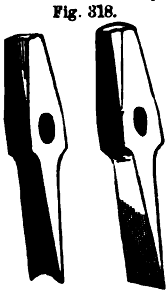
is low, long, and narrow, and it is designed expressly for the black, waxy prairie lands of the south.

Black Lead. Properly, *graphite.* It is used sometimes for mixing with sand, and for blacking molds; also frequently for polishing patterns to prevent adhesion. It exceeds all other carbonaceous matter in incombustibility. The uses of graphite are multifarious; for pencils, crucibles, polish, lubricant, electrotyping, etc., see GRAPHITE, page 1010, "*Mech. Dict.*"

Black Mor'tar. Take good fat lime, and use no sand, but mix it with fine coal-dust instead of sand. Merely to paint the joints black, mix lampblack with boiled linseed oil. In the first case it is put in place with the pointing tools; in the second ca-e, it is applied by the particular kind of brush u-ed by house-painters for that purpose.

Black'smiths' Chis'el. A hammer-shaped tool with one sharp edge, and used in cutting iron by a blow delivered with a hammer.

Fig. 318.

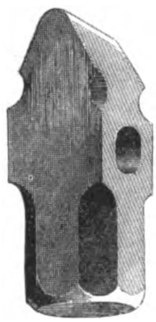


Blacksmiths' Chisels.
(*a.*) *Gouge chisel.*
(*b.*) *Hot chisel.*

Black'smith's Lathe. A lathe of moderate size, adapted especially for performing repairs in workshops and factories. A special lathe for this purpose turns 12″ in diameter over shears, is arranged to be driven by steam, water, horse or hand-power, is self-acting, with means of varying the feed, and can be employed for turning, boring, or drilling, as occasion may require.

Black'smith's Sledge. A heavy hammer wielded by the blacksmith's helper, and having a cross or straight peen.

Fig. 319.



Blacksmith's Cross-peen Sledge.

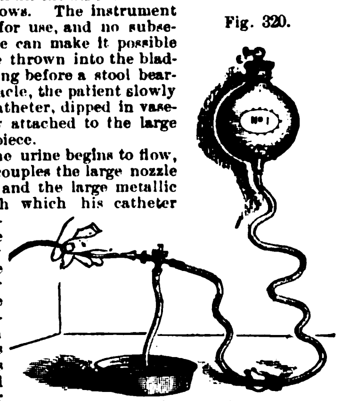
Black Wash. (*Molding.*) A fluid application to the surface of dry sand molds, loam molds and cores, consisting of very thin *clay wash*, with an addition of powdered charcoal. When dried it forms a thin layer, which prevents *sand burning*, and gives a clear skin to the casting, performing the same function as *blacking dust* on green sand molds. It is also used as a *parting* in loam molding.

Blad'der In-ject'or. An instrument to wash out the bladder. It consists of a soft rubber catheter, with injection apparatus and valves.

The instrument may be described by a detail of the manner in which the patient uses it.

He prepares eight ounces or more of the injection fluid at a temperature of 110° F. The bag, filled with the warm fluid, is hung up about 6′ from the floor. The stopcock is now turned on till all the air is forced out of the tube and a jet of water follows. The instrument is now charged for use, and no subsequent disturbance can make it possible for any air to be thrown into the bladder. Now, standing before a stool bearing some receptacle, the patient slowly introduces his catheter, dipped in vaseline, and already attached to the large metallic mouth-piece.

Fig. 320.



Dr. Keyes' Bladder Injector.

As soon as the urine begins to flow, he immediately couples the large nozzle of the stopcock and the large metallic mouth-piece with which his catheter has been provided, and the urine flows promptly through the short rubber tube into the vase on the stool before him. When the urine has escaped, he turns the stopcock and the bladder slowly fills. As soon as the organ begins to feel distended, he turns the stopcock again. The simple motion of turning a stopcock does not communicate the slightest jar to the neck of the bladder, while the water flows in and out of the body, obeying the natural law of gravitation, so slowly and quietly that the patient scarcely perceives it.

He may thus wash his bladder very thoroughly four, five, or six times, without any change of the instrument or its adjustment, except the simple turning to and fro of a stopcock; and this he does until the water flows c clear from his bladder.

Blad'der In'stru-ments. (*Surgi* are of various kinds, not including the rating for stone in the bladder, lithotom tic, lithoclastic instruments.

The figures refer to *Tiemann's "Armamenta gicum."*

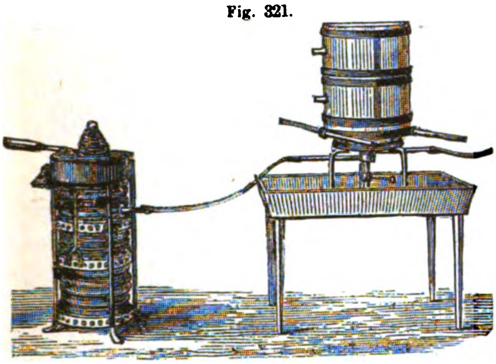
Blast Gas Fur'nace. An apparatus used for the fusion of refractory metals, etc.

Fig. 321.



Griffin Blast Gas Furnace.

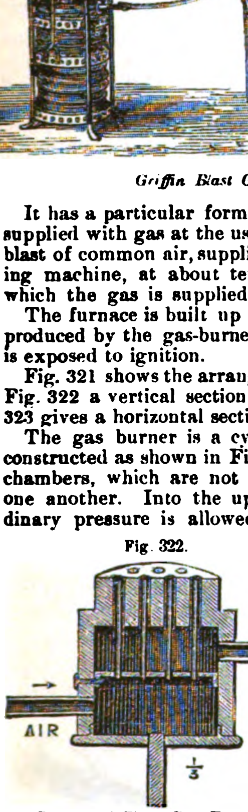
It has a particular form of gas-burner, which is supplied with gas at the usual pressure, and with a blast of common air, supplied by bellows or a blowing machine, at about ten times the pressure at which the gas is supplied.

The furnace is built up round the flame that is produced by the gas-burner, and the crucible that is exposed to ignition.

Fig. 321 shows the arrangement of the apparatus, Fig. 322 a vertical section of the burner, and Fig. 323 gives a horizontal section of the burner.

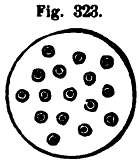
The gas burner is a cylindrical iron reservoir, constructed as shown in Fig. 322. It contains two chambers, which are not in communication with one another. Into the upper chamber, gas at ordinary pressure is allowed to pass by the tube marked GAS. Into the lower chamber, air is forced by the tube marked AIR.

Fig. 322.



Burner of Blast Gas Furnace.

Fig. 323.



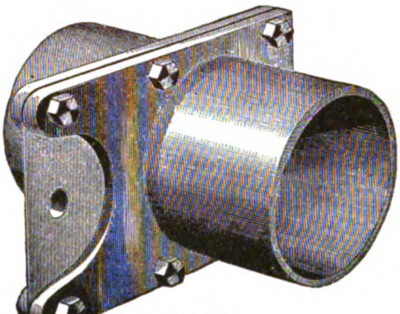
Section of Blast Gas Furnace.

The upper part of the burner is an inch thick in the metal. Through this solid roof holes are bored for the escape of the gas. The air passes from the lower chamber through a series of small tubes placed in the center of the gas-holes, and continued to the surface of the burner, so that the gas and air do not mix until both have left the gas-burner, and then a current of air is blown through the middle of each jet of gas. The bottom of the gas-burner is made to unscrew, and the division between the two chambers, which carries the air-tubes, is removable, for the purpose of being cleaned. The gas has usually had a pressure of 0.5″ of water, and the blast of air about ten times that pressure. The quantity of gas used in an hour is about 100 cubic feet.

When the gas is lighted and the blast of air is put on, the flame produced by the gas-burner is quite blue and free from smoke. It is 2″ in diameter and 3″ high, and the point of greatest heat is about 2″ above the flat face of the gas-burner. Above this steady blue flame there rises a flickering, ragged flame, several inches in height, varying with the pressure of the gas. In the blue flame, thin platinum wires fuse readily.

Blast Gate. The stop-cock or valved aperture of a blast-pipe.

Fig. 324.



Blast Gate.

Blast-heat'ing Stove. A stove or oven for heating air for blast furnaces.

"*Chemiker Zeitung.*"

"*Scientific American Supplement*," 2800.

See, also, list under EXPLOSIVES.

Blast'ing Gel'a-tine. A new explosive agent, discovered by M. Nobel. This substance, called in England, "*Blasting Gelatine*," is formed by dissolving collodion cotton in nitro-glycerine in the proportion of 10 per cent. of the former to 90 per cent. of the latter. The result of the solution is a gelatinous, elastic, transparent, pale-yellow substance, having a density of 1.6, and the consistence of a stiff jelly. The new explosive is in itself much less easily affected by blows than ordinary kieselguhr-dynamite; but it may be rendered far more insensible to mechanical impulse by an admixture of a small proportion (from 4 to 10 per cent.) of camphor. Experiments have been carried out, the result of which is to prove that the new explosive possesses, weight for weight, 25 per cent., and bulk for bulk, 40 per cent. more explosive power than ordinary dynamite. With moist gun-cotton, gelatine compares nearly as favorably.

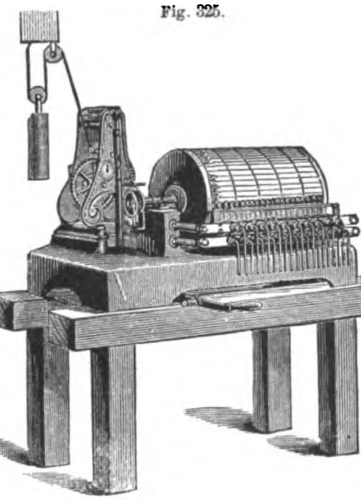
Blast-Re-cord'er. An instrument for keeping a record of the time a hot-blast oven is in blast. The ovens, of the Whitwell class, for instance, are used alternately, the work of each being intermittent, as is the case also with the Siemens' and Ponsard regenerators, and the punctual shifting of the blast to the respective sides of the twin stoves is important. See REGENERATOR, GAS GENERATING FURNACE, etc.

In the illustration, Fig. 325, the recorder is adapted to indicate the performance of twenty-one pairs of ovens, each of which has its iron pencil which records the performance on the paper, in manner following: —

A pipe leading from the blast pressure terminates at a cross-bar opposite the drum, to which the pencil mechanism is fastened; when the blast comes on a small piston is caused to project forward forcing the pencil upon the paper; the joint

Fig. 325.



Bailey's Blast-Recorder.

is made air-tight by means of an elastic diaphragm, about an inch in diameter. The diagram completes a revolution by clockwork once a week, and the number of hours worked by each oven can be at once seen by the length of the stroke which its pencil has made upon the paper.

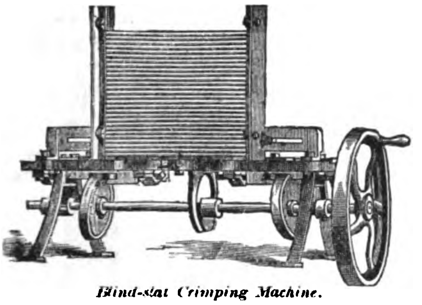
Blind′-slat Crimp′ing Ma-chine′. A ma-

Fig. 328

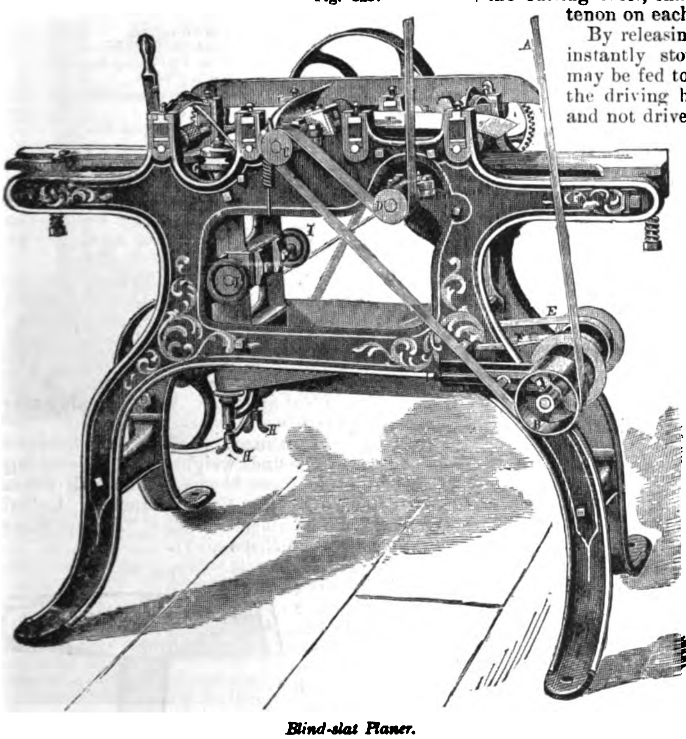


Blind-slat Crimping Machine.

chine used for compressing the ends of stationary blind slats so as to fit and fill the mortises. It may be operated by hand or power. The slats are placed in a hopper, or receiver, at the top of the machine, and the rotary motion given to the balance wheel operates the dies by a combination of cams, and this motion will drop a slat, carry it to the dies, compress both ends, and throw it off.

Blind′-slat Pla′ner. A planing machine for finishing slats for window-blinds, doing the work on both sides, and rounding the edges simultaneously. *I I* are hand-wheels by which the edge-cutters *G* are regulated to any width of slat. The table is regulated by screws underneath. *C D* are the pulleys of the upper and lower cylinders, each of which has four cutters. The machine has four sets of feed-rolls. *F E* are bands from pulley *B*, leading to the edge-cutter arbors.

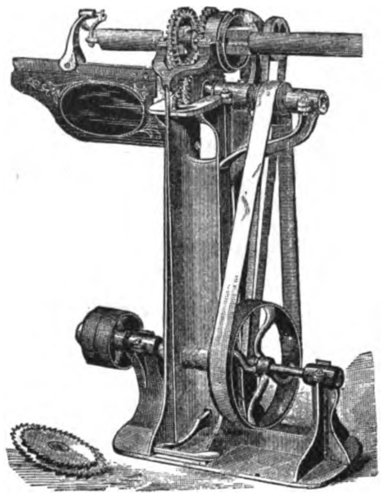
Fig. 329.



Blind-slat Planer.

Blind′-slat Ten′on-ing Ma-chine′. A machine which operates upon long rods which have been dressed to the shape for slats. The slat is fed endwise through rotating chucks, the shoulder being pressed against an adjustable gage for regulating the length of slat. By the peculiar con-

Fig. 330.



Blind-slat Tenoning Machine.

struction of the revolving cutting tools, two tenons are cut and divided with one cutter head simultaneously at one operation. A pressure upon the treadle causes a rotation of the slat and at the same time depresses the chucks carrying the slat against the cutting tools, enabling them to form a perfect tenon on each end.

By releasing the treadle the chucks are instantly stopped, in order that the slat may be fed to the gage, at the same time the driving belt is slackened, so as to slip and not drive. It will work any length of slat from 1¾″ up to 24″, and will make any size of tenon desired. See also Blind Machinery on pp. 298–300, "*Mech. Dict.*"

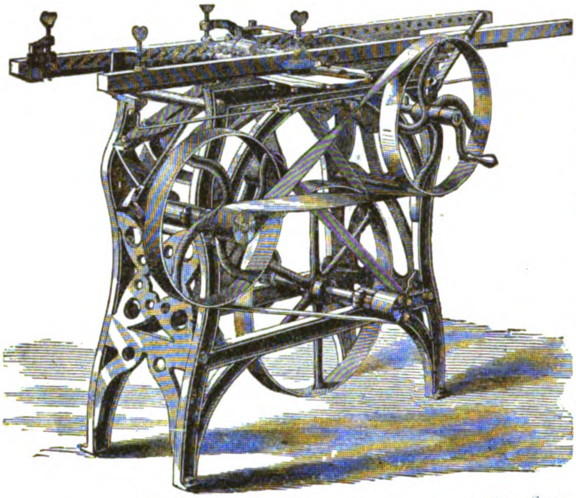
Blind′-stile Bor′er and Mor′tis-er. This machine acts upon two stiles at once, and will make mortises of any length, from a round hole up to 2½″; or it will bore stiles with round holes for rolling blind slats. See Fig. 331.

Blind′-stile Rout′er. A machine for cutting the recesses for blind-rods; in fact, a boring machine for the tenons of slats which occupy each an oblique mortise in the stile. See Fig. 332.

Blind Stitch. (*Harness.*) An ornamental stitch placed upon the outside cover to a blind or strap, the under side of which is covered by the lining. A stitch that is shown on one side only of the leather.

Blind-wir'ing Ma-chine'. This machine (Fig. 333) has guides for conducting the staple to the rod ; a device for feeding the staple between the guides, a driver for forcing them into the rod, and

Fig 331.

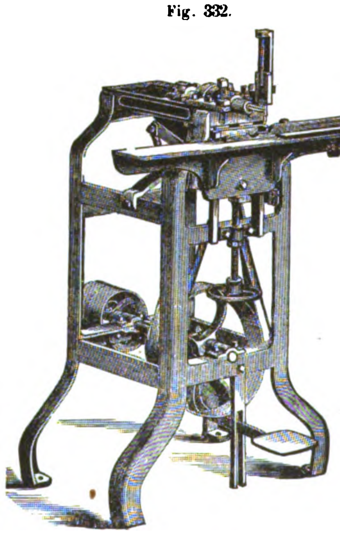


Blind-stile Borer and Mortiser.

a device for moving the rod forward any required distance as each staple is driven.

It is mounted on a substantial iron column and worked by foot, leaving the operator free with both hands to manipulate his work. It will space off, and set and drive at the rate of 80 staples per minute.

Fig. 332.



Blind-stile Router.

Blis'ter Steel. (*Metallurgy.*) Another name for cement steel; made from wrought iron in a cementation furnace. Figs. 1197, 1198, p. 509, "*Mech. Dict.*"

Block. 7. (*Add.*) An engraved wooden stamp, used for printing fabrics before the invention of the roller printer.

Block-printed linen was produced in Flanders in the fourteenth century. See BLOCK-PRIN 303, "*Mech. Dict.*"

8. (*Arch.*) A plain or enriched projectii ion in an entablature.

9. (*Pulleys.*) *Bouche*, the metallic bushing of th

Channel, the opening in the shell to hold the sheave.

Cheeks, the sides of the shell.

Coak, the bushing of the sheave.

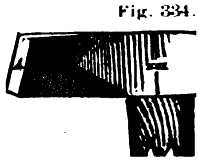
Block'ing Ham'mer. 1. A ste from one to two pounds weight, used masses of flint to form blocks from w can be detached by the *flaking* hamm also a *quartering* hammer. — *Evans'* "*A Implements of Great Britain,*" 17.

2. A hammer used in straightening saws. The face at *A* is slightly rounded, and its shape, combined with its line of motion, gives it a sort of draw blow, which spreads the

Fig. 334.



Blocking Ha

force of the displacement of material in a given direction, and not merely equally on all sides. — "*Scientific American*," * xxxvi. 259.

Block'ing Ma-chine'. A machine in which the crude cone-shaped hat-body is brought to shape.

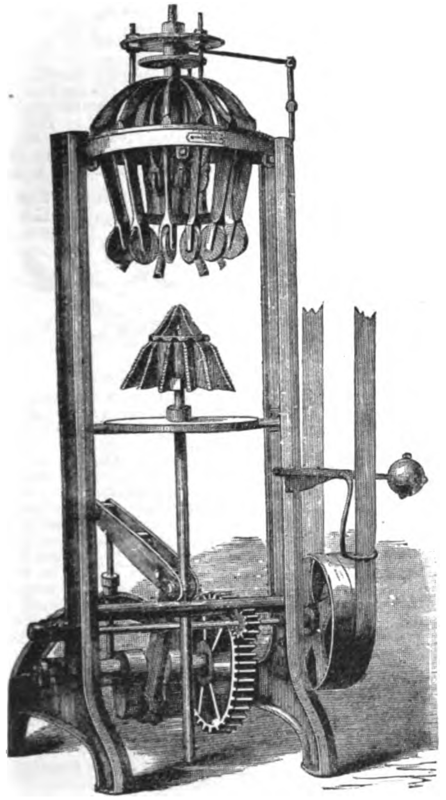
The operation consists in pulling out the edge to develop the brim, and widening out the upper part to form the tip and the side crown.

It is necessary, in order to stretch the hat, to soften the felt in boiling hot water, and the handling is exceedingly difficult.

The first machine for the purpose was invented by D. Beard, of Guilford, N. C., and patented May 28, 1816. It was a blocker made of a number of pieces hinged at their lower ends to a bench and spread from the center by a treadle, while the hat body was held on the block by the operator. This was the only invention in this part of the hat manufacture until that of W. A. Fenn, of Danbury, Conn., patented April 21, 1857.

In Fenn's machine, two pairs of conical rollers were put into a frame so arranged that the upper pair could be pressed upon the lower ones. The forward pair of these rollers revolved at a slightly faster speed than the other pair, and,

Fig. 335.



Eickemeyer's Hat-stretching Machine.

when the edge of a hat body was clamped between the lower and upper rollers, that part of it which was between the two pairs was drawn out, and the hat body thus gradually stretched around the edge until sufficiently flattened to form the brim See also his patents, April 14, 1857; January 19, 1858.

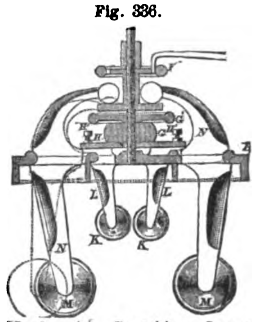
A number of machines of this kind came into use, but, their action being slow and doing but part of the work, the machines did not prove of sufficient advantage to bring them into general use.

The first machine which performed the stretching of a hat body successfully, on wool as well as on fur hats, was the corrugation stretcher invented by R. Eickemeyer, and this machine in its various modifications to suit the different kinds of work is now almost exclusively used in the hat factories of this country.

The machine illustrated in Fig. 335 represents a stretcher now in use in the wool hat factories.

A ribbed and recessed former is mounted upon an upright spindle, which receives motion through a walking-beam and connecting-rod from the crank-shaft. Upon the cast-iron side frames the head of the machine is supported; in this head the stretching devices are suspended. The details are more clear in some respects in the sectional view, Fig. 336.

Fig. 336.



Head with Stretching Levers (Hat-stretching Machine).

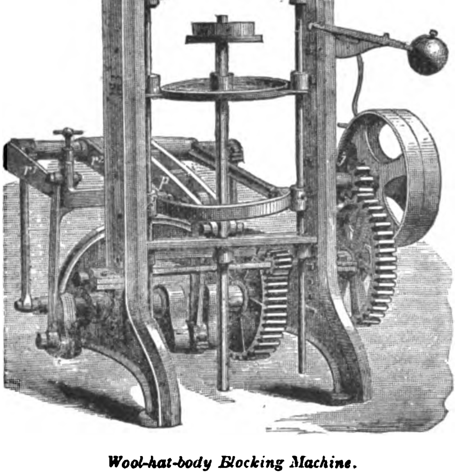
A series of levers, *L*, corresponding in number with the recesses in the upper part of the *former*, *D*, is suspended upon bearings and held in position by a plate, *H*, upon which a rubber spring, *G*, is pressed by a screw-wheel, G^1. In the lower ends of the forked levers smooth rounded rollers have their bearings.

Another series of rollers, *M*, with levers, *N*, and corresponding in number with the ribs in the lower part of the former, is also suspended from this head, and these latter levers are adjustable by a hand-wheel, *F*, nearer to or farther from the center of the machine, as shown in dotted lines on one side of the sectional view.

A hat body properly wetted with hot water, or by steam, is placed upon the *former* while the machine is in motion. The former moving upward brings the hat body in contact with these rollers which enter the recesses between the ribs of the former, and the hat body is thus readily stretched. Five or six upward motions are required to develop the tip and brim fully, the operator shifting the hat body around the center every time the former is at its lowest position, to present other parts of the hat body for contact. The hat having been stretched, it now remains to make what is called in the trade the *band*, namely, the sharp angle formed by the junction of the brim and side-crown.

This operation is performed on the blocking machine, of which Fig. 337 is a perspective view, while in Figs. 338, 339,

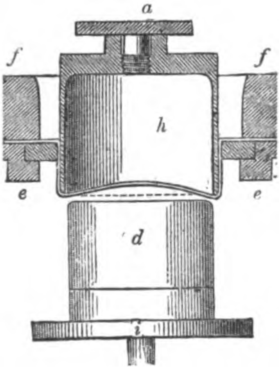
Fig. 337.



Wool-hat-body Blocking Machine.

and 340 the action of the machine upon the hat is illustrated. The machine consists of a frame, in which an upright sliding-spindle is centrally mounted. Upon this spindle, which is operated from the crank-shaft by the walking-beam, is the block *d* (Fig. 338, etc.), upon which the hat to be drawn is placed. A supporting plate, *e*, which receives motion through two rods from a lever, r^2, from the adjustable crank on the side of the machine, receives the hat. When the plate *e* is raised, a plate, *f*, which rests upon brackets on the frame, clamps the hat brim, and the two, continuing to move up, draw the hat body over the banding shell *h*. The block-carrier *i*, with the block *d*, has in the mean time also moved up to position shown in Fig. 338.

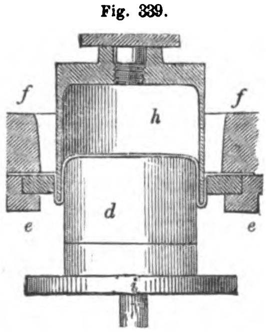
Fig. 338.



Banding Machine. First Position.

The clamping plates *e f* now commence to descend, while the block *d* continues to move up, and enters the banding shell, drawing the side-crown over the round edge of the shell *h*, as seen in Fig. 339.

Fig. 339.



Banding Machine. Second Position.

These motions continue until the plates *e f* rest upon the flange of the block-carrier *i*, and the hat is drawn perfectly smooth upon the block *d*, as shown in the last of the sectional diagrams, Fig. 340.

The spindle now begins to move down, when the clamping-plate *f* is left upon the brackets of the frame, the hat and block are removed, and the operation repeated on the next hat.

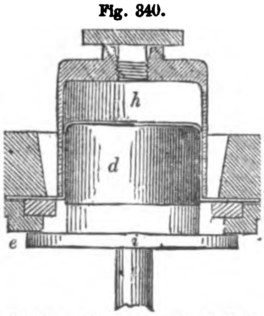
With the use of the stretcher, Fig. 337, and one of the blockers here described, 20 dozen of wool hats can be stretched and blocked per hour by two operators.

To adapt the principle of stretching by corrugation to fur hats, a number of modifications were required. It was found advantageous to separate the *brim-stretcher* from the *tip-stretcher*, and to substitute round-edged bars for the round-edged rollers.

See BRIM-STRETCHER, TIP-STRETCHER.

For the finishing-blocker, see HAT-SHAPING MACHINE.

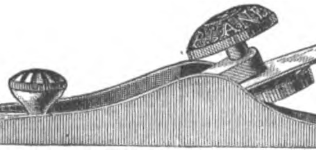
Fig. 340.



Banding Machine. Third Position.

Block Plane. A plane, the bit of which is set at a very acute

Fig 341.



"*Victor*" *Block Plane*

angle to the working surface, to enable it to plane across the grain of the wood: as di from a *smooth* plane, which see and com

Block Sys'tem. A system used more than one train from occupying a between stations at the same time.

By this system a train is not allow station *A* until the signal-man at *A* the signal-man at *B* that the precedin reached *B*, or that the line is clear bet *B*.

The system is confounded in some ca interlocking system of switches and a latter, however, is used only in com switches at stations, junctions, etc, an ing to do with the movements of tra stations.

Blo m'a-ry. (*Metallurgy.*) 1. A form of furnace for the extraction of malleable iron from ore.

The term may be held to include the various native processes not yet disused entirely i practiced from time immemorial in Asia and 5220, p. 2221, "*Mech. Dict.*"). These furnace scale, open at top, and are frequently made c with openings below for the tuyeres of tl used to urge the fire. Iron sand, or rich pu heated with charcoal, and the metal agglutin (*loup*), which is hammered to remove dross, a *bloom*. The heat of the furnace is not suffic metal. The Catalan furnace is a notable ex lan Furnace, Fig. 1185, p. 502, "*Mech. Dict.*" form is found in Silesia and Bohemia, as v iron countries of Europe, as a ready metl rich ores where wood is abundant, and wi pense for plant.

The description by Diodorus Siculus of t in the island of Elba in his time is quite luc ment that it forms an iron *sponge* brings l accord with the metallurgists of to-day; or us say.

In the Catalan furnace the ore is princ upon a sloping wall of the furnace opposite the rest of the cavity filled with charcoal. to the bottom, and the agglomerated mas intervals of time.

In the German blomary the furnace is fill ing charcoal, and the broken ore is placed newed from time to time as it sinks down th until enough has gathered at bottom to fo is withdrawn and forged into a *bloom*.

The German blomary has been somewha troduced into the United States, and the n by, the *Champlain forge*, *Jersey forge*, in and classes of ores upon which it has b used. The Northern New York blomari amounts of metal for the Pittsburg steel

The original forges among rude nations w clay-walled structures; refractory stone w iron boxes are now frequent, lined with ref

The French Catalan forge is about 40″ ×
The German blomary forge is about 21″ ×
The Northern New York, 28″ × 32″, 36″

The figures vary very much, but these are approximate.
At the Moisic works, on the Lower St. Lawrence, the magnetic iron sands are worked in a German blomary, with a hot blast at 600° Fah., and the slag is withdrawn from above the iron by tapping.
Pig-iron is converted into blooms in 58 blomaries, which are mainly located in Pennsylvania.

Blooming mill, Springfield, Ill. * "*Engineering*," xxix. 372.

2. A furnace in which pig-iron is purified, and made fit to be forged into a *bloom* of malleable iron. A *puddling* furnace.

Bloom. (*Leather.*) A yellowish deposit upon the grain-side of a hide or skin derived from the bark used in tanning. Its ease of removal depends upon the hardness of the water used by the tanner. The softer the water the more readily can the bloom be removed.

Bloom Truck. A small iron truck on two

Fig. 343.

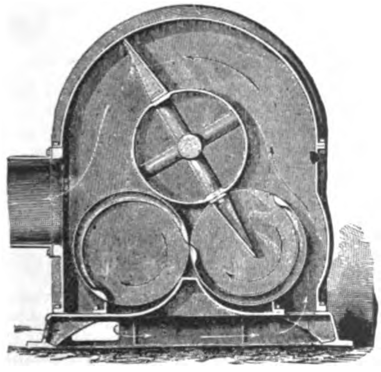
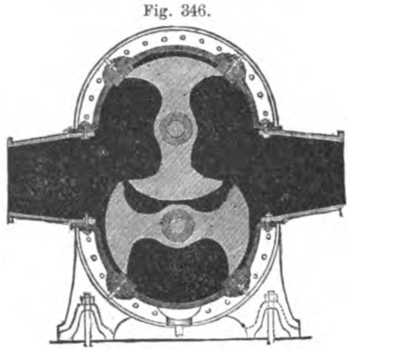
Fig. 345.



Baker's Pressure Blower.

Blow. (*Founding.*) A casting is said to *blow* when, in consequence of the dense nature of the sand or the inadequate *vent* provided by the molder,

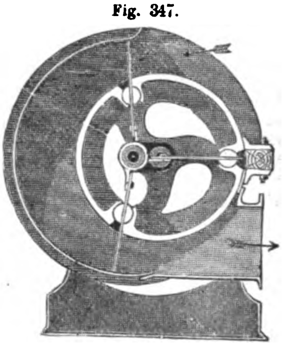
Fig. 346.



Root's Pressure Blower.

the gases and steam force their way through the molten metal instead of passing quietly off. This takes place occasionally with great violence and noise, masses of the fluid metal being thrown from the mold.

Fig. 347.



Mackenzie's Pressure Blower. (*Smith, Sayre & Co.*)

Blow'er. 1. Additional to the forms of duplex rotative pistons (shown on p. 1985, "*Mech. Dict.*") acting in concert and forming what are known as pressure blowers, — inasmuch as the air inclosed is absolutely driven, — are some other forms, which do not need specific detailed description, as the sectional views will be readily comprehended.

Fig. 348.

Enfer's Piston Bellows (*French*).

Root's mine ventilator is a form of blower. See "*Scientific American Sup.,*" x. 1588.

The terms *blower*, *blowing engine*, *blowing machine*, though perhaps readily distinguishable, are used somewhat indiscriminately. The *blowing engine* is properly a machine having the power within itself, and in this respect the air-compressing machine (which see) is closely allied. They are all forms of air-pumps, and mechanical ventilators are congeners. *Insufflators*, *injectors*, *ejectors*, *atomizers*, *aspirators*, also have many features in common with blowers. *Bellows*, perhaps, are the most common examples of the class.

Emery's Report, "*Centennial Reports*," vol. vi., Group XX., contains notices of —

Fig. 348 is a French form of blower, the rotative motion of the hand-wheel being converted by crank and pitman into a reciprocating motion of the piston in a cylinder. It is double-acting.

Fig. 349 shows a blowing machine for the laboratory or assay office, to be used in connection with a blast gas-furnace (which see), or similar apparatus.

2. (*Mining.*) A strong discharge of gas from a hole or fissure.

Blow′-gun. A tube with a missile propelled by the breath.

Blow′ing En′gine. The reciprocating piston-blower, driven by beam-engine, is shown in Figs. 3, 4, article "*Machines Sufflantes*," tome ii., *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," ed. 1877.

Fig. 349.

French Circular Bellows.

The same article has the trompe, bellows, tympanum, helix, etc. See under the following references also: —

Blow′ing Fur′nace. (*Glass.*) One which the melted glass is worked, after been previously fused in a *melting* furnac then transferred to the *blowing* furnace; tl tents of the melting-pots being transferred cession. This is the preferable practice wh is cheap. In America the glass is usually direct from the melting furnace.

Blow′ing Ma-chine′. See Blower; ing Engine.

Blow′ing Tools. (*Mining.*) A small blasting instruments.

Blow′-off Cock. A faucet to allow a

"*Iron Age*," xix., February 22, p. 3.
Mang. and Chrome . "*Sc. American Supplement*," 2080.

Blue Pro'cess for Cop'y-ing. A mode of copying tracings in lieu of re-tracing them.

On a board as large as the tracing lay two thicknesses of blanket to give a yielding backing; lay on this the copying paper, sensitized side upward, and upon this the tracing, which is covered by a glass plate to hold all smoothly. Expose in sunlight for from six to ten minutes, or under a sky-light for thirty minutes. Remove the paper, drench it with water, and hang by one corner to dry.

For the sensitizing solution, take in vessel: —
1¼ oz. citrate of iron and ammonia.
8 oz. clear water.
In another vessel: —
1¼ oz. red prussiate of potassa.
8 oz. water.
Mix solutions, and keep in yellow bottle or away from light. The solution is applied with a sponge, and the paper laid away in the dark. When dry, the paper is yellow or bronze; after exposure, a darker bronze; after washing, the blue tint appears with lines in white.

Blu'ing. A fine blue tint is obtained by boiling iron or steel articles in the following mixture: — Dissolve 4 oz. hyposulphite of soda in 1¼ pint of water, and then add a solution of 1 oz. acetate of lead in 1 oz. of water.

Blun'ger. (*Ceramics.*) A revolving bar in which the materials for pottery are incorporated.

The materials, with sufficient water to form a *slip*, are agitated by paddles, on a horizontal axis which revolves in the box. The slip is run off to the *strainer* or *consolidator* (which see).

Blunt Gor'get. (*Surgical.*) A lithotomic instrument for forcing an opening through the prostate gland, in place of cutting.

Fig. 139, Part III., Tiemann's "*Armamentarium Chirurgicum.*"

Blunt Hook. (*Surgical.*) One for grasping

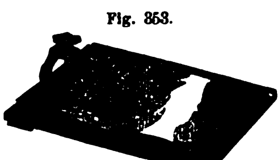
Board Clip. A device for holding paper on a board. Especially intended for telegraph dispatch blanks which are written upon the top blank of a pile and then torn off.

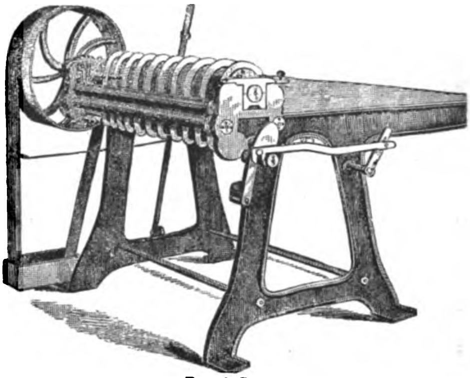
Fig. 353.



Board Clip.

Board Cut'ter. 1. (*Bookbinding.*) A machine with circular shears for cutting binders' board into sizes for use. The frame and bed are made of cast iron, the shears and shaft of cast steel. The board is first cut into long strips, and then, by the adjustment of a latch, the bed carries in the strips for cross-cutting.

Fig. 354.



Board Cutter.

Board Cut'ting Ma-chine'. 2. A machine for cutting thin boards from balks or squared logs.

A powerful machine of this character, invented by Bartlett, has an oblique knife the length of the log, and the boards are shaved off in the manner of a veneer.

"*Scientific American*," * xxxviii. 143.

For the various machines used in Veneer cutting and working, see Figures 6937–6952, pp. 2699–2702, "*Mech. Dict.*"

Board'ing. (*Leather.*) Doubling the leather with the flesh sides together, and driving the fold forward and drawing it backward by the graining-board. It makes the leather supple and raises the grain.

Board'ing Knife. (*Whaling.*) For cutting the *blanket piece* of blubber; the long piece which is flensed or peeled from the sides of the whale.

Board Scale. A weighing balance for assorting, and for ascertaining the number of sheets of pasteboard to make up bundles of 50 pounds.

Board Sea'son-ing Ma-chine'. A machine in which boards are subjected to heat and pressure in order to dry them straight. A large machine of this character has large, flat, steam-heated boxes, which are in vertical series, and pressed together by hydraulic power.

Boil'er Clamp. A form of clamp for holding parts in apposition while being drilled or riveted. That shown opens 4″ in the jaw and runs back 4½″.

Fig. 360.

Le Count's Boiler Clamp.

Boil'er Cov'er-ing. The Chalmers-Spence covering has a dead air chamber of one inch or more between the covering and the surface covered.

This is secured by taking a wire cloth to which is fastened every 4″ or 6″ a stud of an inch or more in length which keep the wire that distance from the surface of the object covered. A non-conducting composition is plastered over the wire. Patents, 80,709, Aug. 4, 1868; 96,738, Nov. 9, 1869.

Asbestos fiber in sheets, or mixed with some cement, is used with advantage.

Sawdust mixed with flour paste. — "*Textile Manufacturer*."

See also references under BOILER, *supra*.

Boil'er Feed'er. Cook's automatic boiler-feeder is operated primarily by the uncovering of the open lower end of a vertical pipe which projects downward into the boiler. The water sinking below the open end of the pipe allows steam to pass upward and operate the devices which supply water until the level rising closes the pipe opening.

The boiler feeders of Pratt & Whitney, of Hartford, Conn., and Macabie's *Alimentateur Automoteur*, made by Voruz, of Nantes, France, act by means of a head of water and a float in a chamber governing the valved steam passages.

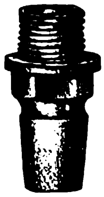
See also FEED-WATER HEATER, etc.

Boil'er Fer'rule. A tubular bushing for a hole in a domestic heating boiler, affording means of attachment for a pipe of supply or discharge.

Fig. 361.



Boiler Ferrule.

Boil'er Fit'tings. Those portions or attachments which are additional to the mere shell. The term includes the following, but they may not all be present in every boiler: —

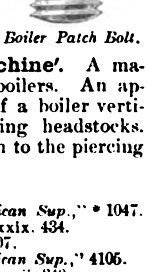
Bearers.	High water indicator.
Blow-off cock.	Injector.
Damper.	Low water indicator.
Dead plate.	Man-hole cover.
Economizer.	Mud-hole cover.
Feed valve.	Safety valve.
Feed-water apparatus.	Steam-pressure gage
Furnace front.	Stop valve.
Fusible plugs in tubes.	Tube plate.
Gage cocks.	Ventilator.
Grate bars.	Water gage.

Boil'er In'di-ca'tor. The electric boiler indicator of *Lethuillier & Pinel*, of Rouen, shown in Paris in 1878, consists of a float and stem, the latter making electric connections at various heights, which are communicated by wire to an indicator-tablet, like an annunciator, fixed anywhere, say in an office, or at the rooms of the boiler inspector.

"*Scientific American Supplement*," * 2751.

Boil'er Patch Bolt. A peculiar form of bolt for securing a patch to a boiler. It is threaded into the boiler, the chamfer rests against the patch and the square is for the application of the wrench.

Fig. 362.



Boiler Patch Bolt.

Boil'er-plate Clip'per. A shears specially arranged for sheet-iron. In that of Fisher, the plate lies upon a table traversing a track, and the shears work at such an angle as to give the proper calking bevel to the edge of the sheet. The tail of the lever which works the movable shear is worked by a cam.

Boil'er Shell Dril'ling Ma-chine'. A machine for drilling rivet holes in boilers. An approved form drills on both sides of a boiler vertically suspended above the standing headstocks. The shell is rotated for presentation to the piercing and countersinking drills.

See also p. 320, Fig. 763, "*Mech. Dict.*"

Boil'er Wash'ing Ap'pa-ra'tus. The system of washing locomotive boilers of S. J. Hayes, Superintendent of Motive Power, of the Illinois Central Railroad, is shown and described in "*Railroad Gazette*," * xxiii. 364.

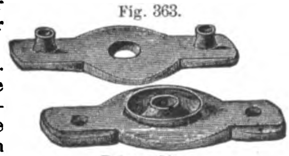
A 2¼" pipe hung from the roof trusses of the round-house is carried completely around it in a line directly over the back dunes of the engines as they stand in the pits, and provided with a stop valve at each pit. A steam pump supplies water under heavy pressure. Each engine has a crown wash-pipe and an attachment for washing the cylindrical part of the boiler. The operation is performed after every round trip.

Bo-la'ta Gum. A substitute for gutta-percha. It is the milky sap of the bully tree on the banks of the Orinoco and Amazon rivers in South America. The operation of winning the gum is similar in every respect to that employed with caoutchouc and gutta-percha. It much resembles gutta-percha, but has, however, some superior qualities. It is tasteless, has an agreeable odor on being warmed, can be cut like gutta-percha, is tough and leathery, is more elastic than gutta-percha, and consequently more flexible. It becomes soft, and may be joined together at about 120° F., but requires 270° F. before melting, higher than gutta-percha. It is completely soluble in benzole and carbon bi-sulphide in the cold. It becomes strongly electrified by friction, and is a better non-conductor of heat and electricity than gutta-percha.

Also known as *balata*.

Bol'ster-plate. A plate in a wagon where the front bolster turns on the axle or the sand board.

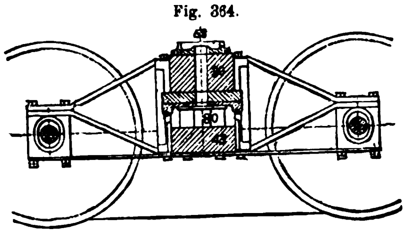
Fig. 363.



Bolster Plate.

Bol'ster Spring. 1. (*Railway.*) One (80, Fig. 364) interposed between the transverse beam (43) of a truck and the truck-bolster (30) which receives the weight of the car on the center plat (63).

Fig. 364.



Railway Truck Bolster Spring.

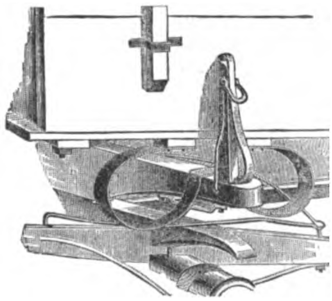
2. (*Wagons.*) *a.* A caoutchouc spring between the bolster and axle to give a degree of elasticity to the bed.

b. Fig. 365 shows a steel spring interposed between the wagon-bed and its bolster to absorb the jar and make the riding more easy.

"*Iron Age*," * xxii., Dec. 5, p. 9.

Bolt. (*Fire Arm.*) 1. The sliding piece in a needle-gun which drives home the cartridg carries in its axial recess the firing pin.

Fig. 365.



Wagon Bolster Spring.

2. The part which in a snap-gun passes *lump* of the barrel, to hold the barrel into tion when the gun is closed.

3. (*Mining.*) A passage leading from road into a side of work.

Bolt Clean'er. A machine or attac cleansing the bolting cloth of mills of th flour and offal.

Collins's automatic cloth cleaner is a to bolts precisely, but to the sieves of purifiers. It has beaters of soft leather in spiral form on a shaft beneath the siev as when revolving to slap the cloth lightly.

"*American Miller*," * viii. 369.

The Cogswell & Finn flour-bolt cleaner has a brush suspended over the reel by arms secured to a shaft which projects through the side of the chest, so that the brush can be lifted and dropped as desired. A coil spring prevents the brush jumping when passing over the ribs of the reel.

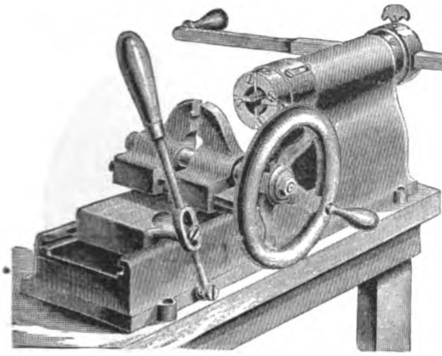
Bolt Clip'per. A double lever tool for cutting off the superfluous length of bolt beyond the nut. The nut *E* lies in a square of the jaw *D*, and the bevel edge of the jaw *C* is brought against the bolt. The tool is of cast steel except the handles, *A*, *B*, and the catches in the arm *F* give different ranges of leverage.

Fi

B

Bolt Cut'ter. A machine for threading bolts. Fig. 367 is Pratt & Whitney's hand bolt-cutter.

Fig. 367.

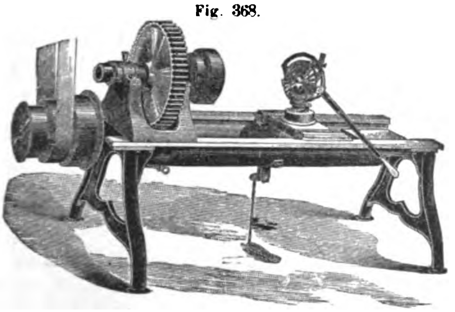


Hand Bolt-cutter.

The bolt is held in the vise, which has a right and left-hand screw, and is tightened by the hand-wheel. The die is revolved to cut the thread, and the bolt is advanced by the lever, which moves the vise slide in the shears. The machine is placed on a bench, and is intended for carriage and jobbing shops. The crank is lengthened or shortened at will; for tapping, the collet on the spindle is replaced by a tap-chuck, and the nuts are held in the vise.

Schlenker's stationary die bolt-cutter is shown in Fig. 368. The bolt is held and revolved in the

Fig. 368.



Stationary Die Bolt-cutter.

head chuck, which is hollow, so that a rod can be advanced axially to have a thread cut on its end. The arrangement of the dies is such that as soon as they begin to cut they will close as far as the stop will allow them, and a series of bolts may thus be cut of the same size. As soon as the bolt is cut the required length, the dies are opened by the lever and the bolt taken out without running the die off the thread. The action of the dies is similar to that of a lathe tool.

The "National" double head bolt-cutter is an open-die machine in which the bolt-cutter head is advanced to the bolt, the latter being held and rotated in the hollow lathe-head and chuck. The bolt is instantly released when threaded; the die blocks contain chasers made on the interchangeable system.

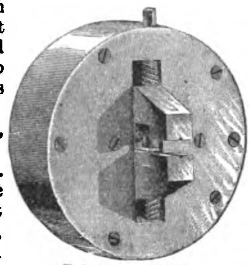
Bolt-cut'ter Chuck. A chuck for holding a bolt to be cut in a turret-head machine. In these machines the bolt is held in a chuck and advanced alternately to one or other of the dies in the turret head.

Fig. 369.

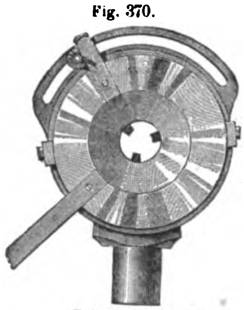


Bolt-cutter Chuck.

See Fig 6824, p. 2665, "*Mech. Dict.*"

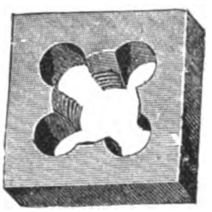
Bolt-cut'ter Head. Fig. 370 shows the die of the Schlenker bolt cutter. It is stationary, the bolt being revolved and advanced to the cutter, see Fig. 368. The chasers are simultaneously advanced or receded in the head by means of a lever which has an adjustable stop, so as to limit their penetration in making a number of bolts of similar size.

Fig. 370.



Bolt-cutter Head.

Fig. 371.

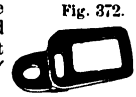


Bolt Die.

Bolt Die. A nut with a thread chased in it, used for cutting threads on bolts and rods. Fig. 371.

Bolt Dog. Used in chucking bolts to be turned or chased. It is bolted to the face plate, spans the center, and has a square to engage the bolt head. Made in sizes from $\frac{5}{16}''$ to 2″ inclusive. Fig. 372.

Fig. 372.



Bolt Dog (Le Count's).

Bolt Feed'er. An apparatus to feed the meal to the flour bolt in equable quantities. *D*, Fig. 373, is the case, *E* the spout leading to the bolt, and *B* the lever for lifting the screw *A*.

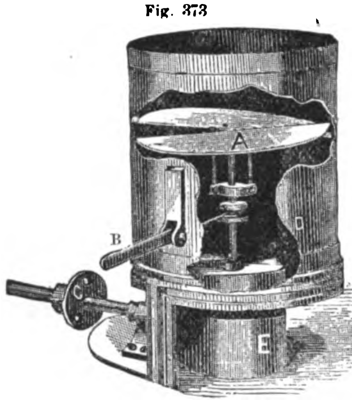
Bolt For'ging Ma-chine'. A machine for forging iron bolts.

Burdict's bolt-forging machine is operated without clutch gear, cam, or springs, the main shaft, slide, and forging dies are in constant motion, and the blank is advanced to the dies by means of a connecting-rod, pawl, shaft, and toggle, and the blank is automatically discharged when headed. The blank rests against a stop, and is only guided centrally by the holding dies while being forged, thus leaving them full size under the head. The machine is capable of making from 3,000 to 8,000 square head blank bolts in 10 hours, according to size.

The Abbe bolt forging machine is a machine of similar capacity and quality

Bolt-head'ing Ma-chine'. Another name for the bolt-forging machine, which see. The Brit-

Fig. 373



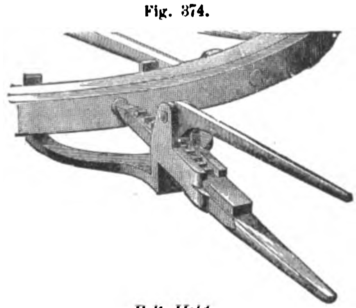
Bolt Feeder.

ish machine of *Greenwood & Batley*, Leeds, is vertical in its action.

A vertical fast-moving screw, with three square threads, raises the work-holder to the die, the latter be'ng stationary. The hot bolt-head is thus brought into the die, and swaged to form. The bolt-holder has a dwell at its upper position, and, as it descends, a pin beneath pushes out the bolt.

Bolt Hook. (*Manége.*) A check-rein hook; the base or point by which it is attached sets flat upon or passes between or under the plates of the saddle-tree, and is secured by a bolt.

Fig. 374.



Bolt Holder.

Bolt Hold'er. A clamping tool to hold the head of a bolt to prevent its turning while the nut is being screwed on. It is a frame containing a sliding bar, having on one of its sides a rack which is engaged by a sector lever. It is shown as applied to put on a tire bolt.

Bolt'ing-cloth Clean'er. See BOLT CLEANER.

Bolt'ing Mill'stone. A French invention by M. Aubin.

The lower millstone has panes with screening cloth of wire gauze, to allow the meal to escape before reaching the skirt.

The device is shown at Fig. 375. Starting from the bosom of the stone, every other furrow is suppressed, and a metallic box inserted containing the wire gauze. A knocker is suspended in the box to hasten the sifting.

Aubin's. Safford's Report "*Centennial Exhibition Reports*," * Group I., vol. iii., p. 180.

Bolt'ing Saw. A machine in which stuff is sawed out of the log or balk to *bolts* or pieces of a size, adapted for working into the object required.

Bolt-point'ing Ma-chine'. A ma pointing or shaping the ends of bolts of fı 1″ diameter.

Fig. 375.

Bolting Millstone.

The bolt to be pointed is held in the vis adjustable on the column of the machine erated by a lever and right- and left-ha

Baugh's Grinding Mill for Bones, etc.

A is the top breaker fitting on the vertical mill-shaft *K*. The breaker is varied with the kind of work to be performed.
B is the nut which secures the breaker.
C, circular grinder or middle breaker with holes for stud bolts, to tighten the grinding sections *DD* on cone *I*.
F, stationary grinding plates. *G*, lower cylinder sectional plates, held by nuts *HH*.
O, lighter lever, etc., for adjusting upward pressure of cone *I* and its plates *DD*, against the concave *G*.
JJ, wipers to discharge ground stuff.
L, feathers on upright shaft *K*.
M, step. *N P*, driving gear.
R R, fast and loose pulleys.
S, fly-wheel. *TT*, bolts holding cover.

Bone Black, Ar'ti-fi'cial. Woody matters impregnated with phosphate of lime dissolved in hydrochloric acid. The phosphates are thus distributed as they are in natural bones. The mass thus prepared is ignited. The difficulty consists in obtaining products of a sufficient density and mineral richness, and free from foreign salts. The charcoal obtained has to be washed in excess of water to remove chloride of calcium, if poor coprolites have been employed. — *M. Melsens.*

Bone Glass. A semi-translucent glass used for lamp-shades and globes. A proportion of bone dust is added to the frit, and it is supposed that the phosphate of lime remains suspended in the glass. *Philip Fischer* in "*Glashutte.*"

The result resembles the cryolite glass, otherwise known as fused porcelain. See Cryolite.

Bone Hold'er. (*Surgical.*) A bone-grasping forceps, in some cases combined with a *rongeur*, or bone-gnawer.

Dr. Darby's, Fig. 79, p. 24, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Bone In'stru-ments. (*Surgical.*) Those used in osteotomy, and in some cases of fracture and necrosis.

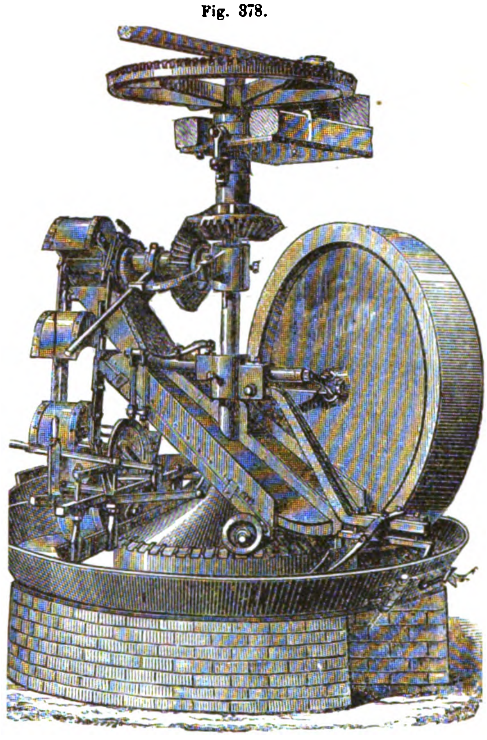
Among them are the following, which see: —
Bone drills.
Periosteotomes.
Exsection instruments.
Saws: Amputating, exsecting, subcutaneous, bow, circular, Hey's, metacarpal, head, trephine, antrum drill, etc.
Osteophor; forceps of various kinds and sizes.
Bone cutters, bone staffs, hooks and levators.
Trepanning elevator and raspatory.

Bone Mill. A machine for crushing bones for use, as animal charcoal in sugar processes, or for a fertilizer.

Fig. 377 is a vertical sectional view of Baugh's mill for crushing, grinding, and pulverizing bones, phosphatic rocks, minerals, ores, slags, etc.

Fig. 378 is a French bone mill on the Chilian principle. It resembles some forms of oil-mills, amalgamators, and cement mills, having an edge

Fig. 378.



Bone Mill. Jannot fils, Treil (*Seine et Oise*).

stone and scrapers. It has also an elevating device which lifts the stuff from the annular pan and discharges it down a screen and in front of the stone.

In the machine of Picksley, Sims & Co., of Manchester, England, the bones intended to be ground are thrown into the hopper, and after falling upon the cutting bed, they are pressed by feed rams against the teeth of a revolving cylinder in rapid motion. The reduced bones fall into an oscillating or revolving riddle attached to the mill, which separates them into two qualities, namely, dust, and half-inch bones. At the first operation the following proportions are obtained:

Dust	45 per cent.
Half-inch bones	30 per cent.
Coarser sample (to be re-ground) . .	25 per cent.

Davids' bone-mill is a disintegrator on the same principle precisely as the disintegrator (*Carr's*), Fig. 1655, "*Mech. Dict.*"

See the following references: —

Hull, Br.	* "*Engineering*," xxx. 57.
Saville St. Foundry Co., Br. .	* "*Engineering*," xxvi. 295.

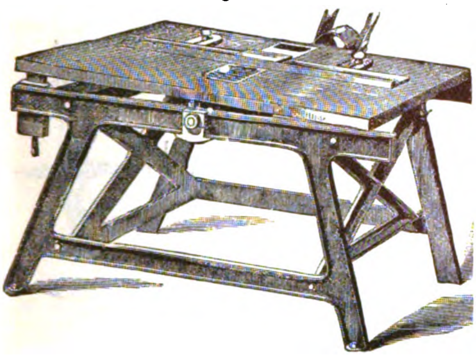
rolling folded sheets instead of pressing folded signatures being laid upon the run between the rollers. The upper r tically adjustable, equally at both ends, by means of the hand-wheel and bevel-gearing.

Book Saw'ing Ma-chine'. A machine for sawing channels in the back of a pile of signatures

Fig. 383.



Book Sawing Machine.

to hold the cords to which the separate signatures are sewn. See SEWING PRESS, Fig. 4884, p. 2124, "*Mech. Dict.*"

The machine, Fig. 383, has a frame of cast iron, and a spindle of cast steel running in composition boxes. It has 5 saws adjustable on the mandrel to any length of book, and there firmly held by nut. The bed is planed smooth and hung on journals at one end, the free end being elevated to such degree as to give the required protrusion of the saws through the slots in the table. The fence or guide is adjustable, and held by set screws.

Book Sew'ing Ma-chine'. A machine for sewing signatures on to a band or cord for binding.

The book sewing machine of the Swiss inventor, Sulzberg, is described under article "Reliure," tome iii., Fig. 2231, *Laboulaye's "Dictionnaire des Arts et Manufactures,"* ed. 1877.

It folds by successive action between rollers in pairs, as in the ordinary folding machines; then pierces and sews the signature.

The Singer book-sewing machine takes sheets already folded and stitches them along the line of the final fold which is given them by a pair of rollers between which they are passed.

"*Scientific American*" . . . * xxxv. 223.

It is adapted for the stitching of signatures, but does not appear to be adapted to sewing them together to common bands or cords.

Smyth's sewing machine has as many stitches as cords, each being independent. The signatures are hung upon the horizontal arms of a four-arm reel which presents them, then drops, makes a quarter revolution, rises, and presents the next signature which hangs upon the next arm in succession. The signature is clamped, the row of needles come into operation, secure the signature, and the arm then drops away, and another is presented as before.

The Wheeler & Wilson book-sewing machine produces a book, the signatures of which are firmly united by loops of the band-thread, secured by a metallic pin within the center of each folded signature, each loop being so formed as to completely encircle the metallic securing pin.

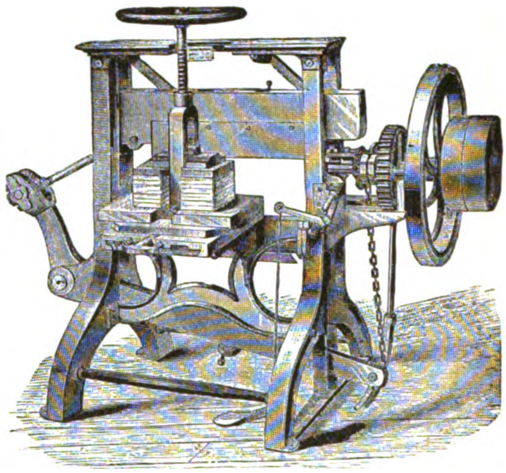
To operate the machine, the table in front of the bed is raised to its full height, the driving-wheel turned until the needles are above the throat-plates, the signature (opened) is then placed upon the needles, the pressers then force the signature firmly to the throat-plates, the needles recede, forming loops into which the material to form the securing pin is passed and severed; the needles now recede quickly, and by the loops of thread draw the securing pin down to the center of the signature, and the signature firmly upon the table in front of the bed. During this operation the arms above the bed recede far enough to permit that part of the signature which lay under them to be closed by means of a folder (placed in the rear of the needles), upon the part already drawn upon the table. This folder is provided with a projection from its lower front edge, which forces down the table upon which the signature is folded to a distance equal to the thickness of the signature last closed upon it, so that the top of the last signature is always in the same relative position to the bed and needles as was its predecessor during the time of sewing. To secure firmness of stitch, each thread is provided with tension devices, as is common to all sewing machines, and operates in a similar manner.

Book Stitch'ing Ma-chine'. Neidbruger's stitching machine for bookbinders is shown in "*Scientific American Supplement,*" * 1748. It operates on single signatures.

See also WIRE BOOK-SEWING MACHINE, Heyl's machine for fastening signatures to bands by means of wire staples.

Book Trim'mer. A machine for squaring the

Fig. 384.



Book Trimmer.

top, bottom, and front edge of a pile of books unbound. In the machine, Fig. 384, two of such piles are shown in the clamp, the backs of the books towards each other, so as to expose the other edges of each of the piles. The carriage being pushed up to position, the foot is pressed upon the treadle, when the knife quickly descends, making a draw-cut, and then at once returns to its starting-point. The pile is then withdrawn, rotated 90° to bring a new face to the knife, the cutting action repeated, and so on for each of the four faces.

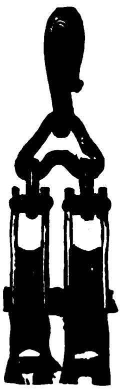
The Standard Machinery Co.'s Steam Power Automatic Book Trimmer operates as follows: — Books are placed on the table, and clamped as with other trimmers; upon moving the shipper, the table advances to the knife, and the cut on one side is made, thereupon the table recedes, makes a quarter turn, advances again to the knife, again recedes, and so continues in operation till all four sides are cut, when the machine stops, the books can be removed, and a fresh lot substituted. As the table works perfectly free while cutting, and needs no attention, the operator is at liberty to get ready another lot of books, thereby saving a large proportion of time.

Boom. (*Lumbering.*) An artificially inclosed bay, in which logs are collected to prevent their drifting away by a current or tide.

The boom is usually made of spars or timbers chained together at the ends, and so anchored or staked as to inclose an area of water. A *boom* is found at each end of a *slide*, which is a chute to help logs over falls, rapids, or shoals. See, also, SHEER-BOOM.

Boom Sheet Block. The block through which the sheet of the boom is rove. In the example, Fig. 385, the block is double.

Fig. 385.



Double Block for Boom Sheet.

Boom Tack'le. (*Nautical.*) A tackle consisting of a double and single block and fall, used in rigging out or in a studding-sail boom.

Boot. 1. (*Surgical.*) Junot's dry cupping boot is a gum boot with an air-tight band on its upper border, and an air-pump to exhaust the air from around the leg. See DEPURATOR, "*Mech. Dict.*"; and AËROTHERAPY APPARATUS, *supra*.

2. (*Manége.*) A covering for any portion of a horse's leg; made of leather, or of felt and leather.

Boot Clean'ing Ma-chine'. A machine with expansible last to suit different sizes of boots, and with means for rotating the boot while the brush is briskly reciprocated upon it. The motions are obtained by turning the handle,

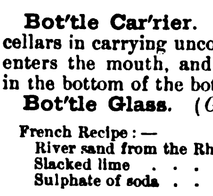
Bo'som Staff. An instrument used in testing the straightness of the faces of mill-stones.

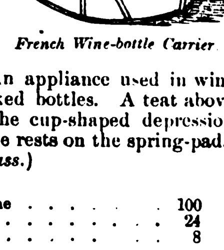
The bosom of the mill-stone is a central depression, and the staff is adjustable to test the symmetry of the concavity.

Fig. 394.



Bosom Staff.

Fig. 395.



French Wine-bottle Carrier

Bot'tle Car'rier. An appliance used in wine cellars in carrying uncorked bottles. A teat above enters the mouth, and the cup-shaped depression in the bottom of the bottle rests on the spring-pad.

Bot'tle Glass. (*Glass.*)

French Recipe: —

River sand from the Rhône	100
Slacked lime	24
Sulphate of soda	8

Belgian Recipe: —

Sand from near Charleroi	10
Peat ashes from Holland	20
Sulphate of soda	15
Limestone	5
Cullets (broken glass)	50
	100

France produces annually 100,000,000 to 120,000,000 bottles, representing a value of \$4,000,000. The price is from \$2.50 to \$3.50 per 100 bottles of from 21 oz. to 2 20 pounds. Champagne bottles having to bear the pressure of the wine, cost from \$4.60 to \$5.60, according to quality.

The operation of blowing the bottle is as follows : —

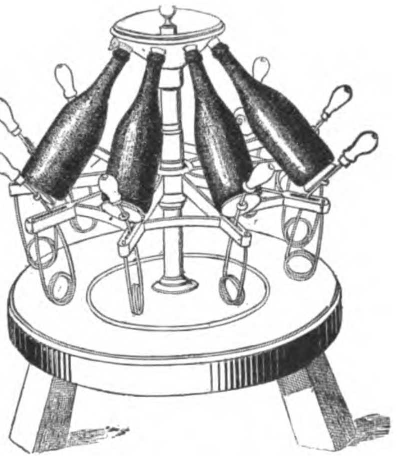
A piece of metal (melted glass) is gathered on the end of the *ponty*, is blown, swung, and rolled till brought to a given size (according to the description of bottle) and shape : then placed in a two-part mold (generally of iron), and by means of a compressing piston expanded against the inside of the mold which shapes it. When withdrawn from the mold the bottom is *pushed* (for some kinds of bottles); is detached from the *ponty* by cracking the glass by means of a piece of cold iron. The bottom of the bottle is put in a spring-tool; the neck is re-heated and the mouth properly shaped by a pincers which has forming blocks and fits the inside and outside of the mouth.

Sometimes the bottom alone is formed in the mold.

A furnace in France generally consumes about 374 pounds of coal for every 100 bottles of 28.80 ounce weight, or 1,820 pounds of coal for 220 pounds of bottles.

Bot'tle Hold'er. A stand for holding bottles, either in the bin or the rack — full or empty.

Fig. 396.



Bottle Holder. (*Vins Mousseux.*)

Bow'er. (*Nautical.*) One of the ing anchors at the *bow*. They are calle and *small* bower; not on account of size, but position.

The *best* bower is starboard.

The *small* bower is port.

Bowl. (*Fishing.*) The *pound*, *pot*, or *crib* of a weir or *pound net*. See POUND NET.

Bow'line Knot. (*Nautical.*) A combination of the reef-knot and carrick bend used for furnishing a bight that will hold upon a rope's end; as a bight on a boat's painter, to be thrown over a post on a wharf.

Fig. 400.

Bowline Knot.

A running bowline-knot has the knot made on the bight, instead of on the standing part, and makes a bight that travels upon the standing part.

Bow'line on a Bight. (*Nautical.*) A form of knot or bend. See 17, Fig. 2777, p. 1240, "*Mech. Dict.*"

Bow'sprit Shrouds. (*Nautical.*) Ropes or chains from the outer end of the bowsprit to the luff of the bow, giving lateral stay to the bowsprit.

Bow I'ron. One of the bow-shaped straps attached to the sides of a wagon body to hold the end of the bows on which the tilt is stretched and supported.

Fig. 401.

Bow Iron.

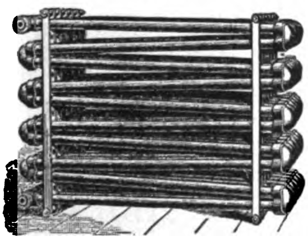
Bow Joint. One of the pieces concerned in the folding members of a carriage top.

Box Bar'row. A capacious, four-sided barrow, such as is used for carrying coke, saw-dust, etc.

"*Scientific American*" . . . * xxxix. 322, Fig. 7.

Box Coil. (*Heating.*) A steam or hot-water coil of many members, occupying a cubical space comparable in its proportions to a box.

Fig. 402.



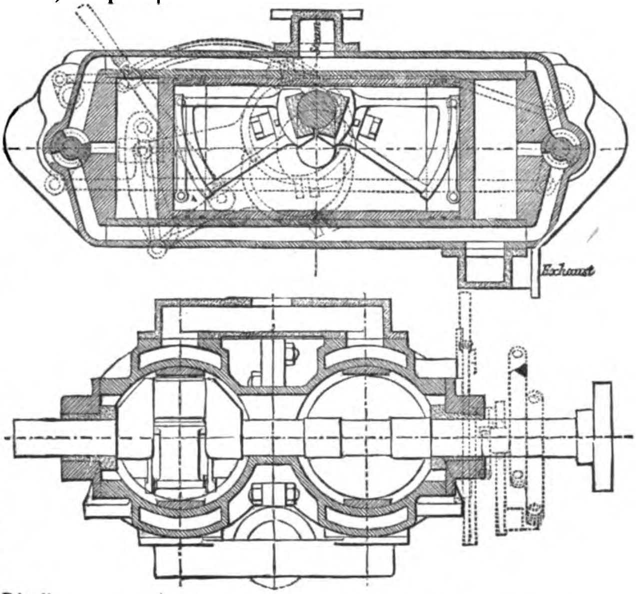
Box Coil with Return Bends.

Box En'gine. A peculiar form of engine in which the parts are all in compression, and which has but two joints. It is singularly compact, as a 25 horse-power engine, with steam at 65 pounds, occupies a space 14″ × 32″ × 13¼″, and weighs 364 pounds.

The engine consists of a cast-iron casing forming a cylinder traversed at the middle of its length by the crankshaft. The piston is formed of two rings connected by means of distance pieces, while a plate is secured to each end, and between these plates the sectors, which act as connecting rods, move freely.

The use of these sectors or quadrants in place of the ordinary connecting rods forms one of the features of the engine. The sectors roll on the inner faces of the piston plates, and are supported by bridle rods of wrought-iron, the wearing parts are case-hardened, and the pins on which they move are of steel. In the ends of the sectors are fitted the crank-pin brasses, so arranged that they may easily be set up until they are completely worn through; the motion of the arcs of the sectors being a rolling motion, there is practically no friction. The brasses of course are under the same conditions as those of an ordinary engine.

Fig. 403.



Outridge's Box Engine.

The valves used are of cylindrical form, having passages for the inlet and outlet of the steam, one valve being placed at each end of the cylinder. They are held between centers of hardened steel (as they do not bear on the shell there is very little if any wear) and are actuated by an eccentric attached to a rod connected to both by means of short levers; the motion of the eccentric causes the valves to vibrate. The engine is solely under the control of the reversing lever, and may be stopped, started, reversed, or linked up with the greatest ease, the valves always being in equilibrium.

The clearance spaces are small, the amount being only one fortieth part of the cubic contents of the cylinder, as compared to one twelfth part, which is the general practice in small engines of the ordinary type. This object is gained by the use of very short steam ports, the general practice being to make the ports ¾″ in length.

A lubricator is fitted on the steam-pipe and the oil is carried past the valves into the interior of the cylinder in the usual manner. An oil cup is also fitted to the hand-hole door, by means of which oil is introduced between the inner faces of the piston-plates; in this the crank-pin is partially submerged at each revolution, the splashing caused by the passage of the crank through the oil thoroughly lubricates all the working parts inclosed within the diameter of the cylinder, and oilways are cut in the bearing brasses, through which the oil constantly trickles and thereby reduces the chances of hot bearings. When once the lubricator has been charged and a proper quantity of oil placed between the piston-plates, the engine will run for twenty-four hours without attention.

Box Form'ing Ma-chine'. A machine for forming sheet-metal boxes, such as those for condiments, baking powder, cocoa, etc.

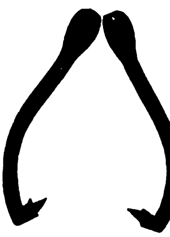
"*Iron Age*" . . . . . * xx., November 22, p. 1.

Box Hook. 1. A hook used in handling boxes; somewhat like a cotton-hook, which see.

2. A hook made on the plan of a cant-hook; used in closing boxes packed full of fish.

3. Hooks used in pairs in swinging boxes from a lifting-tackle. Fig. 404.

Fig. 404.

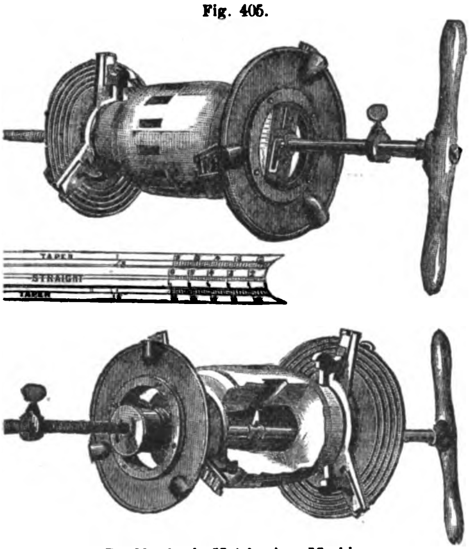


Box Hooks.

Box'ing Ma-chine'. A machine for boring out the boxes of hubs. Fig. 405. It is adjustable to bore either a straight or taper hole.

The upper figure shows the chuck for the larger end, with the device for varying the taper of the hole. The lower figure shows the chuck for the smaller end, and also shows the interior, a portion of the hub being broken away to expose it. The adjusting rule, shown between the figures, enables the operator to set the bits for cutting a straight hole or one with any required taper.

Fig. 405.



Double-chuck Hub-boxing Machine.

Box Man'gle. One of which the weight is formed by a box containing stones or blocks. Fig. 3043, p. 1383, "*Mech. Dict.*"

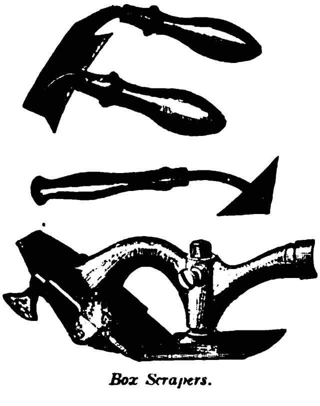
Box Pack'ing. Fibrous waste saturated with oil for the packing of axle boxes.

Box Re'lay. (*Electricity.*) A portable relay instrument which is inclosed in a box.

Box Scra'per. A tool for scraping names off boxes for re-addressing.

The illustration shows a double handle scraper, a single handle scraper, and an adjustable scraper with plane bit.

Fig. 406.



Box Scrapers.

Box Valve. A box section in a pipe containing a valve, and having a cover for access. Fig. 407.

Bra-bant' Plow. A peculiar form of plow, made either single, double, or turning-mold-board.

It is named from Brabant, in Flanders, and is rapidly spreading over the North of France. Whatever may be the peculiarity of the mold-board, one or more, the plow has always its beam adjustable in the standard of the avant-train.

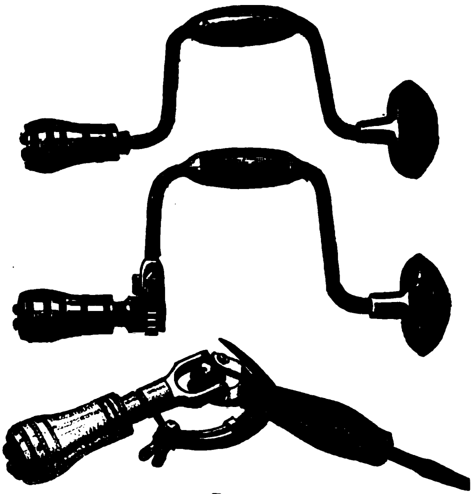
Brabant Single Plow.

Brace. 4. (*Add.*) A revolving tool-holder, of which three forms are shown in Fig. 409: Straight,

Fig. 409.



Braces.

Ratchet, Angular. An *extension* brace is one with a lengthening section for very deep holes.

8. (*Mining.*) (*Add.*) *b.* The platform over the mouth of the shaft or winze, and to which the tackle is hooked.

Brace Tre-pan'. (*Surgical.*) A trephine saw mounted on a brace: in effect, an annular bit in a brace.

Fig. 72, p. 20, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Brack'et Cock. One projecting from a wall in manner of a bracket, as distinguished from one on a post rising from the basin slab. Fig. 410.

Brack'et Cut'ting-off' Saw. A cross cutting saw mounted on a projecting bracket, its arbor traversing to and fro so as to carry the saw across the stuff which lies upon the table beneath. Fig. 411. The table has rollers to facilitate the endways motion of the timber between cuts.

Fig. 410.

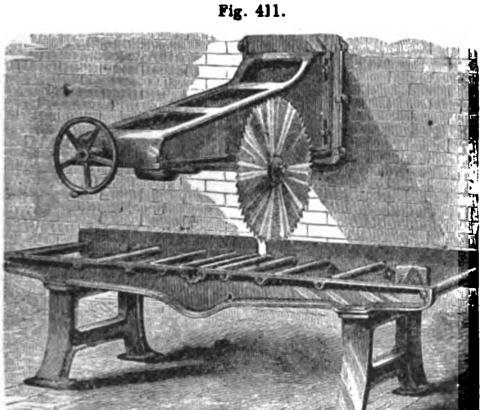
Bracket Basin Cock.

The machine is specially designed for car and bridge shops, ship-yards, etc. The bracket is adjustable vertically on the wall-plate, to compensate for the wear of the saw. The saw carriage is gibbed to the ways, and the traverse movement is by rack and pinion connected with the hand-wheel in front. The traverse is 38″; sawing capacity for boards is 30″ wide, and for timbers 12″ × 24″.

Brad Driv′er. An instrument, Fig. 413, especially designed for nailing moldings to the panels of doors. It has a brad-holder and a plunger driven by a mallet.

Bra-doon′. (*Manége.*) A small bit having loose rings; used as a second bit for bearing reins in curb bridles. *Gag bradoons* have holes in the rings through which a strap is passed, the ends of which are connected with the reins; when made in this way they are very severe, and are used only for riding bridles. *Link* and *T bradoons* are bits having links or T-s attached

Fig. 411.



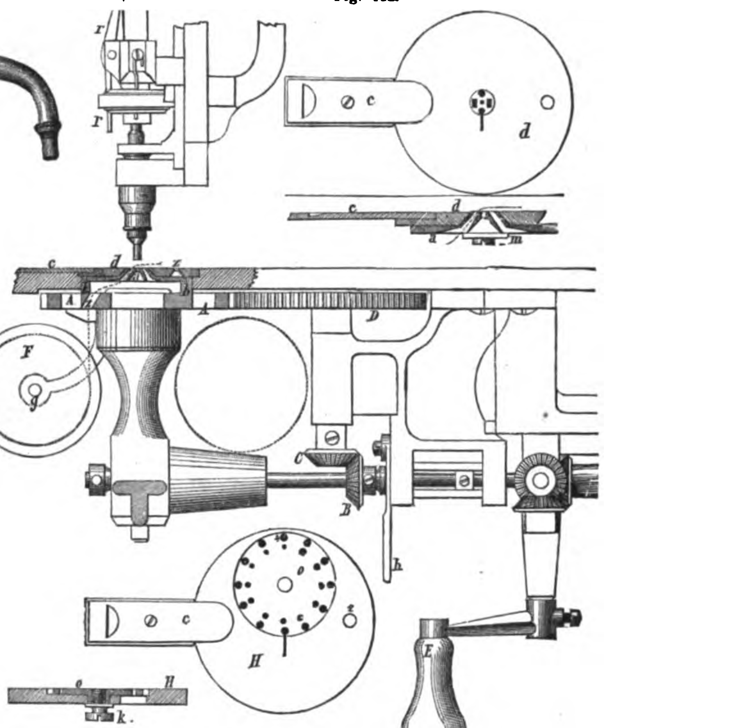
Bracket Cutting-off Saw, with Traversing Arbor.

to the rings, by which the head collar is attached; they are used only for military purposes; bradoons are made with stiff and with jointed mouths.

Braid′ing Ma-chine′. A machine which sews braid on to cloth. A species of embroidering machine.

Cornely's braiding machine (Paris) is founded upon the Bonnaz embroidering machine, having combined with the latter a braiding apparatus which presents the braid to the needle always in the direction of the feed, so that it will stitch it to the cloth in its center.

Fig. 412.



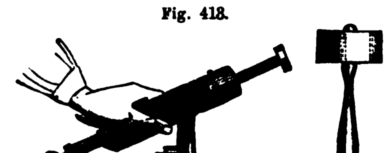
Cornely's Braiding Machine.

The braiding apparatus consists of a braiding disk *a*, which is fitted within the rim or crown of the large wheel *A*. Upon turning the crank handle *E*, the wheels *B*, *C*, *D* turn the wheel *A* and the braiding disk *a*, which presents the braid to the needle always in the direction of the feed.

To use the braiding apparatus a braiding guide must be selected, through which the braid can slide easily. Braiding disks are adapted for the respective sizes of braid.

Withdraw the slide *c*, raise the plate *d* by inserting the curved point of the hook knife into the hole, lift the end of the braid by means of the wire-hook through the slot *Z*, in wheel *A*, and draw it through the braiding guide. Place the spool *F* on its spool-holder, *g*, and the India-rubber washer upon the end of the spool-holder to prevent the spool from sliding off. Set the braiding disk *a* upon the rim of the wheel *A* and in such a manner that its projection *m* enters into one of the recesses of said rim.

Fig. 413.



Thorndike's Brad Driver.

It is very important that the guide from which the braid issues should always be in a true radial line with the feed lever *r* of the machine, and that the braid should fit nicely in said guide, or else it will not be stitched in its center; it should, however, not be too tight in the guide, as in that case it would draw and ruffle the material.

In case it should be necessary to adjust the braiding guide it can be done by adjusting the position of the wheel *A*. To accomplish this, raise the lever *h*, and push the wheel *B* to the right, thus the wheel C becomes free, and the wheel A can be turned independently of the crank handle E; adjust the braiding disk to its true position, push the wheel B against the wheel C and lock it by means of the lever h.

The braid should always pass from below the spool F into the passage Z, as shown in dotted lines, and never from above the spool, as it will bear against the side of the passage Z and thus draw or ruffle the material.

For embroidering purposes a plate, H, is supplied with each machine, and is to be used instead of the plate d.

To change the needle-hole in plate o, loosen the screw k, push the disk o out of plate H, turn it until the needle-hole to be used will be in the center of plate H, and push it home into the plate H, taking care that the tooth 4 enters one of the notches in the circumference of disk o, and tighten the screw k.

The *Wheeler & Wilson* new No. 10 sewing-machine is a perfect braider.

Brain Knife. (*Surgical.*) A knife used in making sections of the brain in *post-mortem* examinations and for microscopic purposes.

Fig. 326, p. 95, Part I., "*Tiemann's Armamentarium Chirurgicum.*"

Braize. Charcoal powder. It accumulates around charcoal works at furnaces, and is a source of danger. Suggested to be blown into the furnaces of the hot blast. — "*Mining Journal.*"

Brake. 1. (*Railway.*) See AIR BRAKE, VACUUM BRAKE, etc. For details of various car-brakes, see *Forney's* "*Car-builders' Dictionary.*"

2. In casemate and ships' guns: a compressor to check the recoil of a gun. See description on pages 500, 501, "*Ordnance Report,*" 1877.

3. (*Manége.*) A severe bit, formerly used in England. It is referred to by Nares.

4. A form of testing device. See DYNAMOMETER; DYNAGRAPH, "*Mech. Dict.,*" *et infra.*

Brass. An alloy of copper and zinc. See pp. 358, 359, "*Mech. Dict.*"

A native brass is found on the south fork of the Yuba River, California, analyzing as follows (*Stillman*): —

Copper	85.02
Zinc	11.02
Antimony	3.82
Iron	0.09
	99.05

"The specimens are in the form of small, somewhat flattened, concretionary masses, from ½ to ¼ centimeters in diameter, and destitute of apparent crystalline structure. Color, from dark reddish-brown to yellowish-white; streak, faint yellowish-white; specific gravity, 8.33; somewhat brittle; slightly incrusted with green carbonate of copper." — "*Mining Record.*"

See *Larkin's* "*Practical Brass and Iron Founder's Guide*," 12mo.

Brass Black'ing. A dead black color; used freely with French optical instruments.

Make a strong solution of nitrate of silver in one dish, and of nitrate of copper in another. Mix the two and plunge the brass. Remove, and heat evenly until the required dead blackness is obtained.

Brass Col'or-ing. Surface coloration by lacquer or chemical action.

To obtain —

Browns of all shades, immerse in solution of nitrate or perchloride of iron, the strength of the solution determining the depth of the shade.

Clean the brass, leave in damp sand, then polish with a dry brush.

Violet: Dip in solution of chloride of antimony.

Chocolate: Burn on the surface of the brass moist red oxide of iron, and polish with graphite.

Olive Green: Make the surface black by means of a solution of iron and arsenic in muriatic acid, polish with a black-lead brush, and coat, when warm, with a lacquer composed of one part of lac varnish, four of turmeric, and one of gamboge.

Green and light coating of Verdigris: Dilute acid, followed by spontaneous drying.

Orange, inclining to gold: Polish, and plunge for a few seconds in a warm, neutral solution of acetate of copper.

Grayish Green: Dip in a bath of copper.

Moire: Solution of sulphate of copper.

Steel-gray Bronze: Dilute boiling solution of chloride of arsenic.

Blue Bronze: Strong hyposulphite of soda.

English Brass Color: Heat to redness, dip in sulphuric acid, then in dilute nitric acid, wash, dry in saw-dust.

Black Bronze: Coat with solution of platinum, or chloride of gold mixed with nitrate of tin.

Japanese Bronze: Solution of sulphate of copper, alum, and verdigris.

Black: Polish with tripoli, wash with solution of nitrate of tin, 1; chloride of gold, 2.

Or, dip in bath obtained by dissolving copper filings in nitric acid; then heat over charcoal; repeat to develop color.

Or, mix a strong solution of nitrate of silver in one dish and nitrate of copper in another, mix the two, plunge the brass, heat to develop color.

The following is a recipe which gives to brass a variety of shades, according to the length of the exposure or the amount of the application. First appears a light color, then all shades successively from red, dark blue, light blue, and finally brown: Dissolve 60 grains bitartrate of potassa in a liter of water, to which add 30 grains tin salt (protochloride of tin) dissolved in a fifth of a liter, heat to boiling, and allow the resulting precipitate to settle. The clear liquid is now to be poured, under constant stirring, into a solution of 180 grams of hyposulphite of soda in one fourth liter of water, and again heated to boiling, during which operation a quantity of sulphur will be separated. The resulting clear solution is then ready for use.

Old German Recipe: The sulphide of copper produces similar effects.

Brass Fin'ish-ing.

See article from "*Ironmongers' Review*" (Br.) on Brass Finishing, including —

- Turning.
- Spinning.
- Burnishing.
- Coloring.
- Bronzing.
- Lacquering.
- Etc.

Reproduced in "*Iron Age,*" xxi., May 9, p. 7.

Brass'ing. Electro-brassing is done by first washing in hot potash bath, then pickling the article to obtain a clean metallic surface, free from oxide, and removing the black scale by scouring, and then exposing in the depositing bath with strong battery power.

The methods employed for brassing cast iron, zinc, steel, are detailed by Mr. Alex. Watt, and reproduced in "*Scientific American Supplement,*" 2610.

Brass Lac'quer-ing. A means of preserving brass from tarnishing without giving it an artificial color. (For the latter see BRASS COLORING.)

The brass is pickled, scoured, and washed; dipped in nitrous acid for an instant, washed in clean water, dried in saw-dust. Then dipped an instant in nitric acid, washed in a weak solution of argol, and dried in warm saw-dust.

"So prepared, the goods are conveyed to the lacquer room, where they are heated on a hot plate and varnished.

"The varnish used is one of spirit, consisting, in its simple form, of one ounce of shellac dissolved in one pint (imperial) of methylated spirits of wine. To this simple varnish are added such coloring substances as red sanders, dragon's blood, and annatto, for imparting richness of color. To lower the tone of color, turmeric, gamboge, saffron, Cape aloes, and sandarach are used. The first group reddens, the second yellows the varnish, while a mixture of the two gives a pleasing orange.

"A good pale lacquer consists of three parts of Cape aloes and one of turmeric to one of simple lac varnish. A full yellow contains four of turmeric and one of anuatto to one of lac varnish. A gold lacquer, four of dragon's blood and one of turmeric to one of lac varnish. A red, 32 parts of annatto and eight of dragon's blood to one of lac varnish.

"Lacquers suffer a chemical change by heat and light, and must, therefore, be kept in a cool place and in dark vessels. The pans in use are either of glass or earthenware, and the brushes of camel's hair, with no metal fittings." — *Ironmongers' Review*

Lacquer for small arms and bright work of ordnance is made of turpentine, oil, and beeswax, sometimes with the addition of litharge or of resin. In the latter cases the compound is really a paint or a varnish, and the term lacquer is a misnomer.

Fig. 421.

Brazing Blow-pipe.

Brat'tice Cloth. A cloth used in a mine in place of a brattice of plank.

Proposed to be made of wire cloth, so as to prevent being burned by explosion or other accident.— "*Mining Journal.*"

"*Scientific American Supplement,*" 948.

Bray'-plank (*Grain Mill.*) The beam supporting the adjustable end of the bridge-tree.

Brew'er's Fau'cet. A faucet with two brass cocks.

A double faucet: that is, two faucets from a single stem which enters the barrel or vat, and a small faucet at the fork for sampling. A RACKING FAUCET, which see.

Brick Bar'row. A flat-bottomed, sideless, high front board wheelbarrow, for off-bearing bricks, and conveying baked bricks to the kiln. The wheel is set farther back than usual, and the bricks piled in ranks on each side.

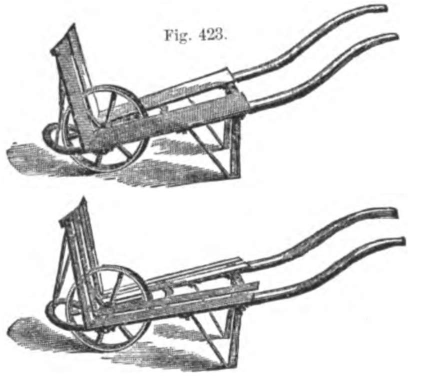
Brick, Hol'low. A brick with cells, for ventilation or to prevent passage of moisture. See Figures 897–899, "*Mech. Dict.*"

French hollow bricks are made by Gaillon, Levallois-Perret, and Hugede, Faubourg St. Honore, Paris. See also article "*Briques Creuse*," and Figs. 3438–3441, *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," vol. iv., ed. 1877.

Brick Kiln. Two systems of continuous kilns for burning bricks, tiles, etc., have come into prac-

tical use — the French system of Colas, also known as that of Borie (Fig. 901, p. 371, "*Mech. Dict.*"); and the German system of Hoffmann, the well-known annular kiln or Ringoven (Fig. 903, *Ibid.*).

Fig. 423.



Brick Barrows.

The principle of the kilns of Colas, Borie, and their imitators, consists in placing the air-dried bricks on small railway trucks forming a long train. This is slowly moved through an arched chamber, provided in its center with fixed fireplaces for burning the bricks; the fire in these kilns is stationary, while the bricks are moved forward. The principle of the Hoffmann kiln is just the reverse; here the bricks are stacked in an annular burning chamber, and remain stationary while the fire travels through them, leaving burnt bricks in the rear and advancing into and among the green bricks. The annular shape of the burning chamber allows a continuous operation of the kiln, the fire progressing in the circuit without interruption, while the burnt bricks behind the fire are continually replaced by green bricks. The first-named system is also worked continuously, the train being supplied in the rear with trucks containing green bricks, at the same rate as trucks with burnt bricks are withdrawn in the front.

On the *Colas* principle is the *Dueberg* kiln described in —

"*Engineer*" . . . . * xlvi. 191.
"*Scientific American Supplement*" * 2358.

The Foster kiln, for which see —

"*Engineer*" . . . . * xlvi. 385.

2. A plank to cover the gap between the platforms of two connected cars.

Bridge, safety, *Frazer* . . * "*Scientific American,*" xxxv. 5.

3. An arrangement for measuring the resistance of an element in the circuit, Fig. 1840, p. 779, "*Mech. Dict.*"

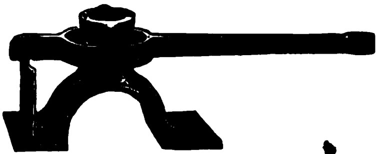
Meter resistance, *Hockin* . . . * "*Teleg. Journal,*" v. 239.
Wheatstone . . * "*Teleg. Journal,*" v. 288.

Bridge Guard. A suspended system of ropes used to warn train-men of bridges which are not high enough to permit them to stand on top of the cars. To a horizontal arm which projects over the track wires are attached, and to these pieces of rope. The height from the top of the car to the lower end of the wires is sufficient to allow a man to stand upright, but if he does so in passing under the guard he is struck by the ropes, which warn him that the train is approaching the bridge, which without such warning he might strike.

"*Railroad Gazette*" . . . . * xxiv. 627.

Bridge'pot. (*Milling.*) The socket of the mill spindle carried by the lighter-screw which adjusts the vertical height of the runner to grind close or coarse.

Fig. 425.



Arch Bridgepot.

The arch bridgepot, shown in Fig. 425, is intended to be used for straddling the driving-shaft where bevel-gear is used. On bridgepots used in portable mills the fulcrum is so arranged as to allow of placing the lighter-screw to the right or left of the meal spout at will.

Bridge Sad'dle. The block which rests upon the summit of the pier of a suspension bridge, and over which the wires pass, and upon which they rest. See Fig. 4519, p. 2011, "*Mech. Dict.*"

Bridge Test'ing Car. A car with a tank capable of being loaded to the required strain *in situ.*

A car said to be owned by the State of Connecticut, and used in testing railway bridges, is thus described: —

"The car is to be used on every railroad bridge in the State at least twice a year. It consists of an iron tank resting upon three trucks, the tank being capable of holding eighty tons of water. On the center truck are four hydraulic jacks, operated by one lever, and by these the entire weight of car and contents can be thrown upon the center truck. In case a weakness is discovered, the floodgates are opened by a single lever and the water instantly let off, relieving the bridge of 80 tons weight. The car will weigh about 60 tons, and when the 80 tons of water are added, the full test will be 140 tons. This weight may be lessened, of course, if desired." — *Chicago Railway Review.*

Brim-poun'cing Ma-chine'. A machine for shaving hat brims, to remove the shaggy fibres. See POUNCING MACHINE.

Brim Stretch'er. A machine for stretching the brims of felt hats, developing them out of the edge of the crude cone. See Fig. 427.

The brim-stretching ribs which support the brim are mounted upon a vertically reciprocating spindle which is operated by the treadle, and these ribs are provided with a spreading mechanism and are operated by the hand lever on the side of the machine. An adjustable metallic block supports the crown, and by its position determines the height of it. The upper stretching devices consist of a series of automatically reciprocating brim-stretching ribs, arrayed in a horizontal plane, equidistant from each other, in a circular line; each operating from a common center in a different vertical plane. A crank-shaft which has its bearings in the framing receives motion through the belt from a counter-shaft, and should make 500 revolutions per minute.

Through the connecting rod a reciprocating motion is given to the rocking shaft and the rods which carry the ring to which the outer ends of the vibrating stretching ribs are attached.

The hat body to be stretched, having previously been drawn out on the tip by a *tip-stretcher*, is placed upon the former of this machine and the treadle depressed, bringing the two sets of stretching ribs in working position. The hand lever is now gradually raised, and the hat-body thus spread to cause the vibratory ribs to act upon it.

When the hand lever has been raised sufficiently high to bring the spreading ribs to their full extension, the former is lowered, the hat-body shifted slightly upon it and the operation repeated until the brim is perfectly flattened out.

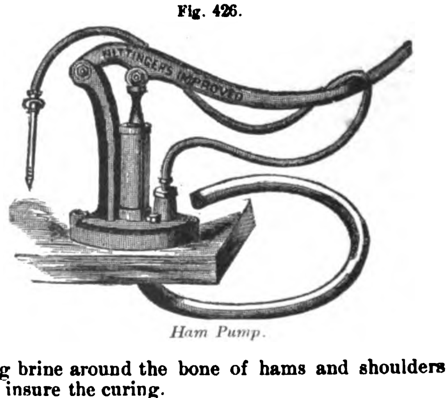
The rapid motion of the vibrating ribs enables the operator to stretch the hat while it is hot and injury by tearing is thereby prevented.

Machines made on the same principle for use in factories where all the work is done by hand are now very generally used, and but a very small percentage of all the soft wool and fur hats are now blocked in the old manner.

The finishing of fur hats is done upon a fur hat blocking machine which has an oval former, and acts upon the crown and brim simultaneously. See HAT-SHAPING MACHINE.

Brine-for'cing Pump. A pump for injecting brine around the bone of hams and shoulders to insure the curing.

Fig. 426.

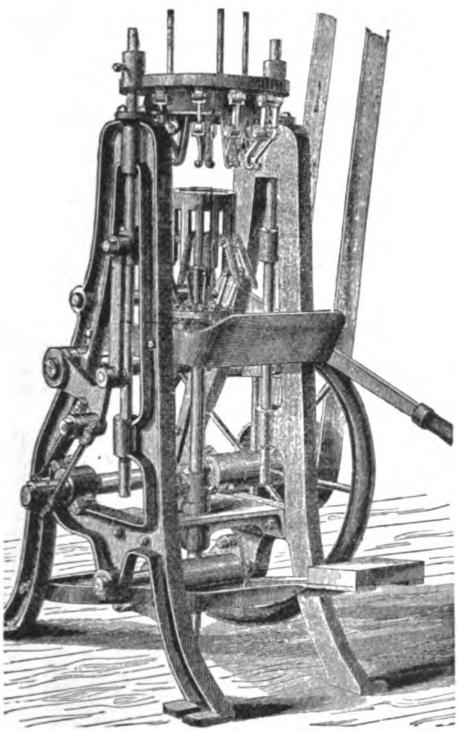


Ham Pump.

Bri-quet'. Fuel compressed into brick-like blocks. A product of increasing economic value, composed chiefly of inferior coal or coal waste, to which is added coal-tar as a cement.

France, Belgium, Germany, and even Great Britain manufacture this new fuel, France obtaining part of her supply of the raw material from Wales, and finding a market for the sale of a portion of the manufactured product in Italy, where it is used as fuel for locomotives. Machines for the manu-

Fig. 427.



Eickemeyer's Power Hat Brim Stretcher.

facture of this fuel are numerous, and several forms are shown under PEAT MACHINE, p. 1646, "*Mech. Dict.*" France annually produces about 700,000 tons of briquets and Belgium about 500,000 tons; Germany and Great Britain, respectively, manufacture large quantities. At present the use in Europe is mainly upon steamships and in locomotives. In the United States a successful attempt to manufacture compressed fuel from anthracite coal dust has been made on a large scale at Fort Ewen, near Rondout, N. Y., and to-day the enterprise is firmly established, the fuel, which is in large lumps, being supplied to steamships and locomotives. Loiseau's apparatus has attracted and deserved marked attention.

Two large manufactories of patent fuel are running in Wales, one the Crown Preserved Coal Company, of Cardiff, under the H. Walker Wood Patent, having a capacity for 500,000 tons annually. The process has been worked there since 1857.

Another, the Coal Company of Merthyr, Swansea, producing 200,000 tons annually. The composition is small coal and coal-tar pitch. The process has been carried on there for twenty years.

See FUEL, ARTIFICIAL, p. 921, "*Mech. Dict.*," *et infra*. Marseilles. *Engineering*," xxvi. 367.

Bris'tle Pro'bang. (*Surgical.*) A probang having on a section of its length a number of bristles arranged lengthwise, so as to catch over and include fungoid or other matters, and furnish a means for the withdrawal of the same. There are several forms, either a bunch of bristles tied at each end, or a frame upon which cords are strained so as to form a sort of cage.

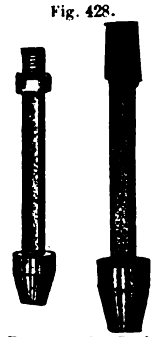
Fig. 336, p. 83, Part II., and page 5, Supplement, *Tiemann's "Armamentarium Chirurgicum."*

Brit'ish Gum. Torrefied starch; used in calico manufacture. Dextrine. See p. 691, "*Mech. Dict.*"

Broach. A reamer, for rounding or enlarging a drilled bore.

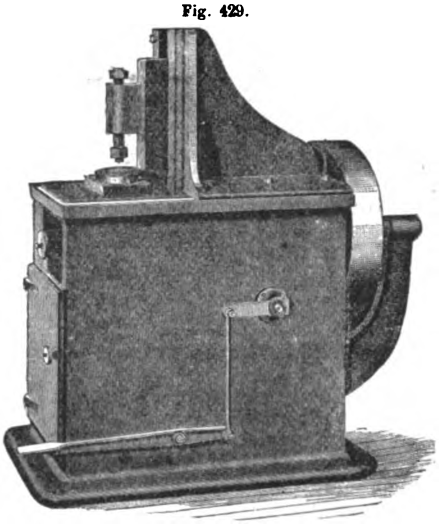
Broach'ing Press. A machine designed to make holes by the planing action of a vertically moving tool; especially useful in making holes of such diametrical form that they cannot be finished by any rotary motion, as by drilling or boring. It may be used as a slotter, and also for finishing the outside of work. The pitman which carries the slide is attached to a worm-wheel that runs in a pan of oil; a heavy balance-wheel and the Pratt friction-clutch furnish the means for a steady equable motion, and for stopping and starting instantly at any point of the stroke, which is from 1″ to 7″.

Fig. 428.



Broaches, for Rock-drilling.

Fig. 429.



Broaching Press. (Pratt & Whitney.)

Broad'cast. (*Printing.*) Matter set up to run the long way of a page, and having its top along the left-hand edge.

Broad'cast Seed'er. A machine for scattering seed upon the ground, as distinguished from one which sows it in drills.

Broadcast seeders are power and hand, and each of those kinds has as representatives two varieties: those which scatter widely, imitating the human hand in throwing, and those which sow a breadth equal to the width of the implement.

Of the power machines: The Cahoon machine acts upon a scattering principle. The seed hopper is carried in a wagon and discharges on to a wheel rotated by chain connection from a sprocket wheel on the hind-wheel axles. The rotation of the scatterer disperses the seed widely, from 16 to 36 feet in total width, according to the seed; timothy and wheat being at the opposite ends of the scale. The scattering wheel revolves in a vertical plane.

In Buist & Alden's machine the wheel is horizontal.

In the hand form of the scattering kind, the Cahoon drill consists of a bag carried in front by a neck strap, and a scattering wheel rotated by hand.

In a French form of the same implement, shown in Fig. 430, and made by Pernollet, of Paris, the scattering wheel is vertical as in the Cahoon, and the width of wheat sown is 7 to 8 meters.

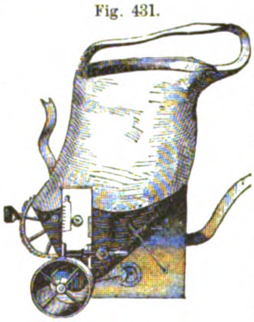
Fig. 431 shows on a larger scale the apparatus detached

Fig. 430.

Sowing with the Pornollet's Centrifugal Broadcast Sower.

from the person. An index on the side shows the condition of the opening which graduates the passage of seed according to the quantity desired to be sown.

Fig. 431.



Centrifugal Broadcast Sower.

In regard to machines for sowing widths equal to the track machines, such are both power and hand.

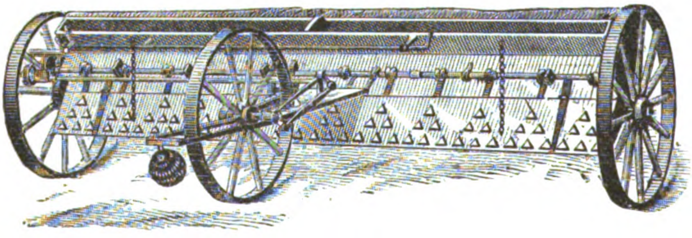
Of the power machines there are at least three varieties: —

The convertible drill, in which the shares and seed tubes are replaced by spouts which scatter the seed upon the surface of the ground, each of the eight spouts covering with seed its proportionate width of the track of the machine. Many of the American seed drills are thus convertible. In France the same practice is pursued, a broad casting spout of sheet metal being substituted for the seed-conductor. See Fig. 124, p. 113, Knight's report, "*Paris Exposition Reports*," vol. iv.

Another form of broadcaster is represented by the "Buckeye" 11-foot broad-cast sower. This has a force-feed at each of 7 openings, and has conductors which lead the seed near to the surface of the soil; but, instead of dropping it in the rear of the shares, — none of which are present, — the seed drops on a scattering plate from which it bounces on to the ground.

A third form of the machine broadcaster is that common in England and on the Continent of Europe. The seed,

Fig. 432.



Ramussen's Broadcast Seeder.

issuing from the series of spouts, falls down an board, whose length is equal to the width of the h striking against triangular studs, arranged in quinc ion, is dispersed over the whole space of ground be wheels of the machine. The machine illustrated is Danish, made by Ramussen & Co., of Stubbekjø resembles in all material respects that made by Sons, of Peasenhall, England. The Danish mach ever, is so constructed as to be capable of bein

Charcoal Broiler.

sliding on ways, a canopy to conduct th the chimney, a pit beneath for draft and a sliding cover, to contract at pleasur space above the gridiron.

Brok'en (*Masonry.*) A f stone work in continuity of co maintained. Se

Brok'en Ran (*Masonry.*) A which the level is not strictly See Range.

Bro'mine tus. The sou mine in the U is the mother l remains after the extraction of salt. The following description of the process is condensed from the "*Moniteur Scientifique*" : —

"The saline liquors, when first pumped up from the pit, mark 9° Baumé. They are evaporated in long iron boilers to 15° Baumé, allowed to settle, then farther evaporated to the crystallizing point in wooden tubs heated by steam. The first crystallization forms the salt of commerce. The tubs, five in number, are placed side by side, and every day the liquor is decanted from one to another, — from No. 1 to No. 2, then to No. 3, and so on to No. 5. The crystallized salt is removed from each tub after draining off the liquid. When the brine reaches tub No. 5 it has become mother liquor, and consists principally of chlorides of calcium, magnesium, sodium, and a little chloride of aluminium, with varying proportions of bromides of sodium and calcium. Tub No. 1 is filled every day with fresh brine, so that the process becomes continuous. The mother liquor, marking 30° to 38° Baumé, is evaporated to 45°, thus separating a new quantity of salt. The liquor is then decanted into stone stills; materials for the production of chlorine are added; and heat is applied in the form of steam injected directly into the still, until all the bromine has been eliminated and evaporized. It then passes into a condenser, and thence into a receiver."

Bronze. An alloy of copper and tin: the most ancient artificial alloy.

The molds for casting bronze articles are found in many European countries, as are also pieces of runners and sprues made in running the metal into the mold. In general, the proportions are 90 copper, 10 tin: but tables in *Wilson's* "*Prehistoric Man*," pp. 310, 312, and vol. i., p. 388, of the "*Mechanical Dictionary*," indicate various proportions and additions, in many cases, doubtless, unsuspected impurities.

The addition of a small quantity of iron, insisted upon of late as so valuable in the constitution of brasses and bronzes is seen by table on p. 61, "*Mech. Dict.*," to have been anticipated in the ancient bronze weapons of England and Ireland, the coins of Rome, weapons of South America, and the Chinese *packfong*.

Herrera specifies "crucibles to melt copper," as contained in the canoe met near one of the Guanaja islands, manned by a Yucatan cacique, his wives, children, and 25 rowers.

See also *Worsaal*, "*Primeval Antiquities of Denmark*," pp. 137, 138.

In addition to the compositions given on pp. 387–389, "*Mech. Dict.*," the following may be noted. Patents of —

Doubleday, No. 160,885. Copper, glass, antimony, tin, spelter, and lead.
Kirk, No. 201,536. Copper, tin, arsenic.

AUSTRIAN STATE RAILWAY BRONZES AND BRASS.

Bronze Black'ing. A concentrated solution of R R B methyl violet in a boiling solution of 4 parts shellac and 1 part of borax, in 15 to 20 of soft water.

Bronze Col'or-ing.

"The *soft bronze* color of medals is obtained by rubbing with a mixture of blood-stone and graphite, applied with a brush.

"*Antique green* effects are reached by dipping the metal into a solution of 10 parts by weight of salt, 10 parts of cream of tartar, 10 parts of acetate of copper, 30 parts of carbonate of soda in 200 parts of vinegar.

"*Satin finish* is produced by green vitriol or copperas and subsequent treatment with wax.

"*Old green* is obtained by several coats of acid and a final coat of wax.

"*Grayish green* is produced by sal-ammoniac." — *M. Grinand*, in Paris "*Technologiste*."

In the Japanese practice, the coloring is done in many different ways, each manufacturer having his own particular process, which he modifies according to the composition of the alloy and the color he wishes to produce. The chemicals used for this purpose are very few in number, and limited to vinegar, copper sulphate, and verdigris as the principal substances; other materials used less frequently, consist of iron sulphate, red oxide of iron, lacquer, and an infusion of *Eryanthus tinctorius*.

See BRONZING; see also PATINA, ORUGO.

Bronzed Glass. A new kind of ornamental glass, so called from its dark metallic appearance, like old bronze. It is a dark green glass, which has been subjected to corrosive vapors in such a way as to bring out the iris hues and give the appearance of great antiquity. This effect is enhanced by the classical shapes in which the vases are blown, resembling the ancient Roman glass of the museums. Viewed by transmitted light this glass is dark green, like glass colored by oxide of copper.

See IRISATED GLASS.

Bronze Paint.

Recipe: — For iron. Ivory black, 1 oz.
Chrome yellow, 1 oz.
Chrome green, 2 lbs.

Mix with raw linseed oil, adding a little Japan to dry it. It gives a bronze green. Gold bronze may be put on the prominent parts of the object, rubbing on with a piece of plush before the paint is quite dry.

Another: —

To one pint of methylated finish add 4 oz. of shellac and ½ oz benzoin; put the bottle in a warm place, shaking it occasionally. When the gum is dissolved let it stand in a cool place two or three days to settle, then gently pour off the clear mixture into another bottle, cork it well, and keep it for finest work. The sediment left in the first bottle, by adding a sufficient quantity of spirit to make it workable, will do for the first coat or coarser work when strained through a fine cloth. Next take ½ lb. of finely ground bronze green — the shade may be varied by using a little lamp black, red ocher, or yellow ocher; let the iron be clean and smooth, then take as much varnish as may be required, and add the green color in sufficient quantity; slightly warm the article to be bronzed, and with a soft brush lay on it a thin coat. When that is dry, if necessary, lay another coat on, and repeat until well covered. Take a small quantity of the varnish and touch the prominent parts with it; before it is dry, with a dry pencil lay on a small quantity of gold powder, and then varnish the whole.

Bronze Steel. Name given by Uchatius to his gun-metal alloy. The Rosthorn gun-metal, Austrian Navy brass, Parke's British gun-metal, and Overman's bell-metal, contain notable quantities of iron in their composition.

"*Scientific American*," xxxvii. 403
"*Scientific American Supplement*," 1299.
"*Engineer*," xlii. 331; xliv. 254, 310.
See also list of "*Brasses and Bronzes with the addition of Iron*," table, p. 61, "*Mech. Dict.*"

Bron'zing. Giving the appearance of bronze to a surface by a covering of metallic dust.

The surface, if of metal, is usually covered with oil varnish, and when almost dry the bronze powder is dusted upon it.

BRONZE COLORS.

Real Gold. — Made of scraps of gold leaf, mixed with honey or gum, ground on a tablet, washed and dried. Different shades are obtained by alloying with silver and copper: red, reddish, deep yellow, pale yellow, greenish. Gold powder may also be obtained by dissolving in aqua regia, and drying.

Imitation Gold. — Obtained from the waste of Dutch leaf, triturated in gum, washed and dried. The color depends on the proportions of copper to zinc. Violet and green shades are obtained by heating with oil, paraffine, or wax.

Mosaic Gold. — Tin 64.63, sulphur 35.37; soluble in hydrochloric acid, aqua regia, or boiling caustic potash. Used for bronzing plaster casts, copper, and brass, by mixing with 6 parts bone-ash and rubbing on wet.

Mosaic gold may also be obtained by heating sulphur 6 and tin amalgam 16 with mercury 1 and sulphur 4.

Or, stannic acid 8, sulphur 4.

Or, fuse pure tin 12, mercury 6, to an amalgam, and mix with flowers of sulphur 7, and sal-ammoniac 6. Heat in a retort, and after the vapors escape the mosaic gold will be found at the bottom.

Silver Bronze. — Scraps of silver foil triturated in oil.

Imitation Silver Bronze. — Imitation silver leaf similarly treated.

Mosaic Silver. — Amalgam of tin 50, bismuth 50, and mercury 25. The metals being melted and stirred and the mercury added. When cold, grind with a muller on a stone.

Copper Bronze. — Copper foil rubbed fine and ground.

Bronze Powder or Antique Bronze. — 16 copper and 1 tin beaten into leaves and ground. Bright yellow, copper 83 parts, zinc 17: orange, copper 90 to 95, zinc 5 to 10; copper red, copper 97 to 99, zinc 1 to 3.

Greenish Copper Bronze. — Copper bronze mixed with acetate of copper (verdigris). Imitates the antique *Patina*.

Patina Powder. — Bronze treated with different salts: Vinegar, nitrate of copper, sal-ammoniac, oxalate of potash, etc.

Brownish Gold Bronze. — Iron rust mixed with any of the copper bronzes according to color.

Gold-colored Copper Bronze. — Boil together an amalgam of zinc 1, mercury 12, some hydrochloric acid, a solution of tartar crystals, and copper bronze precipitated from the nitrate by iron. The color is varied by shorter or longer boiling.

Or, boil the copper bronze with a solution of 1 part gold in aqua regia; evaporate, dissolve in water 8 parts, and add ½ part ignited magnesia, then boil. The precipitate of oxide of gold is filtered, placed in a flask, and 8 parts cyanide of potassium poured over it.

Blue Bronze. — White bronzes colored with aniline blue.

SUBSTITUTES FOR BRONZING.

Tungsten Bronze. — Tungstate of soda and tungsten forming gold-yellow crystals; magenta or violet bronze, a tungstate of tungsten and potash.

Chromium Bronze, or violet chromium chloride.

Titanium Bronze, Crystallized Iodide of Lead, etc.

Coal Tar Bronzes, such as acetate of rosaniline, murexine, and green hydrochinon.

Mica Bronze. — Mica pounded into fine flakes, assorted in fineness and dusted on to a prepared or varnished surface. Colored, —

Pink, by cochineal.
Carmoisin, by bluish fuchsia.
Violet, by Hofmann's violet.
Blue, by prussian blue.,
Violet-blue, by logwood.
Green, in shades, by turmeric and aniline blue.
Golden, by turmeric.
Silver, pure mica.
Black, by logwood and litmus.

A ground of proper color must first be laid on, and the mica powder dusted on before the ground is quite dry. Excess of mica is brushed off.

For Cast Iron, without the use of metal or alloy. — The article is cleansed, coated with a uniform film of some vegetable oil, and then is exposed in a furnace to the action of a high temperature, which, however, must not be strong enough to carbonize the oil. In this way the cast iron absorbs oxygen at the moment the oil is decomposed, and there is formed at the surface a thin coat of brown oxide, which adheres very strongly to the metal, and will admit of a high polish, giving it quite the appearance of fine bronze.

Process for producing a Green Bronze on Iron. — One part of sylvate of silver is dissolved in twenty parts of oil of lavender, forming a sort of varnish, which imparts a beautiful and permanent green bronze appearance to cast and wrought iron, sheet iron, and wire. The surface to be bronzed is cleansed and dried, but need not be polished. The varnish is thinly applied with a camel's-hair brush, and the object heated quickly to 300° Fah. The proper temperature is indicated when the article shows an even bright green color. — *Paul Weiskopf in "Dingler's Journal."*

For Cast Iron. — Coat the surface of the iron (cleaned by acid and well etched) with ferrocyanide of copper, applied with linseed oil. Before this coating is entirely dry, apply bronze powder by means of a fine brush, and then polish with a burnisher. When the surface is entirely dry, wash and etch to the color desired. The use of the alkaline sulphides for the etching produces olive-green and black colors, which closely resemble those on the Japanese bronzes.

For Rifle Barrels, to Prevent Rusting. — A modification of the Barff process. Pass the current of air slowly and at a high temperature over the articles to be covered, care being taken to secure an entirely free circulation about the articles. Articles exposed for five hours at a temperature of 536° Fah., resisted the action of emery paper and dilute sulphuric acid.

See various recipes and processes, p. 389, "*Mech. Dict.*"

See, also, BRONZE PAINT.

For giving Bronze Color to articles of Copper, Brass, or Zinc. — *Roncou's* process: Treat with a composition of —

Sulphate of potassium	6
A salt of lead	6
Ammonia	12
Acetic acid	8
Hydrochloric acid	8

Antique Imitation. — Apply alternate washes of dilute acetic acid and exposure to the fumes of ammonia.

A quicker method: Immerse the articles in a solution of

1 part perchloride of iron in 2 parts of water. The tone assumed darkens with the length of immersion.

Or the articles may be boiled in a strong solution of nitrate of copper.

Or they may be immersed in a solution of 2 ozs. nitrate of iron and 2 ozs. hyposulphite of soda in 1 pint water. Washing, drying, and burnishing complete the process.

Chinese Process of Bronzing Copper.

The following ingredients are pulverized and mixed: —

Verdigris	2
Cinnabar	2
Sal Ammoniac	5
Alum	5
Beak and liver of duck	2(!)

Make into a paste with vinegar and spread over the scraped surface of the copper. The object is exposed an instant to the fire, cooled, and the operation repeated until the required tint is attained. Addition of sulphate of copper gives a browner tint, and borax a yellower shade. The color is durable and not affected by air or rain.

Bronzing Wood, Leather, Paper, etc.: Dissolve gum lac in four parts by volume of pure alcohol, and then add bronze or any other metal powder in the proportion of one part to three parts of the solution. The surface to be covered must be very smooth. In the case of wood, one or several coats of Meudon or Spanish white are given, and the object is polished with an iron of proper shape. The mixture is painted on, and when a sufficient number of coats have been given, the object is well rubbed; the coating obtained is not dull, but can be burnished. A transparent varnish is applied to preserve the metallic appearance thus obtained.

Soluble Glass in Bronzing. — "*Bottger* varnishes objects of wood, porcelain, glass, or metal with soluble glass, and then shakes bronze powder over them." — *Dingler's Journal.*

Plaster Casts. — The casts receive first several coats of a rapidly drying linseed oil varnish. When the surface has been thickly and evenly covered, and the varnish is completely hardened, another coat is given with a varnish composed as follows: Linseed oil varnish, 1 part: copal varnish, 1 part; oil of turpentine, 1-15 part. The copal varnish must be free from alcohol. This varnish will be dry enough in from 18 to 24 hours; the coat must be quite glossy and adhere slightly to the fingers. Powdered gold, silver, or copper bronze is now applied with a soft brush. The surface is then rubbed with cotton wadding, by which a very beautiful finish is imparted to it. The most important point is that the linseed oil varnish is perfectly dry before the other varnish is applied, and the latter must be of the proper consistence before bronzing it. — *Chem. Zeitung.*

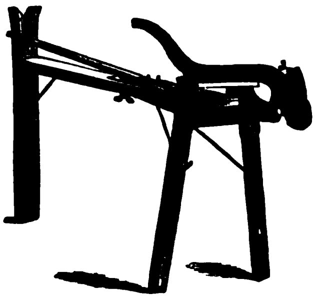
Broom Sew'ing Ma-chine'. A species of vise, with clamping jaws operated by a screw so as to firmly hold the broom while it is being sewed.

Broom Trim'mer. A rack with a bevel-slotted aperture, on the end of the rear post that surmounts the table, and holds the broom with the assistance of the adjustable clamp on the table, while the pivoted knife trims it off.

Fig. 436.



Broom Trimmer.

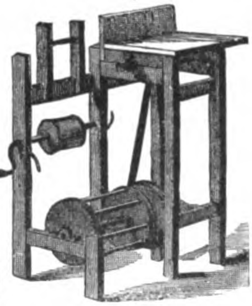
Broom Vise. A clamp in which the round bunch of corn brush is flattened and held while being sewn.

They are made to work with levers or with screws. Fig. 437 shows the former.

Fig. 437.

Broom Vise.

Fig. 438.



Broom Winder.

Broom Wind'er. A machine for winding corn brush, and tying it with cord or wire into a round bunch preparatory to flattening it in the vise and sewing. Fig. 438.

Broth'er-hood En'gine. A popular form in Britain of a THREE-CYLINDER ENGINE, which see. See, also, DYNAMO-ELECTRIC ENGINE, *infra*.

Brown'ing. To confer a brown tint on iron or steel, dissolve in —

Water	4 parts.
Crystallized chloride of iron	2 parts.
Chloride of antimony	2 parts.
Gallic Acid	1 part.

Apply the solution with a sponge or cloth to the article and dry it in the air. Repeat this any number of times, according to the depth of color which it is desired to produce. Wash with water and dry, and, finally, rub the articles over with boiled linseed oil. The metal thus receives a brown tint and resists moisture. The chloride of antimony should be as little acid as possible.

Bruis'ing. (*Leather.*) Doubling the grain side of a hide together, and rubbing it on the flesh with a graining-board.

Brush. Machines for making brushes have been adapted to manufacture certain kinds. The majority of kinds are hand-made. See pp. 392–394, "*Mech. Dict.*"

Brush binder, for clamping the bristles to the handle, *Blair*, * "*Scientific American*, xxxiv. 118.

Brush machine.

Woodbury, * "*Manufacturer & Builder*," x. 198.

Woodbury, * "*Vienna Exposition* (1872) *Report*," vol. iii, p. 309.

Woodbury, * "*Scientific American*," xxxviii. 351.

In the making of artists' brushes the following bristles and hair are employed: —

Hogs' bristles, varnishing brushes.
Bears' fur, varnishing brushes.
Badger hair, graining and gilding brushes.
Sable tail hair, finest artists' brushes.
Camels' hair, second only to the sable.
Ox hair (from the insides of the ears), striping and lettering brushes.

Ashworth's brush-comb, for the hair or the manége, has steel wires attached to an elastic caoutchouc membrane on the handle.

Brush Dike. A device for causing deposits to take place, and for deflecting the current in localities that are to be built out.

The floating brush dike is made by taking saplings from 20′ to 30′ long and from 4″ to 6 or 8″ in diameter, and nailing, or fastening to them with wire, scraggy brush of any kind obtainable in the locality. This forms what is known as the *weed*. Instead of the saplings rope may be used to hold the brush. To one end of this *weed* is attached an anchor of sufficient weight to hold it in position against the current; to the other a buoy to hold up the downstream end and prevent it from going to the bottom under the pressure of the current against it. These *weeds* are placed from 10 to 20′ apart, thus forming the floating dike.

Their action is to check the current gradually without producing that scouring effect to which the solid dike gives rise. This done, a portion of the material that is rolling along the bottom or being carried down in suspension is deposited, and causes a rise in the bed of the river, which changes its channel to the direction desired.

See DAM; DIKE; FLOATING BRUSH DIKE, etc. See list under HYDRAULIC ENGINEERING.

Brush Hold'er. (*Surgical.*) A staff for a brush for applying medicaments to the larynx, œsophagus, conjunctiva, etc.

Figs. 97, 343, 344, 349, 349 *b*, Part II., *Tiemann's* "*Armamentarium Chirurgicum.*"

Brush'ing Ma-chine'. 1. A machine used to brush up the nap on woolen under-shirts, jackets, drawers, or stockings, and put a good surface on the goods.

It consists of a framing of cast-iron, with two fluted rollers for drawing in the goods, also a pair of wooden rollers clothed with teazles or wire cards, according to the quality of the goods to be operated on. The fluted rollers revolve slowly and take in the goods whilst the covered rollers revolve at a great speed, brushing the goods as they are passed through.

2. Curtis & Marble's machine for dressing and cleaning the surfaces of piece goods, has calendering rolls and dampening box attached. It is arranged with one brush and two card rolls for each side of the goods, and is intended to finish them by once running through. It is entirely covered in, and has a fan-blower arranged underneath to carry off dust and lint.

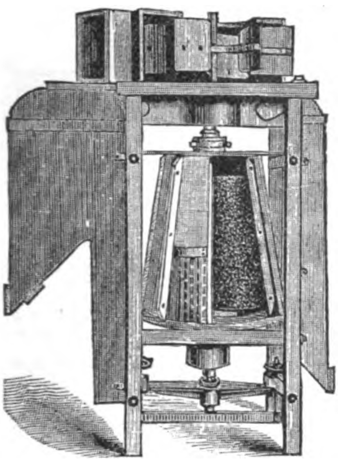
3. A wheat-cleaning machine. In some cases combined with a smutter, so as to have the scouring quality of the latter with the polishing action of the former.

In the Becker brush the concave jacket is of punched iron and steel wire, between which and the brush the wheat passes, polishing and scouring and taking the dust out of the crease, and the fuzz off the end of the berry, without disturbing the bran. The brush may be raised or lowered while in motion. A suction fan removes offal. Fig. 439.

The "Victor" brush has a series of annular inclined trays and brushes, through which the wheat passes in succession. It is known as a *double-brush*, the grain passing moving and stationary brushes, while a blast of air is drawn by an aspirating fan in the reverse direction. Fig. 440.

The brushing is done by a series of concave circular brushes attached to an upright shaft, which act against an opposed series of convex brushes, *c*, which remain fixed to the case. The surfaces of the brushes coalesce when at the closest adjustment, but when at work are separated by a sufficient distance to give passage to the wheat. The grain falls upon the upper surface of the fixed upper brush, gravitates to the center, and is caught by the upper revolving

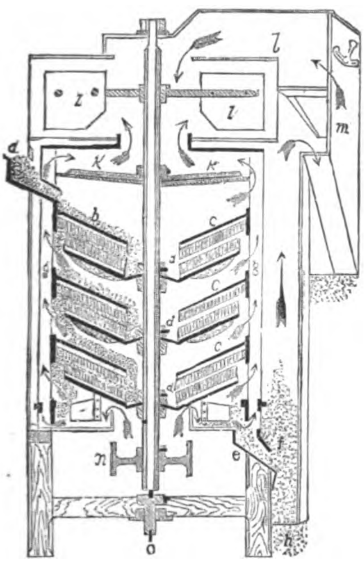
Fig. 439.



Becker Cone-brush.

brush, driven up the incline by centrifugal force, and dropped again to have the same operation twice again re-

Fig. 440.



" *Victor* " *Brush Scourer.*

peated. Each set of brushes has an independent ventilator which carries the dust upward to the suction fan, whence it is expelled from the machine.

e is the final discharge spout; *n* the driving drum; *g*, ventilator shaft; *k*, cover of brush chamber; *l*, fans and fan-case.

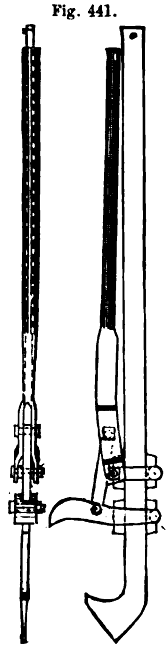
Brush Jack. (*Hydr. Engineering.*) A tool for grasping brush and confining it while being bound into fascines for dikes or dams. The saplings are pinched between two hooks.

It is also used in making mats; the saplings and brush being placed in layers, the hook is thrust through, engaging the lower pole, and the upper hook thrust down, pinching between them a mass of limbs, which are then tied to the pole by the aid of the needle. The handle has two hook-clutches which are slipped over the upper end of the rod, and the upper hook is worked down by using the handle in the manner of a pump-brake. See Brush Needle.

Brush Nee′dle. (*Hydr. Engineering.*) A needle for passing a wire around a bunch of brush in a mat. Fig. 442.

The wire is passed through the eye of the needle-bar and pushed through the mat. A man below removes it, and on the needle being pushed through on the opposite side of the pole replaces the wire in the eye to be drawn back. The wire is cut, the two ends twisted together, and the jack released by prying or hitting the lower or hook clutch on the back end.

Fig. 441.



Brush Jack.

Brush Plow. A strong plow, the land side welded to the share, which latter is of hard-rolled untempered steel. Adapted for plowing among roots and brush in new ground. Fig. 443.

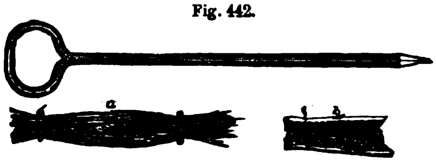
Buck′board. A spring-board wagon, Fig. 444, in which the yielding of the board gives the elasticity to the seat.

In the illustration the buck-board is combined with thorough-brace springs, *F*, *G*, which add to the ease of the rider. Side bars, *B*, connect the front bolster, *A*, with the rear axle. *C C* are side braces.

"*Sc. American*," * xxxviii. 166.

Buck′et. 1. A vessel for holding or lifting water.

Fig. 442.

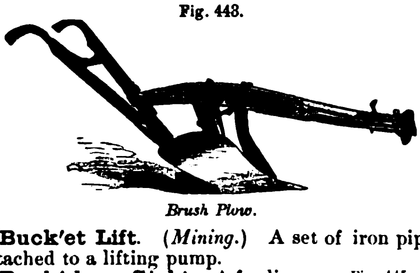


Brush Needle.

2. A valved plunger in a pump-stock.

Bucket plunger pump, *Wright* * "*Engineering*," xxi. 420.
Rubber bucket for chain pumps.
Kenyon . . . . * "*Sc. American*," xxxvi. 310.
Bucket ear, *Darkin* . . . . * "*Sc. American*," xxxv. 206.

Fig. 443.

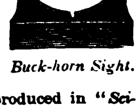


Brush Plow.

Buck′et Lift. (*Mining.*) A set of iron pipes attached to a lifting pump.

Buck′-horn Sight. A fowling-piece sight with a branching horn on each side of the sight-notch.

Fig. 445.



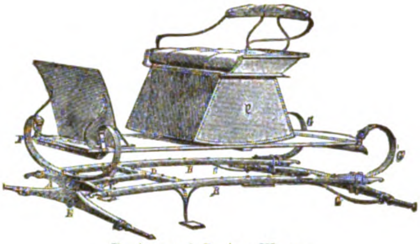
Buck-horn Sight.

Buck′skin Loom. A German pattern-chain loom, with certain peculiarities, and named from the dense and soft character of its product.

"*Zeitschrift für Textil-Industrie.*" Reproduced in "*Scientific American Supplement*," * 2705.

Buck'wheat Hul'ler. A machine for removing the hull of buckwheat before grinding, by

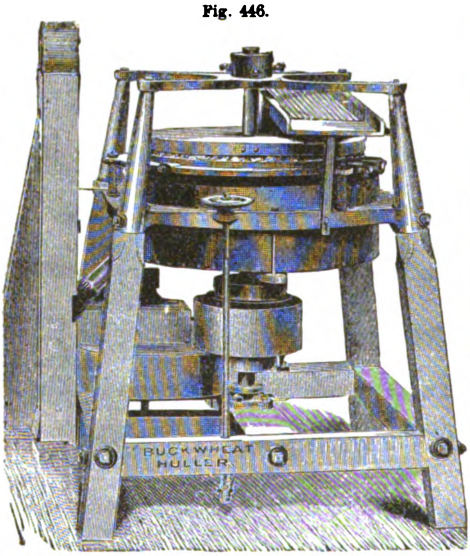
Fig. 444.



Buck-board Spring Wagon.

passing between sandstones, adjusted by tram-studs. The upper stone is stationary, and can be turned over to use either surface and utilize nearly the whole thickness of the stone. A riddle removes foreign matters from the grain before it reaches the stone.

Fig. 446.



Buckwheat Huller.

The machine has a separating trunk and fan by which the hulls are separated from the grain, and the former blown into a refuse trunk.

Cranson's * "*American Miller*" . . . . viii. 336.

Buck'wheat Shuck'er. Another name for the buckwheat huller, which see.

Bud'dle. A species of ore-separating device, using water on an inclined surface. See Fig. 962, p. 398, "*Mech. Dict.*"

Richards's buddle is on the principle of the Barker mill, the water and slime escaping at the ends of hollow arms projecting from a hollow and rotating shaft, and received on a circular table which has a slightly convex surface.

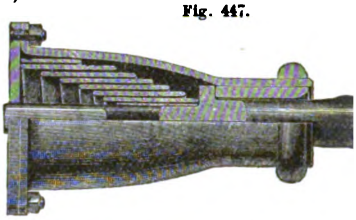
"*Mining and Scientific Press*" . . . * xxxv. 153.

Buf'fer. 1. A block of India-rubber placed on furniture to prevent the defacement of walls by contact of the furniture. A door-stop.

2. A spring block or pad to receive the impact of connected or colliding railway carriages in a train, to absorb the jar.

Fig. 447 is a British form, made by Ibbotson, of Sheffield, England. Other forms are sh 399, "*Mech. Dict.*"

Fig. 447.



Turton's Wrought Iron Spring Buffer

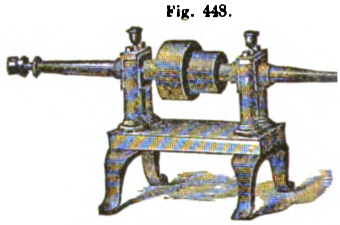
Buf'fing. (*Leather.*) Taking off thin from the grain side with a buffing-slicker skin is very thin; the object being to n hide imitate calfskin. The operation is fi whitening.

Buf'fing Lathe. A polishing lathe

Fig. 448.

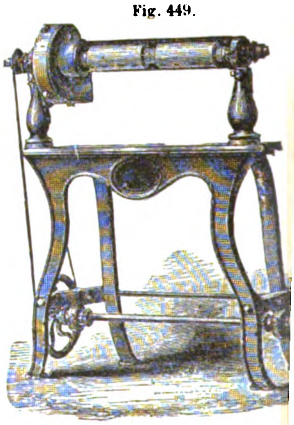


Buffing Lathe.

silver and nickel platers, etc. The buffer cotton, walrus hide, or other material, is the end of the arbor, which is shown secured by the screw-nut. The buffer is emery, crocus, rouge, rotten stone, put etc.

Buf'fing Ma-chine'. A machin wooden roller covered with sand-pape

Fig. 449.



Shoe-sole Buffer.

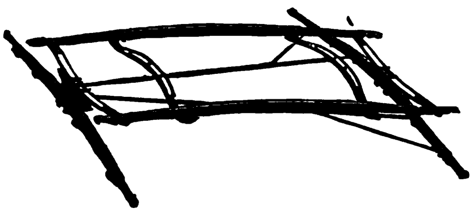
for buffing shoe-soles, etc. A suction upon the same shaft and draws the partially enveloping sheath and disch duct.

The paper is held by a clamp, dispensing with nails.

Bug'gy Spring.

The Brewster spring has half-springs interposed between the axles and the side bars, and other half-springs between

Fig. 450.

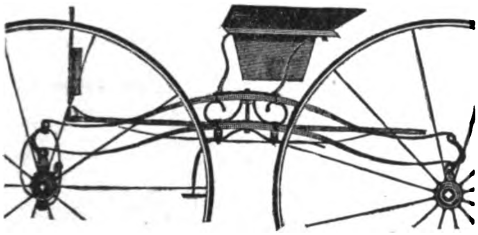


Brewster Side-bar Wagon Spring.

the body and side bars, giving the effect of a full elliptic spring, while retaining the modern and stylish appearance of the half-spring wagon. They can be made lighter, hung lower, and are as suitable for country roads as the full elliptic spring wagon.

The "Dexter" spring consists essentially of two "Concord," or side springs on each side; one spring above the

Fig. 451.



"*Dexter*" *Spring.*

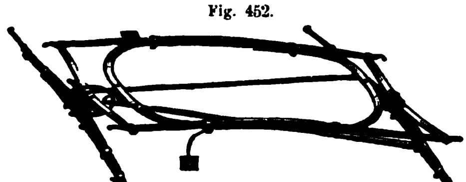
other and parallel to it. The two springs are rigidly connected at their centers, and pivoted at their ends to spring links above or on either side of the axle and spring-bar. The spring-links are rigidly attached to the head block and rear axle respectively.

The parallel motion of the springs prevents rocking of the axles. One spring being above the other prevents side motion and the settling of the body to one side. The absence of a reach allows either wheel to pass over an obstruction almost independently of the other wheels. The elasticity of the springs takes much strain off the fifth wheel, and cushions the stroke when striking an obstruction.

Patents, June 16, September 15, 1874, June 15, 1875.

The Stiver's circular combination spring has a circular

Fig. 452.



Stiver's Circular Combination Spring.

spring used in connection with end half springs, securing the effect of the full elliptic spring.

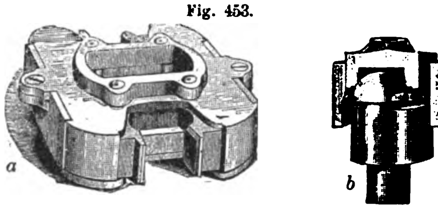
Bu'gle. (*Add.*) The simple bugle or clarion is written on the G clef like the trumpet. It possesses 8 notes. There are bugles in B♭, C, and in E♭. The keyed bugle has 7 keys which traverse chromatically a compass of more than two octaves from B♮ beneath the stave up to C above. The bugle with *pistons* or with cylinders has a lower compass than the keyed.

Buhr Dress'er. An implement for channeling and facing millstones. See MILLSTONE DRESSER; FURROWING AND FACING MACHINE.

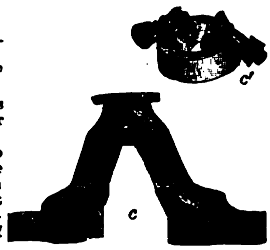
Buhr Dri'ver. The stud or projection on the millstone spindle which acts upon the bail of the millstone to drive the latter. The ordinary device is shown at G, Plate XXII., "*Mech. Dict.*," article "*Grinding Mill.*" The bail is also called a balance-rynd.

Fig. 453 shows several forms of drivers.

Fig. 453.



Buhr Drivers.



a, is the Duvall central-cross mill-buhr driver.

b, is the "Universal" buhr-driver.

c c', show Sergeant's back-lash bail mill-buhr driver.

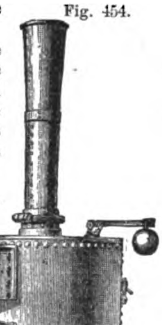
Each of them aims to have a perfect drive free from rattle and with such a degree of freedom that the runner stone shall adjust itself to the face of the bed-stone.

See "*American Miller*," * vii. 300, and elsewhere.

Buhr Rub'ber. A block composed of emery and a cement; used in cleaning, sharpening, and facing down buhrs. *Millstone levelers, Furrow dressers*, are synonyms or analogous devices.

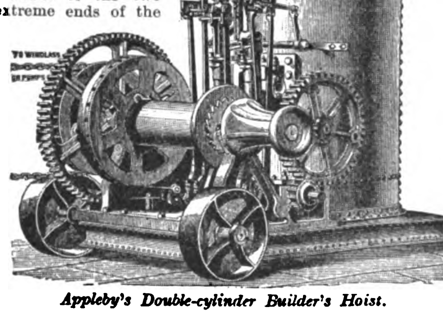
Build'er's Hoist. A form of steam-hoist used in lifting stone, brick, mortar, lumber, etc., in constructing buildings. The cage, the barrow, or the material, as the case may require, is suspended by a rope from a tackle, the fall passing to the drum.

Fig. 454.



Of a larger size, but of the same general construction, are hoists for railways, docks, and harbors, for lifting up to three tons. More powerful engines assume a substantially different form.

When employed for hoisting building materials, the engine is usually put down in a central position, and the chains or ropes are carried away in opposite directions to the two extreme ends of the



Appleby's Double-cylinder Builder's Hoist.

works, and there hoist the bricks, mortar, etc., in barrows on to the scaffolds, along which they are wheeled to serve the bricklayers.

The hoists are usually made with two speeds: one for ordinary building work, and a slow speed for hoisting columns and girders, timbers, stones, etc. The weight lifted direct from the barrel is about 1,500 pounds, and for heavier loads blocks and falls are used. The size employed for lifting barrows is 3-horse power nominal, but they are made up to 12-horse power, and with single or double cylinders. Fig. 454. The ends of the shafts are extended, so that a capstan, a pump arm or pulley may be fitted for transmitttng power for other purposes, and each engine has reversing gear and all the usual appliances.

Build'er's Knot. A form of knot shown at 27, Fig. 2777, p. 1240, "*Mech. Dict.*"

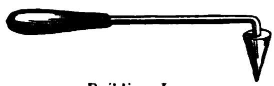
Build'ing Block. Material shaped into blocks for building. See

Clayton	* "*Scientific Amer.*," xxxv. 242.
Hollow concrete	"*Scientific Amer.*," xxxv. 406.
Stone, marble, cement, etc.	"*Scientific Amer. Sup.*," 2020.

See also BÉTON; CONCRETE; STONE, ARTIFICIAL, etc.

Build'ing Iron. (*Electrotyping.*) A heated iron applied to a strip of wax to cause it to flow down from the point on to the blank of the model in order to make corresponding depressions in the plate in the larger spaces where there is no type.

Fig. 455.

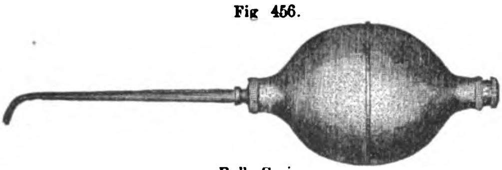


Building Iron.

Build'ing Wax. Wax used in building up the blanks in the molds for electrotype plates. It is cut in strips 8″ to 10″ long by ⅜″ wide, and must be kept dry.

Bulb Syr'inge. A dentist's syringe used for blowing debris from cavities after excavating.

Fig 456.



Bulb Syringe.

A valve in the base end of the bulb admits the air instantaneously.

Bulk'head Door. A door in the bulk-head of a ship built in compartments. It is to be capable of instant closure, and self-fastening. Some are closable from the deck in emergencies. See

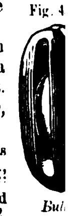
* *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," iv., article "*Boulets*," Figs. 3426 *et seq.*

2. (*Nautical.*) Or jib-sheet block; the l name indicating the purpose. Made of *lignum vitæ.*

Fig. 4



Bul

Bul'let For'ceps. (*Surgical.*) An instrument to be introduced into a wound to grasp and extract a bullet. See BULLET EXTRACTOR, Fig. 970, p. 402, "*Mech. Dict.*"

The United States Army bullet forceps has scoop-shaped ends. Fig. 115, p. 40, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Hamilton's bullet forceps is a long-nosed pincers with toothed jaws. Fig. 124, p. 42, *Ibid.* It resembles the *sequestrum forceps*, Fig. 4884, "*Mech. Dict.*"

Thomasin's has scoop and claw. Fig. 128, *Tieman*

Gross's has loop and claw. Fig. 123 *b*, *Ibid.*

Bul'let In'stru-ments. (*Surgical.*) ments used in exploring for and extracting from the person.

They are known by names which are expressive uses and application: —

Bullet forceps.	Bullet extractor.
Bullet scoop.	Bullet screw.
Bullet seeker.	Bullet probe.

Bul'let Ma-chine'. (*Cartridges.*) l fed in bars, which are 2′ or 3′ long, and h diameter of a bullet; the compressing and dies cut off pieces, compress and shape ther

British, "*Ordnance Report*," 1877, Appendix L., Figs. 97*x*–97*z*. The process is about as follows: —

At Woolwich: The melted metal is poured into s and as soon as it solidifies, but before it is cold, it by hydraulic pressure through cylindrical holes in t long strings. This process is to prevent the forma bubbles in the bullet, which would cause it, whe swerve from its course. The leaden strings are tl ried to the bullet-molding department, where th into lengths and roughed; then shaped in one ma finished in another. They have now to be plugg plugs were formerly made of wood, but are now from a special powder, which solidifies after bei into form.

Bul'let Patch'ing Ma-chine'. A for enveloping the cylindrical portion of lets with paper, to prevent the "leading grooves of the barrel.

In Borchardt's machine, the operating arrang on a circular table, supported by a hollow standa which an upright shaft passes from the actua that runs under a false floor. The connection friction wheels, which insures the instant stop machine in case of any impediment. The bull to the machine by hand, and the patch is pres bullet and secured by a minute drop of mucilag matically, and is rolled closely around the bullet tion of flexible rolls, at the rate of 45 or 50 pe about 20,000 per day of ten hours, including sto operatives are required to run the machine pro action of the machine is easily controlled by mea lever and clutch. The machine may be adapted and styles of rifle projectiles. The bullet-pat out with dies. The patches require damping to and uniform folding.

Bul'let Scoop. (*Surgical.*) An i with a scoop-shaped end, to be used as a tractor, the scoop being passed behind tl

Tiemann's "*Armamentarium Chirurgicum*," Fig. 116.

Bul'let Screw. (*Surgical.*) An with a fine gimlet-screw point, to be s a bullet as a means of withdrawal.

Tiemann's "*Armamentarium Chirurgicum*," Fig. 119.

Bul'let Seek'er. (*Surgical.*) An of the nature of a probe with an enlar introduce into a wound to find the bull the jar of impact or by the coloration of the bulbous head of the instrument.

The references are to Part I. of *Tiemann's "Armamentarium Chirurgicum."*

Tiemann's bullet seeker has a burr head which acts as a rasp upon the bullet and shows traces of contact. Fig. 117.

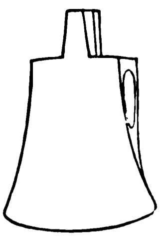
Nélaton's has a rough porcelain head which is marked by contact with the lead. Figs. 120, 126.

Tiemann's bullet seeker, Fig. 121, has a flexible stem.

Sayre's instrument has a vertebrated stem, and follows the windings of a deflected bullet. Fig. 122.

See, also, *Bullet Probes*, pp. 40, 42, as above, and p. 403 of *"Mech. Dict."*

Fig. 459.



Bull-head Axe.

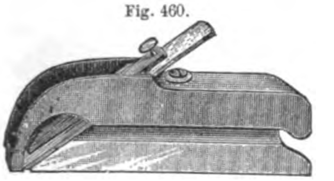
Bull′-head Axe. A poll-axe. One with a small poll for stunning a bullock, by striking it on the forehead.

Bul′lion Point. (*Glass.*) The thick portion at the center of a disk of crown glass.

Bull Net. (*Fishing.*) A large hoop-net, worked with ropes and blocks.

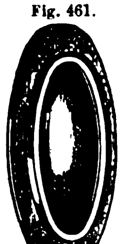
Bull′-nose Rab′bet Plane. A plane with the bit at the end, in order to enable it to work up close into corners. Named from a fancied resemblance to the muzzle of a bull. It is made open or close by a screw on top.

Fig. 460.



Bull-nose Rabbet Plane.

Fig. 461.

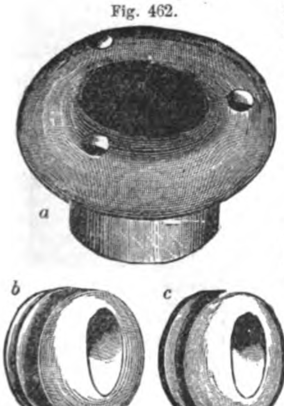


Bull's Eye.

Bull's Eye. 1. A strong round glass in a metallic frame let into a deck or side of a vessel to give light to a cabin. Fig. 461.

2. A form of rope-leader (Fig. 462) without a sheave. Known by other names also, *lizard* for instance.

Fig. 462.



Bull's Eye.

a. Floor bull's eye of lignum vitæ.
b. Lignum vitæ bull's eye for iron straps.
c. Bull's eye for wire or hempen rope.

Fig. 463.

Bull's-eye Condenser.

Bull's-eye Con-den′ser. (*Optics.*) A means for condensing the light from a lamp, or of obtaining parallel rays from diverging ones. It consists of a plano-convex lens of deep focus. Fig. 463.

Bump. (*Fire Arm.*) The corner of the stock at the top of the heelplate.

Bung. Several forms of automatic vent, the siphon, gravitating ball, and separated chamber and ball, are shown in Figs. 2554-2556, *Laboulaye's "Dictionnaire des Arts et Manufactures,"* tome iii., ed. 1877, Article *"Vin."*

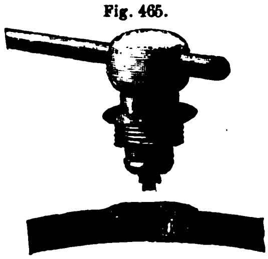
Fig. 464.

Talley's Bung and Vent.

Talley's bung has a vent in a recess, so that the bung may be driven flush with the outside of the cask. The vent has side openings and a piston valve.

Bung Buck′et. Also known as a *velinche*, *water thief*, *thief-tube*, etc. See Fig. 6925, p. 2696, *"Mech. Dict."* A *sampling* tube. A tube open at both ends is inserted at the bung-hole; the upper end being closed with the finger, the tube with its contents is withdrawn.

Fig. 465.

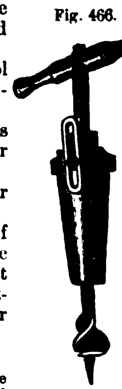


Cornell's Screw Bung Bush and Wrench.

Bung Bush. More correctly, bung-hole bush. The bush is tapering inside and outside, the outer surface having a screw thread for screwing into the bung-hole. The wrench for screwing the bush into place consists of a shank and a conical plug or core; the core has an irregular base, around which are loosely fitted a series of sections, which press equally in all directions against the interior of the bush as the core is rotated.

Bung′-hole Bor′er. An auger and annular reamer. It bores a complete round hole, regular taper, and holds its own chips. Fig. 466.

Fig. 466.



Bung-hole Borer.

Bung′-hole Brush. A tool for cleaning the insides of barrels.

The illustration, Fig. 467, shows it in position for entering, and for operating, respectively.

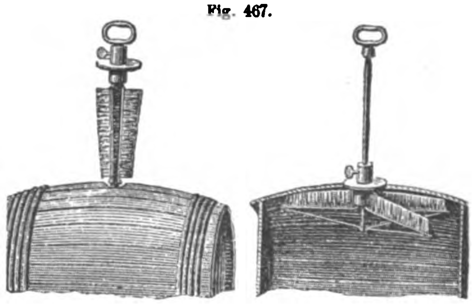
Bung Lathe. A lathe for turning taper bungs. Fig. 468.

That shown is by Arbey, of Paris. It is a small special lathe with an oblique tool on the rest which slides transversely in cutting down, and in adjusting for bungs of different diameters.

Bung Ma-chine′.

In Kirby's bung-cutting machine the square blocks are placed in a vertical pile in the hopper, and fed automatically one by one to the plunger, by which they are forced through

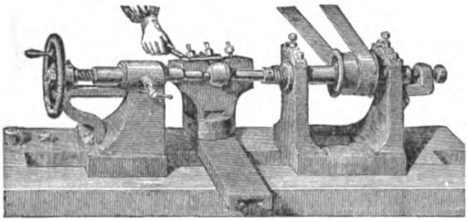
Fig. 467.



Bung-hole Brush.

the circular cavity of the cutter, and formed into cylindrical blanks. Each block as it is fed into the machine serves as a cutting-board for the next preceding block. The bungs are subjected to a great pressure so as to condense the wood.

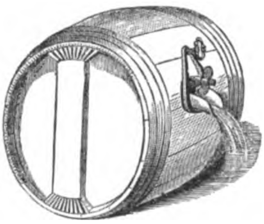
Fig. 468.



Arbey's Bung Lathe.

Bung Spout. An attachment to a cask at the bung-hole to form a lip for the latter, and enable the contents to be discharged without dribbling. Especially intended for heavy oils and molasses.

Fig. 469.

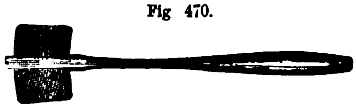


Bung Spout.

Bung Start. An instrument to start a bung by beating the bung stave of the cask. A *flogger*.

Bun'ion Ap'pa-ra'tus. (*Surgical.*) An apparatus which permits

Fig 470.



Bung Start.

freedom of motion in the vertical plane while the malposition of the toe is gradually rectified by constant lateral traction. The apparatus consists of a delicate lever of spring steel, with an oval ring in the center which is provided with hinges at its anterior and posterior margins. It is attached to the instep by a laced band, and the toe to the extremity of the spring by a piece of webbing.

Fig. 78, p. 39, Part IV., *Tiemann's "Armamentarium Chirurgicum."*

Bun'sen Bat'te-ry. (*Electricity.*) One having amalgamated zinc in sulphuric acid and carbon in nitric acid, with an intervening porous cell.

Prescott's "*Electricity*," * p. 66; Ganot, * 687, 688.
Noad, London, 1859, * 281.

Azapis' improvement consists in replacing the acidulated solution of the Bunsen by the cyanide of potassium, etc. "*Scientific American*," xxxviii. 266; xliii. 266.

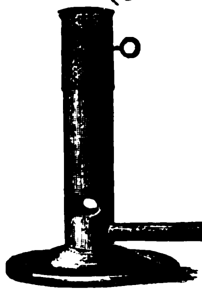
Fitzgerald, mod. of Bunsen: depolarizes by a secondary current, calcic dihydro-chromate is substituted for the nitric acid. "*Scientific American Supplement*," 764.

Bun'sen Burn'er. A form of gas burner, the invention of Bunsen, and especially adapted for heating. Its performance depends upon the proper admixture of gas and air. See 14 Figures, pp. 2411, 2412, "*Mech. Dict.*"

"It can be made of glass. A tube of glass, 4″ or 5″ long by ¼″ to ½″ wide, is taken, and by blowing out the glass, heated at two points by the pointed flame, the air holes at the bottom are produced. The gas is introduced at the center of the bottom of the tube by an upward-bent glass qu tube, with the delivery end shaped like a cross (X), a fo well adapted to mix the rising current of gas with the i This tube is fastened to the lamp by a foot, made of plas of Paris, in which it is imbedded. A short piece of glass t ing may be fastened by a rubber coupling to replace fr tures. This lamp is much better for the flame reactions th the ordinary metal lamps." — *Dingler's Journal.*

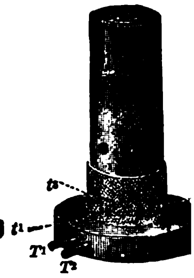
Wallace's improved Bunsen burner has an adjustable of perforated metallic plate, which enables it to burn a m more inflammable mixture of air and gas than is poss with the ordinary burner. The tendency to light withi also completely prevented, whatever may be the press quality, or quantity of gas passing. By raising the ca the necessary height a perfectly solid flame is obtaine a novel and valuable feature, since it allows any subst to be heated to be put much nearer than usual to the ce of the flame without interfering with combustion. It ca made from one inch to two inches in diameter, and is c ble of burning as much as 40 cubic feet of gas per hour.

Fig. 471.



Wallace's Solid Flame Bunsen Burner.

Fig. 472



Godefroy's Bunsen Burner.

M. Godefroy's new burner, Fig. 471, is composed c concentric sheet-iron cylinders. The first and thi pierced with lateral holes at the base. The intervals b the cylinders communicate, some with the pipes, t_1 joining the exterior gas tube, T, and others with the t_3, t_4, which unite with the tube, T_2. Wire gauze pl the base of the apparatus prevents the flame from flic while it regulates the introduction of the air. Or internal cylinders may be used if desired, in which high and regular white flame is produced.

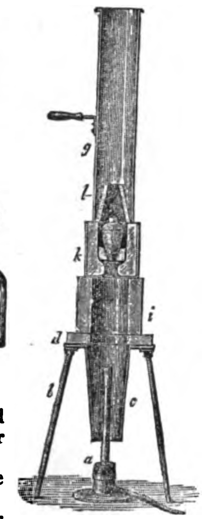
Single-jet Burner Furnace.

Fig. 475.



Bunsen Crucible Furnace.

with a single jet burner and crucibles in position on their rings.

Bun'sen Lamp. See Bunsen Burner.

Bun'ter. The bumper or buffer of a railway car. The bar on the front end of the car, which strikes against a similar bar on an adjacent car in coupling. It often forms the draw-head. See Buffer.

Fig. 476.

Buntline Leader.

Bunt'line Lead'er. An eyelet for rope, — specifically for a buntline.

Buoy. The illuminated buoy is the invention of a German, *Pintsch.* The buoy is made the recipient for a large body of compressed, rich, and heavy gas, produced by distilling shale or any fatty material. An ingenious regulator provides for the regular supply of the lamp, which will burn three months, night and day, with only one filling, the light being visible at a distance of about four miles. An electric lighting apparatus might be employed, so that the light could be extinguished at sunrise and restored at night, giving a much longer duration to the working of the buoy.

* "*Engineer*" . . . . xlvii. 289.

The illuminated buoy of Lieut. Cook, R. N., is mentioned under Buoy, "*Mech. Dict.*" Phosphide of calcium is added to the composition of the fuse, and takes fire on being wetted when the buoy is thrown overboard, and burns persistently even in rough water which dashes over it.

Bu-rette'. A graduated glass tube for transferring small quantities of fluids. See p. 408, "*Mech. Dict.*" Similar instruments are known under various names, such as Dropping Tube, Dosimeter, Pipette, etc., which see.

Dr. Bunte's gas burette for the examination of mixtures of gases. "*Journal for Gas Lighting,*" * reproduced in "*Scientific American Supplement,*" * 1603.

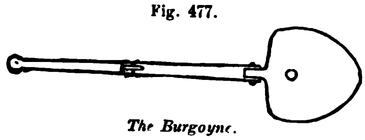
Bur'glar A-larm'. A bell, located in the sleeping room, when set for the night, rings upon the opening of any door or window in the night. The connection is by electric wires. See various forms, "*Mech. Dict.,*" pp. 408, 409.

Western Electric Manufacturing Co.; the electric connection is made with any or all rooms, can be turned off in the morning by hand or automatically, can be arranged to keep on ringing until stopped; connection can be made to doors, shutters, and windows, the latter so arranged that they may be left open for ventilation at any desired height, and yet give an alarm if disturbed. The system may be connected to a police station, and applied to safes and banks.

Powell . . . . * "*Sc. Amer.,*" xlii. 210.
Window fastening, *Saurbrey.* . * "*Sc. Amer.,*" xxxvii. 294.

Bur-goyne'. The British name for an intrenching tool; a combination of spade, axe, and

Fig. 477.



The Burgoyne.

mantlet. The handle is jointed to facilitate packing. The sharp-edged spade forms an axe; when used as a mantlet against bullets, the soldier fires through a hole in the blade.

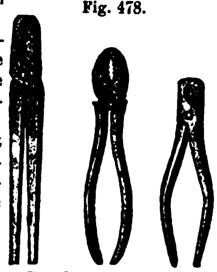
See Intrenching Tools, Fig. 2691, and Trowel Bayonet, Figs. 6673, 6674, "*Mech. Dict.*"

Burn'er. The tubular wick, with access of air to exterior and interior, is the invention of Argand. See page 142, "*Mech. Dict.,*" and list on page 1247, *Ibid.*

Lungren . . * "*Scientific American,*" xxxviii. 355.
Carcel burner . * "*American Manuf.,*" Jan. 10, 1879, p. 18.
See also Bunsen Burner; Gas Burner.

Burn'er Pli'ers. Pinchers for unscrewing or screwing burners and small connections. Fig. 478.

Fig. 478.



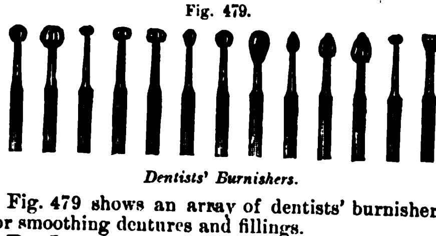
Gas-fitters' Burner and Meter Pliers.

Burned Sand. (*Molding.*) Sand in which the tenacity imparted by the clayey part has been destroyed by heat.

This happens to all that part which comes in contact with the casting, extending, in the case of large castings, to a considerable depth. It is removed as far as possible with the casting. That which remains renders the old sand weak. When fresh river or sea sand cannot be had, burned sand may be used for *partings.*

Bur'nish-er. A tool for smoothing by mechanical compression in rubbing.

Fig. 479.



Dentists' Burnishers.

Fig. 479 shows an array of dentists' burnishers, for smoothing dentures and fillings.

Bur'laps. A coarse canvas used in upholstery and elsewhere.

Bur'ring En'gine. An electric substitute for the various foot-power machines which have been devised for facilitating operations on the teeth, excavating and shaping cavities, dressing down and polishing fillings, separating teeth, etc.

The speed is about 2,500 revolutions per minute. A gear-joint allows motion at any angle. The motion is reversed at will. The engine complete weighs 12 ounces.

See Dental Drill.

Bur Thim'ble. An attachment to the finger to support the end of the bur drill when operating; designed for the protection of the hand and the easy operation of the instrument.

Fig. 480.

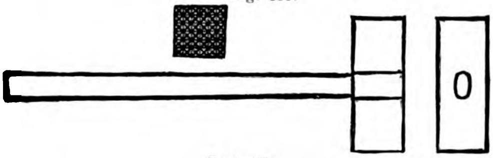
Bur Thimble.

Bush Ham'mer. (*Stone Working.*) A square prism of steel, with ends cut into pyramidal points. The cutting face is from 2″ to 4″ square. One end has sometimes the form of an axe. The tool, Fig. 481, is used in dressing and stunning.

The various forms and methods of stone working are considered under their special heads, and collections of the terms may be found under MASONS' TOOLS, etc., page 1405, "*Mech. Dict.*" and STONE WORKING, *infra*. See also lists under HAND TOOLS; MACHINES, *infra*.

Bush-ham'mered Stone Work. (*Stone Cutting.*) Work in which the roughnesses of the stone are pounded off with the bush-hammer. The sequence of operations with limestone is (1) rough-

Fig. 481.

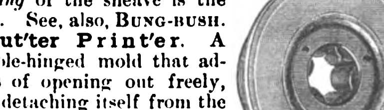


Bush Hammer.

pointing; (2) tooth-axeing; (3) bush-hammering. Sandstone is seldom bush-hammered, as the stunning makes it scale.

Bush Hook. A brier hook; bramble hook;

Fig. 482.

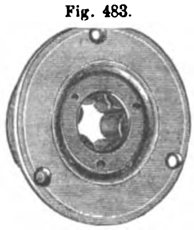


Bush Hook.

bill-hook. A hook-ended cutting tool for cutting bushes, grubs, briers, etc.

Bush'ing. (*Nautical.*) The metallic reinforce of the cheeks of a tackle-block, where the pin passes. The *bushing* of the sheave is the *coak*. See, also, BUNG-BUSH.

Fig. 483.



Block Bushing.

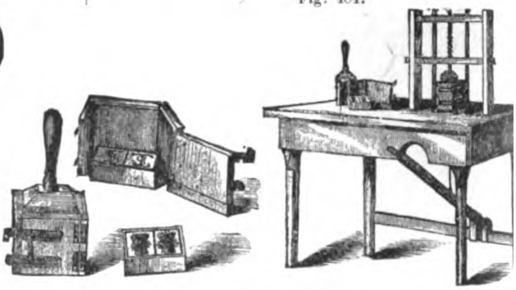
But'ter Print'er. A double-hinged mold that admits of opening out freely, and detaching itself from the butter without marring it.

The butter is weighed and placed in the mold, when it is forced by a plunger on the block at the bottom of the mold that contains the impression. The plunger is operated by a lever in connection with the main frame, and, when the pressure is removed, is retired by the action of a spiral spring. Fig. 484.

But'ter Tub. A tub in which butter is stored and shipped, especially the latter. Fig. 485.

Koehler's butter tub is oval, of white cedar, bound with galvanized iron or brass hoops. Within the tub is fitted the tin cooler, having a removable chamber for ice at each end — which is a great improvement on the old style, with stationary ice chambers — saving a great deal of inconvenienc filling the chamber with ice or removing unnecessary ice

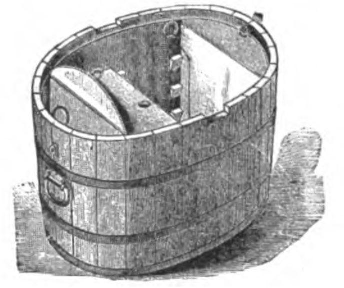
Fig. 484.



Butter Printing Apparatus.

water therefrom. On the tin are constructed a seri ledges, on which rest the shelves for supporting the butter, being used without shelves for roll butter.

Fig. 485



Butter Tub.

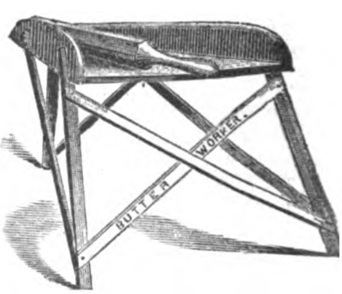
hinged cover having a fixture at one end and a hinge l the other can be locked for shipping. Hinges, has fixtures are tinned to render them rust-proof.

But'ter Work'er. A tray with roller tc the butter-milk from the butter.

The illustrations show three forms with rc

In Fig. 486 the roller is pivoted at the end and r sector.

Fig. 486.



Whipple's Butter Worker.

In the rotary butter-worker, Fig. 487, the butter on a rotary circular table and is confined by a crank shaft which revolves the table also rotates t conical presser that works the butter. As the pre the paddles as they leave the butter slightly raise allows the passage of the buttermilk to a groove a periphery whence it passes by a tube to the well ter of the table.

The butter-worker, Fig. 488, consists of a tray, a with paddles which is turned by a crank, and from end to end of the tray. The roller is ren the tray by turning the long end of small butt side of the tray, which admits of the roller comin the end of the tray, and allows the clamps whic

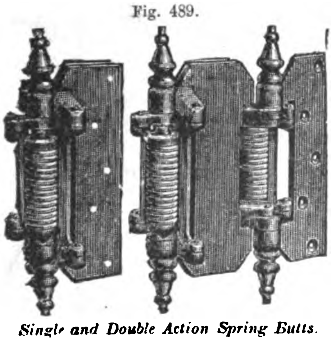
Butt Hinge. A door or casement hinge adapted to be fastened to the edge of the object, and hidden when the latter is closed. Differs from the hook strap, T, and other long-membered or ornamental hinges which are displayed upon the door.

Fig. 489.



Single and Double Action Spring Butts.

Geer's butts, shown in Fig. 489, exhibit several points of value. The figure on the left is for a single door of the usual action, but with a spring to close the door automatically and having its greatest power at the point of closure, the least when opened to a right angle; and also holding the door in open position. The double action hinge allows the door to swing either way. They are not rights and lefts, but adaptable to either edge of a door.

Loose-pin	* "*Iron Age*," xxi., April 11, p. 9.
Spring, *Geer*	* "*Iron Age*," xxi., Feb. 7, p. 1.

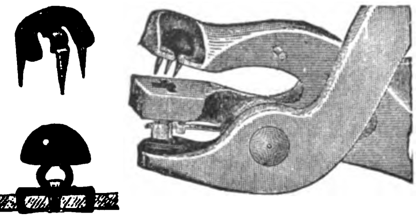
Butt Lathe. A stock-turning lathe, invented by Blanchard. A gouge 18″ in diameter, that makes from 3,400 to 3,600 revolutions per minute, is guided by an iron pattern the shape of the stock required. The stock goes through a set of these machines before it is ready for polishing.

But'ton. (*Surgical.*) A species of clamp for holding the suture, in operations for vesico-vaginal fistula. The invention of *Bozeman*.

See Figs. 268–271, Part III., *Tiemann's* "*Armamentarium Chirurgicum*."
The *button-adjuster* and *button-shaper* are accessories.

But'ton Fas'ten-er. A clasp which hooks over the eye of a shoe button and is then clinched to the shoe.

Fig. 490.



Heaton's Button-setting Instrument.

The illustration shows the article, its attachment, and the tool. It is applied without previous piercing of the leather; has sufficient freedom of motion; can be removed by unclinching the points.

Button apparatus, Covered . .	* "*Sc. Amer.*," xxxvii. 175.
Button sewing-machine, *Fries*.	* "*Sc. Amer.*," xxxv. 6.

But'ton-head Bolt. A carriage bolt with spheroidal head. Fig. 491.

Fig. 491.

Button-head Carriage Bolt.

But'tress. (*Add.*) Buttresses are *Close*, like extended pilasters.

Open, with perforations in the profile.

Flying, with half an arch suspended, bearing against the clerestory or a wall.

But'ty-gang. A word used among English contractors to signify a gang of from 10 to 13 men, who do a piece of work for a given sum divided equally among them, except a small additional sum to the head of the gang. *Helps's* "*Life of Thomas Brassey.*"

Buz'zer. 1. A small, rapidly-revolving wheel, used in grinding or polishing small objects. It is plied with emery, crocus, rouge, etc., according to requirements. Named from its whirring sound.

2. A telegraphic call in which a vibrating hammer strikes a sounding piece and gives out a buzzing sound, which, in certain cases, is preferable to a bell.

Buzz Pla'ner. A small planing machine for wood. It is named from the whirring hum of its rapidly revolving knife-cylinder, and is used to take out of wind and smooth up small stuff.

Bye'-pass. 1. A cut across furnished by an extra pipe of smaller dimensions, leading around a certain chamber, valve, or apparatus which is temporarily cut out of the circulation.

The *bye-pass* is found in: —

Mackenzie's surface condenser.

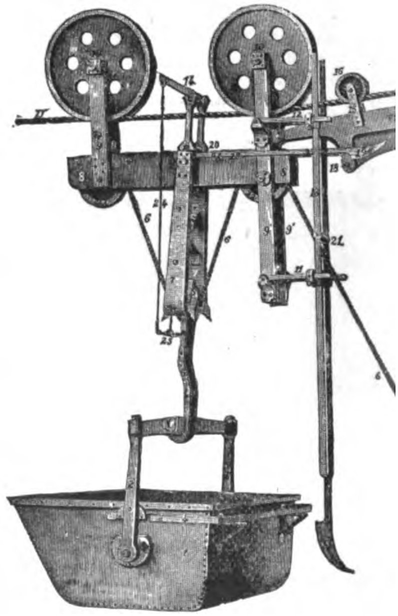
Ca'ble Car'ri-er. A means of tran rough materials; stone, sand, lime, coal, e a suspended bucket traveling on a wire Fig. 494.

Fig. 494.



Brown's Cable Carrier.

While filling the tub, the carrying bail 2 is turne when filled the bale is turned upright, and there the dumping bail 4. The bail is then attached to block 5, through which the hoisting rope 6 pas over pulley 22, to the hoisting drum (not shown.) When the load is raised, the upper edge of block 5 enters between the inwardly curved ends of the hooks 7, 7′, which separate and pass over the block, falling together beneath it. The block is then lowered and rests upon them, transferring the load from the rope to the hooks.

These hooks are attached to levers 19 pivoted at A and having a limited movement, the weight depresses their inner and raises their outer ends, unhooking them from pin 18 on the holding block 15. Simultaneously with the transfer of the weight to the hooks, the hoisting rope and drum are released from the power and the carriage with its load descends the cable 17; and when it reaches the point where it is desired to deposit its load, the drum is again thrown into connection with the power, arresting the outward progress of the carriage, and starting it simultaneously upon its return. The hoisting rope, passing under roller 21, between the two parts of dumping hook 13, is by it deflected downwards as the carriage passes out, and when the drum is thrown into gear the straightening of the rope raises the hook which is pivoted upon levers 11 and 12, brings its point, 13′, in contact with the dumping bale, unlocks the tub, which capsizes, ejects its contents, attains its upright position, and relocks itself while upon its return.

When the carriage reaches the holding block it is stopped, and the tub is raised until the block, acting upon projections 26 on the inner sides of the hooks, forces them apart sufficiently to allow of its passing down between and clear of their points. A notch on lever 14 retains them apart until the block has passed their points and strikes the jointed lever 25, which, through rod 24, raises lever 14, releasing and allowing them to fall together.

The tub is then lowered and the operation repeated.

By the use of this machine (hoisting power being furnished) material can be conveyed a thousand feet, and piled to any height, with the labor of one man.

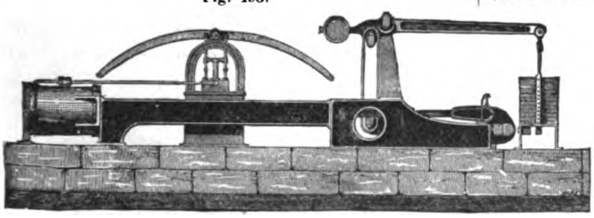
See, also, WIRE-WAY, Fig. 7006, p. 2798, "*Mech. Dict.*"

Ca′ble Screw. A fastening for boot-soles; a wire in shape of a twisted cord.

Ca′ble Screw Ma-chine′. One for putting screw pegs into boot and shoe soles. It goes round the sole in 15 seconds, putting in 80 to 85 wire pegs.

Ca′ble Test′ing Ma-chine′. The machine shown in Fig. 495 is made in accordance with the

Fig. 495.



Chain Cable and Anchor Testing Machine.

"Board of Trade" (British) regulations, operating by medium of dead levers upon an active weight. The series of levers is similar to that in compound beam scales, the strain being given by a hydraulic ram of 8′ stroke. The great length of stroke is for the purpose of taking up the stretch of the cable when testing lengths of 20 fathoms at a time. The machines are made to test up to 200 tons. A hydraulic gage indicates upon a scale the strain upon the levers.

For chain-testing establishments, in addition to the testing machines there are required steam-pumping apparatus, cable-shears for cutting out defective links, capstans for hauling the chains, a hydraulic anchor crane, and a blacking apparatus; it is usual also to add a more powerful short machine to test a few links of the largest cables to destruction.

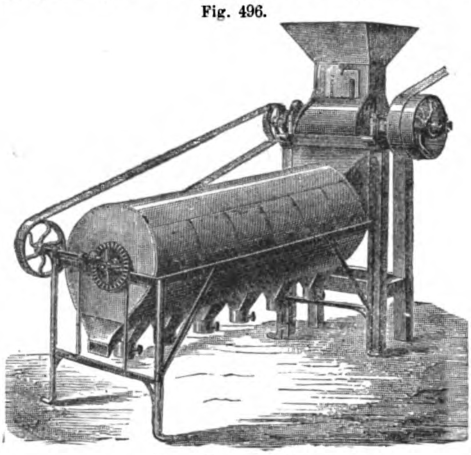
The cable-testing apparatus of Giffard's captive balloon, Paris, 1878, was a hydraulic press mounted above a frame so as to bring a strain upon a section of the cable which had two eye-splices to the holder and puller respectively, the latter depending from the piston of the press. An accumulator is arranged to prevent any shock from the rupture affecting the manometer which registers the tension.

"*Scientific American*" . . . . . . * xxxix. 194.

Ca′bres-to. A halter. A word of Spanish introduction used on our Western plains. Properly *Cabestro: Cabresto* in Portuguese.

Ca-ca′o Grind′er and Sort′er. A machine for grinding the cacao nut and sorting the result

Fig. 496.



French Cacao Machine.

into different finenesses. The distance between the cylinder and its concave is adjustable in order to determine the fineness of the result. The ground cacao is sorted into six sizes, and refuse.

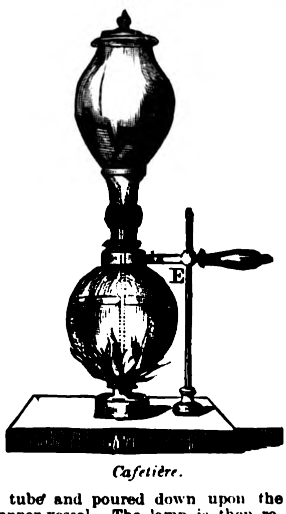
In the cacao mill of De Batiste, Paris, France, the cacao is put in a hopper having at the bottom a screw which partially grinds the nut and feeds it into the center of a pair of stones, similar to a pair of grist-mill stones. These grind it into a liquid which collects in a pan surrounding the lower stone.

Cacao manufacture . . . . . "*Sc. American Sup.*," 1014.
Chocolate machinery, *Menier* . "*Engineering*," xxv. 443.
Cocoa . . . . " *Sc. American*," xxxv. 278.

Cafe-ti-ere′. A French apparatus for making infusion of coffee.

The apparatus has two bulbs and connecting neck with ejector tube.

Fig. 497.



Cafetière.

As shown in Fig. 497 the lower bulb contains water which is in process of being heated by the alcohol lamp. When steam forms above the water, the latter is raised in the central tube and poured down upon the ground coffee in the upper vessel. The lamp is then removed, the steam soon condenses and the water is drawn down through the coffee so as to have the grounds as dry as fresh sawdust.

The *Etzenberger* steam tea and coffee filter is on larger scale but involves the same principle of action.

Cage. (*Add.*) 6. A prison of iron bars.

Iron cages are now frequently made for prisons in the South and West, to be used when there is no conveniently available material except wood.

Cais'son. An iron-lined shaft; or a shaft used in pneumatic subaqueous excavation. Pages 49, 420–422, "*Mech. Dict.*"

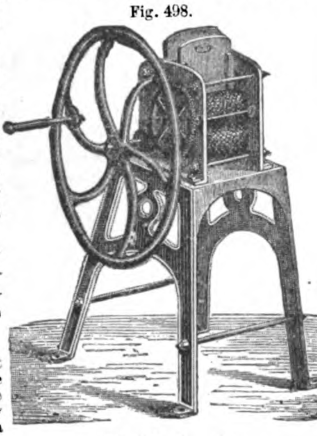
Cake Grind'er. A machine for breaking linseed oil cake for food for stock. The cake is dropped into the hopper edgewise, is broken in pieces, and these ground by passing between toothed rollers.

Fig. 498.



Oil Cake Grinder.

Cake Ma-chine'. A machine for cutting dough into cakes.

Ruger's soft cake and jumble machine takes the dough previously prepared in a dough mixer, spreads it on an apron, and cuts it into cakes of the required size and shape; cakes, snaps, jumbles, drops, fingers, bars, etc. The cakes are taken from the apron with a peel. There is no automatic scrapper as in some forms of cracker machines. See CRACKER MACHINE.

Cake Steam'er. A machine for *washing* cakes, snaps, and crackers. It has an iron frame having an endless chain apron for carrying the pans of cakes underneath a dome where steam and water are sprayed upon the cakes, causing them to spread, and then by filling the dome with hot steam a thin skin forms over the cakes, by which, when baked, they acquire a rich, cracked top, and glossy color.

Cal-cim'e-ter. An instrument invented by Scheibler, and modified by Pellit & Salteron, for making volumetric analyses of bone-dust, meerschaum, and other compounds containing lime.

"*Scientific American Supplement*" . . * x. 4002.

Cal'ci-mine. A superior kind of wash for walls. See also KALSOMINE, "*Mech. Dict.,*" p. 1222.

Cal-cin'ing Fur'nace. A furnace for roasting ores.

In the Gestenbrofer furnace, named after the inventor, was first introduced the feature of burning the sulphur of pyritic ores to accomplish the calcination.

In practice, the sulphurous fumes are used to make sulphuric acid, which is used to make soda from common salt.

See paper by Holloway read before the "Society of Arts," London, February, 1879, "*On a New Application of a Process of Rapid Oxidation by which Sulphides are Utilized for Fuel,*" referred to in "*Engineering and Mining Journal,*" xxvii. 201; xxix. 423.

Poole's Super-calender Rolls.

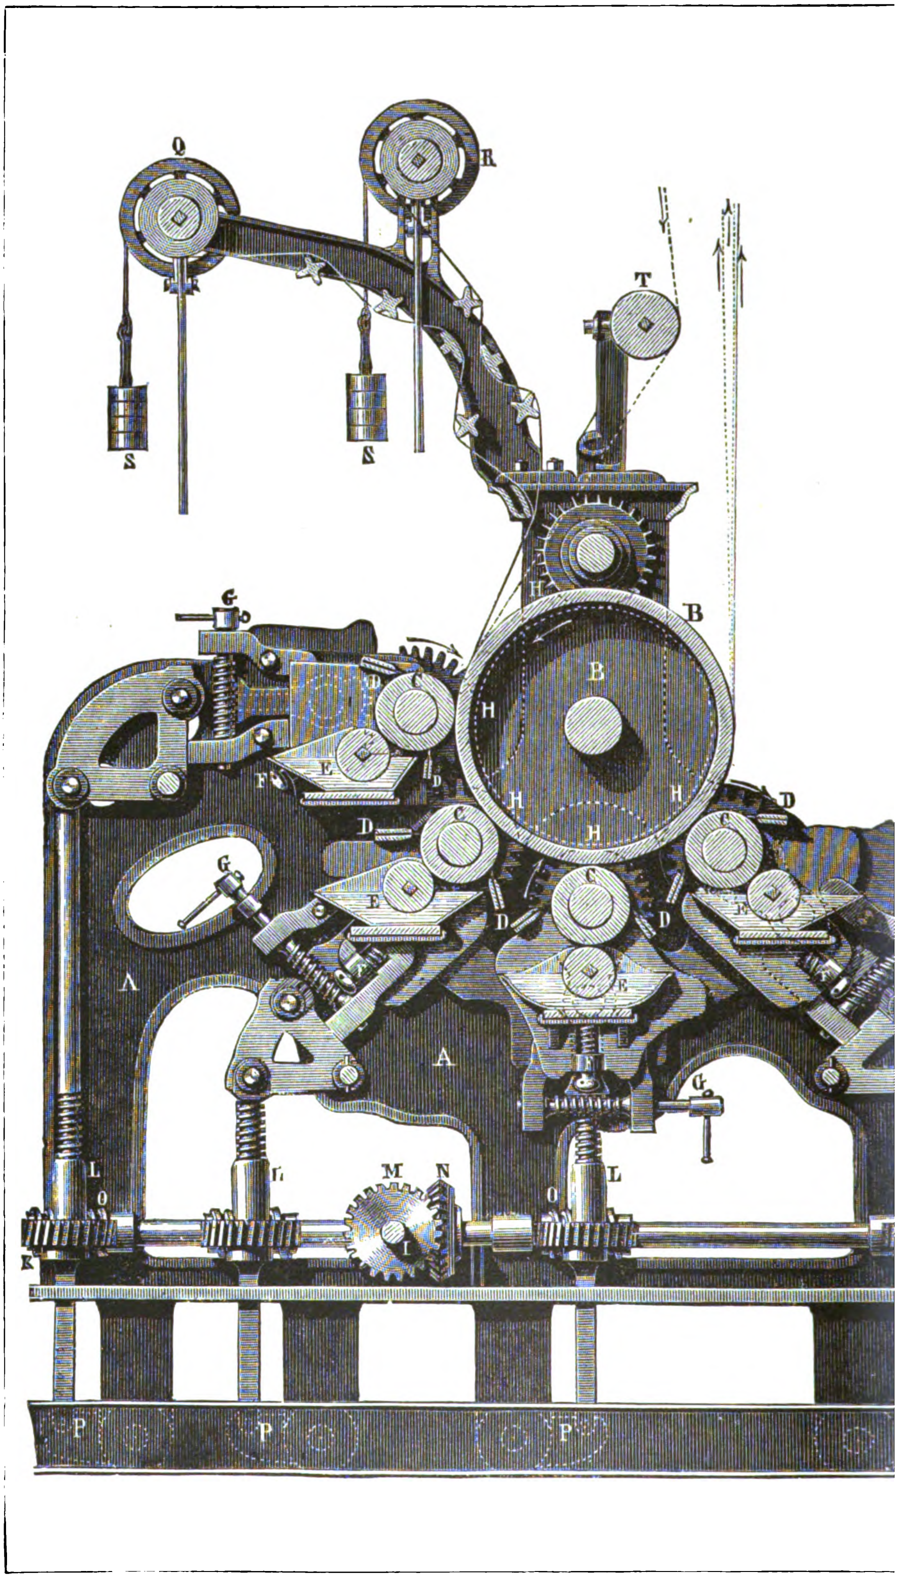

PLATE VI. CALICO PRINTING MACHINE. (In four colors.)

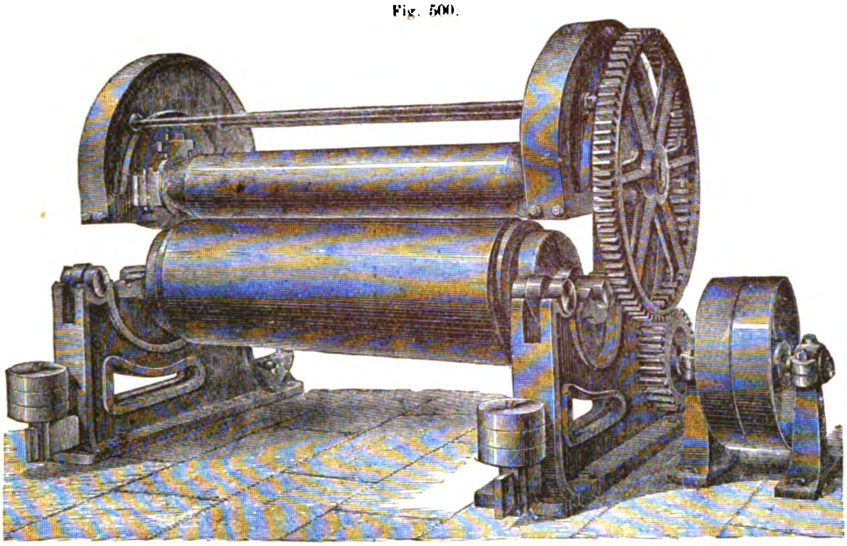
Fig. 500.



French Calendering Machine. (*Pierron & Dehaitre, Paris.*)

Small machines are made for watering or moiring ribbons, etc.

4. In paper-making for expressing the moisture from the felted web, and giving a surface to the incipient paper.

Poole's calender rolls are shown in Fig. 499.

The figure represents a stack of super-calenders for a paper machine, but their rolls are adapted for various uses, working in paper, rubber, gutta-percha, brass, copper, flour, etc. As shown, the rolls *A A'*, etc., are of chilled iron, *B B'*, etc., are paper. The number and dimensions are varied to suit the work required of them. They are put in motion by a friction pulley, and the strain is carried by large wrought iron rods, connecting the caps of the upper with the lower bearings of the lower roll. The gearing at the side belongs to the winding arrangement.

5. A machine for running rubber into sheets, or spreading it upon cloth.

When the rubber has been thoroughly mixed, it is, by means of large iron calender rolls, "run" into sheets of the required thicknesses — three to four feet wide — and then rolled or cut into various shapes and sizes, and made up by the workmen into the various articles required, ready for vulcanizing. Cotton fabrics are combined as a base of strength with the sheets intended for belting, hose, and other articles requiring it.

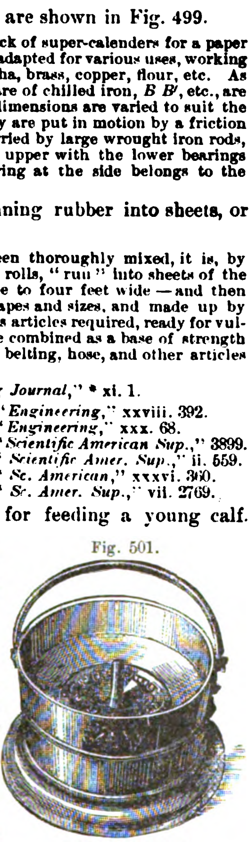
Calf Pail. A pail for feeding a young calf. The teat in the center is hollow, and the milk is drawn through it by the natural action of sucking.

Fig. 501.



French Calf Pail

Calf muzzle, *Miller*, * "*Sc. Amer.*," xxxvi. 386.

Cal'i-co-print'ing Ma-chine'. A machine for printing tissues. It was originally designed for cotton prints or calicoes, but has more lately been applied to a very great variety of fabrics of wool, linen, silk, and other materials, and of various mixtures of these and others.

The modes of printing are various, but the greater number concern the chemical side of the question and are described on pages 426–429, "*Mech. Dict.*"

Plate VI. shows a machine for printing in four colors which will give a clearer understanding of the construction and operation than one for printing in twenty-four colors, which might have been selected. The latter has a larger central cylinder so as to make it possible to arrange around it a series of twenty-four different impression rollers, each having its own paraphernalia of color-roller, color-trough, doctor, and the necessary means for adjustment.

The plate shows a transverse vertical section of the machine. A, is the frame of the machine on which the various parts are mounted. B is the impression cylinder, and around it are four engraved cylinders, C C C C, which receive their color from felt-covered copper rollers which revolve in the color-troughs, E E E E. Each of the graven cylinders has two doctors, D D, one to remove superfluous ink in advance of the impression being delivered, and the other one to catch and remove any fluff or fibre which might adhere to the cylinder and so be carried into the color. The doctor is a steel blade held by an adjustable screw against the cylinder and having a back and forth movement in the direction of its length.

The plate shows three webs passing around between the impression cylinder and the engraved cylinders. That passing from Q is the fabric to be printed. It passes over several wing rollers and flat surfaces which spread it evenly and remove folds and wrinkles; the tension being maintained by a weighted strap, S, which acts as a brake upon the axes of the cloth roller and prevents its paying out too fast.

Next to the tissue to be printed is a cloth called a doubler (*doublier*) which unrols from R and has the same smoothing devices and brake weight S as previously mentioned.

The doubler lies at the back of the fabric to be printed, and is itself backed by an endless blanket, which is shown coming past the roller T and the spiked roller H; this lies next to the impression cylinder, the doubler and blanket together acting just as the blankets of an ordinary copper-plate printing-press, to form an elastic spongy backing to the fabric and force it into the graven lines from which it absorbs the colors.

Each graven cylinder, as has been said, has its own set of devices, color roller, and trough, and these, with it, are mounted upon a carriage which can be set towards or from the impression cylinder B. A system of gearing, M N O L K, actuates these altogether, but individual adjustments of any one set are made by a screw G, which acts upon its own set.

The cylinder is rotated by a gear-wheel on its shaft, and the graven cylinders by the planetary gears H H H H.

On the right are shown the tissue, with the doubler and the felt proceeding toward the drying chamber.

The Monteith (Glasgow) hydraulic press, for calico printing from flat plates, is shown in article "*Impression sur Étoffes*," Fig. 43, *Laboulaye's* "*Dictionnaire des Arts et Manufactures*, tome iii., ed. 1877.

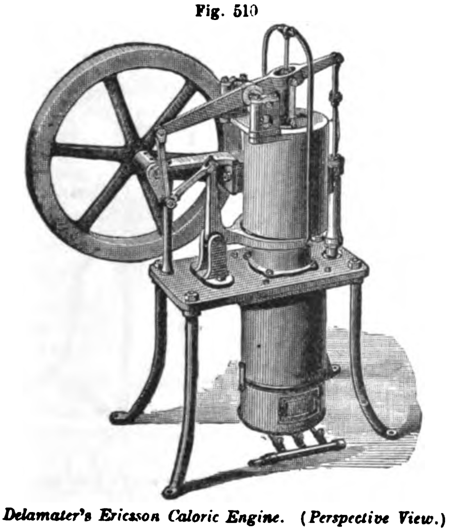
Cal'li-graph'. A writing machine.

Cal'o-ric En'gine. The name given by *Ericsson* to the heated-air engine. His earlier form of engine was given in Fig. 84, p. 40, "*Mech. Dict.,*" and accompanying description. His device was followed by a host of others. See Figs. 85–94, pp. 41–45, *Ibid.*

The illustrations below show the latest and a very compact form of the *Ericsson* engine.

Fig. 510 is a perspective, and Fig 511 a sectional view of the

Fig. 510



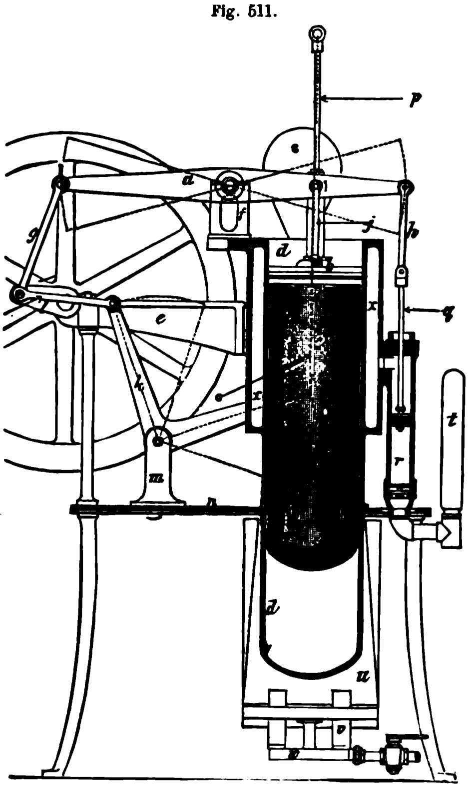
Delamater's Ericsson Caloric Engine. (*Perspective View.*)

engine pump and furnace. The engine is specially intended for domestic use in lifting and forcing water from wells and cisterns, or from city mains, to tanks on upper floors of buildings.

No steam is employed, and any kind of fuel will answer for this engine, but coal-gas is preferable, the consumption being 15 cubic feet per hour for average house use.

The action of the engine is to alternately heat and cool the air confined below the air-piston *b* in cylinder *d*, the heating of the air generating a pressure which acts on the air-piston, causing it to move through its upward stroke, actuating the pump *r* and fly-wheel by means of beam *a* and links *j h g*. The momentum of the fly-wheel and contraction of the air cause the return stroke. The office of the transfer piston *c*, by its movement derived from the crank through link *l* and bell crank *k*, is to displace the air from the lower or heated part of the cylinder *d* to the upper or cold part, and *vice versa*.

Fig. 511.



Delamater's Ericsson Caloric Engine. (*Sectional View.*)

u is the gas furnace, *t* the vacuum cylinder, *x* the water jacket, *e* fly-wheel bracket, *f* beam center bearing

The Brown caloric engine has the furnace separated from the working cylinder, has valved connections between the two, and uses the hot air expansively. The inlet and outlet valves operate independently of each other. The furnace is supplied with coal by a cut-off bottom hopper while the machine is in motion

The steam siren fog signal at the Centennial was operated by one of these engines. See Fog Trumpet.

"*Scientific American Supplement*" . . . * 749.

Cam'ber-ing Ma-chine'. A machine for giving a vertical curve to a railway rail. Such rails are used at the summits and feet of inclines and at the junction of grades of varying inclination.

Also used to curve a rail to such a degree that it will be straight when cooled.

See Figs. 8, 9, and pp. 372, "*Engineering*," xxix.

Cam Cut'ter. A special machine-tool made to cut and finish cams of all curves up to 5″ diameter. It is made with either single or double heads. The carriage for reception of the blank is gibbed to the bed, and has sufficient traverse toward or from the cutter-spindle to cut to any required depth. The cones of the cutter-spindles carry 2″ belts. The feed is by worm and gear, and has variable speeds. Machines are built for cutting either periphery and face or periphery alone.

Cam'el. (*Hyd. Eng.*) A float for raising a vessel.

Ships over shoals.
Clark & Standfield, Br. . . * "*Engineering*," xxiii. 370.
See, also, Depositing Dock; Dock; Floating Dock, "*Mech. Dict.*," *et infra.*

Cam'el's Hair Pen'cil. A small brush used by artists, the tuft being made of the hair of the camel. Similar brushes of differing degrees of elasticity are made of fitch, badger, squirrel, goat, and sable.

Cam'e-o Cut'ting. In the process of cameo-cutting the method in Italy is as follows: —

The shell is first cut into pieces the size of the required cameo by means of diamond dust and the slitting mill, or by a blade of steel fed with emery and water. It is then shaped into a square, oval, or other form on the grindstone, and the edge finished with oil stone. It is next cemented to a block of wood, which serves as a handle to be grasped by the artist while tracing out with a pencil the figure to be cut on the shell. The pencil-mark is followed by a sharp point, which scratches the desired outline, and this again by delicate tools of steel wire, flattened at the end and hardened, and by files and gravers for the removal of the superfluous portion of the white enamel.

The cameo cutter selects from the shells which possess the three layers: (1) those which have the layers strongly adherent to each other; (2) those in which the middle layer is thick; (3) those in which there is a good distinction of color between the layers; and (4) those in which the inner layer is of the color suited for his purpose.

The central layer forms the body of the relief, the inner layer being the ground, and the outer the third or superficial color, which is sometimes used to give a varied appearance to the surface of the figure.

See, also, article in "*Scientific American*," xlii. 69.

A fictitious cameo is made from lava or from steatite. In the case of the latter, after the cutting is finished the cameos are inclosed in an air-tight crucible, heated at a red for several hours, and allowed to cool slowly. then flint-hard. Color is given by immersion f hours in dyes, — saffron, gumboyl, campeche, blood, etc.

Cam'e-o Glass. Glass cut in imit cameos.

Cups and bowls for this purpose are formed of body or layer of dark blue glass, with an outer layer of even thickness of opaque white glass, in design is wrought by carving or grinding down to colored sub-layer, or foundation. This outer whi about ⅛″ thick, and is chiseled in high relief, in manner to that by which the Portland Vase in Museum was formed, and also the Pompeiian Vi museum at Naples. It is a difficult task to get glas that have exactly the same degree of shrinkage o The two differently colored pastes must shrink ex or cracking would result, especially when the out chiseled away in forming the design. — *Blake.*

Cam'e-o In'crus-ta'tion. (*Glass.*) ure, say a small porcelain bust, is introd a small cylinder of glass, which is then cl it.

Cam'e-o Press. A small screw-pres ing a convex roundness to photograph The bed and platen are in cameo and in spectively, and the object is pressed betw

Cam'e-ra. A chamber used in obta tures. See p. 433, "*Mech. Dict.*"

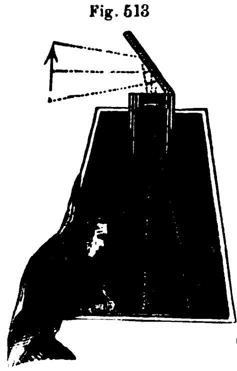
Cam'e-ra Lu'ci-da. A glass prism to the eye-piece of a microscope. Described and shown at Fig. 1043, p. 434, "*Mech. Dict.*" The instrument shown at Fig. 512 has a lens to magnify the pencil point; a very important adjunct in making drawings of microscopic objects.

Fig. 5

Beck's Cam

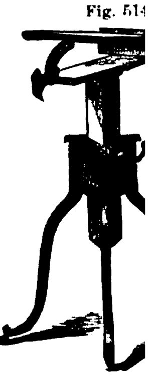
Cam'e-ra Ob-scu'ra. The camer shown at Fig. 1044, p. 434, "*Mech. Dict.* a long time but little more than a toy. its development into the photographic ca

Fig. 513



The Camera Obscura.

Fig. 51



Bowditch's Ca

removes it far from this criticism, yet i lately been adapted in a worthy way to use: the throwing of an image on a piec to facilitate making sketches, drawings, The camera obscura, shown in Fig. 513, has a reflector and a lens, by which the magnified image is thrown upon the paper in the camera, the only light entering at that point. A curtain at the back of the draftsman occludes other light. The lens is in a sliding tube, which may be raised or lowered to adjust the focus. The height of the box must not be less than the focal length of the lens. The mirror is hinged to adjust its direction.

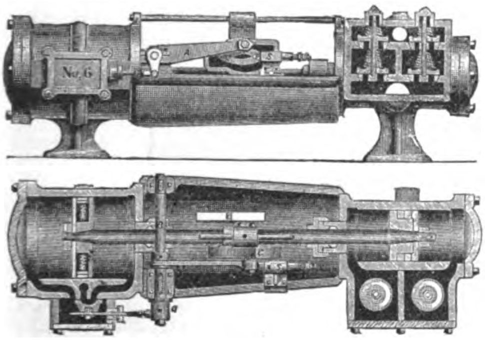
Cam'e-ra Stand. A table to support the photographic camera, having adjustments for height and inclination.

Cam Loom. One in which the harness is operated by cams instead of by pattern chain, jacquard, or other device.

Cam Press. One in which the action of the punch or shear is due to the rotation of a cam: as distinct from a screw, lever, or pendulum press.

Cam Pump. A steam pump, the motions of which are obtained by the media of cams; as distinct from other mechanical means.

Fig. 515.



Dayton Cam Pump.

In the case illustrated in Fig. 515, the steam valve is a plain slide valve, worked by means of a cam bolted on the piston-rod, and moving with it, and by the shape of the cam the stroke is slowed down at each end, giving ample time for the water cylinder to fill, and water valves to close before the return stroke. This insures a full stream every stroke, and prevents the pump piston from striking against the water when the cylinder is but partly filled, it being impossible for the steam valve to be thrown into such a position as to shut off steam and stop the pump.

Cam'py-lom'e-ter. An invention of M. Gaumet. A pocket instrument capable of giving at one reading the metric length of any line, straight or curved, on a map or plan; and the natural length corresponding to the graphic length on maps, with a scale of one 80,000th or one 100,000th, or multiples or submultiples of these scales.

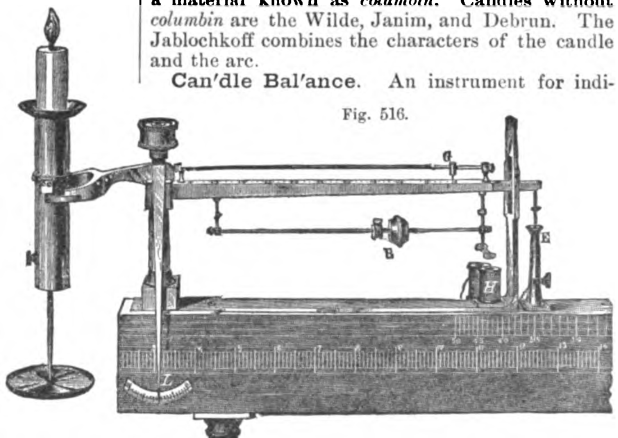
Can Bod'y Form'er. (*Sheet Metal Working.*) A machine for forming the bodies of cans. The locks for the seams being first formed on the blanks, and they placed in position, a single movement of the lever presses the former into the mold and two hinged side-pieces spring forward and clasp the ends of the blank around the back of the former.

Can'dle. (*Electricity.*) An arrangement of carbons in an electric light. The carbons are placed parallel, and as the waste of the two must be equal, they are fed by alternating currents. See ELECTRIC CANDLE.

The Jablochkoff electric light is the most noted of the class; in this the carbons are separated by a material known as *columbin*. Candles without *columbin* are the Wilde, Janim, and Debrun. The Jablochkoff combines the characters of the candle and the arc.

Can'dle Bal'ance. An instrument for indicating when a candle has consumed a set amount of the material of which it is composed.

Fig. 516.



Goodwin's Candle Balance.

The instrument is shown in Fig. 516, *G* being at zero, the weight, *B*, is made to counterpoise the candle. The weight, *G*, being then shifted to the mark indicating the amount to be consumed, the candle is lighted. When the amount is consumed, the balance-lever falls, an electric circuit is completed at *E*, and the armature is drawn to the magnet *H*.

"*American Gas-light Journal*" . . * July 3, 1876, p. 6.

Can'dle Lamp. A lamp, the stem of which holds a candle forced upward by a coiled spring. Used in railway cars and traveling carriages.

Fig. 517.

Candle Lamp.

Can'dle-mold'ing Ma-chine'. A candle-molding machine, made by Wunchmann of Leipzig, was shown at the Centennial Exhibition, 1876.

It is constructed of iron, and designed for molding either paraffine, stearine, or tallow candles.

The molds, 100 in number, stand in two double rows in a close cast-iron box, where they are made steady in the upper and lower walls, but so that they can be taken out, one by one, with ease.

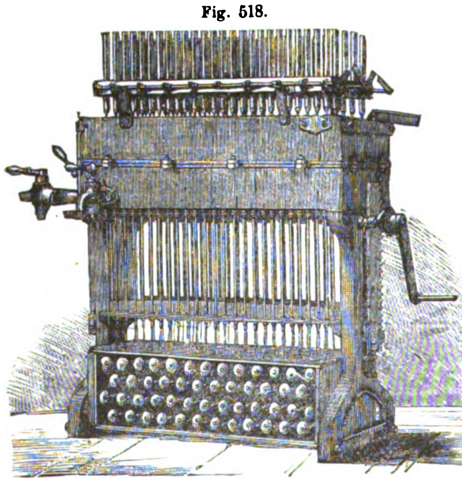
Each of the molds is a tubular structure open at both sides. In it moves a piston that constitutes the mold for the apex of the candle, and is itself attached to a slender iron tube. At the lowest stage the piston shuts the somewhat conically shaped mold close and tight.

All the pistons are secured to a frame by means of long slender tubes, and are raised and lowered simultaneously, by a crank, pinion, and notched bar.

In the lower part of the machine is the wick-box, which can be closed. It contains a hundred wick spools, the wicks passing through the box-cover into a piston tube traversing the piston itself, but by means of a simple contrivance shutting it up so closely that the liquid mass cannot permeate.

Above the two troughs that inclose the double row of molds at the top, is an apparatus called the *clasper*, that serves the purpose of holding the candles on their being raised from the molds. It can be turned on hinges back over

Fig. 518.



Wunchmann's Candle-molding Machine.

to the side of the machine till it rests against tw
It is opened and shut by means of small levers and
There is a simple attachment to centralize and hol
wicks immediately over the molds.

The procedure in operating is as follows: Wher
have been introduced, they are in the first inst
fast to a little piece of wood laid crosswise over t
The centralizing apparatus is then applied, and st
mitted into the compartment containing the mo
are thus quickly heated by its playing around t
liquid is then admitted into both troughs, and the
filled.

The centralizing apparatus is then withdrawn
water introduced into the compartment.

As soon as the liquid surface over the molds
sufficiently firm, it is cut off by a shovel adap
purpose. When the candles have cooled they ar
of the molds by turning the crank, and draw the
the spools along with them. The candles pass t
open claspers, and, on reaching the highest stag
made fast. The crank is then turned backward
tons shut up the lower ends of the molds. In d
wicks are cut and the candles removed.

The cut, Fig. 518, shows the candles in raised
held by the claspers.

Can'dle Pol'ish-ing Ma-chine'.

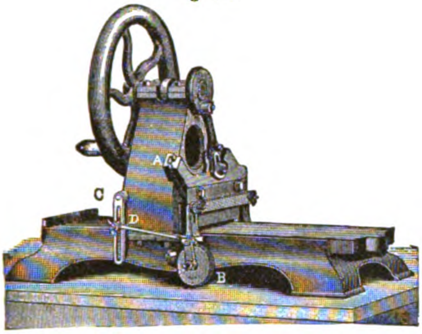
English Candy-rolling Machine.

Goodwin's, "*American Gaslight Journal*," * July 3, 1876, p. 6.
See JET PHOTOMETER.

Can'dy-roll'ing Ma-chine'. A machine with various patterns of rollers for stamping candy in sheets. The pan is $8\frac{1}{4}''$ wide, and each roller is provided with lever and clutch wheel, so that any one can be thrown in or out of gear instantly, without affecting the work of the others.

Can'dy Sli'cer. A guillotine machine for cutting candy into strips or blocks.

Fig. 521.



Candy-slicer.

The cutting-knife is raised and lowered by means of a crank-wheel, and a shearing motion is imparted by the inclined guides *A*. The carrying bed has a rack, and is moved forward by the action of a pinion-wheel on a shaft which carries at its outer end the ratchet-wheel, *B*, operated by a pawl attached to an arm, *D*. The outer end of this fits in a slot in a vibrating arm, *C*, up and down which it is adjusted to regulate the width of the candy slices.

Cane Cul'ti-va'tor. An implement made for the Cuba and West India market, with three broad, round-nosed flat shares, and an expansible frame.

Cane Cut'ter. See CANE MILL.

Cane Knife. An implement for cutting sugar-cane. It varies in different countries and provinces, from the shape of a butcher's cleaver to that of a broad-sword. See MACHETE.

Fig. 522.

Cane Knives. Louisiana Pattern.

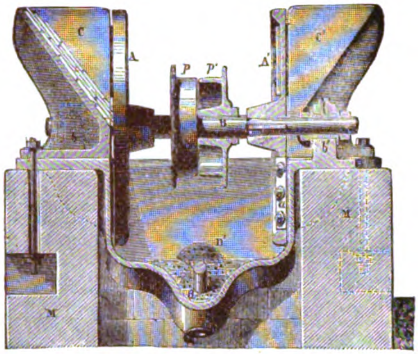
Cane Mill. The French process of *Philippe* is a departure from the ordinary, consisting in cutting the cane into thin slices with a machine, submitting them to levigation in water in a trunk in which a lifting screw rotates, and pressing them in a rotary eccentric press. See also Mignon & Rourt, "*Technologiste*," xxxviii. 81.

The Figs. 523, 524, 525 show the three stages of the operation, the two latter being, in fact, consecutive, but detached for convenience of illustration in limited space.

The cane cutter of Philippe is shown in Fig. 523, and consists of two root-cutters, composed of cast-iron disks, *A A'*, keyed upon the same axis, *B*, furnished with a fixed pulley, *p*, which communicates the movement, and a loose pulley, *p'*, which receives the belt when the motion of the cutters is to be stopped.

The axis *B*, turns in brass boxes in the pillow-blocks *b b'*, cast with a cistern, *D'*, which receives the sliced cane from the cutting-mill, and which serves at the same time by its

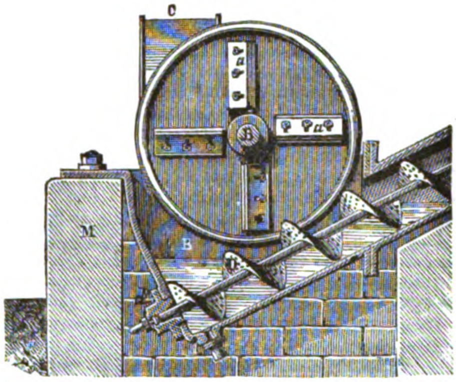
Fig. 523.



Cane-cutting Mill.

large extent to afford a seat for the elevating screw. The whole is bolted to the stone columns in masonry *M*, in

Fig. 524.



Cane-cutting Levigator.

common with the two hoppers *C C'*, into which the cane is thrown by armfuls.

Four slicing-knives *a*, are fixed on the face of each disk, inclined in their seats like the bits of planes.

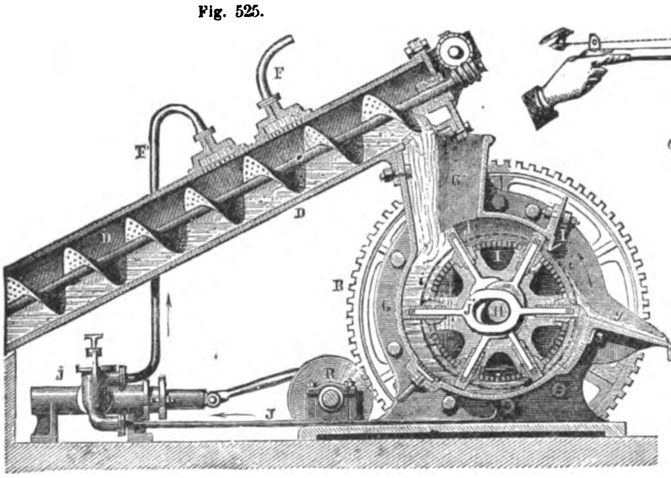
The slices of cane obtained by the action of the cutters, and arriving at the bottom of the cistern, are subjected to levigation. The bottom of the cistern corresponds in shape with the Archimedean screw *D*, the lower end of which revolves in a step, *d*, with an adjusting screw, while the upper end rotates in a bronze collar in the cap which closes the upper end of the inclined cylinder of translation. The endless screw receives rotation from a helicoidal gear whose axis carries the pulley *E*. On the top of the inclined trunk are two boxes which cover the orifices by which the liquid arriving by the pipes *F F* is distributed in the interior over the blades of the screw.

The endless converger is, so to speak, the instrument of levigation of the slices which readily traverse the trunk inclosing the screw, imbibing the liquid and undergoing osmosis more or less complete. When the slices arrive at the summit, they fall into the hopper *G* of the rotary press, which consists of a cylindrical shell *G*, cast with a bed-plate, and with ends in which are bearings of the arbor, *H*, on which is keyed the hollow drum *I*, which is eccentric with the shell *G*.

The pressing is done by six palettes of bronze, *j*, carried by the drum, which catch the mass of slices from the hopper and carry them into a more and more confined space between the drum and the concave shell, finally arriving at the discharge spout *g*, placed at that part of the envelope where the slices escape from the point of greatest pressure.

The drum *I* is cast iron, and its periphery is pierced with a multitude of small openings leading to parallel circular channels covered with perforated steel plates, so that the juice expressed from the slices escapes into the interior of the drum from whence it is discharged laterally at an opening in the central vertical line. Thence is taken by a pipe, *J*, and pump, *j*, and elevated, to be poured again by the pipe *F'* into the trunk where the elevating screw operates.

Fig. 525.



Eccentric Cane Press.

The six bronze palettes are cast hollow, and are connected in pairs diametrically across the wheel. Each pair has a yoke in the mid-length, and they slip radially, the ends of the palettes keeping their places against the interior periphery of the concave shell.

The drum *I* turns slowly, the power being applied by a pinion on the axis of the wheel *R* to the spur-wheel *B*.

The concentration of the juice is performed by means of a hot-air apparatus, also the invention of M. Philippe, and shown in Fig. 66, article " *Sucre*," in *Laboulaye's* " *Dictionnaire des Arts et Sciences*," tome iii., ed. 1877, to which the author is indebted for the basis of the foregoing account.

The process bears some relation to the Roberts diffusion process, which also employs water to dissolve the sugar of the cane, a substitute for the ordinary cane mill.

Armstrong 100-*ton Gun.*

one of eight made by Sir W. G. Armstrong & Co., of Elswick ordnance works, Newcastle-upon-Tyne, for the Italian government, to be placed on board the turret-ships "Duilio" and "Dandolo." One of these ships was built at Spezzia and the other at Castellamare, and each is of 7,000 tons burden. The gun is made on the well-known Armstrong principle, having 27 grooves and as many bands of about equal width. The rifling is an increasing spiral on the parabolic development, winding up with a twist of 1 in 45 calibers. The depth of the grooves is $\frac{1}{8}''$ throughout. See p. 158, "*Mech. Dict.*"

The weight of the gun is 227,360 pounds.
Extreme length, 32′ 10½″.

Length of bore, 30′ 6″.
Diameter of bore, 17″.
Outside diameter of gun: muzzle, 29″.
Outside diameter at breech, 77″.
The barrel is in two pieces made into one in
up. There are three layers of coils over the t
the gun.

The weight of the projectile is 2,000 pounds.
Work developed at the muzzle, 39,000 foot pc
Velocity 1,400′ per second.
The loading gear is hydraulic.

Caout'chouc Ar'ti-fi'cial. To a thick solution of glue add tungstate of soda and hydrochloric acid. A compound of tungstic acid and glue is precipitated which, on cooling, may be drawn into sheets.

Caout'chouc Ce-ment'. Pulverize shellac; soften in 10 times the quantity of ammonia. This will become liquid in time, and will dissolve the surface of caoutchouc, rendering it easy to unite it with glass.

Caout'chouc Sol'vents.

Of the solvents of caoutchouc, its distillate caoutchoucine may be placed at the head of the list: the others best known are pure chloroform, carbon disulphide, rosin, oil, and coal naphthas, rectified oils of turpentine, gutta-percha, tar, lavender, sassafras, ocoten, rosemary, amber, ambereupion, terebene, benzine — C_{12} H_6 — hydrochlorate of terebene, benzole — C_{14} H_6. Anhydrous oil of turpentine dissolves 49 per cent. of caoutchouc. A mixture of 6 to 8 per cent. of absolute alcohol and 100 of carbon disulphide is an excellent solvent. Sulphuric ether, which alone is but a poor solvent, dissolves rather more, if about 5 per cent. of anhydrous alcohol be added thereto. Hot alcohol dissolves out about 4.712 per cent. of a soft resin. It is sparingly soluble in hot fused oil — hydrate of amyl C_{10} H_{11} HO; readily at a gentle heat in melted hog's lard, or in very hot whale oil. After swelling up in oil of turpentine or in naphtha it is soluble in hot linseed oil.

Cap. (*Add.*) 14. (*Fire-arm.*) The metallic covering placed on the end of a pistol-shaped handle.

15. A short terminal section of a pipe, with a removable stopper called a *plug*.

16. (*Mining.*) *a.* A vein is "*in the cap*" it is much contracted.

b. A flat piece of wood placed between the the punch and the roof of the mine.

17. (*Manége.*) A small crescent-shaped pi leather placed on top of a collar. Not the *pad* is sometimes of metal and goes below it on th of the horse.

Ca'pel. (*Mining.*) A rock composed of schorl and hornblende, occurring in connecti tin and less frequently with copper ores.

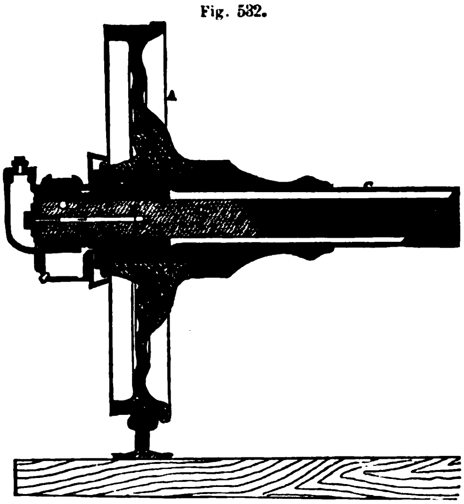
Car Ax'le. At the Centennial Exhibition (1876) were shown several axles which had for their object to allow the wheels of each pair to revolve independently of each other.

In the *S. L. Harrison* axle, each wheel is fixed to a sheath which extends to the center of the axle, and which revolves with the wheel to which it is attached, upon the axle.

The *Auchinloss* axle is divided in the middle, and there held in place by a sleeve about two feet long, in which the parts can revolve separately. In this case each wheel revolves with its own half of the axle.

"The axle of the *Miltimore Car Axle Company* was applied to one of the trains running in the Centennial grounds, and with a notable diminution of the friction in passing round the very sharp curves on this railway. In the construction of the Miltimore axle, the wheel *A* is mounted on, but not fixed to, a sleeve, *C D*, which revolves round the fixed axle *B*, upon which the car rests; the sleeve being kept in place by the axle boxes *H*, which are fixed to the main axle; the

Fig. 532.



Miltimore Car Axle.

wheel *A* can, moreover, revolve round the sleeve *D*, when, by reason of a curve or inequality in the road, one wheel is required to move with more rapidity than the other." — *Capt. Galton*. See, also: —

Car'bo-az'o-tine. An explosive: —

Nitrate of potassium	61.04
Sulphate of iron	0.73
Lampblack	24.65
Sulphur	13.58
	100.00

Car-bol'ic Ac'id Pa'per. Used for packing fresh meats, in order to preserve them.

Prepared by melting 5 parts stearin at a gentle heat, and then stirring in 2 parts carbolic acid, and afterwards 5 parts melted paraffin. The mass is well stirred until cool, and is then applied with a brush to the paper.

Paper saturated with other tar or petroleum products is also used for defending clothes, furs, etc., from moths or ants. U. S. Patents 88,519; 105,160; 94,357.

Car'bon-a-ta'tion Pan. (*Sugar.*) *Carbonatation* is the saturation of the defecated beet-juice with carbonic acid gas.

"The carbonatation pans in which the defecated and the scum juices are treated, are furnished at the bottom with a pipe, pierced with three parallel rows of small holes, ⅛" in diameter, through which the carbonic acid is forced into the liquid. There are also coil pipes or double bottoms, for heating by steam while the process is going on. When foaming has ceased, the carbonated juice is drawn off into large receivers or settling tanks, where it is allowed to settle, after which the juice is ready for the filters, unless, as is often done, it is subjected to a second carbonatation. In many works, the carbonic acid gas is produced from the calcination of limestone, instead of the combustion of charcoal.

"In the *Perier & Possoz* process of defecation and carbonation, the milk of lime which is used must be finely divided through a close metallic sieve, and must contain two per cent. of lime, indicated by 10° on Beaumé's areometer. One measure of this solution is gradually added in eight or ten successive additions, to every forty measures of the juice which is to be operated on. During this the temperature of the juice is raised from 188° to 158° Fah. Carb.-acid gas is now turned into the juice, while it is being stirred, and at the same time a small stream of milk of lime is continuously fed into it. This lime is quickly dissolved and precipitated, carrying down with it most of the coloring matters and the impurities contained in the liquid. The proper moment for arresting the carbonatation is indicated by a chemical test of the juice. When this point is reached, the juice is drawn into settling tanks and allowed to settle for about twenty minutes. From these tanks it is run into a second set of defecating pans, where more lime is added. The carbonic acid is at once turned on, and continues to flow into the juice until complete saturation is effected, which is known by a chemical test, nearly the same as before. The juice is now brought to the boiling point, to drive out the free carbonic acid, and is then run into a second set of settling tanks. In these tanks it remains until it has cleared itself sufficiently, when it is ready to be conveyed to the charcoal filters for further treatment.

"In *Jelinek's* process, defecation and carbonatation are simultaneous, and terminate in a single operation, instead of two successive ones, as in the previous method.

"The pans which are used are furnished with a carbonic acid coil-pipe, and are deeper than the ordinary defecating pans. The juice, as it is admitted to them, is comparatively cold, and must never exceed a temperature of 140° Fah.

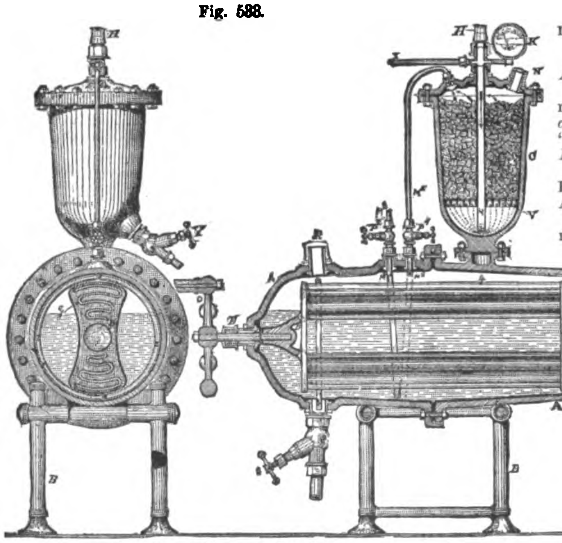
"At least two per cent. in weight of lime is added to the juice, in the shape of milk of lime; and carbonic acid gas being admitted, the heat is gradually increased until the precipitates form rapidly and fall to the bottom.

"This process is based on the theory of acting on cold juice at first so as to produce a solution of saccharate of lime, out of which the carbonic acid gas precipitates the lime as carbonate of lime, which carries with it a certain amount of organic matter, freeing at the same time, the sugar, which recombines with a portion of the lime, to be again freed by a second decomposition of the saccharates and a consequent precipitation of carbonate of lime, and so on for an indefinite number of times during the period of a single operation."

Car'bon-a'ted Bev'er-age Ap'pa-ra'tus. Apparatus for impregnating liquids with carbonic acid gas.

In the apparatus, Fig. 533, a corrugated agitator is employed in a stationary fountain. The beaters *G* are of tinned copper attached to a tinned bronze frame, and the bearings

Fig. 533.



Matthews' Corrugated Agitator.

E F and the agitator itself are covered with tin to avoid contamination of the beverage. The agitator is revolved by the handle *O*, which passes through the stuffing box *E*. The corrugated beaters carry up the liquid into the gas space and also submerge the gas in the liquid, bringing the two into intimate contact and causing the rapid absorption of the gas by the water. See also pp. 2235-2237, "*Mech. Dict.*"

Aërated water machinery, *Hayward, Tyler & Co.*, Br. * "*Engineering*," xxvi. 287, 349.

Car'bon-a'ted Stone. An artificial stone in which carbonic acid and steam are used artificially as re-agents in the composition. The object is to hasten the carbonation beyond that incident t exposure to the air, by exposing the com sand and cement to an atmosphere of carboni and vapor of water.

Car'bon-ates. (*Mining.*) *Soft carbonates*, containing carbonic acid, with a base of lead. *carbonates:* the same, with iron for a base.

Car'bon Bat'te-ry. (*Electricity.*) O which carbon replaces the copper element. The original and most important of this cl that of BUNSEN, which see. See also FAURE TERY, see also *Jablochkoff*, "*Technologiste*," LECLANCHÉ BATTERY.

Car'bon Bronze. An anti-friction all vented by Baldwin & Weisman. Its basis is c and it is made in Pittsburg. See —

"*Iron Age*" . . . xvii., May 4, p. 24; xxii., Sept. 1
"*Mining and Sc. Press*," xxxviii. 227.

Car'bon But'ton. A variety of lam compressed by a screw press in steel dies to disk about $\frac{1}{16}''$ long and $\frac{1}{4}''$ diameter. It i as a portion of an electric circuit, as an el resistance. In practice it is placed in a sma into which is dropped a little disk faced wi tinum. Contact is made at the top and with wire. It may be adjusted to any res within the range of its own limit which chosen. The limits may be varied also pressure employed in making the carbon If the pressure be increased the sensitiveness button is very materially augmented. — *Ed*
See CARBON TELEPHONE.

Car'bon Clamp. (*Electricity.*) The connector for the carbon element in the It is screwed to the carbon, and a bindin affords attachment for the wire. See Fig.

Car'bon Pro'cess. (*Photography.*)

graphic process in which prints are obtained in carbon, either in lamp-black or in ink. See CARBON PROCESS, p. 461, *"Mech. Dict."*

Braun's Carbon Process (Dornach, Alsace-Lorraine). The method is as follows: A negative is obtained by the ordinary collodion process. Paper covered with a mixture of gelatine, coloring-matter, and bichromate of potassium is exposed to light behind the negative. On removal from the copying-press, a layer of caoutchouc is placed on the gelatine. This is then washed in lukewarm water, and the paper and part of the gelatine thus removed. When the remaining gelatine is dry, it is attached to the paper backing by means of a thin layer of gelatine spread on the latter, and the caoutchouc is dissolved off by benzine. Most beautiful carbon prints are thus obtained. The process requires nice manipulation and great care, but does not necessitate an outlay for presses and their appurtenances.

Obernetter's process (Munich). This is very similar to that of Albert (p. 57, *"Mech. Dict."*). The first part, viz: the preparation of the two coatings, is almost identical. After the exposure behind the negative, however, Obernetter covers the gelatine with impalpable zinc-powder, and then heats it in an oven to 200° C. The plate is then subjected to the action of dilute hydrochloric acid and washed, and it is thus rendered capable of receiving an ink on those parts where no zinc is attached. Obernetter thus obtains a plate from which more impressions can be taken than from even that of Albert. The grain produced in the picture is also of great advantage.

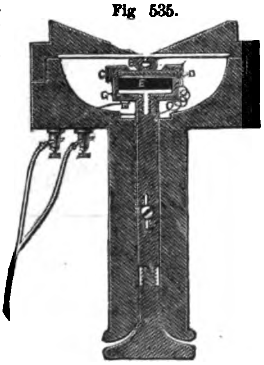
Car'bon Tel'e-phone. That form of telephone invented by Edison, in which a piece of compressed carbon is placed in a galvanic circuit, the vibrations of the diaphragm causing by pressure variations in the electrical resistance of the carbon, resulting in the production of an undulatory current capable of producing in the receiving instrument sonorous vibrations similar to those which were made at the transmitting end of the wire.

"English Mechanic" . . . . * xxvii. 381.

Fig 535.



Edison's Carbon Telephone.

In Fig. 535, the ferrotype diaphragm of the mouth-piece lies upon *B*, which is a piece of rubber resting on an ivory disk, *C*, beneath which is a piece of platinum, *D*. The block of compressed or gas-carbon is represented by *E*, and beneath that is a plate of platinum, *G*, with a screw to attach it to the stem. The latter can be advanced or withdrawn by means of the screwed end-piece, so as to bring the ivory disk, and consequently the carbon, with more or less force against the diaphragm.

Car'bon Test'ing In'stru-ment. An instrument for the determination of the relative quantity of carbon in steel. See, also, CARBON INDICATOR, *supra;* and CARBUROMETER, *infra.*

For fire-damp detectors see GRISOUMETER, and references *passim.*

McCreath's analysis app. . . * *"Eng. & Min. J.,"* xxiii. 169.
Ryder's magnetic testing instr. * *"Eng. & Min. J.,"* xxiii. 27.

Car'bon-zinc Con-nect'or. A binding post used in making the necessary connections between the elements of the galvanic battery.

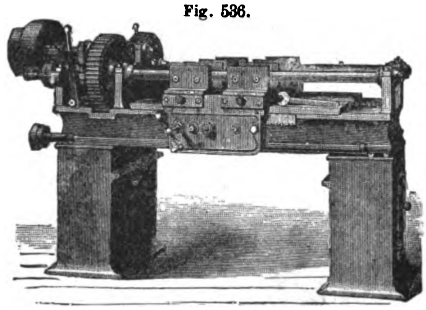
Car-bor'ing Ma-chine'. A boring machine of large size for boring the sills and other timbers of cars.

Such are horizontal, angle, etc. See ANGLE CAR-BORING MACHINE.

Also Fig. 818, p. 341, *"Mech. Dict."*

Car'-box Bor'ing Ma-chine'. A machine to bore the brass boxes for car axles; it is furnished with two boring bars of steel 2⅝" diameter, and so arranged that either bar may be used independently of the other. A slide-rest is provided for each bar, and is so arranged that four boxes may be operated upon at the same time, on each rest.

Fig. 536.



Car-box Boring Machine.

The rests are operated by means of a rod feed; can be used in either direction, or instantly detached and operated with a quick hand movement. The boring-bar is of sufficient length to admit cutters for rounding both ends of the boxes without removing them from their places after being bored.

"Railroad Gazette" . . . . * xxi. 415.

Car'-box Drill. A tool for removing broken cap-bolts from car-truck boxes. The horns projecting below the base are made to include the box, and the pointed set screws take hold of it. — *Thorne & De Haven.*

Fig. 537.

Car-box Drill.

To remove the broken bolt, a hole is drilled in it for a short distance, the drill then removed, and a square drift with tapering edges substituted in the spindle and forced into the hole by the feed-screw, until its edges are slightly imbedded in the bolt. By turning the crank and feed-screw in the reverse direction, the broken bolt will be readily backed out.

See also *"Railroad Gazette"* . . . . . * xx. 75.

Car'-box Grind'ing Ma-chine'. A machine for fitting car brasses by means of an emery wheel turned to the correct circular shape by means of a diamond tool. See Fig. 538.

The brass to be ground is put in a clamp, which is set in planed ways and passed beneath the emery wheel. The detached portions below (*B C D E*) represent parts and boxes in various conditions.

Car'boy. A large globular bottle for acids.

Carboy barrow, Fr. . . . . * *"Sc. American,"* xxxix. 322.

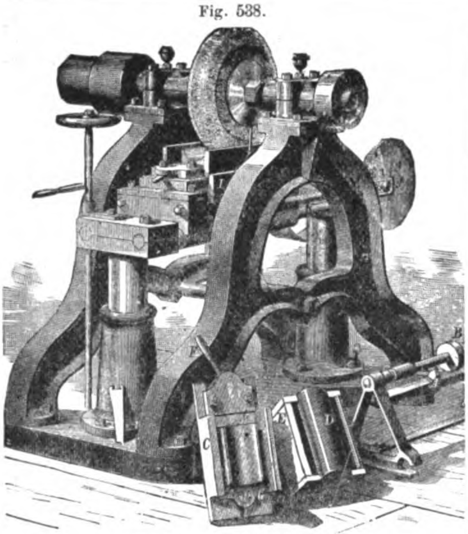
Fig. 538.



Car-box Grinding Machine.

Car′bu-rom′e-ter. An instrument invented by M. Coquillon for determining the composition of gases contained in fuel, as regards their contents in carbonic oxide, hydrogen, and hydro-carburets.

The general principle of the apparatus is the same as the inventor's GRISOUMETER (which see), (fire-damp detector), the hydrogen and hydro-carbon being determined by means of combustion in contact with palladium wire, while the other constituents are absorbed by special solvents.

"*Engineering*" . . . . * xxiv. 317.
"*Scientific American Supplement*" . . . . * 1615.

Car′cel-bec. The French unit of illumination. Given the preference over *candle-power* and the equivalent German and other words, at the Electrical Congress, in Paris, 1881.

Car Coup′ler. A link, hook, or bolt connection between adjacent railway cars.

Miller's arrangement is automatic, and used with his platform. It consists of two heavy iron hooks which act as draw-bars, and are made to engage with each other by springs when the cars come together. See *C C*, Fig. 1607, p. 466, "*Mech. Dict.*"

Janney's. The outer end of the draw-bar is made of a forked or U-shape, and to one arm an L-shaped knuckle or clutch is pivoted, so that when the two draw-bars come together the two knuckles engage into each other. A buffing or compressing device, consisting of two buffers, one on each side of the draw-bar, is also used in connection with the self-coupling apparatus described.

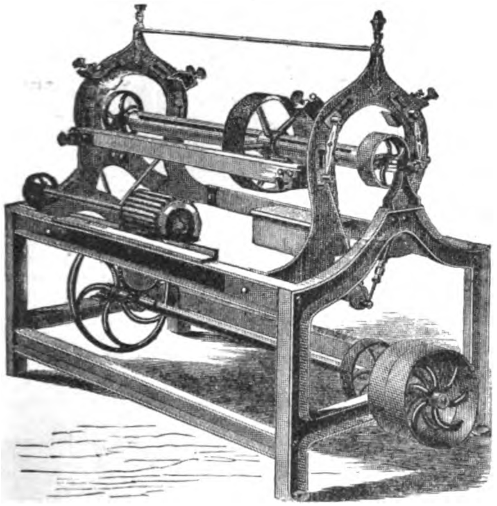
Card'-grind-ing Ma-chine'. A machine for grinding the card clothing of carding machines, to give the shape and sharpness to the ends of the wires.

The card roller or flat is placed in bearings or clamps in the machine, and the grinding wheel traversed back and forth in front of it. The wheel runs clear past the end of the roller or flat, as the case may be, before it stops and commences the backward motion. The traversing grinding roller is held to be an improvement upon a full-length roller, the inequalities of which are repeated upon the card-roller or flat.

Fig. 542 represents the *Hardy* traverse-wheel grinder, for grinding from 1 to 4 top-flats at a time, with a cylinder

Fig. 542.

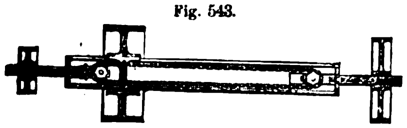


Traverse-wheel Card-grinder.

brush for cleaning out the teeth before the grinding is done perfectly. The motion of the grinding wheel is caused by a screw inside of the slotted and hollow shaft on which the wheels slip and with which it rotates.

Fig. 543 shows Roy's mode of traversing the grinding-wheel; the motion is rapid, the wheel traversing from 10 to

Fig. 543.



Roy's Traverse-wheel Card-grinder.

20 times per minute, according to the length of the card. The motion of translation is by an endless chain and bevel gears inside of the sleeve, which is at the same time the axis of the wheel.

Edwards's mode of clothing the grinding cylinders with emery cloth is described in

"*Scientific American Supplement*" . . . . * vi. 2179.

The grinding machine of *Platt Bros.*, of Oldham, Britain, shown at the Centennial Exhibition, in 1876, was arranged for grinding either two rollers or two clearers at the same time, and for carding-engines both 40″ and 48″ on the wire.

In the most modern construction the machine carries a ventilating fan, and has setting-on apparatus to move the parts to be ground parallel with the emery cylinder; this machine, however, is not adapted for two widths of carding engines.

The machine of *Dobson & Barlow*, of Bolton, Britain, is for grinding rollers and flats, one of each at the same time. It has a cylinder 12″ in diameter, and can have a fan applied. It occupies but a small space. The flat passes slowly over the cylinder while grinding, and returns quickly, thus saving time in grinding. This is a small-sized machine, but they are made to grind two or more rollers or flats, as required.

In the machine of *M. A. Forbush*, of Philadelphia, the grinding cylinder has an angular thread cut from one end to the other, and the card cylinder rests in bearings on the frame and is revolved by a belt from a pulley on the grinder-shaft. Flour of emery and oil are used, and the shape of the end of each wire on the card agrees with that of the angular tooth.

In the carding machine of *Platt Bros.*, of Oldham, Britain, the card clothing on the flats is ground when the machine is in full work, thus avoiding any loss of time and any necessity for a separate grinding machine.

Car'di-a-graph'. An instrument for recording the beats of the heart. It is usually applied to the chest.

The *sphygmograph*, as its name indicates, is applied to the pulse.

The *pneumograph* and *myograph* are also instruments of research of allied character.

The *sphygmograph* of Dr. Keyt (see SPHYGMOGRAPH) is also capable of being used as a *cardiagraph*, for tracing the action of the heart's apex against the chest wall. The base of the instrument is pressed down upon an intercostal space, at the point of greatest impulse, which is usually between the fourth and fifth ribs.

The cardiac apparatus of *Marey* is referred to in

"*Scientific American*," * xxxvi. 51.

"*Scientific American Supplement*," * i. 117.

Laboulaye's "*Dictionnaire des Arts et Manufactures*," tome iv., article "*Graphiques*," ed. 1877.

The telephone is used in auscultation, for cardiac murmurs and different varieties of respiration ("*Boston Medical and Surgical Journal*") and, it may be added, though not apropos of the chest, that the *microphone* has been used by Sir Henry Thompson in lithotrity to detect by sound the contact of the lithotrite (or sound) with fragments of stone.

See, also, PLETHYSMOGRAPH; CHEILOANGIOSCOPE.

Car-di-am'e-ter. An instrument for measuring the rate or force (or both) of the heart action. See CARDIAGRAPH.

Cammann's cardiameter is an instrument for measuring the distance of the apex beat from the median line. It is of the nature of a compass, with sliding bar and graduated index.

Fig. 273, p. 84, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Car'di-gan-jack'et Ma-chine'. A knitting machine adapted to making knit jackets. It is a circular rib machine, making the polka or one-and-one stitch; and the one shown by Gimson & Coltman, of Leicester, England, at the Centennial, had an action by which it could form a welt at any time, according to the length of jacket required. It is fitted with a dial for indicating the length and number of courses made. It will produce in a day 6 dozens of bodies.

See also SLEEVE MACHINE.

Lamb's Cardigan-jacket machine is also adapted for the polka, or one-and-one rib stitch.

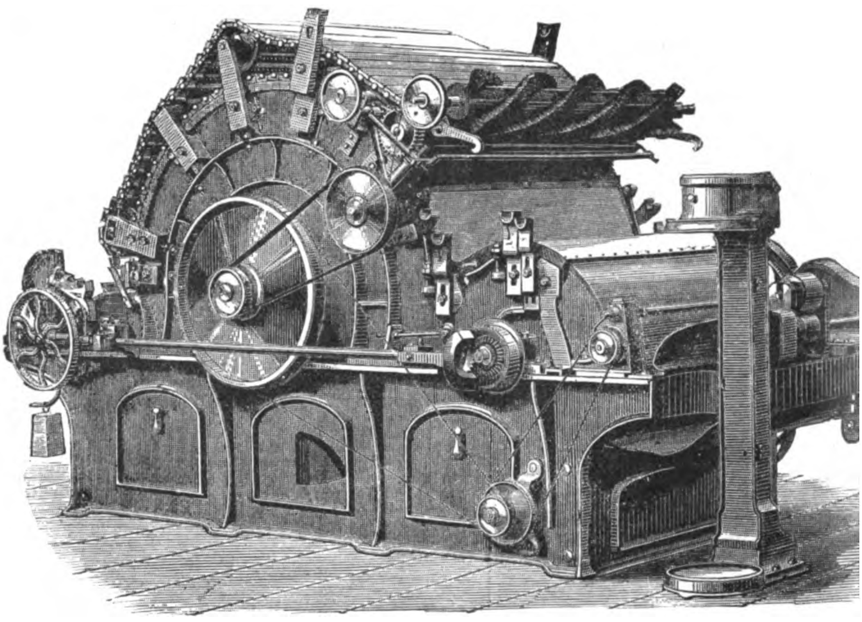
It is described in G. W. Gregory's report on knitting machines. — "*Centennial Reports.*"

Card'ing Ma-chine'. The *revolving*, or *traveling-flat* carding machine, exhibited by Dobson & Barlow, of Bolton, Britain, at the Centennial, has a *cylinder* 50″ in diameter, 40″ wide on the wire; *doffer* 24″ diameter, *takers in* 9″ diameter, also 70 iron *flats* 2″ broad, which have been tested by an apparatus which insures perfect accuracy.

The flats travel over the cylinder supported on a flexible iron bend which has 5 adjusting screws, and by this means the flats can always be accurately set at the proper working distance from the cylinder. The machine has fixings for grinding the flats while the card is at work: also for grinding the cylinder and doffer separately. No less than 27 flats are always at work on the cylinder at any time.

The machine has a taker-in with inserted wire, and containing eight separate coils in every inch. This make of

Fig. 544



Dobson & Barlow's Carding Machine.

taker-in is preferred on account of its not being so liable to choke as the ordinary wire, but is always clean, and requires no grinding. This card is also arranged for stripping out the cylinder by power, and has an angular bar casing under the cylinder only, with adjustable plate to and from the doffer, adjustable knife under taker-in, and sheet-iron division between the cylinder and the taker-in, to keep the waste from each separated.

The advantages of this card are, that the flats can be ground on the machine. The fixings for supporting the flats, knives, etc., are fitted on planed surfaces cast with the bends, so that they are not liable to be moved from their proper positions. All the flats are well borne up when not working on the cylinder, so that the person setting them may be able to test their accuracy without difficulty.

The cylinder and doffer can be ground separately at one time, if required.

The composite carding machine of *Dobson & Barlow*, of Bolton, England, has a cylinder 45″ in diameter, 40″ wide on the wire; doffer 22″ diameter, taker-in 9″ diameter, two rollers 6″ diameter, two clearers 4″ diameter, and 16 flats 2¼″ wide, stripped in three different ways. The six flats at back nearest the feed roller are stripped three times, the five center ones twice, and the five at front once, thus stripping those flats most charged with waste more frequently than the flats nearest the doffer which are least charged.

This stripper is so arranged that a quick motion is given during the time the flat is being stripped, in order to prevent any collection of fly in its absence from the cylinder. The flat stripper is also cleaned by a top stripper, thus allowing the flat stripper to pass underneath the flat perfectly clean, and without the necessity of touching the wire, except in one direction, and that when stripping the flat.

See also, French carding machine; Figs. 1324–1326, article "*Laines*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," tome ii., ed. 1877.

In *Platt Bros.* (Oldham, Britain) carding machine, the oiling apparatus for wool is applied under the first burring (steam) cylinder, the oil being supplied to a trough in which a smooth roller works; above this roller, and in contact with it, is another roller covered with cloth, which is also in contact with the burr roller. The oil is taken from the smooth roller by the covered roller, and from the covered roller to the teeth of the burr roller, by which it is imparted to the wool as it passes over the same. The oil is fed regularly to the trough from a cistern by means of a siphon.

In the triple burr roller arrangement the wire on the first roller is of the coarsest pitch, that on the second of an intermediate pitch, and that on the third roller of a finer pitch; the large burrs, etc., are thrown out by the first guard roller, the intermediate burrs are thrown out by the second guard roller, and the finest burrs by the third guard roller.

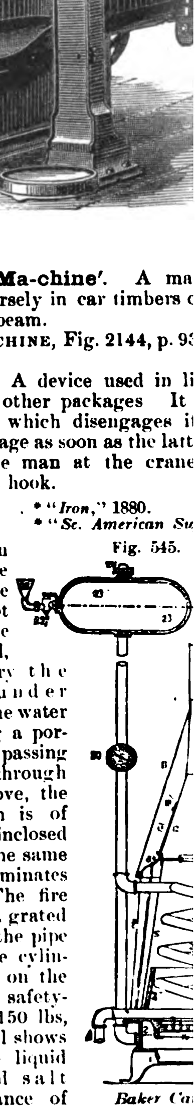
Car Heat'er. In the Baker heater the heat is applied to the car by means of hot water led round the car on the floor level, with bends to carry the pipes horizontally under each row of seats; the water is heated by coiling a portion of the pipe, and passing this coiled portion through a circular iron stove, the fire-box of which is of wrought iron, and inclosed in an envelope of the same material, which terminates at the chimney. The fire is fed by opening a grated lid. Both ends of the pipe terminate in a close cylindrical cistern placed on the roof of the car. A safety-valve is loaded to 150 lbs, and an indicator dial shows the pressure. The liquid used is a saturated salt water. The allowance of

Fig. 545.



Baker Ca

heating surface is 4½' of pipe per passenger. See also page 484, "*Mech. Dict.*"

The French system of heating cars is by portable hot-water heaters placed on the floors of the cars. The apparatus by which they are expeditiously heated in sufficient numbers at large depots is described in a French report, and reproduced in "*Scientific American Supplement*" * vii. 2815.

Acetate of soda in solution is now used on the Paris, Lyons, & Mediterranean Railway. The substance has great latent heat: being heated, the salt dissolves; in cooling, crystallizes; is again heated to redissolve the crystals.

Ca-ril'lon. 1. A chiming or bell-ringing apparatus; or the chime itself. Page 472, "*Mech. Dict.*"

2. A stand of bells mounted on a frame, and used with brass bands.

In Gillest & Bland's (British) carillon machine described in "*Iron*," and reproduced in "*Scientific American*," the difficulty of keeping correct time, owing to the different power required to drive the barrel in different passages of the music, is thus avoided: —

The hammers are always kept raised, and are only allowed to drop by the agency of the musical barrel. The instant they fall they are lifted again, and, so long as the lifting is accomplished quickly enough, the time of lifting has nothing to do with the production of the air. That is determined solely by the musical barrel, which, being relieved of the work of lifting, has little or no strain on it, can be made small and light, and will always revolve at the same rate, and so insure that the tune shall be played in perfect time. It also follows that rapid passages can be played with great ease and precision.

The carillon of the Champ-de-Mars at the Paris Exposition of 1878 was the manufacture of M. Bollee, at Mans, and the statement was made in the presence of the author that the carillon of Buffalo was made by the same founder.

History of the rise and development of carpet-weaving in America: *Hayes* in "*Centennial Report*," v. 70-75. See also page 475 *et seq.*, "*Mech. Dict.*"

Car'pet loom. The Dornan ingrain carpet weaving needle loom is arranged for 16 colored wefts, the vertical lifters being arranged in two ranks and the threads being passed through holes in them so that the thread appropriate to the pattern is lifted into the path of the carrier needle and carried into the middle of the shed where it is met by a hook which catches the weft thread and retires with it to the other selvage where it is knit in by a latch-needle.

The Jacquard mechanism determines the selection of the colored weft thread by raising the weft-lifter. The spools of yarn are placed on skewers on a frame upon the floor. A part of the pattern is given by the warps of solid color, being due to the concurrence of the same colors in the warp and weft. The warp is laid double in the shed.

A forked temple is combined with the jaw temple and a finger extending over the lay holds the several weft-threads in position. The lay operates the let-off and take-up, and the connection with the lay is controlled by a pivoted piece. The Jacquard has a counterpoise motion, having one top-board and two trap-boards. The journals are operated by hooked bars placed in and out of gear with the slides which support the trap-boards.

See, also, NEEDLE-LOOM.

The Murkland power carpet loom is also for weaving ingrain carpets and operates by Jacquard and by shuttles. It carries 20 shuttles and weaves 16 colors. The shuttles are carried in boxes on each side and the selection of color is controlled by the Jacquard, which also governs the warp so as to float the required weft colors in accordance with the pattern. The loom is perfectly automatic.

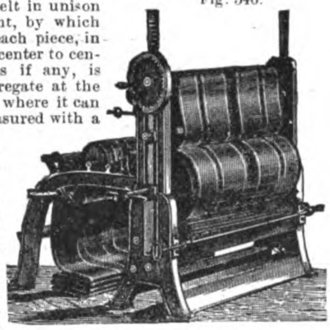
Car'pet Match'ing and Meas'ur-ing Machine'. Carpets which are woven in patterns for matching often vary in the distance from center to center of the figure from various causes, although the greatest care be taken to have them alike. The variations being sufficient to prevent some of them from matching properly, it is customary to measure each piece with a measure corresponding to the length of the figure, and note the difference, whether over or under the standard, on the tag, so that the pieces which agree in length of the figures may be put together.

Short's machine for matching and measuring carpets has an endless belt with divisions of its length corresponding

with the distance from center to center of the figure of the carpet to be matched: also mechanism in connection therewith for drawing the goods over a table alongside of the belt in unison with its movement, by which the variation of each piece, in the distance from center to center of the figures if any, is shown in the aggregate at the end of each piece, where it can be accurately measured with a rule, to be noted on the tag attached to the piece when rolled.

Combined with the mechanism employed for drawing the goods along the matching device, and operating the latter, is mechanism for measuring, singeing, brushing, and rolling the goods at the same time they are matched, by which one movement of the goods answers for all these several operations.

Fig. 546.



Carpet Winder.

Car'pet Wind'er. A machine on which carpet is smoothly wound in rolls from the pile or from the floor. In Fig. 546 the axis is horizontal, and in Fig. 557, the roll is vertical, being a wheel with a vertical spike revolving on a stand placed on the floor of the carpet room.

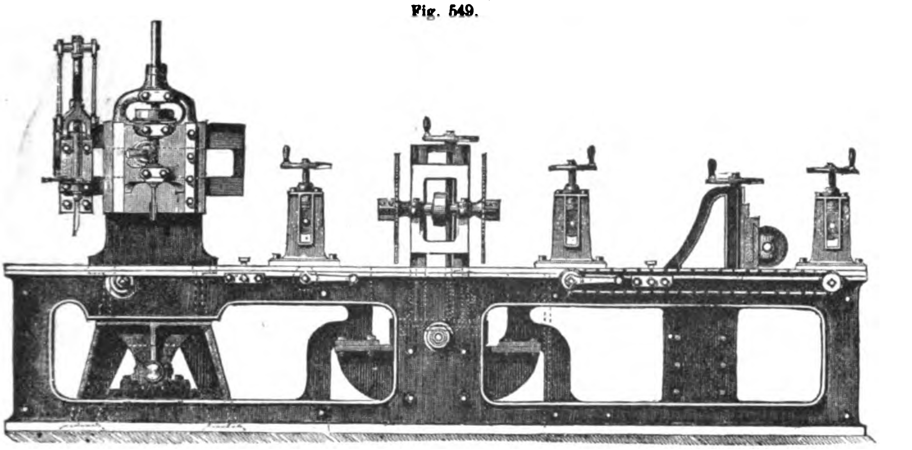
Fig. 549.



Ransome's Car-sill Machine.

without the cutting of the wire or defacing the device.

Car'-sill Dress'ing Ma-chine'. A traverse planer especially adapted for trueing and bringing out of wind the timbers for car-sills. These are planed to absolute shape by being dogged to stiff bed, and not merely dressed to thickness.

The Daniells or traverse planer is used, Fig. 3796, p. 1728, "*Mech. Dict.*"

Car'-sill Ma-chine'. A machine having arranged upon it all the various tools for preparing the sills or sole plates of railway cars. The bed has rollers on which the sills move longitudinally to present them to the various tools for mortising, boring, gaining, recessing, etc. See Fig. 549.

Car'-ten'on-ing Ma-chine'. A large sized tenoning machine, adapted for working on sills and parts of framing of cars.

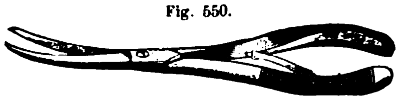
Such a one is the *Gap-bed Tenoning Machine*, Fig. 6305, p. 2532, "*Mech. Dict.*"
See, also, CAR-SILL MACHINE.

Car'ti-lage Knife. (*Surgical.*) A stout, scalpel-shaped knife for severing cartilage. Used in dismembering, post-mortem, dissection.

Figs. 146, 314, 350, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Car'ti-lage Scis-sors. A heavy pair of scissors for dividing cartilages.

Fig. 550.



Cartilage Scissors.

Car Trans'fer Truck. See CAR-TRUCK SHIFTER.

Car'tridge. (*Fire-arm.*) A loaded capsule or case. The case is made of paper or metal; the former, until of late years; now almost universally of metal, — copper or brass.

Cases are *cylindrical* or *bottle-nosed:* in the latter, the portion containing the powder is one or two bores larger than the actual bore of the piece, the chamber being reamed out for that purpose. By this means a shorter case may be used and the proper charge of powder retained.

In cartridge-making 18 different machines are used: 8 to form the case, 3 for the bullet, 5 to make the anvil or cap, and 2 for loading the cartridge.

The first process is called *cupping*, which is done with a die working inside a cutter. A sheet of copper 3'' wide is fed under the cutter by the attendant and a circular blank 1$\frac{3}{8}$'' in diameter is cut, and then pushed through a flaring-mouthed die by the punch, thus making it into a cup-shape about 1'' in diameter and $\frac{3}{8}$'' deep.

In the next machine, called the *first draw*, the cup is fed over the die by the revolving plate and an automatic movement, which takes one at a time off the plate and places it over the die, which is somewhat smaller than the one in the cupping machine. It is then pushed through by the punch. It passes subsequently through four more *drawing machines*, each one making it longer and narrower, until it becomes 2'' long and $\frac{3}{8}$'' in diameter. After the third *draw* it is annealed, having become hard by working.

After passing through the fifth draw it is put in the *trimming machine*, and the edge made even by a revolving cutter which reduces it to a certain size.

The capsule is next put into a machine called the *header*, which spreads the closed end into a head by pressing it into a mold.

The ninth process, *anvil-cupping*, is the same as the first, except that it produces a cup about $\frac{3}{8}$'' diameter and $\frac{1}{8}$'' deep for the cup to hold the fulminate. The anvil is then trimmed in another machine; in the next, called a *venting machine*, two small holes are punched in the head to afford passage for the fire of the fulminate to reach the charge. It next has an impression made in the outside of the head for the wafer of fulminate, and is next put in the *priming machine*, where it receives the fulminate. The practice with *central* fire and *rim*-fire cartridges diverges at this point; in the latter case the fulminate is secured by crimping the case from the outside, the same machine tapering the open end of the case to receive the bullet.

The bullets are made by a machine which cuts about 1'' from a rod of rolled lead $\frac{1}{2}$'' in diameter, and presses the leaden blank in a mold, which gives the shape and makes the three circumferential grooves. The next machine trims the bullets, which then pass through the *lubricator* which fills the grooves with Japanese wax, the object of which is to keep the barrel of the gun lubricated.

The last machine is the *cartridge loader*: the cases come successively under a powder reservoir where a charge of 72 grains is dropped into each, after which the bullet is put in, and the shell pressed around it to hold it firmly.

The following is a list of the machines included in the exhibit of the War Department at the Centennial Exhibition, 1876, under the orders of Lieutenant Metcalfe, in the Government Building; several machines are practically duplicated, as the successive drawing machines for instance: —

Cupping machine.	Priming machine.
Anvil cupper.	Loading machine.
Lubricator.	Drawing machine.
Case trimmer.	Clamp milling machine.
Impression machine.	Bullet machine.
Butt lathe.	Heading machine.
Barrel-boring machine.	Milling machine.
Barrel-turning lathe.	Rifling machine.
Straightening machine.	Bedding machine.
Tapering machine.

Car'tridge Block. A wooden block, bored to receive 8 cartridges, and having attachments by which it is secured to the gun in convenient position for loading. It is shown in Fig. 552 as attached to a *Peabody-Martini* military rifle.

Car'tridge Cap'per. An instrument for securing caps on central fire cartridge-cases. The pivoted lever has a stud beneath, which presses the cap firmly upon its seat. Fig. 551.

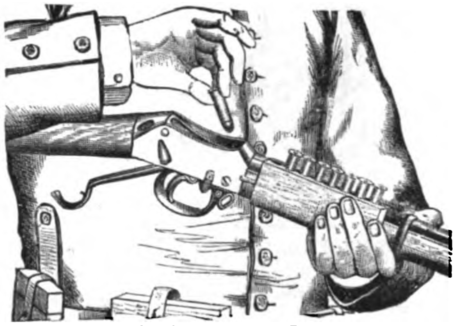
Fig. 551

Parker Bro.'s Cartridge Capper.

Car'tridge-head'ing Ma-chine'. A machine for forming the head or rim of a cartridge case. It consists of a horizontal die, countersunk at one end for shaping the head; a feed punch, to insert the tubes into the die; and a heading punch, to flatten the closed ends of the tubes into the countersink.

The tubes, which are a little longer than the completed cases, are fed into the inclined trough of the machine, whence they are taken up on the feed-punch. A shoulder on this punch, at a distance from its extremity equal to the inner depth of the headed case, prevents it from penetrating to the full depth of the tube, and a surplus of metal is thereby left at the closed end of the tube for the formation of the head.

Fig. 552.



Metcalfe's Cartridge Block.

The feed-punch inserts the tube into the die and holds it while the heading punch advances, presses and folds the surplus end of the tube against the countersink die, thus shaping the head or rim. The headed case is left in the die as the feed-punch retreats, and is expelled by the next case.
The rate is 65 per minute.

Car'tridge-head Test'er. A hydrostatic press invented by Col. Treadwell, U. S. Army, for testing strength of cartridge heads.

Plate XXIII., Ordnance Report, U. S. Army, "*Metallic Cartridges,*" 1873.
Plate XXIV. *et seq.* of the same, show the powder test by eprouvette.

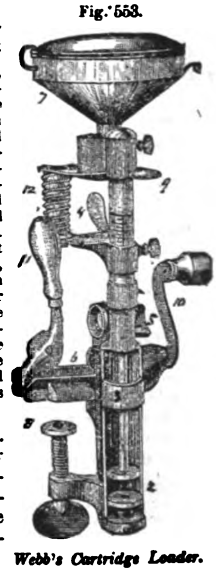
Car'tridge Load'ing Ma-chine'. 1. A machine for loading powder and bullet into a cartridge case.

It consists of a revolving circular plate with holes, and a hopper and powder measure.
The powder is placed in a brass hopper above the machine, and is fed to the cases through a paper tube; the whole inside of a conical shield of boiler iron.
The cases and bullets are fed on revolving plates: the former lifted into the receivers, passed under the hopper and measure for a charge of powder, and then under the bullet-feeder to receive a lubricated bullet. The edge of the case is crimped on the bullet by lifting the former into a contracted space of the receiver around the neck of the bullet.
A bell indicates any failure in the supply of a full charge of powder, and the rate is 35 per minute.

2. On a smaller scale, a machine for reloading cartridge shells.

The machine is clamped to a table, leaving the crimper crank 10 free to turn. The reservoir 7 being furnished with powder, the charger 9 is set to the number of drams required. Hold the shell under the aperture of 12 in the lower shelf of charger, and dump the powder therein. Having loaded the shells with powder, remove the funnel and release the rammer; put the shell in the receiver 2, place the wad on the powder and ram home. Fill the reservoir with shot, set the charger at the gage desired, drop the charge, place a wad on the shot and ram as before; or crimp the shell, placing it in the cradle 6, and rotating the revolving hub by the crank 10. The shell may be shortened before crimping by placing it on 5 and rotating it while the knife 4 is pressed upon it.

Fig. 553.



Webb's Cartridge Loader.

Car'tridge Scales. A machine for automatically verifying the weight of cartridges; invented by *Gootkoffsky*, of the ordnance works, St. Petersburg, Russia.

"The scales are composed of eight balances, slung to the tyre of a small fly-wheel which is brought into action by the main shafting. The cartridges placed by the workmen in the box are caught up by the scales themselves and are placed in the balances. The cartridges are equipoised by a reacting weight placed on the opposite ends of the balances; on the farther rotation of the fly-wheel, the balance gradually comes to an equilibrium, upon which the cartridges of a normal weight, and heavier than the normal weight are declined along with the outer end of balance downward, and are thus pushed off by the scales themselves into the receiver, from whence they fall into a box placed on the floor. The cartridges which are of less than the normal weight, are raised upward and are thrown off by the scales themselves into another receiver, from whence they fall into a locked-up box. The fly-wheel with the balances makes 7½ revolutions per minute, that is, performs 3,600 weighings per hour, or 30,000 per day, allowing for subsidiary work and chance stoppages."

Car'tridge Var'nish-ing Ma-chine'. A machine to coat the interior of metallic rifle shells with an impermeable elastic varnish, to prevent chemical action between the salts of the gunpowder and the material of the shells.

The shells are placed in a hopper, several hundreds at a time, and fed singly into a wheel, with which they revolve, while they are also rotated in the chucks which hold them; this in order to spread the varnish. Forty of them are in different stages of the process at the same time, and the work is done at the rate of 2,000 per hour. The machine is perfectly automatic. The shells are subsequently dried in a sheet-iron furnace.

Cart Rol'ler. A roller which has a cart body mounted upon it. Used in some parts of France for transporting manure on soft prairie ground.

Car Truck. The wheeled frame beneath the body of a railway car.

Safety device, *Root* . .	* "*Scientific American Sup.*," 142.

The principal forms are shown in *Forney's* "*Car-builder's Dictionary*."

Car'-truck Frame Drill'ing Ma-chine'. A multiple drill machine, for drilling at one operation the different holes required in car truck frames.

The frame to be drilled is laid upon the table, which is then fed up to the drills, either automatically or by hand through the gearing. The drills are mounted on an upper frame, at the standard distance apart, and are driven by gearing from the coned pulleys. The drill spindles slide in the vertical holders, which are tubular, and they can be locked in any desired position by set screws at the ends of the holders. The drill spindles can be adjusted on the cross frame to different distances apart so as to suit different patterns of car frames.

Car'-truck Shift'er. An invention, for changing the trucks of cars on roads having different gages, as well as for changing trucks when repairs or new trucks become necessary.

AA represent level outside tracks along the depressed main tracks; *EE* represent trucks on the outside tracks, and *F* the cross-bars or beams for carrying the car body.

To separate trucks from a car body, the car is run to the incline of the pit B, and the small truck *E* placed on each side. The supporting beams or cross-bars *F* are then placed under the frame of the car between the bolsters, the ends of the cross-bars resting on the side trucks at opposite sides of the car. Then, by moving the car over the pit *B*, the car-trucks *D* run down the incline rails, leaving the car body supported by the side trucks *E* and supporting beams *F*. To connect trucks, after the above described process is accomplished, they are run up the incline until the bolt-hole of the truck connects with the king-bolt of the car, and then, by moving the car forward, the king-bolt draws the trucks up to their proper place.

Car Un-load'ing Plow. Dowling's plow for unloading platform gravel-cars, is a V-shaped implement which has two flaring wings. The cars being made stationary, the locomotive is detached, and, being connected to the plow draws it the whole length of the train from car to car, depositing on each side of the track the gravel with which the cars are loaded. See also Patents 63,139, 91,440; grain-scoops for unloading.

"*Railroad Gazette*" . . . . * xxiii. 249.

Car Ven'ti-la'tor. A device for renewing the air of a railway-car. See CAR VENTILATOR, * pp. 490, 491, "*Mech. Dict.*," and AIR FILTER, * pp. 46, 47, *Ibid.*

Winchell's Car Ventilator consists of an air-chamber attached to the roof of the car and extending its entire length. Each end is furnished with a hood, protected by very fine wire gauze screens, through which air alone is admitted to the chamber. Each drum is furnished with a cut-off, operated by a lever within the car, by means of which the supply of air may be regulated. A number of registers in the bottom of the chamber admit the air to the car. When the train is in motion the cut-off in the forward end of the car is opened, and the air enters, passes down through the registers, enters into the car, and, having served its purpose, makes its exit through the rear hood or through the windows, if they are open. In connection with the air-chamber, and for summer use only, are deflectors on the outside of each window, whose purpose is to act as an exhaust, and not only draw out the impure air from the car, but prevent the admission of smoke, dust, cinders, and rain through the open window. These deflectors, which are made of glass, so as not to impede the view from the windows, are operated simultaneously by an iron rod running along the side of the car.

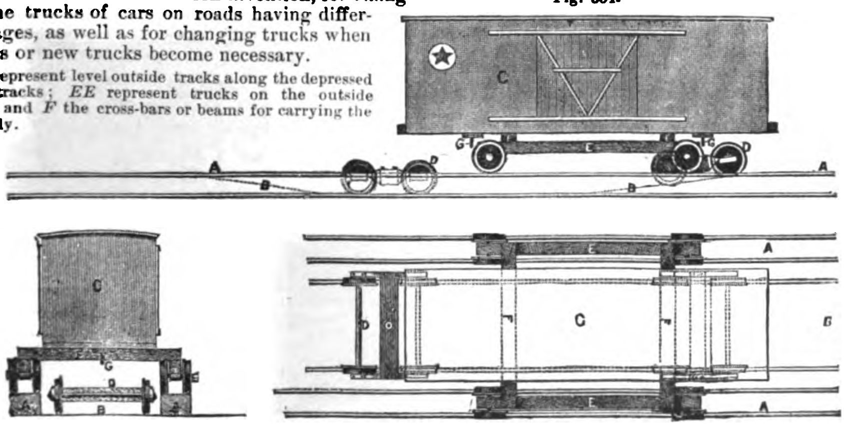
	"*American Railroad Journal*," xlix. 318.
	"*Scientific American*," xxxvii. 262.

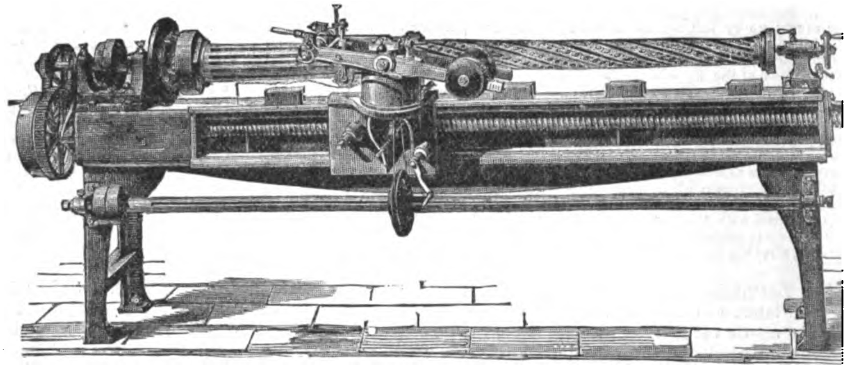
Carv'ing. The ancient, mediæval, and modern, the Orient and the Occident, vie in wood carving.

Fig. 554.



Ramsey's Car-truck Shifter.

Fig. 555.



Arbey's Carving Attachment for Lathes.

It may be said that the art has a renaissance, and the exhibitions show in great numbers imitations of the antique, the grotesque and ornate works of the laborious Orient, and the labors of the graceful modern school.

The Japanese carvings in ivory are familiar, and it may almost be said are beyond praise.

The Chinese carvings in wood are usually in teak, box, and rosewood. Much of the carving in light wood comes from Ningpo; the dark from Canton. Gilding and painting of conventional designs in bright colors are more common than in the Japanese.

The carving of India is all hand work. Sandalwood carving is carried on largely in the Bombay Residency, at Surat, Bombay, Ahmedabad, and Canara. The two former are low relief and foliated ornament. The Ahmedabad is in flat relief, floral and mythological. The Canara, high relief and mythological.

Ebony is carved at Bijnur and Monghyr in geometrical designs.

Ivory is carved all over India: gondolas, elephants, cows, peacocks, statuettes, mythological figures, etc., at Amritsar in the Punjab; Benares, Behrampore, and Murshedabad in Bengal; Travancore and Vizianagram in Madras.

The agate vases of Boroach and Cambay have been celebrated as *murrhine* vases from the time of Pliny.

Black marble is carved at Gya, white marble and reddish sandstone at Ajmere and other parts of Rajpootna. The latter province is celebrated for its white marble idols colored in red, green, and gold. Jade is carved in Cashmere.

The most conspicuous work in Paris, in the Champ de Mars, was the Italian. Usually in low relief, the designs were copies from plants and natural objects, and the beauty of the execution left little to be desired.

Plate VII. shows four panels carved in walnut by Prof. Luigi Frullini, of Florence, and purchased for the Museum of Buda-Pesth.

In regard to the choice of wood for carving, it is said that the magnificent carvings of Grinling Gibbons, at Chatsworth, Petworth, Burghley, Gatton, and other mansions in England are almost exclusively in lime-tree wood (*tilia*). The wood is soft and pliable, and is little liable to split and splinter. It takes a stain well, and, when merely varnished, resembles box.

American walnut is more open in its grain than lime, and more fragile. The color is a great point in its favor — at present.

Sycamore is used for large and coarse work, — bread-plates and bowls, for instance. Chestnut is used also. Holly is a very superior light-colored, even-grained wood.

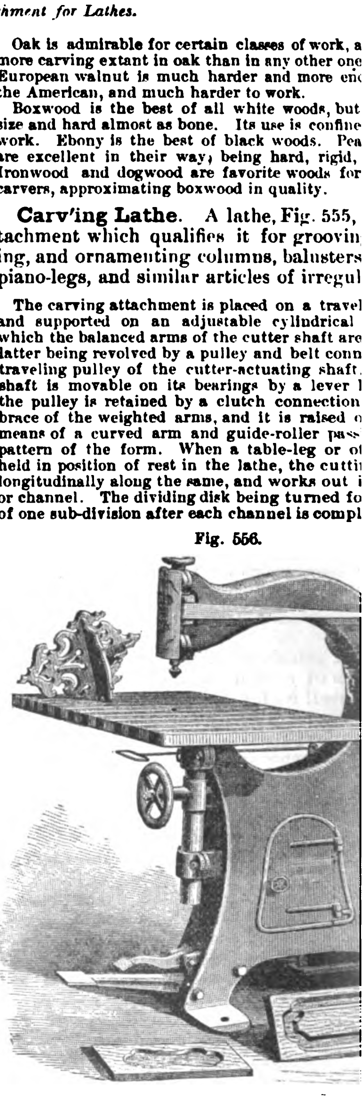
Oak is admirable for certain classes of work, a more carving extant in oak than in any other one European walnut is much harder and more en the American, and much harder to work.

Boxwood is the best of all white woods, but size and hard almost as bone. Its use is confine work. Ebony is the best of black woods. Pea are excellent in their way, being hard, rigid, Ironwood and dogwood are favorite woods for carvers, approximating boxwood in quality.

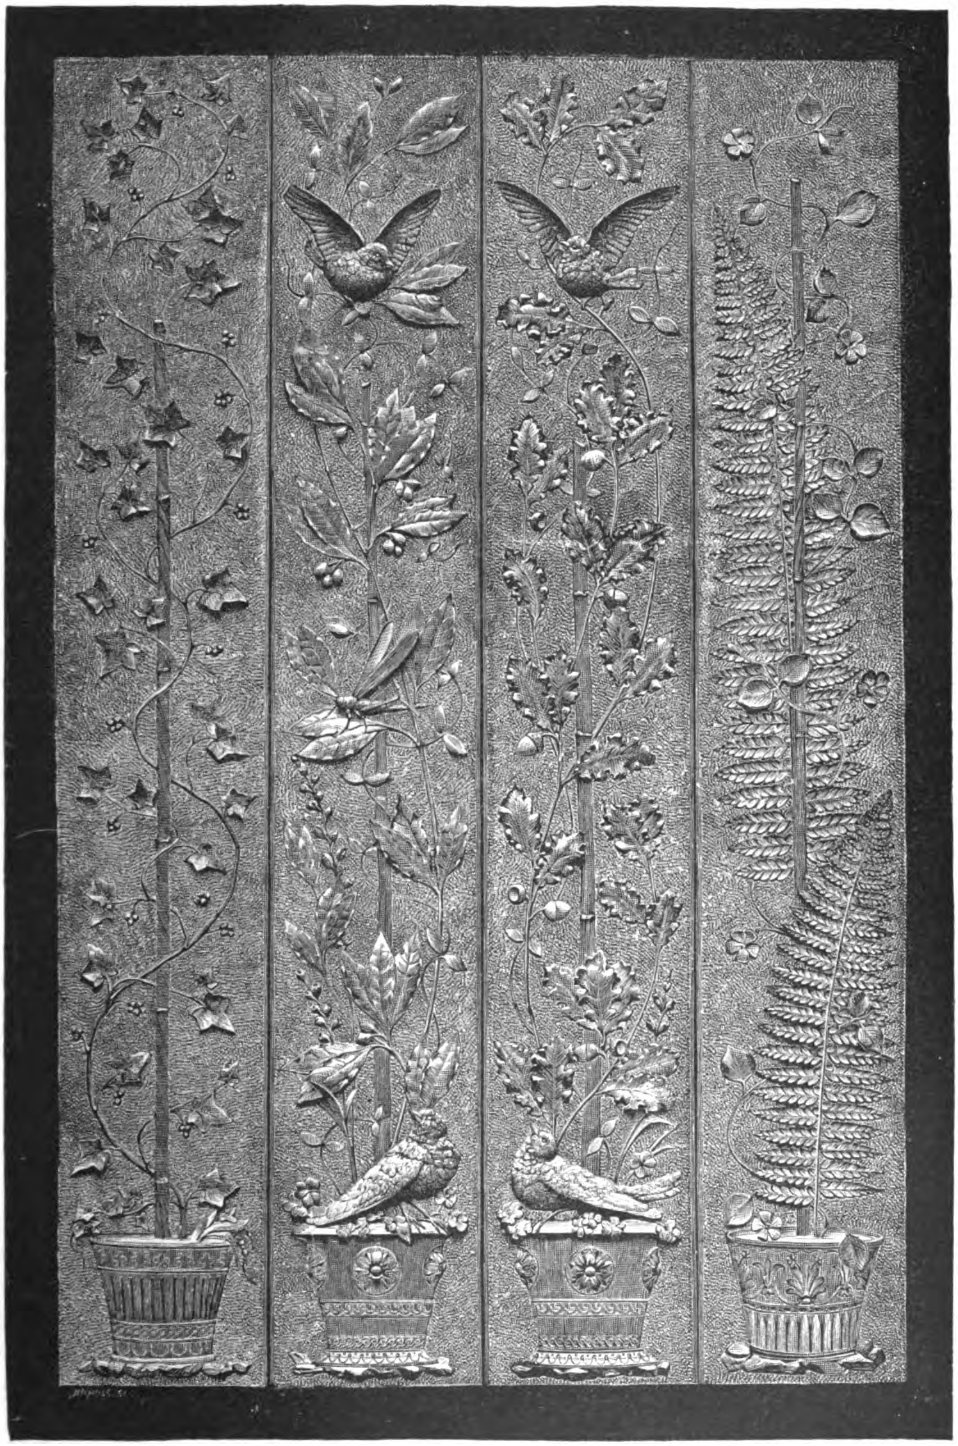
Carv'ing Lathe. A lathe, Fig. 555, tachment which qualifies it for groovin ing, and ornamenting columns, balusters piano-legs, and similar articles of irregul

The carving attachment is placed on a travel and supported on an adjustable cylindrical which the balanced arms of the cutter shaft are latter being revolved by a pulley and belt conn traveling pulley of the cutter-actuating shaft. shaft is movable on its bearings by a lever l the pulley is retained by a clutch connection brace of the weighted arms, and it is raised o means of a curved arm and guide-roller pass pattern of the form. When a table-leg or ot held in position of rest in the lathe, the cutti longitudinally along the same, and works out i or channel. The dividing disk being turned fo of one sub-division after each channel is compl

Fig. 556.



Carving and Paneling Machin



PANELS CARVED IN WALNUT BY PROF. LUIGI FRULLINI, OF FLORENCE.

PLATE VII. SHOWN IN PARIS IN 1878, NOW IN THE MUSEUM OF BUDA-PESTH. *See page* 174

channel is then produced by the return motion of the carriage. By turning the object slowly in the lathe, simultaneously with the revolving and traversing motion of the cutter, helicoidal channels or grooves are formed. For grooving conical parts, the cutter shaft is guided along an inclined guide pattern, or its axis is placed at an angle to the longitudinal axis of the lathe. The cutter adjusts itself to the shape of the object, and carves, by its uniform forward motion, an ornamental groove of equal depth throughout the entire length. For the purpose of pearling or doing other ornamental carving, the cutting tool is guided to the work by a handle, while the object is turned in the regular manner by the dividing disk, so that the pearls may be formed at uniform distances.

The adjustability of the cylindrical standard, in connection with the balanced cutter shaft and handles, admits of the convenient and accurate handling of the carving attachment, so that a large variety of ornamental work may be accomplished on this machine quickly and economically.

Fig. 557

Carving Tools.

Carv'ing Ma-chine'. A machine for producing carvings and recessed or relieved panels on the surface of work; for making edge-molding, ornamental, fret, or bracket work, etc. Fig. 556.

A hollow iron column supports the cutter spindle and the table, which latter is adjusted and regulated to form the required depth of moldings or carvings by means of a hand-wheel and screw, and has sufficient vertical movement to admit of working stuff of 4″ thick and under. The table is elevated by a notched treadle to bring the material in contact with the cutter, and the piece, after being carved, is removed by an auxiliary treadle which disengages a pawl and allows the table to drop to its original position. The cutter may be driven in either direction.

And molding, *Boult* . . * "*Engineer*," xli. 430.
* "*Scientific American Sup.*," 580.

Carving Tools.

Pantograph principle.
Blackman . . . * "*Scientific American*," Aug. 14, 1875.
Arbey, Fr. . . . . * "*Scientific American*," xli. 243.

Carv'ing Tools. Figs. 557, 558 show a number of carving tools, each with its name subscribed. Selected from a still greater number, these yet show considerable variety.

Car'-wash'ing Ma-chine'. An invention of Lord Caithness for washing the sides of carriages.

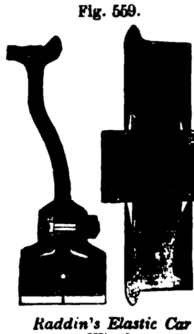
It consists essentially of two large vertical brushes driven by a steam engine. A number of dirty carriages, making up a train of any length, is passed slowly between these revolving brushes; water is thrown upon the side of each railway carriage, 2′ in advance of the brush, from a vertical iron pipe pierced with small holes, placed at an average distance of 8″ from each other. A second water pipe, pierced with similar holes, directs another series of small jets of water directly upon the brushes. The whole arrangement is not very dissimilar in principle to that of hair brushing by machinery.

Car Wheel. Car wheels, cast, wrought, compound, and compressed are shown on pp. 493, 494, "*Mech. Dict.*"

Fig. 559 shows two forms of car wheels, the Raddin and the Bryant.

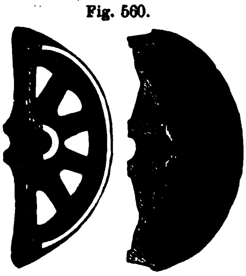
The former, on the left, is an elastic wheel. Being cast in three parts, rubber cushions are interposed between the web and the hub, so that iron does not touch iron, and jars and concussions are absorbed by the rubber.

Fig. 559.



Raddin's Elastic Car Wheel.
Bryant's Self-lubricating Car Wheel.

Fig. 560.



Lobdell's Car Wheels.

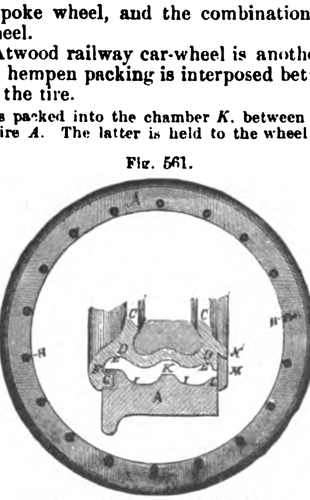
The Bryant wheel, on the right, runs on, not with, the axle, and has a large chamber for oil which oozes through a sponge to the axle.

Fig. 560 shows two of Lobdell's wheels: the hollow-spoke wheel, and the combination double-plate wheel.

The Atwood railway car-wheel is another elastic in which hempen packing is interposed between the rim and the tire.

Hemp is packed into the chamber *K*, between the rim *D* and the tire *A*. The latter is held to the wheel by a lock

Fig. 561.



Atwood Railway Car Wheel.

joint *F G*, and a dovetail ring *M N*. *C C* are the spokes. *H* bolts to secure plate. *F* grooves in rim.

"*Herr Krupp* has lately patented an ingenious mode of manufacturing car wheels. A skelp is first formed of a long flat plate of iron, with a central rib above and corresponding groove beneath, and wide at each end. One end is secured to a rotating mandrel and is coiled on itself, forming the hub; the coiling being continued, the narrow portion of the skelp is wound on itself, forming the web; the coiling of the outer wider end forms the rim. The blank thus formed is placed in the furnace, heated to a welding heat, and welded under pressure into a homogeneous mass of the proper shape, forming the completed wheel. Apart from the facility of manufacture, the invention results in the production of an article of very superior merit, as the fibres of the iron are all arranged parallel to the periphery instead of being tangential or radial, as in wheels constructed by processes hitherto pursued." — "*Railway Review*," xiii. 172.

The endurance of some cast-iron car wheels is very great. Some of the Salisbury wheels of Barnum, Richardson & Co., have made the following record on the Lake Shore and Michigan Southern Railroad: —

4 wheels averaged	185,049 miles.
2 wheels averaged	220,528 miles.
2 wheels averaged	196,967 miles.
3 wheels averaged	189,397 miles.

Lobdell showed at the Centennial wheels which had been 25 years in service on the New York & Erie Railway.

Austrian car wheels by Ganz & Co., Buda-Pesth, made on the American style, were shown in Paris, 1878, one having run 329,400 miles, and another 380,000 miles.

"The paper car-wheels of the Pullman Palace Car Co., are calculated to run 450,000 miles." — "*Chicago Railway Review*."

See Report on "Chilled Cast-wheels for Railways," by *F. Slataper*, "*Centennial Exhibition Reports*," vol. vi., Group XVIII., p. 38 *et seq.*, giving the early history, from Losh & Stevenson, 1826, Bonney, 1829, Elgur, 1833, etc., including —

"*Railroad Gazette*" . . . . . *

Case. *Add.* (*Mining.*) *b.* A vein of quartz, not containing ore, and forming an angle with the lode.

8. (*Founding.*) The cope.

9. (*Fire-arms.*) The capsule of a cartridge.

Case'mate. A vault with an embrasure.

The *Gruson* chilled iron casemate (German) is shown in Plates XXVI.-XXX., Barnard & Wright's report on "*Fabrication of Iron for Defensive Purposes*," U. S. Engineer Department, Washington, 1871.

Casemate carriage for British 10-ton and 25-ton guns. Same report, p. 99, and Plate XVIII.

Casemates. Addendum to Supplement 21 of same report.

Case Trim'mer. (*Cartridges.*) An implement or machine, one or the other, used for trimming the mouths of shells for cartridges. These are fed by a funnel to the tool, which has a knife to cut them to an adjusted length.

Case Smooth'ing Ma-chine'. (*Bookbind-*

Fig. 563.

Sanborn's Case Smoothing Machine.

ing.) A machine for smoothing cloth cases for books; an efficient substitute for the bone folder. The cases are passed between the rubber rollers, two at a time, insides face to face. The top roller is adjustable by means of set screws, to suit any thickness of cover.

Cash'mere. (*Fabric.*) 1. A fine-wool French dress goods, woven with a twill on one side and piece-dyed.

Merino has both sides twilled.

2. A mixed fabric with cotton warp and XX. merino wool weft, made in imitation of the Cashmeres d'Écosse, which are all wool.

This goods is called Coburg in England.

Cashmere shawls. Hayes in "*Centennial Reports*," v. 75, 76.

Cash Re-cord'ing Ma-chine'. A machine on which is made and kept a tally of sums received or recorded.

A given sum being received by a salesman, for instance, he touches the knobs corresponding to (say) $, 1, 2, ., 4, 7, and the record $12.47 appears at a slot, and is at the same time printed on a slip (along with the date and name of the firm) which serves as a receipt, and on a second strip the series of sums which constitute a record of the day's receipts.

"*Scientific American*" . . . . . * xxxviii. 95.

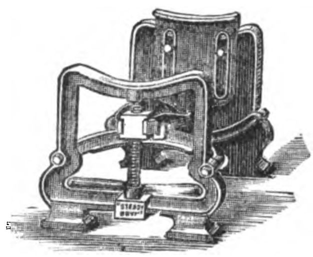
Cas'ing. (*Add.*) 4. (*Glass.*) Enclosing a blown object in another blown piece of similar shape and different color, and then blowing the inner one so that it expands against its envelope, when they may be firmly united by firing, and then finished as one piece.

5. (*Mining.*) A plank partition.

Cask. See Barrel.

Cask Stand. A support or stillion for casks, having an adjustable back support to tilt the cask when necessary. The lift is by a square chased screw, in order to give a steady movement to avoid disturbing the liquor.

Fig. 564.



Cask Stand.

Cas'se-role. A small pan, like a French stew-pan, used in laboratories.

Cas-so-lette'. A pan or tray for perfumes.

Cas'ter. A rolling foot.

Cas'ter Rol'ling-col'ter. A wheel colter mounted on a swivel, so as to present in any direction the plow may be guided. Fig. 1391, p. 596, "*Mech. Dict.*" See Colter.

Cast Gate. (*Founding.*) The channel through which metal flows into a mold. *Ingate.*

Cast'ing. References to devices may be found as follows: —

Preventing honeycombs in	"*Sc. Am. Sup.*," 1842.
Small objects, *Hopkins*	* "*Sc. Amer. Sup.*," 272.
Steel, *Wright, Smith & Butler*, Engl.	"*Sc. Amer. Sup.*," 904.
Case hardening	"*Sc. Am. Sup.*," i. 353.

Cast'ing Net. (*Fishing.*) A net in extensive use in the West Indies, Florida, and elsewhere on the southern coast.

It consists of a circle of netting, varying in diameter from 4' to 15' or more, to the circumference of which are attached, at short intervals, leaden weights. There is a ferrule of bone or metal at a central opening in the net. One end of a long rope passes through this ferrule, and to it are attached numerous cords extending to the lead rope. The net is used by gathering up the casting-rope in a coil on one arm, and taking the net itself on the other. By a dexterous fling of the arm containing the net, this is thrown in such a way as to spread out completely, and it is hurled so as to fall perfectly flat on the surface of the water. The leads sink immediately, forming a circular inclosure, and imprisoning any fish that may happen to be under it at the time. The rope is then hauled in from the other end, causing the entire circumference to pucker inwardly, and the leads and puckered portion come together in a compact mass, in which the fish are entangled.

Cast Por'ce-lain. 1. A milk-white, somewhat translucent glass made from pure cryolite.

2. A uniformly colored or marbled variety of opaque glass made from impure cryolite.

The mixture for the milky variety is: 1 part of oxide of zinc, 4 parts of cryolite, and 10 parts of sand ore, fused in a common pipe-clay crucible, developing a large amount of fluosilicic acid. The pipe-clay is, however, not attacked much by it. This development continues throughout the fusion, and even after it, during the working to a small extent. This glass possesses a considerable hardness and power of resistance; even as a powder it is not attacked by strong acids. According to an analysis of Mr. Hagemann the composition is as follows: —

	Per cent.
Oxide of zinc	6.50
Silicic acid	68.40
Alumina	8.67
Soda	5.85
Oxide of iron and manganese	4.40
Undecomposed cryolite	15.14

The properties of this glass probably depend upon the presence of the undecomposed cryolite; for glass of the above composition, without any combinations of fluorine, is transparent and not colored. Glass with a small amount of cryolite has a milky-white, translucent color, and great brilliancy, refractive power, and strength. With a higher proportion it becomes opalescent, and with more cryolite, opaque and like porcelain.

Cat'a-lan Forge. (*Metallurgy.*) See Fig. 1185, p. 502, "*Mech. Dict.*," and BLOMARY, *supra*.

See also *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," tome ii., article "*Forges Catalanes*," Fig. 1035.

"Catalan forges for smelting iron ore and blomaries for refining pig-iron are largely used in Italy, their number being about 200. Charcoal is the principal fuel used in the furnaces, forges, and blomaries, the Appenine forests furnishing the most of it.

"In the island of Elba they are of unsurpassed richness. The iron ores on this island, and in other parts of Italy, were used long before the Christian era. There are three principal iron districts in Italy additional to Elba — Lombardy, Piedmont, and Tuscany. In all Italy there are about 40 blast furnaces, many of which, owing to the scarcity of fuel, have not recently been in operation.

"There are yet in operation in the United States 64 Catalan forges, for the direct conversion of iron ore into wrought iron; these forges are mainly in New York and Tennessee, and in the former State they are wholly engaged in the production of iron for the manufacture of steel." — *Morrell.*

Saranac . . . . "*Iron Age*," xviii., Sept. 7, p. 9.
* "*Scientific American Sup.*," 628

See also TROMPE.

Cat'a-ma-ran'. 1. A fishing raft used on the Coromandel coast of India. The name signifies "tied-trees," and correctly describes the raft made of 4 or 5 pieces of timber 6' or 7' long lashed together to form a width of 2½', narrowed to a point at one end. The fisherman kneels, and sits on his heels, as shown at Fig. 1186, p. 502, "*Mech. Dict.*"

2. The name has been applied to other craft, especially used on the Hudson River, and in New York harbor. These vessels have twin hulls united, and carry a cloud of canvas, being remarkably staunch.

3. A steam twin vessel similar to the last described, except in the means of propulsion and the necessary appendages of each respectively.

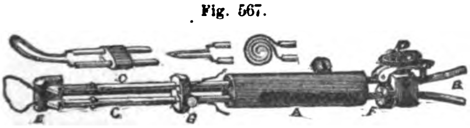
Cau'ter-y. (*Electricity.*) A burning instrument usually consisting of an electro-resisting wire or band of platinum, used in surgical operations instead of the heated spatula. See also ELECTRIC CAUTERY.

Fig. 567 is Dawson's universal electrode for galvanic cautery operations. The various attachments constitute it a

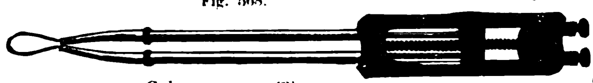
Fig. 567.



Dawson's "Universal" Cautery Electrode.

cautery écraseur, cautery knife, needle, applicator, etc. As an écraseur in the principal instance, Fig. 567 *A* is a solid hard rubber handle, through which pass the conducting rods *CC*, connected with the conducting wires at *B*. The rods *CC*, being hollow half their length, admit of the rods running from the ivory tip *E* to slide in and out like a telescope, which they are made to do by turning the small wheel *F*. This telescoping of the rods keeps up perfect current connection, and at the same time causes a slow contraction of the wire cautery loop at *E*, the ends of the wire being secured in the ivory clamps *G* on the rods *CC*. The current is regulated or cut off and on from the battery by the screw *D*

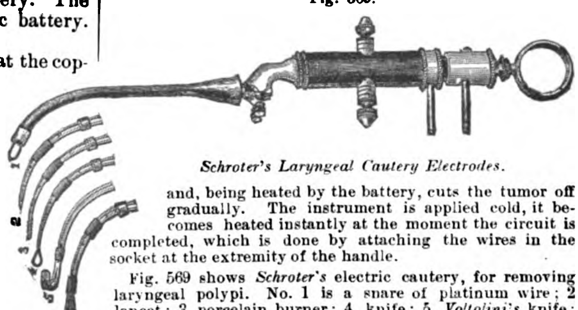
Fig. 568.



Galvano-cautery Sling.

Either of the three smaller instruments is used by withdrawing the tip with its rods and adjusting the substitute into the open ends of the rods *CC*.
In Fig. 568, the loop is formed of flexible platinum wire. By turning the wheel on the handle, the loop is contracted,

Fig. 569.



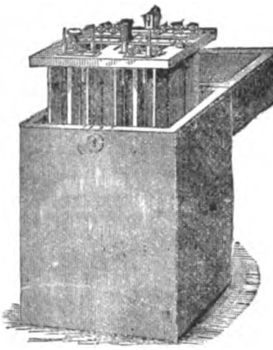
Schroter's Laryngeal Cautery Electrodes.

and, being heated by the battery, cuts the tumor off gradually. The instrument is applied cold, it becomes heated instantly at the moment the circuit is completed, which is done by attaching the wires in the socket at the extremity of the handle.

Fig. 569 shows *Schroter's* electric cautery, for removing laryngeal polypi. No. 1 is a snare of platinum wire; 2 lancet; 3, porcelain burner; 4, knife; 5, *Voltolini's* knife; 6 blunt cautery. Hard rubber handle, sea-horse mounted.

Cau'te-ry Bat'te-ry. A galvanic battery of relatively large electro-motive force and low internal resistance, to be used to heat the platinum wire of a cautery electrode.

Fig. 570.



Cautery Battery.

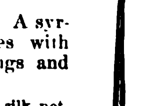
Cau'ter-y In'stru-ments. (*Surgical.*) The application of actual cautery by the battery has many media; among these are —

Écraseurs.
Moxas.
Scoops.
Knives.
Olives, etc.
See CAUTERY, etc.

Cav'al-ry Bit. One having an extended S check-piece, with a loose ring at the lower end, and a loop above the mouth-piece for receiving the bridle-strap. The check and mouth are solid, the latter being made with or without a port.

Ca'ves-son. (*Manége.*) A portion of the apparatus used in breaking a colt, the main feature of which is the nose-piece, which is buckled around the nostrils, having a long rein attached, and by which a colt is controlled until he becomes accustomed to the bit.

Fig. 571.



Cavil.

Cav'il. (*Stone Working.*) A heavy stone hammer with one blunt face and one pyramidal or pointed peen. It is used in a quarry for rough dressing stones for transportation. Weighs from 15 to 20 pounds.

Cav'i-ty Dry'er. (*Dental.*) A syringe for drying dental cavities with warm air, and removing cuttings and bur-dust from excavations.

The rubber air-bulb is covered with silk netting. The other bulb is metallic, and heated over a spirit lamp. In using, the air is expelled, the bulb heated, and the air is then heated by inspiration, and again by expiration as it passes to the tooth.

Fig. 572.

Cavity Dryer.

Ce-les'tial In'di-ca'-tor. An apparatus by which the relative positions of the constellations and principal stars are indicated, so as to enable a person to find them by setting the instrument so that its meridian is in a line with the observer and the north star.

Invented by *Mauperin*, * "*La Nature*," reproduced in "*Scientific American Supplement*," * 622.
See also COSMOGRAPH.

Cell. 1. (*Optics.*) A little frame or shallow box to hold or surround a microscopic object; lying sometimes on a slide, and surmounted by a glass cover.

They are made of glass, block-tin, ebonite, etc., and are of many shapes and sizes.

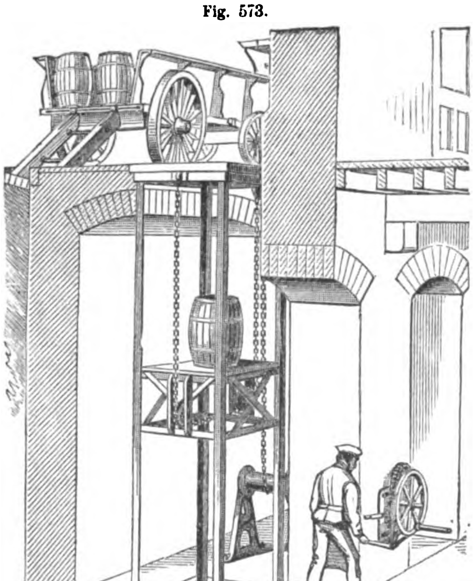
2. (*Electricity.*) A jar or vessel containing the exciting fluid of a battery. See GALVANIC BATTERY.

Cel'lar Crane. A device used in confined situations in streets and warehouses.

The jib of the crane is fixed in the cellar and is made telescopic, so that the load is first lifted from any point within the radius of the crane, and is afterward lifted and carried in a diagonal direction through the doors or flaps until it is high enough to be deposited in the street or on a truck.

Cel'lar Lift. A hoist for raising or lowering

Fig. 573.



Appleby's Cellar Lift.

goods to or from the pavement and the cellar. It works vertically in guides, or on the incline of a ladder, according to convenience.

It is shown in the act of lowering, the man holding the brake.

Cell Cut'ter. A tool for cutting cells out of thin wax: it resembles a wad cutter; any circular tube with a sharp edge will answer the purpose.

Cel'lu-loid. A product having pyroxyline or soluble gun-cotton as its base. A substitute for hardened caoutchouc. Inflammable and dangerous.

Parkesine. Pyroxyline incorporated with linseed oil. Used for knife handles, etc. Named after the English inventor, Mr. Parkes.

Celluloid. Pyroxyline and camphor: —

A solution containing about equal parts of camphor and tetrachloride of carbon, dissolves or softens pyroxyline very readily; and if such a solution is incorporated wit ficient proportion of the soluble nitro-cellulose, a do mass is obtained, which hardens on the evaporatio tetrachloride of carbon; but the material may b made plastic and workable by being heated to a tem between 100° and 125° Centigrade.

Or: the materials may be mixed mechanically at lated temperature.

Or: the camphor may be dissolved in carbon di-s liquefied sulphurous acid, or other solvents.

Parkes process: Nitro-cellulose softened in alco forced into molds under pressure.

The business in this country is understood to b cally under the Hyatt patents, and celluloid made o sue paper and camphor treated with chemicals by ented process. The material is made by the comp sold to parties to make into various articles, the pri graduated according to the ability of the article to given price. The material, while of one quality, is stance, 60 per cent. cheaper for umbrella-handle than for jewelry.

Celluloid may be any color, or mottled. Imit ivory, coral, ebony, horn, tortoise-shell, porcelain, m amber, are easily made.

Celluloid, in its use as a substitute for ivory, ha exercised a great effect upon the ivory industry.

This composition is used for: —

Billiard balls.	Pocket-books.
Combs.	Mouth-pieces for pip
Backs of brushes.	Cigar-holders.
Hand mirrors.	Musical instruments
Toilet articles.	Doll heads.
Whip and cane handles.	Porcelain imitations
Umbrella handles.	Hat bands,
Harness trimmings.	Neckties.
Foot rules.	Optical goods.
Chessmen.	Shoe tips and insole
Knife and fork handles.	Thimbles.
Pencil cases.	Emery wheels.
Dental plates.	Shirt cuffs.
Jewelry.	Collars, etc.

The French process is thus given in the "*Bull.* *Industrielle de Rouen:*" —

"Paper is treated by a continuous process with sulphuric acid and 2 of nitric acid, which convert sort of gun-cotton. The excess of acid is removed ure, followed up by washing with abundance The paste when thus washed, drained, and parti is ground in a mill, mixed with camphor, grou strongly pressed, dried under a hydraulic pres leaves of blotting-paper, cut, bruised, laminated, pressed again in a special apparatus suitably hea said to be hard, tough, transparent, elastic, fusib ing plastic and malleable at 125° C. It ignites with is decomposed suddenly at 140° C. without inflamm gives rise to reddish fumes. It is inodorous, an become electric on friction."

Other compositions of various materials may b follows: see also list under COMPOSITIONS.

Bone-silate.	Ebonite.
Bois-durci.	Eburine.
Boulinikon.	Ebony, artifici
Coral, artificial.	Ivory, artificia
Cellulose.	Hemacite.

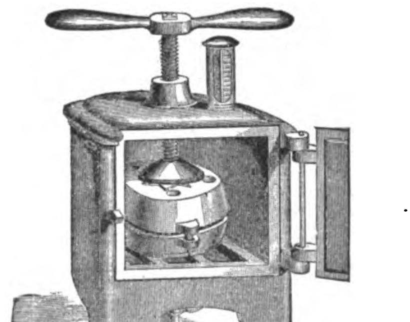
Cel'lu-loid Heat'er. A small oven for packing while heating celluloid plates. It has an inner

Fig. 574.



Heindsmann's Celluloid Heater.

and outer chamber, the latter affording a continuous circulation of heated air. The bottom is ribbed, and the intercostal space filled with plaster to prevent too rapid heating. The door is hinged. The flask containing the teeth and plate is set in, and a clamp screw set through the top of the heater impinges upon the top of the flask. The plaster of the bottom is heated, and the evaporation produces the moist heat which is desirable in the earlier part of the process.

Cel'lu-lose'. The fiber of vegetables; useful especially in the industrial arts as the foundation material for paper; but also of importance as ingredient in the group of objects of which pyroxyline, celluloid, etc., are examples, and as a material which is saturated with nitro-glycerine to produce explosives, under various names.

Ce-ment′. A material for uniting objects or protecting their surfaces.

The compositions differ greatly, and the term is of so wide a signification that it includes mortar, building cements, sticking compositions of gum or resin in solution, pastes, and badigeon for stopping cracks or hiding faults in work; luting for glass or ceramic tubes and vessels. See also CEMENT, pages 507–509, "*Mech. Dict.*"

Besides the recipes and directions found in the following list, there are numerous varieties known under special names, such as BADIGEON, BÉTON, BRECCIA, CONCRETE, HYDRAULIC CEMENT, MORTAR, POZZUOLANA, SCAGLIOLA, STUCCO, etc., in "*Mech. Dict.*" *et infra.* See list on page 1405 of the work cited.

Acid proof: Melt caoutchouc, and add 6 to 8 per cent. of tallow: stir: add dry slaked lime to bring it to the consistency of paste; then add 20 per cent. of red lead.

Or — To a solution of caoutchouc add twice its weight of raw linseed oil; then an equal weight of pipe-clay.

As a lining of cells to make them acid proof: line them with slats of barytes joined with a cement of —

Caoutchouc	1
Turpentine	2
Pulv. barytes	4

To protect a cork from nitric acid: Soak it in a solution of silicate of soda; when hardened, insert cork, and cover with a paste of silicate of soda and pounded glass; wash with solution of chl. calcium. Good for luting.

For protecting wood from acids, alkalies, and corrosive gases: 6 parts colophony, 3 wood tar, fused together, and 4 parts of brickdust stirred in; apply warm.

To unite metal to glass: Powdered litharge . . . 2
Dry white lead 2

Mix; and work up with linseed oil (3) and copal (1) to a dough. The cement is attached to the metal, the glass pressed on, and superfluous cement scraped off.

Or take — Thick solution of glue 2
Linseed oil varnish 1

Boil and stir.

Or — Rosin	8
Caustic soda	1
Water	5

boiled and mixed with half the weight of gypsum.

For fastening letters on glass: Dilute white of egg with water, and add carbolic acid to prevent decomposition; filter: paint the glass with a badger brush; apply the gold or silver leaf; dry; mark the letters with a stencil; put in a warm bath, and remove with the nail superfluous metal.

To stop cracks in glass: Dissolve casein in cold saturated solution of borax; with this solution paste strips of softened bladder on the cracks; dry.

Strong transparent cement, for glass, wood, porcelain, stone. Rub together in a mortar —

Nitrate of lime	2
Water	25
Powdered gum arabic	20

For glass: 1 part India-rubber, dissolved in 60 parts chloroform: 34 mastic; digested at a gentle heat.

Another: Orange shellac, bruised 4
Rectified spirits 3

Put in a warm place, and shake occasionally till dissolved.

To attach wood to glass: Solution of isinglass in acetic acid.

To attach tin to metal: Mucilage tragacanth. . 10
Honey of roses . . . 10
Flour . . . . 1 Mix.

Waterproof cement: Gelatine 5
Soluble acid chromate of lime 1

Cover the broken edges, press together, and expose to sunlight.

To attach wood to wood, or to make cracks in wood water-tight: Lime clay, and oxide of iron; kept dry till wanted, then mix with water and use.

To stick paper, leather, or wood to metal: To a gill of glue dissolved in water add a tablespoonful of glycerine.

To stick leather to metal: Powdered nutgalls dissolved in 8 parts of distilled water; settle 6 hours and filter. Apply this to the leather. Then take a similar quantity of water and add to it 1 part (by weight) of glue. Let it remain in solution 24 hours. Apply to the metal, which should be roughened and heated.

Lay the leather on the metal and dry under pressure.

Rubber Cement: 1 part India-rubber dissolved in 2 parts linseed oil; add quantity sufficient bole, say 3 parts.

For tortoise-shell, amber, etc.: Equal parts mastic and linseed oil, gently warmed, make a good cement, applied warm.

For uniting wood to wood: Shellac dissolved in alcohol. It is well to interpose gauze or thin fabric between the two surfaces. Or shellac, mastic, and turpentine heated, to which isinglass, in small pieces, is added, may be employed.

Attaching small articles to hard surfaces: Coloph pentine, yellow wax, with a small proportion of p sealing wax.

For bone, ivory, mother of pearl, etc.: Glue, dis water and quicklime; pulverized chalk may als ployed.

For ivory: Place pure gelatine in a strong solutio mina. When penetrated by the latter withdraw an mediately. When dry polish.

For porcelain: White of eggs mixed with solutio

Or: 4 parts pulverized oyster shells, and 2 gu preserve in a tightly stopped bottle and when requir mix with white of eggs or warm water to a dough ency.

Or: 8 parts well-burnt alabaster gypsum, 2 parts arabic, mixed with water into a thick paste and drops oil of turpentine added to each ounce of the c

Caseine Cements, for glass, porcelain, stone, a Old cheese rubbed fine and mixed with water, formi to which ¼ part of pulverized lime is added.

Or: 1 part quicklime in water, ¾ pulverized lime stone, 1 pulverized cheese.

Caseine water glass: The caseine is separated fron milk by adding acetic acid, filtering and washi mixed with 6 times its bulk of concentrated water

For artificial meerschaum, coating artificial flo Two to 4 parts of the above is rubbed up with col lution till a thick liquid is obtained that become standing. This is useful for stiffening and wat goods.

Water glass cement. For glass, porcelain, earthen Rub together 1 part finely pulverized glass and 2 fluor spar, add water glass solution till the proper c is attained.

For the joints and edges of stone and marble sl glass, mixed with hydraulic cement to form a thi

For cementing stone, and filling up crevices p painting; fresh blood, slaked lime, brick-dust, hammer-slag, and sand in various proportions.

For the joints of water-pipes, etc.: 2 parts fine 2 quicklime, and 2 hammer-slag, made into a doug or hot oil.

For rendering Hessian clay retorts impenetr slaked lime rubbed into concentrated solution of solution is applied with a brush and after drying heated until the glazing begins to fuse.

German cement for closing joints of stoves: with water, fresh warm blood, and quicklime; i while hot. A compound of wood ashes, fire cla mixed with water is also employed.

Iron cement: 5 parts clay, 1 salt, and 15 i Good to resist heat.

White marble cement: Take 8 parts of resin an to which, when melted together, add 4 parts c Paris. This is used while hot. Apply only a th

Or: Mix 12 parts of Portland cement, 6 par lime, 6 parts of fine sand, and 1 part of infusoria make up into a thick paste with silicate of soda. to be cemented does not require to be heated. twenty-four hours, and the fracture cannot be re

For wood, porcelain, or glass: To a strong sol arabic, 8½ fluid ounces, add a solution of 30 gra of aluminium dissolved in ⅔ of water.

For outside brick-work: Mix 20 parts clean riv quick lime, and sufficient linseed oil to form a This is also useful as a cement for broken stone.

Oil cements. 1. *For porcelain and for luting paratus:* Fine brick-dust mixed with an equal red lead and rubbed or ground with old boiled after being applied, sand is strewn upon it.

2. 6 litharge, 4 pulverized fresh burned lime, bole, mixed with cold linseed oil.

3. *For iron water-pipes:* 12 parts Roman cem lead, 1 litharge, ¼ colophony — pulverize, mix. a 2½ or 3 pounds with old linseed oil, in which 2 o has been boiled.

Or: Equal parts lime, Roman cement, and p finely ground, sifted, and well mixed with linse

4. *Common lead luting* is made of litharge mixed with old boiled oil.

Another is composed of 2 parts red lead, 5 wh 5 fine clay — mix with boiled oil.

5. *For wood:* 1 part pulverized slaked lime flour, mixed with linseed oil varnish.

6. *To make water-holders tight:* Pulverized and cod-liver oil: chemical apparatus may be n oil cake or pressed almond cake, rubbed up wit

7. 10 parts red lead, 25 white lead, 20 pi with boiled oil.

Water cement: 10 parts slaked lime, 19 brick- 5 blacksmiths' dross, 5 powdered quick lime water.

Iron and blood cement: 100 parts pulverize rated with bullocks' blood, 200 parts cement parts iron filings.

Ce-ment′ Cask. Casks, or rather cisterns of cement have been used in Zurich since 1871, by M. Bollert, for storing wine.

First coat selected portions of the cellar walls roughly with cement-mortar, and then with the best pure Portland cement form the other portions of the vessels by pouring the material into suitably constructed wooden molds. The finished vessels may be similar in external appearance to the wooden ones if desired. After the interior is sufficiently hardened, fill with water for 10 days, to ascertain whether they are tight, and also to extract the caustic ingredients of the cement. The latter object is, however, better accomplished with a solution of carbonate of ammonia and subsequent rinsing with water.

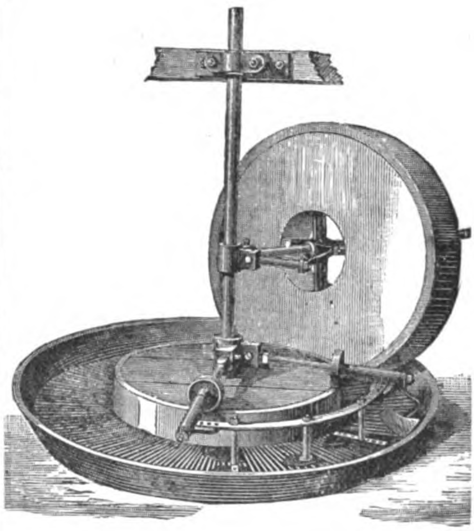
Ce-ment′ Mill. 1. A mill for crushing the auriferous gravel cemented with clay found in the placers of California.

One belonging to the New York & Calaveras Mining Company is cylindrical in form, 41′ long and 6¼′ diameter, set on an incline of ½″ to the foot and revolved. Interior flanges break the cement in passing, water being supplied freely and spaces left to allow the crushed cement to pass out. The bowlders and blocks of cement grind against each other in transitu and the cement is degraded.

2. A mill for grinding cement stone to powder suitable for making mortar, béton. etc.

The machine of *Jannot fils*, of Triel (*Seine-et-Oise*), France, has a Chilian edge-stone traversing in an annular

Fig. 575.



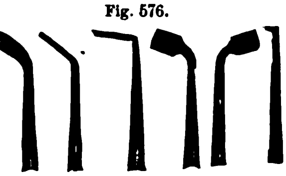
Cement Mill. (*Jannot fils, Triel, France.*)

pan, and with various scrapers which lift the cement and throw it again and again into the path of the stone. A horse is hitched to the horizontal axis of the stone.

It is used for grinding plaster for building, pozzuolana, charcoal, etc.

Ce-ment′ Plug′ger. (*Dentistry.*) An instrument for plugging carious teeth with oxychloride cement.

Fig. 576.

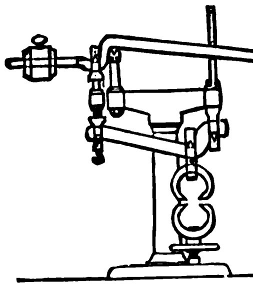


Atkinson's Cement Pluggers.

Ce-ment′ Steel. (*Metallurgy.*) Steel obtained by piling bars of wrought iron in a furnace interstratified with charcoal and exposure to heat without access of air. See Figs. 1197, 1198, p. 509; also p. 2364, "*Mech. Dict.*," *Blister Steel.*

Ce-ment′ Test′er. A machine for ascertaining the breaking strain, or the crushing resistance of cement.

Fig. 577.

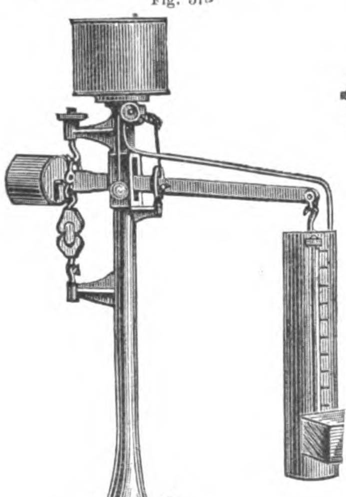


Michaelis' Cement Tester (German).

Fig. 577 shows the apparatus devised by *M. Michaelis*, of Berlin, and which is largely used in Germany.

It has a standard 15″ high, to which are attached two levers, the power of the upper one being 10 to 1, and the lower 1 to 1. The lower lever carries one of the jaws for holding the briquette, while the other jaw is attached to the base plate of the machine, and is vertically adjustable by means of a hand-wheel and screw. From the end of the long limb of the upper lever is suspended a weight-pan, with hooks at the lower end of its framing for carrying a receiver for holding shot. When at rest, the knife-edges of the levers should be on a level, their adjustment being effected by means of the counter-weight on the short limb of the upper lever. In operating with this apparatus the briquette is placed in the holding jaws, which are then adjusted by means of the hand-wheel and screw. Fine shot is then poured into the suspended receiver until the fracture of the briquette takes place. The receiver with the shot is then weighed by an ordinary pair of scales, or it may be weighed on the apparatus itself by hanging it on the hook of the connecting link between the two levers, the weights being placed in the weight-pan. Weighing by independent scales, however, is more expeditious. The weight of the receiver and shot, multiplied by 50, represents the tensile strength of the briquette per square inch of sectional area. The apparatus is portable and does not require to be fastened down for use. It is about 23″ high and 25″ long, and only weighs a little over 50 pounds.

Fig. 578



Bailey & Co.'s Cement Tester (English).

Another machine, on the same principle, is made by Bailey & Co., of Salford, England; but the weight consists of a can, into which water flows from a small reservoir or the summit of the ı
A graduated glass tube indicates the weigh
liquid in the can, and when the cement is
a trigger closes the tap and stops the flow c

The cement tester of M. Hervé Mang
structed for the *Laboratoire des Ponts et C*
of France, is shown in Fig. 579.

The block of cement, molded into the form shov
held between two clasps, the upper one of whi
pended from the short arm of the beam and the
retained by a rod fastened to the frame of the
and capable of adjustment as to length by a hand-
which screws on the thread of the rod. Weight
imately sufficient for the purpose, are placed on the
platform, which is suspended from the end of the
and the smaller weight *P* is then advanced along
uated beam by means of the hand-wheel *C* and
or, for still more delicate movement, by the wheel
moves the worm by pinion and cog-wheel.

M. Mangon remarks that mortar formed of cem
sand 2, should not be subjected to test in less th
hours; and that a test-block 0.04 m. on each side
rowest part, or 0.16 m. square in cross-section shou
after five days at least, 70 kilos before breaking.

The machine made by *Paupier*, of Paris, is ada
for traction or crushing.

M. Hervé Mangon speaks as follows of the P
ment: —

"The applications of Portland cement are ext
merous. Mortar of cement is about as easily e
that made from hydraulic lime. Mason-work i
cement has a solidity, proof against all tests, and
the action of sea-water. With this cement are
light and bold arches and vaults which are among
ishing constructions of the day. It serves to bui
the great reservoirs of the cities. It gives surfa
and moldings as delicate as plaster, with absolut
bility. It furnishes flagging stones of a durabili
stone, and a much cheaper rate. It enters into
sition of the *bétons agglomérés* of M. Coignet, e
extensively in the public works of Paris, and par
the construction of the grand aqueduct for co
water of the Vanne to Paris."

The hydraulic lime of Teil, France, is said to
per cent. of silicate of lime, and to form one of t
cements known. It is used by the "Fire-pro
Co." of New York.

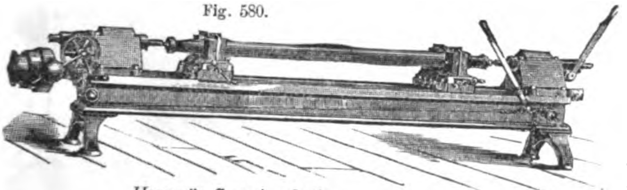
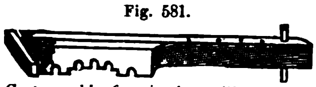
Fig. 580.



Howard's Centering Lathe.

Cen'ter-mold. A templet sweeping upon a center, and used to make circular moldings in plaster, such as those around rosettes on ceilings.

Fig. 581.



Center-mold, for circular ceiling ornaments.

Cen-tes'i-mal Al'co-hol'me-ter. An instrument by *Gay Lussac* for testing the relative quantity of alcohol in a solution of the same. It has a glass spindle, scale 0° to 100°, each degree showing 1 per cent. by volume of pure alcohol of sp. gr. 0.795, in any mixture of spirit and water, at the temperature of 15° Centigrade, or 59° F.

Tralle's alcoholmeter also has centesimal graduation.

Cen-tes'i-mal Scale. 1. A scale in which the poise and the object bear the relation 1 to 100.

2. A scale graduated in hundredths. The French meter; the Centigrade thermometer, invented by Celsius; and the Gay Lussac alcoholmeter, are instances.

Cen-trif'u-gal Ma-chine'. Called also *Dryer, Wringer, Hydro-extractor, Centrifugal Filter, Sugar Dryer*, etc.; under all or some of which heads it is noticed in the "*Mech. Dict.*," *et infra.*

Cen-trif'u-gal Pump. The term *rotary* is usually applied in America to those which have rotary pistons, and the term *centrifugal* to those of the *Gwynne* and *Appold* class.

Rotary pumps, preserving this distinction, are illustrated by 17 Figs. 4465, 4466, pp. 1988, 1989, "*Mech. Dict.*" In Fig. 4466 are also one centripetal and four centrifugal pumps. The rotary blowers, p. 1985, and rotary steam-engines, p. 1991, *Ibid.*, are many of them exactly similar in construction.

Fig. 1216, p. 515, *Ibid.*, illustrates some of the forms of *centrifugal pumps*, and among them the pump of Cogniard *C*, Fig. 1216), as shown at the Paris Exposition of 1867.

Attention has of late been much drawn to the centrifugal pump for draining and wrecking purposes, cases involving the lifting of large bodies of water to a moderate height, and the French have exploited the systems of Appold and Gwynne, the English engineers of most prominence in this line. Cogniard at Paris, Malo-Belleville at Dunkerque, and Dumont & Neut at Lille, are among the principal Continental manufacturers in this line.

Gwynne of Hammersmith, England, has built at Codigoro, near Ferrara, a set of immense centrifugal pumps for the purpose of draining the Ferrara marshes of Italy, which cover an area of 200 square miles, and from which they are expected to be capable of lifting 2,000 tons of water per minute to a height of 12′ as a maximum. The mean lift will be 9′ 3″. Eight pumps are to do this work. They are arranged in pairs, each pair driven by a compound engine. The diameter of the disks of the pumps is 5′, that of the pipes 4½′. The casing is 15′ in diameter. The driving-engines have cylinders 27¾″ and 46⅝″ diameter, with a stroke of piston of 2½′. The cylinders are steam-jacketed. The cranks are so placed as to make an angle of 130° with each other. Surface-condensers are used of 750 square feet of cooling-surface each. Steam is supplied by ten boilers, each having 30 square feet of grate and 730 square feet of heating-surface. These are probably the largest centrifugal pumps, and the whole constitutes the most powerful set of pumping apparatus ever constructed.

The capacity of each of the 8 pumps at the mean lift of 7′ 3″ is 57,000 gallons per minute: the aggregate 456,000 gallons per minute or 656,640,000 gallons per day of 24 hours. This is about 6 times the supply of London, 6 times the capacity of the Croton aqueduct, and double the quantity passing down the Thames above Hampton Court.

A model of the Codigoro pumps was shown at the Centennial Exhibition, 1876.

The drainage pumps of the Haarlem Meer, South Holland, are shown on pp. *116, *739, *1830, "*Mech. Dict.*" These engines are 3 in number, and raise 2,000,000 tons of water per 24 hours, a maximum height of 17.75 feet.

The Heald and Sisco centrifugal pump, exhibited in Philadelphia in 1876, has two forms: A concave arm piston and a hollow arm piston. In the latter case the piston may be described as a wheel having four curved box-shaped hollow spokes, through which the water is drawn from the center through a hollow journal and forced out at the periphery of the wheel. Between the outer face of the latter and the walls of the shell there is a space which gradually widens as the water approaches the exit until it attains the full dimensions of the discharge pipe.

The Andrews centrifugal pump, also shown in Philadelphia, is illustrated at *F*, Fig. 1216, p. 515, "*Mech. Dict.*" Gwynne's at *A*, Coignard's at *B C*, same Fig.

The Enterprise Hydraulic Works (Phila.) pump is under Alden's Patent, April 18, 1848, No. 5513. It has a cast-iron volute-shaped case, in which rotates a disk that has curved tapered wings bolted to each side.

MM. Dumont & Neut's later improvements in this line are shown in Fig. 582, which is a central vertical section and partial elevation. The improvements particularly concern the withdrawal of air which collects at the apex of the turbine chamber and which is a cause of diminution of effectiveness and frequently of stoppage; the latter particularly in cases where the lift is moderate and air is apt to enter at the inlet which may not be entirely submerged at all times. In some cases the air gathers in the center of the turbine where the pressure is least and throws the pump out of action. M. Cogniard devised a plan for removing the air from the center of the turbine by means of a small pump, but the device shown in Fig. 582 is considered more simple and efficacious.

It frequently happens in drainage operations, that air enters at the foot valve of the induction pipe. In this case a communication is established between the circumferential chamber and the center of the turbine by openings *s s′*. When a certain quantity of air is introduced into the turbine it escapes in part by virtue of its levity at these openings, but a portion remains around the central axis. When a quantity of air has thus accumulated, the openings *s s′* eject jets of water at high pressure and drive the air into the vortex of water with which it passes to the eduction pipe, or rising into the apex of the chamber is withdrawn by faucet at the foot of the vase *J*.

The stuffing box is in two parts *o o′*, with a metallic ring *c*, and water from the turbine chamber reaches the journal by pipes *q* and holes *p p*.

D is the discharge pipe; *G G* the driving-belt pulleys; *H H* the standards of the pillow blocks; *I* the bed plate; *F F*, the stuffing boxes; *A M*, the case of the turbine *N b*.

Cen-trif'u-gal Screw. The centrifugal screw has many applications in CENTRIFUGAL PUMPS and VENTILATORS. See under those heads. The screw propeller itself has many features in common with the centrifugal pump, and though now it acts free in the sea, in one of the early forms (*Ericsson's*) the screw acted in a cylindrical trunk. Shaw's propeller pump is shown in Fig. 3977, p. 1810, "*Mech. Dict.*" On pages * 516, 517, are other illustrations of the same principle, and on p. * 2073, *Ibid.*, the same feature is shown as applied to a marine governor; the screw working in a resisting medium is employed to regulate the throttle valve of a propeller engine. The pulley shaft is driven by a belt connection with the engine, and the apparatus is so adjusted that any excess of speed translated by the propeller shaft to the screw in the governor, partially closes the throttle.

Screw ventilator. *Pelzer* . . . . * "*Sc. Am. Sup.*," 4073.

Cen-trip'e-tal Rail'way. It consists of a central or bearing rail, and lateral steadying rails. The running stock has double-flanged wheels bearing upon the central rail, and wheels without flanges on the side-rails. Each set of wheels has a separate and independent axle, and all are arranged to have a swinging and lateral, as well as perpendicular motion, each independent of the other. — *Buzby.*

Cer'a-tome. (*Surgical.*) A knife to divide the iris. *Keratome.*

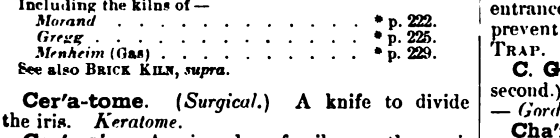
Cer'e-sin. A mineral or fossil wax, the purified product of *ozocerite*, found near the extensive coal-beds of lower Germany and Austria. A substitute for beeswax.

Amber, kauri, ozocerite, are fossil gums.

See list of gum resins and gums, p. 1921, "*Mech. Dict.*," and list of fossil resins, etc., p. 51, *supra.*

Cer'vix U'te-ri Di-la'tor. (*Surgical.*) The internal os is expanded by the instrument, which is introduced while closed, and then expanded with parallel jaws by pressure upon the lever.

Fig. 583.



Dr. John Ball's Cervix Uteri Dilator.

Dr. *Hawk's* dilator is of hard rubber.
Dr. *Sussdorff's* of tupelo wood; a species of *Nyssa*, growing in Florida.

Cer'vix U'te-ri Scis'sors. (*Surgical.*) Bent scissors, smooth or tooth-edged, for amputation of the cervix.

Figs. on p. 81, Part III., *Tiemann's* "*Armamentarium Chirurgicum.*"

Cess'pool Pump. An apparatus for emptying cesspools by means of pump, hose, and wheeled reservoir. Fig. 584.

A 600-gallon tank is mounted on wheels, and has inlet and outlet valves. A 4″ smooth-bore rubber hose, with imbedded spiral to prevent collapse, is used in lengths of 15′ for suction and discharge, having the usual couplings. The air in the tank, as displaced, is driven through a deodorizing can shown in front of the tank, on the rear of which is an indicator. A force-pump connects by suction hose with the vault, and by force hose with the tank. A peculiar flexible rubber tube forms the valve.

Cess'pool Trap. A water joint made at the entrance to a cesspool or pipe leading thereto, to prevent reflex current of fetid gas. See SEWER TRAP.

C. G. S. (*Electricity.*) (Centimeter-gramme-second.) An abbreviated expression for one *dyne.* — *Gordon.*

Cha'fing Plate. A metallic plate interposed between two objects to take the wear. Instances are to be found in the *transom chafing-plate* and the *truck-bolster chafing-plate* of a car truck.

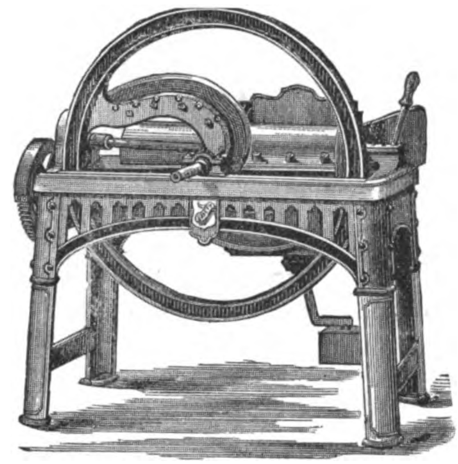
Chaff Sift'er. A machine used to separate seeds and dust from the chaff which comes from the thresher.

Chaff Cut'ter. The machine, with the Edwards (Br.) improvement, for preventing accident, is perhaps the safest machine extant. One can stop the machine, change the direction of feed, or change the length of cut, by a single lever. This is shown at the right of the machine, and is convenient to the left hand of the person who might find his right hand about to be nipped by the rollers. Fig. 585.

Another machine places the shifting lever in such position that a simple pressure even of the body in leaning against it, will stop and reverse the machine.

In another British machine, the same handle which alters the length of cut also acts as a stop-motion, instantaneously arresting the progress of the rollers. Should any hard substance get into the feed when working by power, the attendant moves the handle, which at once stops the rollers and

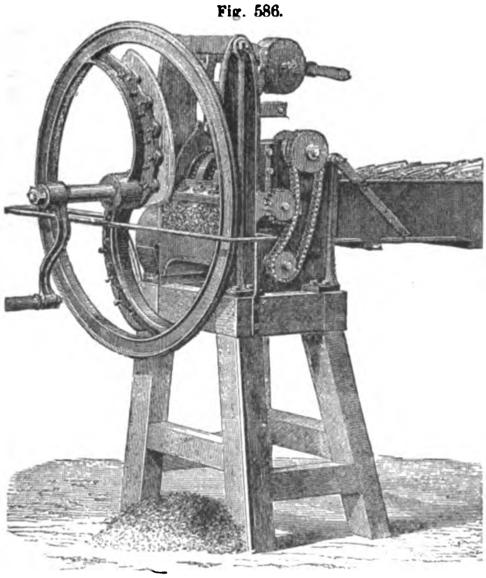
Fig. 585.



Edwards's Chaff Cutter.

throws back the feed about ¾" from the knives, so that the hard substance cannot be struck again. To draw the feed quite back into the hopper the attendant has only to pull round the wheel at the end of the machine, which can be done while the fly-wheel is running at full speed.

Fig. 586.



Albaret's Chaff Cutter (French).

Albaret's Chaff Cutter (French), Fig. 586, shows the favorite French feed motion, by chain. The knives have the same disposition as the British, the best principle as it appears to the writer, that is, a curved knife (or knives) revolving in a plane across the direction of feed. See ENSILAGE CUTTER.

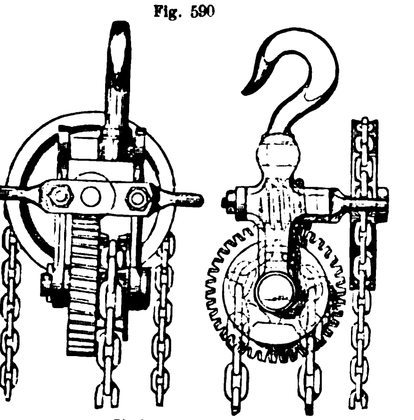
Chain Harrow.

Drawn over the ground, it laps upon a
inequalities and makes a very efficient
in certain conditions of the ground.

Chain Hoist. A lifting tackle in
power is communicated through the m
chain which runs over an indented w
tackle. In Figs. 590, 591, the chain is
and operates a wheel, on the shaft of
worm which gears into a cog-wheel on
the lifting pulley over which the hoist
When one hook of the latter is elevate
is down, and the hoist chain is used bac
alternately.

Chain Loom. A loom in which t
are controlled by patterns on a chain
guished from those operated by cams
quard.

Fig. 590



Chain Pulley Blocks.

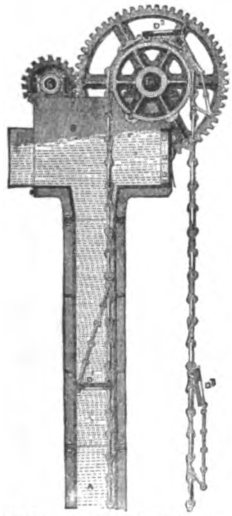
Chain Pump. In which the buckets are attached to a continuous chain. See Figs. 1228–1231, pp. 520–522, "*Mech. Dict.*"

Murray's chain pump is specially adapted for hydraulic constructions, drainage, sewage works, etc., having no clacks nor valves proper to be obstructed by mud, sand, or weeds. The lift is pivoted and slung to the chain, and assumes its position in the up-shaft. If any obstruction enters, a back turn of the chain immediately releases it, the lift folding up, and allowing the obstruction to be carried up in the stream.

Fig. 591.

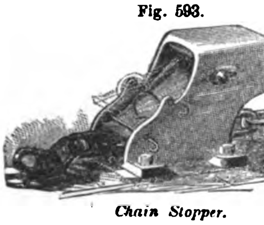
Chain Hoist.

Fig. 592.



Murray's Contractor's Chain Pump.

Fig. 593.



Chain Stopper.

Chain Stop'per. A tunnel with a pivoted flap to engage a link of chain to prevent the paying out of the latter.

Chain-tap'pet Loom. A loom for fancy weaving, in which the harnesses are operated by tappets upon a pattern-chain.

Chair. (*Add.*) 4. (*Glass.*) The bench of the glass-blower at which he sits, rolling the ponty to the end of which the glass under treatment is attached. Fig. 2243, p. 980, "*Mech. Dict.*"

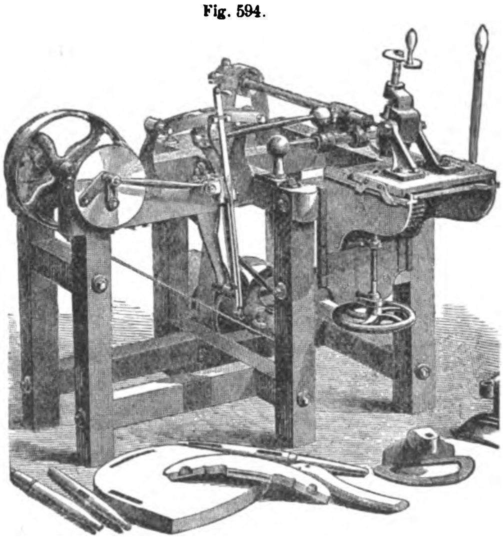
While thus being rotated, rolling by the left hand, the right has the *pucellas*, *shears*, *battle-dore*, to shape or trim; and the swinging, rolling, reheating, blowing, and shaping by tools constitute the manipulations by which the workman, principally guided by his eye, gives the form desired to the plastic mass. *Compasses*, *calipers*, a *rule*, and a *marver* complete the equipment. The *cage*, and the *forked stick* for removing the articles, belong to the boy who runs with them to the annealing oven, technically known as the *leer*.

Chair Mor'tis-er. Fig. 594 is a machine adapted to all kinds of chair mortising, straight or round work; also as a horizontal boring and mitering machine.

The principle of the machine is rotary; the fixed end of the boring bar moves in a ball-and-socket joint, allowing the bar to revolve and the vibrating end to be moved in any direction desired.

The variations from straight to mortises of different curves, are produced by the position of the curved bar, upon which the bearing of the movable end of the boring bar slides; when the bar is placed with the curve horizontal the mortises are straight, and changed to its greatest curve when perpendicular.

Fig. 594.



Lemman's Chair Mortiser.

The range in length of mortise is, from boring a hole to a length of mortise equal to the greatest travel of the cutting bit, and is changed by the stroke of the crank pin being made greater or less, and also by the arrangement of a handle moving the end of the connecting rod, to any position desired, upon a curved rod which produces a greater or less length of the connecting rods, giving any length of mortise desired within the capacity of the machine.

The depth of the mortise is regulated by moving the table, holding the stuff, by a lever in connection with a pinion and rack. The table is raised vertically, by a screw and hand wheel, and provided with three clamps, of different forms, for holding the stuff in the position required for the work.

Chair-stretch'er Lathe. A lathe with a hollow head; like a broom-handle lathe. It has four feeding rolls, two forward and two back of the hollow cutter, and heavy gearing with reversible feed.

Chal'lis. (*Fabric.*) A French worsted dress goods woven upon a gauze or open taffeta loom. It has a silk *grège* warp, and merino-wool weft. It is generally printed. It differs from *barége* in the material of the warp, which in *barége* is of cotton.

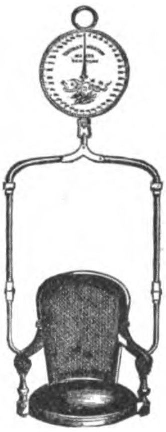
Cham'ber. (*Add.*) 10. (*Fire-arm and Ordnance.*) The space, enlarged or otherwise, occupied by the charge.

Cham'ber Kiln. A brick or tile kiln in compartments; sometimes capable of being heated in succession as with *Hoffman's*, Fig. 903, p. 371, "*Mech. Dict.*"

Johnson, Br. . . . . * "*Engineer*," xlix. 210.
See also BRICK KILN.

Chair Bal'ance. A chair suspended from a spring balance to weigh persons.

Fig. 595.



Chair Balance.

Cham'oied. (*Leather.*) Shamoyed. See TAWING, p. 2500, "*Mech. Dict.*"

Champ-le-ve'. (*Fine Art Metal Working.*) A species of enameling on metal.

Lines are engraved on the metallic surface and are filled with enamel. It is allied to *Niello*.

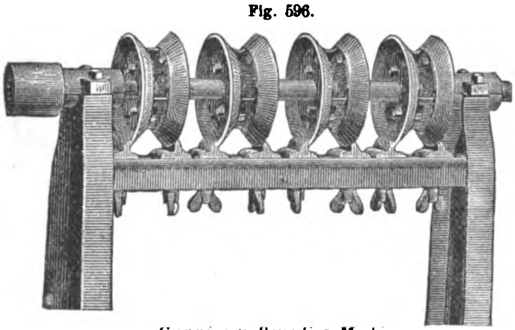
Differs essentially from *cloisonné*, which see. See also INLAYING.

Cham'fer-ing Ma-chine'. 1. A machine for beveling the ends of staves after being set in a cask. See BARREL-CHAMFERING MACHINE.

2. A machine for rounding or cornering timbers, preparatory to putting on the sand-belt; especially used in carriage and implement work.

In the cornering and rounding machine, Fig. 596, the several heads of the spindle are each provided with differently shaped cutters. The amount of corner to be taken off is governed by the distance the bevel-guards are set apart, they being adjustable and retained in position by a set screw in the foot of each. A chamfer of any bevel may be made by having the guards of a bevel to correspond to it. Also known as a *radial planer.*

Fig. 596.

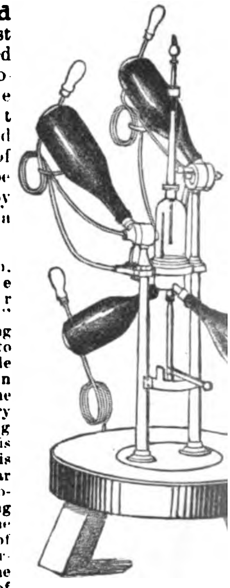


Cornering or Rounding Machine.

Cham'pagne Do'sing Ma-chine'. An apparatus for *dosing*, that is, adding to the wine a portion of sirup, which produces the sparkling ebullition peculiar to this class of wines. Fig. 597.

The bottle of champagne being uncorked, the mouth is placed against the cork-covered mouth of the spout, the bottom of the bottle being pressed by a spring-pad. The handle of the interior faucet is then turned and replaced, a jet of sirup being injected into the bottle. The faucet is of silver, moving on glass, and the pipes all of silver, p side, in order to prevent oxidation or lodgment matters. When the bottle is removed, it is rea corking and wiring.

Fig. 597.



Machine à doser. Tricourt &

Change'a-ble-speed Gear. A nest of gearing placed between the motor and the driven object and so arranged that the speed of the latter can be varied at will by the motion of a lever.

The illustration, Fig. 598, is the changeable gear of the "Climax" mower. By moving the shifting lever to the left, the double clutch is thrown into gear with the slow or ordinary motion. By moving it to the right, this same clutch is thrown into gear with the fast motion. By moving this lever on to the pin in the center of the shifting lever-holder, the machine is thrown out of gear entirely.

Chan'nel Span. (*Bridge.*) In bridges over shallow rivers, the trusses o

Fig. 598.

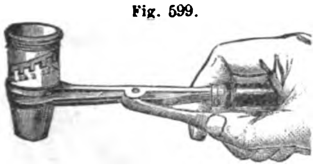
Char'ger. An instrument for measuring powder and shot, and loading into a fowling-piece. One is shown at Fig. 1250, p. 528, "*Mech. Dict.*"

Fig. 599.

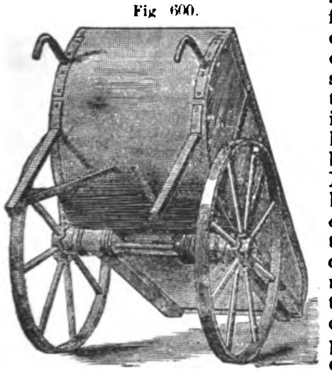


Dougall Charger.

Dougall's charger is a dipper, graduatable by slide for quantity, and discharging the contents into the gun by pressing the lever with the thumb.

Char'ging Bar'row. A double-wheel barrow, for use in iron furnaces for conveyance of coal, coke, limestone, and ore, to be dumped in at the tunnel-head of the blast furnace. It is made of a height in accordance with that of the curb of the furnace mouth, in order to insure the charge being properly dumped. See BELL AND HOPPER, p. 92.

Fig. 600.



Charging Barrow.

Cha'ser. (*Add.*) 3. A *billet*. A short strap on the curtain of a carriage, fastening to a buckle on the back-stay of the top.

Made raised and creased. See BILLET.

Cha'sing. 1. (*Fine Art Metal Working.*) A mode of ornamenting silver ware. It ordinarily follows the snarling tool used in *repoussé* work.

The vessel being filled with a resin composition is placed on a pad, and the surface indented by punches of various forms according to the pattern, and the texture of surface required. Fig. 1256, "*Mech. Dict.*" Fig. 11, p. 290, vol. xxxvi., "*Scientific American.*"

2. Thread cutting on a lathe, by slide rest tool or by comb. See Fig. 1256, above cited.

See also admirable collection of tools, "*Scientific American*," * xl. 223.

Check Chain. (*Railway.*) A chain connecting the car body with its truck, and intended to keep the truck from swinging cross-wise of the track if the truck should become derailed.

Check Guard. A means of preventing tampering with bank checks, raising the figures, etc.

Check-testing apparatus, bank, *Grafelman*.
* "*Scientific American*," xxxvii. 227.

Check protector, *Adair*. U. S. Patent, March 5, 1872, perforates amounts, both figures and words.

Check'ing. Engraved cross-hatching on certain parts of a rifle, gun or pistol stock, to increase the security of grip in handling.

Checking machines are used in armories for cross-hatching the swivel keys of rifles, etc.

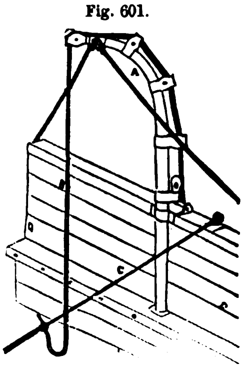
Check Row'er. 1. A corn planter.

2. An attachment to a corn planter by which it is made automatically to drop the seed corn at regular intervals of distance across a field; dispensing with the furrowing out of a field previous to crossing it with the planter, and dispensing also with the assistant at the dropping lever. Haworth.

See CORN PLANTER.

Check Stop. A device used in dredging. The light line *c* breaks when the dredge fills or is foul, brings the slack of the drag-rope *d* on the davit *A* into play, and gives time for the *check stop* — a drum of rubber — to come into play. See DREDGE; also ACCUMULATOR 3, p. 3, *supra*. See also DREDGE.

Fig. 601.



Check Stop for Dredge Lines.

Check Strap. (*Manége.*) *a.* The strap of a harness whereby the collar is connected between the fore-legs to the belly-band, to keep the collar from riding up when the horse is holding back in descending a hill or backing.

b. A strap which couples back the bit of the off-horse to the gears of the one on the near side, to hold back the off-horse when hitched on the *single-line method*, common in the West. A *hold-back* strap.

Check Valve. A valve to prevent reflux of a liquid.

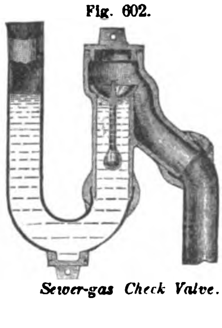
The most familiar instance is the valve below the plunger barrel of a pump, which prevents the return to the well of the water in the stock.

The most familiar distinction of check valves arises from

Shape.	Position.	Purpose.
Globe.	Upright.	Injector.
Disk.	Horizontal.	Pump.
Flap.	Angle.	Sewer gas.
Ball.	Oblique.	Trap.
Butterfly.	Swinging.	Brake.
Piston.		Alarm.
Cone.		Back pressure, etc.

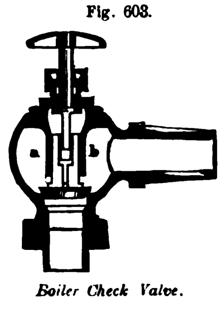
(*Railway.*) In the Westinghouse driving-wheel brake; a valve which is placed in the pipe which connects a driving-wheel brake-cylinder with the air-reservoir. The pressure in the reservoir causes the valve to seat itself or close. The air must then flow through a small hole which is drilled in the valve, which prevents the brakes from being applied too

Fig. 602.



Sewer-gas Check Valve.

Fig. 603.



Boiler Check Valve.

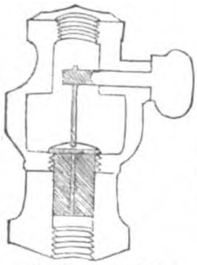
suddenly. When the brakes are released, this valve unseats, and permits a quick escape of the air. *Forney.*

Fig. 602 is *Waring's* check valve for sewer gas traps.

Fig. 603 is the boiler check valve of the injector apparatus of locomotives.

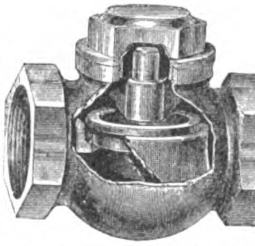
Fig. 604 is the lower check valve of the Douglas pump, placed in the suction pipe of the pump, at a convenient point to get at to let back the water to avoid freezing. Turning the thumb-screw lifts the valve, so that the water will run back.

Fig. 604.



Pump Check Valve.

Fig. 605.



Cushion-seated Check Valve.

Fig. 605 shows Shaw's cushion-seat check valve, designed to prevent hammering on the seat. A portion of the pumped liquid is confined in the annular space around the disk, which in falling seats itself upon a cushion of liquid.

Ball, *Hay & Bassett* . * "*Scientific American*," xxxvii. 182.
Swinging . . . . . * "*Manufacturer & Builder*," x. 220.

Check. (*Add.*) 13. (*Mining.*) The side or wall of a vein.

14. (*Manége.*) That portion of a bit outside of the horse's mouth.

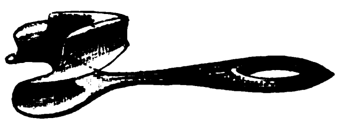
15. (*Nautical.*) Of a block; one of the pieces forming the sides of the shell. These have *scores* on the outside for the *strap*, and holes with *bushing* for the *pin*.

Cheek Re-tract'or. (*Surgical.*) A smooth flat hook to hold the cheek retracted and mouth distended when operating for cleft palate, *staphytorraphy*; or in grafting in cases of deficiency of the soft palate, *uraniscoplasty*.

See Figs. 298, 298 *b*, Part II., *Tiemann's* "*Armamentarium Chirurgicum*."

Dr. Roe's mouth-gag and cheek retractor is a modification of the instrument of *Luer*, in respect of the addition of a

Fig. 606.



Roe's Cheek Retractor.

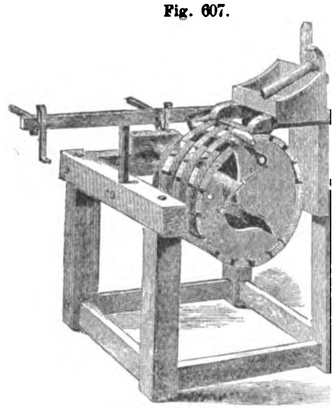
triangular or wedge-shaped block to the external surface of the cheek retracting portion of the instrument, this portion passing between the teeth and distending the jaws. A cord is passed through the hole in the handle and tied behind the head.

Cheese Box Ma-chine'. A bench used in making cheese boxes. A horizontal stem holds the former on which the box is to be built. The box is in fact a cage of slats and hoops which are put together on the former, the latter acting as a core for the frame during construction. Fig. 607.

Cheese Knife. A device for cutting a given weight of cheese in retailing. Fig. 608.

The cheese is weighed and placed on the platform, which is rotatable by the small crank at the side. By referring to the table on the column supporting the knife, there is found opposite the number representing the weight of the cheese the number of revolutions or fractional parts thereof the small crank has to be turned to measure off a pound. Then by turning the large crank, the knife blade descends, cutting off the required sector by a single stroke.

Fig. 607.



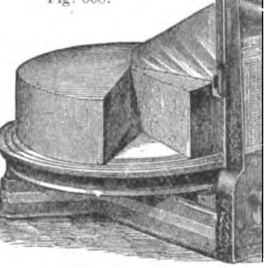
Cheese-box Machine.

Cheese Press. A press for sque curd in the hoops to expel the whey and form cheeses. See pp. 533, 534, "*Mech. Dict.*"

A cheese press for acting upon a whole row of cheeses in their hoops, is shown in Fig. 609.

The hoops (and contents) are placed

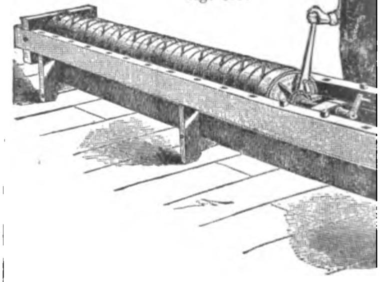
Fig. 608.



Retailer's Cheese Knife.

in a horizontal frame, and advanced by a screv device is adjustable on such part of the length as may suit the number of cheeses to be o The crank handle being then turned gives the first pressure; the power is increased by the use of the lever, — a ratchet on which acts upon a

Fig. 609.



Frazer Gang Cheese Press.

wheel upon the screw. A trough beneath pressed whey.

Compound lever cheese press . * "*Sc. Americ*

Chei'lo-an'gi-o-scope. An appar by *Dr. Huber*, of Greifswald, to enabl tion of blood of a person to be examin

The previous methods of ocular demon circulation have been, by placing the foot o stage of the microscope, exhibiting the ci web. *Perkinje's* experiment, by which an observer is enabled to observe the circulation in his own retinal blood-vessels, is also familiar.

Dr. Huber fixes the head of the subject to be examined in a frame not unlike that used by photographers, on which is fixed a holder for the microscope and a lamp. He then draws down the lower lip of the subject upon the stage of the instrument, with its delicate inner surface upward for inspection, throws a strong light on the same with a condenser, and focuses the microscope, provided with a low-power objective, down upon the delicate net-work of blood-vessels, which can be seen there even with the naked eye. By this simple means the circulation can be observed with the greatest ease and perfection.

Chem'i-cal Fire En'gine. A fire extinguisher which depends upon the evolution of carbonic acid gas, alone or in company with water, for the extinction of fire. See FIRE ANNIHILATOR, "*Mech. Dict.*"

Che'not Steel. (*Metallurgy.*) A peculiar iron is carbonized with such matters as fat, resin, tar.

Chick'en Feed'er. See ÉPINETTE.

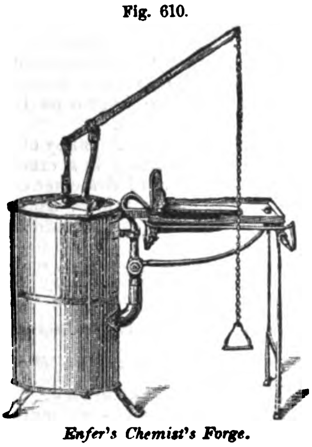
Chick'ley. A gum resembling gutta-percha, obtained from one of the *sapoteæ*, in Guiana.

Chif'ney Bit. (*Manége.*) A curb-bit having a movable short arm attached to the cheek-piece, just above the mouth-piece, for receiving the check-straps of the bridle, the gag-rein or strap being attached to the short arm of the cheek-piece.

Chill. 1. The hardened part of a casting: as the tread of a car-wheel.

2. A portion of a mold against which the molten metal is suddenly cooled in order to harden the casting.

Fig. 610.



Enfer's Chemist's Forge.

Chilled Plow. A plow the mold-board of which is cast on a chill to harden it and increase its wearing and polishing qualities.

Chilled Roll. See CALENDER ROLL.

Chem'ist's Forge. A laboratory forge. That shown in Fig. 610 is by *Enfer*, of Paris. It has a Chinese-lantern bellows in the cylinder, worked by a treadle and lever. It is primarily intended for lamp or gas blow-pipe, but has many convenient applications. Other forms are shown under LABORATORY FORGE, BLOWPIPE, etc.

Chime. 1. (*Music.*) A succession of bell sounds. Bells are usual; wires or bars are occasionally used. Evelyn mentions a chime of porcelain dishes.

Electric chime for clocks . .	"*Sc. Amer. Sup.*," * ii. 702.
Chiming clock, Bombay Univ.	"*Sc. Amer. Sup.*," * iii. 946.
Centennial chime	"*Iron Age*," xvii., June 29, 8.

See *Armstrong's* "*Chimneys for Furnace, Fire-places, and Steam-boilers.*"

2. (*Mining.*) Chimneys are the richer spots in lodes as distinguished from poorer ones.

Chi'na Grass. A fiber resembling the Rhea. It is prepared for manufacture by treating with a hot solution of carbonate of soda.

Chine. 1. The end of a stave at the head of a cask or tub.

2. The edge formed by the ends of the staves.

Chi'nese Pa'per. Commonly known as rice paper. This is prepared by the Chinese from the stems of a leguminous plant, *Aralia papyrifera*; these are cut so as to form a continuous spiral film, which is then pressed flat, and afterwards dyed or otherwise prepared. They also make a true paper from bamboo stems by pulping and forming into sheets.

The Egyptian papyrus was also a pith paper, but the description of its manufacture by Pliny does not convey (as translated) the right impression as to the mode. The stem is a triangular prism; the sides were pared off, and the slips thus obtained united by their edges while yet damp, by means of pressure.

The Japanese and Chinese make paper also from *Broussonetia papyrifera*. See p. 1606, "*Mech. Dict.*" This source yields also the *tapa* cloth of Hawaii, the *masi* of the Fijians. See "*Atlantic Monthly*," xxxi. 233.

Chin-chil'la. (*Add.*) (*Fabric.*) *b.* A camel's hair French goods.

Chintz. (*Fabric.*) From Hindu, *chint* or *chete*, "variegated" or "spotted," whence *cheta*, the hunting leopard.

Chip Syr'inge. A rubber bulb syringe used by dentists to wash away detritus from a tooth under treatment. See BULB SYRINGE.

Chip Break'er. 1. A plate on the back of a plane bit, to bend up the chip and prevent splitting of the board.

2. A clip or piece on the side cutter-head frame in a matching machine; breaking the chip prevents splitting of the edge of the board.

Chis'el. (*Surgical.*) An instrument driven by a mallet for cutting bone. The gouge is a chisel with a curved edge, and has a similar use. Used in *osteotomy*, post-mortems, and dissecting. Chisels are edge or end sharpened, and some have specific names.

The figures refer to *Tiemann's* "*Armamentarium Chirurgicum.*"

Knife chisel	Fig. 86 *b*, Part I.

Chro'mo-strob'o-scope. An instrument invented by Prof. A. Ricco, with colored glass and various designs. It is one of a class of scientific toys depending for its effects upon the persistence of visual impressions.

* "*English Mechanic*," xxiii. 168.
Ricco . . . . . . * "*Scientific American*," xxxiv. 212.

See ANORTHOSCOPE, STROBOSCOPE, CHROMATROPE, THAUMATROPE, PHENAKISTOSCOPE, ZOETROPE, in "*Mech. Dict.*"

Chron'o-graph. The British test of powder is by the velocity of the projectile, a given quantity with a service projectile from a proof-service gun.

The Boulengé chronograph is used. The first target is 45' from the gun, the second 165'. The pressure in the bore is determined by the crusher-gage, — a modification of Rodman's pressure piston. See INTERNAL PRESSURE-GAGE, CUTTER, DYNAMOMETER, PIEZOMETER.

The Boulengé chronograph used at the arsenal of Spandau, Prussia, is shown at Fig. 36, Appendix L., "*Ordnance Report*," 1877, and p. 533.

See *Laboulaye's* "*Dictionnaire des Arts*," etc., tome iv., article "*Instruments d'Optique*," ed. 1877.

"*Scientific American Supplement*," 417.

See also ELECTRIC CHRONOGRAPHS AND CHRONOSCOPES.

Chron'o-scope. An instrument for measuring small intervals of time.

The following electro-chronoscopes are described by Dr. Barnard in his Report on the Paris Exposition of 1867: —

Prof. Wheatstone.	Col. Benton.
Prof. Henry.	Capt. Martin de Brettes.
Capt. F. P. E. Schultz.	Prof. Bashford.
Capt. Navez.	

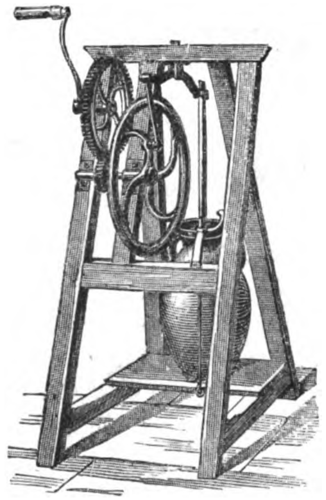
Dr. C. W. Tiemens . . "*Scientific American*," xxxv. 328.

See also ELECTRIC CHRONOGRAPHS AND CHRONOSCOPES.

Chro'no-ther-mom'e-ter. An instrument, the invention of Mr. R. P. Wilson and used in the testing room of the petroleum association of London. The design is to raise the temperature of the oil at the rate of 20° in 15 minutes.

The invention consists of a watch movement in conjunction with a circular thermometer. The watch is provided with but one hand, and the balance-wheel is so adjusted that this hand moves through 20° of the thermometer scale in 15 minutes. It is, therefore, merely necessary, in making an experiment, to set the hand when the mercury reaches 80°, and to regulate the lamp so that the quicksilver and the watch-hand travel round the dial *pari passu*. If the thermometer is observed to be getting ahead of the watch, the light under the water-bath is slightly lowered (this being easily effected by the mechanical arrangement in the wick-holder), and, of course, *vice versa*.

Fig. 615.



Breton Churn.

The inner line of degrees marked on the thermometer scale represents minutes (1 to 15), and the outer line, degrees of Fahrenheit's scale, 20 of which (80 to 100), it will be observed, are equivalent to the 15 minutes, though, of course, in the construction of the instrument, any other desired rate of heating may be provided for.

"*English Mechanic*" . . . . *
"*Scientific American Supplement*" . . . . . * 181.

Chry'soid. A name given by Farmer to his alloys of aluminum which resemble gold and are adapted for watch-cases, chains, and jewelry.

Four series of formulas, —

Cu. Al. Ag.	Cu. Al. Fe.
Cu. Al. Zn.	Cu. Al. Ni.

are given with varying proportions, on p. 71 of "*Mech. Dict.*"

Chuck'ing Ma-chine'. A form of machine lathe. Fig. 614 shows a revolving-head drilling or chucking machine with 8 spindles. Instead of a common tail-stock there is a revolving or rocking head, revolving in a vertical plane, with several spindles, for facing, drilling, reaming, and counterboring small work.

By this means a piece may have several operations performed upon it without being removed from the chuck or face-plate. The several tools are brought forward as desired or in turn by the hand-wheel.

Churn. The Breton churn is shown in Fig. 615. The cream jar is clamped upon its stand and the dasher reciprocated vertically and rapidly by hand crank and gearing.

Churn Drill. A form of drill, the earliest type of which is in one of the forms of implements for obtaining fire by friction of one piece of wood on another.

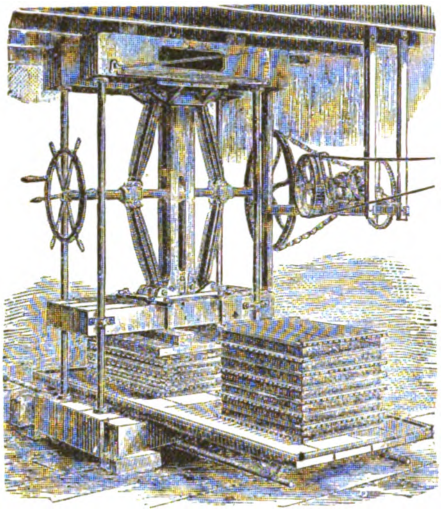
For an improved form see HAND DRILL.

Ci'der Press. The Boomer & Boschert cider press, Fig. 616, has a special grinder with an iron cylinder furnished with 8 steel knives placed in planed grooves across the face of the cylinder and held in place by iron bands at each end. Five concaves of flat steel springs are adjustable to any required distance from the cylinder, and each regulated to any degree of stiffness, but giving way to any foreign matter, such as stones.

The power press has a double platform which runs on rollers so that one cheese may be building while another is pressing.

In running down the press the right-and-left screw is rotated approaching the knees of the pair of toggles, passing through nuts in the knees, and rotated by the hand wheel at first but by means of the pulley, gearing, and chain as the work proceeds and more power is required. The movement

Fig. 616.



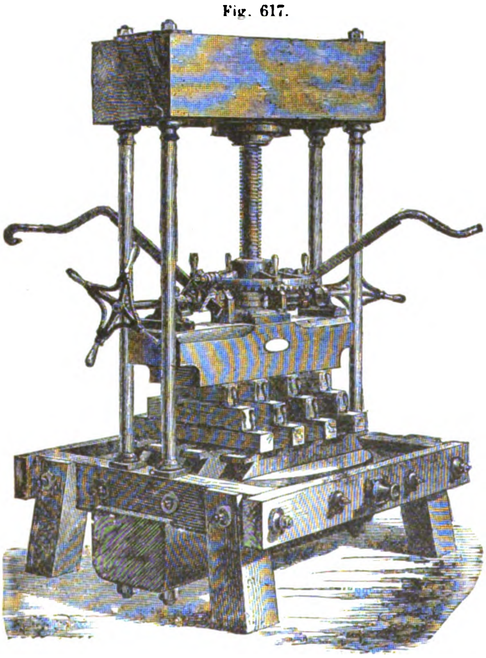
Power Cider Press.

becomes relatively slower as the toggles straighten, and the power increased in a like proportion.

The follower is permanently attached to the end of the toggle arms so that it does not require placing and replacing.

The cheese consists of regular successive layers of pomace, each about 4″ thick, completely enveloped in cloth, each being shaped in a square frame which is raised, leaving the

Fig. 617.



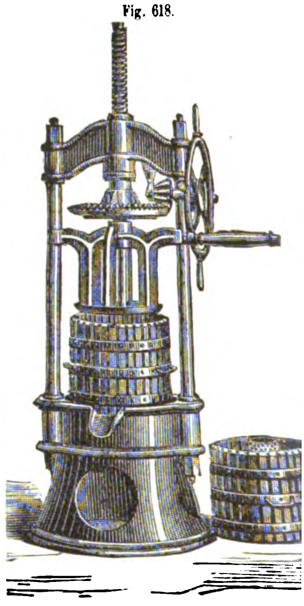
Press of David of Orleans.

same in position. Racks of wooden strips are laid between each layer of pomace.

The press, Fig. 617, made by David of Orleans, is one of the screw-presses of a type so common in France. Its general features will be readily understood from the illustration: The nut is revolved upon the screw and pushes down the follower or upper member of the press. What is notable is the compact mode of obtaining the three powers. Quick motion and relatively small power at the first, the motion decreasing in rate and increasing in power at each subsequent stage.

The first motion is by the central wheel, which has handles projecting upward. The next power is by the hand wheels at the ends, pinions on the wheels engaging the crown wheel. Third and lastly, the brake levers which act by pawl and ratchet upon the pinion shafts in the manner of windlass brakes.

Fig. 618.



Wine & Cider Hand Press. (*Nain Terrel del Chênes.*)

The cider and wine hand-press made by Nains, of Terrel des Chênes, is shown in Fig. 618. It has an exterior and interior crate, so that the pomace is in a comparatively thin body, rendering the escape of the juice more ready and complete It may be said to have two powers; that is, in the first stage the master wheel is rotated by the crank arm, and subsequently by swinging the weight up on the spokes. The follower, it will be seen, is guided upon the standards and descends in the annular space between the crates.

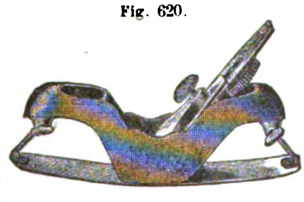
Fig. 620.

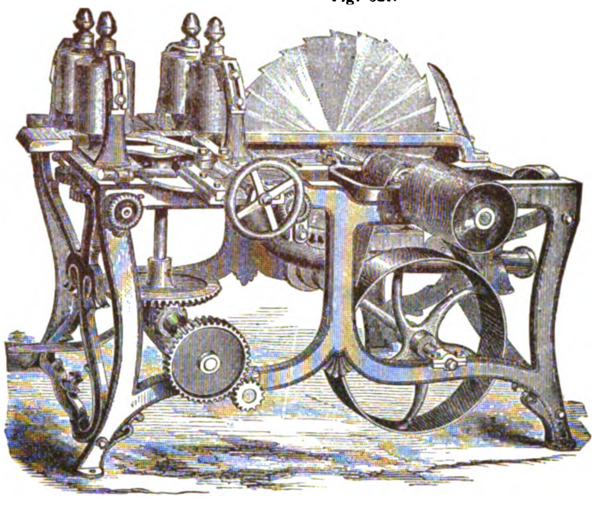


"*Victor*" *Circular Plane.*

Cir'cu-lar Re-saw'ing Ma-chine'. A machine for making bevel-siding and weather-boarding from thicker stuff.

The lumber is fed to the saw by four rollers, which are expansively geared in pairs, so that at whatever point they may be placed, the gearing

Fig. 621.



Circular Re-sawing Machine.

has the same effective feeding force. The rollers are hung upon ball-and-socket joints, which gives them an adjustment for bevel-sawing, and presents the center of the stuff to the saw, however the thickness may vary. The saw arbor has a lock attachment to keep it from moving while the saw is being sharpened or replaced. There are three speeds of feed to accommodate different widths of lumber.

Cir'cu-lar Rib'bing Ma-chine'. A knitting machine having a circular race, and adapted for rib-work, such as Cardigan jackets and sleeves.

The machines of *Gimson & Coltman*, of Leicester, England, are described in G. W. Gregory's report on knitting machines, Group XXII., "*Centennial Exhibition Reports*."

Cir'cu-lar Saw. (*Add.*) 2. (*Surgical.*) A round saw used in osteotomy in deep-seated parts. A substitute for *Hey's* saw.

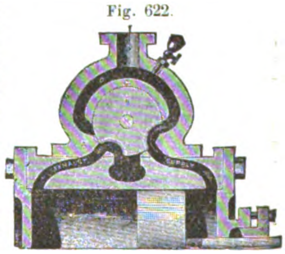
Græfe's . . . . Fig. 66, Part I.
Tiemann's . . . . Fig. 57, Part I.
Tiemann's "*Armamentarium Chirurgicum*."

Cir'cu-lar Spring Bal'ance. See CIRCULAR BALANCE.

Cir'cu-lar Slide Valve. A species of faucet valve. A cylindrical valve with ports made by depressions in its periphery, bringing the respective ends of the cylinder in alternate connection with the steam chest and exhaust port.

The term is not a peculiarly happy one, and will apply as well to the valves of the Corliss and Wheelock engines. See CUT OFF.

Fig. 622.



Circular Slide Valve.

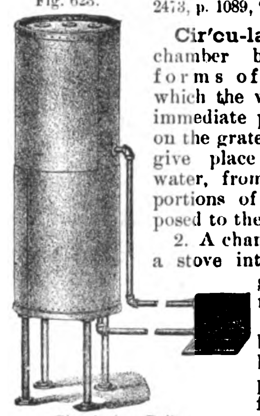
Cir'cu-la'ting Boil'er. A boiler in connection with a heater, through which latter the water circulates to become heated.

Fig. 623 shows a heater for a domestic range, connected by circulating pipes with the boiler.

A circulating boiler, one of the very earliest of its class, is shown under INCUBATOR, "*Mech. Dict.*," which see. The invention of *Bonnemain*, 1777.

See system of steam-heating, Fig. 2473, p. 1089, "*Mech. Dict.*"

Fig. 623.



Circulating Boiler.

Cir'cu-la'ting Drum. 1. A chamber belonging to some forms of steam-boilers, into which the water, heated by the immediate proximity of the fire on the grate, is caused to flow to give place to other bodies of water, from the feed, or from portions of the boiler less exposed to the urgency of the fire.

2. A chamber above or around a stove into which the heated gases pass in order to radiate heat.

3. A water-chamber in a hot-water heater into which passes the hot water from the coil exposed to the fire.

Cir'cu-la'ting Pump. 1. One for supplying water for the condensers of engines. The speed should be in proportion to the temperature of the circulating water and the working conditions of the engine.

2. The air and circulating pump is specially adapted for marine condensing engines. It is a direct-acting pump, and the two pumps are driven from the same steam cylinder.

Cir'cu-la'ting Steam Boil'er. One consisting of two portions unequally exposed to the heat of the furnace, and with connecting pipes or passages by which the water rises from the over-heated and descends from the relatively colder, maintaining a circulation.

Stead's . . . * *Scientific American*," xxxviii. 243.
Other illustrations may be found in Plate LXI., opposite p. 2326, "*Mech. Dict.*"

Cir'cu-la'ting Tube. In a steam boiler; a tube leading from one part of a boiler to another to establish a circulation in a given direction, as from the hotter to the portions more removed from the direct contact with the furnace or flue plates.

There are numerous illustrations of this feature. See Plate LXI. and pp. 2327, 2328, "*Mech. Dict.*"
See also *Oke*, "*Engineering*," * xxii. 328.
See list under STEAM, "*Mech. Dict.*," *et infra.*

Cir'cum-cis'ion In'stru-ment. (*Surgical.*) An instrument for excising the projecting portion of the prepuce beyond the glans in cases of phimosis.

Phimosis instruments, Figs. 1-7, Part III., *Tiemann's* "*Armamentarium Chirurgicum.*"

Dr. Baruth's circumcision scissors have a guard finger upon one blade which acts to prevent the clinging of the prepuce to the other blade when the blades are parted.

The phimosis instrument of Dr. Levis is for the excision of the inner inelastic membrane of the prepuce, or a partial ablation of the preputial integument, instead of complete removal.

Cire Per-due'. Bronze casting in wax. A model in wax is inclosed in a plaster mold, the wax melted out and bronze poured in. Thus the wax is *perdue*, or wasted. The plaster being removed the bronze object appears. See JAPANESE BRONZES; also pp. 500 and 1462, "*Mech. Dict.*"

Day	* "*Scientific Amer.*," xliii. 403.
Rain water	"*Scientific Amer. Sup.*," 2393.
Filter	"*Scientific Amer. Sup.*," 1748.

Clam'mer. A forceps closed by a wei as a tongs in deep-sea soundings to obta mens of the bottom, shells, or of living thereof.

Clam'ond Bat'te-ry. A thermo-ele tery. See p. 2545, "*Mech. Dict.*"

An improved form consists of an alloy of two timony and one of zinc as the negative metal, a tinned sheet iron as the positive element — the the heated junction flowing from the iron to This alloy is cast in the form of a flat bar, br middle than at the ends, and measuring from 2 length by ⅜" to 1" in thickness. The sheet ir stamped out, is placed in a mold into which the is poured; before the alloy has cooled, the mol and the bars are removed. This alloy melts a and expands considerably on cooling. It imp casting, but is always very brittle. The bars radially around a temporary brass cylinder, a mica being inserted between the iron and the vent contact except at the point of junction. of these bars form a ring, and the several ring one above another, insulated from each other b asbestos. The inner ends of the bars are heat sen burner, the flame issuing in small jets in space between the burner and the bars.

See also THERMO-ELECTRIC BATTERY.

Clamp. (*Add.*) 8. (*Surgical.*) A ja to maintain parts in apposition, to prev tion on a line of excision, etc.

Harelip clamp	Figs. 252, 25
Nasal clamp (*Epistaxis*) . .	Fig. 239 *c*.
Ovariotomy clamp . . .	Figs. 439-444

Clamp Mill'ing Ma-chine'. (*Fire-arms.*) A machine used for special parts of the Springfield rifle, such as the firing-pin, etc.

Clap'pers. Two thick plates of iron, between which thin steel springs are placed while hot to be hardened.

Clap Net. One having hinged sections; used in bird-catching.

Clap'per Stay. A detent for the clapper in a bell. Used in silent practice on tower or church bells; a substitute for muffling with pieces of rope.

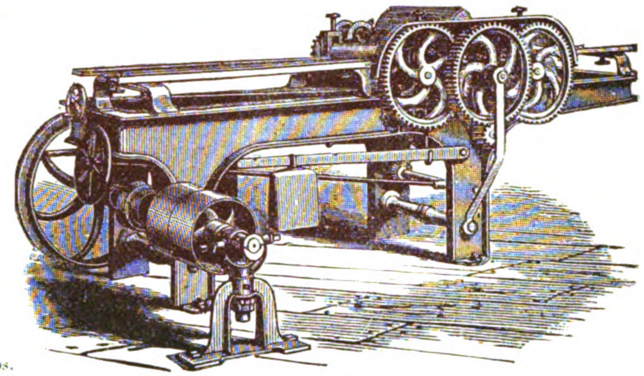
"Engineer" . . . . * xlvii. 243.

Clap'board Pla'ner. A machine for planing clapboards. This, in the Eastern States, means siding or outside weather-boarding for houses. In the West, the term is applied to a 3′ or 4′ board used for roofing.

Referring to the first meaning, as the machine under consideration is of Vermont manufacture, the practice is to saw clapboards directly from the log, towards the center, making a thick and a thin edge. Such boards are 4′ or 6′ long, subsequently planed to a thickness as far back from the thicker edge as will be exposed to the weather; and the exposed edge jointed or molded.

The frame of the clapboard planer is of iron, and

Fig. 626.



Clapboard Planer.

the feed-rollers have a length for taking two clapboards at a time, *sticking* a molding on the edge of each while running through.

The countershaft and pulleys are shown on the floor alongside of the machine.

Clar'i-net. (*Music.*) A reed instrument having a compass of three and a half octaves written on the G clef. Four registers are reckoned on the clarinet: the *low*, the *chalumeau*, the *medium*, and the *high*. There are four clarinets in general use. The *small* clarinet in E♭; the clarinets in C, B♭, and in A. The *alto clarinet* is one in F (low); the *bass clarinet* an octave below the B♭ clarinet.

See also CORNO DE BASSETTO.

Clasp Bend'er. A dentist's tool, for making clasps for teeth. It is a simple pliers in which the respective prongs are convex and concave so as to bend to a circular form anything pinched between them.

Fig. 627.

Dentist's Clasp Bender.

Claude Lor-raine'. (*Optics.*) A landscape mirror. It condenses or diminishes the view into a true perspective effect.

Clav'i-cle Ap'pa-ra'tus. (*Surgical.*) Braces, supporters, splints, and bandages for dislocation and fracture.

Figs. 66, 123-127, 147, 150, Part IV., *Tiemann's "Armamentarium Chirurgicum."*

Clay Heat'er. A heater for houses and halls in which baked clay is substituted for iron in order to avoid the disagreeable or injurious effects of the "burning of the air." It is a rude return to brick stoves, the ultimate quality of which is porcelain. See PORCELAIN STOVE.

Crary clay-heater . * *"Manufacturer and Builder,"* xi. 139.

Clay Tem'per-ing Wheel. A wheel for working clay with water to develop the plasticity. See CLAY MILL, p. 563, *"Mech. Dict."*

Mill, *Hind*, Br. . . . . . * *"Engineer,"* xli. 247.
Mill and Engine, *Jackson*, Br. * *"Engineering,"* xxiii. 154.

Tempering mill . . . . . * *"Manuf. & Builder,"* ix. 33.

Clean'ing Hole. (*Locomotive.*) A term applied to the means for cleaning; cleaning plugs being placed in the corners of the fire-box, and blow-off cock in front.

Clear. (*Glass.*) Said of glass, ware or window, which is free from depolish, etching, or other process which dulls the surface.

The depolishing may be made by grinding, acid, sand-blast, etc.

Half-clear is applied to objects which are partly depolished.

Clear'ing Bat'te-ry. (*Brewing.*) A device used in straining the wort from the vat; operating to moderate the flow when the depth of wort is considerable.

Austrian . . . "*Scientific American Sup.*," Fig. 5, * 4077.
"*Engineer*," * 1. 266.

Clear'ing Ring. (*Fishing.*) One to lower down the line to detach a hook from a root or other obstruction: or from the mouth of a fish. The latter is known also as a *disgorger*.

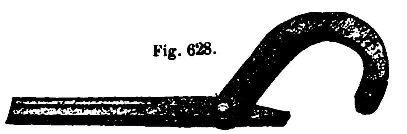
Clear'ing Stone. (*Leather.*) A fine whetstone, used to remove from the currier's knife the scratches made by the rub-stone. The Water-of-Ayr and Welsh clearing-stones are generally octagonal slips, 4″ thick, and from 6″ to 8″ long.

Clear Sto'ry. (*Railway.*) An upper row of windows in a passenger car, above the main-roof, and on the side of the raised or monitor roof.

Clear Way. Said of a valve, hydrant, etc.

One which lifts its valve entirely out of the way of obstructing the flow; not compelling the water to flow around it. Also called *full-way*.

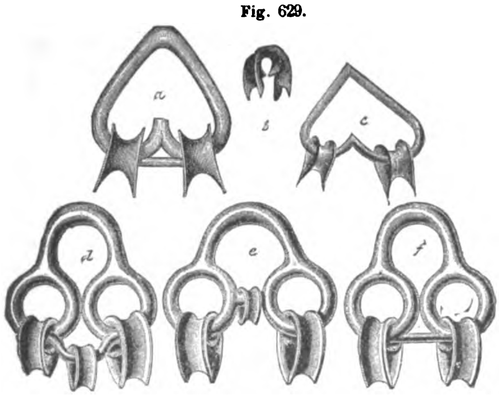
Fig. 628.



Clevis Tongs.

Clev'is Tongs. A form of pipe tongs with a swinging jaw like a cant-hook.

Fig. 629.



Clews.

a. Heart clew.
b. Clew thimble.
c. Ear-ring clew
d. Clew-bow.
e. Clew-bar.
f. Spectacle clew.

Clew. (*Nautical.*) A loop and thimble at the corner or clew of a sail. The means of attachment of the hook of the clew-tackle to the sail; the hook engaging with the loop, and the lashing passing around the thimble and the sail rope.

Clew Thim'ble. A metallic guard or sheath, (shown at *b*, Fig. 629,) over the rope forming the eye of the sail, in order to prevent chafing. In the figure a guard is placed in the interior of the thimble to fit loosely over the body of the clew to prevent the rope from chafing against the upper portion of the eye to which it is attached.

Cli'ma-tom'e-ter. An instrument for indicating the fluctuations in the conditions of sensible temperature. See instrument of Mr. J. W. Osborne, called also *Esthermoscope*, Fig. 6368, p. 2550, "*Mech. Dict.*"

Professor Forbes's instrument, described in a paper, "*Observations relative to the Temperatures to which the Human Body is exposed*,"[1] is intended to determine the "sensible warmth of the air," by which is meant, not the physical temperature which would be measured by an ordinary thermometer, but what might be termed the physiological temperature or warmth of the skin, as it is estimated by nervous persons. The questions of humidity, evaporation, movement of the air enter intimately into the question.

The apparatus consists of a cylindrical can filled with hot water and covered with a non-conductor. In this a copper rod is plunged, its upper end expanding into a cup which incloses the bulb of a thermometer. The heat of the can being assumed as constant, the rod, the lower portion of which is plunged in the can, parts at the exposed portion with its heat, and this rate depends upon the length of rod exposed and the atmospheric conditions. The length of the rod is made variable by sliding in and out of the heated vessel. The length is adjusted to give a constant thermometrical reading, and the length required to give the constant is the measure of the sensible warmth of the air.

[1] [In a letter by Prof. George Forbes, dated May, 1879, and published in the "*Journal of the Scottish Meteorological Society*," vol. v., p. 278.]

Climb'ing Ap'pa-ra'tus. See CHIMNEY.

Fig. 630.

Clinical Thermometers.

Clin'i-cal Ther-mom'e-ter. A thermometer for ascertaining the temperature of the person. It is common to place the bulb in the axilla, and the bulb of the lower instrument, in Fig. 630, is curved for that purpose. The next instance above that is a straight thermometer, with a contraction in the stem at *A*, to prevent the index slipping down into the bulb. The pencil-case thermometer is peculiarly convenient. The bent stem thermometer, Fig. 631, has also an evident provision against loss of index. In the best form of thermometer the front surface of the tube is made in the form of a cylindrical lens, the focus of which is in the column of mercury, thus magnifying it, rendering it easily read off. — *Beck.*

Fig. 631.

Bent Stem Thermr.

Fig. 632.

Clinometer Level.

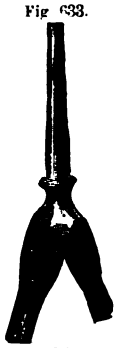
Cli-nom'e-ter Lev'el. An improved form of hand-level, having also an arc divided into angles of elevation and divisions for slopes.

Clip Chair. A form of chair used on some railways in England, to fasten the rail to the metallic sleeper.

The sleeper is an inverted trough, and through square holes punched in this trough a clip chair of rolled wrought iron or cast steel is slipped from the under side. The clip chair is of horse-shoe shape, one side forming a hook about

2½″ wide, and the other side is like one jaw of an ordinary railway chair for taking a wooden railway key. The wooden key fastens the rail tightly upon the sleeper, as well as holding the clip chair in its place.

Fig. 633.



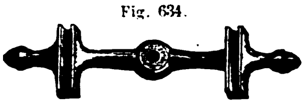
Clip King-bolt.

Clip King′-bolt. (*Vehicles.*) A clip which embraces the forward axle, and the upward extension of which forms a king-bolt.

Clip′ping Ma-chine′. A machine in which the clipping shears (Fig. 1330, p. 567, "*Mech. Dict.*") is driven by power; to clip horses. Similar apparatus are used to cut hair, and to shear sheep. Fig. 4942, p. 2139, *Ibid.*

Horse clipper, *Casey*, * "*Sc. Amer.*," xli. 210.

Fig. 634.

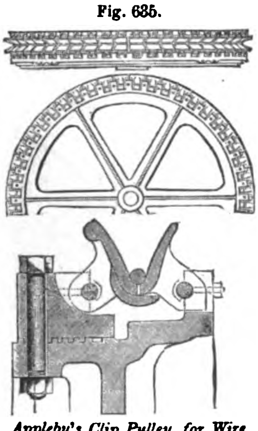


Spring Saddle Clip Plate.

Clip Plate. (*Carriage Hardware.*) A plate lying upon the spring of a carriage, and having channels above for the bows of the clip which attach it to the axle.

Clip Pul′ley. A pulley arranged for a wire rope. The perimeter of the pulley is made up of pivoted clips in pairs, and these close in upon the rope and grasp it, which prevents its slipping upon the wheel. The nipping action of the clips is upon at least half the diameter of the pulley, so that the wear of the rope is almost *nil*, the nipping action ceasing immediately and automatically the moment the rope begins to diverge from the circumference.

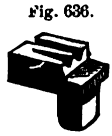
Fig. 635.



Appleby's Clip Pulley, for Wire Rope Transmission.

Clip Swage. (*Blacksmithing.*) A swage inserted in the hardy- hole of the anvil, used in finishing the clips on horse-shoes.

Fig. 636.



Clip Swage.

Clip Yoke. A small plate through which the ends of a stirrup-shaped clip pass, and against which the nuts are screwed.

See also DIAL; ELECTRIC CLOCK.

Clock Reg′is-ter Ther-mom′e-ter. A means for enabling the meteorologist to ascertain the temperature of any given hour of either day or night at will by automatic registration.

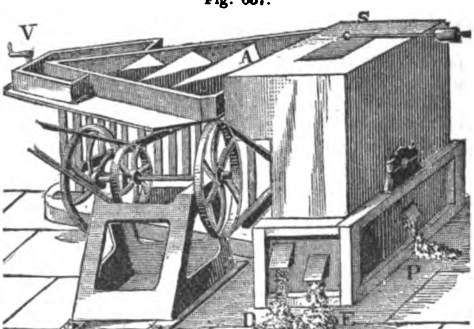
Negretti & Zambra provide for this need in a very ingenious way, which they term their "patent recording thermometer." The tube of the thermometer is bent at the middle so as to form two parallel vertical arms, and it is contracted at its union with the bulb, so that when it is turned over and upside down, all the mercury which is in the arm above the contraction runs round into the other branch of the tube, and there measures exactly the same length, and indicates the same number of degrees on the scale that it did in the first branch in the original position. The clock which carries the thermometer is set like an alarum. It turns the thermometer over, and so secures the register of the temperature at the hour at which its mechanism and hands are set.

"*Journal of the Society of Arts*"	1877.
"*Scientific American Supplement*"	935.

Clod Clear′er. A French machine to remove clods from grain.

The tray has a rocking motion on supporting bars, the crank making 115 turns per minute. The foul grain, etc., entering at *A* is divided to each side, bounced from side to side, and sorted according to gravity; the slope is toward the apex.

Fig. 637.



Aspirating and Vibrating Stone and Clod Clearer. (*Hignette, Paris.*)

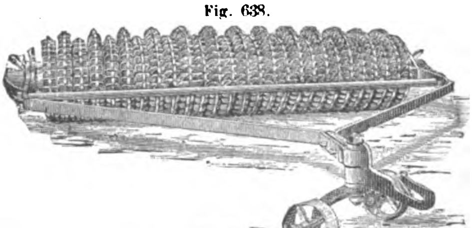
Stone and clods leave at the point *V*, the grain passes into the aspirator, where it is sorted by quality: *D* second quality, *E* heavy waste, *P* second waste; the good wheat has its discharge on the other side (not shown).

See Knight's Report Paris Exposition 1878 . . * v. 199.

Clod Crush′er. A rough-faced roller for breaking clods in the field.

Dr. Knight's report on Class 76 at the Paris Exposition of

Fig. 638.



Clod-crusher and Compressor. (*Demarly, Origny-Sainte-Benoite, France.*)

1878, contains views of the following (see "*Paris Exposition* (1878) *Reports*," vol. v., pp. 99-101): —

Clod-crusher, *Lowcock & Barr*, Engl.
"Excelsior" clod-crusher, *Picksley & Sims*, Engl.
Crosskill clod-crusher, *Puzenat*, Fr.
Clod crusher and compressor, *Demorly et Cie*, Fr.

Fig. 638 shows the Demarly implement. Besides the unequal sizes of the roller sections, in alternate order, they have an ability to slip transversely upon the axis. By this means, though of varying size, they may present themselves in straight line upon a level surface; either may lift in yielding to a large clod; and, as the surface rotation of each is equal, the rate of motion of the larger ones on the common axis is slower than that of the smaller rings, and, therefore, any clods getting between them are ground to powder, and the spaces between them are not choked.

Randell's clod crusher, Br. . * "*Engineering*," xxviii. 35.

Cloi-son-né. 1. (*Fine Art Metal Working.*) A pattern is raised on a metallic surface by means of wire or strips welded on to it, and enamel spread in the spaces, *cloisons*, between the raised metal.

A species of inlaying resembles it in this respect, that the lines are engraved, wires laid into them and the surface burnished down to hold the wire in position.

Champ-leve has lines engraved in the metal and filled with enamel.

Shushikuwan . . . . . . "*Technologiste*," xli. 519.

See lists Fine Art Metal Working; Art in Various Materials; Ceramics.

2. A coin on which a subsequent impression has been imposed on the previous one.

Clos'ing Ma-chine'. A sewing machine for boot-closing, stitching soles to welts, and for light harness work. The machine makes a lock-stitch with two threads, both sides alike.

Cloth-cut'ting Ma-chine'. Of the three power cloth-cutting machines shown at the Centennial Exhibition in 1876: —

Albin Warth's machine employs a reciprocating cutter blade in a turning head at the end of a pivoted arm guided on a track or rail at the side of the table on which the cloth rests. It operates better than a rotary knife on curved lines and corners.

Sanson's machine is a spring-arm band-saw machine, accurate and swift.

Fenno employs a rotary cutter at the end of a universally movable arm.

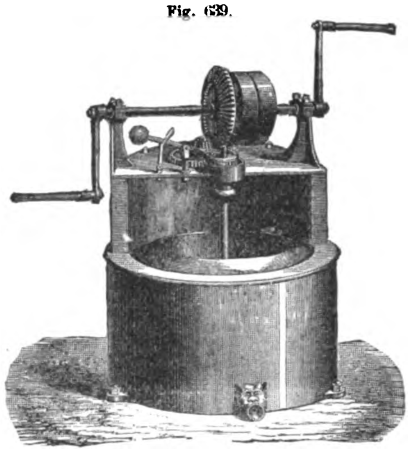
Bolting-up saw for working log into slabs.
Splitting-saw for working slabs into rods.
Cross-cutter or cutting-up machine.
Lathe for rounding.
Slotter.

Cloth In-spect'ing Ma-chine'. A machine in which the cloth is exposed in a smooth, inclined

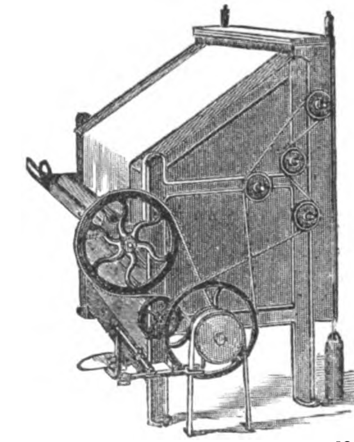
Fig. 639.



French Clothes Dryer. (*Beaume à Boulogne.*)

surface to the view. It may also be brushed, burled, or trimmed during momentary stoppage of the automatic motion.

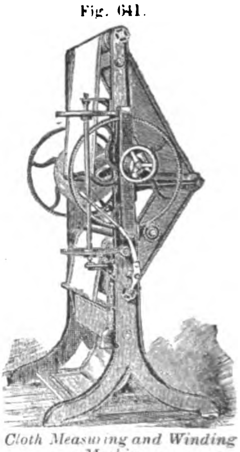
Fig. 640.



Cloth Brushing, Trimming, and Inspecting Machine.

Cloth Meas'ur-ing Ap'pa-ra'tus. A winding machine which takes the cloth from the bolt or pile, runs it over a measuring roller, then over stretching rollers at the back of the machine, and from thence to the winding jaws which hold the board on which it is wound. The measuring roller has a worm which operates the vertical shaft, on the top of which is a dial which indicates the length wound, and the pointer is set to zero for each operation.

Fig. 641.



Cloth Measuring and Winding Machine.

In the cloth-measuring machine of *White, Child, & Co.*, of London, the cloth runs upon a smooth and level table and underneath a wheel of known circumference, the revolutions of which are counted by worm gearing and dial. It is adapted for measuring and rolling cloth in salesrooms.

"*Scientific American*" . . . . . * xxxix. 54.

Cloth Press. A machine for pressing cloth *in transitu* or in bolt.

Nussey & Leachman, Leeds, England, make a powerful automatic machine, in which the woolen cloth is fed intermittingly between steam-heated platen and bed-piece. These are driven together with a force of 1 ton to the square inch, by a steam-pump acting as a hydraulic press. The whole surface is such that the aggregate pressure is 153 tons, and the pressure is maintained for 15″. The platen then retreats, the cloth is automatically advanced, bringing a fresh position between the pressure surfaces, which are again advanced, and so on. The cloth at the feed-end is fed over smoothing rollers. The machine was shown at the Centennial Exhibition.

In the continuous cloth press of *Harwood & Quincy*, of Boston, Mass., the cloth goes direct from the shearing machine to the press where it is brushed and pressed simultaneously.

The cloth to be pressed passes over bars and friction rollers, then over the upper part of a brush, and thence between a roller and concave bearing, and finally over another roller and the plaiter. The bearings are heated or not, as desired; the pressure may be brought up by the lever to 6 tons. When no pressure is required, the machine may be used as a brushing frame only. For the purpose of steaming the fabric it is necessary to heat the roller, and to cover it with a thick felt. — "*Textile Manufacturer.*"

The machine of *M. Hirst* is described in *Laboulaye's* "*Dictionnaire des Arts*," etc., article "*Laine*," * vol. ii., ed. 1877.

Boomer & Boschert . . "*Scientific American*," * xlii. 242.

Davis . . . . Figs. 1344–1348.
Poupart . . . . Figs. 1349–1351.

Cloth Stretch'ing Ma-chine'. A machine for stretching and softening fabrics.

In the machine of *Devilder* (France) several cylinders and rollers are supported by a cast-iron frame, and operated by power transmitted by a belt and gearing. The necessary pressure on the goods is produced by a weight, pulleys, and levers. The goods, rolled on the lower cylinder in the rear part of the machine, are carried between a zinc cylinder and a wooden roller situated directly above the lower cylinder. The zinc cylinder runs in a trough filled with water. By this means the necessary degree of moisture is imparted to the goods. They are next taken up by a bar at the top of the machine, which may be regulated so as to increase or lessen the tension of the goods. From this bar the goods pass to the stretching cylinder, which is composed of sixteen copper plates revolving around, and alternately approaching to and receding from, a common axis. The approach takes up the first half of the revolution and the return the second half. The goods, by this means, are well stretched; they are afterwards rolled on a wooden cylinder below the stretcher. — * "*Revue Industrielle.*".

"*Scientific American*" . . . . * xl. 227.

Cloth Test'er. A machine for testing the strength of cloth by direct pull.

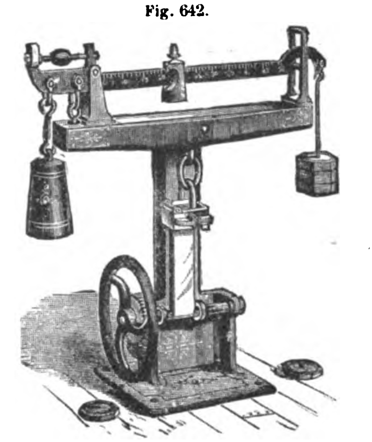
Riehlé Brothers' cloth-testing machine is shown in Fig. 642. One end of the sample of cloth, paper, or twine is inserted in a clamp attached to the weighing mechanism and the other end wrapped around a roller. The strain is put on by turning a hand-wheel, and the beam kept in equipoise by shifting the running weight. The strain is continued until the sample breaks, the result of the test being indicated on the scale in pounds. The scale levers are inclosed in the box in the upper part of the frame.

Yarn, fiber, and paper testers operate in a similar manner. See list under MEASURING, ETC., INSTRUMENTS.

"The official test of resistance of tissues and cordage shows the nature of the yarn and the quantity of matters contained therein by the following triple method: —

"*a*. The weight of the tissue per square yard is taken after the samples have been well dried in the stove or in the sun.

Fig. 642.



Riehlé Brothers' Cloth Tester.

"*b*. The number of threads in warp and weft is ascertained by the ordinary thread counter of a quarter-inch field.

"*c*. The resistance to traction of either tissues or cordage is measured by means of an apparatus which has two jaws, between which the tissue or cord is fixed, one jaw being stationary and the other connected with a lever, which is loaded until the sample breaks. In France the apparatus used is the dynamometer of Perreaux. For tissues the trials are made with bands 16″ long and 2″ wide, one cut lengthwise and another crosswise of the stuff

"The following are the conditions required by the navy and public offices for the following principal tissues: —

Kind of Tissue.	Threads per centimeter. In the Warp.	Threads per centimeter. In the Weft.	Weight per square meter.	Resistance of a band 5 cm. wide. Lengthwise.	Resistance of a band 5 cm. wide. Crosswise.
			k.	k.	k.

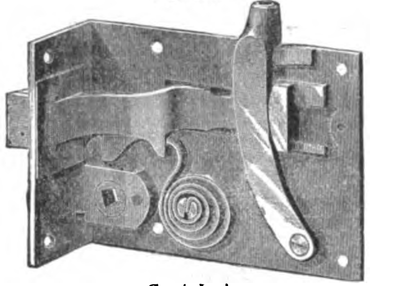
3. A private close carriage of size and pretensions.

Coach Bit. (*Manége.*) One having large scroll or straight checks made stationary on the mouth-piece, loops for the driving rein being placed at different distances from the mouth-piece, by which the leverage is increased or diminished.

Fig. 646.



Coach Lock.

Coach Lock. A spring latch operated either by the cross-bar handle on the exterior, or by a lever from within side the carriage.

Fig. 647.

Coach Screw

Coach Screw. A peculiar form of screw, with a V-thread and a square head like that of a machine bolt.

Coach Whip. (*Nautical.*) Another name for the pennant.

Coak. (*Nautical.*) The metallic strengthening piece in the middle of a block-sheave; pierced for the pin.

Coal Dust Burn'ing Grate. A grate peculiarly constructed to burn the anthracite slack, which has accumulated to such an enormous extent in the anthracite coal regions of Pennsylvania and Wales. The grate has usually a large surface and moderate intervals between bars, and the dust is distributed by a fan-like motion of the shovel. In some cases it is introduced in a gentle and constant shower by mechanical means. See WASTE-BURNING LOCOMOTIVE.

Locomotive, *Wootten* .	See WASTE-COAL LOCOMOTIVE.
Coal economizer . . .	See ECONOMIZER.

Coal El'e-va'tor. The projecting track *C* supports a carriage *B*, over which and through the running-block *A*, the hoisting rope runs, the end being fastened to the carriage *B*.

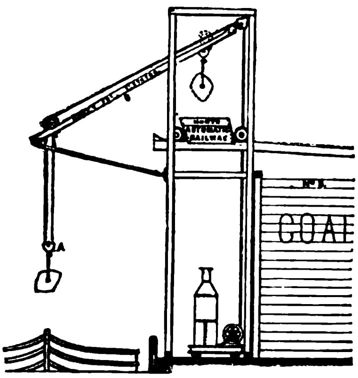
When the hoisting engine starts the rope in motion, the running-block *A*, with the loaded tub attached, rises vertically from the hold of the vessel until the block *A* strikes the carriage *B*. The engine continuing in motion, draws both the carriage and the bucket of coal up the inclined track *C*, until the bucket is over the bin or car, where it is dumped. The rope is then slackened and the carriage and empty bucket run back on the track to *B*, when the carriage is stopped by an adjustable chock and the bucket descends to the hold of the vessel to be refilled. The running block *A* is hooked to another tub already filled and ready to be hoisted.

When not in use, the whole track *C* swings on hinges back against the side of the building entirely out of the way.

The performance is usually 25 to 30 tons per hour.

In *Mariller's* hydraulic coal-hoist, used at Hull, England,

Fig. 648.



Coal Elevator.

the coal wagons are hauled by a *Brotherhood* capstan on to the rising platform, and are hoisted by a hydraulic ram to the required level, when they are run on to the middle platform over the hopper, and are discharged by opening the hopper doors and by tipping with special hydraulic apparatus for end-tip wagons. While the wagons are being discharged, the lifting platform is descending, and is lifted again with another wagon by the time the previous one is empty. The empty wagon passes on to the second moving platform, and, by means of its weight, controlled by a hydraulic brake, is lowered to the ground level, and passes out on to the empty siding. The brake ram, being connected to the hydraulic main, is of sufficient power to raise the lowering platform again to the top without the expenditure of any power beyond that obtained from the empty wagon in its descent. The tipping arrangements allow of the wagon being tipped in either direction, and the hoist is fitted with the usual appliances for adjusting the hoppers and coal chutes.

With properly hoppered wagons, constructed to discharge the coal freely, 300 tons of coal per hour can be shipped by the hoist.

Colliery hoist at Épinac, France * "*Engineering*," xxvii. 367.

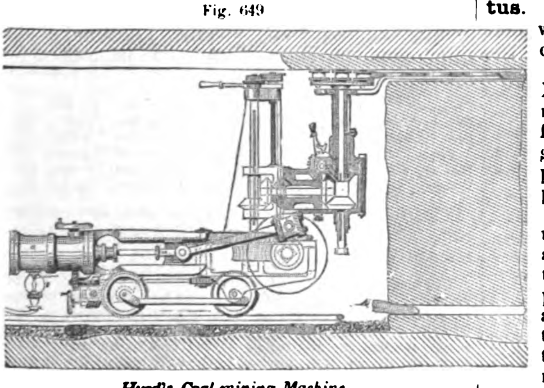
Coal Gas Test'er. See GAS-TESTING APPARATUS, *infra*. See also Fig. 651, next page.

Coal Min'ing Ma-chine'. The coal under-cutting machine of Lechner protrudes into the coal a horizontal shaft, armed with cutters and driven by chain-gearing. It advances straight into the breast of coal.

The Brown machine traverses along the breast and under-cuts to a depth of 4'. It uses cutters on an endless chain protruded into the coal.

The Gledhill machine (British) also advances along the breast. The endless chain of cutters passes over a jib which extends into the coal, and the jib has a capacity for a swinging motion in a horizontal plane so as to cut out at the end.

Fig. 649



Hurd's Coal-mining Machine.

The machine of Hurd & Co., of Wakeford, Britain, has also a jib which protrudes into the coal and around which the chain of cutters passes; but the machine is capable of cutting out all the four faces of the drift by revolving the head of the machine in a vertical plane so as to present the jib below, above, or on either side. The machine has two cylinders, 6'' diam., 12'' stroke, and works by compressed air. Motion is given to the cutters by bevel gearing, and the shaft driving the cutters is capable of being revolved in a vertical plane about the horizontal shaft.

The Payton & Holmes machine (London, England) has a species of saw jib having a number of teeth to which a peculiar pecking motion is given by means of short curves or eccentrics. The jib (or saw) has a swinging motion in cutting in or out and when sunken in the face to its full depth the machine is traversed on rails along the face of the breast.

Coal Oil Fur'nace. See PETROLEUM FURNACE.

Coal Sledge. A peculiarly formed hammer of from 5 to 8 pounds weight, used in coal mining and breaking lumps.

Fig. 650

Coal Sledge.

Coal Test'ing Ap'pa-ra'tus. An apparatus by which the director of a gas-works may readily ascertain the quality of coal.

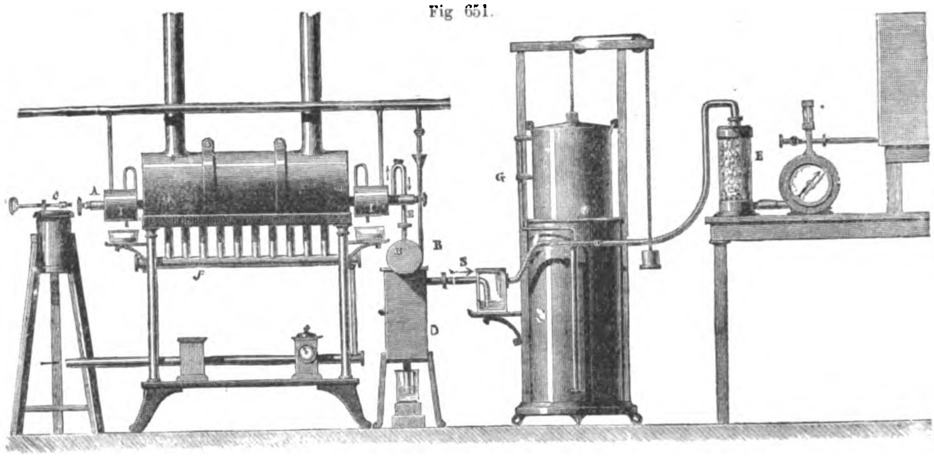
Fig. 651 shows an apparatus, designed by M. Andouin of Paris, by which can be determined, in less than an hour, the quality of coal from the point of view of the production of gas, the quantity of gas and coke, the lighting power of the gas produced, and whether the purification of the gas is easy or otherwise.

This apparatus serves not only to determine the value of different coals, but also to assist in judging of the conditions under which the gas-works is operated day by day, in comparing results under diverse treatment. It also enables the director to determine whether the difference in results is due to change in the nature of the coal or to changes in the mode of operation in the gas-works.

The mode of operating the apparatus is as follows: —

An average sample of the coal being selected, is crushed and charged into an iron crucible. The weight of a charge is 100 to 200 grams, or more, according to the size of the ap

Fig 651.



Andouin's Coal-testing Apparatus.

paratus. The iron tube which has the function of the retort is raised to the required temperature by means of the special means indicated in the figure.

The furnace is heated by gas, which allows the requisite degree of temperature, a bright red, to be maintained steadily by means of a gas regulator which determines the pressure, shown by a manometer communicating with the tube *f*, which brings the gas.

As soon as the required temperature of the furnace is attained (in about half an hour after lighting the gas), which is determined by a pyrometer, the tubular retort is introduced and the opening A closed. The gas, as it is disengaged, passes to the gas-holder G after parting with its tar and ammoniacal water; the holder has a capacity of about 60 liters and maintains a pressure at 0°. The distillation terminated, the gas, which is measured in the holder, is conveyed to the purifier and then to the photometer to be tested for quality.

The retort is withdrawn from the chamber and rapidly cooled, and the weight of the coke is readily ascertained.

The right-hand portion of the apparatus shown in Fig. 651 is ordinarily at some distance from the retorts, but they are shown close together for convenience of illustration. The break is visible near the arrow S. B is the washer; D the condenser; the cooled gas escapes by the pipe S to the gas-holder G, thence by the purifier E and the meter to the photometer. I I are the chambers in which cold water circulates around that part of the retort outside of the furnace. C is a screw to close the tube.

Coal-tip'ping Ma-chine'. One for discharging the corves or mine cars down a grated incline into railway cars or boats. The screen removes grades of dust and small coal which fall into cars or receptacles beneath.

Riggs . . . . . * "*Scientific American*," xli. 290.

Coal-whip'ping Ma-chine'. A form of hoisting apparatus for quickly lifting the large loaded buckets out of a ship's hold. It was formerly done by a set of men called coal-whippers, who used the simple form of apparatus known as a whip. Described on page 2770, "*Mech. Dict.*"

In the coal-whippers' machine the cylinders act directly upon the barrel, and an up-and-down rope is used; the engine and boiler are made separate, and are as light as possible, so that they can be taken in a boat alongside a sailing ship, and readily hoisted on board by the ship's tackle.

In some cases the whole of the winches required to work the cargo in and out of the ship are driven from one engine placed amidships by means of a high-speed cord carried along the deck, and protected by wooden casings.

Co'ap-ta'tion Splint. (*Surgical.*) A stiff cradle bandage to hold the broken ends of bones in apposition. See SPLINT.

Co'balt Pla'ting. Cobalt electro-plating is done in a bath of a neutral solution of the double sulphate of cobalt and ammonium (*Gaiffe*), or the chloride of cobalt combined with the chloride of ammonium and magnesium, or the sulphate of cobalt with sulphate of ammonium or sulphate of magnesium (*Adams*). See also ELECTRO-PLATING.

"*Engineering and Mining Journal*"	xxvi. 136.

Huller, *Guardiola* . .	* "*Scientific American*," xxxvi. 83.
Washer, *Guardiola* . .	* "*Scientific American*," xxxvi. 82.

Cof'fee Cool'er. An apparatus for cooling coffee after being roasted or kiln-dried after treatment to clean it.

The machine consists of a large blower or exhaust, 26″ in diameter, and a large double-bottomed box, the false bottom being of heavy wire cloth. The box is supported on two wheels, so that it may very readily be moved to receive the material from the roaster or dryer; and so arranged that, when the open end is attached to the open side of the blower, the air is exhausted from between the bottoms, and so drawn down through the material, and cooled, without dust or smoke entering the room; the same being blown into any chimney or flue, or out at any convenient opening. — *Burns.*

Cof'fee Hul'ler. A machine for operating upon the coffee berry to remove the husk, or parchment envelope of the grains.

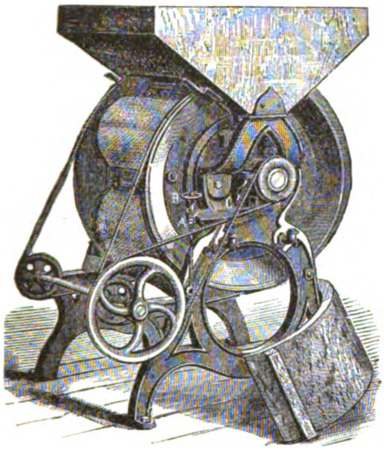
In Lombard's coffee huller the coffee is placed in a hopper that discharges on an endless chain apron which carries it in contact with a system of elastic pads. The pads treat each berry according to its size, retiring and returning readily as the grain of varying sizes pass under them.

The coffee, as it leaves the apron, is riddled by a screen below, being at the same time cleaned by a fan working in connection therewith, and falls into a well, from which it is elevated by buckets on an endless belt, and discharged on to a second endless chain apron that draws it under a stiff brush, by which the berries are polished.

The berries then fall on a second riddle that separates them according to size, and they are discharged at their separate spouts.

Cof'fee Mill. In the granulating coffee-mill,

Fig. 652.



Granulating Coffee Mill.

Fig. 652, the berries are cracked by a coarse roller, and the grains removed by the revolving sieve as soon as they attain a certain degree of fineness, the object being to obtain uniformity of size. The sieve revolves on flanged friction-wheels, the toothed roller and concave do not touch when the machine runs empty. The sieve is made up of 6 semi-circular divisions, which successively return their quotas of coarse stuff to the grinder.

Fig. 653 is a retailer's mill, the roller axis shifted, one cover removed, and the cutting disk exposed. The coffee from the hopper above passes between the attrition surfaces and falls into the tin vessel.

Fig. 653.

Coffee Mill.

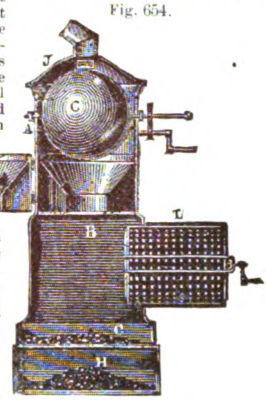
Cof'fee Roast'er. A multitude of small domestic and larger warehouse coffee roasters are in the market.

A French coffee roaster has a spherical chamber of glass, rotating over a special small furnace.

The coffee roaster of Hignette (Paris) has a globular vessel *C*, in which the coffee is roasted by the heat of a brazier, *D*, which is placed beneath it during the operation, but retired, as shown in the figure, and a funnel substituted when the coffee is to be discharged from the roaster into the cylindrical sifter, where the dust and pellicles are removed from it. The globular roaster receives the coffee from above when the opening is brought into temporary apposition with the flue hole in the cover, *J*, of the apparatus.

Fig. 655 shows Smith's portable coffee roaster, adapted to be placed over a stove or range. It is automatic, revolving by steam pressure.

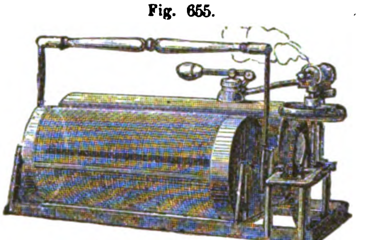
Fig. 654.



Coffee Roaster and Sifter. (*Hignette, Paris.*)

Cof'fer Dam. (*Hydraulic Engineering.*) An inclosure from which water is pumped, to expose the surface of the ground or bottom.

Fig. 655.



Portable Coffee Roaster.

The coffer dam at dam No. 4, Kanawha River improvements, is shown in "*Report of Chief of Engineers, U. S. Army,*" 1878, * ii. 467.

Coil. (*Heating.*) 1. A convoluted pipe used as a heater, evaporator, condenser, as the case may be. The names of coils are derived from their construction, shape, purpose, and application. See the following: —

Bell.	Manifold.
Box coil.	Pipe stand.
Branch.	Radiator.
Circular tank coil.	Return bend.
Coil hanger.	Return bend coil.
Coil heater.	Ring plate.
Coil plate.	Sleeve.
Coil screen.	Soap coil.
Coil stand.	Spiral tank coil.
Condensing coil.	Square spiral tank coil.
Cone joint.	Square tank coil.
Double cone coil.	Taper screw joint.
Flat coil.	Tee.
Flat square coil.	Trunnion coil.
Heater coil.	Tuyere coil.
Helical tank coil.	Tymp coil.
Hour-glass coil.	Vertical tube coil.

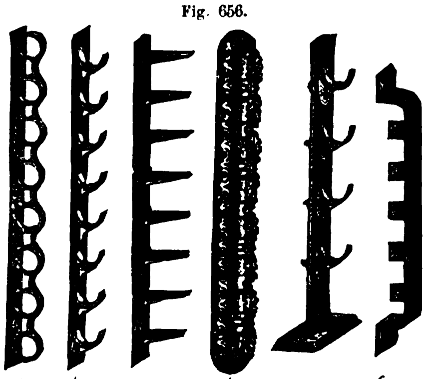
See also instances under CONDENSER, REFRIGERATOR, RADIATOR, FEED-WATER HEATER, etc., etc.

2. (*Electricity.*) *a*. The bundle of soft iron wires in the center of the helix. *b*. The wrapping of insulated wire around the core of an electro-magnet. Fig. 2672, "*Mech. Dict.*"

Coil'ing Ma-chine'. The ovens and machine for coiling bars, for making tubes for cannon, is shown in Plate II., Appendix I. *d*, "*Report of Chief of Ordnance, U. S. A.*," 1877, pp. 400, 412. See also Appendix L, Fig. 75, and p. 549, same report.

Coil Plate. A plate with hooks or rings to support the horizontal coils of a radiator; a steam or hot-water heater, evaporator, or condenser.

Fig. 656.



a b c d e f

Coil Plates.

a. Ring plate. *d.* Rosette plate.
b. Hook plate. *e.* Movable-hook plate.
c. Corner plate. *f.* Wall plate.

Coil Stand. A pair of coil-plates (which see), arranged to stand upon a floor and to support the various coils or convolutions.

Coil Screen. An ornamental open-work of wire concealing a coil, but allowing passage of radiated heat through the openings.

Coil Steam Boil'er. One in which the water in coiled iron pipe is exposed to the heat of the furnace.

See Fig. 5636, Plate LXI., p. 2317, "*Mech. Dict.*"; also, Fig. 2686, p. 1191, *Ibid.*
A double coil steam generator was shown in Paris, 1878, by M. N. Roser, St. Denis (*Seine*).

Coin Al-loy'. An alloy for coins, prepared by Johnson, Matthey, & Co., of London, is

See GAS AND COKE FURNACE, *infra*.

Cold Air Ma-chine'. See AIR REFRIGERATING MACHINE.

Also "*Scientific American Supplement*," 4011.

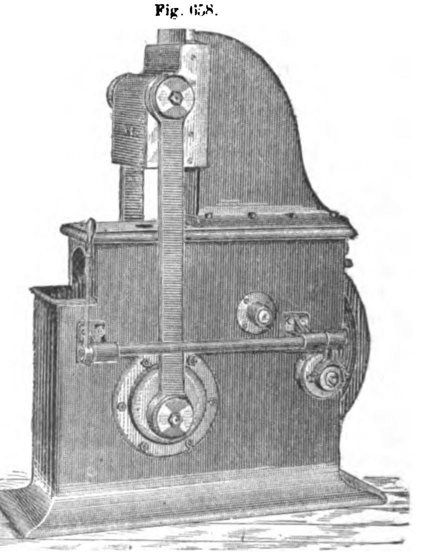
Cold'-i-ron Saw. A circular saw for removing the fag end of a rolled rail. It saws through a cold steel rail 5½″ deep in 18 minutes.

The cold saw used at the Landore Siemens Steel Co. is shown at Figs. 18, 19, p. 14, vol. xlii., "*Engineer*."
Also used for cutting bar iron into lengths for piling, reheating, and re-rolling.

Sellig, Sonnenthal & Co., Br.	* "*Engineer*," xlviii. 472.
For rails	* "*Engineering*," xxv. 382.

Cold-press'ing Ma-chine'. A machine for

Fig. 658.



Cold-pressing Machine.

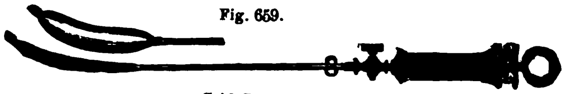
finishing by cold drawing, or for pressing forgings. It has a pressure of from 300,000 to 400,000 lbs.; stroke 1″ to 6″. It stops and starts instantly by means of Pratt's friction clutch.

Cold Shot. (*Foundry.*) Small globules of iron found in chilled portions of a casting.

Cold Shut. (*Add.*) 2. (*Founding.*) An imperfection in a casting owing to the cooling of the metal while flowing.

Cold Sound. (*Surgical.*) *Psychrophor.* Invention of Dr. Winternitz, of Vienna. An instrument for treating pollutions, spermatorrhea, and chronic gonorrhea.

Fig. 659.



Cold Sound

A double current catheter without eyes, the two canals communicating near the point of the instrument. It is introduced into the urethra until its point has passed the *pars prostatica*, and it is then attached by rubber tubing to a reservoir containing water of the desired temperature. On turning the stop-cock, the water flows into one canal and out through the other. In this way the *caput gallinaginis* and the entire mucous membrane are exposed to the mechanical action of pressure and the sedative action of cold.

See also Fig. 56, Sup., *Tiemann's* "*Armam. Chirurgicum.*"

Co-li-fi-ché. (*Ceramics.*) A little prism or tripod of refractory clay, used in a faïence or porcelain kiln to support the enameled or decorated ware in the second firing. They are known as *stilts* and *spurs* in England. See SEGGAR, Figs. 4815–4816, p. 2089, "*Mech. Dict.*" where rings, ridges, and studs are shown supporting the ware in the seggars.

Col-lap'si-ble Boat. One capable of folding for convenient transportation.

See also BOAT: FOLDING BOAT.

Col'lar. (*Nautical.*) 1. A bite at the end of a shroud or stay, to go over the mast-head.

2. A rope formed into a wreath, with a dead-eye in the bight, to which the lower part of the stay is secured.

3. The neck of a bolt.

4. A circular enlargement on a rod.

Col'lar-laun'der. The pipe or gutter at the top of a lift of pumps by which water is conveyed to the cistern.

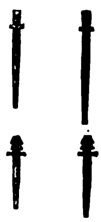
Col'lar Ma-chine'. Vapey's horse-collar blocking machine consists of a former, which can be varied in length, and a tightener rope to draw the leather close to the former or mold by means of lever and screw.

Collar stuffing machine, *Lichliter* * "*Sc. Amer.*," xxxvii. 38.

Col'lar Nail. A nail used in *blind-soling* boots and shoes. *Field & Sons.*

The nail being driven into the heel (or sole) as far as the collar, the outer lift (or sole) is driven on to the projecting pin, and thereby held, without the head of the nail appearing upon the outer surface.

Fig. 660.



Collar Nail.

Col'lar Swage. (*Blacksmithing.*) A swage set in the hardy hole of an anvil and used in swaging a collar on to a rod. The depression in the swage is equal to one half the size of the rod and collar; a top tool laid upon the iron completes the form, the piece being swaged between the two by the blows of a hammer. See also FULLER, SWAGE, etc. See Fig. 661.

Col-lo'dion. Gun-cotton dissolved in ether or chloroform.

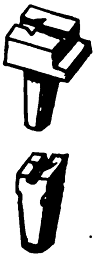
It is used for many purposes. See PYROXYLINE, p. 1831, "*Mech. Dict.*"; GUN COTTON, p. 1036, *Ibid.*

See also CELLULOID, *supra.*

Col'lo-type. (*Photography.*) A name given to the process in which the image is taken upon a sensitive colloid film.

The first attempts were made on metallic plates, and the adhesion of the film was effected by the oxydation of the metallic surface. Albert introduced the use of glass plates, Obernetter used very thin zinc plates. Description of his process in "*Photographisches Wochenblatt.*" Reproduced in "*Scientific American Supplement*," 2671.

Fig. 661.



Collar Swage.

Col'o-phene. A viscid colorless oil, obtained by distilling oil of turpentine with sulphuric acid. See Clarke's Patent, No. 6,001, June 2, 1849.

Col'or Com-par'a-tor. An apparatus by Dr. Leeds, of the Stevens Institute, for making comparisons of tints of color.

A rack holds ten comparison tubes of equal caliber and contents. An adjustable mirror reflects the light downward through these comparison tubes, and the light, after passing through slits (¾" long and ¼" wide), cut in a stage beneath, is reflected outward to the eye by a similar adjustable mirror placed below. In the original apparatus, the supports of the upper mirror are placed at the front corners, so as to make the axis of the mirror in front of the upper row of holes, and permit the tubes to be lowered into their places from the top. Later, it was found more convenient to slip the tubes in from below, which can be done without rising from one's seat, and in this case the axis of the mirror was put directly over the centers of the line of holes, and the mirror made somewhat narrower (3"). A black cloth, hung from the back upper corners, prevents any light reaching the eye except that reflected from the lower mirror.

The comparison is effected by a prism nearly filled with a suitable colored liquid. The prism is constructed by cementing within four straight walls of plate glass the inclined top and bottom sides of the prism It is 10" long, 1¼" wide, 2¾" at the base of the prism, narrowing to 3-16" at the apex. The prism is cut off in this manner at the apex, because, when filled with liquid of the most suitable intensity of color, the graduations beyond this point are too inconsiderable to be of value. The liquid is introduced through an orifice in the base, over which is afterward cemented a glass cover.

"*Scientific American Supplement*" . . . . * 2185.

Col'ored Glass. (*Glass.*) Glass colored in the pot; as distinguished from *enameled*, which has a surface of vitrifiable color baked on.

It consists commonly of two layers, white and colored melted into junction, or one laid upon the other: in some instances, white glass overlaid with three or four colors. There are, however, other modes. See list under GLASS, "*Mech. Dict.*," *et infra.*

The oxides of the different metals form the colors: —

For blues: oxide of cobalt or *safre*, oxide of iron, etc.

Shades of blue, such as *violet* or *celestial:* different proportions of cobalt.

Light blue, for spectacles: a mixture of cobalt and red oxide of iron.

London smoke: a mixture of oxides of copper, iron, and manganese.

Black: by increasing proportions of the last mentioned.

Purple: oxide of manganese. Potash glass with manganese gives a bluish purple; soda glass verges on the red. The color is made of a deeper blue by the addition of cobalt.

Brown purple: a mixture of oxides of manganese and iron.

Ancient purple: a mixture of oxide of manganese and red oxide of iron.

Yellow: a mixture of oxides of iron and manganese; charcoal is supplied in the shape of wood sawdust, an increase of which gives an orange, or in excess red.

A mixture of ochre and silver applied to the surface and baked in.

Green: a mixture of black oxide of copper and oxide of iron; or replace a part of these oxides by one third of their weight of bi-chromate of potassium.

Blue green: add oxide of cobalt to the above.

Yellow green: add yellow oxide of uranium to the recipe for green.

Red or *ruby:* brown oxide of copper, oxides of lead and tin, scales of iron, and borax, are added to the batch in the pot and melted. The glass is dipped out, broken or ground, and remelted, with additional quantities of the oxides and borax. The color is not developed until repeated heatings.

Opal: calcined bones are added to the batch of glass in the pot. Cryolite, 10; white sand, 20; oxide of zinc, 20; make an opal glass, called *Hot cast porcelain*. See also CRYOLITE.

Fluor spar added to the batch.

Laboulaye's "*Dictionnaire des Arts et Manufactures*," Article "*Verre*."

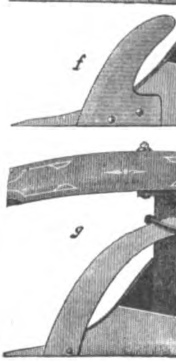
c. Knife colter.
d. Standing colter.

Col-o-rim'e-ter. Dr. Scheibler's method consists in a number of parallel tubes in which solutions of sugar and syrups are examined for relative depths and qualities of color.

Nanquette, "*Technologiste*," xl. 362.
See also DIAPHONOMETER, *infra*.

Fig. 663.



Colters.

e. Quincy cutter.
f. Fin cutter.
g. Sword cutter.

Col'or-ing Met'als Prepare a solution of sulphide of lead by dissolving ½ oz. of hyposulphite of sodium in 1 lb. of water, and adding ½ oz. of acetate of lead dissolved in 8 oz. of water. Heat to 200° Fah., and the sulphide of lead is precipitated in brown flakes.

Metals exposed to the solution become colored —

Brass in the following order, according to the time of exposure, and consequent thickness of the coat: gold, copper-red, carmine, dark red, blue, blue-white, reddish white.

Iron becomes steel blue.

Zinc becomes brown.

Copper, the order of brass, except that the gold color does not appear.

If, instead of the acetate of lead, sulphuric acid be added to the hyposulphite of sodium, the brass becomes red, green, brown, with green and red iris glitter.

See also BRONZING, etc.

Col-peu-ryn'ter. (*Surgical.*) An inflatable bag introduced into the vagina to prevent prolapsus uteri.

Braun's, Fig. 420, p. 90, Part III., *Tiemann's* "*Armamentarium Chirurgicum*."

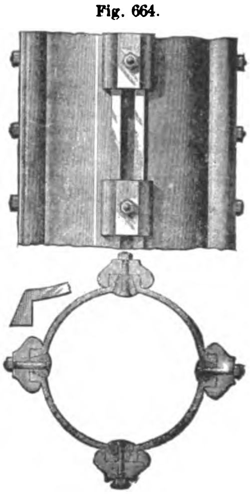
Col'ter. The sward cutter in advance of the plowshare and mold-board. See Figs. 662, 663.

Rotary colter grinder . * "*Scientific American*," xlii. 198

Co-lum'bin. (*Electricity.*) The non-conducting material placed between the parallel carbons of the ELECTRIC CANDLE, which see.

Col'umn. Built wrought iron columns, so much used in modern engineering, are made in segments, which are bolted together. The construction of two prominent forms is evident at a glance. Figs. 664, 665.

Fig. 664.



Built Iron Column.

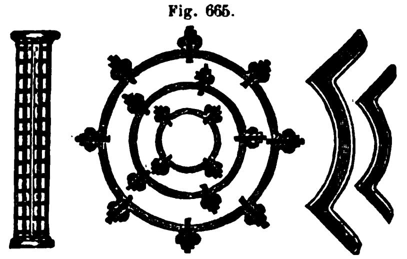
Col'umn Bat'te-ry. (*Electricity.*) One in which the elements are formed into a column. See VOLTAIC PILE.

Comb. (*Add.*) 8. (*Fire-arms.*) The top corner of the stock, where the cheek rests in firing.

Comb making, * "*Manufacturer and Builder*," x. 129.

Com'bi-na'tion Au'ger. An auger used in well or shaft boring. It has a long barrel, inclined throats at the lower end, and detachable horizontal cutters. Used in clay, sand, and other soft or friable strata.

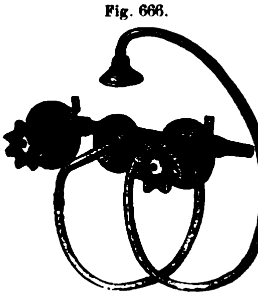
Fig. 665.



Phœnix Iron Co.'s Wrought-iron Column.

Com'bi-na'tion Ba'sin Cock. A shampooing arrangement in which the tube and sprinkler connect with hot and cold water faucets, so as to receive a mingled stream of the required warmth.

Fig. 666.



Combination Cock.

Com'bi-na'tion Lock. 1. A bank or safe lock, the mechanism of which is operated by two graduated dials, whereby one bolt, common to both, is controlled by either of the two independent dials, which latter may be set on two different combinations, thus giving the control to either of two persons.

2. A *permutation* lock: see Figs. 3646–3648, p. 1669, "*Mech. Dict.*"

Com'bi-na'tion Plane. A joiner's plane, capable, by adjustments and attachments, of assuming various capacities: such as plow, fillister, dado, rabbet-plane, matching-plane, etc.

Fig. 667.

Bailey's Combination Plane.

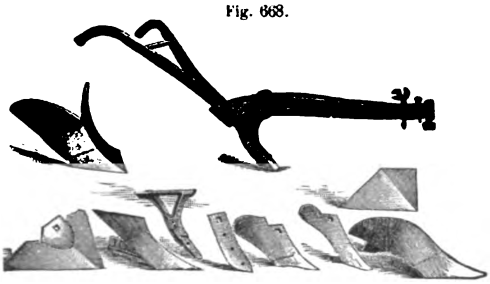
The main feature of the plane is that it has a fence or guide which is made to change to one side or the other, as the nature of the work requires, the fence being also vertically adjustable.

Com'bi-na'tion Plow. A plow having a number of optional shares, so as to be convertible to a number of different uses.

Combination plows are generally those of the smaller class, such as are used in tending crops, rather than those for breaking ground; many are found in the varieties adopted for special culture, such as beets, grapes and garden crops.

Hornsby's (English) plow has a number of mold boards; also potato diggers, hoe frames, etc., either of which can be attached to the beam.

Fig. 668.



Combination Plow.

Farquhar's convertible plow, Fig. 668, has double shovel, single shovel, subsoil, bull-tongue, ridging shares and bodies.

Com'bi-na'tion Open and Peep Sights. A species of gun-sight, Fig. 669, having several sights for different distances. When the leaf is down, a low slit-sight is exposed. When the leaf is lifted, the peep sight may be slipped up and down on the graduated stem, according to the distance of the object.

Fig. 669.

Combination Open Peep Sight.

Com'bi-na'tion Spring. One made by the multiplication of several similar parts.

In elliptic springs for railways see numerous examples in Fig. 1144, p. 483, "*Mech. Dict.*"

Instances of the spiral kind in Fig. 1148, same page.

Combinations of steel and caoutchouc: Figs. 1142–1144, pp. 482, 483, *Ibid.*

Com'bi-na'tion Scale. A scale with several beams.

a. A dairy scale beam which admits of weighing the milk brought by a number of farmers, at the same draft, keeping the weight of each on its own beam. See CREAMERY SCALE.

b. A postal-scale having separate beams and poises, the graduations in grams and ounces (and fractions) on each respectively.

c. A weighing scale with one beam for the cart, and another for the load; with the addition of a third beam for small weights, the second being for the thousands.

d. A furnace scale for charging the barrow with the respective quantities of ore, coke, and limestone, to be dumped into the hopper of the blast furnace. See FURNACE CHARGER.

"*Engineering and Mining Journal*" . . . * xxvi. 313.

Com-bined' Car. (*Railway.*) One with separate compartments for different purposes, as a *combined baggage and express car*, or a *combined mail and passenger car*, etc.

Or: one capable of being converted to distinct uses; as a *combined box and cattle car.*

Comb'ing Ma-chine'. The cotton combing machine of *Heilmann*, of Alsace, is a marvel of ingenuity in preparing cotton for fine counts of yarn. The machine has been somewhat simplified by Dobson & Barlow, of Bolton, England. The action is intermittent, by means of nippers and combs. In the Dobson & Barlow machine the nipper holds the cotton to be combed against the fluted feed rollers. The cotton is drawn up into the top comb by the detaching rollers, which draw it in a straight line from the grip of the two feed rollers.

Com'fit Pan. For making comfits and all kinds of confections known as pan goods. The pan is heated by steam conveyed through an india-rubber tube. Another tube conveys away water of condensation. It does not revolve, but has a peculiar rocking motion. See CONFECTION PAN.

Com'mu-ta'tor. (*Electricity.*) An instrument or arrangement used to change the currents from primary to secondary, or the reverse; to change the polarity of a current; or to change from one to more cells in a constant battery.

Mercury, *Lartigue* . "*Telegraphic Journal*," vii. 153.

Com-par'a-tor. *a.* An instrument for comparing measures of length together. The objects to be compared are laid on an iron bed, and microscopes with micrometric eye-pieces placed vertically over the bed for observation and comparison.

In the comparator of *M. Tresca* but one microscope is used; the bars to be measured are placed side by side upon the bed, which is movable both laterally and longitudinally. One end of the standard is first brought under the microscope, and afterward, the corresponding end of the scale to be tested is by a lateral movement similarly brought into the field of view, and by the slow movement of the scale itself, if necessary, its terminal mark is brought into coincidence with the cross-wires of the microscope. The whole system is then moved longitudinally until the opposite ends of the bars come under observation, when without disturbing the microscope the mark on the standard rule is first brought into coincidence with its cross-lines, and subsequently that on the rule to be tested, the difference in length, if any, between the two being measured by the micrometer.

b. Saxton's comparator consists essentially of a mirror, which reflects a beam of light over double the angle through which the mirror is revolved, and this beam acts as an index by being caused to sweep over a graduated scale, having for its center the center of the axis of the mirror. It will be obvious how measurements may be made by this arrangement. It is applied by Prof. A. F. Mayer to the observation and measurement of the changes in the dimensions of iron and steel bars on their magnetization.

See "*Scientific American Supplement*," * 1519, * 1595, * 1637, * 1694.

c. Lissajous' comparator "consists of a diapason, to one limb of which is attached the object-glass of a compound microscope; the body of the microscope being detached and supported by an independent stand. If the diapason be thrown into vibration, the image of any small object seen through the microscope will appear to have a similar motion, which will be magnified by all the power of the instrument. Let the object be itself a point in a vibrating body, having its direction of vibration at right angles to that of the object-glass, and the combination of the two motions will produce figures, from the analysis of which the character of the vibration of the body observed may be deduced. When the vibrating body is a string, or other object without conspicuous points suited to be used in the comparison, it is necessary to mark it in some manner. Different observers have adopted different expedients for this purpose; but in order to avoid loading the body or altering its condition by adding coloring matters, Mr. Lissajous, in the case of strings, has employed a cylindrical lens to throw a sharp line of light across the object. This creates a brilliant point moving with the string without in any manner disturbing its mode of vibration." — *Dr. F. A. P. Barnard*, "*Paris Exposition Reports*," * iii. 508, 509.

See paper read by Francis Galton, F. R. S., before the Anthropological Institute, London.

Partly reproduced in "*Scientific American*," xxxviii. 389.

Com-pos'i-to. (*Ship-building.*) A *composito* vessel is one built partly of iron and partly of wood: *e. g.*, some of the U. S. Coast Survey vessels which have hulls, the frames and beams of which are of iron and the planking of wood.

See *Wilson's* "*Ship-building*," Wiley & Sons, New York.

Com'pound Ar'mor. An iron plate with steel facing. See ARMOR COMPOUND; also ARMOR PLATING, "*Mech. Dict.*"

Com'pound Cot'ton Press. One in which a hydraulic ram of relatively small area and rapid movement is used to compress the cotton up to a certain point, and then a relatively larger and more powerful, slow-moving ram is used to complete the pressure.

Watson . . . . "*Engineer*," * xlv. 38, 46.

Com'pound Beam En'gine. A beam engine, with compound cylinders, in which the steam is used successively at a higher and then lower pressure.

See in list of references under COMPOUND STEAM ENGINE.

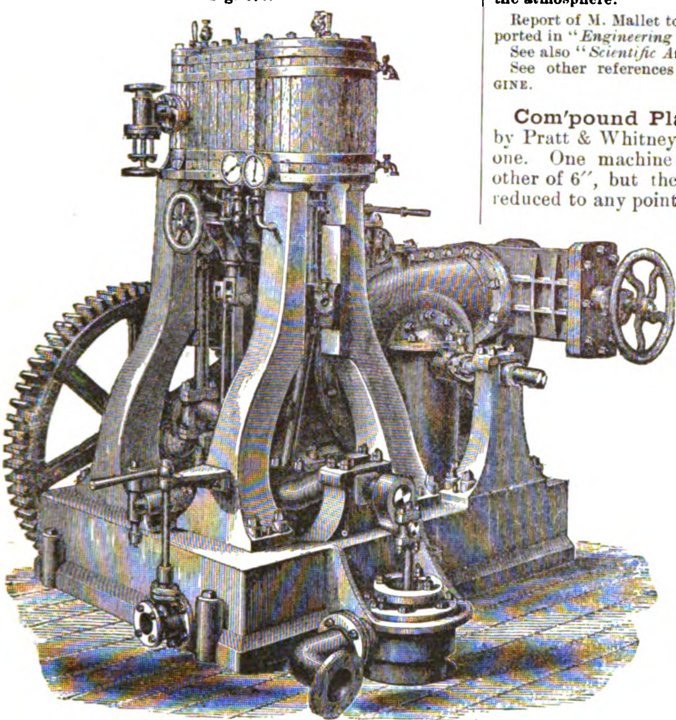
Com'pound En'gine. See COMPOUND STEAM ENGINE.

Com'pound En'gine Pump. Appleby's compound engine applied to the centrifugal pump is shown in Fig. 670, and is used in Egypt, where it forms a remarkable contrast to the norias, shadûfs, etc.

The whole arrangement is self contained, all the various parts being attached to one deep massive cast-iron bed-plate, which carries the crankshaft pedestals and the pedestals for the pump spindle. The engines are of the vertical type, compound and condensing. The high pressure cylinder is 7″ diameter, and the low pressure cylinder 14″ diameter, so that the areas are in the proportion of 1 to 4, and each has a piston stroke of 14″. The valve boxes are between the cylinders, a cover being provided at the top for examination, etc., and the cylinders and valve boxes are felted, and lagged with mahogany. The valve of the low pressure cylinder is the ordinary D valve, but the high pressure engine is fitted with a Mayer's expansion gear, whereby the expenditure of steam can be regulated in accordance with the height to which the water has to be pumped. Each of the cylinders is mounted on, and cast with a pair of strong iron standards, which also form the guides for the cross-head, a portion of them being bored for this purpose.

The jet system of condensation is used, the condensing chamber being formed in the bed-plate. The cock for regulating the supply of injection water and the air pump are in the foreground of the engraving, the latter of the ram and bucket principle, is driven by a crank arm and pin on the end of the crankshaft, the valves being india-rubber disks working on gun-metal gratings. A spur fly-wheel is keyed on to the end of the crankshaft, this drives a pinion on the pump spindle, so that the pump disk makes three revolutions for each double stroke of the engines; this enables the engines to maintain a very moderate speed, and obviates the necessity of the constant repairs, which frequently are a

Fig. 670.



Compound Engine and Centrifugal Pump.

source of inconvenience in very high speeded engines. The pump has 12″ suction and delivery pipes, the suction pipe having a foot valve on it, and the delivery being provided with a sluice valve. The pump disk makes about 600 revolutions per minute, and delivers 2,500 gallons per minute to a height of 20′. Small covers are provided on each side of the pump casing, so that the disk may be examined without taking the pump to pieces.

See also references under Compound Steam Engine.

Com′pound Lathe. The *tour composé* of the French. The term may be held to include the geometric, rose engine, oval, and engine-turning lathes. Which see.

See elaborate article, *cap.* "*Tours Composés*," *Laboulaye's* "*Dictionnaire*," etc., iv., ed. 1877.

Com′pound Lo′co-mo′tive. One using the steam in two successive cylinders.

The compound locomotive has but two cylinders; they are placed on the outside, and act at right angles to each other, as in ordinary locomotives with outside cylinders, the only difference being that the cylinders have different diameters, and that the smaller one alone, in the regular working of the engine, receives the boiler steam directly, discharging it after a first expansion into the larger one, which in turn discharges it into the chimney.

When the engine is to be started, the boiler steam, by means of a special apparatus, which constitutes the sole addition to the ordinary locomotive, and which from its design and purpose is called the *undoing* valve, is delivered directly into both the large and small cylinders, and the latter, instead of discharging it into the former, discharges it into the chimney, the engine in this case acting like an ordinary locomotive. This independent action of the steam in the two cylinders can also be employed when the engine has to overcome a momentarily greater resistance, like a short steep ascent, for instance.

The system just described has been for the first time applied by M. A. Mallet to three locomotives, constructed at Creuzot, for the branch railroad from Bayonne to Biarritz. They weigh in service from 19 to 20 tons each, and have cylinders of 9 7-16ths and 15¾″ diameter, with pistons of 17¾″ stroke. They have four coupled wheels of 47¼″ diameter. The boiler has 484.4 square feet of heating surface, and is worked with a pressure of 142 pounds per square inch above the atmosphere.

Report of M. Mallet to "*French Academy of Sciences*," reported in "*Engineering and Mining Journal*."

See also "*Scientific American*," xxxvii. 260.

See other references under list in Compound Steam Engine.

Com′pound Pla′ner. A machine tool made by Pratt & Whitney. It combines two planers in one. One machine has a stroke of 10″, and the other of 6″, but the length of the stroke may be reduced to any point below these limits. The tool-slide has a quick return stroke, and the cross-feed is automatic and adjustable.

Com′pound Plate Bat′te-ry. One, the negative plate of which, instead of being of one material, is constructed of several different metals soldered together.

Byrne's "*Engineering*," * xxv. 421.

Com′pound Spec′ta-cles. 1. *a.* One in which supplementary frames of colored glass are hinged to the ordinary spectacles, for use upon occasion.

b. The same adaptation of additional lenses to increase the power.

2. The Franklin spectacles of two half glasses of different character in each bow.

Chevalier in "*Sc. Am. Sup.*," * 2264.

Com′pound Spring. A spring in which several different types of springs are united to produce a simple effect.

Specifically: a steel spring surrounding or confining a cylinder or block of caoutchouc.

See instances in Figs. 1142, 1143, 1144, pp. 482, 483, "*Mech. Dict.*"

A *combination* spring may be defined as one in which several similar parts are multiplied to increase the resisting power.

Com′pound Steam Boil′er. One consisting of several separated but communicating chambers, usually having some different functions; for instance, boiler and superheater, or sectional portion with elevated chamber, etc.

German forms: —

Steinmüller	. . . . .	"*Engineer*," June 11 1880.
Pregardien	. . . . .	"*Engineer*," 1. 228.
Piedbœuf	. . . . .	"*Engineer*," 1. 228.

See several examples, Plate LXI., p. 2327, "*Mech. Dict.*"

Com′pound Steam En′gine. An engine using the same steam successively in two cylinders at diminishing pressures.

The *Hornblower* engine, mentioned on page 601, "*Mech. Dict.*," dates from 1781. The *Heslop* engine, patented by him in England in 1790, has lately attracted a good deal of attention. Nine of these engines were built, and one remains, being preserved in the South Kensington Museum, London.

"The Heslop engine has two open-topped cylinders, called respectively the hot and cold cylinder, one on each side of the main center of the beam; both are single acting, their pistons acting in the same direction. The steam, on being admitted into the first or hot cylinder, helps to raise the piston by its pressure underneath; the return stroke is then made by the weight of the pump-rods, etc., in the pit, suspended by a chain working over an arched beam-head. During the down-stroke of the pump-rods, the reduction valve being opened, the steam passes from the hot cylinder to the second or cold cylinder by means of a connecting pipe constantly immersed in cold water, which produces sufficient condensation to *kill* or reduce it to atmospheric pressure as it enters and fills the cold cylinder. The cold piston having arrived at the top of its stroke and its cylinder being thus filled with steam, the injection valve is opened, admitting a jet of water beneath the piston, thus bringing a vacuum into play. In the case of rotative engines, the return stroke is made by the weight of the connecting-rod, crank, and a heavy pair of links attaching the hot piston to the beam, assisted by the momentum of the fly-wheel. The two pistons are heavily weighted in equilibrium, probably to keep the chains taut, and the action of the steam in the hot cylinder simply takes off the weight of the hot piston, and allows that of the cold piston to come into play."

Com-pressed' Air Brake. That form of railway-car brake in which air compressed by some form of pump on the locomotive is conveyed by pipes and flexible hose beneath the cars to cylinders and pistons under each car, by which the pressure is transmitted to the brake levers and thence to the brake-shoes.

The *Westinghouse* and *Loughridge* are notable examples. The other class are known as *vacuum* air-brakes.

Com-pressed' Fuel. Fuel made of materials artificially compounded and pressed into blocks. See Briquette; Fuel, Artificial.

In the works of the "Crown Preserved Coal Co.," at Cardiff, Wales, the fine coal from the colliers is tipped from the wagons, pulverized, mixed with pitch automatically, passes to the heating furnaces to be made plastic, and is thus delivered to the molds, each of which receives 60 tons pressure, forming the block and stamping the name on it. An endless band carries the blocks to the stacking ground. The blocks are regular in shape, weigh 26 lbs. each, and are made at the rate of 40 per minute.

Com-pressed' Glass. A process by Siemens, of Dresden, Saxony.

The glass is tempered by being cast or pressed in chilled molds. It is claimed to be stronger than the glass tempered in oil by the De la Bastie process (see Tempered Glass) in the proportion of 5 to 3.

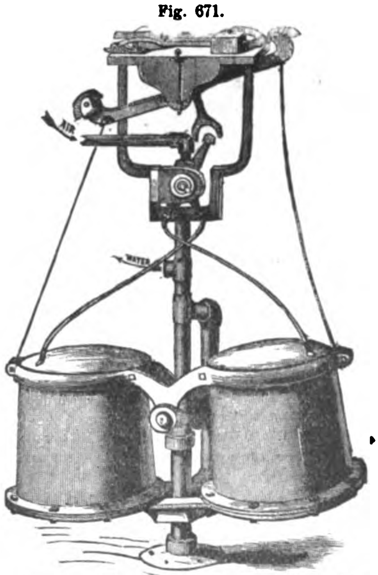
The fracture is fibrous; the glass may be bored and wheel polished; is fractured by the diamond.

Siemens . . . . "*Technologiste*," xxix. 342.

Com-pressed' Air Pump. A windmill works an air compressing pump, and the air is conducted by a pipe to the submerged apparatus shown in Fig. 671.

Two merged chambers rest upon a frame, pivoted to allow them a certain amount of rocking motion in a vertical plane.

Fig. 671.



Compressed Air Pump. (Hartford Pump Co.)

Each cylinder has a valved inlet at bottom, and a discharge pipe at bottom on the inner side, the respective pipes passing to a common upright main. An air valve above determines the access of compressed air to the chambers alternately. This valve is operated by the rise and fall of the chests: the compressed air being always directed to the lower chest. As soon as a chamber is emptied it becomes relatively lighter than the other, ascends, works the lever and valve, and directs the air into the other.

Com-pressed' Gas Gov'er-nor. See Gas Governor.

Com-pressed' Steel. (*Metallurgy.*) Steel condensed by hydraulic pressure, while yet fluid, to give it density, tenacity, and freedom from blow holes. See Whitworth Steel.

The principle of compressing metals while fluid, which has been applied with such effect to steel by Sir Joseph Whitworth, has long been in use in copper works. The mold is placed on the table by a hydraulic press, the melted copper poured in from ladles, and a strong cover adjusted to the mouth of the mold by screws. The hydraulic ram is then set to work, and a pressure of about three tons to the square inch applied. The effect is very beneficial to copper, but on brass the result is just the contrary.

Whitworth . . "*Iron Age*," xxiv., Dec. 4, p. 15.

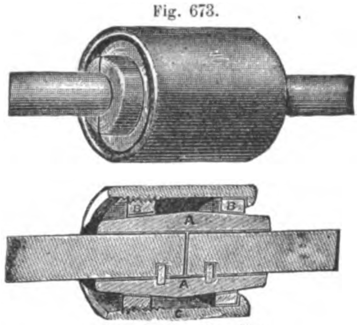
valve, which is compressed in seating itself, the pressure of water being also toward the seat.

Com-pres'sion Coup'ling. A means of uniting adjacent ends of shafts. The compression rings, *B*, are forced up the inclines of the sleeve from

Fig. 673.



Compression Coupling.

each end by a flange at one end and a screw thread at the other end of the cover, *C*, which is rotated by a spanner.

See also Clamp Coupling.

Com-pres'sion Hot'-air En'gine. The terms *hot-air engine*, *air engine*, *caloric engine*, are somewhat arbitrarily given.

The *Rider* engine, Fig. 674, is shown as a pumping engine. Cold air admitted to cylinder *A* is compressed to one third its normal volume by the descent of compression piston *C*, the air being transferred through the regenerator *H* into the heater *F* without appreciable change of volume. Heated by the passage through the regenerator and then by the fire, the expansion of the air raises the power-piston *D*, in turn depressing the compression piston *C*, and so on.

See also CONDENSER. "*Mech. Dict.*"

Con'cer-ti'na. (*Music.*) An instrument of the accordeon family. It is a small elastic box, held horizontally between both hands It is played by knobs pressed by the points of the fingers, and which, raising a valve, cause to pass over the reeds of brass the column of air supplied by the bellows between the two sides of the box. The sides hold the knobs on the outside, and, on the inside, the vibrating plates. The bellows has no valves, but fills and empties by means of the reed valves, which inspire and expire, each in turn, the air necessary for the vibration of the reeds. The *bass concertina* has the compass of the *violoncello;* the *alto* that of the *viola;* the *soprano* that of the violin.

Con'crete. A mixture of mortar with gravel or spawls.

2. (*Sugar.*) Sugar boiled down to a solid mass; to be worked up subsequently in factories provided with superior machinery. See CONCRETOR.

Con-cre'tor. An apparatus for evaporating sugar, bringing the whole juice of the cane to a solid mass, to be subsequently treated with superior machinery. *Fryer's process.*

The apparatus consists of three parts: 1st, a rectangular pan of cast-iron, made in sections, and in all 25′ or 30′ long by 6′ wide and 6″ deep, with a number of partitions running across, extending alternately from each side nearly to the other, and set with a slight inclination, so that the juice runs in at one end, and in a stratum of not more than ½″ in depth, by a long, zigzag course, escapes at the other. The pan is heated by direct fire from below, and in passing through it about two-thirds of the water is evaporated. The juice, now of syrupy consistence, goes thence to the interior of a hollow cylinder of sheet-copper, heated on the outside by the flue gases from the fire under the pan (or by the vapor from the juice therein), while through the inside a current of air is driven, heated by the exhaust steam of the small engine, which furnishes power. This cylinder is 20′ long by 3′ 6″ in diameter, open at the ends, with the exception of a little rim to retain the syrup, set with a slight inclination from the horizontal, and made to revolve slowly — about 6 or 8 times per minute — on its axis. Thence the syrup, now of thick consistence, passes to the exterior surface of a copper-faced iron cylinder of 4′ in diameter by 4′ long, over which it is evenly distributed in a thin layer. This cylinder is heated from within by exhaust steam, revolves upon its axis twice per minute, and receives on the outside a steady blast of heated air, by which the evaporation is rapidly completed and the syrup brought to the consistence of a soft solid, which is removed by a scraper, and can be molded while warm, but on cooling sets into perfectly hard slabs, ready for storage or shipment. The time required for the passage of any given portion of sugar from end to end of the whole apparatus is only about 15 minutes, and with the above dimensions of parts the product is about half a ton of *concrete* per hour. Of course the arrangement may be used to produce crystallized sugar, but it is specially adapted to its intended use of rapidly putting the crude juice into a condition in which it may be kept free from alteration and in small bulk for shipment, to go in due time into the hands of the refiner.

Mallet's report on Group III., in vol. iv., "*Centennial Exhibition Reports*," 1876.

Con-cus'sion Ta'ble. *a.* An ore-sorting table to which concussion is imparted in order to separate the broken ore by gravity. A *percussion* table.

Rittinger's double concussion table, * "*Mining and Scientific Press*," xxxiv. 217.

b. A species of grain cleaner. See CLOD CLEARER, *supra.*

Con-den'ser. A word with several applications, referring to the concentration of volume of an object, as of a solution, a syrup, a gas, an ore, or slime mixed with gangue or impurities.

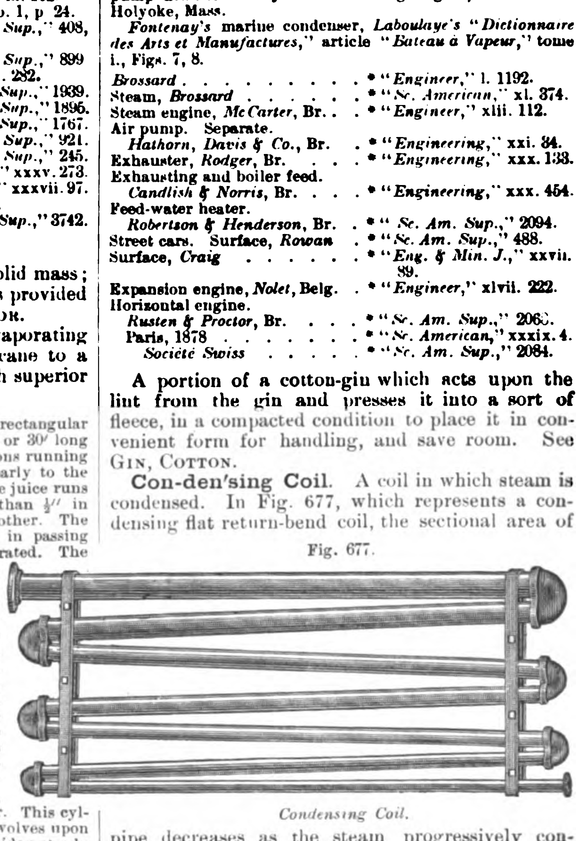
A portion of a cotton-gin which acts upon the lint from the gin and presses it into a sort of fleece, in a compacted condition to place it in convenient form for handling, and save room. See GIN, COTTON.

Con-den'sing Coil. A coil in which steam is condensed. In Fig. 677, which represents a condensing flat return-bend coil, the sectional area of pipe decreases as the steam progressively condenses.

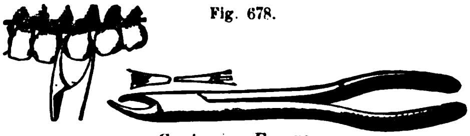
Fig. 677.



Condensing Coil.

Con-den'sing For'ceps. Dental forceps for

Fig. 678.



Condensing Forceps.

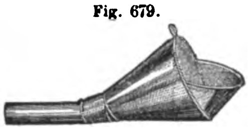
condensing plugs situated between the teeth, near their necks or their lingual or palatine edges.

Con'duc-tiv'i-ty. (*Electric.*) The conveying power of an object. Opposed to *resistance.*

Con'duc-tom'e-ter. An instrument for illustrating the comparative power of different objects for conducting heat, electricity, etc.

Con-duc'tor Head. A funnel spout and leading pipe, to conduct a liquid into a reservoir horizontally or nearly so.

Fig. 679.



Conductor Head.

Used in creameries in pouring the milk from the cans of the collecting wagons into the can on the scale inside the receiving-house.

Con-duc'tors' Valve. (*Railway.*) A valve connecting with the Westinghouse automatic brake, and placed at some convenient point in a car, and operated by a cord extending through the car within reach of the conductor.

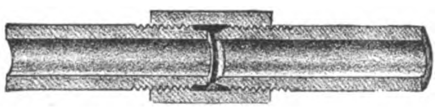
Cone. (*Spinning.*) One of the taper drums in the headstock of a mule, and known as the *backing-off* and *drawing-up* cones respectively.

Cone Gear. (*Add.*) Conical gearing for varying motion was described in *Bramah's* planing machine. English Patent, 1802.

Cone and Cra'dle Mill. A mill which has a conical muller or grinder, reciprocating in a semi-cylindrical concave.

Cone Joint. A pipe joint. The abutting ends of the pipes are conical, and are drawn by a screw-sleeve against a leaden gasket, and thus make a tight joint.

Fig. 680.



Cone Joint for Hydraulic Pipes.

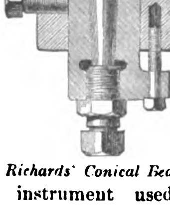
Con-fec'tion-er'y Stove. A sheet metal stove with holes to fit a variety of sizes of confection pans, one at a time.

Steam confection pan, *Brown* . . * "*Engineer*," xli. 226.
French confectionery . . . . . "*Sc. Am. Sup.*," 194.
See also Fig. 1428, p. 611, "*Mech. Dict.*"

Fig. 681.

Confectionery Stove.

Fig. 682.



Richards' Conical Bearing.

Con-form'a-tor. An instrument used in taking the shape of the head at the hat band. Used in shaping hats to fit the head.

Hat conformator and shapes of heads of many distinguished persons, "*Scientific American*," * xxxviii. 143, 146.

Con'ic-al Bear'ing. A compensating bearing for the spindles of shafts in wood machines. The bearing passes through the shell, and the end abuts against the end of an adjustable screw of hard brass having a core diameter equal to that of the spindle. Surrounding the bearing between the end-thrust screw and the spindle is an annular cavity for oil and fibrous packing. Fig. 682.

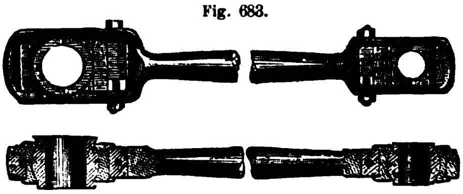
Con-junc'ti-va In'stru-ments. (*Surgical*) Instruments for operating upon the mucous membrane of the eye and lid.

Scissors curved on the flat . . . . . . Fig. 96, Part II.
Pterigium scissors (for removing excrescences from the internal canthus of the eye) . . . . Fig. 97, Part II.
Caustic holder . . . . Fig. 97 *b*, Part II.
Brush . . . . Fig. 97 *c*. Part II.
Of *Tiemann's* "*Armamentarium Chirurgicum.*"

Con-nect'ing Rod. A rod intervening between the piston rod or cross-head and the wrist of a crank or driving wheel.

Fig. 682 shows a connecting rod forged in a single piece and mortised for the reception of the brass boxes, which are curved on their backs and fit the cheek-pieces between which

Fig. 683.



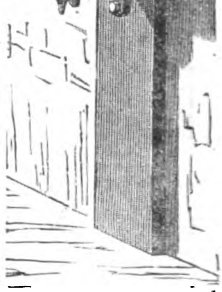
Connecting Rod.

they can turn to adjust themselves to the pins, in the plane of the axis of the rod. The adjustment for wear is by wedge-blocks and set screws.

Connecting rod with solid ends on Brown engine at the Centennial, "*Scientific American*," * xxxvi. 20.

Con'ning Tow'er. The pilot house of an iron clad, usually forward of the funnel in the British practice, and having no sight holes. A reflecting mirror may be exposed above its open top.

Fig. 684.



Console.

Con'sole. A bracket on a wall; in the present case for supporting a hydraulic motor or other object.

Con-sol'i-da'tion. (*Locomotive.*) A type of freight locomotive, the name of the engine, the first in its class, built in 1866, at the Baldwin locomotive works, on the plans of Mr. Alexander Mitchell, to operate a grade of 1 in 40 on the Lehigh Valley Railway, and specially for the Mahony plane, which rises 133′ to the mile.

It had cylinders 20″ + 24″ four pairs of 48″ diameter (pony) driving wheels, connected; and a two-wheel swing truck in front equalized with the front driving wheels. The weight of the engine at work was 90,000 pounds, of which all but 10,000 was on the driving wheels.

Con-sol'i-da'tor. (*Ceramics.*) A system of strainers in which slip is filtered through a series of bags. The consolidator of Needham and Kite is used in England.

Con'stant Bat'te-ry. (*Galvanic Battery.*) One in which the energy is kept constant by prevention of the polarization of the negative element. That is to say: the polarization of the negative plate is prevented by surrounding the same with a liquid which unites with the hydrogen which is given off from the positive plate.

The Daniell's battery, for instance, has an inner vessel of porous clay in which is a rod of zinc with a solution of sodium chloride, or dilute sulphuric acid; the outer cell has a solution of copper sulphate maintained at saturation by crystals on a shelf.

The action is as follows: when the circuit is closed decomposition of the dilute acid takes place in the inner cell; the oxygen of the acid combines with the zinc to form oxide, which is dissolved by the acid to form zinc sulphate. The hydrogen, set free by the decomposition, is liberated on the surface of the copper element, but instead of remaining meets the copper sulphate solution which is also being decomposed into (1) oxygen, with which it combines to form water; (2) copper, which is deposited upon the plate of the same metal; and (3) sulphuric acid, which permeates the porous cell, replacing that with which the zinc was dissolved, and so automatically refreshing the inner cell.

The depolarizing liquid is usually separated from the exciting liquid by a porous diaphragm or cup, but in the gravity battery the separation is effected by the differing specific gravities of the liquids themselves.

Becquerel's oxygen gas battery was the first constant battery. It was the first to employ two liquids or a porous cell. See Becquerel Battery.

See also Constant Battery, depolarizing by secondary current, "*Scientific American Supplement*," 764.

The following batteries come within the definition of *Constant*:—

Bunsen battery.	Leclanché battery.
Daniell battery.	Ponci battery.
Gravity battery.	Smee battery.
Grove battery.	Some of which are synonyms.

The following diagram will explain the reactions that take place in a Daniell's cell when the circuit is closed:—

Negative cell	Zinc	Zn	$ZnSO_4$	Zinc sulphate in inner cell.
	Sulphuric acid	H_2	H_2SO_4	Sulphuric acid, ready to dissolve more zinc.
		SO_4		
Positive cell	Copper Sulphate	Cu		
		SO_4		
	Copper	Cu	Cu.	Copper; deposited in outer cell.

In this diagram the water is not considered, as the reactions are explainable without including it in the statement. See also list under Galvanic Battery.

Con-su'mers' Test Me'ter. (*Gas.*) An apparatus for testing the accuracy of the indications of gas meters *in situ*.

It is usually a 5-light diaphragm meter with a circular dial, the outer circle showing 1′ divided into 10ths, the second circle 10′, and the third 100′ per revolution. The pointers are all adjustable. Unions and gum hose connect the meter with a pedestal and burners. The test-meter is verified by the Meter Prover; which see.

Con'tact Break'er. An arrangement or device to interrupt a circuit. The feature of making and breaking circuit is the essence of numberless telegraphic inventions.

One invented by *Herr F. Niemoller* is thus described:—

"To the middle of a wire stretched horizontally is attached a platinum point which touches the surface of mercury held by a small vessel. The current passes through the wire, and over that part of the wire through which the current passes when all the apparatus in its normal state is a small magnet. This magnet, acting on the current, causes vibrations in the wire, and so breaks and makes contact. The number of vibrations can be readily modified by changing the length of the wire, and as high a number as 1,000 breaks per second can be obtained. By passing an intermittent current over the wire, it can be set in vibration without the intervention of mechanical means. This happens when the fundamental note of the string is in unison with the pitch of the breaker."

Con'tact-vein. (*Mining.*) A vein along the contact plane of, or between two dissimilar rock masses.

Con-tin'u-ous Brake. (*Railway.*) One which is attached to each car of a train, and by connection of the several cars can be operated upon all simultaneously, and from points on the engine and each car.

The systems are various:—

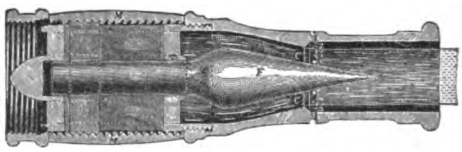
Air compression.	Hydraulic.
Vacuum.	Mechanical.
Steam.	Electric.

Con-trol'ling Valve. A supplementary steam valve adjustable to the maximum amount of steam which the foreman thinks proper to carry, while another valve is used to reduce this quantity, more or less, at the discretion of the workman.

Nash's . . . . "*Scientific American*," xlii. 166.

Con-trol'ling Noz'zle. A means of controlling the size of a stream issuing from a nozzle, by means of a cone valve *F*, which, by rotation of the sleeve *M*, is projected forward or retracted so as to partially (or entirely) close the opening, or leave the water full scope. By this means the pipeman is able to control the size of the stream according to the abundance and pressure of the water.

Fig. 685.



Controlling Nozzle.

Con-trol' Watch. A time-piece used as a watchman's time detector. See Figs. 7083, 7084, p. 2734, "*Mech. Dict.*"

Con-ver'sion. Changing the bore or fitting of a gun, as—

1. The conversion of a smooth-bore to a rifle.
2. A muzzle-loader to a breech-loader.

A report on the fabrication of wrought-iron tubes at the West Point foundry for conversion of Rodman 10″ smooth-bore guns into 8″ rifles, is contained in the "*Report of Chief of Ordnance, U. S. A.*," 1877, iii., pp. 400–412, and Plates I.-VII. accompanying.

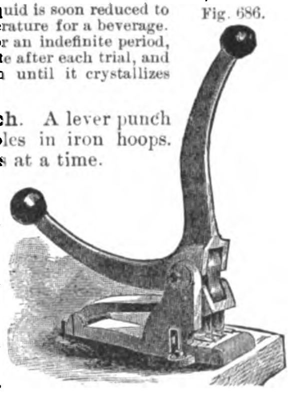
Ladle, *Caspersson* . . . . . "*Am. Manuf.*," Dec. 31, 1880, p. 12.

Cool'ing Cup. An invention of Toselli.

It is described in "*Les Mondes*," and consists of a cylindrical cup for holding any liquid into which may be plunged an inner goblet shaped like an inverted truncated cone, and having a lid which rests on the outer cup. Putting 150 grams of nitrate of ammonia in the inner goblet, filling it with cold water, and stirring it so as to hasten the solution, the temperature of the outer liquid is soon reduced to a sufficiently low temperature for a beverage. The salt may be used for an indefinite period, by spreading it on a plate after each trial, and exposing it to the sun until it crystallizes anew.

Fig. 686.



Cooper's Punch.

Coop'er's Punch. A lever punch for making rivet holes in iron hoops. It punches two holes at a time.

Coop'er-age Ma-chine'. See list under BARREL MACHINERY.

Cop'per. See the following references: —

Ore working . . . "*Sc. Amer.*," xxxix. 209.

Cop'per Bolt. A copper bit; a soldering tool.

Cop'per Cast'ing. Copper highly heated and cast under water, acquires a very beautiful and persistent rose color. A Japanese art. — *Dr. Percy.*

Cop'per-plate Print'ing.

Cylindrical system by roller and scraper, *Godchaux* (Fr.).
Flat plate system, *Robert Neale* (Patented in England, January, 1853).
Hydraulic pressure, *Silbermann*.
Described in article "*Imprimerie*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," tome iv., ed. 1877.

Cop'y-graph. Writing done on paper with a peculiar ink, preferably aniline, is allowed to dry, and then laid upon a slab of gelatine and glycerine which absorbs the ink and parts with it to paper laid upon it. It yields a large number of copies, if promptly taken.

The following is the recipe for making the slab: Best gelatine or glue, 1 part, soaked over night in cold water and the excess of water poured off; the glue is then warmed in a water bath with from 10 to 12 parts of glycerine, to which is added 4 to 6 parts of freshly precipitated sulphate of baryta and 1 part of dextrine, well mixed with constant stirring. During the summer less glycerine should be added than in winter, as the glycerine softens the mixture, while the glue and dextrine harden it. While soft it is poured into a zinc box and cooled. For ink, the aniline ink called Violet de Paris, is best.

The lithogram, chromograph, copygram, hectograph, and numerous other processes are substantially the same. It is the invention of *Stein*, of Vienna.

Cop'y-ing Lathe. A lathe which reproduces a pattern. This may either be a templet, in which case the slide-rest works against the templet, which thus governs the distance of the tool from the axis of rotation of the stuff. The result is symmetrical. The work may consist of table-legs, billiard-cues, etc.

Another form has a capacity for irregular shapes, the pattern revolving and governing the position of the revolving cutter.

See SPOKE-LATHE, Figs. 5451, 5452, p. 2283, "*Mech. Dict.*"
See LAST LATHE, Fig. 2825, p. 1259, "*Mech. Dict.*"
See LATHE . . Figs. 2336, 2837, p. 1264, "*Mech. Dict.*"

See also AUTOGRAPHIC TELEGRAPH; FAC-SIMILE TELEGRAPH.

Cor'al, Ar'ti-fi'cial. Yellow rosin, 4; vermilion, 0.2; melt and mix carefully.

Cord Car'ri-er. (*Surgical.*) A means of carrying a ligating cord to a deep-seated part.

Obstetric cases . . . . . . Fig. 496 *b*, Part III.
Knot-tyer . . . . Fig. 92, Part I.
Ligature Needle . . . . . Figs. 94–96, Part I.
Compress for seminal cords . Fig. 206. Part. IV.

All in *Tiemann's* "*Armamentarium Chirurgicum*."

Cord-mak'ing Ma-chine'. Binns' cord-making machine (Bradford, Eng.), automatic machine for making silk cord, trimmings, fringes, etc.

"*Manufacturer & Builder*" . . . . xi. 208.

Core. (*Add.*) It is often made of green sand, but usually of core sand, molded in a core box, or of loam struck up upon a spindle or core plate; it is dried and black washed. It must be sufficiently strong to bear the flow of metal around it, and sufficiently porous to allow free vent for the gases. There are many varieties: —

Dry sand.	Molasses water.
Flour.	Glue water.
Steam flour.	Sour beer.
Loam and sand.	Brickbat.
Rosin.	Charcoal.

(*Electricity.*) A bundle of wires in the center of the helix, made of soft iron, so that it may magnetize and demagnetize as rapidly as possible.

Core Lift'er. A collar or thimble lowered into a bore, made by an annular rock drill, in order to bring up the core left by the drill. The collar is of the size of the bit, and has on its interior periphery a catch which, on the retraction of the collar, engages the core and lifts it to the surface.

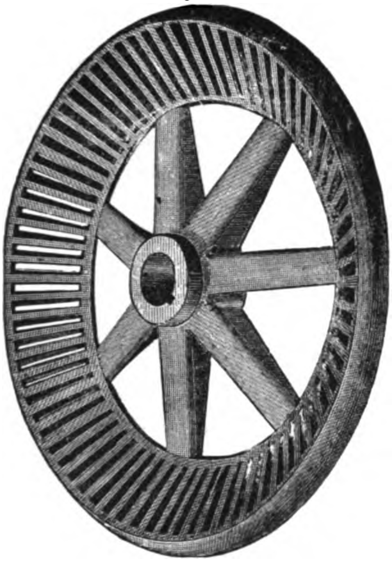
Core Wheel. A wheel with recesses which answer as the interspaces of cogs, or into which wooden cogs may be driven. Fig. 687. Such a wheel is made with cores, which are placed in the mold to form the openings in the wheel.

Cork Arm'-board. (*Leather.*) A graining-board, made of the outer or dead bark of the cork-oak. It has no grooves.

Cork Board. Ground cork incorporated with paper pulp in mixing machines and with powerful presses. The material is springy, light, a poor conductor of heat and sound. A French invention.

Cork'ing Ma-chine'. The form of corking machine used at Bordeaux is shown in Fig. 688 The bottle is placed on its stand, a pan being placed around it to catch the wine in case any bottle should break. The cork is in the sleeve immediately about the mouth, and is forced into the bottle by the piston operated by the lever. It is simple and efficient.

Fig. 687.

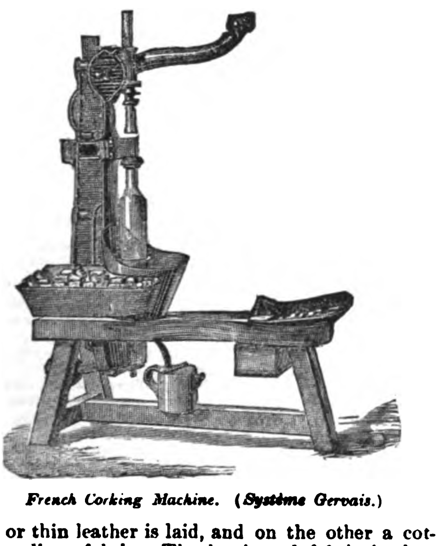


Core Wheel.

Cork Leath'er. Fine slices of cork placed between and attached to layers of leather. *De Beerski & Co.*, Fr.

Slices of cork coated on each side with India-rubber solution; on one side a sheet of cloth can-

Fig. 688.



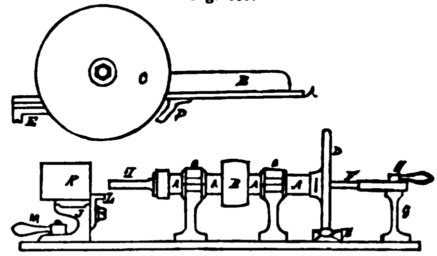
French Corking Machine. (*Système Gervais.*)

vas or thin leather is laid, and on the other a cotton or linen fabric. The laminated fabric is then pressed between rollers. To be used for trunks, driving belts, etc. Veneered with wood for panels. *Block*, Engl.

Cork Ma-chine'. Armstrong's machine for making corks is shown in Fig. 689. The upper figure is the machine for cutting the slab of cork into strips. The cork-slab is laid on the iron table *A*, which is secured by lugs *D E* to a wooden table. *C* is the revolving knife and *B* the gage.

In the lower figure, *A* is a hollow spindle driven by the pulley *B*, and capable of slipping back and forth in its bearings in the standards *C C*. On the right-hand end of the spindle *A* is the flange *D*, the edge of which runs in a groove in the lever *E*, the latter giving the spindle its end motion. On the other end of the spindle *A* is the tubular cutter *I*, which has parallel sides, and an edge produced by beveling

Fig. 689.



Cork Machine.

off the outside. *F* is a long, stationary rod, which runs from the set screw *H* through the spindle *A*, and nearly through the cutter *I*. A piece of cork being placed against the block of hard wood *R*, resting on the gage *L*, the lever *F* is moved, bringing the spindle *A* to the left, and forcing the cutter through the cork. Being retired, the central rod *F* forces the cork out of the cutter. *M* is the mode of adjustment for the abutment *J*.

The cork is tapered by presentation to a steel disk, while itself is slowly rotated

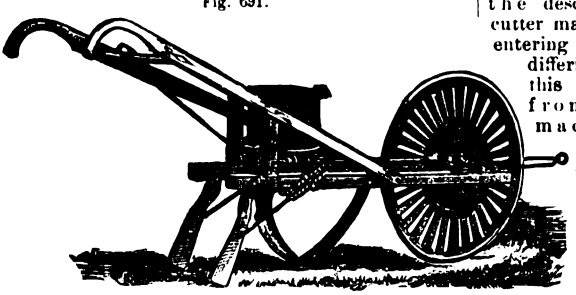
	* "*Scientific American*," xxxvii. 115.
Silver & Deming .	* "*Iron Age*," xix., Jan. 4, p. 5.

Corn Drill. A machine for planting corn in drills. The machine for planting it in hills is called a CORN PLANTER, which see.

Drills and planters are made for either one or two horses, and also to be worked by hand.

In the *Campbell* corn-drill a slotted solid wheel acts as a roller in breaking clods, and helps to prepare the seed-bed for the corn. It also is the drive-wheel which through its pitman rod and geared connections automatically operates the force-feed of the seed from the hopper, which, dropping down through the hollow share that has just provided its bed, is followed by the adjustable covering shares that complete the work. A fender in front curving back to the point of the seed-share clears the track.

Fig. 691.



Corn Drill.

There are three circles of cogs on the drive-wheel which give three different rates of feed, dropping a grain of corn at greater or lesser intervals, say from 12″ to 20″.

Cor'ne-al In'stru-ments (*Surgical.*) This includes *paracentesis*, and *cataract* instruments.

The former are needles and trocars.

The latter are enumerated under CATARACT INSTRUMENTS, which see.

See also IRIS INSTRUMENTS.

Fig. 692.

Round-corner Cutter.

Cor'ner Cut'ter. 1. A machine for cutting the corners off cards or books. Pass-books have the corners removed in order to avoid dogs-ears. The machine makes a round corner. Some cards are also rounded on the corners to suit the fancy or prevent bending too readily at the corners. Some playing cards are thus trimmed. The machine works by a treadle, or by power; in the former manner in Fig. 692. The spring clamp descends upon the object and holds it while the cutter descends, and cuts through the book to the wooden block beneath it.

2. A machine for cutting out notches from blanks of card-board, intended to be bent up to form boxes. The making of a corner notch, and the scoring partially through at the bending places, prepares the blank for being bent into shape.

Fig. 693.

Box-maker's Corner Cutter.

Fig. 693 shows a treadle motion corner cutter. The blank is laid on the table and the descending cutter makes an entering angle, differing in this respect from the machine, Fig. 692, which merely rounds the salient angle of the book or card. See PAPER-BOX MACHINE, page 1616, "*Mech. Dict.*," where various methods and forms of cutting are represented.

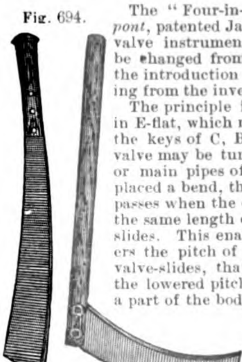
Cor'ner-ing Ma-chine'. A machine for rounding off the corners of stuff; especially used in implement and carriage work. See CHAMFERING MACHINE.

Cor'ner Valve. A valve at a corner, or bend in a pipe. See ANGLE VALVE.

Cor'net. (*Music.*) The cornet with three pistons and with cylinders has a compass of two octaves and two or three notes. Its mechanism allows of its giving all the chromatic degrees within its range.

Cornets are of many varieties as to key, and some have lengthening pieces by which the tone is lowered, but the facility of modulating by the pistons renders this mode of variation less needful.

Fig. 694.



Corn Knife. *Corn Hook.*

The "Four-in-one" cornet of *Conn & Dupont*, patented January 22, 1878, is a sliding valve instrument, so constructed that it may be changed from a higher to a lower key by the introduction of additional piping. Quoting from the inventors: —

The principle is this: First build a cornet in E-flat, which may be lowered in pitch to the keys of C, B-flat, and A. Now, that the valve may be tuned to correspond with open or main pipes of the horn, on each valve is placed a bend, through which the air-current passes when the open tone is used. Precisely the same length of pipe is added to the valve-slides. This enables the player when he lowers the pitch of the cornet, to draw out the valve-slides, that they may be in tune with the lowered pitch. This bend on the valves is a part of the body of the instrument when the open tone is used, but is cut off and its equivalent transferred to the valve-slides when the valve tones are produced."

See also cornets and horns, Fig. 2564, page 1122, and pages 1500-1501, "*Mech. Dict.*," where musical instruments are listed and classed in order of their nature and also alphabetically. See also Fig. 3263, page 1498, *Ibid*, for table of the compass of instruments and voices, showing the place which each occupies on the scale.

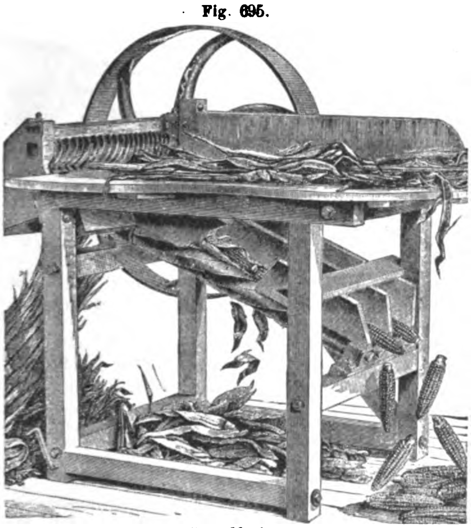
Corn Hook. A hand implement for cutting corn on the stalk. It is used by a draw motion, pulling upward. Fig. 694 shows the corn knife and corn hook. See also CANE KNIFE; MACHETE, *infra*.

Corn Husk'er. A machine for husking ears on the stalk.

Across the end of the frame near the top are placed two picking rolls provided with spiral grooves between which the stalks are fed, so that passing through the rolls they are divested of the ears both large and small. The stalks then drop upon an elevator and are taken away.

The ears, as they are severed from the stalks, drop upon the husking rolls that are placed lower down in the frame, at right angles to the picking rolls, and in an inclined position. Upon the surface of these rolls are spiral grooves for the purpose of allowing spikes to be put on the surface of the opposite roll, and also to allow the ear to settle down between the rolls, so that the hold upon the husk may be more certain. These depressions and spikes being arranged spirally upon the rolls, holding the husks at one end of the ear, and continuing the grasp to the opposite end, make the process of stripping the husk very similar to husking by hand.

Fig. 695.



Corn Husker.

As the ears slide down over the rolls, the husks, being torn off by the steel spikes, are dropped upon the elevator, while the ears pass on to the end of the rolls, and are there received into a basket, thus delivering the stalks and husks in front, and the corn in the rear of the machine at the rate of from 25 to 50 bushels per hour according to the condition of the corn, etc.

Cor'nice Ma-chine'. 1. A machine for shaping sheet metal into sham cornices for buildings.

2. A machine for planing wood into shapes for interior wall cornices.

Hayes . . . . . * "*Manufacturer and Builder*," xi. 217

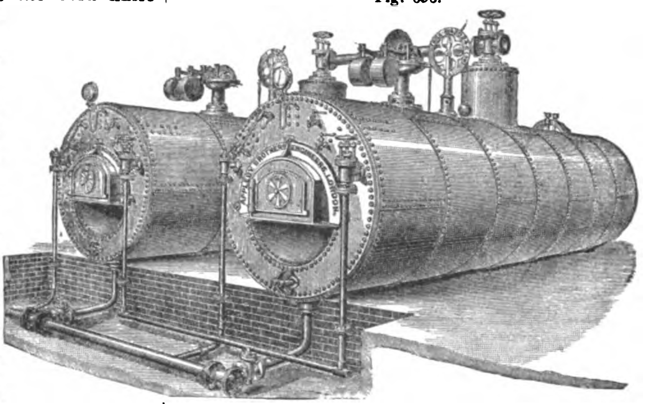
Sheet metal . . . * "*Iron Age*," xviii., Sept. 7, p. 17; Oct. 26, * p. 1.

Cor'nish Boil'er. A boiler formerly made wagon-shaped (*A*, Plate LXI., opp. p. 2326, "*Mech. Dict.*") but now of a stronger form, cylindrical, higher pressure being required than in the atmospheric engine, where steam was only used to fill the space below the piston, in order that by its condensation a partial vacuum might be produced, and the pressure of the air, acting upon the top of the piston, should depress the latter and with it one end of

Fig. 696.



Appleby's Cornish Boiler.

the walking-beam, lifting by consequence the pump-rod at the other end of the beam.

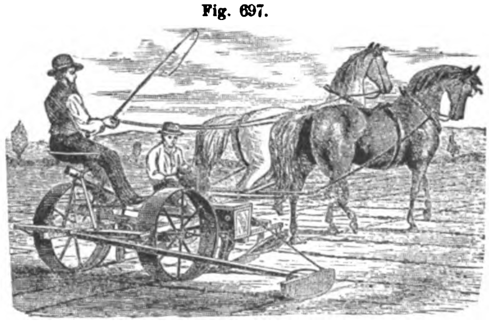
Fig. 696 shows two of a battery of Cornish boilers of the form built by Appleby Brothers, of London, for the locomotive shops of the East Indian state railways. The fittings consist of a furnace front with ventilator, grate bars, bearers, dead-plate, and damper, man-hole and mud-hole, with mud-hole cover and bridge, stop-valve, safety-valve, feed-valve, gage-cocks, glass water-gage, Bourdon's steam-pressure gage, blow-off cock, fusible plug in the crown of each tube, and high and low-water indicator.

Cor'ni di Bas-set'to. (*Music.*) A reed instrument like a clarinet in F (low), excepting that it has a brass bell-mouth, which elongates its lower extremity and descends to a lower note.

Cor'no In'glese. (*Music.*) A double reed instrument, the alto of the oboe, with a compass of 2½ octaves. It is written on the G clef.

Corn Plant'er. Walking, riding, and hand corn planters are shown on pp. 626, 627, "*Mech. Dict.*" Fig. 697 shows a complete machine, with

Fig. 697.



Corn Planter and Marker.

the driver, dropper, and marker. The weights of the operators practically balance each other. The shape of the runner makes a distinct channel in the ground for the reception of the seed. The depth of the channel is regulated by shoes over the faces of the runners. By projections on the wheels conforming to the width of the channels the earth is pushed over the corn, and the furrows are rolled by the broad-faced wheels which support the machine. The planter can be thrown out of the ground when turning at the end of the row and held in position by a catch, until the point of starting on a new bout is reached, when, by a movement of the foot of the driver, the machine is again placed in working position.

The machine is used principally for planting in check-rows by placing a boy on the machine to move the lever when crossing the check-marks, or is made to act automatically as a drill or hill-planter when check-rows are not desired. The marker shown as projecting from the off-side is to mark the ground as a guide for the next bout; when returning, the marker will be shifted to the near side, and so on alternately as the machine goes to and fro across the field.

In the bottom of each hopper is a round dropping-plate with a circle of pockets: into these the grain falls, and the rotation of the plate brings the hole over the tube and the corn passes by the tube to the open furrow at the heel of the runner. The motion of the dropping-plates is derived from the wheels, and different dropping-plates are used for different quantities of seed, 1, 2, 3, or 4 kernels; optional pinions used for dropping in drill-rows are of sizes for dropping at 19'', 15'', 10'', 7'', distance respectively.

The single row planter has the appearance of the walking cultivator, Fig. 1468, p. 627, "*Mech. Dict.*," or of the machine shown at CORN DRILL, *supra*.

Check row planter, *Gruetzel*, * "*Scientific Amer.*," xlii. 243.
Corn planter, *Du Souchet* . * "*Scientific Amer.*," xl. 99.
Hand planter, *Noel* . . . * "*Scientific Amer.*," xxxiv. 86.

Corn Plow. The principal corn plow is a cultivator, and is considered under that caption.

There are, however, special plows made for corn and for cotton cultivation, some of them adapted for either. Those with shifting shares, for operating upon the growing plant at different stages of its growth, are considered under *combination plow*.

Single and double plows and several other forms, mentioned in the list under AGRICULTURAL IMPLEMENTS, belong to this order.

Corn plow and marker, *Burns*, * "*Sc. American*," xxxix. 99.

See also CULTIVATOR.

Corn Shel'ler. A machine for removing corn from the cob. See "*Mech. Dict.*," p. 628.

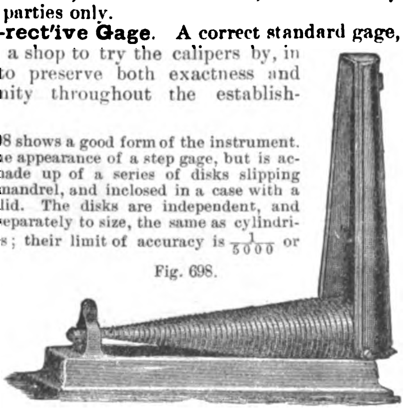
Livingston & Co. . . * "*American Miller*," v. 15.

Cor'po-ra'tion Stop. A stop cock in a gas or water main, outside of a house, to be used by official parties only.

Cor-rect'ive Gage. A correct standard gage, kept in a shop to try the calipers by, in order to preserve both exactness and uniformity throughout the establishment.

Fig. 698 shows a good form of the instrument. It has the appearance of a step gage, but is actually made up of a series of disks slipping upon a mandrel, and inclosed in a case with a hinged lid. The disks are independent, and ground separately to size, the same as cylindrical gages; their limit of accuracy is $\frac{1}{5000}$ or

Fig. 698.



Corrective Gage.

$\frac{1}{10000}$, according to the precision required, and the limit of expense. The sizes are from $\frac{1}{4}$'' to $2\frac{3}{8}$'' by 16ths; from $2\frac{1}{2}$'' to $4\frac{1}{8}$'' by 8ths, making 49 sizes.

Cor-ru-ga'ted Boil'er. A form of house-heating or greenhouse boiler, which occupies a position inside a furnace, and the shape of which exposes a large surface to the fire.

Cor'si-can Fur'nace. Another name for the Catalan furnace. See CATALAN FORGE.

Co-run'dum. A crystalline alumina used as an abradant.

As a cutting agent, *Jenks* . . . . "*Sc. Am. Sup.*," 972.
Occurrence and distribution . . . "*Sc. Am.*," xxxix. 193.

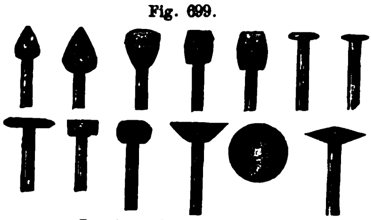
See also EMERY; EMERY WHEEL.

Co-run'dum Points. (*Dental.*) A grinding and abrading tool used on the end of the spindle of

Fig. 699.



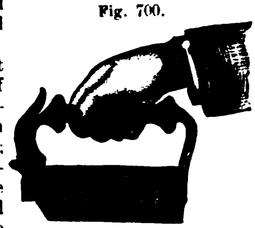
Dentists' Corundum Points.

a dental drill; either in mechanical or operative dental operations.

The set consists of wheels, olives, points, cherries, cones, etc.

Co-run'dum Tool. A grinding tool made of a block compounded with emery, or faced with the same.

Fig. 700.



Millstone Facing Tool.

The term is somewhat generic, a multitude of tools deriving their virtue and usefulness from degraded corundum; but the specific application of the term, in the present case, is to a tool for dressing the surface of millstones, restoring the natural grit; the flat for trueing the face, and the angles for the furrows. See MILLSTONE DRESSER.

Co-si'na. A dye produced by Dr. Carr of Stuttgart, Germany. Its solutions in alcohol are of a delicate rose color in transmitted, and a pure yellow in reflected light.

Prepared from fluorescin, by treatment with bromine in combination with potash.

"*Scientific American*" . . . . xxxiv. 130.

Cos'mo-graph. An instrument resembling an armillary sphere for popularizing astronomical knowledge, erected as a public monument.

Fig. 701.

Rivière's Cosmograph

The long rod indicates the earth's axis, and points to the polar star; the vertical circle is the meridian; the circle at right angles thereto the equator; a vertical point shows the zenith; others mark the tropics and polar circles.

See also ARMILLARY SPHERE, Fig. 336, p. 149, "*Mech. Dict.*," and TELLURIUM, * p. 2525, *Ibid.*

Cos'mo-scope. An instrument to demonstrate the positions, relations, and movements of the sun, earth, and moon. A form of orrery. *Lexcellent*, "*Technologiste*," * xl. 125.

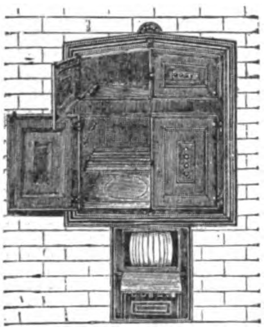
Cos'mo-ra'ma Lens. (*Optics.*) A large-sized double or plano-convex lens.

Cos'to-tome. (*Surgical.*) Rib-cutter. A post-mortem chisel or shears for opening the thoracic cavity.

Chisel costotome, Fig. 322; shears costotome, Fig. 68; Part I., *Tiemann's "Armamentarium Chirurgicum."*

Cot'tage Range. An elevated oven range with dividing horizontal flue, making a direct draft around the lower and upper ovens.

Fig. 702.



Cottage Range.

Cot'ton Cul'ti-va'tor. A three-share, expansible-frame, wheelless cultivator.

Cot'ton Cyl'in-der. A roller used in drawing fibers or slivers in cotton machinery. See DRAWING, DRAWING-FRAME, "*Mech. Dict.*" Osgood's substitute for the ordinary cylinder, covered with cloth and leather, is gelatine treated with bichromate of potassium.

"*Scientific American Supplement*" . . . . . 223.

Cot'ton Gin. See GIN.

Cot'ton Hold'er. (*Surgical.*) A staff to hold a pledget of cotton or lint for application to a wound or cavity.

Cot'ton Ma-chin'er-y. The following list gives the series of machines shown by the Willimantic Linen Co. in their complete exhibit of machines, from the bale of cotton to the spool thread; working upon sea-island cotton. Atlanta Exhibition, 1881.

Cotton gin.	Bobbin spooler.
Cotton picker.	Two-ply doubler.
Three Foss & Pevey cotton cards.	First twisting frame.
Railway head.	Spooler.
Comber doubler.	Three-ply doubler.
Comber.	Second twisting frame.
First drawing frame.	Reel.
Second drawing frame.	Skein spooling machine.
Slubbing frame.	Winding machine.
Intermediate frame.	Ticketing machine.
Roving frame.	Automatic spool turning machine.
Ring spinning frame.	Color card winding machine.

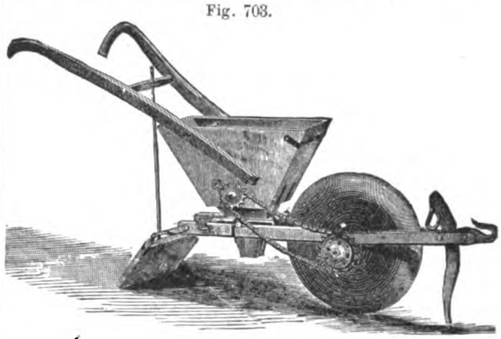
Smith . . . . U. S. Patent, April 10, 1877.

Cot'ton Plant'er. A machine which opens a furrow, drops the cotton seed, and then covers it.

There are many machines for the purpose. A force feed is useful on account of the fibrous clinging quality of the seed.

Conner's cotton planter, Fig. 703, has a tooth in front, followed by the disk wheel, which makes the seed-bed. The drive wheel, through an endless chain, operates the force feed in the hopper that furnishes the seed, and is followed by a coverer that is pivoted to the frame of the planter, and adjusted and held in position by a rod to the handle frame above.

Fig. 703.



Cotton Planter.

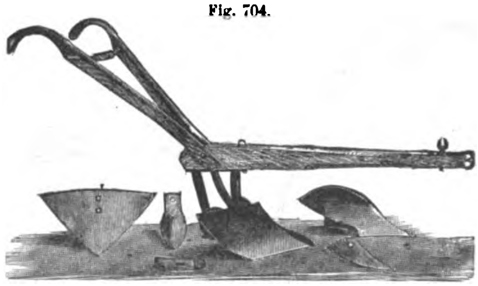
The "Globe" cotton planter gave the best satisfaction at the Atlanta Exposition. It has a barrel which rolls over the ground, being supported by end wheels. Around the equator of the barrel are round holes for the seed to issue. A hoop closes them or opens them to any extent. A spiked shaft in the middle remains stationary while the roller and contents revolve. This keeps the seed stirred. It has the opening share and covering board respectively in advance and rear of the seed cylinder.

Seymour . . . . . * "*Scientific American*," xxxiv. 54.

Cot'ton Plow. A form of cultivating plow differing but little from that employed in tending other crops which are planted in rows and plowed during growth.

Avery's combination cotton plow has adaptations for various duties in cotton tending, as turning plow, scraper sweep, shovel-plow and bull-tongue; five

Fig. 704.



Combination Cotton Plow.

implements with one stock. The half-shovel and scooter may be added if desired.

The rudder wheel acts as a guide, and as a fulcrum in turning or regulating depth, and preventing the implement from dodging and shooting into the line of plants.

See also COMBINATION PLOW.

Cot'ton Pow'der. See TONITE.

Cot'ton Press. See BALING PRESS, "*Mech. Dict.*," *et supra.* Also: —

Compress, *Burr* . * "*Scientific American*," xxxvii. 159.
Hydraulic, *Taylor* * "*Engineering*," xxv. 190.

See list under PRESSES; and REPRESSING PRESS, Fig. 4624, p. 1919, "*Mech. Dict.*"

Cot'ton Scra'per. A cotton cultivator for scraping the earth to or from the plants, as may be required at different periods of the cultivation. The scraper share is shown attached to the stock in COTTON PLOW, which see.

Cot'ton Spin'ning. The Clement process for spinning cotton direct from the seed cotton is mentioned in many of the journals of the day.

"*Engineering and Mining Journal*" . . . . xxviii. 423.
Louisville "*Evening Post and Press*" . . . . Dec., 1879.

The machine is a combined gin and card, making slivers from seed cotton.

It consists of a 36″ top-flat self-stripping card; the attachment (which is a diminutive gin 18 × 18 × 36″), is substituted for the licker-in and feed rollers of the card; its saws are 7″ in diameter, with fourteen teeth to the inch, and revolve from 100 to 200 times per minute. The brush connected with the saws is a cylinder covered with bristles; its periphery revolves a little faster than the saws, and has also a traverse or horizontal motion. The periphery of the card travels a little faster than the brush; a feed table is placed above the card and connected with the attachment by a chute, and gives a regular supply of seed cotton to the attachment. A stop-motion is used to save waste in case of accident. These, with a small drawing roller between the doffer and calender rollers, to reduce the sliver to the ordinary working size, and a cam motion to receive said sliver, are all the changes and additions made to the card.

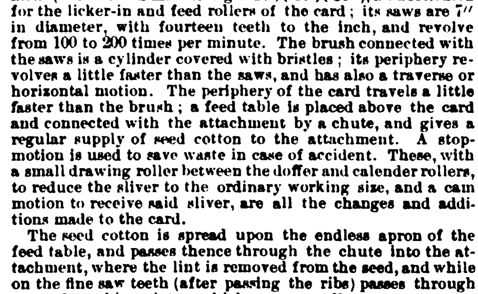
The seed cotton is spread upon the endless apron of the feed table, and passes thence through the chute into the attachment, where the lint is removed from the seed, and while on the fine saw teeth (after passing the ribs) passes through a set of combing plates, which removes all extraneous matter, and delivers the filaments to the brush, which delivers them to the card, and thence through the doffer, small drawing and calender rollers; being delivered as perfect sliver into a revolving can.

Cot'ton Stalk Pul'ler. A machine for pulling out of the ground the old cotton stalks preparatory to chopping or making into windrows and burning.

Brown . * "*Scientific American*," xxxiv. 358; * xxxvii. 230.

Cot'ton Sweep. (*Agric.*) A form of plow used in cultivating the balk between cotton rows: also used in corn cultivation.

Fig. 705.



Cotton Sweep.

Cot'ton-tie Fast'en-er. An apparatus to draw together the ends of cotton-bale ties, in order that they may be riveted or buckled: generally the latter, though the buckle is really but a square loop, around which the ends are bent. See BALE TIE, Fig. 540, p. 218, "*Mech. Dict.*," where 30 kinds are illustrated.

Fig. 706.

Cotton-tie Fastener.

The *Greenleaf* cotton-tie fastener is a clamp, the two members holding each a tie and approached by means of a crank pinion and rack.

Cot'ton Truck. A two-wheeled truck, the sides ending in flat points instead of the usual loop.

Cot'ton Worm De-stroy'er. Apparatus for destroying the cotton worm. There are numerous forms: some adapted for rose, potato, vine, and melon bugs.

Comstock's "*Report upon the Cotton Worm*," U. S. Agric. Depart., 1879, gives varied information on this subject and shows the following apparatus: —

Couch'ing Nee'dle. (*Surgical.*) An instrument for depressing the opaque lens in cataract.

See Needles, Spuds, Spatulas, Curettes, etc., p. 27, Part II., *Tiemann's* "*Armamentarium Chirurgicum.*"

Cou-lomb'. (*Electricity.*) A term for a unit in electricity. It was suggested at the Electrical Congress in Paris, 1881, that the name *coulomb* shall be given to the quantity of electricity defined by the condition that an *ampère* gives one *coulomb* per second. At latest advices the matter of nomenclature of units is yet unsettled.

Coun'ter-bal'ance Crane. One having a load on its frame opposite to the jib to partially counterbalance the object lifted and remove strain from the pintle, or prevent oversetting in the case of movable cranes; *j*, Fig. 1507, p. 643, "*Mech. Dict.*," is an instance. See also LOCOMOTIVE CRANE. See also BALANCE CRANE, Fig. 176, p. 66, *supra*.

Coun'ter-bore. A cylindrical counter-sink, usually made with a pin-drill.

Coun'ter Brace. A member in a frame which transmits strains in an opposite direction to a main-brace.

Coun'ter Cock. A faucet upon a counter for drawing beverages. See Fig. 707.

Coun'ter Gear. Driving gear, for lathes, for instance, attached to a ceiling or post, and connecting by band with the machine or machine-tool to be driven.

"*Engineer*" . . . . * xlii. 258.
"*Scientific American*" . . . . . . * xxxv. 342.

Coun'ter Pump. A pump beneath a counter for drawing liquids from barrels in a cellar beneath. See Fig. 708.

Coun'ter-sink. 1. (*Fire-arms.*) The recess in the rear of the chamber in which the rim of the cartridge fits.

2. (*Blacksmithing.*) A tool with a conical point to punch a tapering enlargement to a hole to receive the head of a screw.

Fig. 707.

Counter Cock.

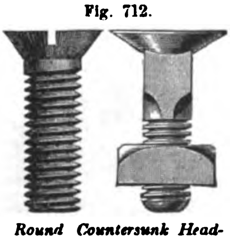
A countersunk head-bolt is one the head of which is buried in a depression in the object so as to be flush with its surface and not project.

Fig. 712.



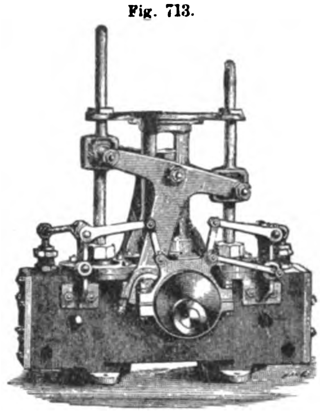
Round Countersunk Head-screw.
Square shank Countersunk Head-bolt.

Coup'led Steam En'gine. An arrangement in which two steam engines act in concert upon a single object; the term is more particularly applied, perhaps, to twin engines. The term *coupled* is perhaps a little astray in characterizing a grouping of a larger number, but the three-cylinder engine of Brotherhood, or the six-cylinder engine of West are *coupled*, in one permissible application of the word, *i. e.*, connected. This obtains in the *organ coupler*, which connects *two or more* of the ranks of keys.

The instance adduced, however, refers to a *pair* only in the twin cylinder engine of Bernays, of London, in which the crank is rotated by the intervention of a triangular connecting rod, made practicable by an ingenious arrangement of eccentric and valve-gear.

The two upright double-acting cylinders are placed with sufficient space between them to receive the crank-shaft. The pistons are connected to one crank by means of a triangular connecting-rod, which causes them to move as if connected to two cranks at right angles to each other. The steam distribution in the two cylinders is governed by one ordinary eccentric and its connections, in a manner analagous to that by which the main crank governs the motions of the two pistons. Two eyes are provided on the eccentric-ring, carrying rods or levers, through which the valves are acted upon. The position of, and distance between, these eyes bear the same relation to the throw of the eccentric as the measurements of the main connecting-rod bear to the throw of the crank, reproducing on a smaller scale the triangular connection between the crank and the two piston-rods in the eccentric and valve-rods, and the steam is correctly distributed. The eccentric is loose on the shaft and is thrown to the right or left for the purpose of reversing the engine. The position of the crank-shaft in relation to the cylinders may be varied in height to suit any required purpose.

Fig. 713.



Coupled Steam Engine.

In this engine there is no dead point, for the reason that the two pistons can never be at the ends of their respective strokes at the same time, since they reach their limit of movement when the crank-pin passes a point in line closest to the pin of the triangle to which either engine-piston attaches.

"*Iron Age*" . . . . . . * xxiv., July 10, p. 1.

Sweeney's Report, "*Paris Exposition* (1878) *Reports*," * iv. 882.

Coup'let. Two united, acting together, as of two elliptic springs, side by side, acting as a single spring. Coupled springs are shown on p. 483, "*Mech. Dict.*"

Triplet, *quadruplet*, etc., express still multiplied combinations of the same order.

Coup'ling. See under various heads, COMPRESSION COUPLING; CAR COUPLING; CLUTCH, etc. See list on pp. 638, 639, "*Mech. Dict.*"

Locomotive coupling rods, *Rose*, * "*Sc. Am. Sup.*," 490.
Safety coupling chain . . . * *R. R. Gaz.*," xxiv. 428.

Coup'ling Valve. (*Railway.*) A valve contained in the case of the hose-coupling of an air-brake arrangement. See BRAKE-HOSE COUPLING VALVE.

Cou'pon Tick'et Ma-chine'. Hoe's modification of the cylinder press for this purpose prints railway coupon tickets at the rate of 1,200 per hour. The paper, laid by the operator sheet by sheet upon the feed table, is delivered automatically to the cylinder, printed, numbered, perforated, brought back and laid down printed side up upon the rack under the eye of the attendant. The form and numbering wheels are on the same bed, and receive their ink from the same rollers. The impression cylinder gears into the bed, turning forward and backward with it, and, instead of fingers, has cords that run around in the spaces between the coupons. A numbering plate is arranged for each different spacing of coupons, so that no time is lost in adjusting the wheels.

Cou'pon Num'ber-ing Ma-chine'.

The French machine, for numbering coupons, checks, lottery tickets, stock-books, etc., is made by Pierron et Dehaitre, of Paris. It is worked by a pedal, and advances the sheet of paper at each stroke of the pedal a regulatable distance.

Cou-ronne' de Tasses. (*Electricity.*) The first cell battery. Invented by Volta, the author of the first pile, which the *Couronne* is said to have preceded. (*Niaudet.*) It consists of a series of glass cups placed in a circle, and each containing a zinc and a copper element, connected to the adjoining one of opposite polarity in the next cup.

Court Plas'ter.

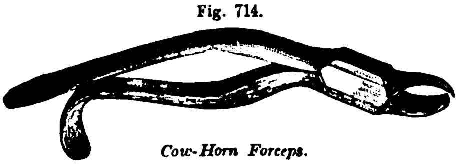
Soak isinglass in a little warm water for 74 hours; evaporate nearly all the water by gentle heat, dissolve the residue in a little proof spirits of wine, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cool. Stretch a piece of silk or sarsnet on a wooden frame, and fix it tight with tacks or packthread. Melt the jelly, and apply it to the silk thinly and evenly, with a badger-hair brush. A second coating must be applied when the first has dried. When both are dry, apply over the whole surface two or three coatings of balsam of Peru.

"*Scientific American*" . . . . . xl. 182; xlii. 105.

Cov'ered Sight. (*Fire-arms.*) One having the sight inclosed in a ring or tube. See BAR AND BEAD SIGHT; BEACH COMBINATION SIGHT; GLOBE SIGHT, etc.

Cove Plane. A molding plane, making a quarter round or scotia. See *j*, Fig. 3194, p. 1465, "*Mech. Dict.*"

Fig. 714.

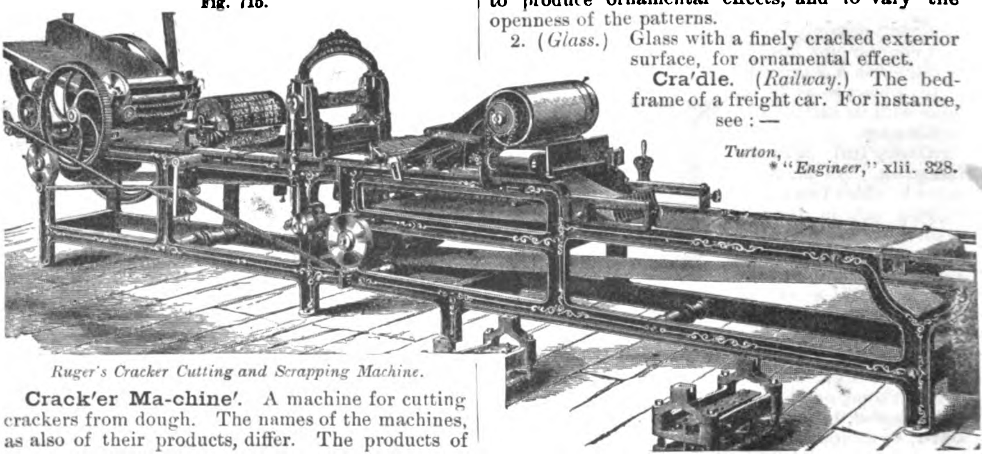


Cow-Horn Forceps.

Cow'-Horn For'ceps. (*Dentistry.*) Forceps for the extraction of molar roots when the crowns are decayed below the process.

They are made in pairs, right and left, for upper and for lower jaw.

Fig. 715.



Ruger's Cracker Cutting and Scrapping Machine.

Crack'er Ma-chine'. A machine for cutting crackers from dough. The names of the machines, as also of their products, differ. The products of the machines are usually known as crackers in this country, while they are called biscuit (*bis cuit*) in Europe. Lately, in this country, products called by the names oyster, butter, soda, milk, are known as crackers; while sweet goods, such as lemon, sugar, cream, tea, albert, etc., are called biscuits.

The machines, besides the generic names of biscuit or cracker machines, are known as *cutting machines* when they simply cut out the crackers from the blanket of dough, and *cutting and scrapping machines* when they automatically remove the scraps of dough from between the crackers. A *short cutting machine* is one with a short apron beyond the cutter, and may be a *two-peel machine* as holding on that portion of its apron, the *peel-end* of the machine, but two-peel lengths of crackers. A *three-peel machine* has an apron of one half greater length beyond the cutter.

The complete cracker machine rolls and dusts the dough, cuts into crackers, biscuits, cakes, and snaps, separates the cracker from the scraps, and places the work on pans.

The process of cracker-making by machinery is as follows: In the first place, the flour is run through a sifter, then put into troughs, where all the ingredients are mixed in by hand and left to stand until the chemical process is completed. The material is then run through the dough mixer, and from thence several times through the dough brake. It is piled up on a table, covered with cloth, and left to stand until it is properly proved, or gets light, then run again through the brake several times, being doubled over each time, and finally rolled out in a long strip the proper width for the machine. It is then placed on the hopper board of the machine, and goes through the rollers, where it is reduced to the proper thickness, falls on the apron or carrier, passes under a revolving brush, then to the cutter, which is changed to cut different shapes. After the crackers or biscuits are cut, the sheet of cut dough passes to the fingers and scrap apron, where the scrap is run over the upper apron, and the crackers pass below and drop into pans placed on the lower or third apron, and the pans are then placed in the oven and baked, which requires from 7 to 15 minutes, according to the kind of goods being baked. The largest set of machinery and oven will bake from 50 to 70 barrels of flour into crackers in ten hours.

See also Prof. *Horsford's* "*Report on Vienna Bread*," "*Vienna Exposition Reports*," vol. ii., § B.

Crack'ing Ma-chine'. (*Milling.*) A machine for fine-lining the surface of a millstone. The scores increase the grinding efficiency. See MILLSTONE DRESSING MACHINE.

Crack'le Ware. 1. (*Ceramics.*) Fr. *craquelle.* Ware, the enamel of which has a multitude of fine cracks, making a sort of reticulated surface. The art is Chinese; but as an actual effect, though not designedly so, many wares overbaked have a cracked glaze. The Chinese had the art of giving the crackle to definite portions of the surface, so as to produce ornamental effects, and to vary the openness of the patterns.

2. (*Glass.*) Glass with a finely cracked exterior surface, for ornamental effect.

Cra'dle. (*Railway.*) The bed-frame of a freight car. For instance, see: —

Turton, * "*Engineer*," xlii. 328.

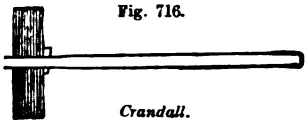
2. The infant's rocking crib.

Automatic, *Vandevort* . * "*Scientific American*," xxxiv. 99.
Attachment for bedsteads.
Robertson . . . . . * "*Scientific American*," xxxvi. 230.

3. (*Mining.*) A suspended scaffolding used in shafts.

Cran'dall. (*Stone Working.*) A hammer made up of a gang of pointed steel bars occupying a slot 3″ × ⅜″ in the head of the bar. There are 10 bars in the gang, pointed at each end, ¼″ square, and held by a key. Used for putting a certain kind of dressing on ashlar. See list of tools under Stone Working.

Fig. 716.



Crandall.

Cran'daled Stone Work. (*Stone Cutting.*) An ashlar dressed by dotting its surface with rows of points, made with a *crandall.* When other rows at right angles to the first are introduced the stone is said to be *cross crandaled.*

Crane. A lifting apparatus with a neck or jib from a planted post. The points which distinguish the crane, derrick, winch, sheers, whin, gin, etc., respectively, are given on p. 63 and elsewhere, and a list occurs on pp. 1110, 1111, "*Mech. Dict.*"

The cranes for handling the steel ingots at the Krupp works are shown in Fig. 41, Appendix L, "*Ordnance Report,*" 1877.

Austrian hydraulic cranes for handling heavy guns. *Ibid.*, Fig. 35.

The new crane of Woolwich, England, which has occupied four years in construction, exceeds 1800 tons in weight, and is capable of lifting 1200 tons.

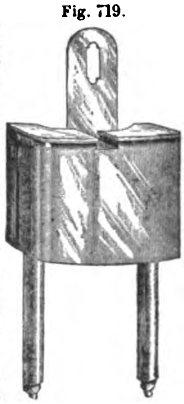
Crank and Fly'wheel Steam Pump. A form of steam pump, as distinct from the *direct acting.*

A crank shaft and rods is interposed between the steam cylinder and pump cylinder.

Crank'-pin Cup. A lubricator for the crank of an engine. The instance in Fig. 719 is one for a propeller. The great and constant strain renders special provision necessary; as it was aforetime with the paddle-wheel shafts, which lifted at each revolution a quantity of oil and poured it on the journal.

Fig. 719.



Crank-pin Cup for Propeller Engine.

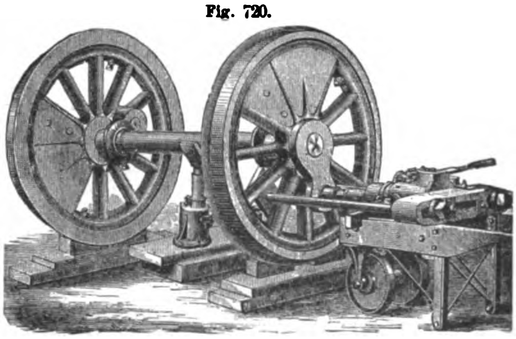
Crank'-pin Jack. An application of the hydraulic press to the pressing on or off of the crank pins of locomotives. The press is supported on a barrow, and is shown as supported by tie bars from the wheel in the act of pressing in a crank-pin. "*Railroad Gazette*" . . * xxi. 550.

Crank'-pin Turn'er. A machine for turning crank-pins in position, and while the wheels are under the engine.

It is fastened by means of scroll and self-centering jaws at one end, to the collar of the crank pin, upon which there is no wear. It is then clamped in position by bolts passing through the spokes of the driver. The tail-stock center is then run up, and if the pin is not bent will fit in the old center, and the machine is ready to operate. The cutter is driven and fed either way by the crank and intermediate gearing which gives motion to the screw. The cutter is bent and fastened by a set screw in the extreme end of the cutter bar.

"*Iron Age*," . . . . * xx., Nov. 29, p. 1.
"*Mining & Scientific Press*" . . . . * xxxvi. 278.

Fig. 720.



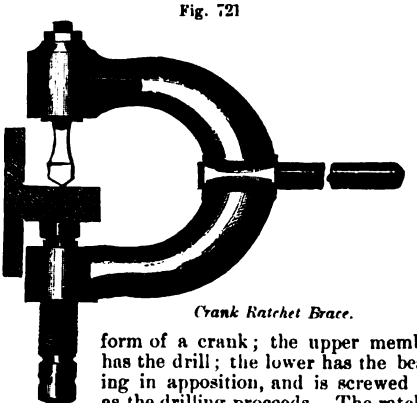
Dudgeon's Crank-pin Jack.

Crank Pla'ner. A metal-planing machine, in which the tool stock is moved on ways above the bed by pitman attachment to a wrist on a crank wheel.

A special machine, for planing cranks, having a short and rapid or variable stroke, is made by Hull & Belden. It has the usual horizontal bed on track; 12″ at full stroke, and Whitworth quick return motion. Cross and angular, or cross and down feed, as desired. The screw runs the length of the bed, enabling the operator to change position of stroke.

Crank Ratch'et Brace. A ratchet brace in

Fig. 721



Crank Ratchet Brace.

form of a crank; the upper member has the drill; the lower has the bearing in apposition, and is screwed up as the drilling proceeds. The ratchet is in the upper head, so that the drill moves only during the effective stroke. See RATCHET BRACE.

Crate Hasp. Hinged hasp and staple for securing the lids of boxes and crates.

Fig. 722.

Crate Hinge.

Cray'on Cut'ter. For pointing crayons: two circular rasps on a lathe arbor set obliquely so that their interval gives the required chamfer to the crayon point. The *chamfering machine* for wood, though on a very much larger scale, may give an idea of the apposition of the rasps.

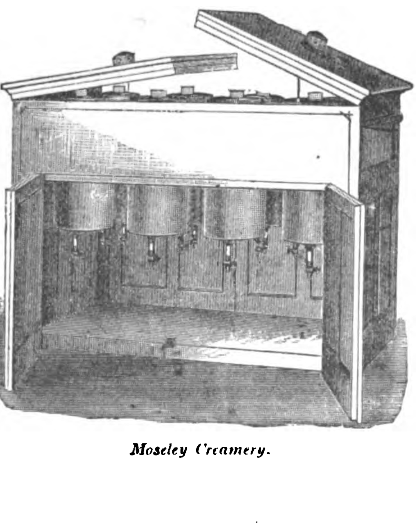
Cray'on Mold. A hinged mold in two parts, each containing a series of semi-circular depressions, the corresponding parts of each, when the mold is closed, form cylinders, in which the crayon material is molded.

Cream'e-ry. An apparatus or closet, with facilities for cooling or heating, in which to place milk jars under favorable conditions for cream-raising.

The *Ferguson* bureau creamery is a large press with shelves for cream, inclosing doors, and with a cupboard above for ice, and one below for the heater which is used in winter. U. S. Patent, August 22, 1876.

The *Moseley* creamery has deep cans suspended in a closet, and with means for drawing off the milk beneath, in lieu of skimming the cream.

Fig. 723.



Moseley Creamery.

The *Scoville* creamery has a wooden box designed to be set in the ground, and has pipes for entry and discharge of spring water. The deep tin pails have cream gages in inches at the sides.

Fig. 724.

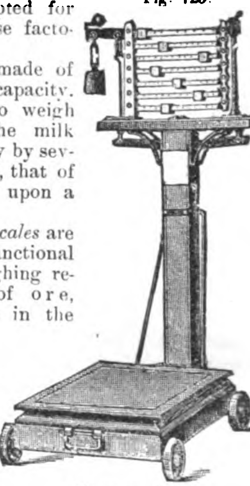
Scovill Creamery	* "*American Inventor*," iv. 173
Cream raiser, *Plumb* . . .	* "*Sc. American*," xli. 7.
Weldon	* "*Sc. American*," xl. 184.

Cream Ware. (*Ceramics.*) *a.* A name given by Wedgwood to a fine, light, yellow paste, invented by him in 1762. He also called it *queensware*,—a compliment to Queen Charlotte.

b. The ordinary *queensware* of the present is *stone ware.*

Cream'e-ry Scale. A scale with several beams, each having a sliding poise, specially adapted for creameries and cheese factories.

Fig. 725.



Creamery Scale.

Such scales are made of from 600 to 1,000 lbs. capacity, and are intended to weigh at a single draft the milk brought to the factory by several different persons, that of each being weighed upon a separate beam.

Furnace charging scales are made with the same functional arrangement for weighing respective quantities of ore, coke, and limestone in the same charge.

Creep'er. A spiral inside a revolving cylindrical grain screen to pass the grain towards the discharge end. A conveyor or a spiral on the inner surface.

Cre-ma'ting Car. One for burning bodies *in transitu* to the Columbaria, disposing of the corpse *en route. Decrescit eundo.* *Kuborn & Jacques.*

Furnace	"*Sc. Amer. Sup.*," 247.
Temple	* "*Sc. Amer.*," xxxvi. 49.

Moist system	* "*Technologiste*," xli. 508.

Cre-mom'e-ter. A specific gravity instrument of the hydrometer form, invented by Chevalier. The scale shows percentages in mixtures of water and pure milk.

Cre'o-so-ting Ap'pa-ra'tus. Apparatus for saturating timber with a solution, to prevent decay.

Bethel's English Patent, 1838.

The works of E. R. Andrews, South Boston, Mass., under Hayford's patent method of creosoting timber, are shown in "*Railroad Gazette*" . . . . * xxiv. 267.

See also cut 7337, p. 2811, "*Mech. Dict.*"

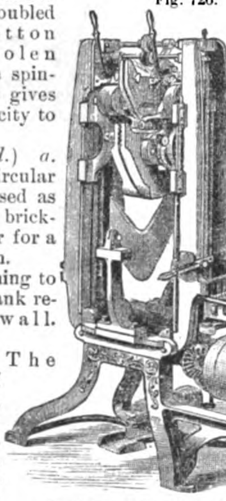
"*Iron Age*," . . . . xx., Dec. 27, p. 7.

See "*Treatise on Dry Rot in Timber*," by T. A. Britton, Spon.

Crest'ing. The ornaments or finials on the summits of iron posts, or along the rails of an iron fence, a balustrade, or on the crest of a roof.

Cre-tonne'. (*Fabric.*) A French dress goods woven on a taffeta loom: it has a doubled and twisted cotton warp, and a woolen weft. The close spinning of the warp gives a peculiar elasticity to the goods.

Fig. 726.



Jamison's Crimping Machine.

Crib. (*Add.*) *a.* (*Mining.*) A circular frame of wood, used as a foundation for bricking in a shaft, or for a pneumatic caisson.

b. A timber lining to a shaft, or the plank revetment of a wall. *Cribbing.*

c. (*Fishing.*) The bowl or pound of a POUND NET, which see.

Crib Break'-wa-ter. One made of logs or timbers notched into each other in the manner of a log house. See instance in Breakwater at Michigan City, Ind.

"*Report of Chief of Engineers, U. S. Army*," 1879, * ii., page 1588.

Crib Dam. One made log-house fashion, supporting a bank of earth which holds the water.

See plans and sections of a dam at New Harmony Cut-off, on the Wabash River. "*Report of Chief of Engineers, U. S. Army*," 1879, * ii., 1440.

Kanawha River, *Ibid.*, 1878, * ii. 467.

Rock Island, Ill. "*Report of Chief of Ordnance, U. S. A.*," 1877, * 354, and Plate XII.

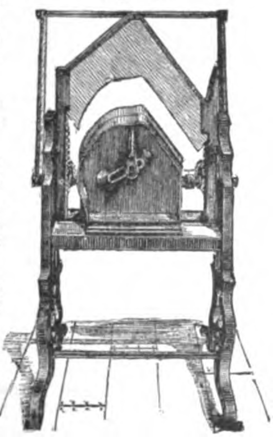
Fig. 727.



Makepeace Crimp Brake.

Crib Muz'zle. (*Manége.*) A muzzle used to correct the equine habit of cribbing.

Crimp Brake. See CRIMPING MACHINE.

Crimp'ing Ma-chine'. 1. (*Sheet Metal Working.*) A machine for crimping the tops and bottoms on can bodies.

2. A machine for crimping the ends of stationary blind slats. An effective machine swages the ends of 150 slats per minute.

3. A machine for crimping uppers of boots and bootees. The piece of leather is forced over a curve-edged board to give it shape.

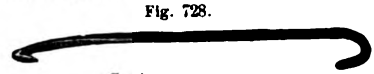
The *Jamison* machine, Fig. 726, has a pair of descending cheeks which slip over the sharp edge of the bent former, crowding the leather over the latter and pressing it at all points, to prevent wrinkles, and to produce regular thickness. It is driven by power.

The *Makepeace* machine, Fig. 727, is driven by hand, and the action is the reverse of the other machine, the bent former descending and crowding the leather into the slit between the two cheeks, which press forcibly against it and smooth out all wrinkles.

The French *cambreuse*, of *Pilon*, Mans, France, operates in yet another way, the jaws ascending to press the leather over the suspended and rigid former. It is specially intended for making upper and back in one piece, and joining at the back (*bottes d'officier, dites "jointure derrière"*).

Croch'et. (*Surgical.*) An obstetric hook for withdrawing the fetus.

Fig. 728.



Crochet, or Blunt Hook.

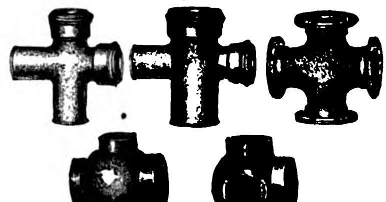
Crooke's Mill. Another name for the radiometer of Professor Crooke. See RADIOMETER.

"*Manufacturer and Builder*" . . . * ix. 229, 241.

Crop'per. A powerful hand machine for shearing off bolts or rod iron. It has holes of varying diameters for different sizes of iron, and the shears operates by a long lever.

Cross. A quadrangular pipe coupling.

Fig. 729.



Pipe Crosses.

a. Cross; two bell ends. *b.* Reducing cross; two bell ends. *c.* Four-flanged cross. *d.* Reducing globe cross. *e.* Corner-fitting globe cross.

Cross'-bar. (*Fire-arms.*) The small bar in a break-joint breech-loader, which, when the barrels are falling, presses out the extractor.

Cross'cut Saw. *Hand.* Crosscut saws are one or two-handled, see p. 649, "*Mech. Dict.*"

Power. The cross-cutting sawing machine, for the woods, is usually a *drag* saw, of which one instance is given in Fig. 1522, p. 649, "*Mech. Dict.*"

Cross-cutting machines for the factory are described under CUTTING-OFF SAW, which see.

See also BRACKET CUTTING-OFF SAW.

Cross File. One having curved faces unequally convex.

Cross-gain'ing Ma-chine'. A machine for cutting gains or slots in timbers crosswise of the grain or stuff. See Fig. 2144, p. 935, "*Mech. Dict.*"

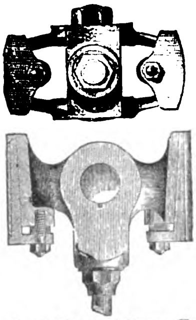
Cross Head. 1. The cross-bar on the end of a connecting-rod or piston, having gibs on each side to fit the slides.

In the instance given, the cross-head has adjustable gibs on each side, turned to fit the slides, which are cast solidly in the frame, and bored out exactly in line with the cylinder. This permits it to freely turn on its axis, and in connection with the adjustable boxes in the connecting-rod, allows a perfect self-adjustment to the line of the crank-pin. Fig. 730.

2. (*a.*) A cruciform-shaped four-handled bar, at the upper end of a drill-rod or earth-auger, and by which the latter is turned; used for drilling or sounding wells or shafts. Fig. 731.

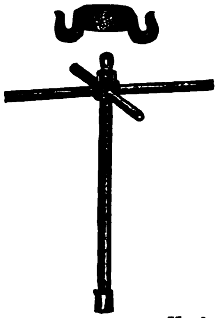
(*b.*) A sleeve with hooks for the suspension tackle of a well-drill. Fig. 731.

Fig 730.



Cross Head of Steam Engine.

Fig. 731.



Well Drilling Cross Heads.

Cross-head, locomotive, *Alexander.* * "*Sc. Am.*," xxxv. 246.

Cross-peen' Ham'mer. One the *peen* of which is crosswise of the direction of the handle.

Cross Rais'ing Ma-chine'. A machine for cross raising the nap of cloth.

Fig. 732.

Cross-peen Hammer.

In cotton machinery a machine for this purpose carries bands of cards by a circular motion in one direction over the face of the cloth.

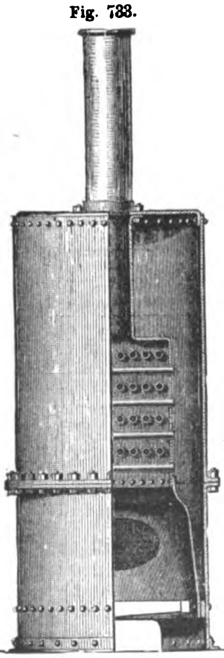
In Delamare & Chandelier's machine (Rouen, France), the cloth is carried by and is stretched across a pair of rollers; over the suspended part of the cloth, rollers covered with metallic cards revolve in a direction at right angles to that of the traverse of the fabric; these rollers have at the same time a to-and-fro motion across the piece, so as to insure their action upon the whole width of the piece.

"*Bulletin of the Industrial Society of Rouen*," reported in the "*Textile Manufacturer*" and "*Scientific American Sup.*," * 2581.

Cross Tube Boil'er. In the usual vertical form, this boiler has one or more horizontal cross tubes, 6″ to 8″ in diameter, placed across the fire-box. See VERTICAL BOILER. The water circulates in these while the heated gases pass around them, and are then conducted by a straight flue to the chimney.

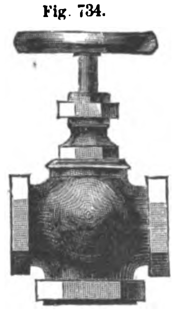
Fig. 738 is another form in which the tubes are smaller and more numerous. The upper and lower portions of the shell are connected by flanged joints bolted together, and the uptake is secured to the crown-plate in a similar manner. The lower part of the fire-box is circular, but above the fire-door it is worked into a square form to receive a square upper box, into which are fitted a number of parallel tubes of such diameter as may be most suitable for the size of boiler and the heating surface required. These traverse horizontally the flame space, the volatile products passing upward among the tubes and escaping by the vertical central flue. The tubes connect the water-space which forms a jacket around the fire-box and flue.

Fig. 733.



Appleby's Cross Tube Boiler. (*British.*)

Fig. 734.



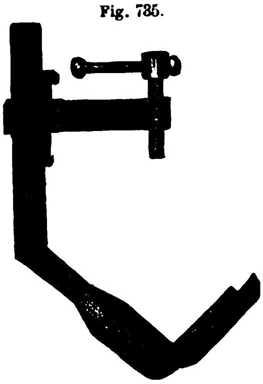
Cross Valve.

Cross Valve. A valve at the crossing or rectangular divarication of a pipe. Fig. 734.

Croup Ket'tle. (*Surgical.*) A small kettle and alcohol lamp for quickly raising a steam for inhalation in cases of croup.

Crow. An implement for gripping beneath a main and holding a tapping-brace above it, when tapping street mains.

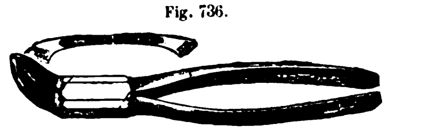
Fig. 735.



Crow.

Crowd'ed-teeth For'ceps. (*Dentistry.*) A narrow-beaked full-curved forceps for removing superfluous teeth which mar the symmetry of the row.

Fig. 736.



Crowded Teeth Forceps.

Crown Arch. An arched plate over a furnace supporting the crown sheet.

Darby's crown-arch for locomotive fire-boxes replaces the ordinary crown bars by an arched plate, 5-16″ thick, with a rise in the center of 6½″. This is riveted at each end of the crown sheet and then stayed in the ordinary way between the ends, with 7-8″ bolts spaced 4½″ from center to center. Angle iron is riveted to the top, to which suitable sling stays are attached.

"*Railroad Gazette*" . . . . * xxii. 356.

Crown Bar. (*Locomotive.*) One of the bars supporting the crown sheet of a boiler.

Crown Poun'cing Ma-chine'. (*Hat Making.*) A machine for pouncing the crowns of hats. The name is derived from pounce or fine sand, and the operation consists in sand-papering the surface of the hat body, or the hat after it has been blocked. See POUNCING MACHINE.

Crown Tel'e-phone. An instrument consisting of two magneto-electric crown telephones united. Each of these consists of a coil, diaphragm of iron, and six permanent magnets, which latter are placed with their like poles together in the center of the coil, the other poles being bent round, into contact with the periphery of the diaphragm. Thus the diaphragm forms the other pole to that within the coil, and in this way the magnetic field is intensified. In the double-crown form the two diaphragms are separated by an air-chamber, with a mouth-piece or orifice, into which a person speaks. The coils are so connected in circuit that the vocal currents generated in each coil strengthen one another. — *Phelps.*

"*Telegraphic Journal,*" vi. 399. See also *Hinkley's, Ibid.,* * vi. 476.

Crown Tre-phine'. (*Surgical.*) A crown saw used in removing sections of the cranium. *b*, Fig. 6647, p. 2624, "*Mech. Dict.*"

Cro'zing Ma-chine'. A machine for making the grooves in casks to receive the edges of the heads.

The work when done by machinery is usually combined with chamfering and howeling and sometimes with leveling.

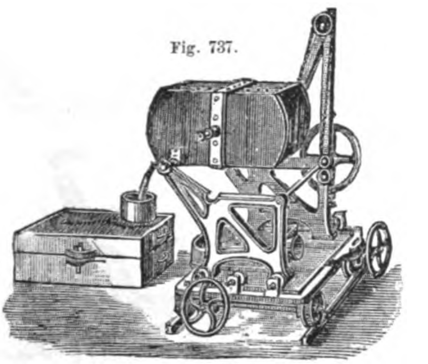
See BARREL CROZING MACHINE; CHAMFERING MACHINE; see list under BARREL MACHINERY.

"*Manufacturer & Builder*,"	* xi. 55.
Steel & Munson's machine	Patent Nos. 160, 966.

Cru'ci-ble Fur'nace. One of the most notable departures in crucible furnaces is that of M. Piat, of Paris, in which the crucible and furnace are moved together to the place where the casting is to be made.

The crucible is fixed within the furnace wall, the weight of both coming upon trunnions when they are lifted from the

Fig. 737.

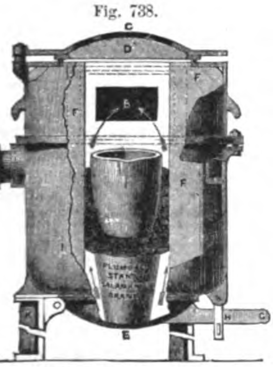


Piat's Crucible Furnace on Movable Carriage.

lower furnace wall. The space between the crucible and the refractory lining of the furnace wall is filled with combustible, the ashes from which fall through holes in the furnace into the ash-pit when the crucible is over the draft. It is moved on a car or by crane to the place of casting, and tipped on its trunnions to pour the metal.

Fletcher's annular hot-air furnace for melting metals has no fire-bars, but a dished bottom secured by a lever. The draft from the fan is admitted at *A*, and courses through the ducts around the fire-clay lining *F*. The crucible stands on a fire-clay pillar and is surrounded by fuel, the gaseous products escape at *B*. *C* is the hinged cover or lid with fire-clay lining *D*. *E* is the hinged bottom with lever *G* and detent *H*. *I* is the outer case or lining, *K* the legs of the stand.

Fig. 738.



Hot-air Crucible Furnace.

The French *calebasse*, a form of crucible used in Europe in melting quantities of iron below the usual duty of a cupola, is shown in *Laboulaye's* "*Dictionnaire*," etc., i., Figs. 355–357, ed. 1877, article "*Calebasse*."

Crush'er Gage. A registering instrument exposed in the bore of a gun to measure the pressure developed by the explosion of a charge. See PIEZOMETER; CUTTER.

To illustrate: a 16-ton steel gun of Vavasseur, fired at Woolwich, had a projectile of 400 pounds, 70 pounds of pebble powder made up into a cartridge 25″ long. The charge being fired at the center, the crusher gage at the rear of the charge showed a pressure of 21 tons to the square inch, the gage at the base of the shot, 18 tons; initial velocity of the shot 1412′ per second. The charge fired at the base, the gage gave pressures of 45.1 and 50.1 tons respectively at the rear of the charge and base of the shot.

Cry'o-lite. Greek *kryos*, "ice," *lithos*, "stone," from its beautiful snowy appearance. This mineral is a double fluoride of sodium and aluminium, and has long been known in cabinets, and to chemists, but has but lately assumed commercial importance.

It has been found at Miask, in the Ural Mountains, in limited amounts, but its great source is the west coast of Greenland, where it is procured in immense quantities at Ivigtout, on Arsuk Fiord, between Julian's Hope and Frederick's. The main deposit here forms a mass, according to reliable authority, 600′ in length, and 200′ in width, and descending to an unknown depth.

The mineral occurs in partially translucent masses of a snowy white color, having very much the appearance of snow ice, whence its name. It is frequently associated with galena, blende, iron and copper pyrites, and spathic iron ore.

In 1850, Julius Thomsen, a Danish chemist, discovered a cheap method of rendering cryolite available for the manufacture of soda and alum.

The employment of Greenland cryolite in the manufacture of aluminium is attributed to Rose, of Berlin. It is also used in the later Deville aluminium process. See ALUMINIUM.

Cryolite is largely used by the Pennsylvania Salt Manufacturing Company at Natrona, Penn., and a number of cryolite products are there made.

It has been used also in making what has been variously called "cryolite glass," or "hard porcelain," a vitreous semi-translucent material, well fitted for some purposes. The proportions used are about, cryolite 1, sand 3; the resulting glass is easily molded and cut, and is noted for its tenacity. See CAST PORCELAIN.

For the milky variety a mixture is employed consisting of the following materials: One part of oxide of zinc, four parts of cryolite, and ten parts of sand, fused in a common pipe-clay crucible, developing a large amount of fluosilicic acid. The pipe-clay is, however, not much attacked by it. This development continues throughout the fusion, and even after it, during the working, to a small extent.

"The utilization of cryolite depends upon Thomsen's observation, that the mineral may be completely decomposed by treatment with lime, either in the wet or dry way, the products of this treatment being, generally speaking, caustic soda, aluminate of sodium, and fluoride of calcium. The ease with which this decomposition can be effected, and the notable percentage (35 per cent.) of soda which the mineral thus yields, renders it a very valuable commercial source of soda and its compounds. The alumina which it contains is used for the production of alum salts.

"Where the dry process is employed, the cryolite is dried, ground to a fine powder, and mixed with slaked lime, or with pulverized chalk, in such proportions that for each equivalent of cryolite there shall be about six of lime. This mixture is then calcined in a furnace at a dull red heat, — not sufficient, however, to fuse it. After a charge has cooled, it is lixiviated, and the dissolved soda and aluminate of soda drawn off from the insoluble residue (fluoride of calcium). By passing carbonic acid gas (obtained from the combustion of coke) through this solution, the soda is converted into the carbonate, and the alumina is precipitated.

"In the wet process, the cryolite is boiled with milk of lime; and according to the proportions of lime employed, the resultant products are caustic soda and aluminate of sodium, or, where the proportion of lime is greater, caustic soda and aluminate of lime, fluoride of calcium being formed of course in both cases. The latter process gives all the soda of the cryolite in the caustic state, the only operation required being evaporation to dryness.

"The aluminate of sodium produced in the operation above described is used in the manufacture of soaps, in place of soda and potash lye. It is completely decomposed by passing carbonic acid gas through it, and the resulting alumina which is precipitated is converted into sulphate of aluminium and alum. The fluoride of calcium, which is a by-product of the treatment of cryolite, is used as a flux in the reduction of gold, iron, and other metals." — *Polytechnic Review.*

Cryp'to-graph. An apparatus designed for secret correspondence.

A metallic plate is perforated with holes.

A tablet is marked off with squares. A plate of the same size and rulings is perforated at a number of the squares in an irregular manner. The plate being laid on the tablet, the message is written, the letters in the consecutive holes as they may run in the line and succeeding lines. The plate is then rotated one quarter round and the message continued, so on for the other two positions of the plate. The result is a confused lot of letters with breaks of continuity. It may be read by a similarly perforated plate laid on the paper, and moved successively as by the writer.

Crys'tal. (*Glass.*) Another name for *flint glass*; a silicate with a base (usually) of lead and potash; but the Bohemian has a base of lime and potash.

Cube Pow'der. Large grained gunpowder for slow burning in large charges in heavy ordnance. *Prismatic powder.*

"*Engineer*" . . . Sept. 16, 1870; March 17, 1876, p. 185.

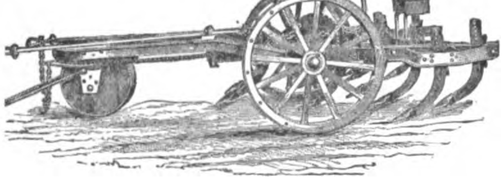
Cuff Frame. A knitting machine specially constructed for knitting cuffs for cardigan jackets and underwear Campbell & Clute.

Cul'ti-va'tor. Fig. 739 is the turning cultiva-

Fig. 739.



Steam Turning Cultivator. (*Fowler & Co., Leeds, England.*)

tor, adapted to be worked by all systems of steam-plow machinery. It may carry from 5 to 13 tines, and rests on 3 wheels, one of which is the steering-wheel. The axle of the two hind-wheels is cranked, so that by its being turned the frame is raised or lowered, and by this means the penetration of the tines adjusted.

The long end of a draft bar or turning lever is provided with two arms to which the two ends of the rope are attached. The arms are set at an angle for keeping the tail rope clear of the implement. The lever itself is held by a vertical stud fixed to the frame considerably behind the steering-wheel. This position of the draft-stud gives the necessary liberty and power to the steering-wheel and enables it to lead the implement at almost any angle out of the line of the pulling-rope.

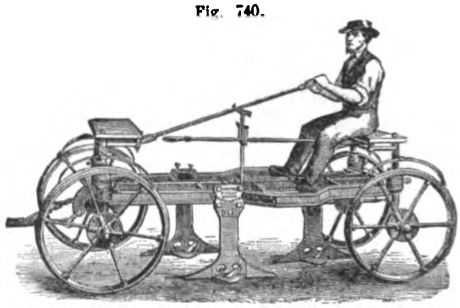
On the short end of the turning-lever is a chain communicating with a quadrant on the crank-axle, and as the lever is pulled round, the chain, acting on the quadrant, turns the axle, lifts the frame, and raises the tines out of the ground.

The plan of operation is as follows: As soon as the cultivator is brought up to the headland, the reverse pull brings the lever around, turns the quadrant, rotates the bent axle, and lifts the tines out of the ground, in which position the cultivator frame is held up by a catch; when lifted the required height, the lever strikes against a stop, and the implement turns into new ground. The man, who never leaves his seat, releases the catch, the tines drop into the ground, and the implement is re-drawn across the field.

This, after the plow, is the most important and efficient implement of the series. Its size is only limited by the power of the engines, which are thus used up to their capability. It pulverizes the soil, working steadily to a uniform depth. The largest machines require but one man in attendance upon them.

Fig. 740 shows the steam cultivator for very deep working, say 16″. It may have 3 or 5 tines, which lift the soil and leave it loose. It has a strong flanged steel frame, shares of various widths from 2″ to 13″, and oblique wings to lift the soil. The tines rock on the frame, so that when the imple-

Fig. 740.



Double Action Steam Cultivator. (*Howard, Bedford, England.*)

ment is to return across the field the points at work are slightly depressed and the hinder points raised.

The *Deere* walking cultivator is shown in Fig. 741. It has the usual two double-shovel plows, attached to a two-wheeled frame with a tongue alongside of which are hitched the two horses which travel on the respective sides of the row under cultivation.

It is peculiarly open and clear, not obstructing the view of the crop, and the spring coupling lifts the plows on their pivots to any adjustable extent, so that a part of the weight is carried and they bear with any desired force upon the ground to turn a moderate furrow when the corn is small, or a deeper one when the crop is more matured. The pitch of the shovels is also adjustable by vertical adjustment of the end of the beams. The distance apart of the shovels is adjustable. One of the wheels is broken to expose the parts more fully.

Cultivators are classed as: —

Ordinary,	Disk,
Wheeled,	Walking,
Rotary,	Riding,
Straddle-row,	Vineyard.
Parallel.	Expanding.

Besides these characteristic names, several of which apply to single implements, as for instance the popular Western implement, the *Walking, Straddle Row, Wheeled Cultivator,* there are several other classes of implements which naturally fall under so general a caption as cultivator: such are known as *scarifiers, extirpators, shovel plows, horse-hoes,* etc. Which see in "*Mech. Dict.*," *et infra.*

The author's report on Class 76 at the Paris Exposition shows the following ("*Paris Exposition* (1878) *Reports,*" vol. v., pp. 90-93): —

French horse-hoes.
French scarifiers.
English lever cultivator.
French extirpator.
"Peerless" cultivator, U. S., American riding cultivator.

English Five-tine horse-hoe and grubber.
Also: French vineyard cultivators, Figs. 221-231, pp. 216-240.
English steam cultivators, Figs. 84-88, pp. 83-86. *Ibid.*

Fig. 741.

Siemen's uterine curette . .	Figs. 295, 299, p. 74, Part III.
Sim's uterine curette . . .	Fig. 294, p. 74, Part III.

Tiemann's "Armamentarium Chirurgicum."

Quires' nasal and ear curette, "*Medical & Surgical Reporter*," July 3, 1880.

See also ENUCLEATOR.

Cu-rette′ For′ceps. (*Surgical.*) A long, narrow forceps, with hollow prongs to grasp and contain foreign substances in the process of extraction. See reference in CURETTE.

Curl′ing Stick. A slightly tapering hot-water tube, around which to curl the hair. — *Oppenheimer.*

Cur′rent. (*Electricity.*) The supposed flow or passage of electricity or electric force. It originates at the zinc surface in contact with the solution, and passes from the zinc to the copper or other negative metal *in the liquid* of the battery, and from the *negative* metal through the connections *externally* to the zinc. The quantity of current flowing through a given conductor is measured by the heat generated, by its influence on a neighboring permanent magnet, or by the amount of gas set free by its electrolytic action.

Cur′rent Ap′pa-ra′tus. (*Hydraulic Engineering.*) Devices used to ascertain the strength, rate, etc., of a current. See CURRENT METER.

Cur′rent Cool′er. (*Brewing.*) One for cooling a liquid *in transitu.*

Fig. 631, p. 264, "*Mech. Dict.*" Also, for Austrian forms, "*Scientific American Sup.*," Fig. 8, * 4077. Also forms of condensers, "*Mech. Dict.*," pp. 507–609.

Cur′rent Me′ter. The subject of current meters has been very carefully considered, and the apparatus tested in determining the velocity of the Connecticut River.

See "*Report of the Chief of Engineers, U. S. Army*," 1878, * ii. 304 and Plate VII. The plans adopted were by surface floats and the *Waltman* tactiometer.

Cur′rent Reg′u-la-tor. An apparatus for regulating the motion of dynamo-electric machines.

That of Hospitalier is composed of a resistance bobbin, formed of insulated wire wound on in a single layer, and having each turn stripped of its insulating covering for about 0.4 of an inch at the same spot. A curved lever, controlled by an electro-magnet at one end, and by an adjustable spring on the other, moves forward or backward on the bare portion of the bobbin if the current weakens or strengthens, until the resistance is adjusted by the decreased or increased number of turns in the circuit, and equilibrium is produced.

Cut'-off. 1. An apparatus used in steam engines to admit steam to the cylinder during a portion only of the stroke of the piston, allowing it to work expansively after the entrance of live steam from the boiler has been *cut off*.

Pages 665, 667, "*Mech. Dict.*," give illustrations, Figs. 1566–1571, of the cut-off arrangements of
Corliss.
Winter.
Stevens.
Allen.
Slide Valve.
Slide Valve, Merrick.
Sickels.

At the Paris Exposition, 1878, a great variety of cut-off valves was shown, the slide valve, however, being used by more than half the builders represented there. Double-beat valves, Corliss valves, and a few of piston form, were used by the remainder.

In all cases of slide-valve engines, except of very small ones, some arrangement for cut-off, by the use of an additional slide, was adopted; while in but few cases did the plan obtain of dividing the valve in two parts, that is, placing a valve at each end of the cylinder, so as to reduce the port contents, or distance from the under face of the valve to the cylinder, the advantage of which arrangement is apparent and would be considerable.

There were several instances in which an additional valve on the back of the main slide had some form of trigger release for working expansion, which, controlled by a governor, can close suddenly, while some few others used four separate slides — two for admission and two for exhaust — placed at the ends of the cylinder. Some of the compound engines had a single slide for both cylinders. There were some examples of receiving-valves, double-beat, above the cylinder, with slide valves for their exhaust placed below the cylinder.

The usual practice in horizontal engines is to place at least the exhaust valves underneath the cylinder, in order to allow ready escape for water, the receiving valves being on top of the cylinder; but there were examples where all four of the valves were below the cylinder or were arranged on its side. In engines having Corliss valves the usual arrangement was maintained of placing the valves above and below the cylinder.

The Wheelock engine valves are all beneath the cylinder.

Valve movements were in large variety in Paris, the most important being those having an automatic variable cut-off controlled by the governor. This point receives more attention in Europe than any other single feature in steam engines.

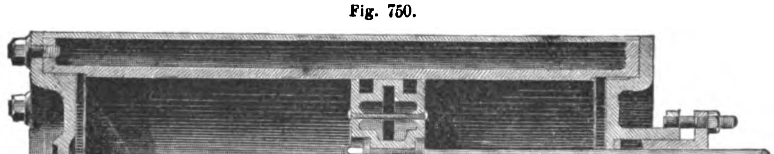
Many novel methods are in use, but all those using piston or double-beat valves employ some arrangement for tripper-gearing, by the introduction of a detent, or the alteration of the position of a wedge or incline. In some cases the motion is taken from the pitman, but generally from an eccentric on the main shaft or on a lay-shaft alongside, the governor controlling the position of the device for determining the point of cut-off.

Several automatic cut-off arrangements are in use in Europe with slide-valve engines, but the larger portion of them have some form of extra slide-valve, whose position is determined by right and left screws, the screw-shaft being rotated by the governor. Either this arrangement, or something its mechanical equivalent covers all, excepting those where the Rider gear is used and some other cases where the governor rotates an eccentric which varies the point of closure.

The Wheelock steam-engine furnished the power to operate the machinery in the United States, Swedish, and Norwegian sections at the Paris Exposition, and received a Grand Prize.

The peculiarities of this engine are a reduction to the simplest expression of the instantaneous cut-off valve, which forms the chief feature in the modern first-class engine. Side and sectional views of the cylinder are shown. Instead of four ports this engine has but two, one at each end of the cylinder, directly underneath it. There is at each end of the cylinder, close behind the port, one main and one cut-off valve, views of which are shown in Figs. 750 and 751. Each main valve has a cavity for exhaust, is slightly conical in shape, and is carried in hardened-steel bushes on hardened-steel trunnions

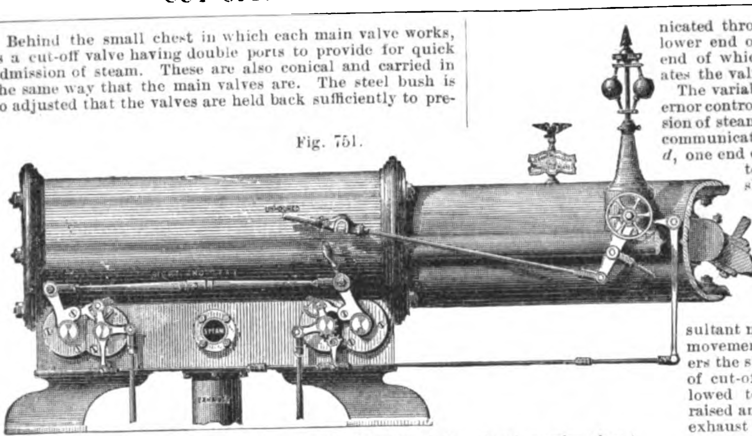
Fig. 750.



Wheelock's Steam Engine. (Longitudinal section through cylinder.)

Behind the small chest in which each main valve works, is a cut-off valve having double ports to provide for quick admission of steam. These are also conical and carried in the same way that the main valves are. The steel bush is so adjusted that the valves are held back sufficiently to prevent contact between the sliding surfaces, thus transferring the slight wear to the gudgeons and bushes, which would be inconsiderable in very long service. The cut-off valves are released by the action of the governor, and are closed by weights falling in dash-pots.

Fig. 751.



Wheelock's Steam Engine. (Side view of cylinder, showing valve glass.)

nicated through a lever, *a*, to the lower end of a toggle, *b*, the other end of which attaches to and operates the valve-stem, *c*.

The variable motion from the governor controls the duration of admission of steam into the cylinder, being communicated to the toggle by a rod *d*, one end of which attaches to the toggle and the other to a slide, *e*, carried on an arm, *f*, worked by the positive motion, the position of which slide on the arm is regulated by the action of the governor, through the rod *g*, the arm *h*, and the rod *i*, and the resultant motion gives a determined movement, which raises and lowers the steam-valve for all degrees of cut-off. The valve is never allowed to drop, but is quickly raised and quickly lowered. The exhaust valve may be operated in any convenient manner.

The arrangement not only reduces the clearance to a minimum, but guards against a trouble found in four-port cylinders, in a waste of steam through the exhaust-port if there be a leakage in the cut-off valve.

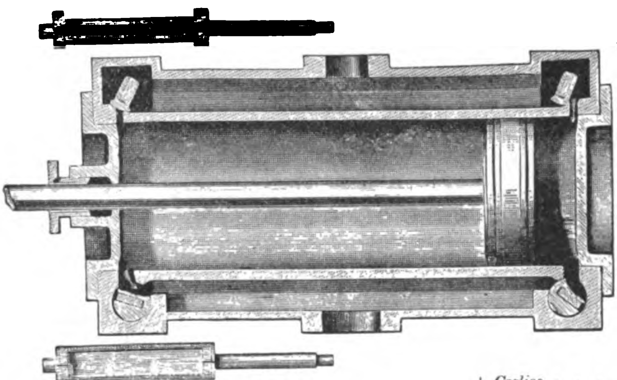
The mechanism for moving the valves is exceedingly simple and effective, easily gotten at, and not liable to excessive wear.

The packing-rings are self-adjusting segmental lap-joint rings, making an effective and tight piston. This was demonstrated on several occasions by removing a cylinder-head and operating the engine with the cylinder open.

The dimensions of the engine exhibited were —

Diameter of cylinder, 17″.

Fig. 752.



Corliss Steam Engine.

Length of stroke, 48″.
Diameter of fly-wheel, 14′.
Width of face, 25″.
Average steam pressure, 60 lbs.
Revolutions per minute, 62.
Estimated horse-power, 125.

The arrangement of the Corliss valves is shown in Fig. 752. There were in Paris many representatives of this form of engine from most European countries; although, as at Vienna, in 1873, Mr. Corliss personally did not exhibit, yet his engine was largely and admirably shown by other parties. See, also, Fig. 5666, p. 2341, "*Mech. Dict.*"

The steam-engine exhibited by A. Collmann, of Vienna, Austria, has an ingenious arrangement of valve-gear differing from the usual system of catches and pawls.

The engine is shown in a perspective view in Plate VIII., and in transverse section in Fig. 753.

The valves for the admission of steam are caused to operate by means of the combination of two motions, one of which, taken from the main shaft through miter-wheels, is constant, while the other, taken from a governor, is variable. Referring to the Plate, a constant motion is commu-

See also EXPANSION VALVE GEAR.

2. A device in a stove magazine to separate the ashes and clinker from the fire, and to hold the fire in position while the ashes and clinker are tumbled off the grate and then removed. The grate being restored, the cut-off is withdrawn, and the fresh fire is allowed to fall upon the grate.

3. (*Sewing Machine.*) A device used with a hooked needle for the purpose of closing and opening the barb, to retain the thread in the needle during its passage through the goods or leather, and allow it to escape after the needle is withdrawn.

Cut′-off Saw. See CUTTING-OFF SAW.

Cut′-out. (*Electricity.*) A device for disconnecting telegraph instruments from the main line.

In *E. Gray's* (Patent 110,970), two springs hinged to the plates to which the terminals of the main line are connected, and separated by an insulating block, are provided each with a platinum-tipped contact-screw, and are so arranged that when turned into one position said screws bear against each other and complete the main circuit; but when in the other position, the springs bear against the terminal beveled studs of the loop or instrument circuit, thereby separating the contact screws and completing the circuit through the loop.

Cut Splice. (*Nautical.*) A loop splice made by a short piece of rope, the strands laid open at the ends and spliced into a standing rope, as in *k n*, Fig. 5435, p. 2279, "*Mech. Dict.*"

Cut Stone. (*Stone Cutting.*) Another name for ashlar, which see. The term covers all squared stones with smoothly-dressed beds and joints.

The following are modes of face-dressing (which see): —

Bush-hammered.	Pointed.
Crandaled.	Rough pointed.
Fine pointed.	Rubbed.
Peen-hammered.	Tooth-axed.

Cut′ter. 1. (*Ordnance.*) An instrument for determining the pressure per square inch exerted within the bores of cannon or small arms by the ignition of powder.

This form of instrument for the purpose derives its name from the fact that the pressure of the igniting powder is exerted upon a piston, the reverse of which has a cutter which makes a mark (cut) upon a copper block. See, also, CRUSHER GAGE; PIEZOMETER.

Fig. 754.

Milling Cutters. (Brown & Sharpe.)

Plates III., X., accompanying Appendix I. *b*, to "*Report of Chief of Ordnance, U. S. A.*," 1877, are illustrations of such *cuts*, and the text accompanying pp. 373-396, describe the instrument and results, referring to Plates I.-X.

Several forms of cutters are there described.

The Rodman cutter is also used in Lieutenant Metcalfe's recoil dynamometer for small arms. "*Ordnance Report*," 1878, Appendix N., p. 109.

2. (*Agriculture.*) An instrument attached to the plow to cut the sod or weeds in advance of the share or the breast of a plow. There are several kinds and modes of attachment. See COLTER.

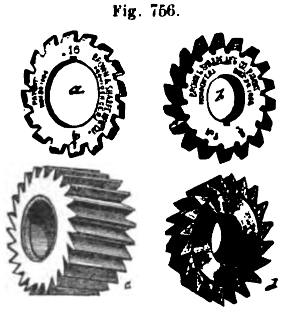
Fig. 755.

Milling Cutter.

3. (*Machinery.*) A cutting tool in a lathe, planer, or milling machine. Figs. 754, 755, 756, show several forms of rotary in milling machines and some forms of special machinery of cognate character.

Fig. 754 shows two forms of milling cutters: the upper one is for cutting the teeth of gear wheels,

Fig. 756.



Screw-slotting Cutters.

a. For making twist drills.
b. For grooving taps and reamers.
c. Grooving and milling cutter.
d. Angular cutter.

and can be sharpened by grinding without changing their form.

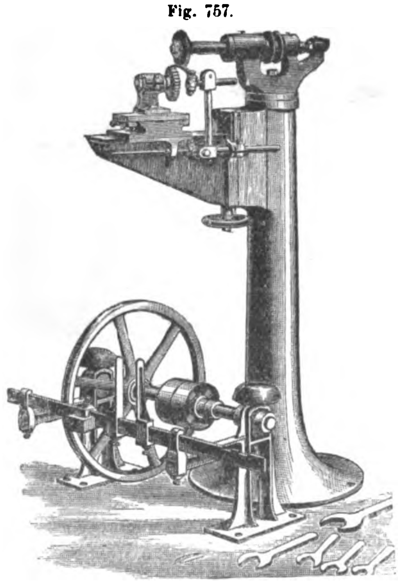
The lower cutter in the figure is for milling sewing machine and gun parts of irregular form.

Fig. 755 is a screw-slotting cutter.

Fig. 756 shows four cutters.

Cut'ter Grind'er. Is a tool for shops and manufactories in which rotary cutters of any style are used for gear-cutting, milling, or slotting. A columnar support, with a broad base, sustains the spindle-head, the cutter-holder and guide. The platen to which the holder and guide are attached may be adjusted in height to suit the diameter of the cutter to be operated upon. The guide rests against the tooth that is being ground, thus gaging the work accurately, even though there may be irregularity in the size of the teeth. The machine is adapted to cutters of all sizes and styles of teeth, whether straight, beveled, or spiral.

Fig. 757.



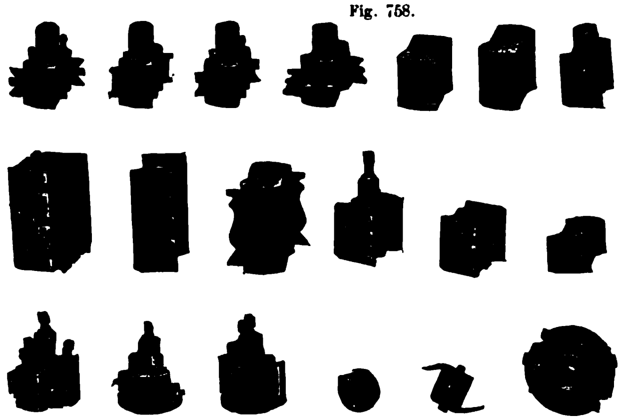
Cutter Grinder. (*Smith & Coventry, British.*)

Either small grindstones or emery wheels may be attached to the spindles.

Cut'ter Head. (*Wood Working.*) A rotary cutter stock in a planing, grooving, matching, or similarly-acting machine.

The illustration shows a variety of heads, includ-

Fig. 758.



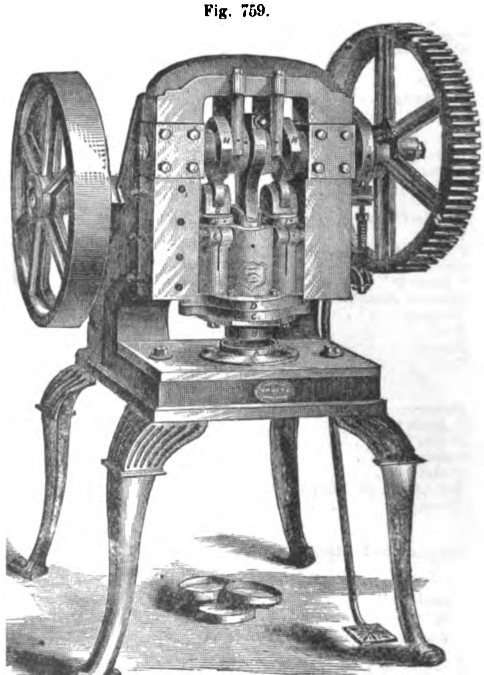
Cutter Heads.

ing sash, door, straight-cap, slotted combination molding, panel, matching, grooving, gaining, beading, coping, etc.

Cut'ting and Draw'ing Press. A machine made in various sizes for different grades of work in cutting a blank out of sheet-metal and forming it into shape at one operation. The machine shown is adapted for articles not exceeding 8″ in diameter and $1\frac{1}{4}$″ deep.

The die *A* is secured to the bed of the press and the cutting punch *B*, which also acts as blank-holder, to the adjustable plate *C*. The pressure of the punch upon the blank is regulated by the screws *F F*, which are bored out to receive the casing *G G*, on the lower end of which are rubber washers to allow for difference in the thickness of the tin. The

Fig. 759.



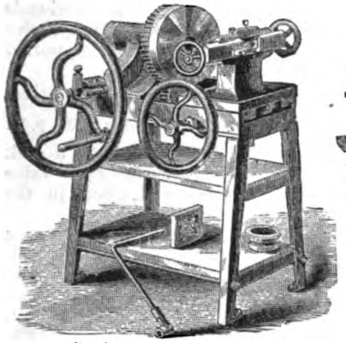
Cutting and Drawing Press.

cams *H H* force down the cutting punch and blank holder and a central drawing punch forces the blank into the shape required. The slide is kept against the cams by a weight.

The *Bliss* cutting, drawing, and stamping press performs at one operation, the cutting of the blank, drawing it into shape and embossing any required design upon it. It is particularly designed for work that is lettered, beaded, countersunk or embossed, such as sardine and blacking boxes, covers and bottoms of cans and lard pails, etc.

Cut'ting and Screw'ing Ma-chine'. A machine especially adapted for cutting off wrought-iron pipe and tapping the ends for coupling lengths. The pipe is held in the hollow head which has a universal chuck, and the dies are held on an adjustable pillar. The chuck-head is revolved by crank and fly-wheel or by power.

Fig. 760.

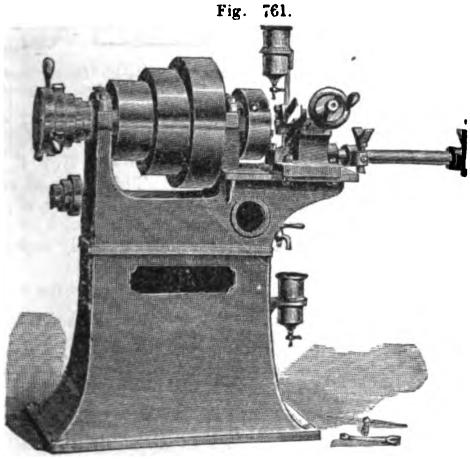


Cutting and Screwing Machine.

Cut'ting Ma-chine'. A machine for cutting crackers from the blanket of dough. See CRACKER MACHINE.

Cut'ting-off Lathe. A machine with which rods, bars, and pipes are cut to length. The object is passed through a collet at the rear end of the spindle, and held in front by a concentric chuck. The steadying collets are changed to fit various sizes of bars. The feed is automatic or by

Fig. 761.



Cutting-off Lathe.

hand and the speeds variable. The *Slate* cutting-off tool is used, the stock of which receives the cutter in a channel on its side, and the cutter is held in place by flanges on the stock and two hook-headed bolts, allowing the cutter to be advanced as it is ground for sharpening.

* "*Engineer*" . . . . xlii. 42.

Cut'ting-off Saw. The cutting-off saw is a cross cutting machine adapted to the shop. The cross cutting machine for the woods is a *drag*-saw. Fig. 1739, p. 738, "*Mech. Dict.*"

16

Cutting-off saws are of several kinds: single and double; the latter may be *double-enders*, for sawing boards to a length, cutting off both ends at once.

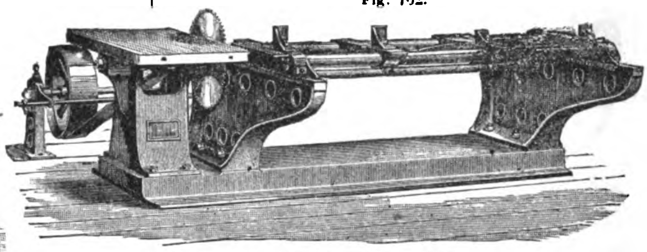
1. In the *railway cutting-off saw* the saw arbor is on a carriage which traverses on planed guides, to and fro. Fig. 4134, p. 1867, "*Mech. Dict.*"

2. The *bracket cutting-off saw* traverses on a bracket above the table upon which the staff lies. See BRACKET CUTTING-OFF SAW, *supra*.

3. The *swing cutting-off saw* is pendulous from the ceiling, Fig. 6127, p. 2471, "*Mech. Dict.*"

4. The *carriage cutting-off saw* has a carriage in which the stuff lies and which moves on ways transversely to present the stuff to the saw.

Fig. 762.



Carriage Cutting-off Saw.

Cut'ting-off Shears. A bar shears for cutting bar or rod iron to lengths. Fig. 586, p. 241, "*Mech. Dict.*"

Cut'ting Punch. A circular-edged punch used for cutting grommet holes in sails, cutting wads from cloth or paper, disks or planchets from leather or metal, making tongue-holes in straps and in various other uses and connections. See WAD-PUNCH, Fig. 7001, p. 2717, "*Mech. Dict.*"

Oval or oblong cutting punches are used for some purposes, — for setting-in oblong grommets, for instance.

Cy'clad. A circular iron-clad. A style adopted in several vessels of the Russian navy, as the "Novgorod," "Admiral Popoff."

"*Engineer*" . . . . * xli. 75, 93, 244.

Cy-cloid'o-graph. An instrument invented by *Dr. S. Zmurko*, for the practical drawing of cycloids.

"*Scientific American Supplement*" . . . . . . 505.

Cy'clo-graph. An instrument invented by Worthington (Eng.), for drawing arcs of great radius.

It is a rolling instrument having two wheels of different diameters on a single shaft, one being capable of adjustment towards or from the other. The nearer the two are in relation to each other, the smaller will be the radius of curve described by a pencil attached to the shaft near the larger wheel.

"*Scientific American Supplement*" . . . . . * 3907.

Cy-clom'e-ter. An instrument for counting revolutions. Shown as adapted to a bicycle in —

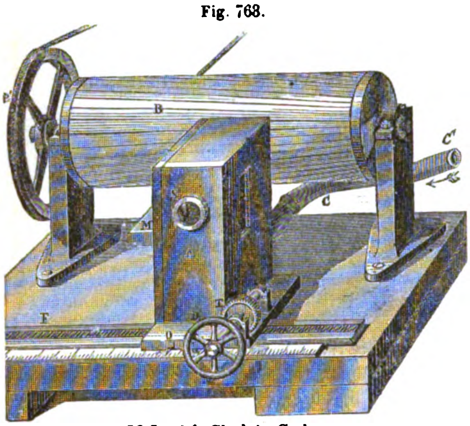
"*Engineer*" . . . . * xlv. 234.
"*English Mechanic*" . . . . * xxvii. 321.
"*Mining & Scientific Press* . . . . . . xxxvi. 403.

Cy'clo-scope. An instrument invented by Professors McLeod and Clarke of the Royal Indian Engineering College.

Its purpose is to measure the velocity of revolution, and enable it to be determined at the moment of observation.

B, Fig. 763, is the cylinder with its ruled paper covering. The wheel *R* serves to put it in communication with the machine, the rotary speed of which is to be measured. The movable box contains a reed or vibrating lance, which performs the functions of a tuning-fork, and to which is fastened a small plate of zinc, in which there is a slit about equal in width to the breadth of the lines traced upon the cylinder. The lance vibrates 60 times per second. The small-toothed wheel *T*, and the wheel *D*, being situated upon the same axis with the box *A*, the latter can, by simply turning the wheel *D*, to the right or left, be moved to any position in front of the cylinder. At *S* is an opening through which the lines are examined; it contains a lens for the purpose of magnifying the images. When the apparatus is to be operated the plate is caused to vibrate by means of a small bellows, the tube of which is seen at *C C'*. The box *A* carries an index by means of which the speed is

Fig. 763.



McLeod & Clarke's Cycloscope.

read upon a graduated scale. Supposing that the cylinder is revolving and that we wish to learn its speed, we place the eye at *S*, and with the right hand turn the wheel *D*, until we meet with the stationary wave which has served to determine the divisions; the index *O* will then point to the figure that indicates the speed.

The idea of the machine is founded upon the observation that if a series of objects (points, for instance) are moving with a certain velocity, the eye loses their outlines and

Fig. 76.

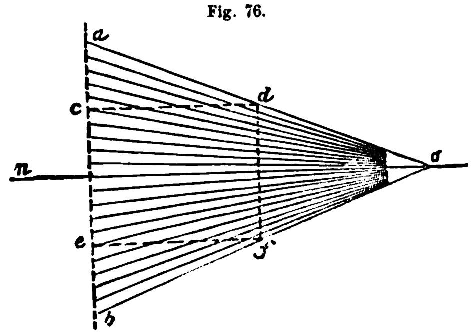


Diagram of Ruled Paper for Cycloscope.

blends them together into a line. The ruling of the paper on the cylinder is such that the lines are much farther apart at one end than the other, and this is conveniently accomplished by cutting an oblong piece sufficient to wrap the cylinder, out of a piece ruled as in the figure.

It will be evident that when the cylinder is revolving at a given rate the number of repetitions of the line, which, as viewed through the slit, is equivalent to a dot, will be much greater at one end of the cylinder than at the other.

The device is much more fully described in "*Proceedings of the Royal Society*," in "*Popular Science Review*" and "*La Nature*," and copied into the "*Scientific American*," xli. * 131; "*Scientific American Supplement*," 1188, 1366. See also "*Engineer*," xlviii * 225.

Cyl'in-der Bor'ing Ma-chine'. A cylinder borer, portable, and adapted to the reboring and refacing of locomotive cylinders while the cylinder is attached to the engine, is made by the New York Steam Engine Co. under Chapman's patent.

The machine is so arranged that it can be attached to an engine standing on the track, and is driven or worked either by hand or power to bore the cylinder and turn and face the edges of the flanges. The boring head slides upon a bar 4″ in diameter, one end of which is placed in a bushing fastened in a stuffing-box, and the other end runs in a bearing bolted to the cylinder-flange. The boring head has three tool-holders, which will receive either boring, facing, or turning cutters, and each or all of the cutters have an automatic and a hand feed. These machines will bore a cylinder as small as 15″ and as large as 20″ in diameter, with an extreme traverse of head of 32″.

Boring machine.

Sharpe, Stewart & Co., Br. "*Sc. Am. Sup.*," 2094.
Portable . . . . . . * "*R.R. Gaz.*," xxii. 355.
Flanders . . . . . . * "*Min. & Sc. Pr.*," xxxvi. 289.
Measuring instr., *Giegly* . * "*Engineer*," xlix. 259.
Molding, *Tuck* . . . . . * "*Sc. Amer.*," xxxv. 51.

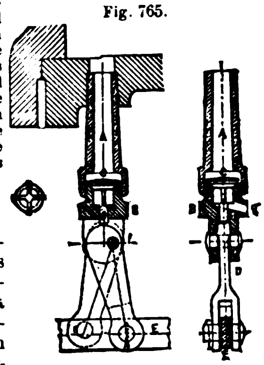
Cyl'in-der Car. A cylinder with wheel-ends adapted to run on a railway track. The cylinder is loaded full, and rolls, the load not being supported on axles.

There have been many patents on this idea.
Prosser's . . "*Scientific American*," xli. 293.
"*American Manuf.*," March 26, 1880, p. 12.

Cyl'in-der Cock. Figure 765 shows a cock operated by pressure of an eccentric against a valve normally closed by the pressure of steam in the cylinder.

The view shows two sections at right angles. The tube *A* is screwed into the cylinder, and into it is screwed a plug *B*, the end of which is the seat of valve *C*. The eccentric of the lever *D* is pivoted at *f*, and is moved by the rod *E*, pressing the eccentric against the stem *s* of the valve. *g* is the exit for the steam or the water of condensation, as the case may be.
"*Railroad Gazette*," * xxiii. 436.

Fig. 765.



Hayes & Schlack's Locomotive Cylinder Cock.

Cyl'in-der For'ging Mill. Blakey's forging mill for making tubes consists of a rotating mandrel, operating in combination with a series of surrounding rolls, which first bend the blank, then weld it, and, by continued rolling, impart a finish to the welded article.

"*Iron Age*" . . . . * xviii. July 27, p. 1.

Cyl'in-der Glass. (*Glass.*) This method of manufacture is much older than is generally supposed. It is so much superior to the *crown-glass* process that it has at length almost entirely superseded it.

The Venetians and Bohemians blew cylinders for the windows of the 12th and 13th centuries.

Cylinder blowing was introduced into France from Bohemia in the beginning of the 18th century.

France now manufactures it in great quantity. *La Compagnie des Verreries de la Loire* produces annually 590,000 square yards of white, and 89,000 yards of colored glass.

In the north of France 25 to 30 furnaces of 8 pots produce 4,500,000 to 5,000,000 square yards.

Annual production value: 1873, $4,400,000.
1878, $3,000,000.

Composition of French window glass: —

White sand	100
Sulphate of soda	35 to 40
Lime	25 to 35
Powdered coke	1.5 to 2.0
Binoxide manganese	0.5

Cullets in variable quantity, usually the same quantity as the sand. Arsenic is sometimes added to refine the glass; vaporizing in the pot, it passes through the glass, stirring the mass, and refining it.

Green sticks of wood are used for the same purpose, and, in Bohemia, a potato at the end of an iron bar. It is the steam in each case which escapes through the *metal*, as the melted glass is termed.

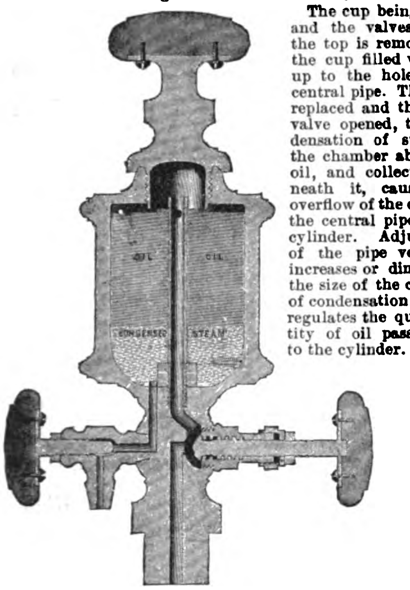
A workman usually blows during 20 hours and averages from 16 to 17 per hour, making sheets 22″ × 21″.

The cylinders are split with a diamond on the stick, guided along the edge of a wooden rule laid inside the cylinder. See Flattening Oven.

Cyl'in-der Grind'er. A machine tool with automatic traverse feed, for finishing cylindrical gages, such as those for gun-bores, etc. See Cylindrical Gage.

Cyl'in-der Lu'bri-ca-tor. An apparatus for supplying a regulated and constant quantity of oil to a cylinder.

Fig. 766.



Cylinder Lubricator.

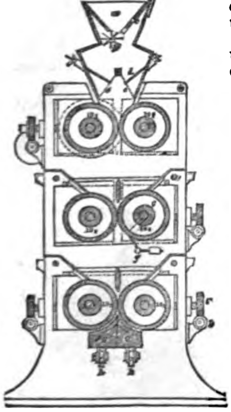
The cup being empty and the valves closed, the top is removed and the cup filled with oil up to the hole in the central pipe. The cover replaced and the steam valve opened, the condensation of steam in the chamber above the oil, and collecting beneath it, causes the overflow of the oil down the central pipe to the cylinder. Adjustment of the pipe vertically increases or diminishes the size of the chamber of condensation, and so regulates the quantity of oil passing to the cylinder.

Cyl'in-der Mill. A grinding mill in which the action of rollers is substituted for that of face stones.

(*Milling.*) The cylinder or roller mill, the *Walzenmühle* of the Hungarians, consists of two small parallel horizontal steel or porcelain cylinders placed near to each other, arranged for adjustment and revolving from above towards each other. In the great mill of Pesth the rollers are about 5″ in diameter, the surfaces of some having sharp longitudinal furrows.

Fig. 767 shows a mill with three pairs of rollers and an intervening space between the pairs. The action depends upon the distance of the rollers from each other and the character of their surfaces.

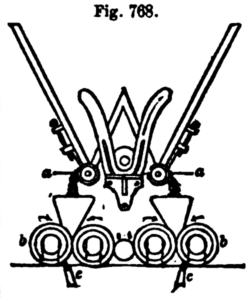
Fig. 767.



Cylinder Grinding Mill.

Smooth, and revolving with uniform speed, the action is to crush soft wheat or split hard wheat into fragments; or, if far apart, to split the berry lengthwise.

Fig. 768.



Wegmann's Porcelain-cylinder Mill.

Smooth and revolving with unequal velocities, the action is to mash the grain.

Grooved cylinders, with equal velocity, indent and crack the grain; with unequal velocities tear it.

The product is not heated; no dust flour is produced. In the Pesth mill the wheat, before attaining its last disintegration, passes between from 18 to 24 pairs of rollers. Its effect is a grade between *high milling* and *low milling* (which see).

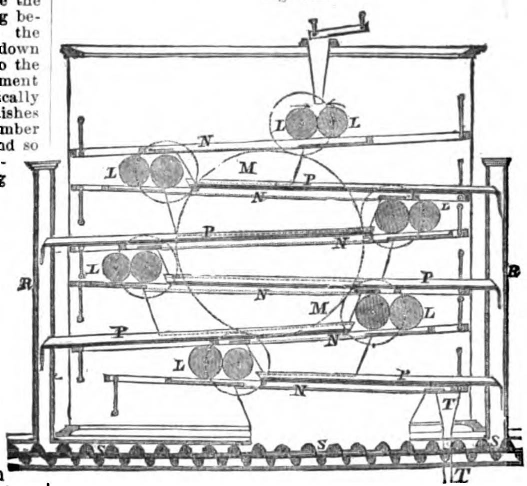
It is claimed to render grits and middling purifiers unnecessary.

That it is impossible to injure the quality of the flour in milling.

To secure a larger proportion of clean, pure flour.

Fig. 768 is a sectional view of *Wegmann's* porcelain-cylinder mill. *aa* are the feed cylinders; *bb*, the porcelain cylinders; *cc*, scrapers with glass edges to clean the cylinders.

Fig. 769.



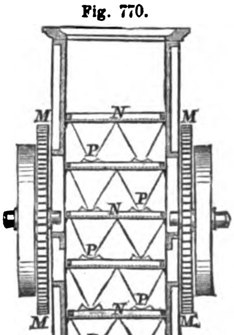
Buchholz Cylinder Grinding and Bolting Mill. (*Section.*)

See also Grits Mill.

Figs. 769, 770, show the *Buchholz* roller mill.

The cylinders revolve with unequal velocity and are all set in motion by a single large cog-wheel *M*. The pointed and purified grain is fed in between the highest pair of rollers *L L*, to be cracked, as it passes through, into coarse fragments, and more or less flour, grits, and bran, which are received upon the inclined shaking-sieve *N*, where they are sorted; the grits and fine flour passing through to the trough *P*, to be discharged into the upright receiver *R*. The groats and bran pass on to the next pair of rollers, to be further reduced to finer groats, grits, flour, and bran. Falling upon the second sieve the flour and grits pass through to the trough *P*, while the bran and groats pass on to the next pair of rollers, and so on until the groats having been reduced to grits and flour, all the bran is collected in *T T*, and all the flour and grits in *S S*. The screw conducts the flour and grits to a bolt, where the flour is bolted off, and the remaining grits graded in the centrifugal machine.

Fig. 770.



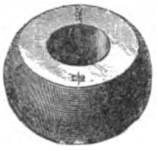
Buchholz Roller Grinding Mill. (*End View.*)

Beyer, * "*Technologiste*," xxxix. 348.

The whole system of milling has undergone great alterations within a few years past, and the new processes, which have given a name (*new process*) to the flour produced are largely used at the principal flour centers of the United States, Minneapolis, for example. Some of these improvements concern the method of grinding, *high* or *low*; others the principle of grinding, attritition (stones), or mashing (rollers); others the mode of handling the result, bolting and purifying.

Cy-lin'dri-cal Gage. A gage for measuring the external or internal diameter of cylinders. The plan was initiated by Whitworth, of England, and the system is often referred to under his name as "Whitworth" gages.

Fig. 772.



Cylindrical Gage.

They are made in sets, arranged in a box, of sizes from $\frac{1}{16}''$ to $2''$, varying by sixteenths of an inch.

They consist of steel cylinders and rings hardened and ground very accurately to standard sizes. These fit into each other. The first is used for measuring the size of holes, and the last for measuring the outside of cylindrical objects, and they are called *internal* and *external cylindrical gages*. They are generally used as standards alone, from which other tools and gages are made of the proper size.

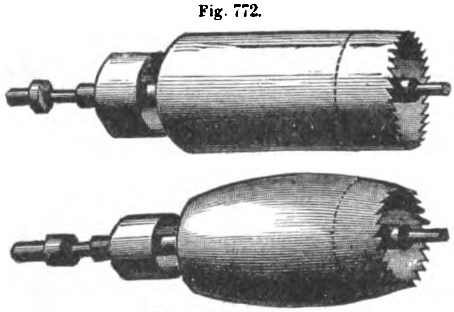
Cy-lin'dri-cal Glass. 1. A form of glass made to correct astigmatism; *i. e.*, a non-spherical form of the cornea of the eye.

2. A reading glass, for avoiding the distortions produced by an ordinary spherical reading glass.

Cy-lin'dri-cal Saw. "General Sir Samuel Bentham made cylindrical and crown saws for the British Admiralty previous to 1804. Its extensive application is, however, American." — *Richards.*

In the form shown in Fig. 772 the length of stuff that can be sawed is limited, but in another form described by *Richards* it consists of a tubular shaft or cylinder, around

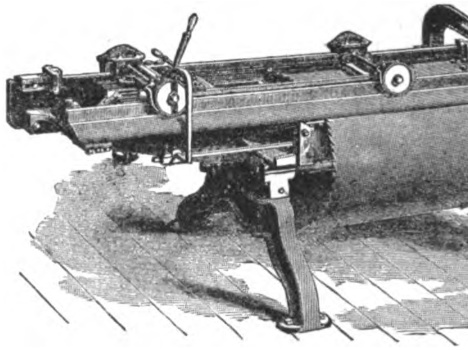
Fig. 772.



Straight Cylinder Saw.
Bilging Cylinder Saw.

which the belt passes supported in semicircular or half-bearings of the same diameter: to the end is attached a short crown saw that is as much larger than the cylinder as will clear the belt. The belt is wide, very thin, and uniform in thickness. The wood is carried over this saw by means of a carriage, the saw cutting out a semicircular core, the belt *running in the kerf* and passing through with the saw. It is

Fig. 773.



Whitney's Stave Saw.

intended for making cylindrical wooden pipes, or more especially eave troughs and conductors for the roofs of buildings.

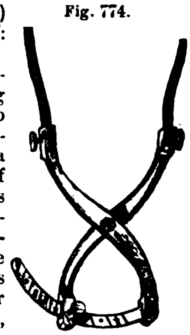
Fig. 773 shows *Whitney's* cylindrical saw, for making pail-staves out of the balk. A steel cylinder with teeth at one end is carried at the extremity of a well-supported horizontal spindle. The length of the cylinder is somewhat greater than that of the bucket for which the staves are destined, and its diameter is such as to give them the requisite curve.

Cy-lin'dri-cal Sieve. One in which the wire surface is cylindrical; the material being usually fed in at one end and discharged at the other.

See Grain Cleaner, Starch Sieve, Drying Machine, etc.. for examples.

Cyr-tom'e-ter. (*Surgical.*) An instrument for diagnosis: for measuring the chest.

Fig. 774.



Dr. Weed's Cyrtometer.

Flint's cyrtometer is a compass with short arms holding strips of lead long enough to encircle the chest. An indicator may be set at any point by a thumb-screw. The strips of lead are easily molded so as to fit any elevation or depression of the chest; the thumb-screw is then loosened, and the instrument removed. The parts being restored to their former position and placed on paper, the exact shape of the chest can be traced by a pencil.

Fig. 272, p. 84, Part I., *Tiemann's "Armam. Chirurgicum."*

Dr. Weeds' cyrtometer has flexible aluminium strips to bend around the chest, and is not designed to obtain the shape, but the circumference merely.

Cys-ti'tis Eye'let. (*Surgical.*) A short flanged tube, used in inflammation of the bladder.

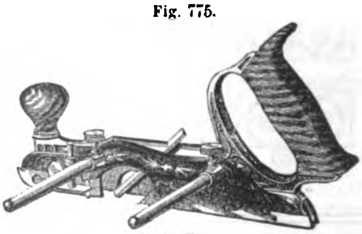
D.

Da'do. (*Add.*) (*Arch.*) A die with a projecting panel.

Da'do Plane. A tool consisting of two sections: a main stock with two bars, and a sliding section, having its bottom face level with that of the main stock.

It can be used as a dado of any required width by inserting the bit into the main stock, and bringing the sliding section snugly up to the edge of the bit. The two spurs, one on each section of the plane, will thus be brought exactly in front of the edges of the bit. The gage on the sliding section will regulate the depth to which the tool will cut.

Fig. 775.



Dado Plane.

By attaching a guard-plate to the sliding section the tool may be converted into a plow, fillister, or matching-plane.

Dai'ry Im'ple-ments. See CREAMERY; CHEESE; CHURN, etc.

Dam. 1. (*Hydraulic Engineering.*) A bank or structure across a stream.

Mattress and rubble dams in river and harbor improvements, jetties, revetments, and dams proper, are shown in the "*Reports of the Chief of Engineers, U. S. Army.*" Among others the following: —

Savannah River, 1879 . . . . • i. 742.
Corpus Christi, 1879 . . . . • i. 934.
Coffer Dam (Kanawha River), *Ibid.*, 1878 • ii. 466.

Kanawha River, "*Sc. American Supplement*," 1251.

See also BARRAGE; CURTAIN; DIKE; MATTRESS, etc. Also list under HYDRAULIC ENGINEERING, "*Mech. Dict.*," *et infra.*

2. (*Mining.*) *a.* A stopping of sand, clay, or brick-work built across a passage to exclude water or choke-damp, or prevent access of atmospheric air to fire-damp.

b. Choke-damp or foul air (Cornish).

3. A shield of sheet rubber clasped around the crown of a tooth to exclude saliva while the tooth is being excavated and filled.

Dam'as-ceen'ing. (*Fine Art Metal Working.*) The art of incrusting one metal on another and thoroughly incorporating. Generally, the incrusting is of gold or silver wire on the surface of iron, steel, or bronze.

The surface is engraved and undercut, the wire laid in, and the object is then hammered.

There are several common forms of damasceening: *Kuft* work and *bidiri* work, for instance. Cheap kuft work is merely gold leaf laid on to a rough etched surface, to which it adheres, while it is wiped off the smooth surfaces.

Bidiri work has for a ground an alloy of copper, lead, and tin, blackened by dipping in a bath of sal-ammoniac, saltpeter, salt, and blue vitriol.

Da-mas'cus Steel. (*Metallurgy.*) A steel made from the native iron obtained by bloomary process; broken, melted in a crucible with pieces of wood, the crucible luted and the steel melted. It is an Indian cast-steel, better known as *Wootz.* See p. 2264, "*Mech. Dict.*"

"*Mining & Sc. Press*" . . . . . . xxxvii. 87.

Dam'ask-ing Met'als. (*Add.*) (*Fine Art Metal Work.*) The Japanese process called *mokume*, which may be translated "veins of the wood," is a sort of damask pattern composed of variously colored metals, chiefly white silver, red copper, and a dark blue alloy. Pieces of this very difficult sort of workmanship are produced by overlaying and soldering together a certain number of plates of the metals or alloys, by hammering, welding, resoldering, filling up the hollow spaces with new metal, and repeating these operations many times; finally, when stretched out into a thin sheet, this composition shows a peculiar pattern, composed of veins of the different metals.

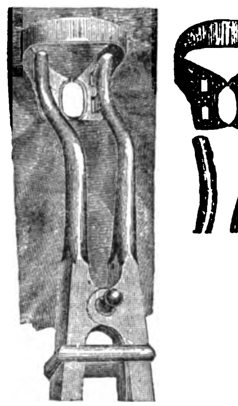
Dam Clamp. (*Dentistry.*) A device to hold a rubber dam in position around the tooth. Fig. 776 shows several forms and patterns, one of them *in situ.*

Fig. 776.

Rubber Dam Clamps.

Dam Clamp For'ceps. (*Dentistry.*) A device for putting a rubber dam clamp in position around a molar. The prongs are held at their distention by the slider on the handles, studs on the forceps jaws engaging in perforations in the flanges of the clamp. — *Dr. Elliott.*

Fig. 777.



Dam Clamp Forceps.

Damp'en-ing. 1. (*Leather.*) The moistening of hides previous to skiving or shaving.

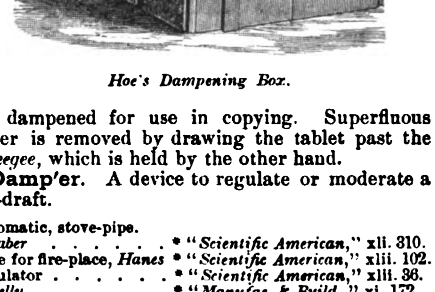
Leather under treatment is occasionally moistened with a wet sponge to make it dry evenly.

2. (*Copying.*) The wetting of bibulous paper or tablets for copying letters, etc.

3. (*Printing.*) The wetting of paper previous to printing.

Damp'en-ing Box. A case in which tablets are dampened for use in copying. Superfluous water is removed by drawing the tablet past the *squeegee*, which is held by the other hand.

Fig. 778.



Hoe's Dampening Box.

Damp'er. A device to regulate or moderate a fire-draft.

Automatic, stove-pipe.
Taber . . . . . . • "*Scientific American*," xli. 310.
Plate for fire-place, *Hanes* • "*Scientific American*," xliii. 102.
Regulator . . . . . . • "*Scientific American*," xliii. 36.

"Peerless" . . . . • "*Manufac. & Build.*," xii. 30.
• "*Manufac. & Build.*," ix. 232.

Damp'er Reg'u-la'tor. A self-acting arrangement in which pressure of steam acts upon a damper or register to regulate the sectional area of a flue or draft-hole. As the steam increases in pressure in a chamber, a piston or diaphragm is moved, and acts upon the damper in the flue. There are many forms of the device, agreeing in the main features.

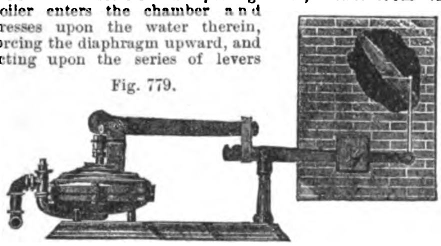
Barrett's flue damper is a butterfly valve regulated by the steam pressure in a special chamber, connecting by steam-pipe with the boiler, and adjusted by means of a balance arm and ball.

In Kelly's and Woodruff's the steam acts upon rubber diaphragms, passing between them, lifting the upper one and depressing the lower, the effective motion being the sum of the two.

In Watton's device (British), the escaping steam from a safety valve fills a subsidiary chamber, and, by depressing the piston, acts upon the lever of the damper.

In the "Peerless" damper-regulator, steam from the boiler enters the chamber and presses upon the water therein, forcing the diaphragm upward, and acting upon the series of levers

Fig. 779.



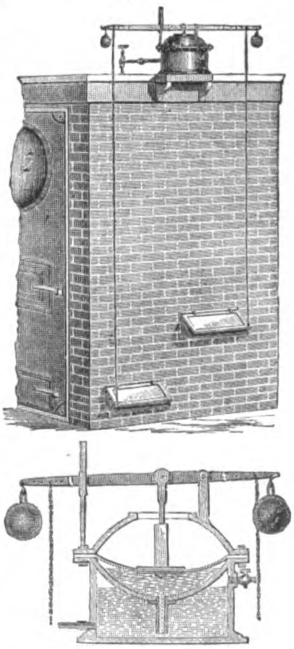
"*Peerless*" *Damper Regulator.*

which controls the damper. The steam pressure is always present, and its extent is the measure of the area of sectional opening in the flue.

The Norcross steam damper-regulator works without diaphragm or plunger, acting by displacement of water in a counterbalanced arm.

Fig. 780 gives two views of the Nason draft or damper-regulator. The upper view is a perspective of the side of the low-pressure boiler furnace, showing the apparatus *in situ*, and the connection with the draft doors. The lower figure is an enlarged sectional view of the apparatus itself.

Fig. 780.

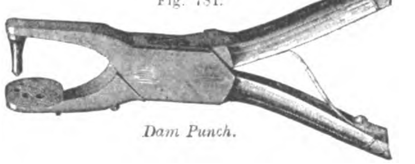


Damper Regulator.

Damp Sheet. (*Mining.*) A large sheet placed across the gate road to divert the course of the air.

Dam Punch. (*Dentistry.*) A cutting punch, for perforating coffer-dam rubber, to be used in excluding saliva from a tooth while being filled. It has on one jaw a solid cone which cuts against either one of a series of perforations of graded sizes. The die may be rotated to bring either hole beneath the punch. Stretching enlarges the size of the hole to go over a tooth. *Dr. Ainsworth.*

Fig. 781.



Dam Punch.

Dan'cing Flame. A small drum has a very delicately sensitive elastic skin stretched over it. A stream of gas passed through this drum will burn as usual till some one begins to sing near it, when the flame, under the influence of the vibrating skin, commences to shake in a manner which is varied indefinitely, according to the pitch and intensity of the notes of the tune.

Dan'iell Bat'te-ry. (*Electricity.*) One having its zinc in sulphuric acid, and its copper in sulphate of copper, with an intervening porous cell. "The most perfect battery yet invented." *Niaudet.*

See CONSTANT BATTERY.

Dark Tent. A portable dark chamber for photographers in the field. It is mounted on a light tripod stand. The tent, camera, trays, and plate pack in a box. The windows are of orange-colored silk oil-cloth, protected by yellow cloth.

Two forms, for buggy and for hand respectively, are made.

Fig. 782.

Robbin's Dark Tent.

Darn'ing Ma-chine'. A machine for darning stockings, clothing, etc. The article or fabric to be darned is held between notched blocks, which throw it into corrugations so that the series of needles carried by a reciprocating needle-bar will pass through and through portions of the fabric.

Fig. 782.

Darning Machine.

The eye-pointed needles move in grooves in the blocks, their eyes in the same horizontal plane, and when they are passed through the fabric are all threaded by the same thread. This thread is then drawn out in loops from between each needle, and each loop is placed on a pin of a loop-holder (shown to the left) adjustable to or from the work-holding blocks to adapt the loop to the size of the hole, and on the return movement of the needle bar each needle draws a doubled loop through the fabric at each side of the hole to be darned, and leaves the thread extended across the hole. The loops of thread are then cut at the eyes of the needles and the fabric is turned on the holding blocks and clamped, so that the needles in their next movement will draw the loops then to be formed across and interweave them with the loops of thread or yarn previously laid by the needles.

Fig. 784.

Dash Lamp.

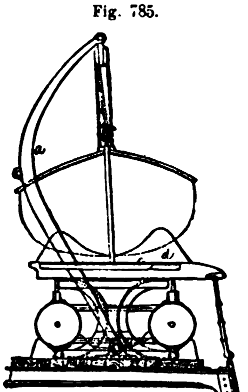
Dash Lamp. A lamp for the dash-board of a vehicle.

Daub'ing. (*Leather.*) Or dubbing. A mixture of tallow with either neat's-foot oil or sperm oil. With it dampened leather is coated, rendering the leather supple and impervious to water. *Stuffing.*

Dav'it. The boat-lowering and hoisting apparatus of the vessels of the American Steamship Company (British) is shown in Fig. 785.

The davits *a* are of round iron bent to the form shown, and hinged to brackets *b* on the deck. Each davit passes through a slot in a horizontal guide *c*, attached to suitable standards, and connected with the hand-rail of the ship. The boat is slung from eyes in the heads of the davits by suitable tackle, and is supported upon the standards by blocks *d*. These blocks are hinged to the standards, and the davits are kept in the ordinary position by a key and pin passing through the slot. When it is desired to lower a boat the pin and key are removed, the supporting blocks thrown over on their hinges, and the davits fall forward, throwing the boat clear of the ship's side. It can then be lowered by the tackle. The illustration also shows the form and position on board, of the sheet-iron rafts which these vessels all carry. The rafts are stowed under the boats, the whole being very compactly arranged, but always ready for an emergency.

Fig. 785.



Ship's Davit.
(American Steamship Co)

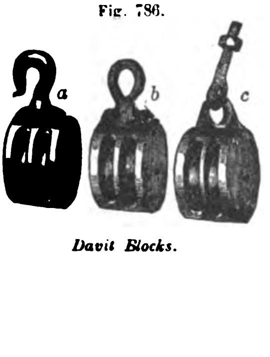
See Boat-lowering Apparatus, p. 114, *supra*; Davit, p. 678, "*Mech. Dict.*"; Boat-lowering Davits, p. 314, *Ibid.*

Dav'it Block. (*Nautical.*) One specially adapted for the tackle of ships' davits. The figure shows three kinds.

a. Swivel-hook block.
b. Swivel-eye block.
c. Screw-bolt and nut-block

Other davit-blocks have beckets to complete the combinations. See also Detaching Hook.

Fig. 786.



Davit Blocks.

Dead Blocks. (*Railway.*) Blocks projecting from the end of a freight car to receive the concussion when the buffer springs are compressed.

Dead Lock. 1. One having a supplementary bolt which acts as a detent to the main bolt to prevent its being moved even by the key.

2. (*Railway.*) A car-door lock operated in each direction by the key alone.

Dead Stroke Ham'mer. A hammer the stroke of which is not affected by the recoil of the crank or helve by which it is operated. Fig. 1600, p. 680, "*Mech. Dict.*"

Hull & Belden, * "*Engineering & Mining Jour.*," xxiii. 338.

Dead Weight. The weight of rolling stock, the live weight being the *load.* The following is from the report of Captain Galton, one of the British Commission at the Philadelphia Exhibition, 1876: —

The following Table shows a Comparison between the Weights and Carrying Capacity of some Railway Cars: —

Gage.	Weight of Car in lbs.	Capacity in lbs.	Total Weight.	Proportion of Dead Weight to Paying Loads.
Flat Car.				
4′ 8½″	16,000	20,000	36,000	1 to 1.25
3′.	7,500	19,000	26,500	1 to 2.5
Box Car.				
4′ 8″.	17,000	20,000	37,000	1 to 1.17
3′.	10,000	17,600	27,600	1 to 1.6
Coal Car.				
4′ 8½″	17,000	30,000	47,000	1 to 1.7
3′.	9,000	20,000	29,000	1 to 2.2

Deal Frame. A saw-mill for ripping pine logs into boards, p. 2042, and Fig. 1601, p. 680, "*Mech. Dict.*"

Ransome, Br. . . .	* "*Engineering*," xxv. 424.
Worssam, Br.	* "*Engineering*," xxvi. 490.

De'bris E-vac'u-a-tor. (*Surgical.*) An instrument for removing powder and fragments of calculi after crushing, in the operation of lithotrity.

The following may be found on pp. 44, 45, Part III., *Tiemann's* "*Armamentarium Chirurgicum*": —

Nelaton's evacuating apparatus.
Van Buren's debris syringe.
Glover's evacuating apparatus.
Tiemann's debris tube and obturator.
Van Buren's evacuating catheter.
Tiemann's double current catheter.
Nott's double current catheter.

See also Stringes in same work. See also Chip Stringe, *supra* and list under Surgical Instruments.

De-cal'co-ma'nie. The art of ornamenting by transfer.

De-can'ter. 1. An apparatus designed by Evrard, of St. Etienne, for sorting the tailings of coal washings.

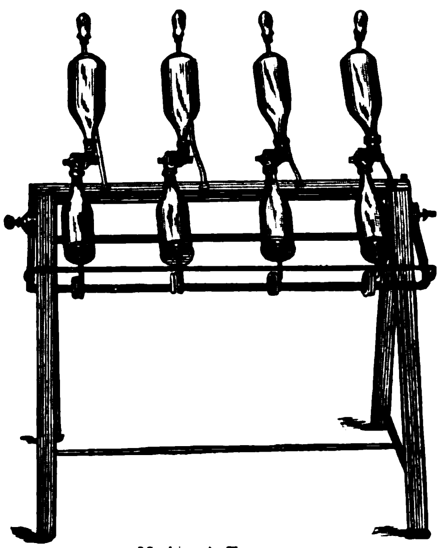
Althan's report in Group I., "*Centennial Exhibition Report*," * vol. iii., p. 297.

2. A glass bottle to contain wine at table.

3. An apparatus for transfusion of wine.

The machine by Tricout & Co., of Reims, is constructed of unoxdizable material, and, being for the champagne cellar, operates without the loss of gas. A machine with 4 faucets operates on 1,500 pint bottles per day. The full bottles being beneath and the empty ones above, a turn of the handles reverses the relative position, and the wine passes into the other bottles. See Fig. 787.

Fig. 787.



Machine à Transvaser.

De-cap'i-ta'ting Hook. (*Surgical.*) A curved instrument, sharp in the concave, for beheading the fetus in cases of obstructed labor.

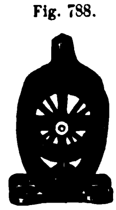
Fig. 527, Part III., *Tiemann's "Armam. Chirurgicum."*

Dec'i-mal Meas'ur-ing Ma-chine'. A lever scale in which the weight and the object weighed are as 1 : 10. The *bascule-décimale* is much used in France. Made by Paupier, of Paris; Duru, of Bordeaux.

Kerr, Br. . . . . * *"Engineer,"* xliii. 162.

Deck Block. (*Nautical.*) One attached to the deck, as in the illustration, in which a small block is pivoted to a base-piece, which is bolted to the deck.

Fig. 788.



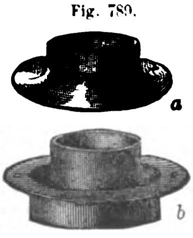
Deck Block.

Other deck blocks are connected by beckets to deck-hooks, or by hooks to deck-eyes.

Deck Hoist'ing En'gine. (*Nautical.*) A hoisting apparatus on deck, used for getting in and out cargo and stores, getting guns, etc., aboard. It is also used on the deck of a lighter for pile-driving, or snag-lifting. As shown, Fig. 790, it is intended for working from two different points. The drums are worked independently of each other by friction, and the operations of hoisting, lowering, and stopping are controlled by the use of levers on the side of the engine, no foot-brake being needed.

Deck Pipe. One leading through a deck, affording a passage for a smoke-pipe, wind-sail, etc.

Fig. 789.

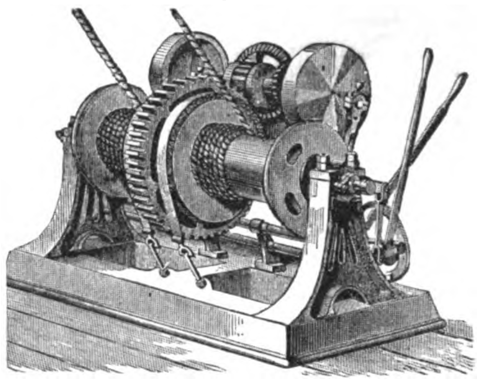


Deck Pipes.

a. Plain deck pipe.
b. Water deck pipe.

Deck Pump. One arranged to screw into a metallic deck-plate when required for use, and to unship the whole working gear when not required; a cap covering the opening in the plate, and leaving the deck perfectly clear.

Fig. 790.



Bacon's Deck-hoisting Engine.

De-com-pos'ing Fur'nace. A chemical furnace. Used in the soda industry in decomposing chloride of sodium with sulphuric acid.

Jones & Walsh's decomposing furnace, Middlesborough, England. Paper read before Newcastle Chemical Society, March 23, 1876. Reported in *"Scientific American Sup.,"* 305. See also Professor Jenkins's Report, *"Paris Exposition Reports,"* 1878, iv., pp. 44 *et seq.*

De-cor'ti-ca'tor. An instrument or machine for removing the skin, such as the bran of wheat or other grain; the surplus bark or moss from neglected fruit-trees, etc.

Glove and bow, *Sabate*, * *"Scientific American,"* xxxvi. 182.

De-coy'. When artificial, a wooden, tin, or real-plumaged bird to induce wild birds to settle within range of the ambushed gunner.

Ducks, brants, pigeon, plover, curlew, snipe, are among the commoner kinds.

Decoy duck, *Redmond* * *"Scientific American,"* xli. 247.

Deep Sea Ther-mom'e-ter. One for ascertaining the temperature of the sea at any required depth. It has in some respects the features of a sounding instrument, as the knowledge of the depth is one part of the problem. See SOUNDING APPARATUS, pp. 2247–2249, " *Mech. Dict.*"

The thermometer is contained in a heavy brass frame, finished at the bottom by a propeller-like spiral fan. The fan revolves as it passes through the water, and a registering device put in motion. The required depth being reached, the motion is stopped, by which action the thermometer is turned over and the temperature registered.

Subject discussed in a paper by Dr. Mann, read before the Society of Arts, and reproduced in *"Scientific American Supplement,"* 934, 935.

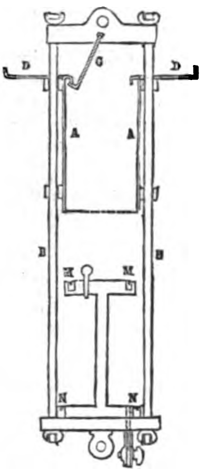
Negretti & Zambra . . * *"Scientific American,"* xxxix. 83.

Deep Wa'ter Bot'tle. A bottle for fetching up sea-water from determinate depths to ascertain its saltness, aërial contents, and temperature.

Four Swedish instruments for this purpose were shown at the Philadelphia Exhibition in 1876. They are all grounded on the same principle. The water-specimen is drawn up in a cylindrical vessel, the walls of which form a separate piece, which, while the instrument is sinking in the water, is raised above the bottom and top of the vessel, but falls and unites with these at the depth from which the sample is required. Thus during the descent the water passes freely through the cylinder, but at the depth required the different parts of the vessel come together and inclose therein the water, which is thus obtained altogether unmixed with the water of the upper strata.

The instrument of Ekman of Stockholm, is shown in Fig. 791. *a* is the open cylinder, sliding on two bars *b b*: before the instrument is immersed in the water, the cylinder is raised and suspended by the hook *c*. Attached to the cylinder is a horizontal flange, *d d*, the size of which is so calculated, that its resistance against the water, when the instrument is descending at the rate of about 6 decimeters per second, is equal to the combined weight of the flange and cylinder. As the instrument really sinks faster than that, the cylinder, as soon as the descent begins, is immediately raised somewhat more, and the hook *c* falls aside. The cylinder nevertheless still continues raised in consequence of the water's resistance to the flange, as long as the instrument continues to sink; but as soon as the line to which it is fastened is hauled in, the cylinder falls. Its under and upper (down-turned) edges then enter into the ring-shaped grooves *m m* and *n n* in the bottom and top, which are filled with a compound of wax and tallow, in which marks have been previously made with the cylinder. The cylinder contains the last body of water which occupied it: that at the level where its downward course was arrested.

Fig. 791.



Ekman's Deep-water Bottle.

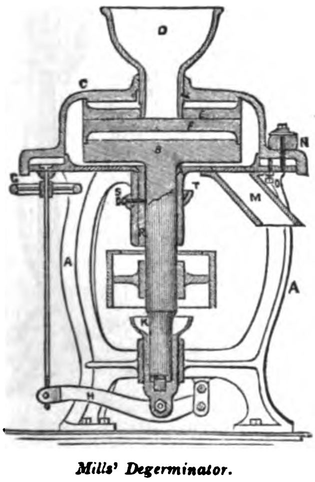
Def'e-ca'tor. An apparatus for removing the feculencies of juices and sirups. See p. 683, "*Mech. Dict.*"

Vibrans (sucre).
"*Technologiste*," xxxvii. 323.

De-flec-tom'e-ter. Askenasy's apparatus for measuring the curve of deflection of a metallic bridge under a passing load, and used upon a bridge over the Rhine at Mayence, has a drum attached by a clamp to the bridge and moved by interior clock-work to rotate it once in 10 minutes. At the approach of a train the detent is released and the drum commences to rotate. By a special arrangement the rate of movement of the drum may be regulated to obtain curves of equal length for trains of different speeds. The drum is covered with a roll of paper gummed at the edges, so as to answer for numerous experiments, the portion covered by the curve being detached after each experiment. The tracing is made by a pencil in a stationary position, the drum oscillating vertically in front of it. Shown in Class 54, Group VI., Paris Universal Exposition. See also EXTENSION MEASURING APPARATUS.

De-form'i-ty Ap'pa-ra'tus. (*Surgical.*) Instruments for curvature of the spine or legs, for club feet (*talipes*), etc., are classed under this head.

Fig. 792.



Mills' Degerminator.

See CURVATURE APPARATUS, CLUB-FOOT APPARATUS, TORTICOLLIS, TALIPES APPARATUS, etc.

De-germ'i-na'tor. (*Milling.*) A mill for rupturing the wheat berry along its crease to detach the germ, which is afterwards separated from the split wheat by a short reel covered with wire cloth.

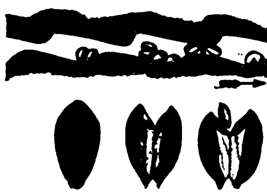
Mills' degerminator is of iron, with two furrowed disks 16″ in diameter, of the same metal, between which the wheat is rolled and cracked, freeing the germ. The disks *E F* have marginal rounded corrugations, with smooth depressed bosoms. Fig. 792.

A is the frame; the spindle-head *B*, resting in the oil-pot *K*, supports the runner *F*, which is raised and lowered by the lighter-bar *H* and handwheel *G*.

D is the hopper; *C* the husk which carries the upper stationary disk *E*, which is trammed to the lower one by the set-screw *O* and bolt *N*. *T* is the tallow-pot and *S* a set-screw regulating the gib *R*. *M* is the delivery spout.

The wheat, previously graded as to size, rolls on its side along the bosom till it reaches the corrugated skirt; ascends the easy incline (see sectional view), rotating on its axis, until it bears with its creased side on one or the other disk, when it is split open and the germ escapes from the broken grain.

Fig. 793.



Sectional View of Disks in Degerminator. Wheat Natural and Degerminated.

The figures are — a vertical section; a section illustrating the action of the disks; and wheat in its natural and degerminated conditions.

De-gla'zing. (*Glass.*) The process of giving a dull or ground surface to glass by acid or mechanical means.

De-gum'ming Ma-chine'. A machine used in treating silk before dyeing. See SILK-DEGUMMING MACHINE.

De la Rue Bat'te-ry. (*Electricity.*) A battery in which chloride of silver forms the negative. See CHLORIDE OF SILVER BATTERY.

Delft Ware. (*Ceramics.*) Ware made at the city of Delft in Holland, which has been celebrated for its potteries for over three centuries. As England was largely supplied from that city, the word became a synonym for table-ware pottery.

Ware of the better kinds was made as thin as China porcelain, pure in color and of most various and fantastic shapes; sets of dishes to represent all the viands served upon them being among the number.

Pottery probably came from Delft to England.

"Crockery, china, and delft" was the refrain of an English song.

Dem'i-fixed. Or *semi-fixed*. Said of a steam-engine which is not intended to be stationary, but which has supports of such a nature that it may be moved by proper appliances, but has not wheels for transportation like the *portable* engine.

Dem'on-stra'tion Len'ses. (*Optics.*) A set of lenses showing the various forms, viz.: —

Double concave.	Plano concave.
Double convex.	Meniscus convex.
Plano convex.	Meniscus concave.

Den-sim'e-ter. An instrument for ascertaining the density or specific gravity of an object.

1. The instrument of Colonel Mallet and M. Bianchi for ascertaining the specific gravity of gunpowder, is described on p. 685, "*Mech. Dict.*"

The densimeters used in the office of the constructor of ordnance, U. S. A., for determining the specific gravities of metal for cannon, and for ascertaining the specific gravities of large grained powders, are described and illustrated in the

"*Report of the Chief of Ordnance, U. S. A.*," 1877, iii. pp. 394-400, and Plates I., II., accompanying.

In the British service the density of powder is rigorously determined, each cake being tested.

The density of rifle powder is fixed at	1.725
Pebble powder	1.77 to 1.81
R. L. G.	1.67

The *densimetre à mercure* is employed in the Russian arsenals to obtain the specific gravity of gunpowder Shown at Plate II. accompanying Appendix 1 (c), "*Ordnance Report*," 1877.

See also the mercury densimeter of Colonel Mallet of the French army, "*Ordnance Report*," 1879, Appendix 1., p. 111, and Plate VI., Fig. 14.

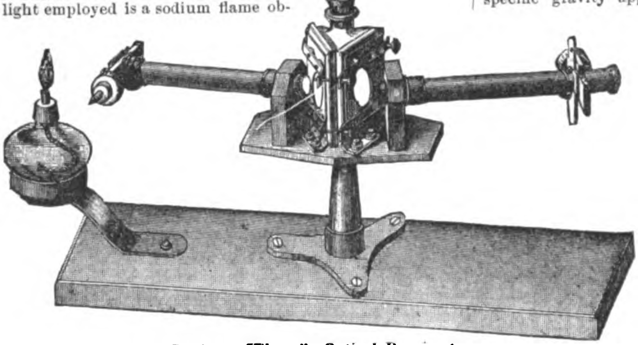
Densimeter for gunpowder, Br. . * "*Engineering*," xxv. 236.

2. The instrument invented by Professor Hilgard of the U. S. Coast Survey, for determining the density of sea-water by its refractive power, is shown in Fig. 794. It is an efficient substitute for the hydrometer or salinometer, as it is not affected by the motion of the ship. See U. S. Coast Survey Report, "Methods and Results," Appendix No. 10, Report for 1877.

The Hilgard densimeter follows the suggestion of Prof. Wolcott Gibbs for an apparatus for the "Hassler" in 1871, 1872.

Fig. 794.

The basis of this instrument is the change in the refractive power of a saline solution of greater or less density. The instrument consists of a hollow prism filled with the water under observation, transmitting from a collimating telescope a line of monochromatic light to an observing-telescope in which the refracted position of that line is read by means of a micrometer. The monochromatic light employed is a sodium flame ob-



Professor Hilgard's Optical Densimeter.

tained by adding a small proportion of a solution of common salt to the alcohol of the lamp. The temperature of the liquid under observation is found by means of a thermometer inserted through the neck of the hollow prism, but which is withdrawn when the optical observation is made.

The glass prism rests on three little knobs so as to have a firm support. Attached to the stand carrying the telescopes are two guides, by means of which the prism is made always to occupy exactly the same position, so that all observations are made under the same angle. A small thumb-screw on the side of the prism, not seen in the plate, forces the prism closely into the guides.

The slit in the focus of the collimating lens is very readily made by drawing a fine line through a black coating (such as engravers' etching ground) on the inner surface of a glass diaphragm. In the illustration this diaphragm appears mounted on a micrometer slide, which was deemed desirable for general experimental purposes, in order to make the observations under the condition of equal refraction on both faces of the prism: but in the instruments for practical use on board ship the slit is in a fixed position. The image of the slit in the field of the observing-telescope is a sharply-defined bright-yellow line, which is pointed upon with a fine dark spider line carried by the micrometer.

The relation of the angle of refraction to the density of sea-water having been ascertained experimentally in the office, as well as the temperature-corrections for different degrees of salinity, it is only necessary to determine for each instrument the difference of micrometer reading between distilled water and sea-water of an ascertained specific gravity, and from this and the ascertained law construct two tables for its use: one giving the reduction to the standard temperature of 60° Fahr., in terms of micrometer-divisions, the other giving the specific gravity for the difference of reduced readings on distilled water and on the specimen of sea-water under observation.

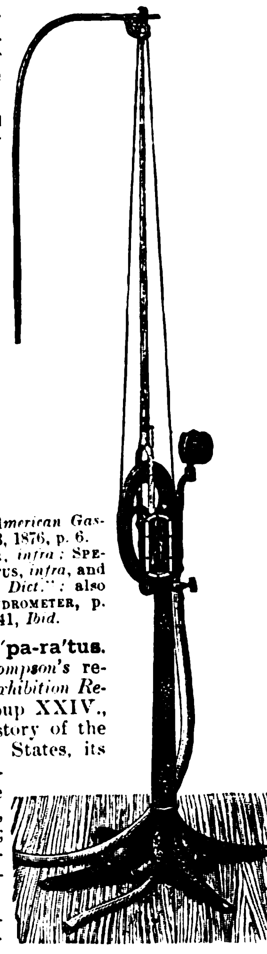
3. Huch's densimeter is adapted to indicate in either degrees Baumé or Brix, the exact density of saccharine solutions continuously during the whole operation of boiling.

"A chamber like a salinometer tube or water-gage is attached to the head of the boiler, and in this is a floating areometer. A platinum weight is suspended from the areometer, and being in the solution, which is continually renewed, the areometer index finger shows constantly the graduation corresponding to the gravity of the sirup.— "*Dingler's Journal*." Reproduced in "*Scientific American Sup.*," * 2560.

Den'si-ty. (*Electricity.*) Used erroneously as an equivalent to *intensity* or *tension*. The same *quantity* of electricity may pass through different sized wires, but the *density* of the current passing through the smaller wire will be greater than the density of the current passing through the larger wire. Other things being equal, the density bears an inverse proportion to the sectional area of the conductor.

Den'si-ty and Spe-cif'ic Grav'i-ty Ap'pa-ra'tus. An apparatus for testing as to relative and actual weight.

Fig. 795.



White's Water Motor Dental Engine.

Goodwin's density and specific gravity apparatus for gas testing, "*American Gas-light Journal*," * July 3, 1876, p. 6.

See also DENSIMETER, *infra*; SPECIFIC GRAVITY APPARATUS, *infra*, and pp. 2255-2257, "*Mech. Dict.*"; also BALANCE, p. 212; HYDROMETER, p. 1153; AREOMETER, p. 141, *Ibid.*

Den'tal Ap'pa-ra'tus. See *Dr. J. H. Thompson's* report," *Centennial Exhibition Reports*," vol. vii., Group XXIV., p. 11, *et seq.* "History of the art in the United States, its progress and modern practice. Base plates of Vulcanite, Celluloid, etc.; Dentures; Mechanical and Operative Dentistry."

Dental foil manufacture, *Williams*, * "*Sc. Amer.*," xxxv. 18.

See also list on p. 685, "*Mech. Dict.*"

Den'tal En'gine. A machine for running the dental burs, drills, etc., which act by rotation. In the ordinary dental engine, the S. S. White and Morrison patterns, the power is by treadle to a fly-wheel and a band from this to a grooved pulley on the summit of the column, thence by flexible shaft to the drill. The illustration, Fig. 795, shows the application of a water-motor engine, which has from 15 to 20 pounds pressure. The multiplying effect is such that a speed of 3,000 revolutions per minute of the bur is attained.

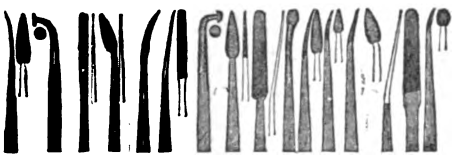
A counterbalance is connected with the rocking arm by a chain, the links of which are caught over a hook or pin. By lengthening or shortening the chain the tension may be varied at pleasure; or the counterbalance may be so adjusted that the rocking arm will remain in any position in which it is placed.

The water motor is attached to the portable stand and swivels or turns in the top of the column. The frame of the motor carries the driving wheel to the trunnions of which the rocking arm is hinged. The supply and waste water-pipes are shown in the cut.

Petit, Electro-magnetic, * "*Scientific American*," xxxiv. 259.
Allen, Plugger, electric, * "*Telegraphic Journal*," iv. 209.

Den'tal File. These are very numerous, minute, and peculiar, adapted for plug finishing, for lateral and crown cavities, etc. See Fig. 796.

Fig. 796.

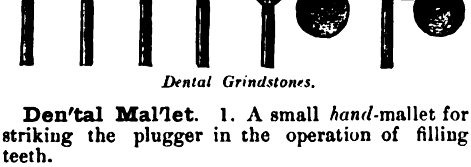


Murphy's Dental Files.

Den'tal Grind'stone. Grinding stones fastened on mandrels and made in a variety of forms for the delicate and minute operations of mechanical and operative dentistry.

They are made of Arkansas stone, Hindostan stone, or Scotch stone (Water of Ayr).

Fig. 797.



Dental Grindstones.

Den'tal Mal'let. 1. A small *hand*-mallet for striking the plugger in the operation of filling teeth.

A *live-blow* mallet is of steel.
Wood-cased mallets are of seasoned laurel or brier root, filled with metal a little harder than pure lead.
Metal-cased mallets are seamless tubes filled with lead, and give a *dull blow*. They are in sizes 3, 4, 6 ounces.
Tin mallets are made in sizes $1\frac{1}{2}$, $2\frac{1}{2}$, $3\frac{1}{2}$ ounces
Composition mallets are of an alloy a little harder than lead.

2. An *automatic* hammer, operated by spring interiorly. See Figs. 1610, 1611, p. 686, "*Mech. Dict.*"; also Figs. 3835, 3836, p. 1749, *Ibid.*

3. An *electric* mallet, in which the impulse is given by electro-magnetism. See p. 1749, "*Mech. Dict.*," and instances cited. Fig. 3837, p. 1750, *Ibid.*

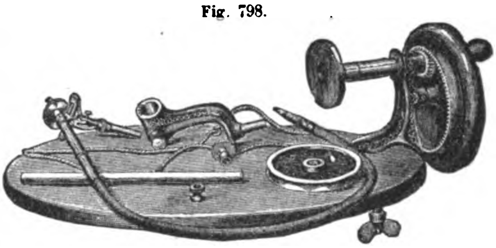
Spencer . . . . . * "*Scientific American*," xxxv. 18.

Den'ti-phone. An instrument for conveying audible pulsations of the air by way of the teeth to the bony structure of the head, and thus to the ear. See AUDIPHONE.

Den'tist's Lathe. A small table lathe adapted for turning, grinding, drilling, polishing, etc., in mechanical dentistry. The *dental engine* occupies the same relation in operative dentistry.

The apparatus shown in Fig. 798 will perform the duties of both laboratory and operative lathe. It is shown

Fig. 798.



White's Dentist's Lathe.

mounted as a lathe proper, but the parts are shown lying upon the table which, when mounted, constitute the apparatus as an engine or drill, having the functions shown in Fig 795.

De-ox'yd-ized Bronze. A mixture of copper and tin, conpounded under certain conditions of proximate purity, and with a certain flux.

It is said to possess superior malleability, approaching gold alloys in this respect, while its tenacity and solidity are very great. It flows readily, is easily handled, and is capable of being re-worked. It is also receptive of a high, smooth finish; wears well, and is used for machine journals, car bearings, etc. It is now in use at the Philadelphia Mint.

De-phos'pho-riz-ing Pro'cess. (*Metallurgy.*) A process for the elimination of phosphorus from iron in the refining furnace.

Snelus, in England, patented in 1872 the use of lime or of limestone for the lining of furnaces, in which iron is refined while fluid.
Thomas & Gilchrist patented in 1879 a basic calcareous or magnesian lining for convertors, adding lime or oxide of iron and lime to the charge. See BASIC LINING.
The U. S. Patent of Jacob Reese is dated 1866.
Kunkel's U. S. Patent, dated 1866, claims the use of dolomite in the treatment of iron.
See also Hargreave's English Patent, 2461, of 1868.
See discussion in "*American Manufacturer*," June 6, 1879, p. 10, etc., and authorities therein cited.

Dep'i-la-tor. (*Surgical.*) An instrument, tweezers, for example, for pulling hairs.

Henry's depilating forceps . . . . . . p. 2, Part II.
Cilia forceps . . . . p. 2, Part II.
Tiemann's "*Armamentarium Chirurgicum.*"

De-pol'ish-ing. (*Ceramics.*) A term applied to the process of removing the vitreous glaze from porcelain, and leaving it with the peculiar dull luster of the ordinary surface of ivory. It is known as ivory porcelain. Gold work ornaments show upon it with a fine effect.

The parallel process in glass working is called *deglazing*.

Lockert on . . . . "*Technologiste*," xl. 51.

De-pos'it-ing Dock. (*Hydraulic Engineering.*) A caisson for raising vessels clear of the water and depositing them on staging for examination, cleaning, or repairs, the caisson retiring to repeat the operation on other vessels.

The depositing dock of *Clark & Standfield*, of London, built for the Russian Government at Nicolaieff on the Black Sea, is shown in Plate IX. Its duty is to raise or lower vessels, to deposit them upon fixed timber staging and again remove them when required; also to lower into the water vessels built upon an even keel on such staging.

The staging on which the vessels are deposited consists of a number of parallel rows of piles driven into the ground in a direction transverse to the length of the vessel: the space between each row is clear and open and of sufficient width to receive the projecting pontons of the dock, which carry the vessel at a height somewhat above the top of the piles.

The pontons of the dock are tubular, parallel and fixed at one end to a longitudinal frame or floating girder: at the other end they are free so that the whole structure represents a comb, of which the pontons are the teeth and the girder the back. The dock is sunk beneath the vessel, and the water being pumped out the dock rises, carrying the vessel with it. It is then floated to the staging, the pontons entering into the openings between the stages, and the vessel itself with its gridiron and bilge-blocks being clear above them. A little water admitted into the pontons allows them to sink and deposit the vessel and its grid on the staging. The girder, to which the horizontal pontons are connected, and which form the floor of the dock, carries a row of hollow vertical cylinders of such a length that when the pontons are submerged beneath the vessel, the tops of the cylinders are a convenient height above water. A platform occupies the tops of the cylinders, and this vertical portion contains the engines, pumps, and valves for working the dock.

The stability of the structure is effected by an arrangement of parallel bars attached to a floating caisson at the back of the dock, so that while the dock is free to ascend or descend in the water it cannot move out of its horizontal position without capsizing the caisson, which is made sufficiently wide and heavy to render such movement impossible. The pontons have sufficient buoyancy to support the vessel without any assistance from the floating girder or vertical tubes. The latter are in fact carried by the girder.

Each of the pontons is divided into 6 independent water-tight compartments, irrespective of the compartments in the girder and vertical tubes, and the pontons vary in number in action from 15 to 30; the whole dock is divided into from 100 to 200 separate water-tight compartments connected with the pumps by independent pipes and valves. A number of compartments are horizontally sealed up, so that the structure cannot entirely sink even were the valves to be left open.

The dock is so constructed that it can be divided at mid-length into two halves, each provided with its own engine and pumps, and either part is capable of docking the other.

"*Engineer*"	* xlvi. 64; * 75.
"*Sc. Am. Supplement*"	* 392; * 661.

See also list under DOCK.

De-pres'sor. (*Surgical.*) A clamp or valve to hold an object out of the way during an operation.

Tongue depressor	Fig. 265 *b*, Part II.
Vaginal depressor	Fig. 246, 8, Part III.

Tiemann's "Armamentarium Chirurgicum."

Der-i-va'tion Reg'u-la'tor. (*Electricity.*) A form of *polyphote* regulator for voltaic arc lights in which the regulation is effected by the variations in the differences of potential in the lamp. There is but one regulating electro-magnet, with fine wire and *in derivation*. — "*Electrician.*"

The Gramme and Crompton regulators on the continuous current principle and the Mersanne, Gérard, and Lontin fed by alternating currents, are of the derivation order.

Der'ma-to-log'i-cal In'stru-ments. (*Surgical.*) Instruments for skin-grafting, etc. See *Tiemann's "Armamentarium Chirurgicum."*

Transplantation scissors	Fig. 291, Part I.
Nævus needle	Fig. 80, Part V.
Scarifying spud	Fig. 84, Part V.
Epilating forceps	Fig. 85, Part V.
Glass pleximeter	Fig. 90, Part V.
Piffard's needles	Figs. 82, 83, Part V.
Depilating forceps, etc.	Fig. 7, Part II.

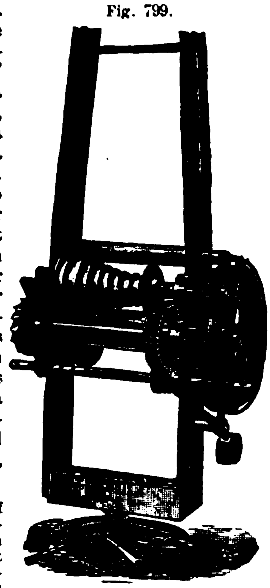
Dermopathic instruments are considered under ACUPUNCTURATOR, HYPODERMIC SYRINGE, SCARIFICATOR, LEECH ARTIFICIAL, DEPURATOR, CUPPING GLASS, etc.; also in "*Mech. Dict.*"

Der'rick. A species of hoisting apparatus: the term properly includes the machines which have an adjustable boom stayed from a central post which is held vertical by guys.

Mason	* "*Scientific Amer.*," xxxviii. 223.
Steam, *Lyman*	* "*Am. Manfr.*," June 27, 1879, p. 13.
Revolving	* "*Scientific American*," xlii. 114.

Der'rick Crab. The winch or hoisting arrangement at the foot of the leg of a derrick. The distinction made on p. 687, and elsewhere, "*Mech. Dict.*," being maintained — a *derrick* has one leg, with a swiveled post; a *shears* has two legs, a *crane* has a post and jib, or a curved jib which answers for both when a sufficient anchorage or base can be obtained to render a stay for the upper end of the post unnecessary; a *whin* has a vertical axis on which a rope winds and is moved by a horse sweep; a *capstan* has a vertical drum rotated by bars, etc.

Fig. 799.



Derrick Crab.

Fig. 799 shows one of Appleby's crabs for derricks, adapted to be run by hand cranks (not shown). The actual derrick shown is for 1½ tons and is erected in Columbo Harbor, Ceylon.

De-sil'ver-iz-ing Lead. A process used in reducing argentiferous galenas.

Lautenthal	"*Eng. & Mining Jour.*," xxx. 236.
Flach's zinc process	"*Scientific American*," xxxvi. 238.

Chair, *Taylor*	* "*Scientific American*," xxxv. 294.
Satchel, *Kaplan*	* "*Scientific American*," xl. 323.

Des'si-ca-tor. An apparatus, in a laboratory, for promoting the absorption of the moisture of bodies. A porcelain dish with capsules or watch glasses, under a bell-glass, an absorber of moisture being included under the bell.

The term is also applied — somewhat inaccurately — to a similar inclosure to keep substances dry while weighing.

A *bain-marie*, or a sand-bath, may be used.

De-sul'phur-iz'ing Fur'nace. A roasting furnace for ores containing sulphur. See p. 690, "*Mech. Dict.*," and CALCINING FURNACE; DECOMPOSING FURNACE; ROASTING FURNACE, etc., *supra et infra*.

Willard . . * "*Mining & Scientific Press*," xxxvii. 145.

De-tach'a-ble Tooth Saw. Another name for the *insertable tooth* saw.

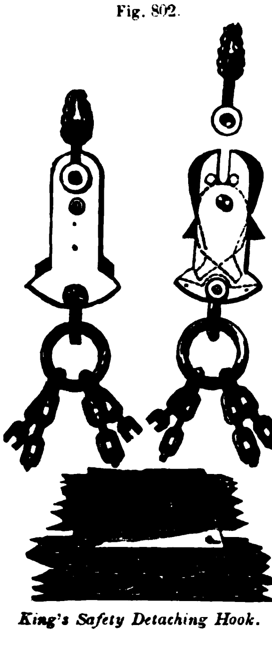
See 26 examples, Fig. 4593, p. 2035, "*Mech. Dict.*" Also as applied to stone saws, 20 examples in Fig. 5884, p. 2402. *Ibid.*

Brunet & Cochot's French patent, *Brevets*, vol. iv., Plate XV.

De-tach'ing Hook. 1. One for releasing the traces of a horse from the carriage. Referred to on p. 690, "*Mech. Dict.*"

2. One for casting loose the cage from the hoisting rope in case of overwinding in mine shafts.

Fig. 802.



King's Safety Detaching Hook.

King's safety detaching hook for mines and collieries, is shown in Fig. 802. It prevents the cage from passing over the wheel in case of overwinding, that is, when the steam-engine is not stopped in time. The figures show it as it appears at work, and as detached in the case of accident. Also the safety plate on which the cage remains suspended in case of becoming detached. 1500 of these hooks are said to be in use in British mines.

Fig. 803.

Cathcart's Detaching Hook.

3. One for releasing a boat from the davit tackle, as soon as the water is struck. Figs. 1596, 1597, p. 678, "*Mech. Dict.*"

Fig. 803 shows Captain Cathcart's detaching hook. It has a gravitating trigger which throws the ring out of the hook as soon as the weight is taken off the latter. The figure shows it in both conditions.

De-tect'or Gal-va-nom'e-ter. (*Electricity.*) A low resistance galvanometer used in testing condition of wires, etc., in laboratories and telegraph offices.

Dev'il's Claw. (*Nautical.*) A hook used to stopper the cable when the windlass is wanted for other uses.

De-vit'ri-fi-ca'tion. (*Glass.*) A process of subjecting glass for a long time to a high heat renders it opaque and hard like white porcelain.

Reaumur, in 1727, succeeded in the experiment by exposing it as described for 12 hours. It becomes extremely hard, acquires a noticeable fibrous structure, becomes a better electrical conductor. Glasses with a potassic base are more amenable to the process than those with a sodic base.

Bottle and window glass devitrify readily, and the contents of a pot in working will sometimes acquire the quality, losing its transparency.

Di'ag-nos'tic In'stru-ments. (*Surgical.*) Those for exploring, to ascertain the condition, natural or morbid, of parts.

The list embraces the following. They may be found in the specific lists (surgical), and under their specific titles, *infra* and in "*Mech. Dict.*" Also in Part I., *Tiemann's* "*Armamentarium Chirurgicum*," on the pages noted: —

Clinical thermometers	Page 75.
Urinary examination apparatus	Page 77.
Auscultation instruments, stethoscopes, pleximeter, and percussor	Page 81.
Stethometer	Page 84.
Cystometer	Page 84.
Cardiameter	Page 84.

Sphygmometer	Page 87.
Hæmarheumoscope	Page 88.
Dynamometer	Pages 88, 285.
Piezometer	Page 88.
Microscope	See *infra*.

Di'a-gom'e-ter. Palmieri's diagometer is an instrument designed to test the quality of oils, and is based upon the principle that olive oil is a poorer conductor of electricity than any other oil in common use. The oil is poured into a glass vessel, into which dip two brass rods which are kept the same distance apart while experimenting with different oils which are in succession poured into the glass. An electroscope determines the relative conductivity of the oils as the electricity passes from point to point through the oil.

The instrument may also be employed to detect the presence of cotton in silk fabrics. — *Professor Ricco.*

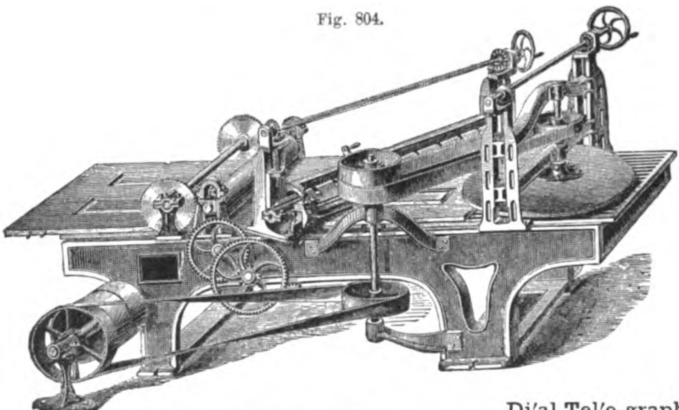
"*Scientific American*" . . . . . . * xxxix. 185.

Di-ag'o-nal Pla'ner. A wood-planing machine in which the planing cylinder has an oblique position relatively to the line of motion of the stuff under treatment. The machine is especially intended as a substitute for hand-planes in making doors, frames, blinds, etc. A door is shown as passing through the machine, beneath the feed-roller, then under the diagonal planing cylinder, and then below the polishing disk. Fig. 804.

"*Mining and Scientific Press*" . . . . * xxxv. 49

"*Manufacturer and Builder*" . . . . * x. 151.

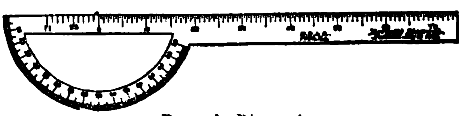
Fig. 804.



Diagonal Planing and Polishing Machine.

Di'a-graph. A platting instrument, combining a protractor and scale.

Fig. 805.



Barnett's Diagraph.

Dial. A graduated circle with numbers or point marks.

See illustrated article "*Cadrans Solitaire*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," vol. iv., ed. 1877.

One found at Tusculum	* "*Scientific American Sup.*," 4098.
Self recording, *Davis*	* "*Scientific American Sup.*," 616.
Self registering sun, Br.	"'*Scientific American*," xxxvii. 97.
Illuminated	"*Scientific Amer.*," xxxix. 402.
Luminous watch . . .	"*Scientific Amer. Sup.*," 2822.

(*Add.*) 6. (*Mining.*) A compass for taking bearings in mines.

7. (*Lock.*) The lettered or numbered face-plate of a permutation lock.

8. Various modes have been proposed and some of them put in practice for illuminating dials and signs at night.

Recordon's plan for watch dials is to place a Geissler tube containing a gas which gives a brilliant light in front of the dial. A battery about the size of a thimble is attached as an ornament to the watch chain. To consult the watch, press a spring and the current passes and illuminates the dial. The battery lasts a year in operation.

A plan for an illuminated public clock dial, is to employ a magic lantern to throw the picture of a common watch upon a suitable white screen in a public place.

Illumination of a town clock dial by gas in the rear of the glass dial plate is common; also by reflected light, p. 1171, "*Mech. Dict.*"

Phosphorescent paints for luminous dials and signs: —

1. Heat strontium theo-sulphate for 15 minutes over a Bunsen lamp and then for 5 minutes over a blast lamp.

Or 2. Heat equal parts of strontium carbonate and lac sulphuris gently for 5 minutes and then strongly for 25 minutes over a Bunsen lamp, and then over a blast lamp for 5 minutes.

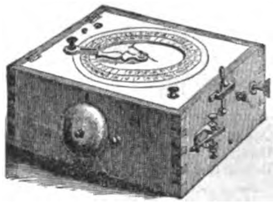
Or 3. Precipitate strong aqueous solution of strontium chloride by means of sulphuric acid; dry the precipitate and heat to redness for some time in a current of hydrogen. Then over a Bunsen lamp for 10 minutes, and 20 minutes over a blast lamp.

Mix either of these with pure paraffine for use as a paint and expose to sunlight.

1 and 2 give greenish phosphorescence; 3 a bluish phosphorescence.

The luminous clock dial of M. Balmain, of Paris, is painted with a composition into which enters a phosphorescent salt; storing up the light of day to give it out at night. Sulphide of calcium in varnish is stated as the preferable agent.

Fig. 806.



Dial Telegraph.

Di'al Tel'e-graph. A simple form of telegraph adapted for the use of persons who do not know the special systems or alphabets. It is only necessary to move the handle to any letter or number on the dial and a delicate needle in a corresponding instrument will point to the same letter. The needle of the receiving instrument is shown in the center of the dial, the sending handle on the exterior. The needle of the receiving apparatus passes through the center of the hollow shaft of the transmitting apparatus, and the same dial answers for both. A call-bell is attached to the instrument.

Di-al'y-sis Ap'pa-ra'tus. An apparatus consisting of a large flask with a faucet, a series of glass funnels and connecting siphons, and a final receiving vessel. Each funnel has a plaited filter made of parchment paper.

The process is described and the apparatus represented in "*Journ. de Pharm. et Chim.*" Reproduced in "*Scientific American Supplement*," * 2672.

Di'a-mag-net'ic. (*Electricity.*) A term applied to substances like glass, resin, bismuth, the poles of which tend to move from the strong to the weak places of electro-magnetic force. — *Gordon.*

Dia'mond. Mechanical uses of the diamond are noted in the following references: —

Millstone dresser, *Millot*	* "*Engineer*," xlvi. 255.
Drill (Pa. Co.)	* "*Scientific American Sup.*," 495.
Boring machine, *Penn. Diam. Drill Co.*	* "*Engineer*," xli. 447.

Technical uses of . . .	"*Iron Age*," xviii., Dec. 14, p. 5.

See also pp. 696, 697, "*Mech. Dict.*"

Dia'mond, Ar'ti-fi'cial. A gem made of a clear white strass.

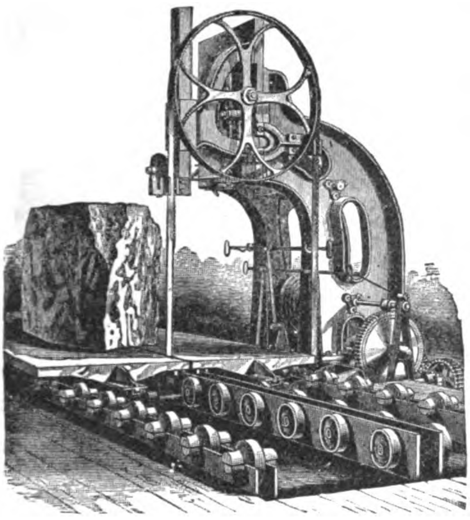
Loysel's paste:	Pure silica	100
	Red oxide of lead	150
	Potash, calcined	30
	Borax, calcined	10
	Arsenious acid	1

The paste has great brilliancy, refractive and dispersive powers and a specific gravity similar to that of the oriental diamond. It fuses at a moderate heat, and acquires great brilliancy by keeping in a fused state for several days to expel the superabundant alkali and perfect the refining.

Dia'mond Band'-saw. An application of the band-saw to the cutting of stone. The endless blade is set with diamonds and propelled by mechanism, which at the same time moves a bed-plate carrying the material to be sawn.

For sawing curves and scrolls narrow blades are used. The feed is made variable according to the kind of stone and its thickness. On one occasion, at the American Institute Fair, it sawed a block of

Fig. 807.



Diamond Band Stone-cutting Saw.

Newark brownstone, 3′ 2½″ × 3′ 3″, a superficial area of cut of 1,501¼ sq. inches in 22 minutes.

For circular stone saw see Fig. 5883, p. 2401, "*Mech. Dict.*"

Dia'mond Pan'eled Stone Work. (*Stone Cutting.*) Stone ashlar with the margin tooled and the face rising gradually in four triangular planes to an apex at the center.

The *sunk* diamond panel has a sunken margin, while the *raised* diamond panel starts immediately from the inner line of the usual tooled margin.

Dia'mond Stone Saw. A saw furnished on its edge with diamonds and used in cutting stone.

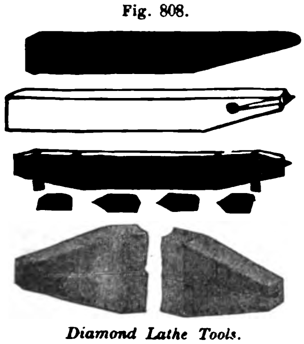
See Diamond Band Saw, Fig. 807; Stone Saw Circular, Fig. 5883, p. 2401, "*Mech. Dict.*"
Young's diamond reciprocating stone saw. *Hinton's* Report, "*Vienna Exposition Reports*," 1872, vol. iv., section D, p. 16.
Willard, Whittier, & Co's. diamond saw quarrying machine. *Ibid.*, p. 17.

Dia'mond Tool. 1. A tool which has a diamond mounted in a handle or holder and used to dress and turn up emery wheels, grindstones, hardened steel calender rolls, etc.

2. For forms of carbon points, see Fig. 1098, p. 461, "*Mech. Dict.*"

Fig. 808 shows diamond holders in which carbons are set permanently or in adjustable stems for the purposes above expressed. The lower figures in the cut show Dickinson's patent clamp.

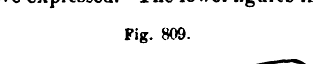
Fig. 808.



Diamond Lathe Tools.

Fig. 809 is a diamond hand-tool.

Fig. 809.



Diamond Hand-tool.

Dia'mond Truck. (*Railway.*) A car-truck with iron side-frames which are diamond-shaped. The journal-boxes are rigidly bolted to the sides, and have no vertical motion in the frame. See figures on p. 489, "*Mech. Dict.*"

Di'a-nem'o-scope. An instrument invented by M. Stanek, and having for its object the analysis of the more complicated motions of a double slide-valve system.

Proceedings of the "*Institution of Architects and Engineers in Bohemia.*" Reported in "*Engineering*," * xxiii. 420.
* "*Scientific American Sup.*," 1332.

Di'a-pa'son Clock. A form of clock made by Breguet, of Paris, in which a diapason (tuning-fork), is substituted as a regulator in place of a pendulum or spring balance-wheel.

* "*Reports of Artisans at Paris Exposition to the London Society of Arts*," p. 361. (Published by Bell & Bately, London, 1867.)

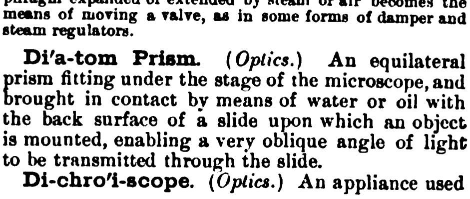
Di'a-pho-nom'e-ter. An instrument used in testing spirits (*Savalle*, Fr.). By it is determined the relative transparency of the sample when the reactive principle is added to the spirit. The degree of transparency preserved is the measure of the purity, and the comparison is made by the eye, the sample being held alongside specimens of determinate quality. * "*Technologiste*," xl. 169.

Di'a-phragm Fur'nace. (*Metallurgy.*) A roasting furnace in which ore is treated while dropping from one to another of a series of diaphragms in a vertical shaft. — *Haskins.*

Di'a-phragm Valve. One which closes by the pressure of a diaphragm against an opening, and *vice versa*. See Fig. 1636, p. 698, "*Mech. Dict.*"

Fig. 810 shows the principle adapted to a ball valve, where the ball floating in a cistern or boiler closes the water-induction opening on arriving at a certain height in the cistern.

Fig. 810.



Diaphragm Ball Valve.

Another form of diaphragm valve is that in which a diaphragm expanded or extended by steam or air becomes the means of moving a valve, as in some forms of damper and steam regulators.

Di'a-tom Prism. (*Optics.*) An equilateral prism fitting under the stage of the microscope, and brought in contact by means of water or oil with the back surface of a slide upon which an object is mounted, enabling a very oblique angle of light to be transmitted through the slide.

Di-chro'i-scope. (*Optics.*) An appliance used

Fig. 811.

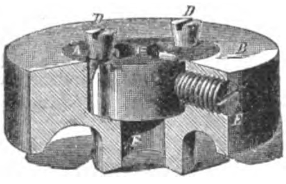
Sorby's Dichroiscope.

with a double image prism to give the complementary colors of an object examined under the micro-spectroscope. See Fig. 1640, p. 699, "*Mech. Dict.*"

Die. A hollow screw-cutter for cutting threads in bolts, etc.

Fig. 812 is Wiley & Russell's adjustable die. *A* is the die proper; *E*, the collet or holder; *D*, taper-head screws which govern the size of the cut; the points of these screws hold in a rim at the bottom of the socket; *E*, binding screws which close the dies together from the sides and hold them firmly; *F*, guides for bolts being threaded.

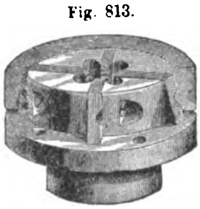
Fig. 812.



Wiley & Russell's Adjustable Die.

Fig. 813 is the Pratt & Whitney die. It consists of four chasers inserted in radial recesses in an iron disk or collet, encircled by a heavy wrought-iron ring, with adjusting screws. Each chaser is beveled in the ring, and is grooved on one side to receive the hardened point of a screw that is inserted in the collet to hold it firmly in position. Four screws extend up through the central flange of the collet, two of which serve to draw down the ring and move the chasers simultaneously toward the center to reduce the cutting size of the die, the other two screws hold the ring in the desired position or force it upward to enlarge the die.

Fig. 813.

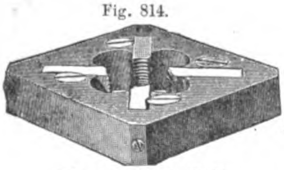


Pratt & Whitney's Adjustable Die.

The chasers, when dull, can be slipped out and ground on an ordinary grindstone, and be thus sharpened till worn out.

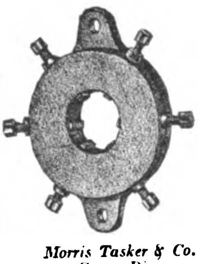
Fig. 814 is the Morse adjustable die. The die is fitted with chasers which are readily adjusted to take up wear or any variation in the size of the pipe. They can be sharpened when dull by grinding. The parts are made interchangeable.

Fig. 814.



Morse Twist Drill Co. Adjustable Die.

Fig. 815.



Morris Tasker & Co. Screw Die.

Fig. 815 is the Morris, Tasker & Co. die, with six chasers set up by screws. It is to be used in the head of their screwing machine.

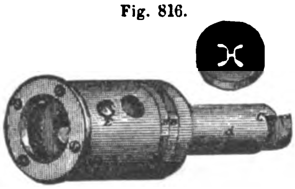
Die Hold'er. A head clutch or clamp for dies in a stock, brace, or machine. It is a form of chuck, the obverse of the drill chuck, shown on p. 276, *infra*.

Fig. 816.



Die Holder.

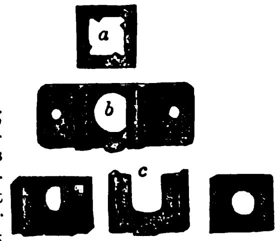
Fig. 816 is *Brown & Sharpe's* die holder for use in the revolving heads of screw machines, especially where it is desirable to cut the thread up to a shoulder or to a given point, or to run the tap into a shoulder for a given distance only, and this is necessarily a delicate operation, requiring expertness to avoid breaking the threading tool or injuring the shoulder of the screw. The engraving represents a patented device to remedy this difficulty, without regard to the skill with which it is operated.

Fig. 817 shows a solid die and die holders of the *Morris Tasker & Co.* screwing machine.

Di'e-lec'tric Ma-chine'. A simple and powerful static conduction machine constructed by M. Carré. It has revolving wheels of hardened rubber, the electricity being supplied by friction on stationary rubbers placed in front. It is a machine of singular power and capacity as evinced in the production of sparks, illumination of Geisler tubes, piercing of glass and charging batteries of Leyden jars.

Abbe le Dantec.
* "*Sc. Am. Sup.*," 3902.

Fig. 817.

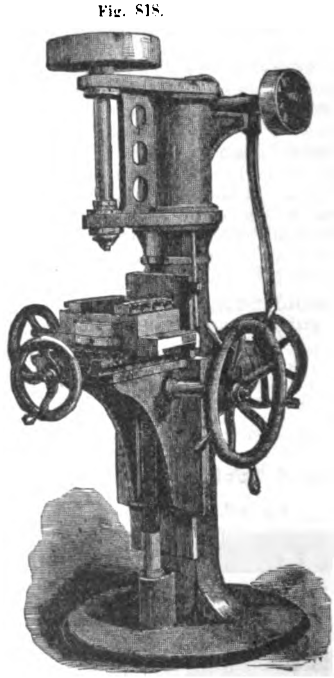


Die Holders for Screwing Machine.

a. Solid die.
b. Solid die holder for use in head of screwing machine.
c. Reducing pieces for holding square dies.

Die-sink'ing Ma-chine'. In principle this machine is similar to the profiling machine, but it has a far greater range. The work may be moved in all directions, and may be guided by a pattern or controlled by the hand of the operator. It is well adapted to forming recesses of a circular, annular, or irregular shape; works very smoothly and free from chatter. The various feeds are entirely independent.

Fig. 818.



Die-sinking Machine.

The work to be operated upon is held in the vise, which may be moved in all directions horizontally by compound slides on the table of the machine, and may be elevated or depressed by the vertical movement of the platen. The cutter, which may be of any suitable size or form, revolves with the spindle which is driven by a belt, giving much smoother action than is possible with gears. The greatest distance between the end of the spindle and top of the table is 24″. The platen has a vertical adjustment of 16″, and the horizontal movements of the vise are 10″. The countershaft has two sets of pulleys, giving two speeds, which may be varied on the spindle by a cone with three grades.

Di'e-ther'o-scope. An instrument invented by *M. Lurini* for measuring the variations in the refractive condition of the atmosphere.

"*Scientific American Supplement*" . . . . * 477.

Dif'fer-en'tial. (*Electricity.*) A coil of electrified wire having such relation to another electrified coil or to an armature (or needle) common to both as to produce polar action contrary to that produced by such other coil.

(*Electric Lamps.*) A conductor of high relative resistance — used with electric lamps in series, — which operates in the twofold capacity of shunting surplus current to the next lamp and of shortening the arc of its own lamp, so as to maintain equal action in all lamps of the series. (See ELECTRIC LAMPS.)

Dif'fer-en'tial Ap'pa-ra'tus. See under the following references and the articles *infra.* DIFFERENTIAL PULLEY, etc.

Thermometer, *Dufours* . . . . * "*Sc. Amer. Sup.*," 3952.

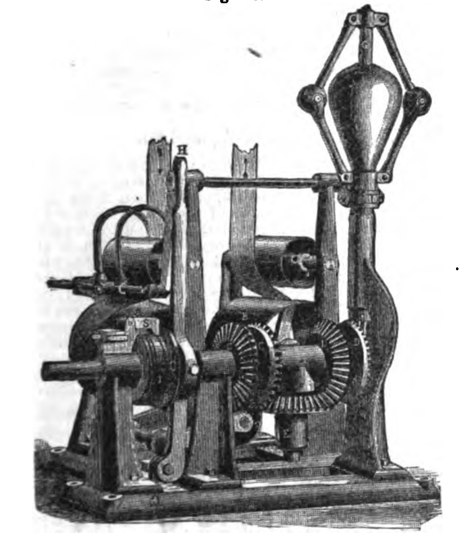
Dif'fer-en'tial Gal'va-nom'e-ter. (*Electricity.*) An apparatus consisting of a needle as in an ordinary galvanometer, but round the frame of which are coiled two wires of the same kind and dimensions carefully insulated from one another; separate currents being passed through them in opposite directions, the needle by the direction and extent of its disturbance indicates which current is the stronger and in what degree.

Dif'fer-en'tial Gov'er-nor. A water-wheel governor. The motion is positive, the revolving balls are merely indicative of the speed of the motor and are not regulators.

The operation of the governor is as follows: —

Two pulleys, *A* and *B* are geared respectively to *C C* and *D D*. Pulley *A* is the frustum of a cone, its diameter at the center of its face being the same as that of the regular pulley *B*. The gears *C C* and *D D* are loosely set on the shaft *F*. The gear marked *E*, enters into *C* and *D*, and is loose on a stud which is fastened to the shaft *F*. The shaft carrying the pulley *A* has upon its end a small gear (not shown in the engraving) which communicates motion to the

Fig 819.



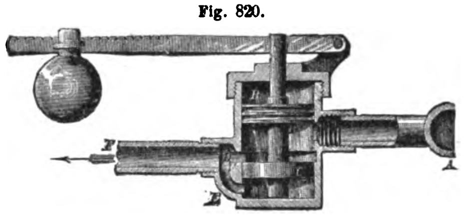
Weaver's Differential Governor.

gears *C C*. Upon the end of the shaft carrying the pulley *B* is a similar small gear (not shown in the engraving), which gives motion to the gears *D D*. Motion is communicated to pulleys *A* and *B* by a belt running in the direction indicated by the arrows. On the lower end of the governor shaft, *G*, is a small gear, which receives its motion from the gear *D*. When the belt is running in the center of the two pulleys *A* and *B*, the speed of both is the same, as their diameter in the center of face is the same. Consequently *C C* and *D D* run at the same speed, and have an equal action on the gear *E*; and hence the stud upon which the gear *E* revolves is held stationary. Now, upon the addition of a load, the speed will be checked, and the balls of the governor will fall. By this act, the belt on pulley *A* is, by proper connections, moved towards the larger end of the cone, thus causing the gears, *C C* and *D D*, to revolve with unequal velocity. This motion of the gears causes the gear *E* to be carried around on the gears *C C*, which, by means of connections with the shaft, opens the gate. Upon the decrease of the load, this operation is reversed, and the gate shut. The purpose of the lever *H* is to throw the governor out of gear by means of the flange *O*, and the clutch *I*. The flange is held out of gear by the latch marked *S*. The object of this arrangement is to enable one to hoist the gate, and when the proper speed is attained to throw the governor into gear by lifting the latch *S*.

Dif'fer-en'tial Move'ment. For the principles and illustrative instances of the transference of a movement at different rates in other directions, conversion of movements, etc., see "*Differential*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," Paris, 1877, vol. i.

Dif'fer-en'tial Press'ure Reg'u-la'tor. A contrivance to enable steam to be taken from a

Fig. 820.



Hand's Differential Pressure Regulator.

boiler or steam-pipe at any initial pressure and delivered equally at any pressure for which it is set

Steam is taken from pipe *A* and passes to the chamber where it acts equally upon the apposed surfaces of *B* and *C*, being so far balanced. The steam, however, passes by duct *D* beneath the piston *C* and exerts an upward pressure; this is balanced by the weight on the lever which tends to depress *C*. If the steam pressure should rise above that for which the lever ball is adjusted, the steam will raise *C* and partially close duct *D*, so that the *quantity* of steam passing to the object to be heated is diminished in proportion to its increased pressure and heat.

Fig. 821.

Differential Pulley Block.

Dif'fer-en'tial Pul'ley Block. Fig. 821 show the Moore's improved form of differential pulley block as manufactured by the Providence Tool Co. It has the following features: —

The lifted weight cannot run down of itself when suspended; both chains take an equal share of the load, so that the block hangs plumb; a hook can be attached to each end of the lifting chain so that when one load is raised the other hook is in position ready for work.

Weston . . . . . * "*Iron Age*," xxi., Jan. 17, p. 1.
Weston . . . . . * "*Scientific American*," xlii. 851.

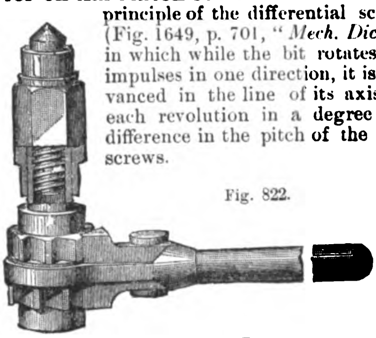
Cherry . . . . . * "*Engineer*," xlii. 88.

Dif'fer-en'tial Pump. In Davey's steam pump (Hathorn, Davis and Davey, Leeds, England), the slide valve derives its motion both from the main cross head and from a rod connected with a cataract piston moving with a uniform velocity, the two motions being so connected that the cut-off depends upon the velocity of motion of the main cross-head — in other words, upon the resistance encountered or work to be done by the piston. In the differential pumping engine the cataract piston is connected with a subsidiary steam piston working in a separate cylinder fitted with a small slide valve.

The invention is shown and described in
"*Scientific American Sup.*" . . * 2369.
Hathorn, Davis & Co., Br. . . * "*Engineering*," xxvi. 197.

Dif'fer-en'tial Ratch'et Brace. One on the principle of the differential screw (Fig. 1649, p. 701, "*Mech. Dict.*") in which while the bit rotates by impulses in one direction, it is advanced in the line of its axis at each revolution in a degree the difference in the pitch of the two screws.

Fig. 822.



Differential Rachet Brace.

See also RATCHET-BRACE, RATCHET-DRILL, p. 1882, "*Mech. Dict.*"

Dif'fer-en'tial Reg'u-la'tor. (*Electricity.*) A means of regulating an arc voltaic light, in a polyphote arrangement, by the differential action of the main current that produces the voltaic arc and of a highly resistant derivation established between the two carbons; thus, their distance apart depends both on the intensity of the current and on the difference of potential at the base of the two carbons; and equilibrium is established for each lamp, when the intensity and the difference of potential have reached the point requisite for the good working of the lamp. "*Electrician.*"

The *Siemens'* differential lamp has two solenoids that work on one rod. The *Brush* and the *Weston* have one electro-magnet on which are coiled two wires that act in inverse directions.

Dif'fer-en'tial Screw Pipe Joint. A pipe joint, the invention of M. Brurry, of St. Gallen, Switzerland. The ends of the pipes to be connected are threaded with screws of a different pitch and respectively right and left handed. A coupling, correspondingly threaded, screws on to them simultaneously and draws them together with great force.

Fig. 823.

Differential Screw Pipe Joint.

Bourry, Switz. . . . . * "*Engineering*," xxiii. 388.
* "*Scientific American Sup.*," 1272.

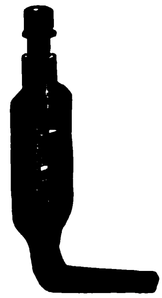
Dif'fer-en'tial Steth'o-scope. (*Surgical.*) A double stethoscope with elastic tubular branches and bells capable of being applied to different portions of the thorax so as to compare the indications at different points.

Allison, Fig. 268, p. 83, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Die Dog. A lathe dog adapted to hold a screw cutting die. Fig. 824.

Dif-fu'si-om'e-ter. (*Gas.*) An instrument invented by Graham to ascertain the rate at which diffusion of gases among one another takes place.

Fig. 824.



Die Dog.

A glass tube of 1″ caliber, 1′ in length, is stopped at one end with a porous plug of gypsum or graphite. The tube is filled with hydrogen, for instance, the open end plunged in a bath of mercury, and diffusion takes place through the plug. The law that the diffusibility of gas is in proportion to the square root of their densities is illustrated by the interchange of hydrogen and atmospheric air, at the expense of the latter, and the tube is eventually emptied.

Dif-fu'sion. (*Electricity.*) The power of a galvanic current to extend its influence in all directions, that influence being never limited to the two electrodes.

Dif-fu'ser. A portion of the apparatus in Clamond's thermo-electric battery, consisting of a series of plates of copper placed all round the battery, and which effect the removal and rapid dispersion of the heat of the solderings by means of the great surface which they present.

Described in "*La Nature*," 1880. Also in "*Manufacturer and Builder*," * xii. 86.

Dif-fu'sion Pro'cess. The Roberts diffusion process is mentioned and illustrated on p. 702, "*Mech. Dict.*" It has been very elaborately extended in some European sucreries. See

Dike. 1. A levee, bank, or dam.

In Japan the dike is formed thus: A kind of strong cylindrical bag, often eight yards and more in length, is made of split bamboo, with wide meshes, and is then filled up with big stones. A certain number of these bags, arranged on a wooden grating, form the foundation of the breakwaters or dikes. When the current is very strong, the ends of the bags are allowed to pass the gratings and to hang down into the sandy bed of the river; gradually they sink deeper and deeper, and finally, being entirely buried in the mud, form a solid mooring. The object of the bags is to keep the stones together, till all the interstices are filled up with sand and mud, when the construction is transformed into a solid mole. The bamboo is said to be of great durability; stems of this tree are also used for weirs and the temporary surroundings of breakwaters. The exterior parts of dikes are often covered with grass matting, so as to prevent their being washed away.

2. (*Mining.*) A wall-like mass of mineral matter filling fissures.

Di-la'tor. (*Surgical.*) An instrument for distending a natural or artificial opening. The term is specially applied to certain instruments, but really includes *speculi*. See Figs. 5360-5363, p. 2260, "*Mech. Dict.*"

See also list of DILATORS, p. 703, *Ibid.*, and ENDOSCOPE, *infra.*

The subject may be pursued by reference to the following figures in *Tiemann's* "*Armamentarium Chirurgicum*": —

Lithotrity	Page 43, Part III.
Meatus urinarius . .	Page 2, Part III.
Esophageal	Page 84, Part II.

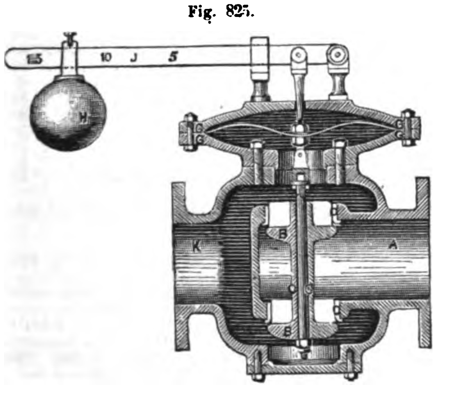
Di-men'sion Stone Work. (*Masonry.*) Said of masonry when the dimensions of the stones entering into it are fixed by specification. See list under MASONRY.

Di-min'ish-ing Valve. A valve to regulate high pressure steam so as to give out a constant and uniform supply of low pressure steam.

The valve is shown by section in Fig. 825. Its operation is as follows: *A* is the inlet for high pressure steam; *BB* is

Fig. 825.



Diminishing Valve.

a double beat valve, with a hole through the stalk *C*, and which shuts against the brass seatings *BD*; *E* is a connecting rod, secured with nuts and washers to the bottom of the valve *BB*, and also to the circular corrugated metallic disk *F*, which is held in position betwixt *GG*. Suppose there is a pressure of 60 lbs. per square inch at the inlet *A*, and 10 lbs. per square inch is required at the outlet *K*, set the weight *H* on the lever *J* at 10 lbs., which pressure will raise the corrugated metallic disk *F*, thereby shutting off the excess of steam over and above the 10 lbs. required. The pressure at the outlet may be varied by moving the weight *H* on the lever *J*.

Din'gy. (*Fishery.*) A small fishing boat. See list under BOAT.

Berthon's duplex dingy, Br. . . * "*Engineer*," xlix. 438.

Di-o-nys'i-us' Ear. An aural instrument for the very deaf. It has a capacious pavilion swiveled on a stand which is planted on the floor, and an elastic tube with a nozzle to be applied to the ear.

Fig. 227, Part II., *Tiemann's* "*Armam. Chirurgicum.*"

Di-op'tric Ap'pa-ra'tus. The refraction system of lighting as distinguished from *catoptric.* See p. 704, "*Mech. Dict.*" See also following instances: —

Consists of Picric acid,	1.5	Nitrate potassium . }	60
Wood charcoal . .	7	Nitrate sodium . . }	
Birch sawdust . .	10	Sulphur	12
		Water	9.5

Made principally at Brunn and Trieste.
"*Eng. & Mining Journal*," xxviii 263.

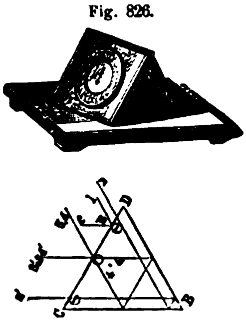
Another published recipe gives: —

Nitrate of potassium	50
Nitrate of sodium	25
Sulphur	12
Hard wood sawdust	13
	100

Di-plei'o-scope. An instrument invented by Bloxam to determine true meridian. *Dipleidoscope*, p. 704, "*Mech. Dict.*"

The instrument is represented in Fig. 826, the upper view showing it in position for observation, and the lower a diagram illustrating the principle of its operation, which is founded on the property of polished bodies, to reflect rays at an angle equal to that of their incidence.

Fig. 826.



Dipleioscope.

The instrument is on a horizontal base, and its anterior face is perpendicular to the meridian of the place. It is an equilateral glass prism with one face exposed, the others being opaque and constituting mirrors. *D C* represents the exterior face of the instrument, and *D B*, *B C* are mirror planes. Suppose that the ray 1 striking *D C* at *E* be reflected towards the eye in the direction 1', the image of the sun will appear, as time lapses, to advance in the direction from *D* towards *C*. The ray 2, traversing *D C*, is reflected by *C B* on to *D B*, and thence towards the eye in the direction 2', and the second image of the sun has an apparent motion in the direction from *C* to *D*, and as the sun culminates the two images mutually approach.

Supposing that the ray 1 shall arrive at 3 and the ray 2 impinge upon 4, it is evident that they will be each reflected in the common direction 3' and 4'; that is to say, that the two images will coincide at the instant of true meridian. The moment passed, the rays continuing to advance, the images again separate themselves, changing their relative positions and mutually recede.

Dip'lo-graph. A writing apparatus for the blind, invented by M. Recordon, of Geneva, Switzerland.

Speaking in general terms, it has lettered disks rotated by the blind writer so as to bring letter after letter in position to imprint upon a paper which moves along before the writer. It is simple but clumsy, far inferior to a type writer, which it would be easy to furnish with raised letters on its plungers: it is hardly worthy of the praise bestowed by "*La Nature.*" Shown in "*Scientific American*," * xxxvii. 210.

Dip'per. A form of dredging machine which has a large ladle on the end of a spar. This is plunged under water, scoops along the bottom, and then rises to the surface, and discharges its load into a lighter.

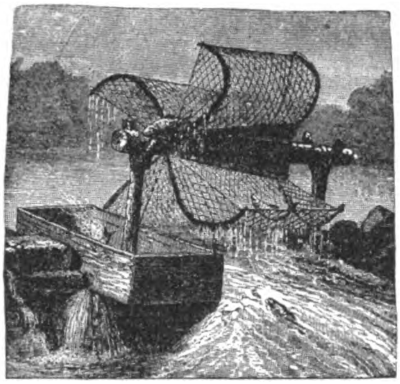
The principle is shown in Fig. 1896, vol. i., "*Mech. Dict.*," though the machine there shown is not aquatic.

Dip'per Ear'-trum'pet. An aural instrument with a dipper or cup-shaped pavilion. The sound waves entering the flaring mouth are reflected by the parabolic bottom towards a common center, and thence conducted by a tube to the ear.

Figs. 225, 226, Part II., *Tiemann's "Armamentarium Chirurgicum."*

Dip'ping Wheel. (*Fishing.*) A contrivance used in Southern rivers to meet local demand for fish.

Fig. 826.



Dipping Wheel.

It is set in the stream so as to be turned by the current, and has a number of dip-nets which raise the fish and tumble them out at the axis in the manner of the scoop-wheel. The inclination of the nets is toward the catching-box at the side.

Dip'ping Vat. (*Ceramics.*) The trough containing fine glazing slip in which biscuit ware is dipped to be covered with the material which, baked on, forms glaze.

Dip Reg'u-la'tor. (*Gas.*) A device used in gas works for regulating the seal of the dip-pipes in the hydraulic main, and for drawing off the heavy tar from the bottom of the main without disturbing the seal. See Fig. 1660, p. 705, "*Mech. Dict.*"

Di-rect'-coup'led Steam En'gine. A form of engine in which the piston-rods of two engines are coupled directly to the same crank.

The term is held to include the form shown in Fig. 713, in which the crank is rotated by the intervention of a triangular connecting-rod.

Di-rect' Fire. 1. (*Fire-arms.*) That kind of action in which the plungers lie and strike the ignition in a line parallel with the axis of the barrel.

2. (*Glass.*) A glass furnace with no artificial draft other than derived from the chimney or stack.

Di-rect' I'ron Pro'cess. A process for procuring directly from the ore an iron which is practically pure chemically, although mechanically mixed with certain impurities. The Catalan, the most ancient of processes, employed to produce charcoal blooms.

The modern direct methods are discussed in a report by A. L. Holley, Group I., "*Centennial Reports,*" vol iii., p. 40. Blair's and Siemens's processes are considered : —

"Blair's consists in deoxidizing the ores rapidly by gas and solid fuel, but without fusion, and then withdrawing the iron-sponge cold, without allowing it to oxidize again. The sponge is compressed and charged into the open-hearth furnace, or it is reheated or charged, or it is melted in a cupola and then treated in the open hearth. The best manner of using the sponge does not appear to be fully settled. Siemens's process consists in melting ore, together with coal and limestone enough to reduce it, in a rotating furnace, tapping off such slag as will run, squeezing the remaining slag out of the ball, and charging the ball hot into the open-hearth furnace. The radical trouble in all direct processes has been the waste of iron in getting it from the sponge into merchantable form. The addition of the open-hearth process greatly relieves this difficulty." — *Holley.*

See also ROTATOR ; SPONGE.

Di-rect'or. (*Surgical.*) A grooved instrument to serve as a guide to a knife, probe, scissors, bistoury, herniatome.

Exploring director	Fig. 135, p. 44, Part I.
Exploring director	Fig. 184, p. 61, Part I.
Allingham's anal scissors director	Fig. 589, p. 121, Part III.
Anal and rectal director	Fig. 591, p. 122, Part III.
Levis, hernia director	Fig. 629, p. 126, Part III.

Tiemann's "Armamentarium Chirurgicum."

Di-rect' Pro'cess. (*Metallurgy.*) One by which a metal is obtained in working condition by a single process from the ore. It is said of malleable iron obtained in loups for blooms by open-hearth process, in contradistinction to the double operation of obtaining pig iron by blast furnace and converting pig into malleable iron by puddling and hammering. See DIRECT IRON PROCESS.

Dis-gorg'er. (*Fishing.*) An implement used in discharging a gorged hook from the mouth or stomach of a fish. It is pushed down along the line, pushes back the barbed point, and thus assists in retracting the hook.

Dis'in-fect'ing Stove. A stove with adjacent drying chamber provided with bars on which to hang the clothes while exposing them to a heat of 159° C.

In the Chemical Department of Public Health of Dresden the following is given as the relative value of the articles stated, as disinfectants, — chloride of lime and sulphuric acid being 100 : —

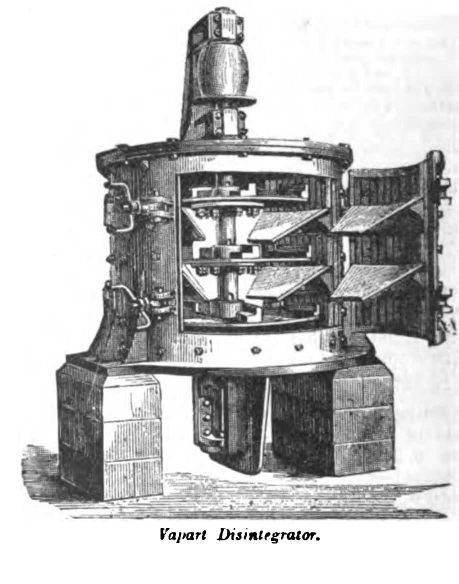
Chloride of lime, with sulphuric acid	100
Chloride of lime, with sulphate of iron	99
Luder and Liedloff's powder	92
Carbolic acid disinfecting powder	85.6
Slaked lime	84.6
Alum	80.4
Sulphate of iron	76.7
Chloralum	74.0
Sulphate of magnesia	57.1
Permanganate of potash, with sulphuric acid . .	51.3

Dis-in'te-gra'tor. A pulverizing machine operating by percussion.

The success of *Carr's* disintegrator, shown at Fig. 1665, p. 707, "*Mech. Dict.*," has been the incentive to the invention of a large class of machines which go by the name of disintegrators, the common feature of which consists in pulverizing by percussion, in the breaking by blows of rapidly revolving arms, spokes, or cages, as distinct from the grinding by attrition between surfaces.

The range of material to which the disintegrator has been

Fig. 828.



Vapart Disintegrator.

adapted has also been very much extended, and includes breaking and pulverizing —

Asphalt rock.	Grain of all kinds.
Bark.	Graphite.
Bones.	Guanos.
Cement.	Minerals.
Coal for patent fuel and coke making.	Mixing chemicals, clays, colors, fertilizers, sugars.
Coprolites.	Oil cake.
Fertilizers.	Ores.

The *Vapart* disintegrator consists of three horizontal platforms keyed to a vertical shaft. The platforms are fitted with vanes placed radially. The shaft is supported below by a footstep, and above by an ordinary bearing. The platforms are inclosed in a cast-iron cylindrical casing, fitted with two doors to give access to the interior. Between the platforms, and attached to the casing, hoppers are fixed to deliver the material to the center portion of the platforms, and opposite the platforms serrated segments of chilled cast iron or steel are attached.

The shaft and platforms are made to revolve rapidly, and the material is first delivered into the machine near the center of the first platform, where the velocity is low. It is then guided by the vane, and by centrifugal force is projected violently against the first series of segments. The broken material falls by its own weight down the first hopper to the center of the second platform, and is again thrown violently against the second series of segments, and afterwards against the third, when the material finally falls out of the machine in a thoroughly disintegrated state. Two arms fixed under the last platform serve to keep the machine clear. The pulverized material can then be led away on a belt or otherwise, as may be convenient.

Various forms of disintegrators are found in the columns of "*Engineering*," October 18, 1878; and proximate dates including: —

* *Carr's*,	* *Wilson's*,
* *Sherwin's*,	* *Vapart*.
* *Carter's*,	

The machines of *Hawksley* and of *Western & Co.*, of London, and *Bichou & Cie.*, of Paris, have been prominent at late expositions.

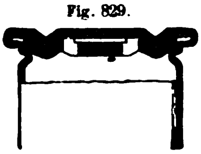
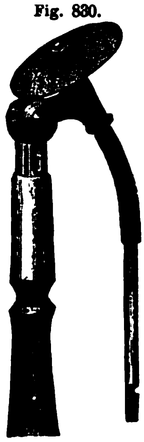
Disk An'vil. A strengthening plate or reinforce placed inside the head of a cartridge to support the impact of the striking pin which explodes the fulminate. See also CUP ANVIL.

Fig. 829.



Disk Anvil.

Fig. 830.



Dr. Hickman's Disk Carrier.

Disk Car'ri-er. (*Dentistry.*) A device for holding a cutting, grinding, or separating disk at the end of a handle while it is rotated by a flexible shaft driven by the dental engine. It is used in separating the teeth, cutting out lingual and buccal fissures, and finishing fillings and rough surfaces.

Disk Cut'ter. An instrument for cutting circles of thin glass for covers of microscopic objects on slides. A diamond is on the end of the arm, which is adjustable to suit the radius of glass cover required. See CIRCLE CUTTER.

Disk E-lec'trode. (*Electricity.*) An electrode for telegraphic instruments in which the connection is secured by the contact of the peripheries of two disks, the axes of which are at right angles. The contact is a mere point or dot. The disks are of brass with platinum wires let into grooves on their peripheries, the densely-drawn hard wire permitting a fine and small contact. — *Cumming.* See TELEGRAPH KEY; also Fig. 847, p. 266, *infra*.

Disk En'gine. A form of steam engine invented by Dakeyne in 1830. Improved by Bishop, Ericsson, and others.

See *Bishop*, c, Fig. 1666, p. 708, "*Mech. Dict.*" (Wabbling).

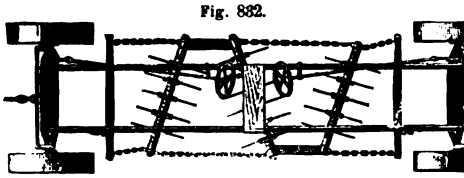
La Dow . . * "*American Manuf.*," July 16, 1880, p. 13.

Fig. 832.



Fowler's Disking Machine.

Disk'ing Ma-chine'. (*Agric.*) A steam-cultivating implement to be drawn by an engine over sod or plowed sod, to renew the ground, or to prepare for seeding. Circular steel disks are presented obliquely to the line of draft so as not merely to cut into the ground but make a slight furrow.

Dis-place'ment Ap'pa-ra'tus. Guerin's continual displacement apparatus consists of a vertical series of vessels; at bottom a flask in a sand bath, a percolator, receiver, and condenser, vertically in the order stated. The vapor of the lower member condenses in the upper one, is received in the next below it, and thence flows intermittingly into the percolator, from whence it reaches the flask at bottom.

"*Scientific American*" . . . . * xlii. 180.

Dis'lo-ca'tion Ap'pa-ra'tus. (*Surgical.*) This includes bandages, splints, apparatus for reducing, and for maintaining restored parts *in situ*, and for preventing recurrence.

Scissors	Fig. 151.

Dis-sect'ing Ta'ble. One with arrangements devised for the convenient presentation of the subject, the disposition of the disjecta, etc.

A table with arrangements for disposition of effluvia is shown in *Laboulaye's "Dictionnaire des Arts et Manufact.,"* Figs. 3630-3632, article "*Insalubres*," tome iv., ed. 1877.

McIlroy's table, shown at the Philadelphia Exposition, 1876, is of convenient size and height, is supported on a stem connecting with a scale beam in the stand, affording the means of weighing the subject; it is dished to the center to collect the liquid of ablution or effusion; has means for the exhibition of disinfectants, etc.

Dis-sue'ing. (*Mining.*) Breaking away the rock from off the walls of a small and rich lode, in order that the ore may be moved without the accompanying worthless gangue.

Dis'tance Meas'ur-er. An angulometer, telemeter, etc. (which see): —

The instrument invented by Lieutenant Unge of the Swedish service is a stop watch to measure the interval between flash and sound. The pointer is placed at XII., and when the flash is observed a button is pressed, and the pointer begins to traverse. When the sound is heard the knob is released and the distance observed. The dial is divided into special peripheries according to the seasons.

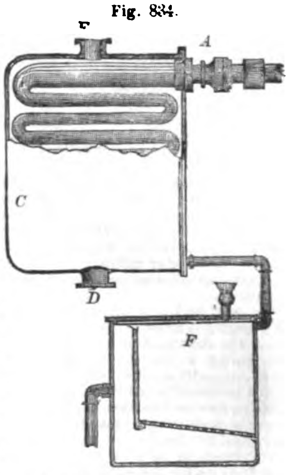
Distance indicator, *Watkin* . "*Scientific Amer.*," xxxvi. 22.

See also TELEMETER, Figs. 6255, 6256, pp. 2513, 2514, "*Mech. Dict.*"

Dis-til'ling Ap'pa-ra'tus. Baird's distilling apparatus for making potable water by condensation of steam from the boiler is used on board vessels of the United States Navy. Fig. 834.

It consists of an aërator, condenser, and filter. The aërator is at *A*; the steam passing towards the coil draws in air at a number of circumferential holes, and the air and steam pass together into the flat coil of copper twined inside. Sea water enters the condenser *C* at *D* and passes off at *E*. The water of condensation then passes by pipe to a filter, *F*, of purified granulated animal charcoal to deprive it of organic matter and oils which come over with the steam. See also STILL, "*Mech. Dict.*"

Fig. 834.



Baird's Distilling Apparatus.

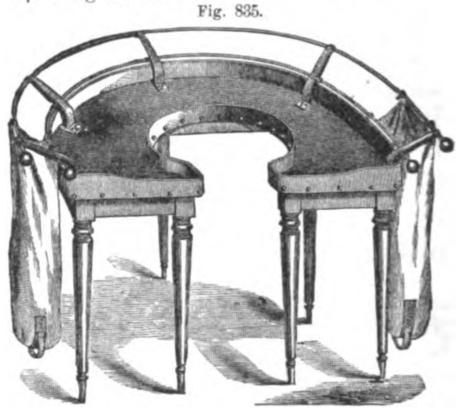
Dis-trib'u-ting Ta'ble. A table on which letters are collected and from which they are distributed into mail bags suspended around it in a horse-shoe form, the distributor standing in the middle. Fig. 835.

Ditch Clean'er. A square-ended scoop set at an angle with the handle to reach the bottom of a ditch while standing on the surface of the ground.

Two kinds are shown: one to push and the other to pull. Fig. 836.

Ditch'ing Ma-chine'. A machine for digging or plowing ditches.

Fig. 835.



Distributing Table.

The ditching machine of Theodore F. Randolph is shown in Fig. 837.

The digger share operates in the grooved periphery of a rotary flanged wheel, and has an adjusting attachment that regulates the depth of penetration. The flanged peripheries of the wheel penetrate and its rotation elevates the loosened soil, depositing it on the slide-way or apron that sheds it clear of the ditch on either side, optionally. A chisel-shaped cleaner attached to the slide-way works between the flanges of the wheel, cleansing it of its load, and guiding the dirt to the apron.

The large machine requires an eighteen horse-power engine to operate it; and it is calculated that it will dig eight cubic yards a minute in clay soil; equal to a man's work for a day, per minute.

Fig. 836.

Ditch Cleaners.

The machine has adjustments for depth, and means for guiding under the control of the man who stands upon the platform. See also, —

Di-vis'ion Cath'e-ter. (*Surgical.*) A double current catheter, allowing liquid to be injected and withdrawn by distinct ducts in the same instrument and simultaneously.

Fig. 1190 *e*, p. 504, "*Mech. Dict.*"

Di-vis'ion Reg'u-la'tor. (*Electricity.*) A regulator adapted to allow several or many lights on one circuit. Usually called a *polyphote* or many-light regulator.

They are of three kinds: —
Differential.
Derivation.
Fixed interval (Regulators *à écart fixe*). See POLYPHOTE REGULATOR, and the above.

Di-vul'sor. (*Surgical.*) An instrument to rend asunder the walls of a constricted passage. The urethral divulsor for obliterating strictures is the most notable instance. See STRICTURE DILATORS, Fig. 5995, "*Mech. Dict.*"

The term *dilator* in one sense includes *divulsors* and in another direction *speculi*; the latter use being to expose, while in the former case it is to expand.

Thompson's, *Gouley's*, and *Holt's* stricture divulsors are shown at Figs. 64, 67, 66, Part III., *Tiemann's* "*Armamentarium Chirurgicum*," in company with other instruments called *dilators*, but the use of which is practically the same.
Anal divulsors and *dilators* on p. 119, Part III., *Ibid.*

Dob'by Ma-chine'. (*Weaving.*) A loom for weaving fantastic patterns; such a loom for instance may contain from 12 to 30 blades. The mechanical principle is similar to that of the Jacquard, of which it might be termed a simplification. In the dobby machine the pattern is obtained by means of little pegs, which according to the requirements are placed in the holes of the bars of a lath work. The bars correspond to the cards of the Jacquard.

Ainsworth's . . * "*Scientific American Supplement*," 3896.

Dock. (*Hydraulic Engineering.*) *a.* (*Wet.*) A basin to contain vessels for loading or discharge.

b. (*Dry.*) An excavation into which a vessel is admitted, inclosed, and exposed by pumping out the water contained in the dock. A *graving* dock, Fig. 2308, "*Mech. Dict.*"

c. A caisson which is sunk in position beneath a vessel and then floated therewith by pumping out the water contained in the caisson, Plate XIX., p. 884, "*Mech. Dict.*"

d. A depositing dock, which raises a vessel by means of sunken and subsequently floated caissons or camels and then shifts it to a staging which it may occupy for any required time, while the floating apparatus repeats the process on other vessels. See DEPOSITING DOCK, *supra*.

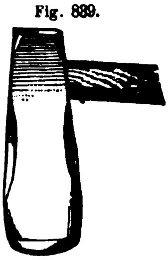
Dock Block. A tackle-block secured on a

Fig. 838.

Dock Block.

Fig. 839.



Dog Head.

dock or wharf to change the direction of a rope passing to a cargo-lifting tackle. It has a universal ball-and-socket joint, to permit the block to swing in any direction.

Dog′-Head. A hammer used by saw makers in stretching the blade, that is, in removing a tension. The weight is about 3 pounds and the length $5\frac{1}{2}''$. The handle, $14''$ long, stands at an angle of 85° with the body of the hammer. Its face is rounding and of an even sweep. Fig. 839.

Do-mes′tic Mo′tor. One adapted for household use, to run sewing or knitting-machines, pump water, etc.

Many small forms of *steam engines* have been specially invented and offered for this purpose. *Gas*, *hot-air*, and *caloric engines* are specially well adapted. *Hydraulic motors*, operated by water from the mains, have an aptitude for this use. Also *spring* and *electro-magnetic* motors.

See under the various heads. Also p. 2123, "*Mech. Dict.*," and list of 72 patents of SEWING-MACHINE MOTORS, on p. 2115, *Ibid.*

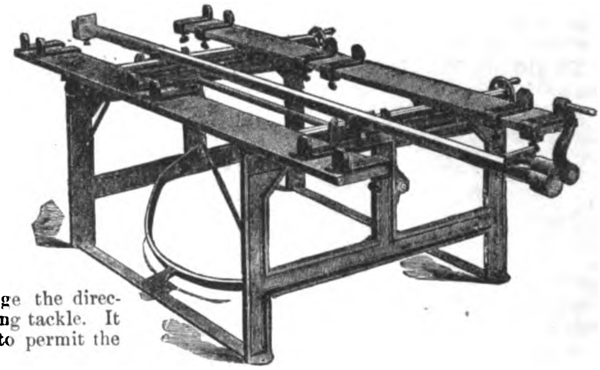
Gray	"*Iron Age*," xxi., May 2, p. 42.

Door Clamp. (*Carpentry.*) A bench and frame on which the various parts of a door are assembled and then pushed together and held by clamps.

The bench shown in Fig. 840 is adapted for door, sash, or blind work; the action of the longitudinal clamp, and the two transverse clamps is evident. The pressure is given on

Fig. 840.

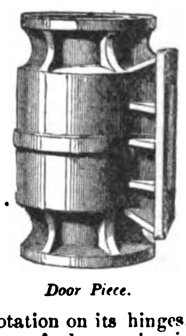


Door, Sash, and Blind Clamp.

each end of the tenon of each rail, the side-pressure being given by treadle while the end-pressure is given by hand.

Door Piece. The valve chamber of the stock of a Cornish pump-lift. A section containing a door or cover, which may be removed to admit examination of the valve and seal, or removal for repairs.

Fig. 841.



Door Piece.

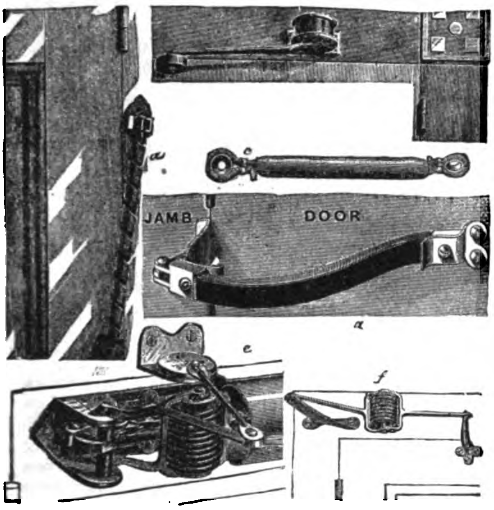
See Fig. 1467, page 626, "*Mech. Dict.*"

Door Rel′ish-ing Ma-chine′. (*Carpentry.*) A machine for trimming a tenon. See SASH RELISHING MACHINE.

Door Spring. An attachment to a door to close it. In some cases the spring operates to keep it open after it has passed 90° of rotation on its hinges. See BUTT HINGE. One form of door-spring is shown at Fig. 1688, p. 721, "*Mech. Dict.*"

Six other forms are shown in Fig. 842, pneumatic, spiral, and caoutchouc, arranged in various forms.

Fig. 842.



Door Spring.

a. " Boss " door-spring.
b. *Sabin's* lever door-spring, with a maximum when the door is closed.
c. " A. B. C.," india-rubber door-spring. *d.* "Centennial."
e. *Geer's* air-cushion door-spring ; the greatest pressure at the point of closure.
f. " Hercules " door-spring ; the same action as the previous one, but not pneumatic.

Dor'mant Scales. Warehouse scales, the platform of which is let in even with the floor, so as to roll a truck upon them.

Do'ry. (*Fishing.*) A small flat-bottomed fishing boat.

Do-sim'e-ter. An instrument for measuring prescribed quantities. The term is frequently applied to a drop-meter such as that of Prof. Thurston, which consists of a steel wire tapered to a point and affording a means of obtaining small drops of equal quantity.

Fig. 843.

Colmar's Dosimeter.

The dosimeter, Fig. 843, is a glass tube with a taper end and graduated to indicate drops, minims, and other measures according to the requirements of any given purpose or capacity. In the top is fixed a syringe with a rod which has an adjustable stop to limit the stroke of the piston to any required extent. By this means any desired quantity may be drawn into the syringe and the traverse of the piston is watched to observe the quantity ejected if it be less than the whole.
See Burette, Pipette, Drop Meter.

Dou'ble Act'ing Pump. One which is effective at each stroke, to and fro. See references : —

Amos & Smith, Br. * "*Engineering*," xxx. 462.
Carr . . . . * "*Manuf. & Builder*," xii. 148.

Dou'ble Bass. (*Music.*) A stringed musical instrument, the largest of its class.

It has three strings tuned in 5ths, or four strings tuned in 4ths. The compass is two octaves and a quarter. To this instrument belong the lowest sounds in the harmony.

Dou'ble Bas-soon'. (*Music.*) A wind musical instrument of lowest pitch in its class.

A double reed instrument which bears the same relation to the bassoon that the double-bass does to the violoncello.

Dou'ble Beam Bal'ance. One with two beams graduated in two systems; the *postal* balance, for instances, in grams and ounces: the *creamery* or *dairy* balance for weighing successive portions of cream or milk at a single draft; the *furnace* scale for weighing respective portions of ore, limestone, and coke at a single draft. See under the above heads.

Dou'ble Bell Pipe. One with a cup-shaped enlargement at each end to receive the ends of those in line with it. See *h* in Bend.

Dou'ble Blast Forge. One with two tuyères acting upon the same bed of coals. *Enfer*, Paris.

Dou'ble Bo'gie. One with a bogie at each end. A Double ender. See Back Truck Locomotive, Fig. 168, *supra.*

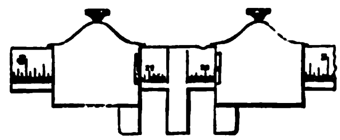
Car, Midland Railway, Br. * "*Engineering*," xxi. 533.
Locomotive, *Fairlee* . . . * "*Scientific American Sup.*," 72.
* *Anderson's* report, "*Paris Exposition* (1878) *Reports*," vol. iv., p. 452.

Dou'ble Bor'ing Ma-chine'. A machine with two augers, bits, drills, as the case may be.

Boring and facing, *Bede et Cie.*, Fr. . * "*Engineer*," xii. 5.
See also Double-traverse Drill, *infra* ; Multiple Drill, etc.

Dou'ble Cal'i-pers. Two calipers upon the same bar graduated respectively on each side of the central zero abutment.

Fig. 844.



Double Calipers.

Useful for making two separate measurements of an object, as the width and thickness of a quadrilateral steel bar.

Dou'ble Car'-axle Lathe. A lathe in which the axle is passed through the center-head and turns on dead centers at the respective ends. Each end of the axle is operated upon at the same time and finished without turning end for end. An equalizing driver attached to the side of the driving wheel distributes the driving force uniformly through the whole axle, overcoming the tendency to lateral strain. Changes of feed for roughing and finishing without changing wheels. Fig. 845.

Dou'ble Coil Gal'va-nom'e-ter. A refinement of the astatic galvanometer, invented by Sir William Thomson. It has two coils, one above the other, exactly alike in their effect upon the compass-needle, situated in the middle of each. A bar magnet above serves to give direction to the needles and may be moved up and down so as to nearly neutralize terrestial magnetism if desired. The connections at the base serve to keep the coils in combination, either as acting together or counteracting one another. Used in submarine telegraphing.

"*Manufacturer and Builder*" . . . . . . * xi. 276.

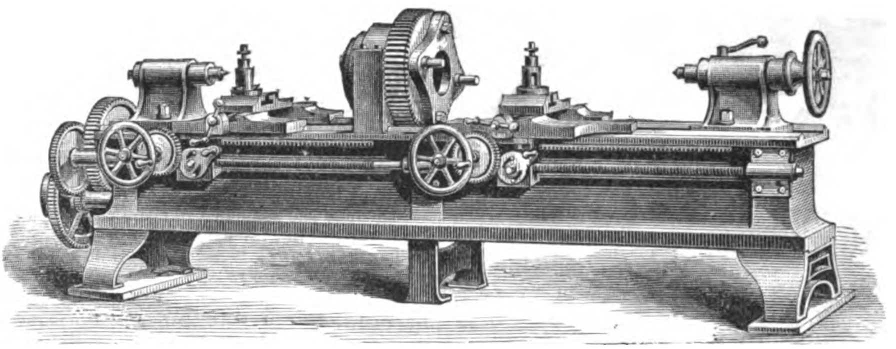
Dou'ble-cone Lamp. A lamp the glass of which consists of a cylindrical equatorial zone, and conico-frustal zones above and below.

Dou'ble-cone Re-flect'or. A form of ventilating reflector for the ceilings of auditoriums. Made in various sizes, diameter 25″ and upward, with from 6 to 150 burners. Fig. 846.

Dou'ble Con-nect'er. (*Electricity.*) A connecter with two binding screws for as many wires.

Dou'ble Cur'rent Cath'e-ter. (*Surgical.*) A catheter with two tubes or a divisional tube, so

Fig. 845.



Niles' Double Car-axle Lathe.

as to permit a current to be injected into the bladder through one duct, while the washing of the bladder passes out through the other duct. See *c*,

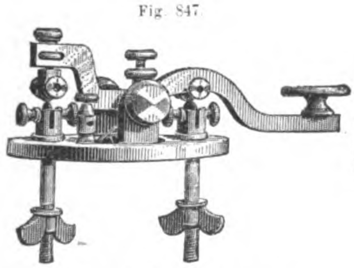
Fig. 846.

Double-cone Reflector.

Fig. 1190, p. 504, "*Mech. Dict.*" Also known as a *Division Catheter*. See also DEBRIS EVACUATOR.

Dou'ble Cur'rent Key. (*Electricity.*) A telegraph key with points or contacts at each end, the two legs being insulated and a third (middle) contact being connected with the base. For data see DISK ELECTRODE.

Fig. 847.



Cumming's Double Current Key.

Of the two points with which the ends of the key connect, one leads to a battery with its positive pole to the line and the other to the corresponding negative pole. The right hand of the key (as shown) being depressed, makes a contact with the point below, and the current passes (say from the positive of the battery) through these contacting points, the trunnions of the key and to the base. When the lever is raised, the reversed current from the negative of the battery flows through the other arm of the key to line by the middle connection.

The three points on the base are insulated from each other and are connected only by the depressing and raising of the key lever. The special device shown is that of Cummings, which has contacting disks for contact, the disks being on axes at right angles to each other and having fine platinum wire inserted in grooves on the peripheries.

Risch . . . . * "*Telegraph Journal*," vii. 93.

Dou'ble Cut Saw. A mill saw having one half the teeth turned towards one end of the saw and the other half the other way, each way from the center. Intended to cut equally up and down and discharge the saw-dust on top and bottom. The latter, of course, is not an object but an incident. — *Davis.*

Dou'ble Cut'ting-off Ma-chine'. 1. A two-headed lathe for railway axles and shafts up to 8″ diameter. Tool slides work at either end simultaneously, feeding together or separately.

2. A double cut-off saw, used by box-makers to square off both ends of dimension stuff at the same time.

Dou'ble Deck'er. Said of two-story or two-tier arrangements.

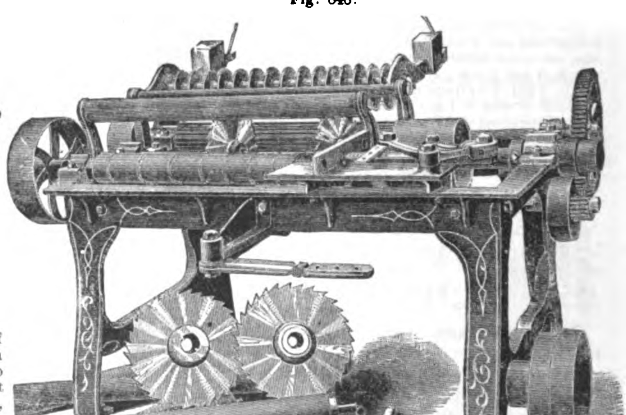
a. A ship with two decks above the water-line.

b. A railway car or street car with seats on the roof. Common in Europe.

c. A hog or sheep car with two decks.

d. A steam-boiler furnace with two tiers of firing chambers.

Fig. 848.



Nichols' Double Edger.

Dou'ble Door. *a.* A door in two portions, upper and lower, swinging or sliding independently :

used in express and mail cars. A pair of half doors in fact.

b. A pair of doors swinging or sliding, mutually approaching or receding, to close or open the doorway.

Dou'ble Edg'ing Ma-chine'. 1. (*Wood Working.*) A machine having a pair of circular rip saws at a regulatable distance apart, to dress both edges of a board at once.

The Nichols' double edger is particularly designed for edging boards in saw-mills, and sawing plank and boards from the mill into joists, scantling, flooring, battens, shingle-lath, etc. Fig. 848

It has a feed roll in front, composed of small saws and collars alternately, and has a fluted roll behind the saws, over which is a weighted flanged press-roll, which serves to keep the board straight. For edging, one saw is made stationary and the other saw adjusted to any width. For ripping, an adjustable gage is provided with a lever running to the operator and a screw on the front feed-roll, which keeps the stuff to the gage.

"*Iron Age*" . . . . . * xx., November 22, p. 1.

2. (*Sheet Metal Working.*) A machine for folding the edges of blanks for pieced tin-ware preparatory to seaming. It is arranged to fold the parallel edges of rectangular blanks to form cans from 6″ to 22″ in length.

Dou'ble End'er. 1. (*Wood Working.*) A cross-cut sawing machine, which has a pair of circular saws at a regulatable distance apart to cut off both ends of a board at once.

Staves are brought to a length in a similar manner by sawing both ends.

The box-board double cut-off saw machine of *Richardson, Merriam, & Co.* is for equalizing stuff, squaring off both ends of box stuff at the same time. It has a frame with a light sliding carriage on which the stuff is fed to the pair of circular saws which are upon the same arbor but regulatable as to distance apart.

2. A file with two points, either end capable of being placed in the handle.

3. (*Nautical.*) A ship capable of moving in either direction, having bow and rudder at each end. A frequent form in ferry-boats.

On double-ender ships . . . . . . "*Engineer,*" xli. 431.

4. (*Railway.*) A locomotive with pilot at each end. A switching locomotive. See BACK-TRUCK LOCOMOTIVE, Fig. 168, p. 65, *supra.*

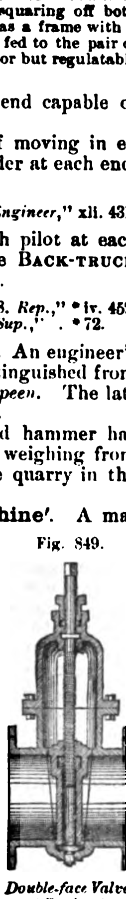
Anderson's report, "*Paris Exposition*, 1878. *Rep.*," * iv. 452.
"*Scientific American Sup.*," . * 72.

Dou'ble-faced Ham'mer. 1. An engineer's hammer, with two flat faces; as distinguished from the hammer with one face and one *peen*. The latter may be square, cross, or pointed.

2. The stonemason's double-faced hammer has two square faces; is a heavy tool, weighing from 20 to 30 pounds, and is used in the quarry in the roughest work.

Dou'ble-face Mil'ling Ma-chine'. A machine tool suitable for milling pieces that have pivots on opposite sides, such as main-spring stirrups or swivels for guns. A geared shaft, with cone pulley of three grades, drives a face-plate which revolves the piece to be finished. The feed is accomplished by means of rack, pinion, and levers, which move the foot-stock spindle, carrying one mill against the revolving piece, and press the piece against a mill held in the head-stock. — *Pratt & Whitney.*

Fig. 849.



Double-face Valve.
(*Section.*)

Dou'ble-face Valve. One coming fairly against a seat on each side of it. The valve jams between two faces, an element of security and support.

Dou'ble Fire'-cock. One having two connections, by Y-branch, for two hose, operated by a single screw valve.

Dou'ble Fluid Bat'te-ry. (*Electricity.*) One having the elements in different fluids to secure depolarization. A *constant* battery, which see.

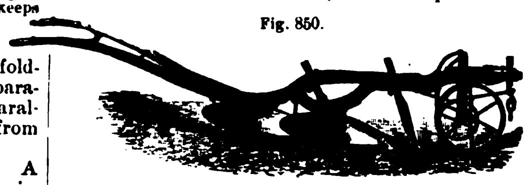
Becquerel's oxygen jar battery was the first to use two liquids, or a porous cell, and was the first constant battery. See BECQUEREL BATTERY.

Dou'ble Fur'nace Boil'er. One having two firing chambers, either double-tier, parallel, or at opposite ends.

Rowan, Br. . . . . * "*Engineer,*" xliv. 418.
Saltaire Mills, Br. . . . . . * "*Engineer,*" xli. 274.

Dou'ble-fur'row Plow. (*Agric.*) One for plowing two furrows at once. A GANG PLOW; the invention of Lord Somerville, the latter portion of

Fig. 850.



British Double-furrow Plow.

the last century, but much improved of late. The original form was of two plows locked in parallel position. That form is scarcely found now, except an implement made at Nancy, France.

Dou'ble-gate Valve. A valve for gas or water mains, having on each side a face which fits against its own seat. — *Isbell.*

See DOUBLE-FACE VALVE.

Dou'bled Glass. (*Glass.*) A glass made of several colors superposed. See FLASHED GLASS.

"It is worked in a different manner from plain glass. Colored glass when first made is generally drawn into sticks of a certain length and annealed. Suppose we now wish to blow an article made of white glass with a thin sheet of outside colored glass. A stick of colored glass is taken and heated gradually; the workman now takes up this stick on the end of his ponty and heats the glass in the glory-hole. When this is sufficiently plastic a quantity is cut off and attached to a blow-pipe also having a small lump of hot glass at its end. The colored lump is now heated again and blown in the usual way into a hollow ball. This ball is opened and formed into the shape of a cup. In the mean time another workman has gathered and blown another sphere of white glass of a suitable size. This sphere is now put into the cup-shaped colored glass, blown, and rubbed together while hot so as to make them adhere. We now have a ball of white glass inside and colored glass outside. This may be finished to any shape desired, in the usual way, with molds or tools." — *Colné.*

Dou'ble Har-poon' Fork. A hay-elevating fork having two harpoons forming a ∩-shaped implement with barbs on the points. A duplication of the harpoon fork, Fig. 2409, p. 1065, "*Mech. Dict.*"

Dou'ble Hook. (*Surgical.*) *a.* A tenaculum with two claws.

b. A two-clawed hook for fixing the eye during operation. *Double tenaculum*, Fig. 79, Part II., *Tiemann's "Armamentarium Chirurgicum."*

c. A prehensile two-armed instrument with two claws on each arm to grasp the eye in operation for extirpation. Fig. 78, *Ibid.*

d. See, also, Extirpation and Fixation Forceps, *Ibid.*, p. 25, Part II.

Dou'ble Im'age Prism. (*Optics.*) A prism of Iceland spar giving a double image of the object of complementary tints, and also used by revolving the images to measure the angle of crystals examined under the microscope.

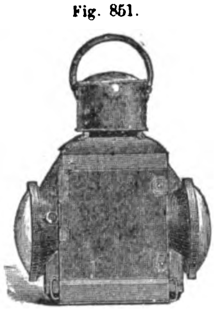
Dou'ble-jaw Vise. A vise having two pairs of jaws, either of which may be brought into play.

See ADJUSTABLE VISE, p. 5.

* "*Engineer*" . . . . xiii. 182.

Dou'ble-lens Lan'tern. One having a lens on opposite sides to throw rays in opposite directions. Used as a tail side-light for trains, throwing light forward and aft.

Fig. 851.



Double-lens Lantern.

Dou'ble-lip Safe'ty Valve. One with two circular concentric avenues of egress for the steam as the valve rises.

Dou'ble-nose Piece. (*Optics.*) A means for using two object-glasses without unscrewing, whereby either is brought into the optic axis of the instrument.

Dou'ble Pis'ton Bal'anced En'gine. A form of engine in which two pistons of equal area reciprocate in a cylinder, mutually advancing and retreating. See next article.

Dou'ble Pis'ton En'gine. One having a pair of pistons mutually advancing and retreating in the same cylinder, each traversing half the length of the cylinder, the steam being alternately admitted between the pistons, to force them apart; and at their ends to force them together. — *Wells.*

"*Manufacturer and Builder*" . . . . * xi. 49.

See also BALANCED ENGINE.

Dou'ble Pit'man Press. A heavy stamping press for sheet-metal work, the slide being operated by two pitmans having eccentric connection with the same shaft. A measure of strength and steadiness.

Dou'ble Plan'ing Ma-chine'. (*Metal Working.*) A large planing machine having two pairs of independent heads on opposite cross-slides movable to any position on the bed. The two slides swivel to any angle and have variable automatic feed in all directions. The movement of the table is by screw and gearing driven by two belts separately shifted.

Dou'ble Plate Wheel. (*Railway.*) A car wheel which has two plates connecting the hub and the rim. The plates are generally corrugated in cast car-wheels, but are flat in the compound wheels.

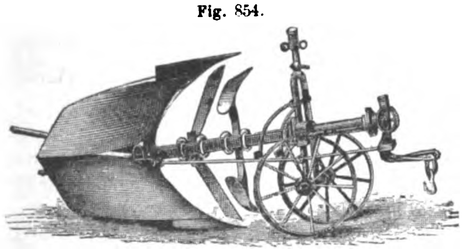
The Washburn wheel has a double corrugated plate next to the hub, about half way to the rim, and a single corrugated plate beyond it. *a a'* Fig. 1170, p. 493, "*Mech. Dict.*"

Dou'ble Plow. (*Agric.*) *a. A double furrow* plow, or one turning two furrows. See GANG PLOW.

b. A plow adjustable to turn a furrow to the right or to the left. A *side-hill* plow; a *turning mold-board* or *reversible* plow. There are four forms of this implement; see under the various heads.

The illustration is the Brabant double plow, which is perhaps the prime favorite in France at the present time. It has

Fig. 854.



Brabant Double Plow.

the skim share or jointer, and to reverse the plow and throw the furrow to the left, it is unlocked at the rear and revolved 180°.

Double plows, French and American, Knight's report, "*Paris Exposition* (1878) *Report*," * vol. v.

See also "*Scientific American*" * xxxix. 168.

Dou'ble Pur'chase. (*Nautical.*) A form of tackle also known as *gun-tackle purchase* with two single-sheave blocks. *c,* Fig. 6159, "*Mech. Dict.*"

The *reef tackle* is also a double purchase.

Dou'ble Rach'i-tome. (*Surgical.*) An instrument with two parallel saws for making an exsection of the spine.

Fig. 333, Part I., *Tiemann's* "*Armam. Chirurgicum.*"

Dou'ble Rud'der. A pair of rudders. Very common on our Western rivers, and on ferry-boats there and elsewhere, but not so much so on sea-going vessels. Twin screws and twin rudders are however, becoming more common in some classes of war vessels.

And movable propeller, *Sadler* . "*Sc. Amer. Sup.*," 1922.

Dou'ble Safe'ty Valve. A pair of safety valves on the same steam-pipe or dome. A measure of safety in case of one becoming rusted fast, or otherwise inoperative. Fig. 853.

Dou'ble Screw. Said of a vessel with two screw-propellers.

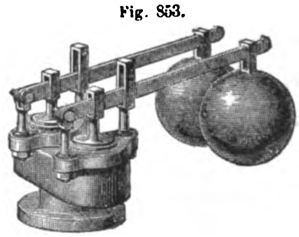
Tug-boat, *Howden*, Br. . * "*Engineering*," xxi. 253.
"*Scientific American Sup.*," 868.

See also TWIN SCREW.

Dou'ble Screw Up'right Vise. A parallel-leg vise. A screw above and one below being operatable by the same handle maintain a perfect parallelism of the jaw faces.

The upper screw is connected by chain to the lower one so as to make their motion simultaneous and equal.

Fig. 853.



Double Safety Valve.

Dou'ble Shap'ing Ma-chine'. A shaper, the heads in duplicate, so as to act upon two portions of an object dogged to a common table.

Wood, *Robinson*, Br. . . . . . * "*Engineer*," xlv. 276.

Dou'ble-shear Steel. (*Metallurgy.*) Blister steel, heated, rolled, and tilted to improve the quality, and the process repeated.

Dou'ble Steam-ket'tle. One kettle within another, the joint steam-tight, and steam occupying the interval.

Dou'ble Sur'fa-cing Ma-chine'. A wood-planing machine which acts upon the upper and lower surfaces of the board simultaneously.

Dou'ble Ten-ac'u-lum. (*Surgical.*) An instrument with two claws apposed by pivoting, in the manner of scissors.

Figs. 454, 461, 462, Part III., *Tiemann's* "*Armamentarium Chirurgicum.*"

The double-claw tenaculum, Fig. 21, Part I., *Ibid.*

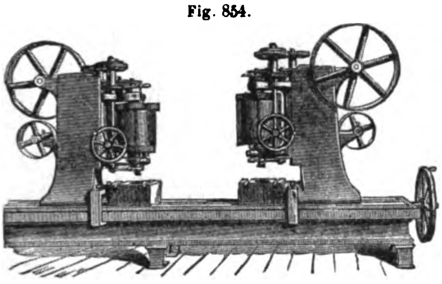
Dou'ble Trans-mis'sion Tel'e-graph. (*Electricity.*) A form of duplex telegraph.

Sieur . . . * "*Telegraphic Journal*," vi. 375.

Dou'ble-trav'erse Drill. A machine-tool for boring holes simultaneously, at both ends of a bridge-link, for instance, to insure exactness where many pieces of precisely the same size and proportions are required. The double-traverse drill has right and left-hand boring machines, sliding on a solid bed, and adjustable to or from each other to suit the required length of links.

The boring machines are so placed as to permit the links to be put in place from one side, and, when done, passed out

Fig. 854.



Sellers' Double Traverse Drill.

on the other side of the machine. The driving is effected by horizontal belts passing over guide-pulleys, and around a drum on the spindles. The cutters are kept cool by water fed to them through the center of the spindle. The two heads are united by bars of wrought-iron, and can slide freely on the cast-iron bed. The expansion of the wrought-iron bars being the same as the expansion of the link being bored, insures uniformity in the length of the finished work.

Dou'ble-truck Lo-co-mo'tive. (*Railway.*) A form of locomotive in which a leading pony truck is added to the driving. See instance in "*Railroad Gazette,*" * vol. xxiv., p. 8, and full-page plate; a locomotive of the Denver, South Park, and Pacific Railroad. The pony truck in this case is to carry the overhanging weight of the cylinder and to protect the front driving-wheels from wear.

Dou'ble-tub Press. A cider or wine press which has two concentric cylinders, the pomace or marc occupying the space between the two, the piston or follower of the press being annular. A French press is shown in Dr. Knight's report, "*Paris Exposition* (1878) *Reports,*" * vol. v., p. 232. The double tub gives two surfaces at which the liquid may exude, and the arrangement is very effective, inasmuch as it is especially difficult to drain the interior of the mass of pomace.

In the instance shown the power is applied by means of a toggle which is particularly suitable, the force increasing as the knees become more and more extended. To put the press in action the platen is depressed by means of a small hand-wheel placed at the end of the screw. When the pressure thus obtained is not sufficient, a stronger force may be obtained by the lever and ratchet-wheel.

See also Fig. 618, p. 196, *supra*.

Dou'ble Tur'bine. *a.* A pair of turbine wheels on the same shaft, one receiving the water from the other. A doubtful expedient.

b. A pair of turbines on the same shaft, receiving the water between them and each discharging outwardly. A *double-head wheel.*

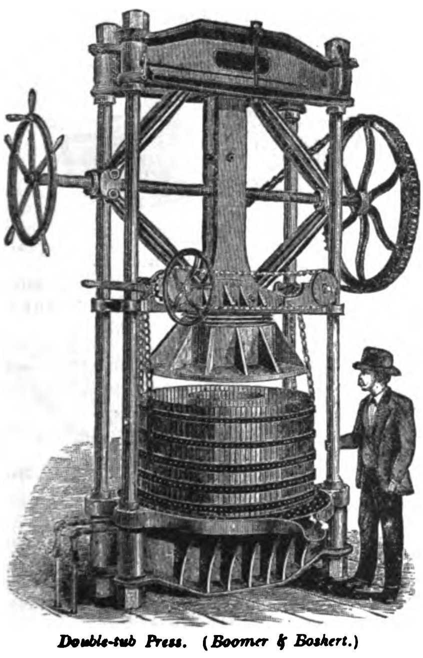
c. A turbine with a partition in the middle of the tier of buckets, dividing the wheel. More curious than useful, and the name a misnomer.

d. A combination of two kinds of turbine on the same shaft, — one a *vertical* and the other a *central* discharge. Leffel. Each receives its water from the same set of guides at the same time, half the water passing to each wheel. This is believed to afford a freer escape for a large volume of water than if the same area of opening were employed in a single wheel on either the vertical or central system of discharge.

Dou'ble Turn'ing-mold'-board Plow. (*Agric.*) A double-furrow plow, having the additional capacity for turning the furrows either to the right or to the left. A gang-plow adapted for hill-side work.

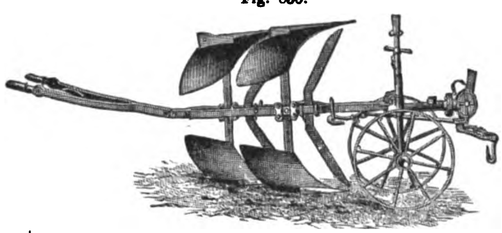
The instance shown is the *Brabant double bisoc,* — a favorite French form. It may be mentioned that the adaptability for mold-board turning is not (in France) for the purpose of plowing side-hills, but to enable the plowman to begin at the side of a field and plow furrow by furrow clear across, reversing the plow at the end of each furrow, — the ancient mode of plowing still common in the Orient. See BOUSTROPHEDON, *k.* Fig. 1613, p. 1655, "*Mech. Dict.*"

Fig. 855.



Double-tub Press. (*Boomer & Boshert.*)

Fig. 856.

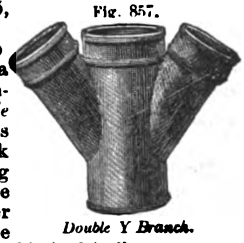


Brabant Double Turning-mold-board Plow.

Dou'ble Wheel'-lathe. A lathe adapted to receive a pair of wheels while on their axle, as in the wheel-lathe, Fig. 7185, p. 2767, "*Mech. Dict.*"

Dou'ble Whip. (*Nautical.*) A *whip* is a rope wove through a single block; in a *double whip* the rope passes through a lower or hook block, and the standing end is secured to the upper block or other point of attachment. See also Fig. 6159, p. 2480, "*Mech. Dict.*"

Fig. 857.



Double Y Branch.

Dou'ble Y Branch. A triple pipe connection, one central and two branching, from a single main.

Dou'bling Wind'ing Ma-chine'. A machine used in thread manufacture to double and at the same time wind the doubled yarn, ingenuity being displayed in securing uniform winding speed notwithstanding the increasing diameter of the wound yarn.

Boyd's doubling winder, * "*Textile Manufacturer*," 1878; reproduced in "*Scientific American Supplement*," * 2179.

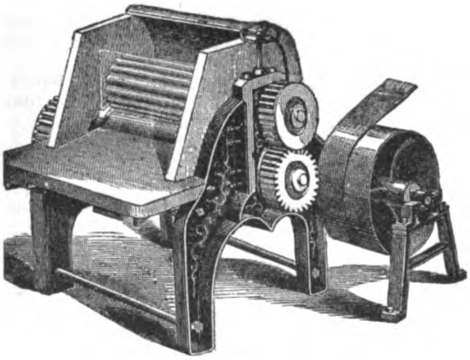
Douche. (*Surgical.*) A syringe constructed for special applications and deriving its name therefrom, as, —

Catarrhal.	Uterine.
Eye.	Vaginal.
Ear.	Hemorrhoidal.
Nasal.	Rectal, etc.

See Fig. 1727, p. 782, "*Mech. Dict.*"

Dough Brake. A bakery machine for kneading dough. It takes the material from the mixing machine, and makes it ready for the cracker machine. Dough brakes are *simple* or *return*. In the former case the dough is laid upon a table, passed between rollers, and discharged on to a lower shelf whence it is picked up and laid on the upper table for the repetition of the process. In the *return* dough brake the labor of lifting the dough is saved.

Fig. 858.



Dough Brake.

The dough is placed on the table, taken by the rollers, passed between the rollers, and carried over the upper one back to the table ready to be doubled and passed through again.

Dough Cut'ter. A circular cutter for stamping out cakes from a sheet of dough. A spring piston ejects the cake from the cutter.

Collins * "*Scientific American*," xxxiv. 355.

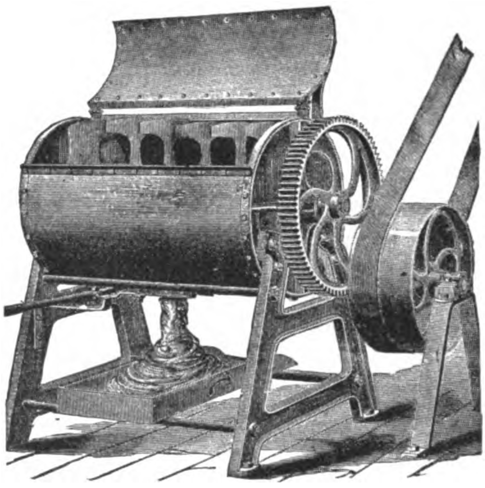
Dough Knead'er. A machine for incorporating dough: violent and repeated pressure is necessary. See Dough Brake. The name of the *brake* is from the pivoted lever upon which the weight of the man was formerly swung in the old method of preparing cracker dough.

The Durand dough kneader is an annular trough driven by steam, and with stirring devices which revolve in the trough while the latter revolves.

Pfleiderer, Br. . . . * "*Engineering*," xxviii. 483.
"*Scientific American*," xl. 246.

Dough Mix'er. A bakery machine for compounding the ingredients of bread, cake, crackers, as the case may be. The machine illustrated is for mixing soft cake dough, beating eggs, and preparing the dough for the machine which rolls

Fig. 859.



Ruger's Dough Mixer.

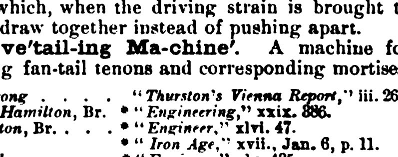
the paste, and cuts and pans the cakes. See Cracker Machine. The dough mixer is a horizontal cylinder with an axis provided with arms which cut, stir, and intimately incorporate the materials. It is discharged below when the gate is opened.

The hard dough-machine is on the same principle, but the discharge of the much more solid dough is by a spout in the manner of a sausage-stuffer.

Doul'ton Ware. (*Ceramics.*) A ware with an ordinary clay body and the salt glaze of stone ware, made by Doulton, of London.

The pieces are thrown, not molded, and are highly artistic, being cut, carved, and incised, with small ornaments in body of another color, added in lines or bands. Some colored slips are used, and a few metallic oxides contribute to the richness of coloring which the final glazing in the open salt-glaze kiln imparts.

Fig. 860.



Dovetail Clutch-coupling.

Dove'tail Clutch'-coup-ling. A device in which the interlocking parts are formed of dovetails which, when the driving strain is brought to bear, draw together instead of pushing apart.

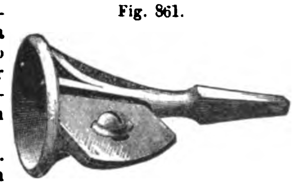
Dove'tail-ing Ma-chine'. A machine for cutting fan-tail tenons and corresponding mortises.

Armstrong . . . . "*Thurston's Vienna Report*," iii. 265.
Tighe-Hamilton, Br. * "*Engineering*," xxix. 886.
Hamilton, Br. . . . * "*Engineer*," xlvi. 47.
* "*Iron Age*," xvii., Jan. 6, p. 11.
Stengel . . . . . * "*Engineer*," xlv. 435.
* "*Scientific American*," xxxviii. 246.

Dow'el Ma-chine'. A machine for turning dowels; the small cylindrical pegs wherewith jointed boards, table-leaves, or staves are connected. It is like a rod lathe, the stuff passing through the hollow head and turned by a chisel or by a special tool, a sort of hollow auger. A *rod, pin, and dowel machine*, Fig. 4394, p. 1961, "*Mech. Dict.*"

Dow'el Point'er. A hollow cone with a bit projecting inwardly, into which a dowel is thrust to point or chamfer the end to facilitate its entrance in driving.

Fig. 861.



Dowel Pointer.

Draft Chain. A chain by which the draft of a plow-team is thrown back on to the part of the beam near the standard, instead of hitching direct to the forward end of the beam.

A draft rod answers the same purpose, and is shown in Fig. 3825, p. 1746, "*Mech. Dict.*"

Draft'ed Stone. (*Stone Cutting.*) Ashlar stone the face on which is surrounded by a chisel draft, the space inside the draft being left rough.

Draft'ing In'stru-ments. See list on p. 736, "*Mech. Dict.*," also the following references: —

Templet, *Davis*	* "*Sc. Am. Sup.*," 3757.
Easel, *Boudriot*, Ger.	* "*Sc. Am.*," xlii. 338.

Pen, *Faber*	* "*Engineering*," xxx. 168.

See also list of Drawing, Writing, Copying Instruments and Processes on pp. 272, 273 *infra*. Also list under Graph, p. 1009, "*Mech. Dict.*"

Draft Reg'u-la'tor. A means of governing the energy of a fire by means of limiting the access of air thereto, or the egress of air therefrom: by devices, that is to say, which control the admission of air to the fire, or govern the sectional area of the chimney. Such is a *damper*. The subject is considered under Damper Regulator, which see.

Woodruff's draft regulator acts by pressure of steam on a diaphragm, excess of pressure closing a damper in the chimney to a regulated extent.

The "acme" draft regulator acts by displacement of water by steam. Patent, October 11, 1875.

For stoves, *Andrews*	* "*Scientific Amer.*," xxxviii. 339.
"Acme"	* "*Scientific Amer.*," xxxv. 179.
Franklin	* "*Scientific Amer.*," xlii. 231.
Turl	* "*Manuf. & Builder*," xii. 76.

Draft Tug. (*Harness.*) *a.* A trace.

b. A short section attached to the draft eye of the hame, and to which the trace proper is buckled.

c. A spring section in a trace to relieve the horse from sudden jerks.

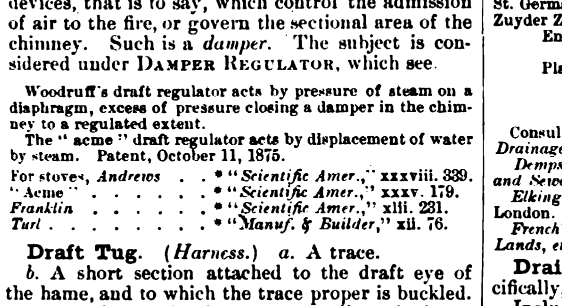
Smalley's	* "*Scientific American*," xlii. 100.

Drag. (*Spinning.*) A device to act as a gentle brake upon the rotation of a bobbin in throstle spinning and doubling frames. — "*Textile Manufacturer.*"

"*Scientific American Supplement*" . . . . . * 2705.

Drag Chain. A chain dragged by a plow in such a position as to gather and turn weeds and trash over into the furrow to be covered by the plow. Fig. 862 shows the mode of attachment.

Fig. 862.



Right Hand Plow with Rolling Colter and Drag Chain.

Not to be confounded with *draft chain*, which is a means of drawing the plow without hitching to the nose of the beam.

Drag Mill. (*Metallurgy.*) Another name for the arrastra. Blocks of porphyry are dragged around in the pan. See Figs. 367–371, pp. 159, 160, "*Mech. Dict.*" See also Amalgamator, *Ibid.*

Drag Saw. A cross-cutting saw for logs. The fact that the cut is upon the *draw* and not upon the *thrust* motion is the occasion of the name. See Fig. 1522, p. 649, "*Mech. Dict.*"

Alters & Basington	* "*Scientific American*," xli. 21.
Giles	* "*Scientific American*," xli. 230.

Drail'ing Tack'le. (*Fishing.*) A trawling tackle, the line with bait, real or artificial, being towed over the surface by the moving boat.

Drails. A jig or artificially-baited hook, used in trawling.

Drain'age. See notices under the following: —

French's "*The Principles, Process, and Effects of Draining Lands, etc.*"

Drain'age In'stru-ments. (*Surgical.*) Specifically, tubes placed in a wound to withdraw pus.

Inclusive also of trocars, canulæ, and aspirators in one of their functions. See Fig. 6665, p. 2629, "*Mech. Dict.*"; and Figs. 120, 121, p. 52, *supra*.

Instruments for *paracentesis abdominis* are given on p. 162, Part III., *Tiemann's* "*Armam. Chirurgicum*," including: —

Drainage trocar.	Clamp Forceps.
Drainage tubing.	Trocars.
Drainage spiral.	Aspirator needles, etc.

Instruments for *paracentesis corneæ*, *Ibid.*, p. 29, Part II.
Instruments for *paracentesis thoracis*, *Ibid.*, p. 131, Part I.

Drain'age Tent. A dilating instrument introduced into the cervix uteri.

The uses and value of sponge, sea-tangle (*laminaria*), tupelo, and solid and tubulous tents, discussed by *Dr Sussdorf*, "*Richmond & Louisville Medical Journal*," May, 1879.

Drain'age Tube. A tube introduced into a wound to form a means of discharge of matter.

Dr. J. B. Hamilton's drainage-tube carrier consists of a stylet, with a hook at the end within a canula; the stylet is moved by a button over a side slot in the canula.

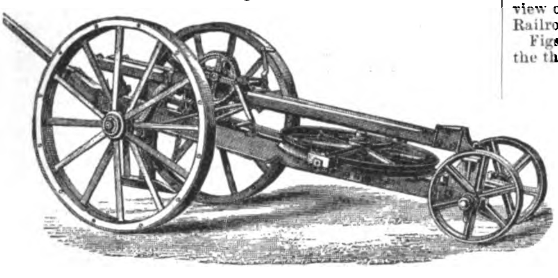
Drain Cock. A faucet attached to a cylinder to draw off water of condensed steam.

Drain Clean'er. A long-handled spade, the blade set on at an angle in order to be able to reach the bottom of a ditch when standing on the surface of the ground. See Ditch Cleaner.

Drain Gage. A device to measure the percolation of moisture — rain, liquid manure, etc. — through soil, and involving elaborate apparatus, is erected at Rothamstead, England, and a description is given in "*Scientific American Supplement*," * 1607.

Drain Grate. A grid at the entrance of a sewer in a yard or street.

Fig. 863.



Steam Draining Plow. (*Fowler & Co.*)

Drain'ing Plow. (*Steam Culture.*) A plow for opening furrows or drains for water. Fig. 863 shows the Fowler draining plow, adapted to be drawn by the plow-engine, which is applicable to various duties of steam husbandry.

It is drawn by the winding engine and rope; see Fig. 5706, p. 2354, "*Mech. Dict.*" It is used either as a mole plow, or to put in drain tile, and is worked to a depth of 42″. The wire rope passes over the sheave, and so draws the plow at but half the rate that it would were it hitched directly to the front of the implement.

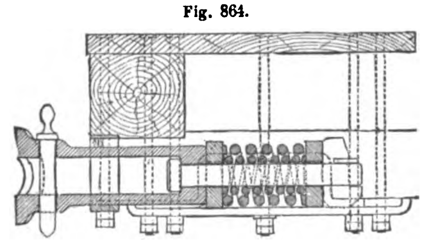
See also DITCHING MACHINE, and items in lists of AGRICULTURAL IMPLEMENTS, "*Mech. Dict.*," and *supra*.

Drain Tile Lay'er. *a.* A long handle with a piece projecting at right angles from the lower end, to place in position drain tile at the bottom of a trench.

b. Some forms of draining machines also lay tile. Some are noticed on p. 741, "*Mech. Dict.*"

Drain Tile Ma-chine'. See TILE MACHINE.

Fig. 864.

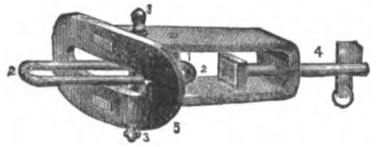


Draw Gear for Freight Cars. (*Pennsylvania Railroad.*)

Drain Trap. A device at the opening of a drain or sewer to allow passage to liquids by preventing emission of gases.

Banner, Br.	* "*Engineer*," xli. 51.

Fig. 865.



Bolt Draw Bar.

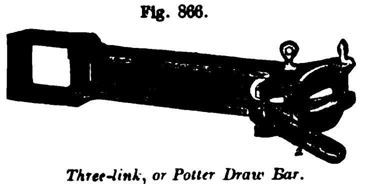
1. Coupling-link Rivet.
2. Fast Coupling-link.
3. Fast Coupling-pin.
4. Draw-bar Bolt.
5. Draw-bar Face-plate.

Draw Bar. (*Railway.*) An open-mouthed bar at the end of a car to which the coupling-links are attached, and with which the car is drawn. The draw-bars are usually provided with springs to give elasticity to the connection between the cars, and arranged so as to resist both the tension and compression to which the draw-bar is subjected. — *Forney.*

These springs are shown in the longitudinal sectional view of the draw gear for freight cars of the Pennsylvania Railroad, Fig. 864.

Figs. 865 and 866 are respectively the bolt draw bar, and the three-link, or *Potter* draw bar.

Fig. 866.



Three-link, or Potter Draw Bar.

Fig. 867 is a safety draw bar, which accommodates itself to draw heads of varying height.

Safford	* "*R. R. Gaz.*," viii. 164.

Draw'bridge. A bridge capable of being moved to leave a free channel for vessels. They are *lifting, swing or turning, bascule, rolling.* See pp. 241, 742, 1721, 1965, "*Mech. Dict.*," and references; also list on p. 380, *Ibid.*

Harlem	* "*Man. & Builder*," xi. 6.
Lifting	* "*Man. & Builder*," xi. 29.
Thames, proposed	* "*Scientific Amer. Sup.*," 290.

Draw'ing. (*Add.*) 5. (*Glass.*) Glass is drawn into tubes or sticks by attaching a ponty to the end of a bulb held on the blowing tube, and running away with it; so that the glass is elongated between the ponties held by the respective men.

In drawing tubes, the glass is blown to a globe, so that as the workman runs off the stick is hollow; the thickness of the glass and bore of the tube are regulated by the quantity of metal in the globe, the size of the latter, and the rate of the motion of the retreating workman.

The stick or tube is constantly rotated, and when the workman has attained his distance the glass is laid on the floor to cool straight. It is divided into lengths by cold tongs. Such tubes furnish the material for beads.

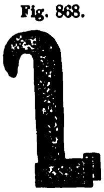
Fig. 868.



Drawing Hook.

Draw'ing Hook. A clutch-hook used in lifting well-rods.

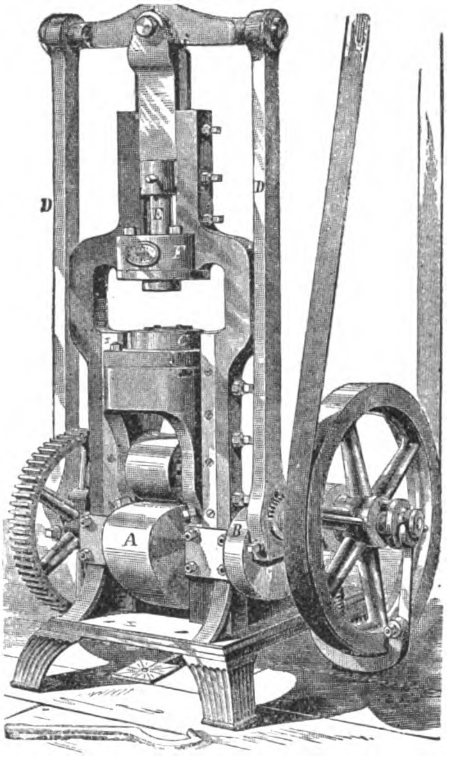
Draw'ing Ma-chine'. (*Add.*) 4. (*Cartridge Making.*) In making fixed ammunition in the United States factories there are five draws to the shell, coming in consecutive course. These machines elongate the shell and lessen its diameter by means of vertical dies descending into depressions beneath. The shells are fed into each machine on a horizontal wheel.

Drawing machine for cutters, Figs. 1-5, "*Engineering*," xxx. 484.

Draw'ing Press. A machine for cutting and drawing sheet metal into hollow ware. In making articles of moderate size it cuts the blank and forms the article at one operation. The work ranges from lantern bottoms, rim-covers, patty-pans, pie-plates, etc., up to 30-quart dish-pans and equally large work of other descriptions.

Power is communicated to the large pulley on the right, which, by means of a simple clutch, operated by the treadle shown under the bed, is thrown into or out of gear at will. From this pulley power is transmitted to a horizontal shaft passing through the lower portion of the frame, on which shaft is a heavy cam, *A*, and also two cranks *B*. The cam, in its revolution, acts upon a roll above it, and so elevates the carrier *C*, of the cutting and drawing dies, which carrier travels in slides in the frame. To the cranks are connected pitmen, *D D*, which connect with a wrought-iron yoke, to which is secured the drawing punch-rod, *E*. At *F* is a cross-

Fig. 869.



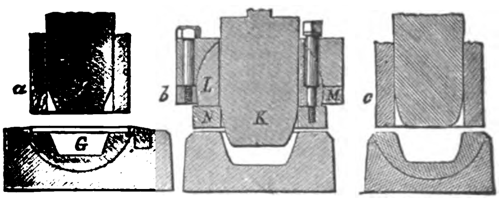
Double-acting Drawing Press.

piece between the two sides of the frame, through which piece operates the cutting-punch.

When the cam-shaft is rotated, the cam raises the die carrier, and the cranks, pulling down the pitman, force the cutting-punch against the metal and into the die below. This will be more clearly understood from the section *a*, Fig. 870, in which *G* is the drawing die, *H* the cutting die, *I* the cutting-punch (stationary), and *J* the drawing-punch. As the die carrier rises, the metal is first pressed against the cutting-punch *I*, between the outer edge of which and the cutting die *H* it is quickly cut, and the punch *I*, entering the die, then holds the edges so cut out as in a vise. At this point the drawing-punch *J* comes down and forces the metal into the drawing die *G*, thus completing the operation.

To obviate the difficulty incident to working in sheet metal not of uniform thickness, in which case the metal will be imperfectly held between the rising die and the stationary cylin-

Fig. 870.



Sectional Views of Drawing-press Dies.

der *I*, the lower portion of the drawing die *G* is made hemispherical so as to form a ball-and-socket joint, which enables the upper face to correspond with the face of the cutting-punch *I*, notwithstanding some slight difference in the thickness of the intervening sheet-metal. The device shown in section *a*, Fig. 870, is especially intended for small ware.

The arrangement shown at *b*, the same figure, is intended for large pans and like objects. In this there is no cutting of the metal by the machine, this having been previously done; there is, therefore, no cutting-die nor punch in this style of machine. The drawing die is a simple concavity without peculiar features, the essential points of the device being found in another means of holding the edge of the blank. The punch *K* passes directly through the ball portion, *L*, which is confined by a ring, *M*, held by the screw bolts, one of which is shown on the left. The edges of the blank are compressed and held between the surface of the die and a lower ring, *N*, which is upheld by another set of screw bolts, one of which is shown on the right. These bolts pass through a large bore in the ball portion, *L*, thus allowing the latter its free play and shoulder in said ball, as shown, so that the latter and the ring are closely united. The ring *N*, therefore, follows the play of the spherical portion, and consequently automatically adapts itself to the thickness of the metal. The punch then descends in manner similar to that already described.

c, Fig. 870 is a section of a simpler form of drawing press without cutter, but possessing the adjustable feature of *a*.

Referring to Fig. 869, it will be observed that the lower slide *C* is carried up by the cam *A* on the main shaft, and the shape of the cam is such that the slide dwells after cutting the blank, while the die on the lower end of the plunger *E* forces the sheet-metal into shape. The upper slide is brought down by the yoke *G*, operated by the pitmen *D D*, from cranks *B* on the main shaft. Thus it will be seen that the strain at the critical moment comes on the main shaft, pitmen, and yoke, — all of steel or wrought iron, — relieving the cast-metal frame. The frame bows at the point where the drawing takes place, thus affording a slight spring and a wider space in which to manipulate the blanks and the ware. See the following references: —

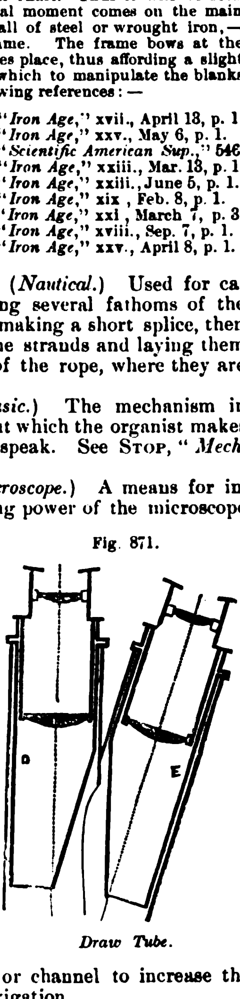
Draw'ing Splice. (*Nautical.*) Used for cables. Made by unlaying several fathoms of the two ropes to be joined, making a short splice, then tapering the ends of the strands and laying them along in the contlines of the rope, where they are secured by seizing.

Draw Stop. (*Music.*) The mechanism in an organ, by drawing out which the organist makes such and such a stop speak. See Stop, "*Mech. Dict.*"

Draw Tube. (*Microscope.*) A means for increasing the magnifying power of the microscope by lengthening the distance between the object-glass and eye-piece without changing for lenses of different power.

Fig. 871.



Draw Tube.

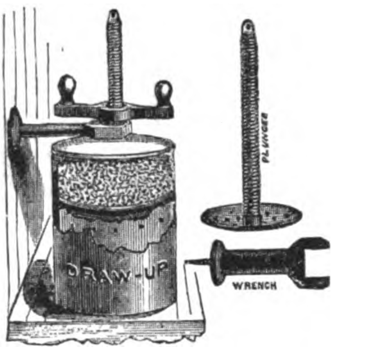
Fig. 871 shows the draw-tubes *D E* of a binocular microscope.

Draw'-up Press. A small domestic press for jelly, fruit, or what not, in which the platen is drawn up by a screw, and presses the material against the lid, leaving a space beneath in which the liquid expressed may collect. Fig. 872.

Dredge. A machine for excavating the bottom of a river or channel to increase the depth and facilitate navigation.

The Eads dredging machine is a sort of plow with a throat, comparable to a carpenter's plane, 4′ in width, and with arrangements for limiting the depth of its cut on the silt of the river-bottom, so that the silt and water shall bear a quantitative relation, the silt occupying so much of the 16″ of throat as the nature of the plowed-up material shall

Fig. 872.



Draw-up Press.

warrant. An Andrews cataract pump of 27″ diameter suction is the lifting apparatus, and the discharge is into tanks of 1,000 tons capacity, with overflows for water as the silt settles to the bottom.

The dredge-boat is 200′ in length, propelled by horizontal high-pressure engines, each 7′ stroke and 21″ diameter, turning paddle-wheels 28′ diameter. It is designed to move at the rate of from 10,000′ to 15,000′ per hour.

See also Excavator, *infra*, and figures on pp. 747–749, and 814, "*Mech. Dict.*"

(*Add.*) 2. (*Fishing*). A rake or scoop, with a net attached, drawn with open mouth in the wake of a vessel to gather oysters or flat-fish, coral, or other objects. See Trawl Net.

Fig. 873 shows the *dredge* and *tangles* of the expedition ship "Challenger."

Dredg'ing Tube. A tube which is lowered from a vessel or scow and burrowing in the silt removes it by means of a connected steam-pump which draws up the solid portions together with water.

This is a feature common in pneumatic dredgers; see list of references under Dredge. See also Figs. 1762, 1763, p. 749, "*Mech. Dict.*"

One form is a closed tube which is lowered into position and then filled by exhausting the air by pump; after which the tube is lifted and discharged, shown in * "*Scientific American*," xxxvii. 371.

Fig. 873.

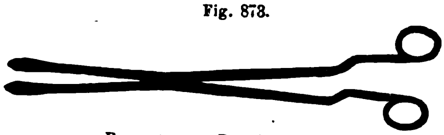
Dredge and Tangles of the "Challenger."

Dres'ser. 1. (*Mining.*) A heavy pick used for preparing the large bunches of ore for loading on the skips.

2. A plumber's wooden mallet, or rather paddle, for closing sheet-lead joints.

Dres'sing For'ceps. (*Surgical.*) An instrument used in applying and removing dressings.

Fig. 873.



Bayonet-curve Dressing Forceps.

Dress'ing Ta'ble. 1. (*Stereotyping.*) A machine for straightening and trueing the edges of stereotype plates; and for beveling and cutting off curved plates for newspaper work and for perfecting presses. See figures on pp. 2378–2381, "*Mech. Dict.*"

2. A brickmaker's table on which bricks are dressed, to make them symmetrical for house-front courses. Fig. 1764, p. 749, "*Mech. Dict.*"

3. A bench on which copper or other ores are hammered, and sorted into qualities.

Drift Net. (*Fishing.*) A gill net suspended from a cork line and having leads at its lower edge. A float at each end carries a lantern and it floats with the tide or current. Such a net is usually 300 yards long, and a number of such are cast parallel with an intervening space of 50 to 80 feet. The gilling ground of the Chesapeake Bay is famous.

Drill. 1. (*Surgical.*) A boring instrument in operations in osteotomy.

Brainard's, Tiemann's, Hamilton's, Howard's, and *Buck's* drills are shown on p. 8, Part I., *Tiemann's "Armamentarium Chirurgicum."*

See list under Surgical Instruments, "*Mech. Dict.*" *et infra.*

Drill for ununited and oblique fractures, *Ibid.*, Fig. 61, Part I.

2. (*Dentistry.*) A boring tool used in mechanical or operative dentistry. See Dental Drill, *supra*, and Fig. 1609, p. 685, "*Mech. Dict.*"

3. (*Machinery.*) A boring tool for metals. See pp. 750–752, "*Mech. Dict.*," and the following references: —

The United States drilling scow, East River, N. Y., is shown in "*Scientific American,*" * xli. 131.

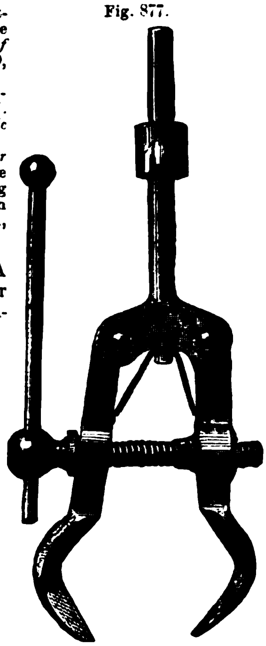
See also Report by *Sir John Hawkshaw* on the Hydraulic Engineering Group, British Reports on the Centennial Exhibition, 1876.

Drip Pump. A plumber's pump for removing drip or collections of water incident to accidents to pipes or in clearing up after work.

Fig. 878.

Evarts' Drive Chain.

Fig. 877.



Drilling Clip.

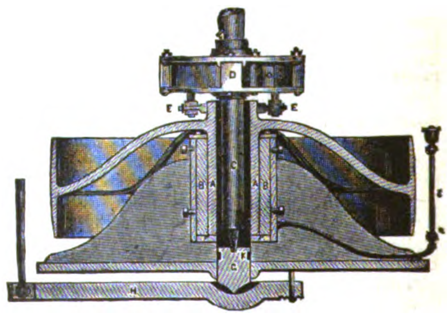
Drive Chain. A detachable link chain used in connection with sprocket wheels, to drive machinery. Each link has a hook and bar at its respective ends, and these may be connected in certain relative position, but cannot be detached when stretched. Fig. 878.

Drive Well. A tube driven into an aqueous stratum, and forming the stock for a pump attached to its upper end.

See notices. * "*Iron Age,*" xxi., Jan. 31, p. 3; Feb. 7, p. 3.
"*Scientific American,*" xxxv. 17.
In England . * "*Scientific American Sup.,*" 1697.
Paper by *Palmer,* "*Scientific American,*" xxxix. 408.

Dri'ving Pul'ley. One receiving motion from a belt, and concerned in driving machinery: as distinguished from a *loose* pulley, which runs free on the shaft, and does not communicate motion. The belt is shifted from the *loose* to the *driving* pulley when the machine is to be started, and *vice versa.*

Fig. 879.



Hafner's Equilibrium Driving Pulley, for Millstones.

Hafner's equilibrium driving pulley, designed for driving mill-stones, is intended to prevent the side draft of the belt on the pulley from putting the stone out of tram. The hub *A* of the pulley works in the bearing *B*, which rests on the bridge-tree *H*, by means of the step *G*. *C* is the spindle of the stone resting on *G*, and *E E* are drivers on the hub, which project upward into the jaws *D* of the coil spring. The arms of the pulley are curved down, so that the strain of the belt is on the center of the bearing *B*, and the side strain does not communicate to the spindle, as the drivers *E* have a freedom of motion in the jaws of the spring.

Dri'ving-wheel Brake. (*Railway.*) One applied directly to, usually between, the driving-wheels of a locomotive. Fig. 749. *Forney's "Car-builder's Dictionary,"* p. 475.

Drogue. A drag-anchor, thrown overboard from a vessel to keep a ship's head to the wind when drifting. See Drag Anchor, * p. 737, "*Mech. Dict.*"

Drop and Trans'fer Ta'ble. (*Railway.*) An arrangement for taking out the wheels of car trucks without removing the trucks from under the car.

Kirby's arrangement is shown in Fig. 880, which gives a side elevation of the truck and a section of the pit, which is transverse to and below the line of rails. The drop table is a truck, *C*, which runs on wheels on a rail under and transverse to the main line of rails, *A*, and has a screw-jack, *E*, which is brought beneath the axle of the pair of wheels, *F*, to be removed. These being lifted, a hinged section, *B*, of the rail is swung open, and the pair (*E*) of wheels lowered into the pit, as shown by dotted lines, the transfer moved off, and a new pair introduced in a corresponding manner.

Drop Bot'tle. One for using in small quantities iodine, creosote, acids, etc., in the laboratory.

Fig. 881.

Drop Bottle.

Warm the bulb over the flame of a spirit-lamp, or in warm water, to expel the air, immerse the point of the pipette in the liquid, and the latter will ascend as the air condenses. When cool, place in the bottle, which should have enough of the liquid to cover the point of the pipette.

When required to be used take it from the bottle, and the warmth of the hand on the bulb will force the liquid out a drop at a time.

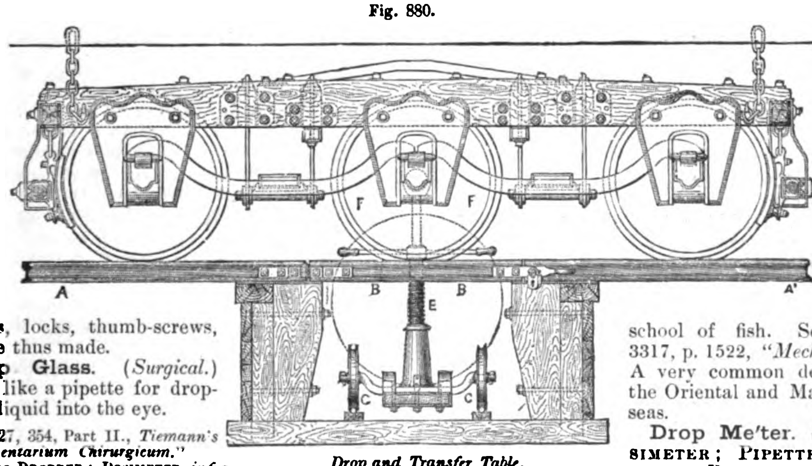
See also Dosimeter; Burette; Pipette, etc.

Drop Cut'-off. (*Steam.*) That form of cut-off in which a weighted bar is released at a regulatable point, and by its fall closes the valve. The Corliss arrangement is a familiar instance.

Drop For'ging. One made in that form of press in which the blow is by impact instead of by mere pressure. A forging made by a drop hammer.

Parts of sewing machines, watches, guns, pistols, drill-chucks, spinning rings, wrenches, clinch rings, shuttles, locks, thumb-screws, etc., are thus made.

Fig. 880.



Drop and Transfer Table.

Drop Glass. (*Surgical.*) A tube like a pipette for dropping a liquid into the eye.

Figs. 27, 354, Part II., *Tiemann's "Armamentarium Chirurgicum."*
See also Dropper; Dosimeter, *infra.*

Drop Ham'mer. A swaging hammer having a vertical motion in guides, or suspended by spring connection from a reciprocating portion. See Dead Stroke Hammer, Drop Press, "*Mech. Dict.*"

See following references: —

Hasse, Br.	* "*Engineering*," xxviii. 396.
Hill	* "*Scientific American*," xxxv. 67.

Peek	* "*Iron Age*," xxi., May 2, p. 41; xxii., Dec. 5, pp. 24, 29.
Pratt & Whitney . .	* "*Eng. & Mining Jour.*," xxi. 298.

Drop-lev'er Scales. A weighing scales with a lever to raise the platform entirely off the working parts of the scale while it is being loaded.

Drop Light. A gas-light vertically adjustable to bring it from a chandelier to convenient table-height.

Taylor . . . . . * "*Scientific American Sup.*," 1363.

Drop Net. (*Fishing.*) A net suspended over the water, and dropped vertically over a passing school of fish. See Fig. 3317, p. 1522, "*Mech. Dict.*" A very common device in the Oriental and Malaysian seas.

Drop Me'ter. See Dosimeter; Pipette; Burette; Dropper, etc.

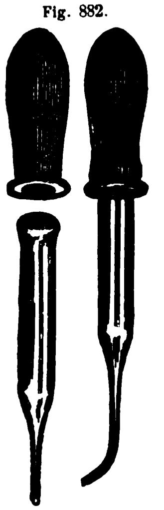
Drop'per. 1. (*Agric.*) A form of reaper in which the grain falls backward from the knife on to a slatted frame which is *dropped* at intervals to discharge the gavel. As the rear-end of the frame drops to the ground the heads of the cut grain catch in the stubble, and the gavel is pulled off in a compact bunch of a width equal to the length of the knife-bar. The dropping is done automatically at regulated intervals, or can be operated at the will of the driver. When the dropper falls, a horizontal rod descends temporarily to arrest the falling grain so that it shall not trail off at the rear of the gavel. When the dropper rises the rod also ascends and allows the grain to fall freely and collect on the dropper. See middle figure, Plate XLVI., p. 1892, "*Mech. Dict.*"

2. A pipette. A tube with a small aperture at its lower and an elastic bulb at its upper end. Fig. 882. By compressing the bulb, and plunging the lower end into a liquid, the tube is filled, and the liquid ejected in drops by gentle compression of the bulb.

Drop'ping Tube. A *pipette, burette,* or *dosimeter.* See DROPPER.

Drop Shut'ter. (*Photography.*) An arrangement for giving a very rapid exposure to a plate in instantaneous photography.

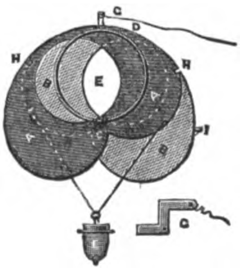
Fig. 882.



Dropper.

It is essentially constructed of two heart-shaped disks, *A A*, revolving on one axis, which is attached to the lower part of the mount of the lens. These two plates, when released by the trigger, have a reciprocal motion imparted to them by means of the weight *F*, which hangs suspended from the upper part of each. The apertures in each plate are thus simultaneously brought in front of the lens, and the exposure rapidly effected. The exposure commences and terminates at the lower side of the center, *E*, of the lens, so that the foreground will get slightly more light than the upper portion of the picture, an advantage which will be readily appreciated by photographers.

Fig. 883.



Duplex Drop Shutter.

D is a ring adapter fitted to the mount of the lens. *G* is a trigger with cord attached, fitting into notches *H*. When the exposure is completed the stop at *I* comes in contact with an overhanging hook near the trigger *G*.

Drop Tube. A PIPETTE. See DROPPER; DOSIMETER.

Drum. (*Add.*) (*Surgical.*) A circular frame over which a membrane is stretched as an object on which are tested the delicate edges of eye instruments.

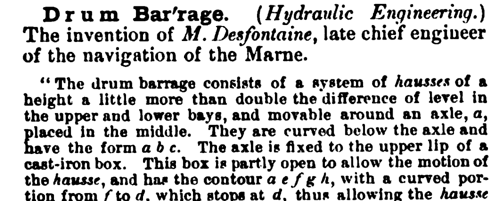
See Fig. 35 *b*, Part II., *Tiemann's* "*Armam. Chirurgicum.*"

Drum Bar'rage. (*Hydraulic Engineering.*) The invention of *M. Desfontaine*, late chief engineer of the navigation of the Marne.

"The drum barrage consists of a system of *hausses* of a height a little more than double the difference of level in the upper and lower bays, and movable around an axle, *a*, placed in the middle. They are curved below the axle and have the form *a b c*. The axle is fixed to the upper lip of a cast-iron box. This box is partly open to allow the motion of the *hausse*, and has the contour *a e f g h*, with a curved portion from *f* to *d*, which stops at *d*, thus allowing the *hausse* to move from the position *b a c d* to the position *b' a' c' d'*, leaving the two orifices *l* and *k*, outside of its path. The upper part of the box is flat, one portion below the other, so that the *hausse*, when lowered into the position *a b'*, is a little below the level *a e*, and thus hidden by it.

"Each *hausse* is fitted to a special box or drum, but all the boxes are pierced with oblong holes, *l* and *k*, so that they communicate when arranged side by side. The drums are fitted together by flanges around these holes, thus affording a communication along the whole line of the *barrage*, both before and behind the *hausses*, with the water in the upper bay.

Fig. 884.



Desfontaine's Drum Barrage.

"It is now evident that if, by means of sluice-gates or valves, the tube *l* is put in communication with the upper bay and the tube *k* with the lower bay, the difference of pressure on the face of the *hausse* will cause it to rise and take the position *b a c d*. If, on the other hand, the tube *k* is by a second system of sluice-gates put in communication with the upper bay and *l* with the lower bay, the system is reversed and the pressure forces the *hausse* to take the position *b' a' c' d'*; *i. e.*, lowers the *hausse*.

The simple turning of a valve thus opens the whole *barrage*. The time for opening is one and a half minutes; the time for closing four and a half minutes." — *Prof. Watson*, in "*Vienna Exposition Reports.*"

See also "*Van Nostrand's Engineering Mag.*," * xvii. 253.

Drum Guard. (*Agric.*) A British invention, to prevent a man while feeding a threshing machine from falling into the throat, and being mutilated by the cylinder. In the British practice the feeder is on top of the machine. Fig. 6395, p. 2557, "*Mech. Dict.*" In the American practice, no such attachment is used.

Drum Weir. The drum barrage of M. Desfontaine. See DRUM BARRAGE.

Dry Cup'ping Ap'pa-ra'tus. (*Surgical.*) An apparatus in which a limb is placed while the pressure of the surrounding air is withdrawn.

For *Junod's* apparatus see ARM; BOOT. See also DEPURATOR, "*Mech. Dict.*," and AËROTHERAPY APPARATUS, *supra.*

Dry Dock. (*Hydraulic Engineering.*) A basin, structure, caisson, etc., in or by which a vessel is exposed clear of the water, for examination, cleaning, or repairs.

See list on p. 715, "*Mech. Dict.*," and DEPOSITING DOCK, *supra.* Also GRAVING DOCK, FLOATING DOCK, "*Mech. Dict.*," *et infra.*

Dry E-lec'tric Pile. A name applied to a hermetically sealed pile; not that there is no exciting liquid, but it is inclosed in insulated and air and water-tight envelope.

C. L. Van Tenac, Paris, * "*Scientific Amer. Sup.*," 913

Dry'er. One form of dryer is that operating by centrifugal action in a wire cage, and is largely used with sugar, wringing clothes, etc. It has various names: *centrifugal machine, centrifugal filter, hydro-extractor, or sugar dryer, wringer,* etc., under some or all of which heads it is noticed in the "*Mech. Dict.*" See the various heads *supra et infra.*

Fig. 883 shows a drying machine of a size to be driven by hand, and such as is used in French laundries. See also list of DRYERS, page 758, "*Mech. Dict.*"

Dry'ing Ap'pa-ra'tus. See the following: —

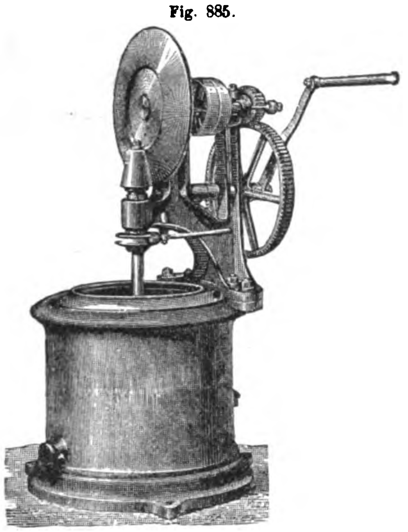
Oven, *Rohrbeck*	* "*Sc. American*," xlii. 180.

Dry'ing Case. (*Optics.*) A copper case surrounded with a chamber containing hot water, for drying tissues and hardening balsam preparations for the microscope.

Fig. 885.

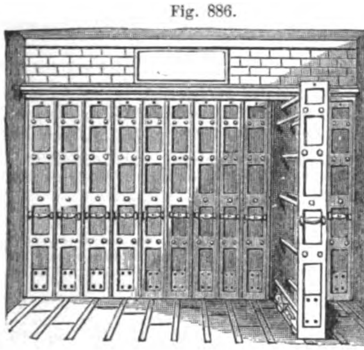


French Laundry Dryer.

Dry'ing Cham'ber. The closet in which printed stuffs are artificially dried; the tissue, accompanied by its *doublier,* passes in a zigzag manner over a large series of rollers near the ceiling and floor respectively of the room. After a certain course the *doublier* parts and goes to its own roller, while the tissue proceeds to the folding-room.

Dry'ing Clos'et An apartment made up of

Fig. 886.



Drying Closet.

a series of "draw-out horses" for the suspension of clothes to dry. It is heated in any suitable way, and is used in asylums and public laundries.

Dry'ing House. 1. (*Powder Making.*) A building remote from those in which the mechanical operations of powder-making are carried forward, and heated by steam from a distant boiler-house.

The steam pipes are laid along the floor, and have expansion joints. The temperature by thermometer is visible through a pane of glass, and the ventilators operable from the exterior. Wooden racks hold trays of sheet copper, or wooden frames with canvas bottoms to contain the powder. The maximum temperature is 130° F., and the time employed 18 hours, with an additional 6 hours for cooling. Pebble powder requires 135° F., and 36 hours exposure.

Russian dry house, Fig. 22, accompanying appendix to "*Ordnance Report,*" 1877.

2. (*Fruit.*) A structure, usually a tall wooden one-story out-house in which trays of fruit are exposed in an ascending column of heated air. See FRUIT DRYER.

Dry'ing Ma-chine'. (*Add.*) 2. The centrifugal machine is also used for drying fabrics, sugar, and other material. See DRYER.

3. A machine used in England for drying calicoes and printed cloths, consists of a furnace heating a column of air in a flat or slightly inclined trunk, through which the cloth passes on an endless apron. See Fig. 2262, article "*Lechoir,*" *Laboulaye's "Dictionnaire des Arts et Manufactures,"* tome iii. The French machine, article "*Impression sur Étoffes,*" Figs. 45, 46, *Ibid.*, tome ii.

Dry'ing Room. 1. (*Ceramics.*) The room in which green ware is dried previous to baking or burning, as the case may be. Some wares are baked to the biscuit condition, then ornamented and glazed; subsequently burned.

2. (*Linen.*) See DRYING CLOSET.

3. (*Calicoes.*) See DRYING MACHINE.

Dry'ing Stove. 1. (*Gunpowder.*) A close chamber in which powder is dried. A *drying house,* which see.

See also "*Ordnance Report,*" 1879, pp. 108, 109; and Plate V., Fig. 10.
Drying stove, for testing samples, *Ibid.*, Plate X. *b.*

2. (*Founding.*) A large fire-proof room usually heated by an open fire, used for drying cores, dry sand, and loam molds. It is furnished with racks and shelves inside, and is usually provided with a flat carriage traveling on rails extending to the crane, and has large iron doors.

Dry Pile. (*Electricity.*) A voltaic battery in which the positive and negative plates are disposed alternately with an intervening fibrous disk, combined with a deliquescent salt.

Zamboni's, Ganot's "Physics," 693, N. Y., 1877.

Dry Screen. (*Mining.*) A machine in which crushed dry mineral is sifted into sizes in order to treat it farther by processes which tend to separate different qualities by differences in speed, centrifugal or otherwise, principally due to differences in specific gravity.

Revolving dry screen . "*Min. & Sc. Press,*" * xxxiv. 33.

Dry Wash'er. A machine for sorting minerals by means of agitation, impulse, or air-blast, without the use of water, and so arranged that metals — gold or tin especially — are selected from the gravel, etc., by virtue of their greater specific gravity.

There are many devices which come under this definition. *Krom's* ore concentrator, for instance, Plate XXXIV., p. 1567, "*Mech. Dict.,*" and Figs. 3415, 3416, *Ibid.* Also ORE SEPARATOR, p. 157, and Figs. 3421, 3422, *Ibid.*

Du'al Burn'er. A lamp burner with two wicks: flat or argand.

Fig. 887.

Dual Burner.

Du'al Tel'e-phone. Invented by Pritchett. One end of a hinged and covered magnetized bar is fitted with a padded receiving ear-piece, and its other end is fitted with a transmitting mouth-piece. It is held by one hand, and adjusted to the ear and mouth by one motion; obviating the use of two instruments.

* "*Telegraphic Journal*" . vi. 471.

Dub'bing. (*Leather.*) *Daubing.* A mixture of tallow and either neats-foot or sperm oil. The dampened leather is coated therewith and rendered supple thereby. *Stuffing.*

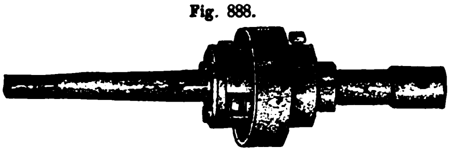
Duck'ing Boat. A low-sided boat with a well in the center for the fowler, and sharp at both ends, so as to be readily paddled either end forward. *A double-ender.*

A cedar duck-boat of some celebrity, "Central Republic," is 12' long, 3' 11" beam, depth 12". This boat was navigated by Mr. Bishop, of Lake George, from Pittsburg, Pa., via the Ohio and Mississippi Rivers and Gulf of Mexico to Cedar Keys, Florida, during 1875, 1876.

Duck's'-foot Cul'ti-va'tor. A cultivator with wide flanged shares, resembling the splayed foot of a duck. Such a cultivator has usually an expanding frame held to the width desired by perforated connecting rods and set screws. See shape of hoes in Fig. 2521, *b*, p. 1107, "*Mech. Dict.*"

Dudg'eon Ex-pand'er. (*Plumbing.*) A tool

Fig. 888.



Dudgeon Expander.

for expanding leaden packing into the internal flange recesses of pipe connections.

Dum'my. *Add.* 4. (*Print.*) A blank book in which copy and cuts are pasted in the way desired for the make-up of a book to be printed.

5. A card on which a number of cuts or views are arranged to be copied as a group, photographically or otherwise.

6. (*Binding.*) A book made up with leaves of a given number and size and weight of paper, and bound in such a style as to represent the finished book in external appearance and size.

Dump'ing Grate. A tipping grate in a stove or heater.

Dump'y Bit. (*Manége.*) A curb bit having the length of the lower arm of the cheek piece so reduced that it is but a trifle larger than the upper arm.

Dump'y Lev'el. A surveyor's level with a short telescope of large aperture.

Dancer, Br. . . . . . * "*Engineering*," xxvi. 140.

Du'plex Air Com-pres'sor. See Air Compressor, Plate I., p. 14.

Du'plex Bor'ing and Fa'cing Ma-chine'. A tool intended for such work as boring out both ends of a coupling rod at once, or boring two cylinders at the same time, or facing two valve seats on the same piece simultaneously.

Bede et Cie., Verviers, Belgium . "*Engineer*," * xli. 5.

Du'plex Bor'ing, Turn'ing, and Groov'ing Ma-chine'. A machine having the characteristics of a double-ended gap-lathe, with two face plates and tail stocks and separate driving gear; also a hollow head spindle, which admits of the passage of a car axle so as to present the ends of the axle or the wheels thereon for simultaneous action by the various tools for turning, boring, or key-way grooving.

Atock . . . . "*Engineering*," * xxi. 310.

Du'plex Ma-chine'. One capable of performing similar operations upon two pieces of work simultaneously. Instances are given under two heads; *supra et infra.*

Du'plex Plan'ing Ma-chine'. One having duplicated parts capable of acting upon two faces of the same piece, or two pieces independently, etc. The adjustments are according to construction and purpose. Adamson's is furnished with two tables, each provided with independent driving gear, the arrangement being such that the tables may be worked either together or separately. The machine can thus be used as one large planing machine with independently set cutters operating on two faces, or as two smaller independent machines. Or a piece may be bolted to one, and operated by a tool carrier on the other.

"*Engineering*" . . . . * xxi. 291, 294.

Du'plex Slide Rest. A lathe with a tool-rest on either side of the object being turned. See Duplex Lathe, Fig. 1803, p. 763, "*Mech. Dict.*"

Dy'na-graph. (*Railway.*) A machine for recording the phenomena occurring to a train in traveling upon a railway track.

Pambour, in his book on Locomotive Engines (edition of 1836, p. 83), discusses the question of determining the friction and resistance of railway rolling stock, and details the difficulties which accompanied the attempts to solve the problem. The interposition of a dynamometer between the engine and the car or cars was the means applied.

The apparatus of Prof. P. H. Dudley is placed in a car and uses 14 recording pens which make diagrams of the various phenomena.

The dynagraph track inspection record is traced on a continuous roll of profile paper wound in a length of 150′ upon a drum. The paper has various groups of rulings and the tracings are made by glass tube-pens filled with *eozine*.

The following diagram gives the nature and order of the indications on the record, — the broad paper ribbon which is shown in Plate X., as passing beneath the pens and wound upon a roller at the left of the machine.

The places of the tracings and explanations are shown in the column, which is not a *fac-simile* but merely an explanatory statement in columnar form.

10 seconds.

Seconds.

(*Tracing.*) Representing elevation of rail on curves.

The machine as represented in Fig. 1, Plate X., is placed in an eight-wheeled car, 50′ long, constructed especially for the purpose. The draw-bar of this car is connected with a piston which works in a cylinder under the floor, and which is filled with oil. (Figs. 2, 3.) These are so arranged that if the draw-bar is subjected to strains of either tension or compression they are resisted by the oil in the cylinder, and the former is therefore subject to the pressure due to the strains on the draw-bar or the resistance of the train. The cylinder is connected by a pipe, *f*, Figs. 1, 2, and 3, with a smaller cylinder *a*, 7-16″ in diameter at the top of the machine. This has a piston fitted into it which is connected by a rod with the parallel motion *b c d*. This latter carries a pen, *e*, which draws a diagram of the resistance of the train on a roll of paper, *A A*, 30″ wide. Part of the diagram drawn by this pen is shown at *g g*. The roll of paper is placed in the drum *C*, and is drawn over the table *A A* by feed-rolls, *D D*, and is wound up on the drum *B*. These drums and rolls are driven by a worm-gear on the axle, shown in Figs. 4 and 5, which operates the vertical shaft *E E*, Fig. 1. The worm-gear, being on the axle, is underneath the floor of the car, and is not shown in Fig. 1. The shaft *E* has a miter-wheel at the upper end which gears into a pair of miters, *F F*, which are loose on a horizontal shaft, *G F*.

A clutch collar *N* is attached to the shaft by a feather and is arranged so that it can engage with either of the miter wheels, so that the machine can be used in running in either direction. The shaft *G F* has a pinion on it, not shown in the engraving, behind the pair of change gear wheels *G*. This pinion engages with one of the wheels *G* and that with the wheel *H* on the horizontal shaft *L I*. On this shaft are four worms, *L*, *K*, *J*, and *I*. *I* and *L* are keyed to the shaft, but *J* and *K* are attached to sleeves which are loose on the outside of the shaft. Either *J* or *K* can be driven by the clutch *M*, which is attached to the shaft by a feather. The worms *I* and *L* drive the worm-wheels *O* and *P*, which are connected to the shafts of the drums by the friction produced by springs (one of them shown at *h*) against disks, *i*, *i*, the purpose of the drums being simply to wind and unwind the paper, and keep it taut; which is effected by the friction arrangement. The paper is fed over the table uniformly for the distance traveled by either pair of the feed-rollers *D* or *D′*. Only one of each pair of these rollers is shown, the other being below the surface of the table. These rollers are 2.472″ in diameter, and are made of steel and ground with the utmost precision, so as to be 0.003″ larger in diameter in the center than at the ends, the object of this being to draw the paper through evenly. If the rolls were made perfectly straight they would be liable to seize the paper on one side more than on the other The paper can be wound by the mechanism in either way, that is, from *C* on to *B*, or from *B* on to *C*, so that the instrument can be used while running the car in either direction.

As stated before, the pen *e* draws a diagram of the resistance of the train. A stationary pen, *j*, draws a straight base line on the paper as it is rolled across the table. When there is no tension or compression on the draw-bar and cylinder underneath the car, and consequently no pressure on the fluid in the cylinder *a*, its piston is drawn back by the springs *s s* and with it the lever *b c*, so that the position of the pen *e* corresponds with that of *j* and the base line which the latter draws. So soon as there is any pressure in the cylinder *a* its piston is forced outward against the tension of the springs *s s*, and consequently the pen *e* is carried away from the base-line a distance proportional to the pressure, and the diagram thus indicates the tension on the draw-bar.

The speed of the train is recorded by means of an electrical attachment with the chronometer clock *Q*. This is arranged so as to break an electrical circuit every second, which releases an armature of an electro-magnet at *R*, with which one of the pens, shown at *k*, is connected. This moves the pen 1-16″ horizontally, which produces an indentation in the line which is drawn on the paper. The distance between these indentations indicates the space traveled over in one second. The next pencil to *k* is arranged so as to make a similar record every ten seconds. Still another pen can be used to record minutes.

A pen is also arranged so that by an electrical connection it records each revolution of the driving-wheels. Another records the mile-posts as they are passed, which is done by an assistant, who touches an electrical key at each post. The alignment of the road, that is, the curves and straight lines, are recorded by a pen in a similar way. A pen next to this is connected with a water-meter attached to the feed-pipe of the locomotive, and records the quantity of water consumed at different times and places. Still another pen is arranged so that an assistant on the locomotive records every shovelful of coal as it is put on the fire. The same pen has been used to record the time that black smoke escaped from the chimney. A pen is also provided which records the distance run by the car, and another records the indications of an anemometer on top of the car. At *z* is the fourteenth pen, which records the surface of the track. This is done by a small vessel or cylinder about 3″ in diameter, which is attached to the equalizing lever immediately over the journal-box. This vessel is filled with oil and covered with a thin metallic diaphragm, which is pressed down by a spiral spring. The chamber containing the oil is connected by a pipe with a gage, *m*, which also has a similar diaphragm which acts against a compound lever carrying the pencil *z*. The jolting of the car over inequalities of the track produces pulsations in the diaphragm over the journal-box, and consequently more or less pressure on the liquid, which pressure is communicated to the upper diaphragm at *m*, and thus recorded by the pen *z*.

An integrating apparatus is also attached to the instrument at *S*. This consists of a plate, *S*, which is attached to the end of a vertical shaft driven by the gear-wheel *O* and a worm, not shown in the engraving. The speeds are so arranged that the plate makes three revolutions per mile run by the car. A small wheel, *n*, which is attached to a rod, *q*, connected with the piston in the cylinder *a*, bears on the plate *S*. When there is no pressure in the cylinder, the small wheel *n* is exactly in the center of *S*, and consequently the revolution of *S* does not cause the wheel *n* to revolve. When the piston is forced out by the pressure, the small wheel is carried beyond the center of the plate *S*, and consequently the movement of the latter then causes the small wheel to revolve. Of course the greater the pressure in the cylinder *a* the farther will the wheel *n* be carried from the center of *S* and the greater will be the path on which it rolls, and consequently the larger the number of its revolutions. At each revolution of the wheel it breaks an electrical circuit, and connecting by a wire with one of the electromagnets at *R* operates a lever which carries one of the pens shown at *k*. It is obvious from this that the greater the pressure on the cylinder *a* the larger the number of revolutions which will be made by the small wheel *n*, and therefore that they will be a measure of the work done; so that multiplying the number of revolutions by a known constant will give the number of foot-pounds.

The disk *S* is graduated on the edge, and has a vernier attachment with which very minute measurements can be made of the distance run.

The battery jars for working the electrical apparatus are carried underneath the car in a locker, and are connected with the magnets by the wires shown at *r*.

The pens consist of small glass tubes, which are drawn to a fine point and filled with eozine, one of the products of coal-tar distillation. A half grain of this is dissolved in an ounce of water, and makes a beautiful red color.

The draw-bar cylinder *B* is shown in plan in Fig. 2, and in section in Fig. 3, and is 4″ in diameter, and has a pair of large pistons, *A A*, which fit into it at each end. Into these an auxiliary pair of pistons, *C C*′, are fitted. These are used in making experiments with light loads. The packing is of the ordinary kind used in hydraulic rams. *D* is the draw-bar which is connected with the pistons by a frame, *E E*. In drawing a train the cross-bar *G* presses against the piston *C*′, and in pushing the bar *F* presses against *C*, so that in either case the strain on the draw-bar produces a corresponding pressure on the liquid (oil) in the cylinder. The pipe *L* connects the main cylinder *B* with the smaller cylinder *a*, Fig. 1, on the dynagraph above, the working of which has already been described.

Figs. 4 and 5 represent the worm gear on the axle by which motion is transmitted to the mechanism above through the shaft.

See account of Bavarian experiments by Baron M. M. Von Weber, "*Transactions of Am. Soc. C. E.*," February, 1879, and reference to same in "*Railroad Gazette*," * xxiv. 375.

Dy-na'mo-e-lec'tric En'gine. A steam-engine adapted for driving a dynamo-electric machine. While many forms of steam-engine have been used for this purpose, the direct acting has some more peculiar features of compactness and special adaptation.

Fig. 890, Plate XI., shows the adaptation of the *Brotherhood* three-cylinder engine to driving a *Gramme* machine. The engine consists of three steam cylinders arranged radially around a framing at equal angular distances apart, their axes converging in a point: within the central space around this point revolves a crank axle, which is kept in rotation by the successive impulses of the three pistons which are connected to its crank-pin by connecting rods, the heads of which are provided with brasses bearing against it; and a circular distributing valve revolving with the shaft regulates the admission of steam to each cylinder in succession and determines the position of the cut-off, and, therefore, the period during which each cylinder is being worked by the expansive force of its imprisoned steam.

(*Horizontal Section*)

(**Elevation.**)

Fig. 891. ***Pacinotti Magneto-electric Machine.***

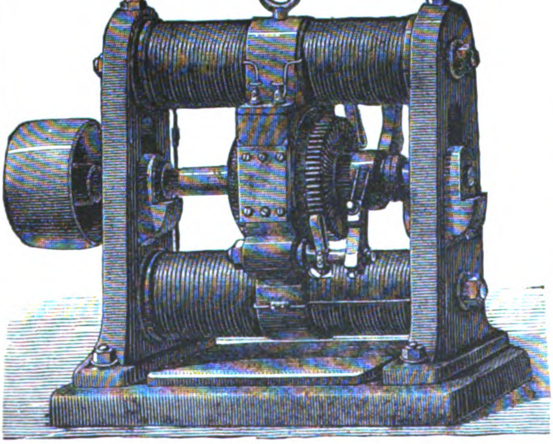

Fig. 894. ***Gramme Electric Light Machine.***

The shaft and armature spindle lie in the same line and are coupled direct to one another, thus avoiding the use of belting or gearing. The apparatus represented was constructed for the British government for torpedo work, the current being utilized in a *Serrin* lamp. The machine absorbs 13 horse-power, running at 500 revolutions per minute, when it produces a light of 48,000 normal sperm candles.

The consumption of steam, which is worked at 80 lbs. to the square inch, is 41.1 lb. per indicated horse-power per hour. The weight of the whole apparatus is 4,256 lbs., of which the *Gramme* machine represents 2,240.

Dy-na'mo-e-lec'tric Ma-chine'. Speaking generally, the term dynamo-electric machine is applied to any one which produces a current of electricity, by the conversion of dynamic or mechanical energy into electric force by the movement of some of its parts in the neighborhood of others.

More definitely, "An electro-voltaic generator whose magnetic field is derived from an *electro*-magnet, in contradistinction to a magneto-electric generator whose magnetic field is derived from a *permanent* magnet." — *Sawyer.*

In the still more modern terminology, a machine for translating motion into electricity, in which the magnetic field in which the armature rotates is formed by electro-magnets having their coils connected in a circuit with the coils of the armature and the main line, whereby upon starting the machine with a minimum of magnetism in the cores of the field magnets, an inter-reacting cumulative action takes place, the initial magnetism creating an initial current in the armature, which, flowing around the field magnets, increase their force, in turn reacting on the armature coils, and so on until the maximum current is produced when the field cores attain saturation.

The discovery of electric induction by Prof. Faraday, in the year 1831, drew the attention of the scientific world to the possibility of utilizing motive power as a means of generating a current of electricity.

"Faraday demonstrated before the Royal Society that if a magnetized bar of steel be introduced into the center of a helix of insulated wire, there is at the moment of introduction of the magnet a current of electricity set up in a certain direction in the insulated wire forming the helix, while on the withdrawal of the magnet from the helix a current in an opposite direction takes place.

"He also discovered that the same phenomenon was to be observed if for the magnet was substituted a coil of insulated wire, through which the current from a voltaic element was passing: and further, that when an insulated coil of wire was made to revolve before the poles of a permanent magnet, electric currents were induced in the wires of the coil. It is on these discoveries that are based the action of all magneto-electric machines." — "*Journal of the Society of Arts.*"

Pixii was the first to construct a magnetic machine. His machine had a revolving permanent vertical horse-shoe magnet above which was fastened an electro-magnet, and the poles of the two brought into close proximity. As the poles of the permanent passed those of the electro-magnet, a series of reversed currents were set up in the wires of the latter. A small circular commutator was placed below the horse-shoe magnet and revolved with it.

Saxton placed the permanent magnet horizontal, and the axis of the revolving electro-magnet in corresponding position. He also increased the relative size of the horse-shoe magnet.

Clarke placed the axis of the electro-magnet at the side of and at right angles to the permanent, so that its poles were made to pass those points of the latter where the greatest strength was to be obtained. A commutator placed on the spindle of the electro-magnets corrected the reversal of the currents generated.

In the Niaudet machine the current is continuous. A number of bobbins with soft iron cores are fixed parallel to an axis with which they revolve. The poles of these bobbins turn between the poles of the permanent horse-shoe magnets, one magnet being at each end of the bobbins; a sort of duplication of the Clarke machine. The bobbins are joined in series, with connection made at the point of juncture to a commutator. Two contact springs make the connections to the terminals of the machine.

The Nollet ("Alliance") machine (1850) was originally intended by its inventor for the decomposition of water, the hydrogen gas to be carbureted by passing through camphene, and used for lighting purposes. It contains a number of gun-metal disks running on a horizontal shaft, and carrying near the circumference of each disk a series of 16 bobbins with soft iron cores, arranged equidistant and parallel to the shaft, and free to turn with the disks between the poles of 8 horse-shoe permanent magnets, the poles of which are placed radially to the shaft. The faces of the magnets are parallel to the disks, so that in each circumference there are 16 poles corresponding to the 16 bobbins. The bobbins are connected in series, one end of the wire being connected to the shaft, and the other to an insulated ring upon the shaft; to these are connected the terminals.

The machine has been largely used for light-houses in France: at La Hève and Grinez, for instances.

The Holmes machine (1856) differs from the Nollet in the arrangement of the bobbins. They are held between two brass disks in two or more concentric circles, the bobbins rotating in front of the poles of a number of permanent magnets fixed on the frame, and arranged radial to the axis. This gives a quicker succession to the contacts. A commutator directs the alternating currents so as to pass off in the same direction. The South Foreland light, and afterwards the Dungeness lighthouse, were lighted by means of this machine. In later machines, the magnets are made to turn while the bobbins are fixed.

In the Siemens-Halske machine (1854) the electrical magnet was replaced by a cylindrical bar of soft iron with four longitudinal grooves × section, in which insulated wire is wound parallel to the axis, so as to form a complete cylinder. One end of the wire was soldered to the axis, and the other to an insulated ring at the extremity of the axis; these connected to the respective terminals. The poles of a permanent magnet were so formed as to embrace the cylinder without touching.

The Wheatstone machine is in general use for private wires in Great Britain, applied to the A B C telegraph. Attached to the poles of a permanent compound magnet is a set of 4 bobbins, the soft iron cores of which are fixed permanently to the magnet, two to each pole. In front of these cores is a soft iron revolving armature. The cores of the bobbins being fixed to the poles of the magnet, receive polarity from them and form 4 poles, 2 North, and 2 South. The turning armature passing in front of these poles induces currents in the bobbin wires, which by connections actuate the needle of the telegraph instrument.

The original dynamo-electric machine, or accumulative generator, is described in the English patent of Sóren Hjorth, of Copenhagen, No. 2,198, October 14, 1854. It is perhaps the most remarkable, from one point of view, of the series. It describes and illustrates a "Magneto-electric Battery," so constructed that "the currents induced in the coils of the revolving armature are allowed to pass round the electro-magnets; consequently, the more the electro-magnets are excited in the said manner the more will the armatures be excited, and more electricity of course be induced in the respective coilings; and while a mutual and accelerating force is thus produced in this manner between the electro-magnets and the armatures, an additional or secondary current is at the same time induced in the coiling of the electro-magnets by the motion of the armatures, the said current flowing in the same direction as that of the primary current after having passed the commutator. The direction of the current induced in the coils of the armatures will of course be reversed according to the change of the respective polarities, and the commutator is therefore applied for the purpose of causing the same to flow constantly in the same direction."

The cores may be cast-iron, or steel magnets.

It would seem that the invention of Sóren Hjorth and the English patent of 1854 had been entirely overlooked by the British, German, and French experts; and the claim of Dr. Siemens and Sir Charles Wheatstone to the invention of the accumulation generator, in 1867, was made in apparent ignorance of the claims of the Swedish inventor of 13 years previous. The latter claims are now revived, and the history of the dynamo-electric machine must be re-written: *e. g.*, the account in "*Engineering*," xxiv. 307; xxviii. 63, etc. —

"Early in 1867, an announcement was made to the Royal Society simultaneously by Dr. C. W. Siemens and Sir Charles Wheatstone, of the discovery made independently by Dr. Werner Siemens and Sir Charles, of the reaction principle of magnetization, by which a very powerful electric current may be generated through the building up of the effects of action and reaction taking place between an electro-magnet and a magneto-electric inductor revolving in its magnetic field, and included in the same circuit."

It appears that the discovery was announced by Dr. Werner Siemens to the Berlin Academy of Science a month before its announcement to the Royal Society. Mr. S. A. Varley and Mr. M. G. Farmer were also working on the same invention apparently about the same time.

The Wilde machine (1866) is one of the foundation machines, using a Siemens-Halske armature between the poles of a field electro-magnet, which is excited by a small hand magneto-electric machine. It may be compared to one small Siemens machine placed on top of another of larger size. The current from the smaller one is used for magnetizing the two powerful electro-magnets of the larger one: the latter replacing the permanent ones ordinarily used in the Siemens.

The first machine for the production of an electric current constant in direction and intensity was the electro-magnetic ring machine of Dr. A. Pacinotti, of Pisa, Italy, 1860, and described in "*Il Nuovo Cimento*," June, 1864.

The peculiarity of the machine was the movable electro-magnet in the form of a circular iron ring in which the magnetic poles were movable, instead of remaining stationary, as in the previous machines. The machine as shown in Fig. 891, Plate XI., and the description following, have reference to its application as an electro-magnetic machine, but Pacinotti indicated, in the Italian publication referred to, a way in which, by the use of the same annular armature, the electro-magnetic may be converted into a magneto-electric machine capable of producing, by the constant use in connection with it of a permanent or electro-magnet, a continuous current of a constant direction.

"This movable ring of iron had the shape of a spur-wheel of 16 teeth, and was firmly secured to the axis of the machine by means of four strips of brass. Small wooden wedges were placed upon the teeth of the ring, and the space so formed between each two of the wedges filled up regularly with insulated copper wire. These spools were all wound in the same direction, and the terminal end of each was soldered to the beginning of the one succeeding it, so that the whole system of 16 spools virtually formed a single coil of wire surrounding the ring in a regular manner, and returning upon itself.

"Wires were soldered to the separate points of juncture and were led, parallel to the axis of rotation, to an equal number of insulated pieces of brass, mounted in two rows upon, and slightly projecting from, the surface of a disk firmly secured to the axis.

"The iron ring, with the bobbins wound upon it in the manner already described, was mounted in a horizontal position between the two legs of a powerful upright electro-magnet, the distance of which from the ring could be adjusted at pleasure by means of a set screw and a slot in the lower connecting cross-piece. Contact rollers *k k* were made to press, one on each side of the axis, against the lower wooden disk carrying the strips of brass, so that during the rotation of the ring all of the latter were brought successively into contact with them. When, therefore, the terminal posts *h h′* are placed in connection with the poles of a galvanic battery the current will pass, supposing it to enter at *h* (+), by way of the binding-post *l* to the roller *k*, and through the strip of brass on the disk against which the roller may happen to press at the time, up to the two wire coils of the armature whose point of juncture is in connection with the strip of brass.

The current here divides, each portion passing in an opposite direction through the spools surrounding each half circumference of the ring, to meet again to form one current at the left contact roller *k*, whence the reunited current passes to the second binding-post *l′*. From here the current proceeds to the leg *A* of the electro-magnet, circulates around it, and, after acting similarly with regard to the other leg, *B*, passes back by way of the binding-post *h′* to the negative pole of the battery. Magnetic poles thus became developed in the iron ring at the points *N S*, the position of the contact rollers having been so chosen as to bring about this effect, and the actions of attraction and repulsion taking place between them and the poles of the stationary electro-magnet gave rise to the rotation of the ring.

"In order to turn the action of the electro-magnet upon the magnetized iron ring to the greatest possible account, Pacinotti provided the two poles with armatures, *A A A*, *B B B*, of soft iron, which were made to surround the ring very closely for over two thirds of its circumference. Strips of brass, *E E*, *F F*, attached, served to give them greater security. In the elevation of the machine here given these armatures have been omitted in order not to conceal the ring and its surrounding spools." — *Prof. Henry Morton.*

In the Lontin machine, Fig. 892, Plate XI., the revolving armature is in the form of a central boss, *P*, into which are fixed 10 or more radial bars, *D*, of soft iron, circular in section, and slightly conical, and each wound with a coil of insulated copper wire, the ends of which are connected together in series and to a cylindrical commutator. The armature wheel revolves in the field of two powerful electro-magnets, *A A*, fixed vertically into an iron base-plate, by which they become the two limits of a horse-shoe electro-magnet. The cores of the radial magnetic inductors as they revolve approach very close to the poles of the inducing magnets *A A*, being at their point of closest proximity when in horizontal position. When the machine is revolving in the direction of the arrow all the radial bobbins above the horizontal line are receding from the left hand, the South pole of the magnet, and approaching the North pole, and the bobbins below the horizontal line *vice-versa*, the currents in the upper half of the circuit are in one direction, and those below are inverse.

The coils are coupled together in series, and each pair of contiguous coils is connected to a sector, *C*, of the cylindrical commutator, there being as many sectors as bobbins, and insulated from one another by strips of vulcanized rubber. Against the surface of this commutator collectors are pressed by springs, the one taking off the positive current and the other the negative, and the currents so induced are transmitted through the coils of the large vertical electro-magnets, the machine being on the dynamo-electric or reaction principle.

The figure shows a Lontin machine with 4 induction wheels fixed on the same shaft, each wheel carrying 10 bobbins. The bobbins are monnted helically on the shaft, so as to avoid any interval of inaction.

Up to the period of the invention of the Pacinotti machine the armature had its magnetism reversed as it rotated, involving a loss and waste of power. The Italian inventor devised the idea of the ring, and rotating the ring between the poles of a magnet in such a way that there should be no reversal of poles, but merely the traveling of the poles around in the ring. This ring was surrounded with wires from which the induced current was taken. The idea involved was embraced in the Gramme machine, and accepted by electricians only after much dispute and opposition. Gramme appears, however, to have been an independent and original inventor.

The Gramme machine, Fig. 893, Plate XI., consists of a permanent field magnet, between the poles of which are armatures of peculiar construction, formed by coiling around a soft-iron core a wire of copper, forming the entire coil into an endless bobbin, in the shape of a cylinder or ring; the wire being provided at suitable intervals with metallic rods or conductors for allowing the proper exit of the electric current generated. These rods extend axially of the core, and at their ends on diametrically opposite sides of said axis connect with two rolling commutators which lead to line.

It must be said, however, that neither Pacinotti nor Gramme originated the ring armature; for Elias, in 1842, constructed an electro-magnetic motor, the armature of which was an annular coil surrounding a ring core, having 6 polar protuberances at equal distances apart, and which revolved within a similar ring, forming the field-magnet.

In Fig 893, Plate XI., *H* is the permanent electro-magnet, having additional poles, *h h′*, of a circular shape, so as to correspond with that of the cylinder or endless large bobbin, *A*. The poles are kept insulated from each other by means of the non-magnetic portions, *i i′*, and the large bobbin or cylinder *A* is composed of a continuous series of small bobbins connected end to end, the junctions being each connected to a conductor, *C*, which conductors are kept insulated from each other; on the free ends of these conductors act the rubbers or connecting rollers, *S S′*, for carrying the currents respectively to the posts *X X′*. The cylinder, or large bobbin, *A*. revolves by means of the shaft *D* in standards *B*, and motion may be transmitted to the shaft *D* by means of the crank *I*, and pulleys, or other mechanical contrivances. A^2 represents the soft iron core of the cylinder or large bobbin *A*.

In the earlier form of the Gramme machine the inventor mounted three rings upon one spindle, each revolving within the magnetic field of two very large rectangular electro-magnets. One of these rings supplied the current by which all the electro-magnets were excited, and the others were united so as to produce the external or useful current. But in the newer and far more powerful machines this arrangement is superseded, there being but one induction ring, and the coils of the electro-magnet are included in the circuit, the whole of the current traversing them. Fig. 894, Plate XI., represents the modern Gramme machine, such as is used for illumination purposes. The ring is mounted on a horizontal shaft which is revolved at a speed of 900 revolutions per minute within the electric field of the four horizontal electro-magnets shown in the cut. The two upper magnets are united to a common pole-piece, which embraces about three-eighths of the circumference of the ring, and the two lower magnets are connected to a similar pole-piece opposite in polarity to that attached to the upper magnets.

The Siemens machine, Fig. 895, Plate XII., has a cylindrical armature, the "longitudinal induction bobbin" revolving between two double poles of two pairs of electro-magnets.

The armature consists of a metallic cylinder with copper wires wound axially over its surface. The peculiar system of winding is the invention of Von Alteneck, who was thus associated with Dr. Siemens in the device. The system of winding and the possible variations are the subject of an elaborate article by M. Breguet, published in "*Engineering*" and reproduced in "*Van Nostrand's Engineering Magazine*," * xxii. 375.

These longitudinal coils of wire completely envelop the iron cylinder or armature, each section being wound parallel to a different plane passing longitudinally through the axis of the cylinder, there being as many of such planes as there are sections to be wound, and at equal angular distances from each other around the circumference of the

cylinder. The ends of these coils are connected to a number of copper sectors insulated from one another, which together build up a cylindrical commutator rigidly attached to the armature spindle with which it revolves; and the currents are collected in a similar manner by conducting brushes pressing against the commutator as it revolves.

This system, consisting of the iron cylinder with its enveloping coils, is rotated at a high velocity within a powerful magnetic field produced by a series of electro-magnets, the coils of which are included in the circuit of the rotating armature through the brushes, and are magnetized thereby. The curved bars, seen above and below the revolving armature, are of soft iron of rectangular section, and are the prolongation of the cores of the powerful electro-magnets, shown on each side of the armature, the cores of which are long flat bars wound with insulated wire.

The magnet cores, instead of being flat continuous plates, are divided longitudinally into several bars having air spaces between them, the object of which is, firstly, to prevent cross-currents being induced in the magnets; secondly, to maintain the lines of magnetic force parallel to the length of the bar: thirdly, to permit of a circulation and escape of air between the revolving armature and the magnets, so as to reduce the accumulative heating of the machine; *lastly*, for convenience of manufacture.

Of the curved portions of the magnetic cores, each surrounds two sixths of the entire circumference of the induction cylinder, so that two thirds of it are embraced by the magnets, and the coils of each set of magnets are so wound as to produce a point or pole in the center of the length of the cores, a North consequent pole being produced at the mid-length of the upper set of magnets, and a South consequent pole being produced at the corresponding point in the lower set of magnets. Thus a very intense magnetic field is formed within the cylindrical space included between the upper and lower sets of magnet bars, and within this space is revolved at a high velocity the induction cylinder or armature, which has been described.

In the Brush machine, Fig. 896, Plate XII., the wires are wound in slots in the revolving cylinder, and the projecting parts between the slots are brought nearer to the faces of the poles of the field magnets than in the Siemens machine.

Referring to Fig. 896, the machine is seen to consist of two large horse-shoe electro-magnets placed with their similar poles facing each other, the armature revolving between them. The currents are generated in the coils of copper wire wound upon the armature. The coils are 8 in number, opposite ones being connected end to end, and their terminals carried to the commutator, which consists of segments of brass, secured to a ring of non-conducting material carried on the shaft. The commutator is so arranged that at any instant 3 pairs of coils are interposed in the circuit of the machine. The current is conveyed from the commutator by means of brushes made of strips of hard brass joined together at their outer ends and connected with a binding screw on the base.

The Wallace-Farmer machine, Fig. 897, Plate XII., has a magnetic field produced by two electro-magnets, with the poles of opposite character facing each other. Between the arms of the magnets, and passing through the uprights supporting them, is the shaft, carrying at its center the rotating armature. The latter consists of a disk of cast-iron, near the periphery of which, and at right angles to either face, are iron cores wound with insulated wire, thus constituting a double series of coils. These armature coils being connected end to end, the loops so formed are connected in the same manner on to a commutator of the same construction as that of the Gramme. As the armature rotates the cores pass between the opposed North and South poles of the field magnets, and the current generated depends on the change of polarity of the cores.

In the Weston machine, Fig. 898, Plate XII., the rotating magnet is inclosed in stationary coils in an annular stationary iron shell. The coils are wound in cylindrical form upon a skeleton frame of non-magnetic material, within which the electro-magnet rotates. The latter is mounted upon a neutral axis, and its periphery moves in close proximity to the surrounding coil. Apertures at the end of the cylinder admit air into the space within the coils. The skeleton frame is divided into 8 segments, and each of the three coils traverses the entire exterior of the skeleton frame, extending across the ends of the cylinder, from the segment on one side to the segment diametrically opposite, and the free ends of the coil are respectively connected with two stationary brushes bearing upon directly opposite sides of the cylindrical commutator.

In a late patent of Weston, the skeleton core is rendered discontinuous by a series of deep transverse grooves, and by a longitudinal slit from end to end of the armature, and currents of air are passed through to counteract the heat produced by the resistance of the current, and which might destroy the insulation and does increase the resistance.

Maxim's dynamo-electric machine, Fig. 899, Plate XII., has an armature of soft-iron rings with the wire wound parallel with the axis, both plates and wires being so arranged that a free circulation of air is admitted through the armature to prevent dangerous heating. The commutator is large and heavy, and the sections curved in a right and left spiral, so as to avoid any break in the current.

Maxim's current regulator, a governor for dynamo-electric machines (Patent No. 228,543), is automatic in case of an over-current to cause the operation of electro-magnetic de-

vices, releasing or bringing into action mechanism for shifting the position of the brushes, and thus reducing the current.

The Edison magneto-electric machine, Fig. 904, Plate XII., and Figs. 901 to 905, has a revolving armature, a cylinder of wood with two iron heads, and around the cylinder and between the heads fine iron wire is wound. At the ends of the cylinder, outside the iron heads, are disks of hard rubber, and the wires forming the induction helix are wound lengthwise of the cylinder into notches in the edges of the disk.

The Edison machine exhibited at the Electrical Congress, Paris, 1881, is shown in Figs. 904, 905, and is thus described by Comte Th. du Moncel: —

"The field magnets were

Edison's Dynamo-electric Machine.

arranged as a derivation taken from the commutator, putting it into the induced circuit, as in Wheatstone and Siemens' systems. Then the armature was arranged on Siemens' principle, so that the wire consisted of bars of copper. These bars lie close to each other around the cylinder which forms the armature, and they generate the current. Their

Fig. 904.

extremities correspond to disks of copper (at right angles to them) laid one against the other at the ends of the cylinder, and insulated from each other. Each bar is fastened to its corresponding disks in such a way as to form a single circuit enveloping the cylinder longitudinally, and which is made perfect through the coupled bars two and two with the commutator blocks (made after the Gramme pattern). Figs. 904 and 905 give an idea of this new arrangement. The center of the cylinder itself is occupied outside of the rotating axle by a cylinder of wood, which, in its turn, is surrounded by a thick tube made of a series of very thin disks of iron, separated from each other by tissue paper. This arrange-

Fig. 905.

ment facilitates the rapid changes of polarity in the plates. This tube is terminated at its two extremities by two thick clamping disks which are made to compress the others laterally, and the copper disks of the working coil occupy the two compartments at the extremities of the cylinder, as seen in Fig 905. Under such conditions as those the resistance of the generator is small, and permits of great subdivision of the current in multiple arc; nor is there any insulation to be burned, and it is even possible, in case of deterioration of the bars, to renew them easily, for they are simply screwed against the upper disks corresponding to them. In another arrangement adopted by Mr. Edison, the field magnets lie horizontal instead of being placed vertical "

Seeley's disk armature is an amplification of the idea of "Arago's disk." The disk is constructed of insulated wire revolving in a magnetic field arranged radially with reference to the axis of the armature.

The disk consists essentially of wire wound in radial directions, so that the radii on entering may be moved before magnet poles of the same name, while the radii outgoing move before the opposite poles. The whole mass of the disk, so far as it is practicable, is filled out or made up of the radial winding, and the sectors of out and in wires are equal in number and symmetrical in form and arrangement.

Dy-nam'o-graph. (*Surgical.*) An instrument for registering the muscular power of the hand of an individual applied to the compression of an elliptic spring. See DYNAMOMETER.

Dyn'a-mom'e-ter. 1. (*Surgical.*) An elliptic spring with indicating finger and graduated arm, to be collapsed by the grasp of the hand, as a measurer of the muscular power of the hand of the individual.

Fig. 283, Part 1, *Tiemann's "Armam. Chirurgicum."* Another instrument has a bulb to be compressed by the hand, ejecting a liquid which rises in a tube against a graduated scale. Fig. 285, *Ibid.*

2. A machine used for testing the lifting strength of persons. See HEALTH LIFT; LIFTING MACHINE; EXERCISING MACHINE.

3. An instrument for measuring the compression exerted by a charge of powder in explosion.

Such an instrument is also known as an *internal-pressure gage*, or a *piezometer*: each of which see.

Lieut.-Col. Benton's dynamometer is designed to be used in connection with the Rodman pressure gage, for the purpose of determining the pressure per square inch exerted within the bores of cannon and small arms by the ignition of powder. It may also be used for testing the strength of materials, or for measuring their compression within certain limits.

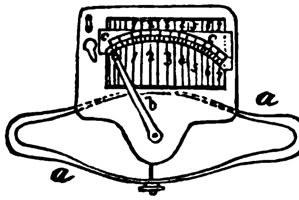
The apparatus is described in the "*Report of the Chief of Ordnance, U. S. A.*," 1877, * 874 and Plates I.-V

Lieut. Metcalfe's dynamometer for measuring the recoil of fire-arms, measures the recoil by means of a cut made in a material of uniform resistance, such as copper or lead, by a Rodman knife interposed between the metal and the butt of the gun. See Appendix N and plate, "*Ordnance Report*," 1878, p. 109.

4. An instrument for measuring tractile force exerted by an engine or team.

A simple form is that of Miller. It is self-registering, and consists of an ordinary dynameter spring, *aa*, with needle, *b*, and graduated scale, *c*.

Fig. 906.



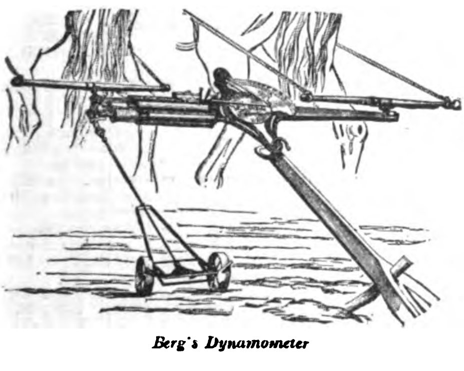
Miller's Dynamometer.

A strip of paper carefully ruled to correspond with the graduated scale is caused to pass under the needle at a uniform rate, by means of rollers moved by a train of gearing, with a fly to regulate the motion. This mechanism is inclosed in a box beneath the graduated scale. Every impulse of the power is accurately noted upon the graduated paper by a pencil attached to the needle, enabling the operator to determine, not only the mean and extreme draft, but also the unsteadiness of draft as indicated by the range of vibration of the needle.

The instrument is connected to the object, the draft of which is to be tested, and to the power used, by a hook and clevis.

The dynamometer of *Berg*, Kjöbenhavn, Denmark, is shown in Fig. 907. Draft upon the double-tree condenses a spring and causes a pointer to traverse a graduated sector and show the force exerted. Attached to the pointer arm is a rod which moves a traversing pencil, the point of which rests on a traveling band of paper, which is rotated by a small trailing carriage.

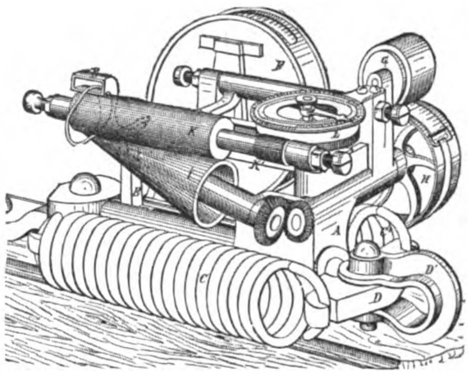
Fig. 907



Berg's Dynamometer

The dynamometer of *Baldwin & Eickemeyer* was used at the Centennial Exhibition in 1876 in testing the mowing machines. It differs from other dynamometers in so far as it compounds the average draft applied to the machine for a given distance, — say, 100 feet, — and thus facilitates the tests very materially, as all calculations of diagrams are avoided.

Fig. 908.



Baldwin & Eickemeyer's Dynamometer.

Two coiled springs, *C C'*, united by cross-bar *D*, and attached by clevis *D'* to the double-tree of the team, form the connection between the draft-power and the pole of the machine to which the apparatus is hooked. The cross-head *D* is the forward end of a T-shaped bar fitted into the frame on the extreme end of which the belt-guide *E* is fastened. The position of the belt-guide thus depends upon the amount of power applied to the clevis *D'*, as the springs lengthen or contract by variations in the said force.

To record and average the draft so applied is the function of the recording mechanism. The base-line of 100' is measured by a tape line 100' long, wound up in the tape case *F*, which is drawn out through a slot and passes between the rubber friction roller *G* and the driving pulley *H*. One end of a string is fastened to the ring in the end of the tape line and the other end of the string to a peg in the ground As soon as the team starts, the tape line begins to pay out, turning the driving pulley *H* until the 100' is expended, and setting in motion the recording mechanism which ceases when the tape is expended. A pair of bevel wheels connects the shaft of the driving roller *H* with the conical roller *I*, giving it a determined number of revolutions during the expenditure of 100' of tape

Above the conical roller *I* is a parallel roller *K*, which is sustained on conical end screws, and its shaft carries a worm *K*, which engages the gear on the periphery of the drum of the indicator dial. An endless cord passes between the rollers *I K*, issuing through a guide *F*, carried by the post *E* on a stem of the T-bar *D*. When no strain is applied to the clevis *D'*, *E* is at the rear position shown in the cut, and were the apparatus even in motion by means of the strain upon the tape line, the end of which was fast to the ground peg, no indication would be given upon the recording dial, because as the endless cord is on the point of the roller it gives no motion to the roller *K*, and, through the latter, to the dial. When, however, strain is brought by draft on the clevis *D'*, the endless cord is drawn forward, and the cord passes between rollers *I K* at such point between the apex and the base of roller *I* as the draft may have occasioned. The heavier the draft the larger the portion of the roller *I* traversed by the cord and in exactly the same proportion is the motion of the roller *K* and accordingly of the dial. Any fluctuation in the draft exerted is immediately manifest by the creeping of the cord toward the point or toward the base, as the power exerted diminishes or increases, and equally, the indicator travels more or less slowly. The extent of the motion of the indicator is the sum of all the effects, and it is set to zero at the commencement of each trial.

The reading of the indicator is the perfected record, and no calculations of diagrams are necessary.

Emerson's dynamometer, in one form, is shown at 5, Fig 1813, p. 768, "*Mech. Dict.*" Quite a variety of lever dynamometers, fixed and portable, are now made on this principle. These dynamometers are graduated by applying the

Meter = 39.37079 inches, approximately 1 1-10th yards.
Millimeter, 1-1000 meter = 0.0394 inch.
Kilo, *i. e.*, kilogram = 1,000 grams = 2.2046 pounds avoirdupois, approximately 2 1-5th pounds.
Kilogrammeter = a force of 1 kilo exerted through 1 meter.
Hectare = 2.471 acres.

* Essays marked thus * employed the dynamometer with the weaker springs; the other essays were with a more powerful instrument.

†† Ordinary height of stubble. ‡‡ Extra short stubble.

The dynamometer used was that belonging to the *Conservatoire des Arts et Métiers* of Paris. Tests and calculations by Professor Tresca, *fils*, of the *Conservatoire*.

weights at a point which, if revolving, would describe a circle of a given number of feet, the smallest size at 4, the larger from 10 to 60, depending somewhat upon the speed they are run.

The same method is used to compute the power as described in water-wheel tests. Suppose the instrument to be graduated upon a 4′ circle, pulley making 500 revolutions per minute, weight indicated after deducting centrifugal force, 35 pounds, $500 \times 4 = 2{,}000 \times 35 = 70{,}000 \div 33{,}000 = 2.12$.

The manner of using the portable dynamometer is to place it between the motor and the machine to be tested, level and secure it to the floor, then belt from motor to driving pulley of dynamometer, and observe the weight indicated, caused by centrifugal force of the levers (equivalent to balancing scales), then belt from pulley of dynamometer to pulley of machine, from the weight then indicated, deduct the centrifugal force, then compute as before described.

These dynamometers are usually made in two sizes. The small size, capable of testing up to 5-horse power, and large one up to 25-horse power.

The table on the opposite page gives the tests of harvesting machines at the Paris Exposition of 1878. The trials took place at Marmont near Paris, and the writer was member of the special jury as well as of the class. It is appended as indicating the thorough method of testing: —

The machine operating in crop.
The machine operating but not in crop.
The machine empty, moving but not in operation.

The column " Estimate of power required to cut one hectare " is the ultimate result *in nuce*.

turbations of the ground in case of earthquakes. See SEISMOMETER, *"Mech. Dict.," et infra.*

Ea'sel. A frame or tripod on which a board, canvas, or other object is supported at a convenient angle for drawing, plotting, or painting.

That shown is by Boudriot, of Hague, Germany.

The drawing board is suspended from two sliding frames by ropes passing over pulleys on the top of the easel, and it

Fig. 912

Draftsman's Easel.

is balanced by a ball weight attached to the ropes. The board can be inclined at any angle by means of adjustable telescoping struts. The easel has adjustable arms, carrying sliding carriages, from one of which a lamp is suspended, and a small table for the instruments from the other. The easel can be adjusted to suit persons of different heights, and to accommodate different kinds of work.

Fig. 913 shows Brownell's easel for painting and striping pottery. The vase is placed on the turn-

Fig. 913.

Porcelain Painter's Easel.

table, and the hand-rest adjusted to a convenient height and position to bring the hair pencil to bear upon the object, which is chucked on the table by means of centering pins in the flanged rim.

Eas'ing Valve. A small valve in the center (say) of a large valve, the former being lifted by a moderate power, to equalize the pressure before the large valve opens.

Eb'o-nite. Another name for hard black rubber. The inventor, Charles Goodyear, between 1840 and 1850, made a number of finely molded articles in this material.

It is produced by the process of vulcanization, the heat, quantity of sulphur, and time employed being in excess of the ordinary vulcanization. The hard and fibrous rubbers of the Malayan Archipelago are preferred to the Para or the African rubber for this purpose.

The carefully washed and dried rubber is mixed by means of heated rollers with from 25 to 50 per cent. of sulphur (which must be free from acid), according to the hardness required. 3 per cent. of lampblack may be added to improve the color, and calcined magnesia is sometimes added. The material becomes plastic while hot, and non-elastic when cold.

The ebonite is cured in steam at 135° C. during a period of from 6 to 10 hours, according to the thickness of the article. At a heat of 140° to 150° C. the process is shortened.

Ebonite in its plastic state is molded in tin, type metal, or tinned brass molds. A very slight application of oil, followed by black-leading, prevents adhesion.

Ebonite works like horn or ivory, and can be turned, but requires a high rate of speed. It is dressed down by flour-glass paper and fine emery, and polished by cloth charged with fine brick-dust and water, oil, or paraffine; subsequently by rotten-stone or tripoli.

When heated, it may be bent to shape, so that articles such as bracelets are made flat, heated to 100° C., and bent to shape. Junctions are easily made in the vulcanizer when the ebonite is not at its hardest condition.

The uses of ebonite depend largely upon its properties of hardness, elasticity (in certain grades), electrical non-conductivity, compactness, inertness toward most chemical products, capacity for shaping by molds, turning, polishing.

Gutta-percha, shellac, asphalt, graphite, are added to some compositions, and sulphur as high as 60 per cent. An approved formula is

Rubber	100
Sulphur	45
Gutta percha	10

Combined under heat. Molded in a material not affected by the sulphur; exposed to a heat of 315° F. in a steam pan, at a pressure of 12 pounds to the square inch.

Eb'o-ny, Ar'ti-fi'cial.

Boil oak wood for 48 hours in a solution of alum, and then brush over with a decoction of logwood, prepared as follows: —

Boil 1 part of logwood in 10 parts of water; filter, evaporate to one half. To each quart of this solution add 12 drops saturated neutral solution of indigo.

After the application of the dye rub the wood with a saturated filtered solution of verdigris in hot, concentrated acetic acid, and repeat till the required black color is attained.

Or. Boil 2 quarts of water with ½ pound of logwood and add 1 ounce pearl-ash; wash the wood with this first, and then with the following wash: 2 quarts of water boiled with ½ pound of logwood, ½ ounce sulphate of iron, ½ ounce of acetate of copper, and ½ pound rusty steel filings.

Or: Dip in a solution of logwood. When dry, rub clean, dip in a solution of bichromate of potassium; dry and rub again.

Or: Wash repeatedly in a solution of sulphate of iron. Dry; then wash repeatedly in hot solution of logwood. Dry; wash with sponge and water. Dry; rub with linseed oil.

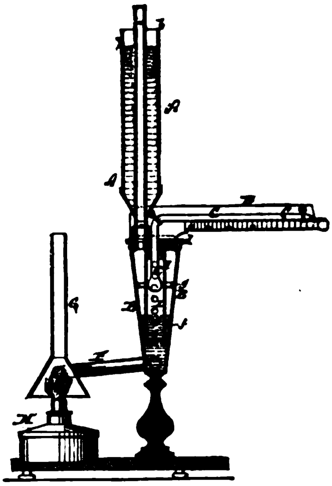
E-bul'li-o-scope. (*Add.*) The ebullioscope of M. Malligand, of Paris, is an instrument for ascertaining the quantity of alcohol present in liquids. U. S. Patent, No. 173,128.

It was found by the Abbé Brossard-Vidal that alcohol holding certain matters in solution, such as sugar, resins, citric

Fig. 914.



Malligand's Ebullioscope.

and tartaric acids, gives a different result, the presence of these matters in moderate quantities not affecting the boiling-point of the alcohol in which they are dissolved. This fact led to the method of estimating the proportion of alcohol present in wines and other alcoholic liquors by comparison of their boiling-points with the boiling-points of different mixtures of alcohol and water in known proportions.

In using the apparatus, pure water is placed in the boiler until it reaches the lower ring *f*, or mark, in the boiler. The water is then boiled, the boiling-point being noted by bringing the zero of the movable scale *E* opposite the degree indicated by the mercurial column *C*. The water is then replaced by the liquid to be tested, care having been taken to rinse out the boiler with some of the same, so that no water is allowed to remain. The boiler is then filled up to the upper ring *g*, or mark, in the boiler, and cold water supplied to the condenser-vessel *b*, attached at the top of the instrument. The lamp is then lighted, and as soon as the mercurial column becomes stationary in the stem, then, by means of the mercury above the scale *E*, the degree of the boiling is at once indicated.

The peculiarities of the instrument consist in the condensers *a b* for returning the vapors of the liquids under test, so as to keep them at normal strength; in heating the liquid in detail by pipe *F* through the flame, thus insuring circulation and proximate equality of temperature throughout the boiler *B*.

See HYPSOMETER, for the instrument for ascertaining altitudes by the observation of the boiling point of water.

E'bur-ine. Dust of ivory or bone compounded with gum tragacanth or albumen, by pressure and heat; colored at pleasure. The name adopted by the French inventor, Latry.

A cement is usually added, but the organic matter in the bone seems to answer if the heat be carefully regulated.

The material is a grayish-white, but may be colored by pigments, an addition which renders albumen necessary. It is used in connection with *bois-durci* or wood concrete (made of sawdust and bullocks' blood).

Eburine may be colored and molded, and made to imitate jasper, malachite, lapis-lazuli; to form moldings, seals, cameos, ornaments of various kinds.

Latry . . . . "*Technologiste*," xxxix. 221.

See list under COMPOSITIONS, p. 212 *supra;* also EBONITE, p. 290.

E'bur-ite. See EBURINE.

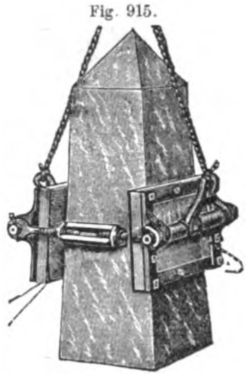
Ec-cen'tric Chuck. An oval and eccentric lathe chuck of considerable range and variety of work is shown in "*English Mechanic*," and reproduced in "*Scientific American Supplement*," * 1413.

See also *Penney* . . . . . * "*Engineering*," xxv. 308.

Ec-cen'tric Clamp. A lifting arrangement for stone monuments, columns, pillars, etc., which should not be defaced by leaving holes or by clamps which mar the surface of the object.

The lifting of the load turns the eccentrics and binds the rubber-faced plates firmly against the object. The size is adjusted by the turnbuckles at the sides.

Fig. 915.

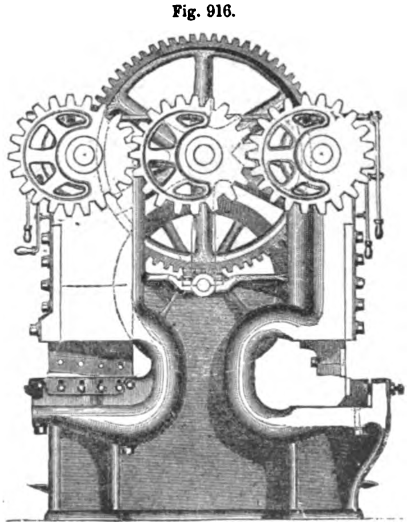


Eccentric Clamp.

Ec-cen'tric Geared Press. An iron-shearing and punching twin-power press in which the power is transmitted through eccentric gearing.

The middle shaft receives a uniform velocity by its large spur-wheel driven by a pinion below. On this shaft is an elliptic gear hung eccentrically, which alternately imparts to the eccentrics on the right and left respectively a slow motion during the penetrating down-stroke and a rapid motion

Fig. 916.



Eccentric Geared Press.

during the up-stroke, increasing the power two-fold in the former case and the speed two-fold in the latter, proximately. The greater part of the upward stroke is in fact accomplished in one-sixth of the time occupied in the revolution of the shaft carrying the shear or punch, as the case may be.

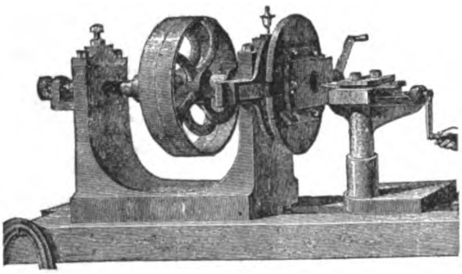
Ivens & Brooks . . . . . * "*Engineer*," xli 450.

Ec-cen'tric Lathe. A lathe with a compound face plate or sliding frame with guides by which the object is so presented that the tool works an oval upon it.

Maxwell of Cincinnati, in 1866, made an important improvement in so arranging the lathe that the amount of ponderable weight was at all times the same on every side of the axis, independent of the piece being turned. This prevented the very serious vibration incident to rapid running of eccentric lathes not thus arranged.

The machine shown in Fig. 917 is made by *Arbey* of Paris.

Fig. 917.

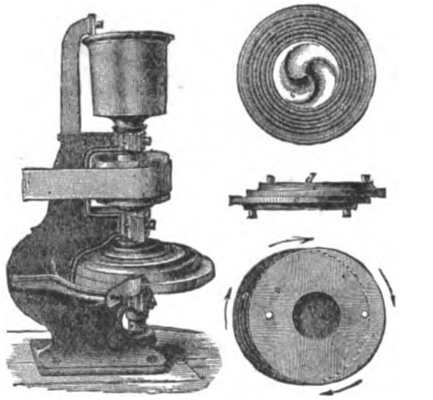


Eccentric Lathe.

Ec-cen'tric Mill. In the Bogardus eccentric mill, both plates revolve in the same direction (with nearly equal speed), on centers, which are apart from each other one or two inches, more or less; the center of the one, or the axis thereto affixed, resting on, or revolving upon a stationary bearing; whilst the prime mover, by means of a belt or gearing, causes the motion of the other plate.

The driven plate communicates motion to the

Fig. 918.



Bogardus Eccentric Mill.

other, the circles which are cut in the plates acting as a revolving shears. The faces of the plates are variously formed for different purposes.

Ec-cen'tric Valve. A stop valve moved by an eccentric upon the valve stem, or, as in the case cited, by an equivalent motion of a short-throw-crank.

See *Elliott & Burnett*, Br. . . * "*Engineer*," xliv. 193.
* "*Engineering*," xxiii. 98.
* "*Sc. American Sup.*," 1570.

Ech'o-scope. (*Surgical.*) An instrument invented by Dr. Speir to intensify sounds produced by percussion of the thorax.

Fig. 267, p. 83, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

E-con'o-mi'zer. An apparatus for heating the feed water by the waste heat from a boiler or furnace. See FUEL ECONOMIZER.

E-cra'seur. (*Surgical.*) A flexible loop for cutting, or tearing loose a tumor, polypus, etc.

The following figures refer to *Tiemann's* "*Armamentarium Chirurgicum.*"

The écraseurs of *Chassaignac*, *Edwards*, *Emmett*, *Tiemann*, and *Barnes*, for uterine and ovarian tumors, are jointed chains. Pages 92, 93, Part III. Of the same class, is *Sims'* porte chain écraseur, Fig. 470, Part III.

The instruments of *Smith*, *Braxton*, *Hicks*, and *Van Buren* for the same purposes, are of wire. *Ibid.*

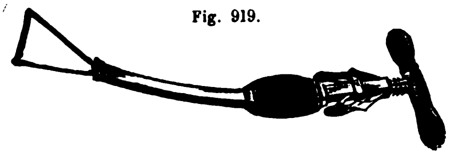
The galvano-cautery sling or écraseur, *Ibid.*, p. 100. See also, *Ibid.*, p. 113, Part I.

Gibbs' Laryngeal écraseur, *Ibid.*, Fig. 338, Part II.

Some écraseurs are shown under CAUTERY INSTRUMENTS, *supra.*

The écraseur of *Dr. J. Harry Thompson* is designed for the rapid removal of uterine polypoid growths. It enables

Fig. 919.



Dr. J. H. Thompson's Ecraseur.

the operator to readily pass the chain around the tumor, the steel springs keeping it taut until the tumor has been completely encircled.

Dr. Nott's rectilineal écraseur is especially intended for the removal of hemorrhoids, and division of the pedicle of ovarian tumors. It is a species of clamp with screw fastening handles, the jaws being respectively a blade and a slit. See Fig. 6, p. 64, vol. vii., Dr. Thompson's report of Group XXIV., * "*Centennial Exhibition Reports.*"

E-de ma-glot'tis Tube. (*Surgical.*) A flat spring ring to be introduced into the glottis to prevent its being closed by swelling.

Edge Grind'stone. One the peripheral edge of which is the portion utilized; as distinguished from surface grindstone.

Edge Key. A tool used in boot-making for rubbing and burnishing the edges of soles. The disks are made of patterns: plain, convex, scotch edge, fluted, etc.

Edge Laid Belt. One made by cutting up the hides into strips of the width of the intended thickness of the belt, and setting them on edge. These strips have holes punched through them about ⅛" diameter and 1" apart. Nails, made of round wire, clinched up at one end for a head and flattened at the other, are used for fastening the leathern strips together.

Edge Mold'ing Ma-chine'. One for cutting moldings on the edges of boards, the latter lying upon a table and presented to a revolving cutter which projects upwardly through a hole in the table. Fig. 3200, p. 1468, "*Mech. Dict.*"

Bentel, Margedant & Co. * "*Manuf. and Builder*," xii. 153.
* "*Engineer*," xli. 412.

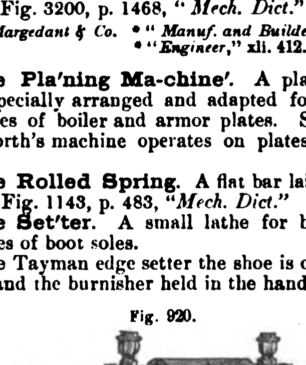
Edge Pla'ning Ma-chine'. A planing machine specially arranged and adapted for planing the edges of boiler and armor plates. Sir Joseph Whitworth's machine operates on plates up to 15′ length.

Edge Rolled Spring. A flat bar laid spirally as in *v*, Fig. 1143, p. 483, "*Mech. Dict.*"

Edge Set'ter. A small lathe for burnishing the edges of boot soles.

In the Tayman edge setter the shoe is carried on a jack and the burnisher held in the hand.

Fig. 920.



Edge Setter.

Edge Trim'mer. (*Boot-Making.*) A small machine for paring the boot sole. The boot is held on a jack, moving automatically, and the knife trims the edge and takes out the feather. — Tayman.

Edg'ing and Di-vid'ing Bench. A circular saw of special adaption for sawing blocks into voussoir shapes, used in one form (Mansel's, Br.) of car-wheels.

The bed is moved to and fro by a screw, and the travel of the bed is adjusted and determined by the movable projections attached to the bed, which, by communicating motion to the system of levers, throw the strap on to one of the three pulleys for stopping, or for motion in one or other direction. The table has a fast return motion given it by means of a double ring of cogs, on the crown wheel fixed to the screw.

Robinson, Br. . . . . * "*Engineer*," xlv. 216.

Edg'ing Ma-chine'. (*Machine-tool.*) A machine with horizontal adjustable bed, and one or more cutters on vertical spindles: used for milling around the inside or outside edges of irregular shapes, and for surfacing and inside milling. A *profiling machine*. Jones, Lamson & Co.

The *Pratt & Whitney* edging machine has an accurate automatic movement for cutting circles of less than 3″ diameter, and their tangents. Made with one, two, or three spindles.

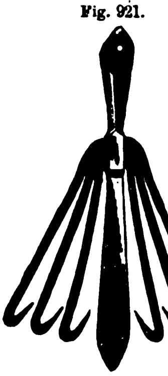
Edg'ing Saw. A circular saw arranged upon a bench for ripping boards to make strips or straight-edges. The board is placed on a movable table and fed past the saw. See also Double Edger.

Eel Spear. (*Fishing.*) A spear, Fig. 921, with 3 or more barbed prongs for catching eels by thrusting it into the mud they inhabit. See also Grains.

Patents:	S. Hedges	No. 172,312.
	C. M. Knowles	218,540.

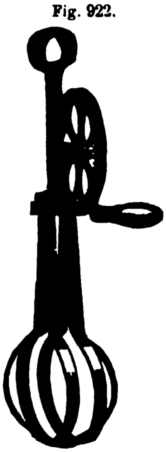
Egg Beat'er. The Dover egg-beater has two revolving flat loops on different shafts, each passing alternately inside of the other, gathering the egg towards the center of the bowl and whirling it in cross currents.

Fig. 921.



Eel Spear.

Fig. 922.



Dover Egg-beater.

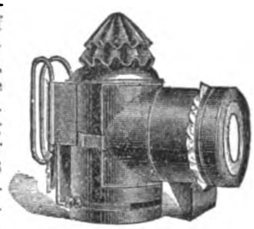
Egg'-end Steam Boil'er. A form of steam boiler with hemispherical ends. When of large size, the longitudinal seams are double riveted. When dished ends are used, the larger sizes have longitudinal or gusset stays, or both.

Egg'-shell Ware. (*Ceramics.*) A name applied to very thin porcelain, resembling the egg-shell in its extreme lightness. Made in Japan, and imitated in Europe.

See Prof. Wurtz, Report (Centennial) on Japanese Porcelain.

Egg Test'er. A dark lantern, having an opening at which an egg is placed in order to observe the condition of its contents; the translucency of a fresh egg, or the condition of the embryo chick observed. The fertility of the egg can be determined after being under heat for 48 hours. Used for commercial purposes in testing freshness of eggs, and in connection with incubators in observing the fertility of the egg and progress of the embryo.

Fig. 923.



Egg Tester.

E-ject'or. A form of pump. See p. 775, "*Mech. Dict.*"

Vacuum brake ejector .	* *Forney's* "*Dictionary*,"	435.

E-las'tic Wheel. (*Railway.*) A car-wheel in which some elastic material is interposed between the tire and the wheel-center or hub to resist the concussions. Different substances are used, such as paper, wood, india-rubber, oakum, etc. See Figs. 1170, 1171, pp. 493, 494, "*Mech. Dict.*"

El'bow. A bent pipe coupling or L joint. See also Bend.

El'bow Ap'pa-ra'tus. (*Surgical.*) 1. An apparatus for the gradual extension of contracted muscles of the arm; false anchylosis of the elbow.

Fig. 53, Part IV., *Tiemann's* "*Armam. Chirurgicum.*"

2. A splint for luxated elbow.

Hamilton's elbow splint, Fig. 148, Part IV., *Ibid.*
Andrews' elbow splint, p. 123, Part IV., *Ibid.*

El'bow Scis'sors. (*Surgical.*) Scissors bent in the blade or shank for convenience in cutting. See several instances in Figs. 4671, 4672, p. 2054, "*Mech. Dict.*"

El'der Brake. (*Railway.*) A brake for eight-wheeled cars, with a horizontal lever having a fixed fulcrum under the car-body, at its center, and pulleys at each end, over which a chain passes, which is connected with the brake-levers of each truck. One lever on each truck also has a pulley or sheave at its end, over which a chain runs which is connected with the opposite lever, and also with the central lever. The latter is connected by rods and chains with brake-windlasses by which the brakes are applied at each end of the car. — *Forney.*

E-lec'tri-cal Di'a-pa'son. An apparatus invented by George M. Hopkins, for compounding rectangular vibrations, so as to produce both sounds and figures.

Sir Charles Wheatstone contrived a small machine for the purpose, using tuning-forks; *Prof. Dolbear* used mirrors on a whirling table to describe curves upon a screen; *Lissajou* drew curves by means of two pendulums. In each of these there was a certain incompleteness; the forks lacked continuity of action, the mirrors gave no sound, the pendulums (as arranged without sustaining power) had neither continuity nor sound. It must be said, however, that *Lissajou* has, since his first invention, applied electricity to maintain the vibration of the diapason.

Hopkins' apparatus has two reeds or tongues vibrated by an electric current and connected with a single mirror, the latter receives a beam of light from a lantern and reflects it through a lens upon a screen. The steel tongues are pivoted at one end and are arranged relatively so that they vibrate in planes at right angles to each other. They are thus the equivalent of the Lissajou pendulums. The image upon the screen is the resultant of the two rectangular vibratory motions.

If only one tongue vibrates a straight line will appear on the screen, which will be inclined at an angle of 45° from the horizontal. The line produced by one of the tongues forms a right angle with the line produced by the other, and when both tongues vibrate simultaneously the two motions combine, and the reflected pencil describes a more or less complex curve, the form of which depends on the number of vibrations of the two tuning-forks in a given time.

The tones of the tongues are varied by moving the slide so that any possible combination of tones within the given compass (in this case an octave and a half) may be produced.

"*Scientific American*" . . . . xxxix. 223.

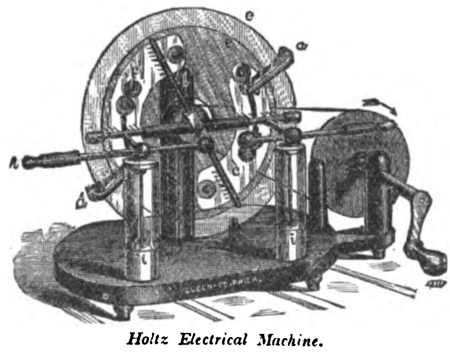
E-lec'tri-cal Gen'er-a'tor. See DYNAMO-ELECTRIC MACHINE; ELECTRO-MAGNETIC MACHINE.

E-lec'tri-cal Ma-chine'. *Franklin's* electrical machine is in possession of the Franklin Institute of Pennsylvania, and was shown at the Centennial Exhibition.

Fig. 925 is the Toepler Holtz electrical machine. The stationary glass plate *e* is held in rubber supports upon the platform, with the armatures *c c* at the back. The inner

Fig. 924.



Holtz Electrical Machine.

circular revolving-plate *e* is attached to the axis, the metallic disks outward. The arms *a a'* are attached to their sockets in such a way that the metallic brush just touches the brass disks when the plate *e* is rotated, but does not touch the plate. *i i* are the condensers.

To operate the machine place the balls close together, turn the wheel in the direction of the arrow until the sparks pass between the balls, then separate them gradually; the wheel-plate being rapidly revolved, a torrent of brilliant sparks will discharge between the balls. The small brass disks on the anterior surface of the plate *e*, when revolved rub against the metallic brushes, on *a a'*, a small quantity of electricity is carried around to the armatures *c c'*, upon the back of the large stationary plate, the initial charge is thus given to the outer plate *e*, this in turn reacts on the revolving plate.

E-lec'tri-cal Sold'er-ing I'ron. A tool for use in tin-shops and at the jeweler's or mechanical dentist's bench.

It consists of two metallic conductors placed side by side, with a small space between them for insulation, and joined at the end by a small piece of platinum or other refractory substance having a high electrical resistance. A handle is provided, having the proper insulation and binding screws for the wires. A simple form of switch is also provided for regulating the current. When the current flows through the tool, the platinum point is raised to a high temperature, and may be used to melt gold or silver solders

E-lec'tric Bat'te-ry. 1. (*Static.*) The Leyden jars.

2. (*Dynamic.*) The battery consisting of a series of galvanic elements. See GALVANIC BATTERY, and list, *infra.*

E-lec'tric Brush. 1. A brush with wire bristles, and having metallic plates in the handle which cause a galvanic action, especially when the brush is dipped in water or used in brushing the damp hair. — Dr. Post.

2. A brush included in an electric circuit, and used upon the hair or flesh as a therapeutic.

3. A circuit closer consisting of a bunch of wire used in telegraphic instruments using perforated slips.

E-lec'tric Bul'let-probe. (*Surgical.*) An instrument which indicates contact with the bullet by a sound induced by the completion of an electric circuit between the points of the forceps and through the bullet. Fig. 3966, p. 1803, "*Mech. Dict.*"

E-lec'tric Ca'ble. Plow for trenching and laying electric cables (French). "*La Lumière Electrique,*" reported in "*Scientific American,*" * xlvi. 246.

E-lec'tric Call. An audible signal communicated by electricity. An *annunciator, call-bell, buzzer,* etc.

E-lec'tric Can'dle. (*Electricity.*) A form of electric light in which the carbons are placed parallel; as in the Jablochkoff light.

The waste of the two must be equal, and they are therefore fed by alternating currents.

1. Candles with *columbin*; that is, a material which separates and insulates them, — the Jablochkoff, which combines the incandescent and the arc.

2. Candles without columbin are arc lamps. The Wilde, Jamin, and Debrun are of this class. The distance apart of the carbons is permanently fixed (*à écart fixe*).

The Clerc and Burean lamps, known as solar lamps (*lampe-soliel*) have nearly parallel carbons, and are allied to the incandescent class by the interposition of lime between the carbon points made incandescent by the passage of the current across them.

E-lec'tric Clock. (*Horology.*) The first clock, the pendulum of which received its impulse from electricity, was probably that of Mr. Bain.

The bob was made with a hole through it, and passed over two soft-iron cylinders, alternately magnetized by an electrical current at each beat of the pendulum.

An accurate regulator may control a number of subsidiary clocks, either upon the foregoing plan or by electricity operating upon their escapements, so as to cause their pallets to move the escapement wheel, the pinion of which drives the wheels to which the hands are connected.

In Shepherd's gravity escapement the pallet is raised by a temporary magnet, and then acts on the pendulum when swinging in one direction. Subsequently he made his magnets to attract and repel alternately.

E-lec'tric Disk. A concave hollow pan, filled with hot water and included in an electric circuit, used upon the flesh therapeutically. *Electro-Masseur.*

E-lec'tric Egg. An electric manifestation in an egg-shaped glass vessel exhausted of air, and having conductors above and below. The connection with the induction coil being made, the tuft of light between the rods assumes an ovoidal form and becomes more nearly spherical as the air becomes more rare.

Hopkins . . . . • "*Scientific American Sup.*," 2645.

E-lec'tric Fur'nace. An invention of Dr. C. W. Siemens for melting in a guarded crucible highly refractory metals. It has the advantage of compactness, obviates the need of chimney, is more economical in the concentration of the effect of the energy of coal, and excludes the atmosphere from the object.

In Siemens' furnace, exhibited before the Royal Society, the positive electrode, which was made of iron, entered from below the crucible containing the metal to be melted, whereas the negative electrode, which was a rod of carbon, was attached by means of a lever to a solenoid regulator. The crucible was surrounded by charcoal contained in a copper vessel to prevent loss of heat, and so intense was the heat accumulated that in about 20 minutes two pounds of broken files were completely melted.

E-lec'tric Gov'er-nor. A device to limit the passage of an electric current. There are many forms and purposes; some are referred to subjectively as in connection with the electric light.

Siemens' electric current governor is founded upon the stretching of a wire by the heating incident to the passage of the electric current through it. This idea is the foundation of some of the devices in electric arc-lamps for regulating the distance between the carbons, and also one or more of the *Edison* regulators for limiting the passage of the current in the process of subdivision of current for the multiplication of lights.

Siemens' device for giving sensitiveness and promptness by increased radiating surface of the strip is shown in

"*Electrician*," reproduced in "*Scientific American*," * xl. 184.

See also DIFFERENTIAL; REGULATOR.

E-lec'tric Ham'mer. An apparatus consisting of three hollow coils of insulated wire having a movable core or rod of soft iron which is free to move up and down under the axial attraction of the coils when a current circulates in them. The central coil is traversed by a constant current which magnetizes the rod or hammer, and the two extreme coils are traversed by alternating currents from a dynamo-electric machine in such a manner that they alternately attract and repel the magnetic rod up and down so as to make it beat like a hammer. The range of blow is limited on one side by a spiral spring placed within an elastic cushion. — *Siemens & Halske.*

The apparatus is primarily intended for working a rock drill.

The idea is familiar in dental pluggers. Fig. 3837, p. 1750, "*Mech. Dict.*"

E-lec'tric Hose. An arrangement by which the fireman at the nozzle may communicate with the engineer at the fire-engine.

A wire runs along in the cotton or rubber part of the hose, continuing the connection as each section is attached, and over this passes electricity, generated by one of the fly-wheels of the engine. Connected with the nozzle is a little contrivance by which the engineer can be directed to turn on, cut off, slack up, or what not, by signals upon a gong attached to the engine.

"*Manufacturer & Builder*" . . . . xii. 18.

E-lec-tric'i-ty. Electrical nomenclature settled by the Electrical Congress in Paris, 1881: —

1. The fundamental units to be centimeter, gram, and second (C. G. S.), as heretofore.
2. The practical units, *ohm* and *volt*, to retain their present definition.
3. The unit of resistance, or *ohm*, to be represented by a column of mercury of a square millimeter section at the temperature zero centigrade.

A committee to ascertain and report height of such column in millimeters.

4. The name *ampere* to be given to the *current* produced by a volt in an ohm.
5. The name *coulomb* to be given to the *quantity* of electricity defined by the condition that an ampere gives one coulomb per second.
6. The name *farad* to be given to the capacity defined by the condition that a coulomb in a farad gives a volt.
7. The French *carcel-bec* given the preference over the English "candle-power," and over the German and other standards, as the arbitrary standard of illumination. But this to be considered only provisional and subject to revision.

E-lec'tric Lan'tern. A glass envelope for an electric light.

Ground and opal glasses have been used with the Jablochkoff light, but the result is the absorption of from 30 to 50 per cent. of the light.

M. Clémandot stuffs the double glass envelope with glass wool.

The transparent part of the lantern is conical in shape and tapers downward. The walls are made of united glass tubes, like Pandean pipes, each filled with glass wool, and closed at top and bottom to exclude dust. Not more than 15 per cent. of the total light is absorbed by this process; the opacity can be varied at will by introducing less or more wool into the tubes; and the light can be tinted any desired color, either by the stain given to the spun glass, or the tubes which build up the wall of the lantern.

E-lec'tric Light. The history of the electric light commences with the discovery of Galvanism by Galvani, of Bologna, and Volta, of Como; and the voltaic arc was first produced by Davy, in 1813, between the charcoal points of two conducting wires. He used for the purpose a trough battery of 2,000 elements.

The invention had not emerged from the domain of expensive experiment until the discovery of magneto-electricity by Faraday, in 1831. The magneto-electric machines of Pixii, Saxton, Clark, Niaudet, Siemens-Halske, Holmes, and Nollet, followed, and the light was adapted to and used in lighthouses: at Dungeness, in England, in 1862; and at La Heve, in France, in 1863. See DYNAMO-ELECTRIC MACHINE, *supra*, and p. 781, "*Mech. Dict.*" The history of the electric light has two branches, the generator and the applicator: the machine, and the light proper.

A great improvement upon the Holmes and "Alliance" (Nollet) machines was made by Dr. C. W. Siemens, who invented a peculiar form of armature known as the inductive cylinder. This was followed in 1866 by the machine of Wilde, who made the remarkable discovery that if a current from a small magneto-electrical machine was made to pass around the coils of a large magnet, the attractive power of that magnet would be immensely greater than the force of the magnets in a small machine. Thus, by working a small machine, passing the currents through the electro-magnets of a large one, and then taking from the armature of the large one the current to be used, great electric power was obtained in a small compass.

The discovery of the reaction principle of magnetization by Hjorth, of Stockholm, Sweden, in 1854, was a remarkable one in the history of the art, but it seems to have slumbered unnoticed until the announcement by Wheatstone and Siemens, in 1867. By this principle of action a powerful electric current may be generated through the building up of the effects of action and reaction taking place between an electro-magnet and a magneto-electric inductor revolving in its magnetic field and included in the same circuit. The subject has, however, been considered on p. 283, *supra.*

Leaving machines (pp. 283–286, *supra*), it may be said that the electric lights naturally divide into two groups:

Incandescent. *Arc.*

The Werderman is a sort of cross, having an incandescent point with an arc around it.

"The voltaic arc is a portion of the electric circuit, possessing all the characteristics of other portions of the circuit. The molecules entrained constitute between the two points a movable chain, possessing more or less conductivity, and more or less heated, according to the intensity of the current on one hand, and the nature and distance apart of the electrodes on the other. What occurs is precisely as though the electrodes were united by a wire or a carbon rod of very small section, and thus it may be said that the light produced by the voltaic arc and the light produced by incandescence are results of the same cause, namely, the heating of a bad conductor interposed in the circuit." — *Fontaine.*

Each plan has its own class of difficulties to contend with. The arc is formed by the passage of the current between two separated carbons. These burn away gradually, the positive twice as fast as the negative carbon. It is necessary that they shall preserve an exactly equal distance, and this brings the necessity for automatic regulation. It is this feature that has given rise to the greater number of the patents on the arc class of electric lights. Various inventions in this department are due to *Archereau, Lacassauge-Thiers, Gaiffe, Foucault, Duboscq, Hefner-Alteneck, Serrin, Browning, Siemens, Brush, Thomas, Jamin, Thomson-Houston, Sawyer*, etc.

The other side of the question, the incandescent class of lights, has also had its own class of difficulties: the necessity for finding a material which shall not appreciably waste when heated to the violent degree necessary. Platinum, iridium, and carbon, are the principal substances employed.

Platinum leaf was preferred to iridium by *Starr*, in his English patent of 1845. (King, Scotch Patent, Nov. 26, 1845, communication.) He afterward used gas retort carbon in a vacuum.

In the case of the carbon, it is of course necessary to exclude oxygen. This has been done in a satisfactory degree by exhaustion, absorption, and exclusion.

By exhaustion, as in *Edison's*, by means of air-pump.

By absorption; by exposure of chemicals which absorb oxygen in the globe.

By exclusion: filling the globe with nitrogen gas, as in *Kosloff's, Sawyer's, Farmer's*, etc.; or filling the globe with hydro-carbon vapor, as in *Maxim's*. The exhaustive process, and the exclusion by nitrogen, were used by *Depretz*, in 1849, in his incandescent lamp, consisting of carbon in a sealed glass globe.

The *Jablochkoff* candle of two parallel carbons separated by insulation material, belongs to another class.

The multitude of devices is now so great that it is necessary, in the present abridged résumé, to do little more than cite the inventions and give references in the cases of over 100 inventors of electric lights, cited in the list below (pp. 301, 302).

The electric light is now used in lighthouses in Britain, France, Russia, Austria, Sweden, and Egypt. The usual limit is machines equal to 200 carcel burners.

The introduction of the electric light into streets, works, and factories, is treated of in an article reproduced in "*Van Nostrand's Magazine*," xx. 70–84.

Plates XIII., XIV., show the principal electric lamps.

Brush's electric light mechanism consists of an arrangement by which the carbon sticks are automatically adjusted and kept in proper relation. See Fig. 925, Plate XIII.

The movable pencil is surrounded by an annulus which binds it and prevents its descent, until, by the increase of distance between the carbon pencils, the current is so far weakened as to cause an electro-magnet to lower its carbon-holding armature and release the bind of the annulus upon the pencil, which slips downward until, by the proximity of the carbon, a current of sufficient force is established to restore the electro-magnetic device to its former position.

A is a helix of copper wire through which a current flows, making an electro-magnet of the soft iron axial core which carries the carbon-holder *B*. The current passes from point *P* to point *N*, embracing the coil, armature carbon-holders, and carbons *F F′* in its passage.

The axial magnetism produced in the helix by the passage of the current will draw up the core, separating the carbon points far enough to produce the light. As the carbons burn away, the increased length of the electric arc increases its resistance and weakens the magnetism of the helix, and, therefore, the rod and carbon move downward by the force of gravity, until, by the shortening of the arc, the magnetism of the helix is strengthened and the downward movement arrested.

An enlarged view, Fig. 926, Plate XIII., shows the annulus *D*, the armature, carbon-holder *B*, lifting tongue *C′* of the core *C*, clamp *B′*, carbon *F*, set-screw *D′*.

The *Maxim* arc lamp Figs. 927, 928, Plate XIII., has a pair of vertical carbons, the holders of which are so connected by gearing or rolling contact in the case beneath, that they mutually approach and establish the current. Thereupon a current passes, an electro-magnet is excited, and its armature draws downward a cord and separates the carbons, the result of which is the establishment of the voltaic arc. As the carbons waste the arc becomes larger, the resistance greater, the electro-magnet feebler, and the carbons are again gradually approached.

Siemens's is an arc lamp; his improvements concern the regulator by which the degree of proximity of the carbons is automatically accomplished. The upper carbon *B*, Fig. 929, Plate XIII., passes through the core of an electro-magnetic regulator *F*. The lower carbon, *A*, is continually pressed upward by the action of a weight, *a*, and restrained by a clamp, *c*, which loosens as the carbon consumes. The upper carbon is, by the release of a wheel, *f*, allowed to descend as it wastes, and the tube carrying the upper carbon is kept floating in balance by the action of the solenoid *E* on its core *P′*, automatically adjusting the distance of the carbon points to suit the voltaic arc.

The *Skinner & Thomas* arc electric light, Fig. 930, Plate XIII., employs (preferably) for the negative electrode an iridium-tipped rod *G*, which is practically indestructible, and secures the immobility of the point of light; the problem of automatic adjustment is thus restricted to the positive electrode *H*, which is of carbon. The maintenance of the predetermined arc-interval until the complete consumption of the positive is obtained by the following means: —

The positive wire *P* from the generator connects with a helix *F* of insulated wire around the non-magnetic bobbin *A*, consisting of a thin, longitudinally split brass tube, the ends of which are respectively secured in collars *B, C*, of vulcanite. This helix *E*, constituting the terminus of the positive wire, has an axial extension of twice the length of the carbon rod. From the collar *C* depends the loop *F*, bearing the erect negative *G*, of copper tipped with iridium. Inside the hollow bobbin *A*, is a loosely-fitting soft iron armature, or *suction-core K*, the brass stem of which, *J*, terminates in the clamp of the positive electrode — the carbon *H*. The weight of the core and its adjuncts is nearly balanced by the counterpoise chains and weight-cups of shot, and the diminution of the weight of the consuming carbon is equipoised by the passing over of the chains from the outside to the inside of the helix. To a cross-bar *O*, on the carbon stem *J*, are fastened two erect brass rods, *R, R*, on the upper ends of which are two wheels, *Q, Q*, which press lightly against opposite sides of the helix *E*, on lines left naked by the removal of the insulating material, establishing electrical connection. One side of the pendant *F* communicates by wires *N′ N″* with the negative rheophore.

The action is as follows: —

The shunt wheels *Q Q′*, having, with their supporting frame *O R R′*, been, by means of set-screw *j*, fixed at their proper height relatively to the core *K*. and the counterpoise *M* having been so loaded as to diminish the virtual weight of core and adjuncts to that which just insures their descent at any relaxation of the coil-magnetism, connection of the wires *P N*, with the generator, causes the current to flow as indicated by the arrows, and thus to impart magnetic properties to the helix *E*, which, in turn, results in elevating the core and its attached electrode *H*, so as to create an arc-interval.

Disintegration of the carbon tip increases the arc-interval and consequent tension and decrease of current, with corresponding reduction of coil-magnetism. This permits the

weight of the positive element to prevail over the upward drag of the coil-suction until the two opposing forces, gravity and magnetism, being restored to equilibrium, the normal arc-interval is reëstablished. These movements are so prompt and delicate that a sensibly uniform light is obtained.

The right-hand portion of Fig. 930, Plate XIII., shows the device for the equalization of arc electric lamps in series, and is termed the "*differential*."

It is well known that no two arc electric lamps, employed in series, behave precisely alike. In one lamp the magnetic lift, incident to increased current-flow, takes place more promptly, and with greater facility, with a consequently greater arc-interval than in the others. Such disproportionate increase of arc-interval in one lamp necessarily weakens the current throughout the series, and thus detracts from the lifting power of all, but most so from those of the most sluggish movement. The heavier working lamps, thus dwindling in illuminative action, cease, one by one, to respond to the continually waning magnetic energy. In strong contrast with and at the expense of this enfeebled action of the weaker lamps, the arc of the most susceptible or easiest working lamp continues to expand until it practically monopolizes the effective activity of the entire circuit.

The remedy for such unequal action lies in a provision whereby — when the arc-resistance of any given lamp becomes higher than normal — the current is automatically diverted from the arc of that lamp to the next lamp of the series — or to "line" or generator, as the case may be, — to sufficiently reduce or counteract the "helix-suction" of the lamp thus regulated, to restore its arc-interval to normal length, and at the same time, by diminution of its arc-resistance, to secure resumption of normal current-flow throughout the series.

Skinner & Thomas's device for this purpose is shown in the right-hand portion of Fig. 930, Plate XIII. On the core *K* is wound a helix *S* of fine wire, which communicates from a point in the positive element (above the electrode) directly with the negative rheophore *N*, so as to shunt the arc. The portion *Q* of the differential wire, which communicates from the differential helix to the rheophore *N*, is convoluted so as to permit the free descent and ascent of the core.

By the expression "differential" is meant that the said helix *S* is so wound as to induce on the core magnetism of opposite polarity to that induced by the main helix, whose magnetism (when a current is passing through the differential), being thus more or less neutralized, operates with diminished suction so as to permit the descent of the electrode until the normal arc-interval is resumed. The prime and the differential coil-magnetisms consequently preponderate alternately at each respective change of arc-interval above and below the normal one.

Proper adjustment of the parts is had when the resistance of the differential is such that, in the normal condition of the arc, the magnetism induced in the core by the prime helix minus the counter-magnetism induced in the core by the differential helix just balances the surplus weight of core and adjuncts over that of the counter-balance.

By aid of this system of regulation a current can be almost indefinitely divided and the double benefit be secured of preventing excessive activity of any individual lamp, and of insuring to each lamp in the series its proper share of illuminative action. See also REGULATOR, *infra*.

The *Thomson-Houston*, Fig. 931, Plate XIII., is an arc lamp, and the invention particularly concerns the regulator.

The carbons are fed by mechanical means controlled by electro-magnetic detent in a shunt of the main circuit. One of the carbon electrodes is attached to the armature of an electro-magnet, and, on the passage of an electric current, said armature is attracted to said electro-magnet, and then held in a fixed position in respect thereto, thus effecting separation of the electrodes. The motion of the other electrode is under the control of a separate electro-magnet, whose coils are in a shunt-circuit around the arc between the electrodes. When the distance between the electrodes is increased by their consumption, the shunted current operates an escapement, which allows the slow approach of the electrode. Said approach ceases when the distance between the electrodes has reached the normal. This cessation of feeding occurs when the escapement above referred to is thrown out of action from the weakening of the current in the shunt-magnet. These actions are independent of considerable variations in the current strength.

In the *Rapieff* light the voltaic arc is produced between four carbon rods arranged in pairs, each forming the letter V. The apices of the V's meet in a common center. A regulator is attached which keeps the carbons at an invariable distance. One of the carbons at a time can be detached without interrupting the current.

In the *Wallace* lamp the light is produced between the edges of two carbon plates, which last 100 hours. The edges gradually consume, and the light flies to the point where the plates are nearest in contact.

The lamps of *Wright*, 1845, *Molt*, *Lontin*, and *Reynier* embrace the plate, disk, or roller principle.

The *Wallace-Farmer* electric light is shown in Fig. 932, Plate XIII.

Like the one just mentioned, the frame carries two gas carbons, forming the electric wick. These slats are 9″ × 3″, the positive (upper) ½″ thick and the negative (lower) ¼″ thick. The lower is fixed, the upper adjustable. In the absence of current the upper rests on the lower; but as soon as a current passes, the armature by which it is suspended is raised in the coil, and separates the carbons ⅛″. The electro-magnet is contained in the box, and the sectional view shows clearly its construction. The arc chooses the nearest points of the carbon edges and gradually wears them away, the electro-magnet being adjusted to keep an equal distance between the nearest points of the carbons at any one time.

The *Reynier* lamp has assumed two forms, *arc* and *incandescent* respectively: the former has two carbon disks revolving in planes inclined to each other, so that the edges approach and a voltaic arc spans the interval.

The *Jamin* electric light is an arc. It has at least two nearly parallel carbons and in some cases not less than three groups of two each; one member in each case is adjustable towards its fellow. The candle has thus two vertical rods which differ from the Jablochkoff in that there is no insulating material between them. They are erected or suspended in sockets, one of which is pivoted so that a small electro-magnet controlling it can maintain automatically the proper distance between the two ends. Fig. 933, Plate XIV.

The carbon pencils are surrounded with an elliptical coil of wire, through which passes the current that gives the light. The coil is in the same vertical plane as the carbon rods. A more elaborate arrangement is shown in "*Plumber & Sanitary Engineer*," * iii. 400.

The *Weston* is an arc light, having two erect nearly parallel carbon rods, the positive twice the bulk of the negative. They are supported in sockets, the negative being pivoted so that its upper end can be adjusted towards and from the positive, towards which it is inclined by a spring. As soon as electric connection is made, the armature of an electro-magnet withdraws the movable carbon from contact and the voltaic arc is established.

Jablochkoff's invention is an electric candle; his object is the "absolute suppression of any mechanical regulator." Instead of automatically feeding them towards each other he fixes them parallel at a short distance from each other and separates them by an isolating substance which is consumed at the same time with the carbons. Fig. 934, Plate XIV.

The separating substance is an earthy infusible powder put around the carbons in a closed envelope of asbestos. The electric stream gradually dissipates the intractable substance, clearing it away from the carbons and exposing them, somewhat as the wick of a candle is exposed by the burning away of the tallow.

a b are the carbons, *e* the asbestos case, *d f* metallic sheath, *h j* jaws, *k* tightening screw, *p n* terminals.

The *Lontin* lamp and the *Reynier* keep a slender rod of carbon in contact with a slowly revolving wheel, touching it on the outer rim and keeping a certain length of the rod incandescent.

The *Reynier* lamp, Fig. 935, Plate XIV., has a slender pencil of carbon, *c*, which is traversed through a portion of its length by the current (from *l* to *B*), and is impelled axially against a revolving contact which carries off the ashes of the carbon. The portion of the pencil between the upper contact *l* and the lower revolving contact *B* becomes incandescent, and burns, tapering away towards the end, the rod being continually fed forward.

Kosloff's (1875) is an incandescent light, the current passing through sticks of carbon in a globe filled with nitrogen gas, the carbon is mounted on an inserted metallic conductor and placed between two insulating supports of porcelain, clay, or other material. The carbons are in a globe, hermetically sealed, filled with nitrogen gas.

In the *Sawyer* electric lamp the feeding of the carbon pencil to the contact piece is effected by a spring and cord running over pulleys. The pencil of carbon is heated to incandescence in a hermetically sealed glass globe filled with nitrogen gas or exhausted of air. The summit of the upper carbon is pressed between grooved rollers. The base of the lamp-globe is imbedded in a cup having an annular space, and the base of the lamp is in two sections, for facilitating the renewal of the carbon. Fig. 936, Plate XIV.

The *Sawyer-Man* is an incandescent lamp. The incandescent strip is automatically fed through one conductor and against another, the part between the two conductors giving a light. The two conductors are supported by spiral standards, the length and extent of surface serving to dissipate the heat and thus preserve the insulation. The whole is incased in a glass globe filled with nitrogen. Fig. 937, Plate XIV.

Edison's carbon-arc lamp is an incandescent lamp. The arc *F* is attached by clamps *G G′* to the platinum wires *W*, which are sealed in the summit of the interior glass dome. At a lower point is an enlargement E E' upon which sits the lower end of the tube, the upper portion of which is the device A around the incandescent arc. The patent No. 230,255 particularly concerns the mode of sealing the wires in the foot, and the mode of exhausting and sealing the dome, to secure entire freedom from oxygen in the interior. B is the pillar of the lamp and D D' binding posts for the wires. Fig. 938, Plate XIV.

In one form of the carbon arc lamp the carbons are of slips of paper or cardboard cut to horse-shoe shape and charred, then mounted by platinum clamps on the sealed wires.

One of *Edison's* regulators is an automatic shunt fitted to the lamp, by which a portion of the current is diverted from the circuit of the light producing portion of the apparatus whenever its temperature approaches an injurious limit.

Edison's expansion, pneumatic, and vibratory regulators are described, illustrated, and compared in an article by F. R. Upton, in "*Scribner's Monthly*," vol. xix., pp. 531-544.

In another of *Edison's* electric regulators he makes use of a coil of wire with a pyro-insulating material between the coils, and a surrounding case rendered incandescent by the heat of the coil. In the same lamp, which is adapted to be used in multiple arc, a thermal circuit is arranged so that the amount of light can be varied at pleasure by an adjusting-screw that regulates the point at which the thermal regulator acts to open the electric circuit and lessen the current, so that the incandescent case can be more or less luminous. The claim for a thermostatic regulator is, however, held by *Maxim* in his patent, No. 247,380, Sept. 20, 1881.

Edison's safety device, for preventing an abnormal flow of current through any branch, consists of a piece of very small conductor interposed in the main conductors of a house or in the derived circuit of a lamp. It is preferably interposed between the line wires and every lamp, limiting to the latter the amount of current designed for it.

Farmer's is an incandescent lamp, the globe of which contains a vacuum, or an artificial atmosphere — say nitrogen. From the stopper of the globe rise two uprights, between which is held a removable carbon slip, which, upon passage of the current, becomes incandescent. Fig. 939, Plate XIV.

The *Maxim* is an incandescent lamp, the light being produced by a strip or conductor of low conductivity, forming a part of the electric circuit. Fig. 940, Plate XIV.

The illumination takes place in a glass chamber deprived of oxygen, but instead of excluding the air by exhaustion, or filling the globe with nitrogen, the air is displaced with a hydro-carbon, preferably gasoline, and such liquid then expelled by heat, so as to leave in the globe a hydrocarbon partial vacuum, or a highly-attenuated atmosphere of hydrocarbon vapor surrounding the conductor or light-giving part of the lamp. The continuous incandescent conductor is mounted upon electrical connections of platinum.

Edison's carbon coil lamp is an incandescent; a filament of carbon either in arc or coil shape, that is, of "carbon wire or sheets coiled or arranged in such manner as to offer great resistance to the passage of the electric current, and at the same time present but a slight surface from which radiation may take place."

The electricity is conducted into the vacuum bulb through platinum wires sealed in the glass.

In Fig. 941, Plate XIV., a represents a carbon coil attached to platinum conductors d d' by a plastic composition of lamp-black and tar. c c', h are clamps.

Khotinsky (French patent, No. 107,307, of March 19, 1875) shows an incandescent carbon lamp, having in its base resistance coils and a switch whereby the current can be passed wholly through the carbon or wholly through a resistance equal to the resistance of the carbon, or if a partial light is desired, then partly through the carbon and partly through a resistance, the arrangement being such that the total resistance is always equal to a certain amount. The current is shifted automatically to another carbon in same lamp when one breaks.

The *Werdermann* lamp has a vertical rod of carbon which impinges at its upper end upon a disk of carbon, Fig. 942, Plate XIV. The upper end of the rod becomes incandescent, and a voltaic arc is also formed.

The upper part only of the carbon rod is in the circuit, and the length of this portion can be increased or diminished by shifting the collar which transmits the current. The rod is kept pressed against the disk by a cord and weight, and consumes very slowly. The disk is negative; 2″ in diameter, 1″ thick, encircled by a band of copper, which is prolonged to a terminal. The positive carbon is a round pencil 3 mm. in diameter, and slides in a tube.

"Dr. Tyndall and Mr. Douglass, chief engineer to the Trinity Board, in reporting lately to the Elder Brethren upon the power of these machines and their applicability to light-houses, give a table showing that a machine weighing not more than 3 cwt. is capable of producing a light equal to 1250-candle power per horse-power expenditure of mechanical energy. Assuming that each horse-power is maintained with an expenditure of 3 lbs. of coal per hour (which is an excessive estimate), it would appear that 1 lb. of coal suffices to maintain a light equal to 417½ normal candles for one hour. The same amount of light would be produced by 139 cubic feet of gas of 18-candle power, for the production of which 30 lbs. of coal are consumed. Assuming that of this quantity, after heating the retorts, etc., 50 per cent. is returned in the form of gas-coke, there remains a net expenditure of 15 lbs. of coal in the case of gas-lighting to produce the effect of 1 lb. of fuel expended in electric lighting, or a ratio of 15 to 1 in favor of the latter. Add to the advantages of cheapness in maintenance, and of a reduced capital expenditure in favor of the electric light, those of its great superiority in quality and its freedom from the deleterious effects of gas in heating and polluting the atmosphere in which it burns, and it seems not improbable that it will supersede before long its competitor in many of its applications." — *Dr. C. W. Siemens*, Address, January 23, 1878.

The annual report of the United States Light-house Board contains the details of some recent tests with electric lamps, made at the Stevens Institute of Technology by Prof. Morton. The results of these experiments are embodied in the following table, in which the term hand-lamp is employed to signify that the distance between the carbons was regulated by hand: —

Machine.	Lamp.	Average Candle Power.	Average Horse Power.	Average Candle Power per Horse Power.
Maxim (ordinary type)	Maxim	3,297	5.483	729
Maxim	Hand lamp	3,930	5.585	704
Siemens	Siemens	4,651	4.863	956
Siemens	Siemens	4,548	4.742	959
Weston	Hand lamp	8,585	4.769	1,800
Weston	Maxim	7,787	4.683	1,663
Weston	Siemens	7,262	5.056	1,436
Weston	Weston	6,063	4.552	1,332
Maxim (with magnets of low resistance)	Maxim	7,524	7.400	1,017
Brush	Brush	4,365	2.8467	1,533
Brush	Siemens	3,532	2.9573	1,194

The results of the attempts at the "Division of the Electric Light," may be divided into four classes, *series*, *multiple arc*, *multiple series*, and the *commutator system*

The *series* system, *i. e.*, with the lamps all arranged in succession in one unbranched circuit, was the first one employed, and is still found to be the best when arc lamps are used.

In the *multiple arc* system the conductor is divided into numerous branches, in each of which is placed one lamp. Two main conductors are run out from the generator and divided and sub-divided while still remaining in pairs, and at various points the lamps are connected so as to bridge the said pair. A ground return is sometimes substituted for one of the conductors. The first mention of multiple arc lighting appears in du Moncel's "*Exposé des Applications de l'Électricité*," Paris, 1857. It has the advantage over the series system, that the extinguishment or breakage of one lamp does not materially affect the others, but as all the lamps are in parallel branches the total external resistance is exceedingly small, and for this reason the system is more particularly adapted for incandescent lamps which are made of such high resistances as 100 and 200 ohms on that account.

The *multiple series* system is a combination of the first and second. The circuit is divided as in the multiple arc, but more than one lamp is placed in each branch, so that the resistance may be made such as desired. This system seems to have been first described in a patent to Sawyer and Man, 205,303. June 25, 1878. *Brush* (patent, No. 261,077, July 11, 1882) shows and claims a multiple series system, in which the different branches are connected by cross connections between the lights in such a manner that the breaking of circuit at one lamp will have no appreciable effect on any of the other lamps in the system.

In the fourth system a *commutator* is employed which so divides the current among different branch conductors each having one or more lamps, that each lamp is traversed by the current for a small fraction of a second. By means of a sufficiently rapid commutator the impulses to each light follow each other in such quick succession as to give the effect of a continuous light.

Secondary batteries were described by Jablochoff in his French patent of 1876, as in a branch or shunt around each light. Fox, in his English patent of 1878, shows a network of conductors between which and the ground return are connected up in multiple arc incandescent lamps and secondary batteries.

E-lec'tric Light Meter. An invention of Edison for measuring the quantity of electric current passing to a light or to a house. A part of the system of divisional current arrangement for public lighting.

The current goes from line by the house-wire to the apparatus, passing through two contacting platinum points and thence to a magnet. The device is to cut a house out of the circuit if too great a flow of electricity should occur. In the latter case the magnet will draw down a lever and sever the contact of the platinum points, thereby breaking the circuit.

E-lec'tric Light Reg'u-la'tor. An apparatus or device: —

1. To determine the amount of current passing to the electric lamp.
2. To adjust the carbons of the arc light so that they shall preserve their exact relative distance.

Of these there are two orders: —

a. The *monophote*, or *one-light* regulator.
b. The *polyphote, many light*, or *division* regulator.

The *polyphote* has three classes: —

a. Differential.
b. Derivation.
c. Fixed interval, or regulator *à écart fixe.*

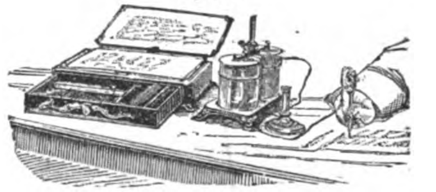
The *Serrin*,* *Mersanne*,* *Jablochkoff*, *Lontin*, *Rapieff* regulators are described on pp. 362–365, "*Engineering,*" xxvi., in a paper read by Mr. Shoolhed before the British Association at the Dublin meeting, 1878.

See also list under ELECTRIC LIGHT. Many of the objects there cited are *regulators*, as upon that feature of the apparatus more ingenuity has perhaps been expended than on other — excepting *generators.*

E-lec'tric Meas'ure-ment Ap'pa-ra'tus. An apparatus consisting of a box of graduated or cumulative resistances, and a galvanometer for determining the electro-motive force, resistance and strength of batteries, and resistance of conductors: for locating faults, breaks, and crosses on telegraph lines or cables; for measuring the amount of any metal deposited in a given time in electro-plating; and for determining the specific conductivity of metals.

E-lec'tric Pen. The electric pen consists of a small electro-magnetic engine, mounted upon the top of a tube pointed at the end. Within the tube is a needle to which is given an exceedingly rapid vertical motion by cams upon the rotating engine-

Fig. 943.



Edison's Electric Pen.

shaft. This needle is projected from the small end of the tube at the rate of 50 times per second. If the pen be held in writing position upon a sheet of writing paper placed on some soft substance, a letter may be written as fast as with an ordinary pen, but the characters, unlike the ink mark formed by the ordinary pen, will be composed of innumerable holes punctured in the paper by the rapid projection of the needle from the tube. The result is a perforated paper, which, treated as an ordinary stencil, will give similar result. The motive power used to drive the engine of the pen is derived from a voltaic battery of two Bunsen cells, shown in Fig. 943.

E-lec'tric Pho-tom'e-ter. Goodwin's electric photometer extinguishes candle and gas, and stops meter and clock by electricity.

"*American Gas-light Journal*" . * July 3, 1876, p. 5.

E-lec'tric Plow. A substitution of a dynamo-electric machine for the steam traction-engine, for the purpose of working the plows. The same arrangement of plow, rope, and installation is used (see STEAM PLOW, "*Mech. Dict.*"), but the power is conveyed to the winding drum on the head-lands of the field by wire from the central station where the engine, boiler, and current generator are situated.

The apparatus was invented by Chrétien & Félix, of Sermaize (Marne), France. The Gramme machine is used.

* "*Revue Industrielle.*"

* "*Scientific American*" . . . . July 17, 1879

E-lec'tric Rail'way. The car travels on insulated rails which form a part of the circuit, and the current works the dynamo machine on the car to rotate the wheels.

Siemens' electric railway at Berlin, between the suburbs Lichtenfeld and the Cadettenhaus, is one and a half miles long with a gage of 3', the rails of the ordinary pattern. A single car is propelled at 9 miles per hour, but might travel much faster; the car holds 20 persons; the dynamo machine is under the car; one rail positive and the other negative. The dynamo machine transmits its movement to the wheels by spiral steel springs. In addition to the ordinary brakes, means are provided to short circuit the machines on the carriages and to cause them to act as powerful brakes. Large stationary engines are used.

In the earlier experiments a central rail brought the current from the generator, the current returning by the outer rails. A copper brush on the car collected the current from the central rail. Several forms have been assumed from time to time. See references, *infra*.

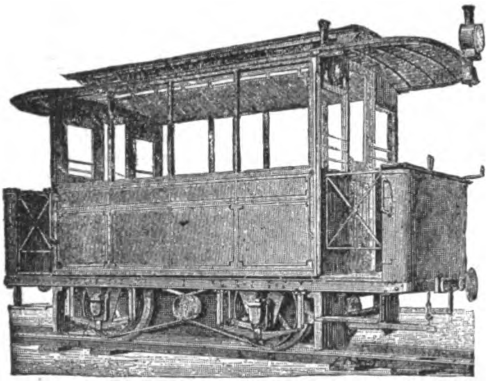
Chutter's engine, "*English Mechanic*," has also the feature of the positive and negative rails.

"*Scientific American Supplement*" . . . . . * 301.

The attention directed to the matter has unearthed a number of old devices. The *Lilly & Colton* electric locomotive described in the "*Scientific American*" for Sept. 25, 1847; *Bone's* French patent, 1848.

The *Edison* railway has a current conveyed to the track by two copper wires, one for each rail. The armature of the locomotive makes 4 revolutions for one of the wheel.

Fig. 944.



Gross-Lichterfelde Electric Railway Car.

There are six systems of electric traction at present in use, or being experimented with, namely : —

1. The small traction machine of Siemens with an isolated center rail, which was worked at the Berlin and Brussels Exhibitions.
2. A self-moving carriage on isolated rail and elevated road. This is an idea of Siemens, which has been temporarily abandoned.
3. The Gross-Lichterfelde Railway. An auto-mobile car with isolated rails, running since May 16, 1881.
4. The tramway shown at Electric Exposition in Paris, 1881. Auto-mobile car, with road on ground level, and conductor suspended above the way.
5. Electric tramway with accumulators. System of Philippart, Faure, and Reynier, Auto-mobile car having in it its own electric store.
6. The tricycle built by M. Trouvé. It is worked by the secondary piles of Gaston Planté, and by a Siemens' coil motor with Trouvé's improvement

E-lec'tric Reg'is-ter. An automatically recording apparatus in which electricity is the moving agent.

The applications are very numerous, and a number are stated in the list following.

Cooley's electric register for rapid vibrations is an electro-chemical instrument in which the vibrating body closes an electric circuit at each vibration and makes an autographic record on a traveling band of prepared paper, through which the current is caused to pass. The number of dots within a given length of the paper, which travels at a calculated speed, indicates with great delicacy the number of vibrations in a given time. — * "*Scientific American Sup.*," 1563.

Various forms of electric registers are to be found in *Comte du Moncel's* "*Exposé des Applications de l'Électricité*," tome iv., Paris, 3d edition, at the pages here noted : —

E-lec'tric Ro-ta'tor. An instrument operating through electrical devices to demonstrate the earth's rotation.

Fouville & Lontin .	* "*Scientific American*," xliii. 52.
	* "*Sc. American*," xxxix. 1, 37, 100.

See also GYROSCOPE, p. 1045, "*Mech. Dict.*," and references to Foucault's Pendulum, pp. 1045 and 1662, *ibid*.

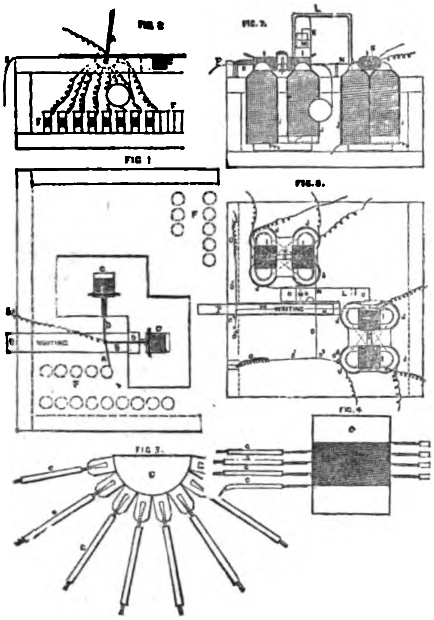
E-lec'tric Switch. A device for turning on the current to lights, etc., which gradually changes the current from an outside path to a path through the light by cutting out successively resistances in the lamp circuit and simultaneously cutting in resistances in the by-path circuit.

E-lec'tric Writ'ing Ap'pa-ra'tus. The autographic telegraph of *Caselli* is described on p. 191, "*Mech. Dict.*," and the Meyer apparatus, * p. 56, *supra*. Sawyer's and d'Arlincourt's, are also referred to on the last-mentioned page. Bonelli's facsimile telegraph is mentioned on p. 784, "*Mech. Dict.*" See also FACSIMILE TELEGRAPH; PANTELEGRAPH, *infra*.

Fig. 945 shows several views of Cowper's apparatus. Fig. 1 in the cut represents the sending instrument in plan, and 2 is an elevation of the same. The writer holds the pen, which is rigidly connected to the traveling contacts, and also to the batteries. The slip of paper on which the message is written moves under the pen instead of the pen traveling over the paper.

"Two sets of thin metallic plates, C C, form the contact apparatus; D D are the light connecting rods, the ends of which make contact with the plates; F F are the resistance coils connected to the contact plates, one coil for each plate, except the first of the series, which is connected direct to line. It will be noticed that the strength of the current entering the line depends upon the plate with which contact is made by the connecting rod. As the rod travels from the first of the series the resistance increases, the current having to pass through N — 1 resistance coils, as well as the line wire, N being the number of plates from the first of the series to the point at which contact is made. Generally, however, as one contact piece travels from the first of the series, the other travels towards the first of its series, and thus, while the current decreasingly varies in one line, the varia-

Fig. 945.



Cowper's Electric Writing Apparatus.

tion is increasing in the other. A slight knowledge of co-ordinate geometry will enable the student to plot the curve of any letter, and to calculate the variations in the strengths of the currents. Figs. 3 and 4 show respectively an eleva-

Fig. 946.

Written Message by Cowper's Instrument.

tion and plan of the thin metal plates, which are insulated the one from the other by paper soaked in paraffine. The receiving instrument, shown in plan and elevation in Figs. 5 and 6, differs from the sending instrument; H H are light soft iron bars on delicate bearings, having the ends surrounded by the coils I I, to which the bars form a movable core. Through these coils the varying currents of the line are sent, which, of course, have a varying action on the core. J J J J are four permanent or electro-magnets, between the poles of which the coils just named are placed. K is a syphon pen. The pen is adjustable from the bridge L, and the ink reservoir is shown at M. The light connecting rods N N transmit the motions of the movable cores to the pen; O O are springs to enable the pen to resist the pull of the magnets, the connections are shown in O^1 O^2 O^3, the latter being attached to a fixed post O^4

"The currents sent through the line wire by the sending instrument vary in strength or power, and cause the light bar of soft iron to move with varying power by its attraction to the stationary magnets; and in order to cause it to take its proper position according to each variation in power, a varying resistance is opposed to it, such as a spring which requires more power to compress it the more it is compressed, that the action of the soft iron bar, combined with that of a precisely similar bar actuated by the second line wire, will cause the position of the pen in the receiving instrument to follow the position of the pen in the hand of the operator at the sending instrument, and thus form the letters. The total strength of the spring or varying resistance can be regulated at will, so that the letters formed by the pen shall be of the same proportionate height and width as the letters written by the operator at the sending instrument. One convenient way of applying the varying resistance to the light bar of soft iron is by placing a very light spring to pull at the end of the bar in the direction of its length, but allowing of the motion of the bar which will thus cause the spring to act with more and more leverage as it moves more out of line with the spring. When so arranged there is required another spring to keep the connection with the pen tight, if such connection is flexible, so that the pen may go backwards as well as forwards over the paper, as the light bar of soft iron moves either one way or the other. But the spring or variable resistance may be made to act both to give the increasing resistance and the power to draw back the pen as well, if the spring is made to pull by a flexible or jointed connection at a fixed point, the line of such pull being parallel, or nearly so, to the light bar of soft iron, while another rigid or flexible connection from the end of the bar to the connection to the spring has the pen attached to it at about the middle of its length, which arrangement will give the same result as the two springs before described." — "*Engineering*."

E-lec'tro Bal-lis'ta. An apparatus for measuring the rapidity of flight of a shot. See BALLISTA. Electro-ballistic pendulum, "*Mech. Dict.*"

In *Boulengé's* apparatus the shot is made to break through two wire screens. The screen is a framework with fine wires, which are cut by the shot. One screen is near the muzzle of the gun, and the other at 100' distance. The screens are in connection with electro-magnets in the instrument house. While the wires in front of the screen are perfect, an electric current passes without interruption, and the electro-magnets suspend two rods of iron. When the shot is fired, No. 1 screen is torn, and the rod suspended to No. 1 magnet drops; an instant afterward, when the shot has reached No 2 screen, No 2 magnet detaches the second rod. The time between the falling of the two rods is so small, that ere the first has fallen half its length the second has dropped upon a trigger, which strikes the side of No. 1 rod. The latter is examined for the mark of the trigger, and the measure of this mark from the end, giving the distance traversed by the first detached rod, the rate being known, furnishes a figure which has only to be compared with a prepared scale in order to read off the number of feet per second at which the shot moved.

E-lec'tro-bronz'ing. A process for putting on iron a durable electro-bronze finish, resembling real bronze.

The articles to be bronzed are first put in a bath of paraffine, which stops further oxidation; they are then coated with a metallic substance and subjected to the electro-bronzing bath, after which they are treated with a peculiar protecting varnish, and are then ready for use.

E-lec'tro-cap'il-la-ry Mo'tor. A philosophic toy by M. Lippmann, founded upon the effect produced upon the capillary constant of mercury when an electric contact is made therewith.

In a glass tank filled with diluted sulphuric acid are two small cylinders containing mercury. A bundle of capillary tubes, open at both ends, is placed in each cylinder, resting on the mercury, each bundle being connected above with one end of a walking beam, to the prolongation of which is attached a connecting rod, crank, and fly-wheel. By means of a commutator on the axis of the fly-wheel the mercury in each cylinder is alternately connected with a small battery; its capillary constant is changed, its ascent in the tubes increased, that side preponderates, and causes semi-rotation of the fly-wheel. This sends the current to the other cylinder, which, acting similarly, completes the rotation.

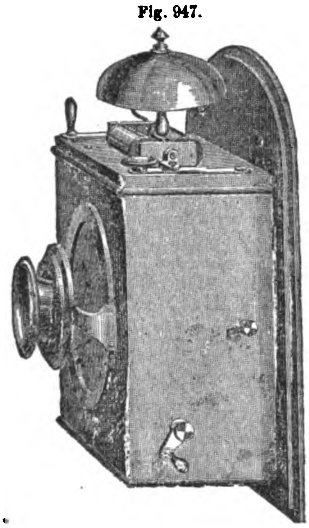
E-lec'tro-cau'te-ry. (*Electricity.*) See CAUTERY INSTRUMENT.

E-lec'tro-chem'i-cal Tel'e-phone. A telephonic receiver by Edison, in principle similar to the electro-motograph, which see.

If a strip of bibulous paper, slightly moistened with a weak solution of potassium hydrate, be laid upon a strip of metal, which by means of a key or contact maker can be connected to one pole of a voltaic battery, and a metallic strip, tipped with platinum, and connected to the other pole of the battery, be gently drawn over the surface of the paper, it will encounter a resistance, the amount of which, all other things being equal, will be determined by the coefficient of friction between the platinum-tipped spring and the surface of the moistened paper. The instant, however, that the circuit is closed by depressing the key, the friction between the two surfaces is reduced, and assuming a uniform tractive force to be exerted upon the strip, it will be found to slip over the surface of the paper every time that the key is depressed; and if the key be moved up and down, a series of pulsations or minute jerks will be felt by a person holding the strip, which pulsations are isochronous with the movements of the key.

The instrument shown in Figs 947-950 consists of a diaphragm which is set into vibration by the variations of friction taking place between a metallic strip and a chemically prepared rotating cylinder under variations of the strength of an electric current passing at the point of contact of the metallic strip and the cylinder. The diagram, Fig. 949, shows the disposition of the principal parts of the

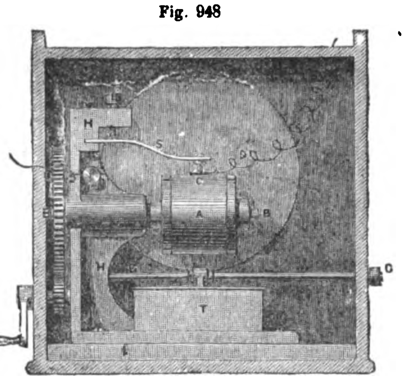
Fig. 947.



Electro-chemical Telephone.

apparatus. *A* is a cylinder composed of chalk and potassium hydrate with a small quantity of mercury acetate molded round a flanged roller or reel of brass which is lined with platinum on those surfaces which are in contact with the mixture, which is kept in a moistened condition Upon the upper circumference of the cylinder, which is caused to re-

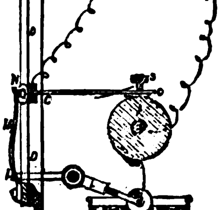
Fig. 948



Electro-chemical Telephone. (Vertical Section.)

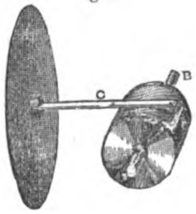
volve on the horizontal spindle *B B*, a metallic strip *C* is caused to press with a firm and uniform pressure by means of an adjustable spring, *S*. The portion of the strip which bears upon the cylinder is lined with platinum, and the opposite end is attached to a diaphragm, *D*, of mica 4″ in diameter, and firmly fixed by its circumference. The cylinder is connected to the copper element of a battery, and the strip

Fig. 949.



Electro-chemical Telephone. (Sectional diagram.)

Fig. 950.



Electro-chemical Telephone. (Detached view of diaphragm and roller.)

C to the zinc pole, with a transmitting telephone included in the circuit. If, when no current is passing through the instrument, the cylinder be rotated at a uniform speed away from the diaphragm, the friction between the cylinder and the strip *C* causes the diaphragm to be drawn inwards, *i. e.*, towards the cylinder, and the diaphragm would take up a fixed position dependent upon its own rigidity and the friction between the cylinder and the strip. The instant, however, that a current is transmitted through the instrument that friction is reduced and the diaphragm flies back by its own unopposed elasticity, the variation of friction being proportional to the variation of the strength of the electric current; and so extremely sensitive is this combination that the variations in the strength of the electric current caused by the human voice speaking against a carbon transmitting telephone instantly produce their corresponding variations of friction, and the diaphragm repeats the words, but very much louder than they were originally uttered at the distant station.

Of the other parts: *H H* is the cast-iron bracket holding the principal parts of the apparatus *G* is a shaft by which the forked lever *L* may be raised occasionally to bring the damping roller *R* from the trough *T* against the roller *A*.

"*Engineering*" . . . . * xxvii. 229.

E-lec'trode. (*Electricity.*) 1. A pole of a battery.

2. An instrument used in the application of electricity usually attached to the free extremities of conductors or cords. Sometimes called *rheophore*.

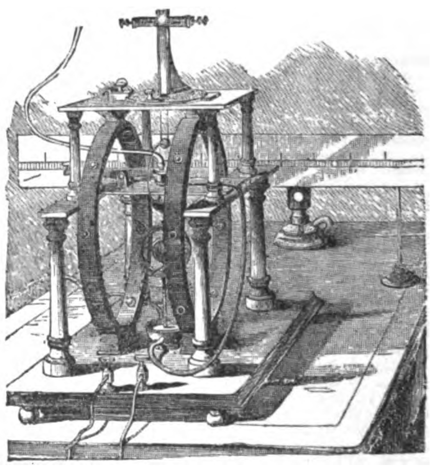
3. (*Surgical.*) Electrodes for various applications in electro-therapeutics are made of shapes appropriate. Among them may be mentioned: —

Plates for the feet, throat, temple, ankle.
Belts for the waist, wrist, arm, leg, knee, etc.
Insulated for rectum, vagina, urethra, bladder.
In form of needles, pessaries, forceps, plugs, balls, plates, sponges, brushes, pads.
60 forms are shown in the catalogue of the "*Western Electric Manufacturing Company.*"

4. One of the carbons (in some cases metal) in the arc electric light

E-lec'tro-dy-na-mom'e-ter. A measurer of the force of an electric current.

Fig. 951.



Electro-dynamometer.

The electrical current traverses the two large spirals of copper ribbon, and also the smaller spiral, whose bifilar suspension keeps it at right angles to the larger spirals when no current passes. The smaller spiral carries a small mirror, and the readings are taken from a distant scale, the light spot serving as an index. The circuit is completed through the smaller spiral by means of mercury cups kept cool by water running through their hollow walls.

Invented by Trowbridge and improved by Edison.

E-lec'tro Gild'ing. See ELECTRO PLATING.

E-lec'tro-graph. An instrument used for engraving the cylinders of copper or brass employed in the printing of woven fabrics and paper-hangings. Voltaic electricity is used to communicate the necessary movements in advancing the cutting tools at the appropriate times.

The cylinder to be engraved is first coated on its outer surface with a film of varnish. The required number of copies are then scratched through the ground by a series of diamond points arranged on the axis of the machine parallel with the axis of the cylinder. The metallic surface is thereby exposed in certain parts and is "bitten in" with acids. Each diamond point is in connection with a small temporary magnet, and the entire series is so arranged *en rapport* with the original design, that intermittent voltaic currents are established, which result in the diamonds being withdrawn from action at proper intervals.

E-lec'tro-har-mon'ic Tel'e-graph. An invention of Elisha Gray, of Chicago, by which numerous musical tones or a number of messages may be sent by telegraph simultaneously, on a single wire.

Figs. 6265-6269, pp. 2516-2518, "*Mech. Dict.*"

E-lec'tro-mo'to-graph. (*Electricity.*) An invention of Edison by which to obtain mechanical effects with an exceedingly small electric force, and upon long circuits, without the intervention of any electric organ.

It is based upon the principle, that if a sheet of slightly roughened paper, dipped in certain solutions, be laid upon a platinized metallic plate, and there be passed over it a strip of sheet metal (lead, thallium, or platinum), on the passage of a current a certain slipperiness of the surface is produced, which makes the friction much less. A metallic bar, held by a spring, is dragged onward by the friction of the traveling paper, but springs back each time a current passes.

See also ELECTRO-CHEMICAL TELEPHONE.

E-lec'tro Mo'tor. See DYNAMO-ELECTRIC MACHINE; MAGNETO-ELECTRIC MACHINE.

E-lec'tro-phone. A telephonic instrument devised by M. Louis Maiché, consisting of an ordinary Bell receiver and a special transmitter. The latter has a glass imbedded in wadding, and placed with its concavity opposite to the mouth tube of the transmitter. Upon the upper edge of the dish rests a ball of carbon, and upon the latter a second ball. When the sound waves set the glass dish in vibration the carbons will be sensible of varying degrees of pressure, and their conductivity will be thereby varied. The corresponding variations of resistance to the current, and consequent variations of potential in the circuit, are revealed as soon at the receiver. — "*Electrician.*"

Maiché . . . . . . * "*Scientific Am. Sup.*," 4098.
Pfeiffer, de Courbettes . * "*Scientific American*," xlii. 151.

E-lec'tro-phys'i-cal Reg'is-ter. The subject of registering phenomena of life is considered in *du Moncel's* "*Exposé des applications de l'Electricité*," * iv. 439. The memoirs on this subject, by Helmholtz, are referred to, and the apparatus of *Boeck*, called by him the Kymographion.

MYOGRAPH. PNEUMOGRAPH.
PLETHYSMOGRAPH. CHEILOANGIOSCOPE.
and references *passim*.

E-lec'tro Pla'ting. On porcelain: In France the object is painted with a mixture to form a basis for the electro deposit This is made by dissolving sulphur in oil of lavender to a syrupy consistence and mixing it under a gentle heat with chloride of gold or chloride of platinum dissolved in sulphuric ether. This is evaporated to the consistence of paint and applied with a brush to the parts of the china on which the plating is desired. The objects are baked to a biscuit before being plunged in the bath.

For *aluminium*. Bath of double chloride of aluminium and ammonium; use a strong battery.

For *magnesium*. Bath of a double chloride of magnesium and ammonium in aqueous solution gives strongly adherent layer of magnesium on copper.

For *cadmium*. Use the bromide to which a little sulphuric acid has been added. An acidulated sulphate gives good results.

For *bismuth*. Deposited upon copper or brass from a solution of the double chloride of bismuth and ammonium by the current from a Bunsen element.

For *antimony*. Use double chloride of antimony and ammonium.

For *palladium*. Use double chloride of palladium and ammonium, with or without the battery.

"*Comptes Rendus*" . . . . xxxiv. 227.

Gilding. Prepare bath of

Potassium cyanide	14 to 16 ozs.
Water	1 gal.
Gold oxide	½ oz.

The gold oxide is made by digesting in a capsule over a water bath, —

Gold	1
Aqua regia	20

The *aqua regia* consists of —

Nitric acid	1
Hydrochl. acid	3

When the gold has dissolved, the solution is digested with calc. magnesia and the precipitated gold oxide washed.

Articles of copper, brass, or german silver are boiled for a few minutes in a solution of caustic potash, washed in clear water, plunged for a few minutes in an acid dip: —

Nitric acid	6 1–5 pounds.
Water	1 gallon.

"*Scientific American Sup.*" . . . . 2540.

E-lec'tro-scope. The electroscope of M. Rameaux consists of two fine fibres of white silk, each fixed at one end by means of a little wax to any support, and free to oscillate in any direction under their point of attachment, and the respective fibres so separated that they cannot foul each other during their swing, or influence each other reciprocally. One of the threads is charged by means of a glass rod with positive electricity. The other is charged by means of a stick of resin with negative electricity. Every body which attracts one of the threads so charged and repels the other is necessarily electrified. Its electricity is of the same sign as that of the thread which it repels. The sensibility of these electroscopes is greater within certain limits as the threads are made finer, longer, and less conducting.

"*Scientific American Sup*" . . . . . . xxxviii. 183.

E-lec'tro-sem'a-phore. (*Railway.*) A semaphore worked by electricity to give signal to approaching trains.

In the block system of railway management, for instance, the road is divided into sections and electric semaphores placed at their termini.

They are also used in the interlocking system which has attained such a great development in the railway termini of the large capitals.

The electro-semaphore is described and represented in "*Railroad Gazette*," * xxiii. 93.

E-lec'tro-si-lic'ic Light. A modification of the electric light arrangement in which one electrode is applied to a glass tube, or wall of a glass vessel containing a saline solution. A white vapor is given off, having a slight alkaline reaction. The glass is strongly attacked and devitrified. The spectrum indicates the silicic character of the light although the intense brightness renders it difficult to perceive the lines. Contact with pure silicon in the shape of crystal of hyaline quartz affords the same character of light. — *Planté.*

E-lec'tro-ther'mo-pile. (*Electricity.*) A battery in which a current is produced by the subjection of an element or group of elements to heat. See THERMO-ELECTRIC BATTERY.

E-lec'tro-typ'ing. A substitute for stereotyping. See page 791, "*Mech. Dict.*"

The bath for depositing an iron surface on electrotype plates consists of a concentrated solution of sulphate of iron and ammonium; the battery of four Meidinger cells. The anode is an iron plate with a surface eight times that of the cathode; the latter is of copper. On leaving the bath the iron is brittle and hard, but when heated to a cherry red it becomes malleable and soft. — *Klein.*

Or: Take 100 parts of ferrous-ammonia sulphate, together with 50 parts of sal-ammoniac; dissolve in 500 parts of pure water, a few drops of sulphuric acid being added to acidulate the solution. The copper plate is connected to the negative pole of a battery of 2 or 3 Bunsen elements, an iron plate of equal size being employed as an anode. The solution is maintained at 60° to 80°. The deposit of iron is of a hard, steel-like quality. — *Bottger.*

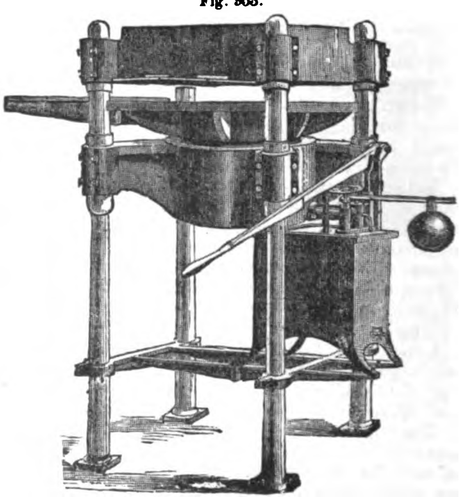
E-lec'tro-type Mold'ing Ma-chine'. A hydraulic press for taking a wax impression of a form.

The platen has a projecting table upon which the form and mold are placed before being placed in the press. The pump is supported by a frame-work on the cistern below the cylinder, and has a safety-valve graduated to give any required pressure.

Fig. 953.



Electrotype Molding Machine.

The molding case having been warmed is placed on a level table, and the melted wax poured in to make a level surface. It is then black-leaded with a soft brush; the form is put on the platen, and the molding case in reversed position on the head of the press, immediately over, but not touching the form. The bed is then raised to give the proper impression.

El′e-ments. (*Electricity.*) In a galvanic battery, the metals or carbon acted upon by the exciting fluid. See various materials in list of batteries in GALVANIC BATTERY.

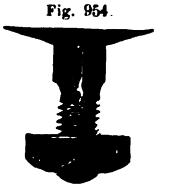
3. (*Surgical.*) *a.* An instrument for lifting an excised or depressed portion of the cranium in trepanning.

b. An instrument for replacing the uterus.

c. A forceps or screw for lifting a tooth or root.

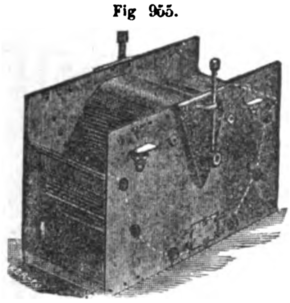
El′e-va′tor Bolt. An iron bolt with a peculiar flat head which is countersunk by pressure into the working face of the belt, while the threaded end and the nut secure the bucket to the belt. Fig. 954.

Fig. 954.



Elevator Bolt.

Fig. 955.



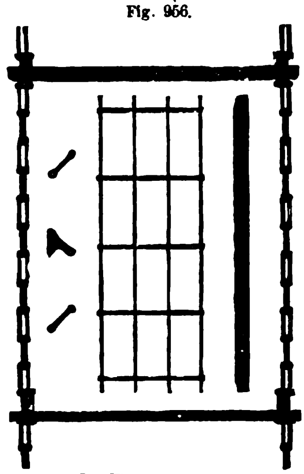
Elevator Boot.

El′e-va′tor Boot. The lower end of an elevator leg. Fig. 955. See Fig. 1863, p. 795, "*Mech. Dict.*" It is of iron and holds the lower roller, around which the elevator belt runs.

Hawkins . . . . * "*American Miller*," vii. 8.

El′e-va′tor Chain. A chain used with ice-elevators. It is flat, runs over pulleys above and below, and has jogs or bars upon it which form rests for the ice as the chain mounts the incline. Figs. 956 and 957 show several forms and detached parts. See also ICE ELEVATOR.

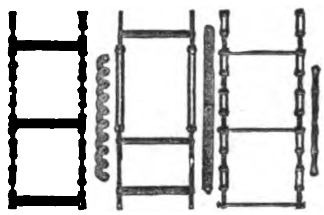
Fig. 956.



Ice Elevator Chains.

El′e-va′tor En′gine. One used in connection with a passenger cage, or platform for hoisting merchandise.

Fig. 957.

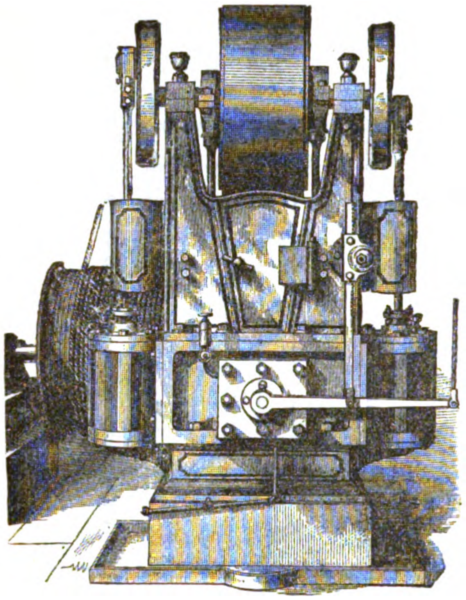


Ice Elevator and Carrier Chains.

The "Metropolitan" elevator, shown in Figs. 958 and 959 comprises (1) a double cylinder and reversible steam engine; (2) a winding drum immediately connected with the engine; (3) a safety drum placed over the hatchway; (4) guide-posts extending from cellar to roof, faced with safety-locks, ratchets, and between which (5) the safety platform is raised and lowered by a wire lifting-rope, suspending it from the safety drum, while another wire rope connects the safety drum at the top of the hatchway with the drum at the foot of the hatchway and immediately connected with the engine.

The speed of the platform is optional, from 60′ to 200′ per minute, and wherever it is stopped it is immovably held by a strong brake, combined with the engine and winding drum. The brake is so arranged as to be brought into and released from action simultaneously with the stopping and starting of the engine, but causing no friction, while the engine is running. The platform is fitted with safety-locking pawls, combined with a steel spring, and mechanism for forcing the pawls into contact with the safety-lock ratchets on the vertical guide-posts in case the rope should break. The greatest possible distance the cage should fall is 3″, the pitch of the ratchets. The safety-drum is the medium through which the motion of the engine is communicated to the platform. Its duty is to limit the rate of motion of the platform, and to stop it if any portion of the engine-gear should break. A governor, *P*, and tripping gear, *K I H*, will in the latter case bring the break *F* into action and stop the platform. An automatic stop-motion limits the distance the platform can traverse to the space between the upper

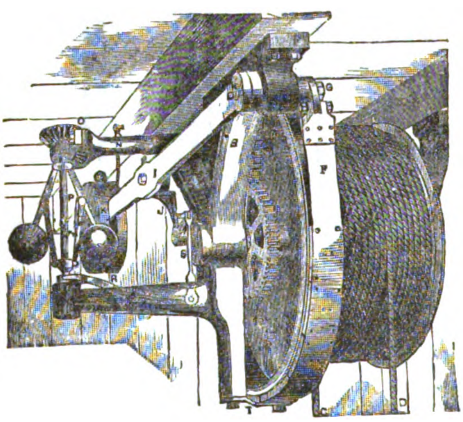
Fig. 958.



Elevator Engine.

and lower landings, automatically shutting off steam at those points.

Fig. 959



Safety Drum.

El'e·va'tor Scales. Large scales weighing 100 bushels of wheat at a time, and placed in the upper story of an elevator to weigh incoming grain before discharging into the storage bins. See GRAIN WEIGHING MACHINE, *infra*.

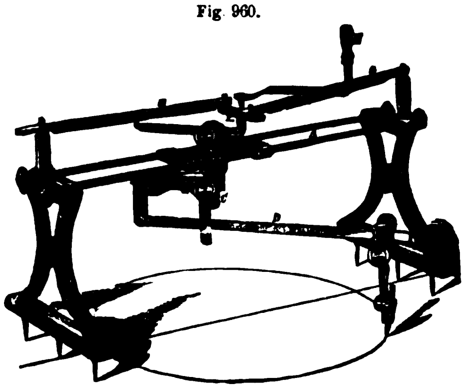
Ell. An L-shaped pipe coupling, at a bend of the circulation. An *elbow*. See BEND. The *ell* is plain, hubbed, or flanged.

El-ler-hau'sen Steel. (*Metallurgy.*) Steel made by adding iron ore (magnetic) to the bath of pig-iron, to reduce the carbon, relatively.

El-lip'so-graph. An instrument for describing ellipses. Toulmin's ellipsograph is a frame placed upon the paper on the drawing-board in a certain relation to the axes of the ellipse to be drawn.

A description of the mode of using will explain the construction: Place the center points upon a line drawn through the minor axis and equidistant from the center of the ellipse. Set the pen point at the extremity of the major axis, and clamp it by means of the binding screw on the arm, then turn the arm 90° to the minor axis and set the pen to its extremity by loosening the binding screw between the parallel rods and sliding the carriage back until the pen point comes to the required point, then clamp it firmly, turn the crank, and the ellipse is drawn perfectly. For small el-

Fig. 960.



Ellipsograph.

lipses, see that the pen point is set perfectly square with the arm *D*. When the pen is set immediately under the arm *F*, the pen will draw a straight line. When the arm *F* is outside the pen point, the motion of the pen is reversed. First start the pen on a slip of paper laid on top of the paper, then when it runs off the slip on to the paper, stretched and prepared for drawing, it will draw a figure complete, and the lines will join.

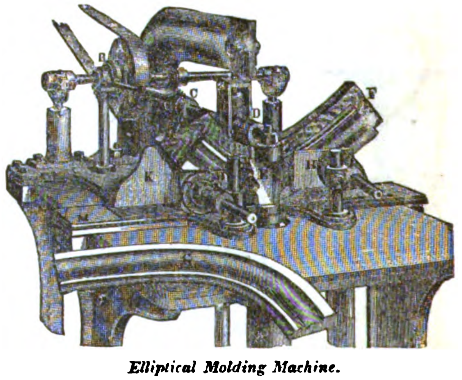
Toulmin . . . . "*Scientific American Sup.*," 689.
Balch . . . . . * "*Scientific American*," xl. 324.

The latter is an attachment to ordinary compasses, and has a double leg, which is used in rotation around the angle of a rectangular triangle laid on the paper.

El-lip'ti-cal Mold'ing Ma-chine'. An attachment to a molding for sticking elliptical or circular moldings on any radius, or, when molding ellipses, to work on a changing radius; as in finishing arches, window and door heads, and architraves.

The Boult elliptical molding attachment is shown in Fig. 961, and is used in connection with an upright spindle. The

Fig. 961.



Elliptical Molding Machine.

parts of the attachment are erected upon an independent bed-plate. The work is attached to a pattern of the desired shape which has adjustable pressure plates for holding the work to the proper position. It has an automatic worm-feed, controlled by a friction clutch matching into a loose pulley.

A is the pulley that drives the feed-works, and receives its motion by belt from a pulley on the counter-shaft that drives the main spindle. *B* is a friction clutch that connects the pulley with *A*, and drives the screw-shaft. *C* is a screw pinion that meshes into a worm on shaft above, by which means the feed roller *D* is driven. *E* shows the upright cutter head. *F* is the form or pattern used with the work attached: *H H* are adjustable pressure plates or guides for holding the work in place. *K* is an adjustable gage or fence governing the thickness of the work. *G* is a piece of the work finished.

The machine will run in either direction for feeding the stuff and working the molding, and will work moldings of any width from 1″ to 5″, and up to 1.75″ in thickness.

E-mail′ Ink. Made by Louis Müller, Leipzig.

Colored inks — black, white, red, blue — used with a quill on glass, porcelain, ivory, marble, bone, mother of pearl, or metal. Cannot be removed by any liquid.

E-maille′. (*Fine Art Metal Working.*) The process of inlaying metal with metal; an oriental process of great labor and patience, consisting of engraving, inlaying the metal which is secured by undercutting, and burnishing. Modern science has much simplified the methods.

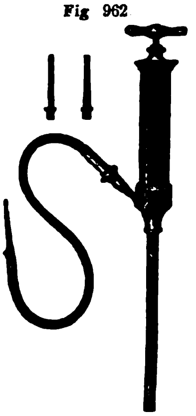
The object to be inlaid is entirely covered with varnish, portions of which are removed by a graver so as to form the design; and thus prepared, it is subjected to the action of a galvanic bath of gold or silver, which deposits the metal in the places laid bare by the graver.

Or: after the removal of the varnish, according to the pattern made by the graver, the object is plunged into a solution of cyanide of silver. The salt is deposited on the lines from which the varnish has been removed; the object is heated in a muffle furnace, and the metal appears on the black patina. Inlaid patterns of gold and silver may be obtained, either of their natural brightness or with a dead surface, the latter being effected by different processes of oxidation; so that, on the same object, by making use of the protecting varnish, designs in gold and silver of various degrees of luster may be combined. — *Morin.*

Em-balm′ing Pump. Tiemann's embalming pump, shown in Fig. 962, is made of brass nickel-plated, and with metallic valves.

Gaurei injected the veins with sulphate of alumina. Falconi injected into the body sulphate of zinc. Chloride of zinc and sulphate of soda are also sometimes used.

Fig 962



Embalming Pump.

For temporary preservation of bodies for anatomical investigations the following requisites are necessary. The body should remain in a soft and flexible condition for a period of at least three months, the tissues should not change color, the *material* should not be injurious to the health of the operator, nor spoil the instruments used in the operation, and it must be either free from or have an agreeable odor, and be cheap.

Dr. Wywodzoff, of St. Petersburg, Russia, recommends thymol diluted with water and glycerine:

℞	Thymolis . . .	sc ij.
	Glycerine	lbs. iv.
	Aq.	lbs. ij.

The Brunelli process: —

1. Cleanse the circulatory system with cold water till the latter issues clear. Time required, 2 to 5 hours.
2. Inject alcohol to absorb water 15 minutes.
3. Ether to abstract fat. 2 to 10 hours.
4. Solution of tannin to form insoluble compound with the tissues. 2 to 10 hours.
5. Dry the body in a current of air previously passed over heated chloride of calcium. 2 to 5 hours.

The Tranchina method: Eight decigrams of arsenious acid, combined with a little cinnabar, are dissolved in 9 kilograms of spirits of wine, and injected, *secundum artem*, into the carotid artery. For more than two months the body remains fresh, inodorous, inflexible, and (thanks to the cinnabar) of its natural color. Thereafter desiccation commences, and it indurates so as to last for any time. Modifications by Gannal and others have improved upon Tranchina's method. — "*Lancet.*"

French railways, *Laboulaye*, "*Dictionnaire des Arts, etc.*," "*Chemins de fer*," 1., Fig. 81.

Em-blem′a-ta. (*Fine Art Metallurgy.*) Ornamental figures in relief, which are large and detachable from the object.

Em-boss′ing Ma-chine′. (*Add.*) 3. Embossing machine for stuffs, Fig. 1869, p. 798, "*Mech. Dict.*" See also *Laboulaye's* "*Dictionnaire des Arts, etc.*," article, "*Impressions sur étoffes*," tome ii., Figs. 61, 62.

Steinlein's machine for embossing fabrics, * "*Scientific American Supplement*," p. 229.

Em-boss′ing Press. 1. (*Bookbinding.*) A press used in embossing or gilding on card-board, leather, book covers, etc.

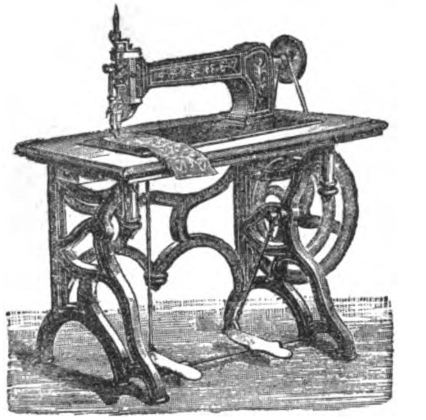
The bed is guided by the frame, so that it does not tilt in giving pressure at the corners. The feed guides or bed are adjustable in either direction. The toggle is driven by a crank within and by means of a friction clutch; the bed can be started or stopped without reverse or jar. The bed is constantly in motion and it has sufficient travel in order to allow the operator time to take off and place the work. An ink fountain and inking attachment are affixed when necessary

2. A press which takes the place of a drop-press in embossing the handles of silver spoons, forks, ladles, etc., and for stamping medals. The press will give a pressure of 1,000 tons and receive dies 2″ × 12″ or 4″ round dies. The upright steel columns that take the principal strain are 5″ diameter and the large nuts have worm gear on their

sides, operated by hand wheel, giving very delicate adjustment.

Em-broid'er-ing Ma-chine'. The Bonnaz

Fig 964



Embroidering, Overseaming, and Braiding Machine

machine is adapted to embroider cloth with a chain-stitch, and to stitch braid or chenille upon the cloth in fancy patterns.

A hooked needle is supplied with thread at each descent below the material by a rotary reciprocating thread-carrier, and the thread is drawn above the cloth. The loop so formed is held above and upon the surface of the material until the needle descends within and draws a new loop up through it. The fabric-feeding foot is universal as to the direction of its movement, and consequently moves the fabric in any desired direction from the needle, thereby permitting the stitching to follow any pattern or design printed or stamped on the fabric. A crank-handle controlled by the operator changes the direction of the feed according to the design upon the fabric to be embroidered

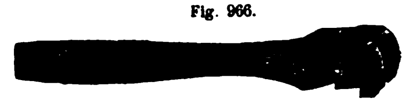
Em'e-ry Pla'ner. A machine tool with a traversing bed, and an emery wheel which takes the place of the cutter or chisel of an ordinary planer. — *Newman.*

Em'e-ry Stone. A mixture of gum-shellac and emery. Soluble glass is substituted for the shellac in Germany, with apparent advantage. — "*Revue Industrielle.*"

Em'e-ry Wheel Dres'ser. A tool to replace diamond tools in dressing emery wheels to shape.

Fig. 966.



Huntington's Emery Wheel Dresser.

The head of the tool has independent loosely-jointed sharp-toothed cutters on a steel mandrel. The hooks on the under side of the tool are for catching upon the rest when applying the tool to the rotating corundum wheel.

The Union Stone Co.'s emery dresser is a diamond mounted in a stock.

E-nam'el. (*Fine Art Metal Working.*) Enameling on metal is of several kinds: —

1 Simple overlaying of vitreous colors which are fused in a muffle.

2. Translucent enamel colors laid over a design which has been etched on (engraved), or hammered out (*repoussé*), of the metal.

3 *Cloisonné* Pattern raised on the surface by means of wire or strips of metal welded on to it, and enamel spread in the spaces between the metal.

4. *Champ-levé.* Lines and surfaces cut out of the metal and filled with enamel. Allied to *niello*

5. Enamel is coarsely laid on, then outlined with strips of copper or gold. A Japanese imitation of true *cloisonné*.

6. A thick coat of enamel is melted on and covered while still hot with a network or shapes of thin gold which imbed in the enamel Finished with the graver. A Bengalese art.

E-nam'el-ing.

Enameling was practiced by the Egyptians, Persians, Etruscans, and Greeks. The practice was to cut out the figure to receive the enamel which was burnt in. It was practiced in Italy as far back as the time of Porsenna, and, later, Faenza and Castle Durante were famous for it. James Tontin, of Chasteaudun, in 1630, invented the opaque enamel; Mortière used it in rings and watch cases; Chartier in flowers; Petitot and Bordier in portraits; Louis Guernier in excellent miniatures.

See article "*Emaillage*," tome iv., ed. 1877, *Laboulaye's "Dictionnaire des Arts et Manufactures*," on iron, porcelain. For composition, *Ibid.*, tome ii., article "*Email.*"

(*Ceramics.*) The enameled steatite figures of the Egyptian pantheon are among the earliest examples of the use of enamel. The colors are white, yellow, blue, green, and purple, and the blue especially is of unsurpassed quality. The base is probably stanniferous.

Bricks found in the ruins of the Mesopotamian cities are also found with stanniferous glaze.

At Warka have been found great numbers of earthenware coffins, many glazed and some decorated.

The Saracens during their occupancy of Spain made great advance and the Hispano-moresque vases and dishes, as well as the tiles known as *Azulejos*, testify to the taste and skill of this remarkable people. The colors were brilliant; red, blue, green, yellow, and white, and the decorations in the style familiarly known as arabesque.

The convent of St. Paul, at Leipsic, is perhaps the earliest surviving instance in Christian Europe of the use of enameled tiles. The monument of Henry IV., of Silesia (d. 1290), in the Kreuzkirche of Breslau, is a fine instance of glazed pottery with a life-sized figure of the deceased.

The stanniferous enamel of the Saracens was rediscovered by Luca della Robbia, of Florence, in the 15th century, and largely superseded the lead glaze. Luca della Robbia ornamented with bassi-rilievi the Campanile of the Duomo, of Florence The process was again rediscovered by Bernard Palissy in the middle of the 16th century.

At the Vienna Exhibition in 1873 specimens were shown of the beautiful tea set presented to Lord Dudley on his marriage. The decoration consists of turquoise blue enamel put on in drops near together, so that the surface appears to be thickly set with turquoise. Each cup and saucer is carefully mounted in a stuffed morocco case. The small set of 6 pieces was valued at $6,000.

(*Glass.*) Wares or panes with vitrifiab'e colors baked on the surface. Glass enamel contains lead, oxide of tin, or arsenious acid, besides metallic colors.

Among other modes of enameling glass, the following is the practice with *etched enamel*: —

The enamel in paste is laid with a brush upon the glass, dried, etched in patterns or designs by tools, and the glass fired to vitrify the enamel and cause it to adhere to the glass surface.

Flocked enamel is when the surface of the glass has previously been deglazed, giving it a dull semi-opaque surface.

Among the most celebrated specimens of glass enamel are the sapphire nuptial goblet, the work of a Muranese artist of the 15th century and now in the museum of Venice: and the Tazza, of St. Mark's Treasury, Venice, blown in black glass, enameled in various colors and gold, with medallions and Coptic inscriptions divided in zones. The tazza is of the 11th or 12th century, and, though not over 6″ high, is valued at 80,000 francs. It was taken from Venice to France by Napoleon, but afterwards restored.

(*Cast Iron.*) Silesian process: After pickling and cleaning the vessels, they are covered with a ground made as follows: Quartz, 50; fluorspar, 7.5, and borax 22.5 parts fused together. Of this, 16 parts, 6.5 to 12.5 of quartz, 4 to 6.5 of clay, and .5 of borax, are ground in a wet mill, with an addition of 2.5 clay and .66 borax. This is laid on and burned, forming a yellowish-brown mass. For the outer coating 2.5 powdered fluorspar, 1 zinc-white, 4.75 tin oxide, .75 bone-ash, and .03 to .5 smalt are well mixed. Of this 9 kilograms are mixed with 16 of finely-ground fluorspar, 9.5 borax, 3 25 soda, and 1.25 to 1.5 niter, and the whole fused together. The product is powdered, and 30 kilograms of it are wet ground with six cups of about 140 c. c. of white clay, and .3 of zinc oxide. This is laid on and burned, completing the work. *Birsch* in "*Dingler's Journal.*"

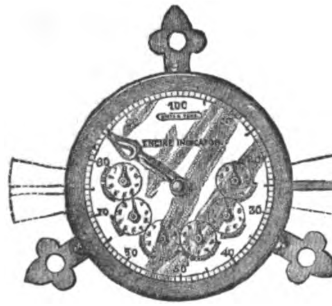
En'gine Coun'ter. A register for keeping account of the revolutions of a shaft, the pulsations of a beam or what not. Usually on the principle of the gas meter; a train of wheels. Illustrations may be found under ARITHMOMETER, pages 143, 144, "*Mech. Dict.*"

Fig 969.



Engine Counter.

The instrument shown is used for indicating the speed of engines, pumps, machines, shafting, printing presses, brick machines, etc. The dials register up to 100,000,000.

En'gine Cup. An oil cup for an engine shaft or cylinder. See LUBRICATOR, Fig. 3011, p. 1361, "*Mech. Dict.*"

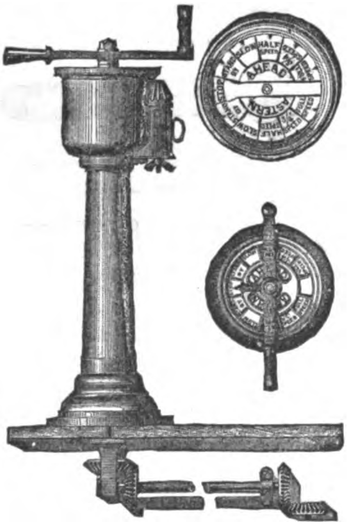
En'gine Reg'u-la'tor. A governor.

Specifically: an invention by Sterberg, of Magdeburg, in which the centrifugal motion of glycerine in a bowl-shaped vessel on a vertical shaft is made to lift a disk, and so operate a stem and governor valve.

"*Scientific American*" . . . . * xl. 195.

En-gi-neer's' Ham'mer. A hammer with one flat, round face, and a transverse edge peen.

Fig. 970.



Engine-room Telegraph. (*British Navy.*)

En'gine-room and Steer'ing Tel'e-graph. A means of communication between the officer on the bridge and the engine-room or wheel-house.

Fig. 970 shows the engine-room telegraph, which consists of a brass pillar on the bridge, with a communicator dial, index handle, and lamp.

The figure also shows the pillar dial, and engine-room dial, and a portion of the bevel-wheel and shaft arrangement for communication.

The steering telegraph is similar, with the necessary variation in the dials, showing the compass-points.

Eng'lish Knot. (*Nautical.*) A form of knot shown at 39, Fig. 2777, p. 1240, "*Mech. Dict.*"

En-graved' Glass. Glass-cutting and engraving are described on pp. 978, 979, "*Mech. Dict.*" A late process of great beauty is as follows: —

Upon a groundwork of milk-white or opal glass thin coatings of blue and rose-pink glass are spread successively. The pink colors are especially remarkable for their delicate gradations and shades of color. A great variety of small objects for decoration are made in this manner. They are handed over to the engraver, who with his wheel cuts through the outer coats of color down to the groundwork of white glass. Extremely fine lines and delicate effects may be so produced. The process invites and requires careful drawing and skilled designing. At the Paris Exposition, 1878 were exhibited services in Egyptian, Celtic, Indian, Assyrian, Persian, Arabian, Greek, and Byzantine designs.

Among the purely decorative objects were a pair of vases, each about 15″ high, upon which portions of the group upon the frieze of the Parthenon are copied by cutting in miniature, — on one vase in intaglio and on the other in relief. Two years were required for the engraving. They are valued at about $2,000 each. One two-handled vase, about 20″ high, is a most elaborate work, representing Pluto and Proserpine in intaglio on the body of the vase, with Grecian and Pompeian ornamentation on the handles and neck.

En-gra'ver's Glass. A lens placed in a small horn tube, and held by the muscles of the eye orbit. Similar to a watchmaker's glass. Fig. 708, p. 2734, "*Mech. Dict.*"

En'si-lage Cut'ter. A machine for cutting green corn stalks or other green feed, to be stored in pits (*silos*) for winter feed.

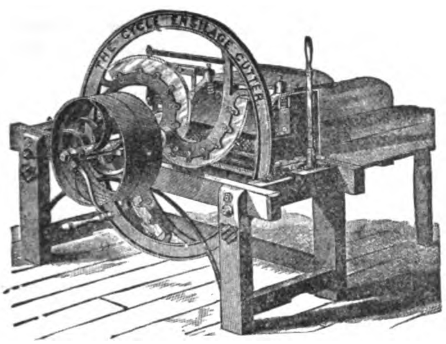
The process of keeping reminds one of *sauer krout*, the material being cut small, pounded, pressed, and placed in a vessel, the sides and bottom of which are air and water-tight. The corn-stalks gathered at the time of silking are cut to a length of say 4-10″, deposited at once in the silos, spread, tramped, covered with boards upon which a heavy weight is placed to condense the ensilage. In winter it is taken out in such a way as to expose but moderate surface to the air, operating in the manner indicated by Fig. 972. The pit becomes charged with carbonic acid, and excludes air when there is no agitation.

The process is the invention of *M. Auguste Goffart*, of Burtin, Sologne, France.

See Dr. Knight's report on agricultural implements at Paris Exposition, in 1878, vol. v., pp. 243-254, cuts of *Goffart's* silos.

The best cutter for the purpose is that of the New York Plow Co., the President of which, Mr. J. B. Brown, has translated M. Goffart's pamphlets and been chiefly instru-

Fig. 971.



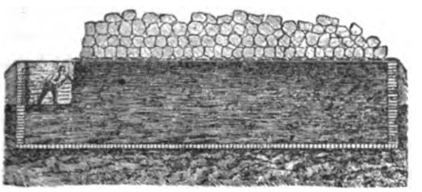
Brown's Ensilage Cutter.

mental in introducing the ensilage of maize to the American farmer

The cutter shown in Fig. 971 has three curved blades on a wheel, rotating in a plane across the throat of the machine. The knives have a long draw-cut, so arranged that the cut is continuous and steady, a following knife commencing to cut before the previous one concludes its cut. The machines are adjusted to cut ⅜'' or ½'', or to ¼'' and 1''.

The feed is stopped and started instantly by a lever. The cover over the knife is not shown. The curve of the knife

Fig. 972.



Emptying a Silo.

is such as to slip away any stones. The steel cutting-plate is separated from the face-plate. The rollers are combed. An endless band elevator raises the cut stuff and drops it into the silo. The cutting power is from 2 to 10 tons of green stalks per hour, according to size of machine. The speed of wheel, 300 to 400 revolutions per minute. The power, from 2 to 4-horse.

Ensilage pits, *Potter* . . "*Sc. Am. Sup.*," 3846, 3861, 3926.

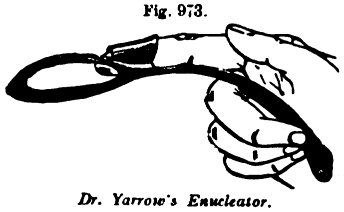
The British Hache-mais, for the French market, is made by Richmond & Chandler, and French machines are also made for the same purpose. See CHAFF CUTTER, page 158, *supra*.

En'to-mo-log'i-cal Pin. A delicate thin pin for impaling objects.

E-nu'cle-a-tor. (*Surgical.*) An instrument, the name of which is derived from the act of uncovering and removing, as a nut from its kernel.

The figures refer to *Tiemann's* "*Armam. Chirurgicum.*"

Fig. 973.



Dr. Yarrow's Enucleator.

1. An instrument with a loop end for removing uterine and ovarian tumors, *Sims'*, Fig. 467, Part III.

2. A sharp comb or claw attachable in manner of a thimble to the end of the finger, to detach and remove a sac or tumor. *Emmett's*, Fig 102, Part V.

In *Yarrow's*, Fig. 55, Supplement, the thimble carries a loop to place over the object: it is practically a serrated scoop on an extension of the index finger. See Fig. 973.

3. An instrument to grasp and extract the eye-ball in the operation of extirpation, p. 25, Part II.

See ÉCRASEUR for an instrument for a somewhat similar purpose, but of different construction.

En'vel-ope Ma-chine'. The machines of Cohen, Lockwood, and Raynor & Co. were shown in operation at the Centennial Exhibition.

Cohen's uses blanks previously made on cutting press. It folds, gums, and finishes 48 envelopes per minute.

Lockwood's machine works from the web of paper, wasting very little stock and making the square pocket envelope, pasted up each side, and with a gummed flap. It cuts from the roll, folds, gums, and counts 120 per minute, delivering in bunches of 25 each, equal to 72,000 per day. It has worked to 160 per minute.

Raynor & Co.'s machine gums and folds envelope blanks, previously cut upon a press. *Ball's* patent; making 48 per minute.

"*Scientific American*" . . . . xxxvi. 281.

Ep'i-cy'cloid-al Mil'ling En'gine. A machine for forming templates to be subsequently used as guides in shaping the cutters for gear-cutting machines. In these machines it is essential that the contour of the milling cutter conform precisely to that of the space between two teeth. The machine is somewhat intricate, very ingenious, and is made by *Pratt & Whitney*.

Ep'i-glot'tis Pin-cette'. (*Surgical.*) A long, delicate forceps, having curved prongs with hooked ends for introducing into the epiglottis to remove foreign substances.

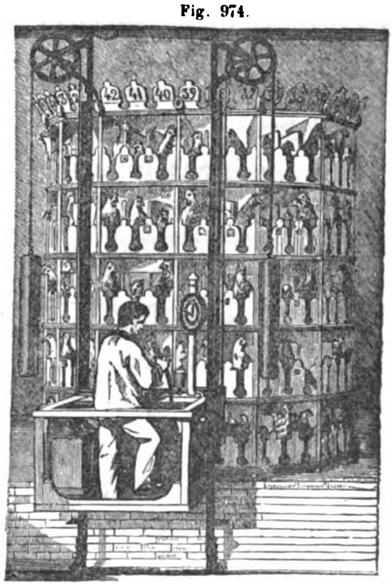
Brun's, Fig. 330, Part II., *Tiemann's* "*Armamentarium Chirurgicum.*"

Throat forceps, laryngeal forceps, and probangs for the same purpose, are shown on pp. 82, 83, *Ibid.*

Ep-i-nette'. A chicken-feeding arrangement used in France.

A cylinder with 5 stories and 14 faces, with 3

Fig. 974.



Epinette (Jardin d'Acclimatation), Paris.

compartments each, is mounted on a vertical axis, so that either face may be presented towards the attendant. The box of the attendant (*gaveur*) is counterweighted so that he can bring himself and his feeding apparatus opposite either of the stories. The capacity is 210 fowls.

On the box of the operator is the feed cylinder, the contents of which are ejected by pressure upon a pedal; a dial shows the amount of food passing. The *gaveur* seizes a chicken by the head, presses upon each side of the beak to open the mouth, introduces the nozzle of the feed pipe, presses upon the pedal and injects the required quantity of food, keeping his eye upon the dial. He then takes the next fowl, completes the round by turning the cylinder one face, winds himself up to the next story, and so on. Duty: 400 chickens per hour. The time required for fattening: chickens, 18 days; geese, 20; ducks, 15; turkeys, 25. Food is a thin paste of barley and corn meal mixed with milk and water. Quantity from 10 to 20 centiliters = 0.7 to 1.4 of a gill at a feed, the maximum being gradually reached.

Epinette on a smaller scale . . * "*Sc. Am. Sup.*," 1295.

Ep'i-la-ting For'ceps. (*Surgical.*) The instrument for transplanting hairs in the skin-grafting process.

Piffard's, Fig. 85, Part V., *Tiemann's* "*Armamentarium Chirurgicum.*"

E-pi-stax'is In'stru-ments. (*Surgical.*) Instruments to avert bleeding of the nose. Among such are the following: —

Nasal clamp.	Rubber tampon (inflatable).
Epistaxis plug.	Laryngeal and posterior nares syringe.
Nasal douche.	Rhinoscope.
Canula.	

E-prou-vette'. An instrument for testing strength of cartridge heads by explosion of powder, is shown in Plate XXIV., Report on "*Metallic Cartridges*," by Major Treadwell, U. S. Army, 1873.

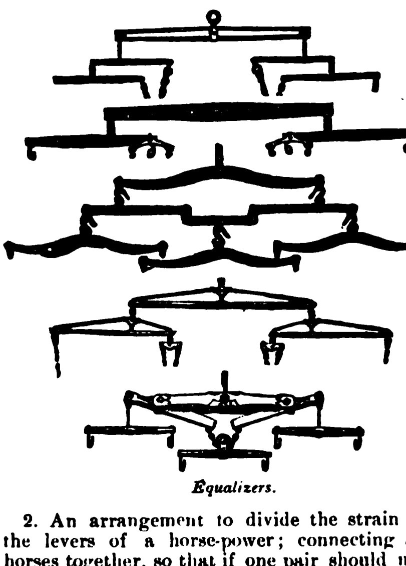
See also article *Poudre*, Figs. 2194, *bis et ter*, *Laboulaye's* "*Dictionnaire*," iii.

E'qual-bar Nest Spring. (*Railway.*) A multi-coil spring in which each coil has a resistance proportioned to its diameter. *S*, Fig. 1143, p. 483, "*Mech. Dict.*"

E'qual-i-zer. 1. A three-horse evener, to throw the strain equally upon three horses abreast.

The illustration, Fig. 975, shows American, British, and French forms, in the order named.

Fig. 975.



Equalizers.

2. An arrangement to divide the strain on all the levers of a horse-power; connecting all the horses together, so that if one pair should make a sudden pull, it draws upon the other horses instead of upon the power, and so does not transmit the irregularity of motion to the machine driven.

E'qual-i-zing Bar. (*Railway.*) A bar, the ends of which rest upon the upper boxes of the axle bearing, and upon which rest the springs supporting the truck frame, seen at *f*, Fig. 1159, p. 488, "*Mech. Dict.*"

E-qua'tion Ap'pa-ra'tus. Electric apparatus for determining the personal equation of astronomical observers is described in *Comte du Moncel's* "*Exposé des Applications de l'Électricité*," iv. 294, 3d edition.

Professor Langley's apparatus for eliminating personal equation by suitable devices during the act of observation, is described in the "*American Journal of Science and Arts*," and reproduced in "*Scientific American*," xxxvii. 170.

E'qua-to'ri-al. A telescope mounted for adjustments in altitude and azimuth; clock-work gives the motion in right ascension.

Reflector (mirror 0.80 m.), by Foucault, at Marseilles, * *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," iv., ed 1877, article "*Instruments d'Optique*," Fig. 37.

E'qui-lat'e-ral Prism. (*Optics.*) An equal angled prism mounted upon a stand, and used for throwing oblique light upon an object under examination with the microscope.

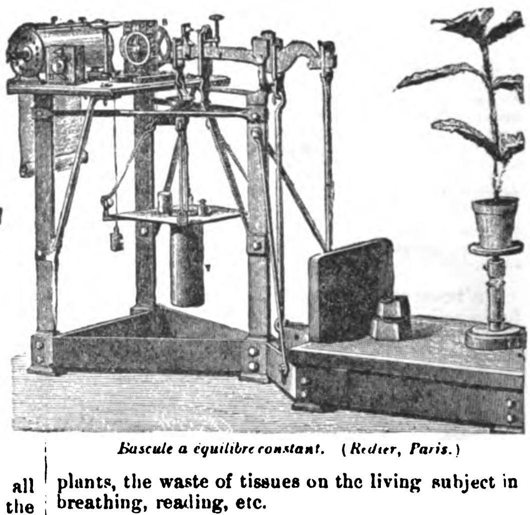
E'qui-lib'ri-um. Equilibrium cock. See EQUILIBRIUM VALVE.

Equilibrium balance. See EQUILIBRIUM SCALE.

Equilibrium couch, *Anderson*, Br., * "*Engineer*," xliv. 42

E'qui-lib'ri-um Scale. A scale which keeps itself in constant equilibrium, and records all changes in the weight of the object, such as the growth of a plant, the evaporation of soil or of plants, the waste of tissues on the living subject in breathing, reading, etc.

Fig. 976.



Bascule a équilibre constant. (*Redier, Paris.*)

On a stand next to the platform are placed the registering cylinder, the clock-work, which rotates slowly, and the double wheel-work, which determine the state of constant equilibrium. The principle by which the equilibrium is restored, as soon as it has been disturbed by some cause or other, is this: If we place on an ordinary balance a glass full of water, counter-balanced by a weight, and if we dip into that glass a mass, whatever it may be, hanging from a thread, the equilibrium will be destroyed: in proportion as the plunger penetrates more or less into the liquid, it will more or less disturb the equilibrium. It is such a plunger which Mr. Hervé Mangon has made use of to establish the state of constant equilibrium on the platform scale in question.

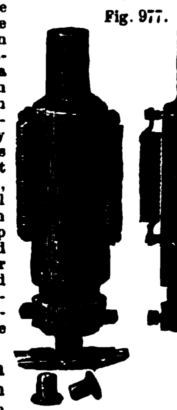
Under the little platform of the instrument is a cylindrical vase, three fourths filled with water; a cylindrical plunger, of which the supporting thread is rolled over a pulley, is lowered or hoisted by the wheels of the pulley as soon as the large platform experiences any augmentation or diminution of weight. The equilibrium restores itself immediately, and the motions of the pulley are transmitted to the lead pencil which passes over the surface of the registering cylinder, leaving on the unrolled paper traces of all its movements. The wheels of the pulley are the same as those used in the registering barometer of Redier; the one goes constantly to the right, with an escape; the other to the left, with twice the speed of the first, and the extremity of the balance, by its motions, determines the freedom of the fan of the second wheel-work, which makes the pulley turn in the desired direction.

"*Manufacturer and Builder*" . . . . * x. 206.

E'qui-lib'ri-um Tool. A drilling or boring tool for metals; having a center steadying pin and a ring of cutters which make an annular groove.

The case holding the cutters is a hydraulic cylinder which is fitted into the drilling-machine spindle socket, being, in fact, an annular ram carrying cutters, inside of which is a steadying pin, with a piston at its upper end working in the cutter ram. The cylinder is charged with soapy water, and when the tool is at rest the cutter ram is kept up by two exterior springs, and the center pin is full out. When the center pin is placed on the center-pop the pressure is transferred by the piston to the outer ram with the cutters, and when the pressure is withdrawn the cutters again retire, being elevated by the springs.

Fig. 977.



Equilibrium Tool.

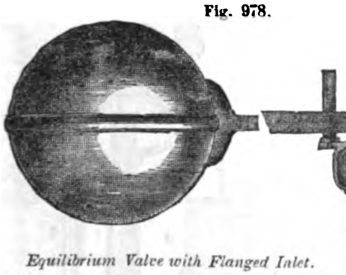
E'qui-lib'ri-um Valve. 1. A valve in which the pressures on the respective sides are in equilibrio; this much decreases the labor of moving them, especially in large stop valves of water mains.

Bagshaw & Sons (Br.), equilibrium sluice valve has balancing pressures above and below, the escapes being bi-lateral.

"*Scientific American Supplement*" . . . . . * 1472.

Booker's (Br.), equilibrium blow-off cock, has a small valve in the center of the larger one. The former being easily and promptly lifted by a quick screw, the water above the valve

Fig. 978.



Equilibrium Valve with Flanged Inlet.

escapes and reduces the pressure so that the water from the boiler forces the valve upward and opens the outlet. Conversely, by closing the small valve the operation is reversed.

"*Scientific American Supplement*" . . . . . * 1441.

Fig. 978 is an equilibrium ball valve for boilers with equal pressure upon the inner faces of the two valves upon the same stem.

2. The equilibrium valve in the Cornish engine opens a communication between the top and bottom of the cylinder, to render the pressure equal on both sides of the piston, Fig. 1884, p. 808, "*Mech. Dict.*"

See also article "*Tiroirs Équilibrés*," * *Laboulaye's* "*Dict. des Arts et Manufactures*," iv., ed. 1877.

E-quip'ment. (*Railways.*) The running stock to make up a train. The passenger train equipment includes the baggage, mail, express cars, and passenger coach; with parlor coach or sleepers in many cases.

Fig. 979.

Lister's Erecting Glass.

E-rect'ing Glass. (*Optics.*) A tube with lenses placed in the draw tube of the microscope to erect the image of the object under view. See Draw Tube.

Erg. (*Electricity.*) The unit of work done by one *dyne*. — *Gordon.*

Es-cape'ment Reg'u-la'tor. A contrivance of Breguet in which the escapement is controlled by a tuning-fork.

The tuning-fork is about a foot long, and gives one hundred vibrations in a second. About midway upon one of the prongs there is a sliding-weight, by which the number of vibrations can be regulated. Projecting from the end of the prong is a small pin, which acts in the fork of a lever. The lever makes one hundred vibrations in a second, corresponding to the tuning-fork. Attached to this lever is a pair of pallets, which act upon an escapement-wheel having ten teeth, and making four revolutions in a second. The tuning-fork in this case regulates the speed of the train. The pallets and escapement-wheel act in a manner similar to the escapement of the striking-train in a repeating-watch. It was found by experience that the vibrations of the fork should be confined to about one degree to give the best results. These vibrations are so completely isochronal that an increase of power, from 4 pounds to 60 pounds on the train, made no difference in its time-rate. The second-hand made a complete revolution in one second. The dial being divided into one hundred parts, with a proper contrivance for starting and stopping, it might be of service in recording time to the hundredth part of a second. — *Carpenter.*

E'so-pha'ge-al Ins'tru-ments. (*Surgical.*) The term includes: —

Throat forceps	Throat lancet.
Throat scoop.	Dilator, etc.
Probang.	Sponge holder.

See list under surgical instruments, "*Mech. Dict.*," *et infra.*

E-soph'a-gus Bou'gie. A spiral flexible instrument for dilating strictures of the esophagus. Made in a variety of sizes. — *Dr. Crawcour.*

Fig. 980.

Esophagus Bougie.

Es'pou-line. (*Fr.*) The peculiar India texture of the Cashmere shawl.

Es-ther'mo-scope. An instrument invented by J. W. Osborne, of Washington, D. C., a thermoscope of peculiar construction to give expression to the aggregate of the climatic influences which tend to affect the normal temperature of the body.

See Fig. 6368, p. 2530, "*Mech. Dict.*" Also paper by Mr. Osborne in the "*Proceedings of the American Association for the Advancement of Science*," Detroit meeting, August, 1875. See also Climatometer, p. 200, *supra.*

Es'the-si-om'e-ter. See Æsthesiometer.

Etched E-nam'el. (*Glass.*) A process of ornamenting glass by laying the enamel on the surface in the form of paste, and then etching it into designs or patterns by means of tools.

Etch'ing. (*Glass.*) Etching on clear and dead white ground is done by means of hydro-fluoric acid.

Combined with modern photographic processes which allow copies of prints to be thrown upon grounds, reproductions may be made at slight expense and of remarkable beauty.

Etching on glass . "*Scientific American*," xxxv. 199.
"*Scientific American*," xlii. 149.

A fluid made by *Kessler* of Paris, is used with a common pen in etching on glass. Shown at Paris in 1878. *Kessler* is said to be the inventor of etching on glass in depolish with fluoric acid.

For steel: concentrated acid	40
Absolute alcohol	10
Nitric acid	10
	60
Or: dissolve soda	20
Iodide of potassium	50
In water	400
	470
For copper: fuming nitric acid	100
Water	700
Add a boiling solution of chloride potassium	20
In water	200
For zinc: crushed galls	40
Water	560
Strain and add nitric acid	2
Hydrochloric	3 — *Herrburger.*

For Fichtner's etching proc., see "*Sc. American*," xxxiv. 200.

(*Ceramics.*) A mode of ornamenting ware in which the glazed surface is covered with a varnish, the pattern etched with a point, the exposed glaze "bitten" with fluoric acid, the varnish removed, the etched lines filled with some strong color or gold, and, finally, the piece re-fired; the glaze softening covers and holds the color.

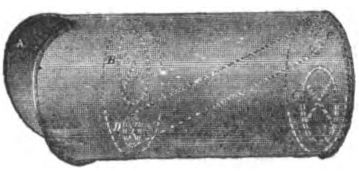
Practiced by Mr. W. Goode, and exhibited by Minton, at Paris Exposition, 1878.

E'ther In-ha'ler. (*Surgical.*) For administration of the vapor of ether as an anæsthetic.

Squibb's, Allis's, Chisolm's, Cheatham's, Speir's, Morton's, Junker's. Figs. 400–406, pp. 115 118, Part I., *Tiemann's "Armamentarium Chirurgicum."*

See also p. 1184, "*Mech. Dict.*"

Fig. 981.



Ether Inhaler.

Fig. 981 is Dr. Morton's ether inhaler. It has a gaping mouth-piece, *A*, and valves *B C* to allow air to pass through the sponge chamber. Also valves *D E* for direct passage of air through the instrument without being impregnated with ether. This valve is used when the breathing becomes stertorous, and obviates the necessity of removing the instrument from the mouth.

Eu'di-om'e-ter. A gas testing apparatus. See EUDIOMETER, p. 810, "*Mech. Dict.*"

Gas testing apparatus, or eudiometer test.
"*American Gas-light Journal*" . . . July 3, 1876, p. 3.
See also FIRE-DAMP TESTER; GRISOUMETER, *infra;* COAL GAS TESTER, *supra*, and references *passim*.

Eus-ta'chi-an Ca-nal' In'stru-ments. (*Surgical.*) For treating the canal. Air bag for inflating the canal. See AIR BAG.

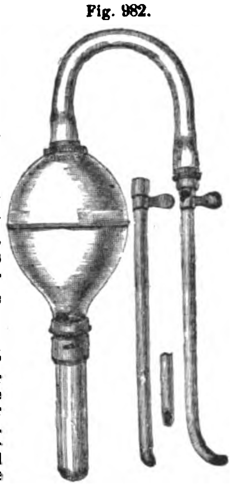
Inhaler for forcing vapors into the canal.
Eustachian spray instrument.
Eustachian catheter.
Nose clamp for holding the catheter.

Eus-ta'chi-an Tube Cath'e-ter. (*Surgical.*) A tube for following the course of the eustachian tube, acting as a dilator and discharger.

E-vac'u-a-ting Ap'pa-ra'tus. (*Surgical.*) An instrument for discharging the debris of calculi after lithopaxy, Fig. 982.

Bigelow's instrument consists of a large catheter, preferably straight with a distal orifice, the extremity of which is shaped to facilitate its introduction and during suction to repel the bladder wall. The elastic exhausting bulb acts partly as a siphon. Below the bulb is a glass receptacle for débris.

Fig. 982.



Bladder Evacuating Apparatus.

Fig. 983 shows Dr. Joseph Warren's vermicular pointed evacuating tube. Its shape facilitates introduction, as it rotates when passing through the urethra.

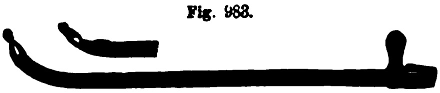
E-vap'o-ram'e-ter. An instrument for determining the evaporation at a given place.

It consists of a flat vessel of known area and capacity, in which rain, etc., is collected, and which is either measured or weighed to determine the loss by evaporation.

The apparatus shown at Fig. 1892, p. 813, "*Mech. Dict.*," is perhaps better adapted for reservoir, river, or tide gage and recorder, than strictly for the purpose of an evaporameter.

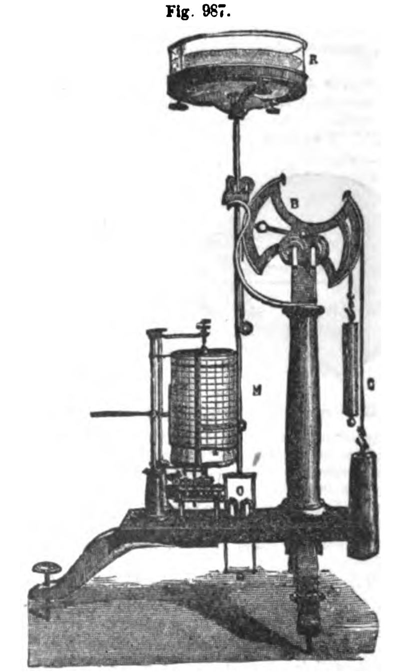
Erkman, of Stockholm, Sweden, showed at the Centennial Exhibition in 1876 a portable evaporameter, and a fixed one resembling that in use at the Käringö Station in the Skager Rack, where the wind has free access from all quarters. These evaporameters are circular, shallow, straight-sided cisterns of Portland cement, showing a surface of 50' square (Swedish). The observer has to register not only the linear sinking of the surface, but also the quantity of water which in the course of the year is poured into or drawn off from each evaporameter. A small channel at the bottom is provided

Fig. 983.



Evacuating Tube.

Fig. 987.



Ragona's Registering Evaporameter.

for the latter purpose. The tests for height of water are by a graduated tubular glass stem, or a plunger rod

The registering evaporameter of Sig. Ragona, director of the Modena Observatory, consists of a glass vessel, *R*, Fig 984, containing water; it is placed on the platform of a balance of which the arm is represented by *B*. A counterpoise suspended by the cord *C* holds the vessel in equilibrium; but this equilibrium is equitable, as the contents of the vessel are continually diminishing by evaporation, so a second counterpoise, adapted to an eccentric, is disposed (as shown in the figure) in such a way as to support the vessel while it diminishes in weight. This counterpoise does not prevent the vessel containing water from rising with the rod *M*, which supports it, in proportion to its diminished weight. While ascending, the rod *M* carries with it a lead pencil, which traces a curve on the surface of a paper cylinder, which is rotated slowly by means of the clock-work *O*.

E-vap'o-ra'tor. See illustrations of many forms in "*Mech. Dict.*," * pp. 811–813.

Badoux's evaporator has a wheel made of circulating tubes and carrying series of coils which dip into the liquid and raise it to be evaporated by the air. It exposes a greater surface than *Schroder's*, shown at D, Fig. 1887, p. 811, "*Mech. Dict.*" They both act upon the same principle. The *Badoux* evaporator is used in sugar and glue work.

Fig. 985.

Ex-change'. (*Telephone.*) A central office in which the wires of any two telephone stations are connected, on call of either.

Ex-ci'sing For'ceps. (*Dental.*) Gnawing forceps, for cutting off projecting parts of carious teeth.

Fig. 986.

Straight Beak Excising Dental Forceps.

Ex'er-ci-sing Ma-chines'. The Centennial Exhibition of Philadelphia, 1876, and the Paris Exposition of 1878, had remarkable, varied, and ingenious appliances for the exercising of the muscles of the body.

The Mechanico-Therapeutic Institution, of Stockholm, established by *Dr. G. Zander* in 1836, led the way in the variety of its apparatus, a part only of which was shown in Philadelphia. The full set consists of 67 machines.

17 machines for active arm movements.
18 machines for active leg movements.
9 machines for active body movements.
23 machines for passive movements.

The passive movements are worked by a steam-engine, and consist of movements as follows, applied to body, head, limbs, abdomen, etc.: —

Shaking.	Rubbing.
Chopping	Swinging.
Tapping	Balancing.
Kneading	Expansion of the chest.

The Mechanico-Therapeutic Institution is open from the 1st of October to the 1st of June, 4½ hours daily for gentlemen, and 2 to 3 hours for ladies. Every patient receives a prescription in which the movements to be performed are enumerated, and the number of the graduated scale of the machine corresponding to the force or the need of the patient is fixed. 12 movements are generally performed daily; after 12 days all or a part of the movements are changed according to the nature of the case treated.

The following is from a spectator: "One machine, when its handles are grasped by the patient, twists the arms; another exercises the flexor and extensor muscles of the wrist, a third pulls the arms back; a fourth exercises the knee muscles; a fifth exercises the muscles which carry the leg outward; and a sixth exercises the ankle muscles. On the seventh the patient lies down and is shaken up so that the extensor muscles of the back are exercised. Another machine is very complicated, and calculated to excite some dismay in the patient, whose 'thorax is pulled upward by means of two levers, while a pad makes a horizontal pressure on the back. The trunk is thereby elongated a few inches, and the spine and walls of the chest are stretched.' There is something about all this dismally suggestive of the rack. In another machine the patient is put through all the misery of horseback riding without any of the accompanying pleasures. He is seated on a saddle, and the latter then becomes possessed of a desire to shake him off. 'This causes the abdominal viscera to be kneaded and rubbed together against each other and the abdominal walls.' There is still another machine, consisting of a couple of wheels having peripheries of padded bars. These, when revolved, serve to warm the feet, the latter being pressed against them. Lastly there is a hammering machine, which has a number of vertical beaters which are set in rapid vibration, so as to hammer the patient in the small of the back or at any desired point."

Another elaborate display in Paris was from the Grand Gymnase of Eug. Pas. The apparatus is very complete, each of the 14 machines being capable of many different applications (Eugène Paz, 34 Rue des Martyrs, Paris).

Ex-haust' Cham'ber. A chamber in the smoke-box of a locomotive, so placed as to prevent the unequal draft of the tubes. A modification of the *petticoat pipe*. *Pollock & Williams.*

"*Scientific American Supplement*" . . . . . . * 2286.

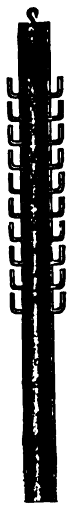
Ex-haus'ter. An aspirator, exhaust-fan, suction-fan, known by many names according to construction or purpose.

For planing mills . * "*Manuf. and Builder*," ix. 125–129.

Ex-haus'ter Gov'er-nor. (*Gas.*) An arrangement for governing the speed of a gas-exhauster engine by the pressure of the gas within the governor, *i. e.*, the governor is self-acting, the make of gas being made to regulate the speed of the engine. When the charges are being drawn from the retorts the production is small and the speed of the engine reduced. When the gas is generated rapidly the pressure of the gas increases the speed of the engine. See GAS EXHAUSTER, and citations *passim*.

Ex-haust' Noz'zle. Shaw's quieting arrangement for exhaust nozzles of locomotives is shown in Fig. 987. The lower end is screwed to the safety-valve pipe, the upper is closed with a cap; the sides are bored for numerous small tubes to equal in their sum the total outlet required. The effect is to prevent the loud sound of escaping steam.

Fig. 987.



Quieting Blast Nozzle.

Brainerd's exhaust nozzle for locomotives has a sleeve upon the nozzle pipes to confine the steam to issue axially and create full draft through the cone beneath or by opening side ports to deflect the relief steam into the cone chamber and decrease the effectiveness of the draft.

"*Scientific American*". . * xxxviii. 98, 262.

Ex-haust' Pu'ri-fi-er. A machine for sorting grain, or purifying middlings by a *suction draft*, as distinct from a *blower*. An *aspirator*, which see.

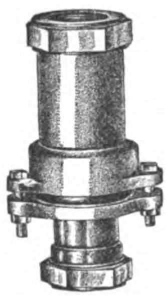
Ex-hi-bi'tion. The following figures are given as to the number of exhibitors and visitors on the occasions named: —

	Exhibitors.	Visitors.
London . . 1851	13,917	6,039,195
Paris . . . 1855	23,954	5,162,330
London . . 1862	26,653	6,211,103
Paris . . . 1867	50,236	8,805 969
Vienna . . 1873	20,205	6,740,500
Philadelphia 1876	-	9,857,625
Paris . . . 1878	-	16,159,719

Ex-pand'ing Chuck. A chuck, the jaws of which are opened or closed to admit objects of varying sizes. See DRILL CHUCK for instances, though other chucks have similar adjustment.

Ex-pand'ing Cul'ti-va'tor. One with hinged bars, capable of being spread apart at the rear, so as to adjust the width of tilth.

Fig 988.



Expansion Pipe Joint.

Ex-pan'sion En'gine. A steam engine working steam expansively. The invention of *Wolff.* See CUT-OFF; EXPANSION VALVE.

Ex-pan'sion Hang'er. A suspended hanger for radiator pipes, permitting the changes in length due to expansion by heat.

Ex-pan'sion Joint. A slip joint, to allow the contraction or extension of tubes incident to the changes of temperature. Applied to coils or lines of steam, hot water, or condenser pipes.

In ordinary instances, it has a cast-iron body, with brass sleeve and screw ends.

Ex-pan'sion of Met'als Ap'pa-ra'tus. An instrument devised by Prof. A. M. Mayer, of Stevens Institute, for the purpose of determining experimentally the co-efficient of expansion of metals and alloys.

The bar, whose co-efficient of expansion is to be determined, is supported on standards in a brass tube, which is made about ¼" shorter than the bar. Against the ends of the bar are placed rubber washers, which are perforated so as to allow the ends of an abutting screw and a rod connecting with the moving mirror of the comparator to come in contact with the ends of the bar. Arrangements are provided which hold the washers perfectly water and steam tight against the ends, while the bar is perfectly free to expand or contract in the tube. Inside the tube are supporting springs, which relieve the standards in some degree from the weight of the bar.

"*Scientific American*" . . . . * xxxvii. 351.

See also DEFLECTOMETER, p. 249, and reference there cited.

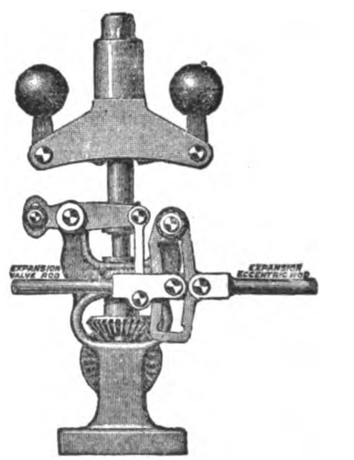
Ex-pan'sion Valve Gear. An automatic apparatus to cut off live steam from the cylinder at any required portion of the stroke.

The Corliss system has been very largely adopted in this country and in Europe, and, to follow the words of M. de Wilde, may be defined —

"As consisting of an assemblage of parts, acting as one upon the cylinder valves under the impulse of an eccentric or cam, while the governor of the engine at the desired moment causes the separation of the assemblage into two distinct portions, of which one continues to obey the action of the eccentric or cam, while the other, which is in immediate contact with the valves, escapes from its influence and closes the steam-port."

Hartnell's expansion-valve gear consists of a sensitive governor acting through a link and die upon an expansion cut-

Fig. 989.



Hartnell & Guthrie's Expansion-valve Gear.

off valve working at the back of the main slide valve, the ordinary throttle valve is dispensed with, and the speed of the engine controlled by means of the expansion valve which regulates the admission of steam into the cylinder exactly in proportion to the duty performed by the engine.

Ex-pan'sive Hol'low Au'ger. One having an adjustability for cutting round tenons of varying sizes. See page 185, "*Mech. Dict.*"

Ex-plor'ing In'stru-ment. 1. (*Surgical.*) A diagnostic instrument, various in kinds and applications. For instances: —

Eustachian canal	Fig. 189, Part II.
Exploring trocar	Fig. 181 c, Part III.; 288–290, Part I.
Small trocar and acupuncture for rectal explorations	Fig. 608, Part III.
Uterine probes and sounds	Page 73, Part III.
Bougies for exploring urethral strictures	Page 9, Part III.
Exploring director for bistouries	Page 135, Part I.

All in *Tiemann's* "*Armamentarium Chirurgicum.*"

See also BULLET SEEKER; PROBE; SOUND; BOUGIE, etc.; see List under SURGICAL INSTRUMENTS, "*Mech. Dict.*," *et infra*.

2. (*Dentistry.*) A fine-pointed probe, right, left, straight, bent, bayonet-shaped, etc., for testing the depth or existence of caries in teeth.

Ex-plo'sion Ma-chine'. A motor which depends for its force upon the explosion of substances generating a gas which is used under pressure in an engine or apparatus.

Several gunpowder engines are noticed on p. 1041, "*Mech. Dict.*"

The gunpowder pile driver on same page.

The gas engines on pages 948, 949, *Ibid.*

See also GAS ENGINE, *infra*.

Laboulaye's "*Dictionnaire*," ii., article "*Explosion*," mentions *Brown's* machine, 1830, and that of *Selligue*, 1834; the latter for moving boats without the intervention of mechanism, the gases issuing at the stern and impinging on the water.

Ex-plo'sives. These may be classed generally as follows: —

Gunpowder.
Gun cotton.
Nitro compounds:
  Nitro-cellulose.
  Nitro-glucose.
  Nitro-starch.
  Nitro-glycerine and its compounds.
Picric acid:
  A trinitro-phenol.
Fulminates:
  Fulminating mercury.
  Fulminating silver.
  Chlorate of potassium and sulphide of antimony; needle-guns of Germany.
  Sulphur and chlorate of potassium.
  Red phosphorus and chlorate of potassium. *Armstrong's*.

The mixture of nitro-glycerine with dry pulverized absorbent substances has given rise to a variety of explosives of which the name *dynamite* is perhaps generic. The following names have been given to various compositions, or the article furnished by various manufacturers. Many of these names are found in their alphabetical places in the present volume. The difference between the articles is largely in the proportions of the materials: —

Dualin.	Jupiter powder.	Titanite.
Giant powder.	Lignose.	Titan powder.
Hercules powder.	Mica powder.	Vigorite, etc.
Neptune powder.	Rendrock.	Vulcan powder.
Potentia powder.	Sebastine.	
	Thunderbolt powder.	

The report of the United States Board of Army Engineers presents the following table as the result of two years' trial of the relative efficiency of the various modern explosives, taking ordinary dynamite as the standard: —

Dualin	111
Hercules powder, No. 1	106
Dynamite, No. 1	100
Rendrock	94
Gun cotton	87
Dynamite, No. 2	83
Hercules powder, No. 2	83
Mica powder	83
Vulcan powder	82
Nitro-glycerin	81
To which may be added for comparison: —	
Blasting gunpowder, No. 1	30

See also table by Bertholet on p. 818, "*Mech. Dict.*"

Explosive by Prof. Emerson Reynolds, Dublin: —

Chlorate potassium	75
Sulphurea	25

The latter is a product of gas manufacture.

The articles may be stored and carried separately without any danger, and the article produced instantaneously by a comparatively rough mixture of the components.

See *Abbot's* report "*Centennial Exhibition Reports*," vol. vi., Group XVI., p. 52 *et seq.* Including: —

Nitrates.	Pebble and pellet powder.
Chlorates.	Nitro-glycerine.
Gun cotton.	Picrates.
Fulminates.

	"*Sc. Am. Sup.*," 134, 2018, 3874.
	"*Eng. & Min. J.*," xxv. 346, 361.

See under the following heads: —

Azotine.	Nitro-glycerine.
Blasting gelatine.	Papyroxyline.
Breaking-down machine.	Pebble powder.
Carbo-azotine.	Pebble-powder machine.
Cube powder.	Pellet powder.
Diorrexine.	Pellet-powder machine.
Drying house.	Petralite.
Drying stove.	Potentite.
Dualin.	Poudre brutale.
Dusting machine.	Powder dusting machine.
Dynamite.	Powder paper.
Explosive gelatine.	Powder-pressing machine.
Gelatine, blasting.	Priming machine.
Glazing barrel.	Prismatic powder.
Granulated-wood powder.	Pyrophore.
Granulating machine.	Pyrophorus.
Gravel powder.	Pyroxyline.
Gun cotton.	Saltpeter and sulphur-grinding mill.
Gunpowder.	Saltpeter, sulphur, and charcoal mixing mill.
Gunpowder machine.	Sebastine.
Herakline.	Squib.
Jelly powder.	Tonite.
Johnite.	Vigorite.
L. S. G.	Vulcan powder.
Lignose.	
Nitro-gelatine.	

Ex-plo'sive Bul'let. Two explosive bullets are mentioned under BULLET, p. 401, "*Mech. Dict.*" These were intended for war, but the military service of civilized nations has not been disgraced by their use to any extent.

Fig. 990.

Explosive Shell.

The Dougall explosive bullet for heavy game is made thus: in pouring the bullet a small copper bottle is suspended in the center of the mold, so that it is inclosed by the lead except at the front where a tige holds the bottle and forms the future charging opening. It is charged with equal parts of sulphuret of antimony and chlorate of potassa, or with common powder, and primed with a fulminate. It is used for elephant, lion, tiger, and alligator shooting especially.

Ex-sec'tion In'stru-ments. (*Surgical.*) Instruments for removing sections of bone by sawing in two places, or by circular incision.

Special bow saw.	Trephine.
Metacarpal saws.	Elevator.
Chain saw.	Raspatory.
Interosseous saw.	Sequestrum forceps.
Circular saw.	Antrum drill.
Chisels.	Rongeur.
Bone drills.	Retractors.
Bone forceps.	Subcutaneous saw.

Ex'sic-ca'tor. A dessicator, which see.

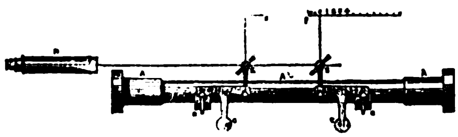
Ex-ten'sion Ap'pa-ra'tus. To extend a fractured limb in order to maintain the coaptation of parts. See COUNTER-EXTENSION APPARATUS; EXTENSION APPARATUS, "*Mech. Dict.*"

Dr. Levi's adjustable-weight leg-extension apparatus.
"*Scientific American Supplement*" . . . . . * 2101.

Ex-ten'sion Meas'ur-ing Ap'pa-ra'tus. An instrument for measuring minute extensions, deflections, and compressions by means of a multiplying optical arrangement.

A A is the test-piece; *B B* clips on the test-piece carrying

Fig. 991.



Willis's Measuring Apparatus.

pins; *C C*, weighted drop pieces forming connecting rods; *D*, a telescope fitted with a cross hair: *E E*, two mirrors turning on axes These have each a line across them for adjustment. *F F* are two scales carried on rails on a beam fixed to the roof, so that they can be adjusted to zero for any length of specimen. In looking through the telescope both scales are seen at once reflected in *E E*, and the figure on each covered by the cross hair is that which is read off for each strain. If both readings alter, the sum of the change is the extension of the bar. The short scale is for the end of the specimen next the lever of the machine, which should not move sensibly, but which does move small amounts due to the take-up of collars, and to differing positions of the steel-yard. The distance from the scales to the mirrors is about 11′. The radius of the levers *G G*, which cause the partial rotation of the mirrors as the specimen lengthens, is about 1½″ with the doubling of the angle caused by reflection; this gives a total magnifying power of about 140 to 1. The extension between certain definite points only on the bar is measured which eliminates errors due to the taking up of the bearings of collars, etc. The reading is, by estimation, up to 1-4000″. See also TASEOMETER.

Extension measuring app., *Willis*, Br. * "*Engineer*," xlvii. 385.
See also EXPANSION OF METALS APPARATUS, p. 320, *supra*.

Ex-ter'nal and In-ter'nal Gages. Standard caliper, ring, plug screw, and nut gages made to exact size and used for measurement and testing accuracy of templates, taps, etc.

Fig. 992.

Standard Caliper Gage.

The system may be said to have originated with Whitworth, but is now carried to great accuracy in several countries. In one case the instruments are of 3 classes, on a scale of precision.

Class *A* guaranteed to 1-25,000″.

Class *B* guaranteed to 1-10,000″.

Class *C* guaranteed to 1-5,000″.

Class *A* adjusted at 75° Fah.; *B* and *C*, 60° to 80°.

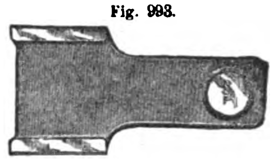
They have a parallel fit from ⅛″ to ¾″ in length; are arranged by sixteenths of an inch from ⅛″ to 2¼″; by eighths to 4″; by fourths to larger sizes. Made also in millimeters.

Fig. 992. External caliper gage for turning: crescent pattern.

Fig. 993 is the flat-bar pattern, internal gage: for boring.

Plain external and internal gages are shown under CYLINDRICAL GAGE, Fig. 772, p. 244, *supra*.

Fig. 993.



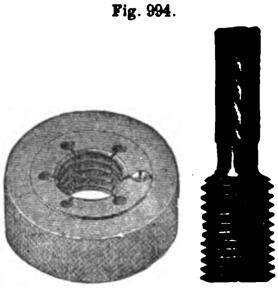
Standard Internal Gage.

Fig 994 shows screw-thread gages, external and internal.

Ex'tir-pa'tion For'ceps. (*Surgical.*) Forceps having on each arm double claws for reaching around and grasping the eye-ball in the operation of extirpation.

Blitz's, Fig. 80, *f*, Part II., *Tiemann's* "*Armamentarium Chirurgicum.*"

Fig. 994.



Screw-thread Gages.

Ex-tract'or. (*Fire-arm.*) The device which withdraws the spent cartridge capsule in the motion of uncovering the breech for reloading.

Ex'tra Cur'rent. (*Electricity.*) The *appreciable* current in the primary coil, which is due entirely to induction.

Eye. (*Add.*) 1. (*Nautical.*) A sheave for a rope; see DEAD-EYE; BULL'S EYE; HEART, "*Mech. Dict.*"

2. (*Vehicles.*) The socket on a shaft or pole which connects with the clip on the axle.

Fig. 995.

Pole and Shaft Eyes.

a. Pole eye.
b. Shaft eye.
c. Shaft eye plain.
d. Completed coupling.

Eye, Ar'ti-fi'cial. A false eye for persons, stuffed animals, etc., and dolls.

The material for the artificial eye is a rod of glass about the size of a pencil. On the end of this a bulb is blown of the size of the eyeball with which it is to match, and having a slight ovality. At the place for the iris and pupil the little sphere is flattened, and a circular patch of black pigment placed in the center to form the pupil. The painting of the iris is a very delicate matter, and the colors and proportion are studied from the sound eye of the patient. With enamel colors from a palette the zone around the pupil is colored, and then a bulb of clear crystal glass is placed over it to form the cornea, flat side down, and is fastened by fusing its edge by the blow-pipe flame. The red veins of the ball are imitated from the sound eye, being fine films of red glass laid on, and subsequently fused. The fitting to the *stump*, as the remaining portion of the ball is termed, is a matter of great nicety.

Eyes for birds, etc., are made in great quantity, both for museums and for the dressing of ladies' hats. Finch, humming-bird, partridge, pheasant, blue creeper (African), and scarlet tanager, are among the most common. Eyes for foxes, stags, rocking-horses, wax figures, prize animals and winners, trophies of the chase, dolls, are also made in large quantities, varying from 1 cent per dozen to 75 cents per pair.

Siemens' sensitive artificial eye, * "*Sc. American*," xxv. 874.

Eye Bar. An iron bar, with a round eye at each end usually. Much used in iron bridge building. Machine for drilling eyes; Fig. 854, p. 269, *supra*.

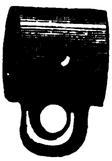
Eye Block. A tackle block with an eye or loop above, for shackle or lashing.

Eye Douche. (*Surgical.*) An apparatus for sending a fine shower of water upon the eye. Agnew's has an elevated pan, hung upon a hook, and a caoutchouc tube with spray nozzle.

Fig. 95, p. 27, Part II., *Tiemann's "Armamentarium Chirurgicum."*
See also Eye Cup, p. 819, "*Mech. Dict.*"

Eye Fer'rule. A thimble with an eye loop. Used with swingle trees, and for many other purposes.

Fig. 996.



Eye Ferrule.

Eye Glass. (*Add.*) A single myopic or presbyopic glass worn in the eye.

A double glass with a spring in a *pince-nez*. See Fig. 1909, p. 819, "*Mech. Dict.*" Also Spectacles, Fig. 5355, p. 2258, *Ibid.*

Blethen's eye-glass.
* "*Scientific American*," xlii. 5.

Eye In'stru-ments. (*Surgical.*) These are for diagnosis and exploration, operation, prothesis. See under the general heads, *b, e, f, g, h*; and under the special titles in following list: —

a. Instruments for operating on the lids and lachrymal ducts: —

Entropium forceps.	Depilating forceps.
Trichiasis forceps.	Eye speculum.
Eyelid tourniquet.	Eyelid retractor.
Cilia forceps.	Lachrymal duct dilator.
Eyelid compressor.	Drop glass.
Canalicula dilator.	Lachrymal syringe.
Probe.	Subpalpebral syringe.
Eye syringe.	Lachrymal gouge.
Conjunctiva forceps.	Fistula knife.
Cauterizing canula.	Canalicula syringe.
Bistoury caché.	Needle forceps.

b. Strabismus instruments.

c. Fixation and extirpation instruments: —

Fixation hook	Extirpation forceps.
Fixation forceps.	Double hook.
Tumor Forceps.	Ophthalmostate.
Pamard's pique.	Lid forceps.

d. Instruments for removing foreign bodies from the eye:

Spud.	Spatula.
Needle.	Curette.
Gouge.	Spoon.
Hook.	Eye douche.
Couching needle.	Forceps.

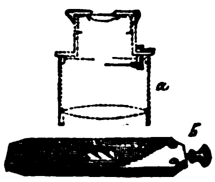
e. Conjunctiva instruments.
f. Corneal instruments.
g. Cataract instruments.
h. Iris instruments. Iridectomy Instruments.

Eye'let Grom'met. A worked hole in a sail, reënforced by an eyelet. See Grommet.

Eye'-piece In'di-ca'tor. A small pointer with lateral movement in the eye-piece of the top lens, for pointing out any particular portion of an object under view.

The eye-piece micrometer is adjusted across the line of sight, and its cross markings divide the field into squares of known size.

Fig. 997.



a. Eye-piece Indicator.
b. Eye-piece Micrometer.

Eye-piece, microscopic.
* "*Manuf. & Builder*," xi. 37.
Telescopic, *Nystrom.*
* "*Sc. American Sup.*," 101.

Eye Pro-tec'tor. Glasses, goggles, or gauze worn over the eyes.

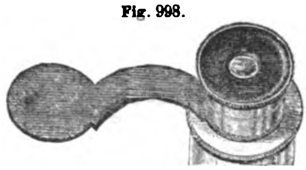
Smoke, or other colored glasses, to moderate the light; goggles to exclude side light; gauze, to exclude dust and cinders. See Spectacles, p. 2358, "*Mech. Dict.*"
The *coquille* glass is egg-shell shaped.
Millers' and turners' glasses are merely white panes of glass or mica, to protect the eyes from chips. See also Goggles, Fig. 2263, p. 991, *Ibid.* Also Iris Diaphragm, Fig. 2697, p. 1195, *Ibid.*

Eye Shade. (*Optics.*) *a.* A hood or vizor over the eyes to protect from upper light.

b. A hood fixed on the eye-piece of a microscope to prevent lateral rays from entering the eye.

c. A piece fitted around the cap of the eye-piece of a microscope, and intercepting the view of that eye which is not in use; in order to prevent the distraction of the attention, or obviate the necessity for the muscular closing of the unused eye.

Fig. 998.



Eye Shade (c).

F.

Fab'ric. (*Fabric.*) A woven or felted goods.

The character depends upon the material and the *armure* or character of the weave.

Varieties of armure: —

1. *Taffeta* with 2 harnesses.
2. *Twilled* with 4 harnesses.
3. *Serge* with 3 harnesses.
4. *Satin* with 5 or more harnesses.

Different effects are produced —

By derivatives from these fundamental tissues.

By greater or less torsion of the threads.

By the direction in which the yarns are twisted.

By variations in the relative sizes of the warp and weft threads.

By causing the weft to pass alternately over two threads and one thread of the warp; making a *rep* or corded tissue.

By different materials of warp and weft.

By colors.

By mixtures of materials in the yarn.

By printed threads making *hit-or-miss*, or *mixtures*.

By looping threads, to make *pile* fabrics; and cutting or non-cutting the loops.

By printing.

By dyeing.

By floating the weft to make dots, spots, stripes, or figures.

By character of material, as of soft and fine wools or of hard and lustrous combing wools.

By two or more warps which are brought to the surface as required by the figure.

By setting up bands of colors or varying yarns in the warp to form stripes.

By adding to the last mentioned a similar arrangement in the weft to make checks or plaids.

By combinations of the crossing threads which occur at variable places.

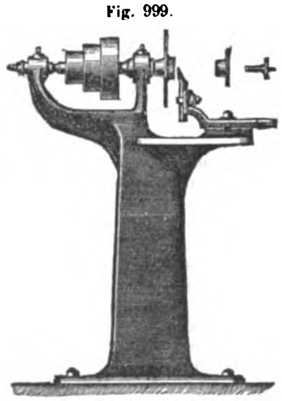
Face. (*Mining.*) The end of a drift or tunnel.

Face Ham'mer. (*Masonry.*) One with one blunt and one cutting end. The latter used for roughly squaring stones preparatory to the use of finer tools.

Fig. 999.



Face Lathe.

Face Lathe. 1. A pattern-maker's lathe for turning bosses, core prints, and other face work. The instance shown works up to 16″ diameter, and stands on 2′ × 2′ on the floor. The spindle is of steel, with brass bearings.

2. A lathe with a large face-plate and a slide rest adjustable in front on its own shears. Transverse usually but not necessarily.

Fetu & Deliege, Fr. . . . * "*Engineering*," xxix. 117.

Face'-plate. (*Add.*) 2. A covering plate for an object to receive wear or shock.

Fa'cing Ma-chine'. (*Milling.*) A machine for dressing the faces or lands of mill stones; that is, the spaces between furrows. A furrowing machine. See MILL-STONE DRESSER.

Fa'cing Tool. See CORUNDUM TOOL; MILL-STONE DRESSER.

Fac-sim'i-le Print'ing Pro'cess. A term including the various systems of printing from a pad — usually of glycerine and gelatine — upon which the original writing in aniline ink has been transferred. See COPYGRAPH; COPYING PENCIL; HECTOGRAPH; and other titles there cited.

Fac-sim'i-le Tel'e-graph. One reproducing autograph messages.

Sawyer's autographic telegraph; also called *copying telegraph, pantelegraph, pantographic telegraph*, was described and illustrated in "*Telegrapher*," 1876; reproduced in "*Scientific American Sup*," * 802. See also "*Iron Age*," xviii., July 20, p. 3.

It operates by placing the thin plate containing the transferred message upon a cylinder at the transmitting end and a sheet of chemically prepared paper around a similar cylinder at the receiving end. As the cylinders are moved along by threads, the synchronous styles are carried around the cylinders and make the synchronous contacts as the transmitting style crosses the lines of writing. See AUTOGRAPHIC TELEGRAPH, "*Mech. Dict.*," *et supra*. See also ELECTRIC WRITING APPARATUS, *supra*, and PANTELEGRAPH, *infra*.

D'Arlincourt . . "*Jour. Soc. Telegr. Eng'rs.*," viii. 15.

Fa'ger-sta Steel. Steel made by the partial decarbonization of crude cast iron containing a considerable portion of manganese, by running the molten iron direct from the blast furnace into a Bessemer converter, where the carbon and manganese are partially removed by being burned out by the oxygen of the air used in the Bessemer process. This leaves in the metal the required amount of carbon and manganese to render it suitable for use. The usual Bessemer practice is first the removal of all the carbon and afterward to recarbonize with spiegeleisen, which is a compound of iron, carbon, and manganese.

"*Iron Age*" . . . . xix., Feb. 1, p. 15.

Fag'got-ed Ax'le. One made of a pile of bars or rods tilted.

Faïence (pr. *fa-iān-s*). (*Ceramics.*) Enameled pottery. There are two species of faïence. the common faïence (*faïence commune*) which is a soft paste, and the fine faïence (*faïence fine*) which has a hard paste.

1. COMMON FAÏENCE is supposed to have originated in Persia, having been brought thence by the Saracens and introduced into Africa and Spain.

The stanniferous glaze which distinguishes faïence (*poterie émaillées*) from the ordinary pottery with plombiferous glaze (*poterie tendre vernissées*) was known to the Egyptians and to the Mesopotamian nations; but the art of enameling ceramic ware and tiles seems to have been again invented by successive persons.

The stanniferous enamel ware of the Saracens of the 12th century is very famous, being in extremely brilliant colors. The tiles known as Azulejos, and the Hispano-Moresque plaques and vases are also celebrated. The Saracenic pottery of the island of Majorca gave a name to the ware *majolica*. The *mezza majolica* of the 15th and 16th centuries had a leaden glaze. See MEZZA MAJOLICA.

The name *faïence* comes from Faënza, in Italy, a town celebrated for its wares, and the most famous potter on the peninsula is Luca della Robbia, of Florence, who flourished about the middle of the 15th century. He rediscovered the stanniferous enamel which soon largely superseded the previously used lead-glaze, which still, however, held its place for common ware, as it does to this day; the third order in the first class of Brogniart's classification. See POTTERY.

French *faïence* took its rise with the admirable Bernard Palissy, of Saintes, about 1535. His work had raised decorations, principally of aquatic subjects, such as fish, lizards, shells, and water plants. He died in the Bastile for his faith.

Common faïence has a soft body (*pâte tendre*), and a tin glaze, colored with various metallic oxides, and is twice fired. The body is composed of plastic clay, argillaceous marl, and sand. The clays are washed.

The following proportions are those of M. Bastenaire d'Audenard: —

	White Faïence.	Brown Faïence.
Silex	0.35	0.38
Ferruginous clay	0.58	0.57
Carbonate of lime	0.07	0.05
	1.00	1.00

The fashioning is done by molding or on the wheel, according to the character of the object. The baking of the green ware is done in a kiln at a temperature from a cherry-red to a black-red, and the subsequent firing after enameling at a somewhat higher temperature. The first firing is frequently done in the same kiln at a point more remote from the ingress of the flame.

The ware in the kiln is inclosed in some way; the modes differ. The style known in France as *l'enfournement en échappade*, consists in building up within the kiln a series of stories with refractory flat tiles and perpendicular supports, the ware being thus in cells, where it rests on the tiles directly, or on the points or edges of little prisms, or tripods (*colifichets*) of refractory clay. See SEGGAR.

See Figs. 3882, 3926, 3927, "*Mech. Dict.*" Also, Figs. 2169, 2180, *Laboulaye's* "*Dictionnaire*," ed. of 1877, tome iii., caption "*Poterie.*" For the system of inclosure in the kiln, see SEGGAR, p. 2089, "*Mech. Dict.*"

Another system is called *l'enfournement en cazette à pernettes*, and consists of a seggar in which the dishes or plates are supported by shifting ledge pieces which fit into grooves around the inside of the *cazette*, or fire-clay box. See SEGGAR.

The enamel for brown faïence is composed of: —

Minium	0.52 to 0.58
Peroxide of manganese	0.07 to 0.05
Common brick, pulverized	0.41 to 0.42
	1.00 1.00

The enamel for white faïence is of two kinds, differing principally in the proportion of tin in the metallic oxides which form an ingredient in the frit.

	Hard Enamel.	Soft Enamel.
Oxide of lead	No. 1. 0.77	No. 2 0.82
Oxide of tin	0.23	0.18
	1.00	1.00

Take of:		
No. 1	0.45	
No. 2	-	0.45
Minium	0.02	
Washed quartz sand	0.45	0.45
Marine salt	0.05	0.07
Soda of Alicante	0.03	0.03
	1.00	1.00

Color is given by Naples yellow, lasuli, manganese, or copper scales.

The ingredients are brought to an impalpable powder and then to a fine creamy condition in which the slip is aspersed over the object, or the latter is dipped into it.

Common faïence is much employed for wall and floor tiles, stoves, chimney plaques, etc., for which purpose any tendency to crack with the heat may be avoided by giving more fusibility to the paste by the addition of lime or alkali, but the addition of lime in any great quantity makes them apt to split with sudden variations of temperature.

2. FINE FAÏENCE, otherwise known as English *faïence*, or *English china*, is a ware of an entirely different description from common faïence; it is an English discovery, and the best quality is still made there. It is the invention of William Wedgewood, born at Burslem, in Staffordshire, in 1730.

Fine faïence is characterized by an opaque white paste, fine dense texture, and sonorous quality. It is essentially composed of a washed plastic clay, calcined flint, or finely ground quartz.

The glaze is a fritted compound of silex, soda, oxide of lead, with the addition sometimes of boracic acid

There are three principal compositions, the names of which signify the use of notable quantities of certain ingredients in the respective pastes.

a. Calcareous or pipe-clay faïence. (Schumann.)

Pipe-clay	0.854
Silex	0.130
Chalk	0.016
	1.000

b. Flint faïence. (Oppenheim and Bastenaire.)

Pipe-clay of Montereau or Dreux	0.87
Silex	0.13
	1.00

Or: (Oppenheim and St. Amans.)

English pipe-clay	0.87
Silex	0.13
	1.00

c. Feldspathic faïence. (St. Amans.)

English pipe-clay	0.62
Kaolin	0.16
Silex	0.19
Feldspar	0.03
	1.00

Or: for "Cream color." (St. Amans.)

English pipe-clay	0.82
Silex	0.16
Feldspar	0.02
	1.00

Or: (Aiken.)

English pipe-clay	0.64
Kaolin	0.16
Silex	0.16
Feldspar	0.04
	1.00

Chalk is present, however, in all the pastes, as it is an incident to the clay and the flint.

The materials are washed, ground extremely fine, sifted, made into a slip which is strained, the pulp condensed by heat, and laid in cellars to ripen; after the manner of the Chinese, who use the clay prepared by their fathers, and prepare a new batch for the coming generation.

The paste is fine, plastic, and easily worked, and the pieces are made on the wheel with templets, gage slips, etc.; but many parts, such as handles, are made in molds and attached. Objects not symmetrical are either molded, or, as in convoluted work, thrown and then pressed to form.

The green ware is baked in the faïence kiln, and the biscuit is treated with the glaze slip either by immersion or sprinkling. The following are some recipes for the glazes of the respective wares cited above as *a*, *b*, *c*.

a. Glaze for pipe-clay faïence. (Schumann)

Calcined feldspar	0.07
Sand	0.31
Minium	0.30
Litharge	0.27
Borax	0.03
Flint glass	0.02
	1.00

Or: (Bastenaire-d'Audenard.)

Quartzose sand	0.36
Minium	0.45
Carbonate of soda	0.17
Niter	0.02
Cobalt blue	0.00001
	1.00

b. Glaze for flint faïence.	(Aiken.)	(Bastenaire.)
Feldspathic sand	0.40	0.42
Minium	0.23	0.26
Borax	0.23	0.21
Carbonate of soda	0.14	0.11
Cobalt blue	0.00001	0.00001
	1.00	1.00

c. Glaze for feldspathic faïence. "Cream color." (Aiken.)

Flinty kaolin	0.25
Silex	0.13
Oxide of lead	0.52
Flint glass	0.10
	1.00

For printed faïence. (Shaw.)

Flinty kaolin	0.28
Silex	0.16
Carbonate of lime	0.04
Oxide of lead	0.30
Boracic acid	0.06
Carbonate of soda	0.16
	1.00

The small quantity of cobalt blue in some of the above glazes is merely to correct the yellow color.

The degree of heat in the final firing of the three classes of fine faïence above noted are respectively: —

	Pyrometric.
a. The pipe-clay biscuit and glazed ware	25° to 30°
b. The flinty biscuit	60°
The flinty ware	12°
c. The feldspathic biscuit	100°
The feldspathic ware	20° to 30°

The setting of the green ware or the glazed article in the kiln is by the same means as described under common faïence (2). See SEGGAR.

The faïence kiln of Staffordshire, Fig. 3926, p. 1779, "*Mech. Dict.*," is inclosed in a large dome, which serves to conduct upward the smoke and flame issuing at the openings of the kiln proper. The furnaces are *à alandier*, so called, probably, from the way the fuel is supported on the grate. The furnaces are placed around the base of the kiln, and the draft is downward through a furnace hole into the fire, and thence by ducts below the floor and chimney to the kiln chamber. See Fig. 36, p. 20, *supra*.

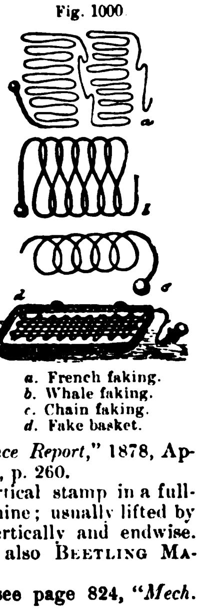
Faïence d'Oïron. (*Ceramics.*) Also known as *Henri Deux ware.* Attributed to a private pottery establishment, the atelier of Hélène de Hange-t-Genlis, widow of Arthur Gouffier, and afterwards carried on by her son. Evidently a labor of love and art devotion.

Biscuit of fine clay is graven and the lines filled in with colored clays, the object glazed and fired. It is very rare. See HENRI-DEUX WARE.

Faïence Stan'ni-fere. (*Ceramics.*) Ware with glaze of oxide of tin.

Fake. A coil or disposition of rope in zig-zag, so as to run free when let go, or when a shot attached to one end of the line is fired, as in life-saving apparatus for stranded vessels.

Fig. 1000



a. French faking.
b. Whale faking.
c. Chain faking.
d. Fake basket.

Fak'ing Box. (*Life-saving Apparatus.*) A box to contain the lines for shot firing to communicate with stranded vessels. A *fake* is a coil of rope; it is usually a helix, and a number of such built one upon another form a tier. In the faking of ropes, however, in the life-saving apparatus the fakes assume another form to enable the rope to pay out with the least impediment, so as to allow good range of the projectile without excessive charge and also avoid breakage of the shot line. "*Ordnance Report,*" 1878, Appendix P, p. 200 *et seq.* Also, p. 260.

Fall'er. (*Add.*) 2. A vertical stamp in a fulling, milling, or stamping machine; usually lifted by cams and allowed to drop vertically and endwise. See STAMPING MILL. See also BEETLING MACHINE, *supra*.

Faller motion (spinning), see page 824, "*Mech. Dict.*"

Faller motion (mule) . * "*Engineering,*" xxx. 511, Figs. 13 to 17.

Fall'er Ma-chine. A machine with vertical stamps or fallers, used in milling goods.

False Joint Ap'pa-ra'tus. (*Surgical.*) Apparatus for ununited fractures.

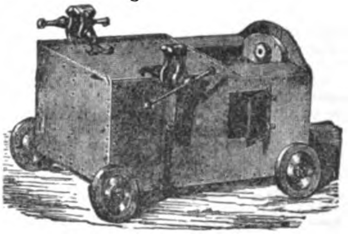
Fan'cy Broad Loom. An efficient loom for weaving fancy goods, worsted coatings, fancy cassimeres, etc. It is made up to 92″ wide, 27 harnesses, and 4 × 4 shuttle-boxes. — *Crompton.*

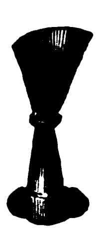
Fan Forge. A transportable form of forge and fan is shown in Fig. 1001. It has tool-chest, two vises, and weighs 800 pounds. See BLOWER; FORGE; BELLOWS, etc.

Fig. 1001.



Fan Forge.

Fig. 1002.



Fan Jet.

Fan Jet. A form of nozzle for watering-pots and engines having a fan or spoon shaped lip which deflects the stream of water into a wide and thin expanding film.

Far'ad. (*Electricity.*) The *capacity* of a condenser which holds one *weber* at a potential of one *volt.* — *Gordon.*

Far-a-da'ic Cur'rent. (*Electricity.*) An induced current, as contrasted with a voltaic or direct constant current.

Far-a-da'ic Gen'e-ra'tor. A generator of electricity named by its inventor after Prof. Faraday.

The armature below revolves between the iron blocks on which the electro-magnets stand. It consists of a cylinder of wood which is wound around with iron wire (see DYNAMO-ELECTRIC MACHINE, Fig. 900, Plate XII.), like a spool. Around the whole spool are numerous loops of insulated copper wire running lengthwise of the armature. The ends of these loops are taken to the cylindrical commutator which is on the armature shaft, and from this brushes made of copper wire take the current from the machine to line.

Edison . . . * "*Scientific American,*" xli. 239, 305.

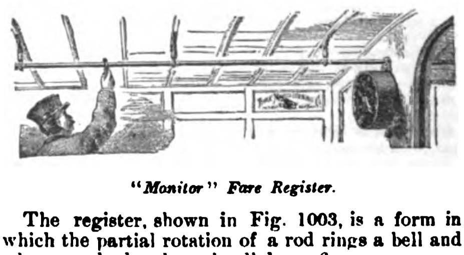
Fare In'di-ca'tor. 1. A device for counting and registering fares. The wicket-gate, ticket-punch, conductor's passenger register, etc., are familiar instances.

2. A device for indicating distance traveled. See ODOMETER, p. 1544, "*Mech. Dict.*"

See FARE PUNCH; TICKET PUNCH.

Fare Reg'is-ter. A device to keep a record of the number of passengers carried in a public vehicle. The conductor's ticket-punch is one form.

Fig. 1003.



"*Monitor*" *Fare Register.*

The register, shown in Fig. 1003, is a form in which the partial rotation of a rod rings a bell and advances the hand on the dial one figure.

Faure Bat'te-ry. (*Electricity.*) One in which the carbon is made in form of a cell filled with nitric acid and closed with a stopper; the pressure due to the evolution of the fumes in the vessel forces the acid through the walls of the cell, which thus performs the double function of a porous pot and a negative pole.

Niaudet. American translation . . . . 174.
See also SECONDARY BATTERY.

Feath'er, Ar'ti-fi'cial. Artificial ostrich feathers are made in New York of celluloid, rattan, and silk, and are an excellent imitation of the original. Patented machines make the silk, the flue, the quill, and combine the flue and silk. The quill-making machine takes an ordinary piece of rattan or celluloid and produces the quill in 15 seconds; the material is drawn between two grooved rolls. In the manufacture of the flues, the silk is stretched between two machines 75 feet apart, which wind, twist, cut, and spin it into a flue.

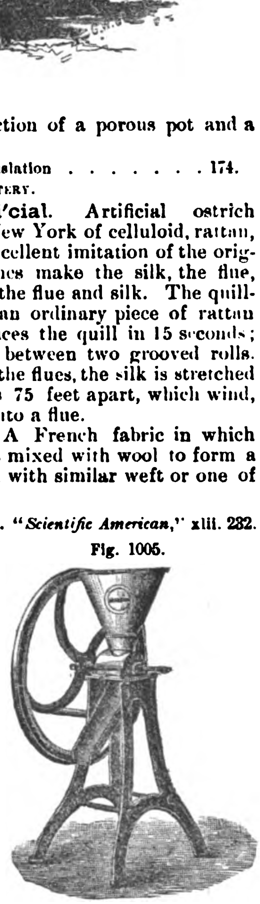
Feath'er Plush. A French fabric in which the down of feathers is mixed with wool to form a warp to be interwoven with similar weft or one of wool alone.

"*Textile Manufacturer*" . "*Scientific American*," xlii. 282.

Feed Boil'er. See AGRICULTURAL BOILER, *supra.*

Feed Crush'er. A mill for flattening grain to render it more easily masticated. A substitute for grinding. The *aplatisseur* of the French. See GRAIN CRUSHER.

Fig. 1005.



Feed Crusher.

Feed Cut'ter. A straw or chaff cutter.

Straw, *Silver & Deming.* * "*Iron Age*," xix., Jan. 4, p. 5.
Fodder, *Dick.* * "*Sc. Amer.*," xxxvii. 115.
* "*Mining & Sc. Press*," xxxv. 225.

See CHAFF CUTTER, ENSILAGE CUTTER, STRAW CUTTER, etc.

Feed Door. A furnace door for entry of coal. For automatic feed, see FURNACE DOOR, etc.

Feed'er. 1. A portion of an apparatus at which the material enters to be treated.

In many machines the feeder is merely a hopper such as in various mills. In other cases the feeder is a definite portion of the machinery which conducts the material in regulated quantities. See BOLT FEEDER; GIN, COTTON.

2. (*Mining.*) A small vein adjoining a larger one.

Feed'ing Tube. (*Surgical.*) These have various applications: for use in cases of lock-jaw, mania, choking paretics, paralysis of the throat, fractured jaw.

The instruments are introduced by the mouth, nose, or anus.

The mouth instruments are gags, spoons, and tubes

The nasal operation may be by a simple funnel, a tube in the pharynx, a tube directly into the stomach. The latter introduced by Dr. Tuke. A soft rubber Nelaton catheter is now used.

The rectal administration is by enema.

Feed Mill. See GRINDING MILL.

Feed Pump. A boiler supply pump. It assumes many forms. See list under PUMP; STEAM ENGINES AND APPARATUS, "*Mech. Dict.*" See the following references: —

Clegg	* "*Scientific American*," xl. 358.
Garrett, Br.	* "*Engineer*," xlviii. 430

Feed Reg'u-la'tor. A device for graduating the feed to the necessity of the object, as of fuel to a furnace, water to a boiler, material to a machine. See FEED WATER REGULATOR.

Feed Wa'ter Clean'er. See FEED WATER HEATER.

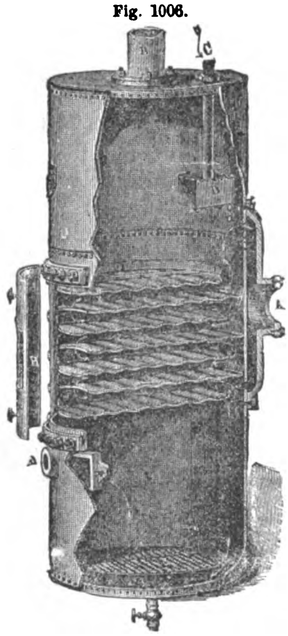
Feed Wa'ter Heat'er. An apparatus to use escaping steam or flue heat in raising the temperature of the water destined to feed the boiler.

These apparatus are of many forms, but of two general classes: —

1. Those in which the steam comes in direct contact with the feed water, as in the common *open heater*.

2. Those in which the feed water circulates through pipes which course through a chamber heated by the exhaust steam, or through a flue heated by the volatile products of combustion.

Fig. 1006.



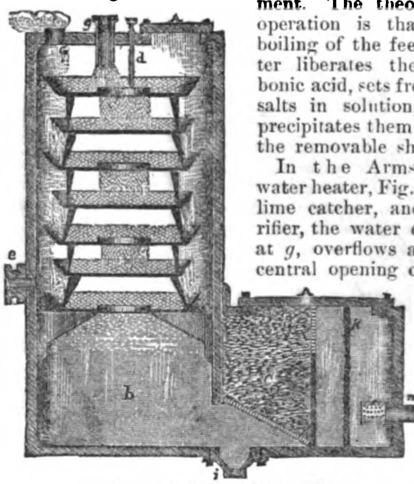
Stillwell Lime-extracting Feed Water Heater.

1. The feed water and exhaust steam mingled.

The Stillwell combined lime-extracting heater and feed-water filter is shown in Fig. 1006.

Steam enters the heater at A, is divided into two currents, upward and downward, and escapes at B. Cold water enters at C, pours over the edge of the over-flow cup D upon the corrugated depositing shelves, and then passes through chamber E, which is filled with a filtering material, and issues at a side opening. The bottom cock is for drawing off sediment. The theory of operation is that the boiling of the feed water liberates the carbonic acid, sets free the salts in solution, and precipitates them upon the removable shelves.

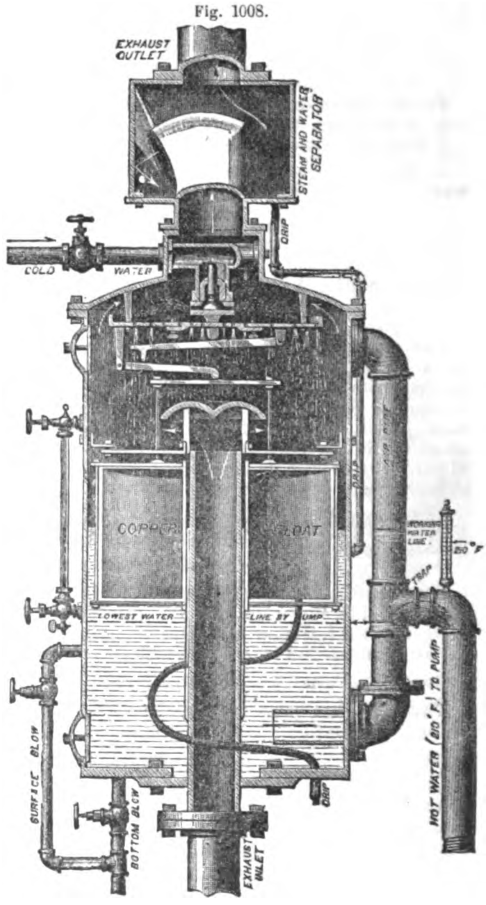
Fig. 1007.



Armstrong's Feed Water Heater.

In the Armstrong water heater, Fig. 1007, lime catcher, and purifier, the water enters at g, overflows at the central opening of the pan, thence into the second pan, over the margin

Fig. 1008.



Green Feed Water Heater.

of which it drips, and so on through the series of six pans, eventually reaching the settling chamber *b*. The water then passes upwardly through a filter, and then through an oil absorbent, *k*, made of burlaps. *m* is the outlet hot-water pipe, *e* inlet steam pipe, and *G* outlet; *A*, movable caps, to allow examination and cleaning; *i*, mud valve.

In the Jasper apparatus, instead of catching the lime and other impurities on shelves or in pans, these matters are detained in the mass of charcoal in the filters.

In the Green feed water heater, Fig. 1008, the water entering by the cold-wa'er pump passes through a valve-way, the position of the valve being regulated by a float below operating through levers, its own position being determined by the water level which corresponds to that in the boiler. The exhaust steam is admitted below, and parts with its heat to the water which trickles in rain through the perforations in the plate beneath the valve. The surplus steam then passes to the separating box above.

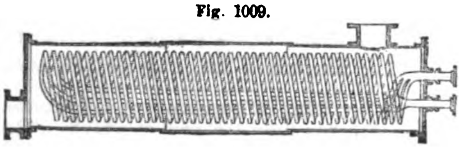
The Waters heater operates also by bringing the spray of exhaust steam in contact with a shower of water in a chamber.

The feed water heater of MM. Legris & Choisy, *Laboulaye's "Dictionnaire,"* iv., Fig. 3458, article "Chaleur Perdue," ed. 1877, is also founded upon the principle of introducing the water of alimentation in a fine spray in a pipe traversed by the exhaust steam of the engine.

2. The other class of feed water heaters consists of apparatus in which the heat of the exhaust steam is transferred by conduction through metallic walls to the feed water.

This is an old form of condenser; also long common on

Fig. 1009.



Feed Water Heater.

the Western rivers for heating feed water for boilers of non-condensing engines.

In Wetherill's, Fig. 1009, the iron exhaust steam cylinder has bonnets at the ends, and the feed water is heated by passing it through numerous coils of copper pipe 1″ in diameter. It is used directly in non-condensing engines, and in condensing engines occupies a position between the cylinder and the condenser.

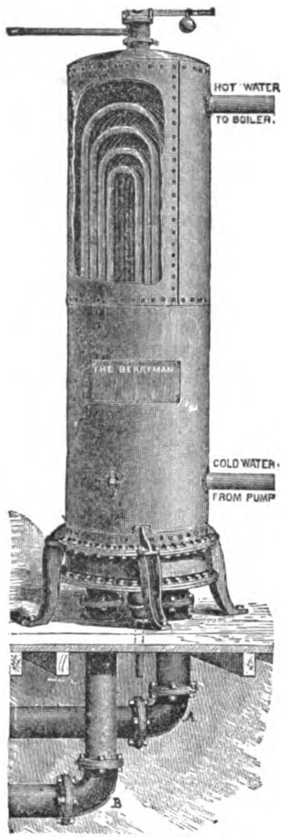
The Hawksley & Wilde (Br.) apparatus is similar in principle.

In Atkinson's apparatus (Br.) the steam passes by a circuitous route, ascending and descending in vertical pipes surrounded by water in a cylindrical chamber.

The Berryman heater is also of this class. The apparatus is placed between the engine and condenser, *B* being the exhaust steam-pipe from the engine, and *A* the steam-pipe to the condenser. Cold water from the pump enters the lower part of the cylinder surrounding the pipes, and departs at the upper end to the boiler. The number of pipes is such as to exceed by 20 per cent. the area of the exhaust steam-pipe *B*.

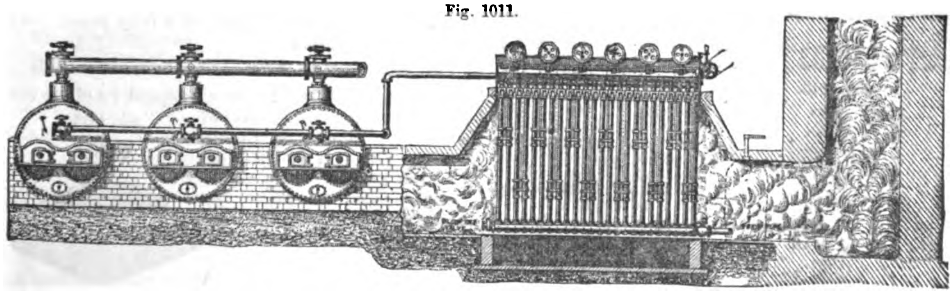
In another form of feed water heater the system of coils containing feed water is placed in the chimney. Such are some of the arrangements where the departing heat of a blast furnace is caused to heat the boiler driving the blast-engine.

Fig. 1010.



Berryman Feed Water Heater.

Fig. 1011.



Green's Fue' Economizer.

Of this class are the Twibill, Babcock & Wilcox, and Green fuel economizers; the last mentioned of which is shown in Fig. 1011. A number of upright water-pipes are placed in the main flue, beyond the boilers, and have scrapers or cleaners which move up and down the tubes to prevent the deposit of soot, which acts as a non-conductor. See Fuel Economizer; Fire Box.

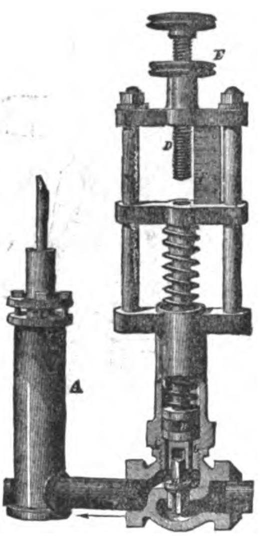
Feed Wa'ter Pu'ri-fi'er. A filter or lime catcher to purify water for steam boilers, to prevent incrustation. Usually combined with a heater. See FEED WATER HEATER.

Feed Wa'ter Reg'u-la'tor. One which proportions the feed to the need of the boiler.

Fig. 1012.

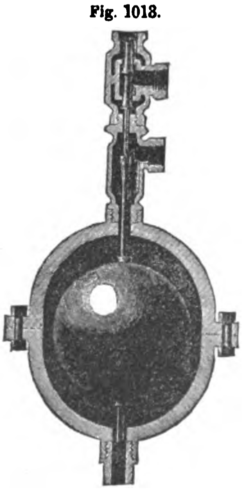


Maxim's Feed Water Regulator.

The Maxim feed water regulator was designed for steam yachts. *A* is an ordinary feed-pump, and the regulator on the right is placed between the pump and the suction. *B* is a piston-valve, pressed down by a coil spring, the valve stem rising and falling in the bar *C*. *D* is a limiting screw, and *E* a set screw. *H* is a feed-valve, and *G* holes communicating with chamber beneath the valve *B*. When the screw *D* is close down the valve *B* is inoperative and the boiler receives water due to the full stroke of the pump. When the screw *D* is up to *O*°, the water simply passes to and fro between the regulator chamber and the pump cylinder which are of equal sizes. The screw *D* is regulated against gage *F* for any quantity between full stroke and *O*°.

In the "Peerless" feed water governor, steam for operation enters the outer chamber of the valve casing, through the upper pipe, and circulates around the valve chamber which is closed by the valves. These are cone-shaped and to their stem is suspended the hollow copper float which rises and falls with the water in the boiler, and thus regulates the valve opening. The valves are balanced and upon one spindle. (Fig. 1013.)

Fig. 1013.



"*Peerless*" *Water Regulator.*

Berryman's feed water regulator is simply a hollow sphere suspended from a steelyard balance, and is connected with the water-space by two pipes of small diameter, one of which terminates just above and the other just below the proposed water-line. When the water falls, steam enters the upper pipe and fills the globe. The weight of the unloaded vessel is insufficient to counterbalance the opposite weight, and it falls, putting on the feed as it descends. When the feed has entered in sufficient quantity to raise the water-level above the mouth of the upper tube, water ascends through that tube into the globe, taking the place of the steam as the latter condenses, and the weight of the now filled vessel causes it to descend, shutting off the supply of feed.

The F. A. Pratt boiler feeder and return steam trap (patent Oct. 31, 1876) has a sphere suspended on one end of a lever in a receiving vessel above the level of the boiler, the other end of the lever being fast to a spindle which goes through a stuffing box to the outside of the receiver and carries a counterpoised lever. A tilting lever actuated as the feeder fills and is emptied of water, actuates the steam valve.

See also, for counterpoise and float actuating a valve, Fig. 761, p. 320, "*Mech. Dict.*" See also LOW-WATER ALARMS, Fig. 3008, p. 1359, *Ibid.*

In the Nathan & Dreyfoos regulator the injector of the locomotive works freely, untrammelled by adjusting contrivances: but the actual feed to the boiler is regulated by a controlling cock, the handle in the cab, by which means a portion of the feed water passing through the delivery pipe from the injector to the boiler is diverted and turned through a pipe to the tender.

Electric feller . . . . * "*Scientific Amer.*," xxxvi. 370.
Felling engine, *Smyth* . * "*Min. & Sc. Press*," xxxviii. 97.

Fell'ing Engine. See FELLER; FELLING SAW.

Fel'ly Bend'ing Ma-chine'. A machine for bending timber to form the rims of wheels. The heavier classes of fellies are sawn; lighter ones are bent.

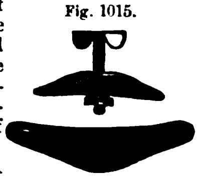
See p. 832, "*Mech. Dict.*," for FELLY MACHINERY, and WOOD-BENDING MACHINE, Figs. 7311-7814, pp. 2803, 2804, *Ibid.*, for machinery not exactly for fellies, but exhibiting the principle.

Fel'ly Hold'er. A plate at a felly joint. See FELLY-JOINT BOLT.

Felly plate, *Cremer* . * "*Scientific American*," xlii. 274.

Fel'ly-joint Bolt One adapted to clasp the joining portions of the rim of a wheel. Shown at Figure 1015. The bolt is halved into the abutting ends of the junction, and the plates embrace the exterior and interior periphery respectively of the rim.

Fig. 1015.



Felly-joint Bolt and Plate.

Fel'ly Ma-chine'. A machine for bending, boring, dressing, planing, rounding, sawing, etc., fellies for wheels.

See p. 802, "*Mech. Dict.*," and list of WOOD-WORKING TOOLS, p. 2814, *Ibid.* Also RIM-PLANING MACHINE, Fig. 4330, p. 1944, *Ibid.*

Fel'ly Pla'ning Ma-chine'. One for dressing the edges of rims for carriage wheels. See * FELLY DRESSER, p. 832, "*Mech. Dict.*," and * RIM-PLANING MACHINE, p. 1994, *Ibid.*

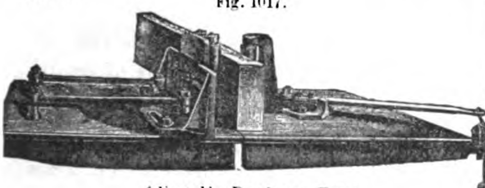
Fel'ly Round'ing Ma-chine'. A machine, Fig. 1016, for rounding the inner peripheries of rims for carriage wheels. It is a species of chamfering machine, planing off the salient edges and giving the required curve.

Fig. 1016.

Felly Rounding Machine.

Fence. A guide on a machine to direct the stuff to the tool, or maintain it in line while passing the tool. Fig. 1017 shows the Arbey adjustable fence and self-regulating roller for band-saw tables.

Fig. 1017.



Adjustable Band-saw Fence.

Fen'cing Ma-chine'. Hall's machine for making fence works upon poles and second growth timber, cutting the posts and rails to proper length, making the mortises in one and the tenons on the other. The posts are straightened in the line of bearings, and countersunk to parallel sides in the process of boring. The rails are sawed to uniform length, tenons and shoulders formed in their extremities fitting the bearings on the posts; all parts are interchangeable.

Flat iron fence . . . . * "*Iron Age*," xxii., Oct. 31, p. 18.

See also machine for making combined wood and wire fence, Fig. 7280, p. 2792, "*Mech. Dict.*"

Fend'er. A screen against a carriage or car step, to keep dirt or mud from being thrown upon it by the wheels. A *fender board.*

Fender for vessels, *Hulster*, * "*Scientific American*," xl. 230.

Fen'es-tra'ted In'stru-ments. (*Surgical.*) Said of instruments such as some forceps, scoops, enucleators, etc., the grasping ends of which have openings, or loops which engage and partially embrace the object.

Fenestrated artery forceps.
Fenestrated ear scoop.
Fenestrated lens scoop, etc.
Obstetric forceps are fenestrated in the largest sense.

Fer'men-ta'tion Bung. One adapted to allow the carbonic acid gas to pass away from the cask or vat, but at the same time excluding the vital air.

Bung, beer (Fig. 27), Austria, * "*Engineer*," l. 303.
Vat, article "*Bière*" . . . * *Laboulaye's* "*Dict.*," etc., i., Fig. 229.

Fer'ro-chrome. The invention of Berthier. Chromium augments the hardness and tensile resistance of iron, but cannot take the place of carbon.

Chromized steel is manufactured in Brooklyn from Baltimore chromite as follows: The pulverized ore, mixed with charcoal dust, is fused with a suitable flux, in graphite crucibles, to obtain a white chromium alloy, corresponding to that of Berthier, and called ferro-chrome, after the analogy of ferro-manganese. — "*Engineering and Mining Journal.*"

"*Mining and Scientific Press*" . . xxxvii. 178.
"*Iron Age*" . . . . xix., June 14, p. 9.

Fer'ro-man'ga-nese. A mineral compound of iron and manganese, of which spiegeleisen is the most prominent example.

Ferro-manganese ores contain from 5 to 40 per cent. of metallic manganese, and varying quantities of silicon.

As manufactured for steel works, in the Bessemer process, for example, ferro-manganese contains up to 95 per cent. of manganese.

The method used at Terre Noire, for the manufacture of ferro-manganese, is as follows: Metallic iron, finely divided, is well mixed with finely ground manganese ores. This mixture is moistened with a weakly ammoniacal or acid solution, and is pressed into forms. The material thus made is smelted in a blast furnace blown at a high pressure with very hot blast. The ore used seems to be a carbonate of manganese. — *M. Emil Huwaldt.*

Fer'ro-phos'phide. A compound: iron associated with phosphorus.

At the Hörde Works in Germany, instead of blowing gray pig rich in silicon, it was found possible to treat white pig, if it contained a sufficient amount of phosphorus. Far from being afraid of phosphorus, about 2 per cent. of that body is required in the pig, in order to give a sufficient degree of heat to the bath. Hörde has begun to make ferro-phosphide with 20 per cent. of phosphorus, and will presently make this alloy to contain 50 per cent. phosphorus. This will be sold to mix with white pig, since the crude metal must contain phosphorus or silicon enough to carry up the bath to the heat required. At Hörde all sorts of pig, even cinder pig, with 3 per cent. phosphorus and 0.5 per cent. silicon are treated. The presence of 0.2 to 0.3 per cent. sulphur could also, it was found, be tolerated. The steel made contained under 0.1 phosphorus and no silicon. — "*Journal de Liége.*"

Fer'ro Si-li'ci-um. A metallic compound used in steel processes, the Bessemer, for example.

The use of *silicon*, iron ore, and *silicon-pig*, is mentioned in a whole series of patents by Nes, of York, Pa.,

Numbers 104,873,	108,287,

Fer'ry Push-car. A platform car which is made very long and used for pushing or pulling other cars on or off a ferry-boat when the latter must be approached by an incline which is too steep for locomotives. The ferry cars are used to connect those cars which are to be taken on or off the boat with the locomotive, so that the latter can push or pull the cars on the boat without running on the incline. — *Forney.*

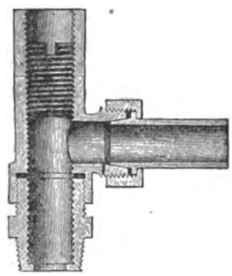
c. Elbow ferrule.
d. Three-way ferrule.
e. Four-way ferrule.

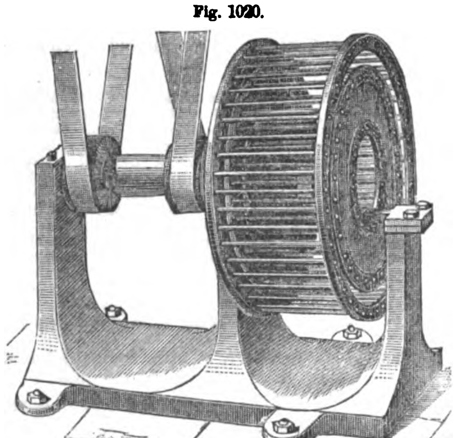
Fig. 1019.



Morris's Stop-valve Ferrule.

Fer'til-iz-er Mill. Fig. 1020 shows a mill for grinding and mixing materials for artificial fertilizers. It is constructed on the principle of the Carr disintegrator.

Fig. 1020.



Fertilizer Mill.

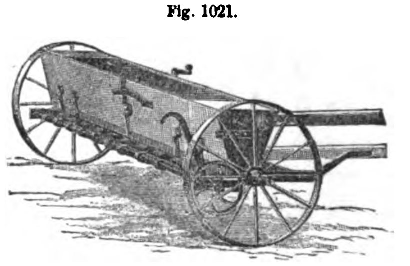
The double operation may be performed with advantage in the machine shown, which is formed of two cylindrical cages of iron bars, which are rotated rapidly in contrary directions. The materials thrown in fragments in at the central opening issue mixed and in a fine powder at the circumference.

See also Bone Mill.

Fer'til-iz-er Sow'er. The machines for sowing dry fertilizers resemble those for sowing grain, and in many cases are combined therewith. See Grain Drill, pp. 1002, 1003, and Wheat Drill, Fig. 7163, p. 2761, "*Mech. Dict.*"

When the fertilizer is long and damp a different mode of discharge becomes necessary. British and French fertilizer sowers are made on the principle of the machine shown in Fig. 1021. It is made by *M. Josse*, of Ormesson, France, and is particularly adapted to damp and deliquescent fertilizers, which are discharged by endless revolving chains passing through the hopper and drawing out the pulverulent material which is disengaged and dropped upon the ground.

Fig. 1021.



French Fertilizer Sower.

See also Liquid-manure Cart, p. 1326, "*Mech. Dict.*"

Fi'ber-faced Pa'per. A means of security against the restoration of the surface of check or draft-paper after it has been tampered with.

It consists in imbedding in the pulp, on one or both sides thereof, a layer of fibers, the outer ends of which are then raised in the form of a nap, confused or intermingled by rotary brushes or other suitable means, and sized to form a surface for printing or writing. — *Anderson.*

Fi'ber Test'er. A means for determining the strength of fiber by dynamometer. See Cloth Tester, *supra*; Yarn Tester, "*Mech. Dict.*"

Fischer	"*Technologiste*," xli. 533
Irlande	"*Technologiste*," xxxvii 28.

Methods of testing to distinguish jute, phormium tenax, flax, hemp, etc., are devised to determine purity of sample. The method of M. Vétillard requires a good microscope, and is as follows: —

The object being a piece of the fiber, is colored according to its nature by means of two solutions: one of iodine, dissolved in a solution of iodide of potassium; the other glycerine, mixed with sulphuric acid, and the process is as follows: —

a. From the tissue, perfectly washed, lixiviated, and cleared of all impurities, threads are drawn from warp and weft, and are observed separately.

b. Dip the thread in the iodic liquid, and dry it with a piece of linen, or, better still, white blotting or filtering paper.

c. Lay it on a piece of glass, such as is used for microscopic observation, and divide and spread out the fibers with the aid of the point of a needle.

d. Place another glass on the fibers, set the whole in the microscope, and then introduce a single drop of the sulphuric solution between the two pieces of glass, and observe the color which the fibers assume when the acid touches them: flax turns blue, mixed more or less with yellow; hemp, green, mixed with gray; jute and phormium, yellow; China grass, gray; flat-rib of gray-blue color. With a little practice of this method it is easy to see the difference between jute and phormium on the one hand, and flax and hemp on the other, which is of itself of great importance when there is a question of adulteration; but it is very difficult to distinguish jute from phormium and flax from hemp, as, according to the manner in which they have been prepared, they assume each other's tints, or so nearly as to deceive the eye. By means of nitric acid, in which the fibers are steeped, the distinction between flax and hemp and jute and phormium is clearly shown, the former not being affected at all, while the latter takes a fine red tint.

Testing Mixed Silk and Wool.

If a piece of tissue of mixed wool and silk is plunged in hydrochloric acid, the silk is soon dissolved, while the wool remains, so that by careful weighing before and after the operation, the proportion of the two fibers is easily ascertained. See also SEPARATOR, 5, p. 2094, "*Mech. Dict.*"

Field Cam'e-ra. See CAMERA.

Field Gun. A transportable gun for operations in the field. See CANNON; also:—

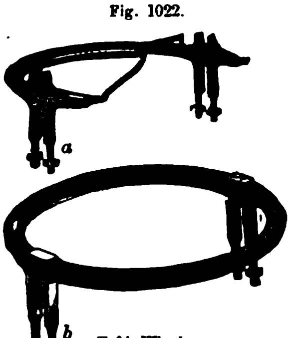
Field Rol'ler. See CLOD CRUSHER; ROLLER.

Field Tel'e-graph. A military telegraph, for use in field operations.

Wire wagon and barrow .	"*Telegraphic Journal*," viii. 121.
	"*Scientific Amer. Sup.*," 1815.

Fifth Wheel. A wheel or segment above the fore-axle on which the bed swivels in turning the carriage.

Fig. 1022.



Fifth Wheels.

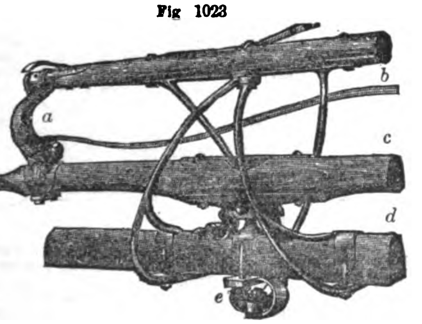
Fig. 1022 shows two forms: one full-plate and one part-plate.

Fig. 1023 is the Dexter fifth wheel, which is so constructed as to steady the axle by three centers: one under the upper spring bar, one about the clip king-bolt, and one under the axle.

a. Larkin's anti-rattler fifth wheel.
b. Full circle fifth wheel.

Fifth'-wheel True'ing Plate. A swage-plate with a number of circles of varying diameter on which fifth wheels are made true by hammering. See Fig. 1024.

Fig 1023



Dexter Fifth Wheel.

a. Spring link. *c.* Head block.
b. Spring bar. *d.* Axle.
e Lower center

Fight'ing Lan'tern. A lantern for ships of war, having a revolving shade to instantaneously screen the light, if required. That shown in Fig. 1025 is the British Admiralty pattern, made to burn candles.

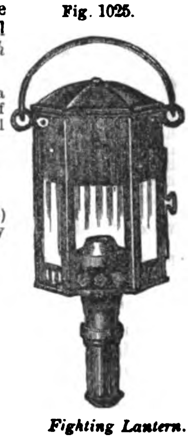
Fig'ure-of-8 Knot. (*Nautical.*) A form of knot. See 7, Fig. 2777, p. 1240, "*Mech. Dict.*"

Fi'lar Sus-pen'sion. (*Electricity.*) Said of a magnetic needle, which is suspended by a filament of silk, as distinguished from one poised on the point of a stud.

Bi-filar suspension is when the needle is suspended by two slightly separated extremely delicate filaments of raw silk, by which the needle is caused to more promptly resume its normal position; *i. e.*, is given a normal tendency to zero.

File. Files have been made of separate pieces of steel clamped together. — *English "Ironmonger,"* 1880.

Fig. 1025.



Fighting Lantern.

Mentioned also by Kirkwood at a meeting of the Royal Scot. Soc. of Arts. Shown, however, in several American patents.

Harston . . .	Jan. 19, 1858.

File Card. A tool for cleaning the metallic dust out of files. It is a section of card clothing, such as is used in carding-machines for wool or cotton.

File Guard. A grooved wooden holder in which a file is inserted, so that the file may be used without abrading the fingers. * "*Scientific American*," xl. 131.

File Hold'er. A helve for a file.

See FILE CARRIER, Fig 1966, p 841, "*Mech. Dict.*," and * "*Scientific American*," xxxix. 117.

Fil'i-form Bou'gie. (*Surgical.*) One of the most delicate (hair-like) proportions.

Fil'ing Vise. A clamp in which a saw is held while being filed. See VISE; also BAND-SAW SETTING AND FILING MACHINE.

Fil'ter. See list on p. 846, "*Mech. Dict.*"

Adolph Le Tellier's filter, made at St. Gilles, near Brussels, has a raised bottom in which are inserted a number of removable vertical tubes, with perforated walls, and with handles at the top. These tubes are surrounded with flat felt filtering rings, through which the liquid must pass before escaping through the perforations in the tubes. The supply-pipe has a compression shut-off, actuated by a float and lever.

Weiskopf, of Morchenstern, Bohemia, employs spun glass as a filtering material.

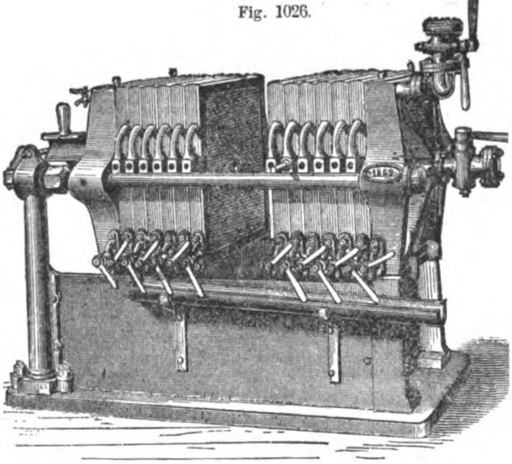
Fil'ter Press. (*Sugar Manufacture.*) One in which the liquid is pressed from a mass — beet-root-pulp in the present instance — and the solid portion retained by a straining device.

The Farinaux press, shown in Paris, 1878, has a series of gridiron-shaped frames, the faces of which are covered with a filtering surface of linen or jute cloth. These frames are arranged parallel to each other upon a strong support, and are brought into close contact by means of a screw-press fixed to one end of the support. The material to be filtered is forced between the frames through a passage along the side or through the center, and distributes itself over the filtering surface; the liquid portion, finding its way into

Fig. 1026.



Farinaux Filter Press.

the interior of the frame, is drawn off at the bottom by means of a stop-cock attached to each one, while the solid portion is held back between the filtering surfaces. When the press is fully charged, the pressure holding the frames together is removed, the frames separated, and the pulp allowed to fall into a recipient underneath. If necessary, the cloth is cleaned by means of a rush.

Fin'ger Mir'ror. A small mouth-mirror attached to a finger clasp; used by dentists.

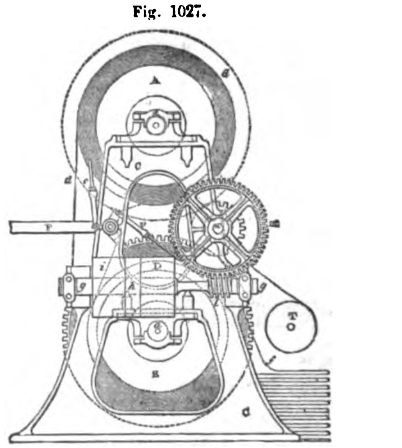
Fin'ger Steel. (*Leather.*) A steel instrument like a skewer or awl used for restoring the edge of the currier's knife while in use.

Fin'ger Tray. A small pan attached by a clasp to the finger; used by dentists for carrying amalgam or plastic filling.

Fin'ish-ing Press. A machine for pressing fabrics.

A and *B* are steam drums having toothed wheels acted upon by cam wheels on the shaft *n*, which is turned by an endless screw and toothed wheel, receiving their motion from a belt and pulley. The cam wheels turn the drums in oppo-

Fig. 1027.



Houston's Cloth Finishing Press.

site directions; one cam wheel only works at a time, the drum not acted upon by the cam wheel being carried along by the friction pulley. Thus the operator is enabled to change the motion of the drum as often as necessary. From the drum *A* to the drum *B* a long sheet or band of copper or steel extends, and alternately winds and unwinds round both drums, carrying the goods along. The fabric is unrolled from a cylinder, *T*, moved solely by the tension of the goods as they are rolled on the cylinder *B*. The copper band is heated on the cylinder *A* and catches in descending the sheet of fabric, and rolls up along with the same on the cylinder *B*. Thus the entire surface of the goods comes in contact with the heated metal, and is equally exposed to the pressure exerted by the concentric sheets of copper. The goods are not strained, but subjected to heat and pressure only, removing all folds. — *Musée de l'Industrie.*

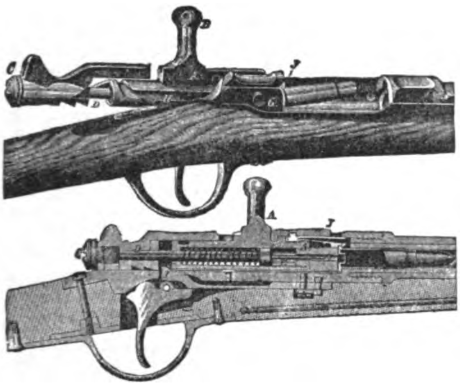
Fire Arm. Fig. 1028 shows the new service gun of Capt. Gras, adopted for the French army.

The upper figure shows the piece in the position as the cartridge is being extracted, and the lower figure as it is ready

Fig. 1028.



The Gras Rifle. The French Service Arm.

to fire. *A* is the movable breech piece operated by the lever. *C* is the dog, at the end of which is a button, to which the rod *D* of the firing pin *E* is attached. *F* is the coiled spring, which throws the pin forward. For loading the gun, the parts are drawn back as shown in the upper figure. The cartridge is inserted and the bolt *A* by the lever *B* is drawn forward. While this is being done, a stop, *G*, enters a cam groove, *H*, in the side of the bolt *A* so that the latter is forced to turn as it is brought forward. In the lower figure it will be noticed that the notch on the dog *C* is almost in contact with the spring stop *I* governed by the trigger. By pulling on the latter, this stop is withdrawn, and the needle is thrown forward by its spring, striking and exploding the cartridge. At *J* is the extractor, the part containing which, though drawn back, does not turn with the movable breech, so that the spring hook always grasps the rim of the cartridge case from above. With this gun it is stated that 45 shots can be fired in three minutes, effective at a range of 5,120 to 5,440 feet.

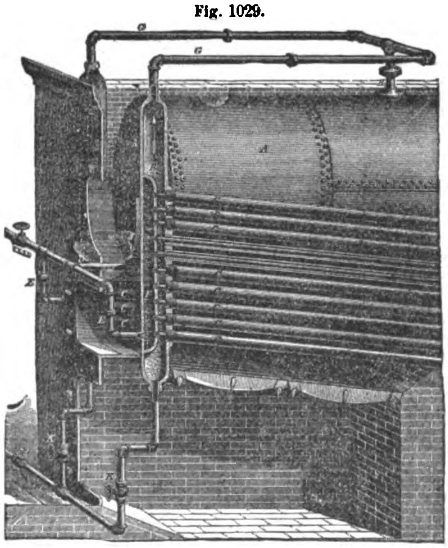
Fire Box. The chamber of a furnace. In the instance shown in Fig. 1029, the sides of the furnace are made up of, or rather lined with, flat congeries of pipes, which act as feed water heaters. Known as *economizers*. See FEED WATER HEATER; FUEL ECONOMIZER; HOT BLAST APPARATUS; REGENERATOR, etc.

Fire boxes in the present instance consist of two sections. each made of ten wrought-iron tubes, *C*, 3″ diameter and 10′ long; one end of each of these tubes is secured to a larger

Fig. 1029.



Fire-Box and Economizer.

chamber *B*; the other end is closed with a cap and reaches beyond the bridge-wall. The chamber *B* is divided by partition *F*, and into this partition ten brass tubes are secured which are open on both ends and reach to near the end of the iron tubes beyond the bridge wall. When two of these sections are placed one on each side of a boiler, and the top of chamber *B* is connected with the top of the boiler by means of the pipe *G*, and a water connection is made with the lower part of the boiler and the section by the pipes *D* and *E*, then the water from the boiler will flow through the ten brass tubes to the end of the iron tubes, and when fire is applied the steam will rise through the space between the brass and iron tubes into the chamber *B* and through the pipe *G* into the boiler, producing a rapid circulation, not only in the tubes but also increasing the circulation in the boiler.

Fire Brick. Usually made of silica and refractory clay, with a small proportion of cementing material.

Some fire bricks are made into which clay does not enter as an ingredient.

In England quartz is ground and freed from iron by sulphuric acid. It is considered better than sand. In Wales bricks are made of ground quartz with one per cent. of lime and water sufficient. The brick is pressed in iron molds, and the lime acts as a flux to cement the quartz.

The composition of good fire bricks is indicated by three analyses: —

Carter County, Kentucky, Clay.

Silica	45 to 64
Alumina	23 to 43
Oxide of iron, a trace.	
Lime, a trace.	
Potash	0.212 to 2.098
Soda	0.283 to 0.728

Belgian Fire Clay.

Silica	64.2
Alumina	32.2
Oxide of iron	2.4
Lime	0.0
Alkalies	1.2
	100

Clays of Forges-les-Eaux and Ardennes, in France; Belgium; Stonebridge, England; Klingenberg, Germany, vary between the following proportion: —

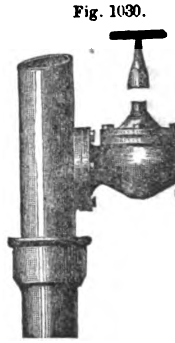
Silica	64 to 71
Alumina	22 to 38
Oxide of iron	0.2 to 4
Lime	trace to 1
Alkalies	trace to 1

Fire bricks, see on, "*Blake's Reports on Ceramics*," "*French Exposition* (1878) *Reports*," vol. iii., 215 *et seq.*

Fire bricks, *Dunnachie* on, "*Van Nostrand's Mag.*," xvi. 6.

Fire Cock. A cock attached to a stand pipe in a building, one cock to each floor, and having a hose attached capable of reaching any part of that story of the building, or the part destined to be within range of that particular stand pipe. In the illustration the apparatus has a cap to be removed and the hose coupling attached.

Fig. 1030.



Fire Cock.

Fire-damp' A-larm'. One for automatically giving notice of presence of fire-damp in a mine.

See also FIRE-DAMP DETECTOR.

Fire-damp' De-tect'or. An instrument for detecting the presence of proto-carbide of hydrogen in a mine. Coquillon's test for quantity is considered under GRISOUMETER.

Forbes's test for presence is founded on the facts that sound travels quicker in light gases than in denser ones, and that air containing fire-damp is lighter than pure air. The instrument detects 0.5 per cent. of impurity.

The test for fire-damp by the observation of the blue fringe of the Davy safety-lamp is only practicable where the atmosphere contains at least 3 per cent. of the explosive gas. M. Galloway has shown that 0.75 per cent. is explosive in presence of fine coal-dust.

MM. Mallard and le Chatelier propose a safety-lamp in which a jet of hydrogen gas is burned instead of the ordinary oil. The flame is hot, gives but little light, and in burning the explosive gas elongates and exhibits freely the blue fringe. 0.25 per cent. is detectable by this means.

Another instrument by Prof. Forbes for detection of fire-damp consists of a resonator of variable dimensions and a tuning-fork of definite pitch. The resonator is a metallic tube, 1″ in diameter and 14″ long, in which a piston slides, so as to regulate the length of the tube. This tube is fixed to a block of wood, to which is attached a tuning-fork whose points are just above the open end of the tube. The tuning-fork is sounded and the piston is moved until the proper length is found, which is indicated by the resonator intensifying the sound of the tuning-fork. Barometric pressure produces no difference on the instrument. The temperature correction is made by reading off a thermometer of the proper dimensions instead of reading off a fixed mark on the piston. The only error is by the presence of dense carbonic acid gas, but the carbonic acid gas tends to destroy the explosive character of fire-damp, and it appears that if the presence of carbonic acid prevented the instrument from indicating fire-damp it would certainly be sufficient to prevent the explosive character of fire-damp.

See also GRISOUMETER; FIRE-DAMP PHOTOMETER.

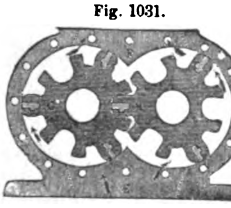
Fire-damp Me′ter. An instrument for determining the amount of proto-carbide of hydrogen in a mine. Coquillon has contrived several forms: one for use in a mine and the other for the laboratory. Both depend on the principle that hydrogen and its gaseous carbides are completely burned in presence of oxygen and a palladium wire heated to white redness See GRISOUMETER.

Fire-damp′ Pho-tom′e-ter. An apparatus by Liveing, of London, for the detection of the presence of proto-carbide of hydrogen in air. It acts upon the principle of using the electric current for causing the combustion of the fire-damp and a photometer for observation of the luminous intensity.

A platinum wire rendered incandescent by the passage of an electric current, is more brilliant in air contaminated with the fire-damp, and proportionally so by increasing the quantity of the proto-carbide. The comparison is made by the photometer of the incandescent wire in pure air and the wire in mixtures of definite proportions of air and fire-damp, and thus a scale is obtained. — "*Transactions Physical Society of London.*" "*Scientific American Supplement,*" * 4030.

Fire En′gine. The Silsby fire engine, Plate XV., has a steam rotary pump, shown in section in Fig. 1031. The boiler is tubulous and vertical, and is shown in Fig. 1032. The engine and the pump are substantially similar, in the former case, however, the pressure of steam drives the three-toed pistons, and in the latter, the pistons drive the water. Steam piston and pump pistons are coupled and connected. The boiler, shown in Fig. 1032, has depending tubes and vertical flues giving a large heating surface. One of the water tubes is shown separately at the left of the boiler. Plate XV. shows the complete engine.

Fig. 1031.



Silsby Fire Engine Pump.

The La France steam fire engine also has the rotary principle.

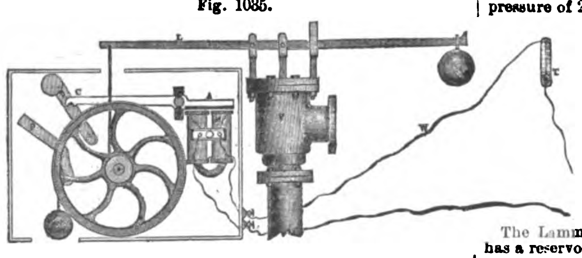
Fire Ex-tin'guish-er. The subject of the portable or fixed apparatus, for projecting carbonic acid gas and water upon a fire, is considered on pp. 866, 867, "*Mech. Dict.*," including a reference to Sir William Congreve.

The larger apparatus, mounted as fire engines, are now in use in our cities, known as the Babcock Fire Engine.

Fig. 1035.



Fire Extinguisher for Mills.

The Anderson & Proctor apparatus, shown in Fig. 1035, is especially intended for mills, and is automatically operated through the medium of electricity, as described in § c, Fire Alarm, p. 849, "*Mech. Dict.*" Thermometers are placed freely at different parts of the establishment, and the raising of the mercury in either to a certain height completes a galvanic circuit, and opens a valve connecting by pipes with the special department from which the alarm proceeded and flooding it with steam.

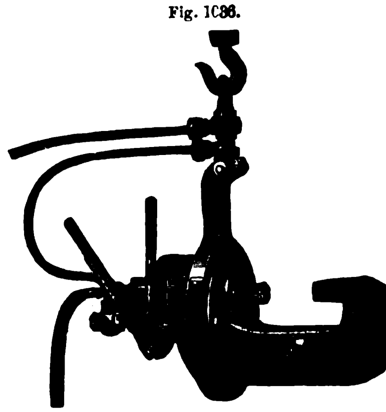
Fire'-hole-ring Riv'et-er. The portable hydraulic riveter, for fire-hole-rings, originally designed by Tweddell for the special purpose of riveting up locomotive fire-hole door rings at Crewe.

The gap is 3.5″ when intended for locomotive work, and 5″ to 6″ when used for riveting on marine boiler front and back end plates.

This riveter is centered in a toothed wheel, which is put in

Fig. 1036.



Fire-hole-ring Riveter.

motion by a pinion, and the machine thus revolves in a vertical plane on its own center and in a very small space. A swivel joint between the outer rock and the suspending chain allows the riveter also to revolve freely in a horizontal plane.

The machine exerts a force of 33,000 foot pounds at each stroke, weighs 400 pounds, and can make 20 to 30 strokes per minute.

Fire'less Lo-co-mo'tive. A locomotive for street railways. That shown was designed for the Crescent City Railroad Company, of New Orleans, by Scheffler. Plate XV.

It has a cylindrical tank 31″ in diameter and 9′ long, with a capacity for holding 300 gallons of water, which is charged into it from a stationary boiler at a temperature due to a pressure of 220 pounds per square inch = 390° Fah. With this charge it runs about 6 miles, the pressure being down to about 40 pounds at the end of the run.

The driving wheels are 30″ in diameter, and the leading wheels 20″, with a wheel base of 5′ 7″. The cylinders are $4\frac{1}{2} \times 10''$. The valve gear consists of a main valve, which works full stroke at all times, and controls the exhaust, with a steam valve on top worked by a link, which governs the admission. Both valves are, however, worked by the same link. The weight of the engine, with the tank full of water, is 8,700 lbs.

The Lamm & Francq motor, used on the Paris Railways, has a reservoir containing 1,800 liters of water at 400° Fah.

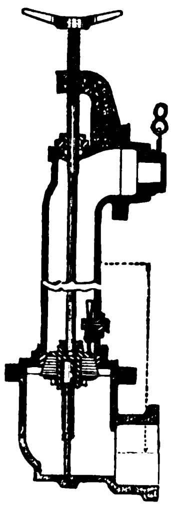
Fire Plug. A device for connecting street mains with suction pipe of fire engine, or with hose for street watering or fire purposes. Used also in factories and large establishments of various kinds. See also FIRE COCK.

Fig. 1037.



Fire Plug (section).

Fire Pot. A solderer's furnace.

Fire-proof'ing. See following recipes and references: —

Wood: Follachi's plan. Place the wood on gratings and separated in a close vessel. Pump in following solution and boil.

Sulphate of zinc, 55 lbs.; potash, 22 lbs.; alum, 44 lbs; oxide of manganese, 22 lbs.; sulphuric acid of 60°, 22 lbs.; water, 55 lbs.; all of the solids are to be poured into an iron boiler containing the water at a temperatnre of 45° C., or 113° Fah. As soon as the substances are dissolved the sulphuric acid to be poured in little by little, until all the substances are completely saturated.

Theatrical scenery: boracic acid, 5; sal ammon., 15; potassic feldspar, 5; gelatine, 1.05; size, 50; water, 100.

Fabrics: In 14 parts of water, heated to 180° Fah., dissolve 10½ lbs. gelatine and 21 lbs. castor-oil soap. Then add 10½ lbs. gum lac, shaking the liquid until the last is completely dissolved. Remove from the fire, and add in small quantities 21 lbs. powdered alum until the alum dissolves. This forms an insoluble alumina soap, closely incorporated with the gelatine and the gum lac. Apply with a brush.

Cloth: Apply tungstate of soda.

Or: a solution of 4 parts borax and 3 of sulphate of magnesia, which precipitates an incombustible and insoluble compound, the borate of magnesia, in the fibers.

Or: phosphate of ammonia, 5 per cent solution.

Or: solution of acetate of lime and chloride of calcium.

Or: sulph. amm. and sulph. calcium.

Or: 5 per cent. phosphate of amm. and 5 per cent. alum. Requires reimpregnation after washing.

Or: for cloth, 8 parts, by weight, of sulph. amm.: 2.5 parts carb. ammon.; 3 parts boracic acid; 1.7 borax; 2 parts starch in 100 water.

Canvas or cordage, wood or straw: 6 parts boracic acid; 15 parts sal amm.; 3 parts borax in 100 parts water.

Paper: 8 parts sulph. amm.; 3 parts boracic acid; 1.7 parts borax. Applied at 122° Fah.

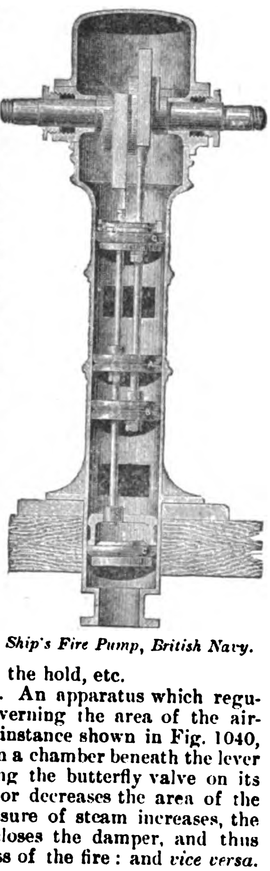
Fire Pump. A pump designed to be used for extinguishing fires.

The Stone pump, shown by two sectional views taken in planes at right angles to each other (Figs. 1038, 1039), is the favorite pump in several European navies. The pump has three pistons, operating one above another in a single cylinder placed on the deck of a vessel and worked by hand cranks. The operation of the pistons is by a two-throw crank, and the suction pipes connect with either of six different parts of the vessel. The same pump may be used to draw water from the ship's reservoir; from a barge alongside to replenish reservoir; from the sea to wash decks or extinguish fire; bilge water from the hold, etc.

Fig. 1038.



Ship's Fire Pump, British Navy.

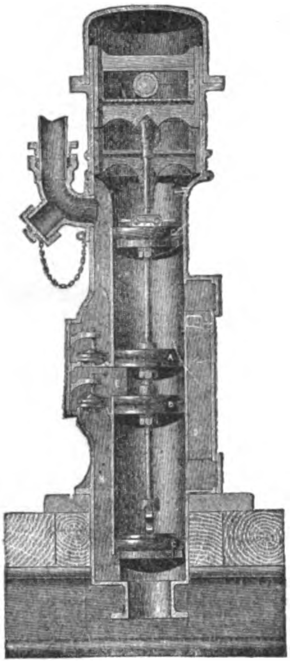
Fire Reg'u-la'tor. An apparatus which regulates the draft by governing the area of the air-duct or flues. In the instance shown in Fig. 1040, the pressure of steam in a chamber beneath the lever has the effect of turning the butterfly valve on its axis, and so increases or decreases the area of the duct. When the pressure of steam increases, the lever rises, partially closes the damper, and thus moderates the briskness of the fire: and *vice versa*. — *Le Van.*

Fish Cul'ture. A number of the devices used in modern fish culture may be reached by means of the following list of United States patents: —

No.	Inventor. Invention.
68,871	*Green*, A wire bottom box anchored. Inclined, to keep water flowing in at bottom.
72,177	*Drexler*, A pen to inclose crabs, turtles, etc.
78,952	*Furman*, Spawn chamber and receiver for young fish.
80,775	*Smidth*. Air pumped through the sea water in chamber.
105,176	*Collins*, A collecting screen beneath the spawning box.
116,112	*Stone*, Box carbonized on inside.
116,995	*Sabin*, Fish nursery. Spawning boxes.

No.	Inventor.	Invention.
136,834	*Holton*,	Spawn trays with upward current.
148,035	*Clark*,	Hatching trays with artificial current.
149,198	*Clark*,	Eggs preserved in layers of moss in refrigerator.

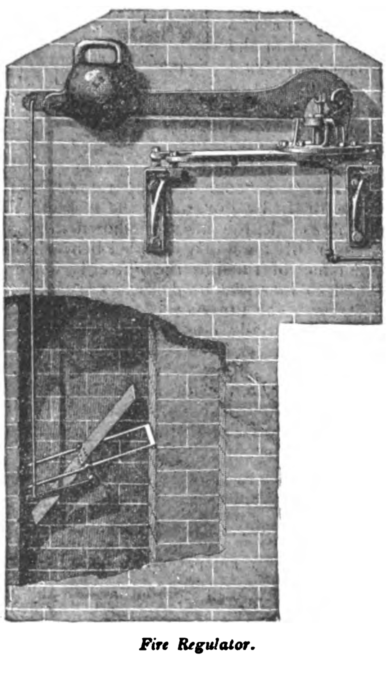
Fig. 1039.



Ship's Fire Pump.

151,080	*Bryan*,	Floating anchored hatching box.
160,002	*Bond*,	Spawning trays and egg collectors.
166,413	*Roth*,	Egg basket and containing box in current.

Fig. 1040.



Fire Regulator.

178,262	*Brackett*,	Hatching box with wire-netting bottom.
180,085	*Wilmot*,	Ova suspended in receptacle by upward flow.
199,527	*Ferguson*,	Ova in vessels mechanically agitated.
207,333	*Wright*,	Hatching box floats and its agitation lifts valves in the bottom and causes upward flow of water.

Fish Hook. The general run of the line of invention in this class may be gathered from the following list of United States patents: —

No.	Inventor.	Subject of invention.
6,207	*Johnson*,	Spring-hook: 21 kinds of hook and modes of attachment.
7,709	*Warner et al.*	Spring-hook.
8,853	*Buels*,	Trolling-hook.
10,771	*Buels*,	Spring-hook.
10,761	*Siglers*,	Combination spring-hook.
13,081	*Cook*,	Spring-hook.
13,?68	*De Saxe*,	Trolling-hook. A spring shield covers the point of the hook when fishing among weeds.
13,649	*Johnson*,	Spring-hook.
14,706	*Buels*,	Fly or trolling-hook.
17,803	*McLean*,	Self-setting trap-hook.
25,507	*Haskels*,	Trolling-hook.
31,396	*Morris*,	A spring draws the bearded points together into the fish.
43,694	*Leinhart*,	A trigger raises hooks which transfix the fish.
44,368	*Gardner*,	Spring-hook.
50,799	*Crandell*,	Combination double-lever hook.
51,651	*Davis et al.*,	Spring-hook.
59,814	*King*,	Spring-hook.
59,893	*Crosby*,	Fish-hook (flattened in bend).
51,951	*Livermore*,	Wire loop to prevent fish from stealing the bait.
54,251	*Johnson et al.*,	Spring or spear-hook.
54,684	*Chapman*,	Trolling-hook, with spring and fly.
58,404	*Goodwin*,	Spiral spring around the hook to press the bait down to point.
60,786	*Rhodes*,	Spring-hook, spinner.
62,042	*Lee*,	The shank made in form of spiral spring.
68,027	*Angilard*,	Lever-hook, and striking-hook to fasten the fish.
70,868	*Leinhart*,	Spring-hook.
70,913	*Sterling*,	One hook on swivel to hold bait, the other to grapple the fish while pulling from the water.
69,221	*Kidders*,	Spring-hook. Two hooks, separate when the fish bites.
77,365	*Fish*,	Hook.
79,446	*Christian*,	Trolling-hook, with artificial bait.
80,151	*Dennett*,	Spring-hook.
86,154	*Heltz*,	Hook, with an eye to attach hook.
94,393	*Kemlo*,	Lock-hook.
94,894	*Kemlo*,	Lock-hook.
94,895	*Kemlo*,	Grapple-hook, with guard to prevent fish from getting loose from barb.
95,755	*Angers*,	Three hooks. When the middle hook is pulled, it loosens the outer hooks, which expand in the mouth of the fish.
104,930	*Chapman*,	Propeller or trolling-hook.
111,898	*Arnold*,	Mode of attaching hook to line.
115,434	*Chapman*,	Propeller or trolling-hook.
117,719	*Arnold*,	Mode of attaching hooks to lines.
121,132	*Mann*,	Trolling spoon-hook.
123,844	*Sinclair*,	Trolling-hook.
129,058	*Pitcher*,	Hook, with double spear, to thrust into fish.
139,180	*Mullaly*,	Artificial fly, hook concealed by the wings.
141,910	*Allen*,	Hook has quadruple bends.
143,146	*Harper et al.*,	Trolling-hook with oppositely revolving spoons.
146,443	*Fitzgerald*,	A squid jigger, with a ring of prongs.
146,764	*James*,	A spinning-squid, with fins which revolve it.
148,926	*Cahoon*,	A mackerel jig, the hook secured in a socket.
149,123	*Hazzard*,	A trolling-spoon fish shaped.
151,394	*Huard et al.*	A spring fish-hook is inclosed in the artificial fish.
153,854	*Skinner*,	The spoon is corrugated to make it more attractive.
157,480	*Perry*,	Hooks spring outward when bait is touched.
163,930	*Dunlap*,	Secondary spring-hook strikes the fish.
167,784	*Pierce*,	Two spoons, position controlled by springs.
171,697	*Place*,	Squid jigger, with a circle of prongs.
171,768	*Buel*,	Duplicate spoon fishing-tackle.
171,769	*Buel*,	Spinning-tackle; adjustable spring-hook on sliding ferrule.
177,639	*Hill*,	Spoon can move along the wire.
181,308	*Brush*,	Float attached to the shank of the troller.
184,627	*Jones*,	Swivel attachment for lines.
185,914	*Gregg*,	Artificial worm of rubber.
186,134	*Jahne et al.*,	A leader swiveled to the line and having two snoods.
189,805	*Smith*,	A circular system of pivoted hooks sprung inward.
190,222	*King*,	A pair of spring-hook claws.
191,165	*Miller*,	A supplementary pivoted spring-hook.
196,648	*Edgar*,	A tongue or mousing extending to the barb.
199,926	*Mitchell*,	Plunger driven into the mouth of the fish.
208,581	*Falvey*,	Rubber crawfish bait on an adjustable hook.
211,996	*Hill*,	Arrangement of movable spoon guide and rod.
218,345	*Wakaman*,	Artificial revolving minnow, with hooks.
223,194	*Vaché*,	Trigger and spring to jerk the hook.

Fish'ing and Whal'ing. The following list embraces the heads under this class: —

Accumulator.
Anchored net.
Aquarium.
Axe.
Babiche.
Bag.
Bag-net.
Bait, artificial.
Bait box.
Bait cutter.
Baiting needle.
Bait knife.
Bait mill.
Bait-mill knife.
Bait net.
Baleen.
Baleen knife.
Banner netting.
Bar net.
Bar weir.
Becket hitch.
Blubber fork.
Blubber hook.
Blubber knife.
Blubber mincing machine.
Boarding knife.
Boat hatchet.
Boat knife.
Boat spade.
Bob.
Bomb harpoon.
Bomb lance.
Bottom-set line.
Bowl.
Bull net.
Casting net.
Cast net.
Check stop.
Check knife.
Chopping knife.
Clam hook.
Clam knife.
Clamms.
Clap net.
Clearing ring.
Collecting seine.
Cork line.
Crab net.
Crib.
Cutting spade.
Dip net.
Dipping wheel.
Disgorger.
Drailing tackle.
Drails.
Dredge.
Dredging tube.
Drift net.
Drop net.
Eel bob.
Eel pot.
Eel spear.
Fatting knife.
Finning knife.
Fish-breeding apparatus.
Fertilizer.
Fish apparatus and processes for oil and manure.
Fish cutter.
Fisherman's knot.
Fish grapple.
Fish-hatching apparatus.
Fish hook.
Fishing line.
Fishing line reel.
Fishing net.
Fishing rod.
Fishing torch.
Fish knife.
Fish nursery.
Fish preparing and preserving.
Fish slide.
Fish spear.
Fish transporting carriage.
Fish trap.
Fish-way.
Flitching knife.
Float.
Fly-hook.
Folding net.
Fyke net.
Gaff.
Gear.
Gill-net.
Grains.
Grapple hook.
Grappling gear.
Grappling tongs.
Gun harpoon.
Gunwale winch.
Half-round spade.
Hammock net.
Handle net.
Hand line.
Harpoon.
Harpoon gun.
Hatching box.
Haul seine.
Head axe.
Heading knife.
Head knife.
Head spade.
Heart.
Heart net.
Heart seine.
Hook.
Hook net.
Horse net.
Ice chisel.
Ice chopper.
Ichthyocolla.
Isinglass.
Jack-lamp.
Jerk net.
Junk hook.
Lance.
Lance hook.
Landing gaff.
Landing net.
Land line.
Leader.
Latch.
Lever hook.
Lily iron.
Line (varieties, see list).
Line-hook.
Lint.
Lip hook.
Lock hook.
Mackerel latch.
Mackerel plow.
Mesh.
Meshing net.
Meter.
Mincing knife.
Mincing machine.
Mincing spade.
Minnow propeller.
Net (varieties, see list).
Net machine.
Net-maker's knife.
Oyster culture.
Oyster dredge.
Oyster knife.
Oyster rake.
Oyster tongs.
Pew gaff.
Pisciculture.
Pocket net.

Pot.
Pound.
Pound net.
Probing awl.
Projectiles.
Propeller.
Purse net.
Purse seine.
Reel.
Ripping knife.
Rocket harpoon.
Scaling knife.
Scoop net.
Seaming.
Seine.
Seine windlass.
Set line.
Sheath knife.
Sheave block.
Sinker.
Skim net.
Slivering knife.
Snood.
Spade.
Spawning screen
Spear.
Spilliard.
Spinner.
Splitting knife.
Spoon.
Spoon bait.
Spring hook.
Spring net.
Squid jig.
Squid line.
Stake net.
Swivel.
Tackle.
Throating knife.
Throat spade.
Throwing line.
Tilting net.
Toggle line.
Tongs.
Torpedo.
Towing net.
Trailing net.
Trammel net.
Trap.
Trap net.
Trawl.
Trawl-boy swivel.
Trawling hook.
Trawl line.
Trawl line roller.
Trawl net.
Trolling bait.
Trolling spoon.
Trot line.
Tunnel.
Vat net.
Weir.
Whalebone.
Whaling apparatus
Whaling gun.
Whaling rocket.
Whaleman's knife.
Whaleman's tools.
Whiffling tackle.
Wide spade.
Wing.
Wing net.
Worm.

Fish'ing Line. See LINE.

Fish'ing Line Reel. The following condensed description of United States Patents will give an idea of the general tendency of invention in this line: —

No.	Inventor.	Invention.
854	*Tiffany*,	Rollers for seine line on rail of vessel.
15,466	*Bailey*,	Crank wheel thrown in or out of gear with reel.
16,626	*Deacon*,	Crank wheel thrown in or out of gear with reel.
24,987	*Billinghurst*,	Line winds on a skeleton ring.
27,305	*Palmer*,	Reciprocating line guide, to wind evenly.
41,494	*Dougherty*,	Friction brake to control unwinding.
43,460	*Van Gieson*,	Frictional instead of positive connection between crank and reel.
43,485	*Ellis*,	Crank wheel can be disconnected from reel.
43,546	*Cummings*,	A spring catch and hook to connect reel and rod.
49,663	*Stuart*,	Reel in the handle; line passes through rod; arrangement for winding snug; disconnecting crank and reel.
55,653	*Hatch*,	Skeleton spool for line.
56,987	*Hartill*,	Mode of hanging spool and "drag" on paying out of line.
71,344	*Vom Hofe*,	Arrangement for reel gearing.
78,546	*Stacy*,	An elastic gum nipper for hand lines.
82,377	*Bradley*,	Reel with two concaved disks.
83,740	*Stetson*,	A screw clamp holds the line sheave on the boat's gunwale.
87,188	*Mounier*,	A pivoted clamp holds the reel for the set line. A bell alarms when bait is taken.
88,026	*Foster*,	A mackerel latch; a button and line channel.
95,839	*Ross*,	A skeleton reel.
96,652	*Altmaeir*,	Reel set between two sections of the rod.
103,668	*Sheldons*,	Reel like a kite-string holder.
112,326	*Decker*,	Mackerel latch; a pinch grip beneath a cleat.
121,020	*Terry*,	Frictional device for angler's reel.
128,137	*Fowler*,	Annular reel of hard rubber.
134,917	*Mooney*,	Mode of attaching to rod and operating reel.
135,283	*Noe*,	Fan regulator connected to reel gear.
147,414	*MacCord*,	One reel may be quickly substituted for another.
150,883	*Orvis*,	Perforated disks to allow line to dry.
161,314	*Winans et al.*,	A friction brake to prevent overrunning.
162,845	*McDonald*,	A roller with several grooves on the gunwale.
166,241	*Winslow*,	Reel in the handle of the rod with an outer movable cylinder.
175,227	*Winans et al.*,	Reel cover and spring brake.
177,544	*Noe*,	Brake to prevent overrunning of the line.
191,813	*Philbrook*,	Reel with thin metal sides, and click mechanism.
195,578	*Copeland*,	Reel in the handle, with bevel gears and exterior crank.
214,495	*Dickson*,	Multiplying gearing in the cap.
216,248	*Voss*,	A crank and shaft in the dory to wind trawl lines.
219,328	*Vom Hofe*,	Construction of reel and control of motion.
220,776	*Wardwell*,	Crank can be disconnected from reel; a reciprocating guide for winding line.

Fish'ing Nets. The following condensed description embraces the principal features of the subject: —

647	*Evarts*,	Floating seine extended from boats.
763	*Hale*,	A square net alongside drawn into bag form, to inclose school of fish.
932	*Tracy*,	Seine with bottom and semi-circular sides.
3,004	*Cook*,	Gill-net, submerged Small floats on seine line, and larger on surface of the water.
3,056	*Downs*,	Form for making nets for taking eels.
3,741	*Carr, Shannon & Co.*,	Fyke for eels.
10,794	*De Saxe*,	Landing-net with expansible frame.
20,125	*Hall*,	Seine with bag attached.
20,725	*Merritt*,	Net rigged overboard by booms.
34,887	*Goodwin*,	Leading nets and funnel entrances to slat trap.
39,676	*Randolph*,	Guide nets leading to pounds or shoal water.
55,635	*Field*,	A bag net.
56,917	*Ferl & Larkin*,	A drop net, Fig 3317, "*Mech Dict.*"
59,429	*Maxwell*,	Net, double, with rigid mouth, the inner being a funnel entrance.
62,481	*Crossman*,	Net, attached to side of boat, so as to be lowered or raised. Fig. 3318, "*Mech. Dict.*"
66,669	*Arnold*,	Net fabric
72,177	*Drexel*,	Securing and feeding crabs.
76,284	*Will*,	Gill-net, with rings for sinkers.
76,387	*Bell*,	Net-attachment for boats, with guys to mast, to hoist or lower.
78,716	*Arnold*,	Mode of making nets
80,274	*Collines*,	Perpendicular wooden braces extend below the sinker line.
82,490	*Cartwright*,	Set-net, to be anchored; the boat is attached about midway of the net, and a line is attached to small end of bag, and can be raised and emptied.
82,913	*Allen*,	Eel-pot.
83,493	*Harper*,	Bottom of seine longer than top, large sinkers.
83,429*	*Wilcox*,	Pound net or trap
87,740	*Wardmiller*,	Dip-net
99,713	*Sabins*,	Purse-net, with bait-box, the net stretched on wires similar to umbrella.
113,292	*Hammond*,	Fish-trap net with two hinged flaps.
113,572	*Rider*,	Net-supporter, to swing with the tide
113,817	*Tierman*,	Pound-net.
117,957	*Alexander*,	Bottom seine, with pursing lines.
120,974	*Jeffrey*,	Seine, with pursing lines.
124,635	*Smith*,	Purse seine, with a portion of its circumference depressed below the surface.
132,476	*Lirandais*,	Umbrella-shaped purse-net.
137,930	*Ketcham*,	A leader and heart conducting to a pound.
144,888	*Campbell*,	Stake for seines.
155,140	*Brewster*,	A leader heart and pound towed abaft a vessel.
167,189	*Nason*,	A landing-net.
194,434	*Howes*,	A bottom-net or pocket.
197,313	*Bates*,	A dip-net set on bottom.
215,031	*Webb*,	Pound net. See NET.

Fish'ing Rod. See the following list of United States Patents: —

10,795	*De Saxe*,	Hollow rod contains all the tackle; float has a trigger to jerk the hook.
20,309	*Underwood et al.*,	Tip has a sheave at the end.
25,693	*Pritchard*,	Line leaders on adjustable ferrules on rod.
35,339	*Vom Hofe*,	Sheave on the end of the rod.
58,833	*Isaacs*,	Enamel surfaces to line guides.
72,667	*Montrose*,	Rod has hinged sections and slipping ferrules.
100,895	*Hubbard*,	Parts of the socket are attached to each section, and screw together.
119,251	*Tout*,	Rod of laminæ of wood and whalebone.
137,015	*McHarg*,	Mode of securing the reel plate.
140,655	*Smith*,	Mode of locking the foot of one section in the socket of the other.
142,126	*Senieur*,	A post and socket to hold the foot of the rod.
154,141	*Hill*,	A mode of jointing the sections; a trigger and spring to jerk fish.

164,828 *Graves*, Line passes through center of rod.
169,181 *Leonard*, Mode of constructing the socket ferrules.
170,183 *Perry*, Fishing rod case of light wood, canvassed.
173,534 *Endicott*, Expansible guide and reel bands.
198,879 *Fisher*, Tip formed of a wire helix coiled into tubular shape.
206,264 *Robertson*, The butt is in two parts, one in the other.
207,665 *Leonard*, Split stay strips, to re'nforce rod.
208,500 *Van Altena*, Reel contained in slot of rod. Line check.
222,681 *Earle*, The entering action has a cap which incloses the socket over which it slips.

Fish'ing Torch. Hamline; a ball of cotton is fed by a spout from a reservoir behind the reflector.

Wilson & Keagle; a wire gauze tube filled with asbestos, which forms the wick.

Fish Knife. A great variety of knives is found in use among fishermen, cleaners, curers, and packers of fish; for ripping, heading, crimping, and trimming of fish. Among them are the following: some of them are synonyms: —

Bait knife. For cutting up flesh for bait.
Bait-mill knife. Used on the rollers of bait-mincing machines.
Cheek knife. For trimming cod-fish.
Chopping knife. For mincing bait.
Clam knife. For opening clams.
Fatting knife. Used in creasing the sides of inferior mackerel, to make them resemble No 1 mackerel.
Finning knife. For removing the fins of large fish.
Flitching knife. For slicing halibut, etc., into steaks or flitches, in preparation for salting and smoking.
Heading knife. For cutting off the heads of halibut, or other large fish.
Mackerel Plow. Also known as a *fatting* knife, for creasing the sides of lean mackerel to improve their appearance.
Net-maker's knife. A blade (2″) without a handle, and the heel of the blade curved so as to fit the finger like a ring.
Oyster knife. A stout knife for opening oysters.
Ripping knives. For splitting the fish to remove the viscera.
Scaling knife. For removing scales. Sometimes has a saw edge.
Sheath knife. The fisherman's knife, worn at the belt.
Slivering knife. For slicing the flesh from the sides of fish to be used as bait.
Splitting knife. For ripping, and for halving the fish before salting.
Throating knives. For opening behind the gills, and then ripping the fish. Frequently double-edged.

Fish Nurs'er-y. A place where spawn is gathered and the young fish protected from the ravages of their natural enemies. See FISH CULTURE.

Fish Slide. (*Fishing.*) An inclined box set in a stream at a small fall or ripple to catch fish descending the current.

The open end of the box is presented up stream and the bottom being slippery the fish are dashed to the upper end of the box and scooped with a landing net.

Used in the southern rivers of the United States to supply local demand for fish.

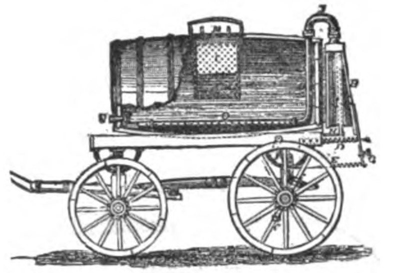
Fish Spear. A lance for bleeding captured whales, etc., or, on a small scale, a *leister* or *gig* for spearing fish from canoes or in holes of streams. See also GRAINS.

Fish Trans-port'ing Car'riage. The transportation of fish and of fish ova is an important consideration in fish culture, and many devices for packing ova and removal of fish from place to place have been devised.

Fig 1043 shows a fish transporting carriage by Haynmerle, of Austria. It consists of a large tank mounted, and with devices by which the running gear is caused to work the bellows and drive a continuous stream of air through the tank to aërate the water. The lever *F*, rod *E*, and spiral spring *D* operate the bellows *B*, forcing air through pipe *T* and distributor *O* into the tank. *M* is an ice tray and *P* a filter. *N*, draw-off cock. *G*, handle for working the bellows when the wagon is at rest. — "*La Nature.*"

See collection in United States Fish Commission Museum, Washington, D. C. Cans, barrels, tanks, force pumps, siphons, aërators, aquaria, bellows, dippers, etc.

Fig. 1043.



Fish Transporting Carriage.

Fish Trap. A device set to catch fish. Snares, pounds, grapples, etc., come under this class. See also NET.

See also, DIPPING WHEEL, *supra.*

List of United States Patents.

3,056 *Downs*, Forming blocks for making eel baskets.
7,709 *Warner et al.*, Spring grapple.
16,014 *Horton*, Spring grab hooks.
16,217 *Van Hosen*, Spring jaws and bait trigger.
20,343 *Garl*, Baited detent and spring nippers.
22,644 *Gray*, Slat cage, with expansible opening slats.
23,154 *Bowman*, Dark chute entrance to trap.
75,075 *Talbot*, Angler's tackle to signal when the fish takes the bait.
76,489 *McCaughan*, Set line with trigger and weight to strike and hook the fish.
77,893 *Koehler*, Set line with trigger and spring.
82,913 *Allen*, Eel pot with funnel of perforated sheet rubber.
85,199 *Beach*, Baited trigger and falling cage.
113,292 *Hammond*, Folding net of basket sections sprung by a line.
123,164 *Fuller*, Float with spring lever to strike when the baited hook is pulled.
131,439 *Harcourt et al.*, Self-closing trap door to cage.
132,476 *Lavaudais*, An umbrella-shaped net closed by trigger and springs.
137,980 *Ketcham*, Pound of net has a funnel entrance and a door to close the entrance.
141,588 *Pavonarius et al.*, Cylinder with semi-circular door sprung by trigger.
156,648 *Peck*, Spring arm to throw baited lines.
178,375 *McRoberts*, Gravitating door lifted by entering fish.
188,503 *Davis*, For fishing in ice-holes; hooked fish makes signal.
198,894 *McBryde*, Swinging gates and mirror for decoy.
201,504 *Davis*, Fish approaching bait press on spring fingers and enter cage.
202,818 *Hesse*, A spring lever to strike fish at the bait.
202,962 *Robertson*, A spring lever to strike fish at the bait, with reel to wind in line.
204,538 *Clark et al.*, Sunken cage with baited trigger and falling door.
215,031 *Webb*, Anchored seine with flaps and pockets.
218,737 *Henderson*, A glass vessel in a trap to hold live bait.

Fishing Electric light under water. Fr. "*Teleg. J.*," iv. 32.
Fishing boats, Berlin Exposition * "*Sc. Am. Sup.*," 3835

Fish'way. The museum of the Fish Commission, at Washington, D. C., affords the best opportunity for study of this subject; and the catalogue of the collection contains detailed information. The devices are capable of classification, as

Gap	Tunnel.
Groove.	Compartmental.
Step	Spiral.
Box or pool.	Moving.
Inclined plane	Partitional.

55,929 *Steck*, A series of inclined planes in vertical series.
57,159 *Livermore*, Inclined series of chambers with tubular connections. Fig. 2003, "*Mech. Dict.*"
126,257 *Brewer*, Zigzag way in bottom of chute.
132,349 *Brackett*, Zigzag chute.
154,216 *Brewer*, Offset boards on bottom of chute.
208,408 *McDonald*, Force of water directed up the chute.
218,299 *McDonald*, Chambers and inclines in chute.

McDonald . . . * "*Scientific American*," xli. 275.
Rogers . . . . * "*Scientific American*," xliii. 22.

Fis'sure Knife. (*Surgical.*) A bistoury used in operations for anal fissure.

Figs. 586, 587, p. 124, Part III., *Tiemann's "Armamentarium Chirurgicum."*

Fis'sure Vein. (*Mining.*) A fissure or crack in the earth's crust filled with mineral matter.

Fis'tu-la Knife. A probe-pointed knife for fistula in ano. *Dr. Kelsey.*

Fig. 1044.

Fistula Knife.

Delicate knives are also made for *fistula lachrymalis*: bistouries also: CANALICULAR INSTRUMENTS are mentioned under that caption on page 157, *supra*.

Fit. In car-axles, that part upon which the wheel is forced.

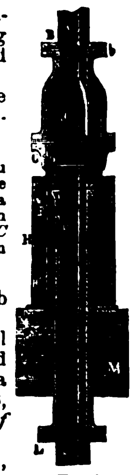
Five Cant File. One for filing M-toothed saws. It has one angle of 108° and two of 36° each.

Fix'a-tion In'stru-ment. (*Surgical.*) A hook or forceps with delicate sharp claws to hold the eyeball steady during an operation.

Figs. 78-80 *d*, Part II., *Tiemann's "Armamentarium Chirurgicum."*

Fixed In'ter-val Reg'u-la-tor. (*Electricity*) A form of polyphote regulator for voltaic arc lamps in which the regulation of the carbons is effected automatically at definitely recurring intervals of time. *Rapieff's* and *Brokies'* lamps are of this order.

Fig. 1045.



Fixed Piston Pump.

Fixed Pis'ton Pump. One in which the cylinder moves, the piston being relatively fixed.

Fig 1045 represents the pump Donnadieu in which the valved piston *D e* is on the summit of the induction pipe *E L K*, on a base *M*. *H* is an outer cylinder in which the skirt *P* attached to the chamber *A B C G*, moves up and down *d* is the eduction valve.

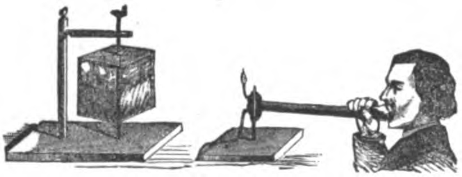
Flake Stand. The cooling tub or vessel of a still-worm.

Flak'ing Ham'mer. A steel hammer, bluntly pointed at each end and used in striking flakes from a flint nucleus. See Fig. 2, p. 18, *Evans' "Ancient Stone Implements of Great Britain."*

Flam'beau-let. A small torch, an allumette.

Flame'less Lamp. A lamp with incandescent spongy platinum. An *aphlogistic lamp*.

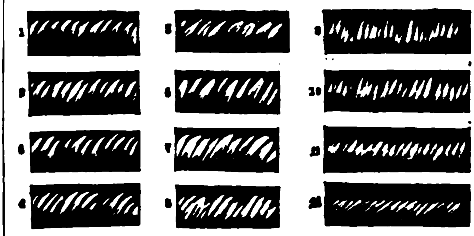
Fig. 1046.



Koenig's Flame Manometer.

Flame Ma-nom'e-ter. An instrument to obtain graphic representation of the condition of the human vocal organ. The invention of Koenig.

Fig. 1047.



Flame Pictures of Healthy and Diseased Voices.

It is composed of a large cube whose four vertical sides are covered with mirrors, and which is revolvable about a vertical axis; of a gas jet, burning with a small flame; and of a mouth-piece which terminates in a lenticular box or capsule. A very thin, tense, and impermeable rubber membrane divides this capsule into two compartments, in one of which the sounding tube terminates, while the other serves as a passage-way for the gas from the conducting tube to the jet at which it is burned.

On singing or speaking into the mouth-piece, sound waves are produced by the alternate condensation and rarefaction of the air within the tube; the rubber membrane acquires a corresponding rate of vibration, and so modifies continuously the rapidity of the delivery of the gas to the burner, causing the gas flame to leap up and down in unison with the sounds transmitted. On rotating the prismatic mirror this but slightly perceptible motion is rendered distinctly obvious, persistence of vision spreading out the image of the flame into a broad serrated band of light.

These serrations vary with the character of the tones produced, as well as the degree of the diseased condition of the vocal chords. In the latter case especially the difference in appearance of the image becomes so striking that a skilled observer can very readily form a correct idea as to the actual state of the vocal organs. The flame pictures shown in Fig. 1047 give some idea of the results: —

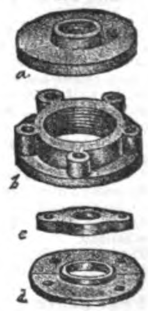
Series 1-4 are healthy notes in different pitches; highest above and the others successively lower.

Series 5-8 are the same in pitch, but with a voice slightly hoarse.

Series 9, 10 are the result of severe hoarseness.

Series 11, 12 are the result of disease, the voice being almost inaudible, glottis open, and the chords scarcely vibrating.

Fig. 1048.



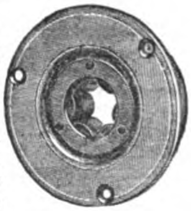
Flanges.

a. Flange.
b. Bossed flange.
c. Oval flange.
d. Collar.

Flange. A plate for covering, or partly closing, the end of a pipe or cylinder.

Flange Bush'ing. A flange carrying a shell which acts as a bushing to a hole. In the example the bushing is for a block sheave and has anti friction rollers.

Fig. 1049.



Flange Bushing.

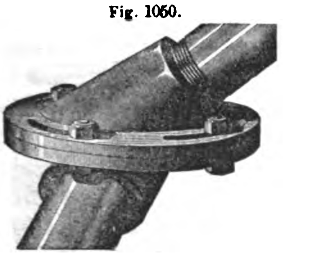
Flange Coup'ling. A device for connecting pipes at any angle from 0° to 90°. It has two circular plates, each flat upon one side and having on the other a short internally-threaded tubular projection, inclined at an angle of 45° to the plane of the plates. The plates are slotted to receive the coupling bolts. Fig. 1050.

Flange Pipe. One having at the end (or ends) an annular projection with holes for bolts, by which it is fastened to a similarly-provided pipe or other object. See Fig. 2007, p. 876, *"Mech. Dict."*

Flange Pul'ley. One with rims to keep the belt from running off. Fig. 1051.

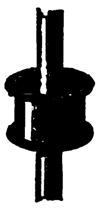
Flan'ging Ham'mer. A machine for turning flanges on sheet-metal for boilers, tanks, furnace-

Fig. 1050.



Flange Coupling.

Fig. 1061

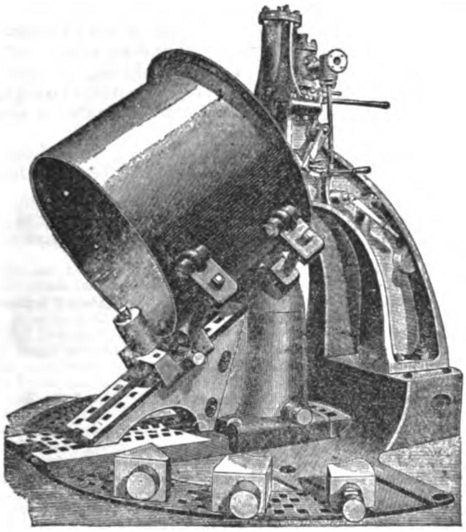


Flange Pulley.

fronts, girders, parts of steam vessels, etc. The machines differ much in size and form, according to the requirements of special work and the size of the object under treatment.

In the machine of Campbell & Hunter, Leeds, England, the flanging block with separate anvil is mounted upon a

Fig. 1052.



Flanging Hammer.

swiveling slide, upon which it can be moved as required. The block has a projecting angular face in front, upon which is carried an adjustable roller or rollers for taking the end thrust of the flues, plates, etc. On each side of the roller carriage are two wrought-iron arms, and two others on each side of the anvil block, each arm having a small runner at the outside end; these arms keep the flue square, and the runners assist it when being turned round. For turning the flue round when flanging, two chain barrels with ratchet motion and sufficient chain are provided; these barrels are fixed in frames upon the foundation plate, one on either side of the flue: the chain is given a lap around the flue and is wound on to the empty barrel as it unwinds from the full one, or the flue can be revolved by hand. Flues up to 4′ in diameter can be done at one heat.

The anvil block is arranged to admit a variety of anvils for flanging end plates up to 15′ in diameter, tube plates, dished crown plates, etc., and for setting back the bottoms of vertical fire-boxes, and the guide block will admit heads to suit.

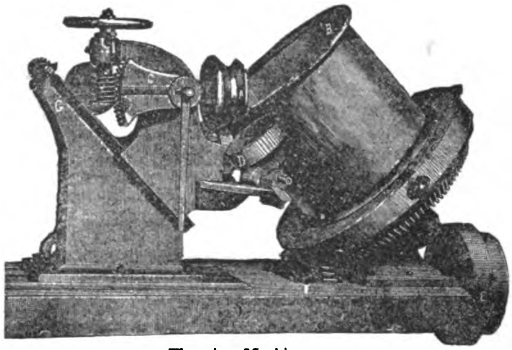
Campbell & Hunter . * "*Engineer*," l 229
* "*Scientific American*," xliii. 854.

Flan′ging Ma-chine′. (*Sheet-metal Working.*) One for making round and oval sunk-head cans, such as are used for packing butter, lard, etc., the heads of such cans being joined to the bodies by a double seam, without solder.

The flanging machine throws out the edge of the body, and the double-seamer closes the top (or bottom) in four movements; but at a single setting of the can, while it is either empty or full.

In Hanson's flanging machine (Br.), the steel roller, *A*, revolves on the end of a segmental rack, its angle of relation to the bending flange of the cylinder *B* being adjusted by

Fig. 1053.



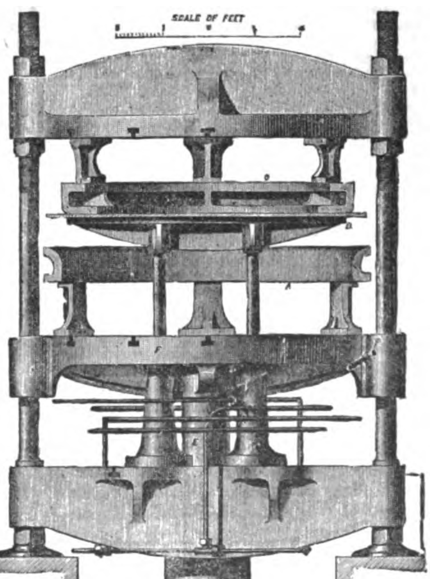
Flanging Machine.

worm wheel. Wheel *A* rotates by friction, and the cylinder by miter gearing from pulley *E*. The distance between the roller *A* and flange *B* is adjusted to suit various thicknesses of plate by means of the slide on the standard *G*, and the miter wheels on its summit. The roller *D* serves to guide and steady the cylinder.

Flan′ging Press. Fig. 1054 represents Piedbœuf's hydraulic press, for flanging, stamping, or straightening boiler plates. As illustrated, the press is arranged for flanging plates.

The plate to be flanged, having been heated, is placed on a ring, *A*, the interior of which is of a form corresponding to

Fig. 1054.



Flanging Press.

that to be given to the plate. This ring *A* is carried on columns which rest on the movable table *F*, this table being raised by the ram *E*, working in the hydraulic cylinder *D*.

The cylinder D is attached to a strong cast-iron frame, which is connected by the four columns to the fixed upper table.

In addition to connecting the upper and lower tables, the columns serve as guides for the moving table E, the latter being furnished with four bushes, which embrace the columns as shown. Four rams in the auxiliary cylinders are run up first, and by means of a table, B, hold the plate about to be flanged against the block C and prevent buckling, and as the table F is raised by the ram of the press, the plate to be flanged is pressed to the shape of block C by the passing over it of the ring A.

Brown, Br. . . . . * "*Engineer*," xlix. 173.

Flan'nel. 1. The first stage in the manufacture of plain cloth.

2. A class of woolen goods of various qualities and finish.

Domett flannels have a cotton warp and wool filling.

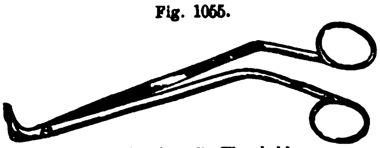
American blue flannel, for coating, is sheared and finished like cloth, but retains the lightness and pliability of the flannel texture.

French plaid is a fancy flannel: it consists of plaids, or broken plaids and checks, dyed in the wool.

See Hayes' "*Centennial Report*," v. 49–52.

Flap Hold'er. (*Surgical.*) A delicate pre-

Fig. 1055.



Dr. Turnipseed's Flap-holder.

hensile instrument for holding flaps of sutures in confined situations; in operations for vesico-vaginal fistula, etc.

Flashed Glass. (*Glass.*) Also known as *doubled glass*. A glass made of several colors superposed; it is worked in a different manner from plain glass.

Colored glass is drawn into sticks of a certain length and annealed. A piece of this glass is heated, attached to the end of a blow-pipe, blown into a hollow ball. The ball is opened, and formed into a cup. A ball of white glass is blown by another workman and introduced into the cup. The two are blown and rubbed together while hot, to make them adhere.

The two are then treated as a single piece, and finished in any ordinary way by molds or tools.

Flash'ing. (*Hydraulic Engineering.*) Artificial assistance to navigation by ponding a river, and suddenly removing the barrier, to carry barges and rafts over shallow places in the stream.

"*Mech. Dict.*," p. 876. See also "*Barrage*."
System on the Yonne, etc., Fr. "*Vienna Exposition Reports*," Watson's Report, iii p. 27.

Flash Light Ap'pa-ra'tus. A device for automatically giving sudden flashes of light at specific intervals as a signal. Flash lights are used in lighthouses as a means of varying the character of the lighting. See LIGHTHOUSE, "*Mech. Dict.*"

The means adopted are large and small governors; the small one giving gas enough to keep the light going, and the larger one acted upon by a time-piece through the medium of electric arrangements. "*Journal of Gas Lighting.*"

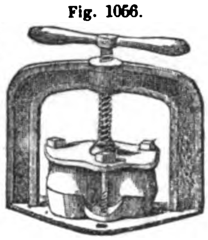
Pebbles . . . . * "*Scientific American Sup.*," 1287.
Flash light on car "*Scientific American Sup.*," 979.
"*Mechanical Dictionary*," p. 877.

Flask Clamp. A dentist's clamp, for holding the flask in which the denture is exposed to heat in the muffle. Fig. 1056.

Flat Bar Spi'ral Spring. One made by bending a flat bar so that its wide face is radial to the axis of the core or mandrel on which it is wound. *s, t, v*, Fig. 1143, p. 483, "*Mech. Dict.*"

Flat Cha'sing. (*Fine Art Metal-working.*) A mode of ornamenting silver ware, producing figures by dots and lines made with a punching tool.

Fig. 1056.



Flask Clamp.

Flat Coil. A heater coil, in steam or hot-water arrangements, the pipes of which are coiled so as to lie in a plane. Such are used against walls, for heating buildings, and on the bottom of evaporating pans.

Flat'-foot Ap'pa-ra'tus. (*Surgical.*) A curved steel sole worn inside the shoe to correct the abnormal flatness of the sole.

Flat Mir'ror. (*Optics.*) One for reflecting parallel rays; as distinguished from a *condensing* mirror, etc.

Flat Rib Knit'ting Ma-chine'. A machine for making shirt cuffs, bottoms for drawers, etc. Campbell & Clute.

Flat'ten-er. (*Blacksmithing.*) See FLATTER.

Flat'ten-ing. (*Leather.*) The same as shaving, except in some cases the skin after skiving is shaved across (*i. e.*, nearly at right angles to the skiving), and then flattened by being shaved again in the same direction as the skiving.

Flat'ten-ing Ov'en. (*Glass.*) A heated chamber in which split-glass cylinders are flattened for window glass. See Fig. 2014, "*Mech. Dict.*"

The usual style of oven has flattening, cooling, and piling-up sections. The flattening stone, supported on a small truck, runs on rails into the oven.

Segard, of Anzin, France, has two stoves carried on carriages, running on rails at different elevations, so that one can be returned while the other is going, one passing under the other. Work performed: 600 cylinders in 24 hours.

In another form of oven the cylinders are introduced into a compartment when they are heated, then flattened upon a stone carriage; the carriage is pushed into a compartment at the head of the *leer* (oven) and from the carriage the sheet is pushed upon iron bars which run longitudinally of the leer, and lie in channels sunk in the stone floor. The bars run upon rollers, and are lifted by a system of levers so as to raise the glass from the floor to move it along in the *leer* when another sheet is to be laid down. The sheets thus advance, step by step, till they reach the cool end of the oven, the bars after each forward motion being lowered and returned to their original position. The oven contains 9 sheets, which make the course in from 20 to 30 minutes.

Another form of *leer* has a rotating stone and compartments.

A form of flattening oven much used in France for baking colors on enameled glass consists of a leer, with compartments attached, for heating and flattening the glass. The flattening compartments contain the usual flattening stone mounted upon a carriage traveling back and forth upon rails from the heating to the flattening chamber. The *leer* contains a number of rollers mounted on cross shafts, and near enough to one another to give a sufficient resting support for the sheets of glass. These rollers receive a slow rotary motion. The cylinder being heated, flattened on the stone, run into the chamber opposite the mouth of the leer, the sheet transferred to the rollers which take it gradually and continuously to the discharge end of the *leer*. Both sides have a chance to cool.

See *Colne's* Report, "*Paris Exposition Reports*," 1878, vol. iii., p. 239.

Flat'ten-ing Stone. (*Glass.*) A flat stone carried by a small truck running on rails, and carrying the cut-glass cylinder; the stone is run into the flattening oven to allow the glass to flatten out. See FLATTENING OVEN.

Flattening table, *Laboulaye's* "*Dictionary*," article "*Verre*," iii., Fig. 2544, ed. 1877.

Flat'ter. (*Blacksmithing.*) A swaging tool or fuller. *a*. Fig. 2124, p. 922, "*Mech. Dict.*"

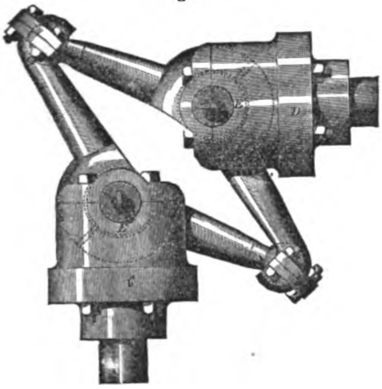
Flesh'er. (*Leather.*) Or *Fleshing knife*. A long, two-handled and somewhat blunt-edged knife, curved to fit the sloping rest of the beam. Its cross-section is concave downward. It is used to scrape off the hair, scarf-skin, loose flesh, and cellular tissue.

Flesh'ing Knife. (*Leather.*) A currier's knife used in removing cellular tissue, etc., from the hide. See FLESHER.

Flesh Side. (*Leather.*) The side of a skin or hide next to the flesh. As opposed to *grain* side.

Flex'i-ble Coup'ling. An angle joint for transmitting motion. A substitute for the gimbal.

Fig. 1067.

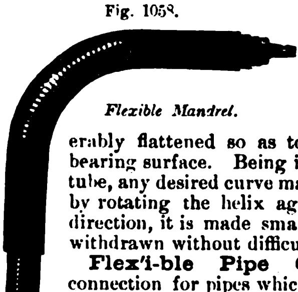


Clemens' Mechanical Movement.

The coupler arms are carried in pairs in their jaws by their hinge-jointed hubs on the pivot-pins *E*. The outer ends of the arms are coupled together by ball-and-socket joints. The weight preserves the balance. * "*Scientific American*," xxxv. 230.

Flex'i-ble Man'drel. A device for bending metallic tubes regularly and quickly, without flattening. It is a stout spiral of closely laid steel wire, preferably flattened so as to give extended bearing surface. Being introduced into a tube, any desired curve may be made; and by rotating the helix against its leading direction, it is made smaller, and may be withdrawn without difficulty.

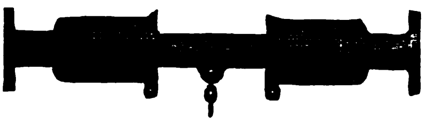
Fig. 1058.



Flexible Mandrel.

Flex'i-ble Pipe Coup'ling. A connection for pipes which allows them to be laid out of line without leaking, and to expand longitudinally without impairing the joint. A tubular section with flanged ends fits in the bells of the respective pipes.

Fig. 1059

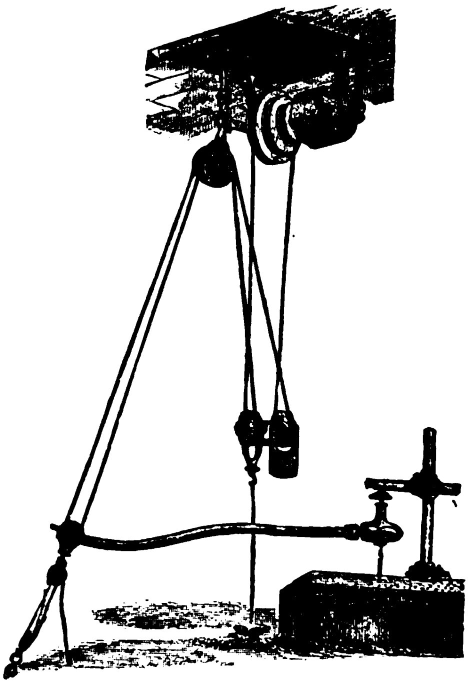


Flexible Pipe Coupling.

Flex'i-ble Shaft. A pliable power transmitter. A coil of steel wire is overwound with another spiral in a reverse direction, this by a third, and so on. The ends of the wires are brazed, and the whole covered with a hose. Its uses are numerous.

Thirion's flexible coupling was shown in Paris in 1867.

Fig. 1060.



Stowe Flexible Shaft.

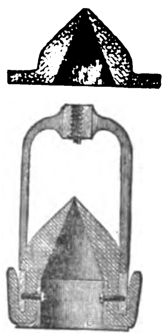
* "*Engineering and Mining Journal*" xxii. 75.
* "*Mining and Scientific Press*" . . xxxiv. 81.
* "*Iron Age*" . . . . xxi., April 25, p. 1.
* "*Scientific American Supplement*" . 816.

Flex'i-ble Sole Plane. See CIRCULAR PLANE.

Flex'i-ble Valve. Perreaux's valve (French) of india-rubber opens as it descends, by the pressure of the water beneath, but closes against any pressure from above. It is used for lift pumps, especially in cases where it is required to pump liquids which corrode metals. They shut quickly, are durable and retentive.

Fig. 1061.



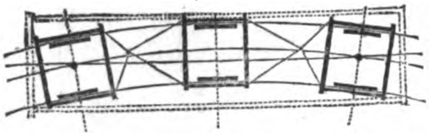
Perreaux's Flexible Valve.

The upper figure shows the form of valve, the lower one its application. It is so designed that, in addition to being a bucket valve, it forms a cup to keep the bucket tight in the barrel.

Similar valves have been made in the United States for deep oil-well pumps.

Flex'i-ble Wheel Base. (*Railway.*) A system of arranging car trucks, which consists in mounting the axles with their axle-boxes, guards and springs in frames separate from the main under-frame of the carriage. The end frames have central pivots, around which they swivel freely, while the middle frame is so arranged that it can slide transversely. The three frames are connected together by articulated radiating gear, so that they act sympathetically, and each axle assumes a position coincident with the radial lines of the curve, instead of remaining parallel to each other, as in

Fig. 1062.



Flexible Wheel Base.

the ordinary construction, in which the wheels grind their way along the sides of the rails. The wear and tear of ties and rails is thus greatly reduced, because the flanges of the tires are always parallel with the rails.

Flint Brick. A fire-brick made of powdered silex, with a sufficient flux to assist it to agglutinate at practicable temperatures.

Flint Glass. (*Glass.*) The use of calcined flints, to furnish silica for the glass, is the origin of the name.

In England, a glass containing lead. Called by French and Belgians *crystal.* Germans call all white glass *crystal*, whether or not lead enters into it; the Bohemian, for example, which has a potash and lime base; and ground quartz furnishes the silex.

The equivalent of what is called in England *white glass* is here known as *lime glass*, and is not equal in brilliancy to *flint* glass, which is an English invention, and that country produces the best specimens.

It is said to have originated in this way: When wood began to be scarce, and coal was substituted as a fuel, it was necessary to cover the glass pots to keep out impurities which colored the glass. As this diminished the heating power, it was difficult to melt the frit, and red lead was added as a flux.

Materials usually employed: —

Carbonate of potash	1
Red lead	2
Sand	3

Oxide of manganese in small quantities acts as a corrective of color.

Boracic acid has been used, and permits of the substitution of oxide of zinc for red lead, and of lime, soda, or baryta for potash. The result is a beautiful glass suitable for table-ware or optical purposes, remarkable for limpidity, whiteness, and brilliancy.

Flitch Beam. A beam made in layers of material pinned together. The invention of *De Lorme.* "*Nouvelles Inventions pour bien Bastir,*" 1561.

The beam, specifically known as the *flitched beam*, is shown in Fig. 313, p. 139, "*Mech. Dict.*," and differs from the *laminated*, which is of thin and bent material, as in Figs. 312, 316, pp. 138, 139, *Ibid.*
See also "*Scientific American Supplement,*" * 2035.

Flitch'ing Knife. (*Fishing.*) For slicing halibut, etc., into steaks or flitches, in preparation for salting and smoking.

Float. (*Fishing.*) 1. *Angling* line floats are of cork, quill, or light wood.

Net floats are of cork, cedar, glass globes, rubber tubing, etc.

Harpoon-line floats are empty kegs, bladders, inflated seal-skins, etc.

The floats of the gill-nets of Lake Michigan are splinters of cedar, 30″ × ½″ × ⅜″.

Glass floats are very common in Europe, having been used in Norway, Sweden, and elsewhere. Were shown in quantity at the Centennial in the Scandinavian department.

See the following patents: —

No.	Inventor.	Subject.
86,609	*Terrell*,	Made of hollow glass.
99,572	*Ingram*,	A wire loop above and pin below, lock the line.
127,218	*Brown et al.*,	Vulcanized rubber with projecting ears.
128,885	*Jewell*,	The float body has a longitudinal wire prolonged into a spiral at each extremity.
165,867	*Quinn*,	Board float loaded at one edge: for trawl lines.
179,490	*Sander*,	Net float with attaching slot.
186,232	*Davis*,	Glass floats for gill-net.
188,755	*Redfield*,	A spiral coil of wire at each end.

2. For raising sunken vessels. A camel or caisson. See those heads: also Fig. 4148, p. 1874, "*Mech. Dict.*" Fig. 1617, p. 688, and list under Hydraulic Engineering, *Ibid.*, *et infra.*

Clark & Standfield * "*Scientific American Sup.*," 2071.

3. A ball on a lever, floating in a cistern to operate a faucet.

Benton . . . . * "*Scientific American*," xxxiv. 310.

4. A wooden trowel, to smooth a mortar surface.

5. (*Mining.*) Loose rocks, or such detached from the original formation.

Float'ing Board. A cast-iron plate, ribbed beneath and planed true on top, for "floating up" tin cans; *i. e.*, soldering the ends inside, the can standing upon the heated plate till the solder runs.

Float'ing Bridge. The landing platform of a ferry-boat; so called by Fulton in his description of the Hudson River ferry, started August, 1812. See Ferry-boat.

Hoogly, Calcutta . "*Van Nostrand's Magazine*," xviii. 475.
"*Scientific American Sup.*," 1897.

Float'ing Brush Dike. (*Hydraulic Engineering.*) A device to check the current of a stream and form a deposit.

It is made by taking saplings from 20′ to 30′ long and from 4″ to 8″ diameter, and nailing or wiring to them scraggy brush of any kind. This forms what is known as the *weed.* Instead of the saplings rope may be used to which to fasten the brush. One end of the weed is anchored and the other supported by a buoy. The weeds are placed in the river 10′ to 20′ apart, and check the current gradually without giving rise to the scouring action produced by a solid dike. A *willow curtain* acts in a similar manner.

See "*Report U. S. Engineers*," 1880, * ii. 1452. *Ibid.*, 1878, * ii 655, sketches Nos. 1, 2.

Float'ing Dam. An anchored dam.

Floating dam in the Dorran Canal, Vienna, * "*Engineer*," xli. 190.

Float'ing Dock. One which is floated beneath a vessel to raise it. See "Bermuda," Plate XIX., opp. p. 884, "*Mech. Dict.*" See also Depositing Dock, *supra*, and the following references: —

Float'ing Lev'er. (*Railway.*) A name applied to the horizontal brake-levers beneath the car-body.

Float'ing Wire Dike. (*Hydraulic Engineering.*) An open wire screen anchored at its lower edge and sustained by buoys along its upper. Its object is to arrest matters floating in the stream and by causing an obstruction obtain a deposit of sediment.

"*Report of U. S. Engineers*," 1880 . . . . p. 1452.

Flocked E-nam'el. (*Glass.*) Enamel ornamentation on glass whose surface has been previously dulled by grinding or acid.

Flog'ger. A bung-starter. An instrument for beating the bung stave of a cask to start the bung.

Floor Arch. An arch with a flat extrados.

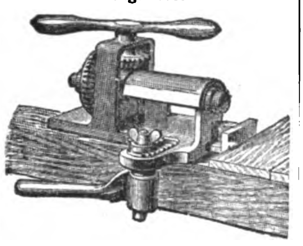
Floor-bor'ing Ma-chine'. One with a large and heavy bed-plate to which the work may be dogged while the drill press is moved to position to work upon it.

Floor Ce-ment'. A concrete for cellar floors and walks.

Broken stone or gravel and sand	4
Lime	1
Hydraulic cement	1

Mix the ingredients dry excepting the lime. Slack the lime separately and add it to the remainder. Work thoroughly and as dry as possible. Apply a thickness of 6''. When set add a coating of cement 1, sand 2.

Fig. 1063.



Floor Cramp.

Floor Cramp. A device for closing up the joints of flooring boards previous to nailing. Fig. 1063.

Floor Hanger.

Floor Fend'er. A knob fastened to a floor, to receive the impact of an opening door and thus protect the wall of the room.

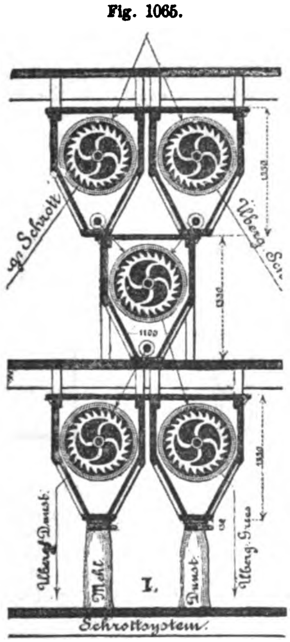
Floor Hang'er. A shaft bearing fastened to the floor. Used for running countershafts and lines when it is not convenient to suspend them from the ceiling joists.

Floor'ing Tile. Ceramic ware for paving. See TILE.

Floor Light. A frame with glass panes in a floor.

Flour Bolt. Fig. 1065 shows an Austrian arrangement for bolting meal. Each of the various cylinders makes a simple division of its contents and the ultimate division of the numerous grades is made by successive actions: Each cylinder rotates in a tight chamber, and has beaters inside to expedite the passage through the cloth of the finer particles. It is particularly intended for roller mills in which the work of grinding is by numerous successive actions, each detaching portions of flour from the material under treatment. See CYLINDER MILL, p. 243, *supea*, and HIGH MILLING, *infra*.

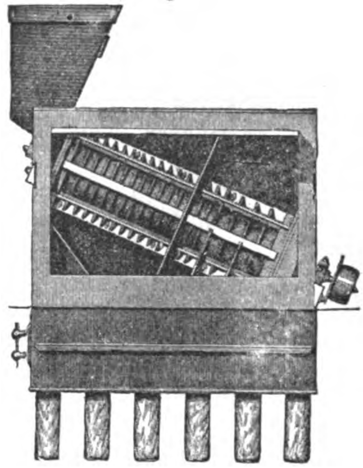
Fig. 1065.



Hoerde's Bolting Chests. (*Vienna.*)

Fig. 1066 represents a form of flour-bolting chest made by Ruston, Proctor, & Co. (Br.) The cylinder is of hard wood, covered with wire gauze of varying fineness. The shaft has horse-hair brushes; the feed is automatic, and the issues for the various grades of fineness discharge into separate sacks.

Fig. 1066.



English Flour Bolt.

The numerous successive boltings in the high-milling new process methods, and in the roller and cylinder mill processes have much increased the uses of the bolt.

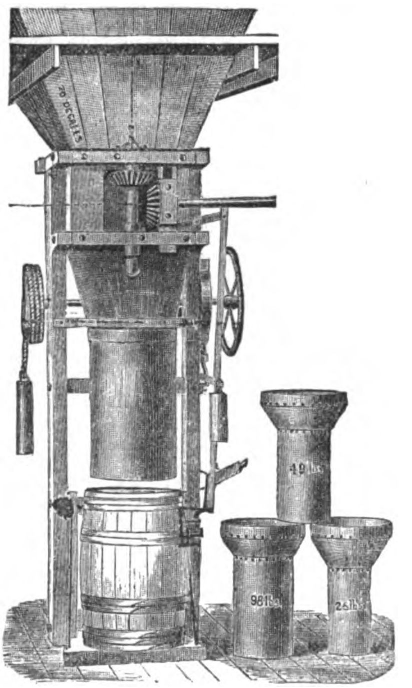
See also GRINDING MILL, ROLLER MILL, CYLINDER MILL, and list under MILL.

Flour Pack'er. A machine for barreling flour. A flour-chest and spout are made in accordance with the size of barrel to be packed by the machine. The horizontal shaft communicates motion by miter-wheels to the vertical shaft and auger which presses the flour into the barrel, the tube receding as the barrel fills. The machine is started by a simple movement of a lever, and stops automatically when the barrel is filled. By change of auger and spout it is adapted for any of the usual sizes of packages. A cut-off valve holds the flour in the bin when changing sizes. See Fig. 1067.

Flow'ing Bat'te-ry. (*Electricity.*) Or *perfluent* battery. One in which the battery is kept constant by the flowing of the exciting liquid through the cell or cells. See PERFLUENT BATTERY.

Flue. A duct for heated products of combus-

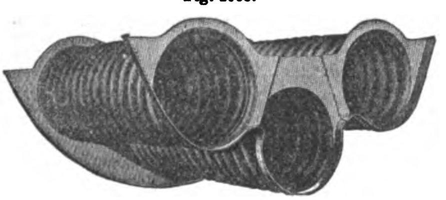
Fig. 1067.



Flour Packer.

tion; a chimney. Fig. 1068 shows Fox's flue (Br.), in which the metal receives greater strength by corrugations.

Fig. 1068.



Corrugated Boiler Flue.

Flume. A long artificial channel or chute for conveying logs or lumber from an elevated situation to distant mill or works.

A chute for conveying water for use in hydraulic or placer mining.

"Cherokee" gravel mines	* "*Min. & Sc. Press*," xxxv. 313.
Lumber	* "*Min. & Sc. Press*," xxxiv. 161.
California	* "*Sc. Am. Sup.*," 1840, * 1509.
Smartsville Cal.	* "*Mech. Dictionary*," p. 891.

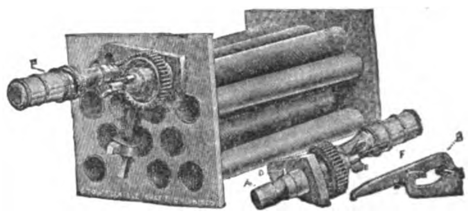
Flume Car. A car to travel in a flume; wheels rest on the sides of the flume, and the water runs a paddle wheel.

"*Engineering and Mining Journal*" . . . . xxi. 223.

Flue Cut'ter. A tool for cutting out a faulty flue or tube, to be replaced by a perfect one.

Fig. 1069 shows a section of boiler with flue cutter in position for use, and the same in detail. The mandrel and tool carrier *A* is inserted in the flue to be cut off, and held in position by the clamps *B B*. The shaft is attached by means of the hand-piece *F*, which is also the means of starting and stopping the cutter when in use. The cutters *D* are forced out against and through the flue as it is cut, by means of the feed-screw *E*.

Fig. 1069.



Flue Cutter.

Flush Box. A cistern for especial use in dwellings where the supply of water is intermittent. The action of Morris's waste preventive flush box is follows: —

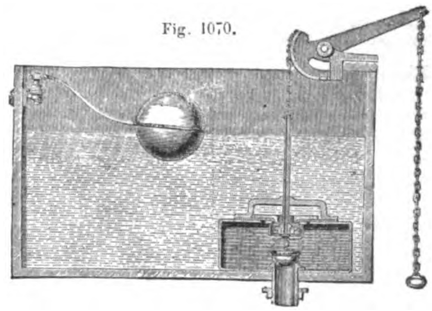


Fig. 1070.

Waste Preventive Flush Box.

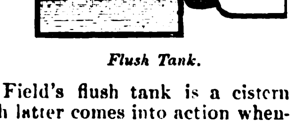
When the lever is pulled, it first closes the communication between the large cistern and the flush box, and then opens the outlet or discharge-valve, and is so arranged that in no case can the valve communicating with the large cistern and the discharge-valve be open or partially open at one and the same time; so that no more than the contents of the flushing-box (about 2 gallons) can by any possibility be used at one operation.

Flush Deck Pump. One the upper surface of which is even with the deck, the chamber depending beneath. It has a hinged cover and the plunger is removable.

Fig. 1071.

Flush Deck Pump.

Fig. 1072.



Flush Tank.

Flush Tank. Field's flush tank is a cistern with a siphon which latter comes into action whenever the liquid attains a certain height in the cistern. It is adapted for the automatic periodical emptying of the cistern. May be useful apparatus in the periodical flushing of drains.

"*Manufacturer and Builder*" . . . * x. 280; * xi. 187.

Flu'ted Glass. (*Glass.*) A mode of treating glass to render it a perfect transmitter of light but prevent observation through it. Used in partitions, doors, and windows. It is much used in Europe, and has semi-circular flutings pressed into it.

It is made by blowing a pear-shaped piece which is then introduced into a brass mold having a number of deeply channeled flutings inside. The glass is now blown, as usual in cylinder blowing, and retains the imprints of the flutings. It is finished in the usual manner, care being taken not to rotate the ponty, as that would distort the flutings. The cylinder in expanding and lengthening reduces the depths of the flutes, but the flutings in the mold are sufficiently exaggerated to meet the flattening of the subsequent operation.

Flu'ted Tap. A tap for making screw holes. Longitudinal grooves in the sides, constitute the thread — cutting edges. See Fig. 6211, p. 2495, "*Mech. Dict.*"

Fig. 1073.

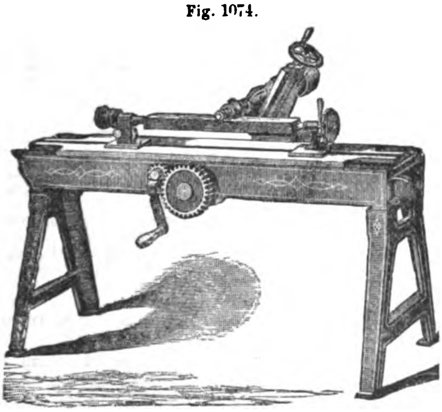
Fluting Iron.

Flu'ting Iron. A laundry iron for fluting clothes. There are many forms. See Figs. 2044, 2046, pp. 893, 894, "*Mech. Dict.*" The damp cloth is pressed between the two surfaces of the heated iron. Flutes may be nickel-plated.

Fluter, *Knox* . . . * "*Iron Age*," xviii., Sept. 21, p. 19.

Flu'ting Ma-chine'. One for grooving balusters, table-legs, etc. The stick is placed on centers

Fig. 1074.

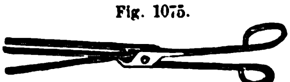


Fluting Machine.

as in a lathe and passed beneath the circular cutter which is mounted on a mandrel and rotated by band-pulley. See also FLUTING LATHE, Fig. 2045, p. 894, "*Mech. Dict.*"

Flu'ting Scis'sors. An instrument for fluting linen, etc. One member is hollow to hold a heated iron rod.

Fig. 1075.



Fluting Scissors.

Fly. (*Add.*) 13. The fore flap of a bootee. A strip of leather which overwraps the front vamp and receives the strings or other fastening.

Fly Hook. (*Fishing.*) One arranged with an artificial fly.

Fly'ing Ma-chine'. See references: —

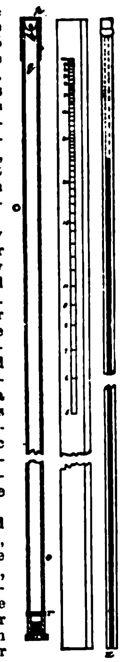
Simonds		"*Scientific American Sup.*," 96.

Fly'ing Sound'er. A name applied to Sir William Thomson's deep-sea sounding apparatus. It consists of a glass tube lashed to a length of line above the sinker and connected to a line of piano-forte wire wound upon a reel from which it is payed out when sounding. By worm on the reel shaft, actuating gearing on a counter, the length of line payed out is shown, but the principal determination of depth is, after the tube has been hauled on board again, by means of the observed condensation of air in the tube when compared with a scale graduated to fathoms according to the known law of compression of air at given depths. The interior of the glass tube is lined with a preparation upon which the entering sea-water — or a liquid contained in the enveloping metallic tube acted upon by the sea-water — shall mark the distance that liquid has been forced into the glass tube, which may be said to constitute a pressure-gage.

The intention is to measure the depth of water below the ship at any time without reducing her speed, but it is equally well adapted for taking soundings when lying to. As a matter of observation, in sounding from a steamer running at 14 knots in water of 70 fathoms depth, the sinker has been found to draw about 195 fathoms of wire off the reel and to take about 40 seconds of time to reach bottom. The counter driven by the wheel indicates the length of line payed out when bottom is reached and the depth may be instantly declared, if there has been sufficient experience in similar circumstances of apparatus, speed of ship, currents and weather, but the observation of the gage tube when brought on board again after sounding affords the more definite determination.

Fig. 1076.



Thomson's Deep Sea Sounding Tube.

The glass tube, Fig. 1076, is of sufficiently small bore to obviate the splashing of water within it during sounding. It is guarded by an outer metallic tube, *o*, which is attached by a length of hempen line to the wire. The lining of the tube is chromate of silver mixed with gum to enable it to adhere to the tube, and the mark is made by the chemical action of the sea-water which is forced out of the sheath into the tube as the apparatus descends. The action is to induce a double decomposition. The chlorine leaves the sodium of the common salt and combines with the silver, while the chromic acid and oxygen leave the silver and combine with the sodium. The chloride of silver, white and insoluble, remains on the glass in place of the yellow chromate.

The tube *o*, shown with its case *o*, and the graduated comparing stick in Fig. 1076, is closed at the upper end and open at the other (*x*), and slips within a metallic case *o*, the lower end resting upon a piece of vulcanite, *r*, to prevent shocks on reaching the bottom. The upper end *p* is removed for the introduction of the tube and then closed, the openings *q* allowing sea-water to enter as the apparatus descends. The lower end of the case *o* has a screw plug removable for purpose of cleaning.

Figs. 1077, 1078 show the apparatus in side and end elevations.

On the bed *A* are the standards *C L* which hold the reel *B* and the brake-drum *K* respectively. The reel is rotated by handles *D*, and on its axis is a worm, *F*, which actuates gearing *a b h i*, to revolve index fingers *f f* on the dials *l l* to indicate amount of wire payed off.

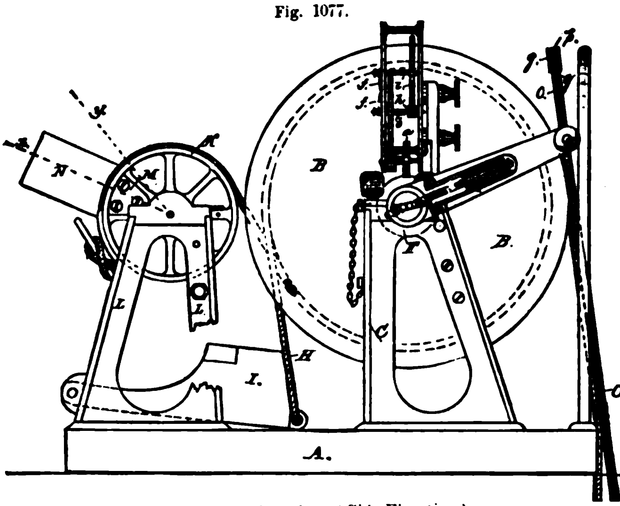
H is a brake rope which takes a turn round the drum *G* and is fastened at its respective ends to the brake-weeel *K*, and the pivoted weight *I*. *N* is a weight which exercises, in the position shown at *x*, a retarding force of 6 or 8 pounds on the drum, but which, when elevated, allows the brake rope to slacken so that the wire can be readily wound back on the reel after a sounding is had.

n n show the position of the sounding lead and *n'* its arming.

When it is desired to obviate the necessity of previous chemical or other preparation of the tube, a pressure-tube is used, open at each end and provided with valves, one at the lower end, to let sea-water enter when the sinker is going down, the other at the upper end to let air escape when it is drawn up, each of these valves remaining closed except when urged in its opening direction by a small definite amount of force.

Using this apparatus, the White Star steamer "Britannic" now takes soundings regularly, running at 16 knots over the Banks of Newfoundland and in the English and Irish Channels, in depths sometimes as much as 180 fathoms.

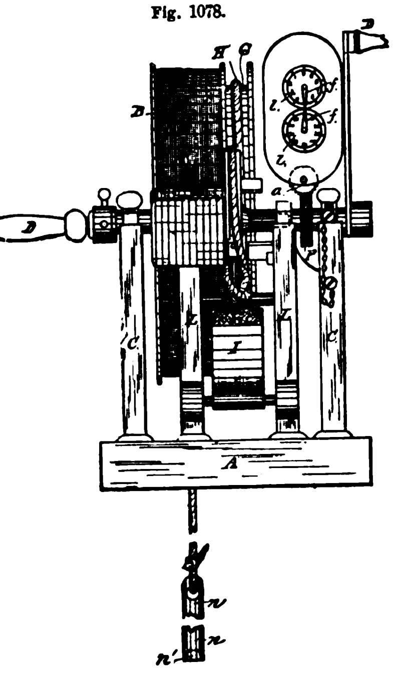
Fig. 1077.



Sir William Thomson's Flying Sounder. (*Side Elevation.*)

The steel wire weighs about 1¼ pounds per 100 fathoms and bears when new from 230 to 240 pounds without breaking. Its circumference is 0.03 inch.
See address of Sir William Thomson, Royal Society, February 4, 1878.
See also SOUNDING APPARATUS.

Fig. 1078.



Sir William Thomson's Flying Sounder. (*End Elevation.*)

Fod'der Cut'ter. A machine for cutting corn stalks for feed.

See ENSILAGE CUTTER; CHAFF CUTTER; STRAW CUTTER.

Fod'der Mill. 1. A mill for coarse grinding of grain for feeding stock.

2. A mill for grinding corn fodder, to render it more easy to feed in mangers, and more readily mixed with bran, or other enriching matter. A substitute for a fodder cutter.

"*Manufacturer and Builder,*" * xi. 70.

Fog Bell. The fog bell of Zaffarini, of Ferrara, Italy, is rung by a rocking air-tight float, which carries a pair of erect hammers with pliable stems. See illustrations, p. 898, "*Mech. Dict.*"

Fog Gun. A signal gun, fired as a warning to mariners during foggy weather.

Explosive gas is sometimes used. See GAS GUN.

Fig. 1079.

Fog Signal.

Major Elliott's account of the fog signal experiments at Dover, England, is found in his Report U. S. Engineers, "*European Light-house Systems.*" Referred to in "*Van Nostrand's Magazine,*" xiv., pp. 109-111.
Wigham . . . . . . "*Technologiste,*" xxxix 339.

Fog Sig'nal. Nearly allied to the gun is the fog signal, made by the discharge of a ball of compressed gun cotton in the focus of a parabolic reflector.

See FOG BELL; FOG GUN; FOG TRUMPET, etc, "*Mech. Dict.,*" *et infra*, and the following references:

Whistle, *Leighton*	* "*Sc. Amer.,*" xlii. 1.

Fog Trum'pet. The siren is a steam trumpet. See Fig. 5114, p. 2191, "*Mech. Dict.*"

The sound is caused by the passage of steam at 70 lb. to the square inch through the openings made by the revolution of one disk with radial slits cut in it in front of a similar disk fixed in the trumpet. The most effective rate of rotation is from 2400 to 2800 revolutions per minute. The trumpet is of cast-iron.

Fig. 1080 shows Brown's siren fog signal, the trumpet, valve, and rotating mechanism being mounted on a semi-portable steam boiler.

Steam is generated in *A* and passes to the valve *B*, which is a perforated disk mounted on an axis and rapidly rotated by a belt from the engine-wheel *D*, in apposition to a stationary disk similarly perforated, so that the steam passes when the holes come in correspondence, and thus causes a series of puffs. The *degree* depends on the pressure, the *pitch* on the rapidity of the succession of the puffs, the *duration* upon the time the throttle is left open, the *quality* upon questions relating to the material of the trumpet, shape of opening, etc.

The fog trumpet of Amadi, of Trieste, was exhibited at Vienna in 1873.

It consists of a trumpet, formerly operated by compressed air, but now directly by steam; is provided with an automatic distributing steam-valve, and with a special valve, with finger-board, to produce sounds of varying pitch.

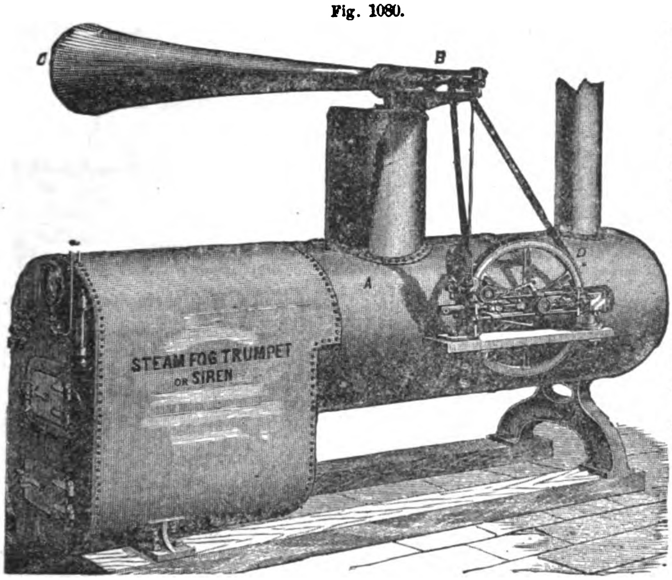
This trumpet, set up on Point Salvore, Istria, is operated by an 8-horse power steam boiler, at 25 lbs. pressure; can produce 30 blasts in 30 seconds, and is audible at 15 nautical miles distance in clear weather.

Report of Major George H. Elliott, Corps of Engineers, U. S. Army. Van Nostrand.

See also "*Van Nostrand's Magazine,*" xiv. 106.

The ordinary fog-horn is a brass trumpet 8′ 6″ long, 3″ diameter at the mouthpiece, and about 23″ at the mouth. It

Fig. 1080.



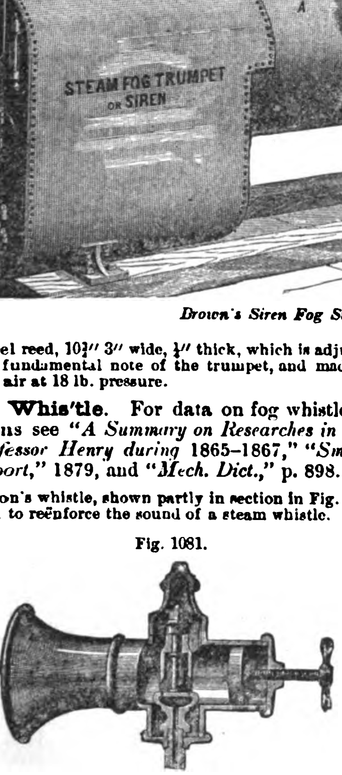
Brown's Siren Fog Signal.

has a steel reed, 10¾″ 3″ wide, ½″ thick, which is adjusted to suit the fundamental note of the trumpet, and made to vibrate by air at 18 lb. pressure.

Fog Whis'tle. For data on fog whistles and fog horns see "*A Summary on Researches in Sound by Professor Henry during* 1865–1867," "*Smithsonian Report*," 1879, and "*Mech. Dict.*," p. 898.

Leighton's whistle, shown partly in section in Fig. 1081, is intended to reënforce the sound of a steam whistle. It con-

Fig. 1081.



Fog Whistle.

sists of a fog-horn containing a steam whistle, behind which there is an adjustable resonance chamber. The whistle has straight parallel sides and straight orifices.

Foil Car'ri-er and Plug'ger. A species of pliers for grasping foil or other filling and with curved ends which, when brought into apposition, form a plugging tool.

Foil, Va'ri-e-ga'ted.

Japanese: Thirty or forty thin plates of gold, silver, copper. and various alloys, are laid one over the other in a given order, and soldered together at the edges, so that the whole forms a stout plate of metal. Punches of various shapes, conical, pyramidal, with triangular, square, or pentagonal sides, are now used to make a pattern of perforated figures, which exhibit on their inner sides concentric circles, triangles, and other forms, corresponding to the punches used. The plate so prepared is hammered and rolled until it has become quite thin, the holes disappear, and the figures have spread out, preserving, however, their parallelism. A number of broken, straight, and curved lines are thus produced, which, as in a Damascus blade, are free of each other, though consistent in themselves in the same metal, their effect being further enriched by the use of acids to modify the colors. It will easily be understood that thin plates prepared in this way, having an extremely flexible nature, admitting relief, with stamped or engraved designs, and capable of receiving the most various colors and forms, will have many uses in decorative art. — *Prof. Lielegg.*

See DAMASKING METALS, p. 245, *supra*.

Fold'er. (*Sheet Metal Working.*) A machine for turning locks or tapping edges of cans. Being adjustable, it will turn narrow or wide locks, or round edges for wiring.

Fold'ing Boat. See list under *Boat*, p. 114, *supra*, and Fig. 2057, p. 899, "*Mech. Dict.*"

Fold'ing Ma-chine'. (*Sheet Metal Working.*) A machine for folding the edges of blanks preparatory to seaming. Generally called a *double-edging machine*.

(*Printing.*) A folder attached to a perfecting printing machine.

(*Bookbinding.*) A machine for folding sheets, signatures, or quires.

Quire, *Richmond*, Br.
* "*Engineer*," l. 314.
Folding and perforating, *Lawrence*, Br. * "*Sc. Am. Sup.*," 2096.

Fold'ing Net. (*Fishing*) One made to shut together to inclose the prey. A *purse* net is a variety.

Food Car. One used in a hospital or asylum to convey rations or food to the wards.

Foot Ap'pa-ra'tus. (*Surgical.*) Includes:

Apparatus for eversion.	Artificial feet.
For club-foot (talipes).	Support for weak ankles.
Apparatus for flat feet.	For short leg.
Splints, bandages, and slings, for fractured or luxated parts.	Contracted tendo achillis.
	For over-riding toes.
	For bunions, etc.

Foot Pow'er. The baromotor of Gaston Bozérain, of Paris, is a combined treadle and hand-lever motor. Shown at the Paris Exposition, 1878.

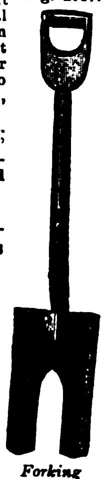
Forging Machine.

For'ging Ma-chine'. Massey's forging machine (Br.) is intended for a class of forgings, such as spindles, bolts, studs, rollers, pins, files, and a great variety of other articles in common use.

It has four pairs of blocks or hammers, $8\frac{1}{2}''$ diameter. The lower blocks can be set up or down while the machine is running. The eccentric shaft is steel, running in very large white-metal bearings. The machine can be worked from both sides, so that two or more men can use it at the same time. Speed, 750 revolutions per minute. Weight 7,000 lbs. Power required to drive, about one horse. Floor space required, 4' 3'' by 3' 9''. Height over all, 6' 6''.

See STEEL PRESS, Fig. 5747, p. 2369, "*Mech. Dict.*" Also, paper on the "*Système Haswell*," at Vienna, by Butler, of Leeds, England. Debate by Paget, Sir Joseph Whitworth, and others. "*Scientific American Sup.*," 712.

Fig. 1087.

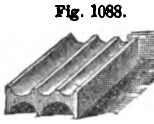


Forking Spade.

Fork'ing Spade. A bifurcated digging tool. The tool with several tines is a *digging fork*.

Form'ing Iron. (*Forging.*) A species of swage block, used by the blacksmith in rounding rods. The grooves of various radii to suit different requirements.

Fig. 1088.



Forming Iron.

Form'ing Ma-chine'. 1. (*Sheet Metal Working.*) A machine for bending tin plate to circular form. The diameter of the circularly bent plate depends upon the relative proximity of the three rollers between which the plate passes.

See also STAMPING PRESS, Figs. 5543–5545, pp. 2304, 2305, "*Mech. Dict.*"

2. The forming machine, Fig. 1089, is adapted for felt, buckram, straw, tin, and what not.

Fig. 1089.

Forming Machine.

See also HAT-FORMING MACHINE.

3. A machine for laying up strands into rope, Fig. 1090. It is on the same principle as Fig. 4442, p. 1981, "*Mech. Dict.*"

For'no-con-ver'tis-seur. A French name, familiar to English speaking metallurgists as the title of the Ponsard furnace for the manufacture of steel.

See article by J. Sylvain Périssé, member of the national jury in Paris, 1878, published in the "*Journal of the British Iron and Steel Institute*," and reproduced in "*Van Nostrand's Engineering Magazine*," xxi. 252.

See also PONSARD FURNACE.

The *Ponsard* furnace, like the *Siemens-Martin* and others, whether applied to metallurgic or other purposes, is a gas generating furnace and has a peculiar regenerator. See GAS GENERATING FURNACE; *Siemens'*, Figs. 1159, 1160, and *Ponsard's*, Figs. 1161, 1162, pp. 886, 887, *infra*, both of them as applied to gas works.

Forty'five De'gree El'bow. A pipe coupling equal to $\frac{1}{8}$ bend. See BEND.

Foun'dry Fur'nace. System of *Piat*, Paris: Reverberating and blast furnaces. The furnace of sheet-iron containing the crucible is on trunnions, or can be unshipped and moved by crane or by hand to the flask. See CRUCIBLE FURNACE.

* "*Scientific American Supplement*" . . . . . 2857.

Foun'dry La'dle. One for carrying molten metal from the cupola to the flasks.

See LADLE; SHANKS, "*Mech. Dict.*" *et infra.*

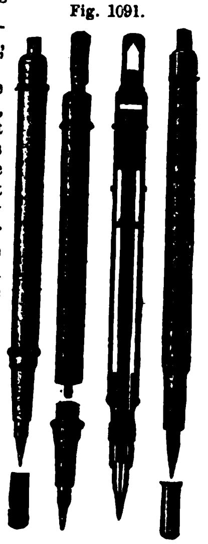
Aikin & Drummond's mounted ladle is supported on two wheels at a point on the shank, which enables a stout boy to counterpoise and push it, holding by the crotches.

Pintsch's ladle, Fuerstenwalde, Prussia, is of wrought iron, and the iron flows from a partitioned channel riveted along the side of the kettle. and opening into the same near the bottom. This excludes floating dross.

French foundry ladle, *Laboulaye's* "*Dictionnaire*," ii., Figs. 930, 931, 947, article "Fonderie de fer."

Foun'tain Pen. One carrying a supply of ink, fed gradually to the point of the instrument. The pens shown in Fig. 1091 have abandoned any attempt at graceful writing, being merely hollow handles with tubular points. A fine needle inside governs the flow of the ink in the Stylographic pen, — the two figures on the right. In the McKinnon pen, the tubular point is fine, and yields ink when pressure is applied.

Fig. 1091.



Fountain Pens.

Foun'tain Pump. A garden or syringing pump, for watering flowers, or applying wet poisons to the cotton worm, etc.

Comstock's "*Report upon Cotton Insects*," 1879,* p. 239, and Fig. 51.

See also SPRAYING MACHINE; SPRINKLER; INSECT DESTROYER, *infra*.

Four-cyl'in-der En'gine. See the following: —

Brown, Winterthur . . * "*Engineering*," xxi. 126, 177.

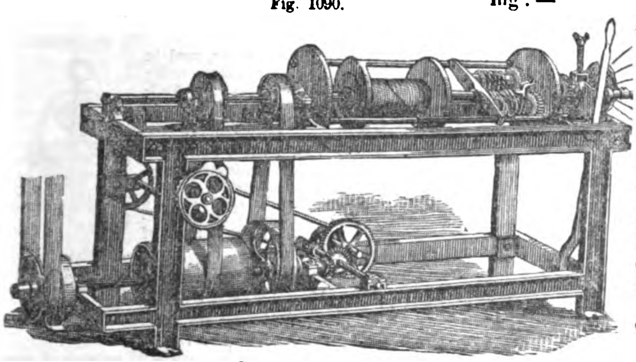
Fig. 1090.



Rope-forming Machine.

Four-high Mill. A rolling mill with four rollers in tier. "*Iron Age*," xxii., Dec. 5, p. 3.

Four Screw Chuck. A lathe chuck in which the object is centered by the use of four screws quadrantically disposed. See DRILL CHUCK, p. 276, *supra*.

Four Spindle Drill. A gang drill with four spindles.

Pratt & Whitney, * "*Thurston's Vienna Report*," ii. 224.

Four-strand'ed Splice. (*Nautical.*) A splice made in a four-stranded rope, or *four cant* rope.

Four Valve Spec'u-lum. A urethral, or other, speculum which has four expanding fingers as in several of the instances, Fig. 5360, p. 2260, "*Mech. Dict.*" Certain speculi are always referred to under their specific names, as *otoscope*, *rhinoscope*, etc. See list under SURGICAL INSTRUMENTS and SCOPE, p. 2056, "*Mech. Dict.*"

Four'-way Cock. 1. (*Railway.*) A faucet in the air-brake arrangement with two passages in it, and used for opening and closing communication between the brake cylinder reservoir, brake pipe, and triple-valve. See TRIPLE-VALVE.

2. A bath tub cock with index, "Hot," "Cold," "Waste," "Shut."

Frac'ture Ap'pa-ra'tus. (*Surgical.*) The list includes splints, bandages, swings, extension apparatus, bedsteads, etc. The distinctions are also drawn from the part affected. See SPLINT, EXTENSION APPARATUS, COUNTER EXTENSION APPARATUS, etc., in "*Mech. Dict.*"

See list under SURGICAL INSTRUMENTS AND APPARATUS, pp. 2459-2461, "*Mech. Dict.*" The following references are to *Tiemann's* "*Armamentarium Chirurgicum*," Part IV.

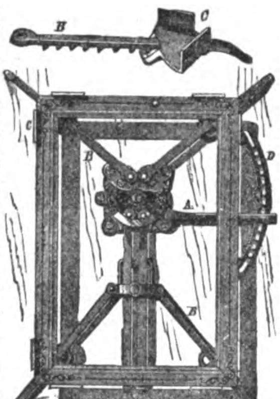
Suspending apparatus	Figs. 102, 103, 120, 130, 140, 154, 156, 157, 174.

Frame Clamp. A device for putting picture and looking-glass frames together. To a single lever *A* moving over a rack *D*, four stretchers are connected each to one of the corner clamps *C* so as to draw them equally. The clamps *C* are adjustable on the stretchers, as seen in the detached view, according to the size of the frame.

Fig. 1092.



Frame Clamp.

Frame Drill'ing Ma-chine'. A machine, Fig. 1093, with several self-acting drilling head stocks for operating on different parts of a locomotive frame at the same time. — *Whitworth.*

Frame'less Spec'ta-cles. Those in which the nose-piece and temples are attached directly to the lenses; bows being dispensed with.

Frame Pla'ning Ma-chine'. A machine with independent self-acting cross slides and tools, for planing different parts of a locomotive frame at the same time.

Frame Slot'ting Ma-chine'. A machine for working on locomotive frames, having several self-acting head-stocks capable of being independently operated.

Frank'lin Spec'ta-cles. The lens in each bow is divided on its major axis; the upper section for *far*, and the lower for *near* observation; for distance and for reading.

Freez'ing Ap'pa-ra'tus. (*Surgical.*) See ATOMIZER; SPRAY APPARATUS, etc., Fig. 181, p.

Fig. 1093.

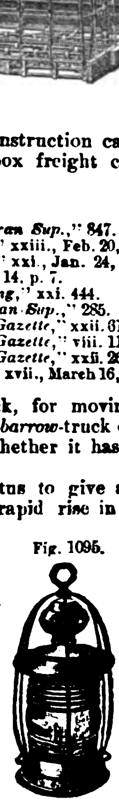
Freight Truck. A hand-truck, for moving heavy packages, known as a freight *barrow*-truck or freight *wagon*-truck according to whether it has 2 or 4 wheels respectively.

Fresh'et Sig'nal. An apparatus to give an alarm upon the occurrence of a rapid rise in a stream.

Gros's freshet signal apparatus, used in the Lot, Aveyron, France, indicates automatically, by electrical means, any variations in level from a higher to a lower point. A float at the higher point communicates its upward and downward movement, by means of a battery and wire, to a needle pointing on a graduated scale. When the rise is such that there is danger, a bell is sounded which sets in action a number of bells in the houses of inhabitants along the banks and warns them of the coming flood.

Fig. 1095.



Fresnel Lamp.

Fres-nel' Lamp. One with a cylindrical lens formed of prismatic zones above the equatorial region.

Fres-nel' Lens. (*Optics.*) A lens consisting of a central portion of spherical section and surrounding rings, so adapted as to direct the rays practically parallel, and prevent their loss by radiation in useless directions.

The *Fresnel* is the third in the series of the great improvements which are now universally adopted in light-houses, using the dioptric system. These three inventions are French, and are the *Argand* burner (1774), the mechanical lamp (*Carcel*), and the *Fresnel* lens (1810). The light is in the focal center of a series of lenses, which assume what may be roughly called a barrel-shape, around the burner. The equatorial portion of the series is a sort of cylindrical hoop, the vertical section of the band of glass showing such lines that the rays passing through it are diverted to a horizontal plane; the rays striking above or below the central zone are intercepted by rings of prismatic section, and are so refracted as to assume a direction parallel to those proceeding from the equatorial region of the glass envelope surrounding the burner. See DIOPTRIC LIGHT, Fig. 1657, p. 704, "*Mech. Dict.*"

Fig. 1096.

Fresnel Lens.

Fret Saw. A jig or band saw, for bargeboard, bracket, and Sorrento work.

Friction Clutch.

Fric'tion Brake. 1. *Prony's* brake. A form of *dynamometer*. Fig. 2102, p. 915, "*Mech. Dict.*"

Richards . . . . . "*Iron Age*," xx., Aug. 30, p. 11.

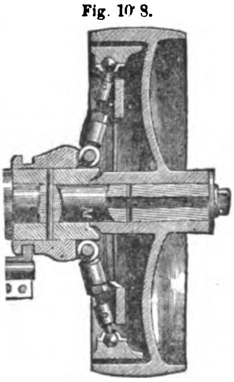
2. A measurer of the lubricity of oils. See FRICTION METER, OIL TESTER.

Fric'tion Clutch. A device by which a pulley is made fast to a shaft so as to partake of the motion of the latter; or one shaft made to partake of the motion of another

Fig. 1097 shows Frisbie's clutch, which fastens by the hub. The cone is moved by the shipper expanding the levers and so locking the parts together that the frictional adherence is equal to the duty of transmitting the motion of one part to the other.

Mason's clutch, Fig 1098, operates by expanding the friction segments against the inner rim of the wheel: a longitudinal sliding movement of the sleeve towards the pulley effects this; and *vice versa*.

Fig. 1098.



Friction Clutch.

A Belgian friction clutch operates by contact of two disks with interlocking face grooves.

See the following:—

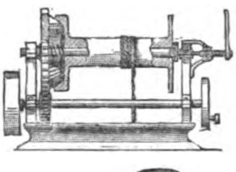
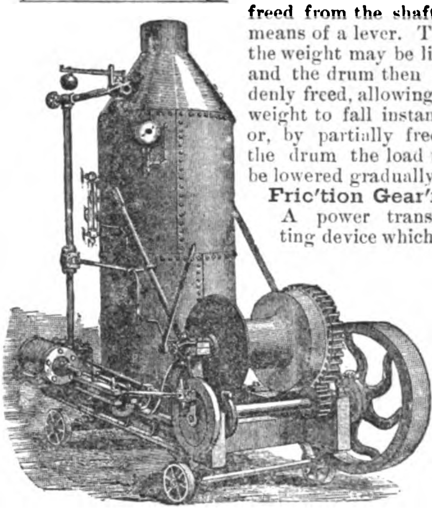
"Giant" . . . . . * "*American Miller*," viii. 225.

Fric'tion Drum Hoist. A hoisting engine operated by friction from a constantly moving shaft. Fig. 1099 shows Mundy's friction drum hoisting machine, used for pile drivers and derricks. It is a portable engine and hoist, but the drum can be locked to or freed from the shaft by means of a lever. Thus, the weight may be lifted and the drum then suddenly freed, allowing the weight to fall instantly; or, by partially freeing the drum the load may be lowered gradually.

Fig. 1099.





Friction Drum Hoist.

Fric'tion Gear'ing. A power transmitting device which depends upon the frictional adherence of the allied parts.

In Van Haagen's, the wheels have square grooves in their peripheries which interlock so as to form intimate bearing surfaces.

See also Fig. 1601, p. 680, "*Mech. Dict.*," where friction gear is shown as working the feed of a sawmill.

Gear . . . . * "*Engineering*," xxiii. 147.

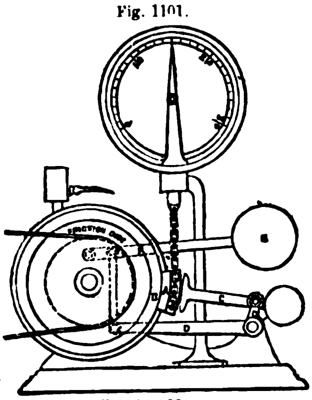
Fric'tion Heat'er. A device for obtaining heat from friction. A cylinder of water has an iron end plate, against which revolves a disk, and the friction of the two generates heat, which is communicated to the water. The latter is conducted in any usual way to different parts of the house. — *Prof. Wills.*

Fric'tion Ma-chine'. An electric machine, generating electricity by contact with amalgamated silk.

Fric'tion Me'ter. A test for lubricators.

The block *A* is pressed against the periphery of the wheel by an arm *C*, which is a segment of a roller, balanced and pivoted on the short arm of the bell crank *D D*, the long end of which is connected by a link to the lever *F*, which has a weight, *E*, on the outer end of it; and a chain connects the friction block *A* to a spring balance. The wheel is to be made to turn to the right at any desired velocity of circumference, by means of a band from a lathe, or otherwise, when the friction of the wheel on the friction block will tend to carry the latter along with the former; but it is prevented from doing so by the chain to the spring balance, which indicates the amount of the tendency of the block to move along the wheel, or, in other words, the total amount of friction on the rubbing surface. — *Napier.*

Fig. 1101.



Friction Meter.

See also OIL TESTER; LUBRICANT TESTER.

Fric'tion Rol'ler Drop. An arrangement for working a drop hammer. Hotchkiss & Stiles. See Fig. 2104, FRICTION HAMMER, p. 916, "*Mech. Dict.*"

Fric'tion Wheel. One operating by the friction of its surface; as in some cases a large buff-covered wheel driving a number of spindles by frictional contact.

See some notices in Cooper's "*Belting*," 206.
See also FRICTION GEAR; FRICTION CLUTCH, *supra;* and FRICTION WHEEL; FRICTION HAMMER, "*Mech. Dict.*"

Friez'ing Cut'ter. A rotative bit for making friezes, moldings, etc.

Friez'ing Ma-chine'. An edge-molding machine. The vertical cutter projects up through the table of the machine and works molding on the stuff fed up to it. It is called a friezing machine, as it is adapted to making frieze moldings for ceilings. See Fig. 3200, p. 1468, "*Mech. Dict.*"

Frit. (*Ceramics.*) The material for glaze of pottery.

A frit for stoneware glaze: —

Ground feldspar	25
Ground quartz or flint	25
Sal soda	25
Clay	15
Boracic acid	10
	100

After being fused in a *frit furnace*, it is run into a stone vat, cooled, broken into fragments, and ground into a fine paste with water in a *frit mill.* The result is a fine slip to which white lead as a fuse and cobalt as corrective of yellow are added.
The porous biscuit is dipped in this slip.

Frit Fur'nace. (*Ceramics.*) A reverberating furnace in which frit for glaze is fused.

Frit Mill. (*Ceramics.*) A tub mill, with buhr-stones in which the material for glaze (see FRIT) is ground into an impalpable slip.

Fromm'hold Cell. A single liquid battery having a platinized leaden plate clamped between two zinc plates with intermediate insulation. Immersed in dilute sulphuric acid.

See Slater & Watson's English Patent, 1852.

Front Cyl'in-der Head. That head which is opposite to the piston. The *back end* has the stuffing box for the piston-rod.

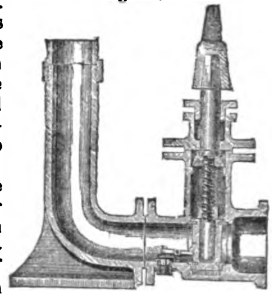
Front Sight. As distinguished from rear or hind-sight. The sight on a gun near the muzzle. It may be *globe, aperture, open,* or *pin.* See SIGHT.

Frost Cog. A toe or projection on a horse shoe to keep the animal from slipping on ice or frozen ground.

Frost'ing. (*Fine Art Metal-working.*) Making a dead surface on the metal so as to give a sombre tint; or it may be done over a part of the surface so as to throw the bright portions into greater prominence and so obtain variety.

Frost Valve. A valve which opens to allow water to escape from the portion of the pipe or pump where it is liable to be frozen. Stone's frost valve is so arranged that the act of screwing down the hydrant to close it opens the small frost valve and allows the hydrant to free itself of water.

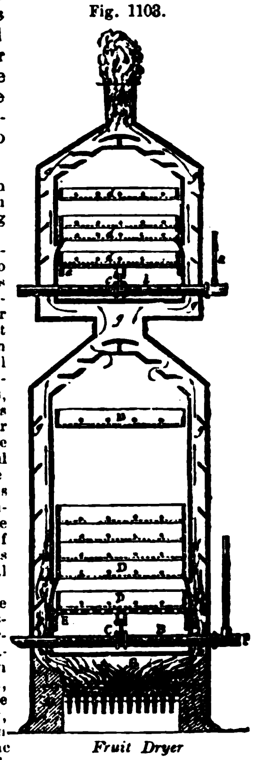
Fig. 1102.



Frost Valve.

Fruit Dry'er. The Reynolds fruit dryer is a shaft in which the shelves are horizontal. The trays of fresh fruit are put in at the bottom, the pile of trays being lifted temporarily for that purpose by means of the lifting bottom *D*, crank shaft *C B*, and handle *A*. From 12 to 20 trays are used; the heat is about 200° Fah., and the fruit in the upper trays is bathed in the steam and aroma of the fresher fruit more immediately exposed to the fire.

Fig. 1103.



Fruit Dryer

The point of delicacy in management consists in prompt drying after cutting to avoid discoloration.

It is a good plan to subject the freshly cut fruit to the fumes of sulphurous acid gas, obtained by burning sulphur in a chamber or cask in which the cut fruit is exposed. This is a plan used from time immemorial to prevent acetic fermentation in wine and cider casks, and also to delay the vinous fermentation with wine or cider. The trays with the finished article are removed from the top one at a time In Fig. 1103 the apparatus has a supplementary chamber above for finishing the operation when a tray of doubtful completion has been removed. Gold medal at Paris, 1878.

In a California machine the trays are similarly disposed but hung on a carrier-chain. The *Williams* machine has a high tower with a furnace at the bottom, and endless chains with wire trays which revolve slowly, causing the fruit last put in to pass first through the hottest part. Bleaching with sulphur is used. The *Alden* process is somewhat similar.

The *Jones* dryer (Farquhar, York, Pa.) is made in three forms, *horizontal, portable, double-flue upright.*

In the *horizontal* fruit dryer a current of heated air is drawn through the two horizontal fruit chambers by an exhaust fan. The chambers are one above the other with side doors for the introduction and removal of fruit trays.

In the *portable* the trays are in vertical columns in a sheet iron box at bottom of which is a furnace. The trays are put in at bottom, the pile being raised for that purpose, and the trays with finished fruit removed from the top. The trays are covered with netting.

The *double-flue* is larger, parts are duplicated, and it occupies the height of two stories, or a cellar and one story

Dietz California fruit dryer has a number of sloping chambers one above another The fruit in wire trays is put in at front and pushed back from time to time as new trays are ready, and the dried fruit removed at the back. The fire-heat circulates in all the chambers, the fresh fruit being exposed to the hottest part.

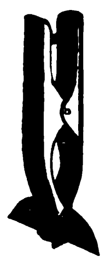
Fruit Pit'ter. A device to remove the stones of fruit, such as peaches and plums.

Hatch's pitter splits the fruit and removes the pit. Each half of the tubular opening carries its own section of the knife, and the two are hinged together so as to expand to any necessary size.

Fig. 1104.



Fruit Pitter.

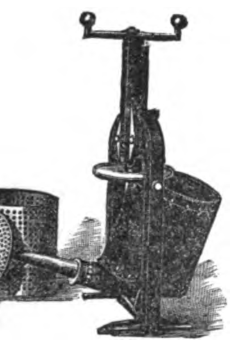
Fruit pitter, *Lillie* * "*Min. & Sc. Press,*" xxxiv. 289.

Fruit Press. Cider, wine, and oil presses are considered under their own captions. Figs. 1105, 1106 show domestic presses for small fruit, and useful also for stuffing sausages. See also DRAW-UP PRESS, Fig. 872, p. 274, *supra*, and list under PRESSES, *infra*.

Fruit (or Seed) Sep'a-ra'tor. A machine which separates and grades cranberries, beans, and seed.

Fig. 1105.



Fruit Press (Open).

Fig. 1106.

Fruit Press (Closed).

The detachable feeder runs on top, and has a trembling motion, combined (optionally) with lateral motion. The sieves are lettered for kinds of grains and seeds, and numbered for places where used. — *Brown.*

Fruit Sli'cer. An open-bottomed box with a follower, to contain fruit, and slipped back and forth in grooves over a knife fixed like that of a slaw-cutter beneath. — *Wharry.*

Fu'el. The table gives the comparative evaporative value of fuels.

The feed water being 212° Fah. when it enters the boiler, the following results were obtained from the consumption of 1 pound of the undermentioned fuels. The first eight give the average of many samples tested by Messrs. Delabecho and Playfair: —

	Specific Gravity.	Pounds of Water Evaporated.		Compar. Values.
Welsh coal	1.315	9.05	By trial	1.000
Newcastle coal	1.256	8.01		0.885
Derby and York coal	1.292	7.58		0.837
Lancashire coal	1.273	7.94		0.877
Scotch coal	1.260	7.70		0.851
British average	1.290	8.13		0.898
Irish anthracite	1.590	9.85		1.088
Patent fuels	1.167	9.20		1.016
French coal (average)	1.310	8.00	Approx.	0.884
Lignites (average)	1.198	6.66		0.736
Dried peat	1.300	4.52		0.500
Coke (average)	0.750	9.00		0.995
Oak	0.930	4.52		0.500
Pine	0.660	2.50		0.276

Wood for Fuel as compared with Coal. — It is safe to assume that $2\frac{1}{4}$ lbs. of dry wood is equal to 1 lb., average quality, of soft coal, and that the fuel value of the same *weight* of different woods is very nearly the same, — that is, a pound of hickory is worth no more for fuel than a pound of pine, assuming both to be dry. If the value be measured by the *weight*, it is important that the wood be dry, as each 10 per cent. of water or moisture in the wood will detract about 12 per cent. from its value as a fuel.

The weight of one cord of different woods (air dried) will be found to be about as follows, for an honest cord of split wood: —

Hickory, or hard maple	4,500 lbs.
White oak	3,850 lbs.
Beech, red oak, and black oak	3,250 lbs.
Poplar (white-wood), chestnut, and elm	2,350 lbs.
The average of pine	2,000 lbs.

The fuel value as compared with coal is about as follows: —

1 cord air-dried hickory or hard maple equal to	2,000 lbs. coal.
1 cord air-dried white oak equal to	1,725 lbs. coal.
1 cord air-dried beech, red oak, or black oak equal to	1,450 lbs. coal.
1 cord air-dried poplar, chestnut, or elm equal to	1,050 lbs. coal.
1 cord air-dried average of pine wood equal to	925 lbs. coal.

Buckeye Engine Co.

Fu'el, Ar'ti-fi'cial.

The artificial fuel of Loiseau is made under Patents 78,982, 104,471, 147,663–147,666, 167,913, 167,914.

1868 Patent: coal dust, clay, saleratus, and shellac made into a paste, formed in molds and dried.

1870 Patent: a protecting covering.

1874 Patents: 1. a mixing apparatus.

2. Clay is dried, reduced to powder, mixed with the coal dust, moistened with milk of lime, kneaded, molded into lumps, the lumps waterproofed with a resinous material.

3. Mixing and molding apparatus. The coal dust with clay and lime-water is placed in a pug-mill, delivered to compressing rollers in a broad sheet, and the compressed lump falls upon a conveying apron.

4. A machine for coating the artificial fuel with a waterproofing composition. An apron dipping into a tank.

5. Molding. The balls are formed by two hemispheres, which are fastened together by bolts. Wire cloth aprons are confined between the hemispheres.

1875 Patents: 1. Mixing and molding. Stirrer blades on revolving shafts feed the composition to the molding cylinders.

2. Coal waste mixed with pulverized clay and diluted rye and lime paste.

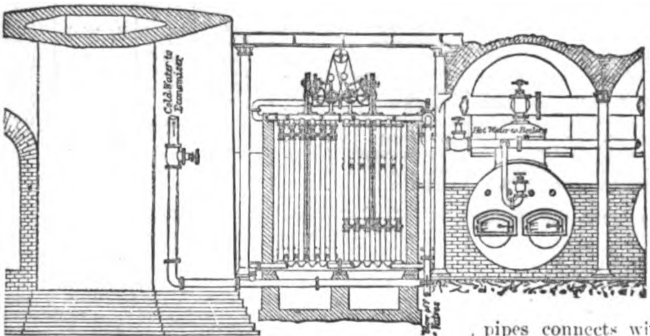
Fu'el E-con'o-mi-zer. An invention of Twibill, of Manchester, England. A feed-water heater by the waste heat escaping at the chimney.

Fig. 1107.

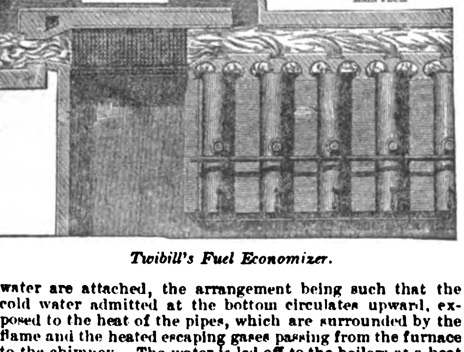


Fuel Economizer.

Statement: "There are two sources of waste in all steam boilers which may in a measure be made to neutralize each other. The gases going to the chimney carry off on an average, according to good authority, 31 per cent. of the fuel, and in the most economical boiler this cannot be reduced below 12 per cent. The feed-water, on the other hand, has to be heated from the normal temperature to that of the steam before evaporation can commence, and this generally at the expense of the fuel which should be utilized in making steam. This temperature at 75 lbs. pressure is 320°, and if we take 60° as the average temperature of feed, we have 260 units of heat per pound, which, as it takes 1151 units to evaporate a pound from 60°, represents a loss of 22.5 per cent. of fuel. All of this heat, therefore, which can be imparted to the feed-water from the waste heat in the escaping gases is just so much saved."

The *economizer* is placed parallel to the battery of boilers, between them and the chimney shaft. It consists of 36 transverse rows of vertical pipes, there being 12 pipes in each row, connected at top and bottom by transverse horizontal pipes. The pipes are of cast iron and cylindrical, the lower end turned slightly conical and pressed into a socket in the transverse pipe beneath, in which it is planted. The transverse pipes communicate at their ends with transverse longitudinal pipes, and to these the inlet and outlet for the feed-

Fig. 1108.



Twibill's Fuel Economizer.

water are attached, the arrangement being such that the cold water admitted at the bottom circulates upward, exposed to the heat of the pipes, which are surrounded by the flame and the heated escaping gases passing from the furnace to the chimney. The water is led off to the boilers at a heat of 280° Fah.

A scraper is provided for each pipe to remove soot from the exterior to keep the heat-conducting character of the iron intact. These are coupled in groups, and kept continually moving up and down by means of gearing, pulleys, and scraper chains.

The *Babcock & Wilcox* fuel economizer holds a similar place between the furnace and chimney. The tubes are connected at top and bottom with horizontal tubes, the lower row of which are connected to a mud-drum, and the upper row are connected together at the end diagonally opposite to the mud-drum. The feed-water enters at one end of the mud-drum and passes out at the opposite end of the upper connecting pipe. The hotter gases, filling the upper portion of the chamber, come in contact with the water at its highest temperature, so that it is possible to heat the latter very nearly to the temperature of the escaping gases before it flows to the boiler.

Ample provision is made for cleaning the interior of the vertical and horizontal tubes, and the mud-drums, by means of hand-holes with metallic joints opposite the ends of each tube. This is important, as in most hard waters sediment will form in the economizer more readily than in the boiler.

By means of a direct flue to chimney, the economizer may be cleaned without stopping the boilers.

Mechanical scrapers worked from above are provided for removing deposits of soot from the exterior of the tubes, the soot falling into a chamber below, from which it may be removed at convenience.

The Miller economizer consists of rows of tubes lining the sides of the fire chamber beneath, and partially alongside of the boiler. The system of pipes connects with the lower and upper portions of the boiler and causes a circulation, as well as adding a large amount of heating surface.

See also list of references under FEED WATER HEATER, pp. 328-330, *supra*. See also HOT-BLAST APPARATUS, *infra*, for a device of somewhat similar construction but for the purpose of heating air for metallurgic furnaces. See also REGENERATOR and GAS-GENERATING FURNACE, for other methods of utilizing escaping furnace heat.

Fuel Feed'ing Ap'pa-ra'tus. In Jucke's device the fuel is placed on an endless chain carried by two rollers and driven by the engine. This endless chain forms the fire-bars, and moves so slowly that the fresh fuel placed upon it at the furnace mouth is gradually carried backward, consumed, and delivered at the rear in the form of ashes and clinkers. The rollers and chain are carried on a sort of trolly, so that the whole can be drawn out when necessary, and the rate of motion is made adjustable to regulate the supply of fuel.
