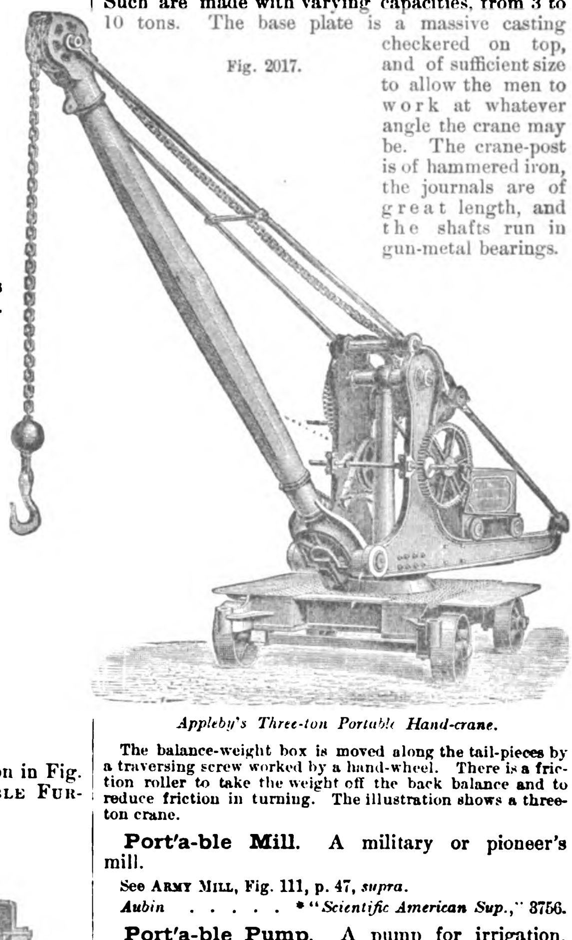
The furnace containing the crucible is moved on wheels, as in Fig. 735, p. 233, *supra*, or is slung from a crane.

Piat, Fr. . . . . * "*Engineer*," xlix. 260.
* "*Engineering*," xxviii. 397.

Port'a-ble Hand'-crane. A crane on a truck. Such are made with varying capacities, from 3 to 10 tons. The base plate is a massive casting checkered on top, and of sufficient size to allow the men to work at whatever angle the crane may be. The crane-post is of hammered iron, the journals are of great length, and the shafts run in gun-metal bearings.

Fig. 2017.



Appleby's Three-ton Portable Hand-crane.

The balance-weight box is moved along the tail-pieces by a traversing screw worked by a hand-wheel. There is a friction roller to take the weight off the back balance and to reduce friction in turning. The illustration shows a three-ton crane.

Port'a-ble Mill. A military or pioneer's mill.

See ARMY MILL, Fig. 111, p. 47, *supra*.

Aubin . . . . . * "*Scientific American Sup.*," 3756.

Port'a-ble Pump. A pump for irrigation, extinguishing fires, for green-house purposes, watering lawns, etc.

See under various titles. Such as HYDRONETTE, AQUAPULT, etc.

In a smaller form a STOMACH PUMP, INJECTOR, SYRINGE DOUCHE, etc., which see.
In one sense, a FIRE ENGINE, which see.
Fig. 2018 shows a French portable pump and tank.
See IRRIGATION PUMP. Figs. 1473-1475, p. 508, *supra*.
See NORIA; PORTABLE ENGINE AND PUMP, *supra*.
Also Fig. 1218, p. 516, "*Mech. Dict.*"

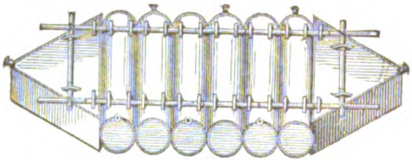
Port'a-ble Raft. One capable of transportation on a journey as distinct from one simply hove overboard from a ship, or made in an emergency from masts, casks, and other floating material. See Figs. 4105–4108, pp. 1854, 1855, "*Mech. Dict.*"

Fig. 2018.

French Portable Pump.

The life-raft, as shown in Fig. 2019, is of a form that might wisely be adopted for use nearer home. Stanley's portable raft was composed of six caoutchouc ponton tubes, which were inflated at pleasure by means of bellows. These tubes rest transversely on three keels, to which are lashed the poles shown above. The bow and stern consist of triangular compartments, and the whole during transportation may be

Fig. 2019.



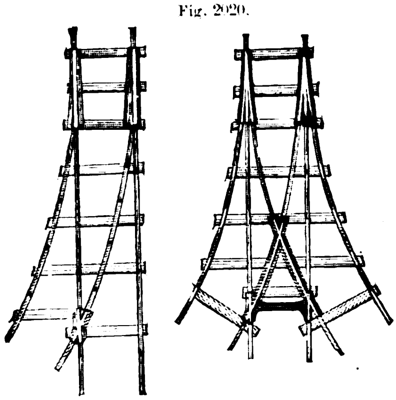
Stanley's Raft.

packed in a convenient form. Its whole weight is 300 pounds, which can be divided into five loads of 60 pounds each.

See also RAFT, "*Mech. Dict.*," *et infra ;* LIFE BOAT, Fig. 1588, p. 542, *supra ;* PORTABLE BOAT, *supra*.

Port'a-ble Rail'way. A system having tracks in section laid down on plantations, in wine caves, or in manufacturing establisements, for conveyance of crops, heavy articles, packages, and what not.

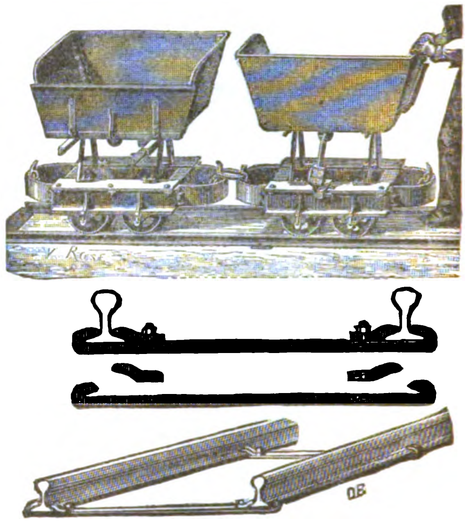
Fig. 2020.



Decauville's Portable Railway.

The system shown in Figs. 2020–2022 is that of *M. Decauville*, of Petit-Bourg, near Paris. The rails have iron ties laid

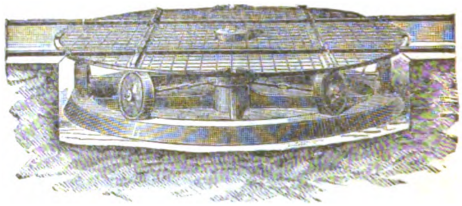
Fig. 2021.



Portable Railway Trucks, Rails, and Track.

in sections of track 5 meters long, more or less, with switches, turn-outs, and turntables, according to the requirements of the special case. It is evident that while in field-railways a curve may be admissible, it will frequently be necessary to substitute a turntable in the passages of a yard or building.

Fig. 2022.



Turntable.

The trucks shown are dumping cars used in plantation use for conveying beets especially from the field to the sucrerie or distillery. Other forms are used in wine caves and in factories and for cane plantations.

Fowler, Br. . . . . . . * "*Engineer*," xlviii. 34.

Port'a-ble Steam Crane. A locomotive steam crane. Used in factories and many public and private works of the larger class.

The crane shown in Fig. 2023 was used in dismounting heavy freight from flat cars at the Paris Exposition, 1878.

The Aveling & Porter portable steam crane is a modification of their traction engine, having the same locomotive power with the addition of the winding drum and crane. The foot of the jib is rigged in front, resting upon the front base-piece of the boiler, and the top is supported by iron rods which are attached to the side plate brackets. The sides of the fire-box are extended upward to form the crank shaft brackets.

See, also, RAILWAY CRANE, *infra ;* STEAM CRANE, "*Mech. Dict.*"

Port'a-ble Steam En'gine. One capable of moving or being moved from place to place. They are known by various specific names, according to purpose, usually. See various captions under PORTABLE ENGINE.

See also PORTABLE STEAM ENGINE, Figs. 3895–3899, pp. 1769, 1770, "*Mech. Dict.*"

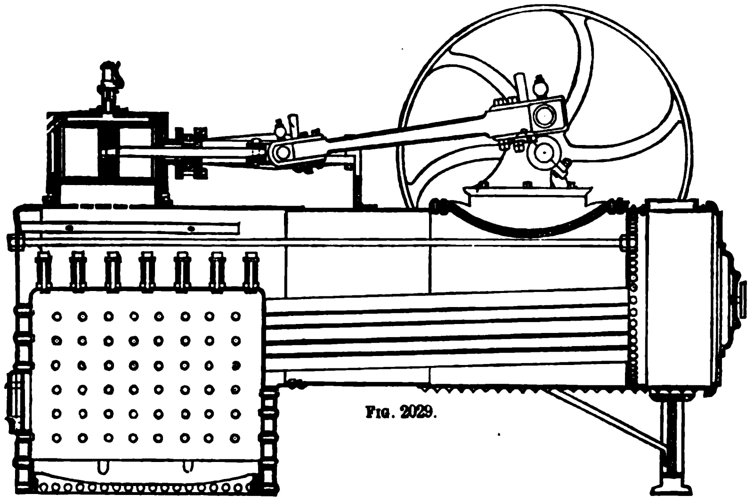


Fig. 2029.

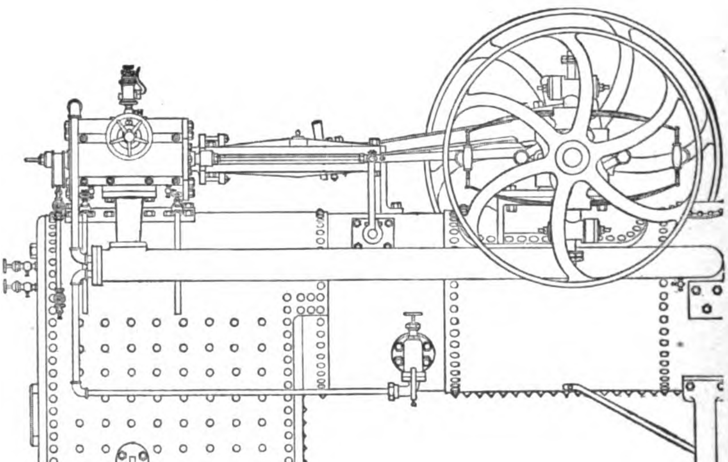

Fig. 2025.

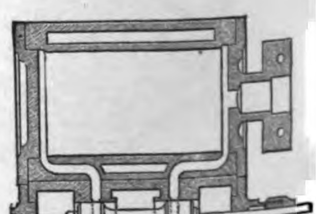

Fig. 2027.

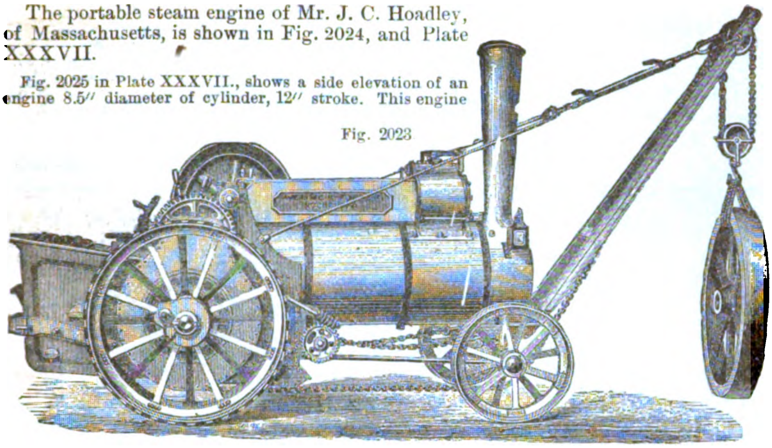
 See page 711.

The portable steam engine of Mr. J. C. Hoadley, of Massachusetts, is shown in Fig. 2024, and Plate XXXVII.

Fig. 2025 in Plate XXXVII., shows a side elevation of an engine 8.5″ diameter of cylinder, 12″ stroke. This engine gives 20 indicated horse-power with 100 pounds per square inch steam gage pressure in the boiler, and four-fold expansion. The boiler easily supplies steam for 25 indicated horse-power.

Fig. 2023



Aveling & Porter's Portable Steam Crane.

Fig. 2026 shows the fire-box end of an engine 8.5″ diameter of cylinder, 12″ stroke, in end elevation.

Fig. 2027 is a horizontal section on the axis of cylinder and steam chest of an engine 8.5″ diameter of cylinder, 12″ stroke.

Fig. 2028 is a side elevation on the larger scale of the governor of an engine 3.5″ diameter of cylinder, 12″ stroke. The leaf springs are straight when unconfined by the links at their extremities. The centrifugal force of the springs, of the sliding heads which confine their thicker ends, and of the adjustable weights attached to these sliding heads, causes the heads to slide outward, toward the binding-nuts at the upper and lower ends of these rods, thereby increasing the tension of the springs, and shifting the eccentric, by means of the toggle-joint at the left-hand, and the sliding-plate to which the eccentric is fast, cast solid with it.

The sliding-plate and eccentric are slotted, as shown by dotted lines. The slot is long enough to admit of shifting the sliding-plate to the other toggle-joint, at the right, which reverses the engine.

Fig. 2029 is a vertical, longitudinal section, on the axis of a similar boiler and engine.

A spray-plate, indicated above the tie-rod, over the fire box, prevents the direct admission of entrained water to the jacket around the cylinder.

Fig. 2030 is a vertical cross section through fire-box and cylinder of an engine 8.5″ diameter of cylinder, 12″ stroke.

An engine of the class represented in the accompanying cuts, and of the same arrangement and construction, was tested at the International Exhibition in Philadelphia, Sept. 7, 1876, under the direction of John S. Albert, Chief of Bureau of Machinery, by Charles T. Porter, Charles E. Emery, and Joseph Belknap, Judges.

An ordinary, commercial engine, made and subsequently used to drive a saw-mill, it was destitute of all the refined appliances for saving heat and for obtaining unusual duty almost universal in trials of this kind. The boiler was entirely naked, and exposed a radiating surface equal to 40 per cent. of its heating surface, to a draft of cool, damp air. The loss caused by this radiation has been found experimentally to be at least 12 per cent.; and about 7-12 of this loss might have been saved by a simple boiler clothing.

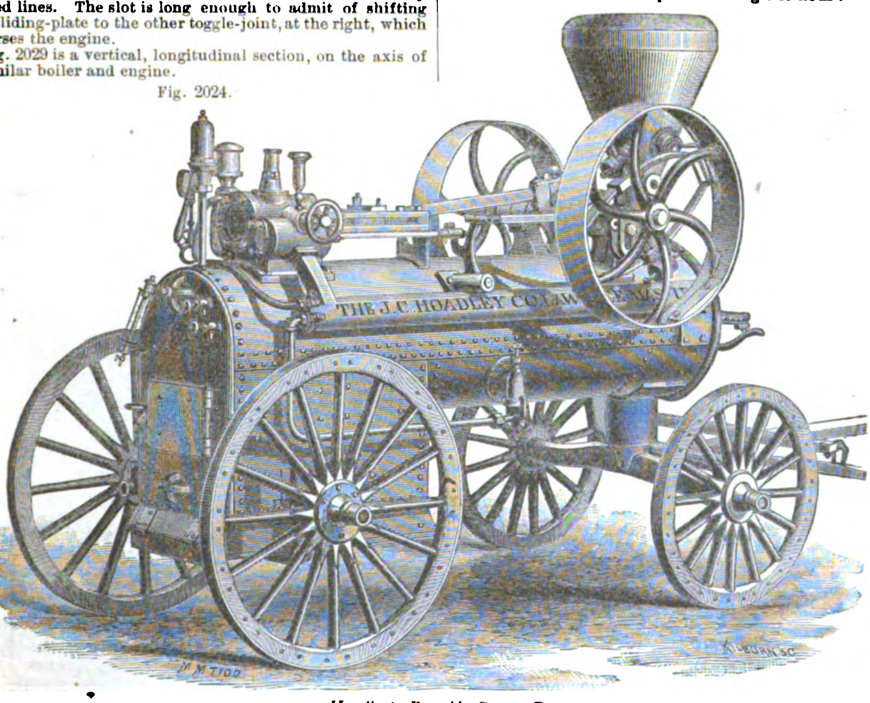
The ordinary anthracite used was wet by rain in transit to the engine, and was fired without special skill by a man who never before saw the engine.

All the conditions were arranged so as to represent the ordinary practice of men commonly using this class of engines. All these circumstances should be borne in mind in comparing results with those obtained by exceptional skill and care from "racing engines."

CONSUMPTION.

For each indicated horse-power during one hour: —

Fig. 2024.



Hoadley's Portable Steam Engine

25.61 pounds of feed-water, by weight.
19.38 pounds of visible steam, by diagram.
3.35 pounds of anthracite coal.
2.95 pounds of combustible.

GENERAL DIMENSIONS.

Engine.

Diameter of cylinder	14.56″
Diameter of piston-rod	2.375″
Length of stroke	1.66′
Capacity of clearances and passages in terms of stroke	.091

Boiler.

Length of shell	16′
Diameter of shell, inside	40″
Length of fire-box, inside	54″
Width of fire-box, inside	34″
Height of fire-box, above grates (whole height, 48″)	44″
Number of tubes	80
Diameter of tubes, outside	2.25″
Length of tubes (between tube-sheets)	113″
Heating surface in fire-box above top of grates, square feet	60.5
Heating surface, tubes, inside, square feet	394.5
Heating surface, smoke-box, square feet	6.5
Heating surface, aggregate, square feet	461.5
Area of fire-grate, 54″ by 34″, square feet	12.75
Ratio of heating surface to fire-grate area	36.2

SUMMARY OF RESULTS OF TRIAL.

Kind of Quantities.	*Pounds.*
Feed-water per dynamometer horse-power, per hour	28.27
Feed-water per indicated horse-power, per hour	25.61
Visible steam per dynamometer horse-power, per hour	21.40
Visible steam per indicated horse-power, per hour	13.38
Coal burned per dynamometer horse-power, per hour	3.69
Coal burned per indicated horse-power, per hour	3.35
Combustible burned per dynamometer horse-power, per hour	3.26
Combustible burned per indicated horse-power, per hour	2.95
Water evaporated per pound of coal burned	7.65
Water evaporated per pound of combustible burned	8.68

EFFICIENCY.

The indicated horse-power is obtained from 300 to 350 pounds of engine and boiler.

The portable horizontal trade engine of Marshall, Graves & Co., is shown in Plate XXXVIII.

The parts are plainly visible, and scarcely need description. The boiler is of the locomotive pattern, with arched crown sheet braced and stayed. The water front extends around the fire-box and ash-pit. The boiler and engine are so far independent of each other that the expansion of the former in heating up brings no strain on the latter. The valve has variable expansion arrangement. The spark arrester has a steam spray. The wheels are of iron, and turn under the boiler. The bed plate forms the heater, and is bolted to the boiler on the cylinder end. The pump is worked directly from the cross-head.

The portable and traction engine of Hooven, Owens, Reutschler & Co., is shown in Plate XXXVIII.

The engineer stands upon the rear plate, and has the starting and reversing levers, and the steering wheel immediately in front. The train by which the relatively rapid piston motion is geared down to the propulsion movement is principally upon the other side of the machine, as shown in the cut; but parts of it are visible above and below the boiler, and the pinion which actuates the spur wheel of the driver is on the side presented. When the engine is in place, the locomotive portion is thrown out of gear, and the force of the engine applied to the band wheel.

Several forms of portable steam engines, locomotive (self-moving), and otherwise, are shown on p. 1770, "*Mech. Dict.*:" also semi-portable at Fig. 3895, p. 1769. The smaller class of engines, such as the Baxter, Fig. 3898, p. 1770, are light in weight, and, in a sense, portable, but not according to the proper meaning of the word as applied in this connection.

Por'ta-ble Wind'ing En'gine. A movable hoisting engine used in many temporary works, either buildings or excavations.

The forms vary with the purpose and the power required.

The instance given in Fig. 2031 is a 12 horse-power, used in railway works. It is mounted on wrought-iron wheels, and fitted with shafts and locking plate. The engine is fitted with link reversing gear, so that an up or downcast cast or double rope can be worked, or lowering may be performed by steam or by the brake. The drum and gear can be readily removed when the engine is to be used for driving machinery.

Porte-ac'id Glass. (*Surgical.*) A small burette to carry a caustic, for application in a deep-seated part.

Porte Ai-guille'. A needle holder.

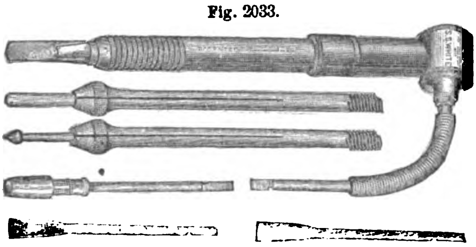
Fig. 2032.

Porte Aiguille.

See Needle Forceps, Needle Holder, *supra*; and Fig. 3306, p. 1518, "*Mech. Dict.*"

Porte Pol'ish-er. An instrument for use with the Dental Engine, Fig. 795, p. 250, *supra*. It

Fig. 2033.



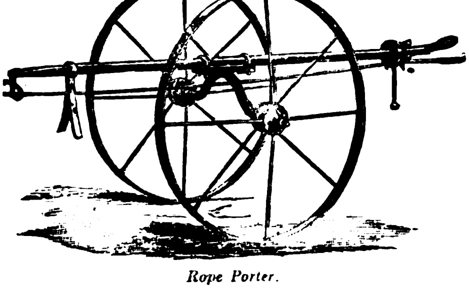
Porte Polisher and File Carrier.

may be considered a kind of chuck; a split screw, which allows the use of different sized points, and their retention by a turn of the sheath. — *Klump.*

Por'ter. Porters are wheeled supports placed along the line of the rope at intervals of 40 yards, to keep the rope off the ground in steam plowing. In another form they are mounted on three wheels, so as to allow them to be moved sideways by the rope.

The *Aveling and Porter's* traveling rope porters are fastened to the rope at intervals behind the plow or cultivator, as it leaves either headland; they travel across the field with the rope, and are taken off as they return. Their release from the rope is instantaneous. They are much less trouble than porters on any other principle, and they save the boys the fatigue of running with the implement across the field. The one which immediately follows the plow or cultivator is provided with a steerage, to prevent those behind from running on the plowed ground, and to keep the back rope clear of the furrow.

Fig. 2034.



Rope Porter.

See Installation of Steam Plow, pp. 2354, 2355, "*Mech. Dict.*"

Port'land Ce-ment'. A favorite hydraulic mortar made from the quarries of the hill of Portland, South Britain.

See Hydraulic Cement, p. 508 and 1144, "*Mech. Dict.*" Also Cement Tester, p. 184, *supra.*

Tests of, *Mann* . . . "*Van Nostrand's Mag.*," xvii. 17.
"*Sc. American Sup.*," 1333, 1427.
"*Scientific Amer.*," xxxvi. 227.

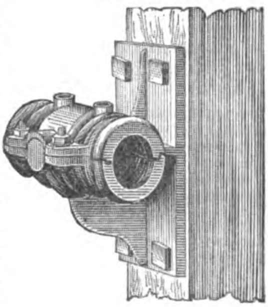
Por'trait Lathe. A lathe adapted to copying busts. It is a species of lathe for turning irregular forms, and depends principally upon the primary suggestion first embodied in useful service by Brunel in his block-making machinery in 1804, and Blanchard's spoke lathe, 1828.

See some data, pp. 1263, 1264, "*Mech. Dict.*," and discussion under article "*Sculpture par procédés Mécaniques*," vol. iii., *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," ed. 1877. Also *Ibid.*, iv., "*Tours Composés.*"

Pos'i-tive. (*Electricity.*) In the battery, the zinc plate or element.

Post Box. A shafting box attached to a post, instead of to hanging or standing pedestal.

Fig. 2035.



Post Box.

Post Drill. One supported on a standard. See Lever Drill, Fig. 1584, p. 541; Pillar Drill, Fig. 1931, p. 681, *supra.*

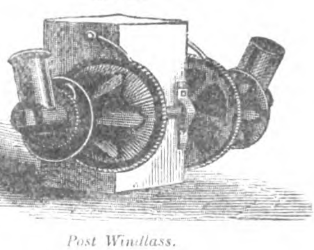
Post Mor'tem Table. One for autopsy, dissections, etc.

A table about 6½' × 2½' and slightly dishing towards a perforated plate in the center, at which water and blood are carried off by a trapped pipe to the sewer. The same pipe carries off fetid air. The table revolves, also raises and lowers, and rests upon a scales in the pedestal which has beams reading to pounds and ounces. — *McIlroy.*

Post Pumps. A form of donkey pump, attached to a port. See Pendulum Pump, *supra.*

Post Wind'lass. A winding machine which is actuated with breaks or handspikes by a reciprocating movement. In the special case it is a windlass of small size and the mode of mounting accounts for the name.

Fig. 2036



Post Windlass.

Pot. 1. (*Glass.*) The crucible in which *frit* is melted to form glass.

Glass pots are open or closed, the latter to protect fine qualities of glass, such as flint, from impurities.

In France and Belgium pots for cylinder glass usually contain 1,000 to 1,200 pounds of glass; in England sometimes as much as 5,000 pounds.

Furnaces usually hold 8 pots. It is a common European practice, and not unknown in America, to make pots thin and replace them regularly at the end of the week; instead of making them thicker to give them a longer lease of life.

The batch is put into the pots in three lots, allowing each to melt before adding another. The allowance of melting time, with a class of large pots, is —

For the first charge	7
For the second charge	4
For the third charge	3

2. (*Fishing.*) The *bowl*, *pound*, or *crib* of a *pound-net*, which see.

Po-tas'si-um-chlo'rate Bat'te-ry. (*Electricity.*) One in which potassium-chlorate with sulphuric acid is used as the depolarizer.

	"*Niaudet*," American translation, 210.
Potassimeter	"*Potassimètre*," *Laboulaye's* "*Dict.*," iii.
Potassa, industry	"*Scientific American*," xxxiv. 260.

Po-ta'to Bug De-stroy'er. A device for sprinkling or dusting poison upon the beetles, or sweeping them off the plants into trays.

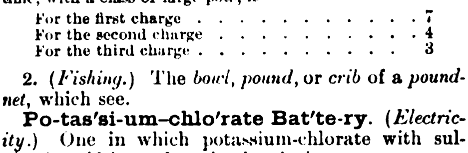
See list, where the devices of this nature are described, COTTON-WORM DESTROYER, p. 226, *supra*.

Po-ta'to Cov'er-er. A one-horse machine with flanged expanding sides that draw the soil from both sides and cover the potatoes, or other ridge crop.

Po-ta'to Dig'ger. Three forms of machines for digging potatoes are shown on pp. 1775, 1776, "*Mech. Dict.*"

Those given in the accompanying Figs. 2037-2039, are respectively French (double effet.), American (*Speer*), British (*Permey*).

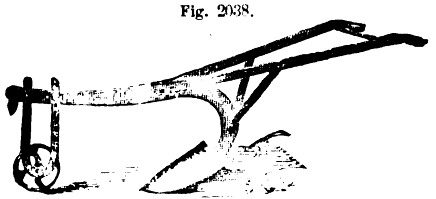
Fig. 2037.



French Potato Digger.

Their action is essentially different. One acts as a plow with lifting prongs to separate the tubers from the soil; an-

Fig. 2038.



American Potato Digger.

other plows up the tubers and soil and separates them by a dancing grating: the third has revolving forks which throw up soil and tubers against a dependant screen.

The "Empire" potato-digger, *Allen & Co.*, is a machine in which a plow is succeeded by bent revolving forks which work through the furrow slice and sort out the potatoes from the soil.

Avery's is a shovel plow with prongs extending behind the share.

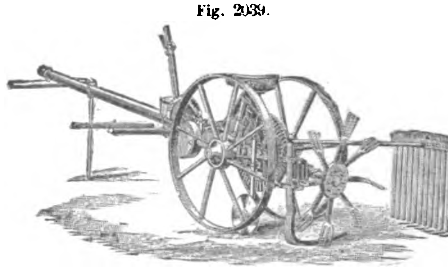
Fig. 2039.



British Potato Digger.

Po'tent. (*Horology.*) A journal plate or bearing in a watch.

Po'ten-tite. An explosive used in the Cumberland and Furness mines, England.

Pot'te-ry. (*Ceramics.*) Pottery is an inclusive term, and comprehends all the varieties of baked clay ware.

Ceramics and *ceramic art* are the scientific terms which include the whole art of making and ornamenting objects of clay.

Even bricks are a class of pottery and are only distinguished from tiles of a common order by their shape. Of the many millions of bricks of which the major part of ancient Rome was built, a large proportion would be termed tiles, if classed according to their shape.

The saying of Augustus that he "found Rome brick and left it marble," has its comment in the fact that the hordes who captured Rome "found it marble and left it brick," for the marble was generally but a covering of slabs which have generally disappeared. The baths of Caracalla and the basilica of Constantine, as examples, are enormous masses of brick walls, from which the white and colored marble veneering has disappeared.

Pottery takes two grand divisions: *soft* and *hard*.

Soft pottery may be divided into four kinds: —

1. *Unglazed*; simply made of baked clay, porous and without lustrous surface.

2. *Lustrous*, or semi-glazed, but imperfectly resisting water.

3. *Glazed*, having a shining surface which is proof against water and uncorrosive liquids.

4. *Enameled*, or having a vitreous and more incorrodible and impermeable surface.

While the archaic and technical interest of the first-named three varieties is very great, the latter includes the principal objects of interest in modern soft pottery manufacture and embellishment.

Soft pottery embraces *faïence* and *majolica*, from Faenza (in Italy) and Majorca, two localities where the art of decorating pottery flourished in times past; in the former, notably in the sixteenth century, and in the latter during the Saracenic occupation of the island.

Almost every nation in Europe is now struggling to lead in the making of faïence, and the influence of the works of Asia, from China, Japan, India, Arabia, and Persia have suggested compositions, designs, forms, colors, and objects which have greatly increased the variety and beauty of European productions.

Hard pottery, or porcelain, is of a more vitreous character than *soft* pottery. Its composition is materially different, and it approaches glass in its character. Porcelain, in breaking, shows a vitreous character, usually white, though the color depends upon the material. Soft pottery has a rough fracture, exposing the porous clay body. Porcelain has a much sharper ring when struck, its material being hard and homogeneous. Pottery is translucent; soft pottery opaque.

Porcelain is divided into *hard* and *soft* paste, indicative of the relative compactness of the material. This may be stated in a general way to be due to the proportions of silica. See PORCELAIN, *supra*.

Stone ware is practically a grade between porcelain and earthenware.

See list under CERAMICS, p. 186, *supra*.

Brogniart divides pottery into 3 classes and 9 orders: —

I. Tender paste; sandy clay, calcareous; generally fusible in a porcelain fire.	1. Terra-cotta: bricks, tiles, and coarse earthenware. Sandy-clay ware, with dead surface, without glaze. 2. Lustrous pottery: thin silico-alkaline glaze. 3. Glazed pottery: lead glaze. 4. Enameled pottery (common faïence): tin glaze.
II. Hard paste. Argilo-silicious. Infusible.	5. Fine faïence: uncolored paste; lead, glass glaze. 6. Stone ware: colored paste, without glaze, or with silico-alkaline glaze.
III. Hard paste. Translucent; argilo-silicious; alkaline.	7. Hard porcelain: k aolinpaste, with feldspathic glaze. 8. Natural tender porcelain: paste argilo-saline, phosphatic, kaolinic; lead, glass, or boracic acid glaze. 9. Artificial tender porcelain: fritted marlaceous saline paste; lead-glass glaze.

I. 1. Fr. *Terre Cuite.* The ordinary and coarser kinds of pottery are made of plastic clay or argillaceous marl tramped, or ground in a pug-mill, and mixed with sand, lime, or cinders, according to the quality of the clay. The drying of bricks is usually in the open air, but of other objects sometimes in ovens.

The produce is an article open and porous, usually not very hard, and the objects are unglazed.

This class of pottery comprises: —

a. Bricks for building, not including *fire bricks* (which see).

b. Tiles for roofing and paving, not including glazed, enameled, and decorated. See TILE.

c. Stove and furnace pots; though these are often of refractory material, and not of the material cited above.

d. Drain tiles, water pipes, and hollow bricks.

e. Common household pottery not glazed, such as the chafing dishes used in Europe.

f. Flower pots and horticultural vases.

g. Sugar molds.

h. *Alcarazzas*, or cooling jars for water; *hydrocérames.*

I. 2. Fr. *Poteries tendres lustrées.* The paste is fine, homogeneous, opaque, and of a red or yellow color; the surface covered with a luster or peculiar alkaline-silicious glaze, now of a reddish or a black color, very thin and resisting. The ware has a dull fracture, and was baked at a low temperature. The Greek, and some other ancient pottery, belongs to this class, and it is not made now-a-days.

I. 3. Fr. *Poteries tendres vernissées.* This class includes the ordinary pottery before the making of *faïence*, and is still common in many countries. The paste is of plastic clay or argillaceous marl and sand, with the addition of lime, when it is not present with the clay. The materials are ground, the objects baked under protecting hoods, the biscuit ware dipped in a slip of lead glaze colored with oxides of manganese or copper.

I. 4. Fr. *Poteries émaillés.* Common *faïence.* Probably invented in Persia; introduced by the Saracens into Spain and Majorca (*majolica*); rediscovered in Italy by Luca della Robbia, born at Florence 1388 (*faïence*); and again by Palissy in the middle of the 16th century (Palissy ware).

The material of the paste is plastic clay, or argillaceous marl and sand. The clay is washed. The material is carefully mixed and milled, the ware baked at two operations; one for the biscuit, and the other for firing after glazing. This is frequently done in the same kiln, the crude being above, and the enameled ware below. The heat of the latter is a few degrees the hotter; the upper from a cherry to a dark red.

The enamel consists of a slip containing red lead, the oxides of lead and tin, sand, salt, soda, and coloring materials, and the ware is completed in a second fire. See FAÏENCE.

II. 5. Fr. *Faïence fine.* Invented by Wedgwood, in Staffordshire, England. The paste is white, opaque, of fine texture, dense, and the ware is sonorous. The glaze is a lead-glass. The material is essentially a washed plastic clay and calcined flints, or quartz finely ground, sometimes with a little chalk. The material of the glaze is fritted, and is composed of silex, soda, oxide of lead, and sometimes the addition of a little boracic acid.

Three principal kinds are distinguished, named from the notable quantities of chalk, silex, and feldspar in their respective compositions; though some chalk always accompanies the plastic clay, which varies from 62 to 87 per cent. in the various pastes of fine faïence.

The clay or kaolin is washed, the silex broken and ground fine, the matters brought to a thin batter with water, strained, and consolidated by evaporation. The paste is placed in damp cellars to ripen.

The baking and firing are at two operations; the biscuit being glazed by dipping or sprinkling with a slip embracing more or less of the following: feldspar, sand, kaolin, chalk, soda, boracic acid, ground glass, red lead, niter, and a little cobalt to connect yellow color. See FAÏENCE.

II. 6. Fr. *Grès-cérame* or *poteries de grès.* Stone ware. Stone ware is solid, very hard, sonorous, and opaque, with a paste more or less fine, and is distinguished as *common* or *fine.*

a. The paste, of coarse stone ware, is of unwashed plastic clay and quartzose sand. The articles are molded or made on the wheel, according to the character of their shape. They are glazed by throwing marine salt into the kiln and into the fire at the period of great heat, and the decomposition of the salt covers the objects with a thin scale of silico-aluminate of soda.

In some cases the unglazed articles are plunged in a bath of yellow ochre and fired; the resulting color is a brown-yellow glaze.

b. The composition and glazing of fine stone ware are essentially different. A feldspathic flux is added to the paste which makes it more vitreous, shown by its brilliant fracture. Kaolin, plastic clay, silex, pegmatite, sulphates of lime and baryta are used in the various pastes for stone ware. The glaze is sometimes by salt, potash, and red lead, placed in the seggars and volatilized in the kiln; or the biscuit is dipped in a lead-glass slip.

The articles are often ornamented by transfer-printing, or painting with metallic colors. See STONE WARE; PIPE.

III. 7. Fr. *Porcelaine dure.* Hard porcelain has a fine paste, is hard, translucent, sonorous, semi-vitreous, with a hard, earthy glaze. It is the most beautiful and resisting of all kinds of pottery.

The paste is composed of kaolin, feldspar, and sometimes of sand, plastic clay, and ground powder of pottery. The utmost care in preparing and compounding the materials is exercised. The mode of fashioning is according to character, the wheel, mold, and, in many cases, the art of the statuary.

After a slight drying in the air, the pieces are baked in the upper chamber of the kiln, inclosed in seggars to prevent soiling by the combustion of the fuel. The glaze is of silex, alumina, potash, and chalk, made into a fine slip in which the article is plunged.

The ware, after ornamenting in the biscuit stage, is burned at high temperature (*grand feu*) to vitrify the materials, giving the translucency and sonority. See PORCELAIN.

III. 8. Fr. *Porcelaine tendre naturelle.* English soft porcelain. This paste occupies a position between fine *faïence* and hard porcelain, differing from the latter in having a large proportion of phosphate of lime. The paste is more plastic than that of the hard porcelain, and is fashioned like fine faïence.

It is baked, and the biscuit glazed, ornamented, and fired in seggars. The glaze is lead-glass, with boracic acid. See PORCELAIN.

III. 9. Fr. *Porcelaine tendre artificielle.* French soft porcelain. This was made at Sèvres until 1804, and then the manufacture abandoned.

The paste is fine, dense, almost vitreous, hard, translucid, and fusible at high temperatures. A peculiar glass, fritted, forms three parts, to one part of marl and chalk, making a composition of little plasticity, which was molded. The difficulty of working it was extreme. The glaze was a glass: of sand, silex, litharge, potash, and soda. See PORCELAIN.

Pou'dre Bru'tale. Coarse, or *cube powder.* Slow burning powder in blocks of determinate size, consisting, in some cases, of cubes 1.5″ thick.

See PEBBLE POWDER; PELLET POWDER, *supra.*

Poul'try Feed'er. A revolving cylinder with coops in stories and in circuit, holding fowls which are successively presented to the attendant, who crams each in turn. A French device. See EPINETTE, Fig. 974, p. 315, *supra*.

Poun'cing Ma-chine'. (*Hat Making.*) A machine for shaving or rubbing the surface of a hat or hat-body to rid it of shaggy fibres. The abradant is usually sand paper.

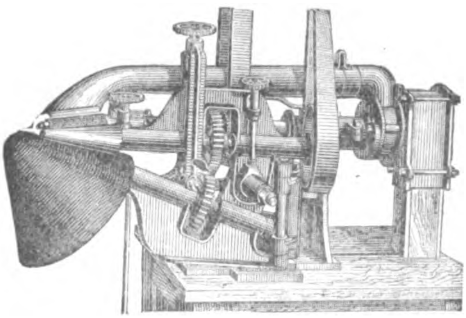
These machines may be considered as next in importance, in hat making, to the hat-blocking machine, and are constructed on two principles.

1. A rapidly revolving rubbing or cutting cylinder which operates on the object while it is fed along upon a yielding bed. This form is used on wool hats and the lower grades of fur hats.

2. A reciprocating motion is given to the rubbing surface or to the hat-body, to rub in two directions.

Fig. 2040 represents Eickemeyer's machine, which is used in both fur and wool-hat factories to sand-paper — or, as it is called in the trade, to *pounce* — hat-bodies when in the conical form, or, when the hat has been blocked, to pounce the brim. It consists of a rotary cutting roller of conical shape which is driven from a countershaft above. This roller is covered with sand or emery paper, and on the opposite end of the roller-shaft is a fan, connected by a pipe which has a mouth-piece corresponding in shape with the cutting roller and directly over it, to carry off the fur or wool pounced off the surface during the operation. Under the cutting roller is a pouncing bed which is adjustable in two ways, namely, so as to set that part of its upper surface exactly parallel with the face of the roller and to vary its position when desired; and also to prevent its upward motion beyond a given point.

Fig. 2040.



Eickemeyer's Hat Shaving and Pouncing Machine.

The bed is pivoted in the rear part of the frame and is operated by a treadle, to facilitate the introduction and removal of the hat. A pair of conical feed rollers, supported in an adjustable swinging frame, which are also driven from the countershaft, furnish the feeding mechanism. The pouncing bed is raised by the treadle, after the hat has been introduced and grasped by the feeding rollers, until the hat-body is in contact with the cutting roller, after which the hat is guided by the operator until its surface is properly pounced.

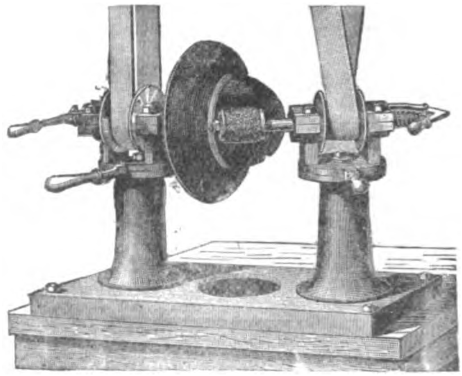
To pounce hat-bodies of different shapes, the position of the feed rollers has to be varied, and for this purpose a swinging frame is introduced which admits of an adjustment closer to or farther from the cutting roller as also in a direction parallel with the axis of the roller. An india-rubber spring presses the two rollers together, while the position of the feed-rollers relative to each other can be adjusted by a set-screw on the hinge joint of that part of the swinging frame which carries the upper feed-roller.

The cutting rollers are usually made of metal, and, in this case, have a spline to hold the sand-paper, but when of india-rubber the sand-paper is glued in the shape of a conical ring which is held on the roller by the expansion of the rubber by means of a nut on the outer end of the spindle.

In wool-hat factories this machine is the only pouncing machine used, as all hats, even such as have been previously blocked, can be pounced, all but a very small piece on the tip, which is pounced when the hat is completed on the finishing lathe.

In the crown-pouncing machine of Wheeler & Manley, the hat is drawn upon a block which is rotated upon a lathe-spindle. This cutting roller has its bearings upon the outer end of a long lever which is pivoted upon a countershaft with a gimbal joint which allows a free motion of the lever in all directions, and enables the operator to bring the cutting-roller in contact with all parts of the crown. In the illustration the cutting-roller is shown as working upon the side-crown, and it is from that position slowly carried over the round edge and brought to bear upon the tip.

Fig. 2041.



Hat-crown Pouncing Machine.

Fig. 2041 represents the Labeaux hat-crown pouncing machine. It has two lathe spindles, supported upon two columns, in bearings which can be turned upon the center of the columns in a horizontal plane. The spindle which carries the hat-block has a slow motion while the roller spindle revolves rapidly. Both spindles can slide longitudinally in their bearings.

The hat is held upon the block by an india-rubber band, and, as both the spindles can be turned in a horizontal plane, and also brought nearer together and farther apart, the operator can bring the cutting roller to bear upon all parts of the side-crown and the tip.

These machines, as previously stated, are used for wool hats and for only the coarser grades of fur hats, and do not produce the fine surface required on the better grades of fur hat; for these, machines having a reciprocating motion are required.

In the *Eickemeyer-Rosecrans* machine the hat is placed upon an upright spindle having a reciprocating rotative motion. The spindle has its bearings in the frame of the machine, and at its lower part is enlarged, forming a roller of sufficient length and diameter to receive two bolts which are each fastened to one end of the roller and one end to a cross-head which is supported in two slides, also fastened to the frame. The slide receives a horizontal reciprocating motion from a crank on the main shaft of the machine. Every revolution of the crank causes the cross-head to wind up and unwind the belts alternately upon and from the roller, and thus causes the block to make a revolution in one direction and then in the other.

While thus in motion, sand-paper is held by the operator against the surface of the hat until the proper degree of finish is attained. Cutting first in one and then in the other direction produces a very short nap, which cannot be obtained when the cutting is done in one direction, as on a machine with a continuously rotating cutting roller.

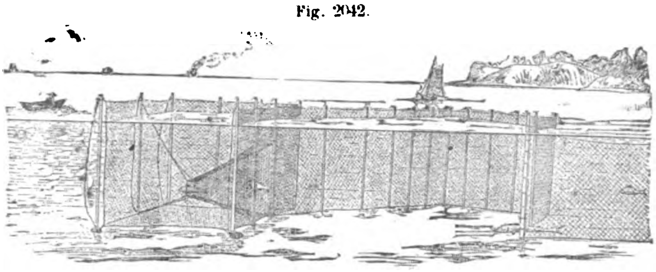
The brim-pouncing machine consists of a pair of rubbing plates, to which sand-paper is attached. These plates are made to vibrate in a horizontal plane in opposite directions to each other, by two cranks on the upright shaft which receives motion from the main shaft of the machine by a half-twist belt. The roller and the upper rubbing plate are raised to allow the introduction of the hat-brim. While the feed-rollers carry the hat around, one plate pounces the under side and the other plate the upper side of the brim. The result is a very smooth surface, and although but one fifth the number of hats can be pounced on this machine that can be pounced on the rotary cutter machine, it is by the manufacturers of fine hats preferred to the former.

The machine is provided with all the adjustments necessary to take up the wear of the working parts, and the upper plate and feed roller can be held up while in motion, so that it is not necessary to stop the machine to introduce and remove the hats.

Pound. (*Fishing.*) A wire or net inclosure into which fish are directed by a leader which intercepts their course along shore and conducts them to the first inclosure, known as the heart, from whence they pass through the tunnel to the more remote inclosure, the *pound* or *bowl*.

In emptying the pound the bottom stay-ropes are cast loose, the tunnel guys pulled up, closing the tunnel, the

Fig. 2042.

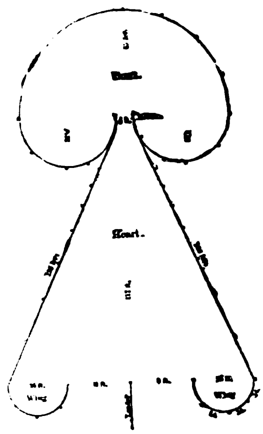


Pound.

bottom raised, driving the fish into one corner, when they are thrown into the boat by a scoop net.

Pound Net. (*Fishing.*) The *heart net* or *pound* consists of three parts, the *leader*, *heart*, and *bowl*, or *pound*, and is variously constructed.

Fig. 2043.



Pound Net, Wood's Holl, Mass.

The leader (of which a portion only is shown) is 265 yards long, reaches from the shore to the mouth, and directs fish passing along shore into the heart, whence they pass into the *bowl*.

The bowl is emptied once or twice a day.

For list of U. S. Patents, see FISHING NETS.

See other forms in "*Report of U. S. Fish Commission*," Part I., 1873, pp. 263, 264.

Pow'der Blow'er. (*Surgical.*) An instrument for blowing a powder upon a part. They are specially —

Aural.	Urethral.
Laryngeal.	Uterine.
Nasal.	

See AUTO-INSUFFLATOR, Fig. 131, p. 57, *supra*; INSUFFLATOR, p. 501, *supra*.

Pow'der Dust'ing Ma-chine'. Gunpowder, whether pebble or granulated, is required to be clean, and the dusting operation intervenes between the pebbling or granulating and the glazing.

Dusting is performed in revolving cylindrical reels, with clothing of canvas or wire cloth of a fineness to suit the grade of powder. A reel 8′ long and 30″ diameter will have 40 revolutions per minute.

In Russia, the powder is dusted in bags. Fig. 26, accompanying Appendix I., "*Ordnance Report*," 1877.

See also "*Ordnance Report*," 1879, Appendix I., Plate IV., Fig. 9, and description on pp. 106, 107.

Pow'der-ing Ma-chine'. 1. A bronzing machine.

2. A pulverizer — which see.

Pow'der Pa'per. A substitute for gunpowder, invented in England.

Paper impregnated with a mixture of potassic chlorate, nitrate, prussiate, and chromate, powdered wood charcoal, and a little starch. It leaves no greasy residue on the gun, produces less smoke and less recoil, and is less impaired by humidity, and it is 5-16 stronger than gunpowder.

For a paper with fulminate, see Fig. 1151, p. 380, *supra*.

Pow'der Press'ing Ma-chine'. A machine in which the powder meal from the breaking-down machine is made into cakes. It is a hydraulic press, the box of which is 30″ × 14″, lined with oaken boards.

The powder has a thickness of 1¼″ between each of the consecutive plates, and is pressed to the determined extent. Pressed cakes, for breaking into pebble powder, are ⅜″ thick.

For ordinary powder, the cakes are broken with wooden mallets, and pass to the granulating machine.

Details of the pressing machine are given in Col. Laidley's report, "*Ordnance Report*," 1877, p. 441.

See also *Ibid.*, 1879, Appendix I., Plate III., Fig. 7; and description on p. 103.

In the St. Petersburg arsenal, the incorporated mixture is pressed into cake in two ways: —

1. By hydrostatic pressure.

2. By passing the mixture between two heavy iron rolls, while spread to a uniform thickness on an endless band of cloth. This is known as the Prussian method.

Pow'der Spoon. A small paddle with which a modicum of powder is applied to a deep-seated part, the uterus especially.

Pow'der Test'ing. In Britain, the chronograph is used to determine the velocity of the flight of the projectile, a given quantity of the powder under test being used in a service gun with a given ball.

In France, the test is in firing to extremity a cast-iron gun of a given model, made of a particular iron, and treated in a given manner, with charges of a fixed weight of the powder to be tested. A new gun of exactly similar character is used for each powder.

In Russia, the French *densimetre à mercure* is employed to test the gravity of powder. See DENSIMETER.

The subject is considered, *supra*, under INTERNAL PRESSURE GAGE; PIEZOMETER; CUTTER; DYNAMOMETER, etc.

In "*Mech. Dict.*," under EPROUVETTE; BALLISTIC PENDULUM; ELECTRO-BALLISTA; CHRONOSCOPE, etc.

Drying stove for testing samples, "*Ordnance Report*," 1879, Appendix I., Plate X *a*.

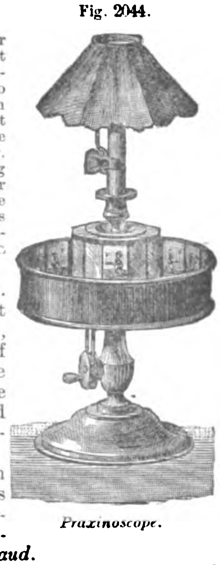
HYGROSCOPE, *Ibid.*, Plate X *b*.

Pow'er. As applied to a machine, signifies that it is moved by power, and not by hand: as *power press*, *power shears*, etc.

Prai'rie Plow. (*Agric.*) A plow with a broad, sharp share and long mold-board, for cutting a wide, shallow furrow, and completely inverting the furrow slice. A prairie breaker. See Fig. 422, p. 130, *supra*.

A California plow designed for work in the tules, which will cut a furrow 38″ wide. The mold-board is 8′ long from the point to the end, sweeping upward with a curve of about 4′ radius. At the end it stands 2′ above the ground. The land side is 7′ long. At the rear a horizontal cutting plate is arranged to cut under the sod on the land side a distance of 10″. The furrow depth is from 3″ to 4″. The plow is attached to a sulky, and requires a team of 12 horses.

Fig. 2044.



Praxinoscope.

Prai'rie Ren'o-va-tor. (*Agric.*) An implement with tearing harrow teeth, drawn over the surface of grass land to loosen the roots and the soil, dislodge moss, uproot weeds, and break up the matted vegetation.

Prax-in'o-scope. An instrument which depends for its effects upon the persistence of visual impressions on the retina. — *Reynaud*.

It however, differs structurally from a number of other instruments which depend also upon persistent impressions. These are the **Anorthoscope, Phenakistoscope, Stroboscope, Thaumatrope, Zoetrope.** See under these titles in the "*Mech. Dict.*"

In the praxinoscope of M. Reynaud the pictures are placed on the inner perimeter of a polygonal box. These pictures represent the consecutive positions of a moving body and substitute each other incessantly, the series in the circle representing a cycle of movements. Turning around a common center there is a concentric polygonal prism formed of mirror plates, and having a diameter equal to the radius of the exterior polygon. The box carrying the pictures and the reflecting prism is revolved at a moderate speed by means of a crank, pulley, and cord.

In the evening the apparatus may be lighted by a lamp or gas flame, the light being reflected downward by a shade. The optical principle involved is explained by *G. Fussandier*, in "*La Nature.*"

Pre'puce In'stru-ments. (*Surgical.*) See Phimosis Instruments.

Wine and cider press, *Quillet*	France.
Wine and cider hand-press, *Quillet*	France.
Toggle-press, *Samain*	France.
Toggle-press, caisson, tampon, and barrel, *Samain*	France.
Trussing-press, *Guilhem*	France.
Forage press, *Guitton*	France.
Ration press, *Guitton*	France.

Press Drill. A drilling machine largely used in gun and sewing machine work.

In the form shown in Fig. 2045, it runs by belts, avoiding the noise of gears. The sizes of spindle pulleys give a variety of speeds for drilling holes from 1-16″ to ¾″ diameter, and the driving cross pulley has 4 speeds. The work is elevated by vertical motion of the table; lever and treadle arrangements being provided for the purpose.

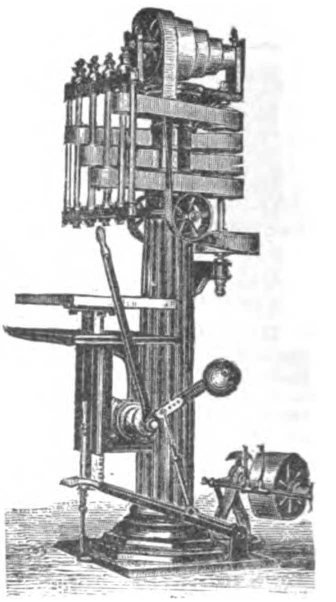
Pressed Fuel. See Fuel, Artificial, "*Mech. Dict.*," *et supra.*

Loiseau; Newton: Anthracite Fuel Co.; Prince's Report in Group I., "*Centennial Reports,*" vol. iii., p. 54.

Loiseau. . . . . "*Van Nostrand's Mag.*," xxiii. 41.

Pressed Glass. (*Glass.*) Glass made in a mold by pressure. This may be solid or with knobs, insulators, etc.; or hollow, as with bottles, which are blown and pressed in a mold; and some other things pressed hollow without blowing.

Fig. 2045.



Press Drill.

Iron molds are generally used, but wooden molds are very common in France.

Press'ing I'ron. A Smoothing Iron; Flat Iron, etc.

See Fluting Iron; Gauffering; Ironing Machine; Smoothing Iron, etc. See also Laundry.

Pres'sure Bar. A device in a planing machine for holding down lumber to be planed.

The long suits of the Woodworth and the Woodbury Patents were upon pressure bars and pressure rollers.

Horton's. . . . . "*Iron Age,*" xvii., April 20, p. 11.

The Pressure Block or Pressure Roller have the same duty.

Pres'sure Gage. An instrument used for indicating the pressure of an elastic material; steam, air, gas, etc. See various forms in Figs. 3939-3942, pp. 1736, 1737, *Mech. Dict.;*" Steam Gage, Figs. 5674-5677, p. 2345, *Ibid.* Also Gages, Figs. 5678-5683, pp. 2345, 2346, *Ibid.*

1. The gas pressure and vacuum gage is shown in Fig. 2046. It has a cast-iron case containing two brass tubes or wells; in one of them is a float, to which is attached a small cord passing over a pulley; this carries a pointer over the range of a dial. Such instruments are generally used near the hydraulic main, or in the exhauster room to indicate the pressure at any time. The pressure gage shows from 0″ to 18″ pressure, and the pressure and vacuum gage ranges from 9″ pressure to 9″ vacuum.

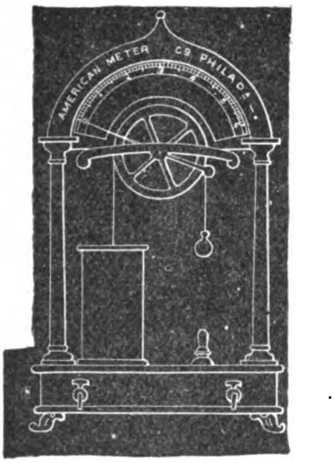
See also *A*, Fig. 3939, p. 1786, "*Mech. Dict.*"

2. An instrument used to detect the pressure in a cannon or fire-arm at the instant of explosion of the charge. See also Crusher Gage; Piezometer.

Fig. 2047 shows Rodman's pressure gage as adapted to the Springfield service gun and cartridge.

"The usual breech arrangement of the gun should have added a projecting frame, *A*, specially made for strength and accommodation of the piston *D*, knife *E*, and copper and steel plates *F* and *G*. A gas check *B* is used to prevent the escape of gas at the piston *D*. The cartridge *C* has a hole in its side the same size as the piston *D* (area 1-10 square inch); the edges of the hole in case are required to be made thin by a special operation, and lay snugly to the side of chamber to

Fig. 2046.



Gas Pressure and Vacuum Gage.

prevent the escape of gas. No reliable results can be obtained if the gas is allowed to escape at this point. A slip of paper is inserted into the case to prevent the powder from falling out; the charge is ignited in the usual manner; the gas forces the piston *D* against the knife *E* into the copper plate *F*, making a cut; the knife and copper are removed to a weighing machine, and a corresponding cut of equal length is made in the same copper. A record of 50 shots gave a maximum of 14,000 lbs., and a minimum of 12,000 lbs. Mean 13,000 lbs. per square inch for the service cartridge — 70 grains powder, 450 grains ball."

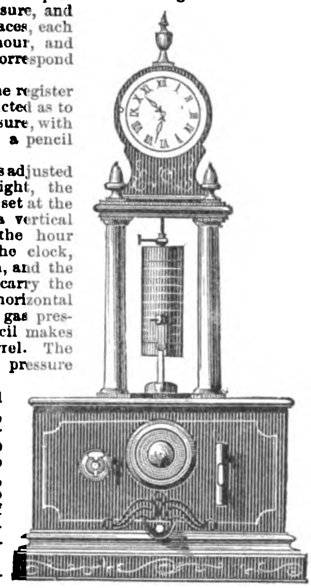
Pres'sure Reg'is-ter. An instrument elastic cording the fluctuations of pressure of an for re-body: steam, air, gas, etc. See Recording Steam Gage, Fig. 5083, p. 2346, "*Mech. Dict.*"

The gas pressure and vacuum register is an instrument used for recording the variations of pressure on street mains, at works, office, or any desired point of distribution, and is made with any required range of from 1″ to 6″ for 1″ working pressure, but is generally made for 5″ pressure to give a range of 12″.

Attached to the clock is a vertical barrel which makes 1 revolution every 24 hours; around this is a printed card divided horizontally, by lines, into 50 spaces, each representing 1-10″ pressure, and vertically into 24 spaces, each representing one hour, and so marked as to correspond with the clock.

Fig. 2048.



Pressure and Vacuum Register.

In the body of the register is a float, so constructed as to rise 12″ for 5″ pressure, with brass rod carrying a pencil holder.

When the water is adjusted to the proper height, the point of the pencil set at the zero line, and to a vertical line representing the hour corresponding to the clock, the gas is turned on, and the float will rise and carry the pencil up to the horizontal line indicating the gas pressure when the pencil makes its mark on the barrel. The tracing is thus a pressure and time line.

The pressure and vacuum register, Fig. 2048, is governed by the same principles as the pressure register, and is designed to keep record also of the degree of vacuum in the exhauster.

The card is divided the same, vertically, but in the horizontal divisions it differs, as it is divided into sixty spaces each representing 1-10″ pressure, the zero line being the twentieth from bottom, the space below the zero line representing 2″ vacuum, and the space above 4″ pressure.

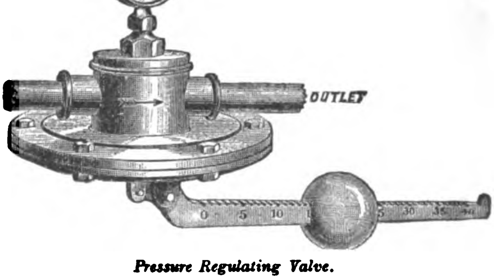
In adjusting the water line in this instrument, the point of the pencil is brought to zero line and to vertical line, corresponding to the hour of day shown by the clock. Gas then being turned on, any change of pressure or vacuum will be duly recorded, the cards to be changed daily and filed away as with Pressure Register.

See also Meter Prover, *supra*.

Pres'sure Reg'u-la'ting Valve. An apparatus to obtain a constant pressure of steam or air from a supply reservoir, wherein the pressure varies.

The form of apparatus shown in Figs. 2049, 2050, is specially intended for the abstraction of steam for heating purposes under pressure in a boiler much in excess of what is

Fig. 2049.

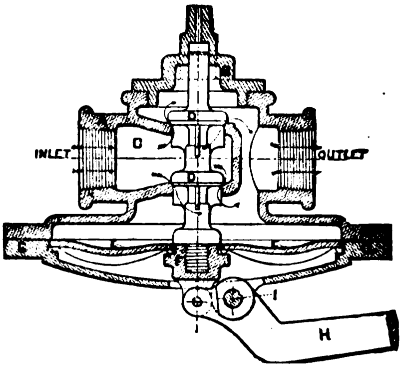


Pressure Regulating Valve.

demanded for the heating. The heating purposes referred to are for vacuum pans, heating apartments, drying rooms, bleacheries, paper machines, etc.

Fig. 2049 is an exterior view of the apparatus with a low pressure gage attached, and a lever beneath, with a weight

Fig. 2050.



Pressure Regulating Valve.

by which the pressure is regulated. The sectional view, Fig. 2050, shows the casing *A* with a screw-cap *B*. *C* is the inlet-chamber, and *D* is a balanced puppet valve, the raising of which allows steam to flow upwardly and downwardly into the main chamber of the valve, and thence to the outlet. The degree of opening of the valve is regulated by a large, flexible, thin, sheet-brass diaphragm *E*, clamped by the bottom-piece *G* to the base of the case *A*. The downward steam pressure on the diaphragm is opposed by the upward pressure of the weight on lever *H*, and this is so adjusted as to open the valve to such a degree as to admit the passage of such an amount of steam as may keep the pressure in the apparatus for which it is provided, at a given pressure, and consequent heat.

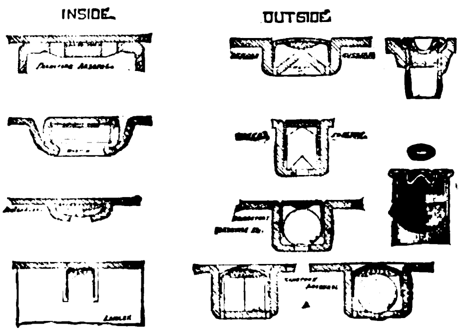
See: * "*Iron Age*" . . . . . . xxv., March 4, p. 9.
* "*Manuf. & Builder*" . . xi. 241.

Pri′ma-ry Coil. (*Electricity.*) The inner coil of the helix.

Pri′ma-ry Cur′rent. (*Electricity.*) That which passes through the primary coil.

Pri′mer. An exploder attached to a fire-arm, ordnance, or cartridge. See FRICTION PRIMER; PRIMER, "*Mech. Dict.*"

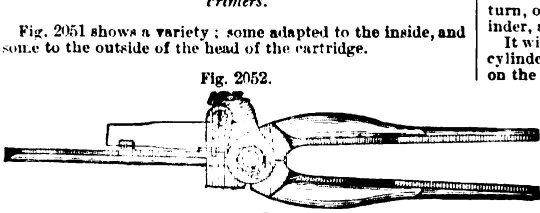
Fig. 2051.



Primers.

Fig. 2051 shows a variety; some adapted to the inside, and some to the outside of the head of the cartridge.

Fig. 2052.



Primer Extractor.

French friction primers, land artillery. *Laboulaye's* "*Dictionnaire*," "*Artifices de Guerre*," Fig. 166.
French friction primers, marine, *Ibid.*, *b*.

Pri′mer Ex-tract′or. A tool used to withdraw the spent primer capsule, in reloading metallic shells. See RELOADING TOOLS.

Pri′ming Ma-chine′. A machine to put the fulminate in the cap, which is to be attached to the cartridge shell.

One which places the fulminate in percussion caps.

Print′ing Press. Perfecting presses, *i. e.*, those which print both sides of the sheet at a single passage through the machine, usually work upon a continuous web of paper, the continuous sheet passing through the machine, passing between a type and impression cylinder, by which one side is printed and then between a similar pair of cylinders which print the reverse side; thence passing to the cutter which severs the sheets and thence to the folder.

Perfecting presses usually print from stereotype plates, some running as high as from 12,000 to 50,000 perfect papers per hour. The following are shown in the "*Mech. Dict.*," at the pages noted: —

Hoe & Tucker, Perfecting Web Press, Fig. 3640, p. 1666.

Walter Press, London "Times," Fig. 3641, p. 1667.

Bullock Press, Web Perfecting, Fig. 3642, p. 1667.

Victory Printing and Folding Machine, Plate XLIII., p. 1798.

Hoe's Web Perfecting Printing Machine, Fig. 7137, p. 2751.

Augsburg (German) Web Perfecting Press, Fig. 7138, p. 2752.

The preparing of stereotype plates involves a loss of at least 20 minutes after the forms have been set up by the compositor. The type revolving newspaper perfecting press of Hoe & Co., shown in Plate XXXIX., is made to print from type forms, from a roll of paper, at a rate of 12,000 per hour, and fold and deliver the perfected papers from one set of forms.

The type which is set up in the usual way in the composing room is placed in curved type beds, known as *turtles*, similer to those used in the multiple cylinder type-revolving machines, shown at page 670, and Plate XI., "*Mech. Dict.*" These beds, which contain the forms for the pages (say four) of the newspaper, are placed upon a large central cylinder around which at intervals are four plain cylinders with blankets on them and which take the impression.

The paper, which is in a large roll say 30′′ or more in diameter, is placed at the end of the machine, and the sheet — the "*web*" — passing through rollers and tapes is conducted around the first of the impression cylinders. As the central cylinder revolves against it the impression of the whole four pages is taken upon the paper. The sheet is then carried over a roller and introduced upon the second impression cylinder when the four pages are again printed upon it. The web of paper is then carried through rollers underneath the large type cylinder and by an arrangement of bars and rollers turned completely over. From the turning apparatus it is conveyed to the third impression cylinder, and again receives, opposite the side printed by the first impression cylinder, an imprint of the four pages of the paper. Again the paper is carried around a roller and introduced around the fourth impression cylinder, against which is printed in its turn, on the back of the impression made by the second cylinder, another of the whole four pages.

It will thus be seen that in one revolution of the large type cylinder four distinct papers or impressions have been printed on the web of paper.

The portion of the central cylinder which is not occupied by the type is used as a distributing surface for ink which is placed in fountains and conveyed by an arrangement of composition rollers to this distributing surface, which in turn carries it to the rollers inking the forms of type, and which are placed between each of the impression cylinders.

The paper, which now contains upon it four complete printed newspapers, is brought by tapes to two

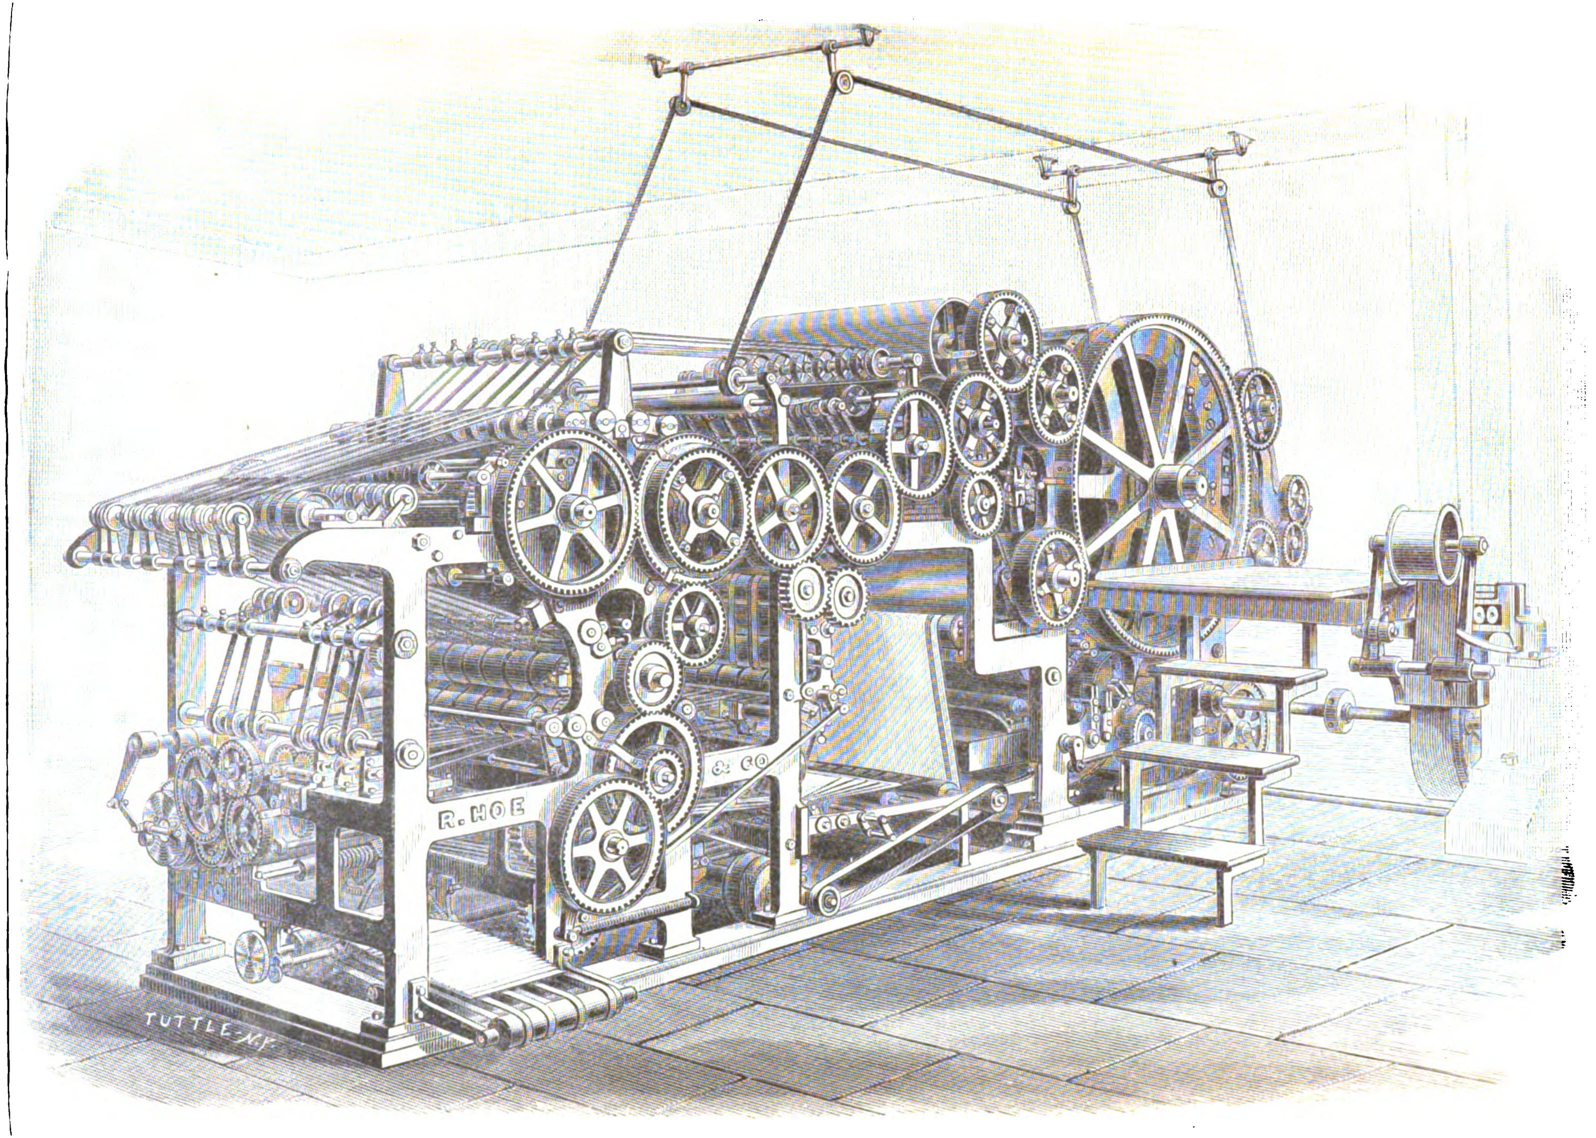


PLATE XXXIX. HOE'S TYPE REVOLVING NEWSPAPER PERFECTING PRESS. See page 720.

cylinders placed one upon the other. In one of these is a knife with a blade like a saw which at each revolution of the cylinders shoots out and cuts the paper apart.

The papers then, carried between tapes, enter the folding apparatus. This consists first of cylinders provided with grippers or fingers which seize the paper as fast as presented by the tapes. Within the circumference of these cylinders is a revolving blade so placed that its edge strikes the paper in the center margin between the pages driving it down between two rollers through which it is carried and given the first fold. As soon as the sheet is clear of the rollers, a knife placed upon an arm strikes it across the center of the page and drives it again between two other rollers which give it the second fold, and this operation is repeated until the required number of folds have been made, when the paper is deposited on a traveling belt or platform, which receives the papers and counts them in 10's, 20's, 50's, or 100's as required. If desired, the apparatus for giving last folds can be disconnected and the papers delivered folded twice for the carrier, the extra folds being intended for the mails.

Besides the foreman of the room only one attendant is required for the press, whose duty it is to watch the roll of paper, and a boy to remove the papers as delivered.

The series of patents to J. T. Hawkins (Campbell Printing Press Co.), Nos. 257,576-257,581, constitute the foundation of the system of printing presses now being built by the company.

The first of the series stated concerns the gearing of the cylinders continuously to the beds, insuring uniformity of surface velocity, and permitting the use of very small cylinders, so small as to make more than one revolution in each direction during the passage of the form or stone; this machine being specially for lithographic printing, and working but one side of the paper.

The next in series adds the perfecting feature, which adapts it to newspaper printing; working the sheet on both sides, taking the sheet, tail first, on the reverse revolution.

The third in series shows a delivery of the sheet, adapted to general book and job printing, where various-sized sheets are printed on the same machine on both sides, avoiding contact of the last-printed side with tapes or fly-fingers.

The fourth adapts the system to the double-cylinder form of press so much used on evening papers of moderate circulation, the speed of which presses is ordinarily limited by the methods employed to impart motion to and overcome the momentum of the bed, the cylinders revolving in one direction only. The equilibrating principle is the peculiar feature of this one of the series.

In the fifth in series the whole system, including the equilibrating principle, is adapted to a perfecting web press working from the original type forms.

The perfecting press of Cottrell & Babcock works sheets. Its foundation is the drum cylinder press, embracing the air-spring and governor.

The rotary attachment consists of two cylinders, — one for curved stereotype plates of the matter to be printed, the other to give the impression. These cylinders are supplied with a feed-board, and revolve in harmony by the instrumentality of the usual gear-wheel attachment, making two revolutions while the drum cylinder of the main press makes one, and yielding the sheet, when printed on one side from the curved stereotype plates, to a supplementary set of grippers on the drum cylinder, in perfect register, when it passes to the flat form on the bed of the main press, and is printed on the other side and piled in the usual manner.

The type cylinder is supplied with an ordinary distributing apparatus for four-form rollers; and as it revolves twice before printing, the form is necessarily rolled twice also, with a fresh supply of distributed ink each time.

At each alternate revolution of the impression cylinder the impression is thrown off by a simple mechanical device, by which means the complete rotary attachment (as it gives the impression on its second revolution) works in harmony with the drum cylinder of the main press.

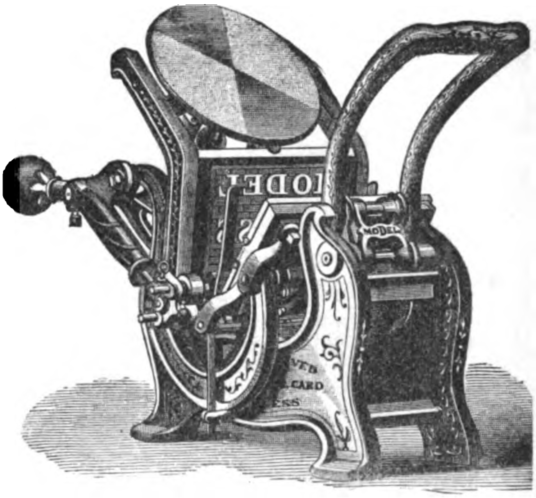
Chromo printing, *Greenwood & Kritch*, Br. As many forms are prepared as there are colors in the picture or lettering, and these occupy the bed in succession; the edition being run through in one color, the form is changed, the next color worked, and so on. It has an upright gang of three inking rollers. The platen vibrates in an arc, then moves horizontally to make the impression.

The small-size hand-presses have arrived at great rapidity and quality of work.

The Daughaday self-inking press is shown in Fig. 2053. The impression is produced by simply pressing upon the handle which acts upon the double toggle connected directly with the platen. The chase is held in place by a screw latch shown at top.

The curved arm shown at the side of the press operates

Fig. 2053.



"*Model*" *Hand-Press.*

the self-inking apparatus. A similar curved arm is on the other side, which insures an equal motion, free from side strain. The ink-roller journals are hinged, and the rollers are kept in contact with the type and distribution-disk by a simple spiral spring inside the arms, so that they not only adapt themselves to the size or irregularity of the type form, but to the curving track, as they approach the ink-disk. The ink-roller arms are very accurately balanced, and pivoted at the rear of the press, as shown, so that there can be no irregular motion. The ink-disk revolves slightly, after the rollers leave it, with each impression, giving a fresh surface for distribution of the ink. At the instant of taking the impression, the inking-rollers remain stationary on the disk, after which the surplus power is used in inking the form for a new impression. There is a *dwell* on the face of the type during the impression.

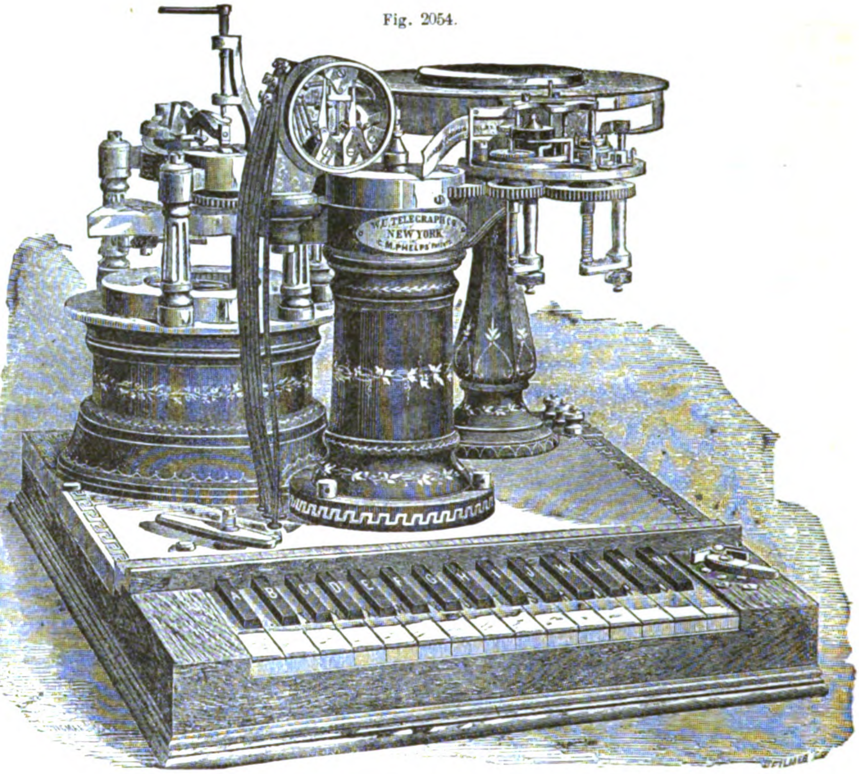
Print'ing Tel'e-graph. One which records the message in readable form. The term is gen-

Fig. 2054.



Phelps' Electro-motor Printing Telegraph.

erally restricted to those which use the common alphabet.

The *Vail, Bain, House, Hughes,* * *Phelps,* * *Anders,* * *Edison,* * *Van Hœvenberg* instruments are described on pp. 1800–1802, "*Mech. Dict.*" See, also, PRIVATE-LINE TELEGRAPH, *infra.*

The automatic printing telegraph of *Edison, Phelps,* * *Meyer* are described in *Lines'* "*Report of Vienna* (1873) *Exposition,*" p. 37 *et seq.*, vol. ii., Sec. I.

The autographic telegraphic is in a sense a printer. *Meyer's* * Fig. 130, p. 56, *supra; Caselli's,* p. 191, "*Mech. Dict.,*" * *D'Arlincourt, Lines'* Rept., above cited, p. 40, *Sawyer's,* * "*Scientific American Sup.,*" 302.

Gray's automatic printer (Western Electric Manufacturing Co.) is largely used on private stock-board and municipal lines.

The sending operator prints out his message in plain letters at the distant end of the line, whether the receiving operator is at the instrument or not. The message is also printed by the transmitting instrument. This printer is self-starting, self-stopping, and self-correcting. Any person who knows how to spell and to read can use it.

In the Phelps electro-motor printing telegraph, Fig. 2054, the type-wheel and printing mechanism is operated by a rotary electro-magnetic engine which is set in action by a local battery.

The apparatus consists of the following parts: —

The transmitting apparatus, consisting of the key-board and circuit-closing devices.

The receiving and printing mechanism.

The automatic unison mechanism.

The electro-motor and speed governor.

"The principle upon which the instrument acts may be described as a combination of the synchronous and step-by-step movement. Like the Hughes apparatus, the transmitting apparatus and the type-wheel of the receiving instrument are caused to revolve synchronously under control of a governor, and each separate letter is printed by a single pulsation of the electric current of a determinate and uniform length, transmitted at a determinate time, but, unlike the Hughes apparatus, the motion of the type-wheel is arrested while each letter is being printed, and is automatically released the instant the impression has been effected. Thus a speed of revolution may be given to the type-wheel in this instrument far greater than it would be possible to attain by means of a step-by-step movement, while at the same time letters which happen to come in direct sequence upon the key-board may be printed from during the same revolution." — "*Journal of the Telegraph.*"

The key-board is seen in front, its black and white keys being lettered, and behind it rises the hollow column of the transmitter, within which is a circular range of 28 slide rods corresponding to the keys of the board. It also contains the mechanism by which the circuit closer is actuated. In the center of the column is a vertical shaft which is rotated 240 times per minute by means of the electro-motor shown on the left, the speed being controlled by a governor. The circuit closing mechanism admits of either the single current or the double current system of transmission being employed by merely changing the connections. The printing mechanism is shown upon the right, and the tape drum at the rear.

The details of the ingenious and complex apparatus are to be found in the "*Journal of the Telegraph,*" *Prescott's* "*Electricity and Electric Telegraph,*" and reproduction of the same, * "*Scientific American Sup.,*" 831, 882.

Prism. The subject is considered under PRISM, pp. 1802–1804, "*Mech. Dict.,*" and several forms are shown in Fig. 3963, p. 1803.

The following are forms used in microscopy: —

Amici's.	Right angle.
Nachet's.	Double image.
Nichol's.	Equilateral.
Diatom.	

Pris-mat'ic Glass. A glass prism used for showing the solar spectrum.

Pris-mat'ic Pow'der. Large grained gunpowder for slow burning in heavy ordnance. Also known as POUDRE BRUTALE, PEBBLE POWDER, PELLET POWDER.

Prismatic powder is molded under pressure into hexagonal prismatic form and pierced with 7 small holes made at the time of molding by tapered spindles. See Machine, Plate III. accompanying Col. Laidley's report, Appendix K., "*Ordnance Report*," 1877, * p. 448, and pp. 523, 525, with Figs. 16½ and 21, Appendix L.

The idea originated, it appears, with Col. Rodman about 1861, but the only machine for the purpose is that of Prof. Vichnegradski, copied into Prussia and Holland.

The prisms are 1″ thick, weigh 600 grains and have 7 holes, each .015″ diameter. Density, 1.65 to 1.75.

Of allied shapes are some of those, sphero-hexagonal, cubical, polyhedral, etc., the subject of trials and a report: "*Ordnance Report*," 1879, Appendix II, 7, * p. 85; and Appendix I., p. 124, and Plate VIII.

The manufacture of hexagonal powder at Du Pont's mill is described on pp. 124, 125, and Plate IX., "*Ordnance Report*," 1879, Appendix I.

"*Engineer*" . . Sept. 16, 1870; March 17, 1876, p. 186.

Prism Bat'te-ry. A form of Leclanché battery in which the usual porous cup is dispensed with, and a pair of compressed prisms containing all the materials formerly used in the porous cup are substituted for it.

These prisms are placed upon opposite sides of the carbon plate, and are kept in place by rubber bands. See Fig. 1574, p. 538, *supra*.

The negative pole is a pencil of amalgamated zinc, and the two poles are suspended from the cover in a solution of sal-ammoniac.

Pris'moid-al Rail'way. A wooden or iron beam is supported on posts, the cars are mounted saddle-fashion; the engine grips the rail. Used in South Africa.

Pris'on. *Cook & Heath's* "Perfected systems of Prisons," is the subject of a brochure published at Memphis, Tenn. Patents, 1874, 1875.

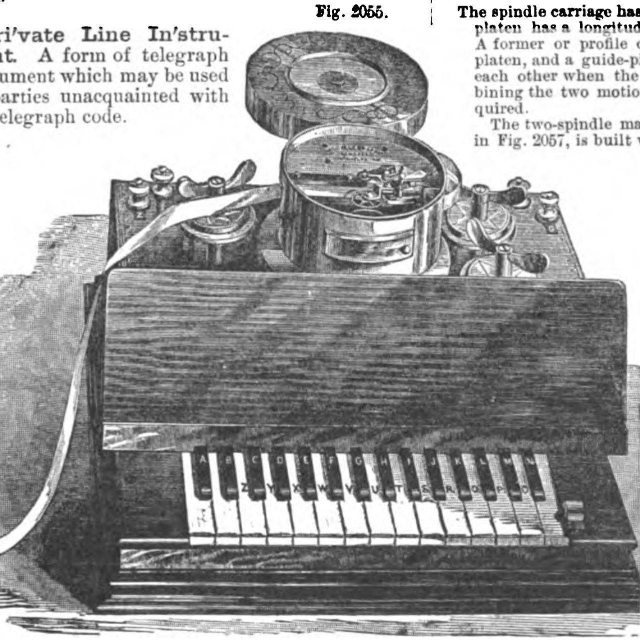
The points of value are the use of cast-iron for windows and doors and lining of cells. An outer wall being of brick or stone.

Between the walls is a mass of dry sand which issues into the cell when the wall is punctured.

The running of the sand actuates an alarm and rouses the guard.

Pri'vate Line In'stru-ment. A form of telegraph instrument which may be used by parties unacquainted with the telegraph code.

Fig. 2055.



Phelp's Private Line Printing Telegraph.

Such a one is shown in the *Auders* instrument, Fig. 3960, p. 1802, "*Mech. Dict.*"

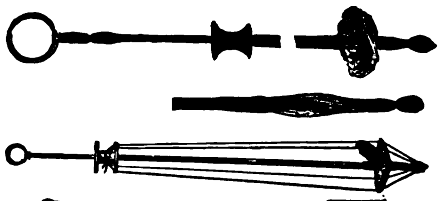
The dial telegraph, Fig. 806, p. 254, *supra*, is another form.

The machine of Phelps, shown in Fig. 2055, has the sending and receiving apparatus on the same stand: the former having a finger-board and the latter an automatic printer.

Pro'bang. An instrument to remove an obstruction from a passage. Several forms are shown in Fig. 3965, p. 1804, "*Mech. Dict.*"

Fig. 2056 shows a bristle probang for removing foreign substances from the throat and air passages.

Fig. 2056.



Probangs and Probe.

A contrivance for the same purpose, in which the disk is brought to a transverse position after the object is passed.

A porcelain bullet probe on a flexible staff.

Pro'cess Mil'ling. A term which, like *new process milling*, refers to the modes of high grinding, or of treating the middlings. See CYLINDER MILL; HIGH-GRINDING; MIDDLINGS; ROLLER MILL, and references *passim*.

Pro-du'cer. (*Metallurgy*.) The fuel chamber and gas producer of a Siemens' or similar furnace. See GAS PRODUCER; GAS GENERATING FURNACE; PONSARD FURNACE; SIEMENS' FURNACE, and references *passim*.

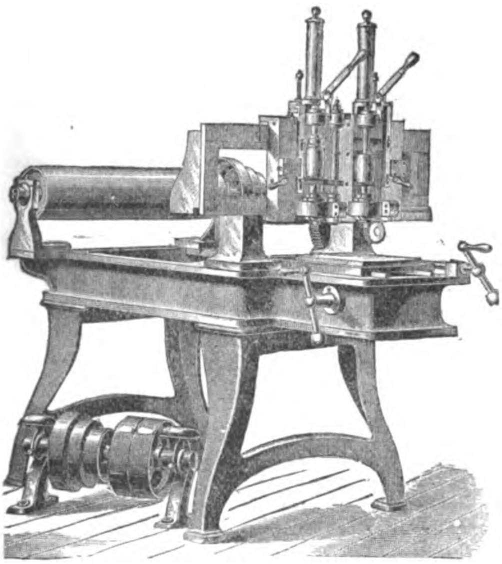
Pro-fil'ing Ma-chine'. The machine is shown in Fig. 3969, p. 1806, "*Mech. Dict.*" The purpose is there described. It is used for milling around the inside and outside edge of irregular shapes, and for surfacing and inside milling.

The spindle carriage has a side motion across the bed. The platen has a longitudinal motion under the cross-head. A former or profile of the shape required fixed to the platen, and a guide-pin fixed to the carriage, act upon each other when the machine is operated, and by combining the two motions give the cutter any direction required.

The two-spindle machine of Pratt & Whitney, shown in Fig. 2057, is built with Parkhurst's device for cutting formers without reversing the fixtures. To produce the forming pattern, the model piece is secured in the place and position afterward occupied by the work to be machined, and the piece to be cut for the forming pattern is placed in the position it will permanently retain. The guide-pin is put in the spindle which usually carries the cutter, and follows the outline of the model piece, while the cutter, in the spindle, which afterward holds the guide-pin, cuts the forming pattern in the exact position it will retain in use. After disconnecting the gearing upon the spindles, reversing the relative positions of the guide-pin and cutter, and smoothing the edge of the forming pattern (if this be necessary), the machine is ready for work. The gearing for moving the table and cross-slide is adjustable by means of double gears, set to prevent back-lash by two independent adjusting screws, and also by a double rack adjusted in the same manner.

The automatic edging machine is of a similar character to the profiling machine, but has an accurate automatic movement for cutting circles of 3″ and less diameter, with their tangents. These machines are made with one, two, or three spindles.

Fig. 2057.

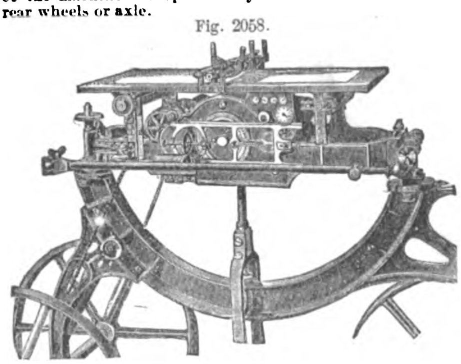


Profiling Machine.

Pro-fil′o-graph. A machine for tracing mechanically the outline of the surface of the ground over which it travels.

It is a small carriage on 4 wheels, and it is designed to make straight lines between stations. When it diverges the angle is taken and recorded on the profile paper. The carriage supports a small table on which is a flat sheet of paper traveling between an unrolling and a rolling drum beneath slits near the ends of the table. The profile is drawn by a pencil held perpendicularly above the table. All the motions of the machine are operated by an endless chain from the rear wheels or axle.

Fig. 2058.



Profilograph.

Underneath the machine hangs a pendulum which maintains a constant vertical position while the machine, and consequently the table, inclines in one direction or the other as it ascends or descends a slope. These angular oscillations are transmitted by proper devices producing reciprocating movements of the paper and the pencil, diverging from the zero which represents a level. The sheet of paper moves positively and the instrument records the distance passed — not the true base of the profile. The scale for the horizontal distance traversed is in the proportion of 1-1500 and the vertical dimensions 1-500.

In operation, each course is a record. A man draws the carriage along from one station to another. The surveyor at each stop notes the length on the distance indicator, draws a vertical line on the profile paper, notes the heights, then repeats the operation. — "*Nature.*"

Pseu'do-phone. An instrument invented by Dr. S. P. Thompson for producing acoustical illusions and for investigating some of the phenomena connected with bi-aural audition.

It consists of two ear-pieces of tin-plate which are held in their places by adjustable straps, one passing over and the other behind the head. Hinged to each of the ear-pieces is a reflector which is capable of adjustment to any angle and thus the sound is directed into the ear, which, being deprived of the usual conditions by which it is enabled to judge of the the direction, is deceived as to the direction of the source.— * "*Engineering,*" xxviii. 195.

Psy'chro-phore. (*Surgical.*) A cold sound. See Fig. 659, p. 209, *supra.*

Pud'dling Fur'nace. One in which pig-iron is subjected to heat, stirring, and chemical treatment in order to refine it. See history and statement, with figures, on pp. 1815–1817, "*Mech. Dict.*"

The processes proceed upon various methods: —

1. The furnaces revolving in a horizontal axis.
2. The pan on vertical axis.
3. Mechanical rabble.

The *Casson-Dormoy* puddling furnace is shown in Fig. 2060 in connection with its adjuncts, the gas producer *B* and the pig-heating chamber *I*.

The gas producer is like the Siemens', but instead of using a regenerator, the incoming air is blown down the sides of the furnace so as to be heated to 800° Fah. when it reaches the bridge at *E*. By means of blast valves a reducing or oxidizing flame is obtained as the condition of the iron may require. The fuel is slack, fed mechanically from a hopper, *A*. The puddling basin *G* is circular and is supported on iron balls in a dish of water, and the contents are first heated in chamber *I*, thence transferred to pan *G* and then boiled, rabbled mechanically, and then balled.

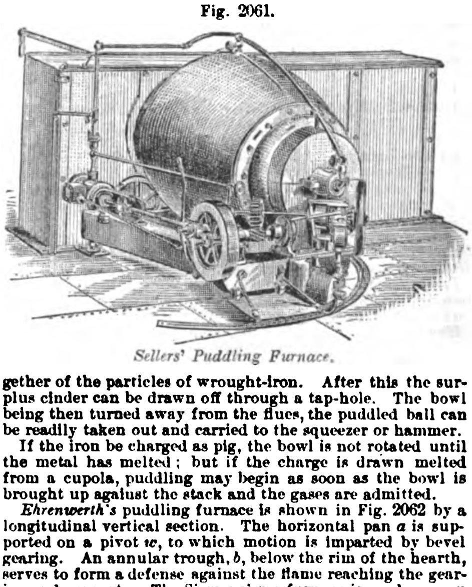
The *Sellers'* puddling furnace is heated from a gas producer. It is flask-shaped. The flame passes in, circulates, and passes out again at the same end by which it entered, on the opposite side of a horizontal partition which divides the opening. The puddler is so placed upon a frame that it can be swung away from the furnace to permit of charging from the front. The parts most exposed to the heat are protected on the outside by water-jackets. The furnace is supported by friction wheels at one end, and on a horizontal pivot at the other.

A small horizontal steam engine is mounted by the side of the furnace, on the same supporting-frame. The whole apparatus is carried by this frame, which is pivoted at the end nearest the open end of the furnace, the pivot-bolt being placed a little on one side and beneath the furnace-mouth.

The engine is so attached that it can be used either to revolve the furnace or to swing the whole machine about the pivot bolt.

The flue stack against which the puddler-bowl closes is merely a rectangular iron casing, within which are constructed the various flues required for the heated air, the gas, and the down-take to the regenerator. A door at the back of the flue-stack can be opened for the ready inspection of the interior of the bowl while it is at work and under heat. In practice, the charge having been introduced into the puddler, and its mouth brought up to the flue-stack, the ignited gas and air are admitted, and burning within the rotating-bowl, act upon the molten metal lying in the bottom of the bowl. The rotation stirs up the metal, which, boiling, *comes to nature*, and is aggregated by the tumbling to-

Fig. 2061.



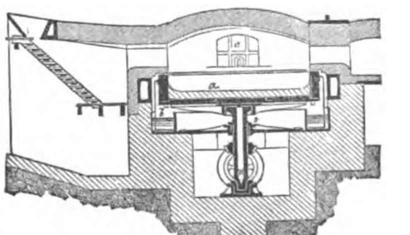
Sellers' Puddling Furnace.

gether of the particles of wrought-iron. After this the surplus cinder can be drawn off through a tap-hole. The bowl being then turned away from the flues, the puddled ball can be readily taken out and carried to the squeezer or hammer.

If the iron be charged as pig, the bowl is not rotated until the metal has melted; but if the charge is drawn melted from a cupola, puddling may begin as soon as the bowl is brought up against the stack and the gases are admitted.

Ehrenwerth's puddling furnace is shown in Fig. 2062 by a longitudinal vertical section. The horizontal pan *a* is supported on a pivot *w*, to which motion is imparted by bevel gearing. An annular trough, *b*, below the rim of the hearth, serves to form a defense against the flame reaching the gearing and supports. The Siemens' gas furnace is used, as seen

Fig. 2062.



Ehrenwerth's Puddling Furnace.

on the left. The special feature is the rotating hearth, *f* being the fort journal, and *l* the neck journal. The rabbles are introduced through holes in opposite doors; one only, *c*, appearing in the view. The rabbles move in right lines, and the motion of the hearth brings all its contents under their action. A plate depending from the periphery of the hearth dips into the water: the latter is continually replenished.

Walker & Warren. Diagonal barrel, horizontal axis flame passing through.

Mandslay. Cylinder revolving on diagonal horizontal axis. Reverting flame.

Tooth. Drum on horizontal axis. The piece removable, to allow the ball to be withdrawn at that end.

Tooth & Yates. Drum on vertical axis, with reverting flue.

Danks. Drum on horizontal shaft, revolving between fire-place, and movable flue-piece. "*Mech. Dict.*," p. 1815, Fig. 3992.

Siemens. Furnace on horizontal axis; reverting flue; regenerator. See SIEMENS' FURNACE.

Crampton. Horizontal axis, movable flue-piece, reverting flame.

Pug Mill. A mill for working clay into plastic condition for brick-making.

The machine shown in Fig. 2063 is a Philadelphia mill, in which the rear end is elevated 12′′. The clay is thrown into a hopper (not shown), passes between rollers which crush the lumps, and thence into the interior of the drum, where it is masticated by blades, and tempered with water introduced through a pipe. The gate at the end governs the discharge.

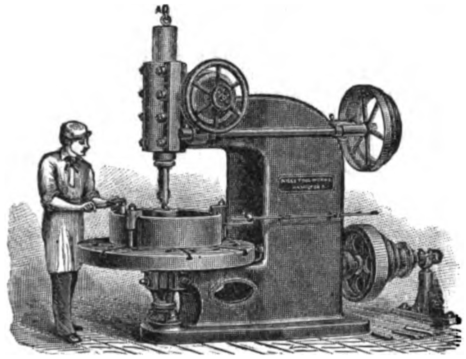
Pul′ley Bor′ing Ma-chine′. A special machine tool for boring the shaft-holes of pulleys, but applicable to other similar uses.

The machine, as shown, receives and bores pulleys 52″ diameter; the face plate is revolved by powerful gearing, driven by a cone, with four steps for a 4″ belt. The tool bar is fed automatically and is counterbalanced; it has quick

Fig. 2064.



Pulley Boring Machine. (*Niles' Tool Works.*)

return hand-motion. The feeds are thrown in instantly by friction; they are actuated by belt and worm gearing, rack and pinion (all cut); the feed-belt has three changes of speed, giving feeds of .0648″, .0441″, and .0279″ per revolution of chuck.

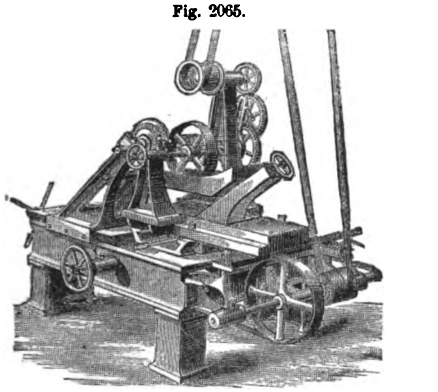
The countershaft is provided with tight and loose pulleys, 24″ diameter, for a belt 4″ wide, and should run 70 revolutions per minute, giving to the chuck-plate speeds as follows: 63, 43, 19, 10 revolutions per minute, thus adapting the machine to bore holes from 1″ to 7½″ diameter. When operating on the latter diameter, the power exerted at the cutting point is 1,800 pounds.

Pul′ley Grind′ing Ma-chine′. Fig. 2065 is a pulley grinding machine made by Thomson, Sterne & Co., of Glasgow, Scotland. It is used for the rims of pulleys, which may be made of the shape required: flat or crowning. The pulleys are cast as thin as may be desired, and the finishing is more thoroughly and rapidly done than by turning.

The machine has an automatic feed, and being self-acting in all its motions, one person can attend to a number of machines.

The different speeds of the work operated on are regulated

Fig. 2065.



Pulley Grinding Machine. (*Thomson, Sterne & Co.*)

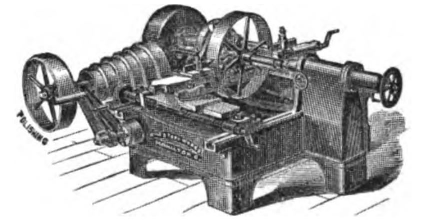
by change-wheels, so as to keep the surface speed somewhat uniform. By a simple arrangement of compound tables worked radially by a worm wheel and connecting rods, the rim of the pulley being ground, can be rounded to any radius.

The pulley being ground runs in a water-trough, which keeps it from heating, and also arrests the dust in grinding. The emery wheel is encased, so that the water and dust carried with it is taken away by the outlet pipe.

Pul′ley Turn′ing Ma-chine′. A special machine tool for turning pulleys, gears, rolls, etc.

It has a large cone pulley, with 6 steps for a belt 4″ wide, and transmits the power through tangent gearing to the main spindle. The carrier plate is of the equalizing type, obviating unequal and lateral strains. On each side of the solid bed-piece are rests which slide in and out on graduated surfaces to suit the diameter of the pulley to be turned;

Fig 2066.



Pulley Turning Machine. (*Niles' Tool Works.*)

these rests can be set angularly to get any desired degree of *crown*; tools are thus operated on both sides of the machine. The feeds are continuous, can be instantly engaged, disengaged, or changed. The spindle of cone pulley runs at so much higher velocity than the main spindle that its speed is suitable for polishing when the latter is turning; a steel mandrel and a suitable rest are provided for polishing.

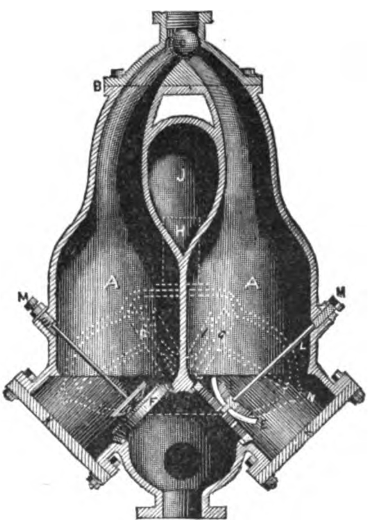
Pul′pit Spec′ta-cles. Spectacles with flat top to the bows to enable a reader to glance over them at an audience.

Pul′sa-tor. A name for the PULSOMETER, which see.

Pul-som′e-ter. A water-raising device, on the principle of the Savery Engine, Fig. 5657, p. 2337, "*Mech. Dict.*"

It consists principally of two bottle-shaped chambers, *A A*, joined together side by side, with tapering necks bent towards each other, to which is attached, by means of a flange

Fig. 2067.



Pulsometer.

joint, *B*, a continuous passage from each cylinder leading to one common upright passage, into which a small ball, *C*, is fitted so as to oscillate with a slight rolling motion between seats formed in the junction.

These chambers also connect by means of openings with the vertical induction passage, *D*, which openings are so formed that the vulcanite valves *E E* and their seats, *F F*, constructed so as to sustain the valves, may be easily inserted.

The delivery passage *H*, which is common to both chambers, is also constructed so that in the openings that communicate with each cylinder are placed valve-seats *G G*, fitted for the reception of the same style of valves as in the induction passage. *I I* are valve-guards to prevent the valves from opening too far.

J represents the vacuum chamber, cast with and between the necks of chambers *A A*, and connects only with the induction passage below the valves *E E*.

K K are flanges covering the openings to the respective chambers, which may be removed for the repair or renewal of valves and seats, when necessary. Vent plugs are inserted into these flanges, for the purpose of drawing off the water to prevent freezing.

L L are rods extending from the valve-guards to the set-screws *M M*, by which the suction seats, valves and guards are tightly pressed to place.

N N are brass socket-headed bolts by which the discharge seats, valves, and guards are drawn down to place.

A small brass air check-valve is screwed into the neck of each chamber *A A*, and one into the vacuum chamber *J*, so that their stems hang downward.

The check-valve in the neck of each chamber, *A A*, allows a small quantity of air to enter above the water, to prevent the steam from agitating it on its first entrance, and thus forms an air piston for preventing condensation.

The check-valve in the vacuum chamber *J*, serves to cushion the ramming action of the water consequent upon the filling of each chamber alternately

Pul'ver-ma-cher Bat'te-ry. A porous jar is surrounded by a silver wire which is rolled spirally, and is used as the negative pole of the element. The exciting fluid, dilute sulphuric acid, caustic potash or sal-ammoniac solution, is filled into the porous jar, through which it percolates by capillary attraction. The positive pole is a rod of zinc, the top of which is covered with caoutchouc in order to avoid accidental contacts which might short circuit the battery. The small spirals of silver wire must be far enough apart not to cause capillary attraction to take place between them.

Pump Au'ger. A long auger for boring wooden logs for pump stocks, or for pipes.

In a modern form the auger is surrounded by a thin metallic shell, in which the volute portion runs loosely. This shell or tube is turned true and straight; it follows and guides the auger, the shavings or cuttings being carried out through its interior. The lips or cutters of the auger are expanded at the end, so as to cut a hole just large enough for the passage of the tube.

The engine shown in Plate XXXIX is the Knowles direct-acting compound condensing pumping engine.

The high-pressure cylinder is nearest to the water end, and to this is connected the main piston-rod, which extends through to the water-plunger. The low-pressure piston has two smaller piston-rods which pass through sleeves cast on the outside of the high-pressure cylinder, and are connected to the main rod by a cross-head at their outer ends. All the stuffing-boxes of the steam end being on a line on the back cylinder head. The steam cylinders and steam chest are properly steam-jacketed. The valve arrangement of the high-pressure cylinder is the same as that of the ordinary Knowles steam pump, viz., a double ported flat slide valve which is surmounted and operated by a round piston, which has a slight rotating motion imparted to it by the rocker bar, which receives its motion from a friction roll attached to the tappet arm. The slight oscillation of the chest piston places its parts in connection with those in its cylinder; it is then driven horizontally by the steam pressure, in which motion it carries the main slide valve, to which it is directly connected. From the front end of the valve-driving piston is extended a rod, which operates the valve of the low-pressure cylinder. The steam is exhausted from the low-pressure cylinder through a coil feed-water heater direct into the jet condenser, which is connected to and operated by an independent air pump, as shown in engraving.

The water end of the engine is of the "inside plunger" pattern. The plunger, which is made of either iron or composition, passes through a broad ring cast in the center of the cylinder, the inner surface of which ring is either grooved to form a water-packing bearing upon the plunger, or is furnished with a stuffing-box, so that the plunger may be packed as may be required by the position of the engine. The water valves are of rubber, working upon composition seats. The suction valves are below, and the discharge valves above the plunger. The valves are readily reached through hand holes situated immediately above the valve plates.

Fig. 2068 is the Gaskill pumping engine, built by the Holly Manufacturing Co. for Saratoga Springs, N. Y.

It is horizontal, of the rotative, non-receiver, compound-beam type. The engine has four steam cylinders, one high and one low-pressure in each pair; the low-pressure (42″ diam., 36″ stroke) beneath the high-pressure (21″ diam., 36″ stroke). There is one pump to each pair of steam cylinders, and each has a double-acting plunger 20″ diam., 36″ stroke. The fly-wheel revolves between, and has its pillow-blocks upon the pump cylinders. The cross-heads of high-pressure cylinders are connected by links to a beam, which is in turn connected, one end to the crank, and the other end to the piston-rod of the low-pressure cylinder and pumps.

The following data were obtained on trial: —

Time	20 hours.
Average pressure by engine gage	74.25 pounds.
Average pressure by, in force main	95.068 pounds.
Average vacuum	27.295″.
Average temp. feedwater to boilers	169.175°, Fah.
Revolutions in 20 hours	21,449.
Revolutions per minute	17.8742′.
Piston speed per minute	107.2452.
Total coal burned	6,750 pounds.
Discharge per revolution	187.125 gallons.
Delivery at 18 revolutions per minute	4,850.280 gallons.
Net absolute duty	108,793,525 pounds.

. Duty: number of pounds lifted one foot high by consumption of 100 pounds good anthracite coal.

Pump Joint Ma-chine′. A machine for boring out and turning down the respective ends of the wooden sections where they meet in coupling to form the stocks of pumps, or which are thus united by socket joint to form pipes for conveyances of water.

The machine consists of a heavy steel spindle, which is placed in the bearings of a lathe head stock. The spindle has a screw chased to fit chucks of different sizes. The end of the spindle has a centering collar, changeable for different sizes by removing a nut, the cutting-knife in the chuck extending the whole length; a second knife at the end, which works at right angles to the first cutter, finishes the end of the stock.

In operating, the stock is placed in a rest, the hole in the stock fitting the self-centering collar. The stick is fed in by hand, and a perfect joint made, each one of the same size. There are two sizes of chucks, 3″ and 3¼″ diameters.

Pump Valve. The moving piece in a pump which opens or closes to allow the water to pass or prevent its return, respectively. See list under PUMPS: VALVES.

Perreaux's flexible valve is shown in Fig. 1061, p. 347, *supra*.

Painter's flap valve for thick and viscous matters has a flexible valve flap which is arranged to close and guard the port, by an extensive superficial contact of said flap and a fixed coincident surface.

Punch and Shear. Punches, single or combined with shears, are shown on pp. 1833, 1834, "*Mech. Dict.*"

The Tweddell punch and shear, to cut 1¼″ thickness, erected in the dock-yard of Toulon, France, is shown in Fig. 2069. The respective ends are separable so as to make two distinct machines. Each tool has its own ram, valves, and water supply; the latter is from an accumulator loaded to 1500 pounds per square inch.

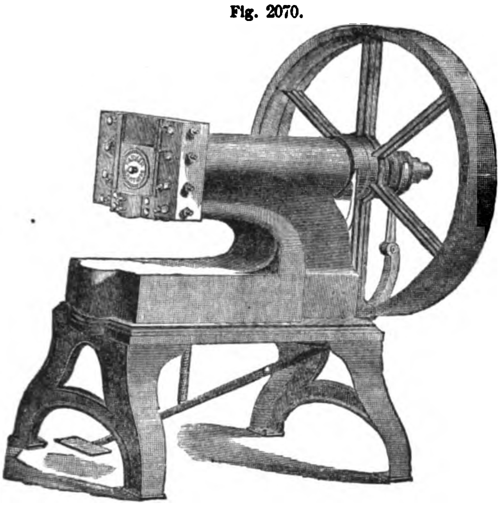
Punching iron, paper on	"*Scientific American Sup.*," 1071.

Punch′ing Press. Fig. 2070 is a view of a Stiles and Parker press with eccentric adjustment.

The slide of the press receives its reciprocating motion from a crank-pin which revolves within an eccentric ring in the sliding block. This block traverses in the oblong mortise in the slide as the crank revolves, thus imparting the motion of the crank to the slide. By bringing the eccentric out of its position by a key and turning the same by a lever, the punch may be adjusted to the die to the hundredth part of an inch.

The amplitude of the motion remains the same, but the range is changed so as to suit dies of various thickness above the bed plate.

Fig. 2070.



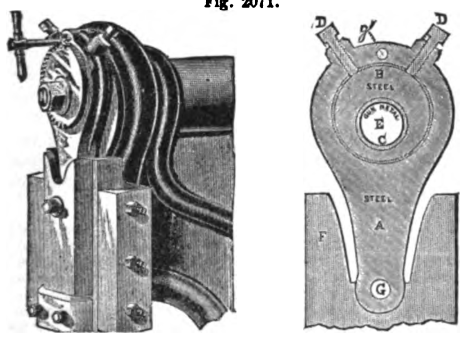
Fowler Press with Eccentric Adjustment.

The eccentric is a substitute for the former plan of placing shives of metal above and below the box.

The Stiles adjustment is shown in Fig. 2071.

The upper end of the pitman *A*, which connects the slide *F* with the crank-shaft *E*, is bored out and enlarged to receive the eccentric disk *B*. The lower end of the pitman is secured to the slide by the pin *G*. The disk *B* is bored out of center, and fits the crank shaft loosely to allow the interposition of a gun metal bushing. The disk is turned by the pinion *g*, and held by the screws *D D*. The pinion is turned by a gear wrench.

Fig. 2071.



Punching Press. (*Stiles Adjustment.*)

By this device the amplitude of the stroke is not changed, but the punch is raised or lowered to the direction in which the disk is turned. The two set-screws will hold the eccentric-ring under the greatest strain. In this arrangement the securing of the adjustment will not throw the bearings out of line, but will leave the pitman as true and free to work as before.

In the Merriman press the adjustment is by means of a right and left threaded screw and two threaded sockets.

Punc'tur-ing In'stru-ment. (*Surgical.*) A term specially applied to the *sonde-a-dard* used in supra-pubic lithotomy; the instrument for puncturing, — speaking in general terms — are so numerous as to make the recitation tedious. See list under SURGICAL INSTRUMENTS.

Pun'jam. (*Fabric.*) A strong cotton cloth made at Vizagapatam, in India. The meaning of *punjam* is "120 threads," and the cloth is denominated 10, 12, 14, up to 40 punjam, according to the number of times 120 is contained in the number of threads in the warp.

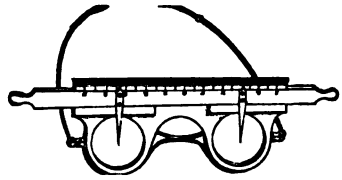
The loose night dress with drawers, *punjanias*, is named from this cloth; or, perhaps, *pijama*, leg cloth. *Jama* is a full dress coat.

Pun'ty. (*Glass.*) 1. Probably from It. *punto*, a point. A glass decanter, for instance. It is said to be cut in *punties* when the ornamentation consists of dots or cup-like depressions, usually circular but sometimes oval.

2. The glass blower's tube. *Ponty, pontil.*

Pu'pil-lom'e-ter. (*Surgical.*) An instrument for measuring the distance between the axes of the pupils.

Fig. 2072.



Chevalier's Pupillometer.

Pu'ri-fi'er. (*Milling.*) A separator to remove bran scales and flour from grits or middlings; a process repeated between each grinding in the *high-milling* process. See MIDDLINGS PURIFIER; GRITS PURIFIER.

In the process of high milling, in the step by step reduction of the grain, starting with the pointed kernels, there are with each grinding three products: coarse fragments, with much bran attached; less coarse fragments, with less bran attached; and minute fragments, with little or no bran attached. These are separated from each other by the sifting and purifying machines. Each of the several products is again subjected to grinding, and the product in each case again sorted into grades, and so on, until the last traces of the white interior of the berry have been separated from the dark hull and graded.

Purse Net. (*Fishing.*) A net stretched on wires, similarly to an umbrella, and, when ready to hoist, closed like a purse. See DROP-NET, Fig. 3317, p. 1522, "*Mech. Dict.*"

Purse Seine. (*Fishing.*) A seine which is closed by pulling upon a line or lines to inclose the fish. They have wings and a bag, and are used in the mackerel fishery.

"Purse seines range in length from 120 to 220 fathoms, and from 750 to 1,000 meshes in depth, reaching the depth of 20 to 30 fathoms of water. The average mesh is 2¼″. They are made of fine Sea-Island cotton twine, and cost from $750 to $1,500 complete. The pursing weight varies from 100 to 150 pounds." — "*Bulletin U. S. National Museum.*"

Thimbles and snatch-block are used for the running rope which closes the seine.

Push Car. (*Railway.*) 1. A light four-wheeled car used in transporting light matter, express packages, mail-bags, etc., in transferring from one train to another, or otherwise.

2. A car used as an intermediate, to connect a locomotive with a train in moving the latter up or down an incline leading to a ferry-boat. See FERRY PUSH-CAR.

Push'er. (*Hat-making.*) One form of hat-fulling machine, which see.

Pyr-he'li-om'e-ter. An instrument to measure the heat of the sun.

Pouillet's heliometer is shown in Fig. 4056, p. 1837, "*Mech. Dict.*"

The pyrheliometer of A. Crova is described in "*Comptes Rendus*" and "*American Journal of Science and Art.*" — "*Scientific American Sup.*," 234.

Ericsson's colorometer, for measurement of solar heat, * "*Scientific American Supplement*," 1103.

Solar engine, * "*Scientific American*," xli. 67.

Py-ri'tes Burn'er. An apparatus in which pyrites is burned to obtain sulphuric acid. See report of *Prof. Jackson's*, "*Paris Exposition Reports*," 1878, vol. iv., p. 10, *et seq.*, having references to those of: —

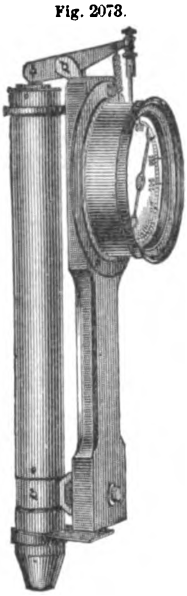
Fig. 2073.



Brown's Pyrometer.

Py-rom'e-ter. Brown's portable hand pyrometer is used as a test gage and check upon those pyrometers which are constantly inserted in the hot blast to ascertain if they are correct and in working order.

It may be described as a metal conducting tube open at each end, for the free current of the hot blast; within the tube is a thin expansion strip, conveying its motion to a dial upon a bar outside of the conductor. On applying this instrument to any orifice in the blast pipe, the hot air rushing through will give an accurate indication in less than one minute. By having several plug holes in the length of the blast pipe, its temperature at any part may be ascertained. It is useful to ascertain the loss of temperature between the stove and tuyere, and the gain derived from covering the pipes.

The instrument is set at the atmospheric temperature previous to the trial, by an adjusting screw.

Py'ro-phore. The name of a body which has the faculty of inflaming by contact with air or water. See pp. 1838, 1839, "*Mech. Dict.*"

The self-lighting signal logs which are thrown overboard to rescue men in the water, inflame on contact with the water. This forms a guide for the man to swim to, and to the boatmen who go to his rescue. The self-luminous safety buoys of the French Marine Service have phosphide of calcium. See BUOY; LIFE BUOY.

The property seems to be due to the rapid absorption of oxygen by the combustible body. Certain metallic oxides, that of iron, for example, reduced by hydrogen at a low temperature, become extremely pyrophoric. By calcining in a luted crucible 6 parts of lamp-black mixed with 11 of sulphate of potassa, a compound of sulphur and carbon is obtained which inflames with great facility by contact of the air.

"*Manufacturer & Builder*" . . . . xi. 24.

Py-ro-ste're-o-type. A process in which an intaglio is burnt in wood to serve as a mold in which a printing plate in relief may be cast.

It is said to be used in France in making music plates, and the apparatus is figured in *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," tome iii., article "*Stéréotypie*."

A block of lime or linden wood, with the design traced upon it, is secured upon the table, and steel plugs of forms suited to the various signs, keys, or notes, and heated by gas, are brought down upon it, to burn out holes corresponding to the shapes of the tool. One tool at a time occupies the plunger-rod, and after all the required impressions have been made by it, another is substituted, and so on.

Py-rox'y-line. See GUN COTTON, COLLODION, *supra*.

Q.

Quad'rant E'lec-trom'e-ter. A form of electrometer invented by Sir William Thomson.

Fig. 2074.

Thomson's Quadrant Electrometer.

It consists of four metallic segments supported in the same plane, but not in contact. They are connected alternately with two projecting knobs and balls (at the right). Over the segments hangs a strip of aluminium by a fine wire, from the inside of a Leyden jar feebly charged (seen at the top). If now one pair of the sectors are charged, while the other are connected with the earth, the strip of aluminium will move towards them if the charge is opposite to that of the aluminium rod and the jar; but if the charge is of the same kind, repulsion will take place and the aluminium strip will move away from them and over the other segments that are not charged. In order to give a directive force to the aluminium strip a small compass needle is attached to it. In order to observe and measure slight motions of the aluminium strip, a small mirror is attached to it, and a ray of light reflected by it upon a scale placed against the wall; the least turning of the mirror will cause this ray of light to travel sideward — in fact, it will act like a very long hand on a dial against the wall.

It is evident that such a delicate instrument should always be placed under a glass shade, in order to prevent disturbances by air currents, such as those generated by breathing near them. In this case the Leyden jar is also under the glass shade, so as to keep it charged longer; it is charged by the curved rod seen under it, which is connected with its inside covering, while the outside covering is connected exteriorly with the earth, when it is charged, but after being charged the connection may be severed. The two knobs seen at the right side below serve to charge the segments.

Quad'ri-cy-cle. A four-wheel vehicle adapted to be propelled by the feet.

The bicycle and tricycle are respectively two and three-wheeled.

"*Railroad Gazette*" . . . . * xxii. 597.

Quad'ri-form Group Flash'ing Light. A peculiar lighting apparatus for light-houses, invented by J. R. Wigham, and first erected at Galley Head, a promontory on the coast of Cork, Ireland, between Cape Clear and the Old Head of Kinsale.

The quadriform arrangement consists of 32 lenses arranged in four tiers, with a gas-light in the focus of each. As the lenses touch each other the lights blend at a few yards distance and form a pillar of light 13′ high and 3′ broad.

The *group flashing* denotes that the flashes from the lenses instead of being *single* flashes, as usually exhibited at light-houses, are each of them, by the repetition, extinction, and reignition of the gas, broken up into four or five beams, which constitute a *group* of flashes recurring at regular intervals, presenting a distinctive appearance. The interval between the groups of flashes is 1 minute; between the flashes in each group 2 seconds. The flashing is accomplished by the same clock-work machine by which the lenses are caused to revolve.

Quad'ru-ple Coil Spring. A car spring made of four coils; in a nest, as in *s*, Fig. 1143, p. 483, "*Mech. Dict.;*" or merely associated in the manner indicated at *u*, same figure.

Quad'ru-ple Nose Piece. (*Optics.*) An attachment to a microscope; a piece having four object glasses of different powers, either of which may be brought into apposition with the body of the microscope; avoiding the trouble of unscrewing and attaching a different power.

Double nose-piece, Fig. 3335, p. 1534, "*Mech. Dict.*"

Quad'ru-plet. Four united acting together, as of springs. *s*, Fig. 1143, p. 483, "*Mech. Dict.*"

Quad'ru-plex Tel'e-graph. An amplification of the duplex system; by the quadruplex system, four messages may be sent over the same wire, simultaneously, two in each direction. See DUPLEX TELEGRAPH, p. 764, "*Mech. Dict.*"

It was used by Prescott & Edison in 1874, by Nicholson of Cincinnati, Myer of Paris.

Quar'ter Sa'ver. (*Knitting.*) A device attached to a knitting machine to prevent the work from running off when the thread breaks or runs out. — *Cooke.*

Quar'ter Tack'le. (*Nautical.*) A tackle used in hoisting aboard water, etc.

Quar'ter-turn Belt. One which has a twist of 90°, transmitting motion between pulleys on shafts at right angles to each other.

Nine dispositions of * *Cooper's* "*Belting,*" Phila., 1878, p. 172.

Quar'ter-turn Goose'neck. A bent pipe coupling having a turn of 90°, and connecting the discharge pipe with the nozzle.

Quartz Mill. A machine for crushing auriferous quartz. See Figs. 4068–4078, pp. 1844–1846, "*Mech. Dict.*"

Hand power, *Eaton* . .	* "*Min. & Sc. Press,*" xxxviii. 217.
Rotary, *Howland* . .	* "*Min. & Sc. Press,*" xxxiv. 25.

Queens'ware. (*Ceramics.*) 1. Queen Charlotte's ware, now known by the contracted title. A celebrated cream-colored Wedgwood ware. It is of white clay and flint.

2. A form of stone ware also the invention of Wedgwood, and occupying a position between porcelain and pottery. See STONE WARE.

Quick'silver Bat'te-ry. See MERCURY BATTERY.

Quick'silver Fur'nace. See MERCURY FURNACE.

Qui'et-ing Cham'ber. (*Steam.*) An arrangement to prevent the noise incident to blowing-off of steam. The sides of the exhaust pipe have numerous small branch tubes, the sum of their areas equal to that of the main pipe.

Shaw's	See Fig. 987, p. 320, *supra.*
* "*Railroad Gazette*"	xxiii. 141.
* "*Min. & Sc. Press*"	xxxvi. 313.

Quin'tu-plet. Said of springs when five of similar type are associated in a group.

R.

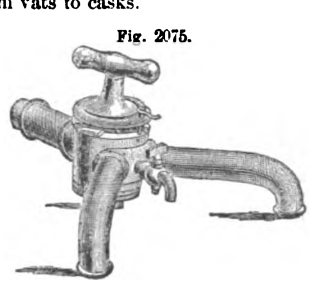
Ra'cer. The British name for a traverse circle beneath the chassis of a gun. See CIRCLE; also Plate VIII., p. 448, "*Mech. Dict.*"

Rack Car. (*Railway.*) A freight car with open slat sides, and a roof. Used for iron in pigs, pipes, and castings; oil in barrels; coke, etc.

Rack-cut'ting Ma-chine'. A machine tool for cutting the teeth of racks. It is a modification of the nulling machine, standing on a column and having, in the size shown (Fig. 2076), a table 31″ long, with a vertical adjustment of 6″, and a transverse horizontal adjustment of 17″. The spindle carries two cutters for *blocking-out* and *finishing* the tooth at the same time. Several racks may be cut at once or a single rack up to a width of 6″. Any pitch and any length of rack can be cut. The feed is automatic, with self-acting, adjustable stop-motion. The driving-spindle has a cone of two grades, and actuates the cutter spindle through the medium of gears.

Rack'ing Fau'cet. A faucet for transferring wines or beer from vats to casks.

Fig. 2075.



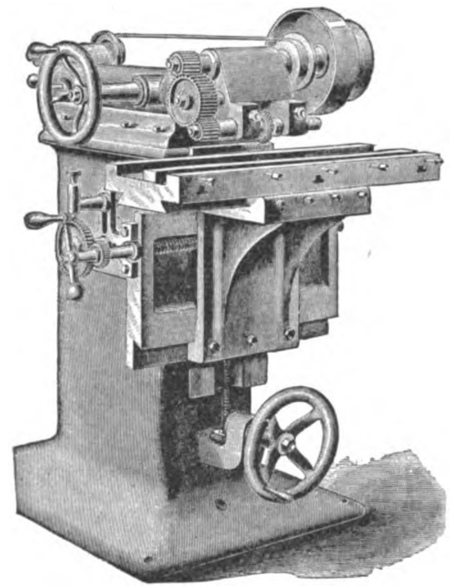
Double-armed Racking Faucet.

Used in running wines off their lees after fermentation or fining; also in filling beer kegs from vats.

The two nozzles enable two kegs to be filled at once, keeping the racking-off uninterrupted. The small spigot in the middle enables the liquid to be examined at any time.

Rack'ing Pump. A pump used in the transference of wines from vats to casks and from cask

Fig. 2076.



Rack-cutting Machine.

to cask when the difference of level prevents the use of siphon or faucet.

Fig. 2077.

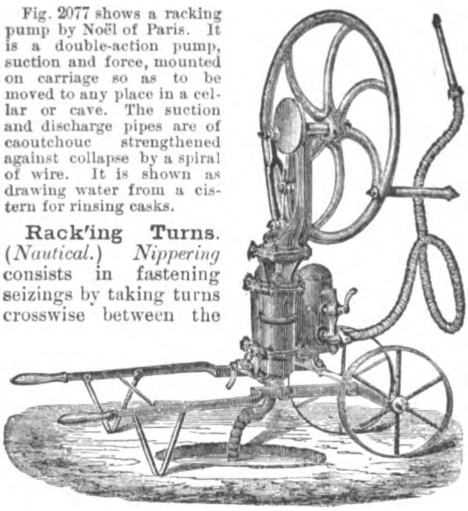


Fig. 2077 shows a racking pump by Noël of Paris. It is a double-action pump, suction and force, mounted on carriage so as to be moved to any place in a cellar or cave. The suction and discharge pipes are of caoutchouc strengthened against collapse by a spiral of wire. It is shown as drawing water from a cistern for rinsing casks.

Rack'ing Turns. (*Nautical.*) *Nippering* consists in fastening seizings by taking turns crosswise between the parts to jam them; and a *racking turn* is a round turn before each cross.

French Racking Pump.

Rack Rail'way. A form of railway having a rack between the rails, engaged by a gear wheel on the locomotive. See p. 1852, "*Mech. Dict.*," and references *passim*.

Ra'di-al Ax'le Box. One which preserves its position radial to the track, even when the car is upon a curve. — *Widmark*, Br.

"The axle-box has planed parallel sides, and is free to slide in a direction which is rectilinear and horizontal, but inclined to the axle of the wheels. The box at the opposite end of the axle is inclined in the opposite direction, so that, when the wheels and axle deviate toward one side in consequence of the curvature of the road, the axle is simultaneously set in an oblique position to the engine frame, but radial to the road, one end being advanced in relation to the frame, while the other is drawn back by the inclined form of the axle-boxes and the intermediate guides.

"As the sides of the axle-boxes are parallel planes, and as there are no flanges, the axle-boxes are free to turn round a horizontal axis which is at right angles to these side planes. Thus one axle-box may rise and the other fall in the guides, as required by the state of the road." — "*Engineer.*"

Ra'di-al Drill'ing Ma-chine'. A vertical drilling machine, the operating portion of which is adjustable on a horizontal arm projecting radially from the vertical pillar. It is used for drilling a row of holes on an object placed on the table beneath. Fig. 4099, p. 1852, "*Mech. Dict.*"

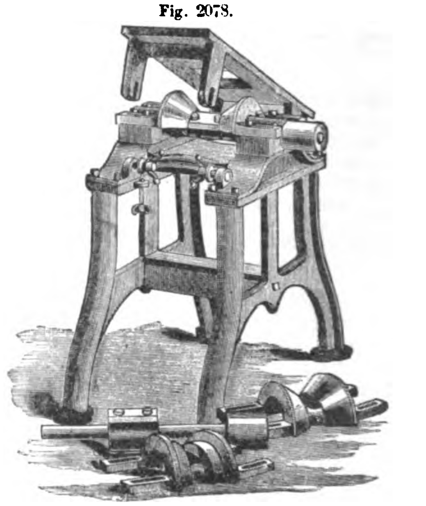
Ra'di-al Pla'ner. A machine for rounding off the corners of stuff, especially in implement and carriage work. Also known as a *rounding machine*, *cornering machine*, or *chamfering machine*; see the latter.

It performs some of the duties of a spoke-shave. It is used for forming pieces of hard wood in irregular shapes and planing smooth where the grain of lumber sets different ways on the same piece. With the adjustable top bed the machine forms a smooth plane for plane surfaces. With a side-jointing head it is adapted for squaring off the ends of hard wood pieces.

Fig. 2078.



Radial Planer.

Ra'di-a'tion Ther-mom'e-ter. One specially adapted for marking the results of radiation from grass, and for ascertaining the direct heating powers of the rays of the sun.

The former are termed *terrestrial* radial thermometers, and the latter *solar* radiation thermometers.

The terrestrial instrument is a minimum spirit registering thermometer, with a forked tube taking the place of the bulb. It is graduated on its own tube, and inclosed in an outer glass jacket. When in use, it is supported with one end on a fork, and the bulb is placed resting on the grass.

The solar instrument is a registering maximum thermometer, with its bulb blackened to facilitate the absorption of solar heat. The instrument is inclosed in a large outer glass tube from which all air has been removed, in order to prevent vitiation of the result, by the communication of its own heat by the air to the bulb.

Ra'di-a'tor. A heating chamber or coil in an apartment. Various forms are shown in Figs. 4101–4104, p. 1853, "*Mech. Dict.*" Fig. 2079 shows a group of accessory parts.

Fig. 2079.

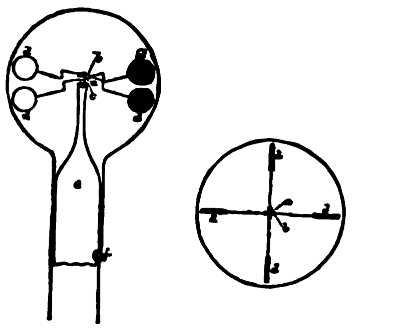
Ra'di-om'e-ter. An instrument invented by Mr. William Crookes for demonstrating the mechanical action of light, and the conversion of radiation into motive power.

According to Prof. Frankland, the movement is due to heat.

The instrument consists of four arms of some light material, to the ends of which are fixed thin disks of pith with one side black and the other white, the black sides for the

Fig. 2080.



Radiometer

four disks all facing the same way. These arms cross each other at right angles and are balanced at their center points on a hard steel point, *a*, resting on a jewel-cup, *c*, so that they may freely revolve in a horizontal plane. A thin glass globe, drawn out to a tube at the lower part so as to form a support, incloses the whole, and is exhausted to the greatest attainable vacuum and hermetically sealed.

When this instrument is placed subject to the influence of light, the arms rotate with greater or less velocity directly in proportion to the intensity of the incident rays.

Prof. Crooke's "*Lecture on Radiant Matter*," British Association for the advancement of Science, Sheffield Meeting, Aug. 22, 1879. Queen, Phila.

Ra'di-o-phone. A modification or application of the radiometer; an instrument for the production of sound by radial energy.

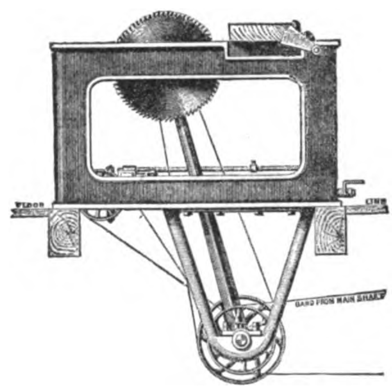
Ra'di-us Bar. A bar or pivoted link which permits any adjustment in which the link forms a radius.

A bar or pivoted link which moves on a center at one end, and at the other is connected to an object to preserve its relative distance, and permit adjustment concentric to the object so connected; *i. e.*, any adjustment or motion relative to the said center while preserving the relative distance.

See the parallel motion in the Cornish steam engine, Fig. 3548, p. 1680, "*Mech. Dict.*"
The hinged link is used in harvesting machines also.

Ra'di-us Saw. A machine saw in which the circular saw is journaled on the end of a radial arm, pivoted below to a shaft, on which is placed the driving pulley. By a pedal or hand arrangement the saw is drawn forward so as to cross-cut the timber on the bench, and falls back by gravity when the work is done.

Fig. 2081.



Ransom's Radius Cross-cut Saw.

It is a form of cross-cutting machine similar in duty, but not in construction, to the TRAVERSE SAW, Fig. 6626, p. 2619, "*Mech. Dict.*"

Ra-fa-el'le Ware. (*Ceramics.*) A name given to *Majolica* owing to so many of Rafaëlle's designs being found on that species of pottery.

Raft. See Figs. 4105–4108, pp. 1854, 1855, *Mech. Dict.*"

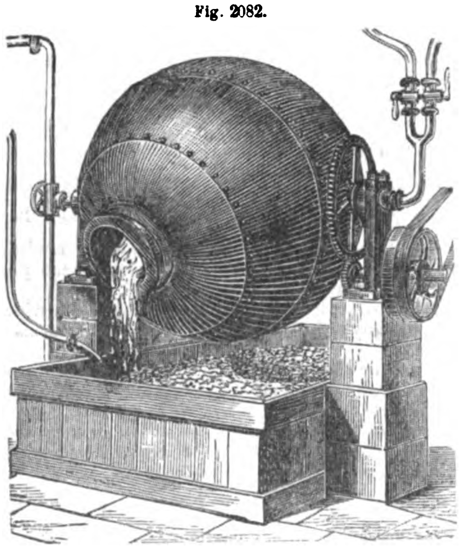
Raft, Life, and Davits, *Cramp* . * "*Engineering*," xxii. 262.

See also PORTABLE RAFT; LIFE BOAT; *supra.*

Rag Boil'er. The rag-boiler is fixed or movable, heated by open fire or by steam; is generally rotative, which gives a continual agitation to the contents.

In the illustration, the boiler is spherical, turning on its axis. Water or steam is admitted at the ends for rinsing or boiling, as the case may be, and

Fig. 2082.



Rag Boiler.

at one end is the gearing for rotation, either to agitate the contents during the process while the cover is closed, or to discharge the contents into the tub when the operation is finished.

The figure shows a spherical boiler, supported on hollow gudgeons, at which water and steam respectively are admitted.

Elevated faucets at the right hand admit the alkaline solution or water, respectively.

On the left are the steam valve and water-pipe, the latter for washing out the tub.

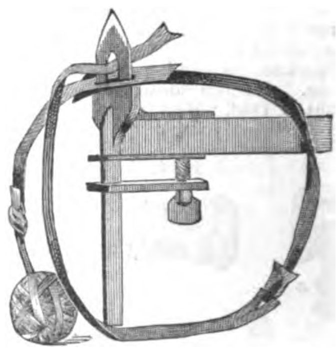
The process of boiling the paper material to make pulp, is for the purpose of disengaging the cellulose matter, and the details of the process, that is, the strength of the alkali, and the temperature and duration of the process, depend upon the character of the material under treatment, the object being to disengage the fiber, uninjured, from the cellulose and other matters which are associated with the fiber in the growing plant. The pectique principle which gives the parchment qualities which are found in some papers it is also desirable to preserve.

Rag Knife. (*Rag Engine.*) One of the knives in the cylindrical cutter, operating against those in the bed, or *bottom plate.* See Fig. 4112, p. 1856, "*Mech. Dict.*"

Rag Loop'er. Used in splicing rags for rag-carpet. It loops them together without sewing. Both ends are impaled on the perforated knife and the end of the last attached piece rove through the hole in the knife and pulled taut. The knife is raised and as its lower end is a pair of prongs it allows the knotted strip to slip off. See Fig. 2083.

Rag Pick'er. A shoddy machine for pulling to shreds woolen rags, stocking clip, hosiery, yarn, wool waste, old carpet, etc., and reducing them to cotton or wool staple, as the case may be. The material is fed from the table between a pair of rollers to the cylinder; this is 16¼″ wide.

Fig. 2083.

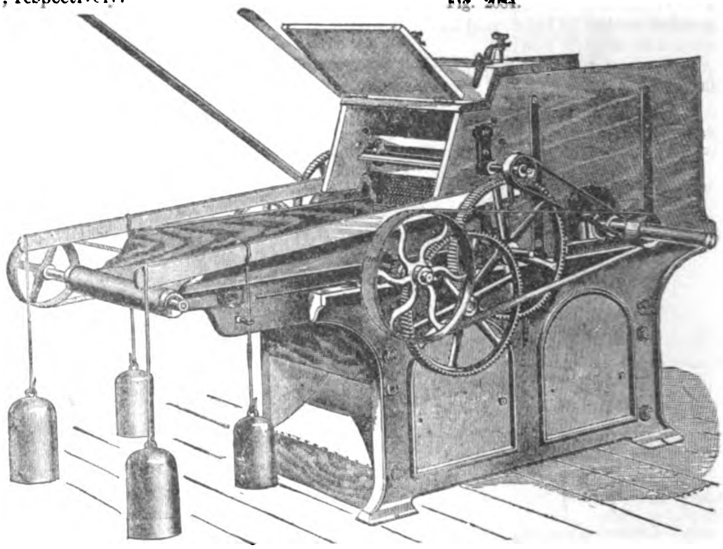


Rag Looper.

The face of the teeth is of steel and they are set in lags on the cylinder. The pressure on the feed rollers is adjusted by slipping the weights out or in upon the levers. The capacity is from 200 to 800 pounds per day, according to size. A lumping attachment throws out lumps and knots from the shoddy. See Fig. 2084.

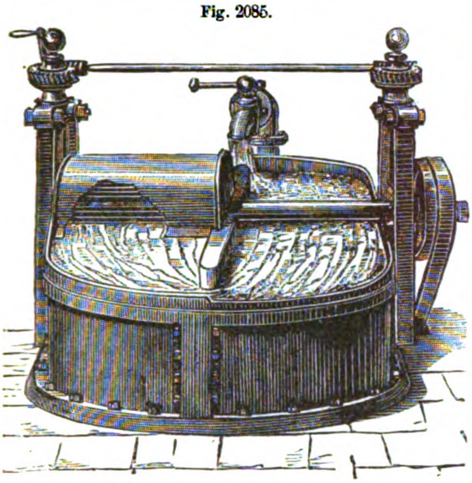
Rag Wash'er. A form of apparatus like the pulping machine in form and action, but differing from it in this, that, instead of having on the cylinder knives acting as shears against the blades of the concave beneath to cut the rags into fine shreds and eventually into pulp, the rag washer has a cylinder with wooden or bronze bars which merely rub the material against a plate beneath, serving to disengage any dirt and traces of the coloring matters or salts incident to the material or the remains of processes through which it has previously passed. In the center is the water supply; on the left the cylinder case; above is the gearing by which the cylinder shaft is raised or lowered so as to adjust its position vertically. See Fig. 2085.

Fig. 2084.



Rag Picker.

Fig. 2085.



Rag Washer.

Rag Wheel. (*Add.*) A polishing wheel made of disks of rags, rove upon a mandrel and clamped thereon. Such a wheel is from 4″ to 8″ diameter and runs at a speed of 7,000 per minute.

For use on iron: use a polishing material of equal parts of Vienna lime, crocus, and beeswax.

Boil these together, cool, cut into cakes. Dip a cake in oil and apply to the rag wheel occasionally.

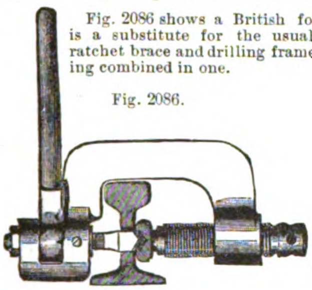
For brass, take crocus 2, wax 1, rouge $\frac{1}{8}$; melt, mix, and apply as in the former case.

For nickel, use rouge with water or oil.

Rail Bor′er. A hand machine for boring the webs of rails for the passage of the bolts of fish-bars.

Fig. 2086 shows a British form which is a substitute for the usual separate ratchet brace and drilling frame, both being combined in one.

Fig. 2086.



Rail Borer.

Rail Key. (*Railway.*) A wedge-piece driven in between the rail and its chair.

Rail Ma-chin′er-y. Machines for rolling, bending, straightening, drilling, etc., railway rails.

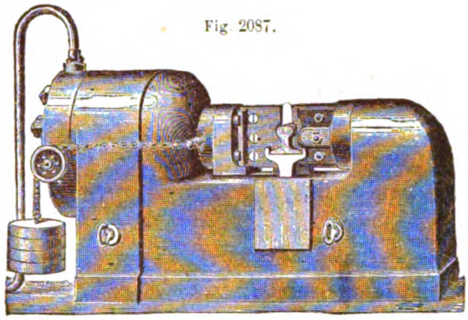
See also ROLLING MILL.

Rail Shears. An application by Tweddel of the hydraulic power to cutting or squaring off the ends of rails. It has one stationary and one movable abutment, the faces of which conform to the shape of the rail to be cut. It is used without the accumulator, which is usual with riveters, the complete plant consisting of a boiler, ram, and shears.

Fig. 2087.



Tweddell's Rail Shears.

The ram has a steam cylinder of relatively large diameter, the total pressure on which is imparted to a plunger of small diameter, producing a corresponding pressure on the water in the hydraulic cylinder. The machinery is entirely controlled by steam valves.

Automatic cut-off gear is fitted to the steam cylinder so as to allow for expansion of the steam. This is effected by opening the tap at the point of cut-off required, and when the piston has passed the opening, the steam escapes through the tap, and closes a specially constructed throttle valve in the steam-inlet passage.

The *Vesuvian Railway* has the double-rope system, a car traversing on each line of rails, one descending as the other ascends, mutually counterbalancing. Each carriage has two compartments each capable of holding 6 persons. The depot and engine are at the bottom, and at an elevation of 810 meters above the sea, and 210 meters above the observatory. A carriage drive leads from the observatory to the railway. The angles of inclination are respectively 40, 63, and 50 in a hundred, at different parts of the ascent. The road is 900 meters long and terminates some distance short of the crater. The ascent is made in 7 minutes.

Railway Elevations. — A British journal gives the following as the highest elevations above the level of the sea, attained by any point on the railways named: —

	Meters.
Apennine line	617
Black forest line	850
Sömmering line	890
Caucasus	975
St. Gothard tunnel	1,154
Bremmer line	1,367
Mt. Cenis line	1,338
Northern Pacific	1,652
Central Pacific	2,140
Union Pacific	2,513
Andes line	4,769

Railway Speed. — The following rates of regular train speed are given in the journals (fractions omitted): —

British.

"Flying Dutchman," Great Western Railway, London to Exeter, 194 miles, with 4 stops, 4 hours 14 minutes; 46 miles per hour.

"Leeds Express," Great Northern Railway, London to Leeds, 187 miles, with 4 stops, 4 hours; 47 miles per hour.

"Morning Express," Great Northern Railway, London to Edinburg, 395 miles, 9 hours; 44 miles per hour.

"Irish Mail," London and North Western Railway, 40 miles per hour.

"Scotch Express," Midland Railway, London to Glasgow, 425 miles; 40 miles per hour.

United States.

"Boston and New York Express," Boston and Albany Railroad, 284 miles, 6 hours, 12 stops; 37 miles per hour.

"San Francisco Express," Jersey City to San Francisco, (ending June 4, 1876), 83 hours; 34 miles per hour. Jersey City to Pittsburg, 444 miles, 10 hours.

See also Locomotive, pp. 555, 556, *supra*.

Average Express Rates.

	Per hour.
Paris & Marseilles Express	66.3 kilometers
Berlin & Cologne (Lelviter line)	60. kilometers.
Spandan & Stendal (Lelviter line)	71.8 kilometers.
Berlin & Magdeburg (Potsdam line)	67.9 kilometers.
Brandenburg & Magdeburg (Potsdam line)	69.15 kilometers.
Great Western, Br.	53¼ miles.
Great Northern, Br.	51 miles.
London & Brighton, Br.	47¼ miles.
London & Northwestern, Br.	47¼ miles.

Rail'way Car Brake. A means for bringing friction upon the wheels of a car to restrain rotation and slacken the speed of or stop the train. The subject is considered under Air Brake; Car Brake; Pneumatic Brake; etc., "*Mech. Dict.*" See references under Railway Brake, p. 1862. *Ibid.*

The Westinghouse automatic brake is shown in Plates XLI., XLII., which, taken together, illustrate the consecutive portions of the apparatus, The plates also show side and end elevations of a locomotive with apparatus attached, and a view of the under side of a part of a locomotive and tender, similarly furnished.

The *Westinghouse* automatic brake consists of the following essential parts: —

The steam engine and air-pump, which produce the compressed air. These are shown to the right hand in Plate XLII., the steam engine above and the air-pump below; the pistons and rods in line.

The main reservoir, in which the compressed air is stored.

The engineer's brake-valve, which regulates the flow of air from the main reservoir into the brake-pipe for releasing the brakes, and from the brake-pipe to the atmosphere for applying the brakes.

The main brake-pipe, which leads from the main reservoir to the engineer's brake-valve, and thence along the train, supplying the apparatus on each vehicle with air.

The auxiliary reservoir, which takes a supply of air from the main reservoir, through the brake-pipe, and stores it for use on its own vehicle.

The brake-cylinder, which has its piston-rod attached to the brake-levers in such a manner that, when the piston is forced out by air pressure, the brakes are applied.

The triple valve, which connects the brake-pipe to the auxiliary reservoir, and connects the latter to the brake-cylinder and is operated by a sudden variation of pressure in the brake-pipe, (1) so as to admit air from the auxiliary reservoir to the brake-cylinder, which applies the brakes, at the same time cutting off the communication from the brake-pipe to the auxiliary reservoir, or (2), to restore the supply from the brake-pipe to the auxiliary reservoir, at the same time letting the air in the brake-cylinder escape, which releases the brakes.

The couplings, which are attached to flexible hose, and connect the brake-pipe from one vehicle to another.

The automatic action of the brake is due to the construction of the triple valve, the primary parts of which are a piston and a slide-valve. A reduction of pressure in the brake-pipe causes the excess of pressure in the auxiliary reservoir to force the piston of the triple valve down, moving the slide-valve so as to allow the air in the auxiliary reservoir to pass directly into the brake-cylinder and apply the brakes. When the pressure in the brake-pipe is again increased above that in the auxiliary reservoir, the piston is forced up, moving the slide-valve to its former position, opening communication from the brake-pipe to the auxiliary reservoir, and permitting the air in the brake-cylinder to escape, thus releasing the brakes.

Thus it will be seen that any reduction of pressure in the brake-pipe applies the brakes, which is the essential feature of the automatic brake. If the engineer wishes to apply the brakes, he moves the handle of the engineer's brake-valve to the right, which first closes a valve retaining the pressure in the main reservoir, and then permits a portion of the air in the brake-pipe to escape. To release the brakes, he turns the handle to its former position, which allows the air in the main reservoir to flow into the brake-pipe, restoring the pressure and releasing the brakes. A valve, called the conductor's valve, is placed in each car, with a cord running the length of the car, and any of the train-men, by pulling this cord, can open the valve, which allows the air to escape from the brake-pipe. Should the train break in two, the air in the brake-pipe escapes, and the brakes are applied to both sections of the train; and should a hose or pipe burst, the brakes are also automatically applied.

The gage shows the pressure in the main reservoir and brake-pipe when they are connected, and the pressure in the brake-pipe alone when the main reservoir is shut off by the movement of the engineer's brake-valve.

A non-automatic brake cannot be made to work satisfactorily upon more than from 10 to 12 cars, while it is possible to work trains of 50 cars with the automatic brake without difficulty. With the non-automatic brake the air is stored upon the engine and transmitted back through the pipe, and consequently there is a loss of time both in putting on and taking off the brakes. With the automatic brake, the air is stored upon each car ready for use, and this supply is readily brought into action by a slight reduction of pressure in the main pipe, which reduction requires the movement of but a trifling quantity of air as compared with that used for setting a non-automatic brake.

A modification of the automatic car brake adapts it specially to freight cars. The operation is the same, but the triple-valve, brake-cylinder, and reservoir are bolted together and avoid the pipe connections.

The following brakes are described and illustrated in Forney's "*Car-builder's Dictionary.*"

Rail'way Crane. A crane adapted to travel on a railway track; either as a wrecking crane, or for loading and unloading purposes. Such are also used in building sea-walls, depositing blocks of concrete in advance of the track, which is laid piecemeal as the foundation advances.

The crane shown in Plate XLIII. is made by Appleby, of London. It is mounted on a permanent way truck with buffers and springs, and has a curved wrought iron jib, and a boiler acting as a counterpoise. It carries a load of 5 tons. It is self-propelling, or the traveling motion can be thrown out of gear, and the crane, being securely locked, can be attached to a train for traveling to any part of the line where its services are required. The cylinders are fitted with link reversing gear, and the several motions are transmitted from the engine shaft; there are four speeds of lifting, and the load can be lowered either by the brake or by reversing the engines; the turning motion is effected through double friction clutches, and suitable gear which drives a wide roller immediately under the jib, and this operation is performed in either direction, and simultaneously with any of the others, and being obtained entirely by the friction of surfaces instead of by toothed gear on the base-plate, the risk of breakage arising from stopping or starting too suddenly is avoided. The derrick motion for altering the radius is worked by worm gear and a pair of chains, one end of which is attached to the crane-frames, the other end coiling round the derrick barrel. The traveling motion is obtained by a shaft passing through the center of the crane post, and driven from the crank-shaft, the lower end of this vertical shaft giving motion to another shaft fixed horizontally under the crane-carriage, and in order to allow of the deflection of springs, the power is transmitted through pitch chains from this shaft to both traveling axles. The crane is mounted on a wrought-iron carriage similar in all respects to the ordinary permanent-way stock. The jib is curved in order to give sufficient clearance for lifting large logs on to trucks, for stacking timber, etc., or even to lift a disabled truck and place it on a platform truck.

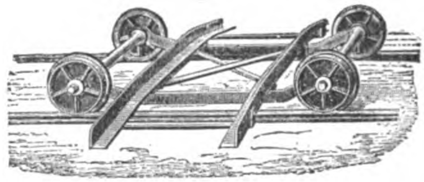
A very large and efficient form of crane of this description is shown at Fig. 5652, p. 2335, "*Mech. Dict.*" A smaller one at Fig. 5651, previous page. See also BALANCE CRANE, Fig. 176, p. 66, *supra*.

There are other forms of cranes which run on rails in manufacturing establishments, machine shops, etc., the floorways of foundries, etc. See also OVERHEAD CRANE; TRAVELING CRANE, etc., "*Mech. Dict.*"

Rail'way Cros'sing. A temporary bridge for carriages across a line of rails. It consists of a pair of angle-irons arched so as to span the track. A somewhat similar device is the hose-bridge which allows street cars to cross fire hose laid across the rails. Fig. 2579, p. 1131, "*Mech. Dict.*"

The form shown in Fig. 2088 is the French transbordeur de wagonetts; the bridge plates are carried on a low truck so as to be transportable on the line of rails which they bridge.

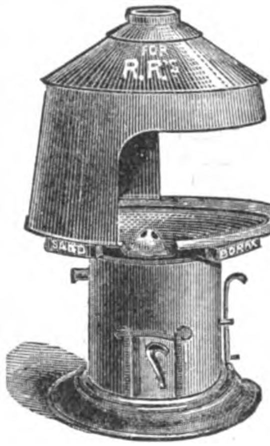
Fig. 2088.



Railway Crossing.

Rail'way Forge. A form of portable forge specifically adapted for work on railways, shown in Fig. 2089. It has a lantern bellows inclosed in the pillar and worked by a handle. The cowl is shiftable to windward to protect the fire.

Fig. 2089.



Adjustable Cowl Forge.

Rail'way Plow. 1. A plow attached to a car or locomotive and used in excavating or ditching alongside the track. See references under PLOW.

2. A snow plow.

Rail'way Scale. A track scale for weighing cars in transitu. See *m*, Plate LXXIII, p. 2754, "*Mech. Dict.*"

Rail'way Sig'nal. The interlocking system of switches and signals is used in connection with switches at stations and junctions.

The block system is used to prevent more than one train from occupying a given space between stations at the same time. See BLOCK SYSTEM, p. 110, *supra*, and references *passim*.

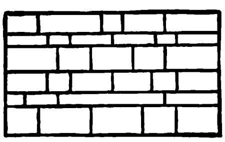
Fig. 2091.



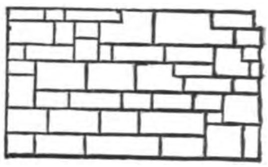
Range Stone Work.

Range Stone Work. (*Masonry.*) Stone work laid in courses.

Range Work may have courses of different thicknesses, but the level joint is preserved.

In *Broken range work* the uniformity is occasionally broken by thicker stones, as in Fig. 2092.

Fig. 2092.



Broken Range Stone Work.

Range work, whether of squared stones, or of ashlar, is usually backed up with rubble masonry, which in such cases is specified as coursed rubble.

Ran'ging Rod. (*Surveying.*) The rod of the chain-man, which is held vertical while being observed by the transit-man.

Heller's self-plumbing ranging rod, for transit field work, is described in * "*Manufacturer & Builder*," xii. 184.

Rar'e-fied Air Ap'pa-ra'tus. Apparatus in which the effect of the diminution of atmospheric pressure on living organisms is observed.

Prof. Bert's investigations are contained in a book of 1168 pages with 89 engravings, referred to in * "*Manufacturer & Builder*," x. 60. See also DEPURATOR, p. 687, "*Mech. Dict.*" The opposite idea is the compressed-air bath. See AËROTHERAPY APPARATUS, p. 9 *supra*, and Fig. 67, p. 31, "*Mech. Dict.*"

Ratch'et Brace. A boring brace, the handle of which is reciprocated, being effective in one direction only, by means of ratchet and click. Figs. 4175, 4176, p. 1882, "*Mech. Dict.*"

Brace	"*Engineer*," l. 6.

Ratchet Coup'ling. A device to uncouple machinery from the driving-wheel when the motion of the latter is suddenly arrested by an obstruction.

A ratchet wheel is placed on the driving-wheel shaft, and slips within a sleeve on the extension shaft. The ratchet is efficient as long as it is a driver, but, if arrested by an obstruction to the master wheel, the sleeve slips on the ratchet and allows the machinery to move on until it loses its momentum.

Fig. 2093.

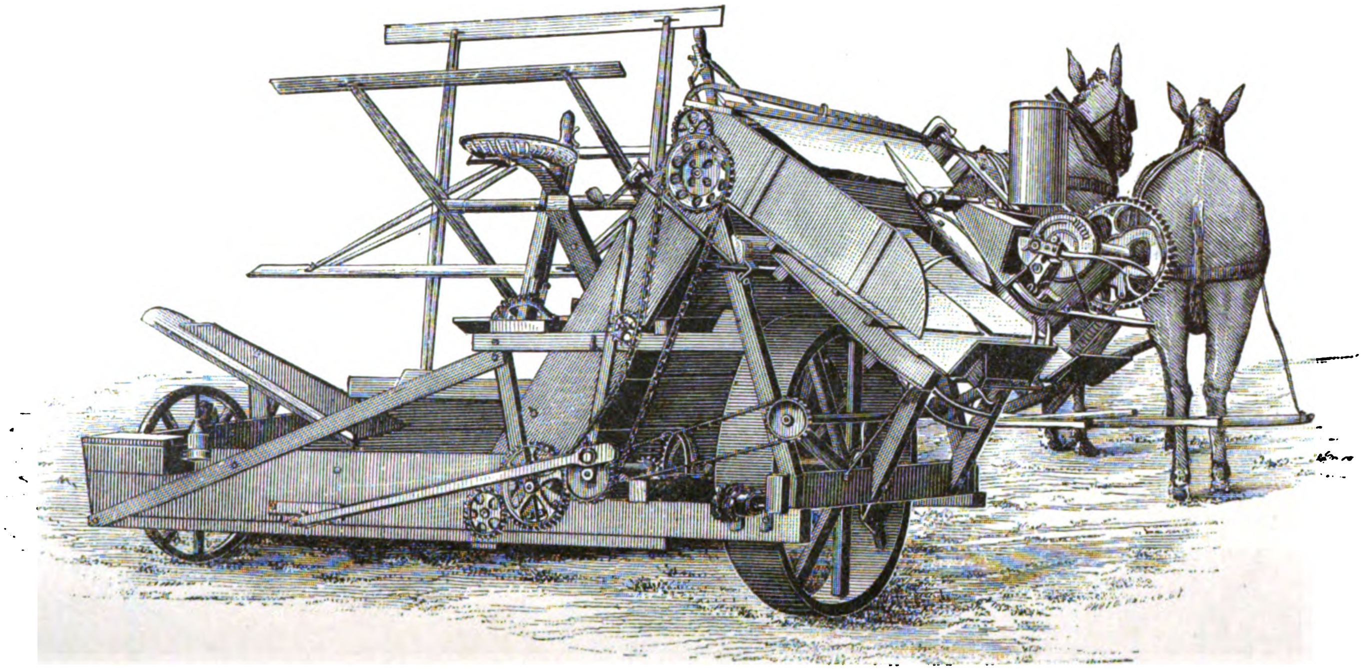
Ra'tion Press. See BALING PRESS, Fig. 184, p. 69, *supra.*

Rat'tle Bar'rel. A tumbling box for castings, to remove sand, and, in some cases, cores.

PLATE XLIV.



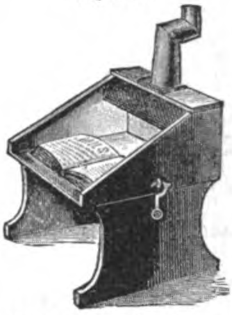
McCORMICK'S TWINE-BINDING REAPER.

See page 748.

Reach. That portion of the running gears of a vehicle which connects the fore and hind axles. See Fig. 2093.

Read'ing Lamp. A lamp for ministers and lecturers. It is so screened as not to send any light into the room but to illuminate the reader's notes which are laid upon the desk.

Fig. 2094.



Lecturer's Reading Lamp.

British Museum reading-room. "*Sc. American*," xli. 36.

Reap'ing Ma-chine'. 1. The history and development of the reaping machine from the Gallic implement of the first century, A. D., to the period of the Centennial Exhibition in Philadelphia, 1876, has been referred to, rather than exhaustively told, on pp. 1888–1898, "*Mech. Dict.*" The classification by structural features is given on p. 1898, and illustrations of the 38 principles of action are given in Plates XLVII.–L., pp. 1894–1897, *Ibid.*

The features which the reaper has in common with the mower are considered under MOWER, pp. 1487–1493, "*Mech. Dict.*" The principles of cutting apparatus on Plate XXX., p. 1489, *Ibid.* The classification of mowers by structural features is given on p. 1488, *Ibid.*, and thirty-six illustrations, occupying Plates XXXI.–XXXIII., pp. 1490–1492, show the variations in the following features: —

Modes of connecting the cutting apparatus with the frame.
Modes of driving cutters.
Styles of cutters.
Truck clearers.

The latest classification of harvesters by structure, embracing the whole subject under 141 heads, is given on page 442, *supra*.

The British experiments in building reaping machines from the period of the Boyce patent, 1799, to the Bell machine of 1826, were numerous and unsuccessful. The side cut was tried in 1806, up to which time the machine was pushed ahead of the horses. The knives were rotary until 1822.

The McCormick reaper, invented and put to service in 1831 and exhibited at the London World's fair in 1851, caused the resurrection of a number of old British devices, especially the machine of Patrick Bell (1826) shown in Fig. 4202, p. 1891, "*Mech. Dict.*" The terms of the French award of the Grand Gold Medal of honor in 1855, express the position of the McCormick reaper as "the type after which all the others are made."

While there have been many valuable improvements in detail it may be truthfully said that to dispense with Cyrus H. McCormick's invention would be to wipe every reaper out of existence. The same may be said of mowers, except the small class known as lawn mowers. The original machine of McCormick embraces the following features: —

The serrated reciprocating blade operating in fingers or supports to the grain being cut.

The platform for receiving the cut grain deposited thereon by the reel, and from which it was raked to the side in gavels ready to bind.

A divider to separate the grain to be cut from that left standing.

Two forms of the combined reaping machines, that is, adaptable for either reaping or mowing, are shown in Plate XLVI., p. 1892, "*Mech. Dict.*," the three figures in the Plate showing the machine as a reaper, a dropper, and a self raker. The single reaper is made with but a single driving wheel and is shown in Plate XXX., p. 630, *supra*.

The McCormick "Daisy" reaper shown in the Plate is a single wheel self-raker cutting 5′ wide and weighing 700 pounds. It is a center-cut machine, the ground-wheel and grain-wheel being in line. It has no cogs in the main-wheel. Both ends of the cutter-bar can be raised at the same time by one lever, operatable while the machine is in motion. By a second lever the guards can be tilted up or down to suit the variety of surface or the condition of the crop. By a simple tripping device the operator can regulate the action of the rakes in forming the size of the bundles.

At the Paris Exposition of 1878 there were exhibited, in the field, in Class 76 (the writer being a member of the jury of that class): 4 binding reapers; 21 simple and combined reapers; 1 steam reaper; 16 mowers.

The binding reapers shown at the Paris Exposition of 1878 were 9 in number, 6 American and 3 British. 4 of the American machines went into the field-trials, all of which used wire, and each of the owners has since placed a twine binder on the market. Two twine binders were shown at the exposition, one American and one British, but did not compete in the field.

The four competing machines were those of —

Cyrus H. McCormick, *D. M. Osborne & Co.*,
Walter A. Wood, *Aultman & Co.*

The results of the trial at Marmont, near Paris, in 1878, are given in detail under DYNAMOMETER, p. 288, *supra*. The McCormick machine was awarded the grand prize, and subsequently the gold medal of the Royal Agricultural Society of Great Britain, Bristol, 1878, where the same machines competed, and again in 1881, at a competitive trial of the prominent twine binders from England and America at Derby, England, the Royal Agricultural Society awarded the gold medal to the McCormick machine.

The McCormick twine binding reaper is shown in Plate XLIV. The grain, as cut by the reciprocating knife, is delivered by the reel upon the platform, which is a moving web of canvas, which carries it to the elevating aprons which deliver it upon the binding table. The position of the band on the sheaf is regulated for long or short straw by means of a shifting lever, which moves the table backward or forward so as to place the band around the middle of the bundle, either in long or in short grain.

The packing apparatus which regulates the size of every sheaf, making them all uniform, consists of two arms with forked points, which work alternately up through two slots in the table. They rise up quickly, raising the straw and moving it gently forward, pressing it into a receptacle, thus forming a compact bundle, and when the regulated amount has accumulated the pressure against the trip-hook removes a stop, thus throwing the binding mechanism into gear. The two curved trip-hooks can be shifted on the sword arm, so as to adjust the bulk of sheaf desired, and when once set for sheaves of any given size, sheaves of that size are continuously made

The binding apparatus consists of a needle arm, gripper, and discharging device, with the necessary gear. The needle arm and part of the discharging device are below the platform, and the gripper, knotter, and two discharging arms overhang the sheaf. After the sheaf has been perfectly tight, and the binding apparatus has been thrown into gear, as described above, the needle arm rises up through the table, carrying the twine with it, and thus encircling the sheaf, places the twine in the gripper, where it is held fast until by a quick motion the knot is tied, the cord cut off, and the discharge arms throw off the bundle to the ground, when the binding apparatus stops and the packers immediately begin the formation of a new sheaf. The discharging device makes the separation between the bound bundle and the unbound grain. The binding material is long-fibered manilla twine. The tension, when once set, binds all bundles with uniform tightness.

The binding apparatus is more specifically shown in Fig. 2095.

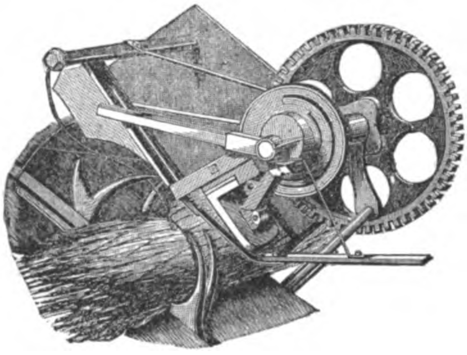
The binding mechanism is attached to that form of American harvester which has traveling platform, elevator, and binding table. The first motion is by a spur wheel on the main axle, 24″ in diameter, which drives a pinion on a counter-shaft, which, at its opposite end, carries a bevel wheel sliding on a feather and actuated by a clutch under the control of the driver. This bevel wheel drives a bevel pinion on a second shaft, running backwards and forwards and parallel to the main driving wheel; on its rear end is a triple wheel, comprising a small chain wheel which drives the binding gear; a spur-wheel to drive the bottom apron through an intermediate wheel, and a larger chain wheel for the elevator, on the other side of which is the pitman crank, working the knife from behind. The binding mechanism comprises first, a shaft, which runs from back to front of the machine under the binding table. On its forward end is a small chain-wheel, driving on to a square shaft with a loose chain on it, so as to adapt its position to the table when the latter is shifted. On the rear end are two cranks, actuating the packers, which sink through slots on the binding table. On the foremost end of the last-mentioned shaft (No. 4) is a small geared pinion, also loose, with a stop pivoted to it, which is held by a pawl actuated by the compressor. On the extreme end of the shaft, beyond the stop, is a clutch with two driving prongs, which engage into the tail of the stop when the pawl is out of gear. When the pawl comes into gear with the stop, the tail of the latter is so depressed as to allow the clutch to clear it, and so the pinion is thrown out of gear.

This pinion, through two intermediate wheels, drives the knotting-gear, by means of a large spur-wheel on the binder-shaft (No. 5), with cams on both sides; that on the outside works a tension lever for the string.

A crank-pin on the outside cam actuates a crank and rocking-shaft, the opposite end of which carries the needle arm.

The compressor is pivoted on a crank at the back of the needle arm; and it actuates first a rocking-shaft, with a cam which locks the pawl which holds the driving pinion on No. 4 shaft already described; and secondly, the lever of a rock-

Fig. 2095.



The McCormick Twine Binding Mechanism.

ing-shaft, the opposite end of which has a crank connected by a spring rod to a cam roller on the inside of the large cam-wheel on a shaft, No. 5; the object being first to compress the sheaf at the moment of its being tied, and then to depress the compressor after the string is cut, to allow of the sheaf being discharged. The crank to which the compressor is attached has also two light discharge arms which serve to depress the hinged tail-boards of the platform, which are fixed at an angle during the collection and formation of the sheaf, so as to prevent any scatter of straw, etc.

The large tyer-wheel, shown in the illustration (Fig. 2095) is keyed on to shaft No. 5, which goes half-way across the table and drives the knotting gear.

The operations to be performed comprise: —

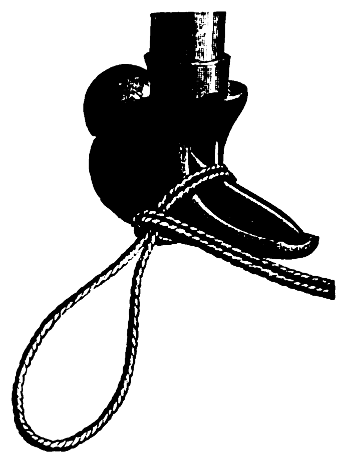
1. Holding the free end of the string.
2. The action of the needle arm and supply of string.
3. The making of the knot.
4. Cutting the string.
5. Discharging the sheaf.

1. On shaft No. 5, near its center, is a cam-wheel, which actuates a plunging bolt kept against it by a volute spring. In the event of an accident to this spring the same action is secured by a central plunger cam on the end of the shaft No. 5.

The plunger bolt works through eyes attached to the knotter frame, and supports a loose rocking frame carrying the twine-holding disk. This disk is about $2\frac{1}{2}''$ in diameter, and has six smooth-edged recesses, into any one of which the string is guided. One edge of this disk works closely between cheeks, between which and itself, by its revolution, it carries and jams the string, and so holds the free end. The rotary motion is communicated by the plunger bolt, lever and pawl, and ratchet, with a spring-catch on the opposite side to prevent it from turning backward, and so liberating the string.

2. The string, which is fed from a tin canister on the top of the machine through a tension-regulator and taker-up of slack, passes through guide eyes and tubes, to the side of the needle arm and along the needle for about one third of its length, without roller or springs.

Fig. 2096.

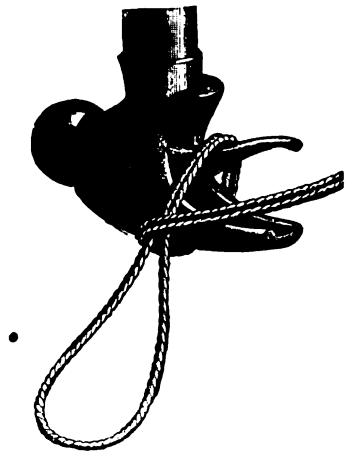


Forming of the Loop by Rotation of the Beaks.

3. The knotter is of the bird-beak type and of the Appleby patent. The lower half of the beak or jaw has simply a revolving motion. The upper beak can be opened by a cam surface and closed by a spring-cam actuating a small roller on the back end of the beak.

The motion for making a knot consists of one complete revolution in one direction only, and is obtained by a short-toothed segment on the cam-wheel on shaft No. 5. Both strands of the string pass over both beaks, as seen in Fig. 2096, and are prevented from getting out of place by a tucker, consisting of a lever actuated by a cam or cam-wheel, and which follows the string as soon as the needle has passed over the beaks; and, without actual contact, it effectually prevents the string getting out of place. At the proper moment for making the knot, the beaks revolve, forming the loop as shown in Fig. 2096. Then the upper beak opens, engages both strings, nips them tight (see Figs 2097 and 2098), and at this moment the knife-arm pushes

Fig. 2097.



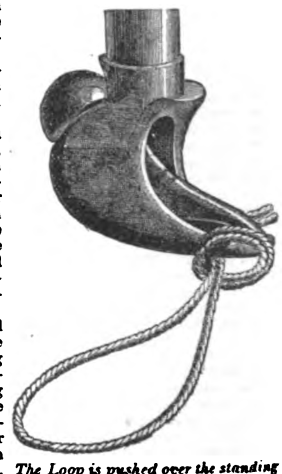
The upper Beak opens to grasp the standing part of the Strings.

the loop over the portion held by the beak, thus making the knot.

4. The knife is fixed to the lower side of the knife-arm, which is pivoted to the knotter frame, and actuated by an inner cam on the cam-wheel on shaft No. 5. It does not actually cut against anything, but it works within a quarter of an inch of a fixed guide which offers the necessary resistance.

5. The sheaf is discharged by the action of the light arms, which are seen in Fig. 2095. These arms are keyed on the knotter-shaft, about a foot apart, on either side of the cam-wheel and gear. Their action is simply to push off the sheaf, as the shaft revolves, the hinged platform and compressor arm dropping at the same moment.

Fig. 2098.



The Loop is pushed over the standing part, thus making the Knot.

A small *butter*, hinged from the top of the frame, with revolving apron, can be set at different angles, according to the length of the crop, these changes being made by the driver whilst the machine is in motion, by a lever-rod. The action of the *butter* is to square-up the butts of the sheaves, and has a very useful office in insuring a neat, compact sheaf. The apron is revolved by bevel gear from the end of the elevator-shaft.

The steam reaper shown at the exposition was by Aveling & Porter, Rochester, England.

It consists of a wide-swath reaper, on the "Bell" principle, driven by a traction engine at its rear. It was a striking revival of the machine invented and used by the Rev. Patrick Bell, at Forfar, Scotland, in 1828, but cut a swath of 12′ wide at the rate of 2¼ miles per hour, over double the work of the Scotch machine. This was no extraordinary advance in point of economy, as the Bell machines worked with two horses and laid the swath in the same manner. The Aveling & Porter machine had a nominal power of five or six times as great.

Like its prototype, the tongue of the machine extends to the rear, the power being behind, but, instead of a pair of horses hitched to the end of the tongue and facing their work, a 10 or 12-horse traction engine pushed the reaper into the grain, the cutting apparatus, grain-reel, and endless discharge-apron being worked by gearing driven by an endless chain from a sprocket-wheel or the fly-wheel shaft of the engine. The endless apron is inclined, and discharges the cut grain in a regular and continuous swath on the left of the machine, with the butts towards the engine and out of the way of the latter, which followed in the rear.

In front of the engine is a crane with tackle operatable from a drum, which may be thrown in connection with the engine when required. During the turning of corners while at work, and in transporting the apparatus to and from the field, the reaper is lifted and hangs suspended from the crane.

The machine is operated and guided by one man, the various levers being conveniently placed; so that the reaper may be raised or lowered, the locomotive moved forward, backed, or guided to left or right, and the gearing which controls the functions of the reaper proper put into or out of operation.

The machine did very good work, but it can hardly be said that it was regarded as of much practical value.

2. A file having two parallel flat sides and two inclined edges, all flat.

Rear′cut Mow′er. One the cutter bar of which is in the rear of the axle of the carriage. As distinct from *front cut* and *middle cut*. See upper figure in Plate XLVI., p. 1892, "*Mech. Dict.*"

Rear Sight. The hind sight of a gun, rifle, or cannon. There are various kinds: *open*, *peep*, *vernier*, *California*, etc. See list under SIGHT. See also HAUSSE.

The rear sight of Russian cannon. "*Ordnance Report*," 1877. Col. Benton's report and Appendix L, p. 578, and Fig. 1.

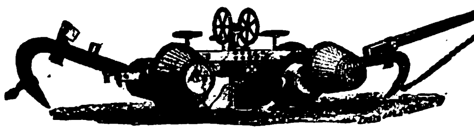
Re-cap′per. A tool used in reloading shells, to put the cap on its seat in the end of the shell. See RELOADING TOOLS.

Rec′la-ma′tion Plow. A plow for breaking new land, grubbing its furrow among roots and stones.

Fig. 2099 is the plow used in the stony tracts of Sutherlandshire, Scotland. It is used in connection with the ordinary steam plow engine.

The plow is preceded by steel disks, which lift the share over stones or other obstructions, so as not to break it or the moldboard. The plow will turn a furrow 2′ wide and

Fig. 2099.



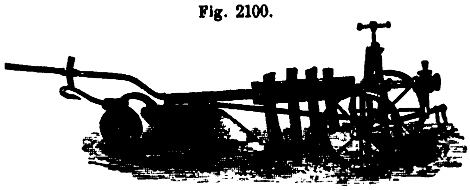
Fowler's Steam operated Land Reclamation Plow.

16″ deep completely over, an operation materially assisted by the rollers, which catch the furrow-slice at the moment of leaving the moldboard. The stones which have been passed over are torn out by the hook-tine which comes behind the plow. They are then removed by men with teams and stone-boats. The tine thoroughly subsoils the land to a depth of 2′, and materially assists the drainage of the soil.

The plow for horses or oxen is a strong one, of ordinary form, but with a stiff and sharp colter for cutting roots. Incidentally many of our heavy plows are calculated for such work as it may occur. Others, like our prairie-breakers, are for stubborn sod, wild-grass meadows, and low situations with patches of willow or hazel, brambles or rose bushes, as the case may be.

The *déboiseuse*, or French clearing plow, Fig. 2100, is designed for clearing ground which has grown up in thickets

Fig. 2100.



Clearing Plow. Delahaie-Tailleur & Bajac, Liancourt, France.

or copses. It is made with 2, 3, 4, 5, or 8 cutters in advance of the plow proper. Each cuts into the land below the preceding one, so that a *déboiseuse* of 5 cutters will divide the roots to an ordinary plow depth.

Re-coil′ Check. 1. An apparatus to absorb the recoil of a cannon, otherwise known as a hydraulic buffer, which see.

See 10″ gun-carriage, with hydraulic recoil check. Plate VI., attached to Appendix H, "*Ordnance Report*," 1876.

2. A spring cushion attached to the butt-end of a gun-stock to take the force of the recoil.—*Miller*, No. 169,465.

Re-coil′ Dy′na-mom′e-ter. An instrument to measure the recoil of small arms.

Lieut. Metcalfe's device is to measure the recoil by substituting for springs a material of uniform resistance, such as copper or lead, and measuring the recoil by means of a cut made in the material by a Rodman knife interposed between the metal and the butt of the gun. See "*Ordnance Report*," 1878, Appendix N, p. 109, and plate.

See CRUSHER GAGE; PIEZOMETER, and references *passim*.

Rec′tal Di-la′tor. (*Surgical.*) A flexible caoutchouc tube, introduced *per anum*, and then inflated, to distend a constricted bowel. — *Dr. Wales*.

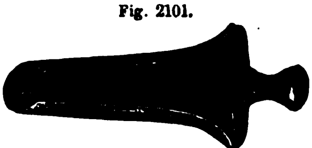
See also ANAL DILATOR, pp. 30, 31, *supra*.

Rec'tal In'stru-ments (*Surgical.*) The list includes: —

Anal dilator.	Hemorrhoidal clamp.
Anal fissure knife.	Insufflator.
Bistoury.	Irrigator.
Bougie.	Ligator.
Cautery irons.	Puncturer.
Cystotome.	Pile clamp.
Curette.	Pile needle.
Dilator.	Porte-caustic.
Divulsor.	Porte-meche.
Dressing forceps.	Probe.
Electrode.	Speculum.
Endoscope.	Sphincter and dilator.
Enema pump.	Sponge holder.
Exploring needle.	Suppository.
Feeding tube.	Syringe.
Fistula scissors.	Tenaculum.
Forceps.	Trocar.

Rec'tal Spec'u-lum. (*Surgical.*) A distending instrument for displaying the mucous surface of the rectum. See ANAL SPECULUM, p. 31, and references *passim*.

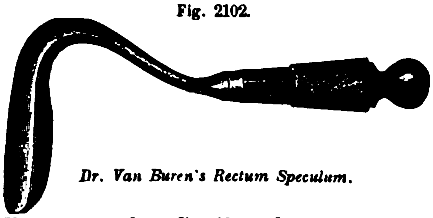
Fig. 2101.



Dr. Allingham's Rectal Speculum.

Figs. 2101, 2102, show two forms, both metallic.

Fig. 2102.

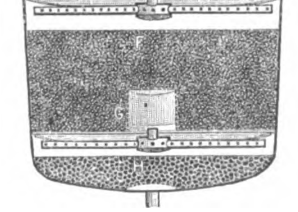


Dr. Van Buren's Rectum Speculum.

Rec-tan'gu-lar Staff. (*Surgical.*) A staff bent at a right angle, serving as a director for the bistoury in the operation of lithotomy.

Rec'ti-fi'er. *Add.* A filtering apparatus for deodorizing and purifying spirits. It usually consists of a leach tub through which the raw spirit percolates through animal charcoal.

Fig. 2103.



Rectifier.

Fig 2103 shows a forcing apparatus in which the liquor under a pressure of 50 pounds per square inch is introduced by pipe *A*. *B* is the cover of the rectifier, *C*, the radial arm distributer; *D*, the upper chamber packed with charcoal free of dust; *E*, the perforated bonnet chamber outlet to distributer underneath; *F*, the second chamber packed with finer coal than the first; *G*, the perforated bonnet chamber outlet to the bottom chamber; *H*, the bottom space and blanketed strainer discharge to delivery pipe, whence the rectified liquor is conveyed to the receivers.

Rec'ti-lin'e-ar E-cra'seur. (*Surgical.*) An écraseur which, instead of a wire loop or chain loop, has a clamp the jaws of which have a fin and groove respectively.

Rec'to-co-lo'nic Ap'pa-ra'tus. (*Surgical.*) Instruments which reach the rectum and colon, such as some forms of endoscopes and enema syringes.

Re-cu'pe-ra'tor. A name applied, sometimes, in England to the *regenerator* of the Ponsard or Siemens furnace.

See REGENERATOR, and references *passim*. See "*Engineer*," xlvi. 231.

Red Lit'mus Pa'per. (*Gas.*) Used as a test to show the presence of ammonia in illuminating gas.

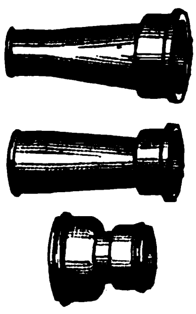
Take 6 parts by weight of water and one of powdered litmus, shake, allow to stand several days. Then add, drop by drop, a small quantity of dilute sulphuric acid until the pink or neutral tint is obtained. Pieces of white filtering paper are then soaked in the solution, dried, cut in pieces of convenient size, and kept in a stoppered bottle.

Re-dres'sor. (*Surgical.*) A replacing instrument, *e. g.*, the uterine redressor.

Re-du'cer. A joint-piece for connecting pipes of varying diameter.

The term is also applied to other pipe connections where one of the members has a smaller diameter. See BRANCH, CROSS, TEE; also list under PIPE COUPLING.

Fig. 2104.



Reducers.

a, *b*. Reducing pipes.
c. Reducing hub.

Re-du'cing Coup'ling. A pipe coupling with ends of varying diameters, to unite pipes of different sizes.

Re-du'cing Press. In sheet-metal working, an auxiliary press for the further deepening and drawing of articles partially struck up.

Re-du'cing Squares. A mode of making reductions of drawings or designs. The original has lines drawn over it, dividing it off into squares, as numerous as the nature of the picture may require.

A piece of paper of the size desired is then divided into a similar number of squares, and the objects contained in the former squares delineated in the smaller ones.

A frame with crossing threads or wires may be laid over the original. The same frame may be erected in front of a person at a desk so as to divide a landscape in the same manner.

Re-du'cing Tee. A T-shaped pipe coupling, the arms of different diameter from the stem, to unite pipes, joining at right angles and having different diameters.

Re-du'cing Valve. A device in the West-

Fig. 2105.

Reflecting Drawing Board.

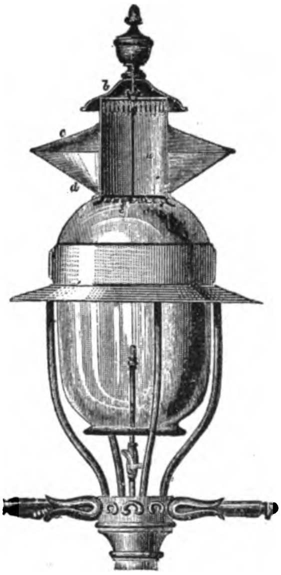
inghouse automatic railway brake to regulate the pressure on the brakes, so as to insure the proper degree of retardation without skidding the wheels, at varying speeds.

Fig. 1, p. 86, "*Engineering*," xxvii.

Re-flect'ing Draw'ing Board. An arrangement to assist in copying drawings. See Fig. 2105.

The drawing to be copied is placed on the board to the left of the glass and the blank paper on the right. The artist stands so as to view the surface of the glass obliquely, and the original drawing is reflected from the surface of the glass to his eye, and at the same time he sees the surface of the white paper through the transparent glass, so that the lines of the drawing appear as upon the white paper, but reversed in position. These apparent lines are to be followed with a pencil on the blank paper.

Fig. 2106.



Reflecting Lamp.

a. Chimney.
b. Chimney cap.
c. Cover to upper reflector.
d. Upper reflector.
g. Metallic clasps on chimney bent against inside of the glass.

Re-flect'ing Lamp. A lamp with upper reflector to throw down the upward beams.

Fig. 2106 shows a form for street use. It exhibits front half of top chimney and upper reflector cut away.

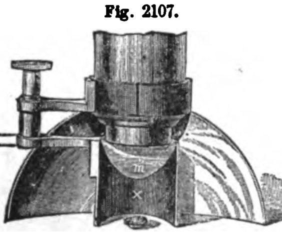
Re-flect'ing Sight. (*Fire-arm.*) The sight has a reflecting surface placed at such an angle as to reflect to the eye light from one direction only.

Stillman's patent . . . . No. 38,965.

Reflec'tor. (*Optics.*) Sorby's addition to Beck's parabolic illuminator, consisting of a plain silvered mirror covering one half of the aperture of the object-glass.

The rays falling upon it are thrown down upon the object, and reflected direct up the tube of the microscope, thereby

Fig. 2107.



Reflector.

producing a mode of illumination exactly the reverse of that of the parabolic illuminator, where the rays impinge at an oblique angle, and so only those diverted by the object enter the field of view.

See also ILLUMINATOR, p. 1171, "*Mech. Dict.*," where the *opaque*, *white cloud*, *oblique*, and *black ground* illuminators are described. See also CONDENSER, SIDE REFLECTOR, PARABOLIC ILLUMINATOR, PARABOLIC REFLECTOR, LIEBERKUHN, SPOT LENS, CATOPTRIC LIGHT, MIRROR, etc., *Ibid.*

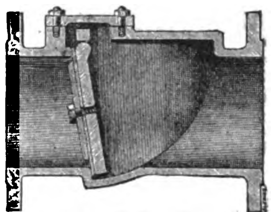
Re'flux Cath'e-ter. (*Surgical.*) A double-current catheter which allows the liquid to pass by one duct and return by another. Fig. *c*, 1190, p. 504, "*Mech. Dict.*" See also DOUBLE-CURRENT CATHETER, p. 266, *supra*, and references *passim*.

Re'flux Valve. An automatic valve to prevent reflux. A back-pressure valve.

Fig. 2108.



Stone's Reflux Valve.

Fig. 2108 shows Stone's cast-iron reflux or back-pressure valve, with clear straightway, to keep the water in mains when the pressure is taken off.

Re-frig'e-ra'tor. The storage, domestic, and railway car refrigerators are referred to on pp. 1910, 1911, and Figs. 4238–4243, "*Mech. Dict.*"

The subject of cooling is also included under ICE MACHINE, pp. 1164–1169, and Plate XXVI., *Ibid.*; ICE-CREAM FREEZER, * p. 1162; LIQUID COOLER, * p. 1326; BEER COOLER, * p. 264; CONDENSER, * p. 607, *Ibid.*

In the refrigerator car used for transportation of California fruit eastward, the car is attached to one of the regular passenger trains, and is provided with a fan-blower, driven by one of the axles, by means of which the air is forced through the ice-chamber and thus reduced to a low temperature. This chilled air is distributed among the fruit-boxes through a large perforated pipe laid along the bottom of the car. After it has circulated among the fruit, it returns to the blower, and is again forced through the apparatus. By this means the atmosphere of the car is kept at the uniform temperature of 40° Fah.

Re-gen'er-a'tor. A chamber in which the outgoing waste gases heat the incoming air.

They are of two kinds: —

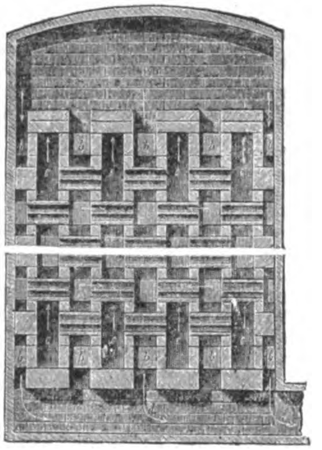
1. Those in which, as in the Ponsard furnace, the waste gases descend through one set of channels inclosing another set through which the incoming air passes, the walls heated by the waste imparting heat to the air. This is on the principle of many feed-water heaters for boilers; and many other instances might be cited.

Fig. 2109 shows the Ponsard regenerator, which is a chamber with a built-in arrangement of hollow refractory bricks. The waste gases from the laboratory or combustion chamber of the furnace come in above, descend through the conduits *b b*, and escape below to the chimney, either directly or after having passed through the flues of a steam boiler, to be therein farther utilized.

The cold air enters below at openings provided with registers, and passes upward through the conduits *c c*, intermediate between the driving flues *b b* of the waste gases, and thence passes to the combustion chamber. The passages *b b* mutually interchange by means of hollow bricks, and so do the passages *c c*. See also GAS-GENERATING FURNACE, Figs. 1161, 1162, p. 387, *supra*.

In Frank's regenerative gas furnace, Fig. 2110,

Fig. 2109.

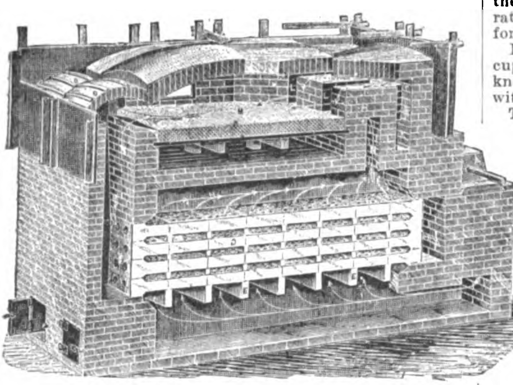


Ponsard Regenerator.

the gas is made in a producer built against the furnace at the right.

The air from the producer enters from the right and is diverted right or left to one or the other regenerator, there being two of them. Passing beneath the regenerator the gas courses upwardly among the stack of hollow blocks *G* and thence to its point of junction with the air which is diverted

Fig. 2110.



Frank's Regenerator Furnace for Glass.

by valve *A* to pass through the other regenerator. The gas and air respectively pass through vertical openings in the blocks *G*, while the hot current from the furnace *M* courses through the horizontal openings in the said blocks and thence to the stack.

2. The other form of regenerator is that invented by M. M. Siemens, and has two pairs of chambers used in pairs alternately.

The chambers have bricks piled up in them, and stacked loosely together so as to expose a great surface. The draft of waste gases passes through one pair of chambers which are for the time being in the line of communication between the furnace chamber and chimney; and the bricks are heated. The other pair previously heated is placed in the duct by which gas and air pass to the furnace chamber, extracting in their passage heat from the bricks. By turning a valve the relation of the respective regenerators is changed. See Figs. 1159, 1160, p. 386, *supra*.

Re-gen'er-a'tor Fur'nace. A furnace in which the outgoing waste heat is made to heat the incoming air of combustion.

Practically, in metallurgy, also in glass and gas works furnaces, the principle has been so much extended that the definition is incomplete as to the best examples of this class. Such are the *Siemens*, *Bicheroux*, and *Ponsard*, for instance, though there are others comprised in the same class.

In the improved form the regenerators are 4 in number, working in pairs. Through one pair the waste heat passes, heating the bricks which are built up in a cellular structure within side of the chamber and thereby absorbing a large portion of the escaping heat. When this is accomplished, a damper is turned, when the waste heat is turned through the other pair of regenerators in order to heat them, and the chambers of the former pair are devoted, one of them to heat the gases coming from the producer, and the other to heating the incoming air which is to be mixed with the said gases on entering the puddling or pot chamber, as the case may be.

Fig. 1999, p. 701, shows the gas producer with its fuel. The grate differs from the Siemens furnace in having a lower horizontal portion on which the depth of the bed of fuel varies according to its composition. The upper part is at the ground level and has one or more feeding shafts with covers. Holes are provided for inspection and stoking. A damper of refractory clay is capable of being slipped in or out to govern the size of the flue conducting the heated gases to the laboratory, as the chamber where the work is performed is called for distinction.

In some cases the fire is fed with heated air from the recuperator, in which case grates are not used. Such are known as superheated gazogens. They are sometimes blown with steam jets or injectors.

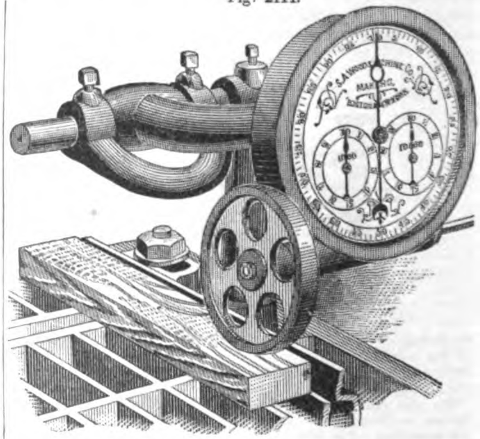
The subject of the methods of using, the purposes of the furnace, and the chemical reaction are considered under GAS-GENERATING FURNACE, pp. 384–388, *supra*. See also REGENERATOR.

Reg'is-ter. A device for recording.

See list, examples, and references on pp. 1912, 1913, "*Mech. Dict.*"

The register shown in Fig. 2111 is for showing the sum of the lengths of boards or other stuff run through a planing machine. The circumference of the wheel is a known quantity and each revolution is registered on the counter, the dials of which represent units, hundreds, and thousands of feet.

Fig. 2111.



Planing Machine Board-register.

Reg′is-ter-ing Scale. A weighing scale made by *Chameroy* of Paris, which, by pressure upon a stud, impresses upon a slip of card the weight of the object on the scale. See SCALE.

Reg′is-ter-ing Ther-mom′e-ter. One which has a means for indicating the highest or lowest point reached between observations.

Registering thermometers are considered on pp. 2548, 2549, "*Mech. Dict.*"

A new registering thermometer by M. Hervé Mangon has a long and fine capillary tube bent on itself, supported by an iron frame, and containing mercury; it passes through the stopper of a bell jar and terminates with a fine point in a mercury dish placed in one scale of a balance; the other scale contains a vessel of glycerine communicating by glass and india-rubber tubing with another glycerine vessel on the same level in an adjoining frame. When, on rise of temperature, mercury is forced out into the vessel, the balance is depressed on one side and an electric contact made, affecting an electro-magnet in the registering apparatus, which is composed of M. Redier's double wheel work with differential train. When the depression referred to has occurred, a suspended float in the second glycerine vessel descends, and raises the glycerine in the first, increasing the weight in that scale. The curve obtained (from a pencil on moving paper) is of zigzag form, the wheel-work being in constant motion, now to the right, now to the left.

See also * "*Scientific American Supplement*," 125, 935.

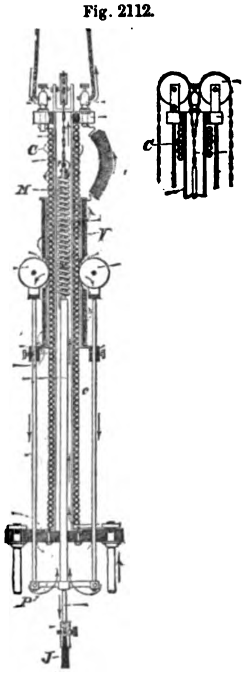
Reg′u-la-ting Valve. One for graduating the effective opening in a pipe to determine the amount of fluid passing.

Reg′u-la′tor. (*Electricity.*) 1. The shield for covering or uncovering the core, thus exposing it more or less to the magnetism of the coil, and in this way regulating the current.

Regulator for induction coil.
Floyd . . . . . . * "*Scientific American Sup.*," 2425.

2. The apparatus for maintaining the relative distance between the carbons in the voltaic arc light. See ELECTRIC LIGHT.

Fig. 2112.



Thomas' Electric-arc Lamp Regulator.

Thomas's regulator for electric arc lamps in series is shown in Fig. 2112.

The figure shows a section in the plane of the lamp's geometric axis; the negative electrode being omitted. Also in a smaller figure the solenoid to a larger scale.

Illuminative equilibrium throughout the series is secured by the respective attraction toward and repulsion from a prime helix *C* on the line of its axis, of two helical current-carriers *M r*, both integrally attached to holder *P* of positive electrode *J*. Of these current-carriers one, *M*, is a solenoid through which current reaches the electrode from the prime helix. The convolutions of this solenoid are such as to cause its upward attraction by the prime, proportional to the strength of the main current. The other carrier, *r*, possesses such resistance as to be comparatively inert during normal or less than normal separation of electrode-points, while extreme electrode separation, on the other hand, operates to shunt portions of current around the electrodes through said carrier. Said carrier, being so wound as when thus energized to be repelled downward by the prime, operates to antagonize and even reverse such excessive lifting action of carrier *M* as would tend to greatly weaken the series-current and to extinguish the weaker lamps.

Strong and broken arrows indicate respectively the course of the main and shunted currents.

Re′in-force′. (*Cartridge.*) A lining or plate to strengthen the head of a cartridge, sometimes also acting as an anvil or a gas check. See CUP ANVIL; DISK ANVIL; GAS CHECK.

Re-lief′ Print′ing. A process applied by Thuillier, of Rouen, and Petit-Didier, of St. Denis, to silken tissues, which are scattered over with brilliant points in relief, and of different colors so as to imitate embroidery.

It is executed with a resinous matter, either colored or left colorless, which is deposited upon the tissue in melted drops by means of a plate engraved in relief. On cooling, these drops acquire hardness enough to form, so to speak, a part of the tissue and to resist friction.

Depouilly and Meyer have devised something analogous for fixing upon very light tissues, like tulles, brilliant drops in relief, which by their limpidity recall pearls or precious stones. They are obtained by means of gelatine or gums deposited while liquid by means of pins arranged symmetrically. This style has been named "diamond tulle." — "*Teinturier Pratique.*"

See also instances referred to under PHOTO-PRINTING PROCESS, pp. 676, 677, *supra.*

Re-lief′ Pro′cess. See photo-relief process, "*Mech. Dict.;*" RELIEF LINE ENGRAVING, p. 1915, *Ibid.*

In Joyce's mode of producing relief-plates for printing, a smooth steel plate is covered evenly with a thin coat of plaster of Paris and potter's clay; the design is then drawn through this (as through wax in etching) down to the plate. A stereotype-metal cast is taken from this reverse-plate, giving lines in relief.

Relief blocks from photos. "*Scientific Amer.*," xxxiv. 196.
Relief stamping press, paper monograms, etc.
Richmond, Br. . . . * "*Engineer*," l. 812.

Re-lief′ Valve. An automatically acting valve which yields to a given pressure to avoid bursting of the object to which it appertains.

1. For barrels containing beer or other effervescent or fermenting contents.

2. For pipes of beer-engines.

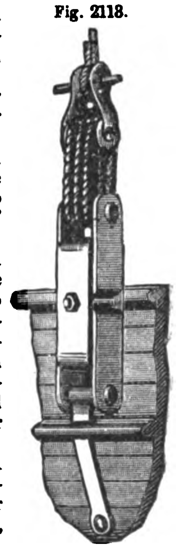
3. For regulating the pressure in fire engine hose. *Bailey; Blake.*

4. For discharging condensed steam from cylinders during intervals of rest. — *Bagshaw*, Br., * "*Engineer*," xlvi. 427.

5. For turning the feed water into the hot well when the boiler is sufficiently full.

6. To provide escape for feed water when shut off from the boiler, the pump continuing to work. — * "*Scientific American*," xxxvi. 351.

Fig. 2113.



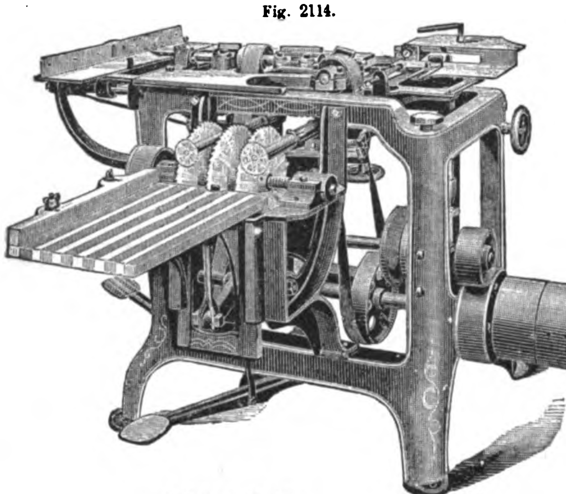
Reliever.

Re-liev′er. (*Nautical.*) A device for attaching the wire shrouds or stays of yachts to the hull. It is an elastic connector involving the compression of a caoutchouc block and giving a certain amount of resiliency to the tension, to avoid breakage of the stay, rope, or what not.

Rel′ish-ing Ma-chine′. A machine for shaking the shoulders of the tenons which bear against the rail of the door, sash or blind.

The machine shown is for sash, window, and blind relishing and for mortising. Such stuff is relished at one operation and handling. Blinds are relished and recess made for end of rod at one operation. The meeting and bottom rail are mortised at one operation by a

Fig. 2114.



Relishing Machine.

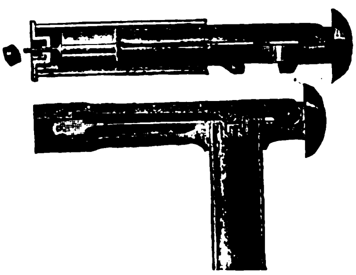
hollow chisel. The door relishing is done at one operation by the five saws shown to the left. All the parts described may be run simultaneously.

Greenlee . . . . * "*Engineer*," xli. 430.

Re-load'ing Tools. For reloading spent capsules of breech-loading fire-arms. A complete set for rifle cartridges consists of primer extractor, charger, loader, and reprimer, which see.

Fig. 2115 shows a single tool with the functions of decapper, recapper, and rammer comprised within a weight of

Fig. 2115.

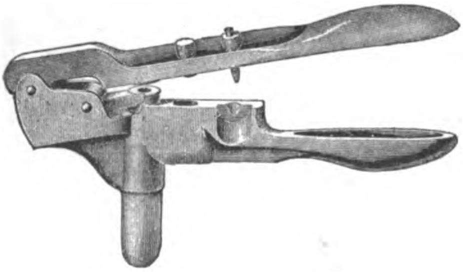


Reloading Tools for Breech-loading Shot-guns.

5 oz. On the side is also a device for extracting expanded shells. — *Providence Tool Co.*

Fig. 2116 is a tool which removes the exploded primer, in-

Fig. 2116.



Reloading Tool for Breech-loading Rifles.

serts the new primer and fastens the ball in its shell, at the same time swaging the cartridge to form.

Rep. (*Fabric.*) 1. A French worsted goods, usually for furniture, made of long combed wool on loom with taffetas armure.

2. A double threaded taffeta with a cotton warp and medium wool weft.

Re-peat'ing Ri'fle. One which fires charges consecutively from a magazine.

The German repeating rifle, made at the School of Musketry at Spandau, is a Mauser rifle with magazine attachment. The magazine is made from steel plate, and contains 11 cartridges. It can be readily put off and on the rifle, and is worked on it solely by opening and shutting the chamber in such a way that at every opening movement a cartridge falls through the groove into the rifle, and by every shutting movement the next cartridge is made ready for use. This apparatus can be attached to all breech-loaders with a cylinder breech. By it 12 rounds are fired in 24 seconds; the magazine can be refilled in 15 seconds. When the magazine is removed the piece forms an ordinary one-barrelled gun.

See also MAGAZINE GUN, pp. 570 *et seq.*, *supra*, and "*Mech. Dict.*"

Rifle, *Winchester*, 1878 * "*Min. & Sc., Press*," xxxvi. 241.

Spandau, Ger. . . * "*Amer. Manufact.*," 1880.

Re-pel'lent. (*Fabric.*) A waterproof cloth.

Re-pla'cing Ap'pa-ra'tus. (*Railway.*) For the replacing of derailed rolling stock upon the line.

N. Ry. of France . . . . * "*Engineering*," xxvii. 459.

Re-plen'ish-er. (*Electricity.*) *a.* A dynamo-electric device of Sir Wm. Thomson, which, in a few revolutions of the armature, induces a static charge of considerable magnitude from primary charges which are practically infinitesimal.

"*Engineering*" . . . . xxiii. 319.

b. That part of an electrometer (Thomson electrometer) whereby the normal charge of the indicator-needle is maintained by occasional connection with a condensor. — *Gordon*, i, p. 42.

Re-pos'i-tor. (*Surgical.*) A replacer. The uterine repositor or elevator, for instance.

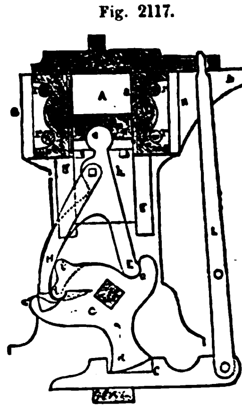
Repoussé. (*Fine Art Metal-working.*) A mode of forming and ornamenting silver-ware by blows delivered internally.

It is done by means of a snarling-tool (Fig. 5248, "*Mech. Dict.*"), which is planted in a vise, while its outer end rests against the interior of the object. A blow on the shank of the snarling iron is transferred to the object and causes an interior dent and an outward bulge.

The Bryant vase is a remarkable success of Tiffany & Co. in this line of ornamentation.

Re-press'ing Press. A machine compacting partially dried bricks by a second pressure, giving them hardness, smoothness, and symmetry.

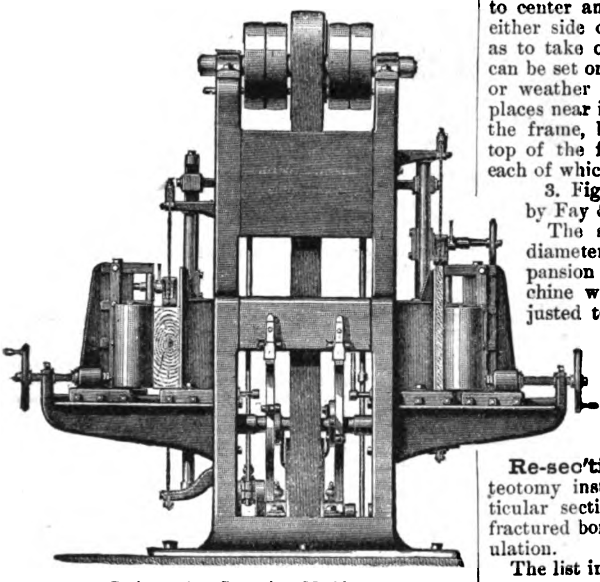
Fig. 2117.



"*Champion*" *Repressing Press.*

In Anderson's press, Fig. 2117, the mold is lined with sheet steel, and may be replaced when worn out. In the sectional view *A* is the mold in which the brick is pressed; *D*, the cap which slides sidewards to the right over the surface *b*, being driven in that direction by the lever *L*, when at the same time the bottom plunger *P* is raised by means of a toggle-joint which elevates the arm *H* by the turning of the cam *C* round its axis, while the projection *d*, fitting in a notch, moves the sliding piece *f* to the left, which acts on the lever *L* and cap *D* mentioned before. By this combined motion the mold *A* is simultaneously uncovered, and the plunger *P* moved to the top of the machine flush with the upper surface of the sides of the mold. When the brick is placed on the surface of the plunger *P*, by a reverse motion it descends with the brick, the cap *D* slides over the mold and is kept in place by proper grippers, secured with nuts shown in the large cut; and by continuing the motion of the cam *C* in the same direction, the arm *E* of another toggle-joint is put in operation, which lifts the plunger sufficiently to press the brick upwards against the cap *D*. The shaft *t* is moved with a long lever at its outer end, for producing the motions described. By throwing this lever backward, the plunger *P* descends, the cap *D* glides to the right, and by further motion of the same, the arm *H* lifts the plunger to the top of the mold, pushing the brick out, when it can be removed and another substituted.

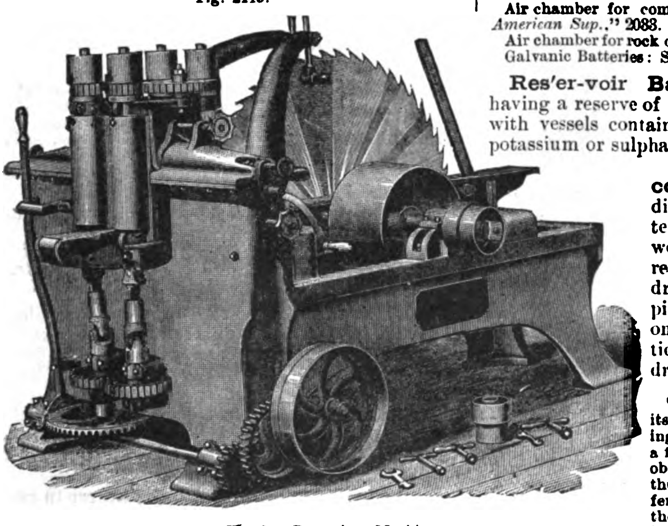
Fig. 2118.



Reciprocating Resawing Machine.

Re-pri'mer. An implement for setting a cap upon a cartridge shell. One of the set of RELOADING TOOLS, which see.

Fig. 2119.



Circular Resawing Machine.

Re-saw'ing Ma-chine'. A machine for sawing timbers and balks of lumber into dimension stuff.

They are of three kinds: *reciprocating, circular, band.*

1. Fig. 2118 is a double resawing machine of the reciprocating order, made by Richards, Loudon, & Kelly, for working on dry lumber up to 8″ thick and 30″ wide. The speed is 400 revolutions per minute. It stands on a stone foundation without top-bracing.

2. Fig. 2119 is a machine of the circular order, made by H. B. Smith. They are made for 24″, 48″, and 60″ diameter saws. They can be made to center any lumber from ¼″ to 8″ thickness; or either side of the feed can be made unyielding so as to take off any thickness required. The rolls can be set on a bevel so as to take off feather edge or weather boards. The saw is guided in three places near its circumference; as it rises through the frame, by arms near the top, and below the top of the frame. The feed is by four rolls, to each of which power is applied.

3. Fig. 2120 is a band-saw resawing machine, by Fay & Co.

The saw-kerf is 1-16″. The wheels 5′ in diameter. The feed rolls are connected by expansion gears operated by friction. The machine will split stuff centrally or can be adjusted to saw off boards or panel stuff of any thickness.

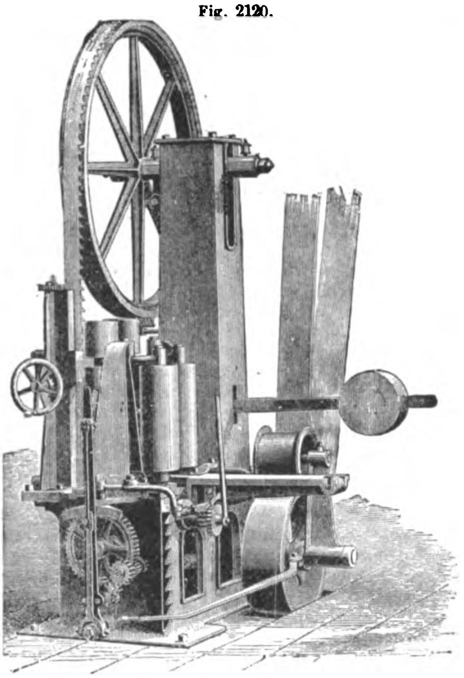
Air chamber for compressed air. *Siemens*, * "*Scientific American Sup.,*" 2088.
Air chamber for rock drills. Plate X., p. 602, "*Mech. Dict.*"
Galvanic Batteries: See RESERVOIR BATTERY.

Res'er-voir Bat'te-ry. (*Electricity.*) One having a reserve of material, as in the case of those with vessels containing crystals of bichromate of potassium or sulphate of copper.

Res'er-voir Lev'el Re-cord'er. An instrument to indicate the fluctuations of the water in the reservoirs of water works. The drum performs a revolution once a week, being driven by a small turret time-piece, and the clock beats seconds. A friction clip in connection with the set dial enables the drum to be set to the true time.

The diameter of the drum is 12″, and its length is 3′, a fluctuation of 6′ being recorded, thus giving a scale of 6″ to a foot. This reduction of scale is thus obtained: The float pulley upon which the chain is fixed is double the circumference of the pulley which actuates the pencil, which is guided by the two horizontal brass bars over the top of the

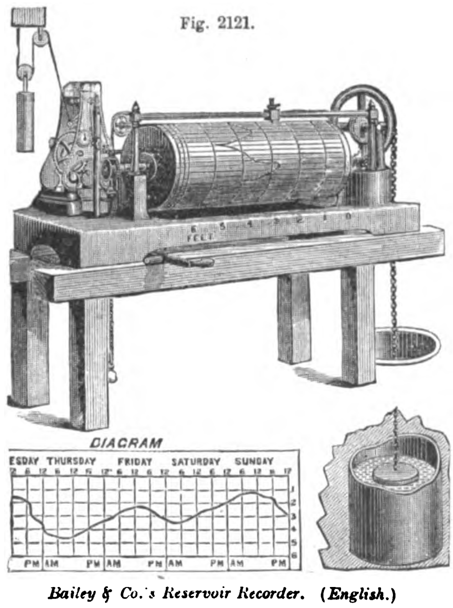
Fig. 2120.



Band Resawing Machine.

drum, in order to prevent any possible error from backlash of the mechanism, or by wear and tear in the ordinary course of use. The float is balanced by a small weight attached to a chain which is fastened to the pencil block; this enables a

Fig. 2121.



Bailey & Co.'s Reservoir Recorder. (*English.*)

very sensitive diagram to be taken. The illustration at the bottom of the engraving shows a portion of a diagram. See:

"*Engineer*" . . . . xlv. 3).

Liquids, inst. for measuring,
Wheatstone . . . . . * "*Telegraphic Journal*," iv. 70.

Re-sist'ance He'lix. A member in a voltaic arc light apparatus, the duty of which is to preserve a constant regulated distance with the carbons.

The constant tendency is to an unequal action, inasmuch as the carbons burn away the positive much faster than the negative.

Such unequal action is remedied by the provision of a high resistance helix shunting the arc: through which current is diverted in proportion to the relative resistances of said high resistance helix and of the arc; the energy of said high resistance helix always acting in opposition to that of said suction core. The resistance of said high resistance helix is so fixed that when the arc is of normal length the forces centered on the electrode movement are in equilibrium.

The two conditions of abnormal arc-length adjust themselves as follows: —

(*a.*) When the arc-resistance is below normal so little current is diverted through the high resistance helix that its energy is inappreciable and the suction core action is unopposed in its duty of lengthening the arc.

(*b.*) When the arc-resistance is above normal, the energy of the high resistance helix is increased sufficiently to overcome that of the suction-core and to reduce the arc to its normal condition. When this adjustment has taken place, the lamp in question resumes its normal resistance. Each lamp adjusting itself in the manner described ensures normal current-flow and equal illuminative action throughout the series.

Re-sist'ance Tube. Clerac's (of the French telegraph administration) tube is a wooden tube containing powdered carbon, with means for giving variability of resistance by compression, constituting a variable resistance rheostat.

* "*Telegraphic Journal*" . . . . vii. 52, 92, 121.

To Count du Moncel we owe the discovery, in 1856, of the variability of the resistance of powdered carbon; which seems to have its first practical application by Clerac.

The telephone transmitter of Edison depends on the same property.

Res'o-na-tor. 1. An invention of Helmholtz for facilitating the analysis of compound sounds.

See Fig. 4270, 4271, p. 1922, "*Mech. Dict.*"

(*Add.*) 2. (*Surgical.*) The resonator which intensifies sounds of a given pitch while diminishing the distraction of others, has been applied to auscultation instruments.

Holden's resonator, Fig. 31, Supplement, *Tiemann's* "*Armamentarium.*"

3. A regulating apparatus in piano sounding-boards, which, by means of screws and iron frame, prevents the sounding-board (as a whole) from making transverse vibrations. — *Steinway*, *Paul's* "*Vienna Exposition Report*," i., Sec. B, p. 388.

Res'pi-ra'tor. A protector covering the mouth; a box furnished with fine gold-plated wire gauze to intercept dust, either in traveling or working in manufactories.

Watson's respirator, to enable the wearer to penetrate carbonic oxide, and other gases, left in collieries after explosions of fire-damp, contains a

Fig. 2122.

Respirator.

solution of caustic potash in a tube, as devised by Mitscherlich and modified by De Koninck. Air containing a dangerous proportion of carbonic oxide is fit for respiration after passing through the potash solution. A valve arrangement ensures inspiration of the cleansed air through the mouth, and expiration through the nose.

The Denayrouse respirator, to enable firemen to enter and remain in places filled with smoke or gas, consists of a tube, having inserted near one end a small tin case containing two peculiar India-rubber valves, — one for inhaling and the other for exhaling air. The end of this tube, which has a mouthpiece, is cast over the fireman's shoulder, the other being left in the open air; and an India-rubber spectacle mask, capable of being molded to fit any features, having been placed over the eyes so as to compress the nostrils, the fireman may enter without fear the most vitiated atmosphere. See also Fig. 4272, p. 1923, "*Mech. Dict.*," in which the fireman carries a sack of vital air.

See also Respirometer, *infra.*

Res-pi-rom'e-ter. The name adopted by Mr. Fleuss for his diver's apparatus for supplying air to a person beneath the surface of the water.

It is a modified form of diver's dress and helmet. The latter, which is no larger than that ordinarily used, has a close circular chamber of about ½ cubic foot capacity, and in this is stored a supply of oxygen under a pressure of 240 pounds per square inch, from a suitably charged reservoir. This affords him sufficient air-food for about five hours. The expired air from the lungs is passed, by means of a flexible tube, to a closed receptacle of vulcanite, which is attached to the yoke-piece carrying the usual rubber dress, which receptacle is filled with spongy rubber saturated with caustic soda. The expired breath is filtered through this soda, which absorbs every trace of carbonic acid, and allows the nitrogen to pass. The air in the diver's lungs and about his somewhat capacious clothing when he first puts on his suit, contains nitrogen enough for indefinite use, and is used again and again to dilute the oxygen, as the latter is constantly supplied from the compressed store in the helmet.

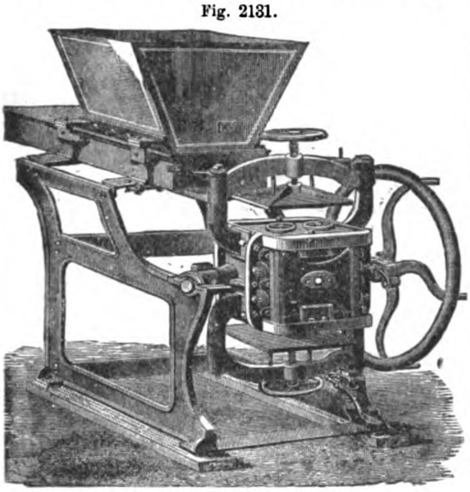
Re-vers'ing Ma-chine'. (*Founding.*) A form of molding machine in which the flask is carried on trunnions so as to be tipped over and the sand rammed from either side.

The operation is as follows: The patterns and followers being properly adjusted, the drag part of the flask is placed on top of sand box; the bridge piece of drawer bottom is let down, when it makes connection between the hopper and flask; the drawer is then pulled out with the sand, dropping it into the flask; then the drawer is taken back into the hopper; the bridge piece is then raised, the binder bar is brought over and fastened down on flask; then the power is applied

Fig. 2131.



Reversing Machine.

which forces the patterns and follower with the sand up into the flask; then the part of the machine with flask on is turned over in its trunnions, thus bringing the flask to lower side of machine with mold up; the power is again applied, which draws the patterns up, leaving the mold complete; the binder is loosened, which leaves the flask resting on the binder plate, which is then swung out and the flask carried away. The cope part of flask is then molded in a similar manner, but taken off from the top.

Re-vert'ing Flue Boil'er. One in which the gaseous products revert on their former course; traversing twice through the boiler, in distinct and successive series of flues.

An instance is shown in Fig. 5638, p. 2329, "*Mech. Dict.*"

Re-vet'ment. See definition of varieties, p. 1928, "*Mech. Dict.*"

Among the forms of revetment for preventing the erosion of river banks may be mentioned the following: The woven brush revetment, the continuous mat, or brush blanket, made of brush, sewed together with wire, and the willow screen made by laying the willows as nearly as possible in juxtaposition and securing them with wire.

The manner of using either of these devices is the same. The bank to be protected should first be graded to a slope of about 2 upon 3 or less, an operation that can be very cheaply performed by the use of hydraulic force-pumps, after which the revetting should be put on so as to extend from the ordinary high-water limit down the bank and out along the river-bed sufficiently far to protect the slope should any unusual scour take place. The total width is usually in the neighborhood of 100′ on the lower Missouri. To sink that portion which is under the water, a small quantity of rock is sometimes necessary, but usually the current itself and the sediment that collects on the brush will suffice for this. See plate opposite p. 1455, "*Report of United States Engineers,*" 1880.

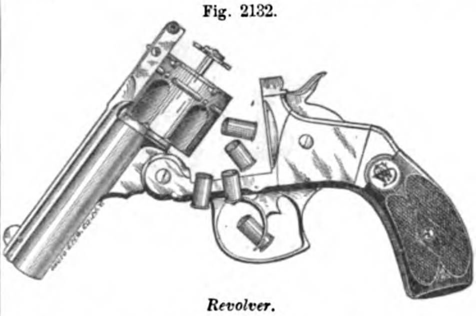
Canal bank revetment, *Ibid.*, 1876, vol. ii., part 2, Plate V., p. 417.

(*Hydraulic Engineering.*) For view and description of the building of the revetment mattress at Council Bluffs on the Missouri River. See "*Report of the Chief of Engineers, U. S. Army,*" 1880, * ii. 1436.

Re-vol'ver. For history and varieties, see pp. 1928–1930, "*Mech Dict.*"

Fig. 2132 is the latest Smith & Wesson revolver with automatic discharge of the spent cartridge capsules. The discharge is moved rearward by the rocking of the barrels on

Fig. 2132.



Revolver.

the hinge to uncover the breach, and throws the capsules clear of the barrels. The discharger then returns automatically into place.

The bull dog revolver is a pocket weapon with short barrel and large bore.

Re-volv'ing Boil'er Steam En'gine. The invention of Fred. Siemens, of Dresden. It has no valves nor pistons. The boiler itself revolves, and from it power is transmitted to the machinery to be driven.

"It consists of a steam-boiler of approximately cylindrical form, carried on an inclined axis about which it rotates. Inside this boiler is a worm or screw composed of sheet-metal, and having such form that each portion of the screw having a length equal to its pitch, closely resembles a funnel which has been slit down one side and slightly separated to unite with others above and below it.

"The lower portion of the boiler has a double bottom, and the upper is surrounded by a spiral of gas-pipe, having a direction the reverse of the funnel-like spiral below.

"Water is placed in the lower portion of the boiler and in the space between it and the external jacket, a communication being established between them by means of small holes.

"Surrounding the whole lower portion of the apparatus is a jacket of non-conducting material, and between it and the boiler is a space through which circulate the gases from the furnace, or, in this case, from the gas-burner by which it is heated, passing off by a small chimney at its upper end.

"The heat being applied, steam is formed, which rises through the water, impinging on the immersed funnel-like spirals, producing a tendency to rotation. Above the water it enters the helix of gas-pipe, and, condensing, flows back into the boiler, its reaction causing further effort to rotate the boiler.

"The boiler being once filled, requires no further attention, as there is no loss of the liquid." — *Vienna Report.*

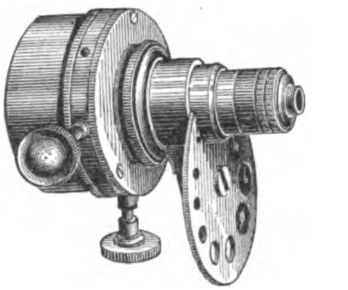
Re-volv'ing Di'a-phragm. (*Optics.*) The diaphragm is used in optical instruments to exclude some of the marginal rays of a beam of

Fig. 2133.



Revolving Diaphragm.

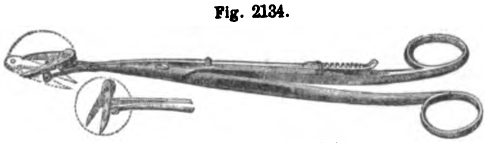
light. It is a means of contracting the aperture. The revolving diaphragm has a number of apertures of varying sizes, either of which can be brought coincident with the optical axis of the instrument.

Re-volv'ing Scis'sors. (*Surgical.*) An instrument for deep operations in cavities of the body.

The blades revolve upon their own axis as shown by the dotted lines. The blades can be presented anteriorly, posteriorly, or laterally.

The blades being short and firm, will cut strong or delicate tissues The rotation of the blades is produced by the in-

Fig. 2134.



Stohlman's Revolving Scissors.

dex finger of the same hand which operates. By depressing the lever near the handles and sliding it forward or backward, the scissors are placed in any required position, and held firmly by allowing the lever to snap into one of the notches; in the same manner the position can be constantly changed at pleasure.

Re-volv'ing Scra'per. A road scraper which revolves completely on its axis; not merely tipping. Fig. 4695, p. 2058, "*Mech. Dict.*"

Re-volv'ing Head-saw Ma-chine'. A screw-cutting machine which contains a number of dies on a head which can be revolved so as to bring either to the work.

Fig. 4734, p. 2067, "*Mech. Dict.*"
A TURRET CUTTER, Fig. 6824, p. 2665, *Ibid.*

Re-vul'sor. (*Surgical.*) An apparatus to apply heat and cold alternately as a therapeutic agent.

McLane's revulsor has two vessels containing hot and cold water, which are passed along the spine or over a paralytic muscle so as to succeed each other rapidly. — *Philadelphia* "*Medical Times,*" * Sept. 4, 1875.

Rhe'a Fi'ber Ma-chine'. For operating upon the China grass, Malay *ramie*, the *Bœhmeria nivea*. See RAMIE MACHINERY.

Greig, Br. . . . . . . * "*Engineer*, xliv. 887.

Rhé E-lec-trom'e-ter. A device by Mariani to investigate electrical discharges between the atmosphere and the earth.

It has a copper wire coiled upon a pasteboard tube, and carrying a traversing magnetic needle upon a pivot above the coil. A small iron bar is inserted axially within the coil. The apparatus is placed with the coil east and west. A spark of high tension passing through the coil magnetizes the bar, which deflects the needle east or west, according to the spark's direction. The iron bar must be de-magnetized by heating before using again.

Rhinoscope . .	* "*Scientific American Sup.*," 1722.
	"*Mech. Dict.*," p. 1935.

Rib. (*Add.*) 7. (*Fire-arm.*) One of the plates above and below, which connect the two tubes, forming the double barrel.

Ribbed Boil'er. One with corrugations or projecting ribs to add to the surface exposed to the fire. Used for greenhouse boilers.

Rib Fab'ric Ma-chine'. A knitting machine adapted to make the rib stitch. It has peculiar adjustments in the power and hand machines, and in some has various capabilities, for making *polka rib*, *one-and-one rib*, etc.

See description by Mr. G. W. Gregory. "*Centennial Exhibition Reports,*" Group XXII., vol. vii., pp. 53-59.

Rib Shears. (*Surgical.*) See COSTOTOME.

Rib'-top Ma-chine'. A knitting machine adapted to make rib-tops of hosiery; with, in some cases, an adaptation to make broad-rib hose throughout.

One by Gisuson and Coltman, of Leicester, England, was shown at the Centennial, capable of making from 200 to 250 dozen pairs of tops per week of 60 hours.

It is arranged to make rib tops with welt and slack course, and is fitted with three carriers: also a pattern wheel, which can be altered at pleasure to make any pattern. The length of top can be varied as desired, and the self-acting winding tackle for receiving the work is as effective as it is simple, only requiring the work of a few moments to take off the fabric and proceed with further productions. This machine can be changed in action, whilst running, to make the royal rib stitch; it will also make the two-and-one rib socks, with welt; it can be worked by steam or by hand. A dial indicating the amount of work done is supplied.

When making broad-rib hose a cylinder pattern wheel is fitted, and this is so adapted that the patterns can be varied through the whole length of hose. It will make 36 dozen pairs of hose legs in the week of 60 hours.

Rice Drill. A force-feed machine for drilling rice. See GRAIN DRILL. WHEAT DRILL, "*Mech. Dict.*"

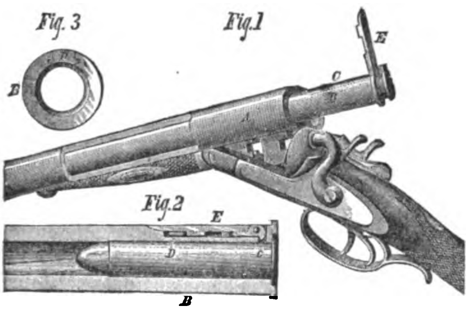
Fig. 2136 shows Stevens' plan for converting a shot-gun to a rifle by slipping a rifle barrel into that of the shot-gun.

Fig. 2136.



Converting Shot-gun to Rifle.

Fig. 1 is a perspective view.
Fig. 2 is a longitudinal section.
Fig. 3 shows the breech of the rifle (enlarged).

The rifle-barrel *B* slips into the rear end of the shot-gun barrel *A*, the flange formed on the end of it occupying the recess made in the shot-gun barrel for the reception of the flange of the cartridge. The rifle barrel has a longitudinal recess for receiving the slide *D* on which is pivoted a lever *E* having at its rear end a short projection, *C*, extending inward.

After the discharge the barrel of the gun is tilted down, and the extractor starts the rifle barrel out of the shot gun barrel; this operation moves the slide *D* slightly, and starts the cartridge shell. Should this prove insufficient the rifle barrel is drawn out far enough to admit of raising the lever *E*, which operation moves the slide *D* and ejects the shell.

Statement of the number of machines, fixtures, small tools, and gages necessary for the manufacture of 200 Springfield rifles per day of 10 hours: —

Names of Parts of Rifle.

Barrel.	Cam latch.
Receiver.	Thumb piece.
Breech screw.	Firing-pin.
Breech block.	Extractor.
Breech-block cap.	Extractor spring spindle.
Guard plate.	Cap with 2 rivets.
Guard bow.	23 screws for parts.
Trigger.	5 springs.
Butt plate.	2 pins.
Lower bands.	2 studs.
Upper bands.	2 washers.
Lower band-springs.	Stock.
Upper band-springs.	Lock plate.
Upper band swivel.	Hammer.
Guard bow-swivel.	Main spring.
Ramrod.	Sear.
Ramrod stop.	Sear spring.
Tip.	Main-spring swivel.
Front sight.	Tumbler.
Rear-sight base.	Bridle.
Rear-sight spring.	Hinge pin.
Rear-sight leaf.	Bayonet.
Rear-sight cap.	Bayonet clasp.

	Cost.
37 machines for making the stock	$60,000
81 machines for making the barrel	54,000
51 machines for making the receiver	23,500
17 machines for making the breech screw	6,600
37 machines for making the breech block	18,100
5 machines for making the breech-block cap	1,800
12 machines for making the cam latch	5,600
10 machines for making the thumb piece	3,800
8 machines for making the firing pin	1,060
9 machines for making the extractor	2,950
1 machine for making the extractor spring spindle	425
14 machines for making the guard plate	4,800
9 machines for making the guard bow	2,900
11 machines for making the trigger	3,600
13 machines for making the butt plate	5,400
10 machines for making the upper and lower bands	5,800
10 machines for making the upper and lower springs	3,300
10 machines for making the upper and lower swivels	3,000
7 machines for making the ramrod	2,570
8 machines for making the ramrod stop	2,735
5 machines for making the tip	1,585
4 machines for making the front sight	1,565
18 machines for making the rear sight base, and spring	6,650
34 machines for making the rear-sight leaf, cap, and pins	15,070
15 machines for making the lock plate	6,100
16 machines for making the hammer	5,800
12 machines for making the main spring	3,490
8 machines for making the sear	2,750
7 machines for making the sear spring	2,050
4 machines for making the main-spring swivel	1,225
12 machines for making the tumbler	4,500
8 machines for making the bridle	2,730
4 machines for making the hinge-pin	1,300
46 machines for making the bayonet	19,575
8 machines for making the bayonet clasp	3,870
13 machines for making screws, pins, and studs	6,120
13 polishing machines, stands, wheels, etc.	2,200
51 forging machines, drop hammers, and presses	89,000
2 sets of forging dies	22,000
18 water-front forges	2,700
4 annealing furnaces	1,600
2 hardening furnaces	1,000
2 blowers (fan blowers)	400
2 sets of gages, 1 working and 1 inspection set	45,000
1 set of fixtures and 2 sets of small tools	115,000
32 machines for tool-making, repairing, etc.	13,600
696 Total for machines, tools, and gages	$532,770

For running the above machines and tools it would require a condensing engine of 32″ × 60″, 300 horse-power; 4 tubular boilers, 16′ × 5′; 2 tubular boilers, 16′ × 5′, reserve. Cost about $25,000.

Floor-space occupied by using all above machines, tools, etc., 125,000 square feet.

See also BREECH LOADER; MAGAZINE GUN; HAMMERLESS GUN: NEEDLE GUN; REVOLVER, etc.

Ri'fling Ma-chine'. A machine for making the spiral grooves in the barrels of guns.

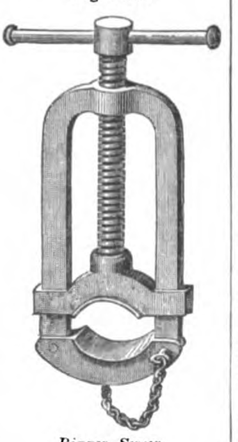
As used in the U. S. armories it is a machine in which the barrel is firmly held while a mandrel carrying a cutting tooth is drawn through it, the mandrel making one and a half revolutions during its passage through the barrel. The barrel makes a third of a revolution between each cut, and the result is a barrel with three *grooves* and three *lands*. The groover is worked automatically, expanding to make the groove deeper as it repeats the cut in the same place, until the groove is deep enough. The barrel is drenched with oil all the time.

The Pratt & Whitney rifling machine gives from one turn to the grooves in 20″ to one in 36″. The cutter-rod carries from 1 to 3 cutters, as the rifling is 4, 5, or 6 to the circumference. An adjustable feed-stop gages the depth of the rifling, and the racks, which are of steel, are double, to take up all back-lash, so that the cutters cannot ride on the lands. An oil-pump feeds automatically at each end of the stroke. The carriage is gibbed on the outside of the long slide, allowing free access to its working parts.

Rig'ging Cut'ter. An apparatus invented to cut the rigging of sunken vessels as a means of removing the masts, etc., which form an impediment to navigation.

"Grosser Kurfürst" . . * "*Engineer*," xlviii. 375.

Fig. 2137.



Rigger Screw.

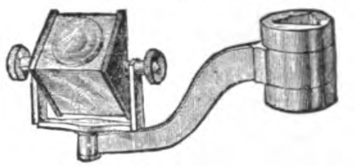
Rig'ger Screw. A clamp for setting up shrouds and stays, one portion being made fast, the part to be hauled taut is lashed to the other, and the parts then approached by means of the screw.

Rig'ging Stop'per. (*Nautical.*) A hold-fast or preventer-rope acting as substitute when a shroud or stay is shot away or stranded in a gale. It may have a knot and laniard at each end, or dead-eyes and tails.

Right-and-Left Coup'ling. A turnbuckle. The link having right-and-left nuts at either end, rods inserted are drawn together or apart by rotation of the link. See TURN-BUCKLE, Fig. 1694, p. 2659, "*Mech. Dict.*"

Right'an-gle Prism. (*Optics.*) An attachment to the microscope stand for throwing light upon an object. It is rotatable on its horizontal axis, and also on a vertical axis, in order to direct the light in the requisite direction.

Fig. 2138.



Achromatic Right-angle Prism.

Rig'id Sus-pen'sion Bridge. A bridge with catenary suspension members, of such form and so braced as to form an unyielding truss.

See Paper by *Fuller* . . * "*Engineering*," xxi. 183.

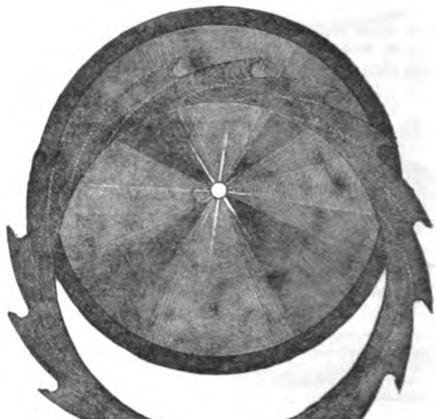
Rim Pla'ner. A machine for dressing the rims of carriage-wheels.

See RIM-PLANING MACHINE, Fig. 4330, p. 1944, "*Mech. Dict.*"
FELLY PLANER, Fig. 1016, p. 331, *supra.*
FELLY DRESSER, Fig. 1940, p. 832, "*Mech. Dict.*"

Rim Saw. A saw the cutting portion of which is annular and mounted upon a central circular disk.

See also RING SAW, *infra.*

Fig. 2139.



Rim Saw.

Ring Boot. (*Manége.*) A caoutchouc or rubber ring on the fetlock to induce the horse to travel wider and prevent interfering. See INTERFERING STRAP, Fig. 2089, p. 1192, "*Mech. Dict.*"

Ring Bush. A socket with anti-friction rings on its interior perimeter, as in some descriptions of rope blocks. See Fig. 263, p, 119, "*Mech. Dict.*"

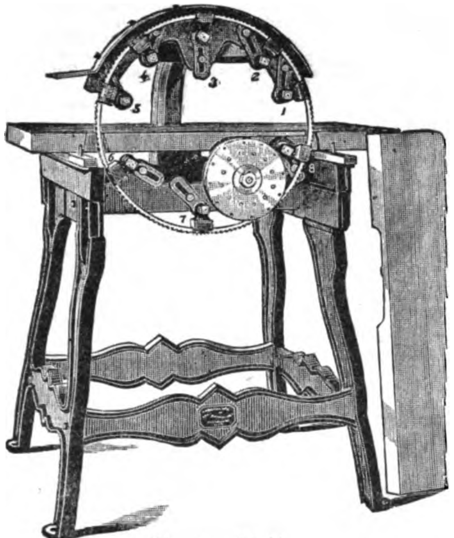
Ring Mal'let. One the head of which is strengthened by rings driven upon it. See *y*, Fig. 3032, p. 1379, "*Mech. Dict.*," where are also shown other forms.

Ring Plate. A ring in a plate attached to a wall to support a steam radiator pipe or coil. See COIL PLATE, Fig. 656, p. 208, *supra.*

Ring Saw. A narrow cylindrical saw with serrated edge running upon guides which strain it and keep it in circular form.

It is a form of scroll saw. The clearance is effected by setting the teeth or making the blade thinner towards the back.

Fig. 2140.



Ring Saw Machine.

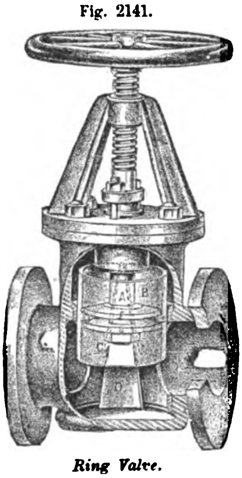
The inside of the saw fits into a groove on the driver which revolves the saw, so that the greater the amount of work on the saw, the tighter the friction holds it; and when the saw is not at work, the friction is only sufficient to revolve the saw. On the opposite end of the driving shaft from the friction wheel are two pulleys, tight and loose, to receive a 2½″ driving belt. The saws can be used from ½″ to 1″ wide. See Fig 4334, p. 1945, "*Mech. Dict.*" See also RIM SAW, *supra*.

Ring Splice. (*Nautical.*) A loop made in a rope by splicing the end to the standing part as in *f*, Fig. 5435, p. 2279, "*Mech. Dict.*"

Ring Top Fur′nace. A charcoal furnace for smoothing irons, etc., having an annular top and cross bars, removable at pleasure.

Ring Valve. A valve of cylindrical shape sliding in a chamber which has a similar form but has apertures which afford a through way when the valve is lifted.

Fig. 2141.



Ring Valve.
A. Valve stem.
B. Ring valve.
D. Wedge.

The valve has a vertical slit on one side and is expansible as the screw forces it down upon a wedge which occupies an axial vertical position within it.

Rins′ing Ma-chine′. 1. A centrifugal machine in which clothes from the rinsing tub are placed in order to remove the water as far as possible by mechanical means, before placing the clothes in the drying closet. See LAUNDRY, Plate XXV., opp. p. 532, *supra*.

2. A machine for passing calicoes, etc., through water to remove superfluous color, etc., acquired in the dyeing or bleaching processes. Fig. 4336, p. 1945, "*Mech. Dict.*"

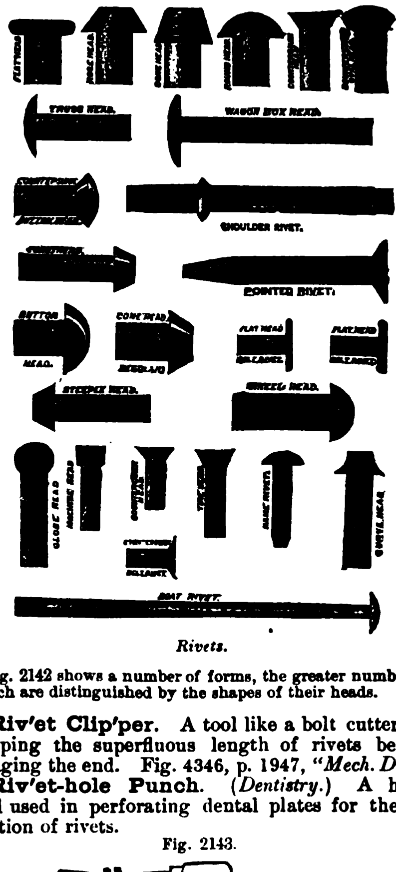
Rip′-Rap. Loose stone pitched around a subaqueous foundation to prevent erosion by water.

Many of the most important railroad bridges have their piers founded on timber cribs filled in with stone, the timber work being carried up to within a couple of feet of lowest water mark before starting the masonry. On bottoms subject to erosion, a plentiful supply of rip-rap is dumped around the foundation and replenished from season to season till well solidified.

This is the usual system in America when the river bottom is of such a nature that a solid bearing on stone, hard-pan, or gravel can be insured. When a soft material overlies a hard bottom, loose stone, *rip-rap*, is thrown in to form a foundation for the crib work or masonry.

Riv′et. A short bolt the end of which is swaged to prevent retraction.

Fig. 2142.



Rivets.

Fig. 2142 shows a number of forms, the greater number of which are distinguished by the shapes of their heads.

Riv′et Clip′per. A tool like a bolt cutter for clipping the superfluous length of rivets before swaging the end. Fig. 4346, p. 1947, "*Mech. Dict.*"

Riv′et-hole Punch. (*Dentistry.*) A hand tool used in perforating dental plates for the reception of rivets.

Fig. 2143.

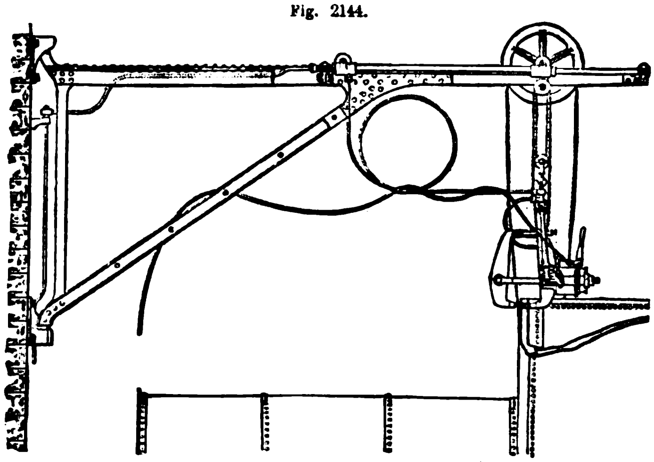
Rivet-hole Punch.

Riv′et-ing Bur. A washer placed on a rivet and upon which the end is swaged down. Used only in small affairs, from 1-10″ to ¼″ holes.

Riv′et-ing Knob. A cup-faced swage for closing down the rivet end upon the object or upon the bur, as the case may be.

Riv′et-ing Ma-chine′. Several forms of riveting machine are shown in Figs. 4349–4354, "*Mech. Dict.*," operating by pitman, cam, steam, hydraulic power, etc.

Fig. 2144.



Tweddell's Suspended Hydraulic Riveter.

Fig. 2144 shows the Tweddell portable hydraulic riveter and crane, for riveting locomotive-boiler foundation rings, wheel-tires, girders, crane-work, boilers, etc. The riveter is suspended from a specially designed hydraulic crane by means of which the riveter is made to command a considerable area without disconnecting a pipe-coupling or breaking a pipe-joint.

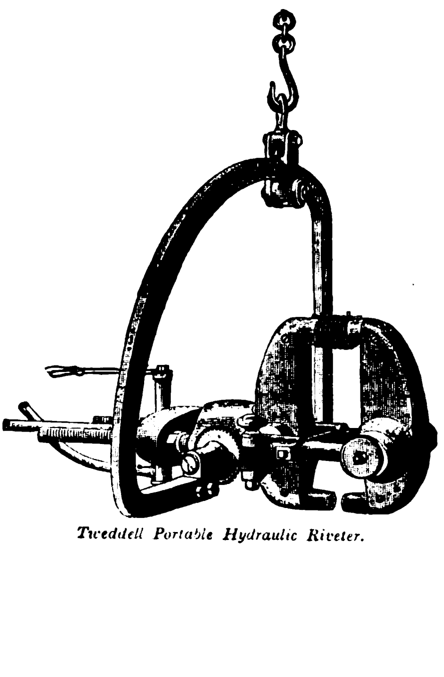
A slightly modified form of the same is shown more in detail in Fig. 2145.

It consists of two levers or arms abutting at one extremity, and carrying at the other two cupped dies, used to form the head of the rivet. Upon one of these levers rests the bottom of a hydraulic cylinder, in which works a plunger, carrying a crosshead furnished with tension bars, which, after passing through guides on each side of the cylinder, are fastened to the other lever, as shown in Fig. 2145. The fulcrum is not situated at the center of the length of the levers, but at a point distant about one third of that length from one end.

The riveter may be adjusted in its hangings to act on seams, oblique, horizontal, or vertical.

One man raises and lowers the riveter, adjusts it to the rivets, and then closes the dies on the rivets. Boys drop the red-hot rivets into place with the head of the rivet uppermost in horizontal work. With a skillful operator, as many as 6 to 10 red-hot rivets may be put in place ahead of him, and he can, on beam work, drive from 10 to 16 rivets per minute.

Fig. 2145.



Tweddell Portable Hydraulic Riveter.

The machine is used with an accumulator which maintains an equable pressure adjustable from 250 to 2,000 pounds per square inch.

See also FIRE-HOLE RING RIVETER, Fig. 1036, p. 338, *supra*.

Small riveting machines are used for closing rivets on small articles of wear and convenience, such as brogans, boots, shawl-straps, valises, etc.

A hydraulic riveting machine driven by pump, and accumulator, is shown under ACCUMULATOR, Fig. 2, p. 2, *supra*.

Road Grad'er. See ROAD LEVELER.

Road Lev'el-er. A scraper for leveling heaps of dumped earth thrown up to form a road; and for rounding the earth towards the center of the road. It is a board, steel-shod, and traversing obliquely with the line of the direction of the road. Shown in *b*, Fig. 4693, p. 2058, and Fig. 4365, p. 1954, "*Mech. Dict.*"

Rock'er. (*Railway.*) A curved iron casting on which the body of a tip-car rests and rocks in discharging.

Rock'et. An illuminating or incendiary projectile.

The various kinds are cited and described on p. 1959, "*Mech. Dict.*"

Boxer's life-saving, rope-carrying rocket, for communicating with stranded vessels, is shown and described in "*Ordnance Report*," 1878, Appendix P, p. 314 and Plate XLI.

Illuminating . . . . "*Scientific American*," xxxviii. 72.

The rocket harpoon is one projected, in whole or in part, by the issuing at the rear of the gaseous results of the explosive.

See list of U. S. Patents, which also includes bomb harpoons and bomb lance, under HARPOON.

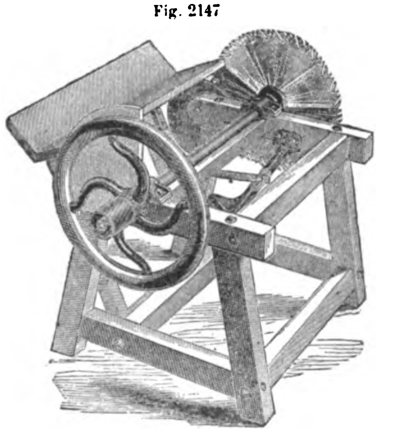
Rock'ing Bar. A bar in a stove or furnace on which the grate rocks, and in some cases tips.

Rock'ing Pier. A bridge pier for supporting a railway track or iron truss across a ravine or valley, its upper end having a motion longitudinally of the said truss as the same contracts or expands. It is a substitute for supporting the end of the truss upon rollers on a rigid pier.

It is used on the Dysdal Viaduct on the Christiana & Fredrikshald Railway, Norway.

The piers which support the superstructure are of wrought iron with lattice-work web. In the longitudinal direction of the viaduct, which is 608′ in length, there is only a single column between each span, possessing no stability in itself, and the upper end is allowed to move along with the superstructure when the latter expands and contracts The lower end of each pier rests on a hinged shoe, so that breaking strains are avoided, and the load is always rendered central to the pier columns. The movement of iron work in a longitudinal direction is transferred to the one abutment on which are the necessary bed-plates, provided with rollers; on the other the superstructure is kept in place by a fixed shoe.

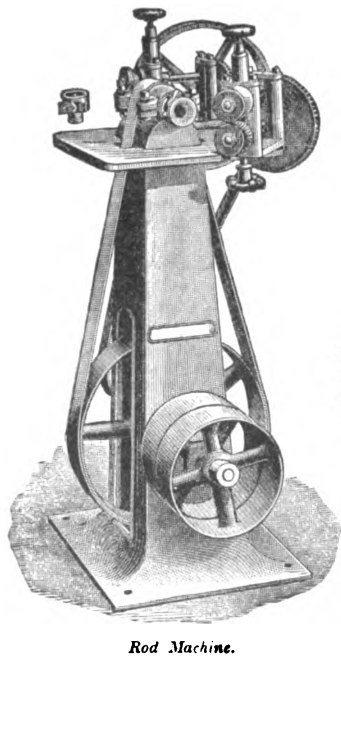
Fig. 2147



Rocking Saw-table.

Rock′ing Saw′-ta-ble. A form of cross-cutting machine in which the stuff is laid on a table which rocks on an axis. The table is counter-balanced by a pendulous weight, and the thrusting forward of the table brings the stuff to the action of the saw, and conversely. Fig. 2147.

Fig. 2148.



Rod Machine.

Rod Ma-chine′. A machine for making round sticks, such as dowels, pins, stretchers, broom-handles, etc.

The revolving head is on the principle of a hollow auger, and is mounted upon a column. A chuck of the proper size is fitted into the hollow arbor on which is the pulley driven by band from the countershaft beneath.

The feeding mechanism consists of two pairs of rollers; the receiving rollers are grooved to receive the square stick; the discharging rollers, circular grooved, to receive and feed out the finished rod. The rollers are geared and driven from one belt; are adjusted to the required pressure for feeding the stuff, and removable for different sizes. The receiving rollers are turned out of the way when changing the chucks or clearing them of broken rods. It will turn from 15′ to 25′ per minute. Three sizes are made: to work 1″ and under, 1½″ and under, 2″ and under, respectively.

Fay . . . . * "*Engineer*," xlv. 435.

Rolled Plate Glass. Rolling glass has been to some extent substituted for casting on tables, in England, France, and Belgium.

" Instead of being cast with the costly apparatus necessary for plate glass of large sizes, this glass is cast in a very simple manner. A basin or dipper is introduced into the glass and filled up: this dipper is suspended upon a hook placed in front of the pot, to enable the workmen to dip and withdraw it with facility when it is full. This dipper is carried over an iron table, and by giving a blow upon it all the cooled filaments and pieces attached to the outside fall off. The dipper is now emptied over the casting table, the thickness of the glass being regulated by metallic pieces or rules. The roller is passed over the mass by the workmen, back and forth. These plates are sometimes imprinted with quadrangular ribs, very close to one another, in order to hide the defects or air bubbles which are likely to occur with this mode of dipping glass. These plates are usually cast about one eighth of an inch thick. They are used for covering hot-houses, for door panels, and for windows." — *Colné.*

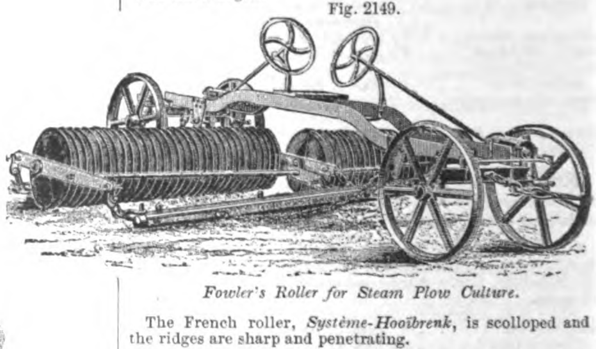
Rol′ler. 1. Land rollers and clod crushers are considered on pp. 572, 1962, 1963, "*Mech. Dict.*," and p. 201, *supra*.

Fig. 2149 is the roller adapted to steam plow culture.

The implement has a width of 15′, and may be fitted with any description of roller, smooth, corrugated, or sectional. The suspended frame is hinged in the middle and can be readily taken to pieces, so that in moving from field to field the two halves are pulled one behind the other, and pass conveniently along an ordinary or a farm road or through gateways.

The French *Tombereau-rouleau* (cart-roller) has a cart body on a pair of iron rollers, for use on soft and treacherous soil. *Guilleux à Segre.*

Fig. 2149.



Fowler's Roller for Steam Plow Culture.

The French roller, *Système-Hooïbrenk*, is scolloped and the ridges are sharp and penetrating.

2. Poole's calender rolls are shown in Fig. 499, p. 152, *supra*.

Poole & Co. . . . . . * "*Scientific American Sup.*," 668.
French calendering machine, Fig. 500, p. 153, *supra*.

Rol'ler Bar. The sharp-edge bar, or knife, in the bed of a rag-cutting machine.

Rol'ler Bear'ing. A socket for a roller journal, having anti-friction rollers on its interior perimeter. Fig. 263, p. 119, "*Mech. Dict.*" A *ring bush.*

Higley . . * "*Scientific American Supplement*," 1412.

Rol'ler Grip. The device for clutching the traveling rope in that system of traction of cars used on London and Blackwall railway in 1844. See ROPE RAILWAY, p. 1983, "*Mech. Dict.*"; INCLINED PLANE, *Ibid.*

The plan adopted in San Francisco and Chicago, and proposed for the East River Bridge, N. Y., consists in grasping the rope between sheaves or grooved steel rollers and applying brakes to the periphery of the rollers opposite the point where they come in contact with the rope. This permits perfect control of the movements of the car, as has been demonstrated on the Silver Street Railway in San Francisco, where there is a two-mile cable on a steep grade.
See WIRE ROPE RAILWAY, Fig. 7293, p. 2795, "*Mech. Dict.*"

Rol'ler Mill. 1. Specifically: a mill in which wheat is made into flour by a cracking process, by passing between rollers consecutively arranged in pairs.

The wheat passes through five sets of rollers, each set closer than the former. These rollers are 30" long and 10" in diameter. After passing between each set of rollers it is bolted. The last rollers have hardly anything but wheat hulls and the waxy germs which do not crack up, but smash together. The first rollers crack the kernels of wheat into say six pieces. The starchy substance which rattles out drops through the cloth sieves or bolting cloths.

These six pieces are broken between the next rollers into thirty-six pieces. Then the white starch crumbs are sifted out again, and the thirty-six pieces are passed between still tighter rollers, which crack them into 216 pieces; another set of rollers multiply each of these particles into six more, making them aggregate 1,293. Another set of rollers screwed together with tremendous pressure makes 7,776 pieces.

The numbers of course are only approximate, and are given merely to make the description of the process more clear.

Campin. "*On the Construction of Iron Roofs, a Theoretical and Practical Treatise.*"

Fig. 2153.

Hornsby's Root Cutter.

Root Cut'ter. A machine for slicing roots for feeding to live stock.

There are various types: conical, cylinder, and disk, plain, toothed, shredding cutters, stepped cutters, double sets of cutters.

Several forms are shown in Figs. 4430–4432, pp. 1975, 1976, "*Mech. Dict.*"

Fig. 2153 is the Hornsby root cutter (British). It cuts the root into finger pieces the whole length of the root. By the disposition of the hopper and curve of the knives the roots are not rolled in the hopper, but drawn toward the center of the disk, the result being that the finger pieces are delivered unbroken.

Fig. 2154 is Pinet's conical disk root cutter (French). The teeth of the knives project beyond the periphery of the cone and remove slices equal to the width of the teeth and of a thickness equal to the distance of their projection beyond the face of the cone. The weight of the roots in the hopper keeps them against the cone. The slices escape into the hollow cone.

Variations in the knives for the purposes of feeding cattle, sheep, etc., are found in several machines, otherwise similar in all features. Such machines are said to rasp, pulp, shred, mince, cut (*émincer*, *râper*, *couper*, etc.), as the case may be.

Root For'ceps. (*Dental.*) An extracting forceps with narrow jaws. See list under FORCEPS, p. 354, *supra.*

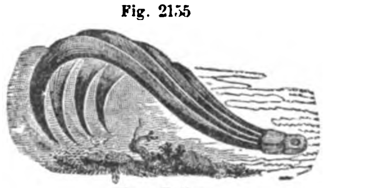
Root Ma-chine'. See under the various heads, ROOT CUTTERS, ROOT WASHERS, etc.; also BEET RASP; BEET ROOT DIGGER; POTATO DIGGER, etc.

Dr. Knight's report on Agricultural Implements (Class 76), at the Paris Exposition of 1868, gives views and descriptions of the following machines for treating roots for food: —

Root-washer, *Bodin*	France.
Root-washer, *Pernollet*	France.
Potato-assorter, *Penney & Co.*	England.
Root-cutter, *E. Bodin*	France.
Root-cutter, *Hunt & Tawell*	England.
Root-cutter, toothed knife	England.
Double-acting root-cutter, *Picksley, Sims & Co.*	England.
Root-shredder, *Maldon Iron Works*, Maldon	England.
Root-cutter, *Pinel*	France.
Root-cutter, frusto-conical cutter	France.
Portable cooking apparatus, *Beaume*	France.
Agricultural caldron, *Fouché*	France.
Agricultural boiler, *Bodin*	France.
Steam-cooking apparatus, *Richmond & Chandler*	England.

Root Pul'ler. 1. A machine for lifting roots from the ground. See ROOT DIGGER, *supra.*

Fig. 2155



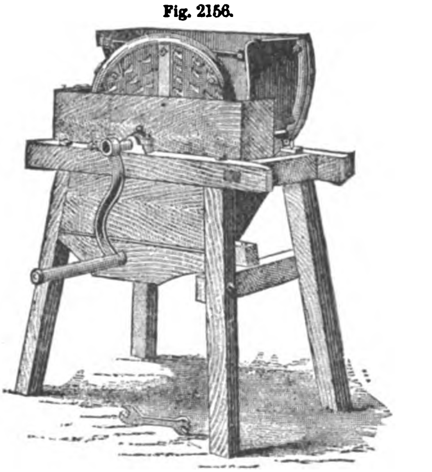
Root Puller.

2. A claw to which horses or oxen are hitched to drag roots from the soil in clearing land.

Root Rasp. A machine for pulping roots. See BEET ROOT RASP, Figs. 262-264, pp. 89, 90, *supra.*

Root Shred'der. A machine for reducing roots to shreds for feeding to stock. The machine shown in Fig. 2156 has a disk occupied by a multitude of tearing points in the sectors between the radial knives. The points tear the cut surfaces of the roots, and then the knife removes the ragged surface.

Fig. 2156.



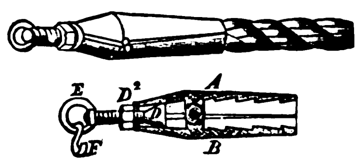
Root Shredder.

Albaret's root-cutter (Fr.), for slicing the beets used in the manufacture of sugar and alcohol, has six notched knives on a disk, and the slices of root pass into the case, and so to the floor below.

Rope Clamp. A device to secure the end of a cord, as in the case of a round lathe belt; or a connector for the signal rope of railway cars.

The clamping jaws, as shown in the engravings, are formed by two semi-tubes, *A* and *B*, made with teeth on their inner faces to hold the rope and prevent its slipping out. A pin passes through lugs on each to form a hinge

Fig. 2157.



Rope Clamp.

joint. This pin may be removed to attach the end of the rope by placing it on one jaw, when the other is laid upon it and the pin inserted. An inclined groove is cut in the solid ends of the clamping jaws, above the hinge, to receive a wedge, *D*, which is formed on the edge of the spirally threaded stem, on which is a nut, resting against a washer. *E* is a swivel ring on the end of the stem *D*, and *F* a hook on the ring for an attachment. The wedge is tightened by turning the nut D^2.

Rope-dri'ving Gear. A means of transmission of power from a driver to machinery. A substitute for belting.

In a notable case, in Manchester, England, the fly-wheel is made to serve as driving drum also; it is 22′ in diameter, and weighs about 20 tons. It is grooved for the reception of 12 hempen ropes, each 6″ in girth, six of the ropes being intended to drive one line of shafting, and six the other. The rope drums or pulleys on the shafting are 5′ in diameter; the rims are made heavy and are grooved, as is the driving drum, but for only six ropes. The width of the grooves is 2 7-16″; total depth, 3¼″; the radius of the bottom curve, ½″; and the inclination of the two sides to each other is about 49°. It will be apparent from these particulars that the ropes do not, even when pressed somewhat out of shape when doing full duty, rest upon the bottom of the grooves, but on the sides, and the wear is, therefore, at the points of contact. The wear, after 18 months' use, was tolerably uniform all around the section, thus indicating that the ropes do not present the same parts of their circumference to be continuously gripped in the grooves.

Rope transmission in mills, *Pearson*	*	"*Engineering*," xxi. 76.

Rope-mold'ing Ma-chine'. A machine for scroll-turning stuff for balusters, stretchers, etc.

The molding is cut by a revolving cutter head, with cutters to suit the style or size of work. The stick being first turned round by a rod machine or lathe, is fed in, and at the same time revolved by the feed attachment, the feed and guides being adjustable to the different sizes. The machine works any size, from 3″ down, making a very smooth finished molding, requiring little or no after finish. By an arrangement for working the stick at an angle with the cutters, the style of the twist can be altered, and made close or open, as desired. — *Rogers.*

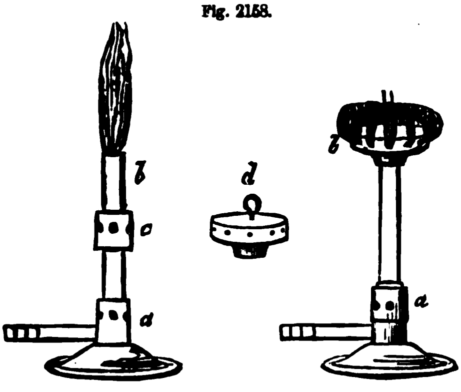
See also BALUSTER LATHE, p. 71, *supra.*
CARVING ATTACHMENT FOR LATHES, Fig. 555, p. 174, *supra.*

Rose Burn'er. Or *Rosette Burner.* A form of gas burner in which the gas issues at a circular series of openings, the jets resembling petals. See BUNSEN-BURNER FURNACE.

See also *b c*, Fig. 5924, p. 2411, "*Mech. Dict.*"

The burner shown in Fig. 2158 gives a single flame for crucibles, and a circle of flames when liquids are to be heated in vessels of glass or porcelain. The burner *a b* is similar to

Fig. 2158.



Rose Gas Burners.

Bunsen's; *c*, a regulator to control the entrance of the air into a box, *a*, and thus prevent the flame from blowing down; *d*, the rose, which divides and spreads the flame when put on the top of tube *b*. *e* shows the single or igniting flame; *b*, the spread or evaporating flame.

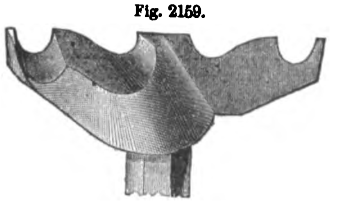
Rose Glass. A celebrated French glass, prepared in a special manner.

A certain quantity of auriferous glass is prepared beforehand, and run in thin plates, and fragments of these plates are used by the glass blower to fuse upon his work, and thus give it a superficial coloration. It often happens that the same composition of auriferous crystal gives plates of very different shades, some colorless, others tinged more or less deeply with rose or red, and some almost black; these differences being due to two causes, namely, the temperature of the furnace in which the fusion has been effected, and the temperature of the mold into which the melted metal is run. For light colored plates the temperature of the furnace is made low, and the mold very cold; blue plates are sometimes produced under the same circumstances, which, if reheated, take the normal color, as do also the colorless and very pale rose glasses. Crystal colored with gold is merely a vitreous matter, holding in suspension metallic gold in a state of very fine subdivision. It is stated that on attentively examining the red plates, it is easy to recognize in the mass a multitude of most brilliant specks of metallic gold, forming a sort of aventurine (which see).

Ro-sette′. (*Nautical.*) A form of knot. See 32, Fig. 2777, p. 1240, "*Mech. Dict.*"

Ro-sette′ Cut′ter. A steel cutter of inverse form for forming a circular ornament of wood.

Fig. 2159.



Boult's Rosette Cutter.

Ros′in Core. A dry-sand core in which rosin has been used for the purpose of increasing the adhesiveness and strength of the sand when dried.

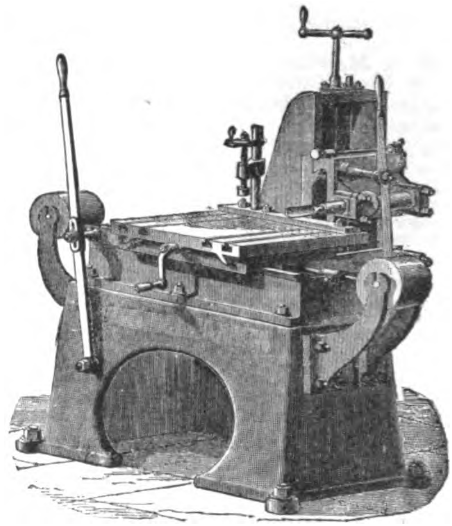
Ros′in Oil. (*Leather.*) A compound of melted rosin and linseed oil.

Ro′ta-ry-bed Pla′ning Ma-chine′. One with a continuously moving bed. See TRAVERSING-BED PLANING MACHINE, Fig. 6627, p. 2620, "*Mech. Dict.*"

Ro′ta-ry En′gine. See ROTARY STEAM ENGINE.

Ro′ta-ry Mor′tis-ing Ma-chine′. A form of mortising machine in which the cutter revolves and works by a routing action; as distinct from the ordinary form, in which the cutting is done by a reciprocated chisel.

Fig. 2160.



Mortising, Routing, and Recessing Machine.

The work is dogged or chucked to a table which has a compound movement and subjected to the action of a rotary router.

Ro′ta-ry Plow. A rotary plow which acts as a spader is shown in Fig. 4464, p. 1988, "*Mech. Dict.*" See also SPADING MACHINE, p. 3252, *Ibid.*

The rotary plow shown in Fig. 2161. The piece acting as share and mold-board is a circular disk or conical frustum

Fig. 2161.

Rotary Plow.

which penetrates the soil, lifts a slice and turns it over. The cut shows a double or two-furrow plow.

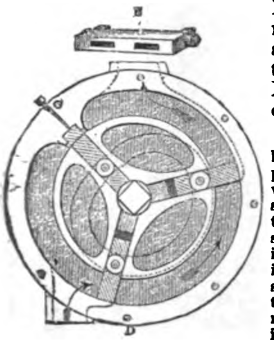
Ro′ta-ry Pump. A pump which acts by a rotary, in contradistinction to a reciprocating action.

Under the caption ROTARY PUMP, pp. 1988, 1989, "*Mech. Dict.*," 24 illustrations are given of rotary pumps of various kinds: single and double pistons and centrifugal.

In the illustration of the Douglas pump, Fig. 2162, the shaded portion with arrows indicates the water and its direction. The pistons are three in number, and operated by a scroll race in which the rollers of the pistons work. By this means the pistons are held against the inner perimeter of the cylinder in which they work, and withdrawn to pass the abutment. Passages through the slides balance the water pressure on their respective sides.

Samain's pump (French) is shown in Fig. 2163. It has four palettes, arranged in pairs and moving in slots in the cross of the arbor. They are so arranged that when one is out, abutting against the interior perimeter of the chamber, the other is in, passing its lowest position in contact with the abutment. The arrows show the direction of the water.

Fig. 2162.

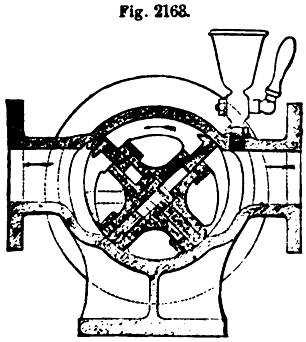


Douglas Rotary Pump.

Fig. 2164 is the Bagley and Sewall rotary pump in which an eccentric ring rotates in the cylinder. It is shown by vertical section.

A is the main case or body of the pump in one piece, on the interior of which is the ring *B*; the space outside of *B* being the cylinder or water space. This cylinder is inclosed by a disk which is attached firmly to the shaft. To the disk is attached eccentrically a ring *E*, a portion of which is always in contact with the outside of casing *A*, and also with the ring *B*, at a point exactly opposite; so that the eccentric ring *E* is really the piston of the pump; the disk and ring being rotated by the shaft driven by pulleys. *I* is the suction port, and *J* the discharge. These ports are separated by the sliding abutment *H*, which moves back and forth on its seat with the throw of the eccentric ring *E*. The tumblers fitted to this abutment adjust themselves to the ring, and as the pressure is constant upon them from above, they effectually pack the ring and prevent any escape of water below.

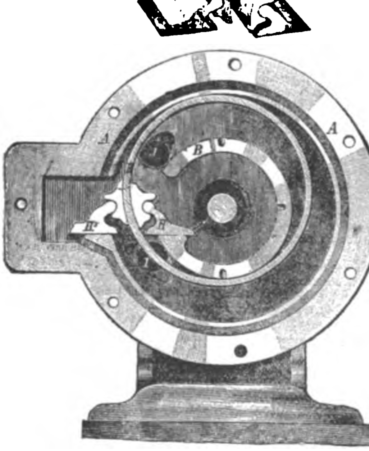
Fig. 2163.



Samain's Pump (Fr.).

The water enters at *I*, and as the piston ring rotates, it is forced before and between it and the casing, around to the upper portion of the latter and out at the port *J*. As the ring rotates it opens a space between its inner periphery and the fixed ring *B*, into which space the water from port *I* enters, filling the interior of the piston, to be forced out as before. The center ring *B* is made enough deeper than the casing *A*, to exactly equalize the contents of the inside and outside of the piston ring *E*, thus securing a perfectly steady flow of water from the discharge. *F* is the cover or outside case. Holes are made through the disk *D* to allow the water to pass through and between it and the outer case, thereby balancing the working parts, and equalizing the pressure upon them. One end of the shaft has a closed bearing in this outer case; the other bearing is in the case *A*. On the shaft, and being a part of the disk *D*, is a collar which is fitted to the seat *K*, making a perfect water-tight joint, by which all "packing" of the pump is avoided. In the center of the seat *K* is a circular groove, which connects by a drilled channel with the suction port. Should there be any tendency to escape of water at the seat *K*, the force of the suction keeps the port closely to the seat, and absolutely sealed against air or water.

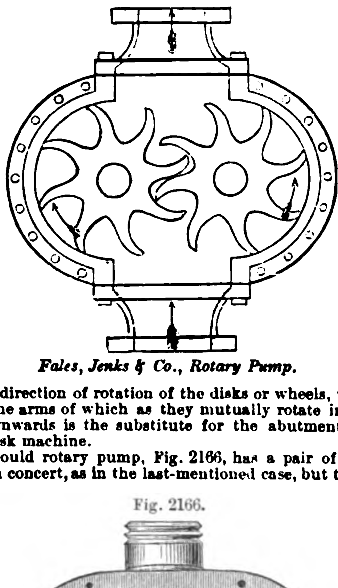
Fig. 2164.



Bagley & Sewall's Rotary Pump.

Fig. 2165 is the double wheel pump of Fales, Jenks & Co. The arrows show the direction of the water, and thus indicate the direction of rotation of the disks or wheels, the contact of the arms of which as they mutually rotate inwardly and downwards is the substitute for the abutment in the single disk machine.

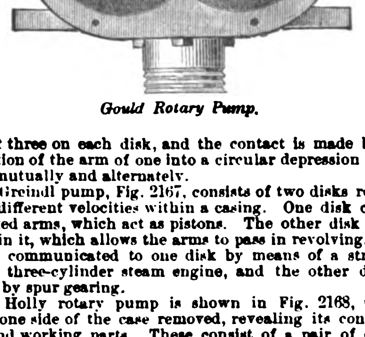
Fig. 2165.



Fales, Jenks & Co., Rotary Pump.

The Gould rotary pump, Fig. 2166, has a pair of pistons acting in concert, as in the last-mentioned case, but the arms are but three on each disk, and the contact is made by the projection of the arm of one into a circular depression in the other mutually and alternately.

Fig. 2166.

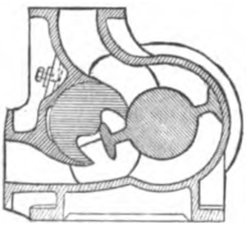


Gould Rotary Pump.

The Greindl pump, Fig. 2167, consists of two disks revolving at different velocities within a casing. One disk carries two fixed arms, which act as pistons. The other disk has a recess in it, which allows the arms to pass in revolving. Motion is communicated to one disk by means of a strap or patent three-cylinder steam engine, and the other disk is driven by spur gearing.

The Holly rotary pump is shown in Fig. 2168, which shows one side of the case removed, revealing its construction and working parts. These consist of a pair of corrugated cams working together within an elliptical case, the ends of the long teeth being packed by blocks of metal inserted into the grooves and pressed out by springs, thus insuring a perfect vacuum and the taking up of any little wear there may be after years of pumping. The water enters at the

Fig. 2167.



Greindl's Rotary Pump.

bottom through the suction *M*, the stream dividing and filling the chambers made by the long teeth, passing around the cams *O* and *P*, and discharging from the top through the outlet *N*. The motion of the pump is equable, continuous, and rotary, the cams working together inwards from the top. Thus, when one chamber has just discharged, another is discharging, another one is on its way, and still another one is just filling, so that the stream is always uniform and steady.

The Silsby rotary pump is shown in Fig. 1031, p. 337, *supra*.

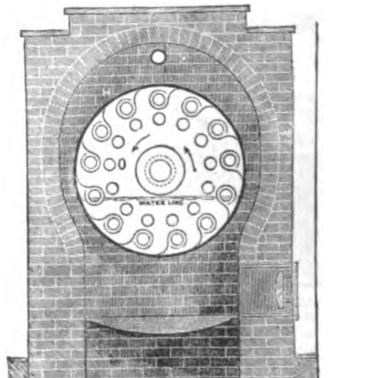
Ro'ta-ry Tu'bu-lar Steam Boil'er. The Pierce rotary tubular boiler (Figs. 2169, 2170) is a cylindrical rotary tubular steam boiler, with two circular rows of tubes running from end to end. The outer rows of tubes are surrounded by buckets or elevators which are so arranged as to nearly encircle them, and to cover the inner surface of the

Fig. 2170.



Pierce Rotary Tubular Boiler.

boiler-shell with water at each revolution. The inner row of tubes act as superheaters for drying as well as generating steam. The boiler is incased in brick-work and is supported upon trunnions at each end in such a manner that it is rotated by gearing actuated by the steam pump that supplies the boiler with water, or other motor power.

The boiler is at all times one-quarter full of water, which amount is unchangeable, being regulated by an automatic feed-water regulator.

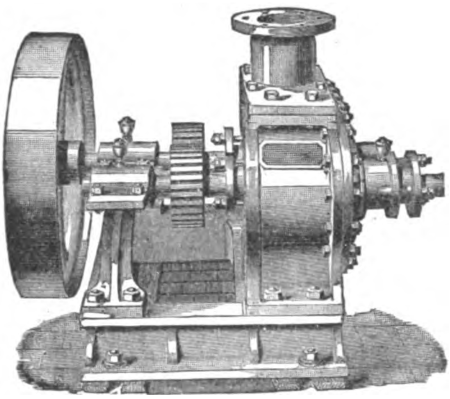
The feed-water is introduced through one trunnion, and the steam withdrawn through the opposite trunnion.

The grate has an area equal to the entire inner base of the brickwork surrounding the boiler.

The flame and heated gases arising from the grate completely surround the boiler, thence pass through the outer row of tubes to the opposite end, emerging into a chamber, thence returning through the inner or superheating row of tubes, en route to the stack or chimney.

Ro'ta-ry Wa'ter En'gine. Behren's rotary water engine (English) is a simple form of motor having but few moving parts. It consists of a casing bored out to receive two piston blocks, which furnish an alternate abutment to each other. The pistons are connected by spur wheels, and their motion is therefore perfectly uniform and continuous.

Fig. 2171.



Appleby Bros. Rotary Water Engine. Behren's Patent.

No power is lost in overcoming the inertia of reciprocating, and no fly-wheel is required. It is the rotary engine common in the domain of steam, but in this case driven by water pressure. The same set of pistons moved by mechanical connection from an exterior motor may constitute a rotary pump. See pp. 1991 and 1988, 1989 respectively, "*Mech. Dict.*"

Ro-ta'tor. An apparatus for producing iron by the direct process.

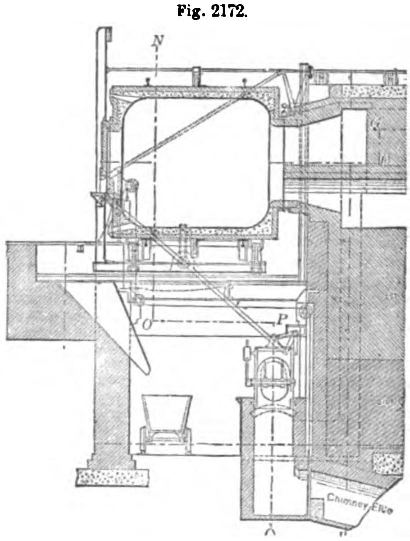
"The apparatus, or 'rotator,' Figs. 2172, 2173, consists of a revolving furnace, lined with oxide of iron. Gas from producers and air from one pair of regenerators enter at one end of the furnace, burn and reverberate within it, and pass out at the same end into the other regenerator. There is a large charging and discharging door at the other end of the furnace.

"At Dr. Siemens' Works, at Towcester, the small rotator, 9½' long by 8½' in diameter, takes a charge of 30 cwts. of ore mixed with 8 cwts. of small coal. In about 2½ hours the reduction of the ore is completed; the slag is tapped off, and the heat and speed of rotation are increased to form the mass into an elongated ball, which is hammered into a bloom. An average of 43 consecutive charges at Towcester gave the following results: —

Iron in ore charged, lbs.	1,274
Coal, lbs.	728
Time for operation	3.12
Blooms made, lbs.	1,113
Loss, per cent.	12.6
Coal in producers per ton of blooms, tons	2

"The particles of iron forming the blooms, if perfectly separated from the slag, are practically pure, however impure

Fig. 2172.

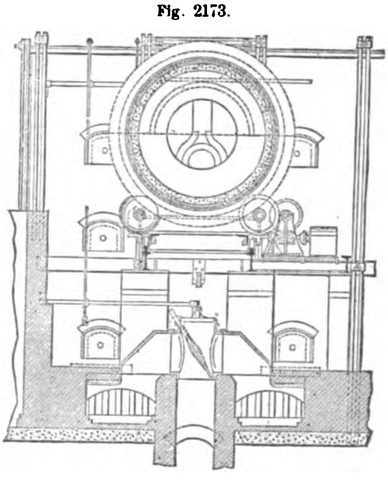


Siemens' Rotator.

the ore may be. The slag contains sometimes 6 per cent. of phosphoric acid and one to two per cent. of sulphur. The pure iron will alone remain in the open-hearth bath, although some few hundredths of phosphorus may be taken up from the slag at the highest temperature.

"The first trial of the process in the United States was at Park Bro. & Co.'s Works, in Pittsburg. There were no serious difficulties, except the oxidation referred to, in the manufacture of the balls into wrought iron. Within the last few months a large rotator, 11' long by 11' in diameter, has been started at Tyrone Forges, Pa., by Mr, Robert J. Anderson, of Pittsburg, to make material for his open-hearth furnaces. Although the operations have purposely been experimental, with various ores and lining materials, enough has been done to show that a product of excellent quality may be got from any ore, and that linings (necessarily oxide) may be adapted to any ore, although a very silicious ore requires the use of so much lime that the repairs of linings are proportionally increased.

Fig. 2173.



Siemens' Rotator.

"In an average week's work at Tyrone, with Robinson ore and the highly silicious Pennington ore, the mixture having about 50 per cent. of iron, the charges were: Ore, 4,000 lbs.; reducing coal, 600 to 700 lbs.; limestone, 250 lbs.: scale and cinder, 800 lbs. The yield of blooms was 1,600 to 1,700 lbs. per charge, or 80 to 85 per cent. of the iron in the ore. The producer coal was 3,800 lbs. per ton of blooms. The week's work was 19 operations, producing 14 tons of blooms.

"The cost of blooms, with ore averaging about $8 and coal $2.15, and with labor charged at the very high rate of $10 per ton, was a little over $25 per ton. Experimental labor is of course excessive, and in this case the men could have just as well run four furnaces as one. Labor should not exceed $2.50 to $3 per ton in a plant of four rotators. The output has been gradually increasing and has reached five operations per 24 hours. The producer coal has also been gradually decreased. Of course working costs can be only approximately determined from experimental costs, but it seems safe to say that blooms can be produced at a small advance over the cost of pig from the same ore.

"The cost of a plant of four rotators, ore crushers, hammer or squeezer, etc., exclusive of building, is about $40,000, and its output with existing appliances only, in regular rather than in experimental work, is estimated at 125 tons per week. This looks at first like a small output, but it must be remembered that the entire blast furnace plant is dispensed with. An obvious improvement, not in any way experimental, is about to be introduced. It is calcining the ores in any suitable kiln and running them red hot into the rotator. As about half the time of the operation is now occupied in getting the charge up to a reducing temperature, it is obvious that the calcining — a cheap operation — will nearly double the output of a rotator plant.

"Charcoal blooms are at present the best material in the market for making fine open-hearth steel; they are used together with the smallest possible bath of Bessemer pig for the finest fire-box plates. If Siemens direct blooms (even should they have more mechanical impurities) are not as good as charcoal blooms for open-hearth steel, the reason is not obvious. Such practice as there is seems to prove them equally good. As I have similarly stated in previous papers describing new processes, the object of these notes on the Siemens' process is not to compare it commercially with other preparatory processes, but simply to state its existing *status* and the probable course and means of its further development." — *Holley.*

Roth'er-nail. (*Shipwright.*) A large headed nail used for fastening the rudder-irons of ships.

Rough'ing Hor'ses. A simple mode of roughing horses, practiced in Russia, consists in punching a square hole in each heel of the shoe, which, in ordinary weather, may be kept closed by a piece of cork. When the ground is slippery, the cork is removed, and a steel spike inserted. If this steel rough be made to fit the hole exactly, it remains firm in its place, and is not liable to break off short at the neck like some of the screwed spikes.

Round Bar Spi'ral Spring. A spring of round steel coiled around a mandrel; as distinguished from a *flat-bar* coiled spring. See illustrations of each in Fig. 1143, p. 483, "*Mech. Dict.*"

Round'ing Ma-chine'. 1. A wood-working machine, also known as a cornering machine, used in chamfering off the corners of stuff; especially in implement and carriage work. See CHAMFERING MACHINE.

2. A machine for making round rods and spindles. See ROD MACHINE, PIN MACHINE, and DOWEL MACHINE.

3. A machine to round book backs. See BOOK-BACKING MACHINE, Fig. 381, p. 120, *supra.*

4. A machine for giving the rounded depressions in blanks for shoe soles. A sole-stamping machine.

Rough Point'ed Stone. (*Stone Cutting.*) When it is necessary to remove an inch or more from the face of a stone, it is done by the pick or heavy points until the projections vary from ½" to 1". The stone is then said to be rough pointed. This operation precedes all others in dressing limestone and granite.

See POINTED WORK.

Fig. 2174.

Round Iron.

Round Iron. The plumbers bulbous iron used in smoothing solder joints of lead pipe.

Round Scut'tle. (*Nautical.*) A scuttle with a circular frame suitable for iron ships, with brass door for glass, brass screw fastening, painted iron frame, and hinged iron dead-door complete.

Round Seiz'ing. (*Nautical.*) A loop made in rope by a single turn on itself, and seizing the crossing. See *c, e,* Fig. 4825, p. 2091, "*Mech. Dict.*"

Round Swage. (*Blacksmithing.*) A form for shaping iron.

Row'ing Gear. Outriggers and various devices to assist the oarsman. See OAR, Fig. 1824, p. 637, *supra.*

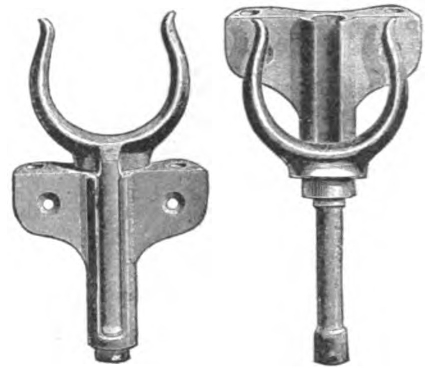
Fig. 2175.

IN POSITION. OUT OF POSITION.

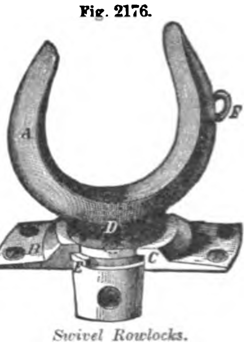


"*Acme*" *Rowlock.*

Row'locks. (*Boat*). Spaces in the gunwale for the oars to rest in rowing; or contrivances on the gunwale for the same purpose.

The Acme rowlock is used without a laniard; and, instead of removing the horns from the sockets when along side of vessels or wharves, as is required with most other rowlocks, simply turn them half way around, and they fall of their own gravity below the gunwale, obviating the necessity of removal from the sockets, except when it is desired to do so.

Fig. 2176.



Swivel Rowlocks.

In Fig. 2176 the rowlock plate *B C* is firmly fastened on top of the gunwale, and does not weaken it like the cutaway swivel rowlock, with sockets.

Fig. 2177 shows an outrigger rowlock wood-lined.

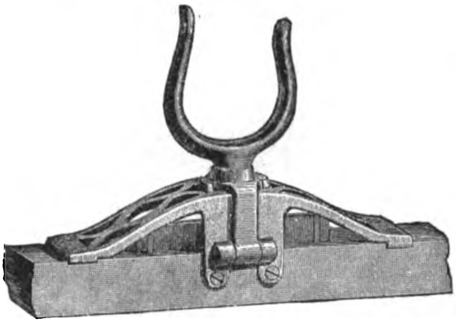
The Navy rowlock, Fig. 2178, is instantly changed from its position to a hanging one, or can be detached from the boat. To detach, turn long horn aft, draw up, and turn out. It is automatic in its motion, adapting itself to the motion of the oar, and always in position to receive it, *i. e.*, "fore and aft" the boat.

Fig. 2177.

Outrigger Rowlock.

Row Mark'er. (*Agric.*) An implement for marking out ground for planting in rows. See MARKER, Fig. 1681, p. 584, *supra.*

Fig. 2178.



Navy Rowlock.

Rubbed Stone. (*Stone-cutting.*) In dressing sandstone and marble, it is very common to give the stone a plane surface at once by the use of the stone saw. Any roughnesses left by the saw are removed by rubbing with grit or sandstone. Such stones, therefore, have no margins. They are frequently used in architecture for string courses, lintels, door jambs, etc., and they are also well adapted for use in facing the walls of lock chambers, and in other localities where a stone surface is liable to be rubbed by vessels or other moving bodies.

Rub'ber. Caoutchouc; a vegetable gummy substance obtained from a number of plants and trees, and entering as an element very extensively into mechanical productions.

The coast region north and south of the Congo is becoming quite an important source of caoutchouc. It is produced by a giant tree creeper (*landolphia*), which grows principally along the water-courses. It covers the highest trees, and frequently considerable extents of forest are festooned down to the ground, from tree to tree, in all directions with its thick stems, like great hawsers. Sometimes its stem is as thick as a man's thigh. Above, the trees are nearly hidden with its large, glossy leaves of dark green hue, and studded with beautiful bunches of pure white star-like flowers, most sweetly scented. Its fruit is of the size of a large orange, yellow when ripe, and perfectly round, with a hard, brittle shell; inside it is full of a soft reddish pulp of an agreeable acid flavor, much liked by the natives. It is not easy to obtain ripe seeds, as the creeper is a favorite resort of a villainous, semi-transparent, long-legged red ant — with a stinging bite, like the prick of a red-hot needle — which is very fond of the pulp and the seeds distributed through it.

Every part of the creeper yields a milky juice when wounded; but, unlike the juice of the American rubber tree this milky sap will not run into a vessel placed to receive it. It dries so quickly that a ridge is soon formed over a cut, and the flow arrested. When collecting it, the natives make long cuts in the bark with a knife, and as the sap gushes out they wipe it off continually with their fingers and smear it on their arms, shoulders, and breasts, until a thick covering is formed. Then they peel it off and cut it into small squares for transportation.

A good cement, that will render india rubber in any form adherent to glass or metal, is oft-times a desideratum with photographers, and in the "*Polytechnisches Journal*" there is a simple recipe given for the preparation of such a compound. Some shellac is pulverized, and then softened in ten times its weight of strong ammonia, whereby a transparent mass is obtained, which becomes fluid after keeping some little time, without the use of hot water. In three or four weeks the mixture is perfectly liquid, and, when applied, it will be found to soften the rubber. We are told that the rubber hardens as soon as the ammonia has evaporated again, and thus becomes impervious both to gases and to liquids. For cementing the rubber sheet, or the material in any shape, to metal, glass, and other such surfaces, the cement is strongly recommended.

The use of the salts of barium for adulterating goods sold by weight is on the increase. Some rubber goods have been found with these salts in the material, which on combustion left as much as 60 per cent. of ash, pure rubber leaving only 2.5 or 3 per cent. The adulterated goods cracked and lost their elasticity.

Rub'ber Cen'ter Spring. A car or vehicle spring with a caoutchouc cylinder or block inclosed in a spiral spring, or otherwise associated; as seen in several forms and instances in Figs. 1142–1144, pp. 482, 483, "*Mech. Dict.*"

Rub'ber Dam. (*Dentistry*). A shield of sheet rubber clasped around a tooth to exclude saliva during operation upon the tooth. See DAM, 3, *supra.*

Rub'ber Dam Clamp. See DAM CLAMP, Fig. 776, p. 245, *supra;* DAM CLAMP FORCEPS, Fig. 777, p. 245, *supra.*

Rub'ber Mop. The mop-head has a plate of thick rubber which is used as a scrubber or squeezer.

Rub'ber Pack'ing Ring. An annular gasket acting as a packing in many forms of pistons.

Rub'ber Spring. A spring of caoutchouc, in whole or in part. See instances in Figs. 1142–1144, pp. 482, 483, "*Mech. Dict.*"

Rub'ber Tu'bing. Impervious rubber tubing; may be made entirely impassable to coal gas by painting it over with a solution of silicate of sodium; otherwise known as water glass.

Rub'ber Tread. A step covering of vulcanized caoutchouc.

Rub'ber Wheel. A wheel with noiseless rubber tire.

Rub'bish Pul'ley. A simple form of tackle-block, used with a rope in hoisting materials from a foundation or excavation. A *gin-block.*

Ru'by Glass. (*Glass.*) Red glass. Made by repeated meltings with the addition of brown oxide of copper, oxides of lead and tin, scales of iron, and borax. The color is developed by repeated heatings with added quantities of the above coloring agents.

Rud'der. The principles governing the proportions and the amplitude of the circle described during its evolution, considered in article "*Gouvernail,*" *Laboulaye's* "*Dict. des Arts et Manuf.,*" tome iv., ed. 1877.

Jury rudder, *Cagliesi* . * "*Scientific American,*" xxxv. 297.

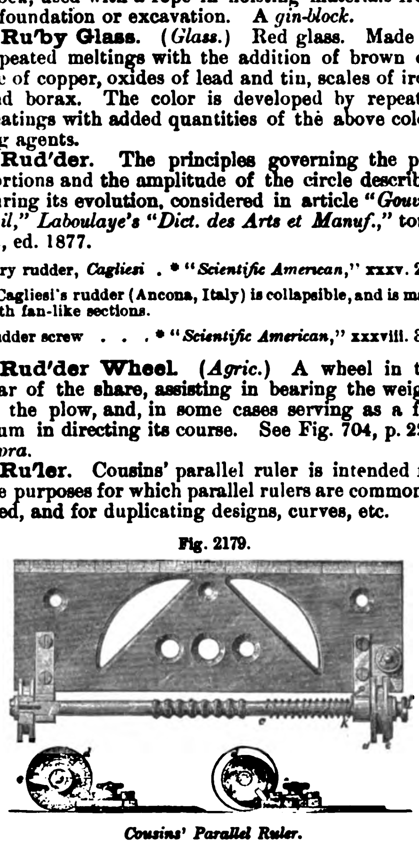
Cagliesi's rudder (Ancona, Italy) is collapsible, and is made with fan-like sections.

Rudder screw . . . * "*Scientific American,*" xxxviii. 306.

Rud'der Wheel. (*Agric.*) A wheel in the rear of the share, assisting in bearing the weight of the plow, and, in some cases serving as a fulcrum in directing its course. See Fig. 704, p. 225, *supra.*

Ru'ler. Cousins' parallel ruler is intended for the purposes for which parallel rulers are commonly used, and for duplicating designs, curves, etc.

Fig. 2179.



Cousins' Parallel Ruler.

The plate *a*, which forms the body of the ruler, has formed in it two oppositely disposed segmental openings, whose straight sides form an angle of 45° with the beveled edges of the ruler. It has also several small circular apertures, which may be utilized in forming curved lines.

Parallel with one of the edges of the plate *a*, a shaft, *c*, is journaled in suitable supports. On the ends of this shaft and outside of the bearings there are grooved wheels, *d*, which do not quite touch the surface on which the plate *a* rests.

To one of the wheels, *d*, is an arm, *e*, secured by the screw *f*, as shown in Fig. 2, and in the groove of the same wheel there is a pin that strikes the stop which is secured to the plate *a* by the screw *i*. This stop is arranged to engage the arm *e* also.

On the shaft *c* is placed a spiral spring, *k*, which returns the pin in the groove of the wheel to the stop on the plate *a*, as indicated in Fig. 3.

The side of the wheel *d* is graduated so that the arm *e* may be adjusted at any required distance from the pin in the groove. This distance governs the space between the lines formed along the edge of the ruler.

In drawing parallel lines the arm *e* having been adjusted as already described, the shaft *c* is pressed down until the wheels *d* touch the paper on which the lines are to be made: this tips up the beveled edge of the plate *a*. The instrument is now moved forward, by rolling the milled portion of the shaft under the fingers, until the arm *e* strikes the stop on the plate *a*, when the plate is allowed to regain its former position and the line is drawn. In drawing the successive lines the operation is repeated.

Section lining is done along the straight edges of the segmental openings, and curved lines are formed along the curved sides of the openings. Various designs may be duplicated by fastening patterns to the plate *a*, so that they will move with it.

Pattern makers use a rule whose divisions are made a certain per cent. longer than standard measure. Iron castings shrink in cooling about 1 per cent. or ⅛ of an inch to the foot. The patterns require to be made proportionately larger. By using the rule ⅛ of an inch in a foot longer than the standard, every measurement of the pattern is made proportionately larger without the trouble of calculation.

Desk rules are either flat, round, or hexagonal. The flat rulers have a beveled edge to avoid blotting the paper with ink flowing from the side of the pen. For adjustable and parallel rulers, see "*Mech. Dict.*," Figs. 4497, 4498, p. 2001.

An instrument for guiding a pen or pencil in drawing straight or curved lines.

Rule Cut′ter. A machine for cutting to lengths rules and leads used in the composition of rule, column, or table matter.

Fig. 2180.

Rule and Lead Cutter.

The front gage is for cutting narrow strips or spaces, and the back gage is reversible, so that it may be set to cut to 9″ in length.

Ru′ling Ma-chine′. William A. Rogers, of Cambridge Observatory, Mass., has a machine for ruling microscopic lines on glass. It will rule 80,000 parallel lines in an inch.

See paper by *Prof. Rogers*, in the "*Proceedings of the American Academy of Arts and Sciences*," where Nobert's plates are considered and the method of their production discussed. Also the modes of preparing diamond ruling-points. See NOBERT'S PLATES, p. 1581, "*Mech. Dict.*"

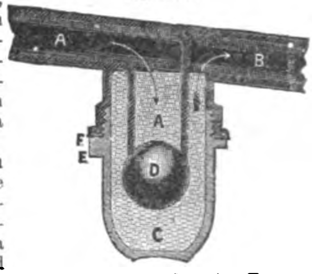
Run′ner. On the stick of an umbrella, the tubular piece to which the stretchers of the ribs are swiveled.

Higgins' automatic runner . .	* "*Engineer*," xlii. 165.

Run′ning Board. (*Railway*). A board placed over the ridge or center of a freight-car roof, and extending the whole length of the car, and which is provided for train-men to walk or run on, in going from one end of a train to the other. — *Forney*.

Run′ning Trap. A depressed bow-shaped section in a pipe, forming a U, through which water passes freely, but the depression remaining filled with water, affords a seal.

Fig. 2181.



Bower's Sewage Running Trap.

AA — Inlet pipe connecting directly with the wash-stand, sink, or other fixtures.

B — Outlet pipe connecting directly with the main waste-pipe.

C — Cup-shaped chamber which always remains filled with liquid up to pipe *B*, thereby floating the hollow rubber valve *D* firmly to the mouth of the pipe *A*, and making a perfect seal.

E — Is a small lug on the cup, to enable a person to screw and unscrew the cup easily.

F — Is a rubber gasket to prevent leakage from the joining of the cup to the body of the trap.

Rus′sian I′ron. The smooth, glossy-surfaced sheet-iron of Russia has been imitated in many quarters with varying success. Below we give one process, furnished by M. Koulibine, a Russian engineer: —

These polished sheets are manufactured from charcoal iron, produced in finery fires and brought into the form of blooms about one inch thick. These blooms are heated to cherry heat and rolled into leaves. Each of these leaves is cut into pieces corresponding to the weight of the sheets which are to be manufactured, and these pieces are piled upon one another and rolled together until the desired degree of thinness is attained. Thus the black sheets are manufactured. To transform these into polished sheets a certain number at a time are heated to red heat and piled one upon another, a black, impalpable powder, which is simply pulverized charcoal, being sprinkled between each two sheets. The bottom and the cover of each packet of sheets thus piled for polishing are formed by two sheets of greater thickness. This packet is then hammered for the purpose of reducing the sheets still further in thickness, under a hammer, the head of which weighs from 1,000 to 1,100 kilograms (say 2,200 to 2,400 lbs.). For giving polish and luster, the sheets, now almost cold, are brought under a second hammer with a large face, rounded at the edges and of the same weight. Finally they are allowed to cool completely, and are then clipped and classified into three classes, according to the perfection of their polish. The sheets of the first class ought to be like a mirror, without a spot upon their surface. The action of charcoal projected upon the red-hot surfaces, and inclosed between them without access of air, may be easily understood. It cements, and thus enables them to take a high polish, while rendering them at the same time less liable to rust. This cementation once having taken place, the sheet should not afterward be returned to the heating furnace. Whether the non-oxidizable quality is due to a carburation of the surface by cementation or by an oxidation which has been supposed to take place in the somewhat tedious process of manufacture, is not yet fully decided. The high quality of the iron used by the Russians has no doubt much to do with the merited popularity their final product enjoys. In the same category is the fact that, while we make most excellent wire from our own iron, we have not yet been able to produce an article quite equal to the Swedish rods for certain purposes. We have no doubt but that in time the American product, or "imitation Russia," which is now perfectly adapted to many uses, will eventually be made equal in all respects to the genuine Russian and exclude it from our markets; but this result will only be accomplished by greater care and skill in manufacture.

See "*Mech. Dict.*," p. 2005.

Rust. It has usually been supposed that the rusting of iron depends principally upon moisture and oxygen. It would appear, however, from the late Dr. Calvert's experiments, that carbonic acid is the principal agent, and without this the other agencies have very little effect. Iron does not rust at all in dry oxygen, and but little in moist oxygen, while it rusts very rapidly in a mixture of moist carbonic acid and oxygen. If a piece of bright iron be placed in water saturated with oxygen, it rusts very little; but if carbonic acid be present, oxidation goes on so fast that a dark precipitate is produced in a very short time. It is said that bright iron placed in a solution of caustic alkali does not rust at all. The inference to be derived is that, by the exclusion of moist carbonic acid from contact with iron, rust can be very readily prevented.

To take rust out of steel place the article in a bowl containing kerosene oil, or wrap the steel up in a soft cloth well saturated with kerosene; let it remain 24 hours or longer; then scour the rusty spots with brick-dust. If badly rusted, use salt wet with hot vinegar; after scouring, rinse every particle of dust or salt off with boiling hot water: dry thoroughly; then polish off with a clean flannel cloth and a little sweet oil.

Or brush with a paste composed of ½ oz. cyanide potassium, ½ oz. Castile soap, 1 oz. whiting, and water sufficient to form a paste. The steel should first be washed with a solution of ½ oz. cyanide potassium in 2 oz. water.

Rust Ce-ment′. Make a stiff paste with 2 parts of sal-ammoniac, 35 parts iron borings, 1 part sulphur and water, and drive it into the joint with a chisel; or, to 2 parts of sal-ammoniac and 1 part flowers of sulphur, add 60 parts of iron chips, and mix the whole with water, to which one sixth part vinegar or a little sulphuric acid is added.

Or mix 100 parts of bright iron filings or fine chips or borings with 1 part powdered sal-ammoniac, and moisten with urine; when thus prepared, force it into the joint. It will prove serviceable under the action of fire. All the above parts are by weight.

Rust, Preserving Iron from. Dodé's method is to coat the surface to be protected with a thin film of borate of lead, having a little oxide of copper dissolved in it, and having also suspended in it bright scales of precipitated platinum.

A red heat is employed to fuse the composition, which is applied by brush or bath. The effect is to cover the iron with a thin, glassy coating of a bright gray tint, unaffected by sewer gases, dilute acids and alkalies, and the heat of a fire.

See article by *Stoffel* in "*Jour. Soc. Arts*," Br., 1879, republished in "*Van Nostrand's Mag.*," xx., p. 13 *et seq.*

Or, paint with melted caoutchouc, to which some oil has been added. The caoutchouc must be melted in a close vessel to prevent its burning, and should be frequently stirred.

Dr. Sterling's plan is to impregnate the structure of the metal while heated with a non-oxidizable substance, — say paraffine or mineral oil.

Barff's plan is to convert the surface into magnetic or black oxide. *Journal Soc. of Arts.*

S.

Sa-bot′. The iron shoe or point of a pile.

Sa-bot′ Ma-chine′. A machine for making the wooden shoes (sabots) extensively used in Europe.

The machines of M. Arbey, Paris, complete the shoe in three operations. The blanks first pass to the shaping machine, adapted to all sizes, where the shoe receives its shape. A second machine hollows the inside, while a third machine gives them the finishing touch and shapes the sole.

Sabot mach., *Arbey*, Fr. * "*Engineer*," xlvii. 255, 262.

Sac-char′i-fi-er. An apparatus for treating grain and potatoes by steam under high pressure, for converting the starch into sugar previous to the alcoholic fermentation.

The grain or potatoes are mixed in a boiler, with about three times their weight of water. Steam is then admitted in such a manner as to constantly stir the entire contents. When steam is admitted to the boiler, the air is allowed to escape through a valve. As long as the latter is kept open the water condensed within the boiler is allowed to run off. When the air has been forced from the boiler, all valves are closed. The material is then subjected to the combined action of heat and pressure for three or four hours, samples being taken from places provided, for inspection. At the end of that time the liquid is of a dark yellow color, and the starch has been completely converted into sugar, although the grains on the pieces of potatoes retain their original shape. Care must be taken to introduce the steam slowly, and to regulate the pressure carefully, or a portion of the sugar will be converted into caramel, unfit for the formation of alcohol. When this operation has been finished the mash is blown out, under pressure, into the mill, the solid particles crushed and the mashed formed into a thin paste possessing all the qualities necessary for the formation of alcohol.

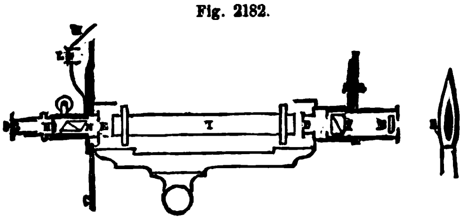
Sac′cha-rom′e-ter. An instrument for determining the value of sacchariferous juices.

The method of determining these values by means of the specific gravity will always find wide application because of its simplicity and satisfactory results.

The action of the saccharometer depends on the fact that ordinary light, when transmitted through or reflected by certain bodies, acquires certain properties which it did not before possess. Among other properties conferred upon the light is that of displaying gorgeous prismatic colors when caused to traverse certain liquids and crystals. These colors, when brought into view by means of a solution of cane sugar, are the more vivid as the solution is more concentrated.

In Laurent's new saccharometer the light from a fixed monochromatic yellow flame is passed through a diaphragm containing a plate of bi-chromate of potash, which absorbs the violet and blue rays. The yellow rays which pass it fall on a bi-refracting prism which turns on the longitudinal axis of the instrument, and in which the second image is diverged to one side and intercepted by diaphragms. One of these carries a thin plate of quartz parallel to the axis, which covers only one half of the diaphragm. Its thickness is one-half wave for the yellow rays. Between this diaphragm and a second one the testing tube containing the sugar solution to be tested is placed. In front of the second diaphragm is the Nichol analyzer, an objective and a concave eye-piece.

Fig. 2182.

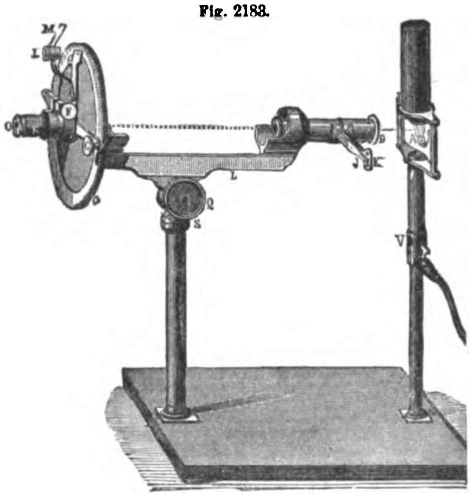


Saccharometer.

The latter three parts inclosed in a tube revolve, the angle through which they move being indicated on an alidade.

In Fig. 2182 *A* is a yellow monochromatic flame, placed at an invariable distance from the instrument. The burner is constructed so as largely to augment the intensity of the flame. *B* is a diaphragm containing a plate of bichromate of potash, which absorbs the violet and blue rays which exist in the flame, while allowing the useful yellow rays to pass. *P* is a bi-refracting prism, in which the second image is diverged to one side and intercepted by diaphragms. It turns on the axis *O E*. *D* is a diaphragm carrying a thin plate of quartz parallel to the axis, the thickness of which is one half wave for the yellow rays. This is fixed and covers but the half of the diaphragm. *E* is another diaphragm: *N*, the analyzing Nicol; *H*, the objective; *O*, concave eye-piece. The system, *O H N*, is mounted on an alidade, which turns on the disk *C* around the axis *O E*. *T* is the tube containing the solution to be tested. *C* is a graduated disk having one or two divisions; one especially for sugar, the other in half degrees of the circle for any rotary substances. *L* is a lens for reading the scale. *M* is a mirror throwing the light of the burner on the divisions and thus obviating the need of any

Fig. 2183.



Saccharometer.

additional light. The new optical disposition consists in the polarizing system, which is composed of two distinct parts — the bi-refracting prism *P* which turns, and the diaphragm *D* which with its half plate of quartz is fixed. In Fig. 2183 this diaphragm is represented enlarged, as it is seen on looking into the instrument. The left half is covered by the quartz plate, the axis of which is also parallel to the line of separation *O A*, and the right half being open allows of the passage without deviation of the polarized light from the polarizer *P*, Fig. 2182.

Sack'er and Weigh'er. A spout with sliding door admits the grain or material to be weighed from the receptacle above. The bag is clipped by a ring to the funnel which is suspended from the back end of a suspended steelyard. When the amount the steelyards are set for is received into the sack, the slide is closed and the flow cut off.

Sack Hold'er. An inclined frame, braced against the floor, forms a rest for the sack in filling while a ring holds the mouth of the sack open and forms a rest for the vessel used in filling.

Sack Emp'ti-er. A contrivance by means of which through a winch, ropes, and capstan, a frame which holds the sack in filling is elevated and tipped to empty the sack.

Emptier	* "*Scientific Amer.*," xl. 19, Fig. 5.
Filler	* "*Scientific American*," xl. 19.

See also BAG FILLER.

Holder . .	* "*Scientific Amer.*," xl. 20, Fig. 8.
Lifter	* "*Scientific American*," xl. 19.
Truck	* "*Scientific American*," xxxix. 323.

Sack Hold'ing Truck. One arranged to hold the sack in vertical position while being filled and having a hoop to hold the mouth open.

Sack Lift'er. 1. A sliding frame on which the sack rests, is elevated by means of a winch to the proper height to shoulder, when the sack is filled.

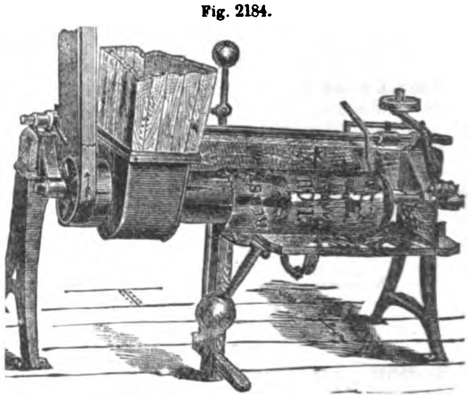
2. A clutch on the rope to catch the gathered end of a filled bag, and lift it up into the mill.

Sack lifters, emptiers, etc. . * "*Scientific American*," xl. 19.

Sack Pack'er. A machine for packing flour in sacks. See Fig. 2184.

The operator places the bag on the screw tube as shown in the engraving, and draws the piston head against the bottom of the bag. He then lifts the tumbling ball, by which movement the belt is shifted to the tight pulley starting the screw to packing the sack. While the bag is being filled the receding piston changes the belt to the loose pulley by means of the shifting rod, and thus stops the screw, enabling the operator to set the stop collar so as to put any amount of flour in the sack that may be desired. When the screw stops, the operator places his foot on the treadle, dropping the sack into an upright position ready for removal, and by this means catching the spill. The sack being removed, a weight returns the turning board to a horizontal position. When this

Fig. 2184.



Sack Packer.

device is used as a mixer, the conveyor flights on the screw pulverize the lumps and mixes in the passage through the horizontal screw tube, discharge being made into a bin below by means of muslin bag or hose.

By the use of reënforce rings on the end of the screw tube, bags of from 12 to 60 pounds' capacity can be packed without changing the tube. Its capacity is from 2 to 4 sacks per minute.

Fig. 2185.

Saddle.

Sad'dle. Fig. 2185 is a view of the saddle complete, with bag, used in the United States mounted service. No padding or raw hide is used. The round, smooth-cut pommel is made as low as possible to escape the highest withers, and the seat is long and flat, the cantle rounding very little. The trees are made by machinery to avoid inequalities, and the bearing surface made as long as possible to distribute the weight over the back of the horse, the whole length of the saddle.

Sad'dle Brack'et. A bracket shelf in a stable or harness room to hold a riding saddle.

Sad'dle Clip. A clip which straddles the spring and axle, and the legs of which are secured by bolt nuts. Fig. 145, p. 61, *supra*, Fig. 150, p. 62, *Ibid.*

Safe. A receptacle where valuables may be deemed safe from attacks of fire, burglars, etc. Generally iron or steel cases, variously prepared. See "*Mech. Dict.*," pp. 2013, 2014, 2015.

Figs. 2186, 2187, are sectional views of the Corliss spherical revolving safe composed of an outer and inner shell, the latter revolving within the former, forming both the door and the receptacle for valuables. The outer shell forms about two thirds of a sphere, and is made in two parts, so that the inner part, called the safe, can be placed within it; these parts are screwed together, as indicated in section, by a screw the whole diameter of the safe. The jointing surfaces of these two parts are ground to an accurate fit, and screwed together like hose coupling, leaving no space between them and making the shell practically one solid piece of metal. The interior swinging part is also one solid piece of metal about four inches thick. The outside diameter of this sphere corresponds with the inside diameter of the larger one, and the joint between the spheres is formed by a series of steps which increase in diameter towards the interior of the safe. The joint is circular and is made an accurate fit, the outside steps being made by grinding, and the inner ones bored and turned by machinery adapted to the purpose. To guard against accidents this safe is always provided with two locks, either of which will open it. The locks may be set on the same or different combinations, and in case either lock should fail from any reason to operate, the safe can be opened by the other. Either time locks, or the ordinary combination locks are employed. The drawings sufficiently explain the inside arrangement and workings.

Safety Winch . .	See SAFETY CATCH; SAFETY HOIST; CAGE: ELEVATOR, etc.

Safe'ty Bolt. One in which the pin is locked in position by padlock or other device.

Safe'ty Brake. An attachment to a crane or other hoisting apparatus to control the rate of descent of an object. It usually consists of a band on a drum, which by pinching opposes the rotation of the latter. See SAFETY HOIST.

Safe'ty Catch. A device to prevent the falling of the cage in the event of the breaking of the rope. Safety catches attached to the cage are held away from the guides while the weight of the cage hangs on the rope, are released and spring against the guides as soon as the strain is taken from the rope, either by its being broken or otherwise. A safety hook detaches the cage from the rope if it is hoisted too far, and "landing dogs" prevent it from being accidentally lowered or dropped into the shaft, when it has been once hoisted above them at the pit-head. See Figs. 4539–4541, "*Mech. Dict.*"

In Cousin's counterpoise catch, used in the Bernissat pits in Belgium, a wedge is forced into the loop encircling the guide-rope by a spring as soon as the hoisting-rope breaks. The wedge is made of wood, and is provided with steel points to insure its taking a hold on the guide-rope in case of an emergency. In ordinary hoisting the wedge is withdrawn and the loop slides freely on the guide-rope. In the counterpoise arrangement, the guide-rope is attached at the bottom of the shaft, but its upper end runs over two pulleys and carries at its end a series of counter-weights placed one upon another, attached by chains. As soon as the winding rope breaks the wedge seizes the guide-rope, which is drawn downward by the weight of the falling cage. This causes the counter-weights to be lifted one by one until the cage has come to a stop, thus avoiding any injurious tearing strain upon the guide-rope.

Safe'ty Chain. (*Railway.*) A chain to attach certain parts to prevent their becoming entirely detached in case of the parting of the main connections.

Among such are coupling chains of platforms, of the brake-rods, etc. — *Forney's "Car-builders' Dictionary."*

Safe'ty Cyl'in-der Cock. A safeguard against injury to a steam cylinder by an accumulation of water. The water of condensation is let out of the cylinder without waste of steam.

Safe'ty Disk. A disk of light sheet-copper is placed across the boiler between the steam and an escape-pipe. An over-pressure of steam fractures the disk and allows the escape of the steam through the pipe.

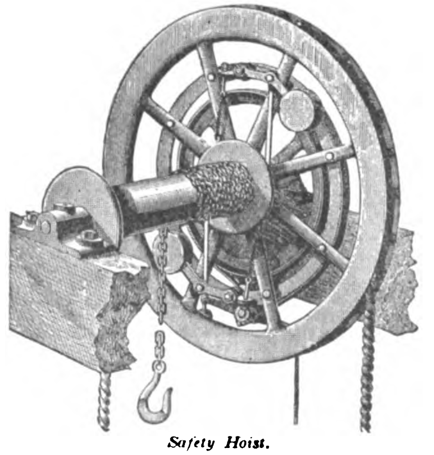
Safety disk for boilers, *Rowan*, Br. * "*Engineer,*" xliv. 148.

Safe'ty Hang'er. (*Railway*). A metallic loop to prevent the falling of a rod in case of breakage.

Among such are those for brake-rods, etc. — *Forney.*

Safe'ty Hatch. A form of safety hatch for elevators, to close the hatchway when the cage is not in the act of passing. The doors are automatic, being pushed aside by oblique bars above the cage in ascending, and by similar bars beneath the cage in descending. The doors are returned by counter-weights. The safety attachment may be seen in detail in CAGE, ROPE ELEVATOR, SAFETY STOP.

Fig. 2188.



Safety Hoist.

Safe'ty Hoist. In Fig. 2188 the safety brake is applied automatically by the governor within the rim of the sprocket-wheel, so that the load, once started down, it is left to itself while the operator gets the next load ready.

Safe'ty Hook. In mines, a hook arranged to clutch a support and hold the cage, should the hoisting rope break through overwinding.

Safe'ty Lamp. A lamp to prevent explosions from fire-damp. See "*Mech. Dict.*," p. 2016.

Coquillon utilizes the property possessed by palladium, of remaining red-hot in a mixture of gas and air at the expense of the compound, in the construction of miners' safety-lamps. The lamp cannot cause an explosion without the palladium giving timely warning.

Dubrulles has invented a lamp which cannot be opened without extinguishing the flame.

Safe'ty Link. A device, a substitute for the safety or check-chains which couple cars to their trucks. Invented by *Thompson*.

* "*Railroad Gazette*" . . . . viii. 117.

Safe'ty Loop. One of the loops by which the body-strap of a vehicle is attached to the body and perch to prevent dangerous rolling of the body.

Safe'ty Pa'per. In addition to what has been stated on page 2017, "*Mech. Dict.*," where about thirty distinctive processes are cited, an improvement in the manufacture of paper for bank notes, bonds, checks, etc., by Mr. Geo. W. Casilear, Superintendent of Engraving, U. S. Treasury Department, may be mentioned.

"This invention relates to the manufacture of bank-note and other commercial paper by coloring the pulp contained in separate compartments with different coloring matter, or by the use of different colored fibrous substances while in the pulp, contained in separate compartments.

"The pulp, having been prepared in the usual manner, is emptied into chests or tubs corresponding in number with the kinds or distinct colors of fiber desirable to be used in making the paper. From thence it is delivered into the compartment vats, each compartment being assigned for a color or alternate color, silk fiber, or other suitable material desirable for making distinctive paper. At the top of the vat is a series of gates, by means of which the flow of pulp is regulated as it passes over the trough and lip and falls upon the endless wire or web. The trough and lip is also subdivided by using thin partitions of brass, to correspond in number and to connect with the compartment-partitions of the vat. The operation being now apparent, the pulp of two or more colors passes over the lip or ledge in separate streams, the colors being divided by the thin partitions in their passage, and unite as they fall upon the endless wire, upon which it forms itself into paper of colored stripes or other material, composed of whatever character of pulp is used in the compartment-vat, desirable for making distinctive papers."

Bank-note paper, Br. . . "*Scientific American Sup.*," 1298

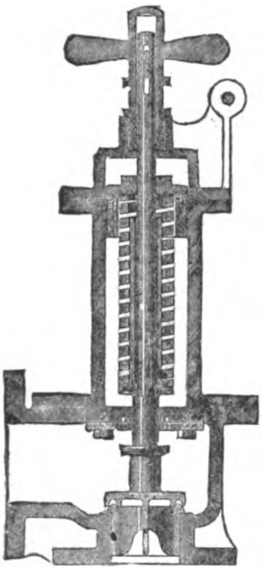
Safe'ty Pin. 1. A temporary pin in a percussion fuse, to prevent the plunger from striking accidentally against the percussion powder. It is held in place by a wire which is ruptured by a weight attached to it when the gun is fired. Fig. 17, p. 523, "*Ordnance Report*," 1877.

2. A garment pin bent on itself, and having a loop which retains the point shut and prevents pricking.

Safe'ty Valve.

Fig. 2189 is a form of valve much used on leading steamships. The peculiarity of the valve consists in the grooved seat V, which has the effect to augment the area at the moment the valve lifts. The result is the valve will blow off to its maximum capacity with an increase of but two or three pounds' pressure in the boiler, and will close tight the moment the pressure falls a couple of pounds below that to which the valve is loaded.

Fig. 2189.

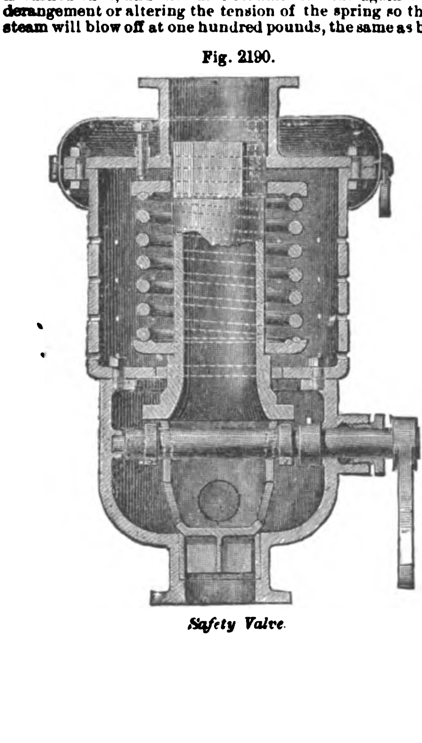


Safety Valve.

In Fig. 2190 the outlet for the steam is carried through the center, and the pressure is always perfectly fair on the valve, there being no side-action whatever, thus rendering the valve very sensitive, and equalizing the wear.

Fig. 2191 is especially adapted to steam fire-engines, where quick stoppages are necessary. Should the safety valve be set to blow off at one hundred pounds, and it be necessary to stop the engine with only fifty pounds of steam in the boiler, it will not be necessary to wait until the steam rise to one hundred pounds, but the wheel *h* is given a half turn up against the valve-spindle *g*, where it will remain and the steam blow off until the wheel *h* is turned back, and the valve resumes its seat again without derangement or altering the tension of the spring so that the steam will blow off at one hundred pounds, the same as before.

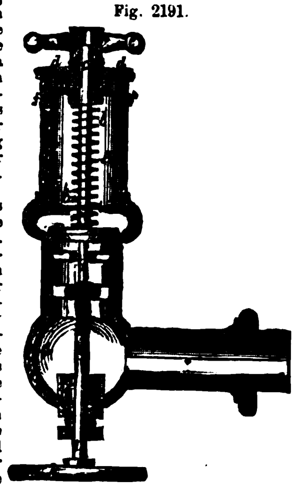
Fig. 2190.



Safety Valve.

Ashcroft's valve has a hollow semi-circular ring on the conical part. The lower seat of the valve has a corresponding annulus at its top, somewhat larger than the one in the valve proper. When the valve is lifted to a slight extent, the steam is momentarily arrested in this space, thus producing a greater pressure, and lifting the valve to a greater height, similar to Fig. 2189.

Fig. 2191.



Steam Fire Engine Valve.

Blake's safety valves are globular, and the orifices are annular. They require no guide-wings or pins, and can oscillate freely on their seats, and are not likely to stick, as they cannot wedge themselves down in the seatings, whilst it is claimed they have nearly double the discharging power of an ordinary valve of the same diameter, and that with a lighter weight on them. The usual size of valve made by Mr. Blake has a 3¼″ outside seating and a 2¾″ inner one. Thus the discharging power of this valve equals an ordinary valve, 6¼″ diameter, while the weight required to load it to 60 lbs. per square inch is only 220 lbs., whereas a 6¼″ valve would require 1,840 lbs. to load it.

Safe'ty Valve, Noise'less. Baird and Allen have patented an arrangement for obviating the noise of escaping steam.

The devices are an expansion chamber and an annular nozzle placed in the locomotive chimney, the effect of which is to produce a regular noiseless escape of steam, instead of an intermittent and sonorous one as at present. The steam from the cylinders, instead of passing directly through nozzles, is discharged into a chamber of ten times the capacity of the cylinders, which will allow the steam to expand in volume and greatly reduce its pressure, so that the noise of puffing will not be heard more than ten feet away.

The Ashton Noiseless Blow-back Safety Valve, is claimed to do away with the din of the steam escaping from ordinary locomotive pop valves, at the same time effecting a considerable saving of fuel. It is so arranged that when the boiler is eased from overpressure, the escaping steam is conducted either to the feed water in the tender, to a muffler, or to the smoke-stack.

Sa'fre. (*Glass.*) The usual French name for the crude oxide of cobalt used as a blue in glass-making. See ZAFFER; COLORED GLASS.

Sail Sew'ing Ma-chine'. A large-sized sewing machine with extensive table for sewing widths of duck to form sails. Used also for sewing sack, bags, tarpaulins.

Sews straight or zig-zag stitch, with dry or tarred twine. Is made single or double, in the latter case to run two seams at once.

Sal'a-man'der. 1. A mass of waste metal from a break in a metallurgic furnace.

2. A cooled mass of metal and cinder in a blast furnace in which the contents have proved refractory and the fire has died out.

Account of blasting a salamander with dynamite. "*Iron Age*," xvii., April 20, p. 9.

Sal Am-mo'ni-ac Bat'te-ry. (*Electricity.*) One in which chloride of ammonium is used as an exciting liquid. See LECLANCHÉ BATTERY.

A *bagration* battery is one in which the elements are immersed in a jar filled with earth sprinkled with sal ammoniac.— *De la Rive.*

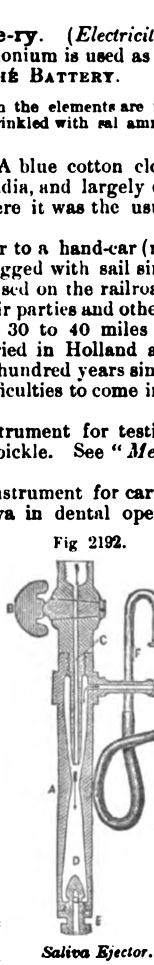
Sa-lam'pore. (*Fabric.*) A blue cotton cloth formerly made at Nellore in India, and largely exported to the West Indies, where it was the usual slave cloth.

Sail'ing Car. A car similar to a hand-car (minus the operating devices), is rigged with sail similar to that of an ice-boat and used on the railroads on the plains, by telegraph repair parties and others, have attained a speed of from 30 to 40 miles an hour. Sailing chariots were tried in Holland and other countries, more than two hundred years since, but labored under too many difficulties to come into common use.

Sal'i-nom'e-ter. An instrument for testing the strength of a brine or salt pickle. See "*Mech. Dict.*," page 2022.

Sa-li'va E-jec'tor. An instrument for carrying off the accumulating saliva in dental operations. In Fig. 2192, the end of the saliva tube *F* is inserted in the mouth of the patient, and a jet of water under pressure passed through the narrow throat of the instrument in the direction of the arrows, drawing the saliva into the vacuum chamber *D*, and out through the end. The check valve *E*, sets the water back in such manner as to close the throat to the external air and produce a vacuum in the chamber above.

Fig 2192.



Saliva Ejector.

Sa-li'va Pump. For withdrawing saliva from the mouth during dental operations. See "*Mech. Dict.*," p. 2023.

Salt Man'u-fac'ture. The manufacture of salt and bromin is carried on very extensively in the Ohio Valley. The salt is shown by chemical analysis to be the purest in America, and its perfect freedom from lime renders it very desirable for dairy use. The salt water is obtained by boring wells from 800 to 1,000 feet through a variety of soil, solid rock, and usually two stratas of coal. It is first pumped into a wooden cistern to settle, then run into iron pans, and boiled until ready for crystalizing, then drawn off into wooden grainers, through which copper pipes of 3 or 4 inches in diameter, filled with steam, pass the entire length of the grainer, heating the brine to an equal temperature. The salt crystals form on the surface, and are prevented from adhering firmly by mixing a small quantity of butter or tallow, which separates them, and they gradually fall to the bottom of the grainer and become salt proper. It is then lifted on platforms by workmen, and left to dry for 12 hours, after which it is packed into barrels, weighed, and ready for market. The salt analyzed shows: Sodium chloride, 97.5; Moisture, 2.0; Foreign matter, .5.

From the waste, or mother-water of the salt works, bromin is extracted, and forms an extensive article in trade, selling at one time for $9 per pound, the specific gravity being about three times that of water. There are six bromin factories in this locality, and when all are in operation they control the price of the foreign market. However, bromin, like all other merchandise, has shared in the decline, and is now sold for 34 cents per pound. The increasing demand for the article for medicinal purposes, and by chemists, dyers, and photographers, has made it a source of immense profit. Large quantities are annually exported.

For apparatus, see "*Mech. Dict.*," 2023, and *Laboulaye's* "*Dictionnaire des Arts et Manufac.*," tome iii., article "Sel."

Salt manufactory, Mich. * "*Scientific American Sup.*," 1621.

Salt Mill. For pulverizing the coarse salt into table salt.

Salt-pe'ter Man'u-fac'ture. The process of securing the saltpeter from the crude nitrate of potash.

Saltpeter manufacture . "*Scientific American*," xxxiv. 5.

Salt-pe'ter and Sul'phur Grind'ing Mill. (*Gunpowder.*) A machine for grinding and incorporating these ingredients in the manufacture of gunpowder. It consists of two edge wheels in an annular pan: the Chilian mill.

See "*Ordnance Report*," 1879, Appendix I.: Plate I., Fig. 2, and description on p. 98.

Salt-pe'ter, Sul'phur, and Char'coal Mix'ing Reel. (*Gunpowder.*) An inclined cylindrical reel, like a flour bolt, used to sift the combined materials.

See "*Ordnance Report*," 1879, Appendix I., Plate I., Fig. 3, and description on p. 99.

Sam-mi'er. (*Leather.*) A machine for pressing water from skins in the process of tanning.

Sam'ple Case. A case for carrying and displaying quality of goods to be inspected.

Sample case, *Davis* * "*Scientific American*," xl. 372.

Sam'ple Cut'ter. A species of rotary shears. A sharp edged disk on a table rolling against an edge and cutting narrow strips of cloth from the roll, to form tailor's or traveler's samples. *Dartois*, French.

Sam'ple Scale. A finely balanced lever scale weighing one pound by $\frac{1}{10000}$. Used for weighing articles in bulk by accurately weighing small proportional quantities.

Sam'ple Spig'ot. A small faucet in the head of a cask.

Sand Band. (*Vehicles.*) A metallic ring on the inside of the hub, extending over a portion of the axle and designed to keep sand and mud from entering the axle-box.

Sand Bar. A bank formed by the settling of sand or silt when one stream empties into another, or a river into the sea. Mode of removing, *Boulogne sur Mer*, * "*Scientific American Sup.*," 1554.

Sand Ap-pli'ance.

Sand distributor. *Chambers*	* "*Engineer*," xlix. 488.
Sand-drying furnace	* "*Engineering*," xxiii. 502.
Sand-papering machine, Flexible, *Fay*	* "*Engineer*," xlv. 435.

Sand Bat'te-ry. (*Electricity.*) A battery in which the elements are imbedded in cells filled with silicious sand saturated with dilute sulphuric acid.

Sabine, London, 1867 . . . . 228.

Sand Brake. An automatic method of stopping a train when the speed exceeds a desired rate, or when cars are detached accidentally.

In Wiseman's automatic sand brake on the axle of every wheel of the train is placed a cylinder, in which a circular plate, keyed to the axle and bearing a number of small blades, revolves whenever the train is in motion. The blade compartment surrounds a cylindrical compartment, which, being filled with sand, is called the sand-box. The upper and the lower portion of this box are in communication with the blade-box by a number of parts, of which the lower can be opened and closed by means both of an electrical mechanism and automatically, while the upper ones, which are smaller, are always open. A plate, keyed to the axle, opens the lower sand-ports with every revolution, but the sand thus escaping is so small in quantity that it is immediately swept back by the blades into the sand-box through the upper ports. As soon, however, as the electrical circuit, which also controls this sand valve by means of an electro-magnet, is broken, the sand flows from the box very quickly, and, packing the blade-box, stops the train. The same will occur as soon as the train moves too rapidly, or when one or more cars are left behind. It is therefore automatic, and its effect increases with the velocity of the train.

Sand Dry'er. For evaporating the moisture.

Two perforated cylinders, one inside of the other. The inner cylinder is perforated at an angle of 45°, and inclosed with a conical top. The outside cylinder is perforated at about 40°, and both cylinders set perpendicular. A blower forces hot air into the inner cylinder, which, striking the conical top, is forced through the perforations, and passes through the sand placed between the cylinders. The outside perforations permit evaporation.

Sand Fence. (*Hydraulic Engineering.*) An obstruction to a current, made of stakes placed A-shaped and driven, and having brush lashed or wired thereto.

Sand-hold'er. A chamber in a pump-stock in which the sand carried by the water is allowed to deposit before reaching the pump-bucket or plunger.

Sand-pa'per-ing Ma-chine'. 1. (*Boot and Shoe Making.*) A drum covered with sand-paper for giving the desired surface to shoe-soles.

2. (*Wood-working Machinery.*) A machine for scouring, finishing, and polishing flat surfaces of wood.

Sand-papering mach., *Fay & Co.* * "*Scientific Am.*," xl. 89.

Sand Pump. A pump for ejecting sand.

The most notable instances are those of the great bridge pier caissons at St. Louis and New York. The discharge of the sand pumps at the east abutment of the New York and Brooklyn Bridge was over 346 cubic yards in 24 hours.

The general arrangement consisted of a water jet discharging upward through the center of a hollow globe: this globe was placed in the caisson at the bottom of an iron tube which extended upwards through the masonry, and was connected with a flexible tube below; the lower end of the flexible tube was kept submerged in the water below the level of the bottom of the caisson, and this water was drawn upwards by the inducing force of the jet, carrying with it a large quantity of sand; the general arrangement was not unlike that of the Giffard injector.

In sinking the Pier No. 5 of St. Charles Bridge over the Missouri River, Eads' sand pumps removed 18 cubic yards of sand per hour each. They were found to work best with a three-inch discharge-pipe and 200 lbs. per square inch water pressure. Three Cameron pumps, with 12″ × 24″ steam, 6″ × 24″ water cylinders were used to supply two of the sand pumps, and were worked up to their full capacity in so doing.

Sand Screen. A sand sifter.

San'i-tas. Russian turpentine and water are placed in huge earthenware jars, surrounded by hot water. Air is driven through the mixture in the jars continually for three hundred hours, the result being a decomposition of the turpentine, and the formation of a watery solution of the substance, to which Dr. Kingsett, the discoverer, has given the name of "Sanitas." After evaporation, the substance, as sold in tin cans, is a light brown powder, of a pleasant taste and odor, and capable in a very remarkable degree of preventing or arresting putrefactive changes. This new disinfectant has been in use for some time in England, and is highly spoken of. It is said to have a pleasant odor, is not poisonous, and does not injure clothing, furniture, etc. For household uses it would seem to be well adapted.

Sa-pon'i-fi-er. An apparatus for the manufacture of glycerine and the fatty acids, by the decomposition of fats and the isolation of their several constituents; stearic, margorinic, and oleic acids and glycerine.

Droux . . . . . * "*Scientific American Sup.*," 2562.

Sap Spout. A device for holding the bucket to the tree and conducting the sap from the tree to the bucket in sugar-making.

In the Eastern States the first flow of sugar-bearing sap which precedes the bursting of the leaf-buds, is specially called "sap." In Ohio and the West it is called "sugar water," and the later juices, which arise in the tree after the "sugar water" has ceased to run, are called the "sap."

Lawrence . . . . . * "*Scientific American*," xxxv. 325.

Sar'dine Shears. A pair of strong scissors, with pointed blades for cutting open the tin boxes containing sardines, potted meats, etc.

Sash Clamp. A clamp for squaring sash and tightening up the joints.

See Blind Clamp, Fig. 326, p. 106, *supra*.

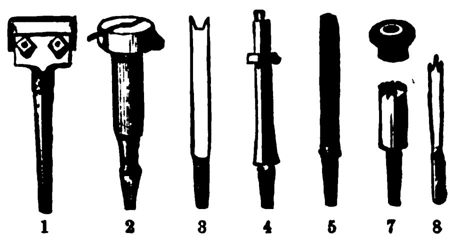
Sash Cramp. A vise for holding sash while putting together.

See Flooring; Carpenters and Joiners' Clamps, "*Mech. Dict.*" and *supra*.

Sash Lift. A handle on a sash for lifting it.

Sash Tools.

Fig. 2193.



1 2 3 4 5 7 8

Sash, Blind, and Pin Tools.

1. Blind slat chisel for stationary slats.
2. Hollow auger, for rounding slat tenons.
3. Double chisel, for sash bars.
4. Staple punch, to prick both rods and slats.
5. Pin tool, for making pins.
6. Tool, for pointing pins.
7. Burr, for rounding slat tenons.
8. Center bit, for blind boring.

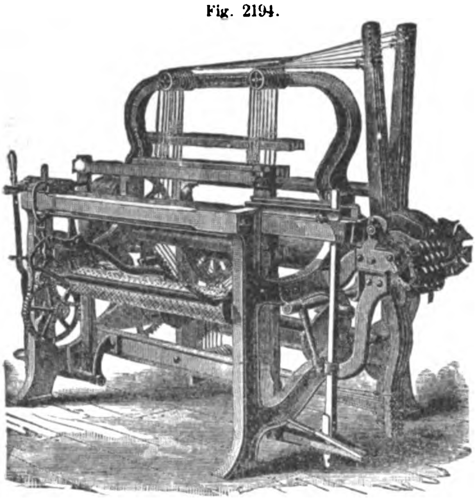
Nos. 1, 3, 4, and 5 may be used in foot-mortising machines. Nos. 2, 7, and 8 in the blind stile boring machine, and small boring shaft.

Sash Rel'ish-ing Ma-chine'. A machine for forming that part of the shoulder of a tenoned piece which projects beyond the part which enters the mortise. This is done at one operation by a cluster of circular saws, part of them set longitudinally of the stuff, with smaller ones set transversely, the front teeth of the small ones being almost in conjunction with the front teeth of the two outside larger teeth, but a little in front.

Sa-tine'. (*Fabric.*) An all-wool French goods with satin weave.

Sat'in-et Loom. A loom designed for heavy goods, such as satinets, twills, jeans, satin stripes, checked cottonades, etc. It usually has 4 boxes at

Fig. 2194.



Satinet Loom.

one end. An endless chain governs and moves the heddle levers and is readily changed to any pattern without the aid of cams. It is of the open-shed type.

The cut shows a plain lathe, single shuttle loom.

Sat'in-ing. (*Fine Art Metal-working.*) A mode of decorating silver-ware by abrading the surface with a wire brush, which is revolved while the object is pressed against it. Soapy water is dripped upon the surface under treatment, the minute scratches giving the sheen of satin.

Sat'in Weave. (*Weaving.*) A style of weaving made on a loom with 5 or more harnesses. See ARMURE.

Sau'sage Ma-chine'.

See STUFFER, Figs. 1105, 1106, p. 359, *supra.*
See CUTTER, Fig. 4587, p. 2032, "*Mech. Dict.*"
See FILLER, Fig. 4588, p. 2032, *Ibid.*

See MEAT CHOPPER, Figs. 1699, 1700, pp. 590, 591, *supra.*
See MEAT ROCKER, Fig. 1702, p. 591, *supra.*

Saw. (*Surgical.*) A large number of varieties of surgical saws are included in the list of saws, p. 2035, "*Mech. Dict.*" See under the following list, which embraces the more important in segregated form: —

Amputating.	Capital.
Bead.	Chain.
Bow.	Circular.
Exsecting.	Maxillæ.
Folding.	Metacarpal.
Heine's.	Post-mortem.
Hey's.	Rachitome.
Interosseous.	Rotating.
Lifting back.	Subcutaneous.

1. Circular saws were first used in Holland. — *Richards.*

The proper periphery velocity of a circular saw is 9,000' per minute, or 100 miles per hour. A saw 12" in diameter should make 8,000 revolutions per minute.

A saw-blade exhibited by Jessop & Sons at Paris, was 10' 8" diameter, 9-16" thick, and weighed 2,638 pounds.

See "*Mech. Dict.*," pp. 2033–2046.

Saw Bra'zing Forge. A forge for brazing the ends of a band or other saw, having an anvil piece with blowing furnace below.

Saw Bench. The bench on which the material rests in being worked.

Fig. 2195 shows the table of a combined cutting-off saw, rip saw, miter sawing, bevel sawing, and dado machine. The saw mandrel is placed on a carriage, and travels on ways. The saw is drawn toward the operator by the foot treadle, which allows the operator the use of both hands to handle the stuff. The mandrel is raised and lowered by means of rack and pinion to adjust the same and dado head to different thicknesses of work.

Saw Guide. An adjustable piece to direct the saw in cross cutting.

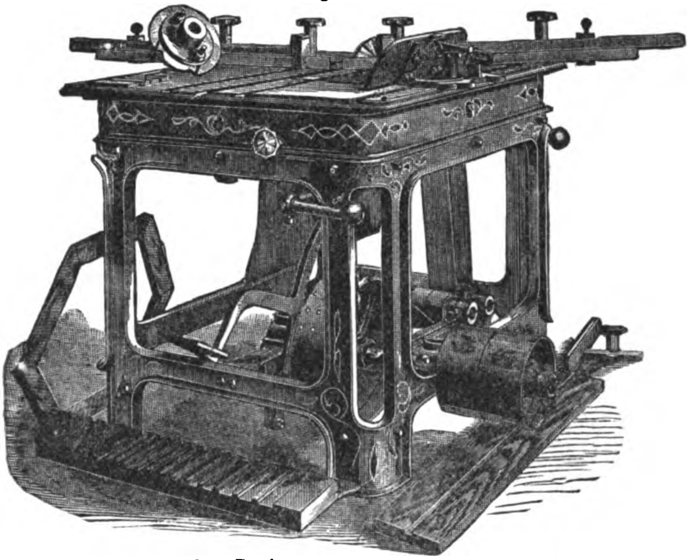
Saw'ing Ma-chine'. One with power-driven saw.

See under various heads in list of 160 kinds of saws, "*Mech. Dict.*," p. 2035.

Saw Joint'er. A device to enable gang saw operators to obtain and retain a correct, parallel, and uniform rake and breast line upon their saws.

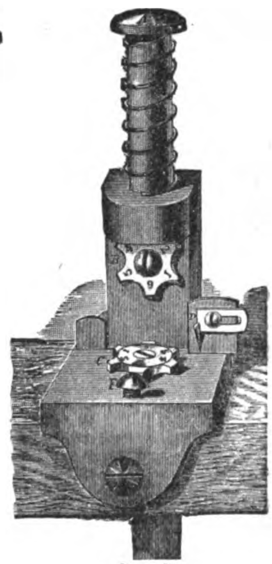
In Pond's saw jointer the saw is placed in a frame having

Fig. 2195.



Saw Bench.

Fig. 2196.



Saw Set.

tracks for the swaging blocks and file holder to travel on. The proper swage and knock-down is given each tooth by two blows on the double swaging blocks. The ways can be run up or down to preserve the breast line of the saws perfect when strained in the gate.

Experience has taught that no matter how carefully saws are strapped, and fitted by hand in the ordinary way, they will, when strained, vary on the rake line from one eighth to one half an inch in the stroke. One of the most important objects to be attained is the keeping of the saws jointed on just such lines as will give, when strained, a perfectly straight breast-line. After a saw is jointed and filed straight, put into the gate, keyed, and properly strained, it will often be found that the teeth are convex instead of being in a line as before the saw was strained. The back is slack. When the strain is forward of the center, that side will be taut, and present a convex edge, which increases or lessens in proportion to the width of the saw and the distance of the strain from the center line. The filer should give the saw a concave that will, when properly strained, become a straight line. To give a concave, so far, the eye alone has been depended upon without any scientific application of instruments. The concave should be made from end to end of the saw teeth, at every point the true arc of a circle. Unless all saws in the gang are jointed exactly alike and exactly right, the result of their action will be to retard the work of the gang, as the saws not properly jointed will wear out first and keep the good saws from performing the work they should do.

Saw Jump'er. A punch to shape the end of saw teeth. See SAW SWAGE.

Saw Set. An implement to spread the teeth of a saw laterally, to regulate the width of the kerf. See "*Mech. Dict.*," p. 2843, 2044.

In Fig. 2196 the plunger is operated by a treadle. The striking part and the anvil are star-shaped and similar in construction. The points are all of different sizes, designed to set different sized teeth.

Saw Ta'ble. A form of sawing machine adapted to trimming the edges of stereotype plates. See Fig. 5794, pp. 2079, "*Mech. Dict.*"

* "*Scientific American*" . . . . xl. 340.

Saw Tem'per-ing. The process by which the saw is given the necessary hardness and elasticity. See TEMPERING, "*Mech. Dict.*," p. 2562.

When large saws are made red hot in tempering and then suddenly cooled, they are frequently bent and buckled. This is usually rectified by a skillful stretching of the rigid spots by hammer and anvil, which liberates the structure until at length it is a flat surface, and runs true as a saw. In the new American system no hammering is resorted to. The buckled saw is compressed in a mold between two flat surfaces, the operation being performed in an oven made on purpose, which is carefully heated up to the proper temperature required to give the saw temper. The oven is allowed to cool down with equal care, and when taken out of the mold the saw is found tempered without being buckled. — *Dr. Anderson.*

Saw Tooth'ing Ma-chine'. One for increasing the depth of saw teeth. See "*Mech. Dict.*," 4616, 4617 *B*, 4636.

Saw Up-set'ter. A tool to turn over or display the teeth of a saw to widen the kerf. See SAW SWAGE.

Scab. (*Founding.*) A protuberance on a casting formed by the washing away of the mold-wall.

Scaf. (*Smithing.*) The tapered extremity or feather edge of a weld-lap.

Scaf'fold. In blast furnace practice, material which has been arched and refuses to melt down.

Scaf'fold-ing. See Elaborate illustrated article, *Laboulaye's "Dict. des Arts et Manufactures,"* vol. iv., ed. 1877, article "*Échafandage.*"

Scales. Devices for obtaining the dimensions or weights of bodies. See "*Mech. Dict.*," pp. 2048–2051, and *supra*, pp. 316, 414, 415.

The American, French (metric), Charriere, and English gages of urethral instruments are given on pp. 5, 6, Part III., *Tiemann's "Armamentarium Chirurgicum.*"

The Fairbanks was the original compound lever weighing scale, though most American scales are of this class.

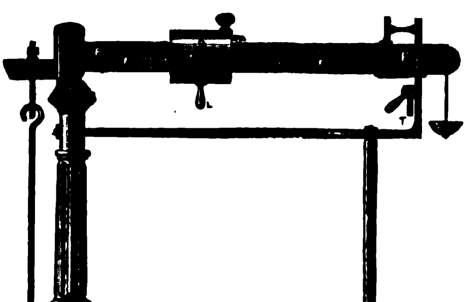
The principle of the platform scales consists in supporting a platform upon a system of four horizontal levers, which are placed in a shallow portable box or in a pit in the ground. These levers are iron bars set on edge, and each hanging upon a fixed knife edge of steel in one of the corners of the box or pit. On the original plan they all met under the center of the platform, their ends resting on the short arm of a fifth lever also of the second order, the long arm of which extended beyond the margin of the platform and was suspended by means of a connecting rod to the short arm of a lever or index beam at a convenient height above the ground. This in all the scales receives the counterpoise and the weights. The platform was fitted to a box or to a recess around the edge of the pit, resting there when not in use. Near each corner a foot projected downward terminating in a steel plate, and as the levers were raised a very little by the depression of the index beam, a knife edge fixed to each of them near the fulcrum reached this plate and together lifted the platform and its load. The weight, it is seen, was thus divided between the four levers resting upon them between their fulcrums and the power, and several times nearer to the former than to the latter. Such proportion of the load was therefore borne by the four corners, relieving the scale beam of this, as the length of the long arm of one of the levers to its whole length. The scale beam was still further relieved by the fifth lever, which was of the same order as the others, and received the weight a little within its fulcrum, which also worked upon a knife edge. In the scales of more recent construction the fifth lever is done away with, and two from the corners and at one end of the box or pit are extended entirely across, meeting each other beyond the opposite end and directly under the scale beam, with which they connect. The other two levers meet the first pair and connect, one with each of them, just midway across. A steel ring at this point hangs upon a knife edge of each of the levers of the first pair, and into this is introduced the knife edge, facing downward, of one of the other levers.

The adjustment of the bearing points is made with the utmost precision, so that the results do not vary if the load is placed successively upon different portions of the platform. Considering the small proportion of the load that actually comes upon the scale beam to be weighed, in the largest machines sometimes amounting to not more than the one hundredth or even the one-thousandth part, the results are surprisingly accurate. At a test made in the Crystal Palace, New York, 52,600 pounds was weighed successively on every portion of the platform of a railroad track scale, and the greatest variation from the main weight was three pounds.

The graduation of the beam is made very exact by machine work, and all the corresponding parts in the scale.

Chamoroy's (Paris) invention is a weighing machine, made to register the weight ascertained, by printing it on tickets during the operation of weighing. This is accomplished by arranging at suitable distances along the edge of the scale beam a series of punches, like those for stamping names or figures on wood or iron, with projecting figures: in a machine for weighing up to a thousand kilograms — about a ton — these figures represent hundreds. A movable plate is inserted in the sliding weight below the beam, and capable of being brought into contact with it by a lever. The ticket is introduced between the plate and the under edge of the beam through an aperture in the sliding weight. These figures print the hundreds; but the tens figures following by a line are set on the under side of a short bar which works in the sliding weight like the bolt of a door. The tickets

Fig. 2197.



Chameray's Registering Scale.

having been already printed with equi-distant spaces numbered to represent the units and divided by dots, when an article has to be weighed, the sliding weight is brought under whichever hundreds figure corresponds to the nearest approximation to the weight, and equilibrium is obtained by moving the short bar, previously mentioned, from left to right in the sliding weight. The ticket is then inserted between the movable plate and the beam, and a smart blow on the lever punches the tens and hundreds figures on the tickets, the position of the horizontal line following the tens figure with respect to the dot and line already printed, permitting of the weight being ascertained and printed correctly to a quarter of a kilogram — ½ lb.

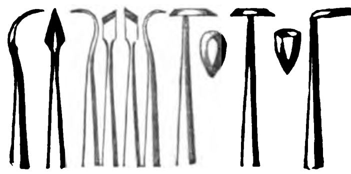
Sca'ler. A dentist's tool for removing scale or tartar from teeth.

Especially shaped and designed for removing deposits of salivary calculus from the necks and interspaces of the teeth.

Fig. 2198.



Dentist's Scalers.

Sca'ling Knife. (*Fishing.*) A knife for removing scales; sometimes has a saw edge.

Scalp'ing. (*Milling.*) Brushing the *hair* or fuzz from the ends of wheat grain to prevent its getting into the flour. One of the refinements of the new wheat processes.

Scan'di-na'vi-an Belt'ing. Cotton cloth woven solid and treated with Stockholm tar. Paper by Cobbett, London Association of Society of Foreman Engineers, reported in "*Scientific American Sup.*," 3800.

Scan'di-na'vi-an Lock. A form of lock for securing hasps to staples. It is made heavy, both branches of the bow withdrawing from the lock. See JAIL LOCK, Fig. 1481, p. 511, *supra*.

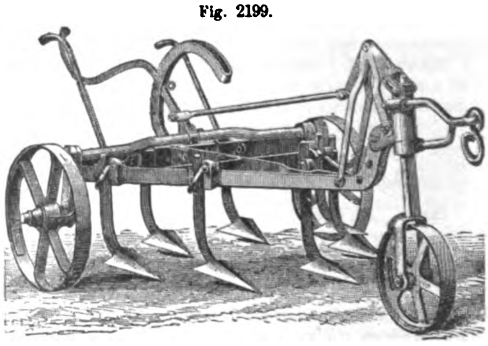
Scar. (*Founding.*) A weak or faulty part in a casting, due to an imperfection of the metal.

Scarf'ing Frame. A holder in which a band-saw is placed while the scarfed ends are brazed together. See BAND-SAW HOLDER, p. 72, and Fig. 199, p. 73, *supra*.

Scar'i-fi-er. A cultivator having long, sharp teeth, with wheels to regulate the depth of cut.

Fig. 2199 is a French horse-power cultivator of the largest class; it is called a *Scarificateur extirpateur*, and is an efficient implement when sufficient power is applied. Seven shares are fixed in the triangular iron frame, the front angle of which has a goose-neck in which the standard of the caster wheel is placed. A single movement of the lever raises or

Fig. 2199.

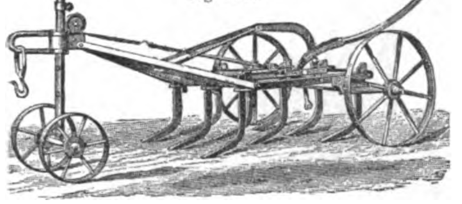


French Scarifier. (*Breloux, Nevers, France.*)

depresses the frame at all points equally, so as to keep it in parallelism with the soil. It resembles some of the cultivators in the series of steam-plow implements.

Fig. 2200 is much like the preceding, but having four

Fig. 2200.



Four-Wheeled Scarifier.

wheels instead of three, and teeth more for stirring than cutting.

Fig. 2201 shows a turning harrow, between a steam cultivator and steam harrow. It is fitted at will for either of two kinds of shares, a broad one for cutting and a square-pointed one for simply stirring the ground. The instrument is in three pieces to accommodate itself to uneven surfaces, and will take in a breadth of 12′ to 15′. The steering frame is adapted to take different harrows, from the lightest seed-harrow up to cultivating tools. On the short end of the turning lever is a chain communicating with a quadrant on the crank axle, and as the lever is pulled around the chain, acting on the quadrant, turns the axle, lifts the frame, and raises the tines out of the ground.

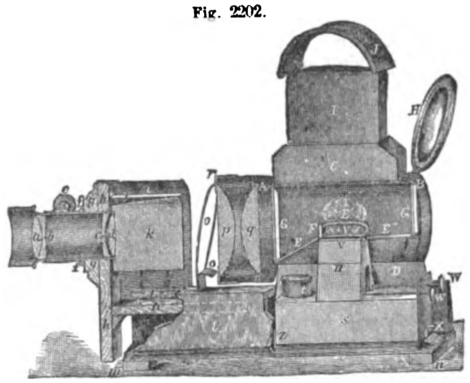
Fig. 2202.



Marcy's Oil-light Sciopticon.

Sci-op′ti-con. A form of magic-lantern for exhibiting photographic objects.

Fig. 2202 shows Marcy's Oil light Sciopticon. The flame-chamber, a distinctive feature of the oil-light sciopticon, is a small dark-lantern in itself, with a front and back-glass, *G G*, suspended by cross-strips in a ventilated protecting shell. Two flames, starting wide apart at *v v*, are deflected as close toward each other as they can be without interfering, over a rising current of air, which thoroughly oxygenates the inner surfaces. The chimney-cap is telescoping, and can be raised or lowered. The reflector *H* is outside the flame-chamber, and answers the purpose of door and reflector. Its burnished surface is kept from tarnishing by a protecting film. The condenser *p q* is suspended free from contact in a chamber separate from the flame-chamber. Its front band presents a good bearing for rests and slides, and the lenses are removable. The extension front is readily removable to give access to the interior of the instrument, and can be drawn forward to suit different lenses.

Schist Oil. Article "*Huile de Schiste,*" Laboulaye's "*Dictionnaire des Arts et Manufactures,*" tome iv., ed. 1877.

Scoop. 1. (*Surgical.*) A ladle or spoon shaped instrument used in removing objects from cavities. Among them are those having the following applications: —

Bone.	Laryngeal.	Sessile tumor.
Cataract.	Lithotomy.	Urethral.
Lens.	Rectal.	Uterine, etc.

Thomas's serrated scoop for the detachment of sessile uterine fibroids has a saw-shaped edge to the scoop.

See also CURETTE.

2. A form of wheel used in lifting water. See Fig. 4677, p. 2055, "*Mech. Dict.*"

3. A spoon-shaped capacious shovel.

4. A bowl-shaped pan on a weighing-scale.

Weighing scoop . . .	* "*Scientific American*," xxxviii. 23.
Scoop, smooth back.	
Hussey, Burns & Co.	* "*Iron Age*," xix., April 5, p. 11.

Scoop Net. (*Fishing.*) A baling net for emptying the fish collected in a pound.

Scor′ing Ma-chine′. The corner cutting and scoring machine is one used in making small boxes of card-board, to cut off the superfluous material from the blank and to make a score on the future angles of the box in order to make the stuff bend readily and accurately at such places.

See PAPER-BOX SCORING AND CUTTING MACHINE.

Score. (*Nautical.*) The groove on the body of a tackle-block to hold the strap.

Scour'er. A form of grain cleaner in which the berry is subjected to a rubbing action to remove all extraneous matters: smut, dust, mildew. See GRAIN CLEANER, SMUTTER, etc., and references *passim*.

Scour'ing. 1. (*Grain.*) A process in which grain is rubbed and brushed to remove smut, dust, mildew, etc.

2. (*Leather.*)

Scouring on the flesh. — On being taken out of the water the skins are spread out and set on the scouring table by passing a steel slicker over the flesh side, which brings the grain in close contact with the table, and, being wet, it adheres to it. A bountiful supply of water is applied and rubbed briskly over the flesh side with a stiff brush, whereby the pulpy portions of the surface are scrubbed off, and the skin presents a soft, whitened appearance and the pores are opened.

Scouring on the grain. — The skin is set on a scouring table by a slicker, which stretches it and at the same time loosens the bloom. The grain side is kept uppermost, and is smartly brushed with a stiff hair brush, using at the same time plenty of water, when the slicker is again used to remove the water and loosened bloom. A stock-stone is often used instead of the slicker to loosen the bloom.

3. (*Fabric.*) A process for renewing the surface of soiled stuffs, removing stains, etc. The dégraissage of the French. *Laboulaye's "Dictionnaire,"* i., "*Degraisseur.*"

Scour'ing Ta'ble. (*Leather.*) A large firmly built table, with a mahogany, bird's-eye maple, slate, or marble top. It is about 12′ long and 4′ wide, so constructed that the water used in scouring may pass off readily upon the side opposite to that on which the workman is engaged.

Scow, Cheap. A small flat boat.

Scow, cheap . . . * "*Scientific American Sup.,*" 897, 410.

Scrap Cut'ting Ma-chine'. A machine for cutting long metal scrap for bundling and reworking. See BAR CUTTER.

Scrap shears.
Parkgate Iron Works, Br. . * "*Engineering,*" xxix. 284.

Scra'per. (*Iron Working.*) 1. A tool used in getting a true face on a metallic surface after leaving the planer.

2. An arrangement for leveling or moving dirt, removing weeds, etc.

A leveling attachment for dirt cars. Two spreading wings attached to the rear car of a construction train run outside the rails near the ties, to level the dirt that has been dumped from the preceding cars.

The Johnson wheeled earth scraper, Fig. 2203, is suspended from the axle by a hanger pivoted at the lower end in the center of the side of the scraper box. The axle being free at the top permits the wheels to roll forward when raising the back end to fill or dump, although the formation of the scraper will not admit of a horizontal position while filling.

Earth car, Leveling attachment for.
Andrews . . . . . * "*Scientific American,*" xliii. 271.
Scraper, Earth . . . . * "*Scientific American Sup.,*" 225.

Pettier's scraper for cleaning in gardens and vineyards has a broad hoe-shaped blade, followed by a row of iron teeth. The blade cuts the weeds and grass off at the surface of the ground while the teeth gather up the grass and weeds, and loosen the soil.

For different scrapers, see pp. 2057-2059, "*Mech. Dict.*"
Wheeled, Fig. 4694, p. 2058, "*Mech. Dict.*"
Revolving, Fig. 4695, p. 2058, *Ibid.*

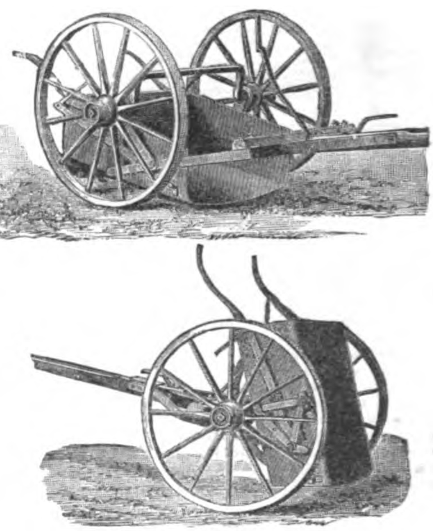
(*Wood Working.*) Fig. 2204 shows Whitney's machine for giving a fine surface to hard woods, particularly where the grain is irregular; a planing machine, in which the wood is carried by rolls suitably placed against a stationary cutter.

This cutter is a steel blade of sufficient length to extend across the machine, secured in a block of such strength as to be safe against springing. This blade is exceedingly sharp,

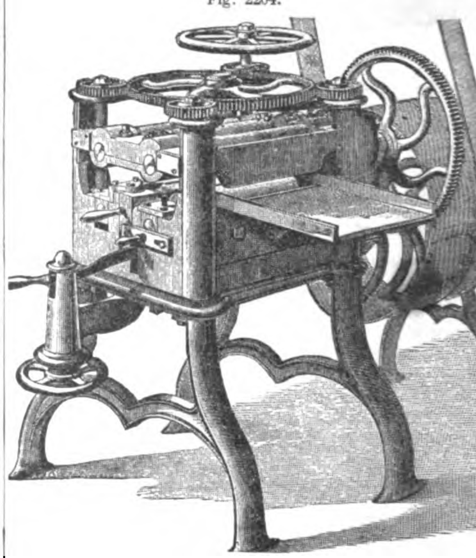
Fig. 2203



Earth Scraper.

and has the feather-edge which is generally considered essential in a scraping-tool for wood. The blade is very carefully set to take the thinnest possible shaving from the surface of the wood, which is given an ordinary good finish on the planing machine before it is sent to the scraper. A little machine accompanies the scraper, specially designed to sharpen the

Fig. 2204.



Wood Scraper.

blade. It consists of a pair of emery-wheels, so set that one can bevel the edge of the cutter while the other squares up the face. The blade is clamped, during the operation, between a pair of jaws, which hold it firmly and precisely in position. As the sharpened blade passes from under these wheels, a stationary steel bar touches the edge, and, sliding along it, turns it, producing the feather-edge.

Scrap'ping. A device for carrying away the scraps of paste, the residuum of the sheet after stamping out crackers, biscuits, or cakes in the machine. See CRACKER-CUTTING MACHINE; PANNING MACHINE.

Scratch'er. (*Plasterers.*) The scratcher is made of pointed slats, set 1" apart, and kept in position by cross pieces; one slat is left longer than the others, and answers the purpose of a handle.

Screen. A separator or partition.

A screen for working ores by the wet process is made of Russian sheet-iron, the smooth planished iron being punctured with fine holes.

Screens for working dry ores are made of wire, and vary in fineness from 900 to 10,000 meshes to the square inch.

A protecting shield around radiators.

A sifting arrangement for sand, etc.

A blind to intercept heat or light.

A riddle or sieve. See GRAIN CLEANER, etc.

A jigger, etc., for ore.

Screw thread forging machine, *Bouchacourt & Delille*, Fr. . . . . * "*Engineer*," xliii. 417.
Screw ventilator, *Pelzer* * "*Scientific American Sup.*," 4071.

Screw Burn'er. (*Lamps.*) *a.* A burner in which the wick is lifted and depressed by a screw. Found in Argand lamps.

b. A burner which fastens by screw thread to the socket of the lamp-top.

Screw Cal'i-pers. In which the adjustment of the points is made by screw. See several forms in Fig. 1029, p. 429, "*Mech. Dict.*"

Screw Cut'ting Ma-chine'. A screw cutting machine takes a rod of iron, steel, or brass, and by an automatic series of operations drops screws at the other end of the machine. One tool cuts the point of the rod down to the dimensions of the screw, another cuts it off, having the head the full size of the rod, another takes it from the last and passes it on to have the thread cut, a cutter passes by and leaves it slotted, another with four iron fingers takes it and transfers it to a fifth cutter, where the head is finished, when still another tool comes to push it into the pan placed to receive it. No intervention is needed until another rod is wanted. See SCREW, *supra*.

Fig. 2206 represents a machine for screwing and cutting off steam and gas pipe. The belting and gearing are arranged for obtaining suitable power and speed for the varying sizes of pipes. The die and head to which it is attached are so constructed that pipe may be alternately screwed and cut off without removing the die from the machine.

See various forms on pp. 2065-2067, "*Mech. Dict.*"

A form of lathe as in Figs. 4725, 4734, pages above cited.

See also BOLT-CUTTER, Figs. 367-371, pp. 117, *supra*; Figs. 770, 771, 777, 778, pp. 324-326, "*Mech. Dict.*"

TURRET LATHE, Fig. 6824, p. 2665, "*Mech. Dict.*"

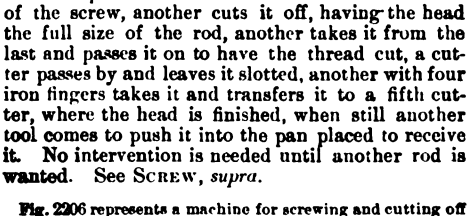
PIPE THREADER, Fig. 3744, p. 1712, "*Mech. Dict.*"

SCREW, *supra*.

Screw Ma-chine'. In sheet-metal working, a machine for threading zinc or sheet-metal screws for can-tops, etc.

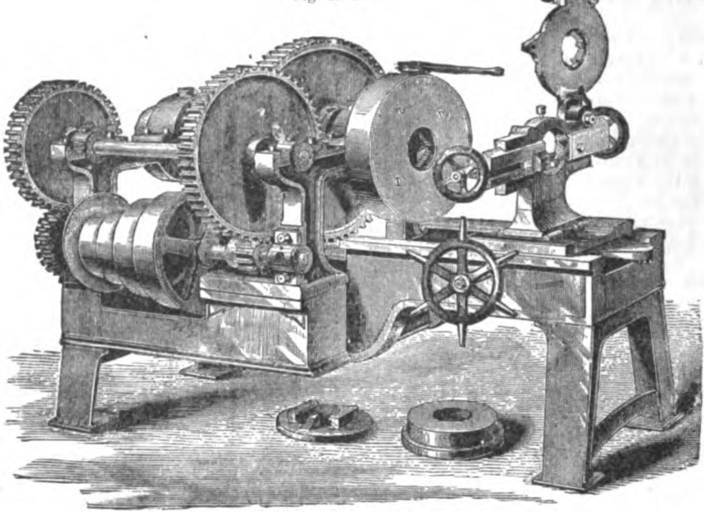
Screw Dog. A clamp to hold the stuff firmly in the carriage, adjustable by a screw.

Fig. 2205.



Extra Screw Dog for Holding Dimension Stuff.

Fig. 2206.



Screw Cutting Machine.

Fig. 2206 shows a feeding or tail screw hung in an iron box, let into the back end of the carriage, so as to come entirely below its surface; on this screw is a nut with a traverse dog for holding the stuff, and operated by a hand-wheel on the outer end of the screw. The front dog for holding the stuff consists of a plate having teeth on one side and running across the entire width of the carriage, and which is held in its place by teeth on an iron plate let into the sides of the carriage, requiring no bolts or keys to hold it firm.

Screw El′e-va′tor. 1. (*Dental.*) A staff with gimlet screw on the end to screw into a root as a means of withdrawal. Fig. 4730, p. 2066, "*Mech. Dict.*"

2. (*Surgical.*) A hard rubber conical screw to force open the jaws of maniacs or lock-jawed.

3. A form of passenger lift in which a screw is used to elevate the cage.

Screw En′gine. Engines of this type, for vessels up to 300 tons, have inverted steam cylinders carried on strong hollow standards, which also form the guides for the cross-heads. The slide valves are between the cylinders, and the valve-box cover is on the side, giving easy access to the valves for examination. The engines have case-hardened link-motion reversing gear, and separate expansion valve.

The condenser is fixed on one side; the air-pump is driven by side levers from the cross-head of the engine. The standards which carry the engines are fixed to a strong cast-iron base-plate; the bearings for the crank-shaft, including the thrust bearing, are also secured to this plate. The screw shaft is coupled direct to the crank-shaft, and passes through a stern tube, as shown. It is usually fitted with a three-bladed screw propeller, but any other form may be adopted, and the propeller is made of malleable cast-iron, gun-metal, or cast-steel, as may be desired, the price varying according to the material employed. The boiler is of the ordinary circular form, with an internal flue and return tubes, the uptake leading to the chimney being in front of the boiler and directly above the fire-door. The boiler is of the best material and workmanship throughout, and is furnished with all the steam mountings and furnace fittings necessary for its safe, efficient, and economical working. A donkey-pump feeds the boiler.

M. Cavé's (Fr.), *Fig. 3417, vol. iv., Laboulaye's "*Dict. des Arts et Manuf.*," ed. 1877, article "*Bateau à Vapeur.*"

Screw Eye. A loop with threaded shank, to be screwed into an object.

Screw Fin′ish-ing Ma-chine′.

Fig. 2207 is specially adapted for small hand-tooling, finishing the heads of screws, pins, and a variety of similar work. A half-inch hole extends through the spindle. Self-adjusting shell chucks are used in the spindle. These are opened by the knee of the operator without stopping the machine, thus saving the time of stopping and starting every time the work is put into the machine or removed. The boxes are self-oiling, running from two to three months without the necessity of oiling them. The machine is arranged for a high rate of speed. Tight and loose pulleys are upon the spindle. Either one or two counter-shafts accompany the machine, as may be desired. They are provided with adjustable hangers, iron cones, and pulleys. First countershaft should run 450 turns per minute. Tight and loose pulleys 6″ diameter, 2¼″ face. Weight of machine with both countershafts, 425 lbs.

Screw for Boot Soles. Article "*Chaussures à Vis,*" * Laboulaye's "*Dict. des Arts et Manufactures,*" vol. iv., ed. 1877. See SOLE-SCREWING MACHINE.

Screw Gage. 1. A device for measuring the pitch of the threads of the screw.

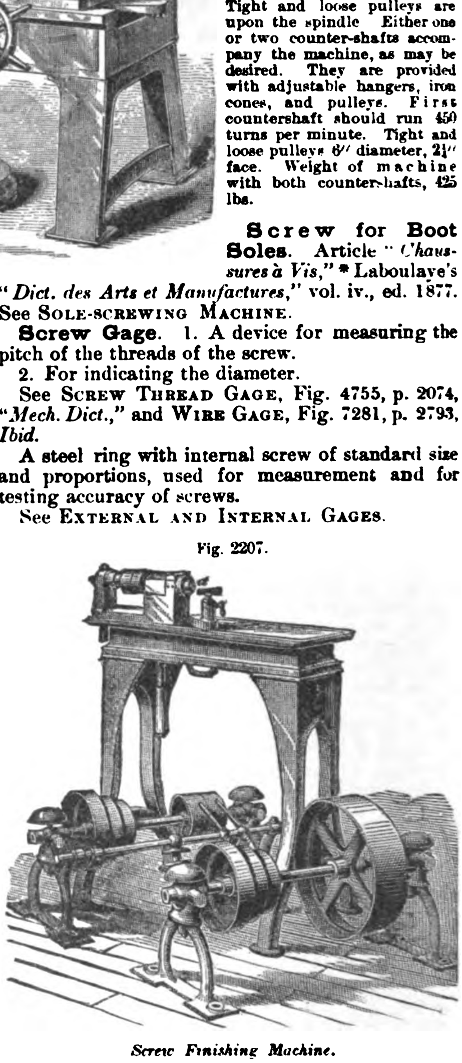
2. For indicating the diameter.

See SCREW THREAD GAGE, Fig. 4755, p. 2074, "*Mech. Dict.,*" and WIRE GAGE, Fig. 7281, p. 2793, *Ibid.*

A steel ring with internal screw of standard size and proportions, used for measurement and for testing accuracy of screws.

See EXTERNAL AND INTERNAL GAGES.

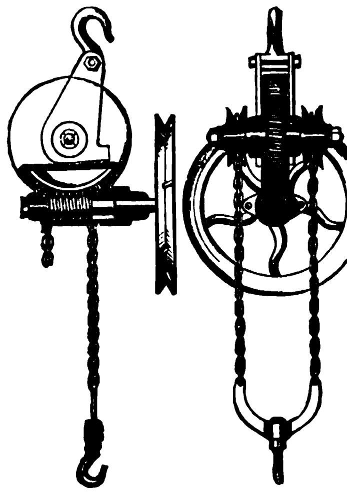
Fig. 2207.



Screw Finishing Machine.

Screw Hoist. In Fig. 2208 the axle of the ordinary large winding wheel has screw threads cut thereon which mesh with the gear on a smaller wheel set above the axle and transversely to the large wheel. On the opposite ends of the axis of the latter wheel are pulleys, over which chains pass which are attached to the swivel hooks below. It will sustain at any point, but will lower rapidly when started.

Fig. 2208.



Screw Hoist.

Screw Hook and Eye Hinge. A hook and eye gate hinge, each part of which has a screw shank.

Screw Hook and Strap Hinge. A hook and eye hinge of which the hook part has a screw shank and the eye part a strap to be secured to the gate or door.

Screw'ing Stock. A stock or handle which holds the threaded nut for making a thread on a bolt or bar. A screw plate.

Fig. 4739. *f*, page 2069, "*Mech. Dict.*"
Fig. 4754, *a*, p. 2074, *Ibid.*

Screw Knob. A curtain knob with screw shank.

Screw Line Box. One the cover of which is depressed by a screw. A *spring* line box is shown in Fig. 1615, p. 552, *supra.*

Screw Ma'king Tools. Taps, dies, stocks, etc. Figs. 4739, 4754, pp. 2069, 2074, "*Mech. Dict.*"

Screw Nick'ing Ma-chine'. One for cutting the nicks in screw-heads. See Screw Slotting Machine.

Screw Pile. (*Hydraulic Engineering.*) The procedure in the setting of the screw-piles for the United States pier near Lewes, Del. (1877, 1878), is carefully shown in the "*Report of Chief of Engineers U. S. Army,*" 1879, * i. 448.

Mitchell, * *Laboulaye's* "*Dictionnaire*," iv., ed. 1877; "*Pilotis.*"

Screw Pol'ish-ing Ma-chine'. See Screw Finishing Machine.

Screw Press. A machine in which the pressure is given by means of a screw. The applications are numerous and the examples are given under specific heads. See list under Press, *supra*, and p. 1784, "*Mech. Dict.*"

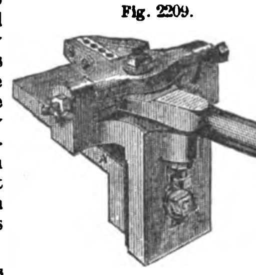
Some of the prominent are under
Cheese Press, Fig. 609, p. 194, *supra.*
Cider Press, Figs. 616–618, p. 196, *supra.*
Olive Press, Figs. 1839–1841, p. 642, *supra.*
Portable Press.
Stearine Press.

Screw Sha'ving Ma-chine'. A machine for turning off wood-screw blanks.

It is furnished with ten spring collets, a cross-rest with two shaving tools, oil-tank, dripper, and countershaft. The collets are opened and closed in the spindle by a hand-lever, and hold screws ⅛″ to ⅝″ diameter, increasing by sixteenths; ⅝″ to 1″ diameter by eighths. The shaving tools are circular, and may be sharpened by grinding without changing their form.

Screw Slot'ting Ma-chine'. The device shown in Fig. 2209 can be attached to an ordinary hand lathe, and is believed to be more efficient for the purpose than any machine heretofore made. An active boy can slot from ten to fifteen thousand screws per day.

Fig. 2209.



Screw Slotting Machine.

A single bolt fastens the platform *A* of this apparatus to the bed of a hand lathe, the long lever projecting in front at a right angle with the bed. An arbor carrying a circular cutter is held in the center of the lathe. The long lever is moved horizontally to open the jaws for inserting and removing the screws, and downward to bring the screws to be slotted against the saw. The stop screw *B* governs its downward motion, and thus regulates the depth of slot in the screw head. The working part of the apparatus can be raised or lowered on the platform front by means of the bolt *C*.

In the Pratt & Whitney machine, the head-stock has a cone of 3 grades for a 2″ belt. The stock holding the vise-jaws and dies may be adjusted toward or from the spindle and transversely across the table. The spindle carries a rotary cutter, against which the head of the screw is brought by a vertical movement of the vise, produced by a hand-lever, rack, and pinion. The same motion of the lever that closes the vise, also raises it with the screw to be slotted, and a weight under the table instantly opens the vise and releases the screw as soon as the pressure on the hand-lever is removed. The machine slots screws of 9-16″ and less diameter. Weight of machine, with countershaft, 500 pounds.

Screw So'ling Ma-chine'. A machine for uniting the uppers and soles of boots and shoes by means of a brass screw made on the machine, operating automatically, whereby it grasps the wire, carries it forward, cuts a thread upon it, screws it into the sole of the shoe and cuts it off in suitable lengths — all at the same time. — *Tyson.*

Screw Steer'er. A device to assist the helmsman in holding the rudder at every point of its movement, to prevent the rudder kicking or running down by surges.

See Steering Apparatus, Figs. 5757–5760, p. 2372, "*Mech. Dict.*," and Fig. 4753, p. 2073, *Ibid.*

Scri'ber. A marker.

Scribing tools, *Rose* * "*Engineering*," xxi. 119, 139, 330, 521.

Scrod'dled Ware. (*Ceramics.*) Ceramic ware, made by taking scraps and pieces of differently colored clays, such as are left over in making vases and plaques, and laying them together, joined but not intermixed, so as to produce a marbled or mottled effect.

Tortoise-shell ware had a similar origin. See also Pâte Changeante.

Scroll Chuck. A lathe chuck in which the dogs are moved in concert by a scroll hidden in the body of the chuck; as in Fig. 4767, p. 2077, "*Mech. Dict.*" Several of the chucks shown in Figs. 874–876, pp. 273–275, and Figs. 1540–1544, p. 529, *supra*, are scroll chucks.

Scroll Lathe. One adapted to turn spiral and scroll work, such as balusters, table and piano legs, etc. See Fig. 555, p. 174, *supra.*

Scro'tal Clamp. (*Surgical.*) A clamp for castrating or for amputation of redundant scrotum for the relief of varicocele Scrotal forceps.

Scro'tal Com-pres'sor. (*Surgical.*) For mechanical pressure on the morbidly distended scrotum in orchitis. A hard rubber globular bag with lacing holes.

Scro'tal In'stru-ments. (*Surgical.*) Instrument for hydrocele, varicocele, etc. The list includes: —

Canula.	Scrotal clamp.
Depilating forceps.	Suspensory bandage.
Injector.	Scrotal compressor.
Varicocele clamp.	Trocar.

Scrub'ber. A washing and brushing, cleansing apparatus.

Scrubber gas, on. *Hunt*, Br. . . . . "*Engineering*," xxii. 48.
Scrubbing machine, domestic, *Stockley* . . * "*Min. & Sc. Press*," xxxvi. 249.

Scuf'fle Hoe. One having a push motion instead of the downward and pull motion.

Scuffle hoe, *Munson* . . * "*Scientific American*," xl. 389.

Sculp'ture. Mechanical aids in reducing the labor of the sculptor and for copying. See article "*Sculpture,*" Laboulaye's "*Dictionnaire des Arts et Manufactures,*" vol. iii., ed. 1877.

Article "*Tours Composés,*" Laboulaye's "*Dict. des Arts et Manufactures,*" iv., ed. 1877, Fig. 42.

Scutch'ing Ma-chine'. One for separating the individual fibers of cotton or flax, which have gone through the preliminary opening process.

Scutching machine, *LeFranc*, "*Iron Age*," xx., July 19, p. 20.

Scut'tle. 1. A small light aperture, closed by a hatch or shutter.

2. A coal bucket

See SIDE LIGHT, "*Mech. Dict.*," p. 2174, *et infra.*

Sea Bat'te-ry. (*Electricity.*) One in which the plates are immersed in the sea, so as to be acted upon by the salt water. Such are used in making luminous signals on buoys, etc.

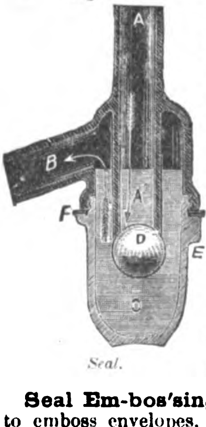
Sea Cock. One opening through the hull into the sea.

Spence's improved sea cocks . * "*Engineer*," xli. 287.

Seal. An automatic valve closing a pipe; or a U-shaped bend in which water collects and prevents passage of air. See SEWER TRAP.

The common siphon trap as used in most sinks and water-closets is subject to two objections: First, the sewer gases in the ascending branch of the trap are in constant contact with the water, and permeate it without hindrance, by which it becomes foul and gives off offensive odors in the other ascending branch of the trap; second, when from some cause or other pressure takes place in the descending branch connected with the sewer, the sewer gas will bubble up through.

Fig. 2210.



Seal.

The inlet pipe connecting with the washstand, sink, or other fixture extends down about half way into the center of an enlarged U-shaped chamber two thirds full of water in which floats a rubber ball fitting tightly up against the end of the inlet pipe, forming a perfect seal. The outlet pipe is in the top of the U-shaped chamber, above the end of the inlet pipe.

See Fig. 5766, p 2374, and Fig. 6618, p. 2616, "*Mech. Dict.*"

Seal Em-bos'sing Press. A press intended to emboss envelopes, or name or initials on note paper, or the stationer's card on any paper they print or furnish. It is worked by a cam and gearing; is very powerful and speedy, and is readily adjusted to any pressure wanted.

Seal Hook. An iron hook which is inserted into the hasp of a freight-car door and to which a seal wire and metal seal are attached.

Seal Lock. A lock in which a seal made of glass, paper, or other material is inserted in the lock in such a manner as to cover the bolt or the key-hole. The lock cannot be opened without breaking the seal.

Seal Press. A pair of levers arranged like a pair of pincers and with two dies with which lead car-seals are compressed on the wire to which they are attached. The two dies leave an impression on the lead so that if the seals are removed or defaced it can be known. — *Forney.*

Seal'skin. (*Fabric.*) The imitation sealskin is made under a process invented by Crosland, of Huddersfield, England, in 1850, by which the short hairs of the cow and calf could be used in the manufacture. The main feature of the process consists in boiling the fabrics for a long time in water, which develops the luster of the fiber.

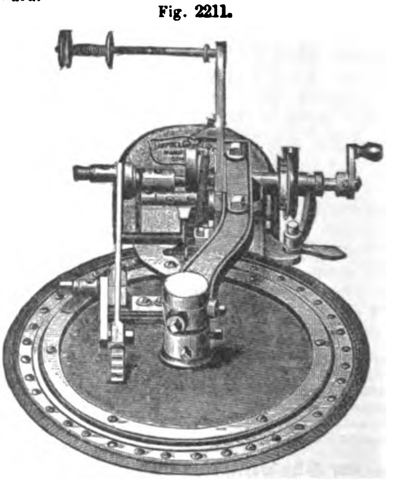
Seal Wire. Several strands of fine wire which are twisted together like a rope, and by which leaden seals are attached to car doors.

Seam'ing. (*Fishing.*) The marginal line which surrounds a seine, and to which the meshes are seized. A *meter* is an outer strengthening line, seized at intervals of a yard. To the meter, on the upper edge, the floats are attached, and to the meter below, the weights.

Seam'ing Ma-chine'. The Royer & Lincoln seamer for use in print works, bleacheries, dye works, and cotton mills trims woven goods neatly and evenly; and joins the margin of cloth outside the seam so that it will pass through the shearing machine without raising the blades.

In this machine the grooved points, on which are placed the loops of the ends of the knit goods that are to be seamed together, are arranged radially and set in a brass ring, which is 16″ in diameter, and is secured in a circular bed that is mounted to turn on an upright axis, and has on its bottom, or lower part, a concentric circle of gear teeth which gear into a pinion fast on a shaft with a ratchet wheel having teeth to suit the gage of the circle of grooved points. This ratchet is turned one step at each revolution of a driving shaft by means of a pawl connected with that shaft, and thereby the circle of points is turned a step equal to the distance from one point to the next so as to bring the next point under the needle. A dog drops into the teeth of the ratchet and prevents the latter and the circle of points from turning backward.

Fig. 2211.



Seaming and Turning-off Machine.

The needle is held by an arm which is mounted on a fulcrum and gets its to and fro motion by a cam on the driving shaft. The looper is held by a separate arm which receives its motion by a side cam connected to the needle cam, so that the points are fed forward one step, as above described, and a stitch is made by the needle and looper at each revolution of the driving shaft.

The points are firmly held in their places by caps or segments with three screws each. The gage can be changed by taking out the brass ring that holds the points and putting in another with more or less points to make the gage required. The ratchet must also be changed for another having the proper number of teeth to turn the circle of points with the necessary step by step movement corresponding to the change of gage.

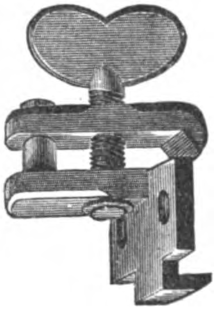
The main driving shaft should revolve 115 to 120 times per minute in order to give a good result.

Search'er. (*Surgical.*) A flexible instrument or sound introduced through the urethra to explore for a stone by contact.

Andrew's, Little's, Gouley's, Bilroth's, Thompson's, Otis's, etc.

Seat Fas'ten-er. Fig. 2212 shows a clamp for holding a wagon seat firmly in position, and for keeping the body from spreading.

Fig. 2212.



Seat Fastener.

Seat Lock. A lock for holding the back of a seat so that its position cannot be reversed. Such locks are attached either to the seat-end, seat-back arm, or the seat-back stop.

Se-bas'tine. A Swedish explosive made of nitroglycerine, wood-charcoal, and certain explosive salts. Ignited by fire it burns readily but does not explode. If confined in detonating capsules it explodes with great force. Patented in Sweden in 1872.

Sec'on-da-ry Bat'te-ry. (*Electricity.*) Invented by Plante. A battery having two plates of large surface immersed in an acid solution and charged from a primary battery, the polarization resulting from the primary current serving upon the breaking of the primary circuit and the closing of the secondary circuit to give a reverse current of great electro-motive force, which may be used for lighting, heating, or other effects.

Planté's secondary batteries may be considered as voltameters made of two sheets of lead rolled up in a spiral, so as to give large surface and small distance of plates. They are charged with dilute acid, which is decomposed by a current passed into the plates, producing peroxide of lead on one plate and a film of hydrogen on the other. In this state the cell itself will furnish a current for a short time. By connections which unite the cells of the secondary for quantity during charging, two Bunsen cells arranged for intensity will produce the desired effect. By connection of the secondary in series for discharge, a very powerful current — equal to that of many Bunsens in series — may be obtained.

Fig. 2213 shows a secondary element as now constructed. In a tall vessel of glass, gutta-percha, or ebonite, are placed two sheets of lead, rolled spirally, and parallel one to the other, and kept from touching by two cords of india-rubber rolled up with them; these two sheets of lead are immersed in a solution of one part of sulphuric acid to nine parts of water. The vessel is closed by a sealed cover pierced with a small hole, through which the liquid can be poured in or extracted, and which also allows the escape of any gas which may be generated during the charging of the battery. The apparatus is surmounted by a disk of ebonite, upon which are fixed two contact pieces in connection with the two electrodes; two clips are also provided for the purpose of holding metallic wires to be made red hot or melted by the secondary current.

Two Bunsen cells, or, in their stead, three Daniell cells, are required to charge this secondary element. During the operation of charging, one of the electrodes oxidizes, a brown coating of peroxide of lead soon shows itself, and the metallic appearance disappears entirely; the other electrode also changes in appearance, — its surface becomes covered with a powdery gray coating.

When the charge has attained its maximum — that is to say, when oxygen commences to be given off by the brown electrode, it is well to disconnect the secondary element from the charging battery, for any further expenditure of the polarizing current is entirely wasted.

The secondary element once charged in this manner and left to itself will retain a portion of its charge for several days; and even at the end of a week it is still far from being exhausted.

The secondary element, when fully charged, has an electro-motive force equal to one and a half times that of a Bunsen; it will redden a platinum wire of a greater or lesser diameter according to its size, or rather according to the size of the electrodes; for it is of course understood that the quantity of electricity which the apparatus can furnish is in proportion to the extent of the surface subjected to the action of the polarizing current and covered with an active electro-chemical deposit.

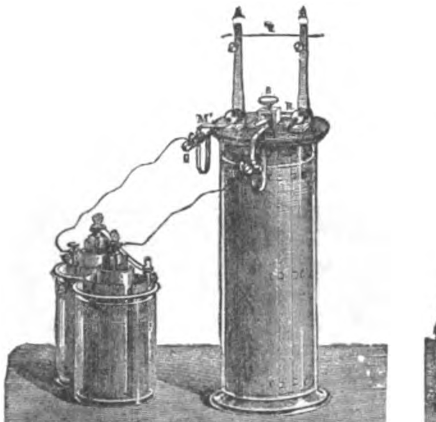
The spiral form of the electrodes gives an element having a large surface and a small resistance within a small space, so that one of Planté's secondary elements is equal to an active or ordinary element of a very unusual size; the small pattern has an active surface of 124 square inches, the large pattern of a surface of 620 square inches.

The current furnished by the secondary element will effect chemical decomposition, act upon an electro-magnet, etc.

A secondary element is all the better for having been charged and discharged a great number of times; at first, when it is almost new, there is an advantage in polarizing the electrodes, sometimes in one direction and sometimes in the other, reversing several times the direction of the charge; but when the element is formed the greatest care must, on the contrary, be taken to charge it always in the same direction.

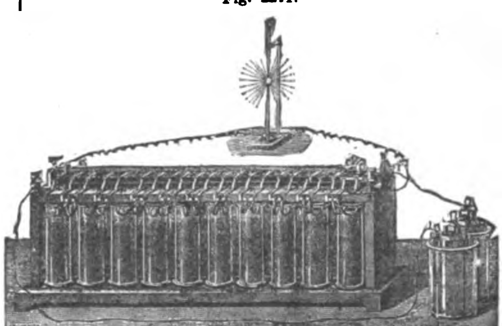
These secondary elements can be joined together, either for intensity or for quantity, and they form batteries capable of producing all the effects of batteries of the ordinary

Fig. 2213.



Secondary Element.

Fig. 2214.



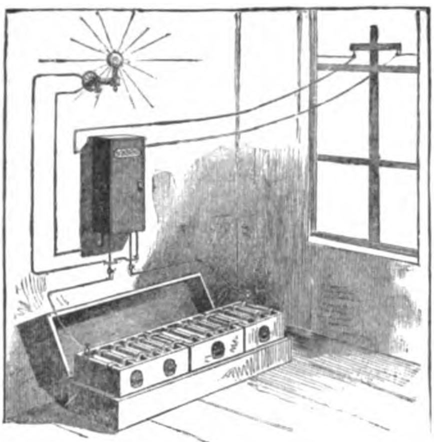
Planté's Secondary Battery.

form, and of the most powerful kind. Fig. 2214 represents a secondary battery as arranged by M. Planté.

Faure, observing that the lead plate of a good battery became coated with oxide of lead, applied oxide of lead to his plates and found that he could make a battery without charging and recharging for months.

Brush claims the invention of a process of effectively preparing his lead plates without any oxide of lead at all. His method is a secret and he claims there is no coating of minium on the plates, the battery can be charged more quickly and discharged more safely, and the process of manufacture is no more prolonged or costly than in the case of Faure's apparatus. The batteries shown in Fig. 2215 are contained

Fig. 2215.



Brush's Secondary Battery.

in a box 8′ long, 15″ wide, and 16″ high. Charged from an arc light circuit wire, they will feed 27 Swan lamps of 16-candle power, and run a small motor of one-horse power. A series of 20 cells, each cell consisting of two lead plates, about 16″ square in size, is sufficient to supply from 40 to 60 Swan lamps of 16-candle power, or as many lights as a good sized house would require. In connection with Swan lamps, one horse power, if used to run a dynamo connected with a battery, will store up sufficient electricity to run from 9 to 10 lamps. This current can be taken from an arc circuit without interrupting the burning of arc lights; the batteries are placed in the cellars of each house where the light is furnished. Mr. Brush says that the batteries are indestructible, and improve with age, the only attention necessary being the addition of water every few months to take the place of that which has evaporated.

In 1801 Gautherot, a French physician, discovered that platinum or silver wires immersed in a saline solution, after having been used for decomposing the salt, gave a current of their own of short duration upon being disconnected from the battery.

In 1803 Ritter made the first secondary battery by superposing a series of gold disks separated by pieces of cloth dampened with a saline solution. He also employed platinum, copper, brass, iron, bismuth, and silver, and remarked that still better results were obtained with carburet of iron and peroxide of manganese. He obtained no effect with lead on account of the solution which he made use of. He used common salt and sal ammoniac.

In 1859 Planté published accounts of experiments made by him upon most of the metals, and many different solutions for the purpose of determining the best construction of elements for secondary batteries.

In 1860 Planté constructed a secondary battery of two plates of lead separated by cloth and rolled up into a spiral and immersed in a dilute solution of sulphuric acid. He afterwards substituted for the cloth two thin strips of rubber.

In 1861, Kirchhof, U. S. Patent, No. 31,545, February 26. Two roughened, perforated, or recticulated platinum electrodes in a solution of nitrate and acetate of lead, nitrate of potash, acetic and nitric acids and nitrate or acetate of iron or zinc, all suggested. Upon charging, one plate became covered with peroxide of lead, and the other with crystallized lead. He also described a switch whereby the cells could be charged, one after the other, while the others were discharging. Also a commutator for the dynamo whereby the charging circuit was always left open when the machine was not running.

In 1866, Percival, U. S. Patent, No. 53,668, April 3. A box with two compartments separated by a porous partition, and filled with powdered carbon, granular lead, or other conducting powder moistened with acidulated water. Copper or lead plates immersed in the powder served as conductors.

In 1867, Leclanché, U. S. Patent, No. 64,113, April 23. Two graphite plates in powdered charcoal saturated with potash water, porous partition.

In 1869, Percival proposed to make the positive electrode of some more active metal, such as zinc, and then to use a neutral solution of the positive metal as with zinc, zinc sulphate, with copper, copper sulphate, etc. Upon charging, peroxide of lead formed on the lead plate and finely divided zinc on the zinc plate, sulphuric acid being set free. Amalgamated the zinc.

In 1869, Varley, English Patent, No. 2,525, makes use of plates of paladium or arsenic on account of their capacity for storing hydrogen. These are used in connection with carbon plates rendered porous for the absorption of oxygen by dissolving out the silica from gas retort carbon by hydrofluoric acid.

In 1876, Jablochkoff, French Patent, No. 112,024, March 23 and October 2, in an electric lighting system places a secondary battery in a shunt around each light.

In 1878, Fox, English Patent, No. 3,988, suggests the use of plates of copper in a solution of bicarbonate of soda. The secondary batteries are connected in a lighting system between the main wires and the ground, thereby serving to store up any surplus energy thrown upon the line.

In 1879, Thomson & Houston, U. S. Patent, No. 220,948, October 28, and English Patent No. 4,400. A series of disks of copper or other suitable metal are arranged one above another, and separated by rings of earthenware, rubber, wood, or other non-conductor. Diaphragms of felt are interposed, and the whole is secured by bolts and end-plates. The solution may be zinc, sulphate, or other similar salt, and must entirely fill the spaces between the plates. When subject to motion the spaces between the plates are filled with sand, pumice-stone, sawdust, or the like. During charging, zinc is deposited on the under side of the plates while the upper sides dissolve to form copper sulphate. In the English patent negative plates of mercury, silver, or lead are proposed, which may be roughened, serrated, or coiled, or may be formed by a tray filled with fragments of the metal. The upper plate may be perforated and varnished underneath. Pieces of hard carbon may be placed upon the upper plate to receive zinc deposit, or spurs or projections may be formed on its upper surface for same purpose.

In 1880, Faure, French Patent, No. 139,258, October 20, applies a superficial coating of lead oxide, spongy lead, or similar active conducting material to the surface of the electrodes, and holds it in place by porous partition.

In 1881, Faure, cert. of add to French patent, February 9, proposes red lead or minium for a coating.

In 1881, Swan, English Patent No. 2,272, May 24. Lead plates, honey-combed, ribbed or cellular, for increasing surface and forming better support for the porous deposit.

It has also been suggested that spongy platinum, amalgamated lead, and zinc or lead wire may be used for electrodes.

Almost any primary battery, whether it be galvanic or thermal, will serve as a means of storing up energy when a current is passed through it in a direction opposite to that of the current which it itself would produce.

It should be remembered that the energy as stored is potential chemical (or in a thermal battery, heat) energy and not electrical; and it is in this respect that it differs from a condenser which, although, like a secondary battery, it discharges a current, the reverse of the charging current, still it does not transform the energy from electricity.

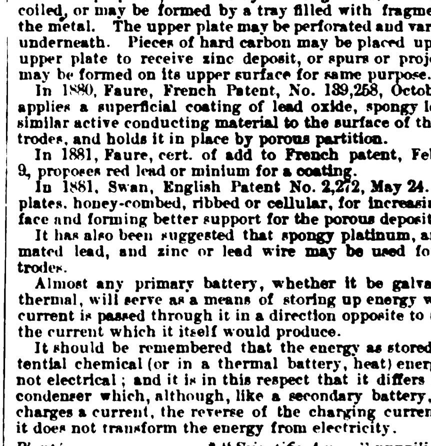
Fig. 2216.



Section Cutter.

Sec'on-da-ry Coil. (*Electricity.*) A coil of wire usually wound upon, but entirely separated from the primary coil by insulation.

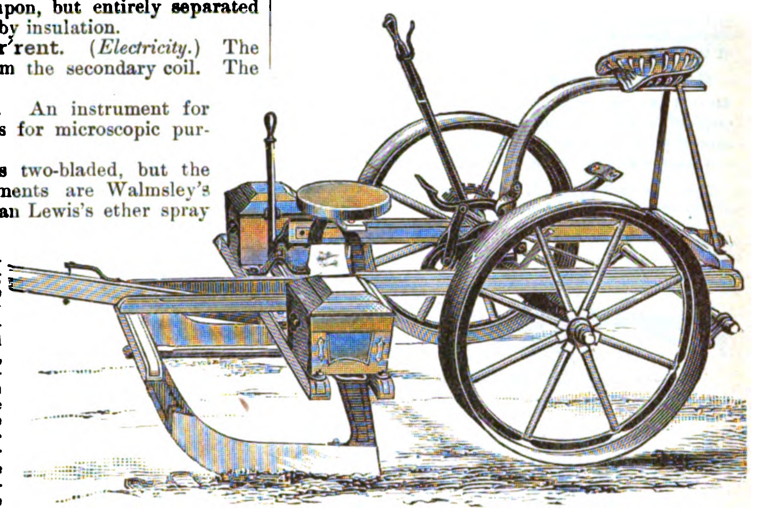
Sec'on-da-ry Cur'rent. (*Electricity.*) The current emanating from the secondary coil. The *induced* current.

Sec'tion Cut'ter. An instrument for making very thin slices for microscopic purposes.

Valentine's knife is two-bladed, but the most delicate instruments are Walmsley's adaptation of Dr. Bevan Lewis's ether spray microtome.

In Fig. 2216, some thickened gum water being placed upon the top of the tube, a piece of tissue, say a portion of the spinal column from a freshly killed animal, may be placed in it, and the nozzle of the freezing atomizer having been introduced into the tube beneath, the tissue will be solidly frozen in from one to three minutes. Ether may be used, but rhigoline is much better. A considerable portion of it will be condensed in the chamber, and can be drawn off by the tube shown in the illustration, for further use. The knife should be kept cold, by placing on a block of ice before using.

Fig. 2217.



Seed Planter.

Seed Drill. A machine for sowing various seeds in drills or rows. See Grain Drill.

Fig. 2218.

Seed Drill (beet) French, McMurtrie's Plate I., Report, "*Department* of *Agriculture Special Report,*" No. 28.

Fig. 2219.

Fertilizer Sowing Attachment.

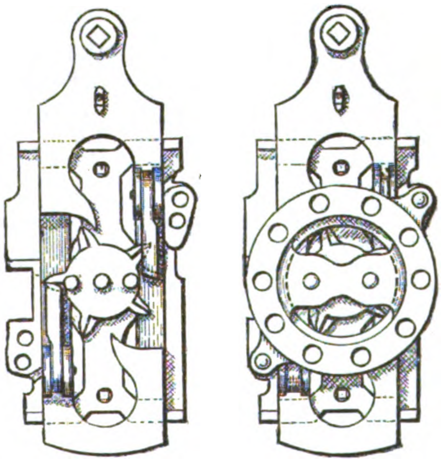
Seed Mi'cro-scope. A small hand magnifier for examining seeds, or living objects, which are inclosed in a case with glass sides.

Seed Plant'er. An implement for planting in hills in contradistinction to *drilling* or *broadcasting.*

In the Farmer's Friend Planter, of Dayton, Ohio, shown in Fig. 2217, the foot treadle and hand lever are pivoted and work together to raise or lower the runners, which are coupled to the frame with a treadle. Pressing with the feet on the rear of this raises the runners, while power applied to the other by means of an independent foot piece forces them into the ground. A hand lever, held by a spring catch, is pivoted to the treadle. The runners adjust themselves to uneven surfaces, and plant two rows at different levels, each the same depth. The entire weight of the machine can be locked on the runners. Gage plates regulate the depth. Fig. 2118 shows a drilling attachment for use in drilling corn. Fig. 2219, an attachment for sowing fertilizers.

Fig. 2220 represents the dropping device, Fig. 2221 *a*, the same with the seed plate removed. The device consists of a slide resting on a bed plate, and pawls pivoted to the sides of the

Fig. 2220. Fig. 2220 *a*.



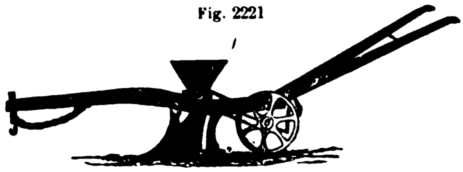
Dropping Device for Seed Planter.

slide for driving the star-shaped casting which carries the seed plate. When the slide is moved, the pawls come in contact, alternately, with the points of the star, moving it round, carying the seed plate with it, dropping seed at each motion of the slide.

Seed'ing Plow. A single row implement known as a seeding barrow. It is made either with cups or brush. Some of these are intended to follow after a plow or in a furrow laid out, while others have a share which opens the furrow.

The Plow Drill, Fig. 2221, shows an old form of drill of Hindustan, probably the one noticed in use in the watered

Fig. 2221



Seeding Plow.

rice fields of the East, by Aristobulus, one of Alexander's generals. These old drill plows are still in use in southern Asia, and were exhibited at the Centennial and the Paris Expositions from India, Java, and China.

Seg'gar. (*Ceramics.*) A vessel of infusible fire-clay to hold ware while being baked or burned in the kiln.

Seg'ment Saw. An annular saw which is made of segmental plates; as distinguished from a solid plate-saw. A vibrating saw with a curved blade, that formed a segment of a cylinder, was some years since patented in England, but does not seem to have come into use; its purpose was the same as that of the tubular saw.

Seine. (*Fishing.*) This in its simplest form is a flat web of netting, with corks or floats at the upper edge and weights at the lower edge, used to inclose an area of water, and by bringing the ends together, either to a boat or on the shore, to secure the fish that may happen to be in the inclosure.

The seine varies in length from a small minnow seine to a shad seine a mile long, hauled in by a windlass worked by horses, oxen, or by steam engine.

A form of net used in sweeping areas of water. Divided into *haul*-seines and *purse*-seines.

A large haul-seine on the Atlantic sounds and bays is 1,000 fathoms in length, but one at Stony Point, on the Potomac, is 8,400 yards. The seine depends from a cork-line, and the lower edge is weighted with leads which sweep the bottom. A line known as the *toggle*-line is sometimes used, so called from its being secured to the seine at regular distances by toggles. At the ends of the seine are the land-lines, which go to shore and pass round the shears-blocks to the windlasses. At the mid-length of the seine is the *bag* of the net, which comes last ashore. The *wings* are the ends.

Seine Wind'lass. (*Fishing.*) A winch to haul in a seine line.

Seis'mo-graph. An instrument for recording shocks or perturbations.

1. The *seismometer* of Prof. Palmieri, p. 2091, "*Mech. Dict.*," was for detecting earthquake shocks and recording their duration.

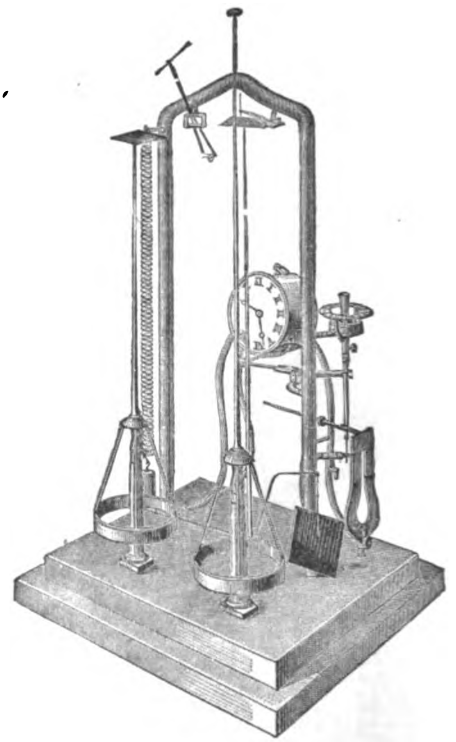
M. Hattori, of the University of Tokio, gives a description of an *earthquake indicator* invented by Choko, about A. D. 132. "It consisted of a copper vessel, the diameter of which was eight shaker or feet, and whose convex cover was ornamented with characters, mountain turtles, birds, and beasts. In this vessel there was one main piston in the middle with its eight branches, wires, and springs. On the outside of this vessel were eight dragon heads, each of them having a copper ball in its full opened mouth. Under each of the dragon heads there was a frog looking upward with its mouth fully opened. The wire works and springs were very skillfully arranged in the vessel, but the cover was closely fitted, and they could not be seen. Whenever the earth shook one of the dragons dropped the ball, the frog underneath received it in its mouth, and produced a sound. By this means the direction of the shocks was ascertained. Once one of the dragons dropped its ball, but no person near it perceived any shock, and all the learned men of the capital doubted the trustworthiness of the machine; but after a few days a mail arrived from Rossi and reported the occurrence of an earthquake there."

Sig. Ignazio Galli's apparatus for registering earthly perturbations at the Meteorological Observatory of Velletri, Italy, consists of six separate devices for observing and recording automatically: —

1. The horizontal amplitude of earth tremors.
2. The vertical amplitude.
3. The direction of the earthquake movement
4. The time of the shock.
5. The intensity of the attending magnetic disturbance.

At one corner of the marble base is a short standard of metal, on the top of which rests an agate cup, balanced by a

Fig. 2222



Seismograph.

ring below, and carrying above a long, slender vertical rod, the whole forming a sensitive pendulum. At the top of the rod is a small silver mirror, carrying a fine needle, the movements of which are observed through a small telescope. Any movement of the base is so magnified at the upper end of the rod that the minutest tremors of the earth are thus made visible.

The adjacent device is substantially the same, except that the vertical rod is shorter and carries at top a sheet of paper covered with lampblack. Resting on this blackened paper is the fine needle of a nicely balanced lever attached to the brass support which arches over the middle of the base. As the earth tremor causes the paper to move the relative extent and character of the movement are marked by the needle on its blackened surface. Behind this part of the apparatus is a weight suspended by a sensitive spiral spring. At the bottom of the weight is a lever, to the other end of which a needle is suspended by a hair, the point of the needle resting on a sheet of blackened paper slightly inclined. This is for measuring the vertical height of the earth movement.

The direction of the movement is marked by the needle of the lever attached near the upper right-hand corner of the frame, on the sheet of blackened paper on the top of the rod which rises from the middle of the base.

To ascertain the quarter whence the movement proceeds and the time of the shock, a truncated metal cone is inverted and balanced on a horizontal metallic disk surrounded by a ring marked with the cardinal points. The instant the apparatus is moved the cone tips against that side of the ring whence the motion proceeds, and in falling acts upon a lever which stops the clock, thus indicating at once the direction of the source of the shock and the time of its occurrence. The intensity of the accompanying magnetic disturbance is measured by the magnet and its attachments. This seismograph is inclosed in a glass case, is small, extremely sensitive, and records the slightest tremors of the earth with great precision.

The Bregnet seismograph, exhibited at the Paris Exposition, 1878, is an instrument for measuring and electrically registering the deviations of a long pendulum under the influence of terrestrial movements or solar-lunar attractions.

It consists of a heavy pendulum suspended by a wire from a support above and carrying a pointer below which traverses in close proximity to a horizontal sheet of white paper, traveling over a flat metallic plate, by the rotation of a pair of rollers in gear with the train of a clock. The pendulum and metallic plate are insulated from one another, and are respectively connected to the two terminals of a small induction coil, which is, by the movement of the clock, periodically placed in circuit for a few seconds with a battery.

When this takes place sparks pass through the paper, between the pointer of the pendulum and the metallic plate, causing a series of perforations on the paper band, forming a record.

"*Telegraphic Journal*" . . . vi 499.

2. The name is also applied to an instrument, invented by Carlisle (England), for recording the shocks received by or the oscillations produced in a vehicle, a railway carriage for instance, when in motion.

Its action depends upon the inertia of a suspended weight attached by an elastic medium to a point of support. If such a point be shifted suddenly in any direction, the suspended body, from its inertia, retains for a moment its original position, and only gradually recovers its relative position to the point of support, and that with an amount of force varying according to the distance through which, and the velocity with which, the point of suspension has been disturbed.

By a mechanical arrangement this force is made to move a pencil at right angles to a straight line which the pencil when at rest is describing upon a strip of paper traveled at a determinate rate by clock work. By this means the time as well as extent of the oscillation is recorded.

A is the base plate and *B* the standard, to the latter of which the weight *C D* is attached by gimbal-joint, allowing it to swing freely. The outer ring *E* of the gimbal is pivoted to the frame at *F F* and the inner ring to the outer, as usual. The weight *C* has a light barrel *D* both turned true to an axis, and the swinging end is supported at the point *G* by springs *H H* suspended from an arm *I* secured at *K* to the frame *B*. At the end of the weight *C* is a hollow axial projecting stud *L* which serves to limit the oscillation of the weight by contact with the ring *M*. When it is desired to lock the weight so as to put the instrument out of action, the lever *P* on shaft *O* is moved, throwing the pin *N* into the hollow of the stud *L* and holding the weight rigidly. The play of the stud *L* in the ring *M* is about 1.25″ in every direction from the axis.

The inner ring of the gimbal is turned out at the rear so as to form a flat annular surface against which a disk is pressed by the spring *V*, and this disk is supported by an arm projecting from the upright rod *a*, a portion of which shows in the figure. Near its upper end the rod *a* has another horizontal arm *b* which connects at point *r* with a rod *c* to move the arm *d* which carries the pencil *e*.

Any movement of the weight swinging on its gimbal-joint produces a thrust motion upon the disk which is pressed against the rear of the gimbal ring, and this motion is transmitted to the pencil by the means just described. The pencil-arm *d* is mounted on the axis *f*, which is surrounded and moved by a spiral spring which brings the pencil back to the base line on the paper after each lateral movement, and an adjustment at *r* in the slotted end of the lever *b* permits the arm *d* to be so adjusted as to show, either all the oscillations indicated by the weight, or only such of them as exceed a certain limit. An index finger *q* and a graduated arc, *s*, afford means for regulating this adjustment with accuracy.

The strip of paper *i* is moved by rollers and clockwork. One of these rollers *l* makes a revolution once in 5 minutes marking minutes on the paper by 1 prick and 5 minutes by 2 pricks. The paper delivered by one roller is taken up by roller *m*.

To observe oscillations, both vertical and horizontal, the instrument is placed on the floor of the car, its axis parallel with the direction of movement. To obtain only vertical oscillations the axis of the weight is across the car and blocks are placed to restrain lateral movement.

The time of starting being noted on the paper, and the clock-work being started coincidently with the engine, the strip is a record of the trip. The instrument is used to test the condition of a track, the personal equation, so to speak, of the machine being known; or that of the track being known or assumed, to test the relative steadiness of different engines or cars passing over a specific portion of the road.

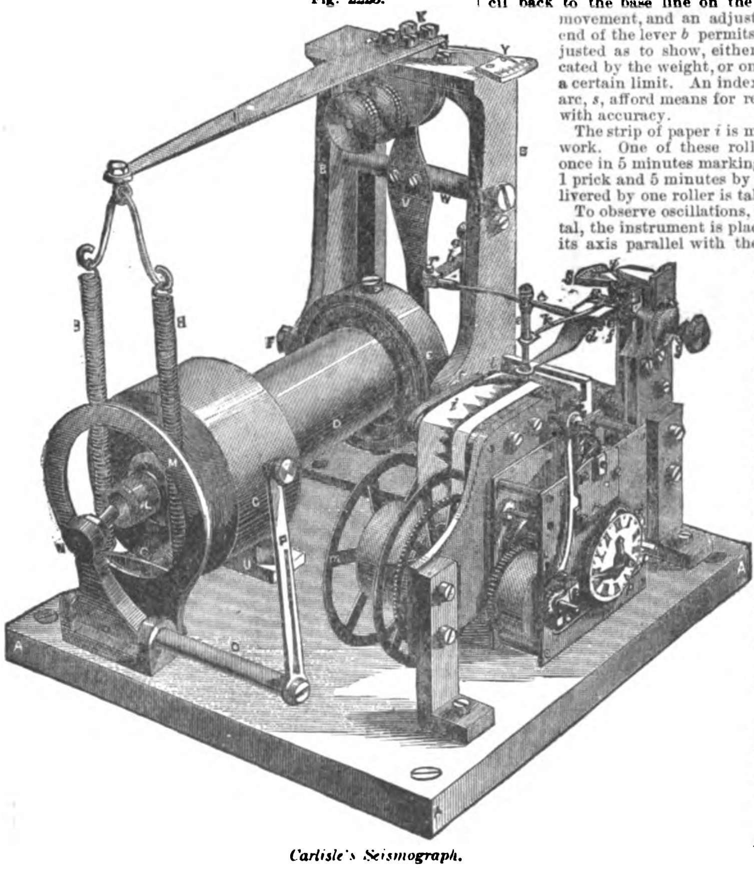
Fig. 2223.



Carlisle's Seismograph.

tive force required on curves and grades, and other similar data is the dynagraph car of Mr. P. H. Dudley.

The indications of the instrument are by no means confined to those given by the Carlisle instrument where the vertical and lateral oscillations of the car under inequalities in the road are interpreted as shocks or perturbations; but it affords numerous additional data for calculations, all of which are drawn graphically on paper by pens which are intermediately connected to the draw-bar of the car or worked by electricity.

The draw-bar is connected with a piston which works in a cylinder filled with oil, the pressure is transmitted through a pipe to another cylinder over a table in the car, and a piston is connected with a pen, which marks on a roll of paper the resistance of the train. Other pens indicate the space passed over each second, each 10 seconds, and each minute, each revolution of the driving wheels, each mile passed, the alignment of the road, the quantity of water consumed by the engine, the quantity of coal used, the resistance of the wind, etc. See DYNAGRAPH.

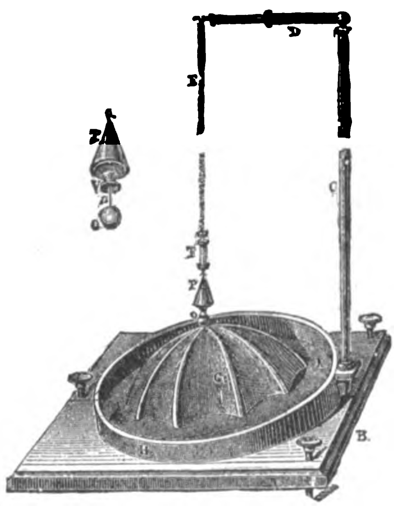
Seismograph, *Carlisle* . * "*Railroad Gazette*," viii. 411.
* "*Engineering*," xxii. 160.
Eastern Ry. of France * "*Engineering*," xxvi. 427.

Seis-mom'e-ter. An instrument for measuring cosmic perturbations or **shocks**. See SEISMOGRAPH.

The application of the microphone as a seismometer is referred to in "*Engineering*," xxix. 498.

Fig. 2224 shows the earthquake indicator of Count Malvaria, of Bologna, Italy. The table is adjusted level by the set screws, which serve as feet. Upon it is a circular inclined plane, *K*, surrounded by a rim, *H*, and carrying in its center a reversed hemispherical cup, *G*, the surface of which is divided into eight channels which are placed so as to correspond with the eight principal points of the compass. The

Fig. 2224.



Malvaria's Seismometer.

summit of the cup is provided with a metallic point which enters a shallow indentation in a ball, *O*. The ball is maintained in place by the concave lower portion, *V*, of a weight, *P*, resting upon it. The weight is sustained by the chain *E*, which is supported by the standard *D C*, and adjusted by the screw *F*.

To set the apparatus, it is arranged as depicted in the engraving, the weight pressing upon the ball just sufficiently to hold it on the apex of *G*. The instant, however, a trembling of the earth occurs, the ball rolls from under the weight, down a channel in *G*, and thence to the inclined plane *K*, through an aperture, *L*, in which it falls, striking spring mechanism, and so firing a gun, or else acting upon a clock so that the latter is caused to stop, thus registering the exact moment of the shock.

In order to determine the direction of the vibrations, a fine hole is made, from bottom up, in the weight *P*. In this a needle, *a*, is placed so that its end rests upon the ball, although its body is then pushed up into the weight aperture. When the ball falls, the needle drops also, but is held by its enlarged head, so that it cannot escape from the weight. It rests, however, in the groove on the cup *G*, down which the ball has rolled; and as this groove must be opposite in direction to that pointing to the course of the impulse of the soil, the true bearing of the vibration is at once determined.

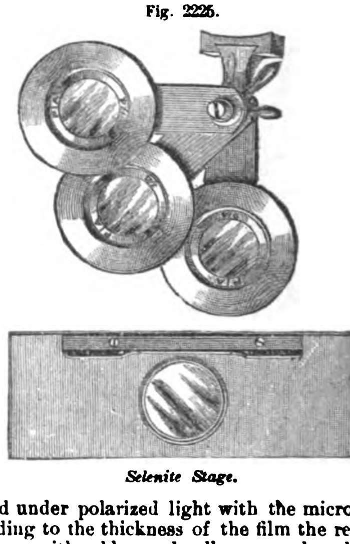
The instrument is said to possess great accuracy, and, doubtless, will serve important ends in localities subject to earthquakes.

Seis'mo-phone. An instrument for distinguishing and locating subterranean sounds, such as that of flowing water, subterranean explosions, etc.

In India, a business is carried on by men called spring-seekers, who generally succeed in designating the subterranean place where water may be obtained; they lie down on the ground and found their judgment on their hearing, which becomes extremely acute by practice. A few years ago, on the occasion of an earthquake at Bagneres-de-Bigorre, in the Pyrenees, Mr. Maxwell Lyte had the idea of placing on the ground an instrument resembling a gigantic stethoscope, and was able to hear the crackings of the terrestrial crust. To M. De Rossi was reserved the honor of raising those empirical attempts to the height of a science. by applying the microphone to the exploration of the soil in its hidden depths. The learned founder of the "Bullettino del Vulcanismo Italiano" commenced his researches in his Observatory of Rocca di Papa, near Rome, and was very soon able to distinguish three different sounds which he could connect with the various movements of his seismatic pendulums. He was able afterward to confirm his results in observing the microphone at Vesuvius, and the solfatara at Pozzuoli, where the movements of the earth's crust are very frequent. Without going any further into the details of that memoir, we must mention the fact that very strong subterranean explosions were heard through the microphone immediately preceding a shock of earthquake. Although M. De Rossi is too prudent to assert the fact, he gives us a glimpse of the possibility of thus predicting approaching cataclysms. However that may be, the *savant* has conferred on science a new means of study which ought to be employed at all meteorological observatories. By establishing facts which have hitherto escaped us, we may perhaps succeed in explaining the causes, still so mysterious, of earthquakes.

Sel'e-nite Stage. (*Optics.*) A film of selenite mounted between two pieces of glass fitted into a brass stage and laid under an object when

Fig. 2225.



Selenite Stage.

viewed under polarized light with the microscope; according to the thickness of the film the resulting colors are either blue and yellow, or red and green, or any intermediate tints with their complementaries.

Se-le'ni-um Eye. A name given by Dr. C. W. Siemens to a small apparatus, in imitation of the natural eye, in which a disk formed by a drop of fluid selenium compressed between mica plates, and with proper electric connections, is made, by the electro-sensitiveness of the selenium to light, to operate two eyelids when exposed to a flash of light, imitating spontaneous blinking of the natural eyelids.

Paper by Siemens, *Royal Institution of Great Britain*, meeting in February, 1876. Report in "*Engineering*," xxi. 161.

Self-act'ing Boil'er Feed'er. An automatic device in connection with the boiler and the feed-water tank, that as the water is reduced below a given level, a valve at the exit of the feed-pipe that has been kept shut by the pressure of the water, opens, and the steam finds passage through the pipe into the feed-water, which has a lower temperature. It will then, although partly condensing, press upon it with the steam pressure as in the boiler, and the water is forced through the feed-pipe into the boiler till the equilibrium is again regained.

Self-act'ing Lathe. A British name for an automatic lathe, having shaper-plates to govern the cut of the tool.

Shaw & Co. . . . . * "*Engineering*," xxi. 406.

Self Bind'ers. Reaping machines which automatically bind the grain as cut. See BINDERS and REAPERS, *supra*.

To show to what immense proportions the manufacture of binders, reapers, and mowers has grown in the United States, we give below the dimensions of the establishments of one of the great firms, the Champion Machine Shops of Springfield, Ohio, the outgrowth, we might say, of the industry of William N. Whitely, whose sole stock of capital, a few years since, was his untiring energy and wonderful fertility of invention.

The six establishments, located in the city of Springfield, Ohio, and devoted exclusively to the production of the Champion Harvesters, constitute one of the largest manufacturing interests in the world. The various factories comprised the following grand total of floor space on January, 1883: —

	SQUARE FEET.
Champion Machine Co.	317,450
Whitely, Fassler & Kelly	1,000,500
Warder, Bushnell & Glessner	485,170
Champion Malleable Iron Co.	140,985
Champion Bar and Knife Co.	160,500
Total	2,104,605

Thus the combined Champion interest occupies a grand aggregate of floor space in the manufacture of Champion Harvesting Machines of 2,104,605 square feet, equal to a room 42,092′ long by 50′ wide, or a building 50′ wide by about 8 miles long, constituting the largest industrial shops in the world. Aside from the figures given, the Champion interest have 50 acres of ground used for lumber yards, railway sidings, and sheds.

The following exhibit of the different kinds of material annually consumed by this interest, based upon the consumption of 1882, cannot but impress the reader with the magnitude of the business done by the manufacturers of the Champion Machines: —

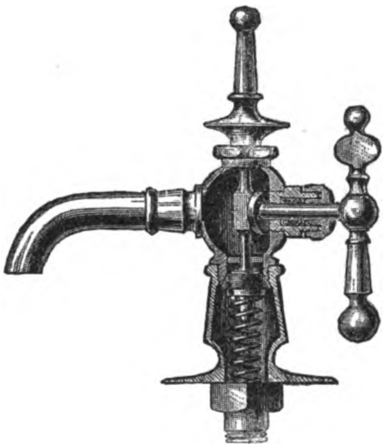
Pig iron	22,000 tons.
Steel	3,100 tons.
Wrought iron	8,200 tons.
Malleable iron	6,550 tons.
Lumber	9,000,000 feet.
Painting materials	221 tons.
Coke	8,850 tons.
Coal	32,600 tons.
Molding sand	6,810 tons.
Grind stones	1,150 tons.
Rivets	212 tons.
Screws	31,400 gross.
Brass spring wire	33,000 lbs.
Paper (apportioned as follows:)	200 tons.
Illustrated Champion	95 tons.
Books and pamphlets	75 tons.
Circulars and blanks	20 tons.
Stationery	10 tons.

The force of employees in 1883 numbers about 3,000, exclusive of the large corps of agents employed in selling the machines. The monthly pay rolls of the combined institutions will average $148,000, or an annual sum paid out for mechanical labor amounting to nearly a million and a half dollars.

Self Clos'ing Fau'cet. One having a valve held to its place by a spring to guard against waste of water through liability of being left open.

The Fuller-Meyer faucet shown in Fig. 2226 is self closing and cannot be forced open by any sudden pressure of water,

Fig. 2226.



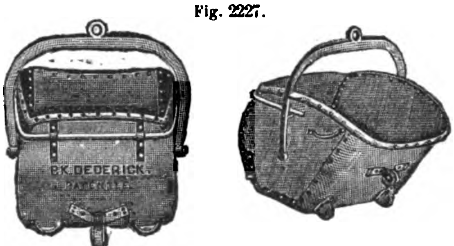
Self Closing Faucet.

such as may be experienced where the Holley and similar systems of waterworks exist. Should the spring become weak or broken it may be kept closed with the handle.

Self Dump'ing Coal Tub. Tubs arranged to dump automatically at a desired point.

Fig. 2227 shows the handles pivoted in such manner that the tubs as long as running on their wheels maintain an up-

Fig. 2227.



Self Dumping Coal Tub.

right position, but when the end of the track is reached the weight turns them on the tubs' axes and dumps them.

Self Lock'ing Hook. One which automatically closes the opening over against the point of the hook. See MOUSING HOOK.

Self-lock hook, *Haines*, * "*Scientific American*," xlii. 339.

Self Mous'ing Hook. A hook having an arm depending from its top part, to enter a hole in the upturned end of the hook and prevent the end spreading under heavy strains.

Self Oil'ing Bear'ing. One in which the oil is placed in a receptacle and fed automatically to the point desired in quantity desired.

In Lane and Bodley's oiler, an oil cell is formed below the matrix of the shaft, in the casting from the bearing. Communicating with this oil cell are drilled a number of small holes, about 1-16 of an inch diameter. At the ends of the bearing proper there are the usual dripping cells communicating with the oil cell mentioned for the return of the oil after it has passed through the bearing. The oil, when the shaft is running at high speed, is drawn rapidly up through these small holes, and circulates through the bearing at a rate much more rapid than can be attained with fibrous feeding wicks. Its adaptation for the bearing of line shafting has been very fully demonstrated.

Sel'vage. (*Mining.*) A thin vein of earthy matter between the vein and walls.

Sem'a-trope. An adaptation of the heliotrope. An instrument designed for army signaling purposes. The object is obtained by reflecting the rays of the sun in any given direction.

Sem'i-fixed. Said of a steam engine bolted to an iron foundation piece on which it may be moved intact. Wheels would constitute it *portable*. *Semi-portable* is used by some makers in the same sense as *semi-fixed*.

Sem'i-mul'ti-flue Boil'er. A steam boiler whose outer shell and internal flue are cylindrical and the ends flat; the front part of the flue is arranged with a fire-grate like the Cornish or Lancashire boilers, but, unlike these, a flue-plate is fixed in the flue a short distance behind the furnace, and a number of wrought-iron or brass flues pass from this to the back of the boiler.

Sem'i-mul-ti-tu'bu-lar Boil'er. A term applied to those boilers in which a portion of the cylindrical shell is occupied by flues. It is a pity that the proper distinction between *flues* and *tubes* is not maintained in the nomenclature; *flues* are for flame, *tubes* for water. See SEMI-MULTIFLUE BOILER.

Sem'i-port'a-ble Steam En'gine. One movable on its foundation-plate; as distinct from the *portable*, which is on wheels.

Semi-portable engine.

Deakin, Parker & Co., Br.	* "*Engineer*," xlvii. 248.
" Eclipse "	* "*Scientific Amer.*," xxxviii. 214.
Garrett, Br.	* "*Engineering*," xxvi. 470.
Semi-portable Steam engine, *Baxter*	* "*Engineering*," xxiv. 49.
Roberts	* "*Scientific Amer.*," xxxviii. 342.

Sem'i-ro'ta-ry En'gine. An engine between a reciprocating and rotary one. The piston has a forward, then an up-and-down and backward movement. It is a very compact engine, with few wearing parts, and is governed expansively.

	* "*Scientific American*," xxxiv. 228.
Higginson, Br.	* "*Engineer*," xli. 115.

Sem'i-tu'bu-lar Boil'er. A name applied to a system of boilers in which the water, first heated in a cylindrical shell boiler, passes thence to a second boiler provided with flues; the intention being that the water shall deposit its sulphates and carbonates in the first boiler, which is more readily cleaned. See instance in "*Engineer*," * xlv. 392.

Sem-o-li'na. A grade of middlings or cracked wheat. To indicate how difficult it is to define the grade, it may be said that Haggenmacher's *semolina purifier*, a famous machine in Austro-Hungary, at one operation divides the meal into four grades of first-class semolina, four of second-class semolina, and two sizes of offal. See cut in "*American Miller*," vi. 35.

Semolina separator	* "*Scientific American*," xxxv. 405.
	* "*Scientific American Sup.*," 327.

Sen'si-tom'e-ter. The invention of M. Warnerke. A species of actinometer for measuring the relative sensitiveness of films.

It consists essentially of different thicknesses of gelatine impregnated with lampblack, and used for photographic purposes. The *actinometer* proper is for measuring the relative actinic powers of light. See ACTINOMETER, "*Mech. Dict.*," p. 11, *et supra*, p. 4. The *Photometer* is for measuring the relative luminous powers of lights. See PHOTOMETER, "*Mech. Dict.*," pp. 1687, 1688, *et infra*.

The gelatine films of various thicknesses, as above described, are placed in little squares on a glass plate. On each square is printed a number corresponding with the thickness of the gelatine, and consequently when two sensitive films are successively exposed behind the plate for a given time that one which upon development shows the highest readable number is the more sensitive.

Sep'a-ra-ting Disk. (*Dentistry.*) A disk of emery journaled in the yoke of a handle and connected by a coil wire to a rotating motor. The disk can, during its rotation, be turned at any angle required in cutting a space between teeth.

Serge Ar'mure. (*Weaving.*) A style of weaving made on a three-harness loom, and producing the serge tissue. (See ARMURE.) In one form of French worsted goods, for instance, the warp has a serge armure of 2 and 1 and the weft a serge armure of 1 and 2.

Ser'pen-tine Mold'ing Ma-chine'. One for carving parlor frames, lounge, sofa, and chair backs, and other crooked work. One form has right and left-handled spindles to allow of turning with the grain of the wood. A guide-piece regulates the depth of cut. The work is held and fed by hand, and the tables are adjustable in height. The machine runs about 5,500 revolutions per minute.

Serres-fines. Ordinarily electricity is applied to the surface of parts only, whether these be external or internal. In some more uncommon cases, however, it is found desirable to penetrate the substance, and pass the current in among the tissues; which is done by certain fine needles, in form and size somewhat as in the engravings here annexed. These are used when it is desired to produce a more speedy effect on certain chronic swellings, as the goitre, when the negative pole is attached to the needle, and certain changes of a chemical nature, with a disintegration of tissue, are effected; so as to cause a resolution, and more rapid absorption, of the gland or part. These may be passed in singly, or two or more be used simultaneously, as in acupuncture. They are made of platina, or steel heavily gilt.

Fig. 2228.

Serres-fines.

Fig. 2229.

Garrigues' Serres-fines.

Dr. Garrigues' improved serre-fine is a form for use where the needle cannot be well used. The chief objections urged against the old form of serres-fines in the treatment of rupture of the perineum had been, that they slipped, caused intolerable pain, did not catch sufficiently deep, cut through, and that the wound did not heal. He thought the chief reason why these objections had appeared was because of the shape which the instruments had heretofore had. If they have no claws, or too short legs, they will slip. They give pain and cut through if the wire is too strong, and the edges of the wound do not unite if the legs of the serres-fines are too short.

The instruments shown have legs which project half an inch, and are armed with minute claws, the spring force is so small that they can be attached to the flesh anywhere, and be worn without pain. The advantage claimed for these serre-fines in the treatment of ruptured perineum is, that they are so simple that it is not necessary even to tell the patient that they are applied.

Ser'vice Box. In the pipes used in the Holly system of generating steam at a central station, and distributing it through underground mains over the city for heating and cooking purposes.

An expansion junction service box is placed at intervals of 100' to 200'. This provides for the free longitudinal expansion and contraction of the mains, and from this box the service pipes are carried underground to the basement of buildings to be heated. The service pipes, having an adjustable hood inside the junction box, may be turned downward, thus taking up the water of condensation as fast as it accumulates, and carrying it forward to the regulator valve inside the cellar walls. At this point the water of condensation being at the degree of heat due to 50 lb. pressure to the square inch, is wire drawn, and by this reduction of pressure it is largely reconverted into steam, and is carried on to the radiators, where it is again condensed. By this device it will be seen that although 50 lb. pressure is carried in the mains, it may be reduced to one or two pounds in the building, and therefore in a house two or three miles distant from the boiler there will be precisely the same result as in a building only a few feet away. The consumer living near the boiler house will have no advantage over the consumer living a mile away, since each will ordinarily carry the same house pressure, and consequently at the same temperature. The system was first tried with a three-mile main in Lockport, N. Y., in 1877, but has since been introduced into a number of other cities.

Ser'vice Clean'er. (*Gas.*) An air pump on a bell-shaped receiver fitted with a cock and having attached a strong caoutchouc hose. The object is to free service-pipes of obstructions arising from condensation of hoar frost or otherwise. The mode of using is to use the pump awhile, then open the cock quickly and allow the air condensed in the receiver to suddenly expand into the pipe, when it drives before it the obstruction.

Ser'vi-ette Ma-gique'. A cloth for polishing metallic ware. A piece of woolen cloth is saturated with soap and tripoli and colored with fuchsine.

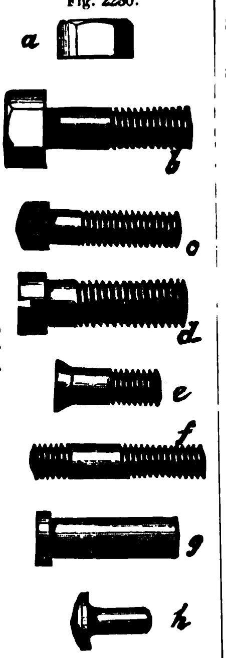
Sixty grains of Marseilles soap to 300 grains of water and 30 grains of tripoli. Saturate the cloth and then dry it.

Set. (*Leather.*) To set a side of leather, it is spread upon the table or stone when wet, and is smoothed out on it by the vigorous use of the slicker, and, owing to its wet condition, the air is easily excluded from under the leather, and it sticks to the table. A thin layer of oil will serve the same purpose.

Set Line. (*Fishing.*) A line laid out in the water in contradistinction to a *hand-line*. See TRAWL LINE.

Set Screw. One to hold some adjustable tool or piece of machinery in place or move it into position.

Fig. 2230.



Set Screws.

a. Hexagon nut.
b. Hexagon-headed set screw.
c. Square-headed set screw.
d. Cheese-headed set screw.
e. Countersunk or cone-headed set screw.
f. Turned stud.
g. Joint pin.
h. Oil pin.

Fig. 2231.

Setting Die.

Set'ting Die. For inserting patent rolled rim conical pointed sheet brass grommets. Fig. 2231 shows setting die for oblong grommets.

Sew'er. A subterranean channel to carry off the refuse slops, surface waters, and other waste liquids and excrement in cities.

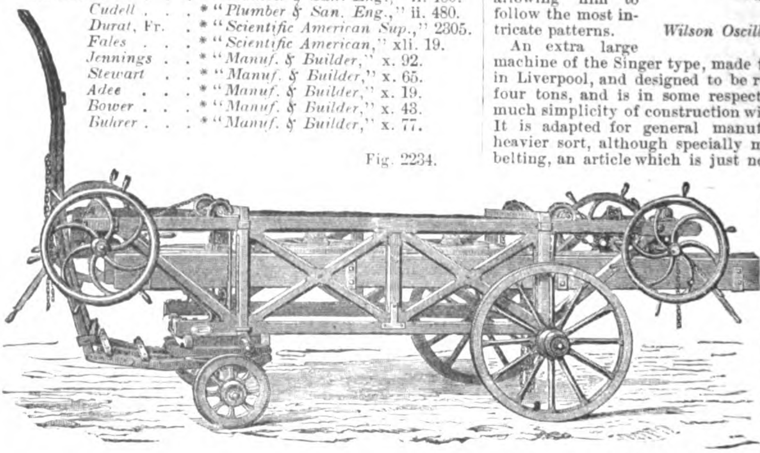
Fig. 2234.



Sewer Shaft Wagon.

Sew'er Shaft Wag'on. A form of wagon for hauling and lowering into the ditch a section of sewer or drain tubing, as shown in Fig. 2234. The axle is bent so as to swing the box below it, elevators at each end hoist or lower the box suspended by the chains at will.

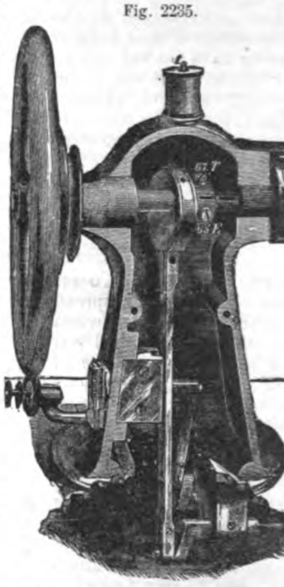
Sew'ing Ma-chine', Dress Pro-tect'or for. Mrs. E. F. Shaw's dress protector for sewing machines is a shell-shaped shield before the crank and pitman connection to keep oil from splashing upon the dress of the operator.

Sew'ing Ma-chine' Tread'le. Wilbrie & Osborn's treadle is made adjustable on the arc of a circle to adapt it to the requirements of different operators.

Sew'ing Ma-chine'. Sewing machines have arrived at that degree of perfection that in their various kinds they do about every kind of work that can be done with a needle. They are deemed almost an indispensable article in every household. See pp. 2098–2124, "*Mech. Dict.*"

Figs. 2235-2237 show the operating devices of the Wilson Oscillating Shuttle Machine, with the shuttle carrier and shuttle. An eccentric on the driver revolves the feed shaft through the vertical lever; a secondary lever, pivoted to the vertical lever midway of its length, operates the rock shaft which oscillates the shuttle; a pin on the vertical lever works in a slide to regulate the motion of the lever. An automatic cut-off in the wheel prevents the machine from running backward and allows the winding of the bobbin with the needle standing still in the work.

Fig. 2235.



Wilson Oscillating Sewing Machine.

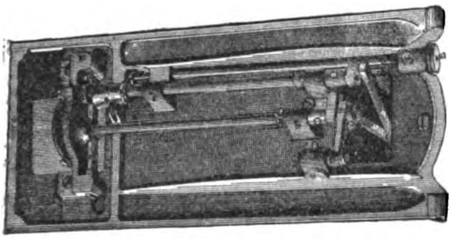
Cole's Universal Feed Sewing Machine does plain and fancy stitching, braiding, etc., stitching in any direction at the will of the operator, allowing him to follow the most intricate patterns.

An extra large machine of the Singer type, made for a manufacturing firm in Liverpool, and designed to be run by steam, weighs over four tons, and is in some respects of new design, uniting much simplicity of construction with great strength of parts. It is adapted for general manufacturing purposes of the heavier sort, although specially made for stitching cotton belting, an article which is just now taking the market as a cheap and serviceable substitute for gearing and the ordinary leather belting.

The material used is of great strength and toughness, and is sewed together in plies or layers up to an inch in thickness. The belting in being sewed together is passed through heavy feed rollers some 9″ in diameter, and more than 8′ in length, getting stretched and pressed in the process. There are two needles at work with shuttles, and the shuttles can be removed from the bottom without disturbing the overlying plies or belting.

The rollers between which the work passes are actuated by reversible worm and cam motions, and the machine has, in addition to these roller feeds, what is known as a top-feed motion, suitable for a higher class of work. The stitch, as in the ordinary sewing machine, can be adjusted from one-eighth inch upward, and the pressure of the rollers on the work passing through the machine can be regulated at the will of the operator.

Fig. 2236.



Wilson Oscillating Sewing Machine.

Pitt's circular feed machine is adapted to sewing elastics in old boots, stitching round goloshes and down the fronts and backs of boots, and other repairs. The operator has control of the stitching motion, and can change the direction without stopping the machine.

Sew'ing Silk. A kind of silk thread, made two-cord and twisted from left to right.

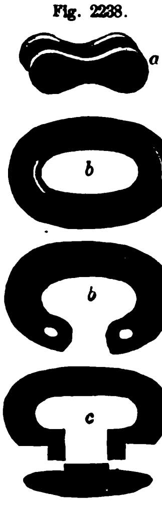
Sewing silk, manufact. of "*Scientific American Sup.*," 1968.

Sgraf-fi'to. See Grafito.

Shack'le. A link by which portions of objects, or lengths of chain are connected. Several types are shown in Fig. 4888, p. 2125, "*Mech. Dict.*"

The term includes also hinged or jointed links, open rings, many forms of loops, lap rings, etc. Fig. 2238 shows three forms of shackle or link: *a* is a "flat link"; *b b* is a link in two sections to be laid upon each other and riveted; *c* is a link closed by a side-piece fitting upon studs. See also Platform Spring.

Fig. 2238.



Shackles.

Shack'le Flap. A man-hole cover attached to the plate by a shackle.

Shack'le Jack. A clamp to compress the anti-rattling rubbers while inserting in the carriage shackles.

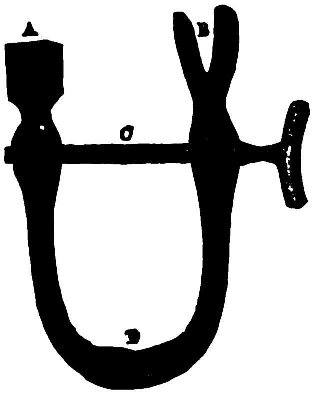
The operation of the jack shown in Fig. 2239 is as follows: Place recess *A* on the back of axle bed, yoke the fork *B* on shaft or pole eye, turn the bolt *C* until the shackle bolts can be slipped easily through the clip hole; the joint *D* accommodates itself to the bolt *C*.

Shack'le Joint. A joint for coupling together the drilling rods in boring a well.

Shade. 1. (*Glass*.) A dome, bell, or other shaped glass cover for protecting clocks, artificial flowers, etc.

They are made in a similar manner to the blown cylinder glass, the glass being kept very evenly distributed by special care and reheating.

Fig. 2239.



Shackle Jack.

Oval cylinders are blown round and then passed between two parallel pieces of wood to flatten them.

Square shades are made by four pieces of wood instead of two.

Round cylinders may be cut before annealing, but other forms require to be first annealed.

Fig. 2240.

Eye Shade.

2. A screen attachment to a lamp to throw the light on to the book or work, and to protect the eyes from the direct rays.

Fig. 2240 shows a form of hood on a magnifying glass to protect the eye from the upper rays.

Shaft. (*Mining.*) The perpendicular, well-like excavation in mines, from which the levels are run.

Twenty years ago the deepest mining shafts in the world reached only about 2,000′ below the surface. The very deepest, we believe, was a metalliferous mine in Hanover, which has been carried down to a depth of 2,290′. The deepest perpendicular shaft to-day is the Adelbert shaft in a silver-lead mine in Prizibram, in Bohemia, which has reached a depth of 3,280′. The attainment of that depth was made the occasion of a three days' festival, and still further noticed by striking off a large number of commemorative silver medals of the value of a florin each. There is no record of the beginning of work on this mine, although its written history goes back to 1527. Quite recently an elegant commemorative volume has been written and printed, which is most interesting to those who have a taste for either the actualities or antiquities of mining industry. There are two other localities, however, where a greater depth has been reached than at the Adelbert shaft, but not in a perpendicular line. These are: 1. The Rocksalt bore-hole, near Sperenberg, not far from Berlin, which, a few years ago, had been bored to a depth of 4,175′. 2. The coal mine of Viviers Remus, in Belgium, where the miners, by shaft-sinking, together with boring, have reached a total depth of 3,542′. Turning from these two mines, no shaft, in unbroken perpendicular line, has as yet exceeded the depth of 3,280′. Taking each singly, the deepest shafts in the world at the present moment, group themselves according to the following order: —

1. The already mentioned Adelbert shaft, 3,280′ deep. As the top of this shaft is 1,732′ above the sea level, the bottom is, of course, 1,548′ below it.

2. Two shafts near Gilly, in Belgium, are sunk to a depth of 2,847′. At this depth they were both connected by a horizontal drift, from there an exploring shaft is sunk to a further depth of 666′, and from there again a trial hole, 49′ in depth, is put down, so that the total depth reached is 3,542′. As they did not, in the bore hole, discover the sought-for coal seam, they have returned to the shaft at the 2,847′ level.

3. The Eimgkerts shaft of the Lugauer coal mining company, Rhenania, Lugau, in the kingdom of Saxony, is 2,653′ deep.

4. The Sampson shaft of the Oberhartz lead and silver mining works, near St. Andreasberg, Hanover, has a depth of 2,437′, and is at present the deepest shaft of Prussian mining.

5. The winding shaft of the Rosebridge colliery, near Wigan, Lancashire, England, has a depth of 2,458′. Coal is drawn from the "hanging on" at the 2,418′ level; the time of the cage running this distance being 55 seconds; the winding rope has, therefore, an average speed of 44′ per second.

6. A shaft at the coal mines of St. Luke, near St. Chaumont, in the Loire department, France, reaches 2,253′.

7. The shaft of the Dunkirk colliery, near Dunkinfield, Lancashire, is 2,069′ deep, but the mining is prosecuted to a further depth of 755′ by shafts from the lower levels, making a total depth of the mine of 2,824′.

8. The deepest shaft of the collieries, near Ronchamp, in France, is 1,881′. A similar depth has been reached by the argentiferous mine near Kongsberg, in Norway. The mines belonging to the Roros copper works, in Norway, have worked to the depth of from 2,540 to 3,270′.

The deepest bore-hole in the world is the artesian spring at Potsdam, in Missouri, which reaches a depth of 5,500′.

The deepest coal shaft in the United States is the mammoth vein, Philadelphia and Reading Coal Co., Pottsville, Pa., 1,855′ deep.

(*Machinery.*) Screw propeller shafts are sometimes made of fluid-pressed steel and forged hollow, saving some 50 or 60 per cent. in weight.

Shaft Bolt. See Fig. 4710, p. 2063, "*Mech. Dict.*"

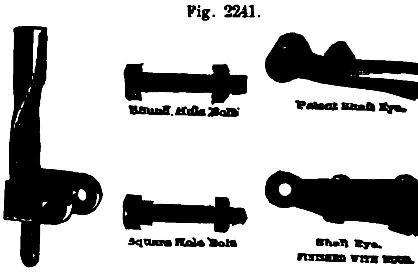
Shaft Bor′ing Ap′pa-ra′tus. See SHAFT EXCAVATOR.

Belgian . . . . . * "*Scientific American*," xxxv. 232.
Kurd-Chandson, Belgian * "*Eng. & Min. Jour.*," xxiii. 434.

Shaft Coup′ling. (*Vehicle.*) The connection formed between the thills and the clips of a buggy.

Fig. 2241 shows the clip with a straight ear, and supporting lug to hold up the shafts. The bolt may be either round or square.

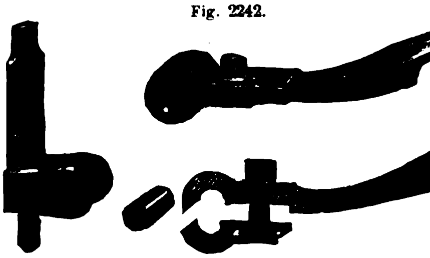
Fig. 2241.



Shaft Coupling.

Fig. 2942 shows the same ear, but having a permanent pin instead of the bolt. The thill eye is made in two pieces, held and tightened on the pivot by a set screw. A rubber packing surrounds the pin to prevent rattling.

Fig. 2242.



Shaft Coupling.

See 20 examples of machinery shaft coupling, Fig. 4896, p. 2127, "*Mech. Dict.*"

12 examples thill coupling, Figs. 6380, 6381, pp. 2553, 2554, *Ibid.*

* "*Scientific American*," xxxv. 19.
Paper on . . . * "*Boston Journal of Commerce*," xx. 171.

Shaft Ex′ca-va′tor. A system of apparatus designed for sinking the shafts in coal mines.

The machines are of colossal size and form, the most prominent feature of the vicinity. A trepan weighing 15 tons, is made of forged iron, and fitted with cutters secured by taper keys, so as to make a cut 6′ long. The trepan is raised by steam power to a height of 3′, and dropped. It is turned at each elevation so that a circle 6′ in diameter is cut. The advance in soft sandstone is said to be 3′ per day. The trepan being withdrawn, a massive iron bucket is fitted into the hole to remove the *débris*. After the first tool has penetrated about 30′, a second trepan, much heavier than the first and having a central guide working in the opening made by the first, is used, and, in the stone above mentioned, it progresses at the rate of about a foot per day. A grapple for recovering broken rods, and a sweep to catch the sections of lifting bars, are also used. There is, besides, a grapple for stones, etc., which is an ingeniously constructed pair of double lazy tongs arranged so that the arms extend to the sides of the hole as the device is being lowered, and scour the bottom as it is being lifted.

When the cutting is finished, circular plates are let into the opening, the bottom plates or cylinder sliding inside of a second ring, and being surrounded with a moss gasket compressed between the flanges. This keeps the water out of the bottom. The second ring is convex beneath and floats on the accumulated water. Then, as ring after ring is added, the water is allowed to escape, the rings sinking gradually. Guides prevent the casing from tilting until it is secured to hard impervious strata, when the shaft is pumped out and is then ready for use.

Shaft-sinking, Belgian system . . "*Van Nostrand's Mag.*," xxiii. 504.

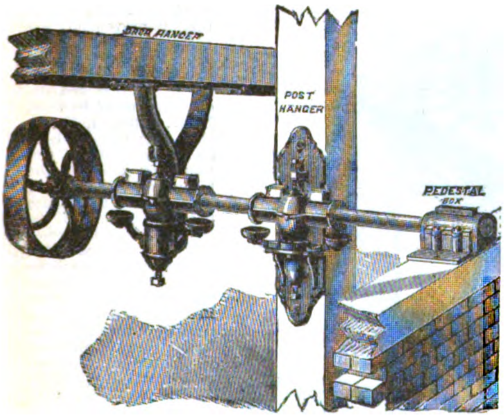
Shaft Eye. The hole in the end of a thill or recess or hole in other shafting through which the coupling pin or key passes.

Shaft Fur'nace. (*Metallurgy.*) The *stücköfen* or *Wolföfen* of Styria was considered the first representative of the high furnace, and the progenitor of the modern *blast* furnace for cast iron. The iron from a single turn of the furnace was taken away in a mass (*stück* or *wolf*) at an opening made at the hearth, and weighed from 1,000 to 1,400 pounds. Some fluid carburized iron ran out, and here the cast-iron continuous process, doubtless, had its commencement, or suggestion. Such furnaces, shaped like two cones joined at their bases, and from 10′ to 16′ high, were common in Styria in the seventeenth century. In 1760 the *flossöfen* was introduced; it was 25′ high, and produced cast iron by continuous process. The *blanöfen* succeeded it, and two tapping tools, for iron and slag respectively.

Shaft Hang'er. A swinging or stationary bracket to support the shaft.

The drop hanger in Fig. 2240 is adjustable, vertically and horizontally, and self-adjusting to any angle, the box working in a socket, and is self-lubricating. The post hanger is also self-adjusting to any angle, and is adjustable vertically and horizontally, the box being moved to or from the post by means of check bolts, without disturbing the plate of the hanger, which is bolted to the post or timber. It also has the improved lubricating box, and both hangers are neat and ornamental in design.

Fig. 2243.



Shaft Hanger.

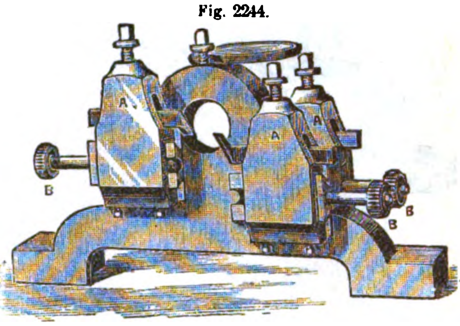
Shafting adjusting line * "*Scientific American*," xxxvi. 24.

Shaft'ing At-tach'ment. An adjunct to a lathe used especially in turning shafting.

It consists of a heavy arch piece bolted on to the rest, carrying three turning tools, two on the front and one on the back of shaft, and having a hole bored out in the upper part of arch to receive bushes for steadying the shaft while turning, or to hold fluted rings for finishing the shaft. The first tool on the front takes off the first chip, and the tool on the back turns the shaft to its proper size. After it passes through the bush the water polishing tool finishes the shaft, leaving it perfectly round and smooth. Each tool is adjusted by a separate screw operating the tool block that carries it. (See Fig. 2244.)

Fig. 2244.



Shafting Attachment.

Shaft'ing Lu'bri-ca'tor. A device for supplying oil to a bearing in which a shaft rotates.

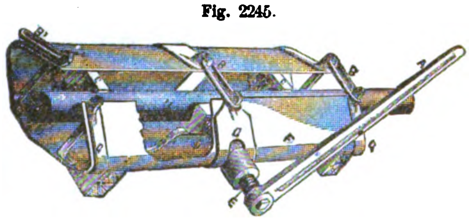
See LUBRICATOR, OILER, SELF-OILING BEARING, *supra.*

Shaft Rub'ber. An anti-rattler. One form is a rubber block with a concave face to fit round the end of the shaft, and hold it in place. See Fig. 4889, p. 2125, "*Mech. Dict.*," and SHACKLE JACK.

Shaft Straight'en-er. Straightening device or bender for shafting, axles, tubes, rails, etc.

The accompanying cut, Fig. 2245, represents a wrought iron frame bound by the bands *G*. These are held together by the links *B* when the machine is being operated, and are thrown back, as shown at *B′*, when the work is to be inserted or taken out. The shaft *H* to be straightened rests against the two movable dogs *C*, and the dog *D* is brought to bear upon the middle and opposite side, then by turning the screw *E* by means of the lever *A*, the shaft *H* may be crooked to any extent.

Fig. 2245.



Shaft Straightener.

Shaft Tip. The ferrule at the end of a carriage shaft.

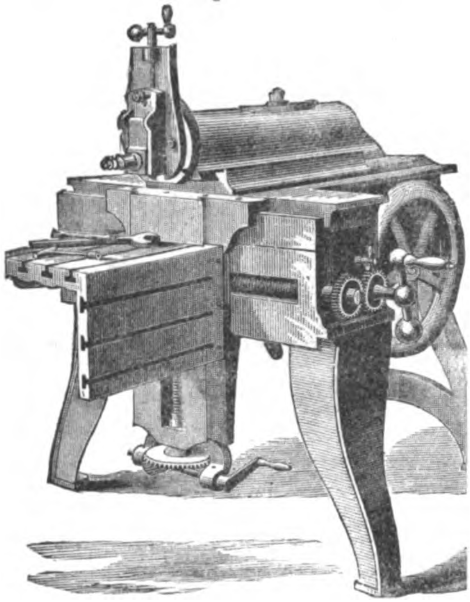
Sha-green'. Hard, colored, metallic spots found on the surface of iron castings; probably produced from the pellets or small spherules found in cavities in pig iron. The analysis of the *pellets* and *shagreen* is similar, showing abundant phosphorus and carbon, and diminished silicon and graphite.

Shank Spring. A spring steel piece to unite the sole and heel of a boot, giving an elastic support to the arch.

Sha'per. A combined lathe and planer.

Fig. 2246 shows Hill, Clark & Co.'s shaper with a 12″

Fig. 2246.



Shaper.

stroke, 22″ cross traverse of table, Whitworth quick return, and rotary planing attachment with self feed.

Sha'per Plate. A pattern plate in a lathe, for instance, which governs the cut of the tool.

Such are found in gun-stock, last, and baluster lathes, etc.

Sha'per Vise. One adapted to hold work to a planer, at any horizontal angle.

In Newell's design the vise turns on a graduated base, so the work may be adjusted at any horizontal angle. One of the jaws is V-shaped for holding circular pieces, and swivels to present either that or the straight face. The actuating screw is protected from chips and dirt and the jaws are faced with hardened steel.

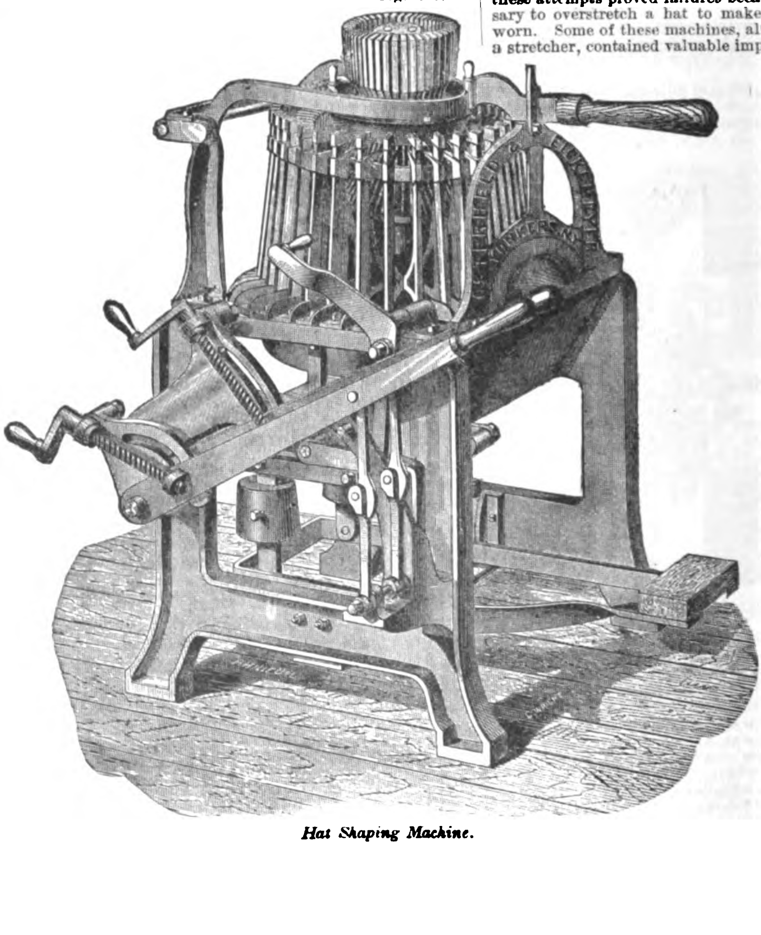
Sha'ping Ma-chine'. To complete the operation of blocking fur hats, after the tips and brims have been stretched on special and separate machines, a finishing blocking machine is employed.

This is represented in Fig. 2247, the invention of R. Eickemeyer.

To block a fur hat it is necessary to bring it much nearer to the size and shape of the finished hat than is necessary in the case of a wool hat, which is more elastic and can be more readily shaped when put on the finishing block, and it is therefore necessary to use blocks and rings of the right oval to shape fur hats.

Many attempts were made to construct machines to block or shape fur hats without previous stretching, but all of these attempts proved failures because it is absolutely necessary to overstretch a hat to make it retain its shape when worn. Some of these machines, although of no use without a stretcher, contained valuable improvements. The first important change was the substitution of tongs to clamp the hat brim in combination with the banding ring and block, in place of the clamping plates, banding ring, and block in the wool hat blocking machine, and this improvement was patented February 26, 1867, by Joseph De la Mar, of Brooklyn, N. Y. W. H. Behrens and Jacob Surerus, of Newark, N. J., patented, May 3, 1870, a machine in which an out-stretching motion was given to the brim tongs, thus adding another desirable feature to the machine. All the improvements of former machines are embodied in the present machine and such others added as were suggested by the experience in its use for a number of years. The hat block, which is composed of 48 pieces, and can expand from 6″ to 8″ average diameter, is in this manner adjustable for all the usual sizes of hats. 36 tongs grip the edge of the brim, taking hold about 3-8 of an inch of the hat body. The tongs being movable to and from the center of the hat block are arranged equidistant around the oval banding ring and the brim is thus drawn out, of equal width all around. The height of the block can be varied between 2½″

Fig. 2247.



Hat Shaping Machine.

and 7″, while the brim tongs have a range of from 2″ to 5½″ of the width of brim.

To shape a hat, or more properly to develop the band, the hat body, the tip and brim being previously stretched, is well soaked in hot water and is then put on the block. The latter has been previously contracted to its smallest diameter and the tongs are resting close to the block. The operator now puts his foot on the treadle and spreads the tongs until the brim slips off the loose jaws and rests upon the lower jaws, when he allows the tongs to close up to the edge of the brim. The loose tongs are now closed upon the edge by a turn of the short hand lever on the left side of the machine. The hand lever to which the banding ring is attached is thrown over the block and fastened by the hook in front of the machine.

The hat brim is now firmly held by the tongs, the operator raises the block by the outer hand lever, and, while depressing the treadle by his foot, spreads out the block to the desired size. The hat is then cooled and taken off, and the operation repeated on the next hat.

Four to six dozen can be readily blocked per hour by a good operator, and, as all the adjustments, — namely, the the size of band, height and diameter of crown, and width of brim, — are made by gages attached to the different levers, the operator can set each part in a few moments.

All sizes of hats from the largest to the smallest can be blocked on the same machine.

Share.

Fig. 2248.

Shares Har′row. One having shares instead of the ordinary teeth.

Shar′py. (*Fishing.*) Local. A long, sharp, flat-bottomed sail-boat.

Shav′ing. (*Leather.*) In this operation the currier's knife is driven from the top to the bottom of the beam, thus taking off shaving after shaving, removing all the inequalities left after skiving, and making the leather of uniform thickness, also leaving a beautiful smooth face on the flesh side. This operation is sometimes called *flattening*. The shaving or flattening is done almost at right angles to the skiving.

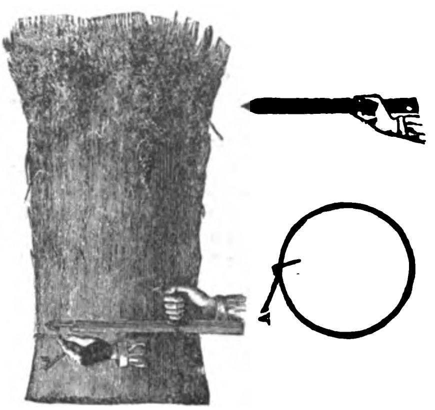
Shav′ing Ma-chine′. (*Stereotyping.*) Hand-machine for shaving stereotype plates, Fig. 5795, p. 2379, "*Mech. Dict.*" Power machines for the same purpose, p. 125, * R. Hoe & Co.'s catalogue, edition 1881.

For shaving hats, in the finishing process. See Pouncing Machine, *supra.*

Sheaf Bind′er. A hand implement for binding the sheaf with cord.

Fig. 2249 shows a French hand-binder. The string is strained around the sheaf by means of the stick. The band is composed of two cords knotted together, forming loops. The point of the tool is introduced through a loop at or near one end, and is thrust as far as the handle permits. The band being placed around the sheaf, the point of the tool is thrust through such one of the other loops as will give the tightness to the band, and the handle end of the tool is then carried over, describing an arc upon the point which is in the sheaf: the loop slips down from the handle to the point end,

Fig. 2249.



Sheaf Binder.

and the loop caught in the notch is then drawn through the loop on the stick, and the latter is withdrawn, allowing the knot drawn through to catch in the loop, where it is held by the expansion of the sheaf. The cords are 5′ long.

At the Paris Exposition were shown various attempts to obviate the use of the bunch of straw taken from the sheaf to form a band. One man proposes to use the bark peeled from osiers, two or three twisted together; these are sold very cheap. Another has cheap hempen strings cut to length and sold in bundles of one thousand each.

It is estimated that the annual crop of France is about 4,000,000,000 sheaves of grain, and that 50 straw bands contain one franc's worth of grain, the whole representing 80,000,000 fr., most of which is lost by shelling out on to the ground or mildewing under the band. Add to this the loss of time in making and applying, and the injury to the grain in the size of the band, which causes dampness to the sheaf. The figures seem formidable, and the *automatique* band is presented to solve the difficulty. The estimate is French, and in the interest of the hempen-band sellers; it is probably somewhat exaggerated.

Fig. 2250 shows a grain-band having a string attached to a block, and after passing around the sheaf rove through a ring. The mode of using it is evident from the engraving: the wooden block being held in one hand, one knee of the operator is placed upon the sheaf to compress it, while the other hand draws the cord through the ring. The expansion of the sheaf pinches the cord between the ring and the block, and makes a perfectly tight fastening.

Fig. 2250.

Sheaf Binder.

The cord and block are treated with tar, and are smoked to render them indestructible by humidity and noxious to insects, rats, and lizards.

Sheath Knife. The fisherman's knife, worn in a sheath.

Sheer Boom. (*Hydraulic Engineering.*) The word is taken from the sheer-boom for logs, used by lumbermen, p. 2141, "*Mech. Dict.*"

A floating structure moored aslant in a stream to direct the current in a given direction to prevent erosion on a certain shore, for instance. Such a boom 750′ in length and furnished with 44 rudders, 20′ long and 16′ apart, is operated by wire ropes and crabs near Rock Island, Ill. See "*Report of Chief of Engineers, U. S. Army*," 1878, * ii. 710.

Anderson's booms are designed for gathering and storing away in an inclosure logs floating down with the current of a river; and the nature of the invention consists in combining, with a sheer-boom adapted to float upon the surface of the water, and to be pivoted to a pier-head, a number of horizontally-vibrating fins or blades pivoted to the said boom, whereby they are adapted to be vibrated outward for the purpose of utilizing the force of the current for placing the sheer-boom in position for work, or inward toward the said boom, for the purpose of causing it to swing down stream out of the way when not in use, or to allow the passage of steamers or other vessels in navigable rivers.

Sheer Pole. One of the spars of a sheer, or a single one with guys and used as a substitute for regular sheers.

Sheet Cal'en-der. A machine for pressing paper, rubber, etc., into sheets and giving it surface. See CALENDERING MACHINE, *supra.*

Sheet De-liv'e-ry. Delivering the printed sheet from the form to the fly.

Cottrell's air sheet delivery floats the freshly printed sheet down the gages, without the use of tapes, to avoid the blurring or smutting sometimes produced by these.

Two pipes leading from the hollow piston of the air-plunger, one conveys the air to the governor, and the other to an air receiving cylinder located under the track. The air in this receiving-cylinder is permanently kept at the highest pressure, which is attained by a check valve in the pipe leading to it. From the air cylinder is an upright pipe connecting with the perforated tubes. In the upright pipe is a trip-valve, operated by a cam, which opens the valve at the precise instant the sheet comes over the wheels, inducing a puff of air sufficient to carry it down to the gages on the fly, and without touching the fingers.

The exact amount of air required to float the sheet can be regulated instantaneously by the pressman, so that the printed sheet is always under perfect control.

The Adams press uses a bellows for same purpose.

Sheet Lead. Lead made in sheets by hammering or casting.

The making of sheet lead for the lining of tea chests, etc., is a somewhat important industry of Hong Kong. It is made principally in sundry establishments to the westward. On entering one, workmen will be seen with shears busily employed in cutting out the sheets of lead into the required sizes and shapes. The shears are simply a large pair of scissors, firmly fixed to a solid block of wood some 2′ in height. The lower blade of the shears terminates in a square piece of iron instead of being pointed, as is the upper blade. The sheets of lead will also be observed to be of small size and somewhat irregular in shape, and this arises from the method of manufacture, as will subsequently be seen. Going further into the shop will be seen an iron pan raised 12″ or so above the ground and carefully finished off. Beneath this iron pan is a furnace, and at the side of the pan next the wall is the flue communicating with it. In this pan the lead is melted, and when judged to be hot enough, the workman takes two of the large square paving tiles, which may be seen almost anywhere in the colony, and these are then smoothly and carefully covered with several layers of unsized paper. Having placed these two tiles before him, one above the other, the workman raises the upper tile with his left hand, and, taking a ladle of the proper size in his right, he dips it in the melted lead and then pours its contents on to the lower tile. He then drops the upper tile and quickly presses the lead out into the form of a sheet. The paper being a bad conductor of heat, the lead does not solidify immediately it leaves the ladle, and, as by long practice the workman always ladles out exactly the same quantity of lead, the sheets made vary but little either in size or thickness.

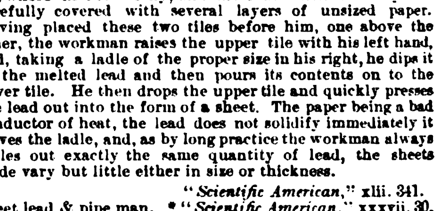
"*Scientific American*," xlii. 341.
Sheet lead & pipe man. * "*Scientific American*," xxxvii. 30.
Sheet lead rolling mill . "*Manufact. & Builder*," ix. 172.

Sheet Point'ing Ma-chine'. A machine for preparing printing sheets for cutting. The needles which project above the surface of the table are adjustable to suit the perforations made by points in process of printing. When a sufficient number of sheets are placed the points are drawn down, leaving the paper accurately piled and ready for the cutting machine.

Page 160, * R. Hoe & Co.'s Catalogue, ed. 1881.

Sheet Trav'el-er. (*Nautical.*) A grommet punched from sheet metal, adapted to slide on a spar, rope, bowsprit, etc.

Fig. 2251



Sheet Traveler.

Shelf' piece. (*Nautical.*) A strake of plank running internally in a line with the decks to receive the ends of the beams.

Shell. 1. (*Nautical.*) The body of a tackle-block. The groove outside is the *score.* The space occupied by the *shears* is the *swallow.*

2. A metallic or paper cylinder, inclosing a cartridge.

Shell truck	* "*Scientific American Sup.*," 514.

3. A Russian tool for turning insides of hollow projectiles. Fig. 26 accompanying Appendix I., "*Ordnance Report*," 1877, and page 528.

Shell Piece. (*Spectacles.*) One of the shields of tortoise-shell or horn, used with spring eye-glasses which clasp the nose.

Shell Re-du'cer. A device for reducing or expanding a cartridge shell.

The instrument is held in the right hand, open far enough to allow the shell to be entered sideways into its seat, catching the flange under a hook in a top piece and entering the open end of the shell into a die. The handles are then pressed together to reduce the shell at the mouth. By opening the handles the shell will be withdrawn from the die; and as it then may be a little too small it can be brought to the exact size of the bullet by the repetition of the same process, using a plug instead of the die.

Shift'ing Lo-co-mo'tive. A yard locomotive. See SWITCHING LOCOMOTIVE.

Shin'gle Ma-chine'. Burt's 12-Block Rotary Shingle Machine has an iron frame carrying two horizontal circular saws at opposite sides of the iron frame, above which, mounted on rollers and revolving above the saws, is a circular carriage divided by radial ribs or arms into 12 sectors of varying widths. At the inner end of each sector is a dog which advances and retreats in the horizontal plane twice in each revolution; this being effected by belt crank levers and inclined planes. A block being placed in a sector at a point midway between the saws, the dog holds it; and the table, revolving, carries the block to the saw, which cuts a shingle off the bottom; the dog then loosens the block and allows it to drop, again gripping it just in readiness for the next saw. The 12 sectors may all be filled at once, two shingles from each being cut at each revolution (or 24 in all).

The shingles may have any desired taper, and may be either 16 or 18 inches long. The capacity of the machine is stated at 200,000 white pine or cypress shingles per day, 30 horse power driving the machine, drag saw, jointer, bolter, etc.

Ship Float. 1. A lighter.

2. The splashers of a paddle-wheel.

* "*Engineering*"	xxiii. 369-371.

Ship Rail'way. A railway composed of several tracks, with a carrying cradle for transporting small coal-laden vessels overland from one body of water to another.

Capt. J. B. Eads's plan of a proposed ship railway across the isthmus of Panama consists essentially of a series of some eight or ten tracks, having a carrying car or cradle consisting of some five sections. These to have 1,000 wheels. Estimating the weight of a large merchant ship and cargo at 10,000 tons, and distributing it over an area of 40 × 500′ would give a pressure on the road-bed of about 1,200 pounds per square foot, cars and all, not half the pressure on the earth under each tie as there is when the driving-wheels of an ordinary locomotive pass over it. A ship railway across this isthmus has been the subject of much discussion, for more than thirty years, in fact.

Eads, "*Scientific American*," xli. 64, 68, 97, 144, 160; xliii. 303.

Ship Scra'per. A triangular or square piece of steel, handled, and with sharpened edges for scraping the keels and decks of vessels. See SCRAPER, "*Mech. Dict.*"

Ship's Tim'ber Saw. A machine for giving the proper lines to ships' timbers. See BEVEL SCROLL SAW, Fig. 669, p. 279, "*Mech. Dict.*," and SAWS, *Ibid.*

Shirt Frame. A Guernsey, or shirt knitting machine.

Shod'dy Ma-chine'. See RAG PICKER.

Shoe Bolt. One with a countersunk head for cutter and sleigh runners.

Shoe Em-boss'ing Ma-chine'. For embossing the vamps of boots. The stamp is heated by steam or lamp, and the boot, which is held on a goose-neck, is forced up against the die by a treadle.

Shoe-ma'ker's Wax. A wax used in making the waxed ends used in sewing leather.

Shoemaker's wax, when made for hand-work, is composed generally of equal quantities of pitch and resin, with 10 per cent. of tallow; after boiling (if good wax), it is pulled until the wax assumes the color of pale resin. The pulling takes out, or, more properly, bleaches, the ingredient pitch, and thereby takes out the coloring all pitch contains. Wax used for machines has all of it too much pitch and tar for clean work; the coloring matter in pitch and tar comes up through the grain; once in it cannot be got out — and wax boiled or heated again, unless in a perfectly clean vessel, and even then, partly recovers the coloring bleached out by hand-pulling. Wax that will work up the pure bronze color so much liked by shoemakers may be made of 4 lbs. resin, 1 lb. pitch, 4 oz. beeswax, 3 oz. tallow — the tallow to be refined, otherwise 3 oz. best sperm oil. The beeswax seems to destroy the coloring matter of the pitch when in that proportion. A good resin wax is superior to any other composition for wear, because it decomposes on exposure and wear into a stony substance in appearance, and looks not unlike pegs of amber when put under the microscope. Wax, with any tar in, or much pitch, when heated continuously, becomes only a dirty discoloring matter, as the oil evaporates, carrying with it all the valuable adhesive or glutinous properties of the pitch, and such wax will most readily soil or discolor the flange of the channel that is laid over it. The above recipe makes a wax which will give satisfaction.

Shoe Pad. A cushion to lessen the shock on a horse's foot.

Shoe Peg'ging Ma-chine'. A machine which takes the pegs in the strip, feeds and cuts them, and pegs on the sole. The preparatory machinery, in getting out the pegs from the log, consists of the slabber, heading machine, boring machine, pointer, splitter, bleacher, fan-blower, steam dryer, polisher, separator, winnower. See PEGGING MACHINE, *supra*.

Shoe Sew'ing. A sewing-machine having a thread-carrying hook in the end of a horn small enough to be inserted inside of the shoe at all points. The hook, acting in conjunction with the needle, sews the sole to the upper with remarkable celerity. See "*Mech. Dict.*," pp. 2162, 2163.

Shoe Sol'ing. Fastening the soles to the uppers by machinery. See "*Mech. Dict.*," pp. 462, 463, and PEGGING, *supra*.

Short'-cheek Bri'dle. A blind bridle having short cheek-pieces with rings at the lower ends, into which the bit-strap is buckled.

Short Cir'cuit. (*Electricity*.) The completion of a circuit by a shorter route or cross-way.

Short'en-ing Knot. (*Nautical*.) A form of knot shown at 40, 41, Fig. 2777, p. 1240, "*Mech. Dict.*"

Short'hair Knife. (*Leather*.) A keen-edged knife used in the beam-house to remove short hairs (new growth) from the hides.

Short Splice. (*Nautical*.) The junction of two ropes intertwining the strands for a relatively short distance. See *i*, Fig. 5435; also *a*, *b*, *c*, Fig. 5434, p. 2279, "*Mech. Dict.*"

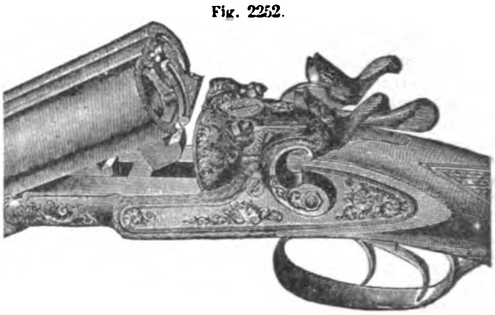
Short Stay. (*Nautical*.) In weighing anchor, it refers to the position of the anchor when nearly under foot in heaving in.

Shot Com-press'or. (*Surgical*.) A forceps to fasten leaden shot upon the ends of a ligature as a substitute for tying. The shot is partially split with a knife, put over the ligature threads close up to the suture, and the shot pinch-closed upon them.

Shot Gun. Fig. 2252 is a breech loading shot gun manufactured at Colt's armory. The parts are interchangeable, and so accurately made that parts of different guns may be intermixed and a gun may be put together from parts taken haphazard. The lock is of the rebounding style, and the firing pins are without springs.

The action bolt which retains the barrel in its place is moved by a lever, back of the hammer, through the medium of internal parts not shown in the engraving. This bolt engages two hooks on the barrels and retains the barrels rigidly in place.

Fig. 2252.



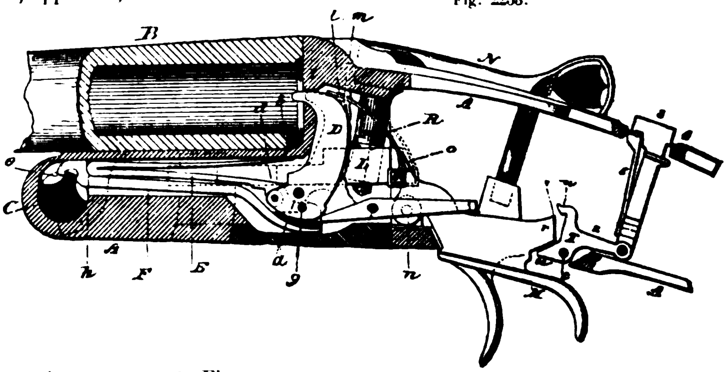
Colt's Breech Loading Shot Gun.

The bolt carrying the shell extractors is engaged by a cam on the bolt, connecting the stock and the barrel, and when the barrel is released by drawing the action bolt and tipped as shown in Fig. 2252, the shell extractor is operated.

Fig. 2253 shows that form of the Colt shot gun, having concealed hammers which are cocked by the *breaking down* of the barrels. The hammers can be locked in this position, to prevent accidents, by a forward motion of the trigger, and released at will by a forward and downward motion of a strp on top of the stock.

The shield or shell-shaped piece formerly placed upon the breech piece of muzzle-loading guns to prevent particles of the cap from being blown into the eye has been entirely dispensed with upon the Colt gun. It was a curious instance of the persistence of a form after its use has entirely departed.

Fig. 2253.



Colt's Concealed Hammer Breech Loader.

Colt . . . . * "*Scientific American*," xlii. 342.

Shot Line. (*Life Saving Apparatus*.) The cord attached to a projectile fired from a piece to fall over a wreck or stranded vessel and thus establish communication between ship and shore.

See pp. 200 and 251, "*Ordnance Report*," 1878, Appendix P.

Braided linen lines, Nos. 3½ to 7, are preferred.

Shroud Knot. (*Nautical.*) A form of knot shown at 48, Fig. 2777, p. 1240, "*Mech. Dict.*"

The shroud knot is a species of splice that, instead of lying smoothly, stands out boldly in an even, well-shaped knot. To make it, unlay the ends of the rope for a couple of feet or so, and then interlace them; then make a single wall-knot with the ends on each part, and finish by laying away and tapering the ends as in a tack-knot.

Shunt. When an electrical current passes by more than one path, that specially intended for its passage is termed the main circuit, while the rest are termed derived circuits.

The effect of introducing derived circuits is to diminish the strength of the current flowing in the main circuit, and when a single derived circuit is applied for this purpose, it receives the technical name of a "shunt."

The law of shunts is as follows: —

The strength of current in any branch of a system of derived circuits, or "multiple arc," as it is termed, varies inversely as the resistance of that branch. Hence by varying the resistance of the shunt we vary the strength of current flowing through the main circuit.

The resistance of the shunt bears a mathematical relation to the current passing in the main circuit, and that by knowing the one the other can be calculated. Thus, in the case of a galvanometer with a variable shunt interposed between its terminals, by observing the deflection of the needle when the shunt is in circuit, we can determine what the deflection would have been without the shunt, by multiplying the reading by a variable factor termed the "multiplying power" of the shunt.

Another fact worthy of notice in connection with this portion of the subject is that by means of a variable shunt the same deflection of the needle of a galvanometer may be reproduced by currents widely differing in strength, and hence all errors due to inequalities in the value of an uncalibrated scale are entirely avoided.

When an electro-magnet situated on a line of telegraph is shunted by a rheostat or "simple shunt," that rheostat tends to become the path by which the extra currents are discharged, and so prolonged is the magnetization, that if the circuit be closed and opened with any degree of rapidity, the armature sticks or remains permanently attracted — a principle which has been employed in double current translation. This retardation is at its maximum when the resistance of the shunt equals that of the electro-magnet. But should the shunt be a second electro-magnet, or, in other words an "electro-magnetic shunt," then the extra current formed in it opposes that formed in the electro-magnet, and both send a current back into the line. The current from the shunt, however, may be so exalted as to neutralize and even overcome that formed in the electro-magnet itself. So that by a properly arranged electro-magnetic shunt, the magnetic retardation in the electro magnet itself may be reduced to a minimum, while a current is sent back into the line immediately after each signal, thus tending to increase the speed at which the line can be worked.

Shunt Box. (*Electricity.*) An English term equivalent to a switch box or board.

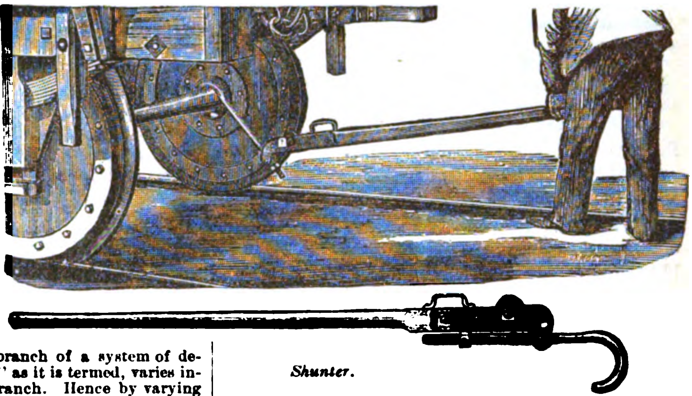
Rymer-Jones . . . * "*Telegraphic Journal*," vii. 128.

Shunt'er. A hand propeller for cars. See Pinch Bar, etc., Fig. 3725, p. 1706, "*Mech. Dict.*"

The illustration, Fig. 2254, will give a general idea of the "Shunter," which is a wooden lever, 6′ long, with a pair of side-plates fixed to it at one end, to which is attached a swivel, through which passes an iron rod, having a hook at one end which hooks over the axle. The other end has a screw with a loose nut, to shorten or lengthen the rod according to the size of wheel; from a saddle which crosses the lever and binds the side plates to the wood, project two lugs, shaped to fit the flange of the wheel. When the shunter is in position with the hook over the axle, the lug comes in contact with the flange of the wheel. Upon raising the lever the lug is pressed against the flange in proportion to the force applied, and becomes fixed; upon continuing to raise the lever, the wheel is caused to revolve in the same direction, and the carriage is propelled forward; upon lowering the lever, it immediately becomes loose, falls again, and the action being continued — every upward movement propels the carriage forward from 9″ to 15″.

To adjust the shunter for working, drop the hook over the axle, and hold out the wooden lever horizontally, then regulate the length of the hook by running the nut forward or back as may be required, so as to bring the projecting lug on the side of saddle about 1″ distant from the edge of the wheel; the length of rod being once adjusted will suit all wheels that do not vary more than 1″ in diameter.

Fig. 2254.



Shunter.

Shunt'ing En'gine. A British term for a yard or switching engine. See one type of such from "*Engineering*," reproduced in "*Scientific American Sup.*," * 4071.

See Switching Engine.

Shunting engine.
London & N. W. Ry., Br. . * "*Engineering*," xxx. 184.

Shut'ter Dam. A dam or gate operated by the water.

Some recent improvements in France of shutter dams, worked by hydraulic pressure, have attracted much attention among engineers, the system comprising — first, a series of great wooden water-gates, movable around a horizontal axis working in a cast-iron shoe secured to the floor of the dam; second, hydraulic presses applied on the down-river side of the floor, solidly anchored in the masonry and designed to work the gates — the piston of each press bearing a cast-iron cross-head working in slides, to which cross-head three rods are attached, for communicating the pressure to a cross-bar fastened in the center of the movable gate; third, a series of copper tubes which puts each press in communication with the generator or reservoir of power destined to transmit water under the pressure of the hydraulic presses; and fourth, hydraulic works built on the abutment of the dam — these comprising a turbine with a vertical axis, a double force pump which receives motion from the turbine, and a reservoir of force. The pumps and the reservoir communicate with each other, and with the presses, by means of three-way cocks, which let the water either into the reservoir or into the presses, or empty it into a discharging tube. The maneuvering of the gates is effected by simply moving these cocks. By putting in communication each press either with the pumps or with the reservoir of power under a sufficient pressure, an ascending motion of the piston is effected, and in consequence the gate rises. By opening the cock into the waste pipe, the water escapes under pressure of the gate, the "*corps de presse*" is emptied, and the gate sinks.

The reservoir force is a regulator of the play of the pumps and also permits the dam to be raised sufficiently, in case of need, to put the turbine in motion.

Shut'ter Eye. An eye for hanging a shutter to, having a projecting flange or support, which is built into the wall.

Shut'tle. A section of a movable dam in the modern system of movable dams. See Watson's Report, Vienna Exposition, vol. iii., "*Civil Engineering.*"

In M. Boule's design the shuttles are placed in tiers, between slight wrought-iron upright supports, 3½' apart, carrying the foot-path, so that the shuttles can be readily removed and replaced. In America shuttles hinged at the bottom, maintained in their places by props, and falling down flat on the apron of the weir when the props are removed, have been introduced.

See BARRAGE DAM.

Shut'tle Race. The inclosure in which the sewing-machine or loom shuttle travels.

Si-cil'i-enne. (*Fabric.*) A silk and wool French goods.

Sick'le Grind'er. A clamp and rest hold the sickle on the grindstone in such a position that all the teeth receive the same bevel.

See Fig. 3248, p. 1493, "*Mech. Dict.*"; Fig. 4205, p. 1898, *Ibid.*

Side Ac'tion. (*Fire-arm.*) One in which the locking fast of the barrel when closed is by a side lever.

Side Bar. A form of spring to give a buggy a sidewise, rolling motion instead of the forward pitching.

Side Bear'ing. Supports which are placed on each side of the center-pins of a car, and intended to prevent too much rolling or rocking motion of the car-body.

Usually there is a plate of iron or steel attached to the body-bolster on each side of the center-pin which is called a *body side-bearing*, and a corresponding plate, block, or roller on the truck-bolster which is called the *truck side-bearing*.

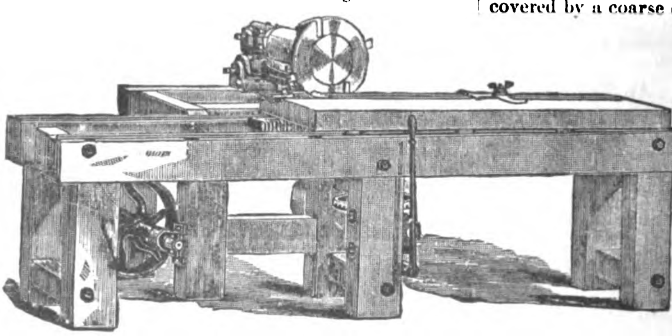
Side Con-dens'ing Lens. A condensing lens, for the illumination of opaque objects, fitting into any of the holes on the stage of a microscope. A pair of stage forceps also fits into the holes to hold small insects.

Side File. For trimming up the outside edges of the cutting points of saws after setting, to prevent setting.

Side-pla'ning Ma-chine'. Designed for planing or jointing the edges of short boards where an accurate glue joint is required, such as cabinet and piano-forte work, and for trying out pieces for small frames, etc. It consists of a long, narrow frame with a self-feeding carriage on which the stuff is fastened by adjustable dogs, and a wing to hold a cutter head.

These machines are usually made to work stuff 5' long, but can be made to work longer when ordered, at an extra cost. The cutter head is adjustable in all directions, has cast steel arbor, and patent self-oiling boxes.

Fig. 2255.



Side-planing Machine.

Si-der-aph'thite. The name of a new iron amalgam which is composed of 63 parts of iron, 23 nickel, 4 tungsten, 5 aluminum, 5 copper. It resists sulphureted hydrogen, is not attacked by vegetable acids, and only slightly by mineral acids. It is really more useful than standard silver, while it can be produced at a cost not exceeding that of German silver. For alloys which have to be silver-plated to prevent oxidation, the inoxidizable iron, as the above is called, is stated to be a perfectly successful substitute.

Fig. 2256.

Side Reflector.

Side Re-flect'or. A means of reflecting parallel rays, mounted so as to bring them to a focus on an opaque object under the microscope.

Si'der-o-stat. An astronomical instrument designed to keep a star within the same portion of the field of a telescope for observation.

An admirable example may be found in Léon Foucault's siderostat in "*L'Astronome Pratique et les Observatoires, en Europe et en Amerique,*" by *André & Rayet.* Paris, 1874.

Side Scut'tle. An opening in the side of a ship, to admit light and air, but which can be closed water-tight. In Fig. 2257 the glass is protected by two dead doors, one inside and one outside.

Fig. 2257.

Side Scuttle.

Sie'mens-Hals'ke Bat'te-ry. (*Electricity.*) A modification of the Daniell battery. In a glass vessel is a spiral copper element in a sulphate of copper solution kept saturated from the crystals contained in a tube through which passes the positive pole. Upon the copper rests a pasteboard disk supporting the diaphragm composed of acidulated paper pulp covered by a coarse cloth. Upon this is placed the zinc element from which the negative pole rises. The vessel is charged by being filled with water.

Prescott's "*Electricity*" . . . * 52.

Sie'mens-Mar'tin Steel. (*Metallurgy.*) Steel made by the Martin process; melting cast iron in a Siemens' reverberating furnace, and adding wrought iron until the required attenuation of the carbon is attained. Oxides and free oxygen are removed by ferro-manganese and the metal run into molds. See p. 2365, "*Mech. Dict.*"

"While the Bessemer process has been making rapid strides, a rival process has gradually grown up by its side, which I cannot pass over without remark. I allude to the open-hearth steel process, with which my name and the joint names of Siemens and Martin are associated. The conception of this process is really as old as that of cast steel itself. The ancient Indian steel, the Wootz, was the result of a fusion of a mixture of malleable and cast iron. Reaumur, as already stated, proposed to melt wrought iron and pig metal together, for the production of steel, as early as 1722; and G. B. Heath — to whom we owe the important discovery that by the addition of manganese to cast steel its malleability is greatly increased — endeavored to realize the conception of producing steel in large masses upon the open hearth of the furnace in the year 1839, and he again has been followed in these endeavors by Gentle Brown, Richards, and others in the same direction.

"When, in 1856, I first seriously gave my attention, in conjunction with my brother, Frederick Siemens, to the construction of a regenerative gas furnace, I perceived that this furnace would be admirably adapted to the production of steel upon the open hearth, and proposed it for such a purpose to Mr. Abraham Darby, of Ebbw Vale, in 1861. Ever since that time I have been engaged in the realization of this idea, which has been retarded, however, by those untoward circumstances which ever intervene between a mere conception and its practical realisation. Although two of my earlier licensees, Mr. Charles Attwood, of Tow Law, and the Fourchambault Company, in France, with whom was my late esteemed friend, Mons. Lechatelier, Inspecteur-General des Mines, succeeded, in 1865 and 1866, in producing steel upon the open hearth, they did not persevere sufficiently to attain commercial results; but it was not until after I had established experimental steel works at Birmingham that I was enabled to combat in detail the various difficulties, which at one time looked well-nigh insuperable. While thus engaged, Messrs. Pierre and Emile Martin, of Cereuil, — who had obtained licenses for furnaces to melt steel both in pots and on the open hearth, — succeeded, after a short period of experimenting, in introducing into the market open hearth steel of excellent quality.

"While Messrs. Martin thus gave their attention to the production of steel by the dissolution of wrought iron and steel scrap in a bath of pig metal, my own efforts were more especially directed to the production of steel by the use of pig metal and iron ores, either in the raw state or in a more or less reduced condition, which latter process is the one mostly employed in this country." — *C. W. Siemens.*

Sift'er. An apparatus to dust dry poison upon plants to destroy insects. For instance: —

Young's sifter to destroy cotton worms. See "*Comstock's Report on Cotton Insects,*" 1879, * p. 246.
Willis's sifter, *Ibid.*, * p. 248.
Davis's sifter, *Ibid.*, * p. 249.
Levy's sifter, *Ibid.*, * p. 250.
Eldridge's sifter, *Ibid.*, * p. 251.
Sifting reel for gunpowder, Br., * "*Engineering,*" xxv. 37.

Sight. "*Ordnance Report,*" 1877, Appendix L, Fig. 110, and p. 582, shows and describes the following: —

Werder (Bavarian).	*Vetterlin* (Swiss).
Comblain (Belgian).	*Chassepot* (French).
Mauser (Prussian).	*Werndl* (Austrian).
Berdan (Russian).	*Martini-Henry* (British).

Mauser rifle (Prussian) sight, Figs. 4, 5, 6, article "*Armes à feu,*" vol. iv., *Laboulaye's* "*Dictionnaire des Arts et Manufactures,*" ed. 1877.

There are various names of sights among which are the following; some of them are synonyms, and some merely refer to position, actual or relative.

Aperture sight.	Leaf sight.
Bar and Bead sight.	Muzzle sight.
Bar and slit sight.	Open bead sight.
Beach combination sight.	Open sight.
Bead sight.	Peep sight.
Buck-horn sight.	Pin-ball sight.
California sight.	Plain sight.
Clover-leaf sight.	Rear sight.
Covered sight.	Reflecting sight.
Front sight	Slit bar sight.
Globe sight.	Sporting sight.
Graduating sight.	Telescopic sight.
Hausse.	Vermer-scale sight.
Hind sight.	Wind gage sight.

Fire-arm, *Warfield* . * "*Scientific American,*" xlii. 245.

Sig'moid Cath'e-ter. (*Surgical.*) A catheter named from its resemblance to sigma (*s*). Fig. 1190 *d*, p. 204, "*Mech. Dict.*"

Sig'nal. A means of communicating between distant points by signs having a known meaning.

Captain Maryatt's code was used in England till 1857, when the English board of trade issued "The Commercial Code of Signals for all Nations," which is now in general use for marine signals. It requires 18 flags, 4 flags only to be used at a time, giving 20,000 messages.

The "Telegraphic Dictionary" and "Signal Box," United States code of 1857, had two books of signals, a distinguishing flag being used when the "Telegraphic Dictionary" was used.

In 1859 Costin's plan was adopted. See *Myer's* "*Manual of Signals,*" New York, 1866, for field work, varied information; or methods and codes by color flags, motion of flags, torches, or of lanterns, flashes, occultations, or puffs; semaphonics, rockets, colored lights, and by sound.

Ward's "*Semaphonic Color Signal,*" Philadelphia, 1866. Radical color patches in green, white, and red; read from the center outward across the concentric circles, which inclose numerals and letters.

Ward's "*International Code,*" Auburn, N. Y., 1867. Message indicated by dips of the flag, so many dips representing a given letter, and a code of abbreviations for possible messages.

Ward's "*Code,*" Auburn, N. Y., 1858. System of 10 flags and 3 repeaters, and a code of 11,000 possible messages.

Roger's "*American Code.*" New York, 1854. Ten breeze and calm flags with a dictionary of 60,000 possible messages represented by the number flags.

Jink's "*Brachial Telegraph.*" New York, 1852. By arm motions.

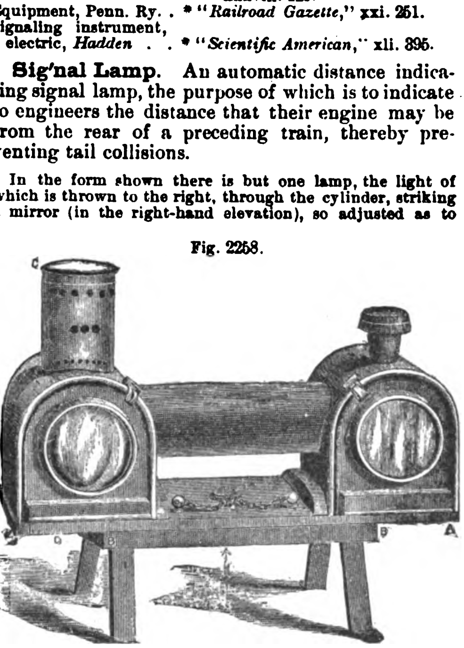
Sig'nal Lamp. An automatic distance indicating signal lamp, the purpose of which is to indicate to engineers the distance that their engine may be from the rear of a preceding train, thereby preventing tail collisions.

In the form shown there is but one lamp, the light of which is thrown to the right, through the cylinder, striking a mirror (in the right-hand elevation), so adjusted as to

Fig. 2258.



Signal Lamp.

reflect a strong white light, which at a distance of one mile and upward, is absorbed by the red light at the left, but inside of a mile, as the train approaches, the two lights separate, thus at ⅞ of a mile blending together, ¾ of a mile, 3″ apart; ½ mile, 12″ apart, ¼ mile, 20″ apart; and ⅛ mile, 28″ apart; thus enabling the engineer to tell when he is running faster than the preceding train, when he is running slower, when the train stops, or when it commences backing. The different conditions of the atmosphere do not interfere with the relative spaces between the two lights.

Sig'nal Lan'tern. For signaling by flashes of light.

Otter's signal lantern with registering apparatus is intended for transmitting signals at night, both at sea and on land, and at distances not exceeding eight to ten miles; the controller is for registering given or received signals, its aim being principally to prevent errors. The system used in telegraphing is the same which has lately been tried and partly adopted in several countries: but the means are different.

Morse's telegraphic lines and dots are represented by long and short flashes; letters and figures, by various groups of flashes. Flashes belonging to the same group are separated by dark intervals of short duration, groups and sentences by dark intervals of longer duration (pauses), the extent of the latter being limited by the skill of the operators.

Two strings are suspended from the lantern and passed through the controller. By pulling the one of these strings long flashes (lines) are produced, and by pulling the other, short flashes (dots).

By pulling a third string, hanging down from the controller, between the two strings from the lantern, a pause will be produced, and the signalized letters or figures are impressed on a self-acting strip of paper.

The strings should be pulled with even force and to their full extent, but without jerking.

Signaling between two or more places is effected in the most convenient and sure manner, by each receiver of a signal repeating on his lantern and controller the signs conveyed. The communication is thereby printed on the above mentioned strip of paper, without it being necessary for the receiver to understand the telegraphic characters.

The lantern may also be employed independently of the controller in transmitting signals and vice versa, the controller used independently of the lantern in receiving signals. In the latter case, three keys, attached to the upper part of the controller should be used instead of the corresponding strings.

A suitable weight attached to the block under the lantern brings into action a proposed new method of distinguishing lights from each other, rendered necessary by their increasing number. It is proposed that each light, on the principle of the above signals, shall describe its name every alternate or every third minute, by combinations of long and short flashes; for the exact reading of which a simple and easily worked apparatus is annexed.

These lights may be either revolving or fixed. In the former case the flashes will be produced by lenses, in the latter by Venetian blinds.

Sig'nal-ing Tar'get. A form used at railroad crossings and switches to indicate to the engineer which train has the right of way, or whether the main track or switch is open.

Two targets, generally a round and an oblong one, and generally painted red and white respectively, are set at right angles to each other on a revolving shaft. These are turned by the target-man by means of a hand-lever, so as to bring either one in a line across the road, in view of the engineer, and indicate to him whether the main track or a switch is open. At night a red or white light on the shaft gives the same information.

A common form at ordinary switches is an upright pivoted lever with target on top. The movement to the right or left indicates the position of the switches.

Sil'i-cate Board. An incombustible board for roofing. Saturate alternate layers of pasteboard with silicate of soda, and with a solution of chloride of barium or other salts, which produce insoluble silicates, such as salts of zinc, calcium, magnesium, and aluminium. The mass of the board becomes saturated with insoluble silicate of barium and silicic acid, which renders it fire and weather proof.

Sil'i-cate Cot'ton. A name for *slag wool.* See SLAG WOOL, "*Mech. Dict.*," p. 2198, and MINERAL COTTON, p. 1446.

Krupp, Essen . . . . . . "*Engineering*," xxi. 19.

Sil'i-con Steel. A steel in which silicon replaces a part of the usual carbon. For instance: —

Nes Patent, 102,068, Feb. 1871.

Carbon	0.600
Silicon	0.552
Iron	98.848

He claims a steel in which the proportion of silicon to carbon is not less than 1 to 2.

See also his patents: —

104,873,	108,287,	109,752,
123,191,	125,212,	145,005.

His silicon is a mica-schist magnetite containing from 30 to 40 per cent. of magnetic oxide of iron. The process of manufacture of steel consists simply in mingling the pulverized ore with molten cast or pig iron, and by oxidation reducing the percentage of carbon until it reaches the standard of low steel. The ore used is from York county, Pa. Views as to the value of this process differ widely, though it seems undeniable that rails made by it last longer than iron, and can be rerolled.

On, *Pourcel*, Fr.	"*Van Nostrand's Mag.*," xix. 560.

Silk. A fiber, the product of the silk worm.

The silk industry of America is growing to very satisfactory proportions, over 40 per cent. of the silk goods used in the country in 1882 being home made. There were some $40,000,000 worth manufactured, as follows: machine twist, $7,000,000; dress goods, $5,000,000; satins, $1,500,000; ribbons, $7,000,000; handkerchiefs, $5,000,000; fringes and dress trimmings, $6,000,000; sewing silk, $1,500,000; ties and scarfs, $1,000,000; tassels and millinery silks, $2,000,000; balance in upholstery and other trimmings. Of this amount nearly one half was manufactured in New Jersey, while Connecticut, Massachusetts, New York, and Pennsylvania produced three fourths of the remainder. The number of establishments manufacturing was about 400, employing nearly 9,000 looms, 6,000 spindles, and paying in wages, $10,000,000. Our manufactories import $10,000,000 to $13,000,000 worth of raw silk annually, and the duty on silk goods amounted in 1880 to $32,000,000, against $45,000,000 for woolen goods, and $51,000,000 for iron and steel. The production of the raw silk at home is increasing very rapidly, however, and we hope to see sufficient raised in the United States in a few years to supply the home demand. The southern States and many northern States are well adapted to the rearing of the silk worm and its food, the white mulberry tree; while a number of parties like Virion Des Lauriers, of New York, and the Women's Silk Association, of Philadelphia, are sending silk worm eggs and mulberry trees to all parts of the country, and buying the cocoons produced. The care of a few silk worms for a month in the spring is both interesting and profitable work, and can be managed exclusively by women and children.

Silk and silk culture in the United States, see *Hayes'* "*Centennial Report*," v. 92-111.

Silk De-gum'ming Ma-chine'. A machine for treating the cocoons to deprive the filaments of their glutinous qualities, which, as first spun by the worms, cause the thread to adhere too closely.

The thread of silk as it unwinds from the cocoon is valueless for manufacturing purposes, several of them combined going to make the staple of commerce. The degumming in the silk districts is accomplished as follows: The cocoons are plunged into water near the boiling point, and moved about so that the gum which fastens the threads becomes uniformly and thoroughly softened. They are then beaten with a small birchen broom, having the tips split, so that the loose threads readily fasten to them. After beating a short time, the operator gets all the cocoons fastened, and taking the bundle of threads, shakes the cocoons till each hangs but by a single one. She now takes up five or more threads (*brins*) according to the quality of silk wanted, unites them, and introduces the combined staple or strand (*fil*) into a little glass eye on one side of the basin. She then forms a second similar strand and introduces it into a second eye on the other side. The strands are then brought together, twisted several times, separated above the twist, and introduced into two other glass eyes or ringlets, through which they are led, one to each end of the reel or *tambour* which is kept revolving in a steady, rapid manner, and to which is also given a certain back and forth side motion. The great object in reeling is to get the threads uniform, rounded, well joined, properly freed from moisture, and so crossed on the reel that they will not stick or glaze, as it is termed. These objects are attained by the twisting and the to and fro lateral movement of the reel, as also by properly regulating the distance between reel and basin.

The uniformity of the thread depends on the skill of the operator, who must supply a new thread as soon as one begins to give out. This is called nourishing the silk, and is done by dexterously casting, with the thumb, the new thread upon the combined strand, to which it immediately adheres. In this she must use much judgment, for the silk of a cocoon gradually gets lighter and finer as it approaches the end, and the uniformity of strand does not entirely depend on the uniformity in number of the individual threads forming it. Whenever the silk rises in locks the temperature of the water is known to be too hot, and when it unwinds with difficulty the temperature is, on the contrary, too low. The operator is supplied with a skimmer with which to remove all chrysalides and refuse silk; also, with a basin of cold water in which to cool her fingers, which are being constantly dipped in the hot basin. This constitutes the whole operation of unwinding; but before the skeins, as they come from the reel, are ready for the manufacturer they must undergo still farther manipulation. The staple is first passed through a cleanser, consisting of a clasp lined with cloth, which catches any loose silk or other matter that may be adhering to it. It is then further cleansed and purged by being passed through four similar cleansers (*purgeurs*), then twisted about 500 times to the yard, then doubled and twisted about 400 times to the yard. It is finally run on reels about 1½′ in diameter, and taken off and twisted in a peculiar knot or hank. Through all these operations the oscillating to and fro lateral motion is kept up, so as to produce the diagonal crossing of the strands, and it will be readily understood that each staple is, in the end, composed of 10 or more of the simple threads first spun by the worm.

Silk Ma-chin'er-y. Danforth Locomotive and Manufacturing Co. (Paterson, N. J.) use —

1. Winding frame for singles.
2. Silk spinning frame for singles; the spindles making 8,000 revolutions per minute.
3. Doubling frame in which the twisted singles are laid together on spools.
4. Reeling mill for spinning doubles; the spindles making 4,500 revolutions.

The size of the thread is according to the number doubled together, for the term is used whether 3 or 20 may be so laid up. Organzine may be two-thread doubles; tram may be 3 to 6 thread, or more. Spindle stop patent, March 24, 1876.

Nonotuck Silk Co.'s (Florence, Mass.) machinery for throwing and finishing spool silk consists of

1. Frame for winding on to spools from the imported skeins of raw silk. Machine has a glass eye for the singles to pass through. Hill's patent.
2. For doubling several threads (from 3 to 20) together as required to obtain the required thickness. This machine has Dimock's patent detachable drop-wire to stop the winding on that particular spool if either of the individual strands should break.
3. For spinning, or twisting the threads together; the machine having a self-oiling spindle.
4. A machine for doubling several of these spun strands together.
5. For spinning these doubled threads, forming a finished cord.
6. For reeling into hanks.
7. Dyeing follows.
8. A soft silk winding frame with Brown's patent rocking or oscillating motion to the top skein carrier to facilitate the work.

A Spool Printer and Spooling Machine, which see.

Silk Man'u-fac'ture. See manufacture of spun silk by Cheney Bros., South Manchester. *Hayes' "Centennial Reports,"* v. 100–102.

Of Paterson, N. J., *Ibid.*, 102-106.
Of Horstman, Phila., *Ibid.*, 107.
In U. S., Wycoff, 10th Census Report.

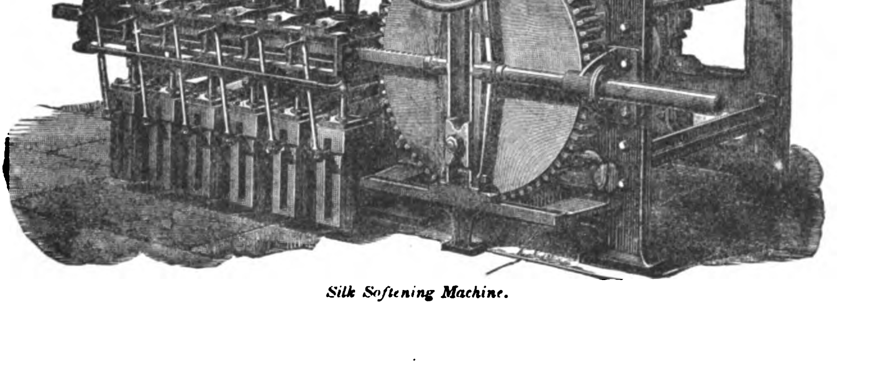
Silk Reel. A reel for winding the silk as it comes from the cocoons in the degumming process. The silk is passed through glass eyes, and through a guide having a transverse back-and-forth motion.

Silk, Sew'ing. See manufacture of sewing silks and machine twist, Nonotuck Co., Florence, Mass., and Danforth Manufacturing Co., Paterson, N. J., *Hayes "Centennial Reports,"* v., 98–100.

Silk Soft'en-ing Ma-chine'. A machine for softening and polishing silk after dyeing.

The skeins of silk are hung over two tiers of bobbins, the lower set free to move up and down, and are stretched by weights hung from the lower bobbins. This tier also moves faster than the upper ones, and has a reciprocating motion, horizontally, to twist and untwist the silk while revolving. See Fig. 2259.

Fig. 2259.



Silk Softening Machine.

Silk Sol′vent. For dissolving silk fiber to be mixed with wool, cotton, or linen fiber for imitation silk goods.

Schlossberger first suggested the use of an ammoniacal solution of protoxide of nickel for dissolving silk. Persoz proposed to use chloride of zinc, and Spiller used concentrated hydrochloric acid. J. Loewe recently described a new solvent, the cold alkaline solution of copper with glycerine, which is not inferior to the above, and with great dilution surpasses them. In very weak solutions, the silk is acted upon slowly; if moderately concentrated, the silk swells up on moistening it a short time; and with a larger quantity it soon dissolves to a thick liquid, which can be filtered, although it filters slowly. By adding hydrochloric acid to the filtrate, the dissolved silk separates in the form of a white jelly; frequently this separation is very slow, and the filtrate appears like a cold solution of gelatine. Wool, cotton, and linen, after being in contact with this solution for hours, is neither attacked by it nor taken up by it. It appears as if the solvent power of the alkaline glycerine and copper solution only extends to the silk. In mixed fabrics, the silk may be readily detected, and even quantitatively determined.

Silk Spin′ner. A machine for spinning and twisting singles for organzine. It has self-oiling spindles and steps. The latter are winged pieces which rest in cups, the wings preventing the vertical motion of the oil which might cause it to flow over the edge of the cup. A cover closes in the oil chamber and excludes dust. The spindles revolve 7,200 times per minute.

Silk Spool′ing Ma-chine′. A machine for winding silk on to merchant spools. See SPOOLING MACHINE; SILK SPOOLING AND MEASURING MACHINE.

Silk Spool′ing and Meas′ur-ing Ma-chine′. A machine for measuring on to bobbins the exact quantity of sewing or machine silk thread; say 100 or 200 yards, or other prescribed quantity.

The one used by Holland Manufacturing Company of Willimantic, Connecticut, has a finger which rotates on a dial-plate, moved by contact of an impelling roller which rotates in contact with the spool.

John D. Cutler & Co.'s (Paterson, N. J.) machine for spooling and measuring silk thread (Patent, March 3, 1874) has a friction wheel of determinate diameter resting against the thread, and communicates motion by worm-wheel to a train which actuates a printer on a graduated dial-plate.

Silk Stretch′ing. A machine for stretching and polishing after dyeing. See SILK SOFTENING MACHINE and Fig. 2259.

Silk Test′ing Ma-chine′. A spring balance has a bar graduated to a scale of weights for the purpose of testing the strength of the thread or filament. The thread is looped over the hook on the end of the spring-bar, and the ends being twisted around the finger, the thread is broken, a spring-catch detaining the bar so that the point at which it broke may be observed at leisure.

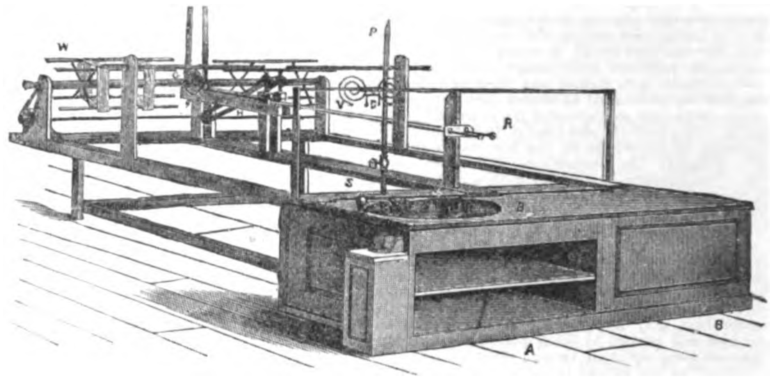
Silk Thread. Sewing-silk is two-cord and twisted from left to right, and machine-twist is three-cord and twisted from right to left.

Silk Wash′ing Ma-chine′. One in which the cocoons are passed to rid them of dirt, worms, glutinous and other refuse matter. See DEGLUTINIZING MACHINE above.

Silk Wind′er. For reeling the silk from the cocoons.

This apparatus, shown in perspective in the accompanying illustration, is double. Each half consists simply of a metal lined basin, *B*, supplied by a faucet, *S*, with cold water, heated to such temperature as may be desired, by steam from the pipe *P*. Immediately above and back of the basin is a transverse bar, *H*, which bears projecting horizontally from it, two stems carrying the *filières F*, which are porcelain disks half an inch in diameter, and each pierced in its center with a small vertical hole. The horizontal bar has a slight traversing motion. Above and across the machine is a transverse bar carrying the *croiseur* or *twister C*, which is a tiny reel with a vertical axis, and set in motion at will, by a train of clock-work. At each side of the *croiseur* is a *trembleur* or vibrator, *V*, which is a spiral spring bearing at its free end a loop fitted with a heart-shaped glass plate. Midway of the machine rise standards which bear a reciprocating cross-bar, fitted with a triangle of wire, apex downward. At the back of the machine are standards bearing a reel operated by a crank or by power, the belt being thrown into

Fig. 2260.



Silk Winder.

operation by a clutch actuated by the rod *R*. The cocoons (containing the dead chrysalides) being placed in a basin of hot water, are softened and rendered more easy to unravel. The free or outer ends of the cocoons are gathered by beating the floating mass gently with a stiff brush of twigs. Two sets of six each of these being selected, are passed upwards through the holes in the porcelain *filières F*, are crossed, passed through the loops on the *croiseur*, through the niche in the glass bushing in the vibrators, then through loops in the triangle, and then to the reel. The machine being then set in operation by the hand crank or by the belts, the delicate threads are unwound from the bobbing cocoons, brought together, intimately twisted, and wound on the reel, which is seen to contain two hanks of the twisted thread.

Silk′worm Nur′se-ry. A frame is made with light square vertical posts connected by horizontal parallel bamboo rods. The rods are placed at suitable distances to support a series of flat trays made of rice straw, in which the silkworms are reared.

Sil′ver. Equivalent 108, symbol Ag. (argentum), specific gravity 10.5, point of fusion, 1873° Fah. Generally occurs as a sulphide, and is often associated with other metals. The ore is ground and the silver separated by amalgamation. "*Mech. Dict.*"

Sil'ver Al-loy'. 65 parts of iron and 4 parts of tungsten are melted together and granulated; also 23 parts of nickel, 5 of aluminum, and 5 of copper, in a separate crucible, to which is added a piece of sodium in order to prevent oxidation. The two granulated alloys are then melted together. Both alloys resist the action of sulphuretted hydrogen.

See also *"Scientific American,"* xli. 103.

Sil'ver Glass. An ornamental ground and cut glass. This glass can be used in the place of plaster, marble floors, or wood inlaid work.

Patented February 2, 1875, *Jones*.

Sil'ver-ing. The formula for *silvering by dipping* is as follows: —

Dissolve 20 grams of silver in 60 grams of nitric acid, and precipitate with a solution of 20 grams of caustic potash in water upon a filter, and wash with water; then redissolve upon the filter with a solution of 100 grams of cyanide of potassium in water; then dilute the whole to 2 liters with distilled water, and use like the gilding solution described in Gilding by Dipping, under GILDING, p. 398, *supra*.

Silvering by Cold Rubbing. — Make paste by thoroughly grinding in a porcelain mortar, out of the light —

	Water	3 to 5 oz.
	Chloride of silver	7 oz.
	Potassium oxalate	10½ oz.
	Salt (common table)	15 oz.
	Sal ammoniac	3¾ oz.
Or,	Chloride of silver	3½ oz.
	Cream of tartar	7 oz.
	Salt (common)	10½ oz.
	Water, to form a paste.	

Keep in a covered vessel away from the light. Apply with a cork or brush to the clean metallic (copper) surface, and allow the paste to dry. When rinsed in cold water the silver presents a fine frosted appearance, the brightness of which may be increased by a few seconds' immersion in dilute sulphuric acid or solution of potassium cyanide. The silvering bears the action of the wire brush and of the burnishing tool very well, and may also be "oxidized." Should a first silvering not be found sufficiently durable after scratch-brushing, a second or third coat may be applied. This silvering is not so adhering on white or pure copper as upon a gilt surface.

For the reflector of lanterns the paste is rubbed upon the reflector with a fine linen pad; then, with another rag, a thin paste of Spanish white or similar substance is spread over the reflector and left to dry. Rubbing with a fine clean linen rag restores the luster and whiteness of the silvered surface.

The paste is sometimes mixed directly with the whiting and left to dry, or until nearly dry, then rubbed down as described.

Sil'ver-ing Glass. Prepare two solutions, says the *"Jeweler and Silversmith"*: —

1. Argentic nitrate is dissolved in distilled water and ammonia added to the solution, till the precipitate first thrown down is almost entirely redissolved. The solution is filtered and diluted so that 100 cc. contain one gram of argentic nitrate. 2. Two grams of argentic nitrate are dissolved in a little distilled water and poured into a liter of boiling distilled water; 1.66 grams of Rochelle salt is added and the mixture boiled for a short time, till the precipitate contained in it becomes gray; it is then filtered hot.

The glass having been thoroughly cleaned with (1) nitric acid, (2) water, (3) caustic potash, (4) water, (5) alcohol, and lastly, distilled water, is to be placed in a clean glass or porcelain vessel, the side to be silvered being placed uppermost. Equal quantities of the two solutions are then to be mixed and poured in, so as to cover the glass. This should be done while the glass is still wet with distilled water. In about an hour the silvering will be completed. Then pour off the exhausted liquid, carefully remove the glass, wash in clean water, rub off silver deposited where not required, allow to dry and varnish silver side with any thin varnish which does not contract much in drying. The time required for the operation depends on the temperature. If the solution be warmed to about 30° C., the silver is deposited in a few minutes, but it is safer to use them cold. The insides of test-tubes, bulbs, etc., are silvered by putting the solutions into them, no second vessel being then required. Throughout the whole operation the most scrupulous cleanliness is the grand essential.

Sil'ver-ing Mir'rors. Some time since the Academie des Sciences offered a prize of 2,500 f. for a method of satisfactorily and permanently silvering mirrors, and which should save the workman the danger of exposure to the effect of mercurial vapors. The prize has been awarded to M. Lenoir, whose process is substantially as follows: —

The glass is first silvered by means of tartaric acid and ammoniacal nitrate of silver, and then exposed to the action of a weak solution of double cyanide of mercury and potassium. When the mercurial solution has spread uniformly over the surface, fine zinc dust is powdered over it which promptly reduces the quicksilver and permits it to form a white and brilliant silver amalgam, adhering strongly to the glass, and which is affirmed to be free from the yellowish tint of ordinary silvered glass, and not easily affected by sulphurous emanations.

Silvering mirrors . . *"Scientific Amer.,"* xli. 232; xliii. 73.

Sil'ver Pro'cess. The plan of Paul's dry-process mill, for working gold and silver ores, is —

1. The calcining furnace; 2, the self-feeder; 3, the stamp battery; 4, dust casing; 5, elevators (these are not used when the ground admits of the battery being set on a level with the pulverizing barrel; 7, hopper for pulverized ore; 8, amalgamating barrel; 9, hopper for conveying ore to the settler; 10, first settler; 11, amalgam safe; 12, hydrostatic settler; 13, concentrator.

The ore is reduced to powder by attrition of quartz, and the amalgamation is speedy. Ore is passed into self-feeders, and that is the last of the handling. The gold contained in it will be found in the amalgam safe, all ready for retorting. The machinery is ingeniously constructed, and works effectively. It is rendered perfectly automatic, so that, from the moment the quartz is put into the feeder until the gold comes from the machine in the shape of amalgam, the stuff is not handled. Only two men are necessary to run a 10-ton mill.

Sil'ver Steel. (*Metallurgy.*) A steel of fine quality with a slight alloy of silver.

Sil'ver Ware. Table ware made from or coated with silver. See CHASING; REPOUSSÉ; SNARLING; GILDING, etc. *"Mech. Dict."*

Silver ware . * *"Scientific American,"* xxxvi. 287, 291, 292.

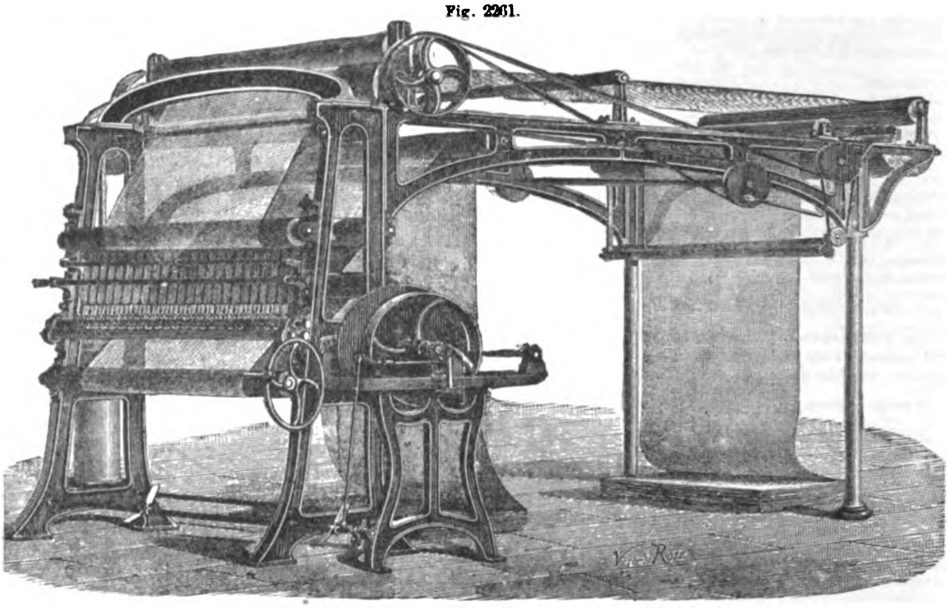
Singe'ing Ma-chine'. A gas singeing machine intended for removing or dressing the nap on woven goods.

In Fig. 2261, the workman has the work directly under his notice, and can vary at any time the intensity of the flame, or the speed at which the cloth is traveling.

The burners are so arranged that the application of compressed air takes place at the moment of the combustion of the gas, and by varying the pressure of the air all the different degrees of heat can be obtained, and thick and thin fabrics singed with equal facility. The upper part of the burner is open along its whole length, and cocks and other means are provided for regulating the line of flame, so as to make it perfectly even, or to reserve, if required, certain parts of the surface of the cloth from the action of the flame. The position of the line of flame can also be varied according to the effect which is required. Thus the flame applied directly under the roller singes the cloth thoroughly, and, it is said, brings out the grain, as is necessary in merinos, cashmeres, etc.; but in the case of delicate tissues, where it is necessary simply to dress the cloth lightly as with a shearing machine, the line of the flame is placed tangentially to the roller, and only takes off the projecting fibers.

The workman can, by means of a treadle, instantly stop the feed of the cloth, and at the same time reverse the line of flame so as to suspend its action; thus fringed shawls can be singed and accidents easily avoided.

Fig. 2261.



Gas Singeing Machine.

This system produces no smoke or soot, so that the most delicate tissues can be singed without altering the color, and after bleaching, dyeing, or printing, without changing the shade.

The mixture of compressed air and gas is effected, so as to produce great economy in gas, and at the same time a great intensity of flame. The intensity of the flame is increased by augmenting the pressure of the air without varying at all the quantity of gas, which latter only becomes then more perfectly consumed.

The general arrangement of the machine with a single flame, as usually made, is clearly shown in the above drawing, but machines are also arranged, when desired, with two or four flames so as to singe both sides of the stuff at one passage.

Sin'gle Coil Spring. One made of a single spring wire, coiled upon itself, with same diameter throughout.

Sin'gle Flu'id Bat'ter-y. (*Electricity.*) A term used for the battery with but a single fluid, in the double fluid battery invented by Daniell. See p. 2187, "*Mech. Dict.,*"

Air as a depolarizer in a single fluid cell is found in
Pulvermacher's . . * "*Telegraphic Journal,*" vi. 388.

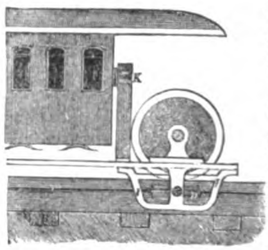
Pulvermacher, Fr. * "*Engineer,*" xlvi. 143.

Sin'gle Plate Wheel. (*Railway.*) A car wheel which has a single plate between the hub and the rim. The plate or disk is sometimes flat, or ribbed on one side, or corrugated.

Sin'gle-rail Rail'way. One in which the cars are supported and run on a single rail, and are braced or steadied by side-rails.

Figs. 2262, 2263 show the details of construction of a new and improved car for single-rail railways, invented by David B. James, of Visalia, Cal. The invention consists of one line of broad-faced wheels in the center to carry the load, and guide wheels to run each side of the rail on vertical axles projecting down from the car, these wheels being to keep the carrying wheels on the track and to prevent the cars from overturning, for which they are contrived to gripe the rail with more or less force The wheels are connected with a platform which is carried only enough higher than the rail to clear it properly, and the car is mounted on pivots arranged in the line of the wheels, and supported on the platform so that the load is balanced on the wheels, and the center of gravity is lowered as much as possible to prevent overturning. The guide wheels running against the sides of the rails are contrived to move forward and from the rail, and provided with springs to keep them in contact. In the locomotive they may be geared with the power and have a lever contrivance for gripping the rail tightly for traction on steep grades.

Fig. 2262.

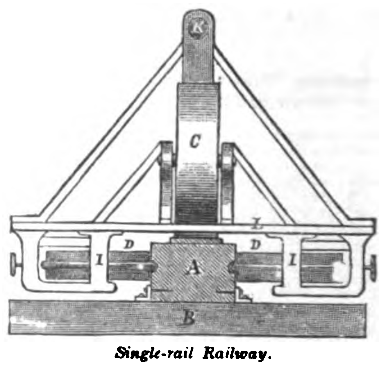


Single-rail Railway.

Fig. 2262 of the engravings is a longitudinal section elevation of the improved railway car, showing the guide wheels, ridged and running in a groove in the stringer. Fig. 2263 is a horizontal section, giving an end view of the car and track, stringer and ties, with side wheels, the ridges in which fit into the groove in the stringer.

In the engraving, *A* is the single rail, of wood, which may be of a single timber, or it may be shod on top with another, to be removed from time to time when worn, the removable one being, say from 2″ to 3″ thick. *B* represents the ties, which may be of any suitable kind. *C* represents the

Fig. 2263.



Single-rail Railway.

carrying wheels of the car; *D*, the wheels for guiding it, and preventing it from overturning, the latter wheels being mounted on vertical axles *F*, projecting down from the car body or supports, *I*, so that the wheels run against the edges of the rail, while the wheels *C* run on top. The axles *F* are mounted in bearings *G*, which are movable toward and from the rail, and have springs to press them against it, by which they are accommodated to variations in thickness of the rail, and allow the car to turn curves readily, without requiring the wheels *C* to be mounted on a pivot or fifth-wheel.

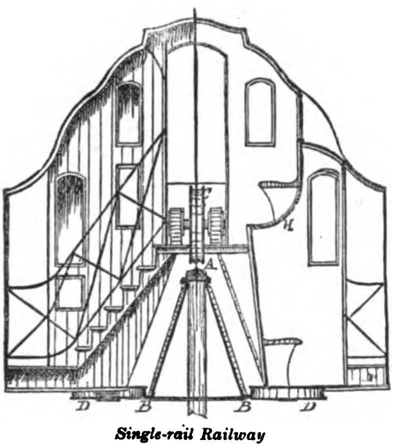
The car body *J* is mounted on the pivots *K*, supported on the platform *L*, which is suspended from the axles of the wheels *C*, the said pivots being arranged in the longitudinal plane of the wheels *C*, so the center of gravity of the load remains more on the wheels than it otherwise would, and the car is more certain of keeping erect in case the load is not trimmed nicely, or the car is jarred or otherwise forced laterally. But to prevent the car from rocking too much on the pivots, and also to prevent it from striking too hard on the platform in case it does rock, buffer springs *M* are attached to the under side of the car body, so as to strike the platform, or they may be applied so that the body may strike against them.

The platform will always run level on account of using only one rail and employing the guide wheels to direct the car, which avoids the necessity of tilting the car as on the curves of the roads of two rails, and thus the difficulty of carrying the cars upright on a single track is greatly diminished.

If considered necessary, the carrying wheels may be banded with rubber to prevent wear of the wood rails, and for running smoothly, but it is believed that the broad surfaces will wear so little as not to need it. By gearing the guide wheels of the locomotives with the driving wheels, and employing levers to cause them to gripe the rails, very steep grades may be ascended. Very abrupt curves can easily be overcome by means of this system, as well as steep grades. The engineering difficulties of a line in a mountainous country could therefore be overcome by it, as a narrow-gauge road overcomes the difficulties of a broad-gauge under such circumstances. The stringer is fastened to the ties with iron knees.

Figs. 2264, 2265 show a road that consists of a single bearing-rail, *A*, of the common T rail pattern laid upon a wooden stringpiece of about 4 × 8 timber, which rests upon the top of a row of posts, or piers, and is flanked by a pair of side rails, *B B*, which are dropped some 4′ 5″ below the level of the bearing rail *A*, and are 3′ 4″ from out to out. A system

Fig. 2264.



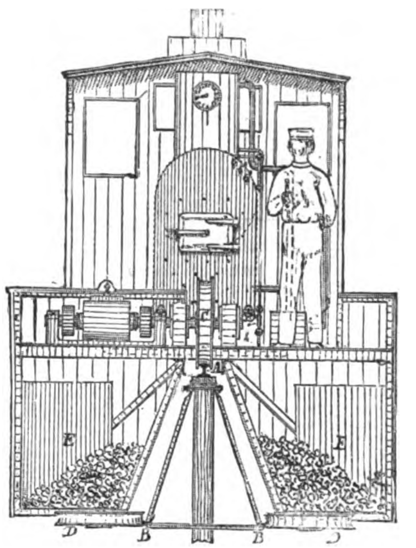
Single-rail Railway

of cross bracing from the main rail *A* to each of the side rails, supplemented by a similar set of braces between the rails *B B*, gives the whole the character of a triangular truss, of great strength.

The locomotive used on this road, of which Fig, 2265 is a rear view with casing removed, runs upon two driving-wheels shown at *C C*, of 28″ diameter; the boiler, of the style known as "locomotive," 12′ long and 34″ in diameter, with 4½′ fire-box, is dropped as low to the bearing-rail *A* as practicable. The frame of the locomotive is made of angle iron, and drops to the level of the side rails *B B* on either side, carrying on each side two guide-wheels *D D*, of 28″ diameter, which run upon vertical axes. Both the driving-wheels *C C* and guide-wheels *D D* are grooved, or, properly speaking, double-flanged, making it impossible for the locomotive to be taken off the track by any accident that does not first actually take the wheels off, and then lift the machine bodily nearly 5′, throwing sideways withal. The total length of the engine is only about 17′. The fuel and water tanks being below the level of the bearing-rail and upon the side-frames, assist in ballasting and steadying the machine. The engines proper are of the La France rotary pattern, the principle of which is that of two gear-wheels running in a tight case.

The road, as shown here, is designed for city and rapid transit where the height above the ground, as well as the length of the span between supports, is necessarily great, but for country roads a much simpler and more economical style of construction is recommended, wherein the roadway consists of a single bearing-rail *A* of iron, the side-rails *B B* being of hard wood, and the side-plates that support *B B* are brought together near enough to bolt directly to the posts,

Fig. 2265.



Single-rail Railway.

which should be of cedar. A road of this kind, capable of carrying a load of four tons per bearing-wheel, is estimated upon as follows. For each mile in length the company estimates: —

Steel bearing-rail, 40 lbs. per yard, at $65 per ton	$1,242.00
Splice-plates and spikes	135.00
Stringpiece 8 × 10, side-plates 5 × 6, side-rails 8 × 4, all of hard or Georgia pine	1,700.00
Lag bolts, plate bolts, and spikes	160.00
Cedar posts, 8″ in diameter, 12′ long, 550 per mile at $1	550.00
Setting in concrete base, 25 cents per foot	137.50
Mill work, squaring ends and boring bolt holes	250.00
Contingencies	825.50
Total	$4,500.00

The above figures are obtained with reference to the south-eastern part of New Jersey, where the soil is sandy; but it is to be remembered that in no case is any amount of grading or earth work to be allowed for, no culverts to provide: the only difference required by small streams is a slight increase in length of posts perhaps (and this is the better rule for crossing all highways and railroads), also an increase of elevation and span, requiring only a little more lumber at such points to reënforce the stringer plates and posts, and no other extra expense; swamps or peat-bogs may require some crib work, but again it is only a call for more cedar, and nothing else. Such a roadway should only need renewal in from fifteen to twenty years. The bridging of highways and streams adds little or nothing to the first cost. The single bearing-rail is about 5′ from the ground as a minimum.

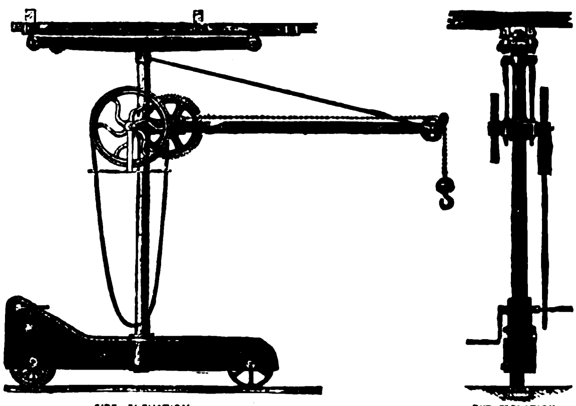
Uno-rail	* "*Mech. Dict.*," Figs. 1210, 6872, pp. 513, 2683.
Palmer	"*Mech. Dict.*," Fig. 1856, p. 792.
Baker	"*Iron Age*," xix., Feb. 8, p. 15.

Sin′gle Screw Turn′buck-le. A link having a nut at one end and a swivel at the other, used in lightning-rods. See TURNBUCKLE, *c*, Fig. 6794, p. 2659, "*Mech. Dict.*"

Sin'gle-rail Crane. A single, mounted rail carrying a crane for shifting to different parts of a room.

Fig. 2266.



Single-rail Crane.

This form of crane, shown in Fig. 2266, is for hand-power, but the general form is the same whether the crane is worked by hand or is driven by a high-speed cord or tumbler shaft. The under-carriage or bogey is fitted with two double-flanged wheels, one in front of the other, and traveling on a single rail, which is usually sunk so as to be flush with the floor, in order not to interfere with the free circulation of foot or wheeled traffic in any direction; the stability of the crane is maintained by the post being keyed securely into the carriage, its upper end being fitted with a horizontal wheel which works between a pair of guides fixed to the under side of a floor, or to the beams or columns; these guides are fixed in the same line as the single rail on the floor and plumb above it, and extend the full length that it is desired to travel the crane; the jib is hung on a shoulder on the post; the thrust of the jib being taken by a pair of friction rollers working against the post; it therefore turns very freely entirely round the post. The gearing is worked from the floor by hauling on the endless hand-rope, and the barrel-shaft is fitted with a self-acting arrangement, which maintains the load suspended directly the hand-rope is released. One of the traveling wheels is geared up to the handle shaft on the carriage, which is the proper height from the ground for easily turning.

It will be evident from the engraving and the foregoing short description that these cranes occupy so little space that they are peculiarly adapted for running between two lines of lathes or machine tools, or for lifting the smaller parts of machines in the erecting shop after the heavy portions have been put in position by the overhead traveler. Cranes of this type have been constructed for many of the leading engineers; they are also usefully employed in wool warehouses or furniture stores where goods are packed from floor to ceiling. For the platforms of railway or dock goods sheds this system affords very great facility for concentrating the crane-power at any given point, and the heavy outlay is avoided for a number of fixed cranes which can neither be always employed nor cover the ground so completely as portable cranes. These cranes lift a load and swing entirely round with it, or travel with it as readily as if it were on a truck on rails.

Sin'gle Shear Steel. (*Metallurgy.*) Blister steel, once reworked by heating, rolling, and tilting to improve the quality.

Sin'gle Whip. (*Nautical.*) A simple form of tackle formed by reeving a rope through a single block. *a*, Fig. 7196, p. 2770; *a*, Fig. 6159, p. 2480, "*Mech. Dict.*"

Sin'glings. The first to come over, the crude spirit of distillation.

Sink'er Bar. A medium length section of a long boring rod or auger stem for sinking shafts. A still shorter section is called a *substitute*.

Sink'ing Pump. A vertical pump adapted to sinking new shafts and recovering abandoned mines.

The pumps are of various capacity. The one here illustrated (Fig. 2267) is next to the smallest made, weighs one thousand pounds, and has a capacity of about eighty gallons per minute. It is built on the bucket-plunger plan, adapting it to gritty water. The removable barrel admits of easy renewal when worn, and swing-bolts give access to both pump-barrel and water-valves. It is also through its attachments made adjustable to the water level.

Fig. 2267.

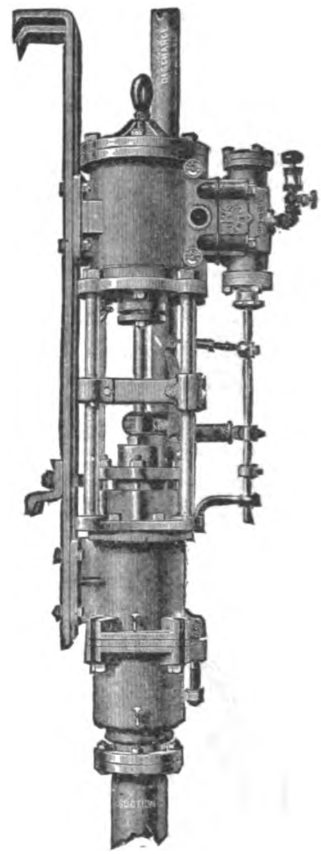


Fig. 2268.

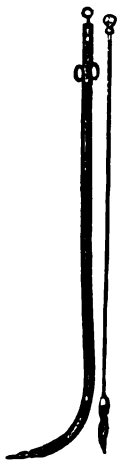

Sinus Probe. *Sinking Pump.*

Si'nus Probe. A vermicular pointed uterine curved probe, used in its peculiar branch of surgical operations. Fig. 2268.

Si'phon. A unique application of the siphon, to enable the transmission of water over higher levels than its source, is described as follows: —

The most remarkable illustration of this principle on a grand scale is to be found at the water works at Virginia City, Nev. The water is brought in an 18″ flume, 4 miles long, to a spur overlooking the Washoe Valley 2100′ above the Truckee Railroad track. There it is received into an iron pipe which after descending into the valley ascends on the other side to the height of 1,540′.

The length of the inverted siphon is nearly 7 miles and conveys two million gallons of water per day. The leading of such a stream of water across such a valley has no parallel in hydraulic engineering. The pressure on the pipe is equal to a column of water 1,720′ high. The orifice of the pipe is 12″ in diameter, and the amount of rolled iron used in its manufacture is 1,150,000 pounds. A million rivets were used in its construction, and 50,000 pounds of lead in fastening the joints. The line of pipe is compelled to twist and curve to fit the inequalities of the ground and crosses 13 steep cañons. At the bottom of each depression a blow-cock is used to remove the sediment, and at each elevation is an air vent. The water when received into the pipe from the flume passes through wire screens and charcoal.

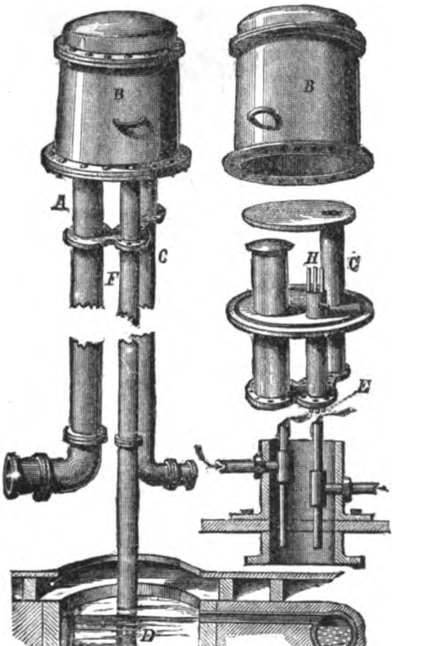
Si'phon, Au'to-mat'ic. A siphon the short arm of which being provided with a valve is actuated and set in motion by the alternate vertical movement given to it.

It is operated without withdrawing the air by suction, through the inertia and adhesion of the liquid.

Si'phon Con-den'ser. An ingenious device for producing a siphon vacuum, profitably employed in a low-pressure engine as a substitute for the air-pump and condenser.

The condenser is placed on top of a vertical tube (say 34' to 40' high) that has its lower end inserted in the hot well.

Fig. 2269.



Siphon Condenser.

Connected also with the condenser are the tubes that convey the exhaust steam from the engine on the one hand and the ordinary injection of cold water on the other.

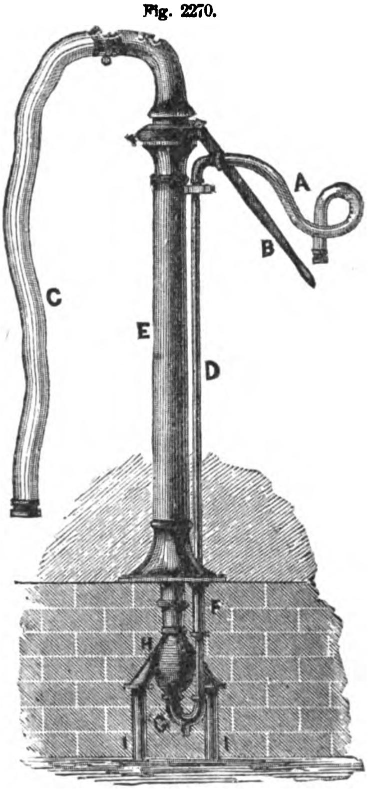
Si'phon Gage. (*Gas.*) A form of gage used in determining the pressure or vacuum in gas pipes. It consists of a convolved pipe in the U of which is a liquid acted upon by the gas admitted by a pipe. The zero in the graduated member is when no pressure is exerted and the liquid is at an equal height in each leg. Below and above this are graduations which indicate inches of water pressure or vacuum.

Si'phon Pipe. A curved pipe that on the principle of the siphon conveys liquids over inequalities in its track.

Si'phon Pump. A device for raising water by the direct action of steam. It combines the powers of a force and lift pump without piston, plunger, valve, or any movable parts, so as to have little about it to wear or get out of order.

Solid bodies of less diameter than the pipes of the steam siphon pass through it without obstruction, thus drawing up and ejecting mud, sand, cinders, fruit, grain, chips, coal, etc., that with a common pump would obstruct the valves. Fig. 2270.

Fig. 2270.



Siphon Pump.

Si'phon Re-cord'er. A delicate recording instrument for the receiving end of submarine cables, the invention of Sir William Thomson.

It has a large magnet with a small movable coil of wire (in the line circuit) suspended between its poles; when a current passes the coil moves, and this movement in the magnetic field is communicated to the siphon pen which thereupon writes the message. The letters consist of a codified series of right and left deviations from the right line, due to the movement of the paper by the mechanical feeder.

Paper by *Ewing* . . .	* "*Jour. Soc. Tel. Eng.*," v. 185.

Si'phon Slide. A device for the retention of small aquatic animals in a position suitable for experiment and observation.

In a slip of thick plate glass a chamber is excavated that has at each end fine perforations, too small to permit the escape of the animal under view, but sufficient to maintain a flow of water. These openings emerge into tubular mouths, to each of which is attached a tightly-fitting elastic tube; one of these communicates with a reservoir of water, whilst the other acts as an escape conduit.

Fig. 2271.

Siphon Slide.

The position of the slide, when in use, must be slightly above the level of the reservoir, while the escape tube must rest below the same, insuring a siphon action in the apparatus. See Fig. 2271.

Si′phon Tel′e-graph Re-cord′er. See Siphon Recorder.

Si′phon Trap. One in form of siphon to prevent the rising of gases from sewers, etc. See Seal; Sewer-gas Check, *supra*, and Fig. 6618, p. 2617, "*Mech. Dict.*"

Si′ren. 1. An apparatus for detecting the sonorous qualities of various kinds of wood and metals.

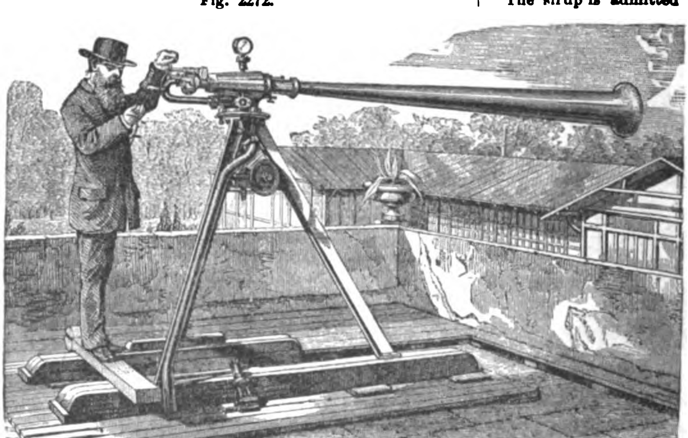
2. An instrument for producing musical tones and for measuring the intonations and vibrations of sound-waves.

For comparison of the Daboll fog trumpet, siren, etc., see "*Smithsonian Report*," 1878, by Prof. Henry, pp. 455–559.

In the grand siren of Lubec a strong system of clock-work keeps in motion a copper disk, pierced with holes at regular intervals. A common air-chamber communicates with a series of tubes that can be accurately adjusted in front of the revolving disk, at any required position. A registry gives the velocity of rotation.

Four of the disks are intended to show the results obtained when the isochronism of the impulses is imperfect from any cause; the fifth shows that impulses coming from different points can unite to form one sound; the sixth serves for experiments on interference; the seventh has eight series of holes, giving the gamut; the eighth has eight series of holes

Fig. 2272.



Siren.

for the harmonics, and the ninth illustrates the phenomena of beats. See also Helmholtz's Double Siren and Oppelt's Siren.

The Centennial Steam Fog Siren or Trumpet and the Austrian fog trumpet are different modifications of instruments intended to denote points of danger to shipping in times of dense fog.

About seventy pounds pressure of steam is employed. As the rotating disk rotates rapidly puffs of steam escape, and as these vibrations quickly succeed each other a sound of great intensity is produced, the pitch of which depends upon the rapidity with which the puffs succeed each other, or upon the velocity of rotation of the disk, precisely as in the acoustic instrument called the siren, used in physical apparatus to illustrate the truth that the pitch of a sound depends upon the number of aerial vibrations produced in a given time. This steam siren has been experimented upon by Professor Tyndall in his recent investigations upon the propagation of sounds through fogs and under other atmospheric conditions, and has proved very far superior to artillery in signaling through fog. See Fig. 2272.

Comparison of the Daboll fog trumpet and siren and other matters in "*Researches in Sound*," "*Smithsonian Report*," 1878, by Prof. Henry, pp. 455–559.

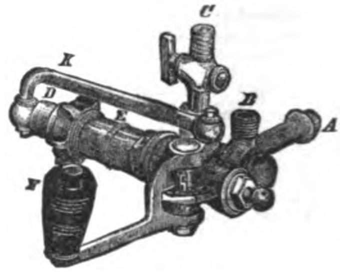
Sir′up Gage. The solid plunger sirup gage, illustrated in the accompanying cut, is a device invented by John Matthews, of New York, for delivering a fixed quantity of sirup and carbonade into bottles at the bottling machine.

Fig. 2273.



Sirup Gage.

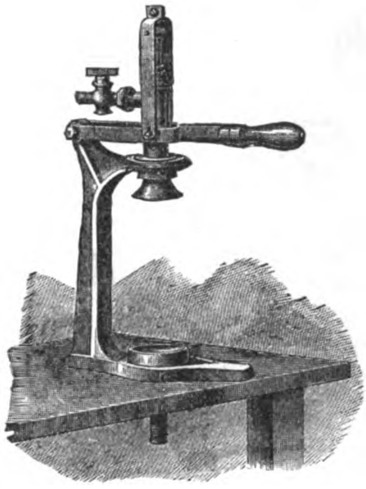
The sirup is admitted to the pump through the inlet *C* and the carbonade enters through the inlet *B*, the mixture passing out to the bottling machine through the outlet *A*. The solid plunger *D* works in the cylinder of the pump *E*, and is operated by means of the handle *F* and the connecting rod *K*. The stroke of the plunger is regulated by means of the pin *H*, which enables the quantity of sirup delivered to the bottle to be accurately gaged. *I* is a guide for the crank which operates the solid plunger.

Sir′up Pump. A device for measuring sirup into soda-water bottles. The pump being secured to the bottling table, the bottles are charged with sirup and passed under the bottling machine. See Fig. 2274.

Sir′up Tank. For soda water.

In the cut (Fig. 2275) is illustrated the portable measuring sub-lift sirup tank invented and introduced by John Matthews, of New York, for use in soda water dispensing apparatus. The glass tank *E* is provided at its lower extremity with a measuring chamber, *S*, and at its upper extremity, with two orifices. Through one of these orifices passes the rod *Y*; the other is intended for filling the tank. The rod *Y* is provided at its lower end with two valves, and at its upper end with a grooved cap, *Z*, into which fits the upper extremity of the lifting bar *V*. Through the rod *Y* runs an opening, *U*, for venting the measuring chamber. *K* is guide for the lifting bar, and *X* is a button on the lower

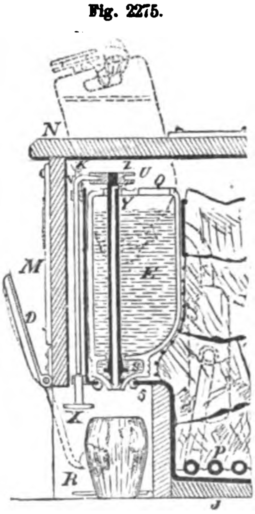
Fig. 2274.



Sirup Pump.

extremity of the bar. The operation of the sirup tank is as follows: When the valve-rod *Y* is at rest, the lower valve on its extremity rests on the lower valve-seat of the measuring chamber. The sirup is now prevented from escaping into the glass, but is admitted from the tank to the measuring chamber. If now the button *X* be raised, either by the hand or by the glass, the valve-rod *Y* will likewise be raised until the upper valve is brought into close contact with the upper valve-seat of the measuring chamber. This will allow the sirup in the measuring chamber to follow into the glass, and will prevent the further admission of sirup into the measuring chamber. The removal of the tank from the apparatus may be effected by raising the guide *K* and turning the lifting bar *V*. The tank can then be taken out as shown by the dotted lines.

Fig. 2275.



Sirup Tank.

Six-cant'ed File. Has an angle of 120°, and is used for hexagonal nuts, wrenches, etc.

Six-cyl'in-der En'gine. The engine consists of a base-plate carrying a casting containing six cylinders arranged in a circle. The axes of the six cylinders are all parallel to the main shaft, which traverses the middle of the casting. A light hollow piston works in each cylinder, each piston having a conical end that bears against a disk. The disk is mounted on a short shaft, having at one end a spherical bearing, while at the other end enters a brass bush fitted to the crank-arm that is keyed to the main shaft.

The pistons are single-acting, the pressure of steam in the cylinders tending always to force them against the disk. The shaft makes one revolution for each complete double stroke of each piston, and as each acts during the same revolution, the six going into operation successively at intervals of 60°, it follows that three pistons are constantly acting on the disk. The strain thus thrown upon the crank and shaft is practically uniform, and there being no dead point, no fly-wheel is necessary. It balances itself. See Figs. 2276, 2277, 2278, 2279, which with the description explain themselves.

See also DISK ENGINE, Fig. 1666, p. 708, "*Mech. Dict.*"

Six'fold Knot. A knot in which one part is wound 6 times around the other before jamming.

Siz'ing. (*Leather.*) A paste made of flour, soap, beeswax, a little linseed oil, and water. It is applied to the grain side with a sponge. It fills the pores and serves to give a smooth finish to the leather.

Sizing cotton goods. *Thompson* . . . . "*Scientific American Sup.*," 1269.
Sizing, history of. . . "*Scientific American Sup.*," 2868.

Skein Screws. A screw with a shallow open thread.

Skein Set'ter. A machine for fitting metallic skeins to wooden axles. See Figs. 148, 151, pp. 61, 62, "*Mech. Dict.*"

Skein Tor'sion Ma-chine'. A machine for twisting silk while under tension. See SILK SOFTENING MACHINE.

Skel'e-ton Bell. An electric call and alarm bell used on railroad trains and other places where such communication is desired from distant points. Such as are peculiarly adapted for railroad trains have a lock attachment preventing any movement of the bell-hammer till it is actuated by the magnets. One variety is made with a continuity attachment causing the bell to continue ringing several seconds after the current on the line wire has ceased, making it useful when a prolonged call is desired.

Skel'e-ton Rol'ler. (*Agriculture.*) An open ribbed roller used in France. The open bars of the drum enable it to answer in a degree the same purpose as the English clod crusher.

Skew'-back. A casting on the end of a truss, to which a tension rod may be attached. It may form a cap, or be shaped to fit the impost.

(*Blast-furnace.*) A ring formed on the inside of the wall of a blast furnace, opposing the descent of stock by diminishing the sectional area at that point.

If sufficient heat gets above the fusion limit of a blast furnace to paste the stock and yet not fuse it, this stock jams on the bosh, forming a ring which if the stock above cannot push it down to the fusion limit, allows this ring to become permanently set and so obstruct the flow of stock.

* "*Iron Age*" . . xxv., March 4, p. 3, Fig. 4.

Skim Net. (*Fishing.*) A large dipping net.

Skin Graft'ing In'stru-ments. (*Surgical.*) The principal special instruments which are used in the transplantation of skin are —

Skin grafting scissors.
Cutisector.
Epilating forceps.
Glass pleximeter.
Scarifying spud.
Milium needle.
Sharp spoon.

Page 11, Part V., *Tiemann's* "*Armamentarium Chirurgicum.*"

Skit'tle Pot. A crucible taking the shape of a skittle, smaller below and bulging towards the top, again contracting at the rim.

Ski'ving. (*Leather.*) The act of removing the rough fleshy portion from the inner surface of a skin by the currier driving his knife obliquely a few inches at a time, and keeping the right hand slightly in advance of the left in the downward motion.

Skiver . . . . * "*Scientific American Sup.*," 101.

Slab'bing Ma-chine'. A tool especially adapted to mill the flats of connecting rods and similar work. It is arranged with bed, tables, and uprights, like planer with a capacity of 25″ × 25″; table 12′ long and operated by a spiral pinion. Spindle to carry cutter 4½″ diameter, 4″ wide, strongly geared, and adjustable to height.

The feed is variable between the extremes, and the table, which is adjustable by hand, has an automatic stop motion to throw out the feed at the end of the stroke. The fast and loose pulleys are 20″ diameter, 3″ face, and should make 114 revolutions per minute.

Slack Bar'rel. One for flour, sugar, cement, fruit, and what not, of a dry character. In contradistinction to *tight* barrel.

Slack Burn'ing Lo'co-mo'tive. See WASTE BURNING LOCOMOTIVE.

Hunt, Br. . . . . "*Iron Age*," xx., Nov. 29, p. 20.

Slack Gas Fur'nace. Casson's new gas and hot blast furnace is applied to puddling furnaces. The coal used — screened slack — is supplied into a hopper and drawn down into the grate. Through the back of the grate it is blown by hot air drawn down from the increased sides of the nearest stack. Hot air is likewise taken in at both the top and bottom of the furnace, and makes its way to the exit of the gas from the gas furnace before it passes over the bridge of the puddling furnace, and the hot air fires the gas. The supply of air is under the control of the puddler and regulates the fierceness of the flame.

The puddling furnace is a double furnace having circular rotating beds that are actuated by mechanical rabbles.

Slag. Blast-furnace slags are usually double silicates of alumina and lime, but vary with the character of the ore, as when the lime is partially replaced by magnesia and oxide of iron, which colors the slag, and in excess is an indication of imperfect working of the furnace.

The glassy slag produced in blast-furnaces is very abundant, and many methods of utilizing it have been proposed. In the Cleveland iron district of England, from three to four millions of tons of slag are made annually. Bricks, paving-stones, slabs, panels, tiles, etc., are made from this material.

About 30 cwt. of slag is made for each ton of pig-iron. The annual accumulation of slag in England is estimated at 80,000,000 tons. Slag is too dark in color to be used for purposes requiring translucency.

At the Cleveland Slag Works, England, in accordance with Mr. Charles Woods's plans, the slag is run from the furnace into two different machines, one of which produces a coarse kind of shingle, and the other a fine sand. For making shingle the liquid slag is run direct from the furnaces onto a circular, horizontal, rotative table composed of thick slabs of iron, kept cool by having water circulated through them. The slowly revolving table carries the slag around to a certain point, when having become solidified, it encounters a stream of water that further cools it, and soon after it comes in contact with a set of scrapers that break it up and clear it off the table, delivering it into wagons placed below that convey it away.

For producing slag sand the slag is run from the furnace into a hollow wheel revolving upon a horizontal axis and fitted with iron buckets inside. A bath of water is maintained inside the wheel at the bottom, and is kept in a state of violent agitation by the revolving action. As the molten slag enters the body of water, it is immediately disintegrated and assumes the form of sand, the water taking up the heat from the molten slag and giving it off in the form of steam.

A constant flow of water is maintained into the machine, and the sand is separated from it and elevated to the top by the bucket plates that are perforated. The slag sand is next dropped into a spout, and thence finds its way into wooden wagons, by which it is conveyed to the slag works for manufacture into brick, etc.

See the following uses and applications: —

1. *Artificial Stone.* — The process of making artificial stone from furnace slag is carried on at the Cleveland Slag Works. It is composed of a wet mixture of —

Pulverized slag	2.5
Ground bricks	2.5
Portland cement	1.0

The mixture is run into molds for building blocks, mantels, cornices, caps, sills, steps, balusters, etc. It sets quickly, and the blocks are ready for use in a week.

2. *Bricks.* — Bricks are made by either of two machines. The slag sand is elevated from the tub, and, after screening to remove coarse pieces, is divided by a revolving measure on the outside and placed at the bottom of the hopper. From another hopper selenitic lime and iron oxide in powder is measured by a similar contrivance, and the two substances unite in the proportion of, sand, 10; lime, 1. The material then passes to a mill where it is incorporated, and thence to the brick molding machine. The production of the machine is 11,000 to 12,000 per day. The bricks, after 4 months' exposure, are said (Kirkaldy) to resist a crushing pressure of 9 tons, and at 3 years of 20 tons. This shows that the chemical combination requires time. The Moss Bay Iron Works (England) also make slag bricks. The slag is ground under edge-stones, then passed through mill stones. The powder is moistened, pressed, and molded into bricks, and hardened in the open air.

3. *Cement.* — The slags, rich in alumina, are preferable for cement, as the aluminate of lime is the principal hydraulic agent in cement.

Mortar is a mixture of slag and 10 per cent. slaked lime.

Cement has an addition of iron oxides. Ransome's cement consists of carbonate of lime, 2: slag sand, 1, burned together. The result gives a cement said to be 30 per cent. stronger than Portland cement.

Concrete is made of the coarse slag at a cost of about one fourth that of brick.

4. *Glass.* — Slags rich in silex are preferable for glass. At the Fenidon glass furnaces, in Northamptonshire, England, the slag is carried in tanks direct from the blast furnace to the glass furnace, there mixed with other materials and worked into bottles. The method pursued is that of Mr. Bashley Britten. The glass furnace is of the Regenerative order, and the tank receives a charge of 500 pounds of molten slag to a due proportion of sand and alkalies. The melted metal runs through a bridge to the working end of the tank, where there are five working holes. Ninety gross of wine and beer bottles are made per day.

5. *Harbor Works and River Walls.* — These can only be economically formed of slag when the works are near the water.

At the Barrow Works the slag is tipped into the sea to make fresh land for the works.

At the Cleveland Works 600,000 tons of slag per annum are used in the continuation of a breakwater and river walls.

6. *Paving Blocks.* — The slag is run into heated molds, and the block is removed and annealed. They are heavy and wear well. Paving blocks and slabs are employed for paving streets, footpaths, stables, coach-house yards, crossings, breweries, curbstones, and channeling.

7. *Pig Beds.* — Slag was formerly granulated and the sand used for pig beds, but this was discontinued for technical reasons.

8. *Road Making.* — Slag was formerly broken up and used for road making in England, and is still largely so used in Silesia. Slag shingle, or coarsely granulated slag is used for road making and paths.

9. *Slag Wool.* — Furnace slag blown while hot into fine threads or filaments has been made at the Clove Furnace, Greenwood Iron Works, Orange Co., N. Y.

The slag is drawn from the furnace into an iron tank carried on a truck. The car is run on a railway to a position opposite one of the apertures in the wool house, which latter is lined inside with thin sheet iron. The slag drops upon a receiver in a small stream, steam is conveyed under the receiver, and as the slag drops it is met by the jet which blows it with great force into the wool house in very thin filaments. The effect of the steam is to detach the slag in small shot which furnishes the basis of the filament. The smaller the shot the finer the filament, so the glass must not be too hot and liquid. By adjusting the heat of the slag and the strength of the steam jet the eventual size of the shot may be reduced to 1-16″ and it is not necessary to separate it from the wool. The lightest wool ascends to the upper story, and is free from the residuary balls. This mineral wool being incombustible and of a fine texture is a good non-conductor of heat, and is employed as a coating for steam boilers, pipes, cylinders, etc. It is called slag wool in England, and silicate cotton in Germany. It is used in Austria for making show cloths, laces, and fancy articles. It is also used in the manufacture of lanterns for electric lights. A patent has been taken out in Germany by Baatsch for the manufacture of prepared slag wool in order to prevent the generation of gases containing sulphur. The wool is placed in a wire netting and rapidly drawn through a dilute solution of water glass (1.2 to 1.3 specific gravity) and emptied on a floor coated with grease. The object is to wet only the surface of the wool without moistening the interior.

10. *Slag for Steam Pipe Insulation.* — Buttgenbach's method: Mix 150 parts of cinder dust, 35 parts by weight of fine coal dust, 250 parts of fire clay, and 300 parts of flue dust, with 10 parts of cow's hair, add 600 parts of water into which 10 to 15 parts of raw sulphuric acid has been poured, and make a stiff dough of the whole. This being applied in layers to the warm pipe hardens rapidly and is succeeded with future layers according to the thickness required. By the action of sulphuric acid gypsum is formed, and the silica rendered free hardens. The mass becomes as hard as porcelain and is still porous.

Slat Crimp'er. A machine used for sharpening, by compression, the ends of stationary slats to fit and fill mortises in the stiles.

The slats are placed in the vertical guides, and are delivered sharpened, one with each revolution of the shaft.

Slate Roof. An economical system of covering buildings with large slates is as follows: The rafters are placed at a distance apart of 1½″ less than the width of the slates. Down the center of each rafter is nailed a fillet, thus forming a rebate on each side, in which the edges of the slates rest, being secured by putty or by a second fillet 2″ wider than the first nailed over it, so as to cover the edges of the slates and hold them down. Each slate lays about 3″ over the one below it. Only half the number is required in this as compared with the ordinary method of slating, and no boarding or battens are necessary.

Slate dresser . . . . * "*Am. Man.*," Jan. 3, 1879, p. 12.

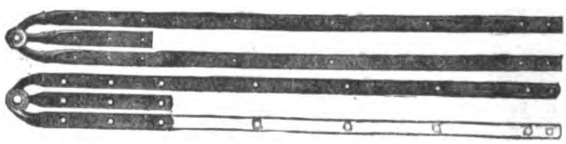
Sla'ting. *Black-board Slating* may be accomplished with the following mixture: 10 ounces pulverized pumice stone, 12 ounces lampblack, 6 ounces pulverized rotten stone, 16 ounces shellac, and 1 gallon alcohol. Mix the first three in enough alcohol to make a thick paste, and dissolve the shellac in the rest of the alcohol. Mix all together. It may be put on brown paper (such as surveyors use), as well as on walls or boards.

Or, dissolve 2 ounces of gum shellac in 1 pint of alcohol, and after it is well dissolved, which will take about two days, add 1 ounce of lampblack and 2 ounces of powdered rotten stone or powdered emery. Apply with a flat brush.

Slat I'ron. The iron shoe or termination of the bow or slat of a carriage top. The shoe is hinged to the stem by a pivot-pin and has an envelope of leather. The illustration represents a three bow pattern made with a sleeve running through the slats to give them free action, and prevent their binding on the nut and turning it off.

Fig. 2180.



Slat Iron.

Sleep'er. *Iron Cross-tie.* This tie is semi-elliptical in shape, resting simply on the ballast. The rail is fastened to the cross-tie by a jaw bone chair that is formed in two portions that hook into one another and hold the rail as in a vise. Half of the chair is fastened to the cross-tie by a bolt preferably on the outside of the track while the other half hooks into the first beneath the cross-tie and is immovable. An ordinary eye-headed bolt entering through the hole of the tie adapts itself to the end of this movable arm, and by its successive tightening compensates for any downward wear of the rail.

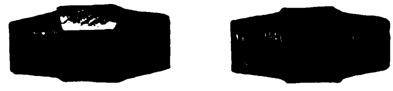
Sleeve. A short, relatively larger, pipe which receives the ends of two smaller ones and forms a coupling therefor. It may have *bell* or *flanged* ends. See, also, HUB, which has a similar purpose but somewhat different shape.

Sleeve Nut. A double nut with right and left hand threads for attaching the joint ends of rods or tubes.

Fig. 2281.



Sleeve Nut.

Slick'er. (*Leather.*) *Steel.* A rectangular piece of steel about 5″ long. The edge is also a rectangle, and is sharpened upon the rub-stone by grinding it perpendicularly, and then upon each side, producing thus two edges (or rather right angles) by which the leather is scraped instead of being cut. It is used to remove excess of water, oil, etc., from leather. Its applications are various. It has a handle like that of a stock-stone.

Glass or Lignum-vitæ. These are similar in form and dimensions to the steel slicker, but the blades are made either of thick plate-glass or lignum-vitæ. The edges are rounded instead of being rectangular. They are chiefly used to smooth out and polish leather.

Buffing. This slicker has a narrower, longer, and very much thinner blade than the others. Its edge has an acute angular longitudinal groove running along it, thus forming two very keen cutting edges, which are kept in proper condition by the finger-steel. It is used by placing one edge and the stock flat upon the leather, the latter being stretched upon the table, and forcibly pushing it forward, taking off thin shavings from the grain surface. When one edge is dulled the slicker is turned over and the other side used until it loses its edge, when the finger-steel must again be brought into requisition.

Whitening. This instrument has almost the same form and dimensions as the buffing slicker, but instead of a reëntrant angle along the edge, it has a very narrow rectangular one, whose angles are kept sharp by the finger-steel.

Slick'er-sides. (*Mining.*) Smooth, polished surfaces of walls caused by violent trituration.

Slick'ing. (*Leather.*) An operation consisting in scraping the leather, to remove superfluous water or grease, and eradicate the marks left by the stock-stone.

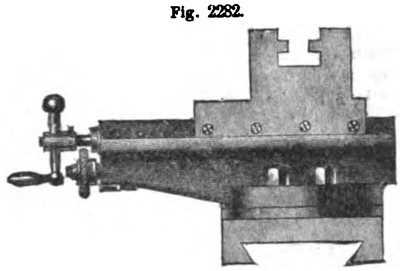
Slide. (*Lumbering.*) A chute for logs over rapids or shoals where such obstructions to floating logs exist in rivers. The slides of the Ottawa river extend at intervals for 200 miles above the city of Ottawa.

On the river Saguenay there is a slide 5,840′ long, with a boom 1,314′; and dams, piers, and bulkhead. The works extend over a distance of about six miles. Slides are constructed on the rivers St. Maurice, Gatineau, Madawaska, Petawawa, and Du Moine. On the rivers mentioned the works are said to comprise: Slides, 12,835′: booms, 67,799′; dams, 17,791′; bulkheads, 346′; bridges, 2,215′; piers, 141.

Slide Cut′-off. (*Steam.*) An independent sliding plate riding on the back of the main valve, of which Meyer's system of valve-gear is a familiar instance.

Slide Rest. This rest has an ordinary cross-feed screw, but by a movement of the clutch, the

Fig. 2282.

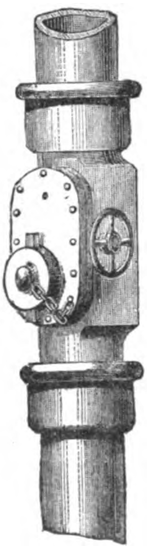


Universal Slide Rest.

screw becomes neutral and transfers its feed through beveled gears, to a screw working at an angle to the first, the upper slide being swiveled, for adjusting to the desired angle, by means of a degree scale.

The upper screw is also controlled by a friction feed enabling the tool to be quickly adjusted by hand without disengaging the clutch on the cross-feed screw, See Fig. 2282.

Fig. 2283.



Slide Valve.

* "*Scientific American*," xl. 404.

Slide Valve. This sliding valve is constructed so as to form part of the conducting pipe, instead of projecting from it as usual, so that the outlet to which the hose is attached can be kept close to the wall.

The sliding valve is worked by a rack and pinion arrangement; the front or cover plate is of gun metal, with the outlet screwed to receive hose, and fitted with gun metal cap and chain, also hand-wheel or spanner or spindle for opening and closing the valve.

Sli′ding Door. One running on hangers, sheaves, rollers, or rail; as distinguished from one swinging on hinges.

Sli′ding-door Lock. A lock made especially for fastening sliding doors of cars, for instance. Such locks usually have a hook which engages in a corresponding catch attached to the door-post. The hook may be locked by a bolt operatable by a key.

Slings. (*Boat.*) Ropes with hooks and thimbles whereby to hook the tackles to the ring bolts of the boat in lowering or hoisting.

(*A hoisting device.*) A pair of hooks for clasping a can or cask to be lifted.

Sling Wag′on. A military wagon for carrying a cannon slung beneath the hind axle, which has a large pair of wheels. Plate XLVI., "*Ordnance Report*," 1877.

Russian gun sling, Fig. 27, Appendix L, same report.

Slip Shave. A point or shave made to slip over the nose of the mold-board.

Slip Stop′per. (*Nautical.*) A cable stopper so arranged as to be cast loose suddenly when required.

Slit′-bar Sight. (*Rifle.*) A form of sight having a plate with a vertical slit. See BAR AND SLIT-SIGHT.

Slit′ting Mill. An English term for a gang of thin saws, used in ripping pine balks, known as *deals*, into thin boards. A resawing operation. See RESAWING.

Slit′ting Shear. A machine for slitting sheet metal.

In Bliss's machines, Nos. 104 and 106 of the 1881 catalogue, sheet metal up to 18 gage (Browne & Sharpe) is received in a roll, fed automatically, and the scrap coiled.

Sliv′er-ing Knife. (*Fishing.*) For slicing the flesh from the sides of fish, to be used as bait.

Sliv′er Lap Ma-chine′. A machine designed to unite in one broad sheet or lap a number of slivers or ends of cotton from the carding engine.

The sliver, when stripped from the doffer of the carding engine, passes to a coiler, by which it is deposited with mechanical regularity into a can. A certain number of these cans are placed behind the sliver lap machine, and the sliver is drawn from them through guides to a pair of fluted rollers which press the fibers, and form them into a fleece. They are then wound on a bobbin revolving between two iron revolving plates. The slivers are made to pass over a number of spoons, so arranged that if any of the slivers break the machine immediately stops. When cotton with short staple is used, two calender rollers are placed on each side of the table to assist the sliver in its passage from the can to the guide plate.

Slot Bor′er. A tool used for opening the cut in connection with slotting machines.

Slot-bor′ing Ma-chine′. A machine intended to supersede reciprocating mortising machines in which the wood had first to be bored so as to give clearance for the chisel; this machine combining the two operations in one.

In these machines the workman presses the borer in with his right hand, and moves the wood with the other. The horizontal machines are especially adapted to usual mortising. See ROTARY MORTISING MACHINE, *supra*.

Slot Dril′ling Ma-chine′. Whitworth's self-acting slot-drilling machine has a sliding head-stock carrying the crank motion. The drill-spindle revolves in conical steel bearings. It has a horizontal slide-bed and two tables adjustable vertically and longitudinally.

Double, self-acting.

Slub'bing Frame. A machine used in the process of cotton spinning next to the draw-frame, to reduce the thickness of the sliver and impart to it a little twist previous to its passage through the intermediate frame, the roving frame (and where fine counts are spun, the jack frame) which delivers it to the mule.

The slubbing frame exhibited by Dodson and Barlow, at Philadelphia, had 36 spindles, 10″ lift, 8″ space, three lines of rollers, and single boss top rollers.

It was claimed to possess the following advantages: —

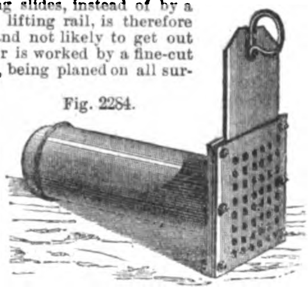
1. The differential motion is completely boxed up, so that no dirt or fly can get among the wheels; there is only one place for lubricating this motion, and the oil cannot work itself out but travels to each bearing which requires lubricating.

2. The swing lever which carries the carrier wheel that drives the bottom shaft, is firmly hung from the beam and has no vibration at whatever speed the spindles may revolve. In the swing there are also loose brackets or slides, which work on a planed surface, and when the wheel becomes so far worn as to be slack in gear with the bottom-shaft wheel, these slides can be loosened, and the wheels can be nicely adjusted by a few turns of a screw.

3. When the frame is doffing, the bottom cone drum is worked up by a screw either from back or front. Both ends of the bottom cone rising simultaneously, it is impossible for the cones to become unparallel.

4. The tapering motion, which is carried on a rail attached to two of the lifting slides, instead of by a bracket fixed to the lifting rail, is therefore much more rigid and not likely to get out of order. The taper is worked by a fine-cut square rack, which, being planed on all surfaces, causes the rack to work very smoothly and consequently a regular taper on the bobbins is obtained.

Fig. 2284.



Sluice.

Sluice. A water way with valve or gate for controlling the flow of water. See "*Mech. Dict.*," p. 2217.

A water way with trap, stop-valve, or screen for the arrest of obstructive substances.

Smoke'-burn-ing Fur'nace. M. Ten-Brink's smoke-burning furnace has the heater placed below with its major axis at right angles and horizontal to that of the boiler. One or two furnaces traverse the heater, making with the horizon an angle of 48°. In these furnaces is placed the grate, formed of a table and bars, the latter resting on the table at one extremity and at the other on a support at the end of the furnace. The table has two lateral sides surmounted by a cover so that a close four sided box is formed upon the door and grate extremities. The front piece to which this box is attached is a plate of cast-iron in which several different openings are made. A flue regulated by a hinged cover above the entrance to the furnace admits air in order to insure the complete combustion of disengaged gases.

Hoyt . . . . . . * "*Scientific American Sup.*," 1120.

Smoke Con-su'mer. The methods proposed for consuming smoke are very numerous.

Papin proposed the downward draft, making the smoke descend through the fire, as in Delasme's base burner, 1685 (Fig. 5911, p. 2410, "*Mech. Dict.*"). In Papin's the draft was obtained by means of a blower; the idea has never fructified into useful form.

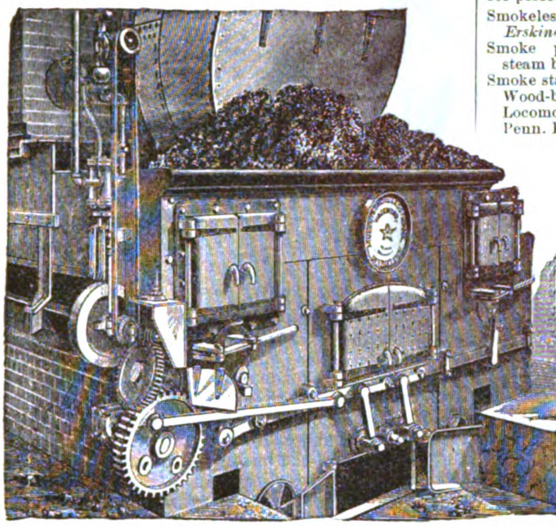
Watt had a wide dead-plate between the furnace doors and grate bars; on this the coal was coked before being pushed back and burnt. This plan is excellent, but requires careful attention. The smoke and gases evolved in combustion of the fresh coal are consumed while passing over the incandescent mass of fuel at the back of the furnace.

A given quantity of air has been introduced above the fire-bars, to insure the combustion of the smoke; this is good in theory, but the regulation is difficult in practice, as, when coal is freshly introduced, a larger quantity of air is required than at other times.

Henderson's mechanical stoker has hoppers above the furnace doors, and the coal is gradually dropped into the furnaces by automatic devices driven by the engine. See STOKER.

Prideaux's has fire doors, in which the air enters through a number of Venetian lattices, and is warmed by contact with metallic plates before reaching the furnace.

Fig. 2286.



Murphy's Smokeless Furnace.

Richardson, C. J. "*The Smoke Nuisance, and Its Remedy by Means of Water.*" With Remarks on Liquid Fuel. London, 1869.

Smoke Con-sump'tion. A new device in smoke consumption on trial in Chicago has special adaptability to all kinds of boilers.

A jet of steam is introduced, creating a vacuum into which the outer air rushes, and the commingled steam and air are delivered into the fire chamber. In this the proportions are one part steam to two hundred parts of atmospheric air. This creates an intense draft, and, it is claimed, the entire consumption of the carbon contained in the soot.

Smoke'less Fur'nace. Murphy's smokeless furnace (see Figs. 2286, 2287) obtains its complete combustion by a natural draft, being fed automatically, and having a steady, uniform feed and therefore an even temperature.

The fuel is put into magazines and pushed very slowly on plates, cooking it before it enters upon the grates. A current of air by natural draft passes over the heated arch above and down at the sides, supplying the mixture of air necessary for perfect combustion.

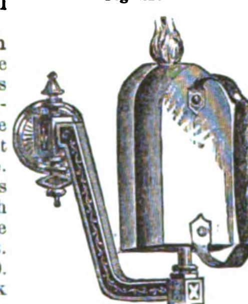
The gas-heating toilet smoothing iron (see Fig. 2289), it is said, can be heated in three minutes on any ordinary gas burner. They are especially adapted for gentlemen to iron

Fig. 2288.

Smoothing Iron.

their silk hats, and for ladies while traveling; also for dress-making and other general uses.

Fig. 2289.

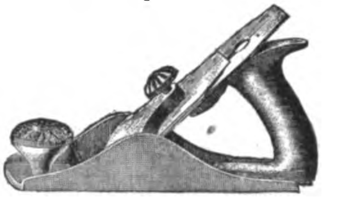


Gas-heating Smoothing Iron.

Smooth Plane. One the bit of which is set at a relatively more obtuse angle than that of a *block* plane. The former is for planing with the grain; the latter across it. See Fig. 2290. See BLOCK PLANE. See also SCRAPER PLANE.

Smut Ma-chine'. A machine for cleaning from wheat the smut, and also dirt and the beard, the latter on the end opposite to the germ. By a certain vigor in the process the bran is also partially removed. The wheat is passed between sharply roughened or pointed iron

Fig. 2290.



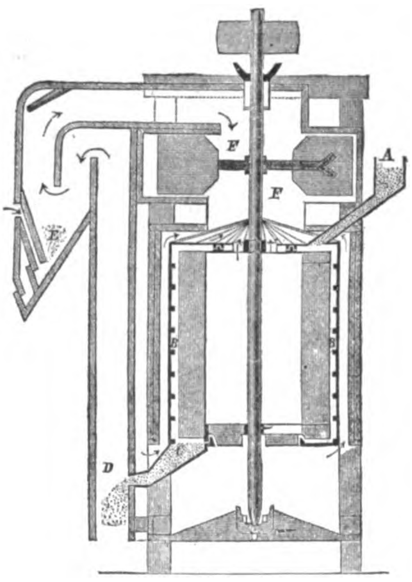
"*Victor*" *Smooth Plane.*

surfaces, as teeth or wire brush, or beaten upon the surface of a cylinder or conical frustum, revolving at high speed within a metallic case perforated with holes or slits, serving the double purpose of permitting the dust to escape and presenting a rough surface.

Howes, Babcock & Co.'s machine for removing smut, pointing, and cleaning grain is shown in Fig. 2291.

The wheat enters at *A*, passes through the cylinder *B B*, comes through *C* to *D*, where it encounters the current of air produced by the exhaust-fan, which conducts the light

Fig. 2291.



Wheat Grading and Purifying Machine.

kernals to *E*, the bran to *F*, and the fan-chamber which leads to the dust and bran chamber. The air moves in the direction indicated by the arrows. The particles of dust, hairs, smut, etc., that pass through the walls of the cylinder *B B*, are carried by the exhaust to *F*. The excellence of the work of this machine is indorsed by Professor Kick in his official report to the Austrian government.

The Eureka smut and separating machine has a separator attachment above the shoe in such manner provided that the dust from the entire machine is all absorbed by the fan.

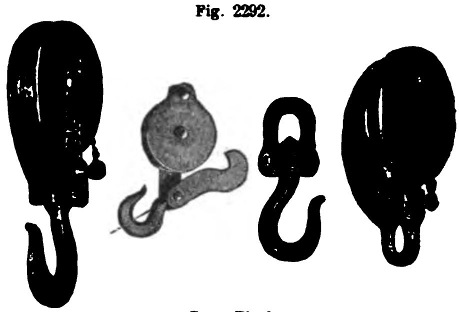
The capacity of No. 2 is 40 to 60 bushels per hour, and like the Nos. 0 and 1 has two separators, one before and one after the scourer. Motion, 625 revolutions per minute. Standard size, pulley 10″ with 5¼″ face.

Snap Ac'tion. (*Fire-arm.*) As distinguished from a lever gun; one which as the hinged barrel closes is fastened by a spring catch.

Snap Block. (*Nautical.*) A block with an opening in the side at which the rope may be laid in the sheave without the trouble of reeving it in. See Fig. 2292.

Snap Ma-chine'. A machine for cutting a

Fig. 2292.



Snap Block.

blanket of dough into snaps. A kind of biscuit; ginger snaps for instance. See CRACKER MACHINE.

Snarl'ing. A mode of producing repoussé work upon any hollow ware of sheet gold, silver, etc., by blows delivered inside. The snarling tool is placed in a vise and the protruding end enters the object and rests against the inside. A blow delivered on the shank of the snarling iron is transferred to the object, and makes a dent which appears as a bulge on the exterior. See SNARLING IRON, p. 2229, "*Mech. Dict.*"

Snatch'ing Rol'lers. (*Printing Machine.*) A pair of rollers driven at a somewhat higher speed than the pair of holding rollers next in the rear of them, in order to *snatch* or break the paper on the lines of the perforations and thus make them into separate sheets.

Sneak Box. The New Jersey sneak box is from 12′ to 14′ in length; the shelving or sideboards on the stern of the boat are used to hold the decoys while the hunter rows to and from the shooting ground. Used by gunners on Barnegat and Little Egg Harbor Bays, New Jersey. The Maryland ducking-sink is used by gunners on the Potomac River and Chesapeake Bay.

Snood. (*Fishing.*) The short line which carries the hook and is attached to the fishing line. A *snell*, *leader*, or *trace*.

Made of catgut, silk, gimp, wire, flax, silk-worm gut, etc.

Snow Flan'ges. (*Railway.*) A bar of iron or steel attached to a car or engine to scrape away snow and ice on the sides of the heads of the rails so as to make room for the flanges of the wheels.

See "*Scientific American,*" xl. 372.

Snow Plow. A plow-shaped apparatus mounted on wheels and propelled by locomotives, used in cutting a way through snow drifts.

Those used in the vast drifts on the Pacific railroad are 13′ high, 10′ wide, and 30′ long. They are mounted on two trucks and weigh 38,000 pounds each. The body of the plow is made of the best lumber, the furrow board of polished ash, running back at an angle of 81° and up, in a half circle of 19″ radius. The apron is of ⅜″ boiler iron and has steel shoes, clamped on the rail by clamps 3′ long. The drifts sometimes become so compacted that they resist the butting action of the plow for a long time, and as high as fifteen locomotives have united their combined power before they could push the plow through the drifts.

Snow plow, *Little* . . * "*Scientific American,*" xxxvi. 226.
Snow plows, railway . * "*Scientific American Sup.*," 731.

Snow Scra'per. 1. (*Railway.*) A plate or bar of iron attached to an engine or car to scrape snow and ice from the rail.

2. An A-shaped plow made of two scantlings and a cross-piece, for cleaning snow off sidewalks. The driver stands on the cross-piece; the horse is hitched to the point of the A.

Snug'ger. A device to impart a smooth and dense exterior and uniform thickness to twine.

Soap. In the preparation of toilet or perfumed soaps, the blocks of rough soap are first cut into thin shavings in a planing machine, and the shavings are then ground with coloring matter, essential oils, and scents, until they form a homogenous paste. The machine for grinding contains granite cylinders, which pass the paste automatically between them, and finally into the upper portion of the hopper, so that the services of only one attendant are required for several machines. After the paste has been ground, it passes to a machine called the *peloteuse*, or mixing mill, which stretches and draws it out and prepares it for being molded and stamped. The *peloteuse* does instantly what at one time required several weeks of scraping, washing, and drying. It is a mortar, in which the soap paste is packed until it is freed of air, and from which it is then forced by increase of pressure, passing through draw plates of any required cross section.

A self-acting cutter divides the stream of soap into blocks of any desired size or weight.

Phosphate of soda is being used in a composition with the common soaps, as especially adapted for use in salt water, as well as fresh water.

(*Glass.*) Binoxide of manganese used to correct the greenish tinge in glass, due to the presence of iron in the sand. Glass made with potash is freer from this coloration but is expensive, hard, and difficult to work.

Binoxide of manganese in excess turns the glass to rose color, purple, and even black, according to the quantity used. It is used in small quantities as a corrective. In the French practice the proportion is 0.5 per cent.

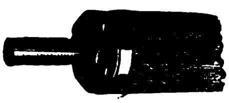
Soap Cut'ter. An apparatus for caking or barring soap in manufacture. See SOAP BARRING AND CUTTING MACHINE, p. 2232, "*Mech. Dict.*," and SOAP CUTTING MACHINE, p. 2233, *Ibid.*

Soap Coil. One fitting the interior of a soap boiling kettle, and through which the steam circulates to boil the ingredients.

Sock'et. A tool used in well boring to recover and lift rods out of the well. They are of different shapes, screwing on to the top of the rod, attaching by gripers, hooks, shoulders, collars, spreaders, etc.

Sock'et Gud'geon. One in which the gudgeon shoulder surrounds the wooden shaft, instead of being let into the shaft. In the illustration (Fig. 2293) it is shown as attached to a conveyor or bolt-reel shaft.

Fig. 2293.



Socket Gudgeon.

Sock'et Pipe. One having an enlarged end to receive the end of another pipe, and contain the lead or other cementing material used in joining the pipes.

Sock'et Wash'er. A washer having a counter-sunk face into which the head of the bolt sinks. See Fig. 2294.

Fig. 2294.

Socket Washer.

So'da Ap'pa-ra'tus. Soda is manufactured principally, now, from common salt.

The manufacture of soda from kelp is comparatively unimportant.

The manufacture from the cryolite of Greenland, is limited practically to that country. Extensive deposits of natural soda, enough to supply the world's demands for centuries, are said to have been discovered in Wyoming territory. Large amounts of the sulphate of sodium are obtained in France and Germany from the mother liquors remaining after the extraction of chloride of potassium.

Jones & Walsh's furnace consists of a large shallow pan, exposed to a free coke fire in which the entire reaction takes place. An axle above the pan having a series of propelling iron shovels agitates the salt. About four fifths of the necessary amount of sulphuric acid is admitted by leaden pipes, and the machinery is set in motion. The evolution of hydrochloric acid is very regular. At the end of fifteen minutes a small quantity is taken out for test, and the rest of the sulphuric acid added.

Camack and Walker admit the chloride of sodium and sulphuric acid at one end of a long horizontal cylindrical rotating furnace, which issues at the outer end in the form of soda.

Hargreaves and Robinson attempt to shorten the process, and effect the formate of sulphate by bringing the gases from the pyrites burners, directly into contact with chloride of sodium at the proper temperature. The finely powdered salt is pressed into small cakes about 1½″ inches thick, and placed in a series of from 8 to 14 cylinders, 15′ in diameter and 12′ high, so united that gas entering at one end of the series must pass through all. The cylinders are kept at a dull red heat for fourteen to twenty days. The current of sulphurous anhydride, air, and superheated steam entering the cylinder in which the reaction is nearest completion, passes on through cylinders containing less and less of sulphate until the mixture of gases and vapor is deprived of all or nearly all sulphurous anhydride when it reaches the last cylinder containing salt scarcely attacked, and issues thence laden with hydrochloric acid to the condensing towers. As the action in one cylinder is completed, it is switched off and emptied and the next is advanced to its place.

See Prof. Jenkins' report on chemical industries, "*Paris Exposition* (1878) *Reports*," vol. iv., page 82, *et seq.* And Kuhlmann's report on The Chemical Acts, Group III., vol. iv., "*Centennial Exhibition Reports*," page 93.

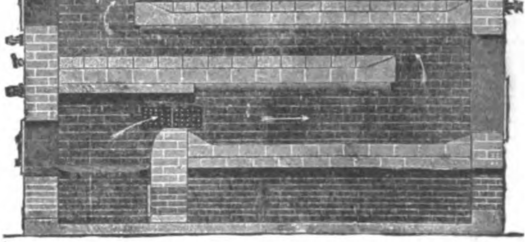
So'da Ash Re-claim'er.

Fig. 2295 shows an ash furnace for reclaiming soda-ash liquor after it has been employed to reduce wood to a pulp. The liquor is first placed in a tank of iron over the top of the furnace, and is generally from 7° to 15° in strength. From the tank it descends first into an iron tray that has a slight slant to allow the liquor to gradually drop on to the next pan or tray. The second tray is made of fire-brick plates, 42″ wide; the third tray is made the same way. The liquor is gradually pushed down over these trays until the incinerating hearth is reached. To reclaim liquid soda ash into black ash requires a long flame and high heat, as not only must the water be evaporated out of the liquor, but

Fig. 2295.



Soda Ash Reclaimer.

the particles of wood must be burned. This requires soft or bituminous coal, waste wood or saw-dust; by discharging hot air on top of the fire the gas is ignited, and the flame is extended to the top pan or tray.

So′da-wa′ter Ap′pa-ra′tus. The principle of making aërated waters by the American system is by charging a cylinder of water with carbon gas, under pressure evolved by the mixing of sulphuric acid and whiting or marble dust. As used in England and her colonies, and on the Continent, the gas is made in a leaden generator, and by its own force issues into a gasometer, where it remains until it is pumped, with the water to be bottled, into the condenser, and is here mixed together by an agitator.

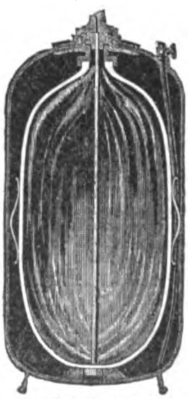
One of the first attempts to make artificial waters was made by Thurniessen in 1560, and from then to the present time the machinery for the manufacture has gradually been perfected. The system at present in use in the United Kingdom and on the Continent, is identical. It is what is called the "continuous direct action process." The principle of this is as follows: The carbonic acid gas is made in a leaden vessel, the carbonate being placed in, generally mixed with water, the acid, which is contained in a continuous vessel, being poured on by a simple arrangement in just sufficient quantities to generate the gas, no more being used than is absolutely required for the purpose, the waste product when exhausted being easily drawn off and a fresh charge inserted.

Various materials are employed as carbonates, these varying, of course, with circumstances, depending entirely on their handiness and cost, whiting, marble dust, carbonates of soda and magnesia, and very many other substances being used. The marble is supposed to effervesce less violently than less compact forms of carbonate of lime.

See "*Mech. Dict.*," pp. 2236, 2237.

So′da-wa′ter Foun′tain. Fig. 2296 shows a seamless fountain with glass reservoir inside a copper one, which withstands a pressure of 500 lbs. There is no pressure on the glass, as it is balanced by the gas between the two shells.

Fig. 2296



Seamless Soda-water Fountain.

So′da-wa′ter Foun′tain Cock. The coupling to which the pipe is attached passes into a square, hollow box, and by means of a thumb-screw is made tight; avoids all twisting and breaking of pipes, and requires no wrench.

Sod Plow. Avery's plow turns the sod either to right or left, and lays it so as to put ordinary grass out of sight.

So′fa Bed. A sofa whose seat is hinged to open out, the under side of the seat and the exposed part of the sofa, when unfolded, forming a mattrass.

Soft-board′ing. (*Leather.*) Boarding or bruising the leather on the flesh-side; it renders the skin very pliant.

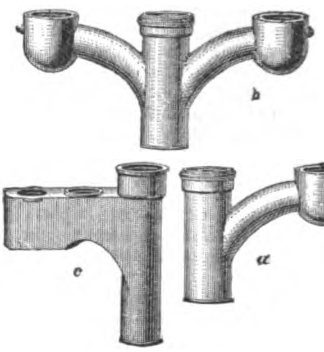
Soft Cen′ter Steel. A composition of iron and steel. A mold is divided into two or more sections by sheet or plate iron partitions. The metals are poured into their respective chambers, and the partitions, fused by the heat, weld the mass together. Used for safes, plows, etc.

The character of the center, that is, whether it shall be "hard" or "soft," of steel or iron, depends largely upon the use to which it is to be put. Where the use demands hardness on the outside for protection against wearing or abrasion, and at the same time considerable toughness in the center, as in plows, the center is soft or of iron. For ease of welding and toughness with rigidity, hard center or steel center is used. — *Iron Age.*

Soft Paste. (*Ceramics.*) A name applied to the material of porcelain, which is semi-hard only. It is of fine clay, with proportions of silex and other substances. A name applied either to the Worcester paste of England or to the *vieux Sèvres*. See PORCELAIN.

Soil Branch. A sewer pipe, making lateral connection with the hopper of a water-closet.

Fig. 2297.



Soil Branches.

a. Single soil branch. *b.* Double soil branch. *c.* Hospital soil branch.

Soil Pipe. A sewer pipe serving a water-closet.

Soil-pipe ventilator, *Boyle*, Br., * "*Engineering*," xxix. 127.

Soil Pul′ver-i-zer. An implement for triturating the earth in preparing for seeding.

See HARROW; DISK HARROW; CLOD CRUSHER; ROLLER, etc.

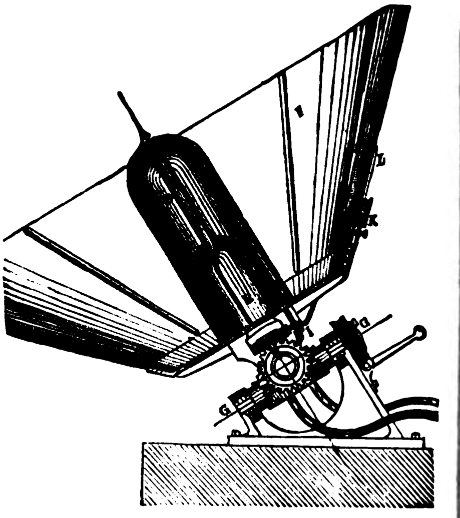
So′laire. An apparatus for using directly the heat of the sun's rays. The resolution of this difficult problem has been attempted from the time of Hero of Alexandria, B. C. 100, by Baptista Porta, Martini, Kircher, Bélidor, Oliver Evans, Ericsson.

The question is considered at some length in *Laboulaye's "Dictionnaire des Arts et Manufactures,"* tome iii., article "*Solaire,*" where Mouchot's apparatus is described and represented.

So′lar Boil′er. An apparatus intended to utilize the heat of the sun's rays.

Fig. 2298 shows Prof. Mouchot's solar boiler. *A* is a glass bell; *B* is a boiler with a double envelope; *D* is a steam-pipe; *E* is a feed-pipe; *F* is a conical silvered mirror; *G G* is a spindle around which a motion is given to the machine from east to west; *H* is the gearing regulating the inclination of the apparatus on the spindle *G G*, according to the seasons; *I* is a safety-valve; *K* is a pressure-gage, and *L* is a water-gage. The mirror has the form of a truncated cone, with parallel bases, and the generating line makes an angle of 45° with the axis of the cone. The incident rays striking parallel to the axis, are reflected normally to this axis, and give a heat area of maximum intensity for a given opening of mirror. The reflectors are formed of 12 silvered sectors, carried by an iron frame in the grooves of which they slide. The diameter of opening is 112.3″ at the top and 39.3″ at the bottom, giving an effective mirror area of about 45 square feet. The bottom of the mirror is formed of a cast-iron disk to add weight to the apparatus. In the center of this disk is placed the boiler, the height of which is equal to that of the mirror. It is of copper blackened on the outside, and is formed of two concentric bell-shaped envelopes connected at their base by a wrought-iron ring. The larger envelope is 31.5″ high, and the smaller, 19.68″; their respective diameters are 11.02″ and 8.66″. The water is introduced between these two envelopes, so that it forms a cylinder 1.18″ thick. The amount of water does not exceed 4.4 gallons, and about one third of the annular space is left as a steam-chamber. The inner envelope remains empty; it is furnished on one side with a copper pipe leading from the steam-chamber,

Fig. 2298.



Solar Boiler

and connected with the motor by a flexible tube. At the foot of the boiler is placed the feed-water tube. The glass envelope or bell is 15.75″ in diameter, and 33.46″ high, the thickness of the glass being .2″ thick. A space of nearly 2″ is thus left between the sides of the glass and the copper envelope.

The apparatus is mounted on an inclined axis, the angle of which can be made to change to correspond with the motion of the sun, and a rotating movement of 15° per hour can also be given to it. To effect this double object, the apparatus is carried on trunnions resting on a shaft perpendicular to their axis, and this shaft forms, from north to south with the horizon, an angle corresponding to the latitude of the place. Two movements result from this arrangement which permit the apparatus to follow the course of the sun, since by a half revolution it turns from sunrise to sunset, whilst by an annual rotation of 46° at most on the trunnions, it is brought opposite the sun in all positions. This double movement is effected by means of worm gearing, the first being repeated at half-hour intervals, the second every eight days.

Experiments made with this apparatus at Tours showed that in 40 minutes 44 lbs. of water were raised from a temperature of 68° to 252°, and thence to a pressure of 5 atmospheres. In less than 15 minutes, 33 lbs. of water of 212° were raised to 307°. Finally, in favorable weather, 11 lbs. of water have been evaporated per hour. The steam generated was employed for driving a pump.

The inventor of this apparatus points out various uses for which it may be employed, especially in warm climates, as, for example, for the distillation of water, either on shipboard or in rainless countries, for the manufacture of ice, in connection with the Carré apparatus for the distillation of alcohol, etc., and in the manufacture of sugar.

So′lar Ca-lor′ic En′gine. Fig. 2299 represents Captain Ericsson's new engine for the utilization of solar heat in the production of motive power. It is calculated that the heat radiated by the sun during nine hours per day, for all the latitudes comprised between the equator and the 45th parallel, corresponds per minute and per square foot of normal surface to the direction of the rays to 3.5 thermo units of 772 foot pounds. Hence, a surface of 100 square feet would give a power of 270,000 foot pounds, or from 8 to 9 horse-power. The engine illustrated is on the caloric system, and has run at 420 revolutions per minute with the sun near the zenith and during fine weather.

Solar caloric engine.

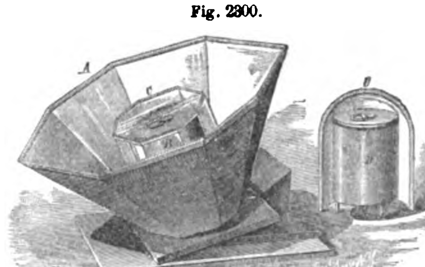
So′lar Cook′ing Ap′pa-ra′tus. A device for utilizing the heat of the sun's rays for culinary purposes.

Fig. 2300 shows Adams's solar cooking apparatus used at Bombay. It consists of a conical reflector, *A*, made of wood and lined with common silvered sheet glass. Inside there is placed a copper cylindrical vessel, *B*, covered by a glass cover, *C*. The cooking vessel is raised about 4″ from the bottom, and the glass cover is 5″ longer than the vessel, and

Fig. 2300.



Solar Cooking Apparatus.

2″ wider, which leaves an interval of 4″ of hot air under the boiler and 1″ all round and at the top. The wedge under the apparatus is to keep it inclined, so that the rays of the sun may fall perpendicularly on the boiler. Glass being diathermanous to the direct or reflected rays of the sun, and non-diahtermanous to obscure heat, the rays penetrate the glass, and, striking on the vessel, become transformed into obscure heat, when they are retained by the glass. The glass cover over the boiler is made octagonal, because, in that form common window glass can be used. The position of the apparatus requires to be changed about every half hour, to face the sun in its apparent course from east to west. The rations of seven soldiers, consisting of meat and vegetables, are thoroughly cooked by it in two hours, in January, the coldest month of the year in Bombay, and the men declare the food to be cooked much better than in the ordinary manner. Several people in Bombay and in the Deccan have tried it, and always with success. If the steam be retained the dish is a stew or a boil; if it be allowed to escape the food is baked. The reflector is 2′ 4″ in diameter. The intensity of the heat is increased by increasing the diameter of the reflector.

So'lar Lamp. 1. Another name for the argand lamp. It has a tubular wick and central duct that admit air to the interior of the flame. See ARGAND LAMP, p. 142, "*Mech. Dict.*"

2. One of the fourth class of electrical lights. In all electric candles the carbons are placed parallel to one another, and as the waste of the two must be equal, they are fed by alternate currents. Some of them have an automatic arrangement for lighting and relighting. The candles without columbin are to be referred to the voltaic-arc class; Jablochkoff's candles possess the characters both of the arc and of incandescence.

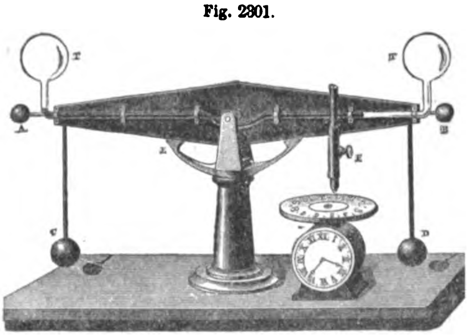
The Clerc and Bureau lamps are allied to the candle by the nearly parallel arrangement of their two carbons, and to the incandescence class by the nature of their light, produced as it is by a piece of chalk raised to a very high temperature, and made incandescent by the passage of the current across the voltaic arc established between the two carbons, and which grazes its surface. In the case of the candles, as in that of the *lampe-soleil*, a certain number of apparatus can be placed in one circuit; hence we might regard them as a fourth class of electric light apparatus by division (polyphote regulators).

So'lar Pho-to-graph'ic In'stru-ment. An instrument for photographing the surface of the sun.

So'lar Ra-di-a'tion Reg'is-ter. An apparatus to automatically register the period the sun shines.

In Fig. 2301 the two bulbs of the thermometer *T T'* are covered with lampblack. The bulb *T* to the left is alone exposed to the open air, all the rest being inclosed in a box. When the sun shines the air contained in the bulb *T* dilates, and the mercury in the differential thermometer is driven into the tube, thus destroying the equilibrium of the balance. The beam then inclines, and the point of the pencil, which is fixed to the support *F*, rests on a paper circle fastened to a copper disk. This disk keeps constantly revolving on its axis, carrying with it a paper dial. When the sun is

Fig. 2301.



Solar Radiation Register.

no longer shining the balance resumes its equilibrium, the pencil ceases to touch the paper, and the tracings made by it are thus broken.

To complete the description of this ingenious apparatus we will add that the metallic balls *A B* are provided with screws, and serve to place the beam in equilibrium. The rods *C D* are made of metal, and are designed to prevent oscillation.

Sol'der. A fusible metal used to join two less fusible metallic bodies.

Jewelers will find the annexed list of silver solders of considerable practical value. Hard solder: Pure silver 16 parts, copper 3½ parts, spelter ½ part. Medium: Fine silver 15 parts, copper 4 parts, spelter 1 part. Easy solder: Fine silver 14 parts, copper 4½ parts, spelter 1½ parts. Common hard solder: Fine silver 12½ parts, copper 6 parts, spelter 1½ parts. Common easy solder: Fine silver 11½ parts, copper 6½ parts, spelter 2 parts. The fusing points of these solders are as follows: No. 1, 1,866° Fah.; No. 2, 1,843°; No. 3, 1,818°; No. 4, 1,826°; and No. 5, 1,802°.

See "*Mech. Dict.*," p. 2239.

A few solders, the metal to which they are applied, and their appropriate fluxes, are tabulated below.

Name.	Composition.
Soft, coarse	Tin, 1; lead, 2.
Fine	Tin, 2; lead, 1.
Fusible	Tin, 2; lead, 1; bis., 1.
Pewterer's	Tin, 3; lead, 4; bis., 2.
Spelter, soft	Copper, 1; zinc, 1.
Hard	Copper, 2; zinc, 1.
Silver, fine	Silver, 66.6; copper, 23.4; zinc, 10.
Common	Silver, 66.6; copper, 30.; zinc, 3.4.
For brass and iron	Silver, 1; brass, 1.
More fusible	Silver, 1; brass, 1; zinc, 1
Gold, for 18 carat gold	Gold, 18 carats fine, 66.6; silver, 16.7; copper, 16.7.
More fusible	Same as above with a trace of zinc.
Platinum	Fine gold.

Material to be soldered.	Solder.	Flux.
Tin	Soft, coarse, or fine.	Rosin or zinc, chl.
Lead	Soft, coarse, or fine.	Rosin.
Brass, copper, iron, and zinc.	Soft, coarse, or fine.	Zinc, chl.
Pewter	Pewterer's or fusible.	Rosin or zinc, chl.
Brass	Spelter, soft.	Borax.
Copper and iron	Spelter, soft or hard.	Borax.
Brass, copper, iron, steel	Any silver.	Borax.
Gold	Gold.	Borax.
Platinum	Fine gold.	Borax.

To solder German silver, pour out some spirits of salt in an earthenware dish, and add a piece of zinc. Then scrape clean the edges to be soldered, and paint over with the spirit of salt. Apply a piece of pewter solder to the point and melt with the blow-pipe.

Comp. . . . . . "*Iron Age*," xxi., March 21, p. 7.

Sol'der Cut'ter. (*Sheet-metal Working.*) A machine for chipping solder into pieces convenient for use in soldering.

A fly-wheel operated by hand carries cutting blades. The operator feeds the bars of solder down an incline, and they are sheared between a bead on the frame and those on the wheel.

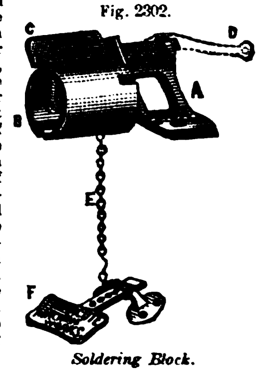
Sol'der-cut'ting Dies. Dies used in cutting out bars of solder in a press, eight in a block.

Sol'der-ing Fur'nace. A new form is adapted to burning coal oil, and is being extensively introduced as a heater for tinners' coppers, taking the place of the charcoal furnace.

Sol'der-ing Block. Used in soldering cans.

Fig. 2302 consists of an inclined frame, *A*; lever and "knife," *C*; expanding cylinder, *B*; chain, *E*; treadle and fulcrum, *F*, etc. A slot in the frame allows the use of different cylinders, from 1 lb. to 1 gallon, and their adjustment up and down, without changing the knife. A slot in the lever allows the knife to be set out for varying lengths of cylinders. Adjustments are also provided in the length of the chain, leverage of treadle, position of cylinder around its center, and "set" of the knife. The latter has a groove to prevent "tinning." The chain passes through the bench and hooks in at *D*. The action of the foot then raises the knife and the spring does the holding down.

Fig. 2302.



Soldering Block.

Sol'der-ing Frame. (*Sheet-metal Working.*) A clamp for holding the parts of a can in apposition while soldering.

Sol'der-ing I'ron. One recently invented has a platinum receptacle in which heat is instantaneously generated with air and petroleum vapor, or air and coal gas.

The Gem soldering iron is adapted to fit on an ordinary gas burner, with the copper up. The handle and tool are hollow, allowing the gas to escape through the point, where it may be ignited and the copper will be speedily heated.

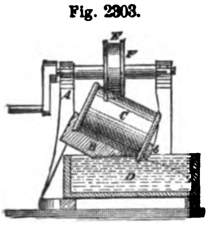
Soldering iron, gas heated * "*Scientific American Sup.*," 4106.
Soldering mach., *Howe* * "*Scientific American*," xxxv. 115.
Soldering tool, *Painter* . * "*Scientific American*," xlii. 178.

Sol'der-ing Ma-chine'. (*Sheet-metal Working.*) Howe's machine is for soldering the tops and bottoms of round cans. The cans roll along in an inclined trench, the edge passing along a shallow groove in which is melted solder. Page 108 of Bliss's catalogue (1881).

For soldering tin cans.

Fig. 2303 shows a machine especially suited for soldering the end seams of cans. *A* represents the frame of the machine, to which is attached a track, *B*, along which the cans are to be rolled. The track is flanged along its side edges to keep the cans *C* in place upon it, and has a side inclination to cause the ends of said cans to rest upon the lower side flange *b'* as they are rolled along said track. The track *B* is slotted in the lower side of its middle part, along the flange *b'* to allow the end seam of the cans to project through into a solder bath *D*, placed beneath it in the frame, and in which the solder is kept melted by a furnace. The bath *D* is of such a length that the cans may make at least one entire revolution with their end seams in the solder. The track *B* is made with an upward incline at one end, down which the cans are rolled in passing from the machine. The cans *C* are rolled along the track *B* by an endless band *E*, which passes around the pulleys pivoted to the frame, and to one of which motion may be given by hand or other convenient power.

Fig. 2303.



Soldering Machine.

Sol'der-ing Pot. For making joints in line wire.

When the upright handle is moved back, it allows a wire to be slipped down the slots, the joint being inside of the pot, which is partly filled with melted solder. The wire is pressed down on each side until it finds a secure lodgment in the bottom of the slots. The clamp is shoved forward so as to hold the wire in place, the arms of the clamp at the same time covering the slots and preventing the solder from running out. The pot is then tipped forward so as to cover the joint with solder, thus making a neat and well protected joint.

Fig. 2304.

Soldering Pot.

Sol'der-ing Tongs. A pair of flat nosed tongs used in brazing the joints of band saws. The saw is held in a scarfing frame, a film of solder placed between the scarfed edges which are lapped together, and then the heated tongs clamped upon them to melt the solder. See BAND-SAW HOLDER.

Sol'der Mold. A mold for running solder into any shape desired.

Sole. A recent inventor proposes to make boots with stone soles. A suitable quantity of clean quartz sand is mixed with a water-proof glue, and spread on a thin leather sole which is employed as a foundation. These quartz soles are said to be flexible and almost indestructible, while they enable the wearer to walk safely over slippery roads.

Sole Cut'ting Ma-chine'. The one shown in Fig. 2305 is adapted for cutting outsoles, insoles, heeling, counters, shanks, etc., and can be used with dies having handles or without. It has a circular revolving block; the die is fastened in a chuck over the block, and can be moved about as desired. The block is worn evenly by the constant revolving motion; the wear is taken up by raising the screw under the machine.

Fig. 2305.

Sole Cutting Machine.

Sole Form'ing Ma-chine'. One for rounding up shoe soles. A rounding up machine can shape 100 pairs of soles per hour.

The rounding is all done by one revolution of the knife, which at the same operation gives to the edge of the sole any desired bevel, and will work to patterns of any size or style, the changes being handily made.

Sole Leath'er Rol'ler. A machine for pressing leather stock into firmness, by passing between spring rollers. See Fig. 5309, p. 2244, "*Mech. Dict.*"

Sole Leath'er Strip'per. Adjustable blades or skivers for stripping the rough side of the leather.

Sole Mold'ing Ma-chine'. For shaping the cut sole to the shape of the last.

Sole Riv'et-ing Ma-chine'. The McKay riveting machine automatically cuts a rivet of the proper length, drives it, and clinches the point on the inside of the shoe. It clinches the rivet on a rotating horn, and thus makes the clinching certain. With the clinching rivet and the perfect length of the nail a thin insole can be used with safety. The rivets are corrugated so that they do not work up into the foot in wearing.

Sole Tile. A flat or bellying tile, according to requirements, for the bottom of sewers, muffles, or other objects in which the whole circumference is not in one piece.

Sol'id Plate Saw. A circular saw made of a single plate, as distinguished from a *segment* saw.

So'le-noid. An electro-dynamic spiral, having the conjunctive wire returned along its axis, neutralizing that component of the effect of the current that is due to the length of the spiral, and reducing the whole effect to that of a series of equal and parallel circular currents.

Sol'u-ble Glass. An alkaline silicate that is soluble in water, but remains unaffected by ordinary atmospheric changes.

The silicates of soda and potash differ from the other silicates grouped under the general name of glass in being soluble in water; hence they are known as soluble glass, liquid quartz, etc. While ordinary glass has been known from very ancient times, these peculiar compounds are quite new to us, having been accidentally discovered by the late Professor Fuchs, of Munich, in the year 1818, while experimenting with a view to the preparation of pure silica.

When soluble glass is applied to surfaces of plaster and limestone a chemical reaction takes place, resulting in the formation of silicate of lime. A vitreous surface is thus produced impervious to moisture and unaffected by atmospheric agents. Soluble glass is also used as a vehicle for mineral colors in a kind of fresco painting, known as stereochromy. The famous frescoes by Kaulbach, in the museum at Berlin, were done in this way. It is also entering into the preparation of paints for ordinary use.

One method of making artificial stone is by moistening fine sand with a solution of silicate of soda, pressing the mixture into molds, drying it and exposing it to a high temperature. The silicate fuses and cements the grains of sand together into a mass resembling sandstone. Any desired color is imparted by the admixture of metallic oxides previous to molding. Thousands of tons of the silicate are consumed for this purpose in England. Another important application of soluble glass is in calico-printing, where it is now extensively used as a mordant. It is even more in demand in soap-making, for which it has advantages over resin on account of its alkaline character. It also enters into the composition of fire-proof cements for stoves and iron-work, and especially for putting up iron fronts for buildings.

Soluble glass, uses of . "*Scientific American Sup.*," 1417.

Son'do-graph. A recording sounding apparatus, which see, specifically; an invention of Lieutenant Pinheiro, of the Brazilian navy, to give a continuous delineation of the bottom of the sea along the line on which it is operated.

See "*Telegraphic Journal*," vi. 426.

Soude a Dart. (*Surgical.*) A cannulated lithic instrument, having a flexible sound projected through it and out near the apex to collide with the stone. See Fig. 153, Part III., *Tiemann's "Armamentarium."*

Sound. Elliott's sound, modified by H. Leonard, is a new adaptation of a long surgical instrument, usually of metal, and partaking of the nature of a probe. It is used especially in making explorations in the bladder in search of stone. It is inserted through the urethra, and a peculiar click is heard when it comes in contact with a stone.

Simpson's sound (No. 8) graduated, and his (No. 9) telescope, for convenience in carrying, are also new modifications of the same instrument. To which may be added Dr. Helmutt's instrument for *supra pubis* puncture. Skene's uterine sound, *sonde de anal, sonde de belloc, sonde de Brisée, sonde à conducteur, sonde de saforest,* and *sonde* or pinchers of Hunter.

Sound Con-cen'tra-tor and Pro-ject'or. Hopkins' acoustic apparatus is a portable and adjustable whispering-gallery, having many useful applications. An air-tight drum or reflector, one head of which is rigid and the other elastic, is mounted on pivots in a swiveled support, and is provided with a flexible tube having a mouth-piece and stop-cock at its free end. Two wires are stretched across the face of the reflector at right angles to each other, and support at their intersection a small plane mirror, the office of which is to determine the position of the reflector in relation to the direction of the sound.

A small ear-trumpet is used in connection with the reflector, to increase the effect by gathering a portion of the sound that might escape the unaided ear. The reflector is adjusted by looking through the ear-trumpet toward the small plane mirror, and moving the sound-reflector until the source of sound is seen in the mirror. The reflector is then focused by exhausting the air from behind the flexible head until the required degree of concavity is reached, indicated by the ease with which sounds may be heard in the ear-trumpet. The air is withdrawn from the reflector by applying the mouth to the mouth-piece.

Sound'er. Sir William Thomson's apparatus for deep-sea sounding while the ship is in motion. See SOUNDING APPARATUS; FLYING SOUNDER.

Sound'er. (*Electricity.*) An alarm or call, made by closing an electric circuit.

The system of telephoning by means of beat of drum, long practiced in Africa, and called by the Cameroons *elliembic*, proceeds upon the principle of signaling by varying the beats according to a code. It perhaps would be too much to call it an alphabet code, and travelers who have noticed it do not seem to have been curious as to the nature of the system. The sound under favorable circumstances may be heard 2 or 3 miles.

The Mani-mani wooden portable signal drum known as the *clincufo* was shown at the Centennial in the Egyptian section, but the great drum *manyunjee* is a hollowed trunk of wood mounted on feet. It has sides of uneven thickness which give a different note aiding in giving variability to the signal. A similar drum from the Fijis is in the National Museum at Washington. See: —

Sound'-house. A marine alarm station from which audible alarms or signals are given in foggy weather. The apparatus are usually fog horns or sirens.

Sound'ing. Devices for sounding and gaging in surveys of the upper Mississippi; including stadia, water-gages, sounding stakes on sand-bars and trees, etc. See "*Report of Chief of Engineers, U. S. Army*," 1880, * ii. 1518.

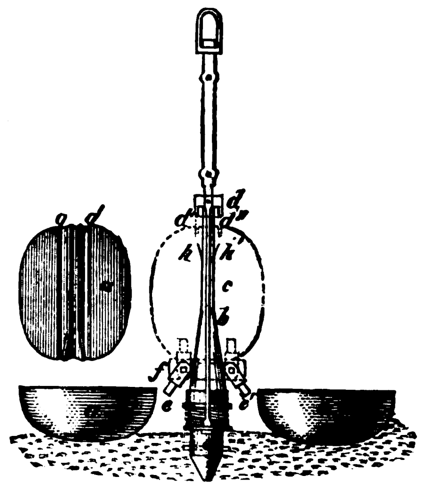
See BATHOMETER in "*Mech. Dict.*"

Sound'ing Ap'pa-ra'tus. A device for bringing up specimens of sea bottom.

In Admiral Sands' device a box is screwed into the bottom of the sounding lead and is secured thereto by a key. It has a conical point and is surrounded by a flanged sleeve pressed downward by a weak spiral spring. On striking bottom the point penetrates the ground and the flange on the collar forces it upward, exposing an aperture through which the mud, sand, or other material enters. When the lead is drawn up the spring reacts, closing the opening so as to prevent the specimen being washed out.

Admiral Sands has also invented an improved self-detaching sounding apparatus to be used in connection with the

Fig. 2306.



Self-detaching Sounding Apparatus.

specimen cup. The sinker is composed of two semi-ellipsoidal pieces a a', having central grooves unitedly forming a tube through which the stem b, attached to the sounding line by a swivel, passes. A rod, c, carrying a collar, d, having downwardly projecting prongs, passes through the stem longitudinally and is attached to the sleeve of the specimen box e. When a sounding is made the two pieces a a' are fitted on the rod, being held by the prongs d' d'' and pens e e' on the cross piece, f, entering the grooves g g'. When bottom is reached the upward movement of the sleeve on e raises the rod c, lifting out the prongs d' d'' on the collar d, and the pieces a a' are thrown off by springs h h' on each side of the stem b.

In an instrument invented by Sir William Thomson for taking flying soundings while a ship is in motion, the essential idea is to measure the depth by the pressure of the water at that depth, which is effected by lowering a pressure gage with the lead line. Of the two forms of gage the first and that chiefly in use consists of a narrow glass tube closed at one end and open at the other. When it is lowered into the sea the water entering the open end of the tube compresses the air column, diminishing its length in proportion as the water pressure increases, according to Boyles' well-known law. The height to which the water rises in the gage tube marks the limit to which the air has been compressed. The indicating mark is shown in various ways,—generally by lining the tube with a colored preparation that is removed as far as the water by pressure is driven up in the tube. The tube is of so narrow a bore that there can be no splashing of the liquid in it during the sounding process. The glass tube is guarded from shocks by a perforated metallic covering. The gage is provided at each end with a mounting containing a valve that opens inward under a definite amount of force As the tube descends into the sea, the lower valve is forced open, and the water enters the tube. When the hauling in is commenced, the lower valve shuts and holds the water that has entered it. On the other hand the pressure of the sea acting upon the upper valve causes it to open, allowing the air within the tube gradually to escape, obviating the danger of bursting from unequal pressure.

In order to ascertain the depth to which the tube has been sunk, a scale is provided, graduated in fathoms up to 100.

Soundings instrument.	
Sir William Thomson	"*Telegraphic Journal*," v. 285.

Sound'ing Board. The sounding-board of pianos is made of spruce, which, with its alternate soft and hard grain, is recognized and used as the best material for the purpose. The beauty and volume of tone in an instrument depend materially upon the sounding-board, and mainly from its quality to react against the molecular vibration of its most delicate inner fibers. This latter process puts the air column surrounding the sounding-board into that vibration that to the ear is perceptible as "tone." The pressure of these several particles of the sounding board against each other, more or less determine not only the power of tone, but its susceptibility, and the singing quality also depends greatly upon it.

Sound'ing Lead. The sounding lead of M. Leocentre, has a helical winged screw at the apex which rotates as the lead descends. On the axis of the helix is a bevel-wheel which transmits motion to a system of gearing, and the hands of two dials registering tenths of meters and meters respectively. The helix ceases to move when the lead touches bottom, and is loose on its axis as it is drawn up.

* "*Sc. American Supplement*," 3805.

Sound'ings Ther-mom'e-ter. The electrical balance thermometer, invented by C. W. Siemens of London, is intended to ascertain the temperature of the ocean at any depth, and is based on the principle that, as the electrical resistance of any metal conductor depends on the dimensions and temperature of the latter, we have only to find the law of the increase or decrease of its resistance for high or low temperatures to be able to determine the resistance from the temperature, or the temperature from the resistance. The deep-sea thermometer, constructed by him on the above principle, consists of a "resistance-thermometer," to which the sounding-line is attached, and of a battery, electrical bridge, and "balance-thermometer," to be used on board the vessel for determining the temperature indicated by the resistance-thermometer at any point of its descent or upon its reaching the bottom. The law of increase and decrease being known, a table is made up, by means of which to correct the deviations of the galvanometer into parts of a degree of temperature.

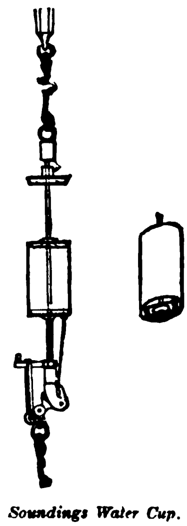
Trowbridge's deep-sea thermometer, "*Coast Survey Report*," 1858.

Six's self-registering thermometer, modified by Miller-Casella, is made in London.

Sound'ings Wa'ter Cup. A cup to bring water from the depths sounded.

An apparatus, designed to bring up one pint of water, consists of the following parts: A stem or spindle 0.5″ in diameter and 20″ in length, terminates at its lower end in a ring for the attachment of the sounding-lead, and at its upper end, in a slotted head, in which is pivoted the detaching trigger. This trigger is 3.5″ in length. It is pivoted at one end in the slotted head, and terminates at the other in a hook, curved upward, in which is placed one end of a rubber spring, as shown in the drawing. Near its middle the trigger carries a swivel for the attachment of the sounding-line; two curved lugs project from its lower side, and work, one on either side of the head of the spindle, so that when either is closed against it, by raising or depressing the free end of the trigger, the other will be open. For convenience of reference, the lug farthest from the free end of the trigger is designated the *rear* and the other the *front* lug. Below the slotted head, at a distance of 3″ from the pivot of the trigger, the spindle carries an arm 3″ in length, projecting in the plane of the trigger, and on the same side of the spindle with it. This also ends in a hook curved downward, over which passes the lower end of the rubber spring before mentioned. This arm slides on the spindle and is furnished with a set-screw, so that its distance from the trigger may be increased at pleasure. At a distance of 8.4″ below this arm the spindle carries a fixed disk 2.6″ in diameter, below this at a distance 4.5″, another disk 3″ in diameter. Passing freely over the former, and closing water-tight upon the latter, is a sliding cylinder 5.4″ in length. This cylinder is open at both ends, the upper end being furnished with a cross-bar and collar, working smoothly on the spindle, to guide the cylinder in sliding up and down. Attached to this cross-bar is a wire sling, ending in a loop, and of such a length that when this loop is placed over either of the lugs of the trigger, the lower end of the cylinder will come flush with the lower surface of the upper disk, as shown in the left-hand figure.

Fig. 2307.



Soundings Water Cup.

A spiral spring, coiled around the spindle between the projecting arm and the collar of the cylinder, tends to force the latter firmly down on the lower disk.

See "*Coast Survey Report*," by Lieutenant Collins, Appendix, No. 14.

The method of securing the specimens with the apparatus, shown in Fig. 2307, is as follows: —

A lead of sufficient weight (10 to 50 lbs., depending upon the depth of water and strength of current) is bent on close to the lower ring of the spindle, and a line, marked to fathoms, to the swivel on the trigger. If, now, the bottom-specimen is desired, the instrument is prepared by sliding up the cylinder and placing the loop of the sling over the *rear* lug of the trigger. A rubber spring is then stretched over the hooks of the trigger and projecting arm, this spring being of such a strength as to yield to the weight of the lead when the apparatus is suspended by the sounding-line, thus allowing the rear lug to close against the head of the spindle, preventing the cylinder from sliding down and closing on the lower disk.

Thus prepared, the apparatus is lowered into the water. On reaching the bottom, the weight of the lead being taken off, the rubber spring draws the hooked end of the trigger downwards, thus allowing the wire sling to disengage itself from the rear lug. The cylinder, forced down by the spiral spring, closes over the disks, and thus the specimen from the stratum in which it rested is secured and drawn to the surface.

For the intermediate specimens the apparatus is prepared by placing the loop of the sling over the *front* lug of the trigger, and supplying a rubber spring of sufficient strength to hold the free end of the trigger down when the instrument is suspended by the sounding-line, thus keeping the lug closed The line is then made fast to the rail of the boat or vessel, at such a place as will allow the mark indicating the number of fathoms from which the specimen is desired to be at the surface when the line has run out taut.

The instrument is then put overboard and allowed to descend freely. As it reaches the desired depth the line is tautened, the rubber spring yields to the shock of the arrested motion, and the cylinder closes instantly, as before.

Sour Beer Core. This term is applied to a dry-sand core in which sour beer or ale has been used for the purpose of increasing the adhesiveness and strength of the sand when dried.

Sour Kraut Cut'ter. A machine for cutting cabbage for kraut. A stationary hopper, has a sliding board with a double edge knife which runs with alternate action, cutting each way. Adjustable screws regulate the thickness of the cut. A follower is used to feed the vegetables to the knife, and is also useful as a partition in cutting small quantities. The cutter is worked by a crank, with its accompanying gearing.

Spade. A variety of spades are used by whalemen.

Boat spade, to disable the whale by cutting its flukes.
Cutting spade, to peel the blubber from the carcass of the dead whale.
Half-round spade, to cut the "blanket" piece to allow the blubber hook to enter.
Head spade, to cut off the head of the whale.
Mincing spade, to cut the blubber small for trying out.
Throat spade, to cut off the head of the whale.
Wide spade, to cut the blubber in the rough, before mincing.

Spade Gun. Invented by Buskett of St. Louis. A detachable spade may be fitted to a socket in the butt-plate and form an efficient implement in intrenching. When not in use it is carried in a recess in the stock.

See . . . . "*Scientific American Supplement*," 1938.
Spade gun, *Buskett* . "*Scientific American Sup.*," 1938.

Span'drel. An inner frame or border for a picture. A *mat.*

Spal'ling Ham'mer. An axe-shaped or chisel-edged hammer for rough dressing stone.

Span'ish Fox. (*Nautical.*) A seizing made by hand-twisting several yarns together and rubbing with hard tarred canvas.

Spank'er Gaff. (*Nautical.*) The gaff of the fore-and-aft sail, which is also called the driver; the aftermost sail of a ship or barque.

The *spanker boom* is the lower spar of the same sail.

Span'ner. A hoseman's wrench. The Skinner spanner has two equal arms, of which the rigid one has a pushing point slightly curved, while the pivoted arm has a drag hook on its end.

Spare An'chor. (*Nautical.*) An additional anchor, the size of the bower.

Spar'ger. A three nozzle self-acting revolving instrument for sprinkling paper, clothes, etc.

Spark Ar-rest'er. A wire or perforated screen to arrest the sparks that ascend smoke-stacks of locomotives, furnaces, etc.

Spark arrester, *Smith* . * "*Scientific American*," xxxvi. 70.
Davis . . . . . . * "*Railroad Gazette*," xxiv. 97.
Graham, Br. . . . * "*Engineer*," l. 41.
Stamp . . . . . . "*Man. & Builder*," viii. 9.
Garrett, Br. . . . . * "*Engineering*," xxx. 539.

Spark Net'ting. A wire cloth over the opening of a locomotive smoke stack, to arrest sparks.

Spawn'ing Screen. A device used in pisciculture to collect the spawn of fish. For list of United States patents, see FISH CULTURE.

Speak'ing E-lec'tric Tel'e-graph. See TELEPHONE.

Speak'ing Tube Whis'tle. A modification of an intonating modulating steam whistle.

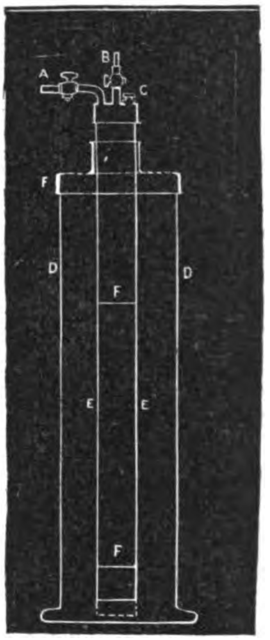
Spears. (*Fishing.*) Fish spears are barbed for securing the fish that are pierced thereby. They were used in very early days. Job speaks of them, as also do early Greek writers. They are of various makes adapted to the fish intended to be caught.

Spear Head. Spear heads are multiform both in shape and in the material of which they are made. They were generally made of stone or quartz by the aborigines of this country; although there was a notable exception with the (at least) partially civilized people who once resided in the neighborhood of the ancient copper mines of Lakes Superior and Huron. They possessed the means of tempering copper, that was lost with them, and notwithstanding all the researches of modern times, has never yet been rediscovered.

Spe-cif'ic Grav'i-ty Ap'pa-ra'tus. Fig. 2308 shows an apparatus for taking the specific gravity of coal and other gases by efflux through a fine opening in a thin plate of metal by Bunsen's method.

The apparatus consists of a glass jar, *D D*, having a perforated top with a collar or sleeve, through which passes a glass tube, *E E*, about 1″ diameter, open at the bottom, but closed at the top by a metallic cap having the connection and cock by which the gas is admitted at *A*; a thumb screw and place for thermometer, *C*, with the pillar cock *B*, on top

Fig. 2308.



Specific Gravity Apparatus.

of which is the exit opening through the thin metal plate. The glass jar *D D* being filled with water to the proper height, the tube *E* can be filled with gas or air at pleasure, thus forming a simple instrument, and one easily operated. Another form, equally simple, and very accurate, is Dr. Letheby's method; the apparatus consists of a glass globe about 6″ diameter, having engraved upon it its exact weight when full of air at mean temperature and pressure (a counterpoise weight being provided exactly equal to the weight of the globe when the air is exhausted): this globe is fitted with two cocks, one of which is attached to a gas pillar; to the other is attached a glass tube ½″ diameter and 7″ long, to which is suspended a thermometer, the end of the glass tube being fitted with a jet for burning the gas.

Spe-cif'ic Grav'i-ty Bal'ance. The instrument employed in the office of the Constructor of Ordnance (U. S. A.) in the determination of the specific gravity of metals for cannon, is simply a form of the hydrostatic balance. It is shown in Plate I., accompanying Appendix I., *c*, to the "*Report of the Chief of Ordnance, U. S. Army*," 1877, and described on p. 394.

The Troemmer instrument for obtaining the specific gravities of large grained powder is a mercury densimeter and is described on p. 396 of above volume, and accompanying Plate II.

Description of the Du Pont, de Nemorirs & Co.'s machine, "*Ordnance Report*," 1879, Appendix I., Plate VII., and pp. 113-115.

Mohr's balance is for taking the specific gravity of liquids by a method which requires no calculation and but a small quantity of the liquid. The apparatus is shown in Fig. 5352, p. 2257, "*Mech. Dict.*"

Spe-cif'ic Grav'i-ty Bot'tle. A slight blown glass bottle of known capacity for obtaining the specific gravity of liquids by weighing measured quantities.

Spe-cif'ic Grav'i-ty Ma-chine'. A new densimeter submitted to the Academy of Sciences, Paris, by M. Gosselin, is very simple in construction and operation. A wooden rule is suspended by a wire attached to some convenient point other than the central point. To the long arm a weight is attached sufficient to balance the body to be examined hung at the end of the other. The latter is immersed in water, and the weight on the longer arm is moved until the rule is again horizontal. A scale on this arm shows at once the density of the body at the point occupied by the weight.

Spe-cif'ic Grav'i-ty Scales. For determining the specific gravity of metals and other substances.

One form is adjusted to accurate balance with its counterpoise and loop removed from the beam, but with double baskets in position, and a vessel supplied with water. In determining specific gravities, the mineral or other solid to be tested is placed in the basket and the pan holder or counterpoise is adjusted to the position, established at a convenient distance from the fulcrum, and marking the extreme working length of the lever arm. One or more of the pans are placed upon the holder to counterbalance the weight of the mineral and a sufficient quantity of the granulated copper is placed in the pan to cause the beam to assume a horizontal position or to stand in perfect equilibrium. The mineral is then removed from the upper basket and placed in the lower basket where it is submerged in the water contained in the vessel. The counterpoise with its load of pans and granular material is then moved along the beam toward the fulcrum to a position where it just counterbalances the submerged mineral. This position corresponds with the specific gravity of the mineral, and the amount being indicated by the graduated scale, can be read off direct, thus giving at a glance the correct specific gravity without regard to the weight or quantity of the mineral or other substance under test.

Spec'ta-cles. Protective spectacles are made of various forms and material to protect the eyes of engineers, firemen, furnace tenders, masons, etc.

The use of such protection from snow has long since been recognized by the Esquimaux and other uncivilized and semi-civilized people.

"In order to avoid the terrible glare of the Arctic snow, we find the Esquimaux have invented snow spectacles. These consist of a piece of wood cut out in the shape of a spectacle; where the glass should be in ordinary spectacles we find two very fine slits. This apparatus I should think would be admirably adapted to drivers of railway engines, who have to encounter snow, wet, and hail, as the engine rushes through storms at express pace. The eye itself is entirely protected, while it gets a fair lookout through the slit in the wood. The ingenuity displayed by these hardy Esquimaux is very interesting and instructive." — *Frank Buckland in* "*Land and Water.*"

Spectacle lens, annular, *Rowell*, * "*Scientific Amer.*, xl. 293.

Spec-trol'o-gy. The science of chemical analysis, by means of the lines of spectra, as modified by the volatilization of different elements.

Spec-trom'e-ter. For measuring the intensity of light.

Prof. J. W. Draper describes in the July, 1879, issue of *Silliman's Journal* a new instrument, which he calls a "spectrometer," and which he proposes to employ to determine the intensity of a light, on the general principle that a light becomes invisible when it is in the presence of another light about sixty-four times more brilliant. He brings the spectrum of the light to be measured into the presence of an extraneous light of known illuminating power, and varies its distance from the instrument until its light is just sufficiently powerful to extinguish the spectrum. The suggestion is novel and valuable, and our readers are referred to the original communication for details. We remark incidentally that, in the use of this instrument, Prof. Draper found that the generally-accepted belief that the yellow is the brightest of the colored spectrum spaces is not true of the prismatic spectrum, and that the luminous intensity diminishes from that in both directions, above and below; that the "extinguishing flame" first extinguished the violet, then the other more refrangible colors in their descending order, and that the red was the last to persist. The red, he found, was invariably perceptible long after the yellow had disappeared. On diminishing the illumination, the red region of the spectrum first comes into view, the other colors following in the order of their refrangibility. He believes this apparent contradiction to be due to the action of the prism, "which narrows, and, as it were, condenses the colored spaces more and more as we pass toward the red, increasing the intensity of the light as it does that of the heat."

Spec'tro-scope. Christie's half prism spectroscopes have ordinary prisms that have been cut in half by a plane perpendicular to the base. In summing up the advantages of the half prisms: Suppose two slightly divergent rays of monochromatic light to pass through an ordinary prism, the angle of separation will not be changed so that the rays emerge at the same angle to each other which they had at entrance. But if two such rays fall perpendicularly upon a face of the half prism, the deviation of one ray in traversing the glass will be much greater than that of the other, and they will consequently emerge at a much wider angle. It is therefore claimed that the half prism is equivalent to a magnifier with cylindrical lenses.

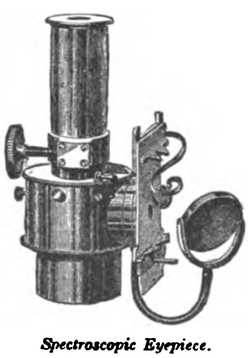
Uses of . . . . . "*Scientific Amer.*," xxxiv. 257.

Spec'tro-scop-ic Eye'piece. (*Optics.*) An adaptation of the spectroscope to the microscope for the examination of minute substances. It consists of a compound direct prism, fitted over a Huyghenain eye-piece, a slit and a supplementary stage upon which an object can be placed for comparison with another which is laid upon the stage of the microscope.

Fig. 2309.



Spectroscopic Eyepiece.

This piece of apparatus fits into the draw-tube of the microscope in place of the ordinary eye-piece, and by it accurate observations are made on the positions of the various absorption bands in the spectra of various fluids, crystals, minerals, etc.

Spec'trum. The several colored and other rays of which light is composed, separated by the refraction of a prism or otherwise, and exhibited, either as spread out on a screen or in direct vision.

Spec'trum Scale. (*Optics.*) A slice of a crystal of quartz of a given thickness, cut parallel to its axis, placed between two Nicol's prisms, and giving a series of black bands. It is used as a standard for recording the position of the absorption bands in objects examined under the micro-spectroscope.

Spec'u-lum. The Storer vaginal speculum is so arranged that by a simple spring attachment at the side of the cusco bivalve, the blades may at once be disjointed, swung around back to back, and there fixed by a turn of the nut upon the screw traversing the handles, with the effect of giving a retractor equal in working facilities to that of Sims.

Neugebauer's speculum consists of four blades, with short, flat handles, all of which fit into each other compactly. Each blade resembles in shape that of Sims, differing but slightly in the curve and in not having its end rounded up. The main peculiarity of the instrument consists in the different blades being so proportioned to each other that any two consecutive sizes may be combined to form a tube; the lateral edges of the smaller are then inclosed within those of the larger.

The larger of the two selected is introduced posteriorly, as Sims' would be; the other enters beneath the pubic arch. The point of the latter, which at the outset is in the hollow of the opposite blade, gradually emerges as the blade is pushed forward.

It requires a little practice to enable one to perform this manipulation without inflicting some pain upon the patient. The result is a perfect tube through which the cervix may be readily inspected. The four blades form three complete specula of different sizes.

Amongst other specula not yet noted are those of Dr. E. B. Turnipseed, Sims' solid and wire instruments, Dr. E. W. Jenks', and Nott's instruments.

Speculum polisher, *Grubbs*, Br., * "*Engineer*," xlii. 160.

Speed. A leg or beam to which a drilling apparatus is attached. The word may not, in this connection, have a very extensive application, but is applied to the beams supporting the drilling tubes in submarine rock-drilling, as at the Rapide aux Galoups, St. Lawrence River.

The comparative speed of various saws and other machine tools are given as follows: —

Velocity of circular saws at periphery	6,000′ to 9,000′ per minute.
Rate of feed for circular saws	15′ to 60′ per minute.
Velocity of band-saws . . .	3,500′ per minute.
Velocity of gang-saws, 20″ stroke	120 strokes per minute.
Velocity of scroll-saws . . .	600 to 800 strokes per minute.
Velocity of planing machine cutters at periphery . . .	4,000′ to 6,000′ per minute.
Velocity of molding machine cutters	3,500′ to 4,000′ per minute.
Velocity of squaring-up machine cutters	7,000′ to 8,000′ per minute.
Velocity of wood-carving drills	5,000 revolutions per minute.

Speed In'di-ca'tor. An instrument for registering the speed at which an engine or machine may at any given time be traveling. Some of them are purely automatic in their construction, while others are in conjunction with their mechanical device operated by hand.

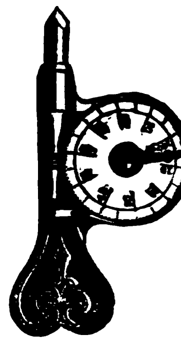
The Harding & Willis Indicator is designed to reveal by a glance at the needle, and without counting or using a watch, the speed at which the engine or machine is working. The small pulley is driven by a quarter-inch band from a second pulley placed on the shaft whose speed is to be indicated. The pulley drives a small shaft on which is fixed inside the casing a small fan with radial vanes. Alongside this fan is placed another one very delicately mounted on a small steel spindle that carries, but outside the fan-box, the indicating needle which works on the dial in the usual way.

The spiral spring always tends to bring the needle to the zero of the instrument, which is, of course, the lowest speed it is intended to indicate. When the fan is caused to revolve it has a tendency, on account of the air inclosed in the casing, to carry round in the same direction the other fan, together with the index-needle, and that against the resistance of the spiral spring. The greater the rate of the revolution to the greater extent is it possible for this fan to overcome the tension of the spring, so that the farther round will the needle be carried. The needle and fan are brought to rest as soon as the pressure on the fan vanes is balanced by the resistance of the spiral spring, the needle then indicating the increased velocity. The dial is indexed for each revolution per minute from 25 to 50, and by means of the eye the divisions may be subdivided to a quarter revolution.

The Union Boston Indicator (see Fig. 2310) is used to register the speed of any revolving shaft, pulley, or mandril.

To ascertain the number of revolutions of the shaft in a given time the point of the indicator is placed in the center of the shaft, and for each hundred revolutions the dial revolves once. Less than one hundred will be indicated by the pointer, which requires to be placed at the 100 before starting.

Fig. 2310.



Speed Indicator.

By a device on the face of the dial a person may feel with the end of the thumb how often it revolves without looking at it, thus enabling the operator to keep correct time.

The Westinghouse Railroad-speed Indicator is an apparatus for ascertaining and recording the speed of a train at any given instant, and by means of automatically constructed diagrams showing the fluctuations of the velocity caused by the applications of the brake.

The principle of construction consists in controlling the escape of water under pressure by means of a small valve loaded by the action of centrifugal force, the arrangement being such that the higher the speed at which the apparatus is driven, the greater will be the pressure exerted by certain revolving weights upon the escape valve, and the higher, therefore, the pressure maintained within the chamber with which this valve communicates, the chamber receiving a constant supply of water from the pumps.

A pressure-gage affixed to the chamber containing the water affords information as to the speed that is attained. The registrations are made on a paper drum similar to that used at meteorological stations to record the velocity of the wind. The heights of the recording lines on the diagram represent pressures on the accumulator of the speed indicator, and these pressures are proportioned to the squares of the speed.

There is a differential speed indicator adopted by all the ironclads of the French channel squadron.

Speed indica., *Butler*, Br. * "*Engineer*," xliii. 293.

Train, *Westinghouse* . * "*Engineering*," xxii. 203.
Ship's, *Normanville*, Br. . . . . . . * "*Engineer*," xlvi. 198.

Speed Meas'ure. Brown's measure (Fig. 2311), has a mercury reservoir and a radial communicating pipe. As the device is revolved by the machinery, the mercury, obeying the centrifugal force, passing up into the tube descends in the axial graduated tube, its sinking being the measure of the speed of rotation.

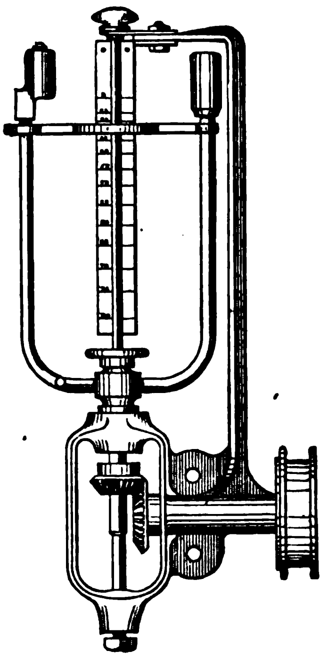
Speed Meas'ur-er. The speed measurer for trains, used at the brake trials at Cassel, Germany, in 1877, consisted mainly of (1) contact instruments, (2) reading instruments, and (3) reading-off instruments.

The contact instruments were fixed by the side of the rails at 33⅓ meters apart along each trial ground, and were all in electric communication with the reading instrument, which, with the reading-off instrument, was fixed in a room of the Buntershausen station.

The apparatus is described in

Speed measurer for trains, Ger., * "*Engineer*," xliv. 235.

Fig. 2311.



Speed Measure.

Speed Re-cord'er. Miller's speed recorder is an indicator of the speed of trains, their stops and delays (necessary and unnecessary), registering the same for reference. See under STEAM GAGE, *infra*

See, also, "*Scientific American Supplement*," 1457.

Theiler, Br.	* "*Engineering*," xxiv. 155.
Westinghouse	* "*Engineer*," xliii. 10.

Speed Reg'u-la'tor. Hübner's governor or speed regulator for railway horse powers is intended for regulating such powers in small factories, etc.

The rim or circle is fastened on the power behind the belt wheel, leaving the shaft in the center. The hub has arms attached, with weighted balls, friction blocks, and a stud with a small coiled brass spring, adjustable with a thumb-screw at the end to regulate the amount of speed needed. As the velocity of speed throws the balls out the friction blocks are pressed against the rim, and act as a brake, but as soon as machinery is applied and takes the power, the balls drop back and relieve the breaking.

See, also, "*Scientific American*," xlii. 245.

Speed regulator for light machinery, * "*Engineer*," xlix. 606.

Speed'y-cut Boot. See HORSE BOOT.

Spel'ter-Sol'der Al-loy'. A good solder for copper and iron is composed of three parts zinc and four parts copper.

A softer solder that is used for ordinary brass work is composed of equal parts of zinc and copper.

A very hard but fusible solder is composed of two parts zinc and one part copper. This solder is so hard and brittle that it can be easily crumbled in a mortar when cold.

The two first solders are first alloyed and cast into ingots. The ingots are allowed to cool in the mold, and then reheated nearly to redness upon a charcoal fire, and are broken up on the anvil, or in a mortar, into a finely granulated state, for use.

Spelter furnace . * "*Scientific American*," xxxix. 402.

Spen'ce's Met'al. A metallic compound consisting of a metallic sulphide mixed with sulphur.

Used for pipe-joints, calking metallic joints, etc.

Announced in a paper read by Dr. Cole before the Society of Arts. Reported in "*Engineering*," 1880, and repeated in "*Van Nostrand's Mag.*," xxii. 371.

Sperge. A charge of distiller's wash. *Muspratt.*

Sphe're-om'e-ter. A sphere-measurer, adapted to measure the radius of a sphere, invented by the French optician De La Roue, to measure the radii of lenses.

This instrument is valuable to opticians, for if they know the radii of the spherical surfaces of a lens, and also the refracting power of the glass of which the lens is composed, they can estimate the general action of the lens on rays of light that fall upon it, and thus arrive at a knowledge of the focal length of the lens.

Sphere Turn'ing Lathe. A lathe for turning spheres; mechanically adapted to the production of a perfect lens.

Its principle is based on the fact that the section of a true sphere at any part is always a circle.

Sphyg'mo-graph. An instrument for indicating the movement of the pulse.

The nature of the circulatory system and even the functions of the arteries and the veins and the nature of the blood were long enigmas.

Praxagoras of Cnidus (300 B. C.) wrote on the pulse, showing that it is a measurer of the force of disease, and discussed the difference between arteries and veins.

Theophilus of Alexandria ("*De Corporis Humani Fabricu*") wrote on the pulse and attributed it to the contraction of the heart.

Erosistratus of Alexandria described the action of the heart, but supposed that the arteries carried air and the veins blood. He noticed the lacteals, but did not understand their function.

Servetus of Geneva (burned 1553), observed the smaller circulation of the blood, that from the head through the lungs and return.

Rialdo Colombo ("*De Re Anatomica*," 1559), successor of Vesalius, at Padua, described the pulmonary circulation.

Fabrizio of Padua (*Acquapendente*), 1562, noticed that the venal valves all opened towards the heart. Harvey was one of his pupils.

Galileo (fl. 1610) invented an instrument for rendering the arterial pulsations visible. Placing one end of a light mirror upon the artery leading to the thumb and the other upon a fixed object, he caused the image of a sunbeam reflected from the mirror upon an opposite wall to vibrate in unison with the pulse. A remarkable similarity exists between this and Sir Wm. Thomson's galvanometer. No apology is needed for naming them together.

The idea was revived by Wenham (Engl.) ("*English Mechanic*," xxiv. 20) who proposed to use a small mirror laid on the pulse and reflecting upon a wall or screen.

Aselli of Milan ("*De Venus Lacteis*," 1627), discovered the function of the lacteals which pour the chyle into the blood.

Santorio of Padua ("*Commentarius in Primum fera Primi Libris Canonis Avicennæ;*" Venet, folio, 1626), invented an instrument for measuring the force of the pulse.

Andrea Cæsalpin ("*Exercitatio Anatomica de Cordis et Sanguinis Motu*," 1628) seems prior to his published work to have understood the greater or systematic circulation. A monument has been erected to him in Rome as "the discoverer of the circulation of the blood," and a table attributing the discovery to him has been attached to the portals of the University of Pisa, where he once taught.

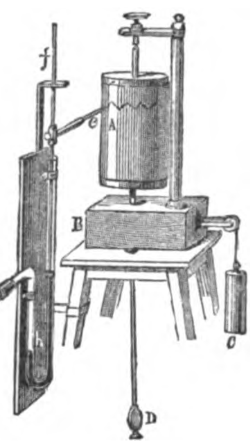
Harvey, in 1616, made the discovery of the nature of the arterial and venal circulations and the double circulation. The doctrine was first publicly discussed and combated as Harvey's, in Europe as well as in England. Within a century of the death of Harvey, the father of modern physiology, Haller, revived the whole controversy, and gave a verdict in favor of the English physician. Holding that the true discoverer of any truth is he who draws it from its sources "at his own risk and by his own meditations, and establishes it by arguments so forcible that they convince those who are longing for the truth," Haller decided that "not to Cesalpinus, on account of a few utterances of obscure meaning, but to Harvey, the laborious author of numerous experiments and the expounder of all the arguments which, in his time, could be advanced, belongs the immortal glory of the discovery of the circulation of the blood."

An apparatus for measuring the force due to the arterial circulation in a living animal, was made by an English physiologist, Stales, during the past century.

He was followed by Ludwig, the present professor of physiology at Leipsic, who contrived a registering instrument, Fig. 2312, to record the variations of pressure of the blood circulating in the arteries.

A tube was applied to the artery of the animal and the varying force of the blood, acting upon a column of mercury, caused a float to rise and fall and a pencil attached thereto traced upon a turning cylinder each oscillation of the manometer.

Fig. 2312.



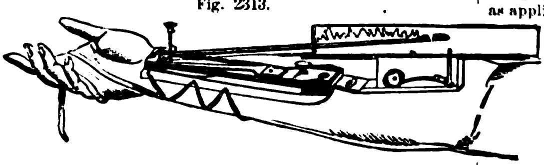
Ludwig's Register of Arterial Pulsations.

This is said to be the first registering instrument constructed for the uses of physiology.

The *sphygmoscope* proper (σφυγμός, the pulse, μέτρον, to measure) that is, the instrument applied to the pulse, was invented by Professor Vierardt, of Tübingen. It was not a *sphygmometer*, or *sphygmograph*, for it neither counted nor recorded the pulsations, but its indicator oscillated in the fashion of a pendulum and afforded a means of counting by the eye instead of by the strokes of the pulse against the finger-ends.

The *sphygmograph* first attained definite shape in the invention of M. Marey. A view of the apparatus detached is shown in Fig. 5380, p. 2365, "*Mech. Dict.*," but its operation will be more readily understood from viewing it in position, Fig. 2313.

Fig. 2313.



Marey's Sphygmograph.

It may as well be mentioned here that instruments which graphically indicate the beating of the heart are applied to the chest, and entitled CARDIOGRAPHS.

Marey's sphygmograph employs a spring pad to rest upon the pulse and the degree of pressure is obtained by means of a regulating screw. This spring device is so light that it follows faithfully the movements which are communicated to it by the exterior pulse, due to the swelling and collapsing blood vessel beneath the skin. These movements are so slight that it becomes necessary to amplify them, and this is done by translating the motion of the spring to a very light wooden lever near the axis of its movement. The outer end of the lever carries a scriber which records on a moving strip of paper, movements many times greater than those received from the artery. Extreme lightness of the lever and the union of the lever with the spring, the movements of which it records in much greater amplitude, are the necessary conditions for a good trace.

The sphygmograph reveals many delicate shades of difference in the pulse, showing the suddenness or slowness of the impulse, its strength or weakness, its length or brevity. The degree of abruptness is indicated by the angle of the line of trace departing from the base or horizontal line. The strength is shown by the amplitude of the excursions of the pencil; the duration, which is tantamount to the rate of repetition, is shown by the position occupied by each beat upon the length of the trace.

The ribbon is moved by clock-work.

The same rules govern as in the instruments for graphically representing articulate sounds, as mentioned under PHONAUTOGRAPH, p. 1678, "*Mech. Dict.*," and illustrated under TELEPHONE, *Logographic curves*, Fig. 6257, pp. 2514, 2515, *Ibid.*

The sphygmograph of Marey was followed by several devices for the same purpose, notably by that of Holden, described in his work "*On the Sphygmograph*," Philadelphia, 1874. He there credits Vierordt with the suggestion of the instrument, and refers to Professor Burdon Sanderson's improvements on Marey.

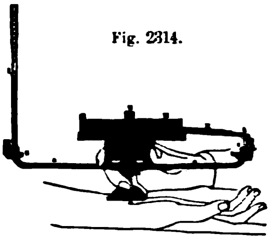
Holden's sphygmograph differs from Marey's (1) in the form of the pulse-spring, which is made to partially embrace the artery instead of merely resting upon it; (2) in conveying a to-and-fro lateral instead of a vertical motion to the tracing pencil; (3) and in a watch-spring device for registering the pressure upon the artery.

See also Dr. Sanderson's "*On the Sphygmograph*," an English work.

The sphygmograph of Dr. Keyt, of Cincinnati, Ohio, illustrated and described in the "*New York Medical Journal*" (xxiii. pp. 25 *et seq.*, plate opp. p. 30), and shown in Fig. 2314, has points of resemblance to the Marey instrument, but still more numerous novel features.

The base or receptacle *a* is made of thin brass, semi-circular above, but with a free, oblong edge below, over which is stretched an elastic rubber membrane which, when in use, lies upon the pulse and partakes of its movements. In the neck of the chamber *a* is a tube, *b*, which has a three-way stop-cock and two lateral branches, *c c*, leading to the two extremities of the instrument. From one of these rises a graduated glass tube in which the liquid affected by the beating of the pulse against the membrane rises and falls in a degree proportioned to the force of the arterial impulse and at a rate, of course, coincident therewith.

Fig. 2314.



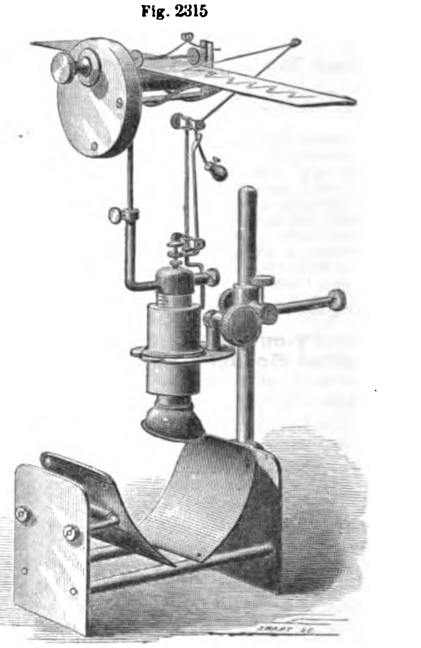
Keyt's Sphygmograph.

At the end of the other tube, *c*, is a small cup, *g*, in which is a disk resting on the fluid in the tube, and from the disk rises a stem, *j*, supporting a lever, *k*, on whose free end is the pencil which makes the trace upon the smoked glass slide which is traversed by clock-work.

The instrument weighs 8 oz. when filled with the liquid, and is 12″ long, 4″ high. The graduated tube folds down to place the instrument in its case. It is usually held by the hand of the observer, as in the illustration, which shows it as applied to the radial artery. Much fuller details of construction are given in the "*New York Medical Journal*," above cited, and republished in * "*Scientific American Sup.*," 117, 118.

Pond's sphygmograph, shown in Fig. 2315, is an improvement upon the *Sphygmoscope*, shown in Fig. 5381, "*Mech. Dict.*" The instrument is capable of adaptation as a sphygmograph, cardiagraph, myograph, or pneumograph, but in the figure is shown as

Fig. 2315



Pond's Sphygmograph.

adapted to the pulse of the forearm, which should lie in the cradle below. The tube, with an elastic membrane at its lower end, rests upon the pulse, and the pulsations, acting upon the membrane, are transferred to the liquid contents of the tube raising the piston; these motions are transferred to the stylus, which makes traces upon the smoked glass plate, which is traversed at right angles to the line of motion of the style. The combination of the two motions gives the graphic representation.

By the sphygmograph we may read the pulse as follows: —

The *amplitude* of the pulse is shown by the height of the undulations.

The *regularity* of the pulse is shown by the rhythmic succession and equal stages and development of the undulations.

The *frequency* of the pulse is shown by the rapidity of succession of the undulations.

The *quickness* of the pulse is shown by the suddenness of the ascent of the undulations.

The *compressibility* of the pulse is shown by the degree of elevation at which is displayed the maximum amplitude of the undulations.

The *tension* of the pulse is shown by the mark of compressibility in connection with the rate and manner of descent of the undulations.

The *dicrotous* of the pulse is shown by the distinct break in the line of fall, or, as frequently seen, a second rise from the line of fall, or bottom of the undulations.

Minor sphygmographic curves are at times shown by the lesser interruptions in the fall of the undulations.

It is suggested that an enlarged shadow of the undulations might be projected on a screen in a clinical theater; or photographed upon a prepared surface moved as in the THERMOGRAPH or BAROGRAPH, Fig. 6350, p. 2546; Fig. 569, p. 234, "*Mech. Dict.*"

Sphyg-mom'e-ter. An instrument for measuring the force, rate and other characteristics of the pulse. The subject is considered under SPHYGMOGRAPH, which see. See also PULSOMETER, page 1825, "*Mech. Dict.*," and article in —

"*Manufacturer and Builder*" . . . . xii. 208.

Sphyg'mo-phone. For rendering audible the sounds of the pulse beats.

In Dr. Richardson's sphygmophone, a microphone is added to a Pond sphygmograph. A thin plate of platinum is mounted on a slip of talc which is placed in the sphygmograph as if for a tracing of the pulse. One terminal from a Leclanché cell is connected to the slip of platinum on the talc, and the second terminal to a terminal of the telephone. The other terminal of the telephone is connected to the metallic rod of the sphygmograph which supports the talc.

The instrument is placed on the pulse in the ordinary way, and the needle thrown back till a good pulsating movement is secured. The needle is then thrown over to touch the platinum strip, which it traverses with each pulse movement and completes the connection of the telephone with the battery: this passing over the metallic plate causes a distinct series of sounds corresponding with the movements of the pulse. The sounds heard are three in number: one long sound and two short, corresponding to the systolic push, the arterial recoil, and the valvular check.

The sphygmophone of Dr. Stein, of Frankfort, consists of a piece of watch-spring, five centimeters long, which is soldered to a small brass frame, and is provided at its free end with a gutta-percha knob which is placed against the pulse or chest. The knob carries a platinum contact plate, opposite to which is a platinum contact point, and these two contacts are connected in circuit with two Bunsen cells and a telephone. The movements of the pulse (for instance) establish contact between the point and plate, and so make and break the circuit. The result is that the natural rythm is heard aloud in the telephone.

Sphyg'mo-scope. An instrument for rendering visible the beats of the pulse.

Such was made by Galileo, by means of a mirror and beam of light; see SPHYGMOGRAPH, where also is mentioned the device of Prof. Varardt, of Tübingen.

See also Pond's Sphygmoscope, Fig. 5381, page 2265, "*Mech. Dict.*" This instrument has since been made a recording instrument, and is further illustrated under SPHYGMOGRAPH, present volume.

Spic'u-lar. A dentist's long curved-nose forceps, for removing small fragments of bone, etc.

Spi'der Hoop. (*Nautical.*) A brass hinged hoop made to clasp around the mast of a vessel, with attachments for the fastening of the futtock-shrouds.

Spie'gel. (*Metallurgy.*) *Spiegeleisen*, "mirror-iron." A crystalline variety of white cast-iron containing from 2 to 10 per cent. of manganese, and a large amount of combined carbon. It is excessively hard and lustrous, and is used chiefly in the Bessemer and Siemens-Martin processes. See below.

Spie'gel-ei-sen. Manganiferous cast-iron. See FERRO-MANGANESE, SPIEGEL, and SPIEGEL IRON. See also *Comptes Rendus*, April 5, 1874.

Micro-structure of . . * "*Scientific American Sup.*," 2668, 2738, 2761.

Spie'gel I'ron. Mirror iron.

In German "Spiegeleisen," which means "mirror iron," is thus called because its fracture shows flat shining surfaces, reflecting light like pieces of mirrors. It is of all iron the richest in carbon, and also the most brittle and hardest, — no steel tool will make an impression on it. It is very fusible, and it is principally used at present in the manufacture of Bessemer steel. In this process most of the impurities are removed from the melted mass by forcibly blowing air through it, which burns them out, but also too much of the carbon, so that at the last stage of the process the iron is reduced to a condition of being almost equivalent to wrought iron, and cannot be poured, the temperature, high as it is, being insufficient to keep wrought iron in the liquid state. Melted spiegel iron is then introduced, which at once combines with the mass under the evolution of a large flame; the iron becomes then at once as liquid as water, and is poured in the molds to make ingots. Spiegel iron is also used to make safes burglar-proof: as an interior filling for this purpose it is cast between sheet-iron lining. It also possesses the curious property of being less magnetic than any other kinds of iron; it is less attracted by the magnet than other kind of iron, and strongly resists efforts to magnetize it, which is contrary to the property possessed by wrought iron, which takes magnetism easily but also loses it easily; while steel takes it with some resistance, but when once it is magnetized it holds it. We have a spiegel iron in this country; it is made from the New Jersey Franklinite ore, and was at first called Franklinite iron. It has commenced to be universally used in place of the spiegel iron, thus far imported from Germany, and will probably supersede it, if it has not already done so.

Spike. The following table shows the amount of spikes to a mile of railroad: —

Size measured under Head.	Average Number per Keg of 150 lbs.	Ties 2′ between centers, 4 Spikes per Tie, makes per Mile:	Rail used, Weight per Yard.
5½ × 9-16	280	5,670 pounds = 38 kegs	45 to 70
5 × 9-16	300	5,170 pounds = 35 kegs	40 to 56
5 × ½	340	4,660 pounds = 31 kegs	35 to 40
4½ × ½	400	3,960 pounds = 27 kegs	30 to 35
4 × ½	450	3,520 pounds = 24 kegs	28 to 85
4½ × 7-16	510	3.110 pounds = 21 kegs	25 to 30
4 × 7-16	540	2.940 pounds = 20 kegs	
3½ × 7-16	675	2.350 pounds = 16 kegs	20 to 25
4 × 3/8	760	2,060 pounds = 14 kegs	
3½ × 3/8	890	1,780 pounds = 12 kegs	16 to 20
3 × 3/8	930	1,710 pounds = 11½ kegs	

Spike Ex-tract'or. An iron lever with a fulcrum hook beneath to clasp the rail and a claw hook at its lower extremity to lift the spike by the head.

Spike extractor . . . . . * "*Engineer*," xliv. 413.
Devine . . . . * "*Engineer*," xli. 42.

Spil'liard. (*Fishing.*) A floating trawl line.

Spin'ner. (*Fishing.*) A trawling spoon-bait which revolves as it tows abaft the boat.

A flanged attachment in connection with a fish-hook to cause a lively motion of the hook and bait.

(*Wool Manufacture.*) Avery's continuous wool-spinner resembles the original Hargreave spinning machine. The roving is fed from the spool by a revolving drum driven from the pulley-shaft, and is delivered to peculiarly-constructed wheels, which seize it at the proper moment and release it again as the spinning occurs, and the required draught is thus given. The drum and the cage-wheel with which it acts revolve at the same speed. The roving, as delivered, hangs down loosely until sufficiently twisted, when the next motion delivers a new supply and takes up that already twisted.

Spin'ning. (*Fine Art Metal-working.*) A mode of forming silver and other ductile metal into shapes. A disk of metal is placed in the clamp in the lathe, and while revolving is pressed by a burnisher which spreads the metal, giving the disk a cup-like form, for instance. Other pieces are worked in a similar way, and form parts such as cover, body, foot, of a pitcher or what not. Fig. 5412, "*Mech. Dict.*"; * "*Scientific American*," xxxvi. 290, Fig. 9.

Spin'ning Ma-chine'. The Byewater spinning machine is remarkable as a continuous spinner in contradistinction to the intermittent work of the mule.

The condenser bobbin containing the sliver, as in the mule, is placed upon the top of the machine, and revolving, delivers its contents to and upon the tops of a number of small porcupines, arranged upon a slowly revolving shaft. The porcupines, on receiving the roving, comb and draw the fibers of the wool into parallel lines, delivering it in an attenuated form to another part of the machine, composed of two very small rollers fitted in a disk.

These rollers, one of which is fluted and the other covered with rubber, constitute a pair of draft rollers, as in the ordinary mule, but are so small in size as to serve only for the reception of one thread. The draft motion of these rollers is obtained by the action of a pair of small toothed wheels, that are covered from sight in the disk. From the great amount of twist imparted to the thread in this movement, and in which the proper degree of attenuation is obtained, a much shorter fiber can be spun with less risk of breakages than in the long stretch of the mule.

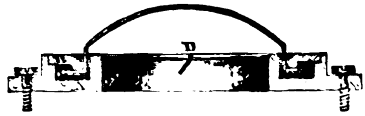
There has already been spun on this machine a material, the waste of silk noils (that is, the noils of the noils), that has hitherto been used only for upholstery purposes, etc., and which in the mule could not be spun into thread at all. The thread on its delivery from the rollers carried in the disk, is passed on to the spindle, and wound upon tubes in the form of a pin or cone, having received its complemental amount of twine.

Any quantity of twist can be put in between the rollers and the spindle, as the latter can be driven up to 7,000 or 8,000 revolutions per minute. The thread is wound upon the spool by the needle flyer. In order to build a proper cop from the yarn the traverse race differs from that found in roving frames, throstle spinning frames, etc., in having an additional movement. Besides the ordinary ascending and descending movements of the traverse, there is progressive ascent made every journey, equivalent to the growth of the yarn cone from the deposit upon it of every layer of yarn.

See CARDING MACHINE, pp. 167, 168, *supra*.

Spin'ning Ring. In Booth's steel-top spinning rings with steel flanges inserted in the base, the traveler draws perpendicularly, so that when the lower steel flange becomes worn the flange can be reversed and become a perfect ring again.

Fig. 2316.



Potter Spinning Ring.

The Potter ring is another modification of the spinning ring. See Fig. 2316.

Spin'ning Rol'ler. Leigh's anti-friction top roller has two bosses, which are covered with cloth and leather, and made from a solid piece of iron. The bosses are loose running on a dead spindle. There is, therefore, no appreciable wear of either hook-saddle, cap-bar, or roller. Each boss can go its own speed, independently of its fellow boss, and therefore delivers out faithfully its proper length. The leather keeps smooth, saves waste, and the bearings being internal, the roller seldom requires oiling. It saves the squares of the under roller to the extent of the variation of the bosses in diameter.

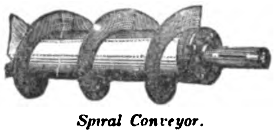
Spi'ral Au'ger. The American form of auger-bit, raising and delivering its chips on the principle of the Archimedean screw. A modification of the spiral auger is also used in well-boring.

Spi'ral Bat'ter-y. (*Electricity.*) One in which the elements consist of plates laid together with something to maintain their distance and then rolled together spiral.

Niaudet . . . . * "*Amer. Trans.*," p. 17.

Spi'ral Con-vey'or. A forwarding device for removing grain to higher levels, when used within a tube or trough in which it works, on the principle of the Archimedean screw.

Fig. 2317.



Spiral Conveyor.

Spi'ral El-lip'-tic Seat'-spring. A spring made of a thin band of steel and wound on a spiral coil, the transverse section of which is elliptical.

Spi'ral Grooved Guide. The spiral grooved guide is a wrought-iron tube, from 8′ to 12′ long, the size of the hole intended to be bored, set with diamonds at intervals, to prevent it from wearing, and provided its full length with spiral grooves, to allow egress for the water and sediment on the way up to the top of the bore-hole.

It is used in boring long holes, and is of especial value in boring for shafts and tunnels; as, by its exactly fitting the hole bored, it prevents the drill from diverging from the direction in which it started, making the hole perfectly straight.

Spi'ral Pump. A pump that raises its water by a spiral flange or screw, on the principle of the Archimedean screw.

Spi'ral Punch. A punch so formed as to cut its way through the metal with a shearing action, which it is alleged does not tend to injure the metal like the ordinary punch.

Spi'ral Seat'-spring. A light spiral spring made of wire for upholstering car-seats

Spi'ral Spring. A spring made of a metal rod or bar coiled in the form of the thread of a screw, so that it can be compressed or extended in the direction of the axis around which it is coiled.

See —

Compound spiral spring.	Nest spring.
Cluster spring.	Paragon spiral spring.
Dinsmore spiral spring.	Quadruple-coil spiral spring.
Double-coil nest spring.	Round-bar spiral spring.
Edge-rolled spiral spring.	Rubber-center spiral spring.
Equal-bar nest Spring.	Spiral elliptic seat-spring.
Flat-bar spiral spring.	Spiral seat-spring.
Group spring.	Spool-shaped spiral spring.
Half-round-bar spiral spring.	Square-bar spiral spring.
Hibbard spring.	Triple-coil nest spring.
Keg-shaped spiral spring.	Wool-packed spiral spring.

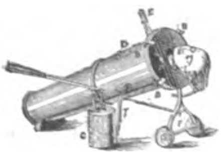
Spi'ral Tube Boil'er. One having a spirally convoluted tube passing across the flame space. See Fig. 5636, Plate LXI., opp. p. 2326, "*Mech. Dict.*"

Spi'ro-phore. A breath-carrier. An apparatus for inflating the lungs in case of suspended animation. *Woillez*, "*Technologiste*," xl. 179.

An apparatus for restoring asphyxiated persons, especially such as have been in danger of drowning, and new-born infants.

It consists of a conical cylinder of sheet-iron closed at one end and open at the other. The case is large enough to receive the body to be treated, which is let down into it as far as the head, that remaining outside. A tightly fitting diaphragm closes the aperture about the neck. A strong air pump containing more than four and a half gallons of air, outside the case, communicates with it by a thick tube. It is worked by a lever, the descent of which produces aspiration of the air confined about the body. The raising of the lever again restores the abstracted air to the case. A transparent piece of glass on the upper part of the cylinder enables one to see the chest and abdomen of the patient, and a movable rod sliding in a vertical tube is made to rest on the sternum.

Fig. 2318.



Spirophore.

When a body is inclosed as described, and the lever quickly lowered, a vacuum is produced around the body and immediately the external air penetrates into the chest, the walls of which are seen to rise as in normal life. The ribs separate, the sternum is pushed up 0.393″ at least (indicated by the movable rod that rests on it). Further, the epigastrium, and even the abdomen below, present an inspiratory projection, which shows that the enlargement of the chest is effected during the artificial inspiration, not only by the raising of the ribs and the sternum but also by the descent of the diaphragm. All returns to the former position when the lever is raised again. These complete respiratory movements may be repeated fifteen to eighteen times in a minute as in a living man.

By means of a tube fixed into the windpipe of the body and communicating with a graduated reservoir of air, over a vessel of water, M. Woillez has measured the quantity of air that thus penetrates into the chest at each pressure of the lever. He finds that this is on an average $1\frac{3}{4}$ pints; whereas the physiological average is only 7–10 pints. More than 22 gallons of air can be made to traverse the lungs of the asphyxiated person in ten minutes.

Splay. (*Architecture.*) The beveled expansion or recess in the wall of a building, as in the abutments in ancient architecture and the approaches to doors, windows, and fire-places necessarily beveled in the heavy walls of those days.

Splice. (*Nautical.*) The joint by which two ropes are united. See "*Mech. Dict.*"

Rails and splices on Penn. R. R. See report by *F. Slataper*, "*Centennial Exhibition Reports*," * vol. vi., Group XVIII. p. 66.

Splice Joint. The connecting joints between rails on railways. The number of splice joints per mile, 2 bars and 4 bolts and nuts to each joint, is, rails 20′ long, 528 joints; rails 24′ long, 440 joints; rails 26′ long, 406 joints; rails 28′ long, 378 joints; rails 30′ long, 352 joints.

Spli'cing Clamp. A hinged clamp with apertures of various diameters to correspond with size of the material intended attached.

Splin'ing Ma-chine'. (*Metal Working.*) A machine for cutting key-seats and grooves.

Splint.

Wood's hammock splint.*
Ahl's adaptable porous splints.
See *Dr. J. H Thompson's* report on Group XXIV. in vol. vii., page 58, "*Centennial Exhibition Reports.*"
Guillery, Hippolyte, Brussels, Belgium.
Perforated zinc plates adapted in shape to the fractured limb.

Splint-cut'ting Ma-chine'. A machine for cutting small slats or splints.

Ransome, of Chelsea, England, has a reciprocating cutting machine for lucifer-match splints, etc.

Split'ting. (*Leather.*) Reducing the sides of leather to a uniform thickness, by passing them through the splitting-machine. The latter can be adjusted to split the sides to any required thickness. It is mainly employed in the preparation of thin and light leathers.

Split'ting Chis'el. (*Stone-working.*) A tool chiefly used on the softer stratified stones, and sometimes on fine architectural carvings in granite.

Split'ting For'ceps. (*Dental.*) For the division of teeth which require to be split before extraction.

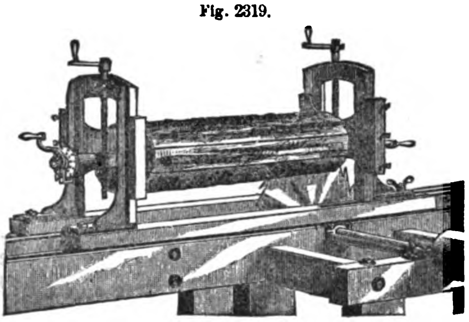
Split'ting Knife. (*Fishing.*) For ripping and halving fish before salting.

Split'ting Ma-chine'. A machine for resawing thick boards.

Split'ting Saw. A saw table with elevating set screw, adjustable clamps, splitting gage, and self-oiling saw arbors.

A machine for splitting round logs into bolts; as a substitute for riving or sawing through and through in parallel

Fig. 2319.



Splitting Saw.

planes. The center sawing machine is used in getting out stuff for axe and pick handles, heavy spokes, etc., and work in which the run of the grain of the wood is of consideration in the fashioning of the article. It has a sliding carriage, furnished with center head-blocks, on which the log is placed, and is provided with a dial-plate and stops by which the log can be spaced into stuff of the desired size. The saw cuts invariably towards the center. Also called a *center saw*.

Split Wheel. A split gear or other wheel so contrived that flanges on the one side of the one part fit upon and are bolted to the side of the other part, to allow of applying to and removing from the shaft such wheels in less space than is required when they are fastened by bolting two flanges together at the sides of the wheel. One part of the wheel may also be dovetailed into the other, to sustain the expanding action of the key, better than in the other way.

Spoke. (*Wheelwright.*) One of the radial arms that connect the hub with rim of the wheel.

Spoke-in-sert'ing Ma-chine'. A spoke-setting machine, for inserting the spokes by mechanical pressure instead of driving.

Spoke-fa'cing and True'ing Ma-chine'. (*Wheelwrighting.*) A machine designed for facing common and patent spokes, and finishing the miter joint on them.

It has a large cast-iron disk, in which are placed three cutting knives. The disk is revolved, and the spoke, being placed in position on the table, is brought into contact with the cutters, finishing it to the desired surface or angle. The table is light and moved on parallel ways, placed at right angles to the face of the disk, and has a spring that returns it from the disk when the cut is completed. It is furnished with necessary stops and guides.

The pulley or disk-shaft, 10 × 5, should make 1440 revolutions.

Spoke Lathe. A machine for turning spokes, gun-stocks, lasts, handles, etc.

Spoke Point'er. A knife held in a cone devised to dress up the tenons of the spoke ready for hub and rim. (See Fig 2320)

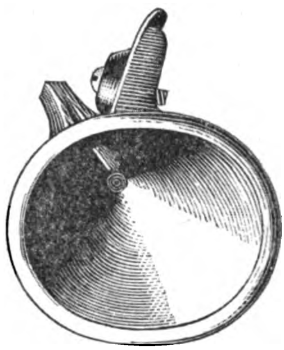
Spoke Pol'ish-ing Ma-chine'. Gleason's spoke polishing machine takes a sand-belt from 6″ to 12″ wide. Its driving pulleys, tight and loose, are 7″ diameter, with 5″ face. It makes 900 to 1,000 turns per minute.

Spoke Set'ting Ma-chine'. Morgan's spoke setting machine has an adjustable frame that is supported on springs so as to be moved vertically as desired by the bolts and crank-nuts. The hub is placed on a central bolt, and is rigidly secured by a crank-nut.

Above the main frame is the guide or set ring on which the posts are placed while being set and driven into the hub.

After the hub is fastened in place, the adjustable frame is screwed down until the center line of the hub is on a level with the circle. The hub is then dotted above the leveling straight-edge, and the bolts are screwed down until the desired dish or set of the bolts is obtained. This is necessary, as all hubs are made with straight front and sloping back mortises, throwing the outer ends of the spokes forward at the same inclination. It then only remains to rest the spokes upon the guide-ring and drive them into the hub.

Fig. 2320.



Spoke Pointer.

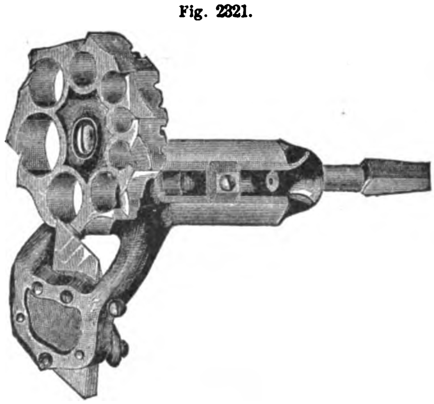
Spoke setting machine, *Morgan* . * "*Sc. Amer.*," xxxiv. 348.

Spoke Shave. A modification of the plane with a handle at each end. The French make a double spoke-shave, with one blade concave, the other convex.

Spoke Ten'on-ing Ma-chine'. A machine provided with a hollow auger, that, rotating around the ends of the spokes, forms the tenons.

In Dole and Deming's spoke tenoning machine, Fig. 2321, the hub is held in a self-centering chuck that admits of rotating the wheel to present the spokes to the hollow auger, the spokes when in position being firmly held on the spoke rest, in line with the auger. Each and every tenon is cut

Fig. 2321.



Spoke Tenoning Auger.

with shoulders uniform in width and in the same plane. With a slight transformation it is changed into a boring machine, for boring the felloes for the spokes and dowel pins. The No. 1 machine is provided with the star hollow auger, capable of cutting tenons from 7-16″ up to 1″. The No. 1 machine is not furnished with legs, being generally clamped in the vise or on the bench.

Spoke Throat'ing Ma-chine'. A machine intended for dressing and shaping the throat (which is reduced a short distance from the hub to add to its flexibility).

Spoke Turn'ing Lathe. Gleason's spoke turning lathe is a modification of the Blanchard. ("*Mech. Dict.*," p. 2282.) It is used for turning handles as well as spokes.

The uprights forming part of the rocking frame are fastened to the rock shaft by set screws. The adjustable upright is movable on the shaft with wrought iron cross bars above, to take in any desired length of model. The center for holding the model in the said upright and the center for holding the spoke admit of being adjusted to any position, so as to turn spokes from the same model of different lengths.

The center is worked by an eccentric lever and is capable of holding the largest spokes. The running shaft extends outside to the left of the machine, and pulleys for driving the model and feed run loosely thereon. The pulley that drives the cutting wheel above has a hollow mandril, running in bearings one on each side. The hollow mandril is fitted with two feathers which fit into slots that run the whole length of the main shaft. The bearings are part of the carriage, that extends down on the opposite side to receive the hollow mandril carrying the pulley that drives the cutter wheel.

Spoke Trim'mer. A tool for trimming the ends of spokes, chair rounds, etc., before using the hollow auger.

Spoke Wheel. A metallic light flanged track wheel for mine cars and other light service.

Sponge Brush. Sponge brushes are of various kinds, in which the sponge tied or wired to a handle is a substitute for bristles.

Sponge Di-la'tor. (*Surgical.*) A dilator in which the absorptive power of sponge is made the means of expansion. *Emmett's*, Fig. 110, Part V., *Tiemann's* "*Armamentarium.*"

Sponge For'ceps. (*Surgical.*) An instrument specially adapted to hold a sponge, and place it in situ. It is usually a long staff with a spring or sliding clasp on the end. Page 81, Part III., *Tiemann's* "*Armamentarium.*"

Sponge, Me-tal'lic. M. Laboulaye treats of the "industry created" by M. Chenot, which, at the time of writing, had not "arrived at a complete success, for the full adoption of the process would completely revolutionize the metallurgic industry; but the results obtained (1877) were extremely important."

For the study of the process he selects the most complex to which the method can be applied, that of the production of cast steel.

The treatment comprises four principal operations: —

1. The reduction of the mineral into the state of sponge.
2. The cementation of the sponge.
3. The compression.
4. The fusion.

1. The reduction takes place on wasted and broken mineral, in a prismatic furnace about 40′ high, furnished with exterior belt of furnace from the mouth 22′ downward. The mineral introduced at the top is subjected to a gradually increasing heat, undergoing a reduction similar to what takes place in the shaft of the blast-furnace. On arrival at the bottom of the belt furnace it is scarcely cherry-red, the iron is completely reduced, but the heat is insufficient to melt it, or even to make it pasty. It forms a porous mass like the spongy platinum whence it takes its name.

Continuing its descent, the sponge cools slowly, and at its discharge at the lower end of the furnace is near the ordinary temperature, in default of which cooling it would rapidly reoxidize, owing to its eminently pyrophone tendency. The discharge from the furnace is made at certain intervals by means of certain devices whose function is to prevent a current of air from passing through the furnace.

2. The sponge, passing to the cementation stage, is plunged in a bath of resin, tar, or some fatty matter, the bath being heated if necessary to maintain its contents liquid, in order that the sponge may be saturated. It is calcined at a heat only sufficient to remove excess of the carbonaceous matter which is collected, and a loup of metal is obtained with a certain quantity of carbon uniformly diffused through it. A second cementation may be necessary to arrive at exact results.

3. The sponge is then broken and afterwards subjected to heavy pressure in order to make it more compact and to reduce the surface exposed to the action of the oxygen of the air.

4. The compacted sponge is broken up, put into crucibles, and treated as usual for cast steel. There is, however, this difference, that in pouring the metal there is a quantity of scoriæ consisting of earthy matter which the previous operations have not removed. The slag, which is very fluid, swims on the metal, is coagulated by a little sand and clay, and readily removed with a ladle

Blair's process is described in, —

"*Scientific American Sup.*"	1991, 1992.
"*Scientific American*"	xxxix. 68.
"*Mining & Scientific Press*"	xxxvii. 2.
"*Engineer*"	xlv. 226, 308.

The United States and European patents on sponge processes are very numerous.

Sponge Pro'cess. (*Metallurgy.*) A process for making wrought iron and steel direct from the ore without the use of the blast furnace.

The reduction by the blomary or German hearth is at a greater heat than that of the sponge process. The temperature in each is below that of melting; in the blomary the iron is obtained in an agglutinated mass, as a *loup* ready for the shingler; but the *sponge* obtained by the other process contains the iron in a metallic state besides the earthy ingredients of the ore. The *sponge* is then worked to a *loup* in a reverberatory, gas, or blomary furnace, to consolidate the metal and remove the earthy matter, and then is hammered to a *bloom*.

The reduction of the ore in the sponge process takes place in a cylinder or cupola furnace, the fuel with which it is mixed being preferably charcoal. The iron is cooled before removal from the reducing current, to prevent oxidation, which takes place rapidly on the spongy mass.

The sponge is then puddled in a reverberatory.

Or it has been added to a bath of pig-iron, as wrought iron is added in the Martin process to make steel by relatively lowering the carbon of the iron.

Chenot, Yates, Benton, Gurlt, and others have devised sponge processes. The method adopted by Blair, of Pittsburg, is a modification of the Chenot.

A cylinder 40′ high and 36″ diameter has at 6′ of its upper end an interior cylinder 28″ diameter, leaving an annular space 4″ wide. The upper half of the cylinder is kept at a red heat by gas burning on the outside, and the charcoal and ore in small pieces are charged at the upper end of the annular space. The carbonic oxide from the reduction burns in the inside cylinder, and the charger is then heated to redness between the two fires. As the charge sinks it occupies the whole interior capacity of the large cylinder, the lower half of which is cooled by a water-jacket. The sponge and remaining portion of the fuel are withdrawn in a cool condition from the lower point of the cylinder.

The sponge is separated from the charcoal, compacted into balls by hydraulic pressure, which are then worked into a bath of metal in a Siemens or other furnace.

Sponge is also made in a Danks rotary puddling furnace; the ore is roasted, added with fuel to the furnace, which is rotated while a reducing flame on the regenerative principle is applied.

In 1876 Blair discovered during some experiments, that by the addition of a small quantity of alkali to the carbonaceous matter mixed with the ore, the action of reduction was quickened to a remarkable extent, and ore which took thirty hours to reduce without alkali could be perfectly done in six hours with it. Subsequent investigation showed that lime in a fallen state answered as well as any other alkali, and on account of its cheapness was most suitable for the purpose. The quantity of lime required being only about five per cent. the extra cost was quite insignificant when placed against the great saving in time. When, however, Mr. Blair came to work the existing furnaces under the new condition of quickened reduction, he found the arrangement could not in any way be altered to suit it. Perhaps a brief description of these furnaces will make the matter more easily understood.

Each reducing furnace consisted of a group of three vertical retorts, each retort being 3′ internal diameter and about 28′ high, surrounded by an outer casing of brickwork, leaving a combustion chamber between the inside of the brickwork and the outside of the retorts. The retorts and outside brickwork stood upon a cast-iron entablature, supported on columns 12′ from the ground; below the entablature, and forming a continuation of each retort, were wrought-iron cylinders, each surrounded with a water jacket for more quickly cooling the iron sponge, and having at the lower extremity a sliding sleeve for discharging it. In the top of each retort a cast-iron pipe or thimble, 2′ diameter and about 6′ long, was inserted, leaving an annulus of 6″ between it and the inside of the retort.

The retorts were heated externally by gas jets, the air for combustion being supplied through apertures immediately above each jet. When the retorts were thoroughly heated and all in working order, the gas generated from the ore under reduction ascended up the inside of the pipe inserted in the top of the retort, and, on meeting with the air, flamed and so heated the pipe. The ore and carbonaceous matter were fed into the retort down the 6″ annulus between the retort and pipe, and, forming a narrow column heated on both sides, were thoroughly heated up before reaching the wide retort below. Thus the ore, on entering the wide retort or reducing zone, was all of one uniform heat, both in the center and on the outside, and hence uniform reduction was the result. This initial heating, as it is called, must be done if the ore is to be thoroughly and uniformly reduced. It was this part of the furnaces which would not suit the quickened action of reduction taking place in the body of the retort below; the ore could not be heated up as quickly as the reduction took place, and hence the two did not work in harmony.

After several alterations, Mr. Blair abandoned the system of external heating, and decided to adopt that of passing a stream of hot carbonic oxide through the mass of ore and carbonaceous matter. He has since made some improvements in the first-named furnace, where the initial heating of the ore is performed as quickly as is possible to be done by transmitted heat, and which is much quicker than the inserted pipe. The new form of reducing furnace adopted by Mr. Blair has several important features. The following is a description of it: —

A vertical retort made of fire-bricks, with an external wrought-iron casing, stands upon a cast-iron entablature supported on columns. The retort is continued below the entablature by a wrought-iron cylinder with water jacket, or as the writer proposes, instead of one wrought-iron cylinder and water jacket, four small ones are suspended, and thus split up the hot sponge into small columns, by this means effecting the cooling much more quickly. At the lower extremity of each water jacket is a conical mouthpiece and valve, so that the iron sponge can be discharged periodically into any receptacle placed under.

The lower part of the retort, where the gas is admitted, is larger than the upper portion. This is done so as to form an overhang immediately above the aperture where the gas is admitted, thus forming a chamber round the mass of ore, etc., and allowing the gas to permeate it uniformly. At the top of the retort is an outlet for the escape of the gas after passing through the ore, which is connected by a horizontal pipe to a vertical one descending to the ground, and there connected to the chimney flue. In the horizontal pipe above named a steam jet is inserted, so as to form a vacuum in the top part of the retort, to induce a regular current of gas through the ore, etc. The retort is fed by an ordinary bell-hopper.

The carbonic oxide is generated in a gas-producer placed a few feet from the reducing furnace, and connected to it by a flue of sufficient capacity. The gas-producer is circular in section, formed of wrought iron plates, lined internally with fire-bricks, and standing on an entablature, which, in turn, is supported at the requisite height by columns of brickwork. Below the entablature, and suspended from it, is a wrought-iron continuation, tapering to a conical discharging valve for allowing the ashes to be from time to time removed.

Apertures for admitting air for combustion in the gas-producer are placed in its circumference, fitted with slide covers to regulate the admission of air.

Mr. Blair uses the Ponsard producer in preference to the ordinary Siemens one, as the admission of air is more easily regulated. The object of using a carbonic oxide gas is primarily to supply heat to the ore, etc., to be reduced. What reduction is effected by the gas is a secondary matter; and in this point the process differs from other attempts where carbonic oxide has been used solely for reducing the ore. It will be seen that in using the steam jet to induce a stronger current of gas through the ore under reduction, the temperature in the gas producer will be increased, and the gas in time become hotter than required, the result being that the mass against which the gas impinges in the reducing furnace, being almost entirely metallic, would become welded together, and so interfere with the regular working of the furnace. To obviate this, a very simple and ingenious arrangement has been made by Mr. Blair, by which the temperature of the gas can be kept at almost one uniform heat. The gas, after passing through the reducing furnace, is still almost entirely carbonic oxide, and on passing by the steam jet becomes mixed with steam; in order to condense it a water spray is introduced at the top of the descending flue to the chimney. A little above the air apertures in the gas producer are two pipes connecting it and the descending flue, so that some of the gas which has already passed through the reducing furnace can be again sent through the gas producer and used over again, and at the same time cool down its temperature. By regulating the slide covers of the air apertures in the gas-producer and the damper in the flue to the chimney, an equal quantity of air and gas can be supplied to the producer. It is found, in practice, the two can be so regulated that an almost uniform temperature can be maintained in the reducing furnace, and a saving effected in fuel; in fact, by the cooling action of the return gas, any temperature can be obtained. The reducing furnace just described will reduce about 200 tons of ore to a metallic state weekly, the dimensions of the retort being 6′ diameter in the upper, and 6′ 6″ in the lower part, by 16′ in height. The height of the whole structure is 36′, and the cost about $3,500.

The fuel used in the gas-producer is coke; and if the iron sponge made is intended for steel-making, the coke should not contain more than .75 of sulphur — the less the better — otherwise the iron sponge will be affected by it. But where pure ore can be had, and coke from washed coal not containing more than the above-named amount of sulphur, this form of reducing furnace is undoubtedly the best for producing iron sponge in large quantities, and the whole of it thoroughly metallic.

The question of the subsequent use of iron sponge is an important one. Where the ore is rich and pure, iron sponge made from it can be at once made into tool steel, the quality of which cannot be equaled by that made from the best brands of Swedish bars. Probably in the case of ore which is not so rich, but still suitable for steel-making, the best way of utilizing the sponge made from it is to melt it in a cupola furnace into pig metal, and while in a molten state pour it into a Siemens-Martin furnace, and in this way convert it into steel. The pig metal obtained in this manner will contain about 1.5 carbon and practically no silicon, the greatest amount of the latter yet found by analysis being 0.25, and the lowest 0 19. If this metal is poured while molten into an open hearth furnace as proposed, there ought to be no serious difficulty in getting six heats from each furnace in twenty-four hours, in place of the two or three heats now obtained. Iron sponge melts readily in a cupola furnace, and the risk of oxidation is less than when it is thrown into a bath of pig iron in an open hearth furnace. The same remarks apply to the manufacture of wrought iron. From the nature of the particles of iron in iron sponge, being so minute, it cannot be balled up in an ordinary balling furnace without considerable oxidation; on the other hand, if melted in a cupola furnace, and the resulting metal, containing so little carbon and silicon, be taken in a molten state from the cupola to the puddling furnace, very little rabbling brings it to nature.

The molten metal can be made almost as cheaply as pig iron; in fact, there is no reason why it should not be made as cheaply.

Sponge Pla-ti′num. The production of spongy platinum, says the "*Metallarbeiter*," is a task more easy in appearance than in reality. The principal requirement of spongy platinum is that it should be spongy, but this obvious requirement is very frequently overlooked, and hard and useless masses of platinum are produced through overheating the sponge and running together the finer particles. Into a concentrated solution of muriate of ammonia drop a similar solution of platinum chloride; a yellow precipitate is formed, which is washed three or four times with hot water to free it from the sal ammoniac. This precipitate, when properly cleaned, and while still moist, is dropped on a very thin platinum wire stretched several times across a small ring of copper, and is then allowed to dry thoroughly. After drying, it is slightly heated over a spirit lamp, contact with the flame of which is to be avoided. As above remarked, only very careful heating over the spirit lamp will give satisfactory results.

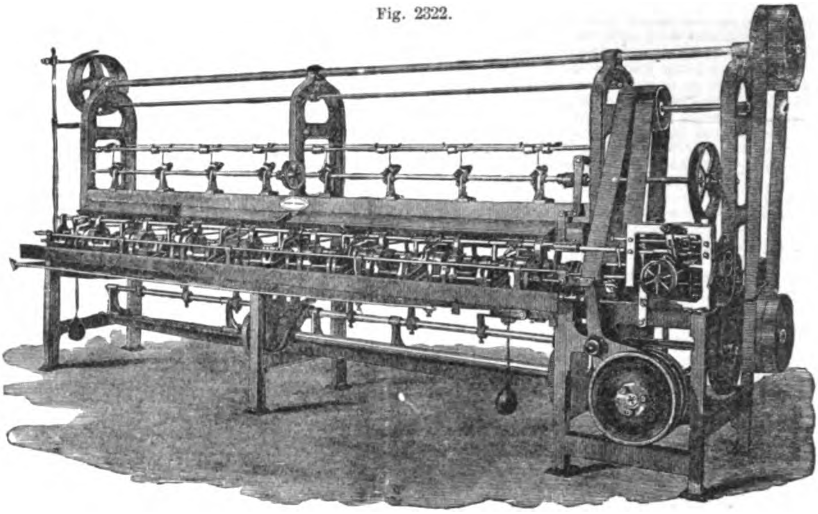
Sponge process, *Blair* . "*Iron Age*," xxi., April 11, p. 16.
"*Scientific American Sup.*," 1991.

Spool Hold′er. A case for holding spools of different numbers of thread placed on the thread-holder of a sewing machine. The spools are placed on pivots and the case revolves so that any spool can be drawn from at will.

Spool′ing Ma-chine′. A machine for winding silk on to 100, 200 yards, or one-ounce spools, for domestic and manufacturing purposes. See also SILK SPOOLING MACHINE.

Fig. 2322 gives a front view of a spooling machine composed of two parts, the portion on the left consisting of eight little duplicate machines arranged in a row, and that on the right, of the apparatus which operates the winding machines. Each of these little machines winds a spool of thread. Back of these is a trough, containing empty spools, and back of this is a shelf which is intended to hold the bobbins of thread. From these bobbins threads are passed through a tension apparatus above them, and carried each to its little machine. The machines are held rigidly together by longitudinal rods, and there are three longitudinal shafts or rods passing through the whole set from the machinery at the right-hand end: the upper one, which we will call the guide-rod, moving back and forth and giving side motion to the thread; the main shaft below and behind, with cog-wheel attachments at each machine for revolving the spools; and a rod in front which carries a steel finger for

Fig. 2322.



Spooling Machine.

moving the thread, as will be explained presently. The spools are held horizontally and longitudinally in position just back of the front finger-rod by clamping-pins like axles, which pass into the holes at the ends and revolve with the spools very rapidly. Just back of each spool is a swinging curved hopper, its upper end reaching almost to the spool-trough previously mentioned, and its lower end open and curving up just under the position of the revolving spool. All that the attendant has to do is to keep the hoppers filled with empty spools, remove the full spools from the lower troughs as they accumulate, and see that the thread is regularly supplied by the bobbins behind.

A thread-guide is fastened on the upper sliding or guide-rod at each machine. The thread passes down from the tension apparatus over this guide to the spool. As the spool revolves, the longitudinal motion of the guide-rod back and forth moves the thread to and fro over the spool, which winds it up layer by layer.

A measuring-gage is attached to the machine, and just as two hundred yards are wound, the spool ceases to revolve; a little chisel moves up and nicks its edge; the sliding-rod in front with its steel finger moves longitudinally and draws the thread over; a hook passes up and pulls it down tightly into the nick; another chisel cuts it off, and the spool drops down into the receptacle provided for it in front. The swinging hopper then flies up with an empty spool in its curved lower end, which is taken up by the axle-clamp and starts into revolution. At the same time the thread, the cut end of which has been held down by the apparatus for the purpose, is pulled over and started on the new spool, and the operation proceeds as before.

The part of a spool on which the thread is wound always has a variable length, increasing as the winding proceeds outward from the center. Provision must therefore be made to give this variable motion to the guide-rod carrying the thread-guides. This is effected in its feed at the right end by giving a variable motion to the stops changing its direction. There are attached to this guide-rod two segmental nuts which are made to come alternately into contact with a revolving shaft having reverse screws contiguous to each other, one screw working in each half nut, causing the nuts to travel first in one direction and then in the other. These nuts connect with an arm with a forked end, which works on a fulcrum and operates over a pair of stops or jaws, pressing on to them and moving above them for one motion, and below them for the other, two heavy springs operating to produce the pressure and change the motion, alternately forcing it down and up, the alternate action of the nuts changing each time in accordance with this motion. By means of a cam and an arrangement of toggle-joint the pair of jaws opens gradually as the thread winds, keeping at a certain distance to correspond to each particular layer, thereby regulating exactly the sliding movement of the guide-rod. When the winding is finished and ready for another spool, the jaws are suddenly closed to their smallest dimensions and the operation is repeated.

Spool cotton works.

Spool Print'ing Ma-chine'.

The spools are agitated by reciprocating rods, and guided through a conduit into a race, from which the forward one is discharged by a flexibly-driven plunger into one of duplicate receivers, in which it is held by a reciprocating holder. During this movement the duplicate printing-dies, having been inked while at rest, move forward, are tipped into horizontal position by cams, and, moving against the spool, print its opposite ends in different colors, and, retreating, are raised into vertical position to be inked, while the rear spool-holder, rising, liberates its spool, and the receiver, making half a revolution, discharges the rear spool by its contact with a discharge arm, and moves into position to receive another spool, when the former operation is repeated, and the printed spool carried to the rear and the new one received are again printed, the former receiving a new impression in a contrasting color.

Spool'-shaped Spi'ral Spring. One narrower at the waist than at the ends. The opposite of *keg-shaped*.

Spoon. (*Surgical.*) See CURETTE; SCOOP.

(*Fishing.*) An object of glass, metal, mother of pearl, bone, or what-not, armed with a hook and towed abaft a boat, so as to shine while in motion and resemble a small fish. Trawling or trolling.

Spray Con-den'ser. (*Steam.*) The condenser, Fig. 2323, consists of two chambers, one over the other; the exhaust steam from the engine is admitted to the upper chamber, and is there condensed by contact with the injection water, which is brought in at the top, and made to fall on a perforated plate, which produces a rain-like spray. The condensed steam and injection water is drained away by alternately creating and destroying a vacuum in the lower chamber. This is accomplished by first opening a valve, and admitting a small quantity of steam at a very low pressure (1 or 2 lbs. per square inch), and then opening a valve to admit cold water; these two valves are actuated by tappets geared up to a shaft to produce seven strokes per minute. A steady vacuum of about 28″ is obtained with about half the water used in the ordinary jet condenser, and the condenser will draw its own water from any depth up to 27′. Salt, muddy, or even sandy water may be used, if pure water cannot be obtained.

Spray'ing Ma-chine'. A machine invented by Daughtry to irrigate growing cotton plants with wet poison to destroy the cotton caterpillar.

See *Comstock's* "*Report upon Cotton Insects*," 1879, p. 242.

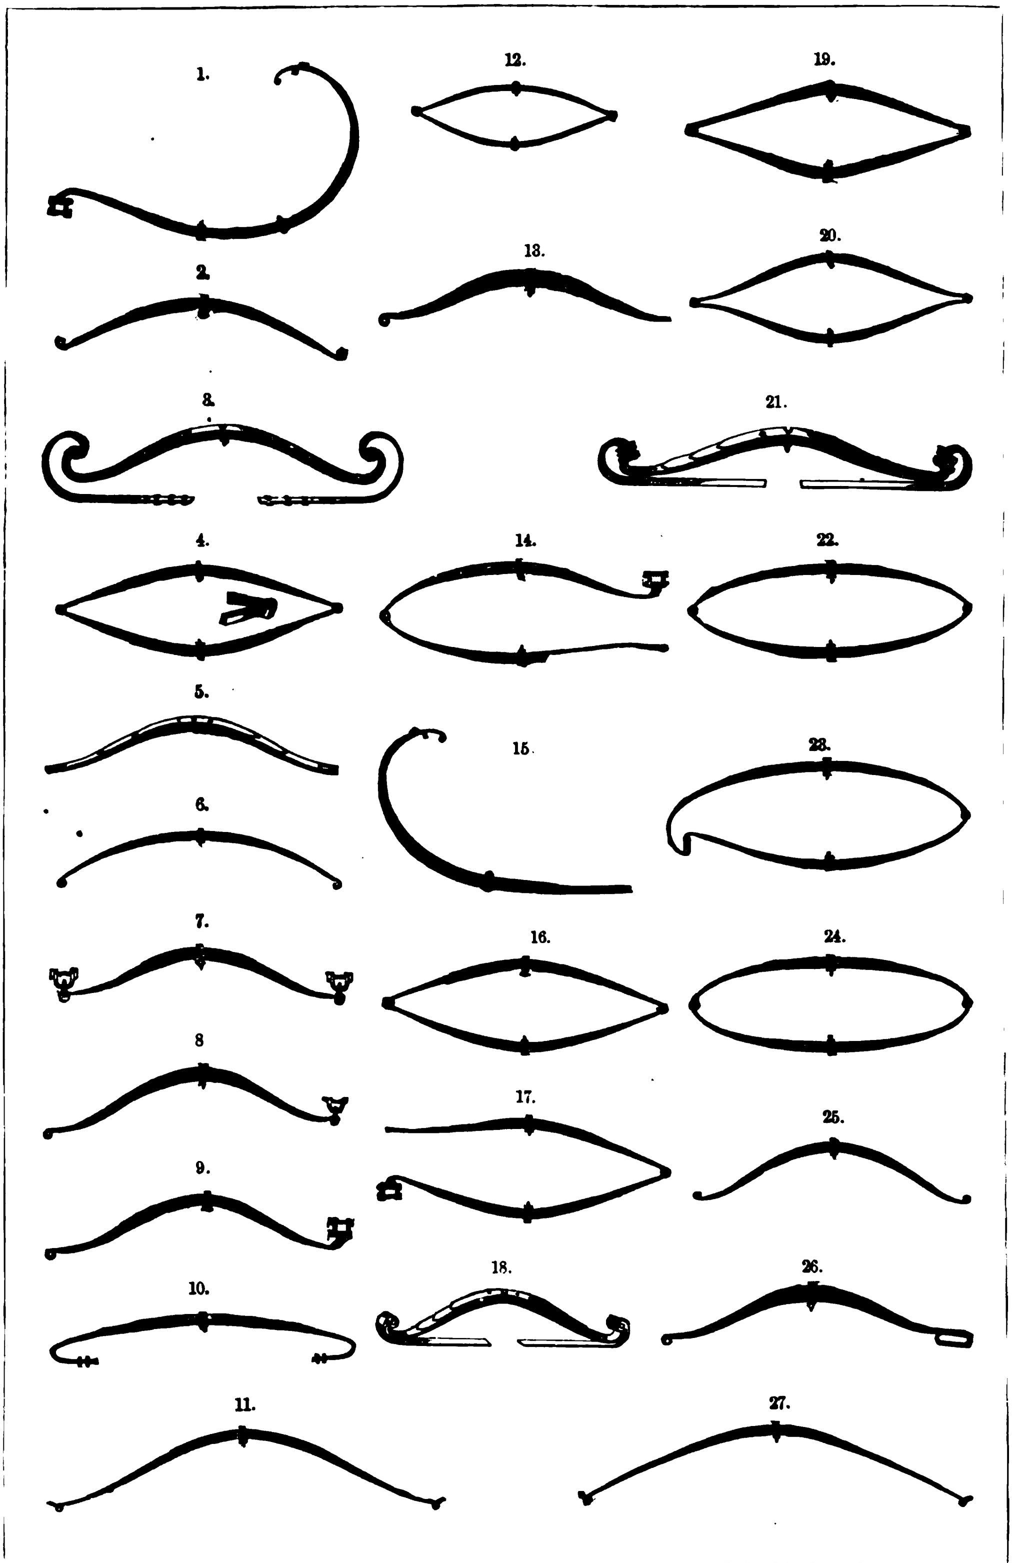

PLATE XLV. SPRINGS. See page 847.

See also SPRINKLER; FOUNTAIN PUMP.

Spray In'stru-ment. The set of atomizers represented in the cut are arranged for spraying

Fig. 2324.

Sprayers.

the throat. The set consists of three straight tubes of strong glass, seven inches in length, tapering at the distal end to a point with only a small perforation. On the right side of this extremity a second little funnel-like tube is strongly cemented. This is for holding the few drops of the medicament to be used, and may be filled from the bottle or with a pipette.

In one instrument the point of the medicine-tube is exactly in front of the air-tube; this is for throwing the spray directly into the throat. In the other two a variation in the direction of the tube gives a corresponding direction to the spray, so that it may be thrown upward with one instrument and downward with the other.

A common Davidson syringe or rubber air-bulb may be attached to the proximal end of the long tube for forcing the air through.

Both tubes, for an inch from the distal end, are flattened on their under surface, and roughened, and serve the purpose of a tongue-depressor.

Spray Noz'zle. For spraying a stream instead of delivering it solid.

The nozzle shown in Fig. 2325 enables the pipeman to approach and enter a burning building; and with it the excessive use of water, and unnecessary damage to goods, may be avoided. It consists substantially of a common nozzle, having a number of small levers pivoted around it near the outer end. These levers extend about 2″ beyond the end of the nozzle, and are inclosed in a neat cup or guard, *A*, completely protecting them from injury. They are bent inwards at a slightly acute angle, resembling the figure 7. The part corresponding to the short leg of the figure is wedge-shape, the thin edge being nearest the aperture of the nozzle. The other ends of these levers (below which they are pivoted) are connected with the collar, *C*, in such a manner that when the collar is revolved one-eighth of a revolution to the right, the wedge-shaped parts of half the levers are projected into the stream, dividing it up into a number of triangular streams. By turning the collar *C*, one-eighth of a revolution further, the remaining four levers are projected into the stream, dividing it up into double the number of streams. These streams, after leaving the nozzle a few feet, become a dense mass of flying spray, covering a large surface, and extinguishing the fire with wonderful rapidity.

Fig. 2325.

Spray Nozzle.

The illustration shows very clearly the solid stream, half spread, and full spread. Any intermediate degree of spread can be given to the stream, according as the pipeman is near to or remote from the fire.

Spread'er. An attachment to the end of a branch-pipe to make it discharge a sheet instead of a jet or solid stream.

Spring. Plate XLV. gives a variety of vehicle springs.

1. C spring.
2. Dray spring.
3. Half scroll spring, button head.
4. Berlin head elliptic.
5. Bolster spring.
6. True sweep side spring.
7. Platform cross spring.
8. Scroll head side spring, hole out of center
9. Scroll head cross spring, hole in center.
10. Spar spring.
11. Double sweep Concord spring.
12. Seat spring.
13. Straight-end truck spring.
14. Coach platform spring.
15. Cradle spring.
16. Full elliptic button head.
17. Coach platform spring.
18. Half scroll spring, button head.
19. Philadelphia elliptic button head.
20. Yankee-end elliptic.
21. Half scroll spring, with loops.
22. Full elliptic.
23. Full scroll spring.
24. French elliptic French head.
25. Coach platform cross spring.
26. Loop-end truck spring.
27. Single sweep Concord spring.

See under the following heads: —

Back-lash spring.	C-spring.

Schumacher. *Jones.*

Spring Band. (*Vehicles.*) An iron strap which clasps the plates of an elliptic spring.

Spring Bar Clip. A clip for fastening the spring-bar to the spring.

Spring Beam. A transverse timber which rests on top of the body-springs of a six-wheeled car-truck. There are two such beams to each truck, on which the bolster-bridges which support the bolster rest. — *Forney.*

Spring Block. 1. A seat secured to the axle to give a larger longitudinal support to the spring.

2. A distance-piece used in some forms of springs.

Spring Buf'fer. A spring device to receive the shock between colliding or impinging objects.

Spring Cap. A socket against which the top of a spring works.

Spring Case. A box inclosing a spring, as in some forms of car-springs shown on pp. 482, 483, "*Mech. Dict.*"

Spring Catch. A Y-shaped spring-piece, the bifurcated parts having their ends turned outward and back, used in raising pipe from drive wells.

Spring Com-pres'sor. (*Optics.*) A means for compressing or squeezing an object whilst under examination with the microscope. The glasses under which it is placed are pushed together by a spring and kept apart by a screw. It is made of convenient size for lying on the stage of a microscope.

Spring Coup'lings. The shackle joining the transverse and lateral springs in side-bar and platform springs in buggies.

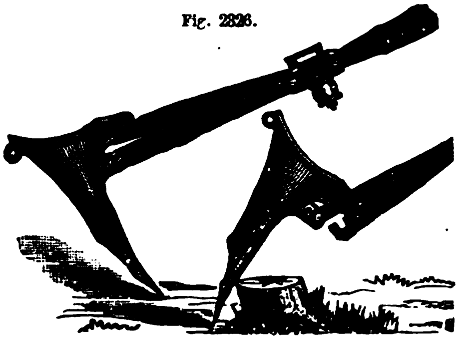
Spring Hang'er. A loop or clevis which sustains a spring beneath an object.

Spring Hinge. One in which a spring automatically closes the door when opened.

Spring Hoe. In the Farmer's Friend Drill, shown in Fig. 2326, the hoe is attached to the drill in the usual way, but is arranged so that the fastening forms a hinge, and when the hoe strikes any fixed obstruction it flies back and passes over it, when the expansion of a rubber spring that is compressed in the operation brings it back to its proper position.

Spring Hook. (*Fishing.*) A supplementary hook, which, when a fish catches the barbed hook, springing down, secures the fish from getting free.

Fig. 2326.



Spring Hoe.

See Fig. 2000, p. 872, "*Mech. Dict.*"; and for list of U. S. Patents, see p. 275, "*Report U. S. Fish Commission,*" Part I., 1873.

Spring Net. One closed by trigger and spring. Used in catching birds. A flap net. Another kind is used in catching rabbits.

Spring Plank. (*Railway.*) A transverse timber beneath a truck bolster.

Spring Sad'dle. A clevis which holds an elliptic spring, as in some car-trucks where a spring rests upon the journal box.

Spring Seat. The support for the lower part of a spring, shaped according to circumstances.

Spring Shack'le. The couplings used in joining the transverse and longitudinal springs in the platform spring system for buggies.

Spring Sha'ping Ma-chine'. A device to supersede the method of pinching heated spring leaves or plates into form by means of tongs, consists of a solid and flexible former, supported on a bed-plate, and a system of cams, drop lever, and screw for shaping.

"*Scientific American*" . . . . xxxvi. 374.

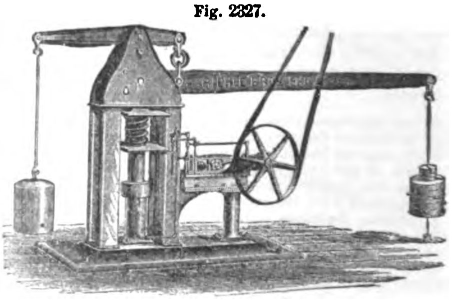
Spring Shelf. A ledge or bracket to afford a seat for a spring.

Spring Stud. A rod passing through the axis of a coil spring to hold the latter in place.

Spring Test'ing Ma-chine'. Fig. 2327 shows Riehlé Bros. machine for testing the elasticity of springs under pressure.

The power pump is operated by a pulley and belt. A lug projects from the corner of the lower table or compression surface; this lug intercepts a pawl that is connected with a valve that controls the flow of the fluid, and when the lower table moves upwards to the desired height, the fluid is diverted from under the plunger back into the reservoir, thus securing a uniform test.

Fig. 2327.



Spring Testing Machine.

The upper table bears against weighing levers, and is comparatively motionless, while the lower table moves upwards and communicates the pressure through the spring to the upper table, and thence to the levers and weights as shown.

Spring Valve. (*Steam.*) A spring balance is attached to the valve graduated to any number of pounds desired, and acts as a check on the valve till the indicated pressure is reached.

Spring Wash'er. A flat spiral spring is cut into sections of one or more laps, and used as

Fig. 2328.

Spring Washer.

a washer; will close up tightly and expand to take up looseness caused by shrinkage of woods or other cause.

Sprink'ler. A machine for spraying or irrigating plants; notably for destroying insects.

See SPRAYING MACHINE; FOUNTAIN PUMP.

Robinson's combined sprinkler and duster for destruction of the cotton worm is shown in *Comstock's "Report upon Cotton Insects,"* 1879, * p. 252.

Sprinkler, automatic fire, *Conant*, * "*Scientific American*," xxxiv. 114.

Sprue Hole. (*Founding.*) A gate, ingate, or pouring-hole in a mold.

Spud. (*Surgical.*) (*a.*) A small instrument with an enlargement on the end, used in withdrawing foreign matters from the eyeball and orbit. It is not so pronouncedly hollow as the curette or spoon.

(*b.*) A dermal instrument of the same shape; used in scarifying.

Spun Glass. (*Glass.*) Drawn by a workman from a hot bulb, or, on a larger scale by means of a wheel. See GLASS SPINNING, p. 983, "*Mech. Dict.*"

In the Austrian section at the Paris Exposition was one of the attractions of the day, viz., the manufacture of toilet articles and stuffs for ladies' wear, made out of spun glass, by Madame Jules de Brunfaut, Vienna. The glass, shown on the counters in large bundles, to all appearance looks like cotton, and is of a remarkable fineness. This glass is spun into threads like ordinary cotton, and is woven into different colored fabrics, sometimes entirely of glass and sometimes with a chain of silk or cotton.

The novelty of seeing fancy articles made of spun glass attracted the eye of the visitor. Ladies were particularly astonished at seeing collars, neckties, cords and tassels, fringes, pin-cushions, little caskets, curled feathers, belts, etc., made of glass. A very handsome ladies' buff-colored bonnet, made of spun glass, with the orthodox feather and ribbons, lined with silk, was the center of attraction. A bonnet of this kind can run the risk of a shower without being spoiled; glass will only look brighter for being washed.

The exhibit included a very handsome cloak, made of knitted wool and lined with glass cloth, the threads being woven a certain distance apart and laid at right angles. This made a very pretty and bright lining, offering a pleasant contrast with the colored knitted wool. The different articles exhibited were made in various-colored glasses. There was quite a variety of colored and white laces; cloths embroidered with glass; very thin woven glass cloth, in which now and then a fine thread of gold-colored glass appeared, making a very handsome fabric. These goods are easily washed by simply dipping in a bath of water and soda, and brushed with an ordinary soft brush.

See SLAG, *supra.*

Fr., *coton de verre*; Ger., *glaswolle.*

Spur. The far-projecting point on the circumferential edge of an auger. It makes the cut, while the *lip* raises the chip.

(*Ceramics.*) A small piece of refractory clay ware having one or more points, and used to support an article in the seggar while firing in the kiln. Also called a *stilt*. Fr., *colifichet.*

Sput. A thimble or annular reënforce to a hole in a boiler.

Squab Cush'ion. A cushion consisting of a bag filled with curled hair, feathers, or whatnot.

Square Tank Coil. A condensing coil of rectangular shape.

Squar'ing-off Saw. A circular saw, fitted to a bench with a sliding table, to square the ends of work.

Squar'ing Plow. For squaring paper in bookwork. The paper being placed on a table, with a board of required size on top, the paper is held firmly down by a screw having a bearing above. The board is provided near its edge with a groove or track for the plow or knife-carrier to travel in. The knife overhangs the board, and cuts the paper to size of the same.

Squar'ing Shears. (*Sheet-metal Working.*) A machine for squaring up tinned plate. It has scales of inches upon the adjustable table, and similar scales upon the arms that support the back gage, which latter has a rack-and-pinion adjustment.

The blade and treadle are balanced by an adjustable counter-weight; the treadle-springs are relieved of the weight of those parts, their only duty being to quicken the return movement of the blade. Page 110, "*Bliss's Catalogue*," 1881.

Another form has two blades set at right angles one with the other, and moving in unison, so that a sheet of tin may with one motion be squared on two sides, or the whole sheet squared in two motions. There are suitable front gages as well as independent back gages, one for each blade.

The gage on one blade can be set to cut a different width from the other, so that part of a sheet of metal can be cut up into a certain width for one article, and the remainder into a different width for another article.

Squaring shears, *Stiles & Parker*, * "*Scientific Amer.*," xl. 82.

(*Bookbinders.*) A curved hand-shear for squaring paper and cardboard is pivoted at one side of a table, and is held up by a balance-weight. The operator adjusts the material to be cut, and bears down on the handle of the shear. A foot treadle presses on the paper alongside of the shear to keep it firm.

Squeez'er. In sheet-metal working, a machine for squeezing or crimping, on the tops and bottoms of sheet-metal cans. See illustrations, p. 90 *et seq.*, "*Bliss's Catalogue*," 1881.

A series of compressing walls, to consolidate and clear of cinders the large masses of crude wrought-iron often produced in the process of puddling.

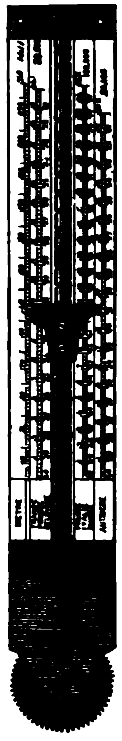
Squeezing, puddlers' balls mach., *Suckors* * "*Scientific American Sup.*," 1288.

Sta-di-om'e-ter. The geographic stadiometer devised by Captain Bellomayce, is designed to show at a single reading the measure of any line, right, curved, or broken, on maps or charts executed on any scale. The toothed wheel shown at the bottom is moved over the line and imparts motion to the longitudinal screw. This, in rotating, causes the ascent or descent of the carriage, the straight edge of which serves as an index.

Eight scales are used, one of 1-80000 for Prussian, French, and Belgian maps; one of 1-100000 for Prussian, Italian, and Swiss maps; one of 1-86400 and another of 1-144000 for Austrian maps, two respectively of 1-21600 and of 1-424000 for Russian maps; one of 1-63360 for English maps, and finally a graduation corresponding to the natural metric scale. This last marking by a simple reduction allows of the instrument being used for maps constructed on any other scale than those mentioned.

The device is held in the hands like a pencil, and as the wheel runs over the line it is only necessary to read the distance traveled on the proper scale to know the exact length of the line. When the index reaches the top of the screw, the instrument is turned around and pushed forward as before, the marking being now read from the top downward instead of in the reverse direction. It is especially useful in the field for military operations, as it does not require the entire map to be spread out flat before it can be used. It of course obviates the employment of dividers, and the usual scale of distances printed on charts.

Fig. 2329.



Stadiometer.

Sta'di-um. The leveling rod of a surveyor. See illustration, "*Van Nostrand's Mag.*," xxi. 141, 142.

Staf'ford-shire Ware. (*Ceramics.*) Household earthenware made in Staffordshire, in England, where pottery had been made as far back as the Roman period.

The red ware of the brothers Elers, from the Netherlands, was the beginning of the new era for the district. Delft was copied; then came Wedgewood, who made the greatest improvements due to one man, so far as we know the history of the art.

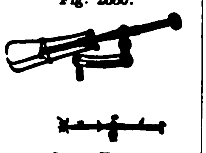
He improved and decorated the old wares; in 1762 invented the *cream* or queen's ware (not the modern invention), made of clay and silex with a clear glass glaze. In 1766 he made his black basalt ware. In 1773 he invented the fine paste for cameos, reliefs, and statuettes, which came to be known as jasper ware.

The queen's ware or ironstone china is perhaps the best known of Staffordshire wares, though many others are made in that country.

See STONEWARE.

Stage For'ceps. Adjustable clamps for fitting on to one side of the stage of a microscope to hold an object for examination.

Fig. 2330.



Stage Forceps.

Stage Mi-crom'e-ter. (*Optics.*) A piece of glass upon which fine lines are engraved, usually of 1-100 and 1-1000 of an inch or parts of a millimeter. It is placed on the stage of the microscope and used for the measurement of objects.

Stain'ing. (*Leather.*) Applying with a hair brush to the grain side of leather a solution of logwood, sal-soda, and soft water. It gives a dark color to the leather.

Stain'ing Met'als.

Metals may be colored quickly and cheaply by forming on their surface a coating of a thin film of sulphide. In five minutes brass articles may be coated with any color, varying from gold to copper-red, then to carmine, dark-red, and from light aniline-blue to a blue-white, like sulphide of lead, and at last a reddish-white, according to the thickness of the coat, which depends on the length of time the metal remains in the solution used. The colors possess a very good luster, and if the articles to be colored have been previously thoroughly cleaned by means of acids and alkalies, they adhere so firmly that they may be operated upon by the polishing steel. To prepare the solution, dissolve one-half ounce of hyposulphite of soda in one pound of water, and add one-half ounce of acetate of lead dissolved in a half pound of water. When this clear solution is heated to from 190° to 200° Fah., it decomposes slowly, and precipitates sulphide of lead in brown flakes. If metal be now present, a part of the sulphide of lead is deposited thereon, and, according to the thickness of the deposited sulphide of lead, the above colors are produced. To produce an even coloring, the articles must be evenly heated. Iron treated with this solution takes a steel-blue color; zinc, a brown color; in the case of copper objects, the first gold color does not appear; lead and zinc are entirely indifferent. If, instead of the acetate of lead, an equal weight of sulphuric acid is added to the hyposulphite of soda, and the process carried on as before, the brass is covered with a very beautiful red, which is followed by a green (which is not in the first scale of colors), and changes finally to a splendid brown with green and red iris glitter. This last is a very durable coating, and may find special attention in the manufactures, especially as some of the others are not very permanent. Very beautiful marble designs can be produced by using a lead solution, thickened with gum tragacanth on brass which has been heated to 210° Fah., and is afterwards treated by the usual solution of sulphide of lead. The solution may be used several times.

Stain'ing Wood. Oak may be dyed black, and made to resemble ebony, by the following means: —

Immerse the wood for 48 hours in a hot saturated solution of alum, and then brush it over with a logwood decoction, as follows: Boil one part of the best logwood with 10 parts of water, filter through linen, and evaporate at a gentle heat until the volume is reduced one-half. To every quart of this add from 10 to 15 drops of a saturated solution of indigo. After applying this dye to the wood rub the latter with a saturated and filtered solution of verdigris in hot concentrated acetic acid, and repeat the operation until a black of the desired intensity is obtained.

Stains for wood, *Black*. "*Scientific American Sup.*," 1994.

Stake. The stanchion, standard, or post placed in a socket on the edge of a gondola or flat car to hold sideboard or freight, as the case may be.

Stake Hook. The clevis or iron loop on the edge of a platform car to hold the stake or stanchion.

Stake Net. (*Fishing.*) A net secured by stakes.

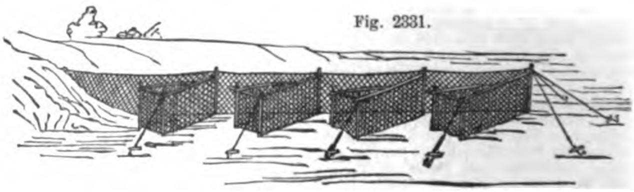
In the example, it is hung on stakes about 21′ apart in a line at right angles to the shore. This part of the net is known as the *bar*-net. At from 30′ to 40′ down stream another row of stakes is set, each opposite a stake in the *bar*-net, and between these stakes a *wing*-net is stretched, having several yards of netting more than suffices for the distance. This end is carried round in the form of a triangle and held in position by poles lashed together at their ends. The free end of one pole is secured to the stake, and of the other to the seaming of the wing-net, and thus secured they float at the surface of the stream.

The triangular portion of the wing is arranged so as to allow an opening between the end of the *hook* and the *wing* through which the salmon enter the triangle.

The netting is made of strong gilling-twine, the minimum mesh allowed being 5″.

The salmon, swimming up the current, come in contact with the bar-net, and turning to pass around it, find themselves opposed by the *wing*; they turn again up-stream, and are pretty certain to enter the *hook*, the netting of which hangs slack. In their efforts to escape they become gilled.

Fig. 2331.



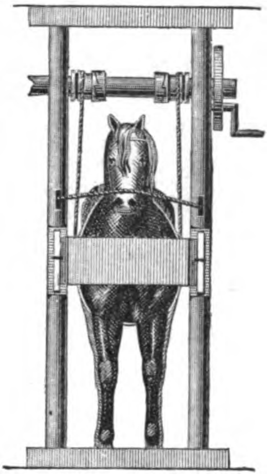
Staked Gill-net for Salmon on the St. Lawrence.

A gill net set in a channel attached to stakes. Such are very common in the Potomac and other Atlantic rivers.

Stall. Fig. 2336 shows a stall for transporting horses or cattle on ship or cars.

Each horse has his own separate box and sling. A shaft runs along above the row of stalls, and on this are loose clutch-pulleys, to which the ropes of the several slings are attached. These pulleys can be clutched with a corresponding clutch on the shaft, and any one or all the horses swung from the floor at will. The sides of the stall are of stout canvas.

Fig. 2332.



Stall.

Stamp. (*Mining.*) Machines for crushing ores.

The old practice of running high stamp-heads at a low speed and high drop has been changed by Western mill men, who erect heavy stamp-heads working at a high speed with a low drop, claiming that they get better results. The weight of a heavy head may be taken at 700 pounds, medium drop of head 10″, number of drops per minute for high speed, 90.

Stamp, *Ball.* * "*Min. & Sc. Press,*" xxxiv. 337, 345.

Canceler, electr., *Dow.* * "*Scientific Amer.,*" xl. 38.

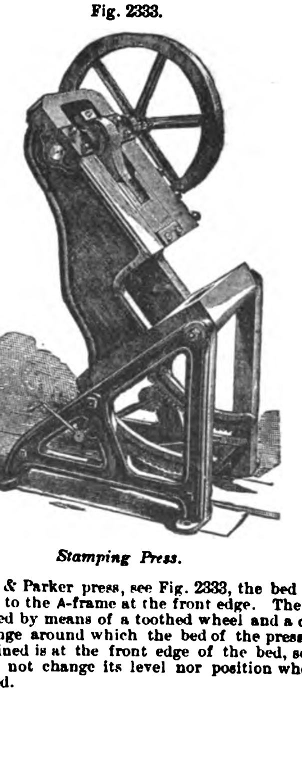
Canceling . . . . . . "*Iron Age,*" xix., Jan. 25, p. 19.

Stamp'er. A machine used in cleaning or filling textile goods. It may have one or more oak tubs about 3′ in diameter, with fallers or stampers of birch, while the framing is of pine bolted together. The tub is fixed on an iron plate which revolves by gearing, while the stampers are lifted by cams and are released so as to fall in succession on the goods being operated upon.

Stamp'ing Ma-chine'. For stamping the soles of boots and shoes with monogram or trade-mark.

Stamp'ing Press. A press for stamping or punching sheet metal.

Fig. 2333.



Stamping Press.

In the Stiles & Parker press, see Fig. 2333, the bed of the press is hinged to the A-frame at the front edge. The inclination is secured by means of a toothed wheel and a curved rack. The hinge around which the bed of the press turns when it is inclined is at the front edge of the bed, so that this edge does not change its level nor position when the press is inclined.

The adjustment of the slides in the guides is made by a very neat arrangement of a V-shaped liner, put into the guide in such a way that it takes up the wear upon the side where the wear comes. As the diagonal pressure in these presses is, owing to the length of the connecting rod, or pitman, very slight, the wear is merely nominal.

The pressure from the eccentric is transmitted to the slide in the form of compressive strains entirely, the end of the pitman bearing in a cup-shaped hollow, the pin merely serving to lift the slide by. The adjustment of the press is secured by a couple of eccentrics, one of which is movable about the other. By loosing the clamp screws shown in the top of the pitman, the outer eccentric may be turned so as to obtain any desired throw, after which the screw is set up and the press is ready for operation. This method gives exceeding delicacy of adjustment, and makes the press capable of doing work of the most difficult character.

Presses of this kind are capable not only of punching plate iron, but of decorating silver-ware. The two operations are fair examples of the extremes of coarse and fine work, though both require about the same amount of power and equally heavy pressures.

Stamping press, *Gordon* * "*Iron Age,*" xxiii., Feb. 6, p. 9.

Stamp Mill. A mill for reducing ores to a comminuted state preparatory to extracting the precious metals by amalgamation.

This ore is worked by the wet amalgamation process. The ore is introduced in an automatic feeder, and is fed under the stamps as required.

It is stamped fine enough to discharge through a screen containing 120 holes to the square inch. Water is turned in the battery at the same time the ore is fed in, and the splash as the stamps drop causes it to discharge, and the water carries the crushed ore with it to the tanks, where it settles.

The battery consists of 5 stamps of 775 lbs. each; they are raised by cams on a revolving shaft, and drop 8″, at the rate of 95 drops per minute. The shoes and dies are of cast steel, and weigh 120 lbs. each. The mortar in which the stamps work is made of cast iron, and weighs 4,400 lbs.

The crushed ore is taken from the tanks, put in the grinding and amalgamating pan, heated by steam, in order to soften the sand, and assist amalgamation. It is ground here for three hours; the grinding muller revolving at the rate of 90 revolutions per minute. The mercury introduced and amalgamated for two hours more. The mass is then drawn off into the settler below, water turned in to cool it, and is stirred by the revolving shoes for two hours and a half, bringing all the particles of mercury together in a mass at the bottom. With the bottom is connected an inverted siphon-pipe, that conducts the mass of mercury containing the amalgam into an iron bowl; from there it is strained through a canvas sack, the mercury going through, and the amalgam containing the gold and silver remaining in the sack. It is then in a condition to be handled, and contains about four fifths of its weight in mercury. It is then put in dishes in an iron retort, placed in the furnace with the pipe at the end to conduct the mercury out. Fire is made in the furnace, and the heat drives off all the mercury, which is condensed and used over again. The bullion is left in the retort, and when taken out is ready to go to the mint for melting.

Ball's patent steam stamping machinery for stamping ores and minerals (see Fig. 2334), is a direct acting vertical stamp mill having a common steam cylinder and slide valve at the top, and the piston rod extended into the stamp stem which works in a cast-iron mortar supported on spring timbers resting on cast-iron sills.

The lower portion of the mortar is circular in form, the upper portion being oblong, with a flat top and vertical sides; on the front and back sides are inclined openings for receiving the screens. The mortar is cast in one piece, and is lined throughout with hard iron linings. There are two feed-hoppers bolted to the top of the mortar, through which the ore is fed to the mortar.

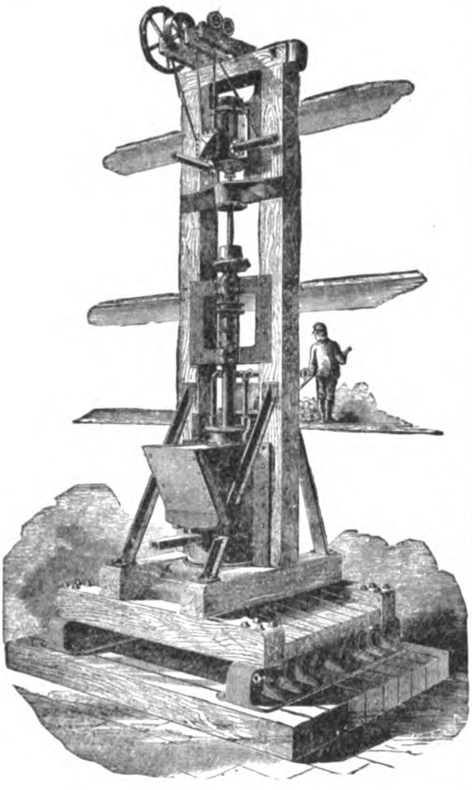
There is also a water urn arranged about a circular opening in the center of the top of the mortar, through which the water is conducted to the mortar.

The stamp shaft or stem works through two boxes which are attached to an iron frame that is bolted to the two upright posts that form the main framework of the machine.

Between the boxes and about the stamp-shaft is a revolving clamp and pulley, having feathers which work in splines in the stamp-shaft; and, by means of a belt on the pulley, a rotary motion is given to the stamp-shaft during its upward and downward motion.

The piston rod passes from the steam cylinder downward through the center of the bunter beam, and into the stamp-

Fig. 2334.



Stamp Mill.

shaft bonnet in which the connection to the stamp-shaft is made. The bunter beam contains a cushion against which the top of the stamp-shaft bonnet would strike, should the stamp-shaft lift too high.

The slide-valve works independent of the stamp-shaft, running a regular number of strokes per minute, and is driven by an eccentric on a shaft, which receives its motion from a countershaft; the two shafts being geared together with two cam gears, by means of which the motion of the eccentric shaft is changed into an irregular motion, and gives the eccentric and steam valve a motion corresponding to the slow upward and quick downward movement of the stamp-shaft.

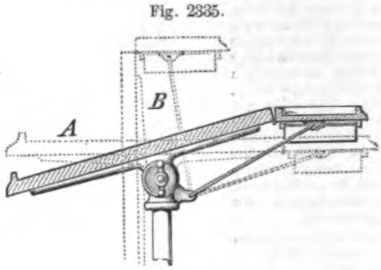
Stand. 1. For holding materials for drawing or painting. The Washburn stand, manufactured at Worcester, Mass., can be fixed at any required height, so that one can use it either sitting or standing; and by turning back the screw at the right, it is allowed to rotate, bringing either side in front. The shelf or ledge for instruments is attached to the back side of the table, so that it is always level, whatever inclination is given to the desk; convenient for the water-cups, ink-stands, etc. Fig. 2335

Fig. 2335.



Washburn Stand.

shows the table fixed at a slight inclination, the dotted lines showing it horizontal at *A* or vertical at *B*. When the table is nearly vertical the whole occupies but little space, and forms a perfect easel. When used for this purpose an attachment is furnished for holding the picture, and the adjustments are so simple that a mere touch is sufficient to effect an entire change in the light which falls upon the work. Under the instrument shelf are provided two drawers for working materials. The table and drawers are made of black walnut or other appropriate wood, nicely finished.

2. (*Microscopy.*) The framework of a microscope, usually implying all save the object glasses and the accessory apparatus.

Stand'ard Bat'te-ry. (*Electricity.*) One to be used as a standard, having a perfectly constant electro-motive force.

Such an one is Latimer Clark's battery, described in "*Phil. Trans. Royal Society*," June 19, 1875.
Niaudet, American translation, 148.

Stand'ard Gage. (*Railroad.*) "Standard gage" means 4′ 8½″ between centers of rails.

Stand Pipe. A vertical pipe in which a column of water is made to rise to give sufficient head for forcing the water to elevated portions of the circuit. See "*Mech. Dict.*," p. 2308.

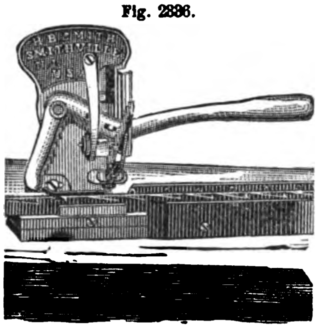
Stand-pipe, Blooming-ton, Ill. . . . . . * "*Scientific American Sup.*," 164.
* "*Engineer*," xli. 51.
Centennial . . . . * "*Scientific American Sup.*," 233.
Sandusky . . . . * "*Scientific American Sup.*," 1746.

Stand Pipe Fire Ap'pa-ra'tus. A portable stand-pipe for obtaining a higher head of water at fires. One section of a pipe is attached permanently to trunnions; other sections are carried in a side rack and attached at the fire. The pipe, 50′ long or more, is raised by means of a wheel after coupling the hose. The lower end is attached to the water supply. Less power is required at the engine to raise the water.

Staph'y-lor'a-phic Ap-pli'ance. *Dr. Gummings'* appliances for congenital cleft palate, * *Dr. J. H. Thompson's* report in "*Centennial Exhibition Reports*," vol. vii., Group XXIV., p. 28.

Sta'ple Dri'ver. An instrument for driving the staples in window-blinds. The one shown in Fig. 2336 feeds the blind the proper distance, supplies the staple, and drives it either in the rod or slat as desired.

Fig. 2336.



Staple Driver.

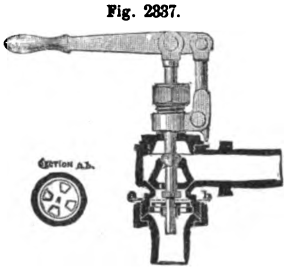
Sta'ple Fas'ten-er. A spring punch for driving and clinching a staple against an anvil block beneath.

Star Feed. A star-shaped device for improvising a feed motion to a slide-rest or to a tool-holding device not actuated by the self-acting feed motion of a lathe or machine. Upon the outer end of the feed screw of the slide-rest a star-shaped plate is fastened. For a slide-rest feed a pin is fastened to the lathe face-plate in such position that it will strike one of the star wings at each revolution.

For a revolving boring bar the pin is stationary and the star revolves with the feed screw of the bar.

Start'ing Valve. The starting valve, shown in Fig. 2337, is operated by a lever; its stem is attached to the valve with a lost motion, and has a small valve in the center of a larger valve. Pressure of the boiler is on top of the valves. Raising the lever and drawing up the valves, the small valve will leave its seat and rise until a check nut has brought up against *d*. This resistance can be distinctly felt, and indicates when the small valve only is open. Through this small valve enough steam will pass to start the jet. A further motion of the lever then raises the large valve, and the pressure, acting on the steam, forces it wide open and holds it in this position.

Fig. 2337.



Starting Valve.

Star Tor-pe'do. A movable chamber or mine charged with an explosive that is fired by contact or by fuse. The star torpedo has a single platinum fuse and battery and one set of wires, and can be fired either on contact or at will as desired. There are two wires leading from the opposite poles of the battery to a contact maker on the nose of the torpedo, by which contact is made between the wires whenever the torpedo is touched by the vessel attacked, and the current thus being free to pass through the fuse, the torpedo is thereby exploded.

Torpedo, *McEvoy*, Br. . . . * "*Engineer*," xliii. 340.

Stath'mo-graph. An instrument invented by Dato, of Cassel, for recording the velocity of railway trains.

"*English Mechanic*" . . . . xxv. 229.

Sta'tic E'lec-tri'ci-ty. (*Electricity.*) Electricity at rest.

Sta'tion-a-ry Bed Pla'ner. The bed is stationary, and the stuff is fed by feed-rollers. The bed has sliding rollers, flush or a little above its face.

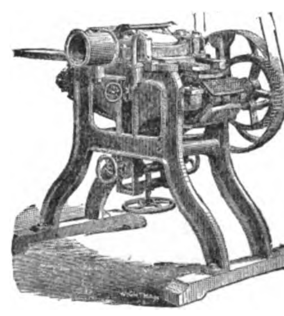
Sta'tion In'di-ca'tor. An indicator operating in connection with the driving-wheels to exhibit automatically the name of the station or street immediately preparatory to arrival.

Sta'tion Me'ter. (*Gas.*) A meter of the largest class for measuring the flow of gas at the works; made from 30″ wide and 30″ long, to 15′ × 15′, of a capacity from 15,000 cubic feet to 2,000,000, per 24 hours. The smaller are in one cylinder and the larger in two sections. They are made with water-line, pressure, and overflow gages, and register clock and tell-tale attachments. The tell-tale tells at a glance any irregularity of manufacture during the 24 hours, the cards being attached and removed daily.

Stave Dress'ing Ma-chine'. This machine has a rotary cutter-head and revolving bed with continuous motion.

The stave is placed on the bed and carried forward in a direct line to the rollers, which are straight, convexed, or concaved, to fit the shape of the stave.

Fig. 2338.



Holmes's Machine for Dressing Sawed Staves.

The rotary head cutters are so made as to smooth and finish the stave, perfect its shape, and give it uniform thickness.

The form may be changed at pleasure and may be made to operate upon one or both sides of the stave.

Revolving cutters are used for dressing staves of all thicknesses; dressing both sides of the staves at the same time without cutting the wood across the grain, that is, leaving the staves winding and crooked as they were rived from the block. This is accomplished by allowing the frame, which supports the cutters, to oscillate or rock in all directions, by which the cutters adapt themselves to the crooks and winds of the stave, the stave having control of the cutter frame. It dresses rived and sawed staves of different lengths and curves, for making kegs, barrels, and hogsheads, and dresses crooked and winding stock to a uniform thickness, leaving it concave and convex as required.

Stave dresser, barrel.

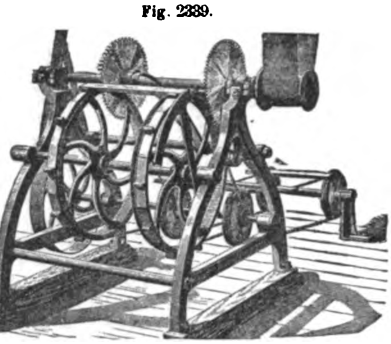
Ashey, Fr. . . . . . . * "*Engineer*," xlvii. 255.

Stave E'qual-i-zer. In Holmes's equalizer, Fig. 2339, the feed is continuous, the staves being simply laid upon the reel, which passes them between the saws and delivers them on to the stave conveyer, which carries them where they are needed.

Fig. 2339.



Barrel Stave Equalizer and Conveyer.

Stave Ma-chin'e-ry. See list under BARREL MACHINERY.

Stay End. The end of a back-stay in a carriage. Stay-ends are sold separately as pieces of carriage hardware, the lengthening rod being added by the blacksmith.

The ends of the stay are bolted or clipped to the perch and hind axle respectively.

Stay End Tie. The rod which connects the stay-end on the reach with the one on the axle.

Stay Rod. A rod which connects two objects to prevent displacement of one or both.

Stead'y Rest. For centering a cylindrical piece in a lathe, slotted pieces are adjustable lengthwise to accommodate the size and position of the shaft.

Fig. 2340.

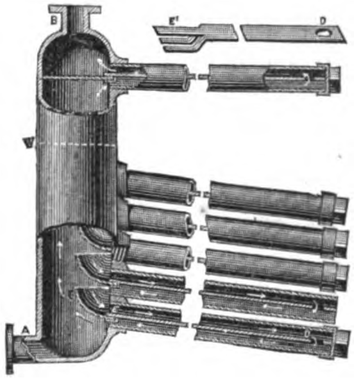
Steam Boiler. A vessel in which water is converted into steam, to be used as a power, a medium, and for other purposes. For early forms of steam generators and the adaptation of steam to mechanical and other uses, see "*Mech. Dict.*"

Of boilers of later construction, and unnoticed in the original volumes of the "*Mechanical Dictionary*," we have the "Corliss," an upright tubular boiler, with a cylindrical shell.

The "Exeter" has a series of sections, each a boiler in itself, rectangular in form. Each section has twelve openings, and is practically a series of connected boxes.

In the "Kelly" (see Fig. 2341) sectional safety boiler, the front chamber of each section is vertical, and the tubes are inclined over the fire at an angle of about one to eight. In

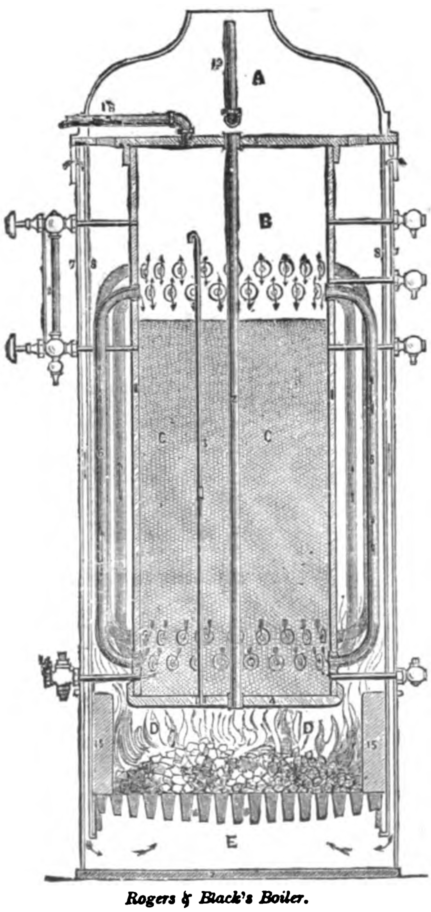
Fig. 2341.



Kelly's Steam Boiler.

each tube there is a partition with diaphragm, and the water-line of the boiler is above all the water tubes, but below a horizontal tube for the superheating of the steam. The

Fig. 2342.



Rogers & Black's Boiler.

theory of the circulation of the water is that the lower portion of the tube will be the most highly heated, and so generate the most steam, which, being intercepted by the partition plate and prevented from rising to the upper part of the tube, passes along the lower side of the partition to the front chamber and thence to the dome.

"Lowe's" tubular boiler has a cylindrical shell and horizontal tubes, like those of a locomotive boiler, through which the heated air and gases pass. Thence the hot air is carried round and under the boiler in front.

The "Howard" sectional safety boiler has tubes inclined from front to rear, with wrought iron steam drum.

"Root's" sectional boiler has an automatic feed regulator regulating the supply of water to the boiler by admitting steam from the boiler into the regulator when the water falls below a certain level.

The "Babcock & Wilcox," is a sectional tubular boiler with horizontal steam and water drum. The tubes are staggered. The end connections are each cast in one piece of steel, and connected with the steam and mud drums by short tubes expanded into bored holes, doing away with bolt connections.

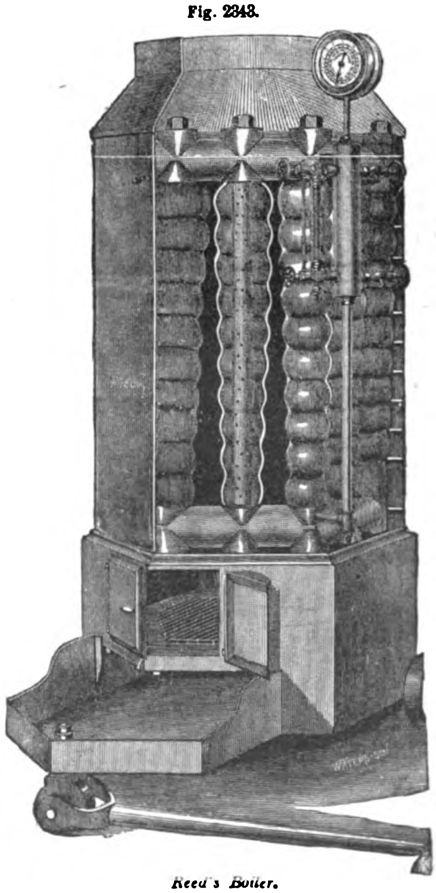
The "Firmenich," is an upright tubular boiler. The base is two large mud drums, one on each side, but two feet below the fire grate. From these rise obliquely over the fire, stacks of wrought iron water tubes that end in two water and steam drums, which are connected with a steam drum in the center, forming the crown of this pyramidal structure.

The "Pierce" boiler is a cylindrical, tubular boiler. The outer row of tubes are nearly surrounded by buckets that keep them submerged in water, and also drench the inner surface of the boiler shell above the water line.

The "Anderson"; each section of this boiler has two front manifolds, and a rear one connected by horizontal sets of tubes. The sections are united to each other by nipples, and the sets of sections by a central column, to the top of which is attached the steam dome.

The "Rogers & Black" (see Fig. 2342), is a cylindrical boiler with tubes outside for heating and circulation.

Fig. 2343.



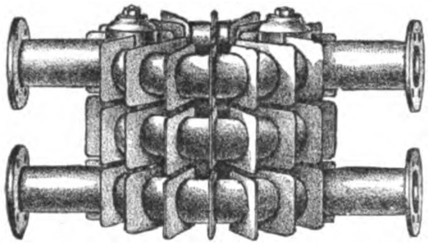
Reed's Boiler.

The "Reed" (see Fig. 2343) **is a corrugated sectional boiler. The sections are of cast iron, being three corrugated pipes, joined at the bottom, top, and at the water-line.**

The "Sectional Ring Boiler" (see Fig. 2344) **is a cylindrical manifold boiler of unique arrangement.**

The "Lynde" generates its steam in tubes that return over the fire seven times, and has a large steam drum. It has an eclipse injector, acme governor, and stop-valve, and Lynde's low-water alarm.

Fig. 2344.



Sectional Ring Boiler.

The "Eclipse" is adapted to either heavy or light service. The castings are of charcoal iron and the tubes lap-welded. All the parts being iron to iron, no calking or packing is required. A large steam drum is attached to the boiler.

In the "McLauthlin" the two heads are stayed by vertical braces, and the smoke bonnet has its aperture over the center of the boiler. The feed-pipe extends across the boiler inside far above the tube-sheet, and is perforated so as to secure extended distribution of the feed-water in minute jets pointing upward.

Steam Boil'er Clean'er. The Hotchkiss boiler cleaner is composed of five principal parts: the reservoir, funnel, up-flow pipe, return pipe, and blow-off pipe; automatic in its action.

The funnel is partly submerged in such position that its opening intercepts the current of hot water flowing towards it. By the action of gravity in water of varying temperatures aided by the pressure on the surface, the hot surface water that enters the funnel flows into the reservoir through the up-flow pipe, displacing constantly an equal quantity of the cooler water therein, which flows back to the boiler.

Purves' automatic boiler cleaner draws impurities from the surface of the water through an automatic skimmer, from which they are passed on into the top chamber, which is constructed with deflecting plates, causing the impurities to fall into the lower chamber, while the pure water passes through a pipe into the lower part of the boiler.

Steam Boil'er Feed'er. Pratt's boiler feeder is also a return steam trap with an automatic device, that drains the water of condensation from heating coils, and returns the same to the boilers, thus doing away with pumps or other mechanical devices for such purpose.

Steam Boil'er Feed'-wa'ter Heat'er. Strong's feed-water heater and filter is a device that in connection between the feed-water and the boiler raises the temperature of the water and cleanses it of impurities.

Steam Boil'er Fur'nace. The heating chamber that is generally placed beneath or inside of a steam boiler. There are various plans of construction in accordance with the description of fuel to be used, the consumption of the gas escaping therefrom, the plan of the boiler with which it is connected, etc.

It is claimed that the fuel of the future will in a great measure be gas, generated by the furnace that then utilizes it not only in the generation of steam, but also in the production of a future supply of gas itself.

The great advance made in the manufacture of steel is due in a great measure to the use of hot air, and to-day steel is manufactured cheaper than iron in the Siemens' gas regenerative furnace.

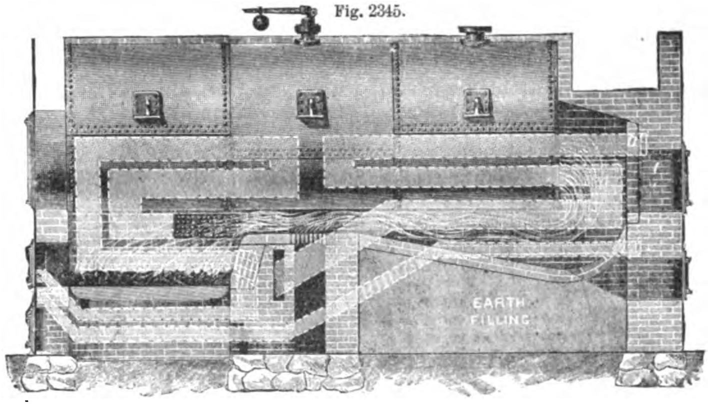
In the old style iron furnaces only a small per cent. of the power of coal was realized. The giant power was unbound, let loose, and after doing but a small percentage of the work it was capable of performing, escaped for parts unknown.

It is claimed that the Siemens' system has so improved the combustion of fuel that it now realizes 20 per cent. of the units of heat contained in coal, a saving of 40 or 50 per cent. in fuel over the old way. In this furnace coal is burned in a retort, and the smoke and gases (carbonic oxide) are carried up a large vertical tube from 12′ to 15′, after which it proceeds horizontally any required distance, and then descends to the heat regenerator, through which it passes before entering the furnaces. Two generators are used on each side, the gas ascending through one, while pure atmospheric air intensely heated by its passage through the regenerator, ascends through the neighboring passage, and both are conducted through passage outlets, at one end of the furnace, where mingling they burn, producing the heat due to their chemical action.

Smith's smoke-consuming furnace (see "*Mech. Dict.*," p. 2330) has a further improvement in its adjustable arrangement; the grate being elevated or depressed, so as to increase or diminish the distance between the fire and the bottom of the boiler at pleasure.

The grate consists of a series of bars, supported by a frame that rests upon a standard which slides in a hollow post, that is slotted on one side to admit the end of a lever which sets into a recess in the standard, and elevates or depresses the same. The lever is pivoted in the upper end of another standard, forming a fulcrum, and is provided with a handle by means of which it is operated. The lever has an attachment by which it can be fastened to hold the grate in any fixed position. There are columns or heaters on the sides of the boiler that take the place of the brick walls, and being always filled with water get the benefit of the heat that would have been absorbed by the brick walls. The bridge wall is hollow and always filled with water and is connected with the main boiler.

Fig. 2345.



Steam Boiler Furnace.

The Jarvis furnace, Fig. 2345, has a unique feature in its setting whereby air is admitted by small flues in the front, and then conducted through a number of horizontal expanding ducts, in which it traverses forward and backward, until finally in a heated state it enters by the furnace bridge-wall and other places, uniting with the products of combustion and causing consumption of the gases. By the arrangement of this furnace it is claimed that all kinds of cheap fuel can be used without a blower. Seeing that it is generally admitted that perfect combustion of fuel does not take place till the gases are fully generated, it follows that gas fuel is one of our first necessities. To get this it requires in the fuel about 40 per cent. of moisture to generate hydrogen, and then utilize the gas with hot air (oxygen), thus giving a hydro-oxygen or compound blow-pipe flame.

In carrying out the idea of the necessity of hydrogen, a wet screening mixture is used in the Jarvis furnace to produce a gas flame.

Steam Cap'stan. (*Nautical.*) A capstan intended for use on steamboats, operated through its connections with the steam power on board.

Steam Car'riage. A form of carriage like the ordinary road carriage, but having steam motive power.

Steam Dry'ing Ap'pa-ra'tus. Drying rooms and houses for seasoning timber, drying purposes in laundries, etc., through the radiating heat engendered by coils of steam pipes.

Steam En'gine. The first steam engine, — the Æolipile of Hero, 150 B. C., — is described in "*Mech. Dict.*," p. 2334, and the subsequent attempts to utilize this powerful agent.

The Westinghouse engine (see Fig. 2346) has the cylinders cast in one piece with the valve chamber, and bolted to the top of the bed-case. The cylinder heads cover the upper ends of the cylinders only, the lower ends being uncovered and opening directly into the chamber of the bed or crank-case. The pistons are of the trunk form, double walled at the top to prevent condensation, open at the bottom, and carrying the wrist pin. The annular exhaust is a narrow belt surrounding the cylinder, opening into it by the ports, and communicating directly with the exhaust outlet. The position of the annular exhaust is such that the ports are uncovered by the piston just before the completion of the stroke. The cranks balanced by the bobs, the crank-pin and the crank-shaft, are all of steel, and may be removed by taking off the crank case-head. The crank-shaft bearings, in the form of removable shells, are lined with babbitt metal.

Dr. Engel, director of the Prussian statistical bureau, gives the following figures: —

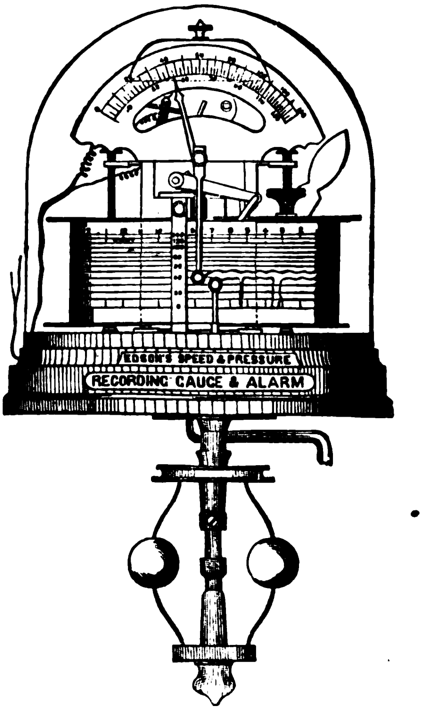
Steam En'gine In'di-ca'tor. An instrument for recording the pressure of steam at any point of the motion of the piston.

Steam Flour Core. This term is applied to dry-sand cores in which the flour has been steamed before it is mixed with the sand. What is meant by steamed flour is flour that has been mixed with water into paste and boiled with a jet of steam turned into it from the boiler.

Steam Gage. An attachment to the boiler to indicate the pressure of steam. See "*Mech. Dict.,*" p. 2344. The apparatus shown in Figs. 2347 and 2348 represents Edson's recording steam gage and speed recorder.

The mechanism of the instrument is first, a train of clockwork which controls the motion of a cylinder covered with a strip of paper, a pencil-arm with a pencil bearing on the paper, and a steel diaphragm of peculiar construction by which, through the details shown, the pencil is worked. This is in brief the construction of the steam gage. The speed-recording apparatus is similar, except that it has a governor driven by a belt from any principal part, and shows the fluctuations from a regular velocity on the same chart as the steam gage. This through the pencil attached to what is in ordinary governors the thrust collar communicating with the throttle-valve. So soon as the engine or train, if the ma-

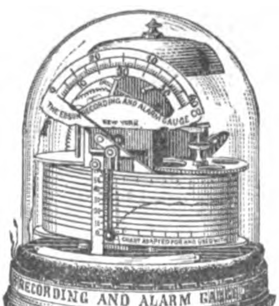
Fig. 2347.



Combined Speed and Pressure Recording Gage and Alarm.

chine is attached to a locomotive, is started, the governor is put in motion and the pencil connected with the paper cylinder. If the speed is uniform the line drawn on the cylinder is straight or nearly so, but any diminution in speed, any stoppage from any cause, is detected at once by the nature of the diagram. If the speed is slower than schedule time, the instrument shows it by fluctuations, or speed-curves in the horizontal line. As will be readily seen, any stoppage outright is shown by the instrument in the form of a loop. This, of course, from the reason that when the train stops the instrument stops, but the paper cylinder goes on tracing a horizontal line, the length of the base of which, or the area of the loop, indicates the time lost by stopping. The place stopped at is also shown, for as all stations can be marked on the paper on the cylinder, any loop occurring between stations shows a stop at once. This record, in connection with the steam card from the gage, forms a very complete diary of the working of the train it may be applied to, and is entirely removed from external interference or being tampered with by interested parties by surrounding it with a glass dome, fitted with a lock.

Fig. 2348.



Recording Steam Gage.

Similarly in regard to the gage recording the steam pressure — its construction and operation are as follows: the readings are obtained from the dial by an index and pointer as usual, operated by a corrugated steel diaphragm of peculiar construction in some respects. Instead of a small disk, such as is commonly used for this purpose, Mr. Edson employs a very large one. The object of this is to equalize the action of the diaphragm and render it more sensitive and even. With the construction of diaphragm, as shown by the dotted lines in the engraving, the elasticity is greatly increased, and the dial indications, as well as the records of pressure, are peculiar to each intrument.

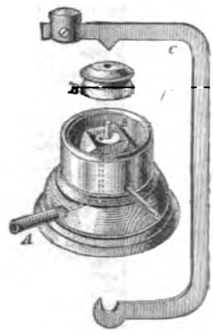
Besides these features there is an electric bell at the back of the instrument which by a simple and obvious arrangement opens and closes the circuit at any desired pressure, giving instantaneous warning of high or low pressures as required.

Ashcroft's "bourdon" steam gage, Fig. 2349, is provided with an elastic ring that prevents moisture caused by steam from gage-cocks entering the interior of the gage and corroding the movement.

Fig. 2349.

Steam Gage.

Fig. 2350.



Steam Gage Tester.

Steam Gage Test'er. An instrument to test the accuracy of the steam gage. See Fig. 2350.

The apparatus consists of a brass base, provided with a pipe, *A*, to be connected with a pump. At *B* is a hardened steel valve and seat, the latter having knife edges for the valve to rest upon, and being made exactly one square inch in area. The valve is guided by a guide-stem in the seat. The water-pipe *A* opens directly under the valve, as shown by the dotted lines. The valve, when in place, makes a tight joint with the knife edges, and the pressure beneath is confined until it exactly balances the combined weight of the valve yoke *C* (which rests by a pointed projection on the valve), and any extra weight which may be suspended from the lower hook of the yoke. With this the accuracy of a gage, at any specified point of its registry, can be ascertained.

Steam Greas'er. An impermeator to deliver the lubricant into the current of the steam, which it impermeates, being carried into the interior parts of the engine in minute globules.

Steam Ham'mer. One operated by steam; technically one in which the hammer reciprocates in guides, the shaft being usually in line with the engine piston, — the piston-rod, in fact, forming the hammer rod.

The steam hammer is usually vertical.

Plate XLVI. shows the immense 80-ton steam hammer of Schneider & Co., Creusot, France. This hammer was finished in 1877 and represented by wooden model of the exact proportions at the Paris Exposition of 1878. This hammer is the largest in the world, and is said to possess more than three times the power of the 50-ton Krupp hammer at Essen. A 100-ton forging may be readily turned upon its anvil by means of four powerful cranes.

The cost was $500,000, including its accessories and the building in which it works.

Machinery is now required to deal with immense masses. Witness the 100-ton Italian cannon for the "Duilio" and sister ship; the Siemens-Martin steel ingot of 120 metric tons, cast at Creusot; a rolled armor plate 13′ 10″ × 8′ 5″, 2′ 7″ thick, weighing 65 metric tons, and exhibited at Paris, 1878. One plate train of the Terre Noire works will roll an armor plate 36.08′ long, 8.2′ wide, and 3.9′ thick.

The hammer made by Ramsbottom, of England, is an innovation upon the usual method.

Instead of a vertical hammer, it consists of two immense masses of iron forming the hammers, which are mounted on carriages sustained by small, strong, friction-wheels, and move toward or separate from each other by moving horizontally on rails. Between them is the anvil, which merely takes the weight of the piece to be worked, while it is struck simul-

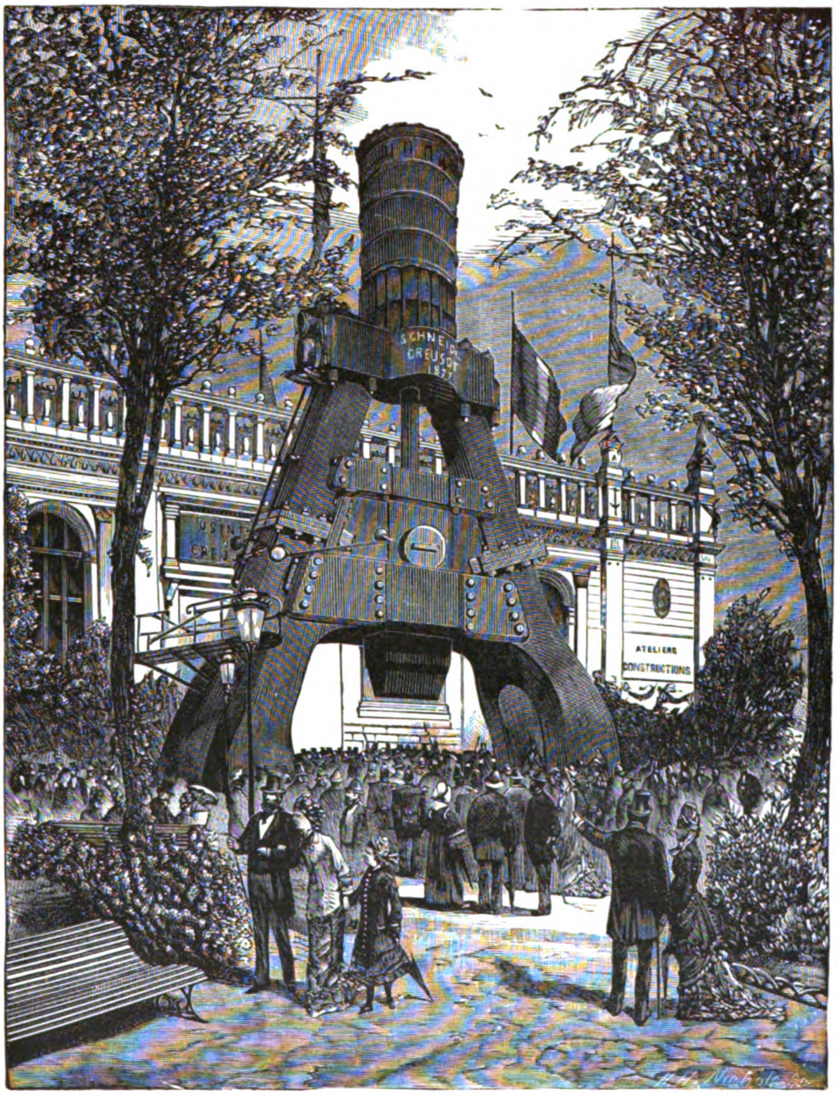


PLATE XLVI. EIGHTY-TON STEAM HAMMER. (SCHNEIDER & CO., CREUSOT, FRANCE.) *See page* 860.

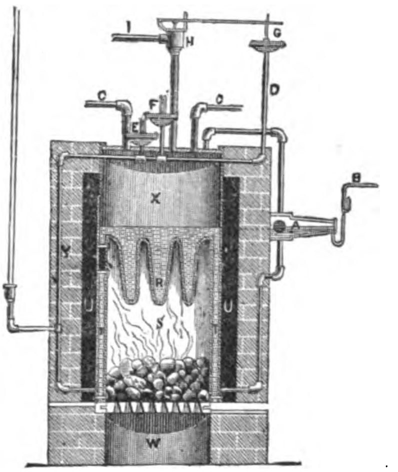
taneously by the two hammers which approach it from either side. The hammers are driven by large steam pistons, which are, in this case, set below the floor and under the anvil. This hammer requires no such foundation as is needed by the usual form of steam hammer, and it possesses the apparently generally unrecognized, but nevertheless important, advantage, that none of the energy of the blow is misapplied to the shaking of the earth and the injury of the buildings; it is all usefully applied to the shaping of the work. For many kinds of work this hammer has such decided advantages over the standard forms that it seems surprising that it has not become more widely known and more generally introduced. Three of these hammers are in use at Crewe, England.

Steam Heat'er. Warner's heater, Fig. 2351, is a low pressure steam-heating apparatus, with the hydrostatic or open column connected with the boiler at the bottom, standing at its side to such a height as to allow a pressure of only two pounds of steam to be generated.

Fig. 2351.

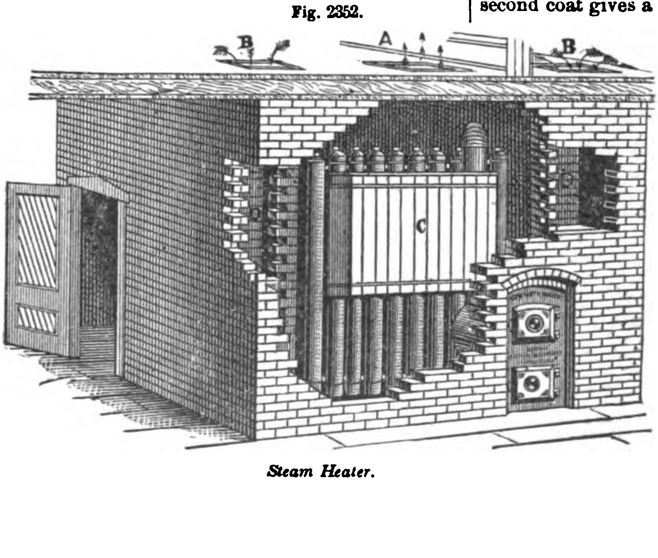


Steam Heater.

In Campbell & Pryor's method of steam heating for dwellings, the steam boiler and radiators are inclosed in a heating room in the cellar, doing away with pipes and radiators in the living rooms, the heat ascending through ordinary registers, while the cold air is drawn off the floors down flues leading to the bottom of the heating-room. Fig. 2352 shows the heating room, hot and cold air registers, and a hot-water battery, used without the steam boiler. The arrows at *A* show the direction of the current of warm air; *B B*, currents of cold air passing off the floor, down flues *D* to near the bottom of the heating room. The water battery, *C*, is a series of connected pipes holding 50 to 100 gallons of water, having a gas-pipe attached and passed around the heating bowl of the stove. When the fire is the warmest this water becomes heated to nearly boiling, giving out its heat again at any time the fire should slacken. By uncovering these water pipes the air may be moistened to any degree desired. A small pipe leads from the bottom of the heating room into the smoke flue to carry off the foul air that may accumulate. The furnace is fed from outside of the heating room.

This method is the invention of A. K. Campbell, Newton, Iowa, who claims that by establishing a current of air through the house and heating chamber he equalizes the temperature of the living rooms so that the difference between the floor and ceiling of a room is only 6° to 10°, while with the ordinary method the thermometer will show a difference of from 30° to 50° between the temperature of the floor and ceiling. He does not warm the large current of outside air usually necessary to force the hot air up into a room already full of air. Fresh air in plenty, he claims, is supplied any house through the crevices of the doors and windows; but he uses a small side pipe, if requested.

Fig. 2352.



Steam Heater.

Steam Heat'er for Steam Fire En'gines. A device for attachment to steam fire engines for heating the feed-water before its passage into the boiler.

Steam Me-tal'lic Pis'ton. A tight elastic piston with equal expansion, and a revolving tendency in the packing rings.

Steam Mo'tor. A small engine for household use, attachable by bracket to the wall, for running sewing and knitting machines, fans, churns, etc.

Steam motor, small . .	* "*Scientific American*," xliii. 390.
Davis	* "*Scientific American*," xliii. 278.
Mayhew	* "*Scientific American*," xliii. 66.
Tyran	* "*Scientific American*," xlii. 163.

Steam Nav'vy. A steam excavator.

Steam Pack'ing. Asbestos steam packing, intended to contend with high temperature, moisture, and friction.

Steam Pipe Cov-er'ing. The peculiarity of the Chalmers steam pipe covering consists in leaving an air space, or dead-air chamber, of 1″ or more, between the covering and surface covered. This is obtained by taking heavy wire cloth, to which is fastened, every four or six inches, a stud one inch or more in length. The wire cloth is then placed over the surface to be covered, the studs keeping it off the necessary distance. A non-conducting composition is then applied from one half to one inch in thickness, which partly penetrates the meshes of the wire cloth and keys itself. The second coat gives a smooth finish.

Leroy's composition: Mix thoroughly 448 parts of a paste of clay, 80 parts of paper pulp, 10 parts zinc wool, 10 parts of hemp, 8 parts of cocoa-nut fiber, 55 parts of charcoal powder, 23 parts of sawdust, 8 parts of flour, and 22 parts of tar. Heat the mixture until it is uniformly pasty.

See also STEAM PIPE COVERING, "*Mech. Dict.*"

Steam Plow.

Dr. Knight's report on Class 76 at the Paris Exposition contains views and descriptions of the following engines, apparatus, and modes of installation. See "*Paris Exposition* (1878) *Reports*," vol. vi. pp. 53-89.

Double-engine steam-plowing tackle, *Fowler*, England.

Steam-plowing engine, *Fowler*, England.

Rope-porter, *Fowler*, England.

Locomotive for the double-engine system, *Aveling & Porter*, England.

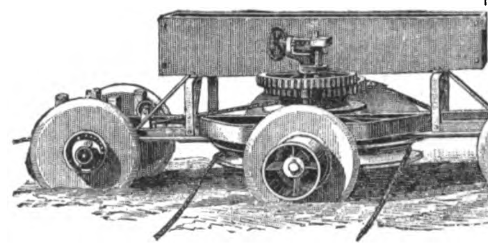
Farmer's engine for all purposes, *Howard*, England.

Single-engine and headland-anchor plan of installation, *Howard*, England.
Engine with two winding-drums, *Fowler*, England.
Movable headland anchor, *Fowler*, England.
Agricultural locomotive, *Aveling & Porter*, England.
Roundabout plan of installation, *Fowler*, England.
Windlass for the roundabout system, *Fowler*, England.
Anchor for the roundabout system, *Fowler*, England.
Portable engine and rear windlass for the roundabout system, *Howard*, England.
Roundabout system, with detached windlass, *Barford & Perkins*, England.
Roundabout system, engine, and windlass combined, *Barford & Perkins*, England.
Self-acting and self-moving anchor, *Barford & Perkins*, England.
Howard's roundabout tackle, *Bodin*, France.
Engine and windlass for roundabout system, *Debains*, Fr.
Installation of the roundabout system, *Debains*, France.
Six-furrow balance-plow, *Fowler*, England.
Three-furrow balance-plow, *Barford & Perkins*, England.
Plow and subsoiler, *Howard*, England.
Steam grubber, *Fowler*, England.
Double-action steam cultivator, *Howard*, England.
Turning cultivator, *Fowler*, England.
Turning harrow, *Fowler*, England.
Steam harrow, *Fowler*, England.
Combined harrow and seeder, *Fowler*, England.
Steam roller, *Fowler*, England.
Disking machine, *Fowler*, England.
Draining plow, *Fowler*, England.
Reclamation plow, *Fowler*, England.

Steam Plow Anchor.

Fig. 2353 shows Fowler's headland anchor, or rope carrier, which is moved along the headland by the motion of the pulley that is turned by the rope; the sheave is connected by a gear to a drum, which winds up a rope stretched along the headland and keeps the anchor opposite its work.

Fig. 2353.



Steam Plow Anchor.

Steam Pres'sure Re-cord'er and High Pres'sure A'larm. See under STEAM GAGE, p. 859, *supra*.

Steam'-proof Ce-ment'. "*Dingler's Polytechnic Journal*" gives a description of the manufacture of a new steam-proof cement, discovered by Mr. A. C. Fox, which it is claimed is not affected by hot or cold water, nor by acids or alkalies. First, a chromium preparation is made in the following manner: 2.5 parts, by weight, of chromic acid are dissolved in a mixture of 15 parts of water and 15 parts of ammonia. To this solution about 10 drops of sulphuric acid, and, finally, 30 parts of sulphate of ammonia and 4 parts of fine white paper, are added. When about to be used, gelatine dissolved in dilute acetic acid is added.

Steam Pump.

The large Blake mining pump has a double plunger, 16″ in diameter, and steam cylinder 23″ in diameter, with a stroke of 24″. This pump discharges 1,000 gallons per minute when running at the regular speed of 23 strokes per minute. These double plunger pumps are intended for mines and for pumping gritty water, they being very hard to wear out. The small cylinder surmounting the main cylinder contains an ordinary spring ring steam piston,—not a valve,—which is the motor for the main valve. The cylinder heads of both cylinders through which the piston passes are cast in one piece, with the connection between them, as in many other steam pumps. At each joint of the valve gearing there is a steel friction roller that can be renewed when worn.

In H. R. Worthington's duplex steam pump, the valve motion is the prominent and important peculiarity, as being that to which the pump owes its exemption from noise or concussive action. Two steam pumps are placed side by side, and so combined as to act reciprocally upon the steam valves of each other. The one piston acts to give steam to the other, after which it finishes its own stroke, and waits for its valve to be acted upon before it can renew its motion. This pause allows all the water valves to seat quietly, and removes everything like harshness of motion. As one or the other of the steam valves must be always open, there can be no center or dead point. The pump is, therefore, always ready to start when steam is admitted, and is managed by the simple opening and shutting of a valve.

The "Knowles" steam pump is a long, connected pump. In the steam chest there are only "two pieces," the valve (which is a flat slide valve) and the valve-driving piston, each being made all in one piece, thus giving only two moving pieces in the steam chest, to produce the entire motion. The steam valve of the pump, being an ordinary flat slide valve, does not have a rotary motion, but simply a horizontal motion, the same as any slide valve. This style of flat valve embodies the most favorable possible conditions for tightness, even after the wear consequent upon a long use. The slight rotary motion imparted to the valve-driving piston, by the rocker arm, simply puts it in a position to be driven horizontally by the steam, in which motion it carries the slide valve with it, the two being directly connected together. It has no springs, screws, yokes, nuts, followers, rings, plunger-cushion springs, movable seats, poppet valves, or studs, inside of the steam chest. The driving piston is entirely independent of exhaust steam for cushioning, thereby working with the same certainty and exactness when exhausting into vacuum (working condensing) as when exhausting into atmosphere. It will also work equally well in a vertical as in a horizontal position.

Steam Ram'mer. One designed to supersede hand-work in the paving of the streets of large cities, where extensive surfaces of stone blocks and cobble-stones are constantly requiring to be laid or repaired, and which can only be imperfectly put down by hand. The apparatus is operated on the principle of the trip-hammer; it can be speeded to strike fast or slow, and will deliver a blow of from 1 lb. up to 1,500.

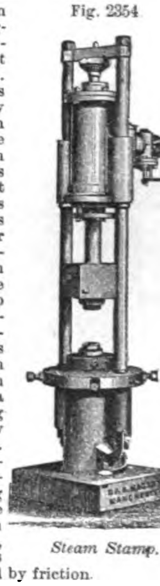
Steam Reap'er.

Aveling & Porter, * Knight's report "*Paris Exposition*," vol. v., p. 158.

Steam Stamp. One for stamping out articles from heavy sheet metal.

Fig. 2354 shows a 3-cwt. steam stamp, specially designed for forging articles of which large quantities are used, by means of dies cut to the form of the finished article. The stamp is not self acting, but is regulated either by the foot or by the hand. When left to itself with the steam turned on, it rises to the top of its stroke and remains in that position until the valve is brought down by the hand or foot of the attendant. It then delivers a single "dead-blow," and rises again, as before, leaving the lower die clear for the removal of the finished article and the introduction of the hot iron for a new one. The upper die is fixed rigidly in the tup or hammer-head, the lower one being adjusted by strong poppet-screws until it exactly coincides with it. The tup is fitted between slide-bars which guide it down upon the lower die, and, with a stamp of adequate size, the forging can be finished at a single blow with a great degree of accuracy. Special arrangements are introduced for facilitating the adjustment of the dies, for removing bolts and similar articles from the dies, for preventing the piston from striking the cylinder-cover, and for adjusting the slides so as to compensate for the wear caused by friction.

Fig. 2354.



Steam Stamp.

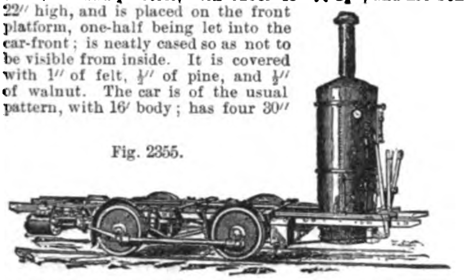
The 5 cwt. stamp will make a bolt 1¼″ diameter, with large square head 2¾″ diameter and 1″ thick, and with very deep square neck, at a single blow.

The principal sizes of these stamps weigh from ½ to 10 cwt.

Steam Street Car. Fig. 2355 shows the operating part of the Baldwin steam street car.

Two 6″ × 10″ cylinders are attached to an inverted cast-iron bed-plate, bolted to the car-bottom near the center-line and in front of the rear axle. The cranks are on the front axle, which has both inside and outside bearings. The jaws for the inside bearings are cast on this bed-plate. The valve-gear is the usual shifting link. The exhaust is carried through a system of pipes, so that it is partly condensed before escaping, and is nearly noiseless. The boiler is vertical, 72″ × 30″ and ⅜″ steel, with tubes 48″ × 1½″, and fire-box 22″ high, and is placed on the front platform, one-half being let into the car-front; is neatly cased so as not to be visible from inside. It is covered with 1″ of felt, ½″ of pine, and ½″ of walnut. The car is of the usual pattern, with 16′ body; has four 30″ wheels, only one pair driven by the engine. Steam brakes stop it in half its length.

Fig. 2355.



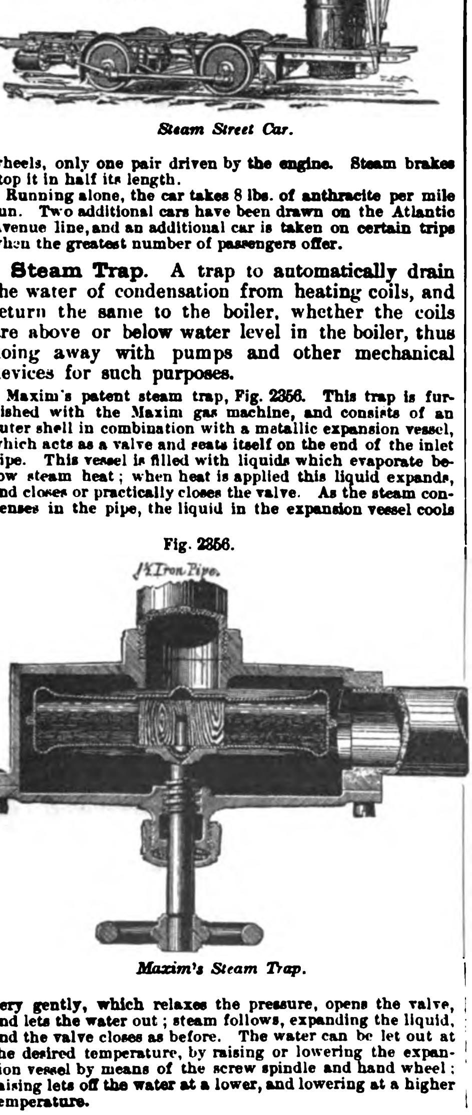
Steam Street Car.

Running alone, the car takes 8 lbs. of anthracite per mile run. Two additional cars have been drawn on the Atlantic Avenue line, and an additional car is taken on certain trips when the greatest number of passengers offer.

Steam Trap. A trap to automatically drain the water of condensation from heating coils, and return the same to the boiler, whether the coils are above or below water level in the boiler, thus doing away with pumps and other mechanical devices for such purposes.

Maxim's patent steam trap, Fig. 2356. This trap is furnished with the Maxim gas machine, and consists of an outer shell in combination with a metallic expansion vessel, which acts as a valve and seats itself on the end of the inlet pipe. This vessel is filled with liquids which evaporate below steam heat; when heat is applied this liquid expands, and closes or practically closes the valve. As the steam condenses in the pipe, the liquid in the expansion vessel cools very gently, which relaxes the pressure, opens the valve, and lets the water out; steam follows, expanding the liquid, and the valve closes as before. The water can be let out at the desired temperature, by raising or lowering the expansion vessel by means of the screw spindle and hand wheel; raising lets off the water at a lower, and lowering at a higher temperature.

Fig. 2356.



Maxim's Steam Trap.

Steam Valve. A door-like cover or device to regulate the passage of gases or fluids through a port. See list, p. 2688, "*Mech. Dict.*"

Purvis's steam valve is actuated directly by the motion of the engine piston without the aid of valve gear, and without the assistance of an auxiliary valve. The whole area and length of the cylinder are utilized. The valve is thrown through its entire stroke by line steam upon its differential areas, and cushioned by the same.

High pressure valve.

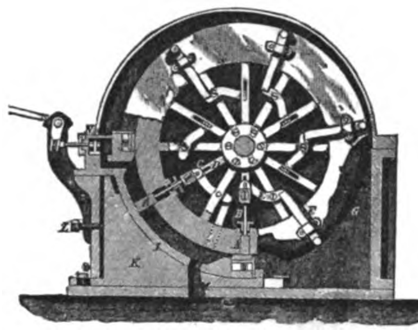
Steam Wheel. In Thomas' steam wheel, Fig. 2357, the impulsive power is communicated only over a segment of the periphery instead of following the piston around the circle.

See Rotary Steam Engine, *supra*, and "*Mech. Dict.*"

Fig. 2357.



Steam Wheel.

Stear′ic Ac′id Ap′pa-ra′tus. Devices used in the extraction of the tallow from the original fats. The fats are inclosed in hair or cloth bags, and subjected to pressure to extract the fluid fats, or the fats are mixed with from 20 to 100 per cent. of water and 1 or 2 per cent. of lime, and kept at a heat of 200° C. for several hours.

Steel. 1. Steel is made direct from the ore by deoxidation followed by carburization.

2. It is made from pig-iron by decarburization. Oxidizing agents, solid or aëriform, are applied to it to eliminate the carbon.

3. It is made from wrought iron by carburization.

Professor Young gives the following outline of the two latter: —

Pig iron converted into steel by —
Solid oxidizing agents, iron ore, saltpeter, etc., without fusion: *Examples* — Puddled steel; Riepe process; Ellerhausen process; Heaton steel.
Solid oxidizing agents, such as spathose iron ore, with fusion, — Uchatius steel.
Oxidizing agency of air, with fusion, — Bessemer steel.
Oxidizing and reducing gases, — Berard steel.
Wrought iron converted into steel by —
Fusion with pig iron, — Martin process.
Fusion with charcoal, — Wootz process.
Heating in charcoal without fusion, — Cement steel.
Heated in carbureted hydrogen, — Mackintosh process.

As steel occupies nearly the middle place between cast and wrought iron in its proportion of carbon, it may be prepared either by decarburizing pig iron, or, on the contrary, by causing wrought iron to absorb carbon. The processes to accomplish these ends may be arranged under five principal heads: A, Fabrication of steel by decarburization of crude or pig iron; B, by carburization of wrought iron; C, by mixing a wrought iron poor in carbon with a pig iron rich in same; D, by mixing pig iron with ore (the pig yields carbon which reduces the ore and transforms the reduced iron into steel); E, directly by means of ore; F, cast steel. Subdividing these systems, we have the following methods under each heading: —

A. — METHODS OF DECARBURIZING THE CRUDE IRON.

1. Steel obtained by a long heating of the crude iron in an oxidizing atmosphere, the metal not being brought to fusion. (a) Tunner's method in sand, where the deoxidation is produced by means of the oxygen in the air. (b) Jullien's method, in forge scales or spathic ore. This produces malleable iron. (c) Herzeeles' method in steam. (d) Thomas' method in carbonic acid. The last two processes have not been employed to any great extent.

2. Natural steel: In this method, employed since the earliest times, the crude iron is melted in a refining furnace with wood charcoal, and decarburized by the ferrous oxide of the scoria. The product is purified by repeated refining.

3. Puddling: This process is the same as the preceding, from a chemical point of view, but is practiced in a reverberatory furnace heated with coal. It is necessary to purify the product by repeated refining or by transforming it into cast steel.

The construction of puddling furnaces has undergone many changes. We may distinguish (a) the ordinary puddling furnace with fixed hearth and heated by coal, (b) the same heated by lignite or peat, (c) the puddling furnaces of Schafhäutl and others, with mechanical rabbles designed to diminish the labor so fatiguing to the workman. These, however, have been entirely superseded by new systems. (d) The Danks furnace, the hearth of which is formed of a hollow cylinder placed horizontally, and turning on its axis, gives a product of excellent quality, and is economical. The interior lining, however, is difficult to maintain. (e) The Ehrenwerth furnace has a horizontal circular hearth turning on a vertical axis. (f) The Pernot furnace also has a circular sole, which, however, is not horizontal, but slightly inclined, so that during its rotation the iron and scoriæ run to the lowest point and are thus in a state of continual motion; while the elevated parts of the hearth, together with the iron and scoriæ thereto adherent, are submitted to the oxidizing action of the air. This furnace realizes the advantages of mechanical puddling without needing any special lining.

4. The Bessemer process: A current of air, finely divided, is passed through the liquid crude iron. The carbon, silicon, and a part of the iron burn, and the temperature is so highly elevated that the iron, decarburized in part or transformed into steel, remains molten. It is then run into molds.

5. Bérard's modification of the above: Air and gases are alternately introduced into the retort with different advantages.

6. Peters' process: The liquefied crude iron in a reverberatory furnace falls in the form of rain in a vertical chamber in which the furnace gases also pass, and in which air is blown so as to decarburize the metal to the desired degree.

B. — METHODS BY CARBURIZATION OF WROUGHT IRON.

1. Indian or Wootz steel: Wrought iron of extraordinary purity, obtained by treating a very pure ore in small chamber furnaces by the direct method, is hammered, made into bars, cut into short pieces, and placed in small crucibles with a few green leaves. The crucibles are hermetically sealed and heated for a long time at a high temperature. The iron is transformed into steel by uniting with it the carbon contained in the leaves, and the steel even partially melts. These half melted masses furnish the famous sword blades and plates of Persia and Damascus.

2. There are several other processes resembling the Indian, which, however, are not carried on on a large scale. There are (a) the Mushet process, in which wrought iron obtained by the ordinary refining method is melted with powdered wood charcoal. (b) The Vickers' process, analogous to the preceding, with the addition of oxide of manganese. (c) The Stourbridge, Brooman, Thomas, and Binks processes, based on identical principles.

3. English cemented steel: Wrought iron of the best possible quality is, in the shape of bars, packed in clay boxes, together with wood charcoal coarsely pulverized. The heating continues for two or three weeks. Without melting, the iron is changed into steel, which by remelting is transformed into cast steel.

4. Parry's cupola steel: Fragments of wrought iron, melted in the cupola with a large consumption of coke or wood-charcoal, may be transformed into steel or even into cast iron according to the length of the operation. This system offers an advantageous method of utilizing scrap, and requires no special apparatus.

5. Chenot's process: In this the ore is reduced by heating it progressively with coal. A non-melted iron sponge is obtained, which is ground and separated as well as possible from the gangues by the aid of a magnet. Lastly, it is mixed with carboniferous substances, and melted under pressure. The principal disadvantage of this process is the difficulty of separating the gangues without losing the steel.

6. Casehardening has for its object the transformation of the surfaces of wrought iron objects into steel. It is done in two ways. (a) The pieces are placed in small sheet iron boxes and surrounded with chips of wood. The boxes are hermetically closed and heated in a forge fire, for 15 or 30 minutes, to an intense red heat. They are then removed quickly, opened, and their contents thrown into cold water, whereby the exterior steel shell is rendered as hard as glass. (b) The pieces are heated to a whitish red and moistened with ferrocyanide of potassium, which acts, by its cyanogen, on the iron, and transforms the surface into steel.

C. — METHODS BY FUSION OF A MIXTURE OF CAST AND WROUGHT IRON.

The two materials may be, both or only one of them, used in a melted state.

1. Bessemer steel, prepared by the ordinary method. The crude and wrought iron here are both liquid, while, as we have previously said, cast iron may be directly transformed into steel. The method most followed, and which leads most surely to the end in view, consists in completely decarburizing the crude iron in the converter, and in adding to the melted metallic iron a rigorously determined quantity of liquid crude iron. The carbon of the latter affects the previously decarburized iron, and makes a steel containing a given proportion of carbon.

2. Crucible steel is obtained by melting in crucibles a mixture of crude and wrought iron. The former liquefies first, and slowly melts the latter.

3. Martin's steel is similarly made, but replaces the crucible with a reverberatory furnace. The crude iron is liquefied under a thin layer of scoria on the concave hearth of a reverberatory furnace, heated to an intense red-white heat by a Siemens regenerator. Scraps of steel and wrought iron of all kinds in desired quantity are added, and the steel is run into molds of cast iron.

D. — METHODS BY A MIXTURE OF CAST IRON AND ORE.

Uchatius steel: The cast iron is granulated by running it into water while molten, and the grains are melted with spathic ore, peroxide of manganese, and wrought iron in crucibles. The ferrous oxide of the spathic ore is reduced by the carbon of the cast iron, and the surplus of carbon unites with the wrought iron to make steel.

E. — METHODS BY PREPARATION DIRECT FROM THE ORE.

The Siemens direct process: The ore is melted alone, without addition of reducing material, at a very elevated temperature; then the iron is reduced and transformed into wrought iron or into steel by adding coal.

E. — CAST STEEL.

For the purification of steel by fusion, cemented, forged, and puddled steel are employed. To improve the qualities of the steel, and notably to augment its hardness, diverse substances are added. Thus we have: 1, silver steel; 2, nickel steel; and 3, wolfram or Mushet special steel.

The Japanese method of making steel is to mix a certain quantity of iron in pigs and iron in bars, cover the mixture with borax, and melt the whole for a week in a small fire-proof crucible. The borax serves to dissolve the impurities in the dross. When the metal is separated from the dross (which floats on the surface) and cooled, it is hammered hard, and alternately plunged into water or oil, after which it is cemented and tempered. The mode of cementing is as follows: The steel, on coming from beneath the hammer, is covered with a mixture composed of clay, cinders, marl, and charcoal-powder. When this plaster is dry, the whole is subjected to a red heat, and the steel is afterwards cooled very slowly in warm water which is allowed to become tepid. Steel thus obtained is not very supple, but extremely hard, because it is not properly tempered or completely freed from its impurities. It would not do for making watch-springs, but is used by the Japanese for swords and sabres which are tempered as many as eleven times, and knives which are tempered four times.

(*Metallurgy.*) Greiner's classification of iron products: —

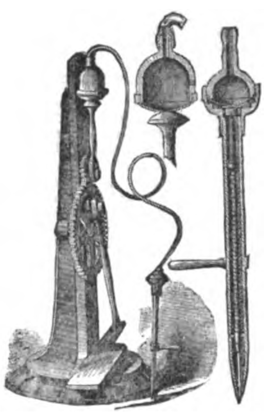
Carbon, per cent.	Iron Series (welded).	Steel Series (melted).
0. to 0.15	Ordinary iron.	Extra soft steel.
0.15 to 0.45	Granular iron.	Soft steel.
0.45 to 0.55	Steely iron or puddled steel.	Semi-soft steel.
0.55 to 1.50	Cemented iron or steel.	Hard steel.

See Sponge Process, *supra.*
See "*Mech. Dict.*," pp. 2363, 2364, 2365, 2366.
Henderson Steel . . "*Iron Age*," xix., Feb. 1, p. 15.

Sten'cil Paste. A mixture of any ordinary pigment with chalk or carbonate of magnesia, to form a paste of the required consistence.

Sten'cil Pen. A pen or needle reciprocated by electric or pneumatic force, for multiplying tracings, etc. Fig. 2358 shows a simple form of pneumatic pen.

Fig. 2358.



Stencil Pen.

Sten'o-chrome. A print showing the colors, shades, and arrangement of a mosaic, made by forming a mosaic plate of colored sections similar to the one to be copied.

Ste'no Com-press'or. (*Dental.*) A spring pad for closing the saliva duct, and absorbing the saliva during operations.

Step Gage. The standard double corrective gage, Fig. 2359, is for testing and correcting fixed caliper gages, and also as a reference to prove dimensions within its range.

Fig. 2359.

Double Corrective Step Gage.

Step Head'stock. In a watchmaking lathe the step head stock, as its name indicates, has a step or conical bearing at the rear of the spindle to reduce friction. This head is for pivoting, jewel polishing, and other work requiring very high speed.

Step Pad. The foot-rest or tread of a carriage step.

Ste-re-om'e-ter. An apparatus for illustrating various mathematical problems.

It has two frames, the upper one being a square, the sides of which are three feet long; and the longer one is formed by two such squares. Both frames are kept in position by four small columns, 4' in height, and standing on four legs, by which the whole is supported and fastened to a common table. In these squares graduated cross-bars (of any desired number) are fastened by screw-clamps. They move horizontally in two directions, parallel to the sides of the square, while similar bars, 4' long, are perpendicular to the frames and parallel to the columns. The cross-bars and framework are made in two pieces of ½" by ⅛", leaving between them an open space of 3-16", in which again a simple screw-clamp moves, holding a needle in position, perpendicular to the bars and frame. These needles are pieces of strong common wire, flattened a little on one end, with an oblong hole in the end. By this arrangement a mechanical way is found to determine the position of any point in space within the apparatus. The shifting of the cross-bars (say north or south), the moving of the clamp in the split of the cross-bars (east and west), and the moving up and down of the needle in the clamps, are true representations of the equations of a point in space. The position of an unlimited number of points can be determined, and, consequently, any solid figure can be represented in contour lines by drawing wires — or, better still, elastic silk cords — through the corresponding points.

Stif'fened Chain Sus-pen'sion Bridge. The first bridge of this kind was erected at Pittsburg, Pa., in 1876-1877. The bridge is stiffened by means of rigid cords which extend (above the chains), at an undeviating angle from the towers to the center of the middle span (800 feet long), where they are connected by a hinge to allow for expansion and contraction.

Stif'fen-ing Ma-chine'. A trough and pair of squeezing rollers used in putting the stiffening into felt hat bodies.

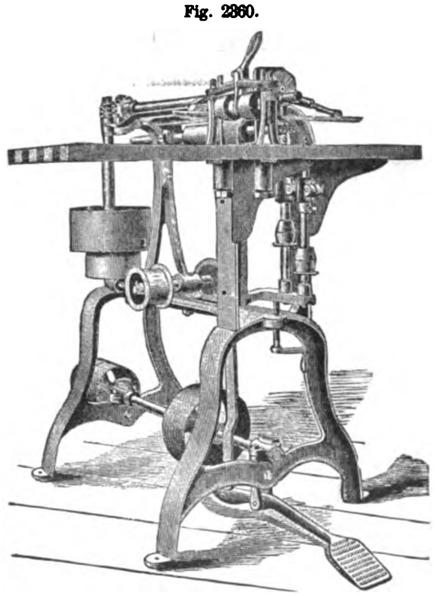
The stiffening is to enable the hat to maintain its shape. a thicker stiffening material is used for the brim than for the crown, and a more expensive material for fine hats than for common ones. A solution of shellac for first-class goods; Irish moss and glue for the rougher article. Two vats are employed and contain the respective stiffenings; the whole hat is submerged in the thinner stuff and the superfluous matter is squeezed out of it by passing it upward between the rollers. The brim alone is dipped in the other vat.

The troughs are heated by steam to keep the stuff liquid, and the hats after this process are ready to be blocked. This is the shaping, flattening the tip, stretching out the brim, etc. See Hat-blocking Machine.

Stile Bo'rer. A machine for boring holes in the vertical parts of a window or shutter frame.

In Fig. 2360, the two vertical bits are used for blinds only, and will bore without any previous marking or laying out,

Fig. 2360.



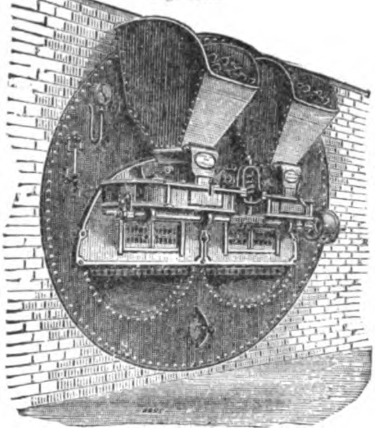
Colburn's Blind Stile Borer.

8,000 holes per hour. The stiles, after being jointed, are placed upon the table, with a ratchet or pattern between them, the lower ends of the stiles resting against two blocks, which are securely fastened to the end of the pattern, and are moved over the bits by means of a pawl working in the notches of the pattern. It spaces its own work at any distance apart, from 1" to 1½", and bores the entire length of the stile without stopping. The mortises are marked on the edge of the stile while the machine is in operation, from corresponding marks on the edge of a thin strip which has been previously laid off and tacked to the side of the pattern, and which can be replaced with any length required. The boring being done from the under side of the stile, the chips drop freely from the bits, and leave the holes of a uniform depth, so that the pivot of the slat may work on the end instead of the shoulder, which renders them less liable to bind or stick fast on the paint.

Stock Stone. (*Leather.*) A flat rectangular scouring-stone, 5" or 6" long and 0.5" thick, fixed in a stock or handle. It is used for scouring, stretching, and removing inequalities in the leather.

Sto'ker, Me-chan'i-cal. Henderson's mechanical stoker (English) has a fuel hopper placed over the fire-door, and from which it is gradually fed into the furnace by automatic gear driven by the engine. See Fig. 2361.

Fig. 2361.



Henderson's Mechanical Stoker.

Stone, Ar-ti-fi'cial. Stones formed by a process of treating a combination of lime and sand.

Ternikoff exposes equal parts of lime and sand to a temperature of 150° C. for several hours in the presence of steam. The material is then pressed and exposed to the air.

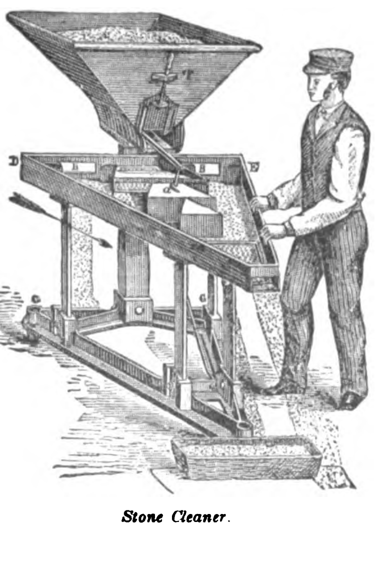
Glaser mills 4 to 6 parts fine sand to 1 of slaked lime and exposes for three days to a high temperature under a pressure of more than three atmospheres; it is then pressed.

Hosmer subjects limestone, cut to shape desired, in boiling water to 5° atmospheric pressure, and then places them in an alum or colored bath, to color as desired. See p. 2392, "*Mech. Dict.*"

Hammered artificial stone, "*Iron Age*," xviii., September 7, p. 3.

Stone Clean'er. For cleaning stones or clods from wheat or other grain.

Fig. 2362.



Stone Cleaner.

In Fig. 2362 the tray has a rocking motion on its supporting bars, the crank making 115 turns per minute. The grain placed in the hopper discharges at the lifted gate, runs over the slanting board, and into the bed of the tray. It is divided to each side, and, as the tray is pushed laterally back and forth by a quick motion, the contents are sorted according to gravity. The wheat issues at the rear ports, *B*, and the stones at the front, *C*, the lowest part of the tray. The apparatus is adjustable for inclination, the front end being kept the lowest. The stones being heavier than the grains and of angular shape, resist the backward blow of the oblique faces of the central block and pursue their way down the slope to the front while the grain passes out at the rear. See SEPARATORS.

Stone Cleav'ing Ma-chine'.

Stone cleaving for dividing granite is effected by means of a prismatic steel cutter inserted with wedges in the under side of the hammer, and opposite a similar one below on the anvil bed. The granite block to be cleft is pulled on rollers over the lower cutter (which is slightly higher than the rollers), and into the proper position. Then a rapid series of blows is given from a short height, followed by a strong blow from a great height. Thus a plate is cut vertically with accurately even surface. The block is next pushed on one plate-thickness, and the process is repeated. The plates obtained are afterward divided into cubical blocks by means of a steam hammer, arranged quite like the former except that the plates, instead of lying on rollers, are placed on small tables resting on spiral springs. By the weight of the stones the springs are compressed, so that the stones come to lie on the lower cutter.

Stone Cut'ting. The modes of dressing stones for masonry come under several heads. Unsquared stones or rubble are perhaps hardly included in the definition, but may be included for completeness of statement.

See under the following heads: —

Bush hammered.	Pitched-face stone.
Crandaled.	Quarry faced.
Cut stone.	Rough pointed.
Diamond paneled.	Rubbed.
Drafted stones.	Rubble.
Fine pointed.	Squared stones.
Peen hammered.	Tooth-axed.

All stones used in building come under one of three classes, namely: —

I. Rough stones that are used as they come from the quarry.

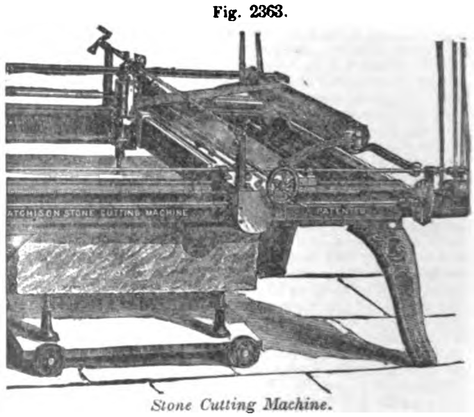
II. Stones roughly squared and dressed.

III. Stones accurately squared and finely dressed.

In practice, the line of separation between them is not very distinctly marked, but one class gradually merges into the next.

Stone Cut'ting Ma-chine'. The Tilghman sand blast will execute in ten minutes what would take a skilled stone-cutter a whole day. The pattern to be worked is cut in and through a flat iron or wooden plate which is fastened on to the stone. The jet-pipe traverses the pattern and the sand cuts away the parts of the stone not protected by the plate. Common sand, crushed agate, and small granules of iron, are used in cutting stone.

Fig. 2363.



Stone Cutting Machine.

Atchison's stone cutter, Fig. 2365, has two tools arranged in a strong head piece, attached to a moving platen, similar to the iron planing machine.

This platen, with the head-piece, is made to move forward and backward over the stone, and the tools, having a perpendicular, reciprocal, rotating motion, cut the surface at the rate of not less than 6,000 blows per minute. The tools are semi-circular in shape at the edge, and can be used constantly for at least forty-five minutes without changing; thus one set of tools will cut not less than 270,000 blows without re-sharpening.

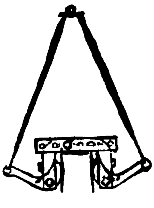
One man can operate three machines, and sharpen his own tools, which sharpening is done readily by the use of a "die."

Among the advantages claimed for this machine are: —

The slight cutting blows produced by this peculiar motion leave the surface "solid" and free from "stunning"; all "wind" or irregularity of surface is overcome, without the process of "sighting" or measuring; the edges of the stone are evenly and perfectly cut without "chipping." This principle is applied to machines for ornamental as well as plain work, in cutting moldings, cornices, ornaments, letters, etc., on all kinds of stones.

Stone Lift'er. Shepherd's lifter, Fig. 2364, has a pair of eccentric lever griping jaws, pivoted in a frame formed of two parts. These parts are adjustable along each other, and may be secured by pins so as to shift the jaws nearer together or further apart in order to adapt for different sized stones. The arms of the jaws are connected by chains to an eye plate, and to the latter the hoisting rope is attached.

Fig. 2364.

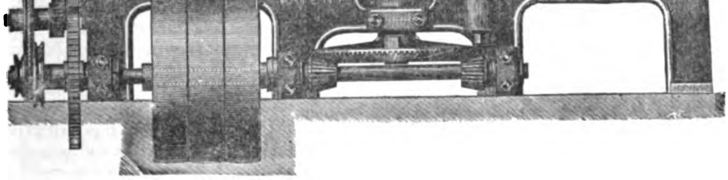


Stone Lifter.

Stone Mold'ing Ma-chine'. In Hunter & Fothergill's stone-molding machine the chief feature is the employment of cutting plates of different lengths, all lettered, so as to be easily picked out and set, like types, to mold. These being built on a shaft, revolve, and take out the rough or waste, comparatively near the mold, when a tool to profile passes several times over and finishes the work. The stone is laid on a cant-table to cant to the proper angle.

The tools in the planing and molding machines are fastened to holders that are bolted to the shafts. There is a pair of tools at each end of the holder. Although the holders, when fixed upon the shafts, act obliquely, as appears upon the stone passing under the cutters, and in such manner as seems incompatible with the production of any definite form, they are nevertheless so arranged, and so act as to turn out moldings of a large size, with many members, rough-cut, with great accuracy. The work is finished by being passed two or three times under cutting or scraping tools of the precise form of the molding to be produced. For a molding of many members, some of them deeply cut, more than one of these finishing-tools is sometimes employed. Mitred work is also executed by the machines with perfect accuracy.

Fig. 2365.



Hunter & Fothergill's Stone Molding Machine.

Stone Sep'a-ra-tor. A device invented by Higuette for removing stones and clods from grain. See STONE CLEANER, *supra*.

Stone Split'ting Ma-chine'. Brook's splitting machine has a row of upright square-shaped bars of steel, bevel-pointed, on which the stone sits. The steam hammer has a corresponding set, with a tooth immediately over each lower tooth. The sudden shock disintegrates the stone in the line of the teeth.

Stone'ware. (*Ceramics.*) *Grès cerame.* A class of ware which may be said to hold a middle place between hard porcelain and fine English faïence.

The paste is composed of fat clay with quartzose sand, and gives a very solid and strong ware, varying in color from a pearl gray to a brown red. It is dense and impermeable, and resists corrosion by acids, being specially adapted for table use.

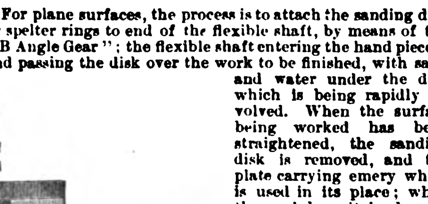
Fine varieties consist of ornamented objects made of a fine paste, white or of various colors, delicately fashioned and enriched with figures in relief, often in paste of another color.

Stone'ware Force-pump. One for pumping acids, bleach, alkalies, vinegar, or other liquids injurious to metals. The working parts are composed entirely of stone-ware, and the gland packed with asbestos.

Stone'ware Kiln. (*Ceramics.*) The stone ware is a reverberatory on the same principle as the common faïence furnace. See FAÏENCE.

Stone'-work'ing Em'e-ry Tools. In the tools shown in Fig. 2387 *A* is the sanding disk; *B* the "B Angle Gear," for emery wheels; *C* the "C Angle Gear," for buffing wheels; *D* fluting roll; *E* disk, for cutting medallions.

Fig. 2366.



Emery Tools.

For plane surfaces, the process is to attach the sanding disk or spelter rings to end of the flexible shaft, by means of the "B Angle Gear"; the flexible shaft entering the hand piece *F* and passing the disk over the work to be finished, with sand and water under the disk which is being rapidly revolved. When the surface being worked has been straightened, the sanding disk is removed, and the plate carrying emery wheel is used in its place; when the work has attained a sufficient smoothness, it is thoroughly cleaned, and then "buffed" by means of the disk shown in "Angle Gear *C*." This buffer is made of heavy felt, or similar material covered with canvas; it is revolved much more rapidly than either of the preceding disks, and the surface being finished is coated with "Tutty," during the operation; finally, a second buffing disk is used without the tutty, which brings the work up to completion. This process is varied somewhat with different grades of stones, but is in the main the plan adopted. The roll *D* is used for fluting work — as columns, edgings, moldings, etc., etc. A rough channel is cut where flute is desired, the roller placed in it, and rapidly revolved; sand and water is also used as with the sanding disks, and the roll is passed back and forth in the channel being cut. In this way channels of 12′ long can be cut and finished in a few minutes. *E* shows a corrugated disk for cutting medallions or rosettes in stone. They are attached to the "Angle Gear *B*," and held up to the work to be done; used as sanding disks they cut rapidly and effectually, doing their work at a very low price.

Ston′ing. (*Leather.*) Driving the stock stone over the leather to remove inequalities, stretch it, and render the grain smooth.

Ston′ing Jack. (*Leather.*) A machine in which the jack is furnished with a stock stone to work the leather.

Stope. (*Mining.*) One of a series of steps or beds into which the upper surface of an excavation is cut; to excavate in the form of steps above a drift.

Sto′ping. (*Mining.*) The act of stoping or breaking down the surface of an excavation with a pick.

Sto′ping Drill. (*Mining.*) One for excavating drifts or horizontally lying beds or steps. Fig. 2367 represents a stoping drill mounted on a column, with a claw-foot and and a jack-screw at top for securing the same in an upright position. This is peculiarly adapted to small tunnels, adits, and stopes, from 4½′ × 6′ to 6′ × 6′ or even larger drifts, and is a simple, cheap, and good arrangement for the desired purpose.

Fig. 2367.

Drill Mounted for Shaft Work.

Stop Plate. A metallic plate in the inside of a journal-box which forms an end-bearing for the axle and checks its end-motion. The plate is either held in position by flanges cast in the box, or is attached to the journal bearing or its key. — *Forney.*

Stop Watch. A time-piece registering seconds and minutes, used in making tests for density.

Goodwin's "American Gas-light Journal," * July 3, 1876, p. 7.
Minute clock, *Ibid.*

A time-piece marking fractions of a second which can be stopped instantly by pressure on a pin.

Stor′age Bat′te-ry. (*Electricity.*) A secondary battery. A galvanic battery devised to act as a conservator of electric force to be withdrawn as required. See *Hinston & Thomson's* battery, "*Journal Franklin Inst.,*" 1880, noted in "*Manufacturer and Builder,*" * xii. 36.

The Faure battery is thus described in the London "*Times*": —

A Faure battery (improvement on Planté's *pile secondaire*) was charged with the electric fluid direct from the ordinary Grove battery. The receptacle consists of four Faure batteries each about 5″ diameter and 10″ high, forming a cylindrical leaden vessel and containing alternate strips of metallic lead and minium wrapped in felt and rolled into a spiral wetted with acidulated water, and the whole placed in a square wooden box, measuring about 1′ cubic and weighing 75 pounds. This was protected by a loose wooden cover through which the leaden electrodes protruded, they being flattened down for convenience of transport.

This box of "electric energy" was sent by M. Faure, in Paris, to Sir Wm. Thomson, in Glasgow, where the "box of electricity," was received intact and potent, holding by measurement within that small space of 1′ cubic a power equivalent to nearly 1,000,000 foot-pounds.

Storm Valve. A screw-down valve to supersede the duty of a gravitating valve in a ship's side during bad weather.

Stove Truck. A truck to run under a stove, having a platform operated by a lever to raise the stove off its feet. The lever is then locked and used as a handle to guide the truck.

Straight′en-ing Block. The anvil on which buckled saws are straightened.

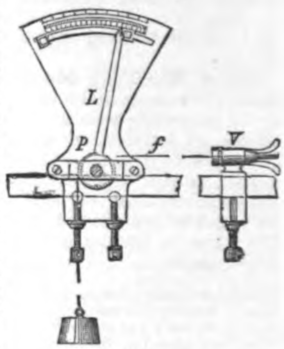
Strain In′di-ca′tor. An instrument for determining by optical means the extension or compression of materials under strain.

Stromeyer . . . . . . * "*Engineering,*" xxx. 337.

Strain Meas′ur-er. An apparatus designed to measure directly the strains to which the different parts of any structure are submitted. It will operate in any position whatever, and under all possible conditions, multiplying the amount of flexure itself, — a result not always obtained in apparatus of this nature.

A metallic wire, *f*, is attached at one end to a winged nut, *V*, which allows of the instrument being adjusted for use. This wire passes over a pulley, *p*, and carries a counterpoise. To keep it from slipping it is held by a small clamp placed in the channel of the pulley. The latter carries an index needle, *L*, which multiplies the distance traversed by its circumference ten times, and the extremity of which moves across an arc graduated in millimeters. The index needle also moves two slides which show the maximum of elongation or compression. The apparatus and the screw to which the wire is attached are mounted in two different ways, one designed to fasten the whole to a truss rod or to the foot of a T-iron, and the other to attach the apparatus to any ordinary surface. The apparatus having been placed in position, the index having been brought to zero, and the wire being kept at a uniform tension by the weight, it will be seen that if the object to which it is attached elongates or shortens, the pulley will be actuated by the wire, and the lever *L* will multiply the actual amount of the strain exerted. To study maximum strains the two sliders are moved up against the extremity of the needle. The apparatus may be used on parts of a structure inclined at any angle whatever. The sensitiveness of the apparatus may be known when it is stated that a lighted match placed under the wire will cause the needle to be immediately deflected one, two, and three millimeters. See Fig. 2368.

Fig. 2368.



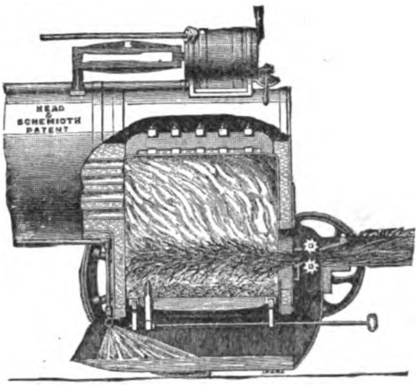
Strain Measurer.

Strap. (*Nautical.*) Or *strop*. The band of iron or rope which goes around a tackle-block.

Strass. (*Glass.*) A variety of lead glass made for imitating gems.

Straw′-burn′ing En′gine. An engine to enable persons residing in countries where coal and wood are not indigenous, or are only to be obtained at a great cost, to generate steam from the vegetable products on their estate. In Russia, Hungary, and on the borders of the Danube, this engine has been found to economize from 30 to 40 francs per day by using the refuse straw instead of coal and wood. In Egypt it is used for working the irrigating machinery of the cotton fields with the refuse cotton stalks, and actual practice has shown that the refuse stalks of a crop of cotton are sufficient to generate steam for working the pumps for irrigating the land, consequently the land finds its own fuel for irrigation. In India these engines are used in the tea plantations for driving the machinery, and

Fig. 2369.



Straw Burning Engine.

the jungle grass which grows outside the tea-gardens is used as fuel instead of coal and wood. In some cases it is used for burning the refuse of the sugar-cane from the mills. See Fig. 2369.

Stream Fence. One across a water-gap. A common form has the panels pivoted permanently to the part at one side of the stream, while the other end is held by pins that will either break under the pressure of the freshet, or allow the end to rise when the stream reaches the board, and allow it to swing loose from the pins. Barbed wires are stretched in same manner with a floating block attached to the loose end.

Street Car. See STEAM STREET CAR, *supra.*

Street Car Mo'tors. See "*Scientific American Supplement,*" p. 2125, for an account of the early street-car efforts of *Latta* and *Todd;* the *Lamm* fireless locomotive at New Orleans; *Baxter's* engine with compound cylinders; *Grantham's* engine (Eng.) improved by *Wood.*

Loftus Perkins. Belgian street-car engine.
Société Métallurgique et Charbonnière, of Belgium.

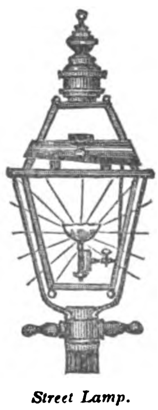
Merryweather.	*Hughes.*
Holt.	*Ransome.*
Baldwin, et al.	

See *Clark's* "*Tramways, their Construction and Working.*" London.
See also Mekarski compressed air street-car motor.*
Lamm & Francq fireless locomotive.*
"*Paris Exposition* (1878) *Reports,*"
*iv. 62-65
See STEAM STREET CAR.

Fig. 2370.



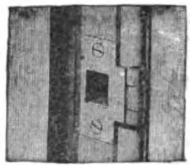
Street Lamp.

Street Lamp. Fig. 2370 shows a tank or reservoir, adjusted to the outside of a street lantern. Connected with the reservoir is a pipe and valve, to which is attached the solar gas burner. By means of a chemical process, the liquid, on its passage through this burner, is converted into gas, which gives a bright, steady flame.

The material used in making the gas is re-distilled naphtha of 72° to 74° gravity.

Strike. The piece on which the latch of a door impinges in closing.

Fig. 2371.



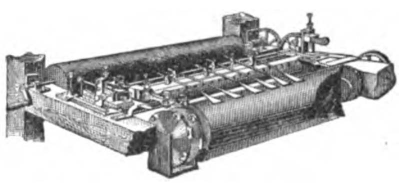
Strike.

Fig. 2371 has a roller for the bolt or latch to strike against, reducing the friction, and forcing the bolt back without noise.

(*Mining.*) The extension of a lode in a horizontal direction.

Stri'ker. The regulator which causes the pens of a ruling machine, in perpendicular work, to strike the head- or cross-line at regular intervals. In the illustration, Fig. 2372, are the cams with sloping corners for opera-

Fig. 2372.



Striker.

ting pen-beams and pens; the cams operating short line, the lifting arms and lifter; and the cam operating gate.

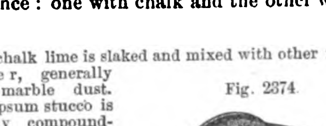
Stri'ker Plate. The nosing of a lock-keeper.

Strop. (*Nautical.*) Preferably *strap.* The band around a tackle-block.

Stub. 1. A blunt-pointed pen.

2. Short files for finishing in and around de-

Fig. 2373.



Stub.

pressions; has a holder fitting in top for parts where the fingers cannot get. See Fig. 2373.

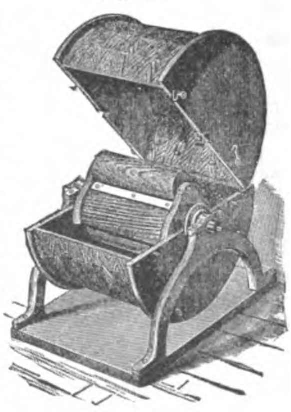
Stuc'co. There are two species of stucco used in France: one with chalk and the other with gypsum.

The chalk lime is slaked and mixed with other matters in powder, generally white marble dust. The gypsum stucco is similarly compounded, but is principally used in interiors. To imitate colored marbles the colors are added before the surface has entirely dried.

In Paris elaborate cornices and architectural moldings are made by forming them *in situ* by means of pattern gages or templets, projecting nails driven into the wall serving to hold the plaster in relief.

Polishing is done by a whetstone of fine grain, one hand holding a sponge with which the surface is occasionally wetted. The last polish is given by a piece of felt, saturated with oil.

Fig. 2374.



Stuffing Machine.

Stuf'fing. (*Leather.*) A mixture of tallow and either neat's foot oil or sperm oil, with which dampened leather is coated. The object is to render the leather supple and impervious to water.

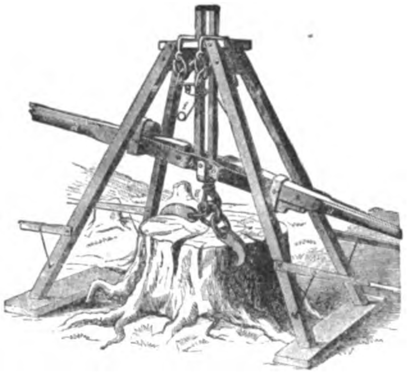
Stuf'fing Brush. (*Leather.*) A stiff brush used in stuffing leather.

Stuf'fing Ma-chine'. A steam chest into which the oil and tallow are introduced and rubbed into the leather by the action of rollers and beaters. See Fig. 2374.

Stull. (*Mining.*) A framework covered with timber or planks to support rubbish in working a stope.

Stump Ex-tract'or. In Fig. 2375, from the center of a tripod is suspended a ratchet wheel, over which a chain is loosely thrown, each link fitting in a corresponding groove. To this wheel a lever is attached, and so arranged that twenty pounds' power will raise, it is said, a ton. See Figs. 6011–6016, "*Mech. Dict.*"

Fig. 2375.



Stump Puller.

Stump pullers are of the lever and claw style, or the tackle, toggle, screw, windlass, or capstan order.

Stump Joint. The form of joint used in the folding carpenter's rule. The ends or stumps of the parts when in line, abut against each other, and allow movement in only one direction.

Sty'lo-graph'ic Pen. A reservoir pen, shaped like a pencil, in which the flow of ink is regulated by pressure of a style upon the paper.

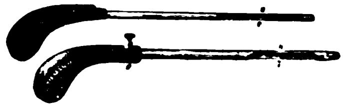
Sub'cu-ta'neous In'stru-ments. (*Surgical.*) See

Shrady's saw, knife, and bone rasp,	Fig. 87, Supplement.
Adams's saw	Figs. 10, 11, Supplement.
Knife	Fig. 9, Supplement.
Hypodermic syringe	Pages 70, 71, Part I.
Tiemann's "*Armamentarium Chirurgicum.*"	

Sub'cu-ta'ne-ous Saw. One to bare and roughen the ends of fragments in bony sections without injuring the flesh.

Fig. 2376 consists of a trocar, fenestrated canula, and staff, with handle and blunt extremity. A portion of this staff

Fig. 2376.



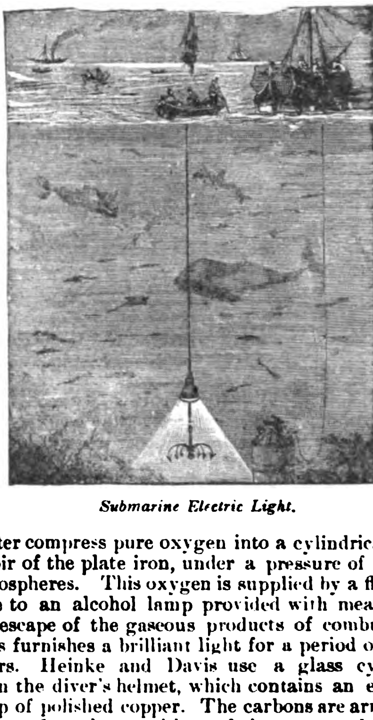
Subcutaneous Saw.

at a short distance from the extremity is flattened, one edge, *B*, being made into a knife-blade, and the other edge, *C*, being provided with saw-teeth. This staff is intended to replace the trocar in the canula after the latter is introduced. When in position, either the saw (*C*) or the knife (*B*) edge of the shaft, according to the way the latter is turned, corresponds with the opening in the canula.

Sub'li-ma'tion. (*Mining.*) The theory that the vein matter was introduced in a gaseous condition.

Sub'ma-rine' E-lec'tric Light Barnet and

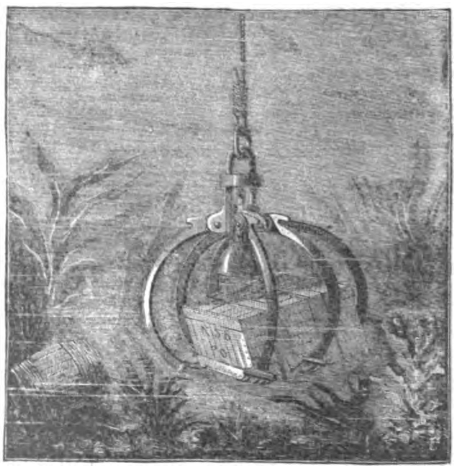
Fig. 2377.



Submarine Electric Light.

Foster compress pure oxygen into a cylindrical reservoir of the plate iron, under a pressure of thirty atmospheres. This oxygen is supplied by a flexible tube to an alcohol lamp provided with means for the escape of the gaseous products of combustion. This furnishes a brilliant light for a period of four hours. Heinke and Davis use a glass cylinder upon the diver's helmet, which contains an electric lamp of polished copper. The carbons are arranged to last four hours without being renewed. The whole apparatus weighs about 27 kilograms, and is capable of furnishing a light equivalent to 20 000 standard candles. See Fig. 2377.

Fig. 2378.



Submarine Grapple.

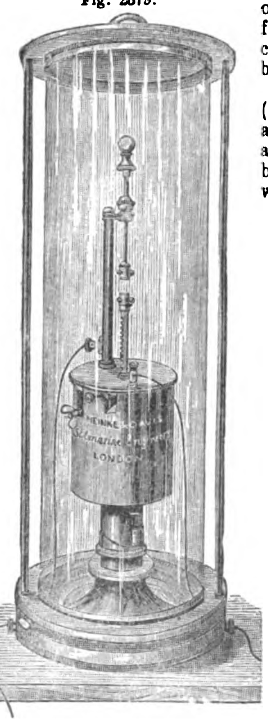
Sub'ma-rine' Grap'ple. For recovering articles on the ocean bed. In Fig. 2378 the grappling fingers pivoted in the head of the block are kept distended by the weight in the center. On the grappling of an article by one or more of the claws the weight is pulled up against the head, and the remainder of the claws close around the article.

Sub'ma-rine' Gun. Experiments on firing guns under water, with a view of sinking vessels by penetration of the hull below the water-line, extend over a long number of years. St. Cyr, 1797, suggested suspending a mortar between two boats. Fulton, 1814, succeeded in penetrating a bulk-head by a cannon fired under water. Philips, of Indiana, 1855, Woodbury, Boston, 1861–1864, arranged ports permitting guns to be fired from below the water-line. See "*Mech. Dict.*," p. 2439.

Sub'ma-rine' Lamp. One for explorations in the ocean's depths. The electric light has taken the place of the oil lights formerly used, requiring no tubes or pumping to supply air to the flame, and giving a sure and brilliant light. See Fig. 2379.

Suc'tion Fan. One for withdrawing the chaff and dirt from grain, or steam and hot air from meal as it comes from the burrs, by suction.

Fig. 2379.



Submarine Lamp.

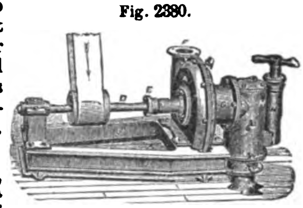
Suc'tion Pipe. (*Hyd. Eng.*) The air-tight pipe under a water-wheel, turbine for instance, which intervenes between it and the level of the tail race. Believed to be the invention of Z. and A. Parker, of Ohio, now common in Europe. It makes the wheel to be placed not exceeding 30′ above the tail race and yet render the whole fall available.

Suc'tion Pri'mer. A device to charge a steam pump ready for starting.

At the extreme right in Fig. 2380 is a small force-pump, worked by hand, used in charging the main pump. Before starting the large pump, the pet-cock, shown on the top of the shell, is opened, and the primer is worked until no more air is driven from the cock. When the pump is evidently full, the pet-cock is closed, and the main pump is then ready to be started.

The pump may be emptied by withdrawing the two screws shown near the top of the suction-pipe.

Fig. 2380.

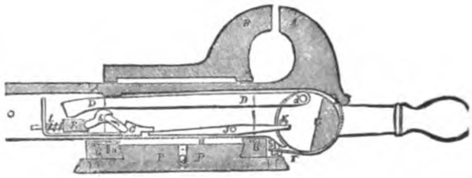


Suction Primer.

Sud'den Grip Vise. One that can be opened or closed the full play of the jaws without the tedium of turning up. See Fig. 2381.

To open the jaws, lift the handle to a horizontal position or as high as it will go, and draw towards you. To grasp the work, push in the sliding jaw until it presses against the work, then depress the handle, which causes the jaws to securely grasp the work and at the same time locks the swivel.

Fig. 2381.

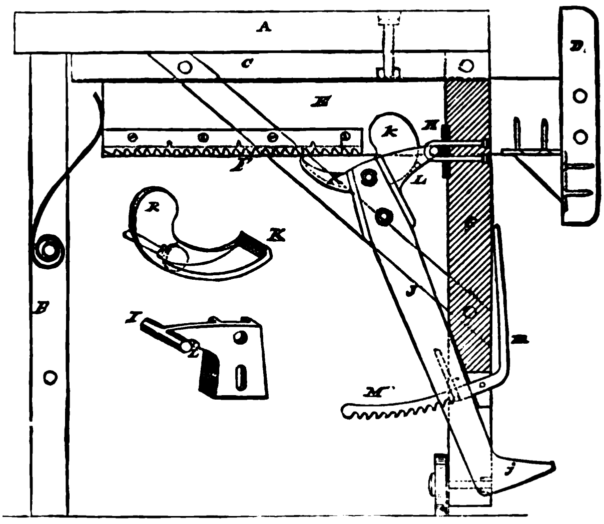


Sudden Grip Vise.

Fig. 2382 is a complementary vertical section of a bench vise devised by Messrs. G. H. and W. H. Knight, of Cincinnati.

The invention is an improvement on those bench vises whose movable jaw is capable of being quickly opened or closed by hand, and, after closure, of being clamped with great force so as to grip the work.

Fig. 2382



Improved Sudden Grip Vise.

A, is a bench top. *B*, a portion of supporting frame. *C*, a vise frame preferably capable of being swung horizontally about a vertical bolt *V*. *D* represents a movable jaw. *E* the customary wooden shaft of same. *F* is a metal rack fastened in a rebate on under side of jaw-shaft. *H*, a step or bearing in breast-board *G*, for fulcrum *I* of bent lever *J* having treadle projector *j*. *K*, a pawl, which when the lever is forced back by the operator, engages in rack *F*, and operates to press back the sliding jaw *D* with the great accumulating force of a toggle. *L*, a stud to hold pawl clear of rack when lever *J* is in normal or inactive position. *M*, a gravitating catch which, until released, holds lever *J* to its effective or gripping condition.

Sug'ar. For machines and processes, see pp. 2442–2452, "*Mech. Dict.*" J. W. Mallet's report, vol. iv., Group III., Centennial Exposition, summarizes the sugar making process as follows: —

CANE SUGAR.

Canes cut, and stripped of leaves.

Juice expressed from canes.

In presses with intermittent action (reciprocal motion).

In presses with continuous action (roller-mills).

Juice.

Bagasse.

Bagasse.

Juice.

Dried, used as fuel, and the ash as manure.

Returned to field as manure.

Macerated with water, or treated with steam, and again pressed.

Exhausted bagasse.

Weak saccharine liquid.

Might well be used as material for paper.

Canes cut into thin slices or chips by revolving knives.

Slices treated with water in a series of diffusion vessels.

Saccharine liquid from diffusion battery.

Exhausted chips (bagasse).

Dried in sun, used as fuel, and then ash as manure.

Spread upon land and plowed in as manure.

Cleared of fiber by settling in tanks.

Simply evaporated to dryness, producing "concrete," to be afterwards refined.

Liquid heated in clarifying-pans, with addition of lime (often of sulphurous acid, or calcium acid sulphite).

Skimmed.

Clear liquid, boiled down in open pans.

Scum.

Allowed to crystallize in coolers.

Drained in centrifugal machine.

Molasses. Reboiled for 2d products, used as food, or to make rum.

Soft centrifugal sugar.

Transferred to potting casks, and drained.

Molasses. Reboiled for 2d products, used as food, or to make rum.

Soft brown sugar (often called muscovado).

Transferred to forms or molds, and drained.

Clayed or washed.

Molasses and drainings. Reboiled for 2d products, used as food or to make rum.

Clayed sugar.

Skimmed, and run through coarse bag filters.

Scum.

Used to make rum (often thrown away).

Clear liquid, filtered through animal charcoal (either now or after partial evaporation).

Boiled down (sulphurous acid sometimes added).

In open pans.

Partly in open, partly in vacuum-pan.

In vacuum-pan.

Allowed to crystallize.

partially in pan, then in coolers.

Transferred to forms or molds, and drained.

Sugar. Washed with a little water or syrup.

Form sugar (nearly white).

Green syrup.

Drainings.

Drained in centrifugal machine.

Green syrup.

Used as food.

Drainings.

Returned to battery, to be reboiled.

Sugar. Washed with a little water or syrup.

Centrifugal sugar crystals (nearly white).

SUGAR REFINING. (CANE OR BEET.)

Raw sugar sifted free from lumps and trash.

Melted down with water (adding a little lime-water).

Clarified by addition of bullock's blood and fine animal charcoal, and heating (sulphurous acid now often used to save blood, and this step very often omitted altogether).

Drawn off, and filtered through bag filter.

Filtered through animal charcoal.

Boiled down in vacuum-pan.

(Filtration repeated, and boiling continued.)

Crystallized in coolers (ultramarine added if necessary for color).

Crystallized partially in pan.

Boiled down dry in pan (only applicable in case of purest syrups)

Transferred to molds, and drained.

Green syrup.

Reboiled, yielding at length molasses.

Used as food

Loaf-sugar.

Clayed, or washed.

Removed from molds, inverted, and dried.

Sugar loaves trimmed by cutting-knives.

Drained in centrifugal machine.

Centrifugal sugar crystals.

Washed.

Green syrup.

Used as food.

Reboiled, yielding at length molasses.

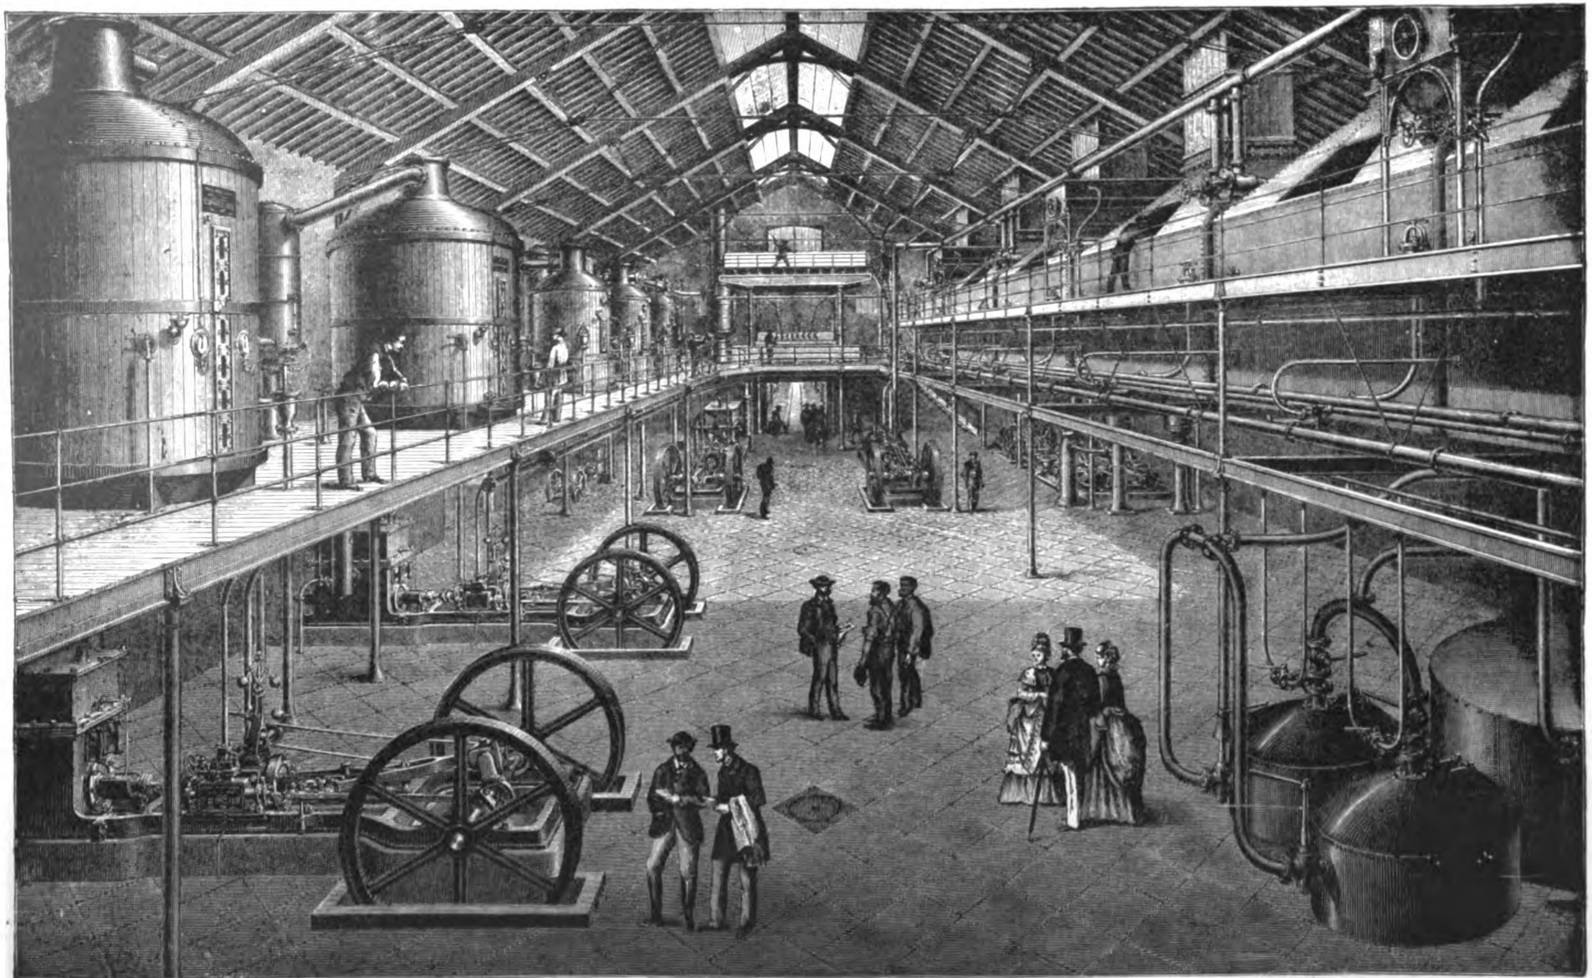


PLATE XLVII. SUGAR-HOUSE, COMPLETE INSTALLATION OF MACHINERY (COMPAGNIE DE FIVES LILLE, ABBEVILLE, FRANCE.) See page 878.

Su'gar House. Plate XLVI. represents a complete sugar house as manufactured by the *Compagnie de Fives Lille*, at Abbeville, France.

This company has built apparatus for operating on sugar-cane, for Java, Reunion, Brazil, the West Indies, and Egypt In the latter country one establishment, on account of the Khedive, is adapted to work 1,800 *tonnes* (Fr.) in 24 hours.

In an iron building 11,100 square meters in superficies are arranged —

4 cane mills.
2 vacuum pan apparatus, *à triple effet.*
4 vacuum pans.
60 centrifugal filters.
2 stills and apparatus.
3 rectifiers.

And various accessories for the crystallization of the sugar, fermentation of the molasses, revivification of the animal black, gasworks for lighting.

Repair shops.

A battery of steam boilers of collective force of 2,600 horse-power, to furnish the motive force, and the heat for the apparatus, is heated by the bagasse.

Railways of a total length of 22 kilometers, with the necessary locomotives and rolling stock, bring 250,000 kilos of cane each 24 hours to the mills. The mill has cylinders of 800 millimeters diameter, with an endless apron cane conductor 30 meters long, and a bagasse conductor of 12 meters.

The vacuum apparatus *à triple effet*, similar to the one shown in the far-end of the gallery to the left, in the plate, will concentrate to a density of 29° Beaumé, 2,200 hectoliters of juice per 24 hours. It is composed of three pans of different diameters, with tubular heating coils presenting a total heating surface of 300 square meters. A circumferential distribution of the vapor is secured by means of an envelope of perforated sheet metal interposed between the cluster of tubes and the exterior walls of the vacuum pan. By means of a central vertical tube of large diameter placed in the pan the juice is caused to circulate rapidly, and great activity given to the evaporation by bringing fresh quantities of juice in contact with the heating surface. Systems of pipes and cocks form communication between the juice and the vapor departments of each pan, so that the work proceeds in continuous order in the series of pans upon the juice which flows through them in succession.

An economy of 60 per cent is claimed to be realized in this apparatus over the single acting pan. An aspirator, feeding the first pan of the series, takes the place of the *monte-jus*: a vacuum chamber placed behind the third pan serves as a *réservoir d'aspiration* to a pump which elevates the sirups at 25° B. into the filters; a tubular condenser has a double action, in condensing a portion of the vapor in the third pan it heats the incoming juice to a temperature of 35° to 40° C.: the other portion of the vapor is condensed by an injection condenser; the apparatus is completed by a double-acting air pump, an aspirating sirup pump, and a pump for the water of condensation.

The plate shows a complete installation of apparatus for the treatment of beet-root juice for the manufacture of sugar, as manufactured by the *Compagnie des Fives Lille*. The establishments where the beets are rasped and the pulp pressed are situated at a distance, and the juice is conveyed by subterranean pipe-lines to the centrally situated sugar factory; the system of Linard, as described by Maumene in his "*Traité de la Fabrication du Sucre*," page 207, *et seq.*

The cartage of beet-roots is very heavy and injurious to the roads, and the area of beet culture which can be made tributary to a single sugar factory is not very large, and had been so frequently reached that it became necessary to devise other means of transportation. Hence the pipe-lines of Linard. Since 1867, the year of the establishment of the first pipe-line at Mont Cornet (*Aisne*), having a length of 8 kilometers, beet rasping works have been constructed in increasing numbers and at greater distances. There were in existence in 1875, 240 of these lines. One of them serves a factory 32 kilometers (20 miles) distant.

The juice should be limed at the works, as it cannot without injury be poured into the pipes in its natural condition. One per cent. lime is employed, which is immediately dissolved, and prevents all alteration of the juice in its travel. By the process adopted by Maumené the juice may even be kept several years without injury, and the liming to the extent of 1 per cent. is a modified application of the process. Derosne, about 1811, was the first to suggest quicklime in the purification of the juice, and the lime kiln or furnace, both for the milk of lime used in the preliminary treatment and for the production of gas for the subsequent carbonation of the lime in a subsequent part of the treatment, is a constant feature in the immense *sucreries* which dot the landscape in the northern part of France and the south of Belgium.

After liming, the juice is allowed to repose for 24 hours and then the limpid liquid is pumped into the pipe, which is buried below the line of frost, and reaches from the *râperie* to the *sucrerie*. The pipe may vary from 2.5'' to 5'' in diameter, according to the amount of juice to be delivered, generally along a roadside, where the *cantonnier* can observe any leak, which always shows itself at the surface of the ground. The highest parts of the conduit are provided with air traps to allow air to escape and avoid (*coups de belier*) concussion. See AIR TRAP.

The condition of the juice is verified from time to time, on arriving at the factory, to determine the proportions of lime added.

The advantages of the pipe-line system consist in spreading the work, as the rasping and pressing require a much larger number of men than the subsequent operations, and they are left in their villages near to their work and their fields; the saving in hauling and deterioration of the roads; leaving the pulp on the farms for cattle and sheep feed; the convenience of buying the juice by the saccharometer degree instead of by the weight of the beets of such varying qualities.

The conduit is used about 4 months, the length of the beet-working season.

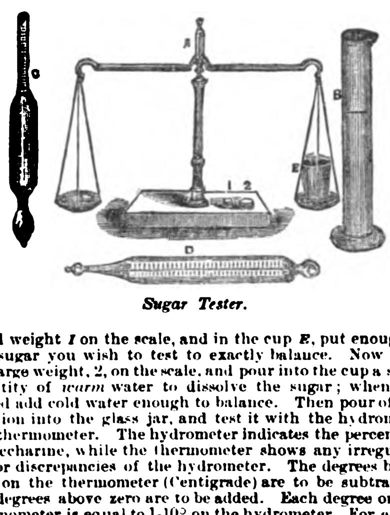
The apparatus shown in the plate will work up the juice of 80,000,000 kilos of beets in a season of three months. It employs carbonating boilers of 300 hectoliters capacity; the vacuum pan, *à triple effet*, will concentrate 10,000 hectoliters of juice in 24 hours

Su'gar Spile. A spile or spout driven into the sugar-tree to conduct the sugar-water or sap to the bucket. Commonly made of alder, although the iron spile to hang the bucket on is extensively used.

Su'gar Test'er. Apparatus for testing grape sugar.

In using, place the metallic cup, in Fig. 2383, on the scale, and balance it with weight not numbered. Then place the

Fig. 2383



Sugar Tester.

small weight *1* on the scale, and in the cup *E*, put enough of the sugar you wish to test to exactly balance. Now place the large weight, 2, on the scale, and pour into the cup a small quantity of *warm* water to dissolve the sugar; when dissolved add cold water enough to balance. Then pour off the solution into the glass jar, and test it with the hydrometer and thermometer. The hydrometer indicates the percentage of saccharine, while the thermometer shows any irregularities or discrepancies of the hydrometer. The degrees below zero on the thermometer (Centigrade) are to be subtracted, the degrees above zero are to be added. Each degree on the thermometer is equal to 1-10° on the hydrometer. For example, the hydrometer indicates 85°, the thermometer 8° above zero. This 8 is to be added to 85, making 85 and 8-10 per cent. If the thermometer should indicate 8 below, it would be necessary to deduct .8 from 85, which would make it 84.2°.

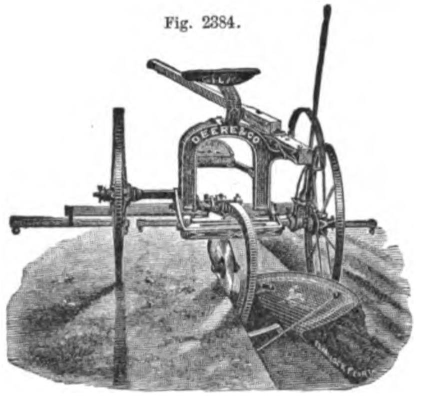
Sul'ky Plow. The Deere & Co.'s Gilpin Sulky Plow, Fig. 2384, is an iron and steel plow with the exception of the tongue and eveners. It is usually drawn by three horses abreast, one horse and one wheel in the furrow.

The team is hitched directly to the end of the plow beam in the natural way, and the plow is operated by a single lever, that locks it in the ground at various depths, so that it cannot jump out on encountering clods and trash.

The sulky plow of the Sacket Plow and Pulverizer Co., of New York, has two plows so arranged and run that one plow skims off the surface sods, stubble, and weeds, and throws them into the bottom of the previous furrow, where they are pressed down and cut by an iron wheel with curved knives, or sharp-edged cross-bars, around its rim.

Following this skim plow is a main plow, which takes up

Fig. 2384.



The Deere Sulky Plow.

the cleared soil to any depth desired, and throws it inside of the iron pulverizing wheel. As this wheel rolls along, the soil is lifted and thrown against its cutting bars and points, and these pare and break it finely, dropping it out loosely behind, putting not an ounce of pressure upon it, but leaving it light and porous and aërated (filled with air).

Sul'phate of Lead Bat'te-ry. (*Electricity.*) The invention of M. Becquerel; consisting of zinc in sulphate of zinc, and lead in sulphate of lead. As improved by Marie-Davy, it consists of a vertical series of tinned iron pans; each pan has a zinc disk fastened beneath it, and is coated inside with pulverized sulphate of lead, moistened with water. The battery is put in operation by pouring water into the pans.

Prescott's "*Electricity*" . . . . * 79.
Niaudet, American translation . . . . 150.
Moseley's modification, "*English Mechanic*" . . * xxiv. 463.

Sul'phate of Mer'cu-ry Bat'te-ry. (*Electricity.*) A battery in which sulphate of mercury is the exciting solution. See MERCURY BATTERY; MARIE-DAVY BATTERY.

Beaufil's sulphate of mercury battery has a solid depolarizer. — "*Teleg. Jour.*," * vi. 397.

Sul'phur and Am-mo'ni-a Test. In order to detect ammonia or sulphuretted hydrogen in illuminating gas it is only necessary to allow a jet of the gas to blow upon a piece of turmeric or reddened litmus paper to ascertain the presence of the former, or upon acetate of lead paper for the latter.

Dr. Letheby's sulphur testing apparatus is a meter with dial arranged to show any consumption from .01 to 1,000 cubic feet, a double dry governor fitted with a regulating cock to maintain an unvarying rate of consumption under the usual street pressure, connected to tube passing through the stand, and leading to a Leslie burner, under which stands a glass beaker containing the requisite quantity of standard liquid ammonia. On this beaker is placed a glass funnel passing up through the burner, and covering it is a trumpet-shaped glass tube gradually decreasing to about ¾" aperture at the top, where it passes through the neck of the large glass cylinder, which has a bent glass tube at the other end rising at an angle of about 45°, the rate of consumption being one cubic foot per hour. An apparatus for ammonia can be supplied with the above, consisting of an ammonia tube, with bulb, etc., at a small additional cost, as the meter and governor can be used — proper connections being made — to pass the gas through the meter "after" the ammonia apparatus.

Sul'phur Con'crete. Mix together 19 lbs. sulphur and 42 lbs. pulverized stoneware and glass. This mixture is exposed to gentle heat until the sulphur melts, when the mass is stirred until it has become thoroughly homogeneous and is then run into molds and permitted to cool. When required for use, it is to be heated to 248° Fah., at which temperature it melts, and may be employed in the usual manner.

At 230° Fah. it becomes as hard as stone, and, it is said, preserves its solidity in boiling water, unites stone, is waterproof, resists acids.

Sul'phu-rine. A new metallic compound. Sulphides of metals, combined with molten sulphur, form a liquid, which on cooling becomes a homogeneous mass of dark gray color and possessing great tenacity, while it is not affected by the atmosphere, and resists acids and alkalies well. It has a comparatively low melting point, 320° Fah., and expands in cooling so that it fills molds very accurately, so well indeed that the marks of a finger on a plate of glass are reproduced. Experiments are being made to test its adaptability for printing and stereotyping purposes, and casts from gelatine molds have been made without destroying them.

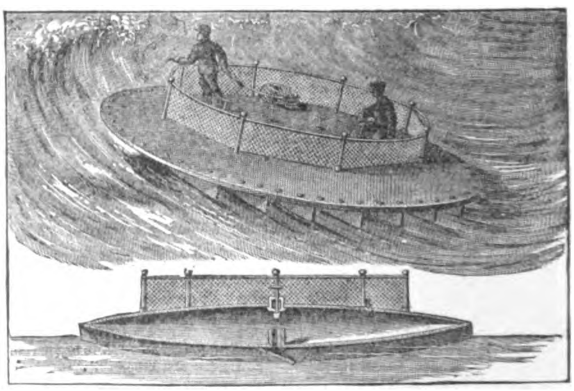
Sump. (*Mining.*) That part of the shaft below the platform used for receiving water.

Sun Burn'er. A burner for a mineral-oil lamp, provided with a chimney that is wide at its base, and held in place by a thin circular metallic plate, cut with indentations around its outer edge, the metallic points acting as springs to hold the chimney in place.

Surf Boat. Fig. 2385 represents a novel surf boat, the invention of Mr. Richard Tucker of Wiscasset. It is a circular boat, with convex upper and lower surfaces, and its entire interior forms a reservoir for holding compressed air to be used in the propulsion of the boat.

The propelling device consists in air nozzles projecting towards the stern, one being placed in each space between the keels, of which there are several. The air nozzles have valves that are operated from the deck. The boat is steered by closing the air valves on one side or the other, as may be required.

Fig. 2385.



Surf Boat.

Sur'face Con-den'ser. One form of surface condenser is recommended by Appleby, where the supply of water is limited or costly, a good vacuum being stated to be more readily attainable by it than by any other method of condensation. As it is a circulating system in which the boiler is supplied from the hot well, the loss of water from steam passing into the atmosphere is but small, and the saving in the avoidance of scale is a marked advantage in some localities. It is used for steam engines, vacuum pans, and elsewhere, when a vacuum is desirable.

The condenser is a vertical series of horizontal copper steam pipes, with cushion boxes at each end connecting with vertical hollow columns. Above is a copper trough with serrated edges, from which water trickles down over the pipes and falls eventually into the hot well from which the boiler is supplied.

The idea has been developed for some time in various branches

The ordinary tubular condenser, in which the coil is submerged in a cistern of cold water, differs in substantial respects (Fig. 1415, "*Mech. Dict.*"), and the condenser for alcoholic vapors of sugar has also the cistern in which the coil is submerged.

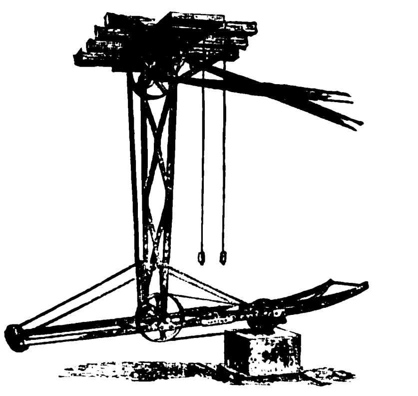
The Derosne condenser, however (Fig. 1421, "*Mech. Dict.*"), one of the train in the sugar apparatus, has the same appearance as the Appleby steam condenser, but their purpose and application are essentially different. In the Derosne the pipes are heated by steam, and the sugar-cane juice from the defecator trickles over them, being heated and partially evaporated on its way to the vacuum pan.

In Appleby's the steam in the pipes is condensed to form a partial vacuum in front of the piston, and the water heated thereby supplies the boiler.

For other systems of pipes in somewhat similar relation, see BEER COOLER, Fig. 631, "*Mech. Dict.*"; LIQUID COOLER, Figs. 2966–2968, "*Mech. Dict.*"; WORT COOLER, Figs. 7360–7372, 7364, "*Mech. Dict.*," etc.

Sur'face Grind'ing Ma-chine'. Thomson's surface grinder, Fig. 2386, has, depending from overhead, driving arrangements, constructed to grind and buff the surfaces of work too large or heavy to be taken to the ordinary grinding machines.

Fig. 2386.



Thomson, Sterne, & Co.'s (Glasgow, Scotland), Surface Grinding Machine.

The illustration, Fig. 2385, shows the machine in position for finishing the exterior of a fire-proof safe, which is run beneath it upon a truck.

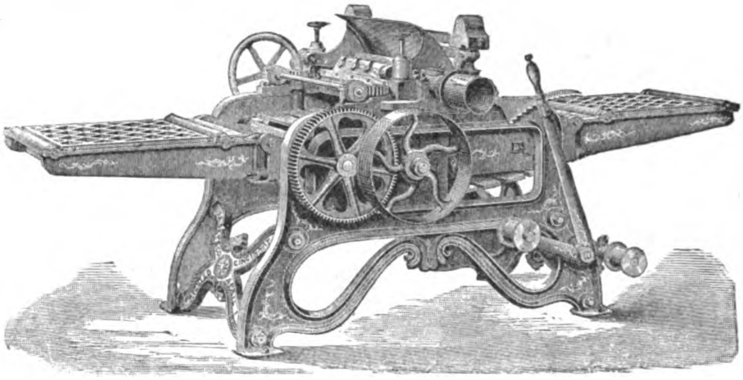
The machine carries a consolidated emery wheel 14″ in diameter by 2″ broad. When required for buffing, the emery wheel is removed and a buff-wheel with spindle and pulley complete put in its place.

The machine carries its own countershaft with fast and loose pulleys. The frame and grinding wheel are balanced by the weight at the opposite end of the frame, so that the operator has easy and complete control in moving the grinder or buffer backward and forward over the work, while the latter is moved sideways on the carriage, which traverses on rails.

Sur'face Mold'ing Ma-chine'. Boult's carver and moulder has a quick, reverse motion and double-edge cutters, cutting designs, either plain or molded, on the surface of the lumber in the solid wood. It molds any production of the scroll saw. It routs for stairs and pew ends, grooves and grounds for inlaying, and veins and traces for carving.

Sur'face Pla'ner. The Farrar surface planer, Fig. 2387, is a machine of a large size, intended for planing-mills, boat builders, etc. It has a stationary cylinder, convenient to have the countershaft either on the floor or overhead. It carries three knives with steel-lip chip breakers and steel journals, with pulley for two driving belts running in self-oiling boxes, with a wrought-iron bonnet, that can be swung clear of the cutters. The rollers have folding weighted levers that are self-adjusting to the thickness of lumber.

Fig. 2387.



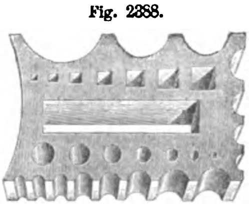
Surface Planer.

Sus-pen'sion Ap'pa-ra'tus. (*Surgical.*) To support a wounded, luxated, or fractured limb. Generally a splint with means of suspension from a frame. Illustrations of the following are in *Tiemann's "Armamentarium Chirurgicum,"* Part IV.: —

Smith's anterior splint for the leg, Figs. 120, 154.
Hogden's suspending apparatus, Fig. 130.
Salt's cradle or swing, Fig. 156.
Clark's suspended splint, Fig. 157.
Buck's suspension apparatus, Fig. 174.
Sayre's suspension apparatus, Figs. 193, 194.

Swage Block. A large perforated and indented iron block for swaging iron into its desired shape. See Fig. 2388.

Fig. 2388.



Swage Block.

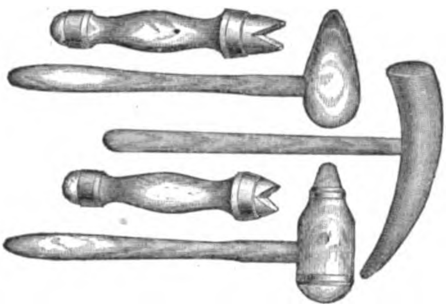
Swa'ging Mal'let. A tool for swaging up artificial plates. Fig. 2388 represents formers used in silversmith's work.

Swan'-neck Nee'dle For'ceps. (*Surgical.*) An instrument for use through curved passages difficult to reach.

Swash Plate. A plate set obliquely on its axis and acting as a cam in a line parallel to the shaft.

Sweat Rol'ling Ma-chine'. A machine for turning the edge of the sweat-leather lining of hats to prevent its marking or hurting the forehead.

Fig. 2389.



Swaging Mallets.

The machine has two rollers geared together and supported in a frame, the upper one held down by a rubber spring to allow it to yield to the varying thickness of the leather.

Sweat Sew'ing Ma-chine'. A machine for sewing the sweat lining in hats. See Fig. 2390.

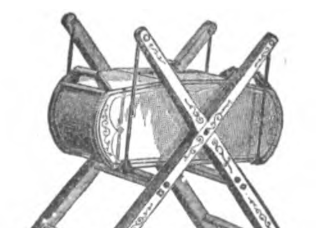
Fig. 2390.

Sweat Sewing Machine.

Sweep. (*Agric.*) A kind of plow used in cultivating crops planted in rows, corn or cotton for instance. The term is especially applied in cotton cultivation, the share or shares being wide and cultivating a wide space to a moderate depth. By the inclination of the share to the line of draft the soil is cast sideways and may throw it either away from the plants while small or towards the row when they are more advanced. See COTTON SWEEP.

Sweep Rake. The rake that clears the table of a self-rake reaper.

Fig. 2391.



Swing Churn.

Swing Churn. A box churn suspended on the pivoted bed irons of the folding frame on which it swings. See Fig. 2391.

Swing'ing Valve. A swinging straightaway check valve. The clapper swings on a pin loosely, and the disk being made separately can be ground in the same as other valves.

Swing Mo'tion Gear. (*Railway.*) The arrangement of parts, — consisting of bolster, spring-plank, swing-hangers, pivots, and pins, — supporting the springs and truck-bolsters by which a car is enabled to swing laterally on the truck.

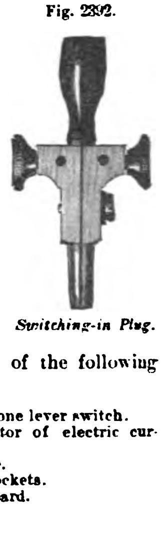
Swing Saw. The swing cut-off saw is used for cutting up stuff for packing boxes, etc. It has counter shaft, hangers, and pulleys.

Switch. For descriptions of switches, crossings, turn-outs, and frogs on Pennsylvania Railroad, see report of *F. Slataper*. "*Centennial Exhibition Reports*," vol. vi., Group XVIII., p. 68.

Switch'ing Eye. (*Railway.*) A cast-iron socket on the corner of a freight car to which a chain or push bar may be applied by an engine on an adjoining track.

Switch-ing-in' Plug. (*Electricity.*) A plug having its two brass sides insulated from each other by a strip of hard rubber and provided with a handle of the same material. The sides are adapted by binding screws to be connected respectively with the terminals of a loop or relay circuit so that when thrust into a plug-hole the two sides of which are similarly insulated and connected with the line terminals, the said loop and line will be in one circuit.

Fig. 2392.



Switching-in Plug.

Switch Ta'ble. The Jones (Fig. 2393) is a telephone exchange switch board or table through which all the subscribers can at any time communicate with each other. It is composed of the following component parts : —

Plug plates.	Telephone lever switch.
Plug connectors with flexible cords.	Generator of electric current.
Drop or electrical indicator.	Treadle.
Spring jack.	Plug sockets.
Engine or generator key.	Key board.
Telephone key.	
See TELEPHONE.	

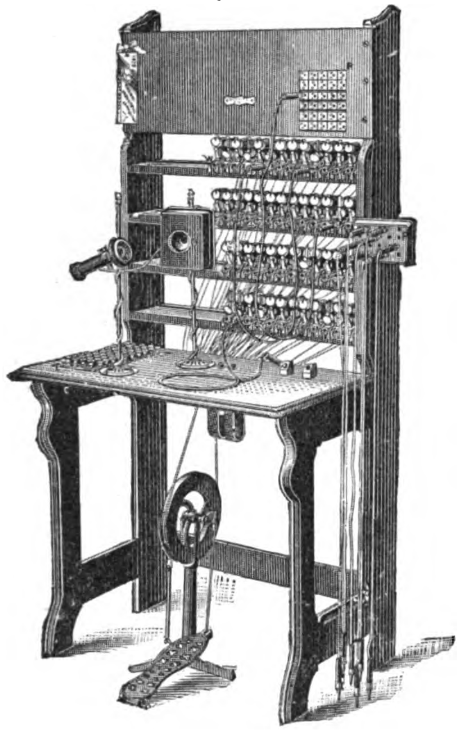
From the instrument of every subscriber in the city a wire is run to the exchange. When a subscriber wants to talk to any other subscriber, he calls up the Exchange by ringing his bell. The Exchange answers, finds out what he wants and who he wants to talk to, calls up that person, and connects or "switches" their wires together; then signals to subscriber No. 1 that he can go ahead and converse with No. 2, and leaves them to talk together as long as they please. When they are through, they signal to the Exchange, and he disconnects them. When it is stated that the average number of "switches" made in the twenty-four hours, in Cincinnati, is 6,000, it will be seen to what an extent the business has grown.

The "switch" tables, of which there are twelve in the Cincinnati Exchange, are in form of a common writing table, with a square frame standing up in front of the operator and fastened to the table. To this frame run the wires brought into the office through the cupola, each one of which is ticketed with the name of the subscriber to whose instrument it is attached.

In each frame are from forty to fifty magnets to which these wires are connected. These act as holders for the wires, and are numbered. Thus one end of each subscriber's wire is attached to the instrument in his office or home, and the other is fastened to this frame or the switch-board. The operator at every board knows the number of each subscriber. On the front of the frame facing the operator are a number of clamps, one to each magnet. There is also attached to each magnet a movable piece of metal, which works automatically. This is the marker, which tells the operator which line calls him, as it drops when the bell at the other end of the line is rung.

Underneath the table is a machine worked by a treadle, which generates the electric current by friction, and is con-

Fig. 2393.

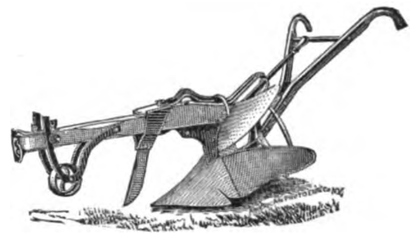


Switch Table.

nected by a wire with a clamp on the table On the table is a key-board, like the key-board of a type-writer. It contains two large keys and a number of small ones corresponding to the number of wires on the frame. One of the large keys is connected with the generator and the other with the telephone, which is fixed on an upright fastened to the table within reach of the operator's ear, leaving him at liberty to use both hands. Hanging on a hook within reach of each table are a number of loops or sections of flexible covered wire with a brass point at each end. This, with a microphone, also on the table, is the apparatus. Now as to how it is used. We will, to illustrate, take the first table, on which the connecting wires are numbered from 1 to 40. Suppose Mr. A. has the telephone No. 1 and Mr. B the telephone No. 25, and that A wants to talk with B. He goes to his instrument and rings the bell. At that instant the little marker attached to wire No. 1 in the Exchange rattles and falls, attracting the operator's attention. He has one of his loops attached by one point to the clamp on his table connected with the generator and as soon as he gets the call takes the other point and inserts it in the clamp attached to wire No. 1, thus connecting the latter with the generator. At the same time he works the treadle and generates a current of electricity, which, by pressing on one of the large keys, he directs into wire No. 1. At the instant he presses this key the current passes over the wire and rings A's bell. The operator slips his finger to the other large key, and applying his ear to the telephone, and speaking at the microphone, says, "Hello!" A, when he hears his bell ring, takes his telephone in hand, and, applying it to his ear, hears the "hello," and calls to the operator, "Put me on Mr. B," or "Connect me with Mr. B." The operator answers, "All right," and proceeds to call up B by directing a current of electricity from the generator through a loop, the point of which he has inserted in the clamp connecting with B's wire. This current rings B's bell. He goes to his instrument, rings back an answer, his marker rattles and drops, and the operator, connecting his telephone with B's, as he did with A's, calls to him that A wants to talk with him. He then connects the two wires, 1 and 25, together by means of a loop, the opposite points of which are in the two clamps connected with their wires. This forms a continuous wire between the telephones of A and B, and the operator, having called to A — who has held his telephone to his ear — that B is ready, they go on with their conversation. By pressing either key No. 1 or key No. 2 on the key-board and keeping his ear at the telephone the operator can hear their conversation. He listens for a moment to satisfy himself that their communication is uninterrupted and then takes his finger off the key. When A and B are through they inform the operator by tap of the bell and he takes away the loop connecting their wires, disconnecting them. Though the operation takes some time in describing, it is very quickly done, not occupying more than a minute if the owners of each telephone are prompt in answering his call. The only delay is with them. The operator is always at his post, and can switch two parties together in a few seconds if they answer as soon as called.

Swiv'el Plow. A reversible mold-board of full size is so arranged on its swivel attachment that in connection with the point it makes also a landside plow. See Fig. 2394.

Fig. 2394.



Swivel Plow.

Swiv'el Ta'ble Clamp. One intended for the attachment of jeweler or amateur vises, without injury to the article to which they are attached. With it the vise can be clamped firmly to any kind of table, mantel, or projection.

Sword Mat. (*Nautical.*) A mat worked with a blade like a sword to drive home the roving threads. It is made with shoulders to protect the laniards of lower rigging, boats, gripes, etc.

Sym-pal'mo-graph. An instrument for making Lissajou's sound curves. — "*English Mechanic,*" * xxv. 18.

Syr'inge. See INJECTOR.

Syr'inge Gun. A tube with piston, ejecting water for disabling humming birds without destroying them.

T.

Ta'ble Brush. (*Leather.*) A soft brush used by curriers to sweep shavings from the buffing table.

Taf'fe-tas Ar'mure. (*Weaving.*) One of the four principal characters of weaving. See ARMURE.

This is a simple form of weaving, having but two harnesses, simply interlacing the threads of the warp and weft.

This is the *weave* of broad-cloth, cotton shirtings and sheetings and *moussseline de laines*.

The variations in the goods are cited under FABRIC.

Take Up. (*Weaving.*) 1. The web roller on which the cloth is wound.

2. The device on a sewing machine for taking up the slack of the thread on the upward stroke of the needle.

Take' Up Mo'tion. (*Weaving.*) A device for automatically winding the tissue on to the cloth beam.

See English form, "*Scientific Amer. Supplement,*" * 4091.

Talk'ing Ma-chine'. During more than a century inventors have turned their ingenuity to constructing machines capable of imitating the human voice, though what practical purpose they might serve, if ever so perfect, it is difficult to discover. One of the latest of these efforts is a machine made by M. Faber.

It consists essentially of three parts, — the wind-producing system, the sound making apparatus, and the articulating arrangement. As for the first, nothing particular need be said; it is simply a species of bellows. The second, the sound-producer, the larynx, is an ivory tube so constructed that within certain limits the length may be varied so as to cause a difference in tone produced. Probably it would have been more successful had some more elastic material been adopted. The articulating apparatus includes a part for sounding the vowels, and another for pronouncing the consonants. The former are due to the passage of air through openings of different shapes, made in diaphragms placed successively in the current of air by the action of levers moved by the fingers: in addition, a special cavity, destined to produce nasal sounds, can be put in communication with the former at pleasure by means of a particular lever. The consonants are produced by pieces, the action of which is analogous to that of the lips, the teeth, and the tongue, and the rolling of the *r* is caused by a wheel. All these imitation organs are put in motion by 14 keys very ingeniously disposed in a way to produce the necessary intensity of action and variation in sequence of the parts destined to pronounce a syllable. The number of 14 keys is sufficient, for by certain variations in the touch the intended sound can be regulated as strong or weak at pleasure. As might be expected, the language of the machine is very monotonous, and is by no means perfect, as some sounds produce a much better effect than others; however, in general, the words pronounced are easily understood. They cannot be compared to the changes in the human voice, and whatever improvements the machine may receive, the question still remains, Of what use is it?

Talking Machine, *Faber* . * "*Scientific American*," xlii. 266.

Ta'mise. (*Fabric.*) An all-wool French goods.

Ta'mise Rep. (*Fabric.*) A corded all-wool French goods.

Tam'pon. (*Surgical.*) *a.* A plug to arrest nasal hemorrhage. See EPISTAXIS.

b. An inflatable plug inserted in the trachea to prevent blood from entering the lungs while the surgeon is operating on the throat above the instrument, the lungs being supplied with air through a silver tube.

Trendelenberg's, Fig. 391, Part II., *Tiemann's "Armamentarium Chirurgicum."*

Tam'pon Screw. (*Surgical.*) An instrument with a screw-end to engage and insert or withdraw a tampon or compress to prevent hemorrhage.

Sims', Fig. 468, Part III., *Tiemann's "Armamentarium."*

Tan'dem En'gine. A steam engine in which the two cylinders are placed in line, one in front of the other, tandem fashion.

See COMPOUND TANDEM ENGINE.

Escher Wyss et Cie. . . . * "*Engineer*," xlvi. 23.
Kingdon . . . . . . * "*Scientific Amer. Sup.*," 3848.

Tan'gent Gal'va-nom'e-ter.

The Western Union standard tangent galvanometer, Fig. 2395, is mounted on a circular hard rubber base provided with leveling screws. It consists of a magnetized needle suspended at the center of a rubber ring, containing the coils. The coils are five in number, of the resistances, 0, 1, 9, 40, and 150 ohms (= 200). The first is a stout copper band of inappreciable resistance; the others are of different sized copper wires, carefully insulated.

The five terminals have plug-holes marked respectively 0, 1, 10, 50, and 200. The plugs inserted at the end of the terminal marked 200, puts in circuit all the coils: at the terminal marked 50, all except the 150 ohm coil: and so on till at the zero terminal only the copper band is in circuit.

An aluminum printer is fixed to the needle at right angles, extending across a 5" dial. On one side the dial is divided into degrees, on the other it is graduated, the figures of the scale corresponding to the tangent of the angles of deflection. The needle is suspended by a jewel and points.

In the base of the instrument are three resistance coils, of German silver wire, of 10, 500, and 5,000 ohms, having terminals and plugs.

Fig. 2395.

Tangent Galvanometer.

A tangent galvanometer has been recently introduced by Louis Schwindler. The galvanometer has two coils, — one of thick wire and few convolutions, offering no more than 1 ohm resistance; another of thin copper wire, having a greater number of convolutions, and resistance of 100 ohms. Two sets of resistance coils for use with the above coils, respectively, one of 20 and 200 ohms, the other of 1,000 and 2,000 ohms. A simple reverser allows the readings of the galvanometer to be taken from either side of zero. In order that the strength of the currents passing through the coils may be as nearly as possible proportional to the tangents of the deflections, the magnet has a length of less than one fifth of the diameter of the deflecting coil. The small magnetic needle carries a thin aluminum pointer fixed in the right angle of the needle. In order that the needle after each deflection may come sooner to rest, the aluminum point carries small wind fans of the same metal. When closing the box the needle is taken off its pivot.

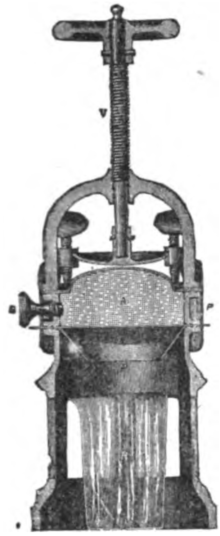
Tank Lo-co-mo'tive. A form of tank locomotive invented by M. N. Forney, of the "*Railroad Gazette.*" It is adapted for narrow gage. The tender end of the frame is carried on a 4-wheel truck; differing in this respect from the plantation locomotive, which has a 2-wheel truck in its larger forms, and is destitute of a truck in the smaller engines, which are supported on 4 wheels only.

The Forney locomotive resembles the usual passenger and freight narrow-gage locomotives modified by connecting the engine and tender in one rigid frame.

Tan'nin-test'ing Ma-chine'. Fig. 2396 represents the "Muntz" apparatus for testing the efficiency of any tanning solution or material. The principle involved consists in forcing a solution containing tannin through a piece of hide. The density of the solution is taken before and after the operation, and a comparison of the densities enables the value of the solution to be readily determined.

The figure shows the internal arrangement. Having taken a small piece of raw hide, and placed it inside, on the base of the apparatus, the india-rubber cover is closed down over it, and secured by the screws in the claws. The liquid to be tested is then poured in on the top of the piece of hide through the small opening, which is fitted with a screw stopper, *B*. This done, pressure is brought to bear by turning the perpendicular main screw *F* at the bottom of which is attached a brass disk, which gradually compresses the india-rubber cover, and forces the liquid to filter through the hide. The screw must be tightened up occasionally so as to maintain the pressure. A glass is placed beneath the machine to receive the liquid, which percolates drop by drop. When sufficient has been obtained to fill a small test glass, the density is taken. To do this the glass should be filled with the first liquid kept in reserve, and the tannometer inserted. In a few minutes it will become steady, and the degree is then noted. The same process must be repeated with the filtered liquid. The difference of degrees between the two densities shows the percentage of tannin in the analyzed substance. This difference is multiplied by 40 if 2½ per cent of stuff is put into water; by 20, if 5 per cent; by 10, if 10 per cent; and by 5, if 20 per cent. For instance, if the tannometer marks for the first liquid 2.8, and for the second 1.3, the difference, 1.5, or 1½°, must be multiplied by 40 if we have taken 2½ per cent., which gives 60 per cent. of tannin; by 20 if we have taken 5 per cent., which gives 30 per cent. of tannin; by 10 if we have taken 10 per cent., which gives 15 per cent. of tannin.

Fig. 2396.



Tannin Tester.

The tannometer referred to is practically a hydrometer, which is supplied with the instrument. With it were detected the valuable properties of *balsamo carpon*, which, when gathered ripe, and the gum taken off free from the fiber of the pod, contains 80 per cent. of tannic acid. It is this gum which weights the leather. Gall nuts are liked by the tanners, but it is now found that the property of gallic acid is to open the pores and allow the other weighting materials to enter the hide. With this small machine, tanners and chemists can test the bark from different trees, some of which are known to yield tannic acid, and are employed for the manufacture of ink and dye, but have never been used for tanning leather. The hide takes from the solution all the properties it requires when the substance is filtered.

Tas'e-om'e-ter. Invented by Steiner, of Vienna, for measuring the strains of structures.

It depends upon the tone given out by a wire or strip when stretched. The wire being attached the variation in length of the bar causes a change in the tone. "*Telegraphic Journal*," vi. 126.

The strain measurer of M. Clevenad, of Paris, is figured in the "*Annales des Ponts et Chaussées*," and is designed to measure directly the strains to which the different parts of any structure are submitted. See STRAIN MEASURER.

See TESTING MACHINE.

Ta-sim'e-ter. A device for measuring very minute variations of temperature.

It is founded on the property, discovered by Edison, that lampblack, when pressed in the form of a button, affects the electric currents passing through the same, and offers a resistance, which diminishes with the pressure, and so sensitive is it that when this pressure varies to the amount of only one millionth part of an inch, the variation in the electric current passing through it will cause a variation in the deflection of the galvanometer needle, and this variation will be in proportion to the pressure. Thus, for instance, if the carbon button is pressed by a strip of vulcanite, and the warm hand is held at a distance of 4″ from it, the expansion by heat of this strip, and the consequent increased pressure, will cause an increase in the conductibility of the carbon, and the electric current which previously passed through and made the galvanometer deflect a certain number of degrees, will cause a greater deflection. The same will take place when a gas flame or a match is ignited in the room, even at a distance of 4′. If a strip of gelatine is used to press the carbon button, its expansion by moisture will be indicated in the same way, when a piece of moistened paper or a wet finger is held at a distance of 4″ or 5″; the heat of a lighted cigar, drying the gelatine, will cause it to contract again, diminished pressure is the result, the current passing through the carbon undergoes greater resistance, and the deflection of the needle will be in the opposite direction.

This instrument is an outgrowth of Edison's experiments with that form of the telephone with which he tried to vary the intensity of electric waves by means of the voice. It promises to be a most important addition to the delicate instruments for measuring very minute variations of temperature.

Thus far the most delicate instrument known to science for determining, for instance, the heat in the different parts of the solar spectrum, has been the thermopile. This instrument is based on Seebech's discovery that when metals of different kinds are jointed together, and the joint is heated, an electric current is produced, passing from one metal to the other. By multiplying the joints and connections of the metals, after the principle of a galvanic battery arranged for very great intensity, very small variations of temperature can be observed by the electric currents generated, and their action upon the magnetic needle of the galvanometer. The great superiority of the tasimeter over the thermopile may be illustrated in a simple manner. If a few inches from the former a hot iron is placed, it will deflect the needle of an ordinary galvanometer say one degree; holding the warm finger 4″ from the tasimeter with the same galvanometer, will swing the needle round some six degrees.

The applications, actual and projected, of the instrument are numerous: —

To warn vessels of the approach of icebergs by exposure to the air or to the water cooled by their vicinity.

To indicate otherwise inappreciable weights, as such laid on the apparatus will affect it.

To record pressures of air in motion; affording a delicate and useful addition to the anemometer.

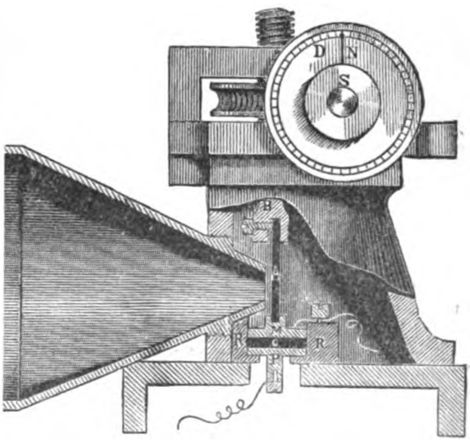
Fig. 2396 shows in perspective the latest form of the Edison tasimeter. See also MICROTASIMETER.

Tasimeter . . . . "*Scientific American*," xxxix. 143.

Fig. 2397.



Tasimeter.

Tast'ing Hole. A hole in a cementing furnace at which trial bars are left to protrude in order to permit examination of the condition of the process.

The same term is applied to holes in other furnaces left for examination of contents.

Taw'ing. Tanning a lamb-skin with the wool on it.

Make a strong soapsuds, using hot water; when it is cold wash the skin in it, carefully squeezing it between the hands to get the dirt out of the wool; then wash the soap out with clean, cold water; next dissolve alum and salt, of each half a pound, in a little hot water, which put into a tub of cold water sufficient to cover the skin, and let it soak in it over night, or 12 hours; now hang the skin over a pole to drain; when well drained spread or stretch carefully on a board to dry. It need not be tacked down if drawn out several times with the hand while drying. When yet a little damp, sprinkle pulverized saltpeter and alum (an ounce each mixed together) on the flesh side, rubbing it in well. It is now to hang in the shade two or three days, the flesh side in, until perfectly dry. When entirely dry, scrape the flesh side with a blunt knife to remove any scraps of flesh. Trim off all projecting points, and rub the flesh side with pumice or rotten stone, and with the hands. Prepared in this way it is white and beautiful, suitable for a door-mat, and also nice for the feet in a sleigh or wagon in cold weather.

Teem'ing. Pouring; as for instance, the weighing of steel ingots during teeming, that is, while running into the mold.

See apparatus of *Ferdinand Moro*, Kladno Iron Works, Austin, * "*Engineering*," xxx. 270.

Tel-au'to-graph. An electrical device for transmitting autographs, or copying designs.

An ingenious application of the same general principles as Morse's telegraphic alphabet. A message is written by the sender in an ink which does not conduct the electric current, and the paper is placed in such a position that a style, or metallic pencil, drawn by machinery across the sheet, covers it with an infinite number of lines, drawn so closely as at first sight to produce the effect of almost continuous coloring, the letters remaining uncolored. Whatever is done at one end of a telegraphic wire can be repeated with ease at the other, and a *facsimile* of the original is inscribed simultaneously, and by the same means, at the receiving station Thus, an autographic message with recognizable signature — or a telegraphic check — may be instantaneously transmitted by any telegraph fitted with the proper apparatus. This system is actually employed on at least one Italian line, and it seems somewhat strange that, considering its extreme simplicity and the great convenience of a recognizable autograph, the use of such a process has not become more general. The possibility of deception and the impossibility of automatic unquestionable record, such as the copying-press gives to letters, greatly restrict the use of the ordinary telegraph by men of business; and both inconveniences are removed, it is said, by the employment of telautography.

Te-lec'tro-scope. An apparatus for reproducing by telegraph the images obtained in the camera obscura. This apparatus is based on the property possessed by selenium of offering a variable and very sensitive electrical resistance according to the different gradations of light.

The apparatus consists of an ordinary camera obscura, containing at the focus an unpolished glass, and any system of autographic-telegraphic transmission; the tracing point of the transmitter intended to traverse the surface of the unpolished glass, will be formed of a small piece of selenium held by two springs acting as pincers, insulated and connected, one with a pile, the other with the line. The point of the selenium will form the circuit. In gliding over the surface, more or less lightened up, of the unpolished glass, this point will communicate, in different degrees, and with great sensitiveness, the vibrations of the light. The receiver will also be a tracing point of blacklead or pencil for drawing very finely, connected with a very thin plate of soft iron, held almost as in the Bell telephone, and vibrating before an electro-magnet, governed by the irregular current emitted in the line. This pencil, supporting a sheet of paper arranged so as to receive the impression of the image produced in the camera obscura, will translate the vibrations of the metallic plate by a more or less pronounced pressure on that sheet of paper.

Tel'e-graph. The following is the chronology of the telegraph.

TELEGRAPHS BY ELECTRICITY.

1774. — Georges Louis Lesage, Geneva, set up the first telegraph line, which consisted of 24 insulated wires for the alphabet, each terminating in a pith-ball electroscope, duly lettered, for indicating by its excitation the succession of letters in the message, the transmitting operator using a manual conductor from an electrical machine.

1787. — Mons. Lomond, Paris employed a single brass wire in connection with pith-ball electroscopes, making use of an alphabet of motions.

1794. — M. Reiser, Geneva, used 36 insulated wires for letters and numerals, in connection with a like number of narrow strips of tin foil pasted on glass; the letters and figures were cut in the foil and made visible by the passage of the electric spark.

1795. — Tiberius Cavallo, England, sent explosive and other electric signals through fine insulated copper wire, using Leyden jars, and sending "sparks at different intervals according to a settled plan."

1798. — D. F. Salva, Spain, worked an electric telegraph through the unprecedented distance of 26 miles, using a single wire, and the sparks of a Leyden jar for signals.

1816. — Francis Ronalds, England, constructed an experimental telegraph line, of a single insulated wire 8 miles long, operated by an electrical machine, or small Leyden jar. His elementary signal was the divergence of the pith-balls of a Canton's electrometer, produced by the communication of a statical charge to the wire. Lettered dials, rotated synchronously at each end of the line, served, in connection with the pith-balls, to indicate the letter designated by the sender. This dial system was the precursor of Wheatstone's dial telegraph in 1839; House's letter printing telegraph in 1846; and Hughes's printing telegraph in 1855.

1828. — Harrison Gray Dyar, America, constructed a telegraph on Long Island, supporting his wires by glass insulators fixed on trees and poles; the electric signals printed themselves upon litmus paper, the spacing of the marks indicating the letters and other signs. Just as Dyar and his partner Brown were seeking capital to set up a line between New York and Philadelphia, a black-mailing agent, failing to extort the concession of a large share in the enterprise, obtained a writ against the two partners on a charge of conspiracy to carry a secret communication between the cities! The case was never brought to trial, but the enterprise was blocked.

According to Steinheil, these various experiments put it beyond a doubt that frictional electricity might be made a successful means of telegraphic intercourse.

TELEGRAPHS BY GALVANISM.

1808. — The first to apply to telegraphy the galvanic battery introduced by Volta, in 1800, was Dr. Samuel Thomas Von Soemmering, of Munich. He employed the energy of a powerful voltaic pile to bring about the decomposition of water by means of 35 gold pins immersed in an oblong glass trough. Each of these electrodes was in connection with one of the 35 wires forming the line. The bubbles evolved at these electrodes were received in lettered and figured tubes, and the messages were thus spelled out. In 1810 Soemmering telegraphed through two miles of wire.

1816. — Dr. John Redman Coxe, of Philadelphia, suggested a system substantially the same as Soemmering's (of which he appeared to be ignorant). He also proposed to accomplish the same result by decomposing metallic salts, as was afterwards done.

1843. — Mr. Robert Smith, Scotland, devised a galvano-chemical telegraph carrying out practically the suggestion of Dr. Coxe. At first he used a separate wire for each letter, the message being printed on a strip of paper wet with a solution of ferrocyanide of potassium. Subsequently Mr. Smith reduced his line to a single circuit of two wires, and worked his system through 1,800 yards of fence wire (1846).

1846. — Mr. Alexander Bain, Scotland, patented in England a galvano-chemical telegraph, different in mechanical details, but similar in its chemical record to the system of Smith.

1849. — Prof. Samuel F. B. Morse, New York, patented in this country a telegraph similar to Smith's.

TELEGRAPHS BY GALVANO-MAGNETISM.

1820. — Hans Christian Oersted, Copenhagen, rediscovered the directive influence of a galvanic conductor on a magnetic needle (Romagnosi's observations of the same in 1802 having attracted no attention). The same year (1820) Professor Schweigger, of Halle, made the first real galvanometer; and shortly after Ampère, in Paris, proved experimentally the feasibility of an electro-magnetic telegraph, in which the galvanometer should take the place of the electrometer employed by Lesage.

1823. — Baron Paul L. Schilling, of Cronstadt, Russia, practically applied Ampère's suggestion. In his apparatus signals were produced by five galvanometer needles, provided with independent circuits.

1824. — Peter Barlow, England, experimenting with considerable lengths of wire, to test the practicability of Ampère's suggestion, was convinced that it was impracticable, owing to the rapid diminution of effect (due to increased resistance), by lengthening the conducting wire. Other inconclusive experiments in the same direction were made by Fechter in 1829, and Ritchie in 1830.

1833. — Prof. Carl Friedrich Gauss and Wilhelm Edward Weber constructed at Gottingen a galvanometer telegraph of a single circuit of uninsulated wire a mile and a half long. The alphabet of signs was made up of right and left deflections of the needle, observed by reflections from a small mirror. Gauss was the first to employ magneto-electricity in telegraphs. Weber added to the signaling device a delicate apparatus for setting off a clock alarm.

1836. — Prof. C. A. Steinheil, of Munich, undertook, at the request of Gauss, the development of the arrangement above described, and constructed a similar galvanometer telegraph line two miles in length, introducing considerable improvements. The next year Steinheil discovered that the ground might be made a part of the circuit, thus dispensing with a second wire for the return circuit.

1837. — Mr. William Fothergill Cooke and Prof. Charles Wheatstone patented in England a galvanometer or needle telegraph very similar to the earlier one of Schilling, employing six wires and five indicating needles. An experimental line a mile and a quarter long was worked with partial success July 25; and one thirteen miles long was established in 1838.

While these experiments with the needle were going on the electro-magnet was being developed and applied.

1820. — The germ of the electro-magnet was discovered by Arago, who observed that the electric current would develop magnetic power in strips of iron and steel.

1824. — William Sturgeon, England, produced the true electro-magnet with its intermittent control of an armature.

The electro-magnet of Sturgeon was improved by Professor Henry in 1828; and in 1829 he exhibited a larger magnet of the same character, tightly wound with 35′ of silk covered wire. A pair of small galvanic plates, which could be dipped into a tumbler of diluted acid, was soldered to the ends of the wire, and the whole mounted on a stand. This was the first magnetic spool or bobbin. This invention was further improved the same year, and in 1830 Professor Henry, assisted by Dr. Philip Ten Eyck, constructed an electro-magnet which lifted 750 pounds. In 1831 he made one weighing 82¼ pounds, which sustained over a ton. In the meantime Professor Henry practically worked out the differing functions of quantity and intensity magnets, and experimentally established the conditions required for magnetizing iron at great distances through long conducting wires. This first made the electro-magnet available for telegraphic purposes.

1831. — The transmission of signals through a mile of copper bell wire interposed in a circuit between a small Cruikshank's battery and an intensity magnet — a practical telegraph — was practiced by Professor Henry.

"This memorable experimental telegraphic arrangement involved three very significant and important novelties. In the first place, it was the first electro-magnetic telegraph employing an 'intensity' magnet capable of being excited at very great distances from a suitable 'intensity' battery. . .

"In the second place, it was the first electro-magnetic telegraph employing the armature as a signaling device, or employing the *attractive* power of the intermittent magnet, as distinguished from the directive action of the galvanic circuit. That is to say, it was, strictly speaking, the first magnetic telegraph.

"In the third place, it was the first *acoustic* electro-magnetic telegraph."

Further on Mr. Taylor pertinently remarks that it is suggestive to consider how different would have been the popular estimate of Professor Henry's labors if he had been worldly-wise enough to secure an early patent on these three indisputably original and most pregnant features of telegraphy.

1837. — Prof. Samuel F. B. Morse devised a magneto-electric telegraph capable of transmitting signals through a circuit of 40′, but failed for longer distances from the circumstance that he used a quantity current. His friend, Dr. Gale, made for him an intensity battery, and added a hundred or more turns to the coil of wire around the poles of the magnet. With these necessary (and radical) improvements the apparatus was made to work through ten miles of wire. In applying for a caveat for his invention, October 6, 1837, Professor Morse specified six distinct parts, not one of which enters into the established "Morse" telegraph of to-day. Mr. Taylor shows that Professor Morse's real contribution to telegraphy consists first in the adaptation of the armature of a Henry electro-magnet to the purpose of a recording instrument; and second, in connection therewith, the improvement on the Gauss and Steinheil dual-sign alphabets, made by employing the single line dot and dash alphabet.

In his general summary of the history of the origin and development of the electro-magnetic telegraph, Mr. Taylor sets down the leading preparatory investigations and discoveries as these five:

1. The discovery of galvanic electricity by Galvani, 1786–1790.
2. The galvanic or voltaic battery by Volta, 1800.
3. The directive influence of the galvanic current on a magnetic needle by Romagnosi, 1802, and by Oersted, 1820.
4. The galvanometer by Schweigger, 1820 (the parent of the needle system).
5. The electro-magnet by Arago and Sturgeon, 1820-1825 (the parent of the magnet system).

The second half dozen capital steps in the evolution of telegraphy were: —

1. Henry's most vital discovery, in 1829 and 1830, of the intensity magnet and its intimate relation to the intensity battery.
2. Gauss's improvement, in 1833 (or probably Schilling's, considerably earlier), of reducing the electric conductors to a single circuit by the ingenious application of a dual sign, so combined as to produce a true alphabet. (The anticipations of this idea by Lomond in 1787, Cavallo in 1795, and Dyar in 1825, are not regarded as practically influential in the progress of telegraphy.)
3. Weber's discovery, in 1833, that the conducting wires of an electric telegraph could be carried through the air without insulation, except at the points of support.
4. As a valuable adjunct to telegraphy, Daniell's invention of a constant galvanic battery in 1836.
5. Steinheil's discovery, in 1837, that a single conducting wire is sufficient for telegraphic purposes.
6. Morse's adaptation of the armature of a Henry electro-magnet as a recording instrument, 1837, and the single line dot and dash alphabet in 1838.

The earlier needle type of electro-magnetic telegraph has found its special application in ocean lines, no element of the Morse system entering into the operation of submarine cables.

The more recent telegraphic developments do not fall within the scope of Mr. Taylor's review. A few other dates, as given by Prescott, may appropriately serve to complete this chronology.

1861. — Reiss discovered that a vibrating diaphragm could be actuated by the voice so as to cause the pitch and rhythm of vocal sounds to be transmitted to a distance and reproduced by electro-magnetism.

1872. — Stearns perfected a duplex system, whereby two communications could be simultaneously transmitted over one wire.

1874. — Edison's quadruplex system was invented.

1874. — Gray invented a method of electrical transmission, by means of which the intensity of tones as well as their pitch and rhythm could be reproduced at a distance; and subsequently conceived the idea of controlling the formation of electric waves by means of the vibrations of a diaphragm capable of responding to all the tones of the human voice.

1876. — Telephone invented. — Bell invented an improvement in the apparatus for the transmission and reproduction of articulate speech, in which magneto-electric currents were superposed upon a voltaic circuit, and actuated an iron diaphragm attached to a soft iron magnet. During the same year Dolbear conceived the idea of using permanent magnets in place of the electro-magnets and battery previously employed, and of using the same instrument for both sending and receiving.

1877. — Edison's carbon telephone was brought out.

To these may be added Edison's electro-motograph or electro-chemical telephone, 1877.

1878. — Duplexing of ocean telegraph.

1879. — Cowper's writing telegraph.

1880. — Field's successful substitution of dynamo-electricity for galvanic batteries in telegraphing.

1800. — Volta, Italian, discovery of galvanism.
Galvani, Italian, discovery of galvanism.

1809. — Soemmering, suggestion of application of galvanism to telegraph.
Oersted, Dane, galvanometer.
Ampère, French, astatic needle.

1825. — Ohm, German, law of strength of current.

1833. — Gauss.
Weber.
Becquerel, constant battery.
Daniell, constant battery.
Steinheil, discovery of earth circuit.

Commander Cameron of the British navy says that the Morse system of telegraphy, as far as it depends on the length of sounds, has long been in use in Africa. He has found tribes that, by stationing drummers at intervals, carry intelligence for miles with great rapidity, the beats of the drum being made in accordance with a previous arrangement of signals.

A message of 69 words, forwarded by the governor of Victoria, announcing the opening of the Melbourne Exhibition, was dispatched from Melbourne at 1 P. M., and reached London at 3.43 A. M., on the same day, or 9 hours 17 minutes before the hour of its dispatch. Allowing, however, for the difference of time between the two cities, it occupied only 23 minutes in transit. The route of the message was over the lines of the Victorian and South Australian colonies, the cables of the Eastern Extension, Australasia, and China Telegraph Company, the lines of the Indian government, the cables of the Eastern Telegraph Company, and the lines of the Egyptian and French governments, and the rapidity of its transmission shows the harmony with which these various administrations work together. The total distance traversed was 13,398 miles.

The annual report of the president of the Western Union Telegraph Company for the year ending June 30, 1880, furnishes many figures of interest to others than the stockholders of the company. The latter, however, appear to have no reason to complain, the net profits of the company for the year footing up over $6,000,000, the capital stock of the company being about $41,000,000. The net profits for the fourteen years from 1866 to 1880 exceed $45,000,000. The telegraph business of the year is represented by 29,215,509 messages, $12,782,894.53 receipts, $6,948,956.74 expenses, and $5,833,937.79 profits. The company has in operation 85,645 miles of line, 233,534 miles of wire, and occupies 9,077 offices. The new offices established and equipped during the year number 548. The number of messages sent was over 4,000,000 more than the year before. The increase in mileage of wire was 22,000 miles; the increase in miles of pole lines was 2,658. The ratio of expenses was 54.3 per cent. of the receipts, against expenses of 56.2 per cent. the previous year, and of 63.9 per cent. the year preceding that, and the cost per message reduced to the average of 22.3 cents, against 23.1 cents the previous year, 25 cents the year preceding that, and 29.8 cents the year ending in 1877.

The wires of long circuits in continental Europe are 5 mm. diameter, weighing about 540 lbs. per English mile.

Smaller lines have wire of 4 mm., = to Am. No. 9, about 320 lbs. per mile.

Branch lines have wire of 3 mm., = 200 lbs. per mile.

In England large and important lines use No. 4 gage, = 800 lbs. per mile.

The majority of American lines has No. 9 gage, = 320 lbs. per mile. A portion of the remainder is No. 8, = 380 lbs. per mile. 3 per cent. is No. 6, = 540 lbs.; and some No. 10, = 270 lbs.

The Cumming periphery-contact telegraph key, it is claimed, has no jar or sticking points, and has a close needle point contact. Two disks are placed at right angles to each other, and the connection between the two is only a needle-point of surface. The adjustability of the electrodes is such that if connection should be arrested, both wheels can be changed in an instant by turning each slightly on its axis to a new bright surface. The electrodes connect firmly, so that the trunnion can be screwed tight without affecting the correct working of the key. The system of wheels and axles forms an elastic bed, that, taken in connection with the dot contact and close adjustment, makes it possible to work the key all day without any lost motion to fatigue the hand or try the nerves.

Commander Perrier read a paper at the last meeting of the Geographical Society of Paris, on the determination of the longitude of Algiers by telegraphy. The exact longitude is 2′ 50.21″ east from Paris, the probable error being only 0.01″. The time required for the transmission of the electricity from Paris to Marseilles was found to be only 2-100 of a second; the distance between these two cities being 863 kilometers, it shows that the velocity of the electricity was not less than 46,000 kilometers per second. Similar experiments tried on the submarine cable between Algiers and Marseilles proved that the time required to travel was 23-100 of a second: for a distance of 926 kilometers this shows a velocity of only 4,000 kilometers. But the battery used for signaling in the aërial line was composed of 100 elements, and only ten elements were used in the sub-Mediterranean cable.

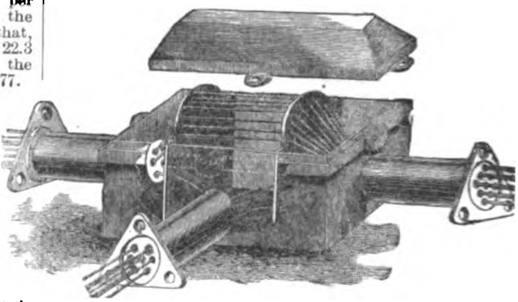
Tel′e-graph Wire. In one form of underground telegraph system the naked copper wires are drawn through glass tubes, which are firmly held in position in the iron pipe by paraffine wax. For lateral connections, as well as convenience in laying, traps are used, into which the pipes are screwed, the wires passing over non-conducting bridges, as

Fig. 2398.



Trap for Underground Telegraph Wire.

shown in Fig. 2398, thus allowing any wire to be taken out and replaced without interfering with the working of the others. The pipes are connected by a coupling, which, after being bolted together, is completely sealed; the traps being closed and sealed in like manner.

By this system there is claimed to be no crossing of wires, no difficulty from atmospheric changes, no cutting of wires in cases of riot, no imperiling of life and property by the breaking down of poles and wires by snow storms or fires (causing interruption of telegraphic communication); but a perfectly reliable telegraphic connection under all circumstances.

Te-lem′a-chon. A name applied by Wallace, of Ansonia, Conn., to his apparatus for transferring power from the Naugatuck river to his factory, a quarter of a mile off. A dynamo-electric machine transforms mechanical power into electricity, and an electric motor reverses the operation and turns the current into power. Loss stated at 20 per cent.

Te-lem′e-ter. A device for determining rapidly and accurately distances on the earth's surface.

Various mechanical devices for these purposes have been invented, but none hitherto similar to that illustrated, devised by Lieutenant Gaumet, French army, which is adapted for carriage in the pocket. A perspective view of the instrument is given in Fig. 2399. Fig. 2400 shows the interior. Two mirrors are disposed on a metallic plate so that an angle of 45° is made between them. One mirror is fixed; the other is mounted on a movable alidade, so that the above angle can be varied from 41° to 49°. A micrometric screw of .04″ travel per turn has a disk on its head, which is divided circumferentially into 100 parts. This screw moves in double nuts on the metallic plate. The disk travels in front of a divided rule, each division of which equals .04″. A spring causes constant contact between the arm of the alidade and the extremity of the micrometric screw.

All the above parts are contained in a rectangular box, as shown in Fig. 2399, having at its rear an opening for the eye, and on the right side a similar aperture through which the

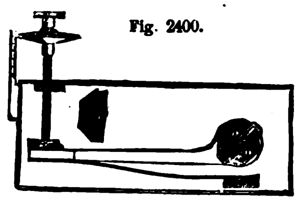
rays pass to the mirrors. The principle on which the device is constructed is a simple application of that of double reflection. When a luminous ray is reflected successively by two mirrors placed in a plane perpendicular to the intersection of the mirrors, the angle formed by the incident and reflected ray is double the angle of the mirrors.

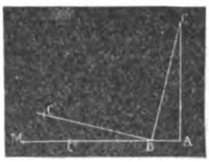
In order to measure the distance by the instrument three operations are necessary. These will be understood from Fig. 2401, and are as follows: 1, to determine the right angle *C A M*; 2, measure a base *A B*; 3, measure an angle at *A C B*. *A C* being the distance to be determined. The observer posts himself at *A*, the point *C* being on his right. The reflected image of this point then appears directly above the direct image of the fixed station *M*, which is regarded in direction perpendicular to *A C*. (The angle *C A M* is right whenever the two mirrors make an angle of 45°.) The observer now, by means of a tape provided with the instrument, measures off a distance along the line *A M* of *A B* = 60′. He then proceeds to *B* and regards anew the signal point *M*, between which and *C* there will no longer be a coincidence, the latter appearing to the right, say at *C″*. To reëstablish the coincidence the movable mirror is turned to an angle equal to ½ *C″ B M*, which equals ½ *A C B*. The angle of rotation of the mirror is in the instrument measured by its tangent by the aid of the micrometric screw. This gives a very close approximation. When the coincidence above referred to is obtained the number of turns made by the screw is read from the scale, and this equals the measure of the tangent of the angle of rotation of the mirror. This angle of rotation is half the angle *A C B*. The relation, therefore, between the distance from the pivot of the movable mirror to the axis of the micrometric screw and double the number of divisions equals the ratio between the unknown distance and the base measure. Therefore, *D* being the distance to measure; *b*, the base taken, say 60′; *l*, the distance of the pivot as above, which in the instrument is 2.2″, and *n* the number of divisions, we have

Fig. 2400.



Telemeter.

Fig. 2401.



Plan reflected in the Telemeter.

$$\frac{D}{b} = \frac{1}{2.n} \quad \text{or } D = b \frac{2.2}{n}.$$

Whence we obtain for each instrument a constant which, divided by the number on the scale, at once gives the distance sought. On every instrument a table prepared from the above formula is fixed so that the observer merely has to glance thereat to determine the distance without calculation.

This invention is in principle the same as that patented in the United States, March 16, 1875, by Mr. William F. Hausch, of Chicago, Ill.

Tel′e-phone. An acoustic telegraph.

A modification of the electric telegraph, whereby sounds, and especially articulate sounds are conveyed to a distance

The telephone of Prof. Alex. Graham Bell, Plate XLVIII., Fig. 2402, consists of an insulated permanent magnet, in form of a cylindrical rod, which is enveloped with a wire coil that communicates at one extremity with the ground and by its other extremity with a similar coil around a like magnet at the distant station whose unattached end communicates in like manner with the ground. Opposite the outer end of each magnet is stretched a thin metallic diaphragm (usually ferrotype sheets) to which a mouth-piece is attached. Sounds projected into the mouthpiece vibrate the diaphragm, and by so doing increase and diminish the polarity of the magnet. This acting inductively on the inclosing coil transmits electrical impulses through the connecting wire to the distant coil, which in turn operates to magnetize and demagnetize its inclosed bar, which finally sets up vibrations on the adjacent diaphragm, similar to that in the sending station, thus converting the electrical impulses back into sound.

The *telephone system* depends for its efficiency upon three distinct elements: the telephone, the microphone transmitter, and the exchange table and system.

The telephone generally used consists essentially of a thin metallic diaphragm, suitably mounted in a sound-receiving chamber with a mouth-piece, and a short bar of magnetised iron secured adjustably in the handle of the instrument at right angles to the diaphragm, nearly, but not quite in contact therewith. A coil of insulated wire surrounds the magnetized bar at its diaphragm end, and is connected with the line wire and with the ground respectively.

Speech or other sounds projected into the mouth-piece cause vibrations of the diaphragm which produce fluctuations in the magnetism of the bar. Induced currents of electricity are thereby brought into play in the coil surrounding the magnet, which, being transmitted by the line wire to the terminus, cause precisely similar vibrations in the diaphragm of the receiving instrument, and thus, by an exact reverse of the previous process, produce sound waves.

Thus by the conversion, so to speak, of sound waves into electrical waves, the transmission of the latter, and finally their reconversion into sound waves, the sounds given to the receiving instrument are reproduced at remote distances with astonishing accuracy; but the favorable results produced are much enhanced by the use of a microphone known as the *transmitter*, which is now used as the sending instrument.

The transmitter is a modification of the principle of the telephone proper, in which a diaphragm mounted in an insulating rubber marginal support vibrates against a spring-supported platinum point interposed between the diaphragm and a disk of compressed carbon. The platinum point and the carbon disk are electrically connected through an insulated coil, surrounded by a secondary coil interposed between the line wire and the ground connection. The object of this invention is to produce secondary pulsations of greater intensity, which, being transmitted by the line wire, practically solve the question of distance in the transmission of sound.

Telephone exchange. Each subscriber to a local telephone system is connected by a line wire to a central office or *exchange*, where, for convenience, the subscribers are grouped to the number, say of fifty, the wires of each group concentrating at a particular desk in charge of an operator clerk, and distinguished by a particular color. At the exchange terminus of each wire is a magnet mounted on a frame, which, when the line is out of use, holds a bright colored disk in sight. These magnets being arranged on shelves in front of the operator, each will drop its disk whenever its patron "calls" the exchange, thus indicating the individual giving the signal.

Each desk has a similar group of magnets and signals connected with the wires belonging to its group of patrons, and, in addition, a number of *plug-sockets* with wires connecting them with the other tables. These plug-sockets are arranged in groups of ten, and each group has its distinguishing color, and is connected with the groups of the same color on each of the other tables; thus each table has as many groups of sockets and connecting wires as there are tables in the exchange. By this means each operator may connect either of the wires distinguished by his appointed color with any other table, and, thus intermediately with any other line wire to such other patron as the original caller may indicate telephonically to the central exchange.

Fig. 2403, Plate XLVIII., represents Edison's new telephone. The chalk cylinder is inclosed in a vulcanite box at the end of the movable arm. The cylinder, when once moistened, remains in that condition an indefinite time, as the box is practically air-tight. The small shaft that runs parallel with the iron arm extends through the side of the box and carries the chalk cylinder. Upon the opposite end there is a small pinion moved by a worm, the crank of which is turned by the finger. The diaphragm of the receiving instrument is covered by the front of the box, except a small central portion sufficient for the exit of the sound. The arm that supports the receiving instrument is jointed so that it can be raised vertically out of the way when the telephone is not in use. The transmitter is contained in the rectangular box; its mouth-piece projecting slightly, and the diaphragm, which is of mica, is supported by a metallic frame and springs inside the box cover. The transmitter is so constructed that a vulcanite arm is secured to the center of the mica diaphragm by a small bolt that is connected to one pole of the battery by a piece of metallic foil or very thin copper wire. The head of the bolt is platinum faced and deeply sunk in the vulcanite arm, the same cavity containing also a piece of carbon pencil, such as is used for electric candles. This carbon fits the cavity loosely, and is rounded at both ends. Its outer end is pressed by a platinum-faced spring, secured to the outer end of the vulcanite arm. The spring carries at its free end, opposite the carbon, a brass weight, and its pressure upon the latter is regulated by the small set screw. A wire or piece of copper foil, connecting with the spring, completes the circuit, which includes the primary of an induction coil contained by the rectangular box. The secondary wire of the induction coil is connected with the telephonic line and a tertiary coil that envelopes the secondary is connected with the rubber and chalk cylinder.

Fig. 2404, Plate XLVIII., represents the "Edison" carbon telephone. He made the discovery that when properly prepared, carbon possesses the remarkable property of changing its resistance with pressure, and that the ratios of these changes correspond exactly with the pressure. On this principle he constructed his telephone. The carbon disk is represented near the diaphragm, which is placed between platinum plates and connected with the battery circuit. A small piece of rubber tubing is attached to the center of the metallic diaphragm, and presses lightly against an ivory piece that is placed directly over one of the platinum plates. When, therefore, any motion is given to the diaphragm, it is immediately followed by a corresponding pressure on the carbon, and by a change of resistance in the latter.

The "Regi" instrument, Fig. 2405, Plate XLVIII., has the special advantage that when once adjusted it continues to operate without readjustment. The peculiarity of the new instrument is in transmitting wave-sounds through a diaphragm that rests upon a conducting substance made of a mixture of silver, reduced to an impalpable powder, and carbon, also very finely pulverized; the above devices being mounted on the end of a slender spring.

In principle the Regi telephone is similar to "Edison's" carbon telephone, and also to the "Hughes," which was based on Edison's.

Professor Gray received a patent for a combination of a telephone with the ordinary Morse instrument, so that the telegrapher may communicate over the same line both by the Morse signals and also by the voice. By use of the quadruplex instrument on such a line four messages may be transmitted by signals in the usual manner, while conversation may at the same time be carried on over the same wire, all without any interference of the different signals or systems.

Gray claims to have first invented and reduced to practice—

1. The transmission of composite tones of varying quality through a closed circuit by the superposition of one set of electric waves upon another.

2. The reproduction of such vibrations by means of a continuously charged receiving magnet.

3. The combination of a magnet with a diaphragm of magnetic metal arranged in close proximity thereto, and adapted to act either as a transmitter or receiver of articulate or any other sound.

"Dr. Luedtge's microphone," Fig. 2406, Plate XLVIII., patented January 12, 1878, some time before the microphone notes of Hughes and Edison were published, has been improved so that the disagreeable sounds that are heard on some other microphones have been avoided, and words spoken into the transmitter are reproduced so clearly and so loud that it can be heard best somewhat removed from the receiver, which is an ordinary "Bell" telephone. With too near an approach a healthy ear might be injured.

Words have been plainly transmitted by this apparatus through a distance of 186 miles.

If a Bell telephone and a Luedtge microphone are brought in connection, a clear, deep, and impressive tone, something like the tone of a fog-horn that can be heard for quite a distance, is perceived at the transmitting as well as at the receiving station.

The essential part of the instrument is the connection between the two electric conducting bodies (preferably of iron, platinum, or carbon). One of the pieces is level at the contact surface, but the other is convex. The electric current passes through this contact, and the variations in the electrical resistance at this point while speaking cause the vibrations of the membrane in the receiving telephone. A peculiarity of the construction is that both of the contact pieces are united to a support fastened to the middle of the membrane, so that both vibrate with the membrane.

Fig. 2497, Plate XLVIII., represents Edison's voltaic pile telephone. A piece of cork, *K*, is fastened to the diaphragm, and presses upon a strip of platinum which is attached to a plate of copper. The latter is one of the terminals of an ordinary galvanic pile. The other terminal plate presses against the metallic frame of the instrument. When the pile is included in a closed telephone circuit it furnishes a continuous current. The strength of this current depends upon the internal resistance of the pile and its polarization, and these are varied by vibrating the diaphragm. The pile is composed of alternate plates of zinc and copper, *Z C*, and a bibulous medium, *G*, between the pairs of plates.

In the Hubbard telephone, as seen in Fig. 2408, Plate XLVIII., the inventor has made use of the Jamin laminated U-magnets to secure great magnetic power with little weight. The ends of the magnet are cut off diagonally, and the poles are each surrounded with a helix of fine insulated copper wire connected as in an electro-magnet. Two of these magnets are attached to an elliptical hoop, which surrounds the head and supports the diaphragms and ear-pieces. Each diaphragm carries a light triangular armature, which fits the poles of the magnets and nearly touches them. The telephones are connected with each other and with the line. The operation is similar to the Bell telephone. The instrument shown in the engraving is arranged as a receiver to be used with any of the ordinary transmitters, but it may be arranged as a transmitter.

Fig. 2409, Plate XLVIII., represents the telephonic instruments of Dr. Cornelius Herz.

The apparatus represented in the figure is specially designed for lines most affected by induction, which renders communication impossible with ordinary telephones.

This plan utilizes two principles discovered by Dr. Herz: the alternation of the current in the line, and employing condensers as receivers. The instrument constitutes a station, completely inclosing, under a compact and appropriate form, all the parts necessary for the call and for communication.

The diaphragm is horizontal, but a funnel placed in front of the box collects the sound and concentrates it upon the diaphragm, and the instrument will transmit words spoken fifty centimeters from it.

Four pairs of microphonic contacts are placed upon an oscillating platform, under the diaphragm and connected with it by a rigid rod, communicating to it all the vibrations of the diaphragm. These contacts are of a special composition, and communicate with the battery and with the line.

In this apparatus it is not necessary to use the induction coil, but it is necessary that the number of elements of the battery in the line be proportioned to the distance of the two stations; for example, between Paris and Orleans it was necessary to use thirty elements of Daniell at each station, in order to obtain the maximum intensity.

In a modification the alternation of the current is accomplished in a different manner, and the induction coil is used in order to diminish the number of elements necessary in a long line.

Originally this instrument was formed of a vibrating plate, having at each side a contact point touching the diaphragm lightly, and the vibrations increased or diminished the pressure alternately upon each one of these contacts, but this form being inconvenient, M. Herz preferred that which is now used, which gives the same results.

The vibrating plate is of conducting material. Below, and touching it lightly, is a cylinder, which rests upon a disk, the two being made of the same material as the plate. The disk rests, in its turn, upon a thin metal spring, which is made adjustable by means of a screw, so as to vary the contact between the three pieces.

The plate and the disk are connected with one of the poles of a battery of four elements, which is grounded at the center. Finally, the cylinder is connected with one of the extremities of the primary wire of the induction coil, the other end being grounded. The secondary wire of the coil passes out from one side to the line, and from the other side to the ground.

An electro-thermic telephone, described by W. H. Preece in a paper before the Royal Society, consists of a telephone receiver whose action is due to the linear expansion of a thin wire under tension when placed in a microphonic circuit.

It has been discovered that each damaged or imperfect joint in a telephonic wire becomes a microphone, taking up the sounds that occur in its vicinity for transmission to the receiver.

The microphone, in fact, is itself two or more conductors, connected together, electrically, by an imperfect joint.

Mr. Geo. Hopkins, of Brooklyn, N. Y., during a thunder storm, connected the gas and water-pipes of his dwelling with an ordinary Bell telephone, and discovered that the electric discharges were plainly indicated by either a sharp crack or by a succession of taps. This occurred when the discharge was so distant that the thunder was inaudible. There was a marked difference in the discharges; some that appeared single to the eye were really multiple. Often the discharges would consist of a series, beginning and ending with discharges larger than the rest, thus: —— . . . . . ——, sometimes it would be thus: —— . . . . ., sometimes the reverse, and often a single crack.

Experiments with the telephone as an indicator of the approach of distant thunder storms seem to prove that the telephonic dispatch was simultaneous with the rays of light, as exhibited by the flash of the lightning, even when the storm was so distant that the sound waves were not appreciable to the ear via the atmosphere. A significant fact, if sound waves with a conductor with a minimum friction can keep pace with rays of light.

The nearest cable station from Alexandria during its bombardment, in 1882, was at Malta, distant about 1,000 miles from the scene of the battle. A press dispatch says that when a telephone was attached to the Malta end of the cable the firing of the guns at Alexandria could be distinctly heard, though no oral communication was possible over that length of cable.

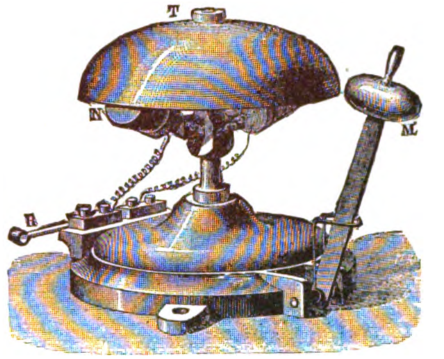
Fig. 2410.



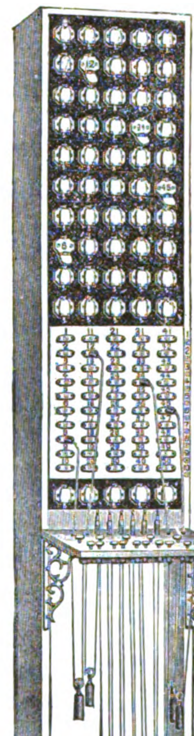
Telephone Call.

Tel′e-phone Call.

The Lorenz telephone call, Fig. 2410, is an alarm or call-bell, in which the magnet *N S* is placed coincident with a diameter of the steel gong *T*. When by means of a hammer *M*, pushed by a spring, the gong is struck in a direction across that of the magnet the vibrations have their maximum amplitude in front of the poles, and induction currents relatively strong are generated in the coils placed on the poles of the magnet. These currents are sent to the corresponding station, and are there received in the Bell telephone, slightly modified, the bobbins being more powerful than in ordinary telephones, and a resonator being also added to them. The latter is a long cone of white iron, truncated at its top, the small end being inserted close to the telephone diaphragm.

"*Telegraphic Journal*," * vi. 439.

Fig. 2411.



Telephone Switch-board.

Tel′e-phone Ex′change Ap′pa-ra′tus. Fig. 2410 is the Western Telephone Exchange switch board. It consists of fifty annunciators for subscribers' wires; fifty spring-jack switches for connecting and disconnecting line wires and annunciators; five annunciators for receiving the clearing-out signals. A shelf with five pairs of cords and plugs, and five sets of keys.

Tel′e-phone Harp. An instrument for making telephonic musical effects more audible for large audiences.

Gower, Br. . . "*Jour. Soc. Teleg. Engineers*," vii. 259.

Tel′e-phon′o-graph. An invention of Edison, a combination of the telephone and phonograph, for making a phonic record of a message conveyed from a distance.

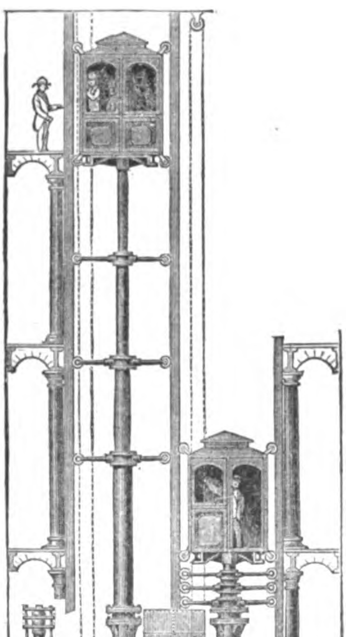
"*Engineer*" . . . . * xlvi. 425, Fig. 27.

Tel′e-phote. An instrument or apparatus for conveying messages or images by transmission of light.

This broad definition may include the heliotrope, but nothing narrower, it appears, will include the various ideas and inventions of Bell, Perry, Ayrton, Edison, Adams, Day, Willoughby, Smith, Sabine, Kerr, Middleton, Michin, and others, who are reported to be working at the problem.
See sketch in "*Engineering*," xxix. 361.

Tel′e-scop′ic El′e-va-tor. Fig. 2412 shows a telescopic hydraulic elevator for lifting passengers or freight to the upper floors of a building.

Fig. 2412.



Telescopic Elevator.

Tel′e-scop′ic Tank Car. One in which the circular sections of the tank are of gradually decreasing diameter toward the ends, lapped within each other.

In contradistinction to the *straight tank* car, in which the sections are alternately inside and outside.

Tel′e-scope Sight. (*Fire-arms.*) A telescope mounted on a fire-arm. It is generally adjustable, in altitude for distance; in azimuth for wind correction.

See patents of J. M. Trowbridge, March 8, 1864, No. 41,874; C. Slotserbek, October 8, 1878, No. 208,765.

Tell′-tale. (*Gas.*) An attachment to a station meter to indicate any irregularity of the production of gas during the 24 hours, the cards being renewed daily.

Tell′-tale Com′pass. A tell-tale mariner's compass, recently patented in England by Mr. H. A. Severn, is intended to serve captains of vessels as a check upon the man at the wheel during their absence, and to insure greater attention on the part of the helmsman.

It consists of an ordinary compass card, to the center of whose upper surface is attached a metallic bar, through the agency of which an electric circuit is closed, and a bell is sounded as soon as the vessel is off her course either way beyond a given amount of latitude. To effect this there are two index hands, which may be set at will at any distance on either side of the metal bar. These hands carry at their ends thick platinum wires, bent downward, so that they are touched by the metallic bar on the compass card as soon as the vessel is out of her course beyond the given limit. These wires are connected to one pole of a Leclanché battery, while the point carrying the card is connected with the other. The compass can also be used in the ordinary manner.

Tem′pered Glass. (*Glass.*) A process invented by M. de la Bastie, which consists in heating a piece or object of glass to such a heat as to approach malleability, but not hot enough to lose its shape, and then plunging it into a bath of fatty and resinous matter, which is heated to liquidity and maintained at a heat of from 300° to 600° F., according to the quality of the glass.

The difference of temperature between the malleable state of glass, say 1400° F., and that of the bath constitutes the "temper."

The glass is much strengthened against injury by a blow, but becomes fractured by being cut with a diamond. It resists great changes of temperature. It is much more elastic also.

It can be depolished and cut by the wheel. See also Compressed Glass.

Tempered Glass, *Bauree* "*Technologiste*," xxxvii. 182-194.
On, *Leger* . . . . "*Technologiste*," xl. 68.

Tem′per-ing. Chisels for dressing French burr stones may be tempered by heating to a dark cherry red, and quenching in the following solution: To three gallons of water add three ounces each of spirit of niter, spirit of hartshorn, white vitriol, sal ammoniac, and alum, and six ounces of common salt, with a double handful of hoof parings.

Fig. 2413.

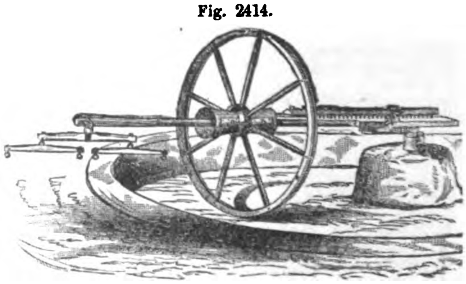
Tempering Gas Heater.

Tem′per-ing Gas Heat′er. A gas heater, Fig. 2413, with directing and concentrating flanges for directing the heat.

Tem′per-ing Wheel. Fig. 2414 represents Allen's clay tempering wheel. It is used in the preparation of clay for making bricks, and for mixing mortar in large quantities; the substance to be worked being placed in a circular pit, as shown in the engraving, of 16′ to 30′ diameter.

It is made with wrought iron or with cast iron arms or spokes, and of any length of shaft required.

Fig. 2414.



Tempering Wheel.

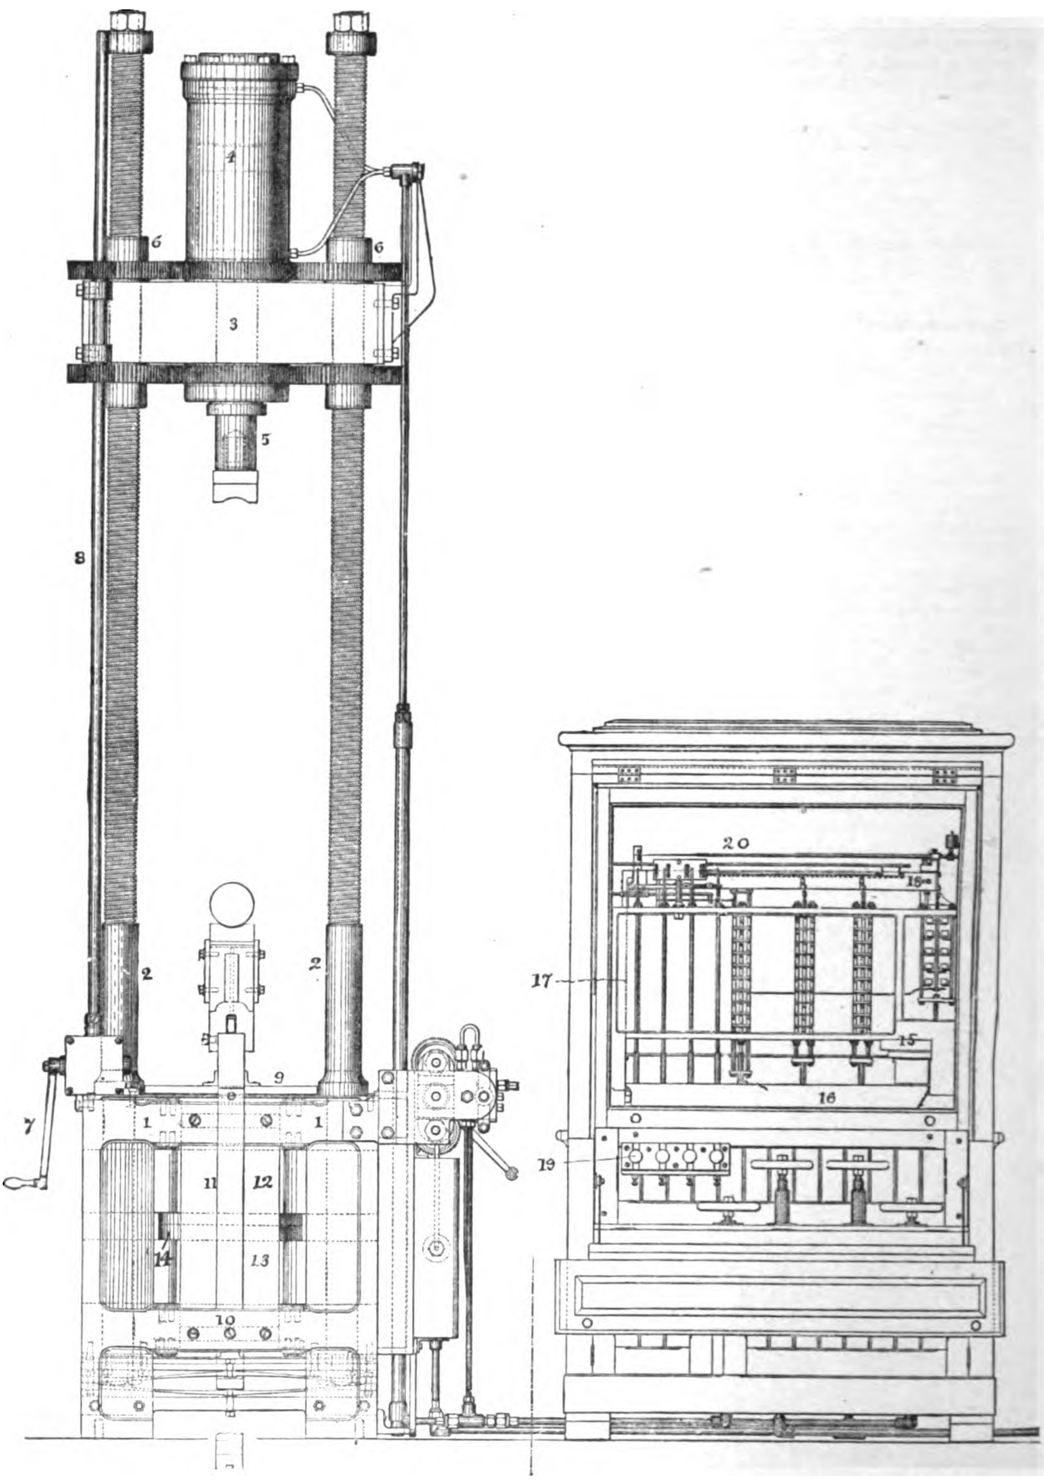


PLATE XLIX. EMERY'S TESTING MACHINE See page 887.

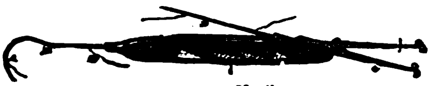
The heaviest piece weighs 830 lbs. The cubic measurement of the whole is about 40′.

Ten-ac′u-lum For′ceps. (*Surgical.*) An instrument for withdrawing and detaining the parietes of an artery to facilitate tying.

Ten-ac′u-lum Nee′dle. (*Surgical.*) A curved surgical needle, Fig. 2415, the invention of Dr. C. J. Cleborne.

Fig. 2415.



Tenaculum Needle.

Ten′der Por′ce-lain. (*Ceramics.*) A soft body porcelain made in Europe.

a. The kaolin body porcelain of England is composed of—

Calcined bone-dust	47
Kaolin	34
Feldspar	19
	100

The phosphate of lime gives a translucent character, but the ware is tender and baked at a low heat.

b. Pâte tendre is a vitreous porcelain, formerly made at Sèvres, before the Böttger recipe for hard porcelain was introduced at Sèvres in 1765. *Vieux Sèvres* was abandoned in 1804.

Ten′sion Ap′pa-ra′tus. Fig. 2416 represents Dalton's apparatus, used by him, for the determination of the tension of the vapor of ether, and is interesting as being the instrument by which he arrived at one of his most important experimental laws, — the law of tensions. Almost all the apparatus of Dalton is of a somewhat rude description; this gives it the more interest, knowing as we do the immense results he obtained with their aid. The one under notice is no exception to this, being made by him of wood, the central figures and lines being written on paper, which is pasted on. It is about 3′ long.

Fig. 2416.

Tension Apparatus.

Ten′sion Rol′ler. A pulley, drum, or roller resting against a belt to cause it to adhere to the driving pulley. A *tightening pulley.*

Fig. 2417.

Dark Tent.

Tent. Fig. 2417 shows a dark tent for use in developing the plates in outdoor photography. The box carrying the tent and forming part of same contains a reservoir and developing tray, and is mounted on a light tripod. One of the many improvements in out-door photography by the Scovill Manufacturing Co., of New York.

Test′ing Ma-chine′. A machine for ascertaining the strength of an object for trial.

A familiar class of machines of this character are *dynamometers*, which are, however, principally adapted to ascertain the power or strength exerted; while those usually termed *testing machines* are intended to ascertain the strength of materials.

There is no absolutely clear line to be drawn between these classes of machines. It is a question of adaptation and application.

The ordinary form of testing machine for ascertaining the strength of metals is founded upon the Roman *statera*, the lever balance, with special arrangements incident to its new function. Such are shown on pp. 2536–2539, "*Mech. Dict.*"

Ordance Department machine, Fig. 6323.
Prof. Thurston's machine, Fig. 6324.
Colt's armory machine, Fig. 6325.
Fairbanks's machine, Figs. 6326, 6327.
Kirkaldy's (English) machine, Fig. 6328.

A number of machines, usually of a smaller size than these which deal with steel rods of inch square section, for instance, are made for various other tests, and these may be found in this volume under the following heads: —

Belt-tension apparatus.	Oil tester.
Cable testing machine.	Paper tester.
Cement tester.	Petroleum tester.
Cloth tester.	Pipe testing machine.
Coal testing apparatus.	Spring tester.
Dynagraph.	Strain measurer.
Dynamometer.	Tannin tester.
Fiber tester.	Taseometer.
Gas testing apparatus.	Test gage.
Lubricant tester.	Wire tester.
Milk testing tube.	Yarn tester.

It should be added that a large number of instruments are also *testers*. As, for instance —

The *photometer* is the tester of the illuminating quality of gas, candles, etc.

The *pulsometer* or *sphygmometer*, of the rate and force of the pulse.

Without adding other instances, please refer to specific index, under the caption MEASURING, CALCULATING, TESTING, AND RECORDING INSTRUMENTS.

In the Emery system of testing machines, scales, gages, and dynamometers, power is transmitted from the load to the indicating device, by means of liquid acting on diaphragms, so as to avoid friction and give the result with the utmost accuracy.

Plate XLIX. represents a fifty-ton testing machine made under this system. It is constructed with a bed, 1, to which are firmly fixed stationary straining screws 2. Adjustably mounted on these is a straining beam, 3, carrying a straining press, 4, in which is a double acting piston, with piston-rod, 5. Geared nuts, 6, operated by a crank, 7, through the medium of a splined shaft, 8, move the straining beam 3 up or down to adjust its position for long or short specimens and to give light strains if desired. Heavy strains, and usually light ones, of either tension, or compression or transverse loads are given to the specimen by the hydraulic press piston, 5. The strain is transmitted directly from the specimen to a yoke consisting of a platform, 9, a beam, 10, and connecting plates, 11, which yoke is fixed in position by flexible plates and transmits pressure in the axis of the machine to a pair of coupled load beams, 12 and 13, between which rests a hydraulic support, 14. With strains of tension, 13 is the free platform and 12 the bed of the scale. For compression or transverse loads, 13 is the bed of the scale and 12 the free platform, the strain being transmitted from the specimen to the support 14 in either direction according to the direction of the strain. The pressure on the liquid in the hydraulic support 14 is conveyed to a small chamber, 15, in the weigh case. From this small chamber the pressure is communicated through a fixed fulcrum plate to the levers 16, 15, and from it through a yoke, 17, to a lever, 18, to which are attached a series of poise-rods, each carrying 10 weights which are operated by levers 19, 18. The weights have values of 10, 100, 1,000, and 10,000 each, depending on which poise-rod they are applied to. An indicator, 20, 19, shows when the scale is balanced. The ratio of movement of the indicator to the platform is 400,000 to 1 in this machine, so that a millionth of an inch movement of the platform gives .40 of an inch at the indicator. The drawing shows the transverse apparatus in position with a specimen ready to be loaded.

A testing machine of four hundred tons capacity built by Mr. Emery for the United States government has been in practical use for seven years without repairs of any sort and its efficiency and delicacy are as great as when first erected.

In regard to this machine the late eminent engineer, Alexander L. Holley, said: —

"The excellence of the machine in every respect is more than satisfactory, and its accuracy is at first sight astonishing, although an investigation of its principles must show that if the weighing apparatus will weigh at all, it must do so with perfect accuracy, because all its movements are absolutely without friction.

"The proof experiments were numerous, and the effects of recoil after sudden ruptures at maximum loads, were watched with great care, but without much anxiety, because the weighing parts affected are by no means delicate in structure and their motion is almost infinitely small. Among the tests were the following: —

"A forged link of hard wrought iron, 5″ in diameter between the eyes, was slowly strained in tension, and broke off with a loud report at 722,800 pounds. The diameter before breaking at the point of fracture was 5.04″; after breaking 4.98″.

"In order to see if the weighing parts had been disturbed by the recoil, which was obviously near the greatest recoil the machine will ever suffer, a horse-hair was next tested; it was 7-1000ths of an inch in diameter; it stretched 30 per cent. and broke at 1 pound. Other horse-hairs varied in tenacity between 1 and 2 pounds. A 5″ round bar, turned down to 3⅛″ in diameter along the center, was pulled apart at 430,200 pounds tension. Then some more horse-hairs were tested; also copper wires 19½-1000ths of an inch in diameter, which averaged 25 pounds tenacity.

"Specimens were subjected to 1,000,000 pounds compression although the contract calls for but 800,000 pounds. After these proofs, delicate structures such as eggs and nuts were tested in compression, and violin strings in tension. It is unnecessary to multiply instances. It seems safe to conclude that bars and structures up to 400 tons can now be tested with perfect accuracy, and that there is no reason to fear the deterioration of the weighing apparatus.

The machine consists of a double-acting straining cylinder and ram on a carriage at one end, and a movable weighing apparatus at the other end. The two are connected by a pair of 8½″ screws, 48′ long. Nuts driven by shafting move the straining cylinder to different places on the screws, so as to test long and short specimens. The weighing apparatus has been described as a reversed hydrostatic press, having diaphragms instead of pistons. The load is transferred by means of a liquid (alcohol or glycerine) by a series of large diaphragms to a series of small ones, and finally to a system of scale-beams. Thus a weight of 800,000 pounds acting through an inconceivably small space, finally moves a finely graduated indicator at the rate of 1-100th of an inch per pound. It is allowed to move through a space of 2″ and is kept balanced by weights mechanically placed quickly on or off the scale-beam. One pound, in moving the indicator 1-100th of an inch, moves the platform against which the load presses, 1-42,000,000th of an inch. The whole arrangement of the scale-beams, the adding and removing of weights, and the fast or slow but always steady application of pressure are ingenious and convenient in the highest degree. By means of universal joints, the pressure pipes are always connected to the straining cylinder, etc., whatever the position. The steam pump and the accumulator have cylinders and weights respectively for high and low pressures, and the machine receives pressure without pulsation, from the accumulator only, when testing

"The finished metal in the machine weighs 175,000 pounds and includes pieces of 14,000 pounds down to those of which 250,000 would weigh 1 pound. The hydrostatic weighing platform of the machine was tested to 1,500,000 pounds, but so perfectly frictionless is it that a horse-hair under a breaking strain of one pound had to move 24,000 pounds of metal. The workmanship is also remarkable. The 8½″ screws, 48′ long, were fitted to gages within 1-1000th of an inch in diameter throughout their length, and similar accuracy was maintained in other parts."

The boiler plate testing machine of E. & J. Fairbanks & Co., used by the U. S. steamboat inspectors, has a capacity of 75,000 lbs.

The weighing apparatus is a regular platform scale, and may be tested with standard weights to prove its accuracy. The strain is applied to the specimen of boiler plate by means of two screws and worm gears worked by a large gear-wheel and a small pinion. The main beam *A* of the scale carries a poise or weight *B*, which moves on rollers and may be run out to 75,000 lbs. The light beam *C* has a finer graduation on it, running up to 6,000 lbs. The poise *D*, on this beam, is moved automatically by an arrangement of clock-work, *E*, attached to the end of the beam.

The platform of the scale *K* rests on four knife-edges in the main levers *F*, one at each corner of the scale. These levers connect with the double lever *G*, through which the strain is transmitted to the lever *H*, and then through the lever *J* to the steelyard rod of the scale and by that to the beam *A*.

The two columns *L L*, with the cross-head and upper clamp *M*, rest on the platform of the scale. The lower clamp *N* is secured to the cross-head *P*, which is worked up or down by the screws *R R*, turned by worm gears *S S*, on their lower ends, which receive their motion from worms on the shaft carrying the gear-wheel *T*.

To make a test, the specimen *V* of iron to be tested is secured in the clamps *M N*, by steel wedges *W W*. When this is done the specimen is the only connection between the screws and gearing and the platform of the scale.

To begin the test the pinion *U* is shipped out of gear, and the gearing and screws are turned by the handle *Y* until a slight strain is applied to the specimen, when the pinion *U* is shipped into gear. As the strain on the specimen increases the beam of the scale rises, causing the automatic poise *D* to move along on the beam until it reaches the point equal to the strain applied to the specimen, when the beam drops and the poise instantly stops. This operation is continued until the specimen is broken, when the point at which the poise stands will indicate the exact number of pounds which were required to break the specimen.

The testing machine of M. Thomasset (French), Fig. 2417½, avoids the blows incident to the piston of the hydraulic pump when moved by a lever, and has a piston moved by a screw, preventing any jar.

The pressure in the pump is obtained by a hand-wheel on whose shaft is a worm gearing into a cog-wheel on the shaft of the screw whose lower end carries the piston. The pressure in the pump cylinder is transmitted by a pipe to the horizontal cylinder in which is the piston whose rod exerts the tractive force upon the piece under experiment. The other end of the test-piece is held by a clasp connected with the short arm of a heavy lever, the horizontal arm of which rests at its end upon the diaphragm of a cylinder, the water in which transmits the pressure to a column of mercury in the manometer standing alongside

The machine requires but little change for making tests in compression. For flexion the piece is supported between two edges, and a third one at the end of the ram is brought against the middle of the piece.

various internal working parts. The dial is so divided as to show hourly rate of consumption by observations of one minute.

The-od'o-lite. A *distance telescope* (theodolite), with a self-registering scale of distances, has lately been invented in Sweden by Mr. Ljungström. The difference between this instrument and others of this class, is principally that the instrument itself effects all the calculations which otherwise are necessary in consequence of the inclined angles, and also that the distances sought are immediately marked on the plane-table. The line of sight upon a leveling-staff having been taken by the telescope which is fixed on a ruler that lies on the plane-table, and can swing round on a fixed needle to a piece as large as the part read off on the leveling-staff, is marked on a movable scale on the instrument, upon which a knob being touched, the point of a needle marks the distance on the paper. The calculating operations are effected by the inclined movement of the telescope, which, by means of a curved line, places the scale at such angles to the vertical plane of the line of sight that the sine for these angles constitute the square cosine for the inclined angle of the telescope, and this sine is then projected towards the movable needle.

Ther-a-peu'tic Ma-chin'e-ry. Fig. 2419, is Dr. Zanders' instrument for treating the muscles of the ankle.

It consists of a sole-plate, to which the foot is secured by means of two sliding stops working on a screw, and adjusted by a small lever. This sole-plate is mounted on a bent axle, the lower end of which is pivoted on to the frame of the machine, and the upper end is connected with a sliding-bar that passes through the spindle of a fly-wheel on the top of the frame. When this wheel is caused to revolve, the axle and sole-plate revolve with it, with an angularity of movement more or less marked according to the distance of the upper bearing of the axle from the center of the wheel spindle. The person operated upon sits in a chair in front of the instrument with his foot secured to the sole-plate as described.

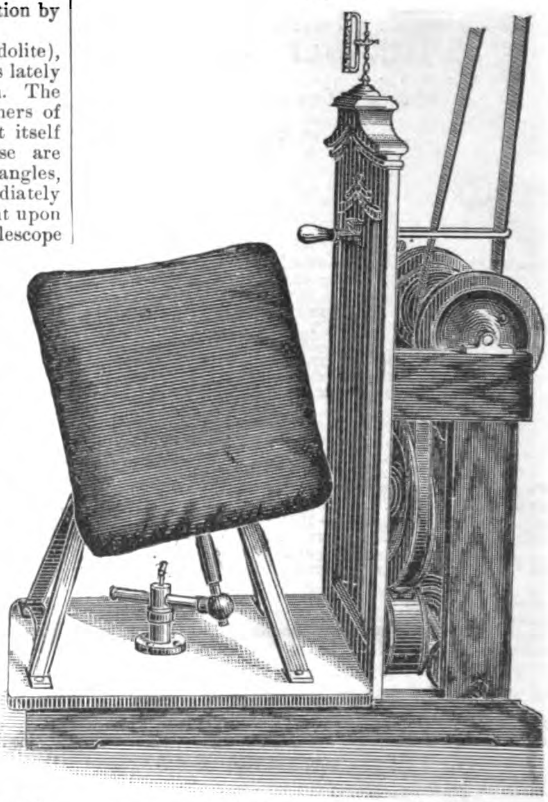
Fig. 2420 represents Dr. Zanders' machine, consisting of a saddle mounted on a shaft, the lower end of the shaft working in a socket on a sliding bar to regulate the motion. The patient, sitting astride of the saddle, is subjected to the influence of a more or less pronounced rolling movement, which brings the muscles of the trunk into action.

Fig. 2419.

Apparatus for Strengthening the Ankles.

Fig. 2421 represents Dr. Zanders' compound machine for acting on the muscles of the legs, and for friction or percussion on any part of the body. The former consists of a horizontal padded cushion, hinged at one extremity and resting on cams at the other, to which a very rapid rotary motion is imparted in such a way that the cushion is thrown into a state of intense vibration. The restorative action of this part of the machine is very remarkable. The other part of the apparatus consists of a vertical spindle sliding in long bearings, and capable of being locked at any height by the set screws shown. A very rapid reciprocating motion is imparted to this spindle by means of the small connecting rod shown on the left-hand side of the engraving. The pad at the top of the spindle is caused to move to and fro with about 600 strokes per minute. This

Fig. 2420.

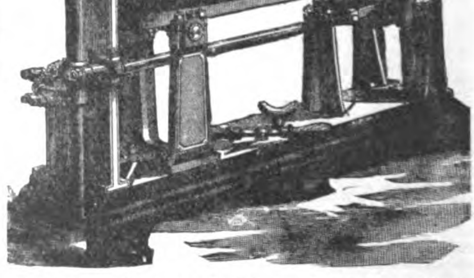


Apparatus for Developing the Muscles of the Body.

apparatus is especially intended for application to the back and shoulder, and different shaped pads are employed according to circumstances.

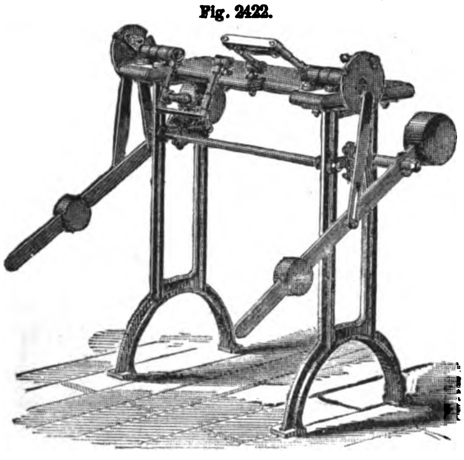
Fig. 2422 represents Dr. Zanders' machine designed for strengthening the wrists. With the fore part of the arm laid flat upon the table of the machine the patient grasps the two

Fig. 2421.



Apparatus for Developing the Muscles of the Legs and Body.

Fig. 2422.



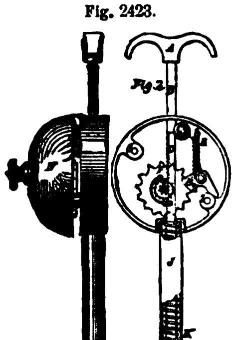
Wrist Strengthening Apparatus.

handles, and slowly raises them, repeating the operation as long as necessary. These handles are not connected with each other, but are hinged on the inner side to the table, and on the outer are connected to a shaft, on the end of which is a short crank, a pin at the end of which fits into one or other of the notches shown around the periphery of the disk, to which are coupled two rods carrying a transverse weighted bar. The effort required to turn this bar upon its center varies with the position of the balance weights.

Ther'mal A-larm'.

Fig. 2423 is an engraving of a very useful instrument designed and constructed by Mr. Stephen Alley, of Glasgow, Scotland, for giving a prompt indication of a hot bearing.

Fig. 2423.



Thermal Alarm for Hot Boxes.

The apparatus consists simply of a brass tube, *J*, which is placed in a hole bored in the cap of the bearing to receive it, the bottom of the tube touching the shaft. At one side, near the bottom, the tube *J* is partly cut away so as to admit of the ready insertion of a cylindrical plug, *L*, formed of a hard grease, or of a composition which will melt at the temperature at which it is desired that the alarm should be given. To insert the plug *L*, the handle *A* is pulled so as to draw up the spindle *B*, and thus, by compressing the spring *K*, make room between the bottom of the spindle and the bottom of the tube for the plug to be inserted. If the bearing becomes heated, the plug *L* begins to melt, and escapes drop by drop through the hole *M*. As this melting takes place, the spring *K* forces down the spindle *B*, and in so doing gives motion by the rack *D* to the pinion *G*, and thence by the ratchet *O* to the striking wheel *F*. This wheel, as it revolves, operates upon the pallet *H*, and alternately draws back and releases the hammer *C*, which, when released, is made to strike the interior of the bell *N* by the action of the spring *F*.

The instrument gives a number of clear and distinct signals as the composition melts, and can scarcely fail to call the attention of the engineer. It is, moreover, a very simple apparatus, and there is nothing about it likely to get out of order.

Ther'mo-cau'te-ry Ap'pa-ra'tus. (*Surgical.*)

An instrument with hollow platinum cautery, which, having been heated to blackness in a spirit lamp, receives a blast of benzine vapor from a spray bellows which heats the cautery to redness, and maintains the heat by an occasional pressure of the air-bulb.

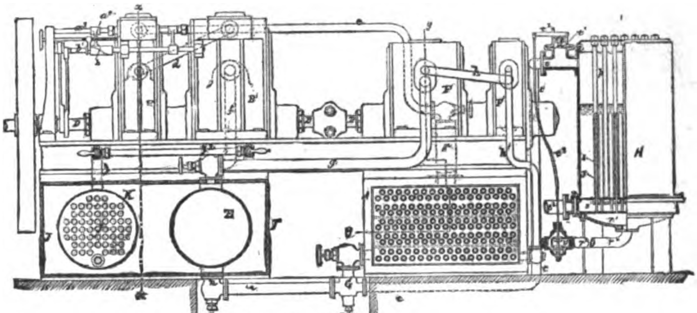
Paquelin's Fig. 482, Part I., *Tiemann's "Armamentarium Chirurgicum."*

Ther'mo-dy-nam'ic En'gine.

Fig. 2424 represents Gamgee's engine, the "Zeromotor." A motor engine with conditions of a closed circuit with a liquid boiling at a low temperature relatively to water transformed into vapor, the molecular energy of which is converted into the mass or molar motion of the piston, so that its initial condition is restored. In this way, in a heat engine, the temperature is extended within which the heat is utilized downward in the direction of the absolute zero instead of upward above the temperature of surrounding objects.

The agent intended to be used is anhydrous ammonia, the boiling point of which at atmospheric pressure approaches closely to 34.4° centigrade. At 0° centigrade its vapor tension is 3,183.84 millimeters, or about four atmospheres, while at 10° it attains to 4,574.03 millimeters or six atmospheres. When the mean temperature attains 20° centigrade no less a pressure is exerted than 6,387.78 millimeters, or nine atmospheres; and at 30° centigrade, or tropical heat, it reaches over 8,000 millimeters, or over 10½ atmospheres in tension. Since at blood-heat 200 lbs. to the square inch is available, it is evident that the usual temperature of ocean or river water is most desirable in practice, and best, it is thought, when below 20° centigrade. The latent heat of ammonia (900° as against 960° for water) is used in developing energy, so as to reduce the amount of rejected heat to a minimum, and obtain a maximum rate of liquefaction.

Fig. 2424.



Thermo-dynamic Engine.

The engine shown in the figure is a double-cylinder rotary engine, *B* being the first or high-pressure cylinder, and *B'* the second or low-pressure cylinder, into which the first cylinder exhausts through pipe *d*. As seen in section, the gas or vapor enters the cylinder *B* through the valve *a* and sliding division-port *a'*, which runs in contact with the eccentric rotary piston *C* in the usual way. The admission-valve is operated from the rocking valve-rod a^3 in the usual way, said rod having an arm, a^2, which bears against the rotating adjustable cut-off cam *b*, whose shaft *b'* is rotated through the medium of eccentrics and connecting-rods from the main shaft *D* in the ordinary manner. The exhaust-port of the first cylinder is shown at *d'* in communication with the exhaust-pipe *d*, which leads to the gas or vapor admitting valve of the second cylinder *B'*. The latter, with its accessories, is similar, except in size, to the first cylinder *B*, the shaft *D* being common to both, and the two cylinders are combined together for operation in the same way as the two cylinders of an ordinary compound or double-cylinder rotary engine.

The pipe *e* conducts the liquefiable gas or vapor to the primary cylinder *B* from the dome A^1 of the part *A*, which, for convenience' sake, will be termed the "boiler."

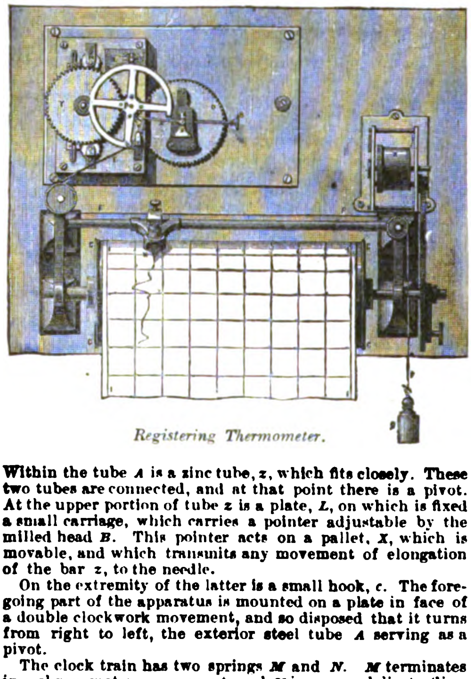
The exhaust-pipe *f* from the second cylinder *B'*, leads into the closed exhaust-vessel *E*. This vessel receives, through the exhaust-pipe *f*, the liquefied vapor and gas from the second cylinder.

From the upper part of the exhaust-vessel leads a pipe, *g*, to the larger cylinder *F* of a compound or double cylinder rotary pump, *F F'*, driven by the rotary shaft *D*. The smaller or high-pressure cylinder *F'*, with its accessories, is the counterpart of the other, and has its induction-port in communication with the eduction-port of the larger cylinder through the intermediary of pipe *h*. The eduction-port of the smaller cylinder *F'*, communicates through pipe *h'*, with the space in boiler *A*, which receives the liquid from which the motor gas or vapor is to be generated.

Ther-mom'e-ter. Fig. 2425 is a representation of Redier' new registering thermometer which operates through the dilatation in a straight line of two metals, zinc and steel.

If a multiplying mechanism be mounted on a steel bar, 39'' long, and connected with a zinc bar of the same length, the difference of the two expansions per 212° Fah. will be about .08''. This difference is used in the present apparatus to register changes in temperature. The thermometer proper consists of an exterior steel tube, *A*, which carries a toothed wheel, *D*, on which multiplying mechanism is mounted.

Fig. 2425.



Registering Thermometer.

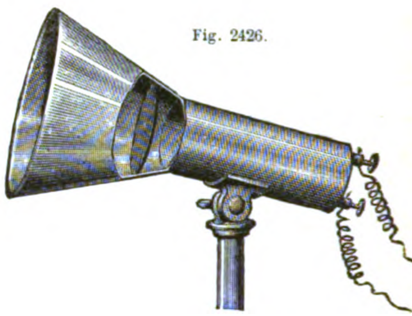
Within the tube *A* is a zinc tube, *z*, which fits closely. These two tubes are connected, and at that point there is a pivot. At the upper portion of tube *z* is a plate, *L*, on which is fixed a small carriage, which carries a pointer adjustable by the milled head *B*. This pointer acts on a pallet, *X*, which is movable, and which transmits any movement of elongation of the bar *z*, to the needle.

On the extremity of the latter is a small hook, *c*. The foregoing part of the apparatus is mounted on a plate in face of a double clockwork movement, and so disposed that it turns from right to left, the exterior steel tube *A* serving as a pivot.

The clock train has two springs *M* and *N*. *M* terminates in a chronometer escapement, and *N* in a very delicate flier, which turns with great rapidity. These two movements are interconnected by the differential train *R R S*. The satellite *S* entrains the axis *A* which on one side carries the pulley *P* on which is wound a cord which moves the pencil, and on the other a pinion, *E*, which engages with the wheel *D* of the thermometer. These two gears are so constructed that the velocity of motor *M* being 1, that of motor *N* will be 2.

We may now trace the operation under a constant temperature. The hook *c* of the needle *A* stops the small fly-wheel. The escapement *E* of the motor *M*, which works constantly, turns the large wheel *D* from right to left. The needle *A* follows the movement and disengages the flier *V* and spring *N*. The latter now being freed, and its velocity being .2, while that of the escapement is .1, tends to turn the wheel *D* from right to left until the needle *A* again catches by its hook, when the same operation is repeated. As the pulley *P* makes the same movement as the wheel, the pencil will trace on paper, if the temperature remains constant, a right line, apparently continuous, but in reality formed of a series of very small zigzags. This movement of constant oscillation is of great importance as regards the sensitiveness of the instrument, as it suppresses the effect of friction at starting and renders the instrument always ready to show instantly the least change of position of the needle. If the temperature augments, the flier *V* remains hooked for a longer or shorter period, proportional to the change of temperature, and as the increase, while turning the wheel *D* from left to right to unhook the flier, also causes the turning of the pulley *P*, the latter will rotate over an angle proportionate to that which the change of temperature causes the needle to pass over. The inverse effect is produced when the temperature falls. The pencil *K*, Fig. 2425, moves on a cylinder, *C*, on which the paper *H* is rolled. The chronometer *R* regulates the movement of this cylinder at a velocity of 0.16'' per hour.

Fig. 2426.



Thermo-telephone.

Ther'mo-phone. (*Electricity.*) An instrument in which sonorous vibrations are produced by the expansion of bodies under the influence of heat. One that produces sound by thermo-action through conversion of forces, or in other words, in rapid expansion and contraction of its circuit by sudden changes of temperature.

Wiesendanger	* "*Teleg. Journal,*" vi. 410.
	* "*Engineer,*" xlvi. 335.
Hughes	* "*Engineer,*" xlv. 344, Fig. 8.

Ther'mo-scope. When chloride of cobalt is dissolved in a definite quantity of strong wine spirit, or alcohol slightly diluted with water, a solution is obtained the color of which varies in a curious manner with the temperature of the surrounding air. Exposed to cold air it develops a bright pink color, which, as the temperature of the air increases, passes through various shades of color, until at last, when the liquid becomes quite warm, it assumes a strong blue or violet blue hue. These color changes are primarily due to the fact that in the cold alcoholic solution the salt appropriates a portion of the water, and when heated, it parts with this water of crystallization or hydration. When the proportions of the chloride of cobalt, alcohol, and water are properly adjusted, and the liquid is sealed in a narrow glass tube, it becomes quite sensitive to change of temperature, and the varied changes of tint when compared with a standardized color scale may serve, within certain limits, as a rough index of the temperature of surrounding bodies, thus constituting the little instrument a thermoscope, if not entitling it to the name chromothermometer, which has been given it. The statements to the effect that changes of color are due to the action of light and electricity or atmospheric humidity, etc., are of course erroneous.

To prepare the solution, dissolve a few crystals of chloride of cobalt (pure) in two or three drachms of warm water, and to this add strong alcohol until, when exposed to a temperature of about 70° Fah., the liquid presents a slaty color, — intermediate between the pink and blue. The proportions will then stand at about twenty grains of the salt to the fluid ounce of alcohol. If too blue, more alcohol or a drop of water may be added to the solution; if it inclines too strongly to the pink a few more grains of the salt.

The solution may be poured into a long, narrow test tube, leaving the upper part of the tube unoccupied, so that it may be subsequently drawn out, and sealed hermetically by means of the blowpipe.

The remarkable properties possessed by some of the solutions of this salt certainly suggest the possibility of applying it to something of greater practical utility than the curious toys in which it has thus far been chiefly employed.

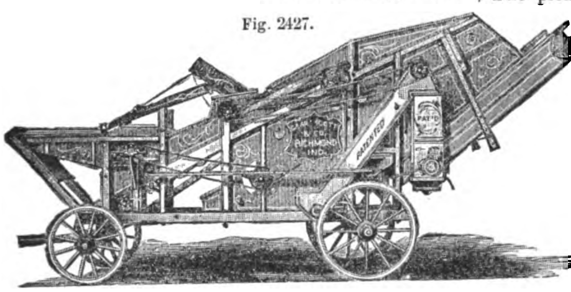
Ther′mo-tel′e-phone. (*Electric.*) Fig. 2426 is a thermo-telephone.

It consists of a thermopile having placed in its collecting funnel a hard rubber disk, as shown in the engraving. A sound made in front of this disk is heard in a receiving telephone connected with the thermopile.

The *rationale* of this is at once apparent when a strip of hard rubber is placed against the lips and bent, so that the strip will be alternately concave and convex. The difference in temperature is very perceptible, the convex surface being cold and the concave surface warm, and, however rapid the vibrations which render the surfaces alternately convex and concave, the result is the same.

Thom′son Bat′te-ry. (*Electricity.*) A modification of Menotti's battery, in which a copper tray

Fig. 2427.



Separator.

replaces the copper plate, and contains the sulphate of copper crystals, and the superstratum of wet sawdust upon which rests the zinc element.

The resistance of the battery is very low.

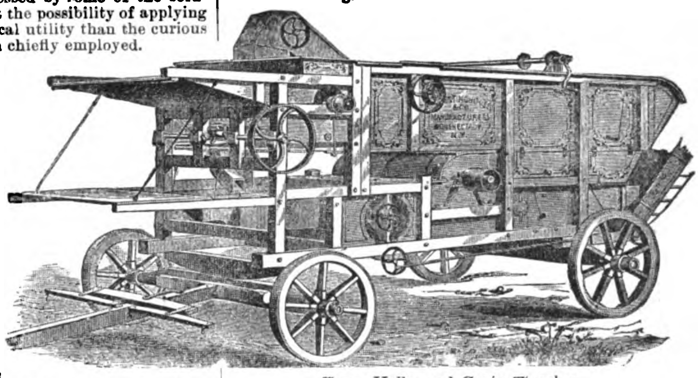
Niaudet, American translation, * 130.

Thrash′er. The Gaar separator, Fig. 2427, is an apron machine whose cylinder has from eight to twelve bars as may be desired, and is full curve spiked. The center heads are placed in the cylinders to increase their strength and the power of their momentum, so that they are not readily checked. All the eight and ten-horse machines, both geared and belt, have outside bearings and pivot boxes on the cylinder shafts. A concave adjuster enables the operator to raise or lower the whole concave any required distance while the machine is in motion.

The grain carrier is shaken its whole length by agitators, facilitating the separation of the grain from the straw. Either screw or drag elevators, as desired. All the geared machines have three hitch gear. The tail chain or straw carrier is shaken its entire length by revolving knockers. The shoe is shaken by a half cross belt, dispensing with the fan cog-wheels and shaker shaft. The cylinders have pivot boxes and steel set screws for adjusting the cylinder endwise.

In the Westinghouse combined clover and grain thrasher, Fig. 2428, the process of separation commences at the thrasher. The cylinder delivers the straw to the vibrating separator, where it is first agitated and loosened by a revolving picker, and a farther division of the seed or grain ensues. After passing the picker, the straw is moved back

Fig. 2428.



Clover Huller and Grain Thrasher.

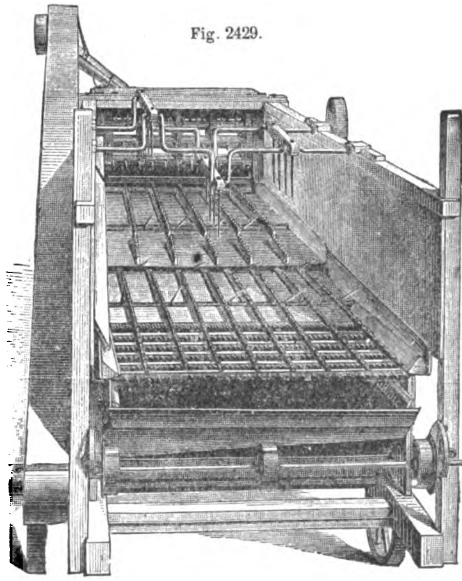
and over a series of shaking forks, which loosen it and permit the grain to reach the open platform, and escape to the grain carrier and fan. The picker, in addition to its help in separating, prevents the straw, with its accompanying seed or grain, from shooting back from the cylinder. The shoe has a short longitudinal action so as not to cause much vibratory motion to the machine.

There is an apparatus for elevating the clean grain or seed as it is discharged from the machine, and emptying either into the measures or bags, making a register of each measure as it is filled.

Thrash′ing Ma-chine′. Fig. 2429 represents an interior view of the Bonanza machine.

It is a vibrator, with large riddle surface, and strong frame, with few wearing points. It has a system of pickers that are useful, especially in damp grain. The front wheels

Fig. 2429.

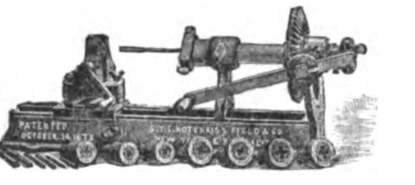


Interior of Separator.

cut under, making it easy to handle. It has many points of separation, and the tables are low.

Thread-cut'ting Ma-chine'. Fig. 2430 represents a self-centering machine for cutting threads in bolts, etc.

Fig. 2430.

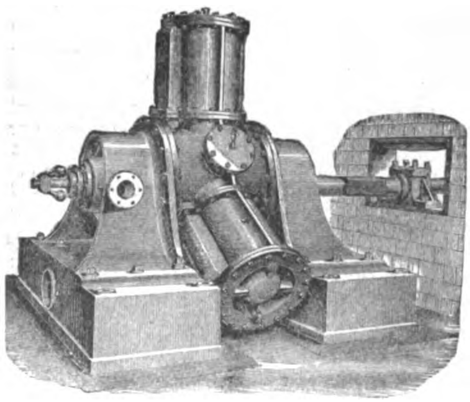


Thread Cutter.

Three-cyl'in-der En'gine. Fig. 2431 represents the Brotherhood engine.

The special advantages secured by the invention are as follows: The engine will start with the crank in any position, there being no "dead center," and a perfectly uniform motion of the shaft is obtained without the use of a fly-wheel; the connecting rods being always in compression, there is no blow on the crank-pin at either end of the stroke, no matter how loose the fit may be or at what speed the engine may be running. The working parts are entirely inclosed and protected from injury; the lubrication is easily effected;

Fig. 2431.



Three-cylinder Engine.

in the steam engine the rotary slide-valve is arranged to cut off at any required degree of expansion, and a governor and reversing gear is readily applied to the steam engine, while the hydraulic engine is made reversible by the addition of Ellington's patent controlling valve.

The high speed at which this engine may be worked, besides developing immense power in proportion to the size of the engine, permits of its being coupled directly to capstans, rotary pumps, fans, circular saws, screw propellers, centrifugal machines, etc.

The pistons are very deep and guide themselves in the cylinders. The connecting rods are of chilled cast iron in the hydraulic engine and of wrought iron well case-hardened in the steam engine, their crank-pin ends working on a hard gun-metal sleeve fitted to the crank-pin, and their piston-ends working in hard gun-metal sockets in the pistons. The crank shaft is of steel, and the crank, where necessary, is counterbalanced. The slide valve is rotary in the hydraulic and the steam engine, and is balanced, special means being adopted to insure uniform wear.

Time Globe. Fig. 2434 shows the time globe.

Mr. L. P. Juvet, of Glen's Falls, N. Y., exhibited at the Centennial a novelty in horological manufacture, which was examined by all scientists with interest, and honored with unqualified praise from all skilled in horology. The time globe, as this invention is happily designated, is a horological apparatus by which the hour at any given place is designated and also the corresponding time anywhere and everywhere on the face of the earth. It consists of a terrestial globe, encircled at the equator by a zone dial, inscribed with

Fig. 2434.

Time Globe.

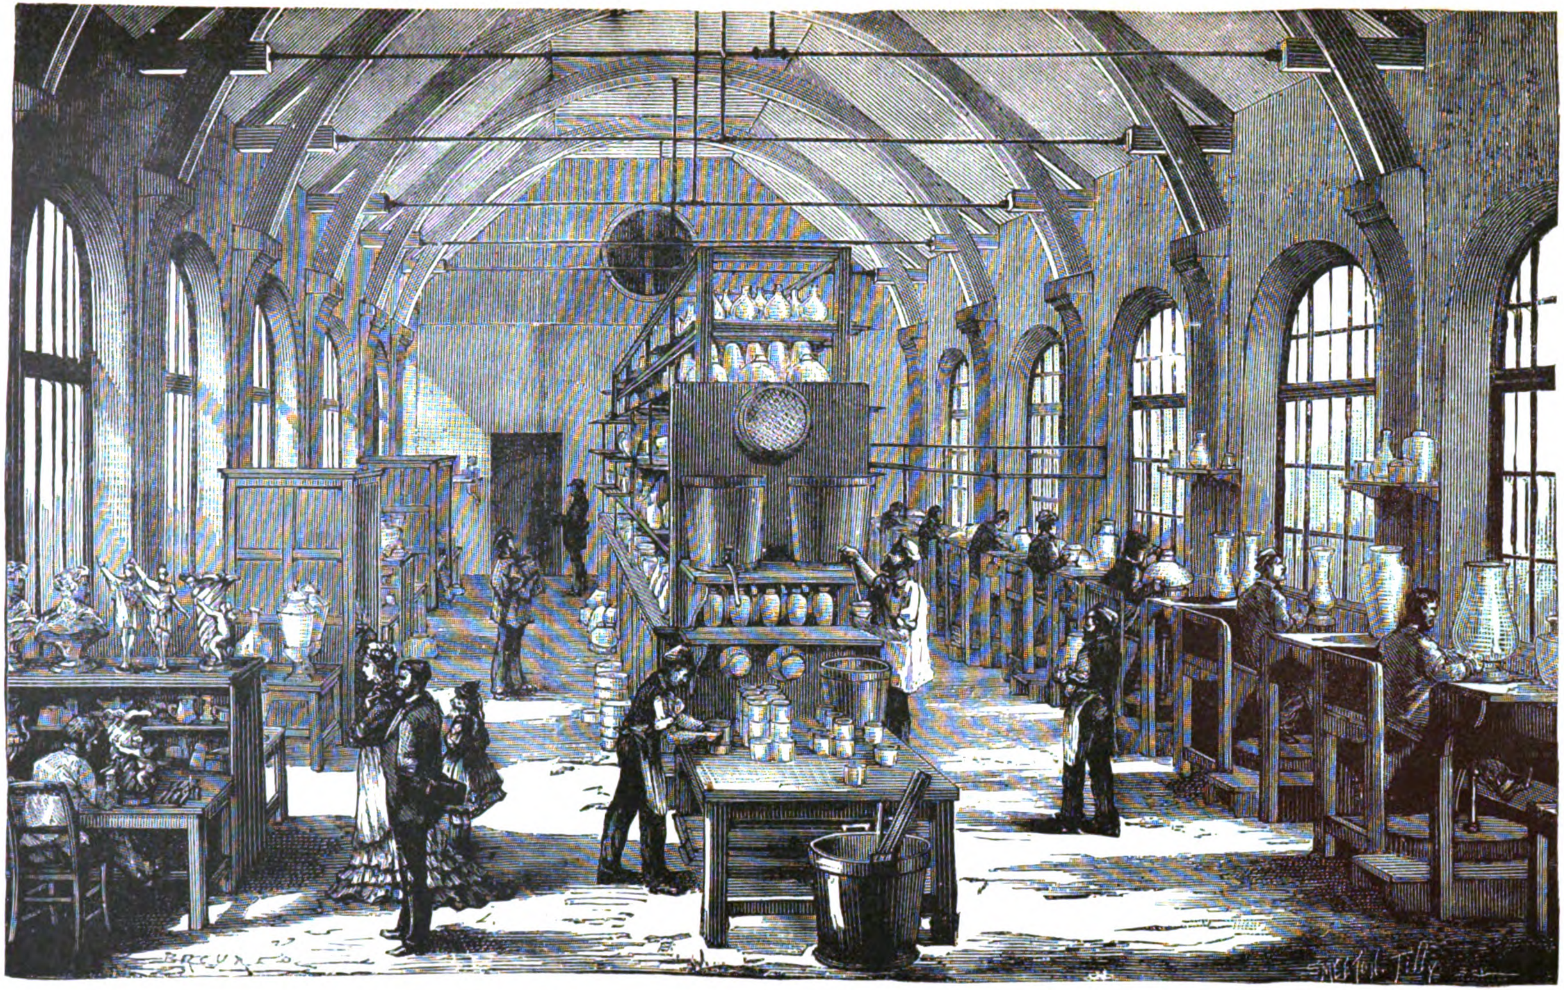

PLATE LI. PORCELAIN MOLDING ROOM. See page 894.

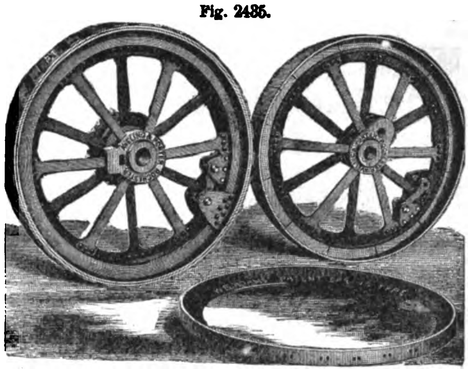
the twenty-four hours of the day and the fractions thereof, while an ordinary clock dial encircles the north pole. The zone dial is stationary, while the terrestial globe revolves on its axis once in twenty-four hours, exactly as the earth does. To set the apparatus in operation for any locality the hands of the clock dial are removed and replaced in position so as to accord with the time indicated by the longitude of that place on the zone dial at the equator. Care must be taken to set the globe in proper sidereal position by the compass, and also that the proper hour of day or night as designated by the zone dial indicates the actual time of day or night, as the case may be. This is easily determined by letting sunshine fall on the globe, and seeing which part is in light and which in shadow. Then set the hands of the clock dial to the actual time of the location, and the terrestial globe revolves on its axis so that the longitude of the location is opposite the same instant on the zone dial. Now the time globe is set, and a glance at the zone dial shows the time opposite every meridian of longitude, and consequently of every place on the surface of the earth. The hands of the clock dial revolve to the right, while the globe revolves to the left, consequently the relative difference in designation of time is maintained, and every meridian of longitude points out its mean time on the zone dial so long as the movement is regulated and kept in proper working order. The movement, which is self-winding in the terrestial globe, is made of two plates, in the center of which stands the main-spring and barrel, with its arbor extending through the globe at the south pole, outside of the meridian ring, where its end is provided with a knot or thumb-piece by means of which the clock is wound up. The shaft of the first wheel extends through the plate and receives a triple wheel intended to transfer to the minute, hour, and globe wheels their proper motions. The axis of these wheels is secured to the upper plate of the works by a flange with pins and screws, extends through the globe at the north pole to the meridian ring, where it is firmly secured by a set screw, and forms with the arbor the axis upon which the globe revolves.

Tire.

Fig. 2485 represents Adams's spring tires for locomotive wheels. To an inner tire of strong spring iron are riveted

Fig. 2485.



Tire for Locomotive Wheel.

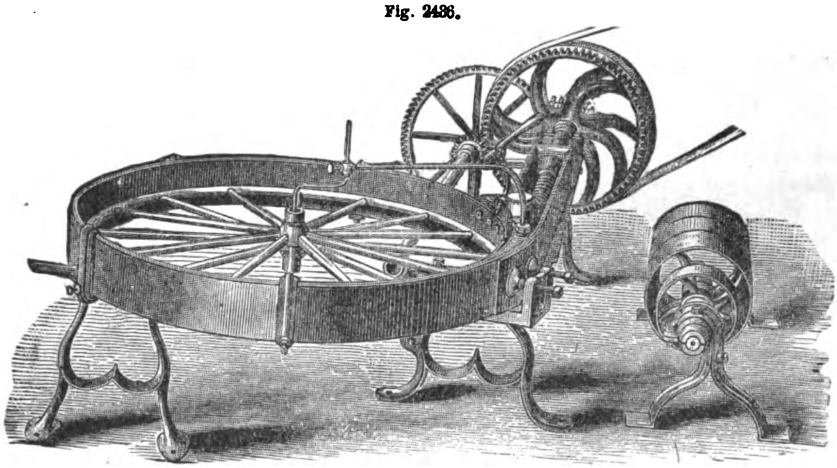
the wrought-iron spokes, while the outer iron consists of a hoop of suitable thickness, stiffened by angle-iron rings running around its edges, and faced with diagonal plates for giving the wheel increased adhesion, as well as for carrying the angle-iron paddles occasionally made use of on soft ground.

Solid blocks of india-rubber between the tires serve the purpose of a spring to the engine without interference with its gearing. The outer and inner tire of each wheel are coupled by a drag link to prevent friction on the rubber blocks.

Tire Set'ter.

The West tire setter, Fig. 2436, is arranged with a strap made up of several thicknesses of thin steel, and capable of being "set up" by a powerful screw, worked by a belt. A

Fig. 2436.



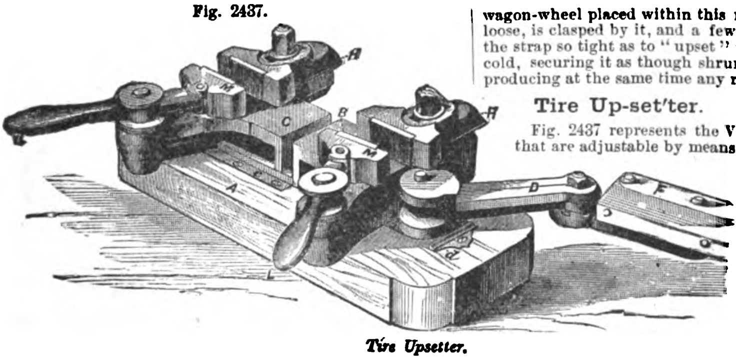
Tire Setter.

wagon-wheel placed within this ring, with its tire perfectly loose, is clasped by it, and a few turns of the screw draws the strap so tight as to "upset" the tire, although perfectly cold, securing it as though shrunken in the usual way, and producing at the same time any required dish of the wheel.

Tire Up-set'ter.

Fig. 2437 represents the Vulcan machine; has levers that are adjustable by means of a joint. They allow of grasping and holding various shapes of iron, from ½″ to 3½″ wide.

Fig. 2437.



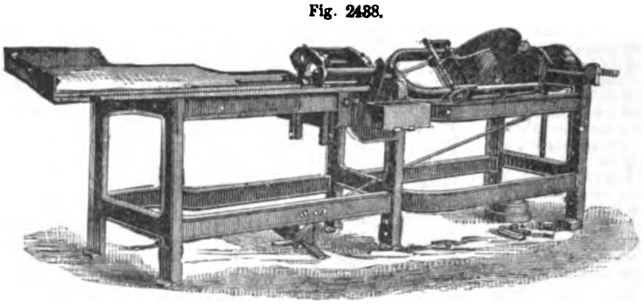
Tire Upsetter.

To-bac'co Spin'ning Ma-chine'.

Fig. 2438 shows the Robinson tobacco spinning machine.

A machine to spin small twist, constructed to run

Fig. 2438.



Tobacco Spinner.

at great speed, light, and without strain, making a fine cord. The rollers pass the twist between them, so as only to require winding up by the bobbin; this is done by a slight self-acting friction which is of a uniform tension and under the immediate control of the spinner. The machines are made to suit different sizes of twist, from 8-16″ to ¾″ and for any sort of tobacco. The quantity which can be spun per day varies from 75 lbs. to 250 lbs., according to size, etc. They will work either long or short-filler, there is no strain on the twist, and shorts can be spun if desired. The tobacco when spun passes on to the bobbin, which when full is very easily replaced by an empty one.

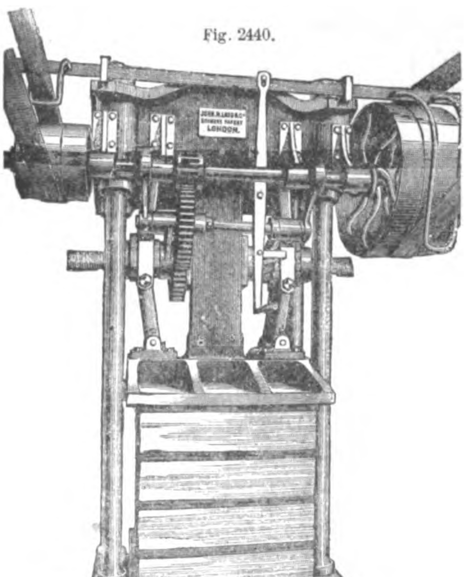
Tog'gle Iron. A harpoon, Fig. 2439, with latch that prevents retraction.

Fig. 2439.

Toggle Iron.

Tog'gle Press. A press in which the power is obtained by the action of one or more toggle joints. See p. 2586, "*Mech. Dict.*"

Fig. 2440.



Toggle Press.

Fig. 2440 represents the Boomer & Boschert. The principle by which its accumulative power is acquired is the combination of four levers acting upon toggle joints, either to approach or to diverge, according to the direction of such rotation, with uniform motion. The power is controlled by a standard fastened to the follower sliding through the head block between the arms, maintaining the follower on a level, and preventing an endwise movement of the screw. The gross load is transmitted through the toggle joints to the top frame or head block connected with the base by the wrought-iron pillars. The power accumulates at each revolution of the screw, the follower decreasing in motion in precisely the same ratio as the power increases, so that at last the accumulated power is almost irresistible. The development of the pressure and the increase of the resistance being so nearly equal, it requires but little motive power to work it. Thus one man can work a press of 150 tons, and for the press up to 600 tons it requires but from one to two horse-power.

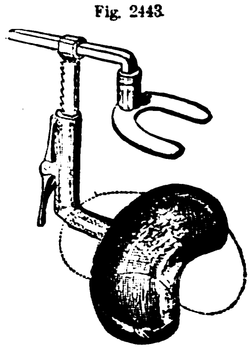
Tongue Holder.

holder for restraining the tongue from interference while the teeth are being operated upon by the dentist. See TONGUE DEPRESSOR, p. 2590, "*Mech. Dict.*"

Tongue Hold'er and Duct Compres'sor. Fig. 2443 represents Dr. Smith's tongue regulator and duct restrainer. By the use of this instrument the tongue is clamped down and held in position as desired.

The sublingual and submaxillary ducts are closed by placing upon them pads of bibulous tissue paper before applying the compress; a pad of paper or a napkin

Fig. 2443.



Tongue Holder and Duct Compressor.

should be placed on the tongue before adjusting the instrument in position for use.

To'nite. Dry nitrated gun cotton. Density 1.50, about the same as dynamite, and occupies in a blast-hole ⅜ the space of compressed gun cotton. Sold as a dense dry cartridge.

"*London Mining Journal*," 1878. See also "*Engineer*," 1878.

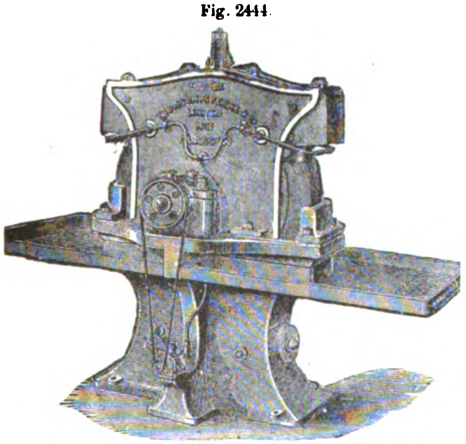
As made at Fernham, England, it consists of finely divided or macerated gun cotton compounded with about the same weight of nitrate of baryta. The gun cotton itself is mainly common cotton waste steeped in nitric acid, and on the excess being forced out by a hydraulic press or otherwise, it is left some time for digestion in vessels of clay. While moist, it is macerated between crushing rollers and then washed. The *rationale* of the latter process is a secret.

As stated above, tonite consists of this macerated gun cotton intimately mixed up between edge-runners with about the same weight of nitrate of baryta. It is pressed into candle-shaped cartridges, with a receiver at one end for the reception of a fulminate of mercury detonator.

Tool Grind'er. A machine for sharpening and polishing tools.

Fig. 2444 is an emery grinder for heavy tools, made by Thomson, Sterne & Co., of Glasgow, Scotland, and is shown with a simple rest for the tools, but is also supplied with special slide-rests for grinding tools in holders. The water is thrown upon the emery-wheel by perforated pipes, which are shown branching to each side from a pipe which rises alongside of the bearing from a small rotary pump driven by a cord from the wheel-shaft.

Fig. 2444.



Thomson, Sterne & Co.'s Tool Grinder.

Tool Mark'ing.

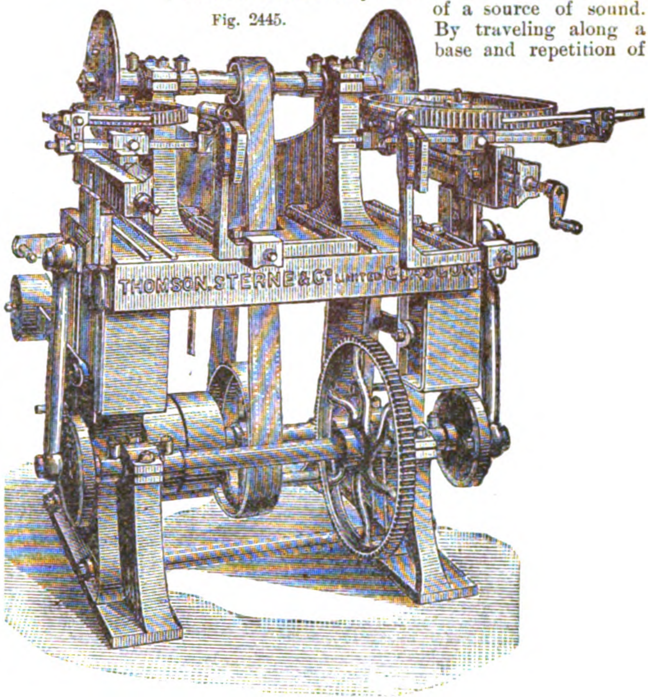
To inscribe your name on steel tools cover the part to be marked with a thin coating of tallow or beeswax. Then with a sharp instrument write the name in the tallow, cutting clearly into it. Then fill in the letters with nitric acid. Let it remain from one to ten minutes. Then dip in water and rub off, and you will have the mark etched.

Tooth Clean'er. A machine for dressing up the teeth of cog wheels.

Fig. 2445 represents Thomson's wheel tool-cleaning machine for dressing between the teeth of spur-wheels. Two wheels can be operated on at once by two emery wheels fixed on each end of the spindle, driven by the counter-shaft.

To'po-phone. An instrument invented by Prof. Alfred M. Mayer to determine the direction of a source of sound. By traveling along a base and repetition of

Fig. 2445.



Tooth Cleaner.

observation it may also, by calculation, be an indicator of distance of the source of sound.

Described by the inventor in the "*American Journal of Otology*" for October, 1879.

The instrument has been made in two forms: the stationary and portable.

In the former case, when used on board a vessel to ascertain the direction of a fog-horn or bell, the apparatus has a vertical rod passing through the roof of the deck-cabin, on the upper end of which is attached a horizontal bar carrying two adjustable resonators. Below these is a pointer, set at right angles with the horizontal bar. Rubber tubes pass through the roof of the cabin and connect the resonator with a pair of ear-tubes. A handle attached to the vertical rod serves to turn it either way, the direction being indicated by the pointer. The resonators are by this means adjusted so that they are brought simultaneously upon the wave surface; that is to say, the horizontal bar is a chord in the spherical wave surface, of which the fog-horn, for instance, is the center; the pointer then represents a radius, or, in other words, coincides in alignment with a line drawn from the place where the sound is produced through the plane of observation.

By sailing the ship at a measured distance at an observed angle from the radius line thus found, a second radius line may in like manner be found, and the distance between the two points of observation is the base-line of a triangle, of which the two convergent radii are the sides. From these data the distance of the fog-horn is readily computed.

The true line of direction is evinced by the clearness of the note imparted, any lateral deviation from the line giving rise to opposition and consequent neutralization of the respective sounds. The connecting tubes being of the same length, when the resonators receive the sound at the same exact instant, the sound pulses, acting together, are reënforced to the ear.

On trial it was found that the direction of sound could be ascertained within one point, say 10°.

The description of the action of the stationary form applies, *mutates mutandi*, to the portable form.

"*Iron Age*" . . . . xxv., March 4, p. 5.
"*Manufacturer & Builder*" . . xii. 79; * 253.

Tor-pe'do. Torpedoes have been divided into *defensive* and *offensive*, and the former into *electrical* and *mechanical*.

I. DEFENSIVE:

1. The *electrical* includes those fired by the closing of a circuit, either by a party on the look-out or by contact of the vessel. They are defined as: *a.* "Electro-contact torpedoes"; *b.* "Torpedoes fired by observation."

a. The electro-contact torpedo is placed so that a vessel running against it will set in motion the electrical apparatus; but it can be rendered harmless as against a friendly vessel by an observer on shore, and as instantly restored to activity by the same agency.

A torpedo fired by contact can be much smaller in its charge than one fired by observation, as the proximity of the latter to the enemy can only be approximately determined, and it must be sufficiently powerful to be fatal to vessels within a considerable area.

b. In the torpedo fired by observation, charges of powder from 500 to 2,000 lbs. are used, to be fired when the vessel is over the spot where such is sunken, to be determined by means of collimators or telescopic observing areas.

The electric torpedo is not itself explosive, and a blow or a fall is harmless, except as it may injure the envelope and cause a leak.

It is preferably lighted by the platinum wire fuse, which is simple, safe, and certain, and can be tested electrically, both before and after it is placed in the torpedo, without the fear of explosion.

The charge may be gunpowder, gun cotton, dynamite, etc. The British prefer gun cotton; America and Sweden have experimented largely with dynamite; Prussia, during the war with France, 1870, 1871, used dualine, another nitro-glycerine preparation; Austria used gun cotton.

2. The *mechanical* includes those exploded by concussion.

ANCHORED TORPEDOES. — The *shell* torpedo is used for the defense of obstructions in rivers and harbors. It is bolted in an inclined position to a frame which is sunk upon the obstructions and loaded with stone.

The *arm* torpedo is of the buoyant anchored class. As the bottom or side of a ship comes in contact with one of the three arms which radiate like spokes at angles of 120° with each other, the hammer is unshipped, and the spring drives it upon the caps, which explode the charge.

The *percussion* torpedo has a loose lid which is displaced by the contact of the bottom or side of a vessel, and, falling off the torpedo magazine, pulls upon some wires which spring the hammers and explode the charge. This was one of the earliest in use during the late war, and continued to be employed to the last. It is understood to have done more execution than any other during the war.

The *submarine* torpedo consists of a water-tight tank of common powder, anchored by two chains below the surface of the water and exploded by electricity, contact, clock-work, or what not. The term is general rather than descriptive, in contradistinction to terrestrial or military torpedoes, and perhaps to those exposed on the ends of spars. See SPAR TORPEDO.

Into the center of the tank pass the terminals of two insulated copper wires, a fine platinum wire passing through a small cartridge of fine rifle powder in the middle of the charge.

Mechanical torpedoes of various forms are described on pp. 2599, 2600, "*Mech. Dict.*"

a. Drifting.	*c.* Boom or spar, Figs. 6554–6556.
b. Anchored.	*d.* Maneuvered.

II. OFFENSIVE:

These may be divided into—

1. The *fish* torpedo, of which Whitehead's (see Plate LII.) is the principal example.
2. Drifting torpedoes.
3. The sea torpedo.
4. Torpedo boats.

1. The fish torpedo has a steel or iron fish-like case; the front fitted with a percussion fuse communicating with the charge. The stern of the Whitehead torpedo has machinery for working a screw by compressed air, which is in a reservoir amidships. It is launched from shore or from a ship, and pursues its course under water.

The Lay torpedo (see Plate LII.), p. 2599, "*Mech. Dict.*," uses condensed carbonic acid gas. A cable containing the electric wires pays out as the torpedo proceeds; two of these are for governing the machinery and the third for exploding the charge.

Col. Lay's torpedoes are still extensively used in Europe, especially in Russia, and his star torpedoes in the Russian navy; and two of his torpedo boats are owned by the United States government. This boat, as recently improved, can be controlled at a distance of more than a mile and a half.

The Ericsson torpedo is launched from a vessel, and has an india-rubber tube which pays out and conveys compressed air, which furnishes the motive power. Fig. 6558, "*Mech. Dict.*," described on page 2599.

2. Drifting torpedoes have cases of various kinds, and are abandoned to drift in a current or with the tide.

3. The sea torpedo is used in action, and is a case maneuvered by lines from the yards of the vessel.

4. Torpedo boats are of several kinds (see p. 2601, "*Mech. Dict.*"), and either carry the torpedo on a spar or a projection from the stern, or are arranged for launching fish torpedoes.

The *turtle* torpedo is so named from its resemblance to that animal, and is placed to prevent raking or grappling for a moored boom torpedo, being connected with the latter by a rope 130′ or 140′ long.

The Whitehead fish torpedo is a spindle of revolution, made of iron and steel, about 14′ long, and having a diameter of 14″, and carries a charge of 20 lbs. of dynamite. It is driven by a propeller and a compressed-air engine, the air being contained in a reservoir. A rudder regulates the depth and the direction, being adjustable so as to direct it along any curve required. The after half has projecting longitudinal ribs, which are extended aft to the ring which surrounds the propeller, and afford rests for the torpedo in launching. The bow, which contains the explosive, may be separated from the body of the torpedo and be stowed in a magazine. The extreme point forward has an arrow-head to stick into the side of a wooden vessel.

The results attained have been speeds of from 10½ to 7¼ knots per hour for distances of from 720′ to 4,500′; but more lately one has been made to run 600′ at the rate of 17 knots, or a mile at the rate of 10 knots. This trial was witnessed by some U. S. officers at Fiume, and is reported in the "*Army and Navy Journal*" of November 28, 1874. It is described in the "*Army and Navy Journal*" as cigar-shaped, made of ¼″ inch steel, and 19′ long, 15″ in diameter. It has a six-bladed screw with expanding pitch, and four T-iron angle pieces running three fifths of its length. A pistol at the bow is exploded by concussion, and in addition there are three triggers projecting from the bow, which may explode the charge by contact with a vessel. This torpedo had no apparent steering apparatus, traveling only in the direction given to it at starting by the adjustment of the rudder. The pressure in the reservoir is 1,000 pounds per square foot.

The action of current is taken into consideration in launching, as well as the rate of motion of a vessel at which it may be launched. It can be launched by projection from a tube by compressed air, or by hand by simply starting.

Mr. H. F. Hicks has designed a gun that is used, like that of Ericsson, to propel torpedoes under water, but the motive power is steam instead of gunpowder. The gun has a number of steam chambers connected with the bore, so as to use steam pressure successively and act on the principle of accelerated velocity, on the plan of Haskel's gun.

Myron Coloney, of St. Louis, has a system of floating torpedoes, with magnets secured to them (see Plate LII.). The magnets are intended to securely attach the torpedoes to iron vessels before exploding.

The torpedo invented by Asa Weeks (see Plate LII.) is believed to be the most powerful and destructive rocket torpedo yet produced. The torpedo proper is a triangular float, having two side wings extending astern, where they are provided with keels or cut-waters. The wings serve to maintain the balance of the torpedo, as it grows lighter from the combustion of the rocket composition, and the cut-waters serve as guiding rudders. The bursting charge of dynamite is in the front compartment of the torpedo, and is exploded by a percussion primer on contact with an obstacle, or is blown up by fire from the rocket charge after the expiration of a suitable interval.

The torpedo is slung at the davits of a steam launch made expressly for the purpose. The prow of the torpedo rises a little above the general surface line to prevent the tendency to run under when striking a wave. The rocket is carried in cylindrical chambers, and the powder is cored out eccentrically to the inclosing casing. This arrangement of the powder secures a nearly uniform combustion. The combustion chambers are surrounded by some refractory substance to prevent injury to the float and danger to the bursting charge. The rocket charge is ignited preferably by an electric ignitor, and the torpedo detaches itself from the davits, being hung thereto by a loop and pin. The rocket runs on the surface of the water, and can be made to travel at the rate of 100′ per second for 1,500′. The cost of a rocket carrying 50 lbs. of dynamite has been reduced below $500.

This torpedo has been adopted by the United States government after full investigation of its merits.

Mr. Weeks is the inventor of a star torpedo operated from the deck of a fast steam launch. He has also a floating or drifting torpedo that is detached from the float when it encounters an obstruction and explodes after sinking a few feet. It is intended to be set adrift in rivers and tideways where the current sets in the direction of a hostile fleet.

Col. Mallory's rocket torpedo has an ingenious arrangement of the rocket charge to secure uniform combustion. The charge of slow powder is made up into a large number of small cartridges, placed in holes radiating from a central chamber in a cylinder of fire clay. The cartridges all burn at once, and as only the end of each cartridge is presented to the flame the extent of the burning surface remains the

Lay Torpedo.

same, and the decrease in weight by burning is regular. The air is permitted to escape at a determined rate from the air vessel that surrounds the torpedo, and so the loss in flotation equalizes the loss in weight due to combustion, the torpedo thus being advanced in a predetermined depth under the surface of the water.

The torpedo-boat invented by Bushnell, of Conn., in 1777, proved the feasibility of this style of warfare by blowing up a British tender in the harbor of New London, and but for the awkwardness of the person in the boat, would have blown up the "Eagle," a British sixty-four gun ship in New York harbor. This same person, in the same year, set a squadron of kegs afloat in the Delaware river, arranged to explode upon coming in contact with anything. They were set adrift too high up, so that they approached in the daytime. One boat was blown up. The British from the shore fired on them, which gave rise to the famous Battle of the Kegs, of which so much sport was made by our revolutionary writers.

The usual arrangement of booms, spars, and nettings for resisting he attacks of torpedo boats having been found ineffectual in the British navy, a magneto-electric light, contrived by Mr. Wilde, of Manchester, for the purpose of detecting the approach of a torpedo boat at night, has been tested. The carbon points and lens are arranged in a box which has vertical and horizontal adjustments permitting the beam of light to be rapidly directed to any point of the horizon and upon any object within the limit of its vertical range. Two steam pinnaces fitted with torpedo arrangement were employed to make a sham attack upon the "Comet," which was provided with one of these machines, but were in each instance discovered before approaching within a mile, the direction of the proposed attack being previously unknown.

(*Fishing.*) Torpedoes exploded under water are employed on the southern coast of the United States for catching fish. The same plan is used by poachers for salmon and trout in Scotland and in trout ponds of New Jersey. The torpedo is exploded by a portable battery.

Cartridges or torpedoes of dynamite, nitro glycerine, etc., are sometimes exploded in schools of fish, and destroy great numbers.

The Austrian torpedoes are well described and illustrated in Barnard & Wright's report, Engineers' Dept. U. S. Army, on the "*Fabrication of Iron for Defensive Purposes*," Washington, 1871.

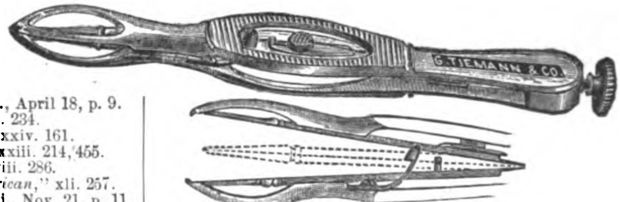
Fig. 2446.



Torsion Forceps.

Tor'sion For'ceps. (*Surgical.*) An instrument (see Fig. 2446) for twisting the end of an artery as a substitute for ligation.

Shown at Figs. 98 *b*, 100, 102 *b*, 163, Part I., *Tiemann's* "*Armamentarium Chirurgicum.*"

Tor'ti-col-lis Brace. A brace for overcoming distortions of the neck.

Tough'ened Glass. La Bastie's toughening process consists in heating the glass, nearly to malleability, but not hot enough to lose its shape, say 1400°, and plunging it instantly, in this state, into a bath of fatty and resinous matter at a temperature of from 300° to 600°. This glass will withstand sudden changes of temperature without damage, as the pouring of molten lead into a tumbler. The strength of the glass is said to be increased many times. Lamp chimneys and other articles thus made are very durable. See Glass, Tempered, *supra*.

In the Siemens' glass works at Dresden there is now manufactured a product which has the same properties as La Bastie's tempered glass, the strength being communicated by the pressure of metallic rolls. Plates can be made by this method of much larger dimensions than by La Bastie's. They have a beautiful look, and can be ornamented with the most complicated designs, at a less cost than ordinary glass. When broken, it shows a fibrous structure, while La Bastie's is crystalline. For equal thickness the resistance of a plate of compressed glass is from seven to ten times as great as that of an ordinary plate.

Tour'ists' Pho-to-graph'ic Cab'i-net. An apparatus is made which works without a silver bath, the silver nitrate having been already united to the haloid salts in the collodion, and a *washed emulsion* is supplied in a bottle.

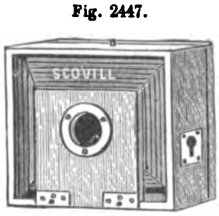
The bottle being shaken and allowed to stand 10 minutes, the emulsion is poured on the glass plate. The glass is previously washed by tripoli in alcohol, followed by French chalk. In 2 minutes the film is set and may be exposed in the camera; or if kept in reserve, dried over a hot tin or spontaneously, in 20 minutes. Non-actinic light, of course, is used in these operations, a portable ruby glass lantern being furnished.

After exposure the film is washed and picture developed by a mixture of pyrogallic acid and ammonia, restrained in action by a suitable quantity of potassium bromide. It is then washed, fixed, and washed again.

The film can be removed to a piece of prepared paper, and when dry can be put in a book, and reimposed at any time for printing. A set of 6 glass plates is furnishing enough, and a blank book may contain the films of a prolonged tour.

Tour'ists' Pock'et Cam'e-ra. Fig. 2447 is the pocket camera of the Scovill Manufacturing Co. of New York, intended for tourists' use. It measures, when folded up, but $5\frac{3}{4}'' \times 6\frac{1}{2}'' \times 2''$, with no projecting parts.

Fig. 2447.

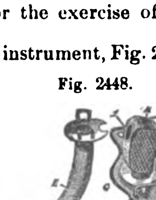


Tourist's Pocket Camera.

Tow'er, Re-volv'-ing. Theodore R. Timby, of Worcester, Mass., in 1841, filed a model and caveat in the U. S. Patent office for a revolving tower or fort, to be revolved by engines within the same; for use on land or water. He was granted a patent in 1862. A tank having been formed at the desired location, with the addition of water supply and exit pipes, the first communicating with a supply tank, and the latter with a drain, the water supply is regulated as desired through these pipes. A metallic battery is floated in this tank, revolving round a central pillar, on which it is lifted or lowered by the adjustment of the water supply in which it floats. Openings in the embankment that surrounds the tank and tower give the necessary opportunity for the exercise of the guns or mortars.

Tra'che-o-tome. Hauk's instrument, Fig. 2448, is to obviate the danger from blood entering the trachea during an operation.

Fig. 2448.



Tracheotome.

It consists of a curved, hollow, sharp-pointed trocar, with handle (also hollow) attached,—the whole about $3\frac{1}{2}''$ in length. It is made to exactly fit the larger of the set of tracheotomy tubes.

Tra'cing Cop'y-ing. A photographic process called the blue process, in which a tracing is used to print from instead of the glass negative.

For the sensitizing solution take $1\frac{1}{4}$ oz. citrate of iron and ammonia, and 8 oz. clean water; and also $1\frac{1}{4}$ oz. red prussiate of potash, and 8 oz. clean water; dissolve these separately, and mix them, keeping the solution in a yellow glass bottle or carefully protected from the light.

The paper may be gone over once with the sponge quite moist with the solution, and the second time with the sponge squeezed very dry. The sheet should then be laid away to dry in a dark place, as in a drawer, and must be shielded from the light until it is to be used. When dry the paper is of a full yellow or bronze color; after the exposure to the light the surface becomes a darker bronze, and the lines of the tracing appear as still darker on the surface. Upon washing the paper the characteristic blue tint appears, with the lines of the tracing in vivid contrast.

Any good, hard paper may be employed (from a leaf from a press copy-book up to Bristol board) which will bear the necessary wetting.

Lay the paper, sensitized side up, on a smooth blanket, and place the tracing on this with a plate of clear glass over all, heavy enough to press the tracing close down to the paper.

Expose the whole to a clear sunlight for six to ten minutes. If a clear skylight only can be had, the exposure must be continued for thirty or forty-five minutes, and under a cloudy sky, sixty to ninety minutes may be needed.

Remove the prepared paper and drench it freely for one or two minutes in clean water, and hang it to dry.

Track In'di-ca'tor. (*Railway.*) An instrument devised to ascertain the condition of the track, indicating irregularities, low joints, etc. One used on the Pennsylvania Railway is designed by R. Pitcairn, locomotive superintendent of the Pittsburg Division.

It is described and illustrated in "*Engineering*," * xxv. 119, 122. See also DYNAGRAPH.

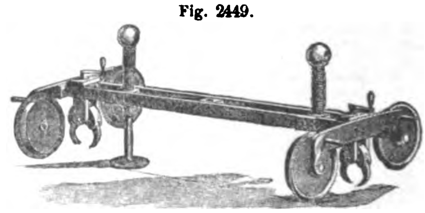
Track'-lay-ing Ma-chine'. A construction machine carrying rails and ties, with devices for delivering them off the front of the train to the laying force. The train is advanced as the work progresses.

It consists in a succession of rollers set in movable frames attached at will to the sides of several flat cars in a train, elevated so as to afford an inclined plane from rear to front. Upon these the ties on one side and the rails on the other are easily rolled or laid by men upon the cars, when they move along over the rollers to the front, and are delivered to the tie and track layers as fast as they can use them.

Track Lift'er. For lifting railroad tracks in ballasting and leveling.

A truck frame with four ordinary flanged wheels running on the rails, has a strong central cross-bar, bearing a spirit-level and scale, by which any degree of inclination is indicated. Through this central bar two powerful screws play in suitable swiveled nuts, and have each a pivoted base plate to thrust against the ground, and a suitable lever at the top.

Fig. 2449.



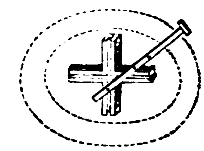
Track Lifter.

Trac'tion En'gine. A form of locomotive engine adapted to travel on ordinary roads. Used to haul threshing machines, and other heavy objects from point to point, and in threshing and furnishing power for different purposes.

Fig. 2451 represents Owen, Lane, & Dyer's engine, geared and speeded for $2\frac{1}{2}$ to 4 miles an hour; will draw a 10- or 12-horse power thrasher with ease; runs in either direction; carries fuel and water for 4 hours' run; will pull up or down a grade of 1 in 12.

See "*Mech. Dict.*," p. 2608.

Fig. 2450.

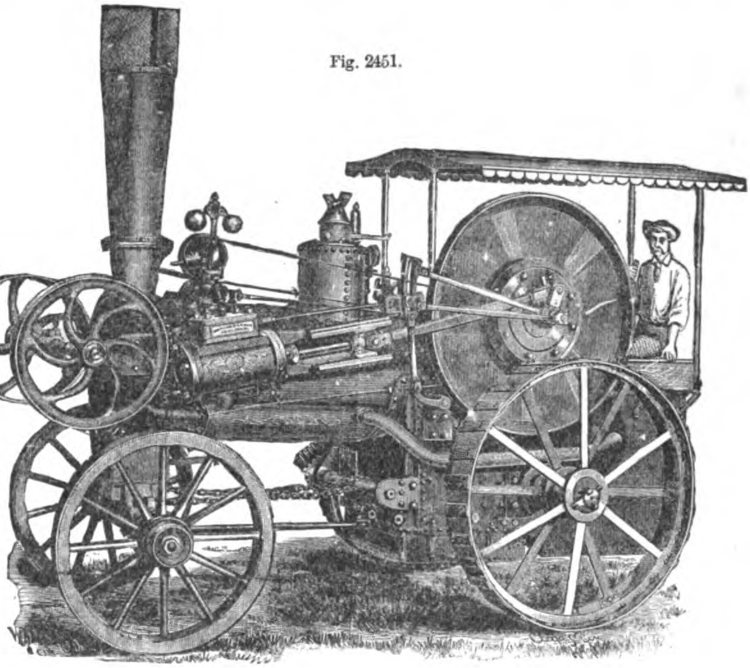


Tram.

Tram. A device for describing an ellipse.

When oval moldings are required two pins are placed in two holes of the handle to the center-mold, and made to move in the rectangular grooves of the cross represented in

Fig. 2451.



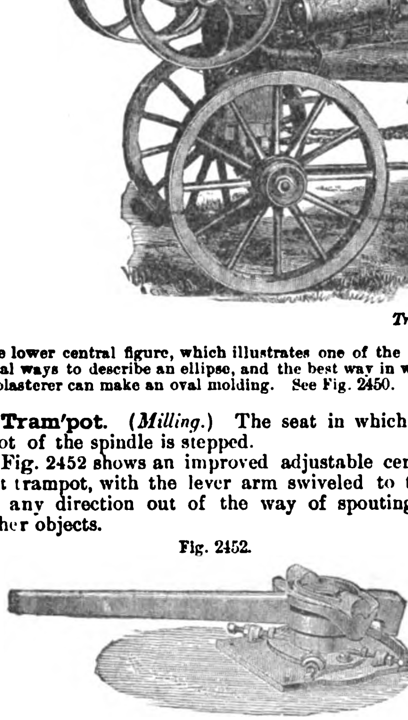
Traction Engine.

the lower central figure, which illustrates one of the practical ways to describe an ellipse, and the best way in which a plasterer can make an oval molding. See Fig. 2450.

Tram'pot. (*Milling.*) The seat in which the foot of the spindle is stepped.

Fig. 2452 shows an improved adjustable center-lift trampot, with the lever arm swiveled to turn in any direction out of the way of spouting or other objects.

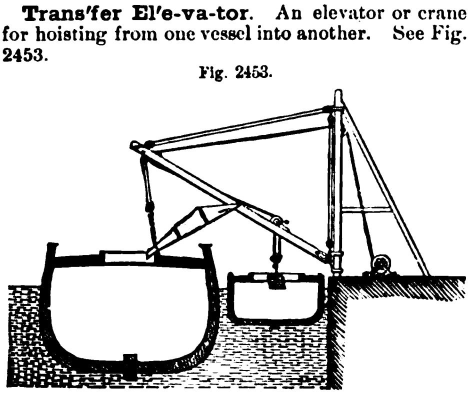
Fig. 2452.



Trampot.

Trans'fer El'e-va-tor. An elevator or crane for hoisting from one vessel into another. See Fig. 2453.

Fig. 2453.



Transfer Elevator.

Trans-la'tor. 1. (*Generally.*) An instrument whereby one form of energy is converted into another. For instance: the *power* of a prime motor, say a steam engine, is *translated* by means of a magneto-electric engine into electricity.

2. (*Specifically.*) A British term for a *repeater.*

Trans-mit'ter. (*Electricity.*) 1. In former practice, the sending forward of a message by an operator at a receiving station was called *transmitting.*

This function is now performed in telegraphy by a *repeater,* sometimes called in Britain a *translator.*

2. The sending instrument in telephonic circuit.

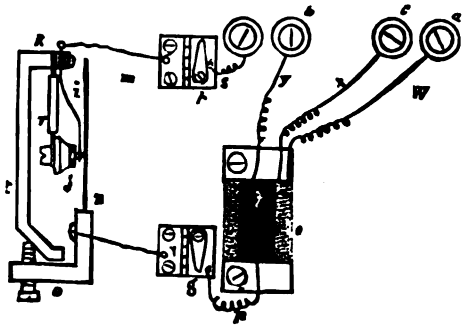
(*a.*) In Bell's *transmitter* (see Fig. 2402, Plate XLVIII.) the message is sent by the variable induced currents set up in a coil surrounding a permanent magnet, to and from which the diaphragm plays.

(*b.*) In the Edison carbon transmitter the diaphragm impinges upon a carbon button through which a battery current is led to line. The vibrations of the diaphragm and the consequent varying pressure upon the carbon affect the conductivity of the latter, and consequently give rise to undulations in the current, corresponding in amplitude and force to the sound vibrations of the spoken message.

(*c.*) In the Blake transmitter, Fig. 2454, a battery current is led through the primary helix of an induction coil, the secondary coil of which is included in the line circuit.

The battery wire comes to the binding post *b*. The circuit goes to primary coil *f*, composed of a few layers of coarse wire, thence by curl *p* to hinge *g*, thence by wire *l* to back frame *v*, thence through screw *o* and adjusting bar *t* to spring *r*, on the end of which is a weighted carbon button, *j*, thence through carbon button and platinum bead to spring *i*, which is insulated at *k*, thence by wire *m* to the hinge *h*, thence by curl *s* to binding post *a*, thence to battery, thus forming a short local circuit, including a battery, a primary coil, and a delicate carbon and platinum contact. The insulated diaphragm *n* bears against the platinum bead, and any movement of the diaphragm, by the voice or otherwise, alters the degree of pressure between the platinum bead and carbon button. Any alteration of pressure alters the conductivity at this point, and thus varies the intensity of the current which the battery is sending through the primary coil *f*. Under the jarring effect of the voice the contact at *j* is constantly altering, and thus giving a series of impulses to the current passing through the primary coil.

Fig. 2454.



Blake Transmitter.

This battery circle is entirely local, and does not go to line.

The line wire with telephone and other apparatus in circuit, goes to binding post *d*, thence by curl to secondary coil *e*, composed of many layers of fine wire wound outside of the primary coil *f*, thence by curl to binding post *c*, thence to ground or continued line.

The telephone or line circuit contains, as far as the transmitter is concerned, only the secondary coil. When a current passes through the primary coil wire it induces a strong current in the secondary coil wire, and thus sends the impulse to the line.

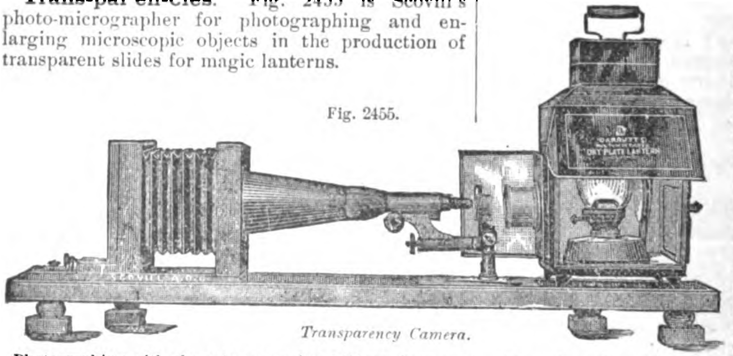
Trans-par'en-cies. Fig. 2455 is Scovill's photo-micrographer for photographing and enlarging microscopic objects in the production of transparent slides for magic lanterns.

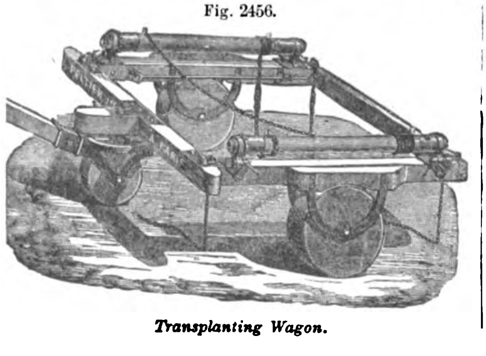
Fig. 2455.



Transparency Camera.

Photographing with the microscope has hitherto been accomplished by the aid of elaborate and costly apparatus, and been applied chiefly to making illustrations for scientific magazines. The process used, that of wet collodion in connection with sunlight, involved the procurement of an expensive heliostat to produce a steady illumination, for with any less powerful light the exposure would necessarily be so prolonged that the coating of the plate would dry and become useless. Now all this is changed, for with the modern improvements in photography which are the result of the introduction of gelatine dry plates, the photographing of microscopic objects becomes easy of accomplishment.

Fig. 2456.

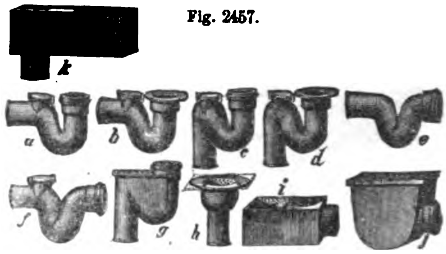


Transplanting Wagon.

Trans-plant'ing Wag'on. Fig. 2456 shows a three-wheeled truck, the frame of which uncouples and surrounds the tree. The chains are crossed under the roots and the tree hoisted out of its hole by means of levers in the holes in the rollers, and transported to the place of planting, where the truck straddles the hole, and the tree is let down.

Trap. A sink or depression in a pipe which allows the liquid contents to fill it permanently at one point and prevent passage of air.

Fig. 2457.



Traps.

a. P-trap.
b. P-trap, with flange for hopper.
c. S-trap.
d. Flanged S-trap.
e. Running or belly trap.
f. Same with hand-hole.
g. Conductor trap.
h. Bell trap.
i. Yard trap.
j. Round bottom drain trap.
k. Stable trap.

Trav'el-ing Crane. A derrick on an elevated track for shifting to different parts of the building. In Fig. 2458 the winch is operated by bevel gearing from the shafts at the side of the building. The transverse shafts have an endwise movement to disengage them from the gearing on the shaft along the side of the room, in shifting the carriage lengthwise of the room.

Trav'ers-ing Saw'ing En'gine. Fig. 2459 shows the Brotherhood three cylinder traversing metal-sawing engine. The whole machine traverses longitudinally in cutting the material to be operated on. The power is obtained from a hydraulic cylinder, and the speed of traverse is regulated by a slide valve. Steam may be used.

Trav'ers-ing Saw'ing Ma-chine'. One in which the saw travels instead of the work operated on.

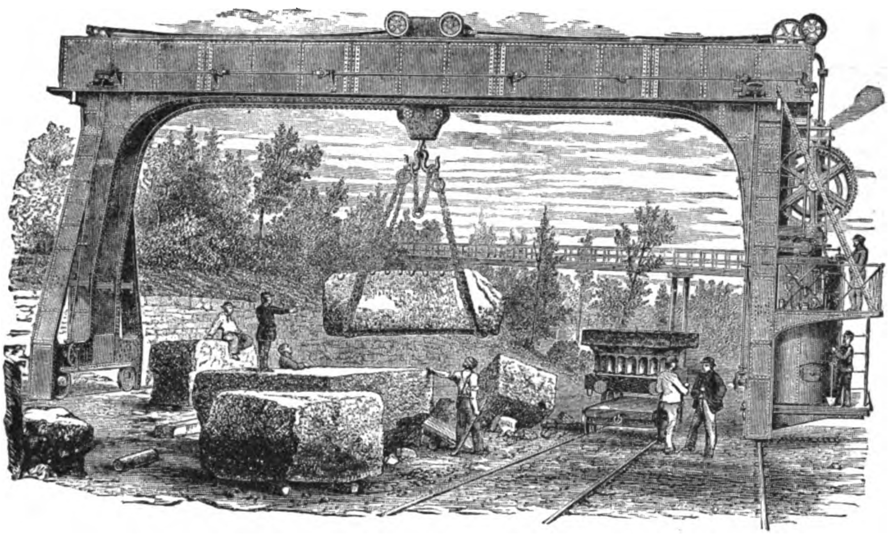
Saws for cutting cold steel are made of soft iron, and run sometimes with a periphery speed of nearly five miles a minute, melting the steel sparks, but not withdrawing the temper from the piece.

Tray Bat'te-ry. (*Electricity.*) One in which the tray forms one of the elements of the combination.

See THOMSON'S BATTERY, in which the tray is of copper.

Tree-fel'ling En'gine. An application of steam for felling trees.

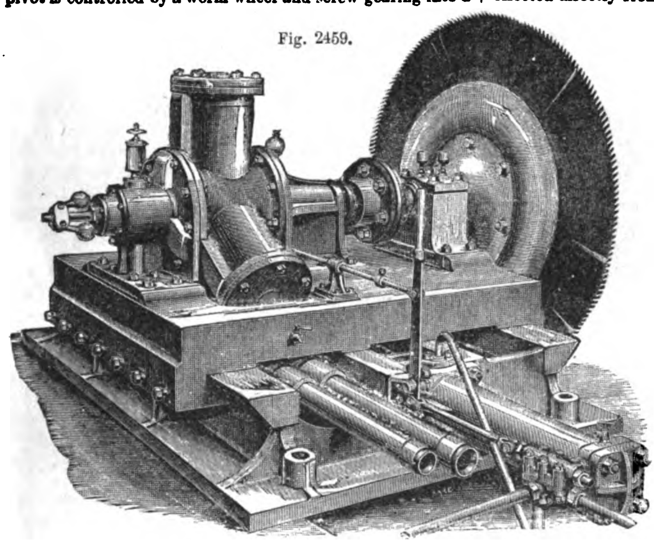
Fig. 2458.



Traveling Crane.

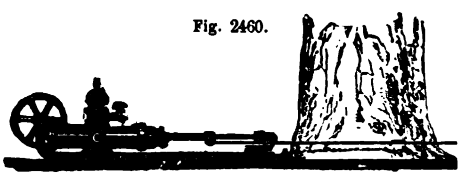
The illustration, Fig. 2460, shows a small steam cylinder, with comparatively long stroke, mounted on a light wrought-iron frame, pivoted on its center; a movement around this pivot is controlled by a worm-wheel and screw gearing into a circular rack. A saw is rigidly fixed to the cross-head, the teeth of the saw arranged to cut only during its in-stroke; that is, the teeth are hooked on one side and have a long bevel on the opposite one; the saw makes a draw-cut during its passage toward the cylinder, which enables a brace between the cylinder-frame and the tree to resist in compression alone the force of the cut. The steam distribution is effected directly from the cross-head, and so arranged as to take full steam for the in or cutting stroke of the saw, and but one tenth the amount for the return or idle stroke.

Fig. 2459.



Traversing Sawing Machine.

Fig. 2460.



Tree-felling Machine.

Trem'bler. (*Electricity.*) A contact breaker for induction coils.

The improvement of M. Trouvé is designed to secure various rates of vibration of the *trembler*, so as to obtain intermittent induction currents of different periods. The length of the vibrating stem is made adjustable, and its range limited according to a scale on the instrument.

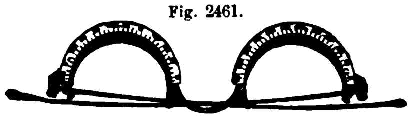
"*Teleg. Journal*" . . . v. 280.

Trial Sight. (*Optical.*) An oculist's case of trial lenses, etc., for testing sight. Nachet's complete series has the following: —

32 pairs each of spherical convex and concave lenses, from 2″ to 72″ focus.
19 pairs each of plain cylindrical convex and concave lenses, from 6″ to 60″ focus.
9 prisms of angles, from 2° to 10°.
4 plane colored glasses.
1 white glass disk.
1 half ground surface.
2 metallic disks with stenopaic slit.
1 metallic disk with hole.
1 metallic disk, solid.
1 adjustable spectacle-frame, with revolving graduated fittings for holding the various lenses.
1 ditto, not graduated.

Trial Spec'ta-cle Frame. Fig. 2461 shows a trial spectacle frame, with double grooves to

Fig. 2461.

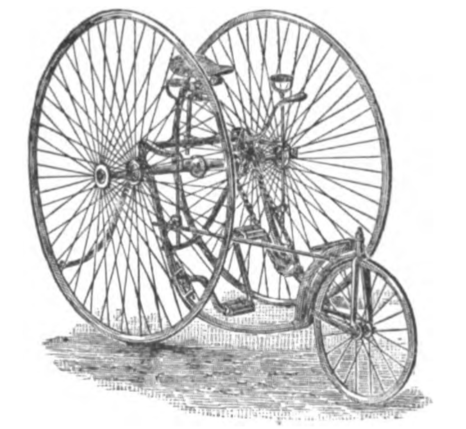


Trial Spectacle Frame.

each eye, graduated to 180°. Any desired combination of spherical and cylindrical lenses can be adjusted in a moment to this frame, and given to the patient for trial. Used for finding the axis of imperfect vision in astigmatism or cylindrical cornea.

Tri'cy-cle. The name was given to a specialized, three-wheeled velocipede in France, as long ago as 1828. It has been made in variously modified forms ever since that time, but has gone into extensive use only in recent years, after the more successful bicycle had led the way, and improved materials and means and modes of construction had enabled it to be made lighter and more effective and elegant. It is now very popular in England and throughout Europe, where it is ridden by ladies as well as by gentlemen, not only for occasional pleasure riding and useful conveyance, but also on very long tours through the various countries. It is rapidly coming into use in America, and the latest and most improved form is the Columbia tricycle, of American make, shown in Fig. 2462. The wheels are 48″ in diameter, the width over all is 38″, and the weight 92 pounds. It has

Fig. 2462.

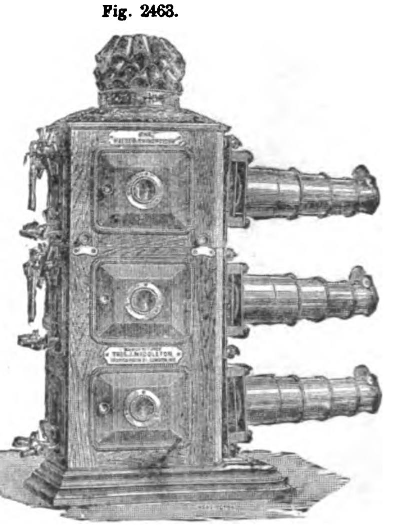


The Columbia Tricycle.

contractile round rubber tires, direct spokes in the suspension wheels, adjustable anti-friction bearings to every shaft, axle, pin, and pedal, and adjustable seat and handles to suit it to the individual rider. Ingenious mechanism is shown in the "balance gear," or compensating axle gearing, by which the power is distributed to both driving wheels, which may run at differing speeds on curves; and also in the friction-disk brake, which with a slight pull on the handle will effectively control the machine on any grade. This tricycle contains fifteen or more inventions secured by United States patents. There is also adapted to it a device by which different speeds may be attained with the same power, or power economized at the expense of speed in hill-climbing; and there are many useful adjuncts called "accessories" for the convenience of riders. The tricycle is brought to such a state of perfection and specialized detail in construction and finish as to be only comparable with the bicycle.

Trin-op'ti-con. The "Malden" trinopticon, Fig 2463, is an apparatus for the exhibition of dissolving views and dioramic effects. It consists of a combination of three achromatic lanterns, which can be used in its complete form; or the bottom portion, that is similar to an ordinary two-tubed

Fig. 2463.

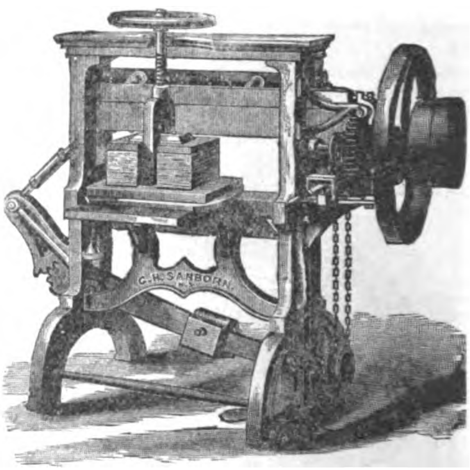


Trinopticon.

apparatus, can be used separately, and the upper can then be employed for phantasmagoric effects.

Trim'mer. (*Bookbinding.*) The Star book trimmer, Fig. 2464, is a single, or double clamp power machine, with a draw-slide knife.

Fig. 2464.



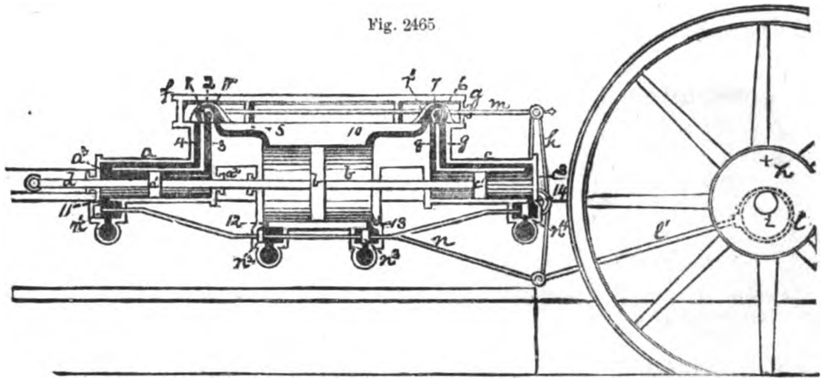
Book Trimmer.

Trip Cut Off. An arrangement to disconnect one portion of the valve motion from the other, so as to allow the cut-off valve to close with great rapidity, the concussive effect arising from stopping the rapidly moving parts being absorbed or taken up by acting upon a confined indestructible fluid, as water, air, etc.

Trip'le Cyl'in-der Steam En'gine.

Alexander's compound balanced piston engine, Fig. 2465, has a large central vacuum or exhaust cylinder, *b*, at each end of which is a smaller working cylinder, *a c*; the pistons of the three have a common piston rod and their valves are operated by the rods *d e* from the eccentric *f*, being so arranged that a part of the exhaust from either working cylinder, as *a*, is conducted into the corresponding end of the exhaust cylinder *b*, alternately through the passages *g g′* at the same moment that the steam is admitted to the opposite end of the other working cylinder: the pressure of the exhaust

Fig. 2465.



Triple Cylinder Steam Engine.

steam from *a* on either side of the piston *b'* is thus caused to help work the pistons *a' c'*. The steam escaping from *a* or *c* is worked expansively in *b*, being reduced to a pressure equal to that of the atmosphere by the time *b'* reaches the end of its stroke.

The remaining portion of the exhaust is conducted through an appropriate post to the end of either working cylinder at which the piston of that cylinder has arrived, to balance the piston so that it may offer no resistance to the action of the large piston in the exhaust cylinder, and to that of the other working cylinder to which the live steam has just been admitted.

Trip'le Flu'id Bat'te-ry. (*Electricity.*) One in which the respective fluids containing the elements are separated by a cell containing another fluid which may be neutral or may have the effect of preventing the entry of the positive liquid into the negative cell, or *vice versa*. For instances, see list under GALVANIC BATTERY.

Trip'le Tel'e-phone. One having two receiving ear-pieces, and a transmitting mouth-piece mounted on one stem, which may be held to the head by a spring.

Pritchett . . . . . * "*Telegraphic Journal*," vi. 471.

Trip'o-li. Infusorial earth: the cast-off shells of microscopic infusoria. Used in the manufacture of nitro-glycerine, cements, as polishing powders, and food.

Tro'car. (*Surgical.*) A perforator, stylet, and canula combined; a three-part instrument.

Trough Bat'te-ry. (*Electricity.*) One in which the elements occupy a series of cells in a common trough.

The earliest of these was Cruikshank's, and the second Wollaston's, which see. See also MUIRHEAD BATTERY.

Trou-vé' Bat'te-ry. (*Electricity.*) 1. A battery consisting of a pile of zinc and copper disks separated by paper disks, saturated with exciting and depolarizing liquids.

See MOIST BATTERY.

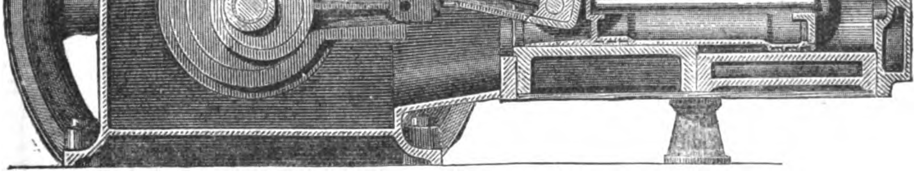
Fig. 2466.



Trunk Engine.

Trunk Steam En'gine. One in which the direct connection of the piston with the crank is secured without the use of the beam or oscillating the cylinder. Fig. 2466 shows Virey's French trunk engine, with the piston rod, crank shaft, and eccentric in the steam chest, attached to the steam cylinder, the revolving shaft working through packings in the steam chest.

Trus'sing Ma-chine'. One for tightening the truss hoops on barrels. Holmes's machine, Fig. 2467, for trussing tight and slack barrels, will drive all the truss hoops upon a slack barrel at the same time at the rate of 1,500 per day. When used for tight barrels the quarter hoop drivers are removed, and the machine is in condition to drive the truss hoops upon tight barrels.

Fig. 2467.

Trussing Machine.

Tube Clean'ers. For cleaning tubular boiler tubes. A steam-pipe having perforations to correspond with the ends of the tubes is fitted to each row of tubes and steam blown through them.

Tube Draw'ing Ma-chines'. Metallic tubes are drawn through formers, somewhat after the manner of wire.

Tubes for particular purposes are drawn inside and out, giving them a hard, smooth finish. Ordinary brass tubes are soldered together and drawn through holes to shape the outside, leaving the inside as it was.

Fore . . . . * "*Iron Age*," xxii., July 11, p. 1.

Tube Valve. A tube forming a valve, held up against its seat by a ball-weighted lever.

Tube, Weld'ed I'ron. Instead of heating the whole of the strip or skelp of iron, Roden heats only the edges which are to be welded together and the parts adjacent thereto. In order to effect this, he constructs a furnace, having a long, narrow opening at its top, and the strip of iron from which the tube is to be made having been bent into a tubular form, with its edges overlapping, is placed upon the said opening in the furnace, the said overlapping parts being alone exposed to the strongest heat of the furnace, while the greater part of the tube, being external to the furnace, is but slightly heated. Near the end of the furnace a bulb mandril, supported on a rod, is situated, the axis of the said bulb mandril being in a line with the axis of the partially formed tube on on the furnace.

The end of the mandril-rod is fixed to a wagon, capable of traveling on a draw bench. Underneath the bulb of the mandril is a pressing-roller, which is pressed upwards or against the bulb of the mandril by a spring or weight or otherwise. A pair of tongs, connected to the wagon of the draw bench or other drawing mechanism, take hold of the partially formed tube at its upper side, and motion being communicated to the said chain, draw bench, or other drawing mechanism, the partially formed tube is drawn off from the furnace on to and over the bulb mandril, its overlapping and heated edges being pressed between the bulb of the mandril and the roller underneath and thereby welded together. After the welding of the skelp has been effected, the mandril and its rod, together with the tongs and welded tube, are removed to a sufficient distance from the furnace to allow the tube to be removed from the mandril. The mandril and other parts are then restored to their original positions near the furnace, ready to act upon and weld a second skelp. By means of this invention, welded iron tubes or pipes can be readily and quickly made, and from thinner iron than can be conveniently used in the ordinary method of manufacture.

Tubular Piles.

Tu'bu-lar Piles. Le Grand's tubular piles, Fig. 2468, are unique in their construction and mode of propulsion, being driven internally and from the bottom, instead of externally and from the top. The piles are made of either wrought or cast-iron, and of thickness to suit the varying circumstances of construction. The lower end of the pile is made solid and pointed, and generally steel-tapped.

The piles are made in sections, which are screwed together with joint sockets. The rammer is raised by rods, rope, or chain, and on being released, falling with its own gravity, expends its driving force on the point just where it is wanted.

This principle of internal pile-driving has been applied to the sinking of tube-wells, and for driving the foundations of telegraph posts, etc. When used in connection with tube wells, the first socket above the perforated end is made sufficiently long to allow of a strong iron ring being placed in the center of it in such a way that the two lengths of tube, when screwed together, butt against it. The interior of this ring is of sufficient size to allow the water to pass freely, but it has a screw thread cut throughout its whole length. During the operation of driving the aperture is closed by a steel square-headed screw plug, the head resting firmly on the ring. After driving, the plug is removed, allowing the water free passage.

Tur'ret. A report on the "*Fabrication of Iron for Defensive Purposes*" was made by Colonels Barnard and Wright, of U. S. Engineers, 1871.

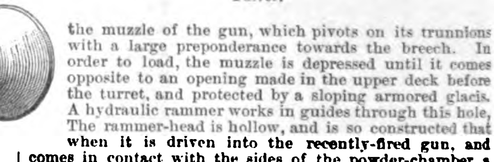
Iron cased forts of Portsmouth, Britain, defenses. Plate LI.
Gruson chilled iron casemate, German. Plates XXVI.-XXX.

Plate LIII. is a vertical section of a tower for harbor or land defense, having exterior and interior walls, with dome-shaped roof, revolving by gearing upon friction rollers. The artillery platforms have guns mounted upon the carriages, which radiate from the common center. The central turret revolves independently of the tower upon a shaft by means of a rod and gearing. On the left of the shaft is seen the circuit-closer, forming the connection between the galvanic battery and the conducting chains passing to each gun. Holes in the top act as ventilators, while at the sides of the turret, near the bottom, are casemates with guns, independent of the revolving tower, while below are walls of subterraneous foundation for the tower, forming chambers for stores and munitions.

Fig. 2473 is a view of the turret and glacis of the "Inflexible."

Two guns will be mounted side by side in each turret. Each gun will be mounted so as to be supported on three points. The trunnions will rest on blocks sliding on fixed beams bolted down to the floor of the turret, while the breech will rest on a third block, sliding like the others between guides, upon a beam or table. Behind each of the trunnion-blocks, in the line of recoil, are two hydraulic cylinders, connected with them by piston-rods. The cylinders communicate by a pipe, on which there is a valve, that, on the recoil of the gun, opens and allows the pistons of the rams to run back slowly, checking the recoil. By reversing the apparatus, the gun can be run out again. The beam on which the breech rests is supported by a third hydraulic ram, fixed vertically beneath it in the turret. By this means the breech can be easily raised or lowered, thus elevating or depressing

Fig. 2473.



Turret.

the muzzle of the gun, which pivots on its trunnions with a large preponderance towards the breech. In order to load, the muzzle is depressed until it comes opposite to an opening made in the upper deck before the turret, and protected by a sloping armored glacis. A hydraulic rammer works in guides through this hole. The rammer-head is hollow, and is so constructed that when it is driven into the recently-fired gun, and comes in contact with the sides of the powder-chamber, a valve opens, and it discharges through a number of holes small jets of water, thus acting as a sponge, and extinguishing any remnants of the charge or of the products of the explosion which may have remained smoldering in the bore. It is then withdrawn, and a hydraulic shot-lift raises up to the muzzle of the gun the charge, the projectile, and a retaining wad, and then a single stroke of the rammer drives them into the gun and home to the base of the bore. Again the rammer is withdrawn, the hydraulic ram under the breech of the gun elevates the muzzle, the turret swings round, and the shot is fired. A 9″ gun, mounted experimentally in a turret at Elswick, and loaded on this system, was brought to the loading position, sponged, loaded, and brought back to the firing point in twenty-three seconds. Equally rapid loading was effected with the 38-ton gun during the experimental trial of the hydraulic gear on board the Thunderer. Thus the first advantage of the system is rapidity of fire; the second is economy of labor. One man only for each gun is stationed in the turret, another works the hydraulic rammer on the main deck, six or eight others

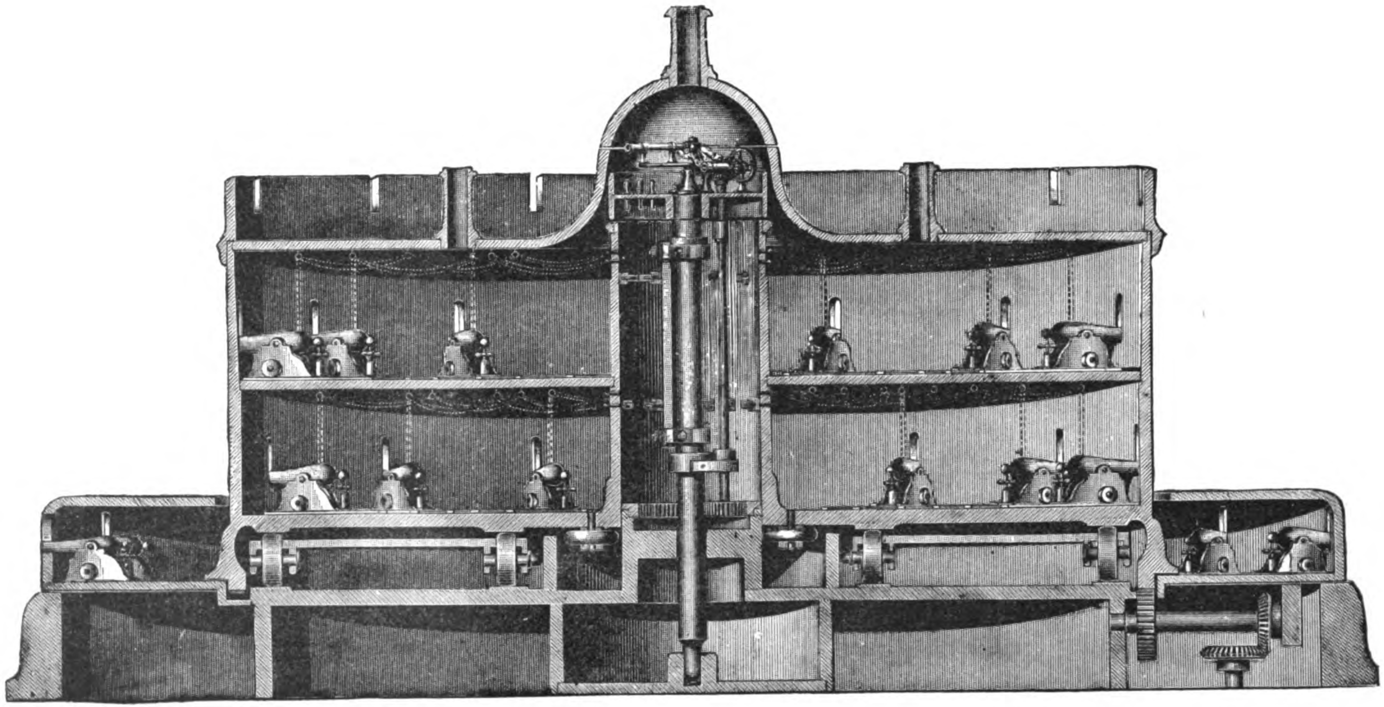


PLATE LIII. VERTICAL SECTION OF REVOLVING TURRET FOR HARBOR OR LAND DEFENSE. See page 908.

are employed in bringing up the ammunition to the shot-lift by means of a small tramway. There are two sets of loading gear for each turret; but even if both were put out of order, the gun could still be loaded, with an ordinary rammer and sponge, by a number of men stationed on the main deck.

The adoption of the system enables very heavy guns to be carried in comparatively small turrets. Those of the Inflexible are very little larger than those of the Devastation; so that with the old plan of having a numerous crew in the turret, and running in the gun in order to load it by hand, only the 38-ton gun could be carried. As it is, it is quite possible that the Inflexible will be armed with even a more tremendous weapon than the 81-ton gun. This has been held in view in designing the ship; and, by a slight modification, it will be possible to mount in each of her turrets a pair of 160-ton guns, with a bore of 30′ and a caliber of 20″.

A minor feature, which will perhaps be introduced in connection with guns of large caliber, is a steel plug containing within it a detonating apparatus for firing a charge of powder. This is intended to be fixed in the vent of a heavy gun, in order to prevent the upward escape of the gas and the consequent gradual erosion of the vent. The erosion very rapidly widens the vent, and at last disables the gun, and the fire has to be suspended until it is revented. Thus this system of firing, which has been invented by Captain Noble, R. A., would greatly increase the efficiency of the gun.

Some idea of the amount of ammunition required for the 81-ton gun will be given by the following calculation: Let us suppose that in an action the Inflexible would fire only ten shots from each of her guns; she would use up more than $6,500 worth of ammunition, burn upwards of 100 barrels of pebble-powder, and hurl nearly thirty tons of iron at the enemy.

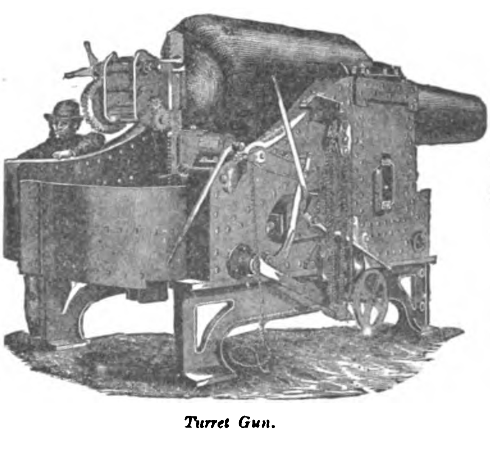
Tur′ret Gun. (*Ordnance.*) One specially arranged to be used in a revolving turret. The peculiarity of guns of this class consists in the fact that their horizontal traverse is effected by the motion of the turret itself, the position of the carriage, with respect to the turret, being invariable.

Fig. 2474 illustrates an 18-ton gun and carriage. The brackets each consist of an inner and outer plate of ⅞″ wrought iron, stiffened by cast iron frames. The trunnions fit accurately between the brackets, having a play of but 1-32 of an inch, and serve to brace them; 1-32 of an inch play is also allowed between the carriage and platform, making the maximum deviation from the true line of sight but 1-16 of an inch. The elevation is effected on what is known as the principle of *compound pivoting*, the gun being raised or lowered by means of a hydraulic jack. The trunnions rest in blocks fixed on the extremities of a curved piece of wrought iron with steel side-pieces, termed the saddle, underneath the center of which the jack is placed; they may be supported at three different elevations on supporting

Fig. 2474.



Turret Gun.

blocks or steps of suitable height. On the highest step the gun may be laid at any angle between 6° depression and 3½° elevation; on the intermediate step between 2° depression and 7° elevation, and in the lowest position between 7° and 13° of elevation; it is shown in the figure in its highest position. The elevating apparatus consists of a straight vertical rack operated by a hand-wheel through the medium of a series of gears.

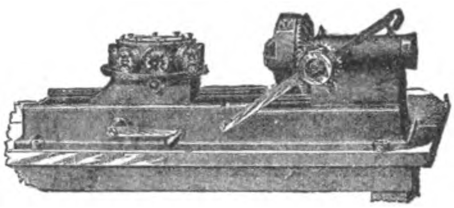
A second hydraulic jack is provided for the purpose of bringing the rollers into action upon which the gun is run out; in case of accident to the jack, tackles at the sides of the carriage are employed for this object.

Wedge-shaped iron plates depending from the brackets and fitting between corresponding plates on the slide act as compressors to limit the recoil of the carriage; and if required, additional friction may be obtained by means of a compressor screw and handle.

Tur′ret Head. The revolving head of a bolt cutter.

In Fig. 2475 the cylinder may be revolved at will, is secured in position by a spring bolt, and holds on its periphery seven

Fig. 2475.



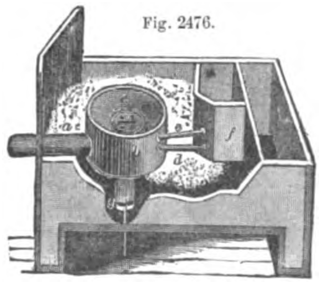
Turret-head Hand Bolt Cutter.

dies, either one of which may be presented instantly to the bolt to be cut, and carried forward by a crank, pinion, and rack. The cylinder holds also a collet, adapted for recessed plates, to receive square and hexagonal nuts of different sizes for tapping purposes. This collet is secured and removed readily, as are also the dies. The revolving spindle is hollow, to receive bolts of any length, and by removing the collet opposite the one that is at work, allowing the bolts to pass through the head, the thread may be cut to any distance required. The spindle is furnished with a chuck for holding the bolt or the tap, and it is driven by a crank, adjustable in length, and by bevel pinion and gear.

Tuy-ere′. A tube for regulating and directing the current of air to the fire in a forge or furnace.

In Bayliss's vertical hot blast and water tuyere and forge, instead of the blast passing into the fire cold, as in the ordi-

Fig. 2476.



Hot Blast Tuyere.

nary tuyere, it passes through a pipe, *a*, and takes a circle of the air chamber *b*, and enters the fire at a temperature of 300° through nozzle *c*, which is a hollow casting filled with water from an iron tank, *f*, by pipe *d*. The steam generated in the nozzle is conveyed to the tank by pipe *e*. Air is admitted to the air-chamber *c* through pipe *g*.

Lloyd's tuyere is an open spray blast for a furnace.

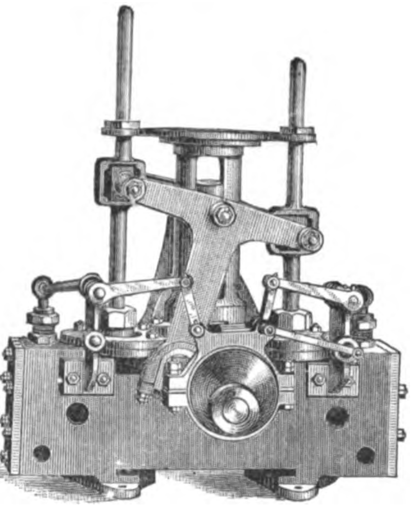
Tuy-ere′ Coil. A convoluted pipe carrying water through a tuyere to mitigate the heat to which the tuyere is exposed in the fire. See "*Mech. Dict.*," Fig. 6827, p. 2666.

Twin Cyl'in-der Steam En'gine. In Fig. 2477, Bernay's twin cylinder engine, the general principle consists in placing the crank-shaft in the center line between the two cylinders, and making the connection between the crank and the two pis-

Fig. 2477.



Twin Cylinder.

tons by means of a triangular connecting-rod, one side of which (that opposite the crank) is guided in a cross-head. The arrangement for correctly distributing the steam consists in directing the motion of the slide-valves of both cylinders by means of one eccentric in a manner analogous to that by which the motion of the two pistons is directed through their triangular connection with one crank. The eccentric ring has two eyes prepared on it, whose up-and-down motion alone is made use of, and to which the valve levers or rods are hung. Straight lines drawn between these two eyes on the ring, and from the eyes to the center of the eccentric, constitute a triangle which bears the same relation to the eccentricity, or throw of the eccentric, as the triangle of the main connecting-rod bears to the throw of the crank. Any kind of expansion valves, and also link-motion, can be used with this engine.

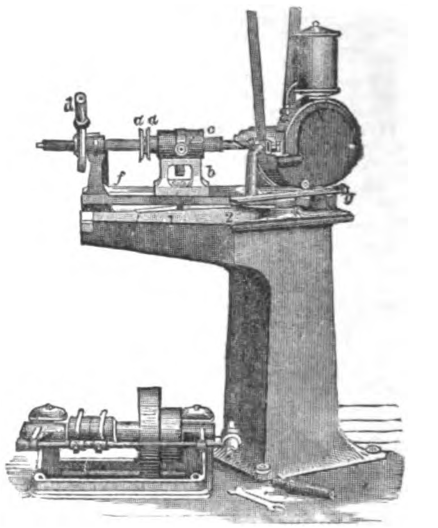
Twist Drill Grind'er. This machine, Fig. 2478, is designed for sharpening twist and other drills from $\frac{1}{4}''$ to $1\frac{1}{2}''$ in diameter, and of any length. All the movements are self-regulating and automatic.

The head-stock of the emery-wheel has a transverse movement actuated by a lever, and is also capable of being set forward relatively to compensate for wear.

Fig. 2478.



Twist Drill Grinder.

The shank of the drill is held in a hollow arbor, the other extremity being supported near the grinding-wheel by a ring in which the drill is centralized by a screw.

The cut is made with mathematical precision, and the presentation is such that the length and angle of cut on the respective sides of the drill are exactly equal.

The emery wheel is kept wet by a trickling stream of water, elevated by a small rotary pump on the wheel arbor, and conducted by pipes from a reservoir in the post to the hood of the wheel; from the drip mass it returns by a pipe to the reservoir.

The pulley has two speeds, and the more rapid may be used when the emery wheel has worn to a smaller diameter, so as to preserve proximately the same speed at different periods in the life of the stone.

The drill-holding portion has a radial adjustment on the point of contact with the stone as a center, to govern the angle of presentation of the drill. A series of 41 rings, adapted to all sizes of drills, goes with the machine.

Type. Nickel is now used in electrotyping, giving a smooth, hard face to the type.

Type Com-pos'ing Ma-chine'.

Paige's type-composing machine has keys by which the different *sorts* are dropped in the required order from the receptacle pockets *h* (Fig. 2479), which contain them. The keys are shown in a group, *a*, in the lower part of the illustration, the right-hand lower one of the set being shown at *b*. The main shaft of the machine is kept constantly revolving, and when a key is depressed, the mechanism at a certain portion of the revolution causes the appropriate type-forcer to push out the lowest type of the rank into the race *m*, when the type-driving rod *o* sweeps it out of the race and into the line of composition, when the justifying mechanism *c* comes into play to form the matter in lines for the galley measure.

The "Felt" machine, patented May 29, 1860, and June 23, 1863, was the first machine constructed to set, justify, and distribute. It attempted too much. It occupied a space 5' × 4' and 8' high, and had 8 type-cases, consisting of 86 channels each, standing perpendicularly, side by side. In front was a key-board of 40 keys, like that of an organ, 7 acting as "stops," which adjusted the keys in relation with any of the 8 cases. Thus the keys acted upon the lower-case letters, the capitals, or the *italics*, at the will of the operator. When the machine was in motion, the "stick," in form and action suggesting the head and beak of a bird, played back and forth against the tubes, gathering the types. These it seized with its pincers, or beak, turned downward, and deposited in the line. When the line was nearly full, a bell announced it, so that the compositor only completed his word or syllable. By touching now the justifying-key, he caused the spacer to draw the line into another part of the machine to be justified, and so resumed his setting. The process of justifying consisted in the removal of the steel spaces, with which the matter was first set, and which were furnished with projecting heads for the purpose of withdrawal, and substituting others. This process was performed automatically, the lead added, and the line deposited on the galley. In distribution, the necessity of nicks in the type was sought to be avoided by means of a register, made in the process of composition. This consisted of a narrow strip of card or paper, in which holes were punched as the types were taken, and by which they were redistributed.

U Bolt. A clevis for the attachment of axles, rods, etc., in machinery and vehicles.

U-cha'ti-us Steel. (*Metallurgy.*) Iron, granulated by running it into cold water, is put into a crucible with oxygen-yielding material, such as spathose iron ore, and the pig-iron gives up its impurities to the oxygen.

Uchatius steel . . . "*Van Nostr. Mag.*," xv. 282, 474.

Un-bran'ning Ma-chine'. (*Milling.*) A machine for removing the bran or cuticle of the wheat grain. The Bentz process.

The process is partially accomplished by a vigorous application of brushes arranged as in the smut machine; also by scalding, which makes the cuticle roll off when rubbed. See SMUT MACHINE.

Un'der-grade. A term as applied to bridges synonymous with *deck* bridge, in which the track is above the truss.

Un'der-ground Haul'ing En'gine. Stevens's underground engine, Fig. 2480, exhibited at the Leeds Exhibition, is specially designed for underground haulage, and the object has been to provide an engine, with drums and everything complete, which shall do the work of four or five horses, and be so small and compact that it will pass underground through any space which is sufficient for an ordinary coal train. The engine is completely erected between two frames of boiler-plate, and the one exhibited, which will indicate about 6 horse-power with 20 lbs. pressure, and is fitted with 2 drums of 2' diameter, occupies a space of 6' 7" by 4' by 3' 5", and weighs 29 cwt. In using these engines no foundation is required, all that is necessary being to spike them down on timber. The drums which work on the second motion are loose on the shaft, and have independent brakes and a clutch for throwing them in and out of gear.

These engines are designed for using compressed air or steam; for the former the exhaust passages are made very large. Most of the new collieries that are now in progress of laying out are being arranged to use mechanical haulage.

Fig. 2481 is a view of the Uskside underground engine.

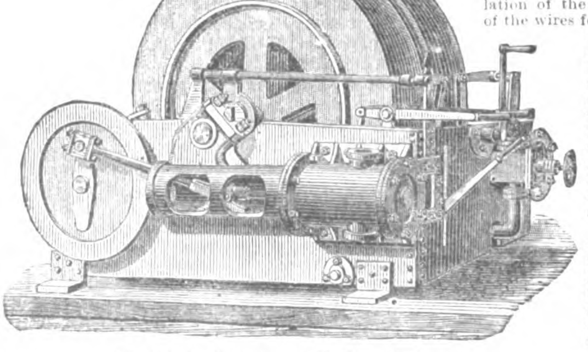
Underground railways . "*Iron Age*," xxi., Jan. 10, p. 15.

Un'der-ground Wires. For telegraph, telephone, and other electric uses.

Underground electric ways arose with the electric telegraph. Messrs. Cooke and Wheatstone, in their earliest telegraph patents, No. 7390 of 1837, and No. 7614 of 1838, describe means for inclosing line wires in conduits to be used underground or placed upon posts above ground. Wooden rails were channeled or grooved upon their surface, and the wires laid in a resinous cement in the grooves. A second rail was then placed upon the first and bound down with iron bands. The wires were covered with cotton and varnished before being laid. They also used various shaped troughs and tubes, into which carefully insulated wires or cables were drawn. Iron tubes, like gas-piping with screwed joints, were laid down, and wires or cables drawn into them. A long coupling sleeve formed a junction-box for connecting up the wires. They also employed a split-iron tube, in the slot of which wires were introduced. The insulating material was poured in upon the wires and the edges of the slot drawn together.

In 1845, Patent No. 10,799, cotton-covered wires were placed in a lead pipe and pitch poured in, the lead pipe being used for the return circuit. In the same year, Patent No. 10,838, wires were laid in railway fences and at crossings, were brought underground and embedded in asphalt. In 1847, patent No. 11,974, parallel grooves were made in sleepers of wood, stone, concrete, or earthen-ware, the wires were then laid therein and supported by insulating supports, marine glue, gutta-percha, asphalt, or Stockholm tar was then poured in hot and an iron cover screwed down over the grooves. In some cases each wire was covered with cotton and then encased in lead. In 1850 Mr. Siemens used a plow, on the carriage of which was a reeled cable. The cable was laid down in the furrow as it was cut by the plow, and then covered under, *vide* Patent No. 13,062. In patent No. 2,710, of 1854, perforated or grooved blocks were made of artificial stone composed of bitumen, sand, and other ingredients. These were molded into the proper shape, and laid in line, and then bare or insulated wires threaded through the perforations. The wires were stretched tight and carefully joined. At the testing and junction boxes the wires were brought out and laid in a notched frame, so as to be readily accessible. Patent 2,089 of 1855, by Dr. Werner Siemens, is of interest as being the first attempt to avoid induction and the consequent retardation. In a cable for underground or submarine use two parallel wires are laid in gutta-percha insulation and one used as the return conductor for the other. As the current in the two is in opposite directions, each neutralizes the inductive effect of the other. Other wires placed in the same cable are each equidistant from the first two wires so as to be equally and oppositely affected by them. In one form a central insulated copper wire is surrounded by a number of iron wires which form the return part of the circuit of which the copper wire is the direct.

Fig. 2481.



The Uskside Underground Hauling Engine.

Patent 119 of 1859. An iron trough laid beside the curbstone contains the wires.

Patent 2,759 of 1859. Earthenware troughs are provided with hooks or notched projections or frames of insulating material on which the wires are supported. The troughs are covered up and sealed with pitch.

Patent 130 of 1868. A conduit of molded blocks of earthenware, with perforations for the wires. The wires are drawn in by pneumatic pressure or by percussion.

Patent 3,863 of 1873. The wires are supported in pipes by means of perforated disks. Dry air is forced into the pipes to absorb moisture and maintain the insulation. The air is dried by being passed over quick-lime or sulphuric acid and pumice-stone. The pipes are of glass, cement, composition, or earthenware.

In the United States but comparatively little has yet been done in underground electric ways, and most of the devices are small modifications of those described above.

In the Brooks system, Patent No. 165,535, July 13, 1875, wires covered with jute or cotton and soaked in paraffine are placed in an iron tube and the tube then filled with heavy paraffine oil or liquid paraffine which is maintained under pressure. Horner, Patent No. 173,170, February 6, 1876, uses a hollow curb-stone in which there is a box or tube containing properly insulated wires. Delany, Patent No. 240,236, April 19, 1881, places within his conduit a pipe for conducting hot air or steam which prevents moisture injuring the insulation. He insulates with powdered talc. Edison, Patent No. 251,552, December 27, 1881, uses semi-cylindrical rods for conductors which are supported in iron tubes by manilla washers; the tubes are then filled with melted asphaltum under heavy pressure.

Every practical underground way involves complete insulation of the wires, protection from moisture, accessibility of the wires for connections and testing, and means for adding new conductors as the needs of the service increase. Perhaps the greatest desideratum, however, is the prevention of induction between different classes of wires. The device used by Siemens has been mentioned. A device, invented by Foucault, Patent No. 90,089, May 18, 1869, is to surround each insulated wire with a thin metallic layer, which is connected to the ground at intervals. This metallic layer is supposed to take up the inductive energy of the wire, and prevent its disturbing action on the neighboring wires.

The first practical device, however is of recent American invention, having been patented to the inventors, Messrs. Bentley & Knight, May 1, 1883. Electric light, telephone, and telegraph wires are all laid in the same conduit. In one form the light wires are run up one side of the conduit and return down the opposite side. Between them are the telephone wires, which cross over at intervals from one side to the other of the conduit, so as to be equally and oppositely influenced by the two branches of the light-circuit. The telegraph lines consist of cables wherein a common return is used for a number of direct lines and neutralizes their inductive effect. In a second form the light wires are crossed at intervals, so that the positive and negative wires exchange their lineal positions; the telephone wires are straight, while the telegraph wires are cabled as in the first arrangement. In a third form the telephone and telegraph wires are both single and are each equally distant from the two branches of the light circuit. The light conductors are made in strips and serve as inductive shields between the telephone and telegraph wires.

The underground telegraph wires of the French cities are thus arranged: The conductor, formed of a wire-cord of four strands, spirally twisted, is covered with a sheath of gutta-percha of about 5 millimeters in diameter, and surrounded by a covering of cotton saturated with wood-tar, and another not so saturated. These envelopes of cotton are dipped in sulphate of copper solution. The cables contain from 3 to 7 conducting wires, according to the needs of the service. They are laid in cast-iron pipes similar to those used for gas, 2½ meters in length, and of a size proportioned to the number of cables. The lengths of a pipe are united by leaden rings; every 50 meters there is a joint of larger diameter, which slides over its neighbors like a sleeve. At the moment of laying the pipes in the trench dug to receive them, a thread is passed through the pipe, which, at the adjustment of each length of 200 meters, introduces a larger cord; one of the ends of this cord is rolled upon a winch, and the other attached to a small iron bar mounted with "gudgeons," which hold the cables to be inserted. The cable is thus drawn through the pipe, passing first over a pulley whose horizontal tangent is in a line with the pipe. If the joints are well made, the pipe is weather-proof, and the cable is sheltered from all infiltrations of water or of gas. The use of the larger joints of pipe above mentioned makes the repair of the cables in case of accident an easy matter.

The wires are run underground in the cities of Berlin, Dresden, Breslau, Dantzig, Stettin, Hamburg, Bremen, Cologne, Frankfort-on-the-Main, Mayence, Carlsruhe, and other large cities and towns of Germany, and in Geneva, Lausanne, Berne, Neufchatel, Zurich, Winterthur, Schaffhausen, Saint Galle, and Lugano, in Switzerland. In nearly all the cities of Europe neither posts nor wires are visible, but the system of underground cables is adopted instead. These cables contain from 5 to 7 conductors each, insulated with gutta-percha, and the whole protected with an armor of iron wires. This system has shown itself in practice to be both economical and reliable. There are now in Paris working lines that have been buried for twenty years, and which have been the cause of little or no expense except their first cost. It is especially worthy of note in this particular that during the reign of the commune, when almost every institution of public utility was destroyed, not an underground wire was disturbed.

U'ni-cy'cle. A one-wheeled vehicle for propulsion by foot-power.

A Danish inventor has invented a single wheel in which is arranged a seat for the traveler who is to propel it. The wheel has one central rim, and to this are fixed the arms, which are, say, six or eight in number, half of them swelled, extended, or bellied out to one side, and half of them similarly to the other side, each set of arms being fixed to a nave or boss; these arms are bent out so far and the naves are so far apart that the traveler, when in the sitting posture, finds room in the wheel between them. The arms are by preference not arranged opposite to one another on the two sides, but intermediately. The naves carry each a crank, and these cranks are by connecting rods jointed to two bell-crank levers, having one arm placed about upright in a position convenient to the traveler to take hold of for working them backward and forward alternately. Each bell-crank lever has its fulcrum in the seat for the traveler, which seat is hung from the naves or axles of the wheel. The seat is by preference made in scroll form, of light, open-worked steel plate or wire-work, or partly so, and may have a part extending overhead to carry an awning to protect against dirt thrown up, and against rain. From each nave there may be hung a leg serving to steady the velocipede while entering the same, but which can be thrown up out of the way when traveling. The wheel, arms, and the rim may be fitted with stiffeners or diagonals to distribute the weight or strain over the rim as much as possible. This unicycle is eight feet and upwards in diameter.

U'nit. A basis for estimating or forming comparisons.

"One pound of good anthracite coal will produce, in combustion, 14,220 units of heat; while 1 lb. of bituminous coal will produce 13,500 units. Let us adopt the round number, 14,000 units: that is to say, the proper combustion of 1 lb. of coal should heat 14,000 lbs. of water 1°, or 140 lbs. 100°, or 14 lbs. 1,000° Fahr. But heating water 1,000° changes it into steam; and experiments have proved that it takes exactly as much heat to change 14 lbs. of water into steam as to heat 140 lbs. of water 100°. Therefore the 14,000 units of heat developed by the combustion of 1 lb. of coal will change 14 lbs. of water into steam; and it is by the intervention of this steam that we have to obtain the mechanical equivalent of the 14,000 units of heat. The well-established mechanical equivalent of each unit is 772 foot pounds. In fact, for every foot that we cause 772 lbs. to descend, we may actually obtain a unit of heat; and therefore we are entitled to expect inversely the development of a force of 772 foot pounds for every unit of heat expended. The 14,000 units of heat, obtained by the combustion of 1 lb. of coal, should give us, then, 14,000 × 772, or 10,808,000 foot pounds. If the coal is burned in 1 hour, we ought to obtain this force per hour; and, as 1 horse power is equal to a force of 33,000 foot pounds per minute, or 33,000 × 60 = 1,980,000 foot pounds per hour, we ought to have 10,808,000 ÷ 1,980,000, or 5.4 horse power per pound of coal consumed per hour. The best engines, therefore, in place of obtaining, as heretofore, only one tenth or one twentieth of the theoretical equivalent of the heat consumed, are reported to have reached nearly one fifth, which is certainly a wonderful advance. Of course, the full theoretical equivalent can never be expected, for reasons which we will not now discuss. Most engineers are agreed on the main features of the most economical steam engines. They are: Proportionally large boilers, with large heating surfaces, and proper grates; heating of the feed-water in the condenser; high pressure in connection with proper cut-off arrangements, so as to utilize the expansion; careful protection from loss of heat by radiation, and intelligent and faithful engineers and firemen." — *Technologist.*

Unit of light: —

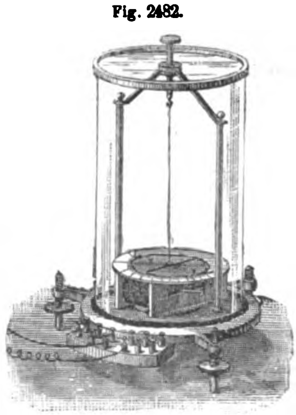
England: Spermaceti candle burning 8 grains per hour.
France: A carcel lamp burning 42 grams colza oil per hour.
Germany: A spermaceti candle giving 1·9 the light of the Fresnel unit.

U'nit and Safe'ty Valve. One exposing 1 square inch to the force of the steam.

U'ni-ver'sal Gal'va-nom'e-ter. Edgerton's apparatus, Fig. 2482, has leveling screws and astatic needles, suspended from the brass arm by a fiber of unspun silk, with arrangement for adjusting the zero of the scale to the axle of the coils.

It is convertible by adjustment from an ordinary quantity galvanometer into one for intensity or into a differential galvanometer for either intensity or quantity.

Fig. 2482.

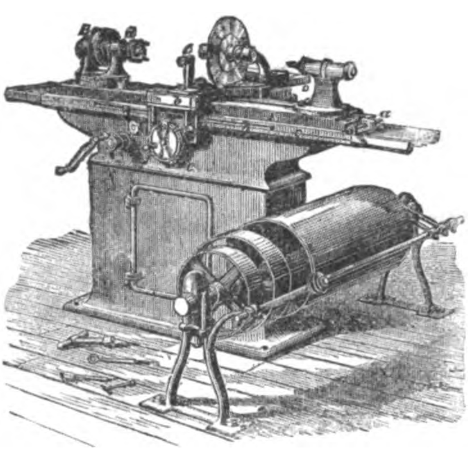


Universal Galvanometer.

U'ni-ver'sal Grind'ing Ma-chine'. One adapted for a great variety of work, with solid emery or corundum wheels.

The movable table is capable of adjustment by a tangent screw and graduated arc, and admits of straight and curved taper grinding with the centers of the machine always in line. It is specially adapted for grinding soft or hardened spindles, arbors, cutters, either straight or angular, reamers and standards also for grinding out straight and taper holes, standard rings, hardened boxes, jewelers' rolls, etc. The work can be revolved upon dead centers or otherwise. The grinding wheel can be moved over the work at any angle, by which means any taper can be produced. Emery wheels from ¼″ to 12″ in diameter can be used either with or without water. The feed-works and slides of the machine are

Fig. 2483



Brown and Sharpe's Universal Grinder.

covered and protected from grit and dust. The grinding of taper holes and angular cutters is provided for with graduated arcs.

U'ni-ver'sal Head. A portion of a watchmaker's lathe with face-plate and dogs for holding the work. See WATCHMAKER'S LATHE, where it is shown in connection with a jeweling rest.

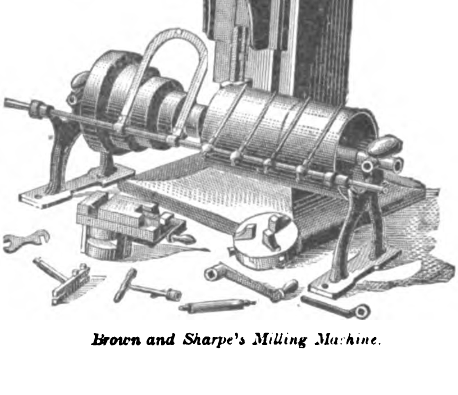
U'ni-ver'sal Joint. For diagrams, illustrations, and calculations; see *"Joint Universel,"* in *Laboulaye's "Dictionnaire des Arts et Manufactures,"* tome ii., ed. 1877.

U'ni-ver'sal Lathe. One for producing various forms, either circular or irregular.

Koch & Müller . . . . . . * *"Engineer,"* xli. 26.

U'ni-ver'sal Mill'ing Ma-chine'. (*Metal Working.*) A milling machine with a capacity and variety of adjustments of the tools and tables, to enable it to do a great variety of work.

Fig. 2484.

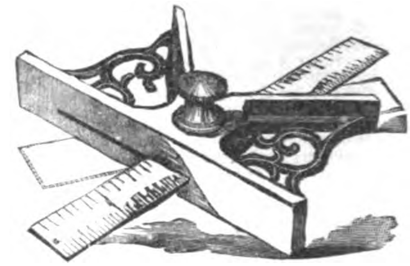


Brown and Sharpe's Milling Machine.

In addition to the movements of a plain milling machine, the one shown in Fig. 2484 has the following: The carriage moves and is fed automatically, not only at right angles to the spindle, but at any angle, and can be stopped at any required point. On the carriage centers are arranged in which reamers, drills, and mills can be cut either straight or spiral. Spur and beveled gears can also be cut. The head which holds one center can be raised to any angle, and conical blanks placed on an arbor in it, cut straight or spirally. Either right- or left-hand spirals can be cut.

U'ni-ver'sal Square. A combined try-square, miter, T-square, rule, and center square for finding the center of a circle. See SQUARE.

Fig 2485



Universal Try Square

Marshall's center square, Fig. 2485, combines in one seven different tools: the try-square, miter, T-square, bevel, center square, depth gage, and the graduated rule.

U'ni-ver'sal Wood Work'er. The Fay wood-worker, Fig. 2486, is a machine in which both sides may be operated, and either side started or stopped without interfering with the other.

As a planer, it is adapted for ordinary surfacing and thicknessing, planing out of wind, surfacing square, beveling, or tapering pieces, facing up bevels and baluster, etc. As a molding machine it will work moldings, either simple or complex, up to 8″ or 9″ in width, stick sash and doors, tongue and groove; and on the wood-worker side it will produce waved, oval, elliptical, circular, and serpentine and rope or twist moldings. Among its other uses are chamfering, cornering, rabbeting and joining window blinds, gaining, panel-raising on one or both sides, tenoning, ripping, cross-cutting, grooving, hand-matching, making glue and table joints, mitering, nosing, squaring up, and a multiplicity of other operations limited only by the skill of the operator.

The molder and wood-worker sides are securely connected upon one solid column with a substantial base, and the two sides of the machine are driven from one countershaft, which conveys power either separately or simultaneously.

The molding side is so arranged as to form a complete four-side molder. The side spindles are fixed to and move with the table, which has a vertical movement of 16″. The feeding rolls are arranged for fast or slow feed.

The wood-worker side is constructed on the same principle and embraces the same general features as the patent variety wood-worker above described.

Un-load'er.

Upright Drill.

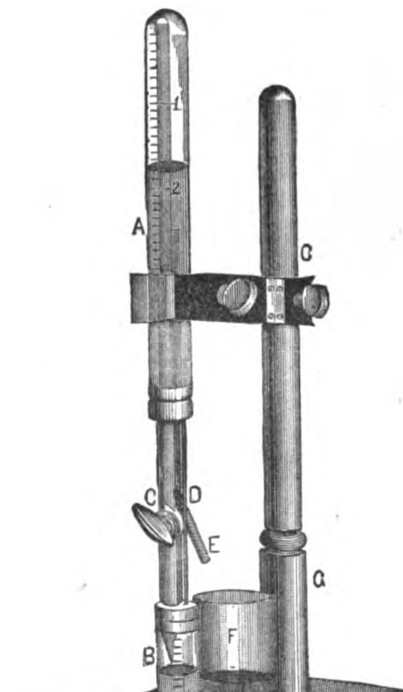
applied to a drill whose mandril is vertical, as in Fig. 2487. See also DRILL; BORING MACHINE, etc.

Ferris & Miles . . . . * "*Iron Age*," xx., Nov. 15, p. 1.

Up'right Mold'ing Ma-chine'. Blaisdell's upright molder has an adjustable table, operated by turning the wheel around the column. The spindle is placed in boxes inside the column, and into this the false spindle is fitted by a new device. The main spindle runs in self-oiling brass boxes.

U're-om'e-ter. In Hüfner's new ureometer, Fig. 2488, for clinical use, the exact methods for the determination of urea in organic liquids are far too complex and tedious to be of more than occasional service to busy medical men, whilst the readier methods are not sufficiently accurate to be of more than approximate value. The method of estimating urea by means of a solution of sodium hypobromite, given by Hüfner, and the modification of it proposed by Russel and West, are very

Fig. 2488.



Ureometer.

convenient for clinical purposes, but even these leave something to be desired on the score of accuracy.

In a recent January number of the "*Practitioner*," Drs. Russel and West state that they have found the hypobromous solution to decompose in hot weather more quickly than they expected, and that it is very important that it be freshly prepared.

They draw especial attention to this, and suggest that the solution be prepared in the following manner: —

A solution of caustic soda is made in water, in the proportion of 100 grams of solid caustic soda to 250 cc. of water. This solution may be made in large quantities, for it will keep good for a very long time. To part of this solution bromine is added, in the proportion of 25 cc. to every 250 cc. of caustic soda solution, at the time it is required for use.

With the view of simplifying the operation of ureometry to the utmost extent compatible with the necessary accuracy, M. J. G. Blackley, of London, devised the form of apparatus represented in the cut. It consists of two graduated tubes, a larger one, *A*, of about 75 cc. capacity, and a smaller one, *B*, of about 15 cc. capacity, closed by perforated india-rubber stoppers, through which pass the tubes *C* and *D*. *C* is the wider of the two, and is provided with a glass stop-cock. Its lower extremity, drawn to a fine point, descends about halfway into the tube *B*. *D* is a narrower tube, and ascends about halfway inside *A*. *E* is a short, slightly bent tube, passing through the india-rubber stopper into the tube *A*, and serving as an egress for the superfluous contents of *A*, which are collected in the beaker *F*, the whole being supported by the wooden stand *G G*.

The method of using the apparatus is as follows: —

The tube *A* is filled with a solution of sodium hypobromite, and its stopper inserted. Then 5 cc. of the liquid to be examined are placed in the tube *B*, and its stopper (which has previously been adjusted upon the ends of the glass tubes *C* and *D*) is inserted to the level of a scratch on the outside, and the stop-cock gradually opened. The hypobromite solution flows down the tube *C*, decomposition takes place, and the gases evolved, ascending through the tube *D*, are collected in *A*. The superfluous hypobromite solution flows out through the tube *E* into the beaker *F*. To complete the operation the apparatus is removed from the stand, after placing the finger over the mouth of the tube *E*, and agitated for a few moments. It is then replaced, and after allowing time for the froth to subside, the quantity of the gas collected is read off. After subtracting the small constant of air contained in the tube *B*, the remainder gives by calculation the quantity of urea present in the 5 cc. of liquid examined. Under ordinary circumstances the whole operation may be completed in five or six minutes.

Fig. 2489.

Instead of having the tube *A* graduated into cubic centimeters, it is convenient to have the graduation indicate at once the percentage of urea, as is the case with the tube supplied with Russel & West's ureometer. — *Journal Chem. Soc.*

U-re'thra Di-vul'sor. (*Surgical.*) See DIVULSOR.

U-re'thra In'stru-ments. (*Surgical.*) These are numerous and included under the following heads: —

Applicator.
Catheter.
Dilator.
Divulsor.
Forceps.
Lithotrity instruments.
Ointment bougie.
Porte-caustic.
Searcher.
Sound.
Speculum.
Staff.
Stricture cutter.
Stricture dilator.
Syringe.
Urethrameter.
Urethratome.

Otis's Urethrameter.

U're-thram'e-ter. (*Surgical.*) An instrument for measuring the diameter of the *meatus urinarius*.

Dr. Otis's apparatus, Fig. 2489, consists of a small, straight canula, terminating in a set of fine steel springs hinged upon the canula, and also upon the distal extremity of the instrument, where they unite. At this point a fine rod, running through the canula, is inserted. This rod (which is worked by a screw at the handle of the instrument), when retracted, expands the springs (six in number) into a bulbous shape, from ten to twelve millimeters in circumference when closed, and capable of expansion up to forty-five millimeters.

That of *Dr. Gross* has a pair of expanding arms on the end of a staff, and an index on the handle to show the degree of expansion in *situ*. Fig. 71, Supplement, *Tiemann's* "*Armamentarium Chirurgicum.*"

Dr. Weir's is on the same principle. Fig. 68, *Ibid.*

Dr. Otis's has expanding jointed toggle arms. Fig. 94, Part III., *Ibid.*

U're-thro-met'ric Sound. (*Surgical.*) An olivary sound in a canula, the shaft being graduated to measure the length of insertion or of projection of the bulb beyond the end of the canula.

Leonard, Fig. 93, Supplement, *Tiemann's* "*Armamentarium Chirurgicum.*"

U'ri-nal. Figs. 2490 and 2491 show forms of portable urinals for convenience of persons afflicted with incontinence of urine. They are adapted for constant wear on the person, and are made of the best rubber.

Fig. 2490.

Fig. 2491.

Portable Urinals.

U'rine Bat'te-ry. (*Electricity.*) The plates are immersed in a trough through which urine flows. Ammonia is the chief excitant.

U'ri-nom'e-ter. (*Surgical.*) Apparatus for making urinary examinations, including —

Balance = 1-50 grain.	Platinum spur for calculi.
Blow-pipe.	Retort stand.
Bunsen burner.	Specific gravity bottle.
Burette, etc.	Test tubes and stand.
Filtration apparatus.	Wash bottles.
Graduated glass.	Water bath.
Hydrometer.	Water oven.
Pipette.	

See pp. 78-80, Part II., *Tiemann's* "*Armamentarium Chirurgicum.*"

U'su-du'ri-an. A material for packing, made of unvulcanized rubber and other substances. It is a non-conductor, and when subjected to the action of steam it is vulcanized and enabled to resist influences which are usually very destructive of ordinary rubber packing. By the application of naphtha to their surfaces, two pieces of the usudurian may be united, and under pressure become practically one, which is a convenience, as the user is thus enabled to build up any desired thickness of packing.

U'te-rine Ap'pa-ra'tus. (*Surgical.*) This embraces the following: —

Applicator.	Forceps.
Cautery.	Injector.
Cervix uteri instruments.	Knife.
Dilator.	Leech.
Douche.	Ovariotomy instruments.
Dressing instruments.	Placenta instruments.
Ecraseur.	Probe.
Electrode.	Redressor.
Elevator.	Repositor.
Embryotomy instruments.	Scarifier.
Excision instrument.	Scissors.

Sector.
Speculum.
Supporter.
Syringe.
Tenaculum.
Tourniquet.
Tumor instruments
Tupelo dilator.
Uterotome.

See under the respective heads. See also Figs. 6881-6885, p. 2685, "*Mech. Dict.*"

U'trecht Vel'vet. (*Fabric.*) A furniture plush made entirely of mohair, or, in the common qualities, with cotton warp. See MOHAIR.

U-vu'la-tome. (*Surgical.*) A knife for operating on the *uvula*. See TRACHEATOME.

V.

Vac'u-um Brake. (*Railway.*) A system of continuous brakes which is operated by exhausting the air from some appliance under each car by which the pressure of the external air is transmitted to the brake levers and shoes. An ejector on the engine is ordinarily used for exhausting the air, and it is connected with the rest of the train by pipes and flexible hose between the cars.

The vacuum brake is to be distinguished from the air brakes of the Westinghouse and Loughridge class in which the brake-levers are operated by compressed air.

The *Smith* and *Eames* brakes are of the vacuum order.

The former has flexible cylinders beneath each car, connected by pipes and hose with an ejector on the locomotive, which operates to exhaust the air from the cylinders. The latter are collapsible, and the movable head is connected to the brake-levers. See Figs. 649, 650, *Forney's "Car-builder's Dictionary."*

The *Eames* brake is similar in mode of operation. *Ibid.*, Figs. 653, 654.

Vac'u-um Pan. A vessel for evaporating saccharine juices in vacuo.

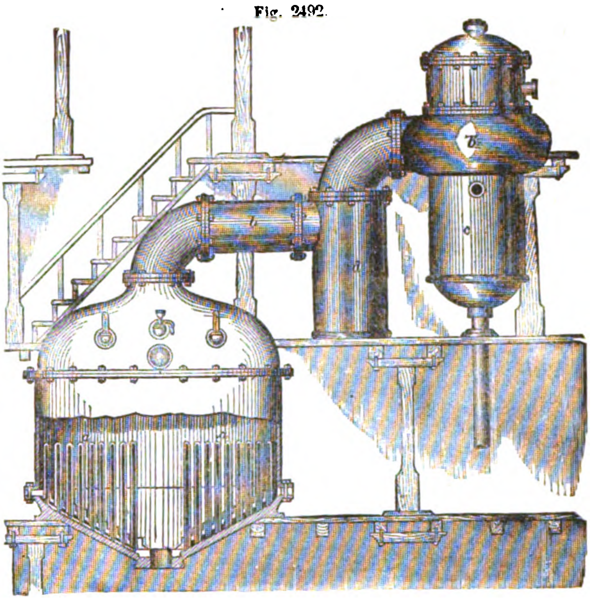
The "drum" pan, so called from its shape, is usually upright, and heated by a series of vertical tubes near the bottom.

In the "Gould" pan, Fig. 2492, the pipe that conveys the vapor to the condenser, passes round the latter, forming an annular space of semi-circular cross-section, joining the body of the condenser, and being continuous with it below and bolted to a flange upon it above.

Water falls upon the perforated reversible spray plate, that has its pivotal axis passing through a stuffing box, and attached to a hand lever, by which the plate is turned to allow the water to alternate to prevent the apertures from becoming clogged. The vacuum pump is connected with the top of the condenser.

The Colwell vacuum pan is elevated on great iron columns three stories high. Inside are four copper serpentines, and into these steam is led. The circulating pump and the centrifugal machines are placed on the first floor. On the second floor is a large receiver which receives the contents of the pan after concentration, in the shape of a dense mass of semi-fluid material, a magma. This goes into the centrifugal machines, which separate the sugar from the molasses. The vacuum pan of Messrs. Colwell and Brother, of New York, is 8′ in diameter, and, in a single operation of three hours in duration, can produce fifteen hogsheads of sugar.

Fig. 2492.

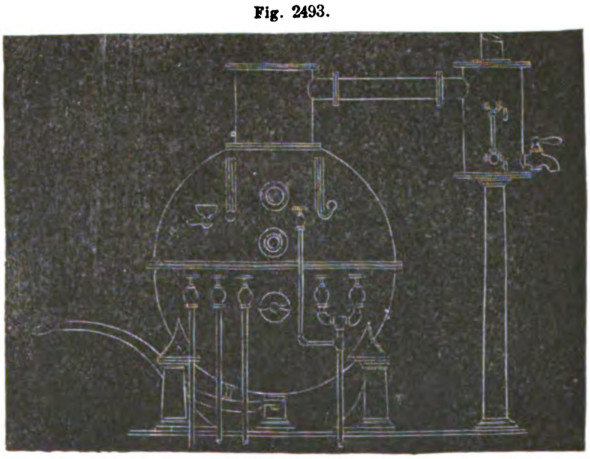


The Gould Vacuum Pan.

The Alvarado pan, Fig. 2493, is adapted to a factory working up fifty tons of beets per day. It is 6½′ in diameter and is 7′ high. The egress valve is operated by a lever from beneath the pan. A dome on the top is connected by a pipe to the safe, which has a glass gage, and a cock for drawing off the syrup that collects in it.

Two coils of pipe inside the pan heat the syrup and obtain

Fig. 2493.



Alvarado Vacuum Pan.

their supply of steam by the pipe connecting with the generator.

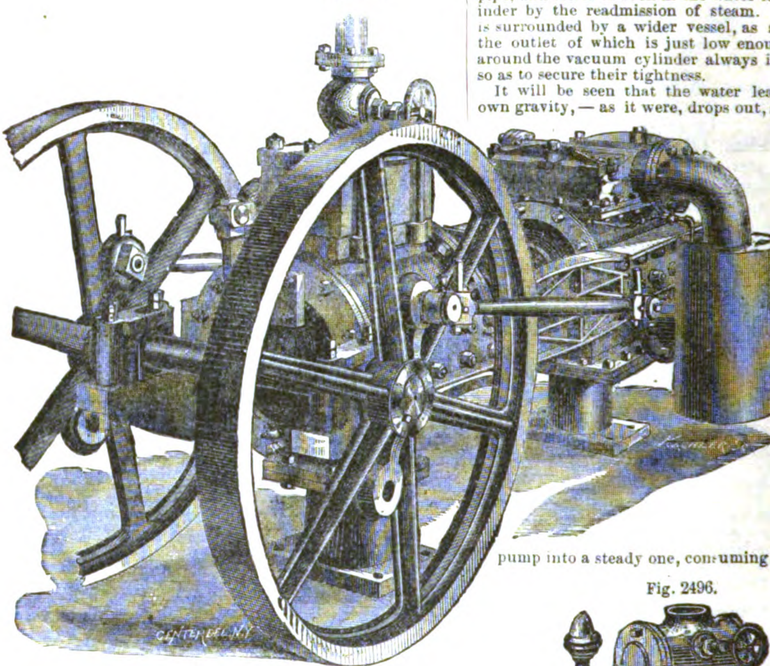
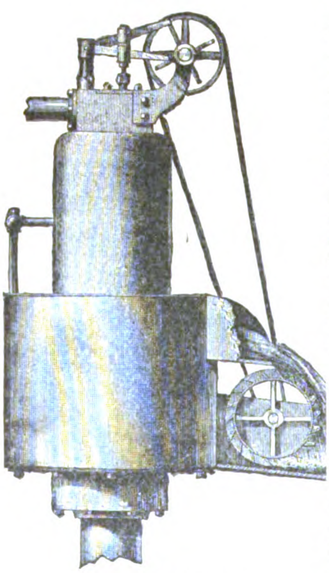
Fig. 2494.



Vacuum Pump.

Vac'u-um Pump. If the exhaust steam of a pumping or other steam engine is allowed to enter a closed vessel, and is there submitted to condensation by cooling, a vacuum will be formed. Such a vacuum may be utilized to raise water, if only the proper secondary appliances are added to make this condensation of the steam the subsequent raising of water, and its discharge and refilling with steam, alternate.

Fig. 2495.



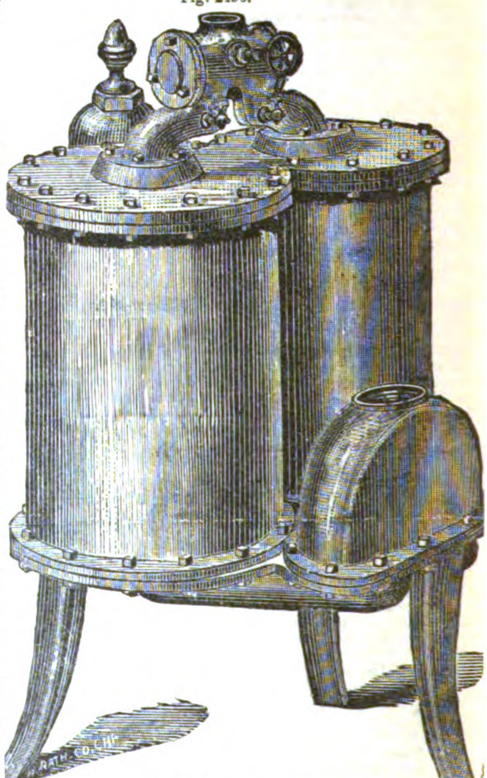
Vacuum Pump.

An ingenious way to effect this alternate action is represented in Fig. 2494, and is the invention of Mr. Wm. Burdon, President of the New York Hydraulic and Drainage Co. Water escaping from the vacuum cylinder is caused to turn a small overshot wheel, which, by means of a belt, is connected with a pulley on top, the revolution of which works the alternate admission of the steam into the vacuum cylinder. This cylinder is surrounded with large valves at its lower end, giving rapid exit to water and closing against its reëntering, while another valve at the top of the suction-pipe and the bottom of the vacuum chamber opens when the vacuum produces suction and draws the water up through the suction-pipe, and closes as soon as the water leaves the vacuum cylinder by the readmission of steam. The vacuum cylinder is surrounded by a wider vessel, as seen in the engraving, the outlet of which is just low enough to keep the valves around the vacuum cylinder always immersed under water, so as to secure their tightness.

It will be seen that the water leaves the pump by its own gravity, — as it were, drops out, so that the steam does not meet with any resistance whatsoever; on the contrary, when it enters it is rather drawn in and acts in this way on the steam-engine from which it is obtained almost like a condenser. The arrangement added to a high-pressure engine changes it practically into something even better than a condensing engine; in fact, into something similar to a compound engine; the steam is first utilized by its pressure and then by its condensation.

In order to change the intermittent action of this vacuum pump into a steady one, consuming a steady stream of ex-

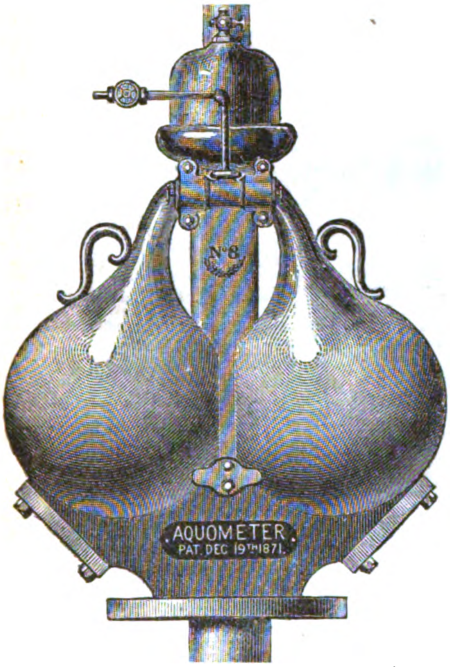
Fig. 2496.



The Nye Vacuum Pump.

haust steam, producing a continuous suction and rise of water and a steady stream of water, two suction pumps may be combined, the steam entering alternately the one and then the other, while this admission may be regulated in the same way as represented in Fig. 2495, or by means of other power, when the pulley is driven by a belt from shafting above.

Fig. 2497.



Vacuum Pump.

The revolution of this pulley opens and shuts the steam-valves alternately, so that the steam entering by the main pipe is in succession first thrown to the right and then to the left vacuum cylinder, so that while in one the steam enters it is being condensed in the other.

There is nothing to prevent multiplying these pumps and connecting them into one system, so as to be able to use all the exhaust steam disposable, when a steady, large stream of water may be obtained raised from a depth equal to that from which any suction pump may raise it by atmospheric pressure.

The "Nye" pump, Fig. 2496, is said to discharge 800 gallons per minute. It consists of two cast-iron cylinders lined with wood, to prevent loss of steam by coming in contact with the metal, the condenser (a plain chamber back of the cylinders), a simple balanced automatic steam valve on top of cylinders, and four valves covering suction and delivery ports.

The aquameter pump, Fig. 2497, has two chambers alternately occupied by water and steam. The steam being admitted by a balanced piston-valve forces the water out, and then condensing, forms a partial vacuum, into which the water rushes under atmospheric pressure.

Blake, * "*Manuf. & Builder*," x. 172.
N. Y. Drainage & Hyd. Co., * "*Man. & Builder*," viii. 29, 100.

Vac'u-um Shunt. An electric vacuum shunt of variable resistance was exhibited by Dr. Stone at the meeting of the Physical Society, on June 26, 1880. The variable resistance was formed neither by a set of coils, a platinum-iridium wire, or a tube of water, but by a Torricellian vacuum at the top of a mercury column, the height of which could be increased or diminished at will.

The apparatus consists of an ordinary barometer tube of glass 32″ long, and terminating above in a short vacuum chamber arranged transversely, and closed at either end by adjustable india-rubber stops, through which platinum terminals are passed. The tube is continued beyond this chamber to a stop-cock, by which small quantities of air can be admitted into the vacuum. The foot of the tube is connected by a flexible india-rubber pipe to an open glass cistern, like that of a Frankland gas apparatus. This cistern is nearly filled with mercury, which, on the barometric principle, ascends the tube till the height of the column above the surface level in the cistern just balances the pressure of the atmosphere. The cistern is suspended by a cord over a pulley, and counterweighted so that it can be raised or lowered through the whole 32″. On passing an induction spark through the Torricellian chamber all the discharge is diverted through this shunt. But on admitting a little air by the stop-cock to render the vacuum less perfect, and raising or lowering the cistern, so as to lengthen or shorten the mercury column, the resistance of the vacuum can be increased or diminished within wide limits. In this way, according to Dr. Stone, a point can be found at which the induction spark due to breaking contact is shunted through the vacuum tube, while the weaker discharge due to making contact is arrested. The induction current is thus obtained in a single direction, a matter of some importance in physiological experiments.

Va-len'ci-a. (*Fabric.*) A French dress goods woven on a taffetas loom. It has a silk chappe warp and a combed-wool weft.

Val'en-tine's Knife. A two-bladed knife for making a thin section of a tissue for microscopic purposes at a single stroke.

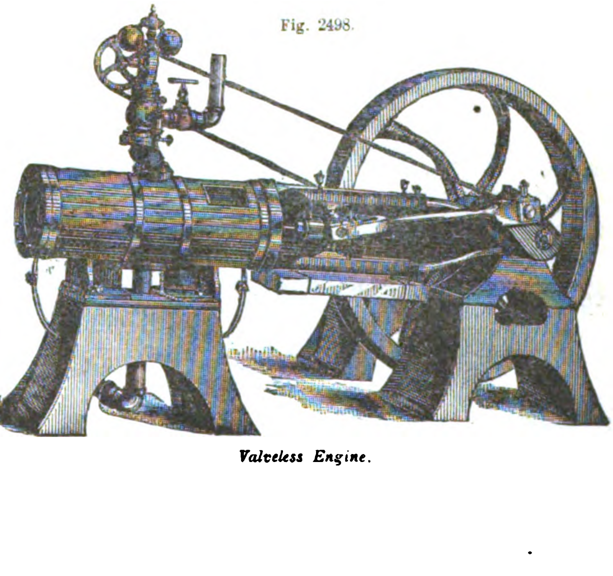
Valve'less En'gine. The "Wardwell" valveless engine, Fig. 2498, is horizontal, with one end of a girder frame bolted to and supporting the cylinder, and the other the pillow-block.

The cylinder has a bore 8″ × 35″; the stroke is 16″. The

Fig. 2498.



Valveless Engine.

pillow-block brasses have side adjustment by wedges, operated by bolts and nuts, from the top capface. The cross-head has V-shaped bearings, and has a gudgeon which provides journal-bearing for the fork-end of the connecting-rod. The piston-rod passes through the cross-head, in which it has journal-bearing for its semi-rotary motion; a nut and check-nut preventing longitudinal motion or "end-play" in this bearing. The connecting-rod has a strap at each end that is secured to it by a bolt passing through the ties, the key serving merely to adjust the brasses. Inside the outer fork of the connecting-rod is bolted a section of a bevel-wheel, with four teeth, and which gears into a similar but five-toothed section, keyed to the extreme end of the piston-rod. The reciprocation of the piston-rod produces an oscillation of the connecting-rod; but the two rods being geared together, the piston-rod and head are given the reciprocating semi-rotary motion desired.

The piston head is solid, having spring packing rings at each end, and a longitudinal spring-packing piece separating the steam passages. The steam port is in the center of the cylinder, at the top; its dimension is 3″ × ¾″. The exhaust port is 3″ × 1″, and diametrically opposite. The steam passages in the piston run along the circumferential surface of the piston head in a longitudinal but curved line which keeps the passage open to the cylinder port up to that part of the stroke and rotation when the cut-off is desired. Here the cut-off is effected by turning the passage sharply at right angles and in the direction of the piston rotation, giving the rest of the stroke under expansive steam. The steam-passage, after the abrupt turn mentioned, continues longitudinally to the end of the piston head; and at the end of the stroke is in communication with the exhaust port of the cylinder, and immediately acts as the exhaust passage, a similar or complementary passage alternating with it for steam and exhaust successively.

Van'ner. A separator and dresser for sifting minerals.

The Cornish vanner is a wide traveling belt of canvas and india-rubber, with a smooth rubber surface and deep flanges on each side, which travels slowly upward, and on the upper end of which the stuff to be dressed is carried by a launder and head. This belt, in addition to its upward motion, has a rapid shaking action imparted by cranks driven from a side-shaft, and the result is that while the waste is washed off the belt, at the bottom the mineral settles upon and adheres to it, and is carried over the upper cylinder and down into a coffer through the water in which the belt passes, and into which all the mineral is washed. The object throughout is, of course, to imitate the vanning action of the miner's shovel, the most efficient separator and dresser known. The machine at West Seton is larger than that put up at New Consols, the belt being 4′ in breadth and its upper surface 12′ in length. The inclination of the belt is 6″ in 1 foot, and the traveling speed about 10′ a minute, while the shakes are going at the rate of about 180 in the same space of time. But the speed, of course, depends upon the character and quality of the stuff. At West Seton the vanner has been tried on the tails of the slimes, and has thoroughly proved its efficiency by taking out all the mineral that is worth anything, that which passes off being worthless and utterly incapable of being treated profitably.

Va'ri-a-ble Cut'-off. One arranged to cut off at different parts of the piston stroke according to the speed of the engine.

In the Wheelock arrangement, Figs. 2499, 2500, the two winged induction and eduction valves *a b* have inclined conical faces, and are fitted rather loosely so as to pack by steam pressure as they wear. They are vibrated, through proper connections, by the rods *c d*, the latter attached to the eccentric. The cut-off valves *e f* have similar faces, and are also rather loosely fitted to insure constant light packing. They are operated by the dash-pot weights through the medium of a series of devices adjustably connected with the governor, so that they may be permitted to remain altogether inactive or arranged to cut off at varying points of the stroke depending on the speed of the engine. *g* is the steam chest and *h* the exhaust chamber, located beneath the cylinder to allow water of condensation to flow away.

Vas'e-line. A product of petroleum. Petroleum jelly. The heavy residuum of distillation is filtered through animal charcoal, which deodorizes and decolorizes the viscid hydro-carbon, and gives the familiar, bland, neutral product known as vaseline. This forms a vehicle for medicaments of various kinds; with 3 per cent. of carbolic acid it is a valuable antiseptic, and cerate for eczema.

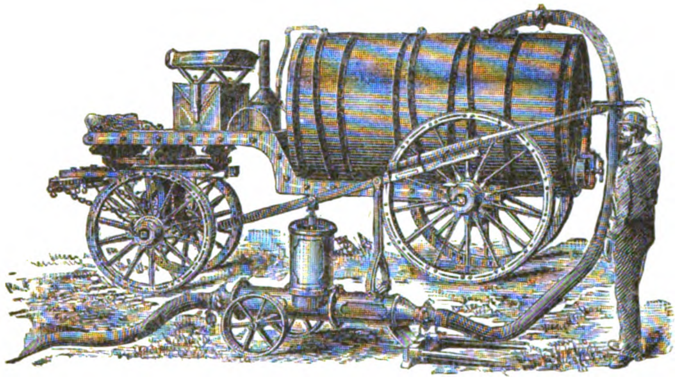
Vat. (*Leather.*) A large rectangular pit used in tanning.

Vat Net. Used as a strainer over a tub or tank.

Vault Emp'ti-er. A combined pump with deodorizing apparatus for emptying vaults, cesspools, etc.

The deodorizing can in front of the tank contains a chemical mixture through which the foul air displaced from the tank must pass in its escape. It is claimed that it is thoroughly disinfected, destroying all offensive odor. See Fig. 2501.

Fig. 2501.

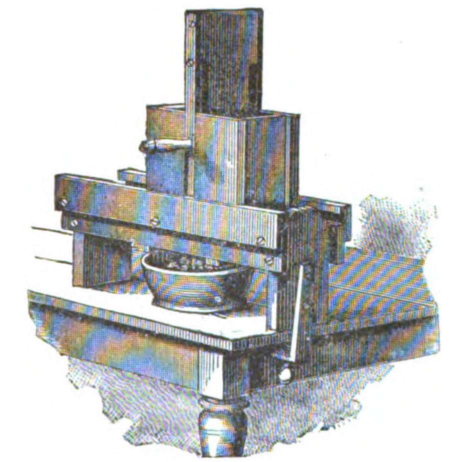


Vault Emptier.

Veg'e-ta-ble Cut'ter. A device for slicing vegetables for cooking or table use.

Fig. 2502 has a two-edged stationary knife, with the bottom of the laterally sliding box in two sections, each end rising alternately, being lifted by cams beneath according as it is working towards the knife or away from it, so as to present the material to the cutting surface of the knife.

Fig. 2502.



Vegetable Cutter.

Veg'e-ta-line. A substitute for ivory, coral, leather, caoutchouc, etc., lately patented in England under the name of *Vegetaline*, is prepared as follows: Cellulose (woody fiber), from any source whatever, is treated with sulphuric acid of 58° B. (= sp. grav. 1.676) at 15° C. (= 59 Fah.), then washed with water to remove excess of acid, dried and converted into a fine powder. This is mixed with resin-soap, in a mortar, and the soda of the soap is removed by treatment with sulphate of aluminium. The mass is now collected, dried again, and pressed into cakes by hydraulic pressure. These cakes are then cut into thin plates, which are shaped by again subjecting them to pressure. By adding castor oil or glycerine to the mass before pressure, the product may be made transparent. Colors may be imparted by the use of vegetable coloring agents. Facts respecting the strength and elasticity of this product are wanting.

Ve-lo-cim'e-ter. An apparatus for measuring the velocity of projectiles in guns.

The methods that have been tried for ascertaining the law of motion of a projectile in the bore of a gun (with a view to finding the law of pressures developed) give only a small number of points of the curve of spaces traversed in given times, and they involve perforation or other injury to the walls of the gun, so that they are applicable only to large pieces.

A new and ingenious method, advantageous in these respects, has been contrived by M. Seibert. In the axis of a cylindrical hollow projectile he fixes a metallic rod of square section, which serves as guide to a movable mass. This mass, or runner, carries a small tuning-fork, the prongs of which terminate in two small metallic feathers, which make undulatory traces on one of the faces of the rod (blackened for this purpose with smoke) as the runner is displaced along the rod. The runner, it will be understood, is situated at first in the front part of the projectile, and while the latter is driven forward remains in place, the rod of the projectile moving through it. The escape of a small wedge between the prongs of the fork at the moment of commencing motion sets the fork in vibration. It can be easily shown that, owing to the very high speed imparted to the projectile, the displacement in space of the inert mass, through friction and passive resistances, which tend to carry it forward with the projectile, is such as may be quite neglected. So that the relative motion of the mass recorded by the tuning-fork may be considered exactly equal and opposite to the motion of the projectile. A study of the curves produced guide to the laws of the motion and of the pressures developed by the charge. Evidently the motion of a projectile, as it buries itself in sand or other resistant medium, may be similarly determined.

Also used to measure the recoil of guns during the first instant after the charge is fired. See TACHOMETER.

Ve-loc'i-pede. Velocipede is a generic name, of French origin, applied to that class of carriages propelled by the feet of the rider, of whatever construction or by whatever mechanical means the power is communicated, so as to drive the vehicle. Less strictly, it has been applied to vehicles propelled by the hands only, and guided by the feet.

The term vélocipède is found in French patents early in the century, and the class of carriages to which it was applied is found to be described and illustrated in the books and the patent records for more than a hundred years past.

Velocipedes, like wagons, have been constructed with one, two, three, or four wheels, and sometimes with greater number. One-wheeled velocipedes, or monocycles, have been constructed in a variety of ways; sometimes so that the rider should be seated above the wheels, but more often that he should be seated inside the wheel, and so as to be propelled sometimes by the hands, and sometimes by the feet. They have never in any form been made a practical success, and their use has been little attempted except for purposes of exhibition.

Scuri, the Italian gymnast, has been more successful with a machine patented by him, consisting of one wheel, axled in a fork or perpendicular frame, and foot-cranks attached to the axle, a handle rod upon the upper part of the fork or perpendicular frame some distance above the wheel, and a saddle attached to a projection from the frame, but with no other supporting or steadying part of the machine touching the floor than the tire on the one wheel.

Two-wheeled velocipedes were made as early as 1816, the first one of which we have any account being attributed to the Baron Von Drais, of Manheim, which had its two wheels in the same plane, one before the other, and was patented in France, and with some improvements patented in England by Denis Johnson, in 1818, under the name of "Pedestrian Curricle." This form of velocipede was patented first in France by Louis-Joseph Dineur, and in the patent it was simply called a velocipede. It acquired the name, however, of *célérifère* and *draisina*, and *draisienne*. This machine was improved from time to time in England, where it obtained the name of dandy horse, and sometimes of hobby horse. In 1821 it was modified in construction by Gompertz, and a rack and pinion attachment, for aid by the hands in propulsion, applied to the front wheel.

In 1819, a United States patent was granted to William K. Clarkson for an improvement "in the velocipede." In all these two-wheeled velocipedes, however, the propulsion was mainly by the thrust of the feet alternately upon the ground as the rider sat astride the horizontal bar or perch; and it was not until 1862 or 1863 that any mechanical means of propulsion was applied to this arrangement of two wheels in the same plane, by which the rider was enabled to take his feet off the ground, and still propel and guide his vehicle. For later developments see BICYCLE.

Two-wheeled velocipedes have also been constructed with the wheels abreast, and considerable success has been attained in the use of this by foot driving mechanism, particularly in the form known as the "Otto," in England. The forms constructed and patented in the United States have differed somewhat in details of construction from that which has achieved some success in England; but nowhere has this form yet become of any extended use or comparative value.

Three-wheeled velocipedes were constructed early in the century, and as early as 1828 were given the more specific name of tricycle. This variety of velocipede, offering as it does by reason of its three points of support, the greatest steadiness of base with least resistance of roadway, and the lightest construction consistent with stability of base, has been constructed with great variety of detail, and become very much specialized, and widely used. See TRICYCLE.

Velocipedes of four wheels have frequently been termed *quadrocycles*, and though at different times and in different countries they have been made in considerable number, they have not been found comparatively practicable as yet, the greater weight, friction, road obstruction, and air resistance, making them less desirable than the bicycle or tricycle.

Velocipedes constructed with more than four wheels have been interesting chiefly for their phenomenal or ingenious construction.

The term velocipede, and the names marine velocipede, water velocipede, etc., have been applied to machines for travel by foot propulsion on the water as well, with various details of construction by means of which the rider was enabled to propel himself; sometimes with paddle wheels, and sometimes with screw or other propellers acting upon the water. The latest and most successful of these has by misnomer been called "marine bicycle," and is at present in considerable use in the United States. It consists of two floats, 4' or 5' apart and 20' in length, connected by bars and crank axle, with pedals for the feet of the rider, and connecting mechanism operating a screw propeller, and a rudder operated by steering bar, held and worked after the manner of the steering mechanism of a bicycle.

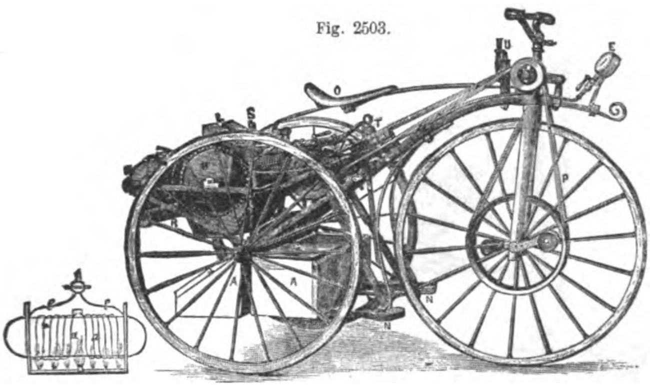
Ve-loc'i-pede, Steam. At the recent Industrial Exhibition at the Champs Elysées, Paris, M. Perreaux, of Orne, exhibited a steam velocipede, which is illustrated herewith. Fig. 2503.

The generator, the fireplace, and the motor are arranged behind the saddle of the velocipede, after the manner of the portmanteau of a horseman. Chains or belts transmit motion from the engine to the wheels. All the parts are small, well put together, and very compact. The small tubular boiler is cylindrical and has a capacity of about three quarts; and at the sides there are two receptacles containing a sufficient supply of water to last during a journey of two to three hours. The piston of the engine is about 1'' in diameter and has a 3'' stroke. The whole engine is a mere plaything, and yet, with a pressure of 3½ atmospheres, it has sufficient power to drive the velocipede at a speed of from 15 to 18 miles per hour. The fireplace which heats the boiler is an ingenious novelty, and consists of a small gasometer fed by wood spirit. The vapor of the alcohol issues through holes, and gives a flame endowed with great calorific power. The fire is lighted at will, and in a few minutes steam is up. A method is provided for regulating the escape of the alcohol vapor, and consequently the intensity of the heat. Externally the boiler is furnished with two tubes rolled in the form of a spiral, so that the steam which is produced circulates through these continuously, and is exposed directly to the fire before entering the motor. The steam being superheated, no water is carried over with it. With a speed of 18 miles an hour, the cost of alcohol consumed is from 40 to 60 cents (this calculation, of course, for France). This is certainly not very economical, but it is very pleasant to have a horse under control which eats only when he works.

Fig. 2503.



Steam Velocipede.

Ve-lom'e-ter. A name given by the inventor, Mr. Durham, of Barnet, England, to a governor for marine propeller engines, to prevent racing of the screw.

"*Engineer*" . . . . * xlvi. 190.

Ve-lon-tine'. (*Fabric.*) A corded French fabric, with fancy wool warp and merino wool weft.

Ve-lours'. (*Fabric.*) A French goods, all wool.

Vel'vet. (*Fabric.*) Old English *velouette*, from the Italian *vellute*, fleecy, nappy, and Latin *vellus*, a fleece.

Ve-neer'. A thin slip of wood, ivory, stone, etc., cemented to the face of some other material to form an ornamental finish thereto.

Celluloid veneers are made by applying a coating of the celluloid, colored, to imitate any desired wood or metal.

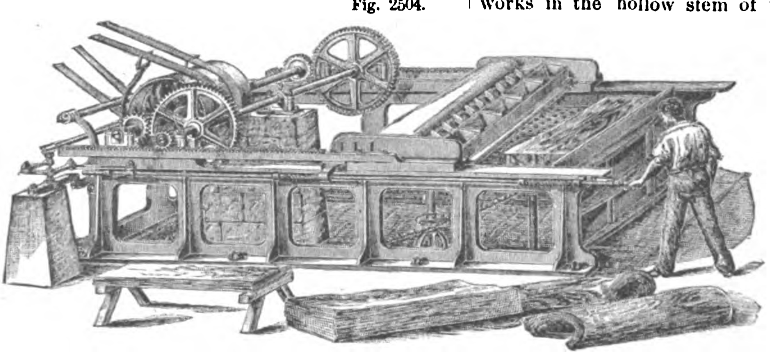
Veneers are cut in two ways, by sawing, and by what is termed a slicing-machine, which is fitted with a sliding knife-block and a thin knife and back iron.

Ve-neer' Cut'ter. The cutter, Fig. 2504, is a slicing machine, and is fitted with a sliding knife-block, and a thin knife, and back-iron, and is used for cutting up blocks 5', 7' 8", and 10' wide.

The cutter is placed obliquely, so as to lessen the shock that might otherwise displace the wood. The thin knife with back iron does away with the special machine for sharpening, that is usually necessary. When the knife rest is unscrewed from the saddle care should be taken to keep the three pieces, the knife-rest, knife, and back iron together.

In machines with connecting-rod motion for blocks 3' 3" the knife is square across the machine or under; so that the fiber is cut along its whole length at once, which is very necessary for some kinds of wood.

Fig. 2504.



Veneer Cutter.

In the larger machines the cutter is placed obliquely so as to diminish the shock, which might displace the wood, but in these machines the workman often places the block parallel to the cutter.

The thin knife with back iron does away with the special machine for sharpening, which is usually necessary.

The wood should first be steamed and the workman should know how to set it according to the grain, to sharpen his knife according to the kind of wood to be cut, and should also watch it drying very closely.

Veneer machines cut from 10 to 15 veneers per minute and from 100 to 150 to the inch, whereas the sawing-machine will not cut more than from 20 to 25.

We allow that for very perfect veneers sawing is better, but for work of usual quality these machines answer admirably. The power required is about 4 horse-power for the large machine; the smaller one can be driven by hand-power.

These machines are also used for cutting veneers up to 4 or 5 mm., and work very well.

Manufacturers of small boxes, etc., profit immensely by their use. In a day of 10 hours, and with horse-power, such a machine will turn-out 3,000 sheets, 4 mm. thick, 16" long, by 10¼" broad.

These veneers are cut so cleanly that for common work polishing is quite unnecessary.

The brick palaces of Assyria, Kouyunjik, for instance, were veneered with slabs of coarse alabaster or gypsum held in place by cramps and plugs of metal or wood.

Each slab usually bore upon its back an inscription recording the name, title, and descent of the king forming the same.

Fig. 2506 is Arbey's horizontal reciprocating saw with a single blade for cutting veneers and thin woods of valuable timber. Has a rising face carriage with automatic intermittent feed.

Ve-neer' Scra'per. Bailey's scraper or plane, Fig. 2505, is an adjustable tool for dressing veneer.

Fig. 2505.

Veneer Scraper.

Vent. Love's liquid vent, Fig. 2507, is a combined gimlet, tubulated vent, and sample pump. It is so operated that as the gimlet opens a passage through the barrel a vent is opened to the plunger that works in the hollow stem of the gimlet, and a sample is drawn from the barrel through the hollow T of the handle.

A spiral spring within gradually stays the piston at the termination of its plunge, the liquid enters the tube above the plunger and on the removal of the thumb the spring lifts the plunger and discharges the liquid through the tube.

The instrument is transferable into a siphon by detaching

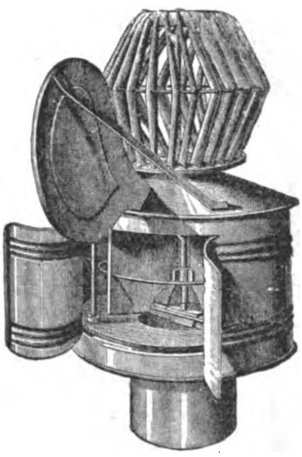
Ven'ti-la'tor. Fig. 2508 represents Gen. Billings's wing fan ventilator.

The ventilator shaft used in connection with this device is enlarged as it extends upward, so that each successive story of a building may discharge into it without interfering with the proper ventilation of the lower stories. The cowl into which the ventilating shaft discharges is large and nicely pivoted, so that it turns easily with the wind. Its flaring mouth gives it peculiar advantages over the ordinary form of cowl, so that this of itself is a very efficient ventilator; but the chief merit of this device lies in the arrangement of the fan and its propelling wind wheel seen at the top of the cowl.

Fig. 2508.



Wing Fan Ventilator.

All the parts are made to work very freely and with but little friction. The fans are arranged so as to swing around the inner periphery of the casing, leaving an undisturbed central core, while the enlarged hood and vertical position of the fans offer no resistance whatever to the upward current of air in case the fan should not be in motion. In motion they force the air out through the lateral opening, thus producing a vacuum, aiding the natural draught or creating one where there is none.

With the wing fan ventilator it is found after many tests that when the wind is not strong enough to run the fan, the peculiar form of the cowl, its enlarged size, and prompt action in shifting itself to windward, will give a regular current of from 100′ to 200′ per minute; while with a fair to brisk wind to run the fan the velocity will go up to 300′ and 400′, while with a strong wind it often records over 500′, and has in several cases reached over 600′ per minute. Six tests made November 20, 1879, at St. Denis Hotel, where there is a 24″ shaft capped with a wing ventilator, showed an average of 438′, being an actual exhaust of fully 100,000 cubic feet of foul air per hour. December 22, 1879, in public school branch of No. 15, Brooklyn, six tests showed a current of from 225′ to 357′ per minute, with 8 12″ pipes leading into two large pipes of 24″ each, showing an exhaust of over 146,000 cubic feet per hour, with only a light wind and no fires. Later in the same day the one in Brooklyn "*Eagle*" building showed a current from 230′ to 270′ per minute. November 20, 1879, the Irving House, where there are two of these ventilators, one over each tier of water-closets, gave a current of 525′, there being a good breeze.

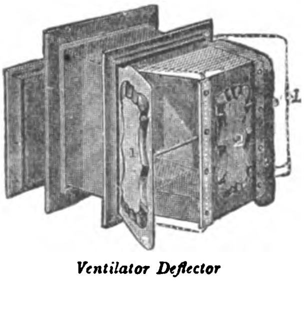
Ven′ti-la′tor De-flec′tor. On railway cars; a window so hung as to draw the air to or from the inside according to its angular position relatively to the line of motion and to the car. See Fig. 2509.

Fig. 2509.



Ventilator Deflector

Ven′ti-la′tor Hood. A shield over the outside of a ventilator to prevent the entrance of sparks, cinders, rain, or snow. It is sometimes intended to direct the current of air either into or out of the car.

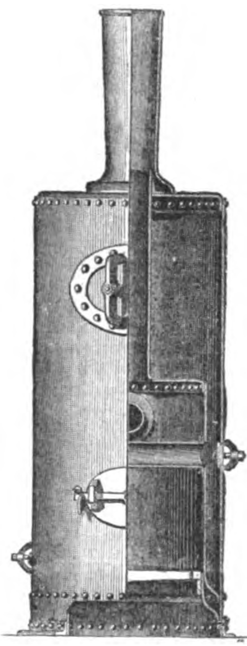
Ver′meil. Silver-gilt.

Ver-nier′ Scale Sight. (*Rifle.*) A hind sight with a vernier scale for accurate adjustment. The peep-sight is elevated or depressed by a screw; the scale on the bar of the sight being slotted.

Ver′tic-al Boil′er. A convenient form of steam boiler occupying but small space and well adapted for those of moderate size. The cylindrical shells are now rolled without longitudinal joints, which adds to the neatness of appearance, avoids to that extent the grooving and corrosion which always begin at the joints, and is convenient for fixing the mountings.

There are many forms: Multiflue, multitube, hanging tube, cross tube, spiral tube, etc.

Fig. 2510.



Vertical Boiler.

Fig. 2510 is a plain form without longitudinal rivet joints either on the shell or fire-box, the boiler space being all around the furnace and flue. The flame space is crossed by two large tubes of 6″ or 8″ diameter, one of which is shown in cross and the other in longitudinal section. A manhole is shown in front and mud hole at one side; on the other side is a cover and bridge for the hole by which the flue is reached to remove scale.

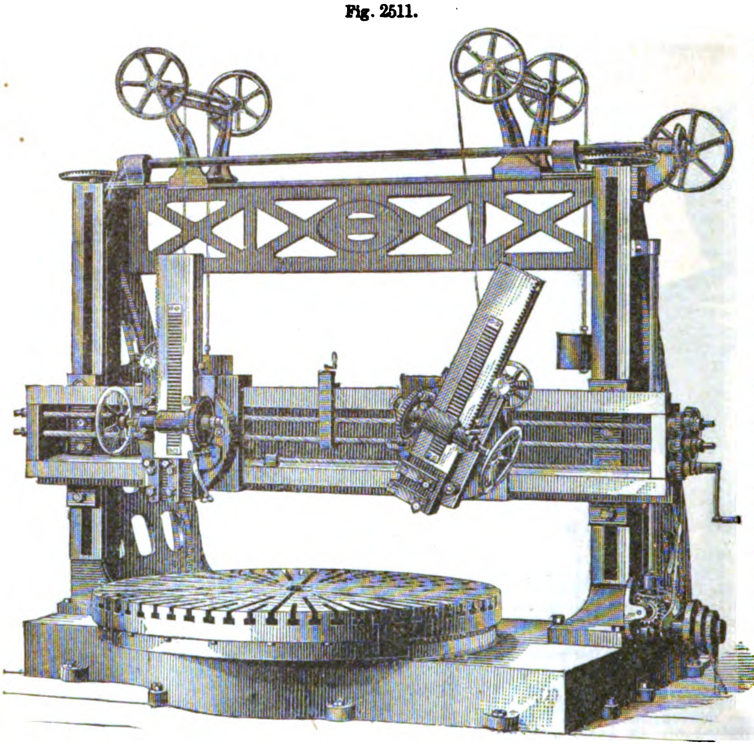
Ver′tic-al Bor′ing and Turn′ing Machine′. The Beuvant machine, Fig. 2511, swings 12′ diameter and 6′ high. The face plate is driven by spur pinion with 20 changes of speed, and is supported upon a spindle, with step to sustain the weight, and adjusted vertically and laterally, giving steadiness to large work.

The tool slide has 30″ vertical or angular traverse, rapid hand-motion, and counterbalance carried on frame of the machine. There is self-acting feed at all angles and in either direction, with four changes. The cross-head is raised and lowered by power.

The French vertical boring machines have their special uses with different kinds of borers and slides. They are used for routing sabots and gun stocks. The rounded ends of the mortise are squared out by a double chisel worked by a lever. The French use a simple hollow bit, like a pod bit, and run the mandrel 2,000 revolutions per minute.

Fig. 2511.

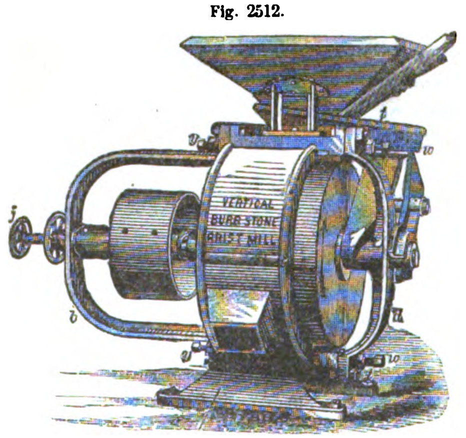


Vertical Boring and Turning Machine.

Ver'tic-al Burr Mill.

Silliman's vertical burr stone mill, Fig. 2512, has large openings for receiving and discharging the grist. It is never liable to choke or clog; the grain drops from the shoe directly into the radiating centrifugal feeder, which throws it evenly between the stones on all sides alike, above as well as below; thus for the first time obviating a vital objection to all vertical mills. In taking the mill apart to dress the stones, the foundation bolts are never disturbed, and each

Fig. 2512.



Vertical Burr Mill.

stone is taken out separately. As shown by the cut it is so constructed that it may be belted to from almost any direction, above, below, or at either side, as most convenient.

See also, Fig. 2316, p. 1021, "*Mech. Dict.*"

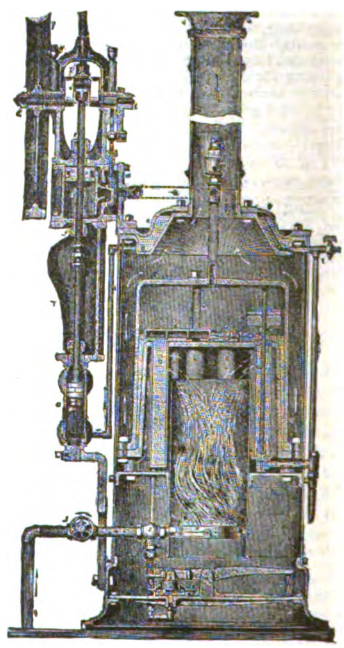
Ver'tic-al Drill. The "Niles" vertical drill is calculated for drilling from $1\frac{1}{2}''$ to the smallest work. The cone has 4 speeds for 2″ belts, and gives a wide range in speed and power; the spindle is driven by cut bevel gear (2 to 1); the arm carrying the belt shifter can be revolved around the driving shaft to suit the direction of the belt; the table arm has a lift of 20″, and can be swung entirely around the column. The base is provided with T slots for securing work, and the table is raised and lowered by a worm and oblique rack, enabling the operator to manipulate the table when it is loaded. By an arrangement of sheaves the spindle and lower stock is balanced by a single weight; the balance weight plays within the hollow column. See UPRIGHT DRILL.

Woodward.

* "*Scientific American Sup.*," 836.

Ver'tic-al Mul'ti-flue Boil'er. A form of boiler with flue pipes extending between the crown plate of the furnace and an upper flue

Fig. 2513.



Vertical Steam Engine.

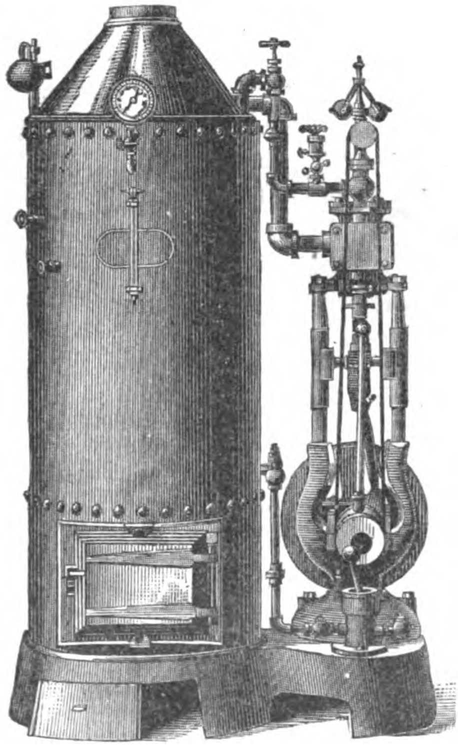
plate, being surrounded by the water in the boiler. See MULTIFLUE BOILER.

Ver'tic-al Steam En'gine. Fig. 2513 represents Maxim's automatic steam engine.

The cylinder is 2″ in diameter and has 2½″ stroke of piston. It is supplied with all the attachments used in large engines, the governor being inside the belt pulley, and operating directly on the point of cut-off, enabling a small amount of steam to do a large amount of work. The engine is ready to work in ten minutes from lighting the gas, and will run all day without any attention whatever. With a supply of gas and water it is its own engineer and fireman. It is admirably adapted to the use of dentists, jewelers, and amateurs.

Lovegrove's portable engine, Fig. 2514, occupies a floor space of only 20″ × 34″. The boiler is 18″ diameter and 42″ high. It is made of charcoal hammered iron and contains 20 2″ tubes, 30″ long, and is tested to 200 lbs. pressure, though the working pressure is from 60 to 90 lbs. With this boiler and a cylinder 3″ diameter and 4″ stroke, is obtained a two horse-power. The engine is fitted with all the necessary accompaniments of pumps, valves, etc., complete. It is furnished with the Pickering governor, and the steam and exhaust connections are quite short, avoiding expense in long pipe and waste of steam. The pulley which drives the governor affords connection for the pump at the same time. The vertical guides are bolted to the base plate, and are fitted up in as plain and substantial a manner as possible. There is a complete supply of lubricating valves, gages, blow-off valve, etc. The fly-wheel is 12″ diameter and 3″ face, and insures steadiness of motion.

Fig. 2514.



Vertical Portable Steam Engine.

In the "Shapley" vertical engine and boiler, the engine is not attached to the boiler but rests on the same base, permitting adjustment of the parts, if necessary while steam is on. The boiler is in two sections, the upper part of which serves as a steam space. The fire-box is conical and from it radial tubes communicate with an annular smoke space having down-cast flues passing perpendicularly through the boiler, and conveying the products of combustion after passing over water to the smokestack, into which the exhaust steam is also discharged.

Ver'tic-al Ten'on-ing Ma-chine'. Fay's car gaining and tenoning machine has traversing cutters and automatic feed. The table is low, and the cutter-heads are adjusted independently by a screw to each, so that they can cut a tenon of the desired thickness, with any proportion of shoulders within the capacity of the machine.

The back of the upright stand carries a head for gaining a double tenon to 4″ in length. This is raised by a screw, and can be moved out of the range of single tenoning. The side of the upright stand has a movable piece, which when taken out makes the whole length of the tenon 12″.

The belt that drives the heads is retained at its proper tension by a sheave and weight in connection with a binder pulley, that compensates for the motion of the heads. The table rests upon friction rollers that run upon planed ways, one of which has a groove in which is fitted a corresponding tongue on the table, to keep it at a constant right line with the line of the heads.

Ver'tic-al Tube Coil. An arrangement for steam heating purposes.

Ver'tic-al Tu'bu-lar Boil'er. The Safety Steam Power Co.'s tubular boiler has the tubes pass at about the water level, through the baffle plate. A large tube hangs from the center of the plate, nearly to the crown of the furnace, and an annular space is left around the outside of the baffle and between it and the outer shell sufficient for the easy escape of the steam and water.

This arrangement is intended to stop the current of steam and water tending to shoot up between the tubes, and compel it to flow outward and escape between the baffle and shell, at which point the steam and water separate. The steam is taken off from the center of the boiler, and as the steam is delivered at the outer edge of the baffle it must flow inward, between and around the tubes, on its way to the engine, becoming dried and slightly superheated.

Vick'ers Steel. (*Metallurgy.*) A steel made by combining iron scrap, ground charcoal, and oxide of manganese.

Vig-net'ter. A mode of making vignetters by means of gelatine-chromate is: —

From a good positive in black or some non-actinic color a number of negatives of different sizes are taken, but in doing this the image on the ground glass plate must not be focused too sharply. Or, where suitable vignettes are already at hand, the negatives can be taken from them directly by any convenient method; either a collodion emulsion may be used, or chromated gelatine, as described below. To prepare the latter a solution is made of five parts pure white gelatine in sixty parts of water, to which two parts of ammonium bichromate are added, and, when the film is afterward to be drawn off, a few drops of glycerine may be introduced to make it less brittle.

After filtering this solution, pour it, while still hot and fluid, on a well-cleaned glass plate; care must be taken to have this plate placed in a perfectly horizontal position, which is best effected by resting it on a larger plate that has already been carefully leveled. The gelatine solution must not be allowed to run over the sides of the plate, or the film may turn out to be too thin; to prevent this give the plate a raised edging of wax. When the chromated gelatine has set, let the plate dry completely in a dark and moderately warm room.

Artificial heat should not be used in drying, especially when the film is afterward to be drawn off; when this is the case, the plate should first be rubbed over with powdered talc or diluted ox-gall, and then, on heating, the film easily flies off.

On plates prepared in this way the negatives are now copied, and that as intensely as possible by a long exposure. The copies cannot be too intense, provided that the negatives are quite black in the center of the aperture. When they have been sufficiently exposed, wash them several times in cold water, and, finally, with distilled water; then plunge them, while still wet, into a solution of one part lunar caustic in fourteen parts water acidulated with one part acetic acid. It will now be seen that the film is coated with a precipitate of silver chromate, which is in the highest degree non actinic, and is much denser toward the side of the plate. Should there be a trace of chromium salt left, as is often the case, it is of no importance; on the contrary, when really intense vignetters are required, it is not necessary to thoroughly wash out the chromium salt. But in order to obtain the requisite transparency in the center of the plate, the whole of the silver nitrate must first be washed out, and then a soft and strong hair brush dipped in dilute nitric acid. This is passed over the plate with a few rapid strokes in a circular direction from the center outward up to the commencement of the shading, and the plate is then quickly rinsed. With a little skill a great variety of effects may be obtained in this way, and any required degree of shading.

After drying, the film is coated with a little castor oil collodion, and then, if it be desired to draw it off, with a hot twenty per cent. solution of gelatine to which a small quantity of glycerine has been added. The plate must be laid horizontal, and the addition of a little alcohol to the solution facilitates its flowing. When the gelatine is set, the plate is placed for a couple of days to dry, and it is again coated with some thin collodion; the edges are then cut through, and the film is drawn off.

Vi-gogne′. (*Fabric.*) A silk-and-wool, or an all-wool French dress goods.

Vig′o-rite. A nitro-glycerine explosive, manufactured at Marquette.

Bjorkmann, of Stockholm, Sweden, gives the following recipe for the manufacture of the new explosive, vigorite: Mix in a wooden or rubber vessel 5 to 20 parts of sugar or molasses, 25 to 30 parts of nitric acid, and 50 to 75 parts of sulphuric acid. 25 to 50 parts of this mixture, called nitroline, are mixed with 15 to 35 parts of nitrate of potash and 15 to 35 parts of cellulose.

Vi-nasse′. The residuum of the wash in the still after distillation.

(*Beet-root.*) The residuum of the distillation of fermented beet-root molasses.

Vine Pull′er. A machine for extracting vines, Fig. 2515. A pair of double-grip pinchers hang by a chain from a double-pivoted lever that surmounts a truck-frame.

Vine Shear. See PRUNING SHEARS.

Vine′yard Bisse. A French double vineyard plow.

Vine′yard Cul′ti-va′tor. Fig. 2516 represents a cultivator as used in the vineyards on the Continent of Europe.

Fig. 2515.

Vi'no-sal-o-rim'e-ter. The vino-salorimeter is a modification of the old colorimeter of Payen, but its dimensions are much smaller, and the addition of the micrometer screw allows the depth of the layer of wine to be measured with accuracy.

Vi'o-lin. For history of the violin in the United States, see report of H. K. Oliver on Group XXV., in vol. vii. of "*Centennial Exhibition Reports*," p. 48.

The President de Brosses, "*En Italie*" (1739), mentions a virtuoso in Florence, Tagnani. "Il a inventé une clef aux violons faites comme celles des flûtes, qui s'abaisse sur les cordes en poussant le menton, et fait la sourdine; il a assez ajouté, sous le chevalet, sept petite cordes de cuivre, et je ne sais combien d'autres mièvretés." I. 272, ed. 1858, Didier, Paris.

The invention of laying the strings over and above each other is certainly a very old one. Even before the invention of the hammer-piano there was added to the bass strings of the old clavichord a string sounding the higher octave. This string was fastened upon a bridge which is situated below the lower strings upon the sounding-board. Various experiments to utilize the crossing of the strings failed utterly, so that even authors of repute believed that strings lying above each other throw their respective vibrations into confusion. This, however, is not the case, as is sufficiently proven by Helmholtz's analysis of the system of sound-waves. This is done no more when lying above each other than by strings lying side by side.

The vina of India has an antiquity of 2,500 years at least. The bow is claimed to have been invented in India.

Pocket . . . . * "*Manufacturer & Builder*," viii. 187.

Vis-co-sim'e-ter. The viscosimeter is the name given to an instrument by means of which the viscosity of a sample of beer can be determined.

It consists in its simplest form of a funnel-shaped vessel, the lower extremity of which is drawn out to a fine point, so that the internal diameter is as fine as a capillary tube. A certain quantity of distilled water being placed in the funnel-shaped reservoir, a determination is made of the quantity which will run through in a given time, say five minutes; for example, we will assume this to be 21 cubic centimeters; the same quantity of the beer to be tested is then placed in the instrument, and an observation made of the quantity running through in the same time, we will suppose this to have been 15 cubic centimeters. This viscosity is in inverse proportion to the quantity of fluid flowing through the tube in a given time; taking the viscosity of water at 1,000, we have the following proportion: —

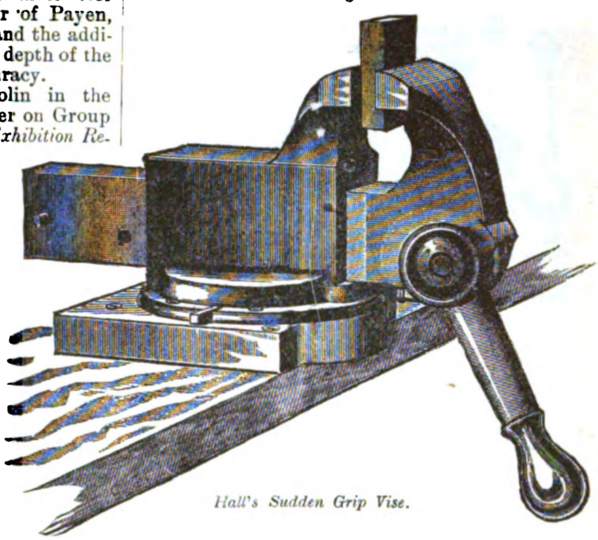
$$15 : 21 :: 1000 : V.$$
$$V = 1400.$$

Many precautions have, of course, to be taken; all determinations must be made at the same temperature, and, if possible, at the same barometric pressure; any excess of carbonic acid gas should be previously removed from the beer, by shaking a portion of it in a bottle until no more gas is given off; if the beer is at all thick it must be filtered, otherwise some of the suspended particles may mechanically close up the capillary tube. The determination of the viscosity of beer is of value for many purposes, for any great excess is an unfavorable sign. Any tendency toward "ropiness" can be detected by this instrument. It would also probably be of considerable value to the practical brewer for testing his worts, with the view of determining the dextrine ratio. A dextrinous wort will run through much slower than a saccharine wort, and we think some very useful results might be obtained by the aid of this instrument. Its construction is very simple, and any one with but a slight experience in chemical manipulation may make one for himself.

Vise.

Fig. 2518 represents Hall's sudden grip vise. It is intended to save the time used in operating a screw vise. The movable jaw and sliding bar are cast in one piece, with a hollow chamber below, to contain the working parts of the vise. The stationary jaw is so cast that the sliding bar fits into it, and with a base to fit the swivel plate. The lever has two disk-like portions on each side to fit into recesses in the under part of the movable jaw, and having frictional surfaces around the peripheries. A band retains the lever in the recess, and an adjustable screw regulates the tension of the band.

Fig. 2518.

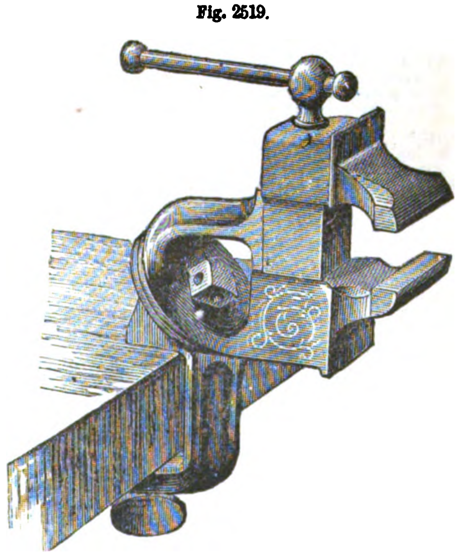


Hall's Sudden Grip Vise.

Smith's heavy chilled beam vise is one with sufficient weight of metal to give it the inertia of an anvil. The jaws move parallel so as to take a firm hold.

Stevens's vertical and horizontal vise, Fig. 2519, here illustrated, is so hung upon an angular swivel that a half revolution upon its base brings the jaws from a vertical position to a horizontal position. In their passage from one position to the other, the jaws occupy every angle of inclination, and the vise may be fastened to its base in any position. Our illustration represents a jeweler's portable or clamp vise,

Fig. 2519.

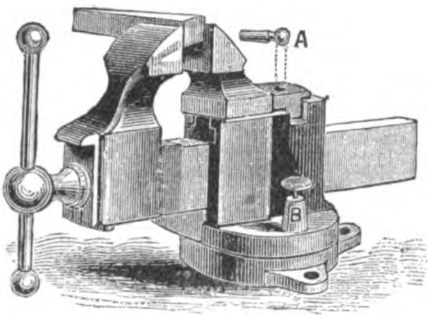


Vertical or Horizontal Vise.

arranged to fasten to any table without marring it. The two plates of the swivel are faced true, and held together very firmly by a central bolt, which may be made fast by a tenpenny nail as a lever to turn the bolt. The larger vises turn upon a large cylindrical bearing which projects into the lower plate, the plates and bearing being turned true, and the binding bolt, or nut, is turned by any wrench beneath the bench. It may be changed from one position to the other in a few seconds.

The Prentiss vise, Fig. 2520, has a back jaw that is adjustable and in use instantaneously conforms by automatic ac-

Fig. 2520.



Angle Vise.

tion to any angle, adjusts itself, and makes firm the object held, whether it be straight, beveled, or wedge-shaped. Or, if desired, by inserting the pin *A*, the jaw becomes fixed and immovable, thus making a perfect parallel, or solid jaw vise.

The adjustable jaw, resting and working as it does upon and against the solid body of the vise, is thereby rendered absolutely as strong and durable as the old permanent jaw. By means of the new patent swivel bottom this vise may be readily adjusted to any angle, right or left, at will of operator, by simply raising rachet-pin *B*, which, on being freed, is instantly forced home by a spring, rendering the vise solid and firm as if stationary.

See also under SUDDEN-GRIP VISE.

The following are the names of vises of various designs: —

Parallel bench vise, round jaws.
Swivel bench vise, round jaws, with cast-steel anvil.

Vise Cap. A brass cap for the upper section (the contact edge) of a vise.

Vise Clamp. A device with serrated jaws for holding pipes, rods, etc.

Vise Clamp. A clamp for temporarily fastening the vise to the bench or other object to which it is attached.

Vis-i-om'e-ter. An instrument by which to determine the numbers of lenses.

A proposed formula of procedure is in multiplying the distance of normal vision (12°) by the distance of distinct vision, and dividing the product by the difference between the two.

Vode. (*Fabric.*) An all-wool French dress fabric made for religieuses.

Vol'ley Gun. (*Ordnance.*) See MITRAILLEUR.

Volt. (*Electricity.*) The *practical* unit of electro-motive force. Equals one hundred million absolute units of potential. 1 volt = 10^8 (C. G. S.). — *Gordon.*

Vol-ta'ic Ar-ma-dil'lo. (*Surgical.*) A battery of plates in a belt or sole, linked together so as to resemble, in a degree, the cuirass of an armadillo.

Vol-ta'ic Pen'cil. There is at the present time scarcely a single branch of industry to which electricity is not lending its aid. Art, however, has thus far received but little benefit from this source, if we except the application of electricity to electro-metallurgy.

An important discovery, however, has just been made in Paris, by M. Bellet, whose invention consists of a voltaic pencil, by the use of which designers and draughtsmen may be enabled to dispense entirely with the aid of the engraver. The editors of "*Electricite*" state that they have examined beautiful proofs of lithographs and etchings obtained, without the use of the engraver, by the effect of a voltaic arc produced at the point of an ordinary lead pencil. Encouraged by this success the inventor has taken out patents in various countries, and a company has been formed to carry out the process, which will soon be placed before the public. At present there are being prepared models of a series of apparatus which will allow any artist, however ignorant of the mysteries of electricity, to reproduce immediately, and without the aid of any artisan, the most delicate and complicated drawings; and this, too, by a very simple process and at a very moderate price. By a slight modification of the system there may be produced: 1. Stencils analogous to those produced by the Edison pen; 2. Lithographs; 3. Etchings; 4. Stereotypes for typographical work. The initiators of this discovery are confident that an entire revolution will take place in the process of illustrating papers by means of their electrography. Either copper or zinc plates may be used. A late number of "*Nature*" describes the *modus operandi* as follows: A thin sheet of paper is attached to the plate. One of the poles of a Rhumkorff machine is connected to the plate, and the other pole to the top of the pen. The electricity then runs through, making a spark which perforates the paper in whatever direction the artist directs the pen. As soon as the drawing is finished, the paper is rubbed over with greasy ink, laid on with an ordinary roller. The paper is removed, and the plate is dipped into the acid, which cuts away those portions not protected by the ink. The light of the spark is said to be sufficient for the artist, even when he works in a dark room; and the pen is stated to be as manageable as an ordinary pencil.

Vol-ta'ic Pile. (*Electricity.*) A number of disks of silver or copper, wet cloth or zinc, in the order named. Invented by Volta in 1800. See Fig. 6990, p. 2714, "*Mech. Dict.*"

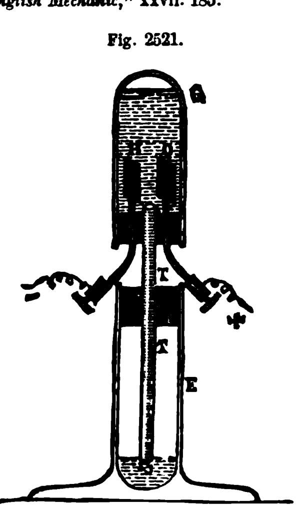
Vol-tam'e-ter. Fig. 2521 represents a detonating voltameter.

Fig. 2521.



Voltameter.

The following experiment, due to M. Bertin, is but little known, yet is exceedingly interesting, inasmuch as it puts on evidence certain phenomena connected with the polarization of electrodes which always take place under different conditions. The simple apparatus, represented in the engraving, consists of an inverted bell glass, *G*, closed with a cork, through which pass two platinum wires provided at their ends with broad plates, *H O*, of the same metal. It is supported by a glass tube, *T*, open at both ends, and fixed in the cork which closes the mouth of a test glass *E*. Two wires from the batteries are connected with the platinum wires by means of ordinary binding screws. The bell glass *G* is filled with water acidulated with one tenth of its volume of sulphuric acid. If this mixture be now decomposed by a strong current from a Bunsen battery of 50 elements, the water will be seen to lower very rapidly; and when the bell glass is almost full of gas, the mixture will detonate spontaneously, and be seen to take fire. This experiment is not attended with any danger whatever; the recomposition of the products of electrolysis takes place immediately, and during the passage of the current. It is necessary that this polarization current should have a certain tension; the phenomenon does not take place with a battery of 30 elements, but is at once spontaneously produced when the 20 elements that are necessary to make up the complement are added. With 30 elements, instead of a detonation, there will be observed a phenomenon of a different nature, but none the less curious. The water, which at first lowers very rapidly to some millimeters below the platinum plates, all at once stops, in spite of the disengagement of gas on the wires. The plates recompose above what the wires decompose below.

By using pure water the decomposition takes place more slowly, and the detonation is not produced, even with 50° Bunsen elements. Still, a curious phenomenon is produced: the water lowers to the base of the plates, and then does nothing but oscillate between the base and top of these. The water is decomposed below and recomposed above. A weaker current, of 30 elements, decomposes the whole.

These curious phenomena are due to the polarization of the electrodes and not to the catalytic force of the platinum, for they may be obtained with electrodes of various metals.

Vo-lute' Spring. A spring made of a flat bar of steel coiled with a kind of scroll resembling the volutes used as an ornament in the capitals of ancient Roman and Grecian architecture. The coil is made in a conical form so that the spring can be compressed in the direction of the axis around which it is coiled.

Vul'can-ite. Sulphide of caoutchouc; sulphur and india-rubber.

India-rubber in its crude state becomes soft when subjected to heat, and very hard and rigid when exposed to severe cold; but, by the vulcanizing process invented by the late Mr. Charles Goodyear, — which consists of incorporating with the rubber a small proportion of sulphur, and subjecting it to from 250° to 300° of heat for several hours, — it is rendered uniformly elastic when exposed to the most intense cold or to any reasonable degree of heat. Steam "heaters" for vulcanizing are of cylindrical form, 5′ to 6′ in diameter and over 50′ long. These heaters are of wrought iron, one end opening on hinges, and through this open end the goods to be vulcanized are run in on a railway carriage. The end or door is then closed, and the steam let on and maintained at the proper temperature, ascertained by the aid of thermometers placed in the top of the heater, until the articles in it are thoroughly vulcanized. Vulcanizing under the pressure of metallic molds or sheets imparts to the articles so vulcanized a solidity and quality not otherwise obtainable. In the manufacture of rubber from 3 to 10 per cent. of sulphur, and various metallic oxides — chiefly lead and zinc — are combined with it; the quantity of the latter depending on the degree of elasticity and other properties required in the article to be manufactured; and to judiciously combine these substances with the rubber in suitable proportions to produce the desired end, as well as in properly vulcanizing it afterwards, requires great experience and skill. A certain degree of honesty on the part of the manufacturer is also essential to abstain from introducing more adulterating substances into his "compounds," and thus cheapen the product at the expense of its quality; and we are sorry to say that this latter practice is carried to excess by some ignorant or unscrupulous manufacturers, whose aim appears to be to make — what always proves very expensive to the consumer — a low priced article regardless of its quality, with a view of underselling more reputable and skillful manufacturers.

It is a common error with persons not conversant with the subject, to suppose that rubber in being manufactured is treated with solvents, and can therefore, if necessary, be run into a mold like molten lead; but this is entirely a mistake, as since Mr. Goodyear's invention of vulcanizing rubber no solvents have been used in its manufacture, the entire mixing being done by the operations of machinery, after the manner of mixing dough for bread; and at no stage of the process up to the time of vulcanizing is the rubber softer than stiff dough, and consequently it has to be pressed and molded into the various forms required.

Vul'can-ized Fi'ber. Paper, paper pulp, or other vegetable fibrous substance that has been so prepared by saturation, and coating with chloride of zinc, or chlorides of tin, calcium, magnesium, or aluminum, etc., as to give it in a measure metallic toughness and strength.

Vul'can-ized Glass. This invention consists in the sudden cooling of all kinds of glass (in proportion to the temperature at which they must be worked), at a temperature relatively high in relation to their qualities, by plunging them into baths composed, when the glass consists chiefly of silicates of potassa and of lead, of the following substances: cheap oils or fats, and by preference paraffine heated from 450° to 550° F.; glycerine, among other advantages, is not so liable to catch fire, and has more favorable properties in regard to the temperature at which the glass has to be worked; glycerine can easily be maintained at a temperature of 480° F., which is its boiling point, when an addition of basic salt raises its boiling point to a constant temperature of 530° to 600° F. The silicates of potassa and lime, and the silicates of carbonate of soda and lime, require a much higher temperature. Hydrated sulphuric acid boiling at 600° to 640° F. can be used with advantage. The silicate of soda and of lime, which melts at 1,200° to 2,300° F., must be cooled in melted saltpeter, or in an alloy of metals composed of antimony and tin, which melts at 460° to 680° F., while for the silicates of borax and baryta the cooling has to be done by an amalgam of lead and antimony, the melting point of which is 750° F.

Vul'can-iz-ing. In vulcanizing caoutchouc the purified and masticated gum is kneaded on warm rolls with the proper proportion of flowers of sulphur. Other substances, as whiting, white lead, litharge, zinc oxide, disintegrated refuse rubber (vulcanized), etc., are often added to increase the volume of the product and economize the more costly caoutchouc. Lead compounds blacken the goods through the formation of lead sulphide.

The heating or vulcanizing is conducted in strong cast-iron cylinders, one end of which is movable and serves as a door. The goods to be vulcanized are loaded upon a car and run in upon a railway extending along the bottom of the chamber. Powdered steatite (soapstone) is freely used to prevent adhesion of the different articles, the goods often being packed in boxes filled with this substance. When the heater is charged and the door made fast, high pressure steam is admitted until the desired temperature is attained. This varies somewhat with the character of the articles — according to Dr. Chandler, five hours at 240° Fah. is said to be the temperature for fire hose. In factories where smaller articles are made, the goods are generally exposed in the heaters for four to four and one half hours, the temperature, at first about 250°, gradually being augmented to 275° Fah., at the termination of the operation. A temperature exceeding 280° Fah. injures the goods. Hard rubber, vulcanite, or ebonite differs from ordinary vulcanized rubber only in that a much larger proportion of sulphur enters into its composition and the vulcanizing process is conducted at a more elevated temperature. Usually the caoutchouc has incorporated with it half its weight of sulphur; but, as in the preparation of soft rubber, various foreign substances — metallic sulphides and oxides, shellac, asphaltum, etc. — are often added. Mixed with a litharge it becomes very black; with sulphide of mercury (vermilion), bright red; and composition similar to the red vulcanite used for dental purposes is prepared with six parts of sulphur, sixteen of caoutchouc and eleven or twelve of vermilion.

The vulcanizing operation is usually conducted at temperatures increasing from 275° Fah. to 305° Fah., the time required being about six hours. The articles are packed in steatite or supported in water trays in the vulcanizer, and, if to present a glossy exterior, are sometimes enveloped in thick tin foil.

Thin sheets of rubber or small articles are sometimes vulcanized by what is called the cold process (Parks's). In this the caoutchouc is simply immersed in a mixture of forty parts of carbon disulphide or benzolene and one part of sulphur chloride. It is next placed in a room heated to 70° Fah., and when all the carbon sulphide has been volatilized the process is in so far complete that it is only requisite to boil the material in one pound of caustic potash in about 2 gallons of water, the vulcanized caoutchouc being next washed to remove excess of alkali. The results of this treatment are not always satisfactory, owing to the superficial action of the vulcanizing substances.

Vul'can-iz-ing Flask. Hayes's flask and clamp is intended for vulcanizing ovens, boilers, etc. The lug joint of the clamp is so constructed that all the strain comes on the casting. The pin only serves to keep the lug in place when not in use.

W.

Wab'ble Saw. One set at an angle to the arbor, to cut a wide kerf or groove.

Wag'on Box Rod Plate. The washers attached to the wagon box on which the rod-nut turns.

Wag'on Seat. Fig. 2522 shows a lap seat spring that is hinged in front so as to make a turnover seat.

Fig. 2522.

Wagon Seat.

Walk'er Bat'tery. (*Electricity.*) A modification of the small battery in which the negative plate of platinum is replaced by platinized carbon of the gas retort.

Niaudet, Am. trans., p. 56.

Walk'ing Cul'ti-va'tor. A corn cultivator or plow with which the driver walks, in contradistinction to a sulky cultivator, in which he rides.

Wall Crane. One affixed to a wall as a hand power foundry or forge wall crane. It is attached to a wall or column so as to command a sweep over a given area, an overhead traveler reaching the nearer positions.

Wall En'gine. One attached to a wall, usually vertical and serving either to drive shafting, or supply feed-water to a boiler. See instances in *Aimer's*.

"*Engineer*" . . . . * xlv. 393.

Wall Knot. The wall knot, either single or double, forms a handsome ending to a rope. To make a single wall untwist the ends of a rope — in half-inch rope the strands must be untwisted for ten or twelve inches — and make a bight with the first strand; pass the second strand over the end of the first, and the third strand over the end of the second and through the bight of the first, then haul tight.

Wall and Crown. This knot should be finished with a crown: Lay the first strand over the walling, the second strand across over the first, and the third strand across over the second and through the bight of the first; then haul the ends tight, pinching the knot into shape as you haul. When it is made snug and tight, cut the ends of the strands off close to the crown.

A double wall knot is made over a single wall by passing the ends, singly, close underneath the first wall, and thrusting them up through the middle, the last end coming up under two bights, then finish with a crown.

Wall Pa'per. Ornamented paper for decorating the walls and ceilings of rooms.

Paper-hangings are necessarily divided into two classes — hand-printed papers and those made by machinery. These papers differ materially from each other in cost of manufacture and durability when in use; a hand-printed paper being worth, at least, twice as much, and frequently twenty times as much, as the same pattern would be if produced by machinery, and, as it is frequently impossible for a person unacquainted with the trade to detect the one from the other, especially if the two modes of manufacture are mixed, great care ought to be exercised in the purchase of paper-hangings; the fact being that very few dealers are aware of the class of goods of which their stocks are composed, and hence arises the great differences in the estimates supplied by competing paper-hangers. The public will do well, therefore, to deal only with practical men. The cause of this great difference we will now endeavor to find out.

There are various kinds of paper-hangings made in this country, all of which are made in pieces of eight yards long, or double pieces, sixteen yards long. In France the standard length is nine yards, and in England twelve. The cheapest kinds of paper-hangings are those manufactured by machinery, in which case the design is cut upon a cylinder, or rather a series of cylinders, for each color requires a separate cylinder. The cylinders, when set in motion, are filled with color much after the manner in which a printing machine is supplied with ink. The papers are run off some hundreds of yards long, and are then cut to the required length of a piece. A machine will print some thousands of pieces in a day, complete with all their colors, while a man will not hand-print more than one hundred, and that in one color only; but then the machine-printer must use his colors so composed that they will flow into the machine in a state something like printers' ink, and must only use such binding materials for sizing his colors as will not be impaired by being subjected to the great heat to which the paper so made must be subjected in the drying process. Now all this is exceedingly injurious to colors, and very much affects their durability and softness of tone; hence the extremely fugitive character of all paper made by this process. The hand-printer, on the other hand, can use his colors in considerable thickness, and as he only puts in one color at a time, and then allows his work to dry in the ordinary temperature of a room, before he adds the next color, he can use as a binding medium a well-made spetch size, and thus produce firmness and stability of color; and as he only lays on one color at a time, he secures clearness and delicacy of outline utterly unapproachable in machine-made papers; in fact, the one will last ten years without fading where the other would not be fit to look at in three.

Block-made papers are composed of various qualities of cartridge-paper, upon which a solid flat ground of distemper is laid, and the design stamped upon it with a block upon which the pattern has been cut. According to the quality of the cartridge-paper and ground-work, as also the number of times it must go through the stamping process to produce the various tints and shading of the pattern, is the price of this kind of paper-hanging regulated.

The next class of papers is composed of those that have satin grounds, the luster of which is produced by friction. These grounds are often embossed with patterns, some of which represent watered silk, and others a flowered or striped pattern. Upon this a colored pattern is printed in distemper, in the same way as upon the plain grounds. This class of paper-hangings is of all others the best, as it is the most impervious to the absorption of moisture from the atmosphere, the most easily cleaned, and decidedly the most durable.

Another class of papers is that called "floured" or "velvet" paper, and is produced by the pattern being stamped on any description of ground-work with Japan gold-size, and dyed wool, ground into a powder, shaken over it while the pattern is wet. This woolen powder, which is called "flour," then adheres to the Japan gold-size, which forms the figure of the pattern. When dry, the loose "flour" is dusted off and the pattern is generally then enriched by the application of additional blocks, with color or dry; in the latter case the "flour" receives an impression which considerably enhances its effect. It is this class of "flour-paper" to which Scott's new process applies. Several coatings of "flour" are added one upon the other, until a considerable amount of relief is obtained. The whole surface is then sized and painted, and a very handsome and durable wall surface produced.

The next class of wall-papers embraces those in which the pattern is either wholly or partially produced by metal. The metal is either applied in powder, in a similar manner to "flour," or in leaves, like those of gold. This metallic powder is bisulphurate of tin, and the leaf metal is made of fine copper, or a mixture of copper with zinc, tin, or some other metal that will give it more the color of gold than when in its natural state. These metals are often added to colored and floured patterns. Paper-hangings upon which leaf metal is employed are much more expensive than those done with the metallic powder only; but the leaf kind has much greater brilliancy, and is more durable than the other, especially — if — as is now very frequently the case — the pattern be stamped into the gold with a die. Many papers so produced are exceedingly beautiful, and are known as "stamped golds." — *American Builder.*

Paper has been used as a wall covering by the Chinese from time immemorial. It was introduced in Europe, as a substitute for the ancient tapestry hangings, by the French, among whom its manufacture has always been a prominent industry. Paris contains numerous factories, employing over 3,000 workmen, and several large establishments exist in the southern cities of France.

In New York City three factories are in operation. Philadelphia has six, producing annually paper hangings to the value of $800,000.

Wall paper is prepared in several different ways. The cheap varieties are rapidly printed by ingenious machinery, but for the more elegant and elaborate patterns hand-labor is almost invariably used. The paper is procured by the manufacturer in large endless rolls, weighing some 80 to 85 lbs. each. In this condition, if of fine quality, it costs about 17 cents per pound; if ordinary or cheap, the price fluctuates according to the market.

The designs to be printed are prepared as follows: Sketches of the different patterns are made in this country by artists employed for the purpose. These, on being approved, are forwarded to France, where elaborate drawings are made from them. Each color entering into the design must be printed separately, so that there must necessarily be as many blocks or types prepared to make the impressions as there are tints in the pattern. The blocks are constructed of two layers of wood, a thin piece of maple fastened to a thicker backing of pine board. Each block is about 20″ wide, 2′ long and 1½″ to 2″ in thickness. On the maple, all of the design to be printed in a single color is drawn and afterwards cut out by engravers, or rather wood carvers, so that the lines are left in high relief. When the carving is completed, the work is brushed over with boiled oil, and, when dry, sent to the printer for use.

The paint employed for coloring the paper is ground color mixed with warm size and passed through several sieves so that it is rendered perfectly smooth and free from lumps.

The design being decided upon, the block carved, and the paint mixed, the first process the paper has to undergo is its uniform covering with a ground tint. This is effected by passing the paper over an endless rubber belt-working on rollers. A copper cylinder at one end of the machine used for the purpose rotates in a box of prepared color. From the cylinder, the paint is distributed to revolving brushes, by which it is applied to the paper passing over the belt. As the paper issues from the machine it is drawn out along the loft and then hung up, in festoons over sticks resting on long frames, to dry. It is then wound on a large reel from which it is cut by boys into pieces of eight yards in length.

In case a pattern resembling oak wood is to be applied to the paper, another machine is employed. The paper is passed around a large cylinder, receiving an impression resembling the grain of oak from a smaller revolving wooden cylinder, which is suitably engraved and covered with the proper colored paint.

The rolls of paper, as they are wound by the boys from the large reel, are sent to a workshop below, where they are stamped with the patterns. This process is done by hand. The workman stands before a table over which passes the paper. Hanging above the table, supported by an india-rubber cord, is the block on which the design is carved. The upper end of the rubber cord is attached to a small wheel traveling on an iron guide, so that the block may be swung from the table over to the place where it receives its covering of color.

The method of making the impression is very simple. The paint is obtained from what is termed the "slush box," which consists of a shallow box, the bottom of which is covered with painted ticking made water-tight. This box floats on water contained in a larger box, so that its bottom is always perfectly level. Inside of the first mentioned box is placed a piece of woolen cloth on which the paint is uniformly distributed. The workman first places the paper across his table, then swings the block over to the slush box, and brings its carved side down on the paint. Next he carries the block back again, and places it on the paper, of course using great care in the registering so that the impression may fall exactly on the right place. A vertical movable arm attached to a frame above is now rested upon the back of the block, and forced down by means of a lever worked by the foot of the operator, thus completing the impression. This process is repeated until the whole piece is covered with the pattern, when it is hung up for from five to ten days until perfectly dry.

If the design is to be gilded, the parts which are to receive the gold leaf are printed in the same manner as above described, only glue size is used instead of paint in the impression. Gold leaf is afterwards applied by girls in the ordinary method.

Satin papers are sometimes prepared by mixing with the coloring matter sulphate of alumina and finishing off with a brush. Velvet or flock paper resembling velvet plush is made after printing the colors, by fixing to the surface some finely ground fibers of wool of the proper hue, by means of glue or white lead and oil.

Paper after being printed is also often embossed by being passed between steel rollers on which a design has been engraved.

The great care which is exerted in printing the many tints of the more elaborate decorations has rendered hand labor necessary in place of machine power; but the expense of producing the material has of course been proportionally increased. Large quantities of the finer qualities of hangings are imported hither from France, but it is a well-known fact that much that is represented as of French manufacture is in reality made in just such establishments and by the same processes as above described.

Of late paper has been printed in patterns which have been suitable for theatrical scenery. At Booth's theater, several of the handsomest scenes are thus made, while in Wallack's the decoration of the entire auditorium is in paper.

In price the fine grades of wall paper vary according to quality, but average from 25 cents to $4.50 per roll of 8 yards.

Paper is extensively used in Japanese houses as a substitute for glass in the windows and sliding doors, and possesses not only the advantage of an immunity from breakage by the frequent earthquakes, but also occasions only a small loss when the house burns down, which happens often enough. Whatever may be its drawbacks, the use of paper for the above purpose is intimately connected with the system of house building in Japan; and it will be long before it is entirely abandoned.

Wall papers are used in all the houses, and are manufactured, not in rolls, but in small sheets ornamented with all kinds of designs printed from wooden blocks, on which the pattern has been cut in relief. The colors having been mixed with some thickening paste, are applied to the block, either by means of a brush or by tamping; after which the paper sheet is laid on the block and rubbed with a flat rubber lined with the smooth bud-scales of bamboo, and used like a printer's ball. Very fine white mica powder is applied to the wall paper, and produces a metallic luster resembling silver.

The crape-paper, which is a most perfect imitation of the real crape, is made by a very ingenious and most simple process. In the first place, that which may be called the matrix-paper is prepared by laying a moistened sheet of strong paper on a wooden board cut with fine grooves, running parallel or crossing one another at very small angles, and by beating it with hard brushes, so as to force it into these grooves. It is then painted over with the frequently mentioned "shibu," in consequence of which operation the paper becomes so elastic that when let go after having been stretched out, it refolds itself. For the production of crape, several sheets of thin moistened paper are laid, alternately with sheets of the above-mentioned matrix-paper, one upon the other. The package is then wound on to a round piece of wood, and pressed several times with a strong lever, as if it were to be stripped off from this piece of wood. By means of this operation, the soft and moistened paper is forced into the folds of the matrix, and consequently folded in a similar manner. By repeating this manipulation 10 or 12 times, each time unrolling it in order to change the position of the paper between the sheets of matrix-paper, and by winding it again on the piece of wood, the paper becomes gradually folded in all directions, the intersecting points of all these folds producing the craped surface. Naturally, this process causes the paper to shrink considerably. This kind of craping is done with printed pictures, and also with colored papers, which are used for coiffures.

The paper imitations of leather are made in the same manner, but of stronger paper. After it has been craped, it is beaten with hard brushes into the molds which produce the relief patterns; and these designs are afterwards painted as required, with the help of "shibu," or the "Ye-no-abura," and lacquer.

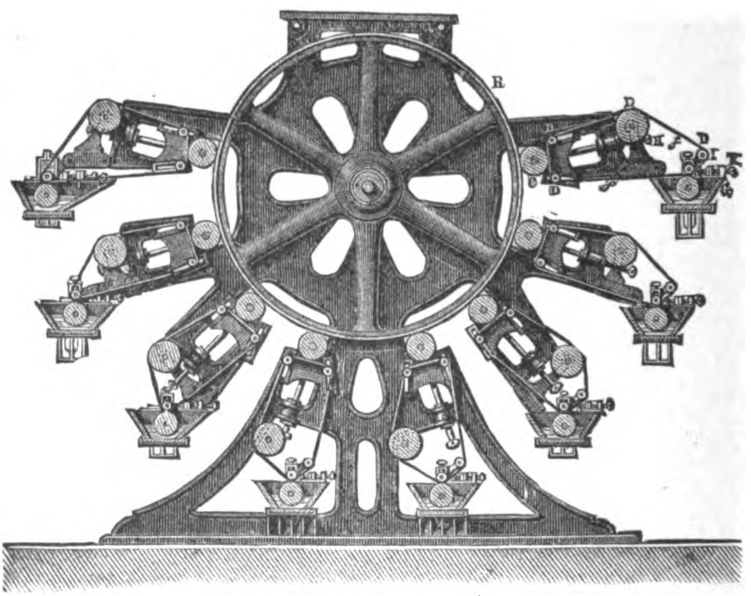
Paper is also often used as a substitute for cloth, for umbrellas, rain-coats, etc., and even for dress cloth. "Shibu," and the "Ye-no-abura," are the means employed for rendering the paper waterproof. This cloth is generally made of paper alone, by beating it to make it soft, and impregnating it with gummy substances, to make it more resistant to the action of water. Another kind of cloth, called "shifu," consists of silk warp and paper woof. The paper is cut into fine strips, twisted together into threads, and spooled for weaving. Paper strings, of great regularity, great strength, and prettily colored, are made in a similar manner, and were formerly used in large quantities for tying up the hair. They are now only used for tying presents and other small parcels.

A veneered wall paper is also made. The wood is cut to the thickness of paper, and by a peculiar process stuck on the paper, which serves as a protection against the influence of the walls on the graining and color of the wood. The delicacy of the machinery employed in cutting so thin a veneer may be gathered from the fact that 200 leaves are cut out of an inch of white maple wood, and 125 out of wood with very open grain, such as oak and walnut.

Wall Pa'per Ma-chine'.

Wall paper machines, printing from cylinders, were made successful by Zuber, of Reixheim, near Mulhouse, about 1832. Rising from the number of 2 or 3 cylinders, they have

Fig. 2523.



Gadd's Wall-paper Printing Machine (English).

attained as great a number as 20, printing in as many grounds, colors, or shades. The machine of Gadd, of Manchester, having 8 cylinders, will, however, give as accurate an idea of the construction as one possessing a larger number. It is shown in longitudinal vertical section in Fig. 2523, and works equally well as a calico printer or wall-paper printer.

Great difficulty occurred in working machines in which the printing cylinders were driven by gearing, as it was necessary to preserve scrupulous exactness in the sizes of the printing rollers in order to secure correct registry of the parts which combined to form the pattern. In the Gadd machine this difficulty has been met by moving the printing rollers by surface contact.

The central driving cylinder *R*, which forms the platen at the back of the continuous paper sheet, whose other side is exposed to the printing rollers *C*, is mounted upon interior arms or spokes whose hub has a bearing upon the central axis to which the driving power is applied. The printing rollers *C*, engraved in relief, are driven by contact with cylinder *R*, and receive their color from an endless felt cloth *f*, which is distended by interior wooden rollers *D D*. Eight groups of inking and printing devices are arranged about 220° of the perimeter of the driving platen cylinder *R*, but a description of one answers for each of the others, as the action of each is similar, each having its part to perform in adding its quota of color to make up the design which is the sum of contributions of each of the series.

The felt cloth, at its lowest position, is pressed by a roller against the color-feeding roller which revolves in the copper color-trough *G*; the pressure is adjusted by small hand-screws above. Two tension rollers, *D D*, are placed near the surface of the large cylinder and are moved between slides by means of a screw, *H*, so that the felt cloth is pressed against the graven printing roller with the required force. In leaving the inking roller, the felt passes against a *doctor* which removes superfluous color. The screw *K* regulates the *doctor*.

Printing rollers engraved in intaglio, similar to those used in printing tissues, are suitable for some descriptions of wall paper, but little charged with color, for delicate designs and for spotted cards.

For printing striped papers a machine has a reservoir composed of as many compartments as bands are required on the endless web of paper. Each compartment is pierced with an opening at bottom, as wide as the width of band required, the whole forming a series of stripes upon the paper traversing beneath, much as, so far as the paper is concerned, paper ruled with wide striping pens on the paper-ruling machines. Figs. 4499, 4500, p. 2002, "*Mech. Dict.*"

The drying of the paper was formerly done by suspending it from rods in a frame, the piece or bolt occupying 2 of these rods. The wall paper sticking machine of J. & E. Waldron, of New Brunswick, N. J., shown at the Centennial, is a great advance upon hand methods. It places the fold of the paper upon the rod which traverses along a lengthy frame, the rods being automatically supplied, adjusted, and the paper hung thereon and then traversed along the frame, and then returns, doubling the length of time of drying exposure within given limits to the length of the machine.

See view of wall paper printing machine, "*Scientific American*," xxxvii. 223.

Other machines in the manufacture of wall paper are the —

Grounding machine, for putting on the body color.

Sticking machine, for hanging the paper in festoons to dry.

Polishing machine, for giving a satin finish to the ground color to be overlaid by the dead color pattern.

Trimmer, for trimming the edge of the paper, *Boust*, * "*Scientific American*," xxxiv. 230.

Wall Pa'per Pol'ish-ing Ma-chine. A machine for giving a satin finish to wall paper.

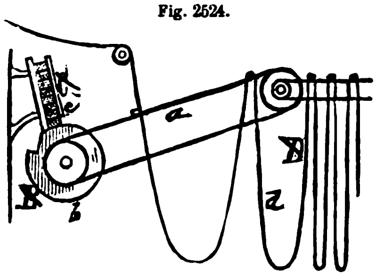
It consists of a central rotating brush against which the paper is repeatedly carried by rotating cylinders. The polish is upon the surface of alumina and oil which is known as the *grounding*.

The printed pattern is usually laid on this in dead color.

Wall Pa'per Stick'ing Ma-chine'. A machine for hanging wall paper in festoons to dry.

The paper from the grounding or the printing machine is conducted between endless belts across which sticks are laid automatically and over which sticks the paper is suspended in festoons. The sticks are so placed that a length of paper measuring just four yards hangs between any two. The belts are kept in constant motion, and, by means of the second belt, the paper is thus conducted along the loft, which measures some 160' in length. Steam coils are placed beneath the belts, and a temperature of 120° F. maintained. About nine minutes are occupied by any one festoon of paper in making the journey from the grounding machine to the point where

Fig. 2524.



Wall Paper Sticking Machine.

it is again made into a roll, and during this period it becomes thoroughly dried.

The device employed for placing the sticks under the paper is represented in Fig. 2524. At the ends of the roller over which the endless belt *a* passes, are two cams, one of which is shown at *b*. Above the cams and resting on their periphery is a pile of sticks, *c*. The cam shoulder equals in height the thickness of one stick. Hence at each revolution of the cam a stick is moved trom the bottom of the pile and carried down on and across the belts. Between the latter comes the paper *d*, which thus falls in folds over the sticks as they are laid in place.

Walls. (*Mining.*) The sides next to the lode.

Wall Scra'per. A broad chisel-edged tool with a socket in which can be inserted handles of various lengths for scraping and preparing walls for papering.

Warp'ing. (*Nautical.*) To move a vessel from one place to another by warps, which are attached to buoys, other ships, anchors, bollards on shore, etc.

Warp'ing Ma-chine'. (*Weaving.*) A machine for laying out the threads of the warp and winding them on the warp roller. The spindles containing the threads turn in bearings in the uprights of the frame, and the threads are carried through a separator and between two rollers, by which they are laid out flat and parallel, and are finally wound upon a roller journaled in the arms and resting upon the drum by which it is turned.

Warping, scouring, sizing, drying, and beaming machine.
Leach & Sons, Engl. * "*Scientific American Sup.*," 1991.

Wash'-ba-sin Valve. A valve for wash basins, by means of which the sewer pipe is claimed to be as effectually closed as the water pipe ordinarily is, and that consequently no sewer gas can escape into the room. The valve being air tight, a partial vacuum is produced above the water trap, which prevents the rush of water through waste pipes below, siphoning the water out of the trap. The construction is also such that the valve cannot be left open when the water is turned off or left shut when the latter is turned on.

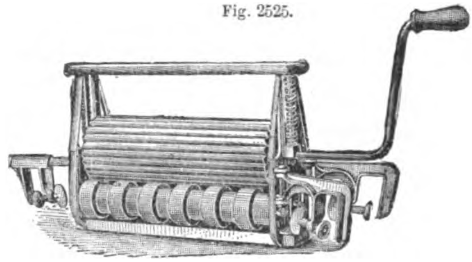
The valve is hinged to the rim of the basin, is made hollow, and of such a weight that as the water rises in the basin it is raised, and the holes covered are so opened that the overflow water may freely escape. The lower surface of the valve is covered with leather, rubber, or similar material, to cause it to cover the overflow holes tightly.

Wash'burn Wheel. A cast-iron car-wheel, designed and patented by Nathan Washburn in 1850. It consists of two plates, which extend from the hub to about half the distance between it and the rim. There they unite into one plate which extends to the rim. The plates are all curved so as to contract when the wheels are cooled without danger of fracturing the wheel. The single plate and the rim are united together and strengthened by curved ribs cast on the inside of the wheel.

Wash'er. The "*Pharmaceut. Centralhalle*" says that, for the purpose of packing joints which are to be hermetically sealed, such as retort connections, couplings, etc., where vulcanized rubber has usually been employed, cellulose appears to be even a better material. It has the advantage of cheapness, it readily absorbs water at first, thereby becoming pliable, and adapts itself more accurately to the surfaces which it is intended to render tight. If a joint is exposed to steam, and is to be frequently opened, the cellulose should be soaked in oil.

Wash'er, Clothes. The Keystone washer, Fig. 2525, has its frame and rollers so arranged that the machine can be attached to the ordinary tub. The washing is done by the united pressure

Fig. 2525.



Keystone Washer.

and friction of the corrugated and ribbed rollers between which the clothes have to pass. A lively pressure is insured by the spiral springs above.

Wash'er, Smoke. Two of the latest contributions to the abatement of the smoke nuisance employ water to wash the smoke as it passes through the flue of the chimney.

The more simple of the two consists of a spray or shower of water driven upward in the chimney flue. The water cleans the smoke of much of its impurities, and falling back escapes below. The blackened water is afterward collected, and under proper treatment yields a coloring material for a fine black paint. The other apparatus is more complicated. It consists of an upright cylinder of boiler plates 14′ high and 5′ in diameter. Inside are a number of sheet iron diaphragms placed one over another, and partly filling the interior. Each diaphragm overlaps the other, and all are perforated with a great number of holes 0.2 of an inch in diameter. The smoke enters below, and a stream of water flows in at the top. The water drips in a shower through the holes, and by the aid of a powerful exhaust, the smoke is forced upward through the apparatus. On its passage, owing to the obstructions caused by the diaphragms, the smoke travels 51′ and is perfectly cleared of soot. The experiments made with this apparatus go to show that the value of such devices depends chiefly on the power of the exhaust or draft, the distance traveled by the smoke through the shower of water, and the perfect subdivision of the water. The amount of water employed seems to be of less consequence.

Wash'er Scrub'ber. The "Standard," washer scrubber consists of a series of cast-iron sections, varying in number with the capacity of the machine. A shaft passes horizontally through the center of these chambers, and is connected at one end with a small engine, or suitable gearing, which furnishes motive power. Each section, with the exception of the two at the ends, contains a number of circular sheet-iron disks which are bolted together and securely keyed to the shaft; indentations in the disks serving to preserve ¼″ distance between them. Water at the rate of about twelve (U. S. standard) gallons per ton of coal carbonized, is admitted at one end of the machine, and after passing through the intermediate chambers, and constantly increasing in strength, is drawn off at the other end of the washer. The central shaft is revolved from four to five turns per minute, and the circular sheet-iron disks rotate with it, the lower halves being constantly immersed in the water while the upper portions always present a thoroughly wetted surface for the absorption of the ammonia as the gas passes through.

Wash'ing Fur'nace. The "Pernot" is a regenerative gas furnace, and has a revolving hearth of 12′ × 3′. The four regenerator chambers have 780 cubic feet capacity. The lining is 13″ thick on the sides and 9″ on the bottom, thus giving a hearth 9′ 10″ × 2′ 3″ deep. The lining is composed of lumps of highly refractory ores, roughly fitted together, the interstices being filled with fine ores, and the whole being glazed at a melting temperature. As the ore melts the lining is refilled until the mass becomes monolithic. The hearth is then fettled.

Wash'ing Rol'lers. For squeezing goods or yarn after being scoured.

Two cast-iron rollers turned perfectly true and smooth, are carried on two cast-iron standards; the pressure is obtained by compound levers with movable weights.

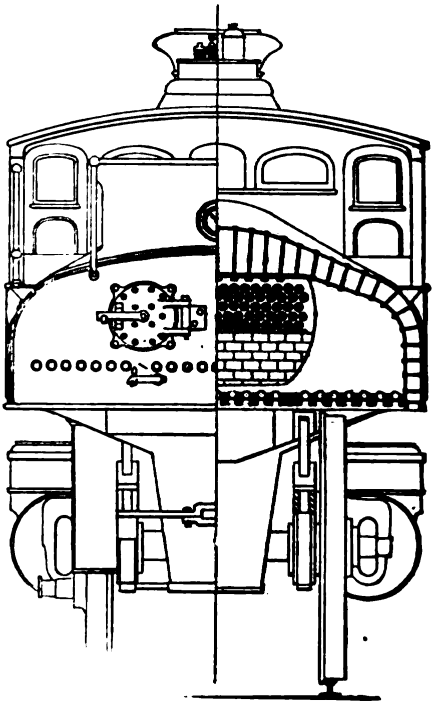
The bearings are of gun metal.

Wash Tub Waste. A stop valve that on removal allows the waste of the wash tub to escape.

Waste Card. A machine for working up and carding the waste, fluff, and broken fiber, that gathers on the floor of the factory.

Waste Coal Burn'ing Lo'co-mo'tive. The Wootten locomotive, Plates LIV. and LV., and Fig. 2526, is especially adapted to the consumption of waste coal, being unique in the large surface area of its grates. It is especially adapted to fast passenger service, by its free steaming qualities, its capacity being equal to the evaporation of 55 gallons of water per minute, enabling it to steadily maintain its speed.

Fig. 2526.



Waste Coal Burning Locomotive.

This result is secured by the peculiar form of furnace employed, by which although waste anthracite can be used as fuel with good results as far as steaming is concerned, yet the rapidity of the exhaust emissions is such as to lead to the discharge from the stack of the finer particles of impurities, contained in the waste coal. But notwithstanding its capacity, in consequence of the passenger service in which it is employed, the smaller sizes of prepared coal are used, so it would be a misnomer to class it as a dirt burner.

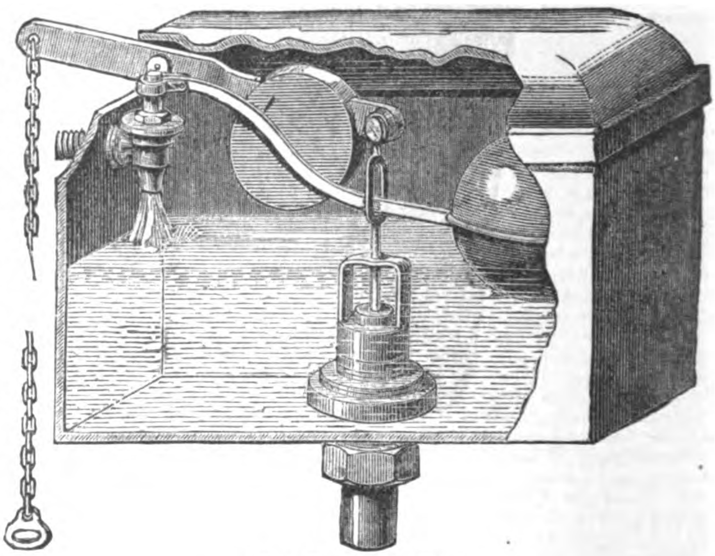
By reason of the moderate draft of these furnaces, and the consequent economy of combustion of fuel, they are enabled to attain an evaporative effect equal to 60 per cent. of the theoretical evaporative power of the fuel used, whether it be anthracite, bituminous, or lignite.

Waste Pick'er. See RAG PICKER.

Waste Pre-vent'er. Stone's positive waste preventer for cisterns, Fig. 2527, is so constructed that, although only possessing one inlet valve and one discharge valve, it yet answers the purpose of a double-chambered cistern. When the water is required to be drawn off from the cistern the inlet valve leading from the source of supply is closed before the discharge valve can be opened.

The valve is attached to the lower end of a socket in which the valve stem, which is connected at its upper end to the ball stem, is allowed to slide up and down a certain distance freely, so as not in any way to affect the valve; but as soon as the required distance is traversed, the valve stem acts upon the socket, and so causes the valve to be governed by

Fig. 2527.



Waste Preventer for Cisterns.

the rising and falling of the ball. When the water from the source of supply flows into the cistern, it raises the ball, and gradually closes the valve until it reaches a certain point, when the pressure on the back of the valve forces it on to its seat, and holds it there, while by means of the

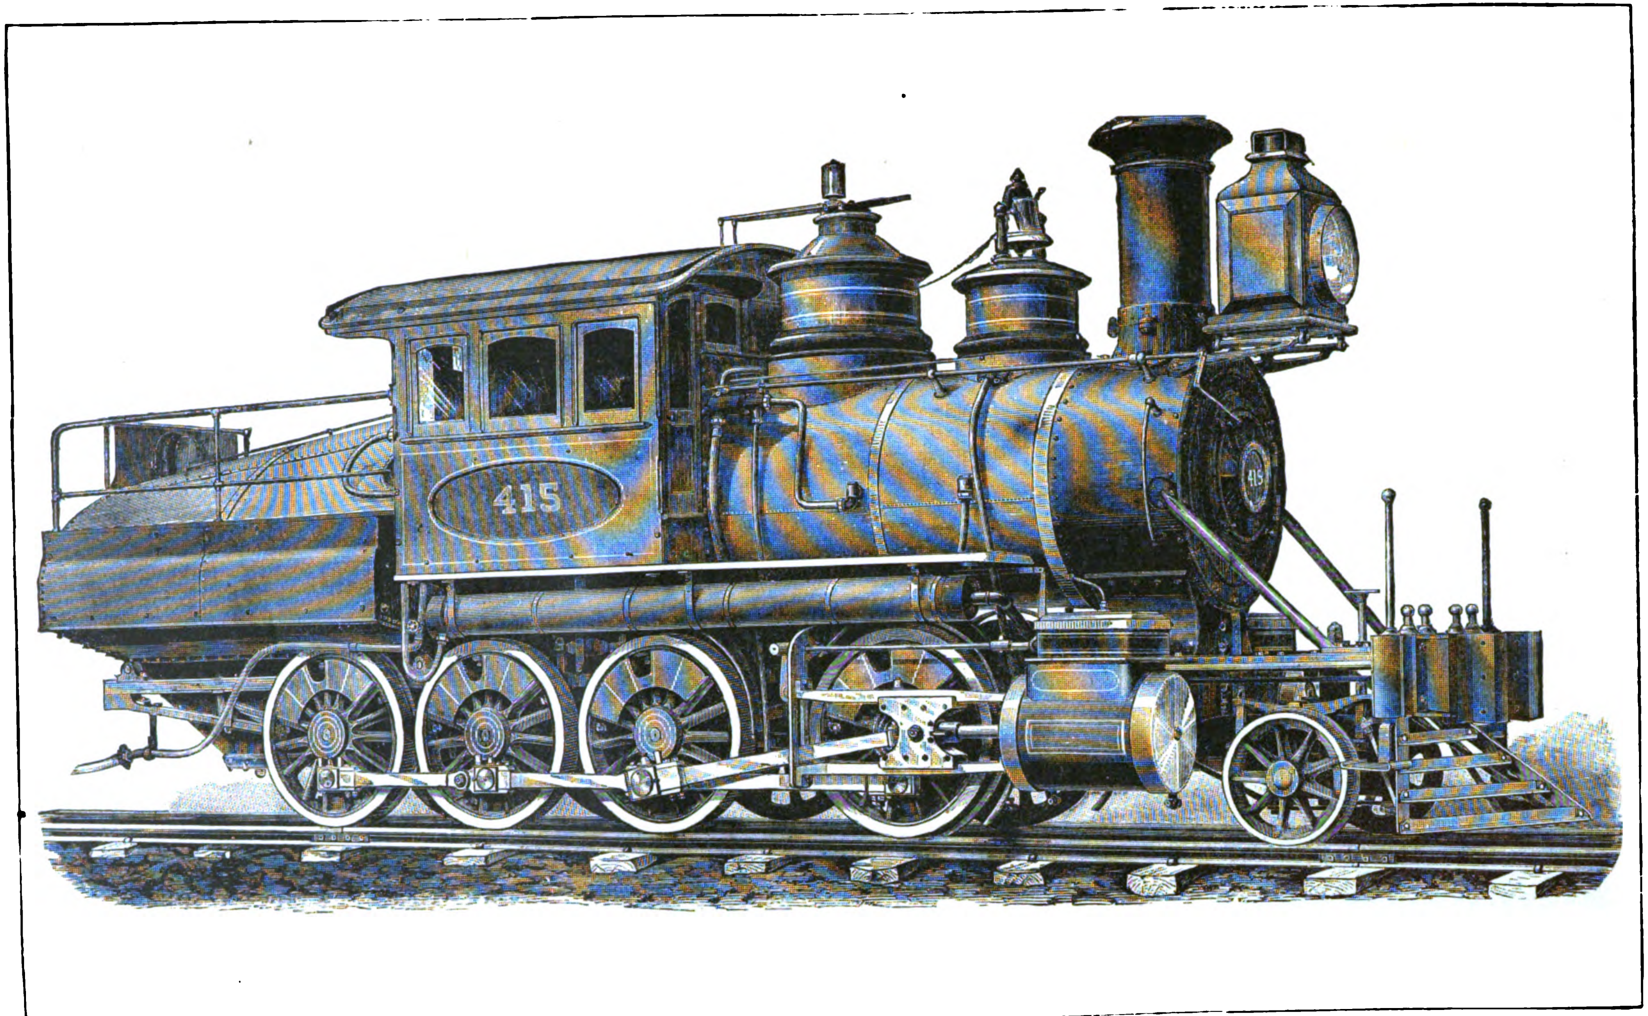


PLATE LIV. WASTE COAL BURNING LOCOMOTIVE. See page 936.

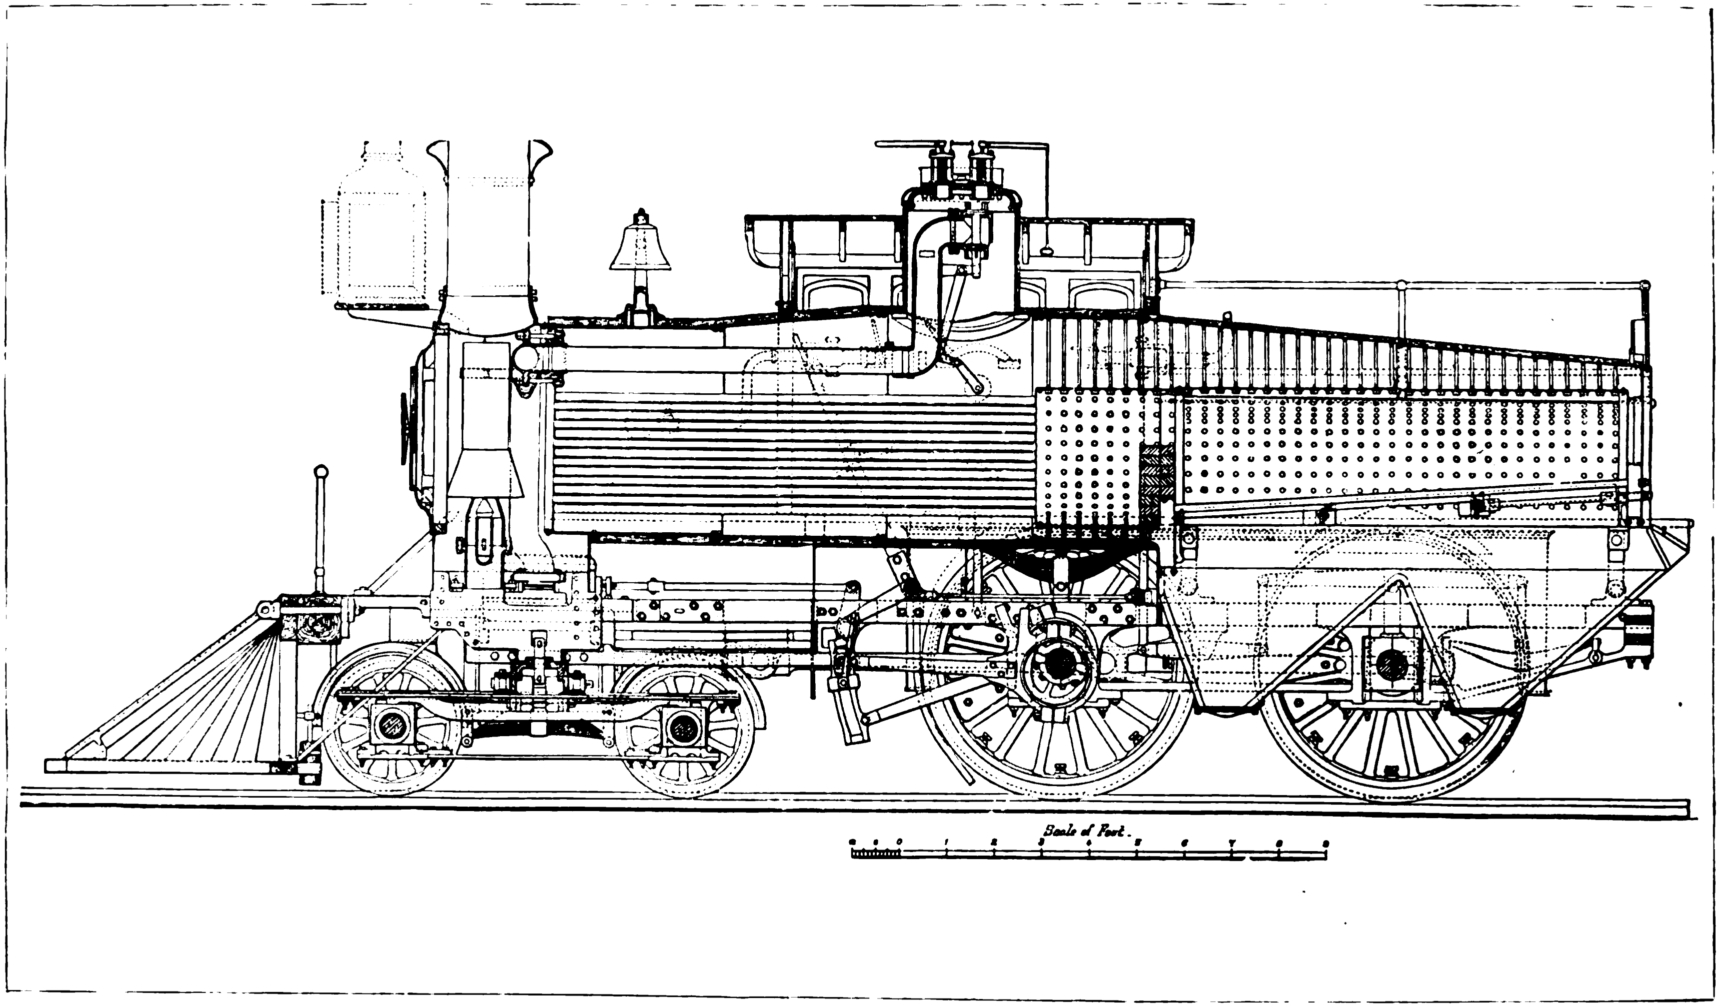

PLATE LV.

WASTE COAL BURNING LOCOMOTIVE. (SECTIONAL VIEW.)

See page 936.

sliding socket, the ball stem can be raised sufficiently high to allow the discharge valve to be opened, so that the water can run out only after the ball valve is perfectly closed.

Or when the lever is pulled and the discharge valve opened, the ball stem and ball are raised at the same time, which can readily be done by means of the sliding socket without affecting the inlet valve, which is held fast on its seat by the pressure of water from the source of supply, as already described. As soon as the water has run out of the cistern, and the lever or pull is let go, the discharge valve is closed, and the ball stem and ball drop, thus opening the inlet valve, and allowing the water to refill the cistern ready for use again.

Watch. Sir Edmund Beckett, a scientific horologist, who is, perhaps, the highest English authority upon the subject, in his work upon "*Watches, Clocks, and Bells*," says: —

"The liability of a watch, like any other piece of mechanism, to require repair, is in the ratio of the number of separate parts which make up its unity. The English watch, with its fusee and chain, is composed of 638 more pieces than the American watch. Dispense with these 638 additional chances of breakage, and it is easy to infer the superiority of American watches, in this one respect at least. The fusee and chain are rejected in the Waltham watch, and the direct action of the mainspring adopted, because the fusee and chain add greatly to the cost and liability to injury of a watch, and are of no practical value for good time-keeping. This change is advocated on the ground that there is greater simplicity of action, less friction in the transmission of motive power, increased facility for using a lighter and more uniform spring, and more room for play in the other parts of the movements."

In support of this view, Sir Edmund Beckett speaks very favorably of the American principle of omitting the chain. After alluding to what he calls the mischievous and common accidents of chain-breaking, and noting the tendency of advanced watch-making to do without fusee and chain, he says: "Accordingly, both in Switzerland and America, which are gradually stealing away our common watch trade, the fusee and the chain are almost universally omitted."

Dr. Hooke raised horology from a mechanical art to a science by propounding its laws and enriching it with valuable discoveries and inventions.

The discovery and application of the laws of isochronism in the balance-spring by Dr. Hooke and Arnold in England, Leroy and Berthoud in France, imparted the most essential quality for keeping a regular rate of time to the chronometer.

"*Isochronism* is an inherent property of the balance-spring, depending entirely upon the ratio of the spring's tension, following the proportion of the arcs of inflexion. A balance-spring, therefore, of any force whatever, having the progression required by the law of isochronism, will preserve this quality, whether it be applied to a balance making rapid or slow vibrations.

"The great advantage of an isochronal spring is its innate power of resisting the influences which cause a change of rate, such as change of position, increased friction as the works become dirty, or the viscidity of the oil at low temperatures." — *Carpenter.*

See list under CLOCK for exhibits of all horological instruments, from *Prof. Watson's* report in "*Centennial Exhibition Reports*," Group XXV., vol. vii.

See also *Dr. Knight's* report, vol. iv., "*Paris Exposition* (1878) *Reports*," p. 403, *et seq.*

Dr. Knight's report on watch-making machine at Waltham, is in "*Centennial Exhibition Reports*," vol. vii., Group XXII., p. 46, *et seq.*

The "*Journal de Genève*," of August 26th, has the following: The watch-making population of the several Swiss cantons may be held as exactly represented by the subjoined table, compiled from the returns of the census for the year 1870: —

CANTONS.	Men.	Women.	Total.
Neufchâtel	11,081	5,383	16,464
Berne	6,392	4,743	14,135
Vaud	2,439	1,313	3,752
Geneva	5,330	1,288	3,618
Total	25,242	12,727	37,969

Berne is the canton in which there has been the greatest rise in the manufacture of watches of late years. It is computed to produce 500,000 watches a year; and, as they are almost exclusively of ordinary quality, their average value may be set down at 40 francs, which would bring up the total of Bernese annual production to 20,000,000 francs ($5,000,000).

Geneva does not supply much over 150,000 watches yearly, but, as eleven twelfths of these are gold, and in part richly ornamented, their value does not probably fall short of 20,000,000 francs.

The canton of Vaud also turns out 150,000 watches per annum, the works of which are generally highly finished; but then they are in great measure exported without cases, as mere works, the average price being about 35 francs, and the total value being 8,000,000 francs.

Besides these, the canton of Vaud furnishes 80,000 musical boxes, which amount to 8,000,000 francs.

In respect to value, Neufchâtel produces nearly half of the entire Swiss watch-making (35 per cent.); the cantons of Geneva and Berne come in for 23 per cent. each, and the canton of Vaud for 9 per cent.

Watchmaker's lathe, *Williams*	"*Scientific Amer.*," xxxiv. 194.

Watch'ma-ker's Slide Rest. A slide-rest to a watchmaker's lathe, adjustable by its set screws, to any angle or position that the work requires.

Watch Tel'e-phone. (*Electricity.*) An instrument which takes its name from its resemblance in form to an old-fashioned watch. Invented by Alfred Niaudet-Begnet, of Paris. It is a Bell telephone in which the magnet is bent into a circular form, and the coil is seated upon one of its poles, the planer of the magnet, coil, and diaphragm being all parallel to each other.

Wa'ter A'er-a-ting Ap'pa-ra'tus. A device for aërating the water supplied to an aquarium. The apparatus is an application of the principle of the "Catalan trumpet" that is used to operate the bellows in the iron furnaces of Spain. It consists of a number of glass tubes, into which the water is forced by hydraulic pressure, carrying with it bubbles of air, the presence and movement of which in the tubes may be plainly seen.

Wa'ter A-nal'y-sis Ap'pa-ra'tus. McLeod's water analysis apparatus, used to determine the purity of drinking water, is an improvement of the one described by Dr. Frankland and Mr. Ward, by which temperature and tensions of fixed volumes of water and gas are tested. This instrument is very much in use. It consists of a measuring tube 900 mm. in length and about 20 mm. in diameter, which is marked with ten divisions, the first at 25 mm. from the top, the second at 50 mm., the third at 100 mm., and the remaining ones at the intervals of 100 mm.

In the upper part of the tube, platinum wires are sealed, and it is terminated by a capillary tube and fine glass stop-cock, the capillary tube being bent at right angles at 50 mm. above the junction. At the bottom of the tube a wide glass stop-cock is sealed, which communicates, by means of a caoutchouc joint surrounded with tape and well wired to the tubes, with a branch from the barometer-tube. At the upper extremity a glass stop-cock is joined, the lower end being curved and connected by caoutchouc with a stop-cock and tube descending through the table to a distance of 900 mm. below the joint. The two tubes are firmly held by a clamp, on which rests a wide cylinder, about 55 mm. in diameter, surrounding the tubes, and adapted to them by a water-tight caoutchouc cork. The cylinder is maintained in an upright position by a support at its upper end, sliding on the sam rod as the clamp. Around the upper part of the barometer-tube a syphon is fixed by means of a perforated cork, through which the stop-cock passes. A small bulb-tube, containing some mercury, is also fitted in this cork, so as to allow of the air being entirely removed from the syphon. The syphon descends about 100 mm. within the cylinder, and has a branch at the top communicating by caoutchouc with a bent tube contained in a wider one affixed to the support. A constant current of water is supplied to the cylinder through a glass tube, which passes to the bottom, and escapes through the syphon and tubes to the drain. To the end of the narrow tube is fastened a long piece of caoutchouc tube, covered with tape, by which a communication is established with the mercurial reservoir, suspended by a cord, so that by means of the winch it may be raised above the level of the top of the barometer-tube.

Wa'ter Bal'last. A mode of ballasting vessels with water, in tight compartments in the bottom of the hull.

Wa'ter Bar'rel Truck. A pivoted water-barrel mounted on wheels, and drawn by hand. The barrel, being pivoted by its spindles, is easily emptied.

Water ballast, on,
Martel (20 Figs.) . . * "*Engineer*," xliv. 174.
Construction . . . * "*Engineering*," xxiv. 186.

Wa'ter Bear'ing. Shaw's water bearing is designed to relieve the pressure on the step of a vertical shaft.

It consists of a disk secured to the shaft, and provided with a circular piston. The water entering from a pipe under a sufficient head, passes into the chamber of the piston and between it and the lower face of the disk, lifting the latter. If the upward pressure of the water be in excess of that necessary to sustain the shaft and the weight it may have to bear, a portion escapes beneath the lower edge of the piston and the shaft settles to its normal position.

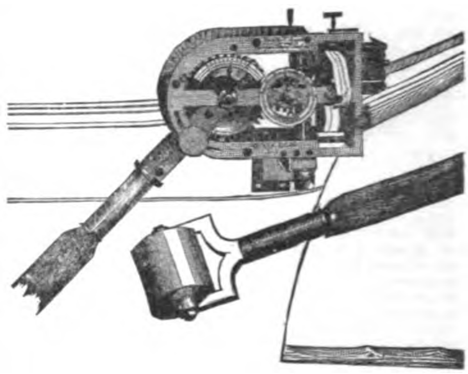
Wa'ter Box. (*Metallurgy.*) An iron box to contain water forming a bottom or side of a furnace in order to prevent it from burning out. Tuyere plates are so protected.

Wa'ter Breast. An improved tuyere for water breasts is described as follows: —

A bronze tuyere is inserted into the end of a water breast, which is bored out conically to receive it, and does not, therefore, call for any packing. The butt end of the tuyere is turned so that it presents a part of a sphere, and the end of the belly pipe is correspondingly shaped to produce a perfect joint. By a simple arrangement, which allows rapid and easy replacement of the tuyere, the movable parts are firmly held together. This is effected by a knee lever under the elbow, at the longer end of which a detachable weight is hung. The pressure exerted by this weight firmly connects water breast and tuyere on the one hand and belly pipe and tuyere on the other. By this means all bolts are done away with, and the weight need only to be removed to allow the different parts to drop apart. When it becomes necessary to replace a tuyere a hook is inserted, and it is readily pulled out. By arranging proper openings at the butt of the tuyere any air entering in the water is trapped and carried off direct by the waste pipe. The discharge pipe is taken off at the top of the tuyere and air prevented from collecting in it. For a short distance outside of it the discharge pipe is elevated, which carries off at once any air or steam bubbles to a higher point outside of the tuyere, thus avoiding danger to it. In order to prevent any water from entering the furnace the water is drawn through the tuyere by suction at the same velocity as if it were forced through. It is claimed that, as by this means the water pressure is brought down below the atmospheric pressure, which is generally smaller than that of the blast in the interior of the furnace, no leakage in consequence of cracks can take place. It was found also by experiment that drawing the water through the tuyere prevents any accumulation of air or steam bubbles, the steady growth of which will ultimately lead to cracking. Great though the advantages of suction may be, however, its use is not a necessary element in the application of the tuyere, which, it will be readily understood, works well with pressure also. The nozzle in the tuyere, as it fits into it well, is cooled by the circulation of the water in the latter, and can therefore be carried very near the end of the tuyere, a circumstance which aids the penetrating power of the blast. The nozzle may be easily drawn out through the belly pipe, if the cap on the tuyere pipe elbow is removed. When fire-brick stoves are used the tuyere pipes are made double, in order to prevent the serious loss of heat which otherwise takes place.

Wa'ter Chan'nel In'di-ca'tor. Echebarn's indicator, Fig. 2528, for water channels was designed to indicate and register the depths of water in the Rio da Prala, which, from the continual shifting of its waters, presents great difficulties to navigation. There is a long rod turning on an axle that is provided with a toothed wheel, and bears an index pointer, indicating on a graduated arc the inclination of the rod from the horizontal.

Fig. 2528.



Water Channel Indicator.

The lower end of the rod bears a roller that travels on the bottom of the river, or the body to be indicated. A toothed wheel drives a wheel train bearing a paper drum, and on a paper band a pencil describes in miniature the condition of the bottom in the line traversed by the vessel.

Wa'ter Charg'er. A device for retaining a body of water always close to the pump, so that if the lower valve of the pump leaks, and the water all runs out of the suction pipe, or if it has been let back to avoid freezing, this charger will still retain a full supply to be readily sucked into the pump, wetting the valves and packing, so as to at once bring the water, and cause the pump to work freely. The charger should be connected into the suction pipe as near the pump as it can be conveniently, and still be out of the way of frost. This charger also greatly facilitates the working of a pump, particularly where the suction pipe has to be of great length, serving as an air chamber in same.

Wa'ter Col'umn Air Com-pres'sor. One operating by the force of a descending body of water, as in some mines and mountain regions. See AIR COMPRESSOR.

Wa'ter En'gine. Wells' water engine is intended to be used as a motor, and also if desired as a pump. The cylinder is mounted on bearings of the case on trunnions. It has a circular valve formed on the lower end, with one port, and fitted to the correspondingly shaped valve seat in which is the inlet and the exhausts for the waste from the interior of the case. Passages are cored out in the cylinder, from the upper end down to the interior of the waste water case, to conduct the leakage to the discharge through the exhaust.

A cap screws to the top of the cylinder for a guide to the piston rod, and these passages enter the cylinder above the piston, under the cover. The oscillation of the cylinder, in the case, alternately opens the supply and exhaust passages.

Wa'ter Gas. Any illuminating gas in whose manufacture the decomposition of water plays a prominent part, as distinguished from the illuminating gas produced solely by the decomposition of bituminous coal, wood, resin, tar, oil, or other like material.

Briefly, the Lowe process is the following: A generator of the ordinary type is filled with fuel brought to a high temperature by the aid of blast. The combustible gases thus formed are carried to a chamber filled with loose fire-brick, called a superheater by the inventor, although it should more properly be termed a regenerator. As soon as by the burning of the generator gases the regenerator has attained a high temperature, the blast is cut off and superheated steam is admitted a little above the grate, and simultaneously small streams of crude petroleum or naphtha are allowed to drop through the current of ascending gases upon the incandescent fuel. The steam is decomposed and hydrogen and carbonic oxide are formed. The products of the decomposition of petroleum, hydrocarbons, pass to the regenerators together with the water gas, where the hydrocarbons are gasified. As soon as the temperature of the generator falls below a certain limit the flow of steam and of petroleum is stopped, fresh coal is charged, and the blast of air turned on again.

Dr. W. H. Wahl gives the following answer to the query, "What is water gas?" "Water gas may be defined to be the gaseous product resulting from the interaction of steam and carbon at a high temperature. Generally speaking, the mode of its manufacture is to pass steam through a thick layer of glowing coal. The result of this procedure will be very easily understood by reference to the following explanation: The glowing coal (carbon) seizes upon the oxygen of the steam, uniting with it to form carbonic acid and liberating hydrogen. The carbonic acid thus formed is, however, obliged to pass through a considerable layer of glowing coal (carbon) before it can escape, and this carbon has so strong an affinity for oxygen that it deprives the carbonic acid of one equivalent of its oxygen, reducing it to the state of a lower oxide of carbon. The product which results from these several reactions is 2 equivalents of hydrogen and 2 equivalents of carbon oxide; or, expressed in chemical terms, $2\,H + 2\,CO$. This product is what is known as water gas. It is incorrect to assert that any positive gain in heating effect is obtained by this process, for the energy expended in the process of decomposing the water is precisely equal to the additional heat given out by the combustion of the water gas over what would have resulted from the combustion of the carbon alone. On theoretical grounds, therefore, there can be no economy in the process; but there is a gain in practice, and this is due to the fact that the combustion of a gaseous fuel can always be effected with greater economy in our furnaces, stoves, etc., than that of a solid fuel. The gain, therefore, is to be ascribed to the physical condition of the fuel, and not to any advantage resulting from the chemical reaction that has taken place. This is a very common error and is entertained even by otherwise well-informed persons. We look upon the future of water gas as highly promising. With its aid it is made possible to produce illuminating gas more cheaply than by any other process, by simply enriching it with the vapors of petroleum or of other substances rich in illuminating elements But the grand field of water gas for the future will lie in filling the place of a fuel for industrial and domestic uses to take the place of coal. We think the time is not very remote when water-gas will be distributed to our houses just as coal gas is now distributed, — when coal and wood fires, with their dirt and ashes, will only be known as things of the past."

Wa'ter Lens. The first microscope in existence consisted of a drop of water. Water lenses as formerly used were unstable and tremulous, and almost if not quite worthless. This difficulty may be overcome, and the drop of water rendered available as a microscope lens by confining it in a cell consisting of a short tube having a glass bottom.

The simplest and cheapest of all microscopes consists of a thin piece of glass, having attached to it one or two short paper tubes, which are coated with black sealing-wax, and cemented to the glass with the same material.

By aid of a small stick water is placed, drop by drop, in the cells until the lenses acquire the desired convexity. Objects held below the glass will be more or less magnified, according to the diameter and convexity of the drop.

An easily made and convenient stand for the water lens is made of wood. The sleeve that supports the table slides freely upon the vertical standard. A wire having a milled head, by which it may be turned, passes through the upper end of the standard, and has wound upon it a strong silk thread, one end of which is tied to a pin projecting from the table supporting sleeve. An elastic rubber band is attached to the lower end of the sleeve, and to a pin projecting from the standard near the base, to draw the table downward. By this device the focus may be nicely adjusted.

Two standards project from the bed-piece for receiving the corners of a rectangular piece of silvered glass which forms the reflector.

The best form of water-cell consists of a brass tube about $\frac{3}{8}''$ long and $\frac{1}{8}''$ to 3-16'' internal diameter, having in one side a screw for displacing the water to render the lens more or less convex. A thin piece of glass is cemented to the lower end of the tube, and the inside of the tube is blackened.

Several bushings may be fitted to the upper end of the tube to reduce the diameter of the drop, and thus increase the magnifying power of the lens.

Water containing animalcules may be placed on the under surface of the glass, and the lens may be focused by turning the adjusting screw. The lens may also be adjusted to magnify objects placed on the movable table.

If air-bubbles form on the upper surface of the glass they may be readily displaced by means of a cambric needle.

Water lens microscope * "*Scientific Amer.*," xxxviii. 258.

Wa'ter-lev'el Gage. A small bell-shaped casting, into the upper part of which a narrow brass tube, open at the lower end, enters. When the ball is submerged the increase of pressure confined in the bell and the tube will be in proportion to the depth reached. The pressure is indicated on a graduated gage. It will be easily understood that as the pipe may be of any length desired, it is possible to place the gage at quite a distance from the water the depth of which is to be measured.

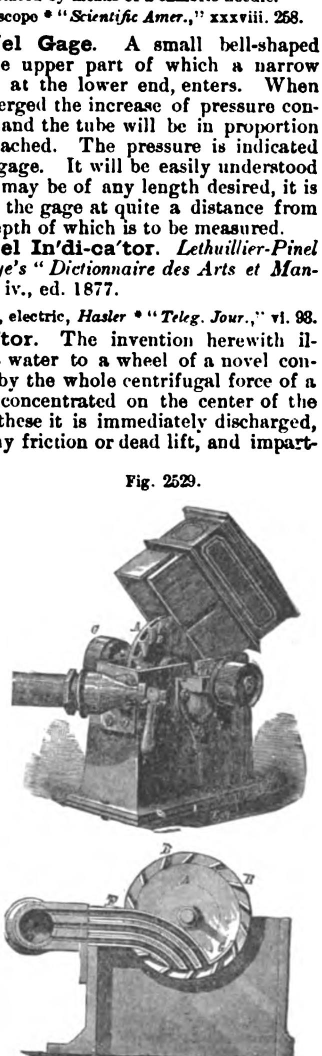
Water level indica., electric, *Hasler* * "*Teleg. Jour.*," vi. 93.

Wa'ter Mo'tor. The invention herewith illustrated applies water to a wheel of a novel construction, whereby the whole centrifugal force of a jet of water is concentrated on the center of the buckets. From these it is immediately discharged, thus avoiding any friction or dead lift, and imparting to the wheel not only a greater impetus, but, it is claimed, a very high degree of power, considering the pressure and the size of the stream used. Although adapted to all purposes where water is used as a motive power, this invention is more particularly designed for use where the supply of water is limited or variable; and this is believed to be a desideratum, as streams of water are liable to much fluctuation at different seasons of the year. More especially is it designed for use

Fig. 2529.



Water Motor.

in propelling light machinery, such as printing presses, sewing machines, lathes, etc., wherever water can be taken from a hydrant. It is also claimed to be well adapted for heavy work.

The disk of the wheel *A* is made of brass of various sizes, and together with the buckets *B B*, is of a peculiar construction and of a capacity to correspond with the size of the stream and the power required. *C C* are the belt pulleys; *D* the supply pipe; *E* a self-packing faucet or stop-cock, which is the subject of another patent obtained by the same inventor. This faucet is capable of supplying one, two, three, or more streams of water of different dimensions through the pipes *F*, which are firmly held in position at the point of delivery of the water on the buckets by a shoe, *G*. The pipes are provided with bushings at their extremity, which can be removed at pleasure, and others of a different capacity inserted. The waste pipe, of course, can be arranged as required, either from the sides or bottom of the casing. The communication between supply pipe and buckets is shown in section in Fig. 2529.

One of the smallest motors capable of being put to practical use is the Hayworth's miniature turbine water motor. It consists of a tube 3″ long and ⅞″ outside diameter, with an oblique inlet by which it can be screwed to the hydrant or faucet. A small stem with a double pulley at the end projects from the upper end of the tube, and is rapidly revolved when the water is turned on. A rubber hose drawn over the lower end of the tube conveys the water off after performing its duty. By an endless cord the motion can be transmitted from the pulleys to a sewing machine or any other machine requiring only light power for driving. The motor is constructed on the principle of turbine wheels, and can be run with water pressure of 10 to 15 lbs. to the square inch. After entering the tube by the inlet, the water first passes a stationary wheel having a series of radial vanes of such a shape as to give the water a spiral motion. Issuing from these vanes, the water strikes against similar vanes of a wheel that is fastened to the above mentioned spindle, and which, by the impact of the water, is made to rotate.

Different sizes of this motor are manufactured. The smallest size, of the dimensions above stated, furnishes sufficient power to drive sewing machines, etc.

Messrs. W. H. Bailey & Co., of Salford, England, have recently designed a new water motor which works under the ordinary pressure of the water sent through the street mains. In appearance it is somewhat similar to an ordinary horizontal steam engine. It has an oscillating cylinder, with parts so arranged that the motion of the cylinder cuts off the supply of water at the end of the stroke, a reciprocating action being thereby obtained and imparted to the fly-wheel by the ordinary crank arrangements. There are no loose valves or tappets in connection with the motor, and all the fixing it requires may be done by a plumber, as there is nothing more to do than to connect the machine with a pipe from the street main. One of the motors is said to be working very successfully at the bottom of a colliery shaft near Bolton, the power being supplied by the water pumped up from the pit by the steam engine. A large number of laden wagons are drawn up an incline with great ease by this means. The motion has also been utilized for sawing timber, printing newspapers, etc. — *Iron Age.*

Wa'ter-proof Ce-ment'.

Glue	4.
Resin	4.
Red ocher	3, with a little water.

Wa'ter-proof-ing. The Neptunite water-repellent process, owned by the International Chemical Company of New York is founded upon the several patents of Mr. D. M. Lamb. It is applicable to all sorts of textile fabrics: paper, leather, etc., in fact to all goods which it is desirable to protect from the action of water and dampness, and which are liable to mildew and decay.

The effect of the treatment by this process is to render the goods non-absorbent, or water-repellent. The property of capillary attraction possessed by all fibrous goods is destroyed. The pores of each fiber are filled with the Neptunite material and the fiber receives a coating of the same. By the action of heat this is thoroughly incorporated into the fibers, giving them the remarkable properties mentioned.

The action of water upon the fabrics treated is very peculiar. When poured upon the goods the water runs about like quicksilver, without showing any disposition to be absorbed or to penetrate. In the case of open goods like grenadine or even musquito-netting, the water can be made to run about like quicksilver without passing through the open spaces.

The advantages given to the goods are by no means confined to the water-repellent quality. The fibers are made tougher and stronger, and do not crack and disintegrate as before treatment. Goods may be rendered proof against moth and vermin; the colors are imprisoned and fastened: the threads are slightly swelled, giving the goods a firmer and more compact texture. This is peculiarly valuable in the case of silks, giving them a hand and body which cannot be secured except by a large increase of the stock used.

It is well known that rubber waterproof garments are pronounced injurious to health from the fact that they confine the perspiration of the body. In the case of the Neptunite garments, however, the interstices between the fibers are not closed, and a free circulation of air is permitted, but at the same time a perfect protection from the rain is insured. Ladies' waterproofs are now made from thin mohair goods and these light garments will afford the same protection in ordinary showers as the unsightly rubber goods.

The process is of almost universal application and is of great economic importance. It is at the present time extensively used, and must soon come to a general application throughout the country.

The solution used is a colorless fluid produced by the action of certain gases upon hydrocarbons, and is inexpensive. It is better to treat the goods in the piece before being made up, but ready-made garments can be treated, though they are more expensive to handle in quantities.

Waterproof soles, which are either inserted into ordinary leather soles or laid into the boot, are made as follows: A mixture is prepared, consisting of 60 parts of resin, 80 parts of tallow, 5 parts of wax, and 5 parts of turpentine. In this mixture linen is soaked, and is thereby rendered water-tight. The sheet of linen is then united to a sheet of wool by being passed between rollers. On the linen side the sole is now covered with a solution of glue to prevent the resinous surface from sticking to the stockings and shoes in walking.

To waterproof leather: Melt one liter of boiled linseed oil, 125 grams of suet, 46 grams wax, and 32 grams resin together over a slow fire, and apply it to the leather with a brush while warm. This composition keeps the leather very soft. The English fishermen have long been using it. They can remain in the water for hours ere it penetrates through the leather.

For making canvas waterproof: It is very easy to make canvas waterproof, without altering its appearance or pliability, by saturating it with a boiling and strong solution of soap, pressing out the excess of this, and then submitting it for a short time to the action of a hot bath of alum, sulphate of aluminum, or acetate of lead, which operation causes the formation of an insoluble alumina or lead soap, which will permeate all the pores of the texture and make it waterproof.

To render fabrics waterproof, M. Dujardin proposes the following procedure: 335 grams each of potash, alum, and sugar of lead, are to be triturated in a mortar until the mass becomes syrupy, to which is then to be added 400 grams of a mixture of equal parts of finely pulverized bicarbonate of potassa and sulphate of soda. To this mixture there should now be given about 50 liters (about 11 gallons) of rain water, and when complete solution is effected, the same is poured into a vessel containing an oleine soap in solution in an equal quantity of water. This mixture is to be stirred for about 20 minutes, or until complete mixture has occurred. To waterproof a fabric it is necessary only to immerse it, with the hand or by mechanical means, into the aforesaid mixture, and to retain it there until by pressure or otherwise the fluid has penetrated to every portion of it. The fabric is then removed, and after allowing the surplus fluid it retains to drop off, hung up to dry. Afterwards it is thoroughly washed in cold water, and again dried. Goods treated in this way, it is affirmed, are waterproof, but still permit free transmission of air. The colors of the goods are in no wise affected. — "*Journal des Fabricants de Papier.*"

Wa'ter-proof Pa'per. Waterproof paper of superior quality, transparent and impervious to fat, may be prepared by saturating good paper with a liquid prepared by dissolving shellac at a moderate heat in a saturated solution of borax. Paper thus prepared resembles parchment, and may be given any color by the use of aniline dyes.

When a sheet of paper is immersed in an ammoniacal solution of copper and then dried, it is said to become quite impermeable to water, and does not lose this quality even although the water be boiling. Two sheets of paper thus prepared and passed between cylinders adhere to each other so completely as to be quite inseparable. If a large number of sheets so prepared be thus cylindered together, boards of great thickness are obtained, the cohesion and resistance of which may be increased by interposing fibrous matters or cloths. The substance so prepared is quite as hard as the closest-grained wood of the same thickness. The ammoniacal solution of copper is prepared by treating plates of copper with ammonia of the density of 0.880 in contact with the atmosphere.

Wa'ter Sup-ply' for Lo'co-mo'tives. The water tanks of locomotive tenders are usually replenished from elevated tanks at the side of the track, either filled by the natural flow of water from a more elevated source or by means of a pumping engine. In some cases the locomotive itself is caused by suitable connections to operate a pump and draw its own water from a reservoir or well.

Either of these methods involves a stoppage of the train, and to obviate this efforts have been made to render the engine capable of supplying itself with water while in motion.

In 1854 Mr. Angus W. McDonald, of New Creek Depot, Va., patented an invention embracing two different methods of effecting this object.

By one the tank of the tender was to be air-tight, so that after being filled and partially exhausted there would be a partial vacuum within. From the side or bottom of the tank a valved pipe or hose was to be dropped into a cistern of water on or under the road, as the engine passed by, when, the valve being opened, atmospheric pressure would force the water into the tank. The other method was to employ an inclined trough or plane at a suitable angle to dip into the pool of water; the velocity of the train causing the water to ascend into the tank.

The latter plan has since been adopted on some railways. A water-trough of cast-iron sections, 18″ wide at top by 6″ deep, is laid upon the sleepers between the lines of rails at such a level that when full the water surface is 2″ above the level of the rails. A scoop of brass, having a mouth 10″ wide by 2″ high, and turning on a hinge, is, when in normal position, kept elevated by means of a balance weight, but is, when used, depressed, and is kept in this position while the tank is being filled.

The upper end of the scoop and the lower end of the delivery pipe are of corresponding circular arcs, so that the scoop forms a prolongation of the pipe when in position for raising water. The limit to which the scoop may be depressed is adjusted by set screws, and is varied as the brasses and tires of the tender become worn, lowering the level of its body. The trough is cast in lengths of about 6′, so as to rest on each alternate sleeper, and is fixed to the sleepers, its height being adjusted by means of wooden packing. The ends of each length are formed with a shallow groove, made water-tight by round strips of vulcanized rubber, the metal not being in contact. The road at each end is laid with an incline of 1 in 100 for a distance of 16 yards, the trough tapering down to a mere plate to allow the scoop to pass clear in entering and leaving it. At each extremity is an overflow pipe to limit the depth of water to 5″.

The orifice of the scoop is just covered by the water, and its edges are beveled off sharp to diminish splashing. The top edge is carried forward 2″ or 3″, and turned up with the same object. The water rushes into the scoop and up the delivery pipe, which is caused to discharge downwardly in order to prevent splashing.

Wa'ter Thief. A tube for drawing water from a cask, barrel, etc., by the bung-hole. A *bung-bucket*.

Wa'ter Tow'er. A portable stand-pipe for use at fires. This invention of Mr. Logan, a practical machinist of Baltimore, having been brought to the attention of the New York Commissioners they invited an exhibition in that city, and Chief Bates was instructed to furnish every convenience for a thorough test of the apparatus. The test was in every way satisfactory, and all who witnessed the operation of the machine, says the "*Fireman's Journal*," expressed the opinion that it was a practical and desirable adjunct to fire departments.

The water tower consists of three sections of iron pipe mounted on a truck; these sections being fitted together horizontally are raised to a perpendicular position by turning a wheel, an operation easily performed by one man; at the upper end of the tower is a flexible play-pipe, to which was affixed a 1½″ nozzle: at the base of the tower are connections for two lines of hose. Engine No. 20 was at a hydrant at Washington Square, and connected to the tower by two lines of hose. When water was first put through the hose, a coupling flew off and had to be sent to the repair shop to be readjusted. Meantime the steamer played through one line of hose, a splendid fire stream being projected through the tower, the nozzle of which was 51′ above the ground. One man on the truck had perfect control of the stream, and by means of a simple gearing was able to depress or elevate the stream, or turn it in any direction, sweeping the horizon at all points and freely sprinkling the promiscuous crowd that had assembled. At a height of 28′ a branch-pipe is placed and two streams were thrown at the same time, being handled with equal ease and facility by one man. Subsequently the tower was lowered and a short section substituted, having a 1¼″ nozzle and a height of 37′. Two lines of hose were connected, and two streams thrown from the tower to a great height and a great distance horizontally.

The ease with which the machine was handled and its effectiveness excited the admiration of all beholders. Firemen, especially, were enthusiastic regarding it, but wanted to see one 70′ instead of 50′ high, and a 2″ nozzle substituted for the smaller. The advantages offered by this machine are the getting of a solid stream high in the air before it leaves the nozzle without the aid of ladders, and the ease with which it is controlled by one man. Of course no greater power is exerted than is furnished by the engines, but half a dozen streams could be siamesed into it if necessary. At the test the highest water-pressure obtained was 170 lbs., while the owner claims that the tower will sustain a pressure of 300 lbs. at the nozzle. As Commissioner King remarked, a 2¼″ stream delivered at that height under such pressure would be bound to make a black mark on any fire against which it was projected. It would also be of great value in "wetting down" buildings contiguous to a fire, as its range would enable it to sweep both sides of the street and keep the buildings wet from curb to cornice.

Wa'ter Wheel. A wheel turned by the action of water.

Wave Mold'ing Ma-chine'. The Ransome wave molder has carriage, feed, and reciprocating scraping cutters. The chisel bar or its connections are elongated to give the stroke, the bar and chisel having a reciprocating motion, but capable of being extended to the depth of the mortise, and yet resisting in its joints the force of the blow.

Wax. The following are some useful recipes for sealing wax: —

Red Sealing Wax, Fine. — Melt cautiously 4 oz. pale shellac in a copper vessel, at the lowest possible temperature; add 1½ oz. of Venice turpentine, previously warmed, and stir in 3 oz. vermilion; pour into metallic molds and allow it to cool.

Red Sealing Wax, Common. — Resin, 4 lbs.; shellac, 2 lbs.; melt; mix in 1¼ lbs. Venice turpentine and red lead.

Black Sealing Wax, Fine. Shellac, 60 parts; Venice turpentine, 20 parts; melt shellac carefully; add Venice turpentine; stir in 30 parts of finely-powdered ivory black.

Black Sealing Wax, Common. — Resin, 6 lbs.; shellac, 2 lbs.; melt. Add 2 lbs. Venice turpentine, and lamp black to color.

Gold Sealing Wax. — Melt cautiously 4 oz. pale shellac in a copper vessel, at the lowest possible temperature; add 1¼ oz. of Venice turpentine, previously warmed; and stir in 3 oz. mica spangles; pour into metallic molds, and allow it to cool.

Colored Sealing Wax. — 4 oz. pale shellac, 1¼ oz. white resin, 2 oz. Venice turpentine; add a finely powdered pigment of the required color.

Bottle Wax. — (1.) Resin, 6¼ parts; beeswax, ½ part; Venetian red or red lead, 1¼ lbs. (2.) Shellac, 3 parts; Venice turpentine, 1½ parts; vermilion, 2¾ parts, or Venetian or red lead, q. s. (3.) Resin, 6 parts; shellac and Venice turpentine, each, 2 parts; coloring matter to suit.

Wax, Graft'ing. This is an article which should be kept on hand ready for use whenever needed, for it is valuable for various other purposes besides that of grafting. All wounds made in pruning trees will heal over much sooner if coated with this wax; and, if a piece of bark is accidentally stripped from a tree, the place should be covered over with it, and the wood will remain sound underneath. A good wax may be made as follows:

Melt in a basin 1 lb. of tallow, 2 lbs. of beeswax, and 4 lbs. of resin; stir well together, and keep in a cool place in the dish in which it is melted. If beeswax is a very costly item, one-third less quantity can be used.

Wax'-thread Sew'ing Ma-chine'. A sewing machine for sewing leather with waxed thread. Such machines are made to work with two threads or with one.

In the single thread machine the needle carries down the thread, which is caught by a looper working in the pillar beneath, and thereby held till the leather is fed forward so that the next descent of the needle will be through the former loop. Provision is made for keeping the waxed thread warm so that it may be flexible. The warming is usually by a lamp which heats a current of air in the duct through which the thread passes. In other cases the thread passage is heated by hot water. The wax is heated by a lamp beneath and the thread is conducted from the spool, through the wax and along a heated passage to the needle.

Way. (*Railway.*) With one exception, the Paris Exposition did not furnish any valuable suggestions of new uses for iron. This exception relates to the introduction of various systems of iron permanent way for railroads, in place of the wooden cross-ties and stringers which are now generally in use.

One of these systems, Hilf's, has been adopted on nearly 1,000 miles of railway in Germany, Austria, Belgium, and other countries. Both the stringers and the cross-ties are of wrought-iron. Other systems, at least one of which substitutes steel for iron, are modifications of the Hilf system. It seems not improbable that one or two of these systems will become popular and even necessary in countries which do not possess an abundance of timber, but at present many objections are made to their adoption. It is alleged that the first cost of an iron permanent way, cheap as iron has become, is much greater than one of wood, and that it is liable to corrode, and is more rigid than wood.

Iron, however, has found new friends in those inventors who have suggested its use in the construction of the so-called permanent way of railroads, and various systems of this new permanent way are now in daily use on the Continent. In Great Britain one or two of them have been used experimentally, and a commencement has been made in shipping iron for the construction of the permanent way of an Indian railroad.

Wear I'ron. The projecting piece of iron fastened to the bottom of a buggy or wagon to protect the wheel from wearing away the body in turning.

Weath'er-board'ing Saw. A combination saw, composed of saw, square, level, plumb, and rule, allowing the carpenter to plumb, space, true, saw, and fit on weather-boarding without other tools.

Weav'ing. The manufacture of fine blankets by the Navajo women is thus described: —

The wool is all spun with the fingers and without the aid of a wheel, the process being very slow and requiring great skill. The colors are all vegetable. As two women spin the warp two others stretch the yarn upon pegs driven into the ground, each thread being as long as the blanket is to be. When the warp is made and arranged, the woof or filling is spun in the same way, and each thread woven in by hand and with the greatest care. In this manner four women make four fine blankets in about three months. The Navajos have not lost the art of weaving blankets. While the men hunt and herd cattle and sheep, the women spin and weave blankets for their own use and for sale. Some are coarse and can be purchased for from $3 to $6, but others are so fine and tightly woven that they will hold water like a rubber poncho, and sell for from $25 to $75 each.

Diagrams showing the principles of various *armures* or dispositions of the harness for twills, satins, etc., may be found in *Laboulaye's* "*Dictionnaire des Arts et Manufactures,*" article "*Tissage,*" vol. iii., ed. 1877.

We'ber. (*Electricity.*) The practical unit of quantity (1 weber — $\frac{1}{10}$ (C. G. S.)). — *Ampère.*

The practical unit of resistance is called the ohm or B. A. unit (1 ohm — one billion absolute electromagnetic units). (1 ohm — 10^9 (C. G. S.).) — *Gordon.*

We'ber-me'ter. Edison has lately patented a "webermeter." This is an instrument for measuring the amount of electric current flowing through a circuit, or in other words a meter for electric currents to tell the number of webers that have been supplied.

Wedge. (*Nautical.*) One of the supporting blocks of a ship on the ways.

Wedge Cut'ter. A dentist's cutting pliers to excise the ends of separating wedges, inside and outside of the jaw.

(*Carpentry.*) A combined relisher and wedge cutter for relishing the rail of a door and cutting the wedges at one operation. The first arbor is perpendicular, the second upright arbor is thrown forward on the right angle to give the bevel to the wedge, and can be adjusted to give different bevels to accommodate different widths of tenons, or can be moved to a perpendicular. The two horizontal arbors are adjusted by screws, and can be moved up and down to cut any width of relish. The two small saws are fastened on end of arbors with screws, the heads being flush with face of saws. The sliding bed moves the length of machine on tracks. The rail to be relished is placed on its worked edge, on the bed, with shoulder against the stop (which can be adjusted to any depth of cut), and run through machine, thus cutting the relish and wedge in one movement. One man can relish the rails and make the wedges for 1,000 to 1,200 doors in ten hours.

Wedge Valve. A wedge-shaped valve driven to its seat by a screw. Used in closing mains, etc.

Weed'ing Hoe. One style is made with three small triangular blades or shares which cut the weeds off at the surface of the ground, or lower, and are adjustable laterally to cut all in one broad row, or spaced apart as desired.

Weed Scythe. See BRAMBLE SCYTHE.

Weigh Can. A can containing a liquid, resting on scales. The indicator is fixed at the present weight less the amount wanted; the faucet is opened, and when the beam rises the flow is cut off.

Fig. 2530.

Weighing Scoop.

Weigh'ing Ma-chine'. Figs. 1423–1425, p. 486, *supra*, show a convenient form of hydrostatic scale for weighing in transitu.

See also STEELYARD, TRACK SCALE, PLATFORM SCALE, SUSPENDED SCALE, etc.

Weigh'ing Scoop. Mery's scoop has a spring balance located in the scoop handle, scale and pointers on the handle, and a stop so arranged as to save the spiral balance spring from damage when the scoop is thrust into any hard, unyielding material.

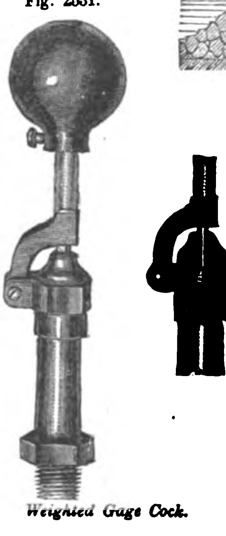
When the scoop is in use the handle is naturally grasped so that the thumb is directly over the stop *L*, and a slight pressure on it when the scoop is thrust into any material prevents the stem from being pushed down upon the spring, and causing any damage to it. The combination of handle and stem is made stiff and unyielding by reason of the stop, thus facilitating the scooping up of any hard unyielding material.

When the material to be weighed is raised up in the scoop, the stop is released and the balance, being free to act, the weight of the material will show on the scale. This arrangement of scoop and scale gives two useful articles in one, and is very serviceable where a large amount of material has to be divided by weight into small quantities.

Weight'ed Car'riage Lathe. One in which the carriage rest is held down by a weight.

Weight'ed Gage Cock. One in which the piston or valve is held to its seat by a weight. See Fig. 2531.

Fig. 2531.



Weighted Gage Cock.

Weight'ing. Loading silks, cotton, and other goods with foreign substances in dyeing, to give them body and weight. This fraudulent practice is resorted to in many cases, the principal weighting material used being chloride of magnesium. Sulphate of magnesium (Epsom salts), oxymuriate of tin, sumac, galls, gums, sugars, salts of lead, oxides of iron, and other articles of a similar kind are used by unscrupulous dyers to give to silk an artificial weight, regardless of the fact that the goods are seriously damaged thereby, for use.

Weir. A dam across a stream to raise the water to a higher level, either for milling, fishing, or navigating purposes.

The rivers Seine and Yonne have been made navigable for small vessels, between Paris and Auxerre, by a system of weirs which give a minimum depth of about 5′.

This has been accomplished by building 34 movable dams, with side locks, and also making three cut-offs; every cut-off has a guard-gate at its head to keep out the flood water, and a movable dam, without a lock, is built across the river just below each gate. See BARRAGE, p. 76, supra, and Plate IV.

The above operations have served to convert the two rivers into a series of navigable pools. Rivers so converted are said to be canalized.

Each weir, 150′ wide, is composed of a fixed and movable portion, the fixed part consisting of a mass of béton, faced with masonry, poured between two lines of sheet piles with an interval of 25′ between the lines. This mass rises to within 3½′ of the upper bay level. This fixed part is surmounted by 33 movable gates 5′ wide, with their tops, when they are up, at 3½′ above the permanent portion. These gates were designed by M. Desfontaine, and called by him *hausses à tambour*, or drum gates.

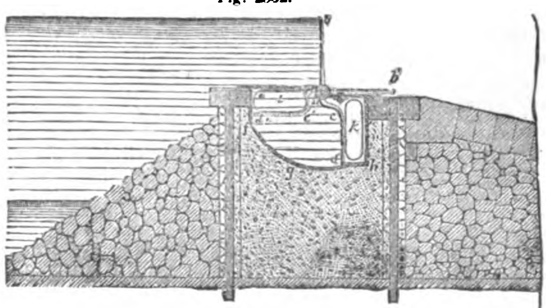
The object was to operate the dam by utilizing the power produced by the fall itself.

The moving apparatus, Fig. 2532, consists of a series of gates, independent of each other, and turning around a horizontal hinge, *a*, placed in the middle. The upper half, *a b*, is the *hausse* or gate, properly so-called; it is this which forms the upper bay. The lower half *a c d*, called the counter *hausse*, has no other function than to carry along the *hausse* in the movement impressed upon itself. It is inclosed in a quarter of a horizontal masonry cylinder of the same length, whose axis coincides with the hinge, and in which it can consequently make a quarter of a revolution. The horizontal one is slightly raised parallel to itself, and the vertical one has been similarly moved back, so as to leave the empty spaces *l* and *k* between the drum and the extreme positions of the counter *hausse*.

By admitting water from the upper bay into the chamber *l*, when the bay is full, the gates are revolved on their axes, and the bay emptied as far as desired. The admission of the water into *k* raises the gate again.

The simplest form of a *fish weir* consists of a fence of brush

Fig. 2532.



Weir.

driven into the sand or mud and forming a curve concave to the ebb of the tide. As the water runs off, becoming more shallow, the fish in the inclosure are detained and are captured when stranded.

A *dry* weir is one on a flat left dry by the ebb of the tide.

Weirs are called *slat* weirs or *brush* weirs when made of boards or brush respectively.

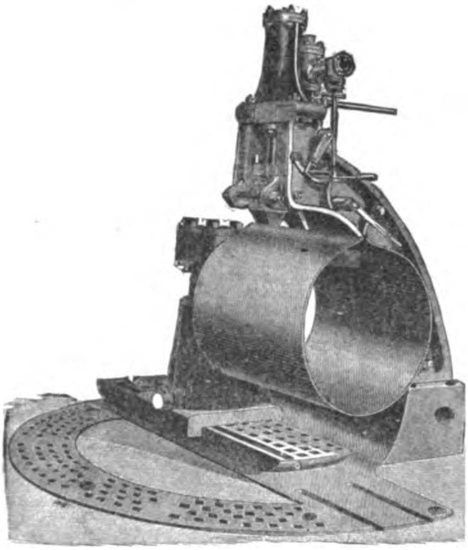
Weirs may have leaders of brush or slats and pounds of net, or the heart and net may be of brush below and netting above.

Weir and *pound* are almost synonymous terms.

Weld'ing. A welding block mounted on the long slide, carries a welding bar, upon which saddles may be fitted for different diameters. The block and bar carrying the flue are traversed along the bottom slide, and as much length as can be heated may be welded at once. See Fig. 2533.

Weld'ing Tubes. Herr Krupp, of Essen, Germany, has recently patented in Germany a method of welding tubes and tires. He draws the tube over one of a pair of ordinary rolls, and then heats

Fig. 2533.



Welding Hammer.

the whole length of the portions to be welded by a special contrivance, which is a portable fire-box, into which air is so blown that the heat is directed against the weld. After the necessary heat is attained the rolls are set in motion and the place to be welded is repeatedly drawn through them. His heating apparatus could, we believe, be replaced to advantage by some gas apparatus similar to that used for heating wagon tires in this country and in France.

Well-bor′ing Tools. The tools used in well-boring may be classed under five heads.

1. Drills, acting by percussion.
2. Augers, for boring by rotation.
3. Reamers, for enlarging the hole.
4. Sand pumps, for extracting detritus or soft material.
5. Grabs, for recovering fallen or broken tools, rods, or tubing, and for raising or lowering rods or tubing.

The simplest plan for operating boring tools is the Chinese; the tools are suspended from a rope which is worked vertically and imparts by its torsion a circular motion to the tool. The well is tubed as the work progresses. This plan, while it has the merit of simplicity, is liable to the objection that the tool is apt to follow fissures, to avoid nodules and hard seams, and thus become deflected from the true course.

The usual mode of boring is to attach the boring tool to the end of a section of rod, which, as the work progresses, is lengthened by the attachment of other rods, which are in lengths of from 10′ to 20′. A vertical reciprocation is given to the drill stock by attachment to a walking beam, by a lever or by other means, and a certain amount of rotation being imparted to the tool at each stroke causes it to fall in a fresh place at each impact.

The tool acting upon the rock, or the scoop upon the sand, gravel, etc., accumulates a quantity of *débris* which requires to be withdrawn from time to time, the rod being lifted and unscrewed, section by section, and the *débris* removed by sand pump if the tool itself has no provision for withdrawing it. The sections are then again attached and the tool lowered to its work.

The loss of time entailed by this plan, in the raising and unscrewing, emptying, reattaching, and letting down has given rise to a number of inventions designed to withdraw the *débris* as it is made. For this purpose was suggested a downcast and upcast current of water circulating through two tubes or on each side of a partition in a single tube. Another device, patented in England in 1844, by Beart, was to make the rods hollow, with water-tight joints, and then introduce a downcast current of water which carried the *débris* up the space between the rod and the wall of the well.

Pumps of various kinds have been contrived, designed to accomplish the same purpose, and other inventors have made hollow drill-rods with a succession of valves, the water and *débris* being supposed to work their way from section to section upwardly by means of the forcible contact of the tool with the yielding strata.

When danger is apprehended from the weight of the drill-rod, a slide-joint may be made which will limit the percussive action to one or two sections at the lower end of the rod while the portion above the joint is counterbalanced so as not to be involved in the blow.

This slide-joint is the invention of Œuyenhausen.

See full-page plate of well-boring tools, p. 2758, "*Mech. Dict.*"

Well Smack. A perforated submerged cage attached to the bottom of fishing smacks for transporting the fish to market alive.

Welt Ma-chine′. A machine to cut leather, cloth, etc., into a series of parallel strips to be used as welts in side seaming. The material is passed into the machine irrespective of its width, the end knife separating the portion not cut into strips before it can be carried against the standard.

Well′-wheel Block. A grooved pulley for the cord of the well-bucket to run over. It has a hook for suspension and anti-friction rollers for the axis.

Wet and Dry Plates. The wet plates used in photography and prepared by the photographer at time of taking a picture, are being largely superseded by the dry or gelatine plate, which can be prepared or bought in advance, and carried around for taking views, or other pictures. These dry plates are practically instantaneous. See work by J. Traill Taylor, published by the Scovill Manufacturing Co., New York.

Wet Broke. (*Paper.*) The moist and imperfectly felted stock or pulp as it leaves the wire cylinder and before being smoothed out on the forwarding blanket.

Wha′ling Ap′pa-ra′tus. For list of U. S. patents on whaling apparatus, harpoons, bomb-lances, rockets, and explosives used in fishing and whaling, 1838–1879, see HARPOON.

Wha′ling Gun. Off the Norway coast, near Wadso, whales are killed by the use of a gun invented for the purpose.

The gun has a chamber about four feet long, is mounted on the forecastle of the vessel, and, being balanced, can be easily moved to allow aim to be taken. The projectile in use consists of a long iron bolt, having at its extreme end four harpoons bound round with a line so as to be flat, and close to the harpoons a five or six pounder shell. As soon as the steamer has approached sufficiently near to the fish, the bolt is fired off, and, if well directed, penetrates deeply into the flesh and blubber of the animal. The whale rushes off at a furious pace, and the effect of his rapid movement is to make the bolt slip back a little, thus setting free the four harpoons from the lines, and, by means of a mechanical arrangement, causing the shell to explode. This generally proves the *coup de grace*.

A fire arm or small cannon hurling a bomb, harpoon, or lance. Patents: —

Brand	June 22, 1859.
Pierce	1865.

See also HARPOON GUN.

Wha′ling Rock′et. A projectile carrying harpoon, line, and explosive, used in whaling.

The Roys rocket has a strong brass cylinder containing the projectile charge. In the front of this is secured a bomb containing an explosive charge, and inside of it is a harpoon attached to the shell. To the rear end of the rocket, is attached the whale line. The bomb has a bearded or barbed point, and when projected into the whale by the rocket explodes, inflicting a fatal wound, the harpoon takes its hold, and the boat is fastened to the whale by the line. These shots are good for killing and fastening to a whale at 30 fathoms distance. The whole apparatus weighs 32 pounds, and is 6′ 6″ in length.

A peculiar rest is used in firing, having on it a shield to protect the operator from the fire which issues from the rear end of the rocket. The rocket is set in the rest, the rear end of which is placed on the shoulder, and by discharging a pistol charge into a hole provided for the purpose, the projectile is discharged and the rocket powder carries the rocket, bomb, and line in the direction required.

Whale'men's Tools, Knives, etc. *Blubber Fork.* Used for tossing blubber into the try kettle.

Blubber Hook. Used in hauling small pieces of blubber on deck.

Blubber Knife. For cutting up blubber for trying out.

Boarding Knife. For cutting the blanket-piece of blubber or long piece which is flensed or peeled from the sides of the whale.

Boat Spade. Used from the boat to disable the whale by cutting its flukes.

Boat Hatchet. Same use as *boat knife.*

Boat Knife. To cut the harpoon line when it becomes tangled in paying out. Kept in its sheath on the bulkhead of the whale-boat, ready for use.

Cutting Spade. Used in peeling the blubber from the carcass of the dead whale. Known as "cutting in the blubber."

Half-round Spade. For cutting the "blanket" piece, to allow blubber hook to enter.

Head Knife. For cutting off the head of the whale; opening the skull to obtain the spermaceti; removing the baleen, etc.

Head Spade. For cutting off the head of the whale.

Junk Hook. Used for hauling heavy pieces of blubber on deck.

Lance. To give the whale its death thrust.

Line Hook. A hook for catching the line.

Lip Hook. A grapnel for catching in the whale's lip, to tow it to the vessel.

Mincing Knife. For cutting the blubber into small pieces.

Mincing Spade. For cutting the blubber into small pieces before trying out.

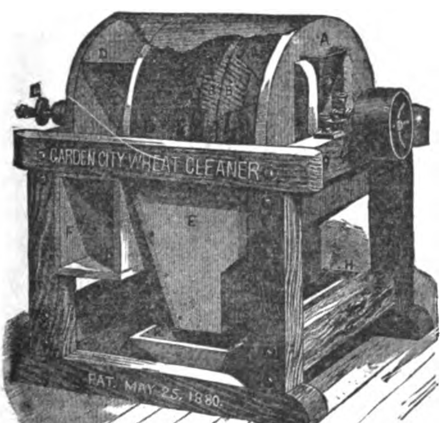
Throat Spade. Flat with a round shank. Used in cutting off the head of the whale.

Whaling Gun. A fire arm or small cannon hurling a bomb, harpoon, or lance.

Wide Spade. Used in the blubber room for cutting blubber in the rough, before mincing.

Wheat Brush. A device for scouring grain. The illustration, Fig. 2534, shows two bristle brushes, with the bristles inclined. One of the brushes revolves while the other is stationary. The wheat enters the hopper *A* and passes to the center between brushes B^1 and B^2, whence it is carried by centrifugal force to the periphery of the brushes, when it falls into the air-chamber *E*, whence the dust is removed by the suction created by fan *D*.

Fig. 2534.



Wheat Cleaner.

Wheat Crack'er. (*Milling.*) A mill for making grits. See Grits Mill.

Wheat Damp'en-ing and Dry'ing Machine'. Apparatus for washing and cleansing smut and dirt from grain, and drying the wheat when washed. See Grain Washer.

Wheat Drill. See Grain Drill.

Wheat Gra'der. A machine for separating the perfect from the imperfect grains, and for sorting out long from round grains, or removing dirt, stones, etc., from grain. See Grain Separator, Stone Cleaner, Wheat Separator.

Wheat Heat'er. (*Milling.*) An apparatus for heating grain before grinding in order to facilitate the loosening of the bran coat. It is usually some form of steam heated chamber, and in Welch's wheat heater, it has a perforated steam ring for damping the grain also, if desired.

It has an interior iron cone, heated by one steam-pipe, and a frusto-conical steam coil a short distance outside of the cone. The live steam pipes of each are above and the waste below. The wheat enters the machine and passes down the channel between the conical coil of pipe and the central iron cone, which is notched on the outside, spreading out and passing through a series of openings in the bottom, where it is collected by the hopper at the bottom of the machine, and spouted to the burrs. The ring just below the wheat induction opening is for steaming the grain, when required: the pipe having its own valve. The space outside the steam is packed with asbestos to prevent radiation of heat. The length of the apparatus is 26.5″. Capacity, 15 bushels per hour.

Several forms of apparatus may be found under the following references:—

Provost, "Victor"	* "*American Miller*," vi. 148.

Wheat Mag'nets. Fig. 2535 shows forms of magnets for inserting in the mill spouts to gather the pieces of wire that may have gotten in from the use of wire binders or other sources.

Fig. 2535.

Wheat Magnets.

Wheat Rid'dle. See Separators, full page of plates, p. 417, *supra.*

Wheat Scour'er. (*Milling.*) A machine which follows the smutter.

It consists of a stiff brush, against which and below, a grooved burr-stone is made to revolve, the wheat passing between the brush and burr-stone. It serves to remove still adhering hairs and loosened portions of the outer bran, and presents, after passing through a blower, a berry of remarkable smoothness and look of purity. By this process, some varieties of wheat lose, beside the hair, portions of the outer layer of true bran, traces of the cigar-coat, and scales from the surface of the embryo.

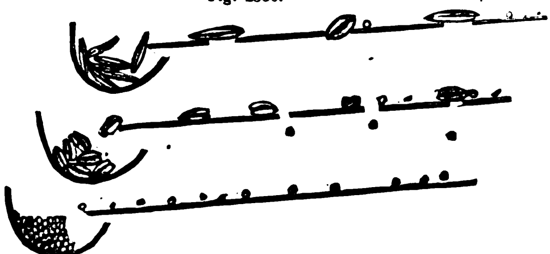
To effect the same end in other mills, the wheat is passed between a grooved steel cylinder and a segment of a stone shell in which the abrasion of the surface of the wheat and the partial removal of the outer bran coat are effected.

Another form has a cylindrical grater operating against a surface of stone. The wheat enters the machine at a spout and comes in contact with a system of cast-iron spiders. Passing through in a spiral form, it is discharged. The screenings are delivered from one spout and the dust from another. The separation can be adjusted by a movable valve.

Wheat Sep'a-ra-tor. The separation of mustard, cockle, and grass seed from the wheat is effected by passing the mixed grains over inclined plates perforated with holes large enough for the smaller seeds to pass through but not large enough for the wheat.

The oat-grain is separated by taking advantage of its elon-

Fig. 2536.



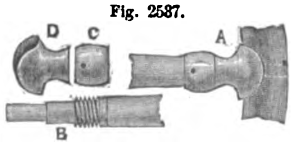
Wheat Separator.

gated form. The mixed oat and wheat grains are discharged in a thin sheet upon an inclined, jogging, thin, iron plate, perforated with round holes, at intervals nicely determined by experiment, abundantly large for the ready passage of both the wheat and oat grains if presented end foremost perpendicularly to the surface of the plate. But as the plate is inclined, each berry must be tipped forward in order to enter a hole. An individual hole is of such diameter that when the wheat-grain sliding forward carries its center of gravity beyond the support of the upper edge of the hole, there will be room for the prow, that is, the forward end of the grain, to sweep downward through the hole without striking its lower margin, and thus the wheat-grain be separated. The oat-grain, however, in sliding down the inclined plane, before the center of gravity has passed beyond the support of the upper margin of the hole, will, by reason of its prolonged hull, extend over the lower margin of the hole, and thus fail to fall through. As the oat-grain advances, the center of gravity will pass beyond the lower edge of the hole and gain the support of the continuous surface before the tail of the berry will have lost the support of the upper edge.

Wheel. (*Vehicle.*) A circular frame supported on an axis, distinguished from a roller by the axle bearing the stress.

Fig. 2537 shows the Raddin elastic adjustable iron and wooden spoke for carriage wheels.

Fig. 2537.



Adjustable Spoke.

The cut shows the manner the felloe is expanded to set the tire. *A* represents a spoke and felloe, with clasp and nut ready to be expanded to set the tire. *B* shows a spoke with screw-thimble to receive the nut *C* and hasp *D*. By turning the nut on each spoke the felloe is expanded, the tire is set, and the wheel made round, which cannot be done by the ordinary method.

Smith's wheel has a metallic hub with the spokes clamped between collars. The outer collar is held on by a jam nut and a loose spoke can be replaced without removing the tire.

The spokes in the Watson wheel pass through a metallic collar encircling the hub, the two parts of which are joined by connecting pieces which form wedges to spread and tighten the spokes as they are driven in.

Wheel Cut'ting Ma-chine'. A device for dividing a circle into any number of equal divisions.

Wheel cutting machine.
Scott . . . . . . * "*Engineering*," xxiii. 381.
Wheel cutter bevel.
Grube . . . . . * "*Scientific American Sup.*," 450.

Wheel En-gra'ving. (*Glass.*) As distinguished from sand-blast engraving or acid etching. See GLASS ENGRAVING.

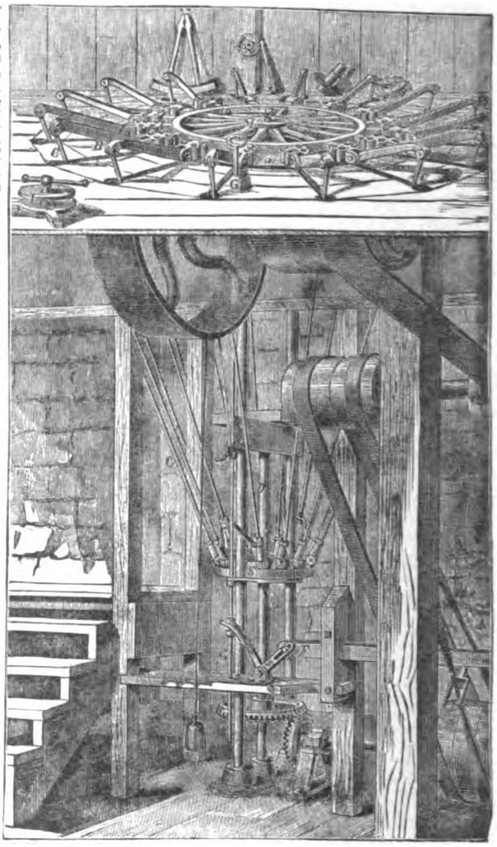
Wheel Hoe. One, or a series of hoes, mounted on a wheeled frame, and adapted to be pushed by hand. Revolving disks are sometimes interposed between the plants and the hoes to prevent the plants being smothered with earth.

Wheel Joint'er. For trimming the joints of staves, heading, etc. See HEAD JOINTER, *supra*.

Wheel-ma'king Ma-chin'e-ry. Apparatus for pressing hub, spokes, and felloes into a solid wheel at one operation.

Fig. 2538 shows Archibald's wheel machine, which occupies space upon two consecutive floors. A strong circular plate of cast-iron, about 7' diameter, having its upper surface faced off true, is placed horizontally level with the second floor. Arranged at equal distances around its outer edge are a number of levers, *B*, equal to the number of spokes to be set in the wheel, having their fulcrums securely bolted to the plate. The long arms of the levers radiate from the plate, about 8' all around; the short arms are formed into cams, or rolling inclines, or curved wedges, acting upon sliding pieces of cast-iron, which move freely in a radial direction, in guides formed in the fulcrum blocks. When the long arms of the levers are raised, the sliding pieces are pressed outwards by springs until they bear upon the cam-shaped short arms of the levers at the point nearest the fulcrum or center of motion of the lever. When the long arms of the levers are lowered, their sliding pieces are forced inwards by the cams, and unite in pressing inward the wheel. The levers are actuated by means of wrought-iron rods, *C*, extending downwards from the ends of the levers, converging to a vertical column, *D*, under the center of the plate, much as the braces of an umbrella extend downwards from the ribs to the stick. A screw is cut upon the central column, and a nut, *E*, answering to the slide upon an um-

Fig. 2538.



Wheel Machine.

brella stick, raises or lowers all the levers at once, with great facility, and with any required power. Motion is given to the nut by means of beveled gears, and a belt with fast and loose pulleys, so arranged that at the upward and downward limits the belt is thrown automatically upon the loose pulley, and the motion of the nut and levers stopped. Any required motion, either up or down, within the range of the screw, can be obtained with great delicacy and convenience by a shipper, *F*, actuated by a shipping-rod, *G*.

Wheel Plow. One having a wheel in adjustable standards depending from the front end of the plow-beam to regulate the depth of the furrow.

Wheel plows.
Ransome, Br. . . . . . * "*Engineering*," xxvii. 486.
Wheel plow, *Howard*, Br. . . * "*Engineering*," xxx. 49.

Wheel Press. A hydraulic press for forcing car-wheels upon their axles.

Wheel Ribs. Projections on the inner side of plate car-wheels to strengthen them.

Wheeled Scra'per. One mounted on trucks to scrape and level newly-dumped dirt on railroad tracks.

Wheel Seat. The part of an axle inclosed by the hub of a wheel.

Wheel'wright Ma-chine'. A machine for doing the different varieties of work necessary in the forming of a wagon wheel.

Some forms will plane wagon or buggy rims when on the wheel, and plane the periphery of a rim made of sections (*i. e.*, sawed felloes), so that each section shall have a true circle of its own, greater than the circle of the wheel, forming what is known in the trade as swelled joints, without which such wheel would be deficient, as the rim is always inclined to dent in at the joints of the felloes. The amount of irregularity can be varied, and is quickly changed so as to plane a bent rim to a true circle.

The rim planer will also plane stuff straight, out of wind, square, and to thickness (and 8″ wide with an extra cutter-head of this width). The upper table may be taken off its hinges without removing a bolt, and a saw board substituted, making an adjustable saw table for rip-sawing or cutting-off, the cutter-head being exchanged for a saw.

The machine thus fitted, and furnished with back-top, adjustable fence and bevel rest, patent gaining and saw frame, is a complete universal wood-worker, without interfering with the rim planer.

On the opposite side, when desired, is attached a spoke saw and wheel tenoner, with or without a boring table. It can be changed to a boring machine without the use of a wrench.

Two men may operate on the machine at the same time, one on the front side and the other on the opposite side.

A horizontal shaper may be made of the rim planer, which will shape, round, and corner all ordinary work.

Whelps. 1. (*Nautical.*) The projecting ribs of a capstan, around which the rope is wound, generally of the form of a frustum, to keep the rope from becoming jammed against the pawl.

2. The teeth or projections of a sprocket wheel.

Whet'stone. A report on this subject by *J. M. Safford* is given in that of Group I., "*Centennial Exhibition Reports*," vol. iii., p. 172, *et seq.*

Whin. (*Mining.*) A machine for raising ores and refuse.

Whip Crane. That form of crane in which the winding rope passes over the periphery of a larger wheel, on whose barrel axis the lifting rope coils itself. Such cranes are independent on rooted posts or are supported above according to the exigencies or facilities of the case; the latter swings completely round, is fitted with three purchases or speeds of lifting, and with break apparatus for lowering. Weights up to 600 lbs. are lifted quickly by pulling directly upon the rope; for weights up to one ton the handle is put on the rope-barrel shaft; for heavier loads the handle is put on the pinion shaft.

The upright and jib are of pitch pine timber, with cast-iron shoes, top and bottom, wrought-iron pivots, and square cast-iron plates for fixing to floor and beam. The jib is fitted with cast-iron bracket and jib-head and wrought-iron tie-rods to the top pivot casting.

Whip Gin. A simple tackle-block, over which a hoisting-rope runs. Also called *gin block* and *monkey wheel.*

Whip on Run'ner. (*Nautical.*) A tackle with two single blocks, one a standing and the other a running block. The fall of the standing-block is spliced round the block of the lower whip. A *whip-on-whip*. *b* Fig. 6159, p. 2480, "*Mech. Dict.*"

Whip'ping. (*Nautical.*) Tying or binding with twine the end of a rope to prevent its untwisting. For list of *whipping*, *lashing*, *seizing*, etc., see SEIZING.

A Spanish whipping occupies an intermediate position between a knot and a splice, and gives a very neat finish to a rope's end. Unlay the rope for 12″ or 15″ and make a crown with three strands. Then carry the strands severally through the body of the rope, downward, as in a short splice, gradually tapering the strands away. In making a Spanish whipping, as in splicing of all sorts, — the long splice excepted, — a marlinespike must be used to open the body of the rope to receive the ends of the strands.

Whip Ma'king. For method of covering whips, see BRAIDING MACHINE, p. 355, "*Mech. Dict.*," and for history, etc., see WHIP, p. 2769, *Ibid.*

The main items of expense in whip making material are rattan and whalebone. The rattan is imported from Batavia and China. The qualities which are too soft, or otherwise unfit for use in whips, are sorted out and sold to the basket-makers. The fine strips which make up the stock of a whip are split out first by hand, and afterwards worked down by drawing them through a shave, which can be gaged. The whalebone is already split when imported.

The main part of most whips is composed of nine pieces. The whalebone is in the center, surrounded by the thin strips of rattan, and secured in place by glue. This compound stock is dipped in glue so that every part is permeated by it, and then run through a machine, which winds it with a strong thread from end to end. It is again wound with rope, so that it cannot warp out of shape, and left to dry. A peculiar turning lathe gives a smooth finish and even taper from butt to tip.

The thread covers are plaited on to the stocks by machines, which are wonders of ingenuity; some carrying as many as 24 spools. Some of the better grades of whips have this cover made of fine gut, prepared from sheep entrails. Sometimes a portion is worked on by hand, and fancy designs in colors, or the owner's name is introduced. A great variety of sticks is used for the stiff portion of the stock, many of them being very handsome, and include the holly and other ornamental woods. The Malacca cane, which grows in the Dutch East Indies, and is imported, is also used largely.

Fine lashes for stage drivers, teamsters, or tandem whips are plaited out of the best California deer skin. They contain from 4 to 24 strands, and are from 4′ to 16′ long. Horse-hide answers for the cheaper grades used by cartmen and others.

Plaiting lashes well can be done only by careful and experienced hands and is all piece-work. Much of it is given out to be done at the homes of the operatives.

Whis'ker Gaff. (*Nautical.*) One of the spars rigged out from the bow to spread the guys of the jib-boom. Also called a *sprit-sail gaff.*

White Brick. A process for the manufacture of white pressed brick from common red clays, consists in mixing or grinding into the common clay a cheap material, chiefly magnesian limestone, which has been reduced to an impalpable and harmless powder by being burned and slaked.

This compound is passed through a series of mixing and grinding mills, and so completely ground that it leaves the last mill reduced to a fine powder; in this state it falls through the feeder into the molds of a powerful steam-pressing machine, is subjected to a heavy pressure, and is delivered at the delivery table a complete and almost dry pressed brick, which, when burnt in the kiln, produces a white brick of good quality. The ingredients added to the clay at once absorb about 40 per cent. of the moisture found in the natural clay, and the grinding is so close and complete that the mixture is thoroughly and evenly amalgamated. The change effected in the color of the red clay on being burnt is due to the presence of the mixture.

White Bronze. A name given to either of several light-colored bronzes. See NICKEL BRONZE; MANGANESE BRONZE. See list under BRONZE.

White Cloud Il-lu'min-a-tor. A round piece of plaster of Paris fitted on the microscope, reflecting a white beam of light, often used instead of the ordinary mirror.

White Glass. (*Glass.*) A term used in England to distinguish certain brilliant uncolored glass from *flint* glass, which has lead in its composition. See FLINT GLASS, CRYSTAL.

Whi'ten-ing. (*Leather.*) The leather is laid over the beam, and with an extremely fine-edged knife a thin shaving is taken from the flesh side.

Whi'ten-ing Ma-chine'. A buffing machine, operated by power, to buff, whiten, or flesh leather in finishing.

Whit'worth Steel.

One of the most interesting of the British steel exhibits at the Paris Exhibition, 1878, was that which embraced various samples of the "Whitworth metal," to which much importance has been attached in Great Britain in connection with the manufacture of ordnance and other articles by the Siemens and Siemens-Martin processes. The exhibit was large, and of a character to favorably impress the visitor. The metal is made of more than ordinary solidity and tenacity by being cast under hydraulic pressure. Cannon and shells of this metal are said to withstand the severest tests, a claim that received confirmation from some of the samples submitted. A propeller shaft was exhibited, forged hollow, which it was claimed was much stronger than a solid wrought-iron shaft of the same size and weighing one-half more. This shaft, forged from a hoop of compressed steel, was 33′ 7″ long, the outside diameter 17½″, and the diameter of the bore 11⅝″. A hydraulic cylinder of this metal was shown which was represented to stand a pressure of four tons to the square inch. For machine tools, in which strength combined with lightness is desirable, the compressed steel is claimed to have no equal. Sir Joseph Whitworth's aim has been to produce a steel that would be free from blow-holes, and this result he has accomplished by mechanical means. A similar result has been claimed by the Terre Noire Company, in France, through chemical combinations.

White'wash. A good durable whitewash is made as follows: —

Take half a bushel of freshly burnt lime, slake it with boiling water; cover it during the process to keep in the steam. Strain the liquid through a fine sieve, and add to it 7 lbs. of salt previously well dissolved in warm water; 3 lbs. of ground rice boiled to a thin paste and stirred in boiling hot; ½ lb. of powdered Spanish whiting; 1 lb. of clean glue, which has been previously dissolved by soaking it well, and then hanging it over a slow fire in a small kettle, within a large one filled with water. Add 5 gallons of hot water to the mixture, stir it well, and let it stand a few days covered from dirt. It must be put on quite hot. For this purpose it can be kept in a kettle on a portable furnace. About a pint of this mixture will cover a square yard.

A recipe almost identical is recommended by the Treasury Department to all lighthouse keepers. It answers for wood, brick, or stone.

Wide Spade. (*Whaling.*) Used to cut the blubber in the rough, before mincing.

Wil'low Cur'tain. (*Hydraulic Engineering.*) A device to curb the rapidity of streams and induce deposit of sediment. Its action is similar to the FLOATING BRUSH DIKE, which see. See also FLOATING WIRE DIKE.

The willow curtain is made of willows 1″ to 2″ diameter, and fastened parallel to each other and 6″ to 8″ apart, by means of wire. It is made of any desired width and length and anchored in position in the stream by weights attached at intervals along the lower edge, and sustained by buoys made fast to the upper edge. — "*Report of U. S. Engineers,*" 1880, pp. 1452, 1459.

The tools and methods are well shown in the "*Chief of Engineer's Report,*" 1879, *ii. 1074, *et seq.*, Plate IV.

Winch. A hoisting machine operated by hand, crank with gearing, and tackle, which should always have a follower or dog, as a safety-brake.

Wind Fur'nace. (*Metallurgy.*) One depending upon the draft of a chimney, as distinguished from a blast furnace.

Wind Gage. A gage attached to a gun to indicate the strength of the wind and enable the person using the gun to make allowance for the deflection of the ball in its flight to the target.

Wind'lass. A drum revolving on a horizontal axis for raising heavy bodies. A capstan has a vertical axis.

Win'dow Bar. A bar intended as a security against children falling through an open window or door. It is so constructed by reversible screws at each end that it can be extended or contracted to fit the doorway or window.

Window Glass. Common window glass is made by the blowing and whirling process. Plate glass is run into molds, ground, and polished.

The irregular thickness of the Pompelian window glass shows that it could not have been blown, and M. Bontemps is of the opinion that it was cast in bronze frames.

The analysis shows the following composition: —

Silica	69.48
Lime	7.24
Soda	17.31
Alumina	5.55
Oxide of iron	1.15
Oxide of manganese	0.89
Oxide of copper	trace

Window glass in wooden frames in France under Louis XIV.

Window glass in use in England, XIIth century.

Window glass in royal palace in Edinburgh, 1661.

Painting on glass in Abbey St. Denis, XIIth century (Le Vieil).

Painting on glass in Abbey Leroux, Anjou, 1121.

Painting on glass in Abbey Tergernsere, Bavaria, Xth Century.

See CROWN GLASS, CYLINDER GLASS.

Win'dow Mir'ror. A mirror mounted outside the window, and capable of being adapted at any angle to reflect the passing objects in the street, to the view of persons inside the house.

Win'dow Op'en-er. A lever or rod by which a window, ventilator, sash, or panel in a clear-story is held in any desired position.

Win'dow Sec'tor. A bar or plate of metal of the form of part of a circle, and which is used as a guide or stop to control the movement of a clear-story window.

Win'dow Tube. A glass or hard rubber tube forming a passage-way for an electric wire into a building.

Wine Heat'er. A machine to preserve wine after it has acquired its best condition from its natural fermentation, against secondary fermentation, and all diseases which arise from the development within the wine of animo-vegetal parasites, such as bacteria, vibria, mycodermi aceti, etc. It is simply the mechanical application of the well-known and well-established theory of M. Pasteur, the eminent French chemist, that subjection of any fermented liquor to an instantaneous heat of 45° to 55° centigrade (112° to 131° Fahr.), or to a slowly acquired temperature of 65° to 75° centigrade (149°

to 167° Fahr.) will destroy or render inert all germs of fermentation or of animo-vegetal life existing therein.

Wine Press. In the common form used in France the main characteristics are the exact arrangement of the gearing on the nut. The inventions of Mabille frères, Marmonier, Primal, and others differ.

The crate is made of a cylindrical series of slats, hooped and latched. Rising from the bed of the machine is the screw, upon which is the follower, which is forced down by the nut. The latter is rotated by the lever, the laborer at the first merely walking round the press. When he can no longer operate thus, he commences a reciprocating movement, drawing the lever back and forth, which he is enabled to do by a species of gravitating ratchet movement in the apparatus upon the nut.

The cotter-keys are gravitating; each motion of the lever turns the mortise-wheel in a constant direction, the action of the cotters being alternate. While one cotter is effective the other slips up out of its seat, slides over the intervening space, and drops into the next mortise. The stroke of the lever is 0.8 meter.

Wine making, Hammondsport . . . . . . * "*Scientific American*," xliii. 79.

Wing. (*Fishing.*) The portion of a hand-seine on each side of that central part which is known as the *bag*.

Wing Net. (*Fishing.*) A net running down stream from one of the stakes of the stake net, to the stake at the mouth of the *hook* net, to guide fish intercepted by the main or *bar* net. See STAKE NET, p. 850, *supra*.

Wing Stop'per. (*Nautical.*) A rope clenched to a ship's beam and at the other end to a cable.

Winze. (*Mining.*) A shaft sunk from one level to another.

Wiped Joint. (*Plumbing.*) One made by placing the parts in the required juxtaposition and covering the joint with a mass of solder.

The wiping action of the woolen pad used originated the name.

Wire. The following table, showing breaking strain of ropes of 133 wires, is from a pamphlet by Messrs. J. A. Roebling's Sons: —

	Diameter. Inches.	Strength. Tons.
No. 1	2¼	74.00
No. 2	2	65.00
No. 3	1¾	54.00
No. 4	1⅝	43.60
No. 5	1½	35.00
No. 6	1⅜	27.20
No. 7	1¼	20.20
No. 8	1	16.00
No. 9	⅞	11.40
No. 10	¾	8.64
No. 10¼	⅝	5.13
No. 10½	9-16	4.27

The following shows the weight and resistance per mile of galvanized iron wires: —

Number.	Resistance.	Weight.	Number.	Resistance.	Weight.
6	10 ohms	550 lbs.	11	25 ohms	220 lbs.
7	12.1 ohms	455 lbs.	12	32.7 ohms	168 lbs.
8	14.1 ohms	385 lbs.	14	52.8 ohms	104 lbs.
9	16.4 ohms	330 lbs.	16	91.6 ohms	60 lbs.
10	20 ohms	275 lbs.			

Wire for Brooklyn bridge, bids . . . . "*Iron Age*," xix., Jan. 25, p. 14.
Wire for East River bridge, making . . . * "*Scientific Amer.*," xxxvi. 127.
Wire manufacture . . * "*Scientific American*," xl. 319.

TABLE OF WIRE RESISTANCE AND WEIGHT.

The following electric resistances are calculated for pure copper wire. The number of feet to the pound is only approximate for insulated wire.

Number.	Diameter.	Feet per Pound.			Resistance, Naked Copper.			
		Cotton Covered.	Silk Covered.	Naked.	Ohms per 1,000 Feet.	Ohms per Mile.	Feet per Ohm.	Ohms per Pound.
8	.12849	-	-	20	.6259	3.3	1,600.	.0125
9	.11443	-	-	25	.7892	4.1	1,272.	.0197
10	.10189	-	-	32	.8441	4.4	1,185.	.0270

Wire Belt. Machine straps of wire, as a substitute for leather, are being made.

The belts are made of the best crucible steel wire, in transverse network of 1 to 10 wires, in any desirable length or width. The two ends of the strap are joined like the middle, so that there is no beginning and no ending, the belt forming an endless band. All the wires run parallel only across the width, in such a manner that one wire catches into the other like a spiral, a continuous, densely woven chain being thus produced, the movability of which is so great as to enable it to go round the smallest pulley. The straps are also made with leather or elastic lining, or bordered with leather, elastic, hemp, hair-tape, or any other material, also its interstices filled with gutta-percha, to supply elastic bands with cotton web, and to prevent their stretching. The tightening of the strap — shortening of the chain — which is only necessary once, namely, when put on by means of a strap key, may be effected very easily and very quickly by taking out any desirable number of wires, and again joining the two ends in the same manner by twisting in the required number of wires.

Wire Book'-sew-ing. In this system of book sewing the book is "sewed flexible" upon tapes or wide bands (sawing the signatures being entirely dispensed with), and the work is equally well done upon all classes of books.

Every signature is sewed "all along" by independent tinned-wire staples, uniting them firmly to the tapes or webbing, thus securing the utmost strength and durability in addition to the valuable feature of thorough flexibility.

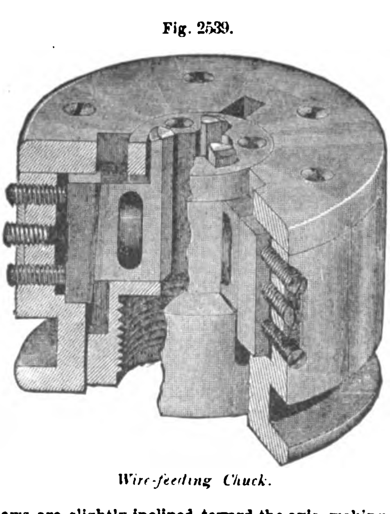
This system is equally adapted to all grades of edition and school book binding, from the cheapest to the most costly full bound books. Also for all classes of blank books, music books, and pamphlets of one or more signatures.

Wire Cut'ting Scis'sors. A double pivoted projecting slide shears for use where there is not play for the common single pivot shears.

Wire-feed'ing Chuck. A screw machine, Fig. 2539. It has an adjustable chuck and wire-feeding apparatus. It is used for making the smallest screws of sewing machines, guns, etc., making from 1,000 to 3,000 screws per day. The chuck is operated while in motion, and the wire is fed through it automatically when loosened, without stopping for each screw. It is adjustable to any sized wire from $\frac{1}{8}''$ to 7-16″ diameter.

It has a hollow cylinder with an outer sleeve sliding upon it. The cylinder contains three jaws fitted to slide in slots which converge to the center; the inner sides of the jaws are parallel with the axis of the chuck, the outer sides of

Fig. 2539.



Wire-feeding Chuck.

the jaws are slightly inclined toward the axis, making each jaw a wedge. The chuck is attached to the machine by screwing the cylinder upon the tubular spindle. The sleeve contains three shoes, fitted into deep cavities which correspond in position to the slots in the cylinder. In the circumference of the sleeve are adjusting screws, so placed that when screwed in their points bear against the outer sides of the shoes until they conform, each to the inclination of its respective jaw in the cylinder. Each shoe has a pair of these adjusting screws, which may be fastened, after being adjusted to the wire, by a pair of set nuts which are tightened by a cone-shaped screw. When the sleeve is moved upon the cylinder toward the spindle, the shoes, acting on the inclined sides of their respective jaws, force them straight toward the center until they grasp the wire. The sleeve is operated by a fork-lever by pins projecting into a suitable groove in its circumference.

Wire Fence. Wires or strips of metal armed with barbs and stretched on posts.

It is nearly fifty years since experiments with wire fencing began to be made, and twenty-five years since it began to be much used. The method promised great economy, both in first cost and in the saving of ground space. Besides, the wire fence was less liable to be blown down, and it would not occasion snow drifts. On the other hand, it was soon found that it was rapidly corroded by the weather, and being inconspicuous was liable to be run down by cattle and horses. When "galvanized," the wire was more durable and more easily seen; and in spite of its inability to stop unruly cattle, wire fencing became widely adopted, particularly in the West, where it is estimated, as many as 150,000 miles of plain wire fencing have been set up since 1850. To make wire fencing stock-proof several devices have been invented and patented during the past ten years, to provide for arming the fence with cattle-repelling spines or barbs of metal.

The "*Holyoke Manufacturer*" states that during the four years the first barbed wire was put upon the market the sales amounted to between fourteen and fifteen thousand tons, and the demand has rapidly increased both at home and abroad. There are several manufactories, and in one instance the works cover three acres and give employment to 1,200 men. The wire is made from Bessemer steel, and is drawn in the usual way. The "galvanizing," or zinc coating, is done by heating the wire in suitable furnaces and drawing it from them, first through tanks of acid, and then through tanks of boiling zinc. A thin and even coating of zinc adheres to the wire, giving it both a handsome finish and a perfect protection from the chemical action of the atmosphere. The barbing is done by automatic machinery. These machines, as described by the "*Manufacturer*," are good specimens of American mechanism, and do their work with lightning-like rapidity, yet with mathematical accuracy. One of the main wires passes through the machine longitudinally. A second wire is fed into the machine at right angles to the first. At each revolution of a certain disk or wheel, the sharp end of wire number 2 is twisted firmly around number 1, and cut off so as to leave a sharp point on the incoming wire as before, while the bit of pointed wire cut off remains as a steel thorn attached firmly to wire number 1. This wire, thus armed with barbs at regular intervals, passes on to a revolving reel, where it is met by wire number 3, — a plain wire without barbs, — and by means of the reel motion is loosely twisted with it. The completed fence wire is thus really a two-strand steel rope, armed with barbs projecting in every direction. The great advantage, besides additional strength, that is secured by the second strand and twist, is an automatic adjustment to changes of temperature. When heat expands the metal the twist simply loosens, and when cold contracts it the twist tightens — all without altering the relative length of the combined wires. The reels upon which the finished product is woven are light, strong, wooden ones, suitable for shipping, and provided with cross-pieces at the ends, on which they can stand, and the barbed wire be protected from injury. Each of these barbing machines turns off 1,200 lbs. of barbed wire a day.

At present wooden posts are usually used as supports for the wire in putting up the fence. But it is believed that iron posts will sooner or later supplant the wood. For study, with a view to new and useful improvements the subject of metallic fences is a promising one for inventors. The demand increases not only with the decay of the old wooden fences, but also with every acre of new land that is opened up to cultivation.

Wire Find'er. (*Electricity.*) An instrument for testing insulation of wires. It has a short ear tube, with ferrotype diaphragm, which is placed in proximity to a magnet which holds the wire between its poles. — *Gott.*

"*Journal Soc. Teleg. Engineers*" . . * vi. 522; * vii. 77.

Wire Gage. An adjustable gage for measuring the diameter of wire, iron, etc.

Wire gage, on a standard * "*Scientific American*," xlii. 233.

Wire-han'dle Ma-chine'. (*Sheet Metal Working.*) A machine for straightening wire, forming it into oval or oblong handles, from 2″ to 3″ long, such as are used on petroleum cans, dripping pans, etc. No. 148 of "*Bliss's Catalogue,*" 1881.

Wire In'stru-ments. (*Surgical.*) Instruments for manipulating wire in surgical practice. The list includes —

Wire adjuster.	Suture wires.
Needles.	Wire twister.
Shot compressor.	

Wire Lath. A wire screen or netting that is applied in the place of wooden lath for holding plaster. It is claimed to be more secure against fire.

Wire Meas'ur-ing, Form'ing, and Cut'-ting. (*Sheet Metal Working.*) A machine for preparing wire for use in making up sheet-metal ware.

Bliss's automatic machine is adapted to straighten wire from the coil, cut it off in lengths not exceeding 72″, or form it into rings of from 4″ to 20″ diameter, suitable for pans, kettles, pails, brackets, etc., or into half-circles for pail-handles, etc.

It is driven by power, quite automatic, and works wire up to ¼″ diameter.

Wire Nail. A round nail made of wire, and used for attaching molding, metallic roofing, etc.

Wire nails, American . "*Iron Age,*" xix., March 15, p. 24.

Wire Pan. A cake-pan with wire screen bottom.

Wire Pla'ting. Immerse in sulphuric acid in which a piece of zinc is suspended. Then place in contact with a plate of zinc in a solution of water (100), tartaric acid (2), chloride of tin (3), soda (3). Let it remain 2 hours, and polish by passing through a draw-plate. — *Dr. Heeren.*

Wire Rope. Commodore Shufeldt has recently ordered the proper authorities of the Boston navy yard to make several 7″ steel wire hawsers. These will probably be the largest wire ropes ever made. The navy department has use for immense hawsers to tow monitors and vessels in distress. They are put on board the men-of war for use when required. The usual appliance is a 12″ hemp rope, but it swells when wet, and gets very heavy by absorption of water. The steel wire hawsers will be 5″ less in diameter, much lighter, non-absorbent, more pliable and durable, and in every respect better. This is a curious, and, in fact, wonderful advance in the application of steel and iron to commercial uses. A hemp hawser 12″ thick is a wonderful thing in itself, but a steel wire hawser 7″ in thickness, better answering the same purpose, is something fruitful of thought to the student in ship building and rigging.

Wire Rope Con-vey'ance. A system of aërial transit on suspended wire ropes has been established to connect the gasworks at Hanover with the neighboring coal station on the Hanover Altenbeck Railway, for the supply of coal to the works. The line crosses the Limmerstrasse and the river Ihme, and is about 625 yards in length.

There are 2 iron wire ropes placed 5′ 10″ apart, and employed respectively for the carriage of loaded and of empty wagons. They cross the Limmerstrasse at a height of 23½′, and the river at about 30′. The cables are respectively 1.12″ and 1″ in diameter, and are constructed of wire of 4 millimeters, about 1-6″, in diameter. They are supported on pulleys at intervals of 24 yards, except in crossing the river, on a span of 57 yards. Resting on pulleys, they are free to expand or contract. They are kept taut by weights of 5 tons and 4 tons respectively.

The wagons are drawn by means of a 9-16″ endless wire rope, supported on rollers at intervals of 60 yards, and driven by a 6-horse steam engine at a speed of 3 miles per hour. The wagons are constructed of sheet-iron, and are capable of holding 3 hectoliters, or 106 cubic feet of coal; they are suspended from the carrying ropes on 2 grooved wheels, one in advance of the other, between which the attachment of the wagon is made. The bodies of the wagons are swiveled, so that they may be easily emptied. They follow each other at intervals of about 60 yards. Allowing for delays, the quantity of coal carried at no time exceeds 180 tons per day of ten hours, and is frequently less, the average delivery being only 135 tons.

Wire Rope Thim'bles. A curved metallic eyelet for protection of the rope from wear.

Wire Rope Tow'age.

The ferry-boat, Waag, is a vessel of 120′ in length, 23′ beam, and 6½′ depth of hold, and draught is of 2½′, is propelled by "overhauling" a chain which lies along the bed of the river between Vienna and Pressburg. The same method is adopted on the Elbe and on other rivers of Europe for towage. The chain is laid on the river-bed, from end to end of the route. The steamer is provided with a winding-drum instead of paddle-wheels, and is thus fitted to haul in the chain at one end of the vessel and to pass it off at the other end.

This method of propulsion, where practicable, is claimed to be more economical of power than the ordinary methods, especially where, as in towing, the losses by slip and by oblique action of the paddle-floats become very serious.

Wire Rope Trans-mis'sion. The use of a round, endless wire rope running at a great velocity in a grooved sheave, in place of a flat belt running on a flat-faced pulley, constitutes the "transmission of power by wire-ropes."

Wire Spring Ma-chine'. A machine for making spiral wire springs.

The wire is first seized by a pair of rollers, one of which has a groove and the other a corresponding milled projection. It is passed under a guide roll, the position of which may be adjusted according to circumstances, and is then carried between a second roller and a guiding sheet which throws it forward. The position of the guide roll determines the diameter of the spiral spring, while the deviation of the second roller and guiding sheet from a position parallel to the first pair causes the spring to become spiral. This deviation is automatically regulated, and the machine is so constructed that when a double spiral has been finished the wire is cut at the proper time.

Wire Test'ing Ma-chine'.

The wire to be tested is held by two clamps, which are drawn apart by a screw and hand wheel attached to one. The other acts upon a long lever, to the longer arm of which a fine chain is attached, which is so connected with a weight that its tension increases in proportion to the movement of the lever. A rod which carries a pencil is attached to the lever, and by a spring the pencil is made to travel along a straight guide-piece. The paper upon which the line is drawn is moved perpendicularly to the direction of the wire through the agency of cog-wheels and a toothed rod. The ratio of the two movements is so chosen that a curve is he result, the abcissas of which, if multiplied by ten, yield the elongation of the wire, while the ordinates register the tensile strain.

Wood Bend'ing. The bending of hard wood, especially beech, is effected at present by means of hot water or steam, a process somewhat costly as regards fuel, and taking a long time. For overcoming these difficulties the following method has been proposed, chiefly for sieve hoops: —

Two rollers are used, one above the other, the upper one having less velocity, so that it acts by holding back, while the lower extends the wood fibers. When the board, thus bent, leaves the rollers, it is fastened in the mouth of the sieve. The upper roller is fluted, the under one smooth. If two smooth rollers were used a very much greater pressure would be necessary.

Wood Bend'ing Ma-chine'.

Fig. 2541 represents one modification of the machinery for bending timber, which has been brought by a number of years' practice to a high state of utility. It consists of a jointed mold made up of cast-iron sections which have two horizontal projecting arms on the flush side, the one above the other, forming a groove between them for the timbers. The end of each of these sections is circular, and is secured like hinges, interlocking in its adjoining section, and held together by a vertical wrought-iron pin. The sections thus united form a series of joints adjustable to any form, and may be extended to any length. This mold rests upon a

Fig. 2541.

Wood Bending Machine.

circular table with a circular frame beneath, 22' in diameter. This table, being 3½'' thick and pierced with slotted holes systematically arranged to receive the fastening of the mold, etc., is mounted upon a hollow shaft of cast-iron, 8'' in diameter, and has a screw-thread cut in its outer surface at the lower end, by means of which the table may be raised or lowered and made to bear a part or the whole of its weight on the shaft-bearing. On the lower edge of the table are circular cogs into which a pinion-wheel meshes, and the power applied to the pinion revolves the table. The table has an attachment fastened on the top at its edge, called the head-block, which receives the small end of timbers and plate-strap covering the outside of timbers. The larger end of timbers is confined in a massive cast-iron clamp, which also receives one end of plate-iron strap. This clamp is mounted upon casters, and having a vertical roller on its back at the larger end, is drawn along by means of the plate-strap as the table revolves, the roller in end of clamp bearing against a vertical bulkhead raised from the floor of the building while the timber is being bent into the groove of joint-mold. The clamp, and also the head-block, have screws passing through their ends, by the use of which pressure on the two ends of the timber is communicated. This end-pressure applied to the timber draws the strap straight and to its full tensile dimensions, and when thus brought up against the outside of the timber, the process of bending commences by revolving the table. A mold for bending knees is arranged upon the same table, and is complete in all its parts, details of which it seems unnecessary to describe. The whole machinery is massive and ingenious, although easily operated.

Wood'bu-ry-type.

Where the subject is in line a positive photograph of it (*i. e.*, positive by transmitted light) is made, and from this is obtained a relief in gelatine by the ordinary method, the result being that the hollows of the relief will all be of one uniform depth, this characteristic producing a level or uniform surface in the resulting mold, which is made by impressing this relief into metal by hydraulic or other pressure, or by the method stated in the second part of this invention. Where the subject is in half-tone, as in a photograph from nature, the process is as follows: In printing on the gelatine film there is interposed between it and the negative a photograph on mica or transparent collodion of what is known as mosquito netting, or Brussels net, which breaks up the resulting relief into a multitude of fine square or hexagonal lines. To obtain from this a printing block the means already described are employed, the resulting block in soft metal being capable of giving from 100 to 200 impressions; but where large numbers are wanted this block is electrotyped in the ordinary way. Diffused light is used to produce the block from half-tone negatives, as in that case the light in the parts that represent the whites creeps around the lines, thus obliterating them in that part, and leaving them strongest only in the parts printing dark. Another method is sometimes adopted: A negative of the network is taken by transmitted light, and copied together with the negative, thus producing a positive with the lines already thereon, from which a relief is made as stated.

The second part of this invention may be accomplished as follows: In place of using a thin film of collodion (as is generally used in the process called "Woodburytype") to hold the gelatine of the relief, a sheet of plate glass is first rubbed over with French chalk or ox-gall, and then coated with the bichromatized gelatine solution as now used. When this is dried and ready for use the side that was next to the glass is exposed for a few seconds to daylight before exposing it under the negative. This has the effect of causing a thin film of gelatine to become insoluble, which after subsequent exposure under the negative will not wash away, but form a support for the photographic image afterwards impressed, thus doing away with the expense and trouble of the double coatings as now practiced. When the gelatine relief is dried in the ordinary way, a thin sheet of tinfoil (same size as the gelatine relief) is attached by gum or other adhesive substance around the edges to the gelatine relief. A stout sheet of plate paper is laid on the back of this and the whole passed through an ordinary rolling press. The tinfoil is by this means impressed into all the details of the relief; but in this state it would be useless to print from. Therefore a shallow metal box is filled with a composition of shellac and asphalt, which on warming becomes soft, but hardens on cooling. This box is placed on a hot plate until the composition softens; it is then placed on the lower plate of the ordinary Woodbury printing press, the foil and relief laid on it, the press closed, and the pressure applied by the under screw. When the composition has hardened the tinfoil adheres to it. The gelatine relief is removed from the foil, and the foil-backed mold used to print from. In place of fixing the proofs by alum or other substance of a like nature, they are varnished with an ordinary varnish composed of shellac and alcohol, giving the print an effect of a photograph on albuminized paper, at the same time protecting the surface from moisture. Sometimes the composition is melted in boxes and used without the foil as a printing mold direct;

when sufficient numbers have been printed the box holding the composition is again heated and can be used over and over again.

The third part of this invention consists in an improved method of printing "Woodburytype" by machinery. This is accomplished as follows: Out of a solid block of iron a cylindrical hole is turned, in which is made to fit very loosely a cylinder of soft metal having a taper or conical hole through it lengthwise. Between the interior of the steel block and the soft metal cylinder the gelatine reliefs are inserted: then, by means of a taper or wedge-shaped spindle (roughened), by hammering or by pressure the soft metal is driven against the iron cylinder, thus impressing the relief on the outside of the metal cylinder, the taper spindle at the same time forming a shaft for the cylinder to be used in the process of printing. This roller, bearing the relief, is then mounted in vertical slots in a frame having a bed of plate glass on which the paper rests, the roller resting on the glass its own weight and being dragged round by the paper itself; or in place of the glass plate the soft metal cylinder is allowed to lie on another fixed or movable roller of metal or glass. The latter may be hollow so as to reduce its temperature in hot weather by a stream of cold water running through it.

Wood'chop-pers' Maul. A large wooden sledge with heavy iron-bound head for driving wedges used in splitting wood.

Wood'en Floor Mat. A sort of grating made of strips of wood, used as a door-mat.

Wood'en Pave'ments.

A rigid foundation of bituminous or cement concrete is universal. This costs more than sand, but it is permanent, and will prevent the blocks from sinking under the wheels. English engineers, in discussing pavements, call the foundation the true pavement, the blocks being the wearing surface only. The "Henson" pavement, with some modifications, is the best for this country. Instead of a layer of tarred paper on the concrete, use a thin layer of pitch, with oil enough in it to make it permanently slightly plastic, setting the blocks upon it while hot and soft, using the strips of tarred felt between the rows, and driving the blocks together. The tarred felt would make a very close joint. Then pour melted pitch over the whole surface, taking care to fill every crevice, and upon this spread fine sharp gravel, which will work into the ends of the blocks and form a surface resembling macadam, and afford a far better footing than wide spaces between the rows, which serve as receptacles for mud and dust. It is easy to keep this pavement clean. No water can penetrate it, so that it will not be injured by frost. The blocks themselves, if creosoted, will not absorb water, and if laid without spaces between the blocks, the drainage will be surface drainage solely, which is of the first importance.

But the pavement would be short-lived if *green* and wet blocks are used. It is not practicable to use, as Mr. North says is the case in London, "wood better seasoned than the pine generally used by house carpenters in this country." Seasoned wood cannot be obtained in sufficient quantities here. But, what is far better, it can be preserved from decay.

No faith can be placed in any method of wood preservation for paving blocks which does not exclude water. The blocks are so short that any soluble preparation is quickly washed out of them, and, if not made waterproof, they are certain to absorb the seeds of destruction from the filth in the streets. The blocks should be well saturated with creosote oil, whose chemical constituents act preservatively upon the fibers of the wood by coagulating the albumen of the sap, while the fatty matters act mechanically in obstructing the pores of the wood and keep the water out. At the same time, as oil cannot be injected into wood full of moisture, the thorough artificial seasoning which forms a part of the process of creosoting as carried on in this country, is as useful to the timber as any of the metallic salt processes.

By thoroughly creosoting the blocks, expansion and consequent throwing out of the blocks is prevented. They will not shrink or expand. The wood is also rendered homogeneous; the sap wood becoming as durable as heart wood. Looking to sanitary considerations, the creosoted wooden pavement is perfect. The carbolic acid contained in the oil is a powerful disinfectant, and as the pavement described will not absorb any deleterious substance from the surface, it has only to be kept clean to maintain the best sanitary condition.

Wooden pavement, Lond. "*Scientific American*," xxxv. 115.
On, (many figures) . * "*Engineer*," xlv. 171, 314.

Wood'en Rail. For wooden rails the best wood is maple, laid with the heart up; hard pine is used in the South.

The simplest form of wooden rail is a stringer cut in 16′ to 20′ lengths, and of such cross-section as the kind of wood or weight of engine requires. 6″ square is usually the best size for stringer, although 5″ face by 7″ depth, is sometimes as good. 4″ face by 6″ depth, or 5″ square, will answer for small engines, if the wood is good; still smaller sizes may be used by placing the cross-ties close together, say 2′ or 2½′ between centers; for large stringers, 4′ between centers will answer. When worn out on top the stringer may be reversed, and when again worn out may be used for ties.

The ties are more easily fitted and laid if made uniform, and of about the same size lumber as the rails; 6″ square is heavy enough. Any cheap lumber not specially liable to decay will do. Ordinary hewn ties may be used, but not being uniform are less convenient for cutting out recesses for rails. They should be at least 3′ longer than the width of the track between rails. The ties must be cut out accurately and uniformly to receive the rails. The recesses should be about 3″ deep, and be at the top face of the tie 1″, and at the bottom of the recess 1½″ wider than the rail. The inner faces of the recesses are perpendicular, and the distance between them is the gage of the track. The bottom of the recess should be level, and ties laid well to afford proper bearing for the stringer.

Wedges made of any cheap wood, or better, of ends of stuff left from rails, are driven on the outsides of rails. They are made of right shape to fit the space left; the reason for making this space wider at the bottom than at the top, is to keep the wedges from working up, so that the rail may be held securely in place.

The stringers must be arranged to break joint on the ties. Both stringers should not break joint on the same tie. The stringers are sometimes sawed off diagonally instead of perpendicularly, so as to lap and be spiked altogether. The cost of lumber for a hard pine wooden road will be about $450 per mile.

With another style of wooden road the stringer is made of hemlock or any cheap lumber, and a maple strip 4″ to 5″ wide and 2½″ to 3″ thick is spiked on to the stringer. By this plan, such a part of the rail as is worn out may be removed without taking up the stringer. The maple strip may be replaced by a T-iron rail considerably lighter than would be required if laid directly on cross-ties; this is preferable to strap iron.

A wooden rail is very slippery when wet, and hard to keep clear of snow and ice in freezing weather. On very bad curves and steep grades a wooden rail is impracticable, and iron must be used.

A locomotive has but one half or two thirds the power on wood that it has on iron; the friction useful for traction is less, and the flange friction is greater. Locomotives for wooden rails should be built very strongly and evenly balanced; the weight should be less, and the drivers larger than for the same size of cylinders on iron rail. A locomotive with six wheels connected, or with four drivers and a two wheel truck, is preferable to a four-wheel engine for wooden rail.

Wood'en Wall Cov'er-ing. A veneer surface for wall paper.

The wood is cut to the thickness of paper, and by a peculiar process stuck on the paper, which serves as a protection against the influence of the walls on the graining and color of the wood. The delicacy of the machinery employed in cutting so thin a veneer may be gathered from the fact that 200 leaves are cut out of an inch of white maple wood, and 125 out of wood with very open grain, such as oak and walnut.

Wood Fa'cing Ma-chine'. A machine used in the manufacture of furniture, sash, doors, patterns, agricultural implements, etc.

It is adapted for planing out of wind, making bevel or square glue joints, facing and edging, surfacing straight, squaring, beveling, etc. The work, as it passes over the tables, needs no dogging or exertion to hold it.

The tables are drawn back or pushed forward, to regulate the cut, by a screw, while the machine is running. The motion of the tables on the wedges, while regulating the cut, secures at the same time a uniform distance from the knives.

Wood Oil.

The curious product of India, called by the English *wood oil* or *Gurjun balsam*, forms the subject of two papers published in the "*Pharmaceutical Journal*," by Messrs. Charles Lowe and Daniel Hanbury. Mr. C. Lowe, who only knew that this resinous liquid is extracted in India, by incisions made in the tree, considers it as a *Copaiva balsam* rendered turbid by a greenish resin held in suspension. The filtered balsam forms a brown and transparent liquid, from which we withdraw by distillation —

Volatile oil	65
Hard resin	34
Water and acetic acid	1

According to Mr. Lowe the volatile oil possesses all the characters of that of copaiva, and the *hard* resin, which he regards as pure *copaivic acid*, free from the *soft* resin, which, according to him, exists in the most part of commercial copaivas, seemed to him to indicate a superior quality as a medicine.

Wood Pre-serv'ing.

The various processes for preserving wood have for their object the prevention or arrest of fungoid growth. This is sought to be accomplished by two main systems; one of which consists in impregnating the wood with a solution of a metallic salt, such as corrosive sublimate, chloride of zinc, or sulphate of copper, and the other includes the several creosote processes. The action of the salts named is purely chemical, and as they are introduced in watery solution, it is evident that subsequent exposure to moisture tends to redissolve them and leave the wood unprotected. Creosoting, while producing the same result chemically, also secures dryness, which alone is sufficient to prevent decay, provided that it can be maintained.

In creosoting, it is essential that the wood should be thoroughly dried, in order to secure complete impregnation, and hence timber is usually seasoned for months before treatment. This is a serious objection, which inventors have attempted to remedy by adding a preliminary dessicating operation. At extensive works at South Boston, Mass., a process known as the Hayford is in use, which consists in drying the timber *in vacuo*, and then impregnating it with creosote oil under pressure. Green timber is fed by a rail track into an air-tight cylinder of boiler iron, 100′ long and 6′ in diameter. This cylinder has been tested by hydrostatic pressure of 200 lbs. to the square inch, and is capable of being hermetically closed. When the charge is in, steam is introduced, raising the temperature gradually, so as not to harden the outside of the wood and prevent the escape of moisture from the interior. Atmospheric air is also forced in at a pressure of from 80 to 40 lbs., to restrain the tendency of the wood to crack. A temperature of 250° to 270° is found sufficient to evaporate the sap, and the whole steaming process occupies from 4 hours for boards to 10 or 12 hours for heavy timber. When it is certain that the sap and vapor have been turned into steam, the direct steam is shut off, and air pumps set to work to free the cylinder from the steam, vaporized sap, and result of condensation. This stage is reached in about an hour. The cylinder being made tight again, and still heated by the coil, a vacuum pump is put in action. Then the creosote oil, previously heated to near the boiling point to render it limpid and penetrating, is introduced under a pressure of 60 lbs., which, added to the drawing power of the vacuum, makes a total pressure of over 70 lbs. to the square inch. The hot oil soon impregnates the wood. If the timber is of very close fiber, the pressure is raised to a higher point. The process completed, the charge is withdrawn and another takes its place.

The process known as "Beerizing timber," takes its name from Sigismund Beer, a chemist of New York City, who discovered that by the use of borax as a solvent the coagulation of sap is prevented, and this without injury to the wood tissues. The obnoxious ingredients being thus removed, the wood is rendered closer in grain and thereby improved in appearance, becomes impervious to decay, and remains unaffected by atmospheric changes.

A recent number of the "*Annales des Ponts et Chaussées*" gives the following information, furnished by the officers of the railway from Hanover and Cologne to Minden. The proportion of pine ties, injected with zinc, renewed after 21 years, was 21 per cent.; beech ties, injected with creosote, renewed after 22 years, 46 per cent.; oak ties, not injected after 17 years, 49 per cent.; oak ties injected with chloride of zinc, after 17 years, 20.7 per cent. The ties which were not renewed appeared perfectly sound. Since 1870 the Emperor-Ferdinand Northern Railway has used only oak ties, injected with either creosote or with chloride of lime.

Hatzfeld recommends, in "*Eisenbahn*," for this purpose the injection of tannin in form of decoctions of substances containing it, as for instance, chestnut and oak bark. The wood is treated with these decoctions in closed vessels at high pressure, and afterwards treated with a solution of the pyroacetate of the sesquioxide of iron. The latter is transformed into a tannate and finally converted into a salt of the oxide by oxidation. This process has now been generally introduced by the larger railroad and telegraph companies in France.

Mr. Lostal, a French railroad engineer, recommends lime as a preservative for wood. He puts the wood to be prepared in large excavations in the ground, and covers them with freshly calcined lime, which is gradually slaked by the addition of water. Wood to be used for mining structures must remain in the lime about 8 days before becoming fully impregnated. The wood becomes exceedingly hard and never rots. Beechwood prepared in this way has been used as material for hammers and other tools in several factories, and is said to have become as hard as iron, without losing its peculiar elasticity. At Strasbourg, lime slacked in a solution of chloride of calcium is used as a fire and weather proof pigment for woodwork.

Wood Pulp Pa'per.

In wood paper manufacture the split 4′ timber is fed into a circular fan-like hopper provided with swiftly revolving steel knives, which cut the timber into small chips in very short order, when a fan drives them up into the loft, where they are shoveled into two steel digesters holding from four to six tons each. Soda ash, and other chemicals, are introduced, a heavy head of steam is turned on, varying in different mills from 100 lbs. to 200 lbs. pressure to the square inch, and the chips are thoroughly separated. Then the pulpy mass is washed out into vats to drain off the chemicals, and after it has become solid it is again washed out and pumped up into the engines and beaten, and the usual process of paper-making is then gone through with.

Some makers think evergreen woods far preferable, as having a larger and more hardy fiber.

The year 1846 — when the German engineer, H. Völter, began his experiments of using, instead of vegetable fiber from flax and cotton, wood fiber, which he prepared by quite a simple expedient — was the beginning of a branch of industry which is already of great importance to Sweden, since that country possesses just what is chiefly required for it: abundant supplies of fir-forests and large waterfalls. The first factory established on this Völter's system was at Trollhättan, in 1857, and for ten years was the only one of its kind, until here and there in the country they began to establish others, so that in 1870 there were six; but from this time their erection was very rapid till 1873, when there were twenty-seven wood-pulp factories already completed or nearly so: but since that time none have been erected.

The observations and inventions made in this branch of industry have not been unnoticed, and therefore the manufactories are calculated to be worked, partly on the chemical and partly on the mechanical method. The chemical method is as yet so new, that it is difficult to say what development it will enjoy. It is certainly true that in this way a better and more fibrous pulp is obtained, but in proportion to the ground pulp, it is also dearer, especially since caustic soda, which is needed for the manufacture, has considerably risen in price. The grindstones that have hitherto been employed in the mechanical method have as yet been generally obtained from Germany, the cause of which cannot be that the material required for it is wanting in Sweden, but rather at the new-established works they have wished to avoid experiments at first, and hence the stones have been brought from such places, where they have already been practically tried. All the machinery, on the other hand, is now made in the country.

The Swedish wood-pulp manufactories extant at the beginning of 1873, may be divided as follows: —

I. *Mechanical*, new works where 100 horse-power is calculated for each grindstone:

a. Eleven Völter's manufactories with vertical grindstones, and the supplying of the pieces of wood by a screw-mechanism. Of these the oldest (Trollhättan) has twenty stones, of which the greater number are small; but besides, there are several large establishments with from five to six grindstones of from 5 to 5½′ in diameter.

b. Two Hartmann's, with small vertical grindstones, and supplied by weights.

c. Four Siebrecht's, with large horizontal grindstones, and supplied by hydraulic pressure.

II. *Chemical*, generally provided with two boilers:

Ten manufactories constructed on different methods (Sinclair's, Lee's, Fry's, etc.). The boiling is generally done with caustic soda, in weight about 25 per cent. of the wood, besides, the so-called half-chemical method is applied, consisting in boiling or steaming blocks of wood, and then grinding them in the usual manner. Some of the more recent paper manufactories in the country manufacture from such pulp a kind of paper very good for wrappers and sheathings.

Wood Screw. A square-headed screw with a coarse thread for fastening together wooden frames.

Wood screws.	"*Scientific Amer.*," xl. 24.

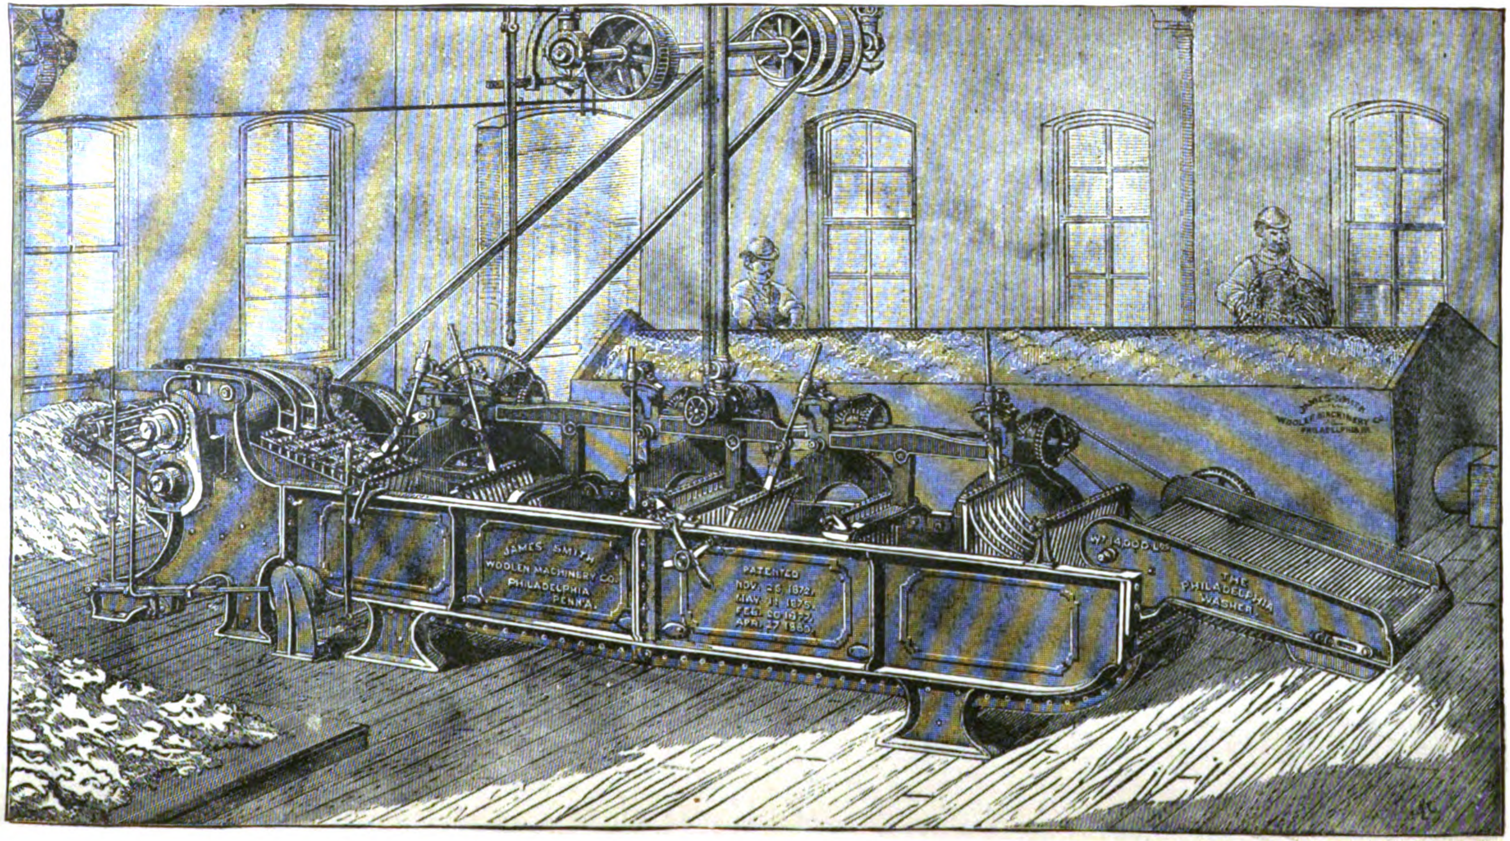

PLATE LVI. WOOL WASHING MACHINE. See page 965.

Wood Stain'ing.

In most cases the staining of wood may be effected so as to produce very bright colors without any previous preparation, as, generally speaking, the mordants employed have a bleaching action on the wood. But in many cases, in consequence of the quality of the wood under treatment, it must be freed from its natural colors by a preliminary bleaching. To this end it is saturated as completely as possible with a clear solution of 17¼ oz. chloride of lime and 2 oz. soda crystals, in 10½ pints of water. In this liquid the wood is steeped for half an hour, if it does not appear to injure its texture. After this bleaching it is immersed in a solution of sulphurous acid, and then washed in pure water. The sulphurous acid which may cling to the wood in spite of washing does not appear to injure it or alter the colors which are applied.

Red. — The wood is plunged first in a solution of 1 oz. of curd soap in 35 fluid oz. of water, or else is rubbed with the solution; then magenta is applied in a state of sufficient dilution to bring out the tone required. All the aniline colors behave very well on wood.

Violet. — The wood is treated in a bath made up with 4¼ oz. olive oil, the same weight of soda ash, and 2½ pints of boiling water, and it is then dyed with magenta, to which a corresponding quantity of tin crystals have been added.

Blue. — Prepare as for violet and dye with aniline blue.

Green. — Mordant the wood with red liquor at 1° B. This is prepared by dissolving separately in water 1 part sugar of lead and 4 parts of alum free from iron; mix the solutions and then add one thirty-second of a part of soda crystals, and let settle over night. The clear liquor is decanted off from the sediment of sulphate of lead and is then diluted with water till it marks 1° B. The wood when mordanted is dyed green with berry liquor and extract of indigo, the relative proportions of which determine the tone of the green.

The wood, mordanted, as above directed, can also be dyed a fine blue with extract of indigo.

Yellow. — Mordant with red liquor and dye with bark liquor and with turmeric.

Besides the aniline colors cochineal gives a very good scarlet red upon wood. Boil 2 oz. of cochineal, previously reduced to a fine powder, in 35 oz. of water for three hours, and apply it to the wood. When dry, give a coating of dilute chloride of tin, to which is added a little tartaric acid, 1 oz. of chloride of tin, and ½ oz. of tartaric acid in 35 fluid oz. of water. If instead of water the cochineal is boiled in a decoction of bark (2 oz. bark to 35 oz. of water), and the chloride of tin is used as above, an intense scarlet, and all shades of orange, may be produced according to the proportions.

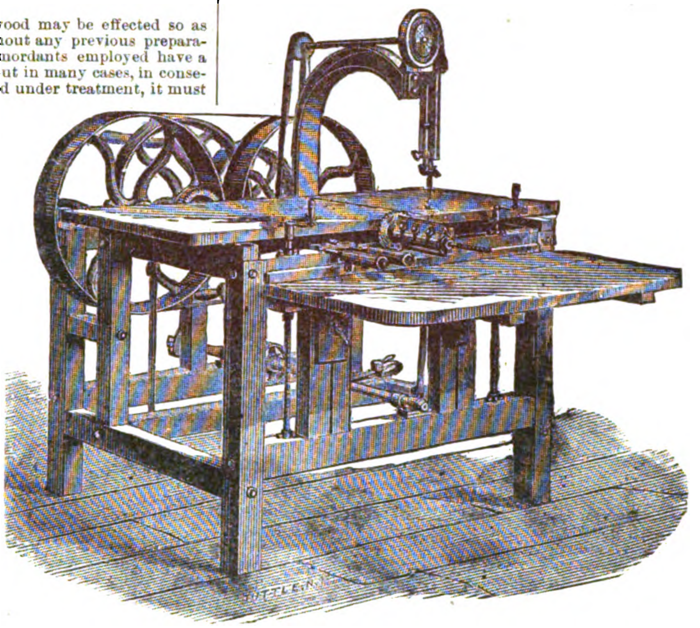
Brown. — Various tones may be produced by mordanting with chromate of potash, and applying then a decoction of fustic, of logwood, or of peachwood.

Gray. — Grays may be produced by boiling 17 oz. orchil paste for half an hour in 7 pints of water. The wood is first treated with this solution, and then, before it is dry, steeped in a beck of nitrate of iron at 1° B. An excess of iron gives a yellowish tone; otherwise a blue-gray is produced which may be completely converted into blue by means of a little potash.

Black. — Boil 8¾ oz. of logwood in 70 oz. of water, add 1 oz. blue stone, and steep the wood for twenty-four hours. Take out, expose to the air for a long time, and then steep for twelve hours in a beck of nitrate of iron at 4° B. If the black is not fine, steep again in logwood liquor.

Wood'work-ing Ma-chine.' The Greenwich Combined Woodworking Machine, Fig. 2542, is a machine for circular and scroll sawing, surface molding, planing, mitering, and boring.

Fig. 2542.



Woodworking Machine.

The scroll saw has a positive motion, and there is a steel bearing at the back of the saw that steadies and keeps it firmly in its place when running, so as to enable those inexperienced in the use of the scroll saw to do true work. Any desired rake can be given to the saw, by turning the hand-screw behind it.

The cutting edges on planing and molding machines should move at a velocity of 6,000′ per minute. Where hard wood exclusively is worked the feed should be one fourth less.

Teeth of circular saws should travel about 9,000′ per minute.

Teeth of band-saws should travel about 4,000 per minute, to obtain the best results.

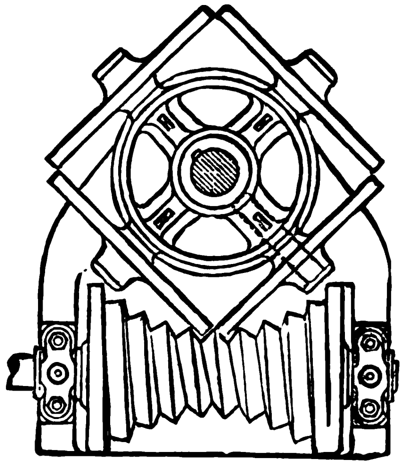
Wool "Ex'tract." Wool recovered from worn mixed fabrics where the cotton has been destroyed by a chemical process. In the year 1865 the amount of *extract* used was 5,000,000 lbs.

Wool Hat Ma-chin'e-ry. See HAT MACHINERY; also the various special machines under the caption HAT, as HAT FULLING MILL; HAT BLOCKING MACHINE, etc., etc.

Wool Wash'er.

Plate LVI. represents "Smith's" wool washer. The ducker is attached to the rake, next to the feed apron, and serves to duck or push down the stock into the liquor. The stock is forced under by the curved lines, as it drops from

Fig. 2543.



Worm Gearing.

the feed apron, and it is carried at once to the bottom of the bowl. A valve outlet is so arranged that the stock cannot wind about the valve levers.

Steam has access to the water through numerous small holes pierced through a pipe extending lengthwise of the machine, under the false bottom, thus distributing the heat. The water is supplied through a chamber in the side of the bowl, obviating any splash in filling it. A double-acting carrier takes the stock up and delivers it to the press rolls. The carrier has teeth, the rear rank of which are nearly as long as those of the stirrer fork. On its forward movement the carrier engages with the stock and takes it up over the face of the chute.

The cone pulley on the main driving mechanism is driven from a like cone pulley on the counter shaft.

Wootz. The genuine Wootz steel comes from India in three forms, namely, in bullet-shaped pieces of a certain weight as they cool in the pots, and which comes from Calcutta; in cakes of 2½ lbs. from Bombay; and in cylindrical rods of about the same weight from Golconda. See "*Mech. Dict.*," pp. 2364, 2818.

Work'er. (*Leather.*) A two-handled blunt knife curved to suit the inclined face of the beam, and used to scrape the hides.

Work'ing Glove.

Ordinary gloves used in husking corn and doing other similar kinds of work, wear out first upon the tips of the fingers and thumb, and upon the ball of the thumb. To obviate the unequal wear, and to render the glove more serviceable, a glove has been devised the body of which is of the ordinary form and materials, and to its inner or palm side are attached pieces of cloth upon which, in places subjected to the greatest wear, there are surfaces that are covered with a protecting coating of sand and rubber. Instead of applying the protective coating to the cloth in this manner, it may be applied directly to the face of the glove.

The rubber coating protects the glove and renders it waterproof at the points to which it is applied, and the sand assists materially in removing the husks from corn; it also renders the glove more effective in grasping objects of any description.

Worm Gear'ing. Hawkin's gearing, Fig. 2543, is a new modification of worm gearing.

It has an arrangement for transmitting circular motion in either direction. It is a plan in which the spiral worm is made of such a length that the edge of one roller does not cease contact until the edge of the next comes into contact; a wheel carries four rollers which turn on studs, the latter being secured by cottars; the axis of the worm is at right angles with that of the wheel. The edges of the rollers come near together, leaving sufficient space for the thread of the worm to fit between any two contiguous rollers. The pitch line of the screw thread forms an arc of a circle, whose center coincides with that of the wheel, therefore the thread will always bear fairly against the rollers and maintain rolling contact therewith during the whole of the time each roller is in gear, and by turning the screw in either direction the wheel will rotate.

Worm'ing. (*Nautical.*) Laying of yarn in the cant of a rope to bring it to a rounder surface before *parceling* or *serving*, which see.

Worm'-thread Tool'-gage. A gage that furnishes a correct guide of form for tools used in turning the threads of worms, when the worm wheels have been cut to correspond. The figures on the gage represent the number of threads per inch of the worm. The slots in the gage are also of the proper depth for their respective threads.

Wor'sted. (*Fabric.*) From Worsted, in Norfolk, England. The wool-workers of that place adopted a comb in carding and a harder twist in spinning, which gave the name to its products.

Wound Ex-plor'er. (*Surgical.*) An electric sound used in searching for bullets.

The electric wound explorer of M. Trouvé, of Paris, was presented to the Academy of France in 1867.

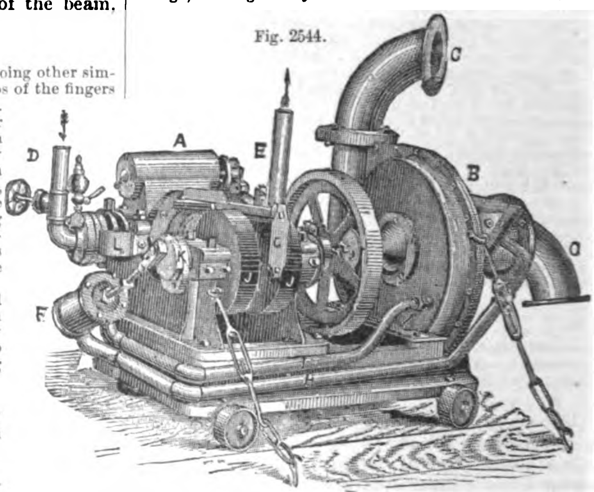
Wo'ven Wire Belt'ing. Woven steel wire belting is claimed to transmit power well, to operate without lengthening, and to run smoothly because there is no overlapping at any place. The spirals of wire are woven across the belting, so that three, four, or more spirals form one link. The space between two links is, besides, filled up with a cross-piece, so that the closely woven netting of spiral wire forms a band of great strength and flexibility. It is faced and lined with rubber or leather.

Wreck'ing Pump.

The "Heald" steam pump, Fig. 2544, is for use in pumping out wrecked vessels. It is actuated by an oscillating engine of short stroke. The rolling valve within the valve-chamber on the cylinder is worked by an eccentric from the engine-shaft. The guides for relieving the strain on the piston-rod project from the head of the cylinder, and are partially concealed by the counter balance-wheels. There is a force-pump used for priming the main pump through the pipes.

It is operated by friction-wheels, connected or disconnected by a lever. There are swiveled elbows for suction and discharge, turning in any direction and detachable. There is a

Fig. 2544.



Wrecking Pump.

device in the cross-head of the guides for taking up the slack occasioned by wear of the parts. There is also a bale, with tubular trunnions, in conjunction therewith for securing a better connection of the steam-pipes with the engine.

Wrench. A lever having jaws at one end adapted to catch around the head of a bolt, or around a nut to loosen or tighten the nut on the bolt.

One jaw is often made adjustable. The "Alligator" has ratchet teeth cut diagonally across one jaw, thus enabling it to bite with three teeth at once. A single wrench will hold many sizes of nuts or bolts.

Robinson's crank-wrench and bit-brace is a combination of the wrench, crank, and brace. It is intended in its crank movement to provide a wrench that will not require to be readjusted at each half-turn; a rotary wrench that turns without removal till the nut is advanced to its place.

As a brace it is clamped to the bit by the set-screw that drives the movable jaw and holds the same. As a vise it is inverted and secured to the bench by a clamp.

The "Baxter" wrench has adjustable sliding jaws that are connected by a set screw that contracts them to their embrace.

The "Rogers" wrench is an elongated ring bar device, diverging to a larger capacity at one end so as to hold nuts of all sizes. A bevel rigidifying sleeve that clamps to the square of the nut, holds it while being operated on.

Wrench Han'dle. A double-arm wrench for use with dies for cutting threads, and other purposes.

Wri'ting. For restoring faded writing. Brush it over with a solution of ammonium sulphide.

M. Von Bibra, in the "*Journal de Chimie*," describes a method of restoring the writing of old manuscripts and the colors of oil paintings which have faded or become discolored by age. For the manuscripts, the writing is treated with recently prepared ammonium sulphide, and in the course of a few moments the characters become distinctly visible. Any excess of the reagent must be removed by washing in cold water, and the manuscript is then dried, either by gentle heat or by means of blotting-paper. Should the characters fade again after this treatment, they should be submitted to the action of a solution of tannin. As it is only in far distant times that carbon writing fluids were used, and as nearly all the more recent manuscripts have been written in gallate ink, it may be said that M. Von Bibra's method can be employed with any writings. For the oil paintings, after having dusted them with a wash leather, they are washed with a sponge and fresh water; they are then covered with a solution of soap (the author recommends shaving-soap, probably that which is known in France as *crême de savon*), which is wiped off with a brush after the lapse of from eight to ten minutes, and when the soap has been completely removed the painting is allowed to dry. It is then rubbed with a soft linen cloth soaked in nitro-benzine, which restores the luster. Lastly, a little olive oil is passed over it, and it is varnished with a white varnish.

Wri'ting Tel'e-graph. Cowper's writing telegraph, unlike previous autographic systems, does not depend upon electro-chemical decomposition. A pencil is moved at the sending station, and at the receiving station a pen charged with ink describes the same movements.

The sending apparatus consists of a pencil under which a continuous band of paper is drawn by clockwork. Attached to the pencil are two light rods placed at right angles to one another. When the pencil is moved, the curves made in forming the various letters cause the ends of these rods to make a series of lateral and longitudinal movements. These ends of the rod pass over the ends of a bundle of brass plates, connected each with a resistance coil, so that their movements over them transmit to the distant station currents of varying intensity. These are utilized at the receiving station in the following manner: There are two strongly magnetized needles on delicate bearings, forming movable cores in coils, which are placed between the poles of four permanent magnets. These magnetized needles are also placed at right angles to one another. Fastened to the point of each is a thread, and these two threads cross one another and are knotted together at the point of intersection. At this central point they carry a tiny pen, consisting of a glass hair-like tube of syphon form, its upper end dipping into a little cistern of limpid analine ink. A traveling slip of paper passes slowly beneath this pen, and as it moves a straight line of ink is drawn upon it. But directly the operator at the sending station begins to write with his pencil, the varying currents thus caused, in the manner indicated, impart varying degrees of strength to the magnets surrounding the needles. The needles are consequently endowed with movements of greater or less amplitude. The crossed threads are pulled by the moving needles, and the curves of the written letters are reproduced by their combined action. By this machine the question of sending autographic messages, so important in many government and commercial affairs, has been solved in a simple and ingenious manner.

X.

Xan'the-ine. (*Chemical.*) A yellow substance soluble in water, which forms the coloring matter of some yellow flowers.

Xan'thi-an. A kind of marble found near Xanthus in Asia Minor.

Xan'thid. (*Chemical.*) A supposed compound of xanthogen with some basifiable or acidifiable element.

Xan'thite. A mineral occurring in rounded grains and foliated masses, of a yellow color, and translucent, consisting chiefly of silica, alumina, lime, oxide of iron, oxide of manganese, and magnesia.

Xan'tho-core. A mineral of a dull red or brownish color, consisting chiefly of sulphur, arsenic, and silver.

Xan'tho-rite. A variety of allanite, of a yellowish color, and containing much water.

Xe'bec. (*Nautical.*) A small three masted vessel used in the Mediteranean Sea. With a fair wind in good weather, it carries two large square sails; when close hauled it carries large lateen sails.

Xy-lan'thrax. Wood-coal, or charcoal. So called in contradistinction from mineral coal.

Xy'lite. (*Mineral.*) A mineral resembling xylotile, of a brown color and asbestiform structure, and consisting chiefly of silica, sesquioxide of iron, lime, magnesia, and water.

Xy'lo-phone. An instrument to determine the vibrative properties of woods and metals.

M. Decharme experimented a short time ago on the musical sounds given by metallic bars of different metals having the same dimensions. He has made similar experiments on different kinds of wood. Notwithstanding the diversity of the kinds of wood examined (38 species and 14 varieties) they were all found to give sounds comprised in the interval of an octave. The most grave sound is mi_4, given by box; the highest mi_5 given by Northern fir. M. Decharme gives a list of the sounds emitted by different woods between the two extremes. The range of sounds from the metals extended from 690 vibrations for lead to 2,762 vibrations for aluminum. Sounds from wood are comprised between those for brass, 1,303.62, and aluminum, 2,762. This is no doubt partly accounted for by the much less range of densities in woods than in metals. Still there are anomalies. Thus, the willow, which, after the poplar and certain firs, was the lightest of the woods experimented on, gives the same note (sol_4) as ebony, which is the heaviest after the tea and the palisander. It was difficult to appreciate the intensity and the duration of the sounds, but palisander, logwood, walnut, and acacia were in the front rank in this respect. (The durations of the sounds did not exceed the fraction of a second 0.5 to 0.7, for the most sonorous palisander.) Northern fir and poplar had the clearest timber.

Y.

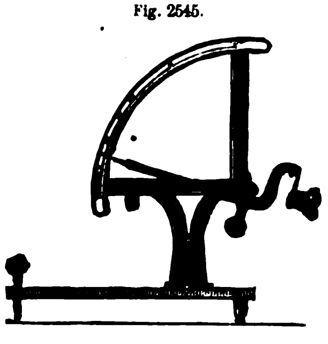
Y. Or fork, for holding boring bars by the square. See also CLAMP.

A branching pipe having a bifurcation like the letter Y. See BRANCH.

One of the forked pieces that support the pivots of a transit instrument, of the telescope, or the theodolite, etc.

Yarn As-sort'er. Fig. 2545 represents an apparatus for the assortment and graduation of yarns.

Fig. 2545.



Yarn Assorter.

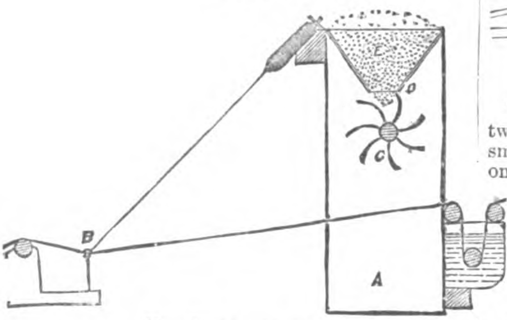
A skein is placed in the cup suspended from the rear arm of the pointer, when the number is immediately indicated on the graduated scale.

Yarn Flock'ing Ma-chine'. *Le Jacquard* gives a description of an apparatus which, though crude, is intended to produce a new effect in the appearance of certain yarns for fancy goods.

The yarn to be manipulated, according to this plan, is passed through the apparatus before being doubled. One thread passes direct from a cop or bobbin, and the other through a trough containing water or a thin solution of size. The latter is then carried through a box, provided at its upper end with a hopper filled with particles of colored wool, broken fiber from rag-ends, feathers, or any desirable substances, which are allowed to fall through an opening at the bottom of the hopper, and upon a revolving fan-wheel which pulls it out and disperses it, throwing it upon the thread passing through the lower part of the box.

In a modification of this arrangement a traveling apron

Fig. 2546.



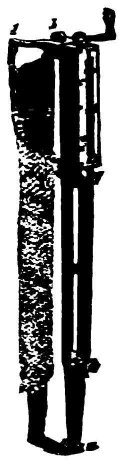
Yarn Flocking Machine.

runs under the threads, and carries any superfluous flocks or feathers back into the hopper. In this manner any foreign substance may be evenly or intermittently twisted into the yarn.

Yarn Print'ing Ma-chine'. A machine for printing warps for tapestry carpets. Short's patent, No. 168,932, Oct. 19, 1875. See TAPESTRY CARPET; CARPET LOOM.

Yarn Test'er. An instrument for testing the strength of yarn. See Fig. 2547.

Fig. 2547.



Yarn Tester.

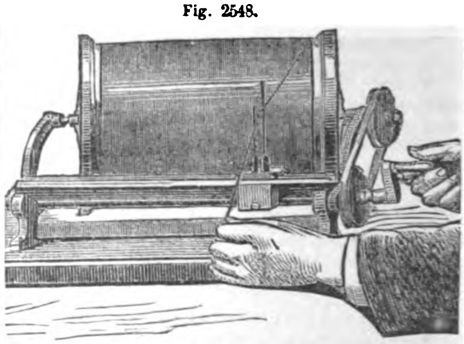
Fasten the foot *a* to the floor, and the legs *d b* to the wall, thus holding the machine firmly in a perpendicular position. Then with a yarn rest, wind from cop or bobbin one knot (or one seventh of a hank or skein) which equals 120 yards. Carefully remove the knot from the reel and place it upon the pins opposite, *g* and *h*: then turn the crank *i* to the right until the yarn breaks. The index point *d* will then show the amount of stretch in inches and eighths, and the upper index *c* will also give the exact breaking weight in pounds avoirdupois.

The machine, shown in Fig. 2548, has for its object the exposure of all unevenness in yarn.

It consists of a black board turned by a strap and pulley from a handle, which latter also revolves a screw, upon which slides a prong-shaped guide for directing the yarn as it comes from the cop, bobbin, or hank. By the revolution of this screw the yarn is wound properly spaced upon the black board, and any unevenness may thus be readily detected, as well as all impurities in the same.

The principle of testing the evenness of the yarn against black boards is not unknown to yarn agents and shippers, but this little apparatus seems to be very handy, and to have the advantage that these boards, with the yarn, may be put aside for ready reference when required.

Fig. 2548.



Yarn Tester.

Yarn Wash'ing Rol'lers. A machine with two cast-iron rollers turned perfectly true and smooth, working on wrought-iron spindles, carried on two cast-iron standards. The pressure is obtained by compound levers and with movable weights, so as to vary the pressure as desired. All the bearings are of gun metal and bored.

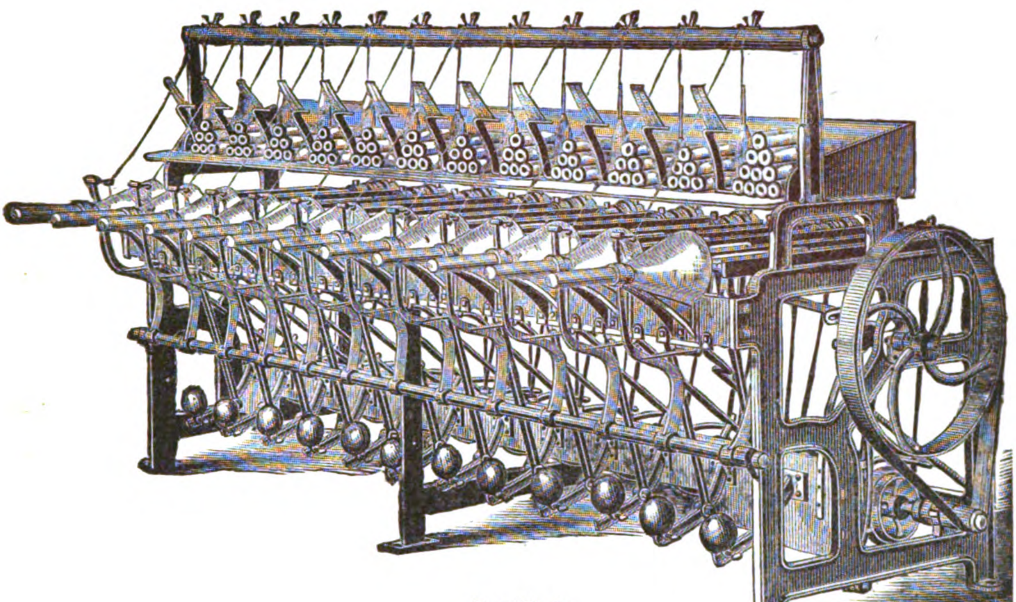
These machines are also fitted up for steam power, with stopping and starting gear.

Yarn Wind'er. Fig. 2549 is Campbell & Clutes' yarn winder for spinning machines.

The yarn is condensed as it is wound on the cone of each bobbin by a glass faced cop-former which leaves the yarn smooth and perfect.

Each sliding bobbin spindle is supported by a sliding journal-box which is at all times close or adjacent to the

Fig. 2549.



Yarn Winder.

base of a bobbin on the spindle so as to prevent the bobbin from shaking and beating upon the cop-former.

Each sliding journal box, with the bobbin spindle and bobbin thereon, is pressed toward the cop former with an adjustable yielding force, by means of a weighted lever having the weight adjustable, so that any desired degree of condensation and solidity can be given to the yarn wound on the bobbin by simply setting the weight to a given point on the lever.

Y Branch. A branch with a divergent stem.

Y Cross. A pipe with two divergent stems.

Yoke. Twin hot and cold water pipes that unite in their discharge, and which have stop cocks that regulate the temperature of the supply.

(*Wheelwright.*) The over-lap tire bolt washer, used at the joints of the felloes.

The arch on which the bell hangs and on whose pivots it swings.

Yt'tri-a. (*Chemical.*) A fine white powder or earth without taste or smell, insoluble in water, and having no effect on vegetable blues. It is supposed to consist of the protoxide of yttrium.

It was discovered by Professor Gadolin in 1794.

Yt'tri-um. A very rare metal discovered in 1828 by Woehler. Its texture is scaly, its color grayish black, and its luster perfectly metallic.

Yt'tro-ce'rite. (*Min.*) A mineral of a violet blue color inclined to gray and white, occurring very sparingly at Finbo and Brodbo, near Fahlun, embedded in quartz. It consists of lime, sexquioxide of cerium, yttria, and hydrofluoric acid.

Yt'tro-tan'ta-lite. (*Min.*) Columbium and yttrium, found in Sweden. It is found of yellow, brown, and black colors.

Z.

Zaf'fer. (*Glass.*) Fr. *zafre, zaffer, saffre;* Sp. *zafore;* It. *zaffera;* Ger. *zaffer.* Impure oxide of cobalt; residuum of treatment of cobalt after impurities are driven off by calcination. Used as blue color in glass-making.

Z Crank. A form of crank especially adapted to use where the minimum of space is one of the most important items of consideration.

The result is a very compact engine of long stroke, the height of the engine being little more than the diameter of the cylinders. In small launches the engine is placed under the smoke-box end of the boiler (locomotive), so that only the space necessary for the latter is required, the engine being in otherwise unused space, and its weight brought to the lowest position possible.

Zinc Dec'o-ra-ting. A chemical process for covering zinc with colored coatings has lately been described by Dr. L. Stille.

The articles of zinc are first brightened by scouring with quartz sand, moistened with dilute muriatic acid, putting them quickly in water and then carefully wiping them dry with white blotting paper. To insure success, however, it is necessary to employ zinc as free as possible from lead, and to have it as bright as a mirror. When these conditions are fulfilled the metal may be coated with a variety of beautiful colors by immersion in a solution of alkaline tartrate of copper for a shorter or longer interval of time, depending on the color that is desired.

Zin'cite. A brittle translucent mineral of a deep red color, sometimes inclining to yellowish, consisting chiefly of oxide of zinc, but containing also a small quantity of oxide of manganese.

Called also red zinc ore and red oxide of zinc.

Zinc Coat'ing. On brass or copper.

The following simple process is recommended by Bottger: Boil a large excess of so-called zinc dust some time, with a concentrated solution of caustic soda, or potash, and place the copper or brass articles to be coated in the boiling liquid. By continuing the heating, after a few minutes a beautiful, mirror-like film of zinc will form upon them by the decomposition of the alkaline solution, in consequence of their electro-negative character in combination with the zinc. It is suggested that the process is applicable to the preparation of disks for dry-piles, and also for forming a layer of tombac, by heating a copper article thus coated, carefully, to about 248° to 284° (best under olive oil), when the zinc will unite with the copper support to form a gold-tinted tombac, and the article need only be quickly cooled in water, or some other suitable liquid, as soon as the desired color is apparent.

Zinc Me'thyl. A volatile liquid consisting of two equivalents of carbon, three of hydrogen, and one of zinc. It takes fire spontaneously on exposure to the atmosphere. Its vapors are very poisonous.

Zin'co-graph'ic Cop'y-ing Pro'cess. In the Belgian "*Bulletin du Musée,*" M. Hannot describes the following new autographic process: —

The writing or drawing is made upon any kind of paper, which should, however, not be very thick. A special ink is used, composed of gum arabic or gelatine ¾ oz., water saturated with bichromate of potash, 1 quart, and sufficient India ink to color the whole. The gum is first dissolved in the solution and the ink afterwards added. The preparation must be kept sheltered from the light, and when used a portion should be poured out in an inkstand of black glass. When the drawing is finished it is exposed to light, whereby the lines are rendered insoluble.

A plate of zinc or a stone is then prepared and polished with emery, and the drawing is placed upon it face downward. Above the latter is laid a sheet of paper covered with gum arabic, and above this two or three sheets of dampened blotting paper. The whole is then pressed. The moisture in the blotting paper reaches the gummed paper, and the gum, dissolved, traverses the autographic paper and affects the zinc or stone everywhere except where the insoluble lines of the design have prevented its passage. A roller of greasy ink may then be passed over the plate, and the grease will adhere only to the lines which are not covered with moisture. Printing is then done in the usual way.

Zin-cog'ra-phy. Engraving on zinc in the style of wood-cuts, as also in the use of the lithographic stone, and taking impressions therefrom.

In a paper lately read before the London Society of Arts, by Mr. Thos. Bolas, F. C. S., the following simple process in zincography is described: Zincography, he said, is similar to lithography, except that a zinc plate is employed in the place of the lithographic stone. The so-called transfer paper is merely a moderately fine paper which has been brushed over, on one side, with a mucilaginous mixture, prepared by boiling together the following: Water, 1,0 0 parts; starch, 100 parts; gamboge, 6 parts; glue, 1 part. This part is written upon with the ordinary commercial lithographic writing ink, which has been rubbed up with water like an artist's water-color. The writing being dry, it is necessary to moisten somewhat the back of the transfer by means of a damp sponge; after which it is laid face downward on a sheet of ordinary roofing zinc, which has been previously cleaned by means of emery cloth. Both being now passed together under the roller of a small press, the transfer adheres to the metal plate; but on damping the back of the paper it becomes easily removable, leaving the writing on the zinc. The face of the zinc plate is now gently rubbed over with mucilage of gum arabic, which is all the better for being slightly sour, and the excess of gum having been sponged off, an india-rubber inking roller, charged with ordinary printer's ink, is passed over the still damp zinc plate a few times. The ink takes only on the lines of the transferred writing, and it is now merely necessary to lay a sheet of white paper on the plate and to pass both through the press to obtain an impression, — an exact reproduction of the original writing.

Any number of copies can be printed by repeating the operations of damping and inking. The zincographic process, thus simplified, is rapid, economical, and within the reach of every one.

Malepeyre. "*Technologiste,*" xxxviii. 26.

Zinc Col'or-ing.

The "*Technologiste*" gives the following process for permanently coloring zinc. The metal must be quite pure, as must also the materials of which the following bath is composed: Tartrate de cuivre, 30 grains; potasse caustique, 40 grains; eau distillée, 400 grains. After being submitted for two minutes to the action of this bath, the zinc takes a violet tint; after three minutes' immersion it becomes a deep blue; in four and a half minutes, green; in six and a half minutes, purple.

The "*Metallarbeiter*" gives the following recipe for giving bright colors to zinc: The objects to be colored are first thoroughly brightened by rubbing with sand and moistening with hydrochloric acid, which is rapidly washed off with water. In order to be successful it is necessary to use zinc free from lead. The colors are produced according to necessity by dipping the object for a certain varying length of time in a solution of tartrate of copper and alkali.

Zinc Pla'ting.

As nickelizing is replacing silvering in some cases, so there are some where nickelizing may be itself replaced for many articles of small value, such as pins, particularly if they contain copper. The manipulation is very simple. Coarse rasped or granulated zinc is boiled for some time in a mixture of three parts by weight of sal-ammoniac and ten of water; the objects are immersed and stirred with a zinc rod. The deposit is silvery bright, and resists mechanical action as well as a coating of nickel. The process can be recommended for goods which are meant for a second coating of some other metal, since any other is easily deposited upon zinc.

Zinc Pow'der.

A powder which is now considerably used in the arts, is said to be composed of zinc, 40 parts; lead, 2.5; cadmium, 4; zinc oxide, 50; zinc carbonate, 2.5, with some traces of non-metallic dust. As a part of the cargo of vessels it is extremely dangerous and ought never to be stowed where it cannot be readily removed. When it is slightly moistened with water it becomes spontaneously inflammable.

Zo'o-gy'ro-scope. A modification and amplification of the zoötrope, in which a series of succeeding instantaneous photographs of an animal (a horse, for instance) in motion are placed on a circular rotating glass, the photographs being alternately illuminated by an oxyhydrogen lantern as the glass turns, throwing a single continuous, yet ever changing, picture upon the screen.

While the separate photographs had shown the successive positions of a trotting or running horse, in making a single stride, the zoögyroscope apparently throws upon the screen the living, moving animal.
