Ful'gu-ra-ta. (*Electricity.*) A spectro-electric tube in which the decomposition of a liquid by the passage of an electric spark is observed.

In that of M. Duboscq, the vertical tube has a pair of platinum wires: the upper one extends nearly to the lower end, and the lower one is surrounded with a short conical glass tube, which by capillary attraction continually supplies the fluid under examination which covers the point of the lower electrode. "*Telegraphic Journal*," * iv. 285.

Full Cir'cle. A form of FIFTH WHEEL, *q. v.*

Ful'ler Bat'te-ry. (*Electricity.*) One having a zinc element, which is permanently amalgamated by placing its enlarged base in mercury in the porous cell, which is otherwise filled with water. The carbon plate is placed in the outer vessel in a solution of sulphuric acid and bichromate of potassium.

The thin portion of zinc is covered with wax, paraffine, caoutchouc, or the like.

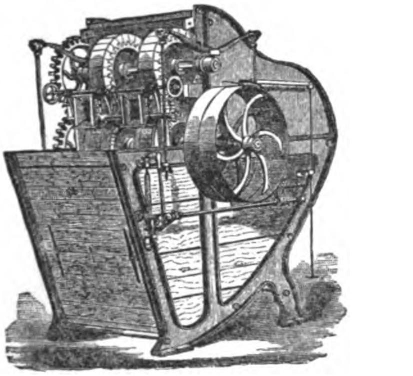
"*Scientific American Sup.*"	* 628, * 1127.

Ful'ling Mill. 1. The old fulling mills were generally of wood, and the necessity for weight gave rise to their being of enormous size. The beating mill, which the nearest resembles the ancient tramping, — practiced in Asia with camel's hair for thousands of years past, — is shown in Figs. 2125, 2126, p. 923, "*Mech. Dict.*" The roller mill, which is more compact, is shown in Figs. 2127, 2128, *Ibid.*; but a still more improved form is the Rodney Hunt, shown in Fig. 1109.

In this mill, the shape of the box answers to the requirements of the work, to avoid useless quantity of suds. The

Fig. 1109.



Rotary Fulling Mill. (*Top casing removed.*)

frame is of iron, and casing of hard pine. The main squeeze rolls have cast-iron shafts covered with wood, the fiber of the wood being presented endwise outward. The bottom rolls have brass flanges between which the top rolls run. The rolls are geared, and pressure is obtained by elliptic springs. All the inside working surfaces are of wood or brass, to avoid staining the goods. By certain attachments the fuller has control of the goods, felting and stretching lengthwise, or felting the width as he may desire. An automatic stop-motion stops the mill in case of the "knotting up" of the goods.

Baldwin . . . . * "*Scientific American*," xxxviii. 38.
Benoit, Fr. . . . * *Laboulaye's* "*Dictionnaire*," ii., article "*Laine*," Figs. 1328, *et seq.*, ed. 1877.

2. A machine in which wool hats are felted; an operation equivalent to the *sizing* formerly done at the battery.

The hat body having been *formed* by a fleece of wool from the carding machine wound upon the cone, and thence removed and given a certain amount of consistence known as *hardening* (see HAT-HARDENING MACHINE), is then to be felted or fulled to give it strength, an operation which compacts the fibers and makes the cone much smaller.

The principle of felting is probably sufficiently well understood, and need not be explained here. See pp. 833, 834, "*Mech. Dict.*"

The precursor of the fulling mill was a machine invented by James S. Taylor, of Danbury, Conn., and patented May 3, 1853, as a hat-shrinking machine.

It had four rollers set with their axes in relatively angular position, which caused a roll of hats placed between them to travel slowly along while turning around between the rollers. Two of the rollers had also a vibratory motion, and the effect was a rubbing pressure, and an advancing motion. An ingenious device, and useful in its day.

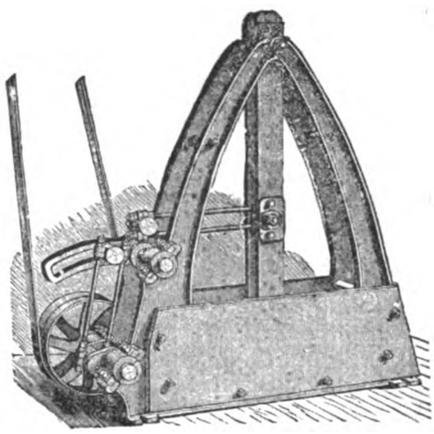
The first successful fulling mill was used in the factory of the "Seamless Clothing Manufacturing Company," of Matteawan, N. Y., about 1860, at which time the company commenced the manufacture of wool hats; and it may be remarked that the use of the fulling mill is yet principally confined to the wool hat factories, the sizing of fur hats being almost wholly done by hand on the battery.

Various styles of fulling mills are now used.

Fig. 1110 shows a mill called a *pusher*, which is used to start the hats — to follow the language of the factory — when they leave the hardening machine. The beater is driven by a bell crank, which receives motion from a crank shaft by means of a connecting rod, which is adjustable in a curved slot in the bell crank to vary the stroke of the beater.

Sometimes one beater is used, but generally two beaters acting in opposite directions, and placed side by side in the

Fig. 1110.



Crank Mill for Fulling Wool Hat Bodies.

same fulling bed, and consequently acting upon two batches of hats in the respective ends of the bed.

To finish the hat body another kind of fulling mill is used, having *fulling stocks*.

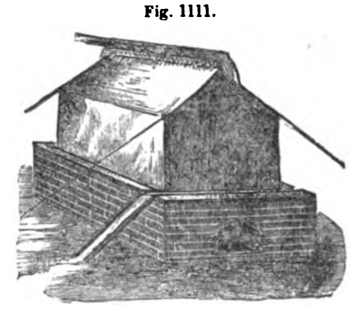
Four cast-iron frames are bolted to a solid foundation; these form the bearings for the beater shafts, and contain the fulling beds. A driving shaft operates two large gear-wheels, to which the lifting toes which actuate the beaters are attached. Two beaters operate in each bed, and the hat bodies placed in a body in each bed, slowly turning by the successive blows, are gradually fulled to a suitable size.

In some cases acidulated water is used to facilitate the fulling of the hat bodies, but in most cases fuller's soap is employed.

Full Way Valve. A pipe valve which lifts entirely out of the current. Also called a *clear-way* valve.

Fume Con-den'ser. An arrangement for condensing heated vapors and fumes, arsenic, zinc,

Fig. 1111.



Fume Condenser.

mercury, etc. See CONDENSER, "*Mech. Dict.*," *et supra.*

That shown in Fig. 1111 has canvas roof and sides flooded with water.

Fu'nis Clamp. (*Surgical.*) A clamp with two steel plates and catch for compressing the umbilical cord.

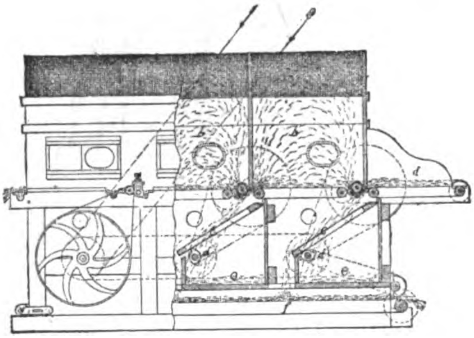
Fun'nel Box. (*Mining.*) An apparatus for collecting slimes from water. *Spitzkasten.* It is a row of square funnels increasing in size and depth, the slime-carrying water passing from one funnel box to another, the increasing capacity of each decreasing the rate of movement of the water, and thereby depositing in the successive boxes solid matter of increasing fineness.

"*Mining & Scientific Press*" . . . . . * xxxiv. 145.

Fur Blow'ing Ma-chine'. A machine to loosen out fur and remove hair and other impurities. The invention of William B. Rotch.

A number of pickers are made to operate upon the fur, which is fed into the machine by a feed upon *A*. The fur is presented to the rapidly revolving picker by two small feed

Fig. 1112.



Rotch's Fur Blowing Machine.

rollers which take the fur from the feed apron. The fur being held by the rollers is combed out, and the lighter portion is thrown by the picker into the upper chamber *B*, while the heavier part falls upon a screen *c*, which, being shaken by double cams on the shaft *d*, causes the hair and other small particles to collect in the box *e*, while the larger pieces fall upon an endless apron and are carried back to be operated upon a second or a third time until all the fur is removed.

The chamber *b* is covered with a wire cloth to allow the fine dust to escape with the current of air which is created by the rapid motion of the picker, and which carries the lighter portions of fur into the chamber, where it is deposited upon a second endless fur apron, passed by a second pair of feed rolls to the next picker, where the same operation is repeated, and so on, until, the fur having passed from 3 to 6 separate pickers, is delivered in an even *bat* ready to be used in the forming machine See HAT-FORMING MACHINE.

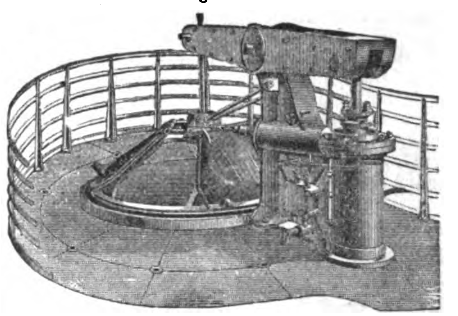
Fur'nace Char'ger. The Weimer furnace-charger consists of an inverted cone placed over the hopper, and doors in the cone opening to admit the ore, flux, and fuel. These doors slide on hinges secured to a revolving ring on top of the cone. Near the tunnel head is a post on which a beam vibrates; the bell inside the tunnel-head is hung to one end, and a piston is suspended from the other and moves in the vertical cylinder. The horizontal cylinder moves the ring to which the sliding doors are hung.

Fur'nace Char'ging Bar'row. See CHARGING BARROW. Fig. 600, p. 191, *supra.*

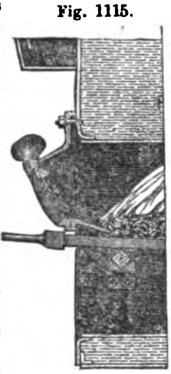
Fig. 1113.



Weimer's Furnace Charger.

Fur'nace-char'ging Scales. A scale with several beams and poises so as to fill into a barrow separate quantities by weight of the ore, fuel, and flux which go to make a charge. This allows the proportional quantities to be collected in the barrow instead of obliging them to be separately emptied into the furnace. The principle is the same as the CREAMERY SCALES, which see.

Fig. 1115.



Furnace Door. (*Section.*)

Fur'nace Door. The fuel opening in front of a furnace. Contrivances have been introduced for causing water to circulate through the hinges and doors to moderate the extreme heat of the engine room.

Ashcroft's balancing furnace doors are shown in Figs. 1114, 1115, in perspective and section.

Fur'nace Feed'er. Methods of feeding furnaces automatically, and also means for avoiding

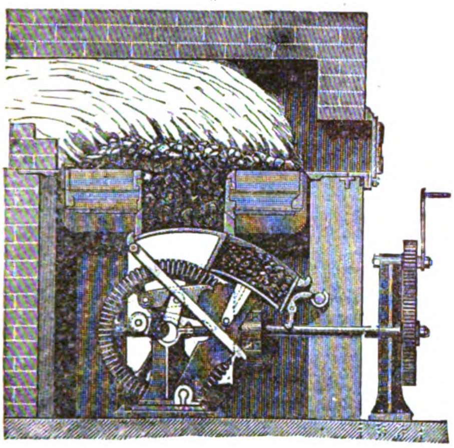
Fig. 1114.

Ashcroft's Balancing Furnace Door.

the wasteful production of smoke, are described on pp. 2224–2226, *"Mech. Dict."* Base burning, bottom feeding, secondary consumption, the dead-plate system, the revolving furnace, and steam injection, are there described. See also list of FURNACES, *"Mech. Dict.," et supra.*

Fig. 1116 shows Frisbie's bottom feeding furnace, in which the coal is fed from beneath; being filled into a box while in the position shown in the figure, the wheel is subsequently revolved, bringing the box into position immediately beneath the furnace when the piston in the bottom of the box is raised and the coal expelled, taking its place as the lower

Fig. 1116.

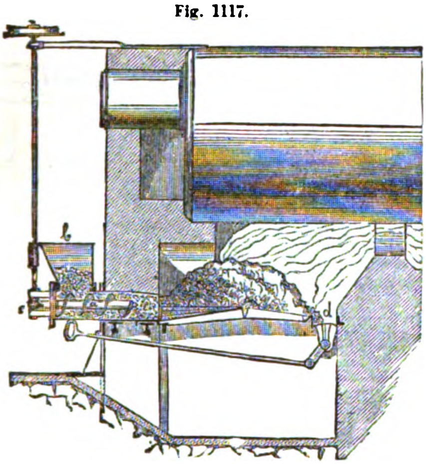


Bottom-feeding Furnace.

stratum of the fuel. A plate on the feed wheel holds up the coal when the box is again brought forward.

Fig. 1117 shows the Schultz furnace feeder. The coal is

Fig. 1117.



Dead-plate Automatic Feeder

placed in a hopper and fed by a continuously moving screw conveyor on to the dead plate in the furnace where it is first converted into coke, the gas escaping through the incandescent fuel.

See also GAS AND COKE FURNACE.

Fu'si-ble Met'al. An alloy with a determinate fusing point, and placed in a position to melt and allow escape of steam or to sound an alarm when the stated temperature is exceeded.

A number of tables of alloys with indicated melting points are given on p. 62, "*Mech. Dict.*" To these may be added, —

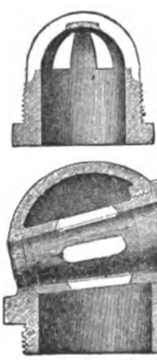
	Bismuth.	Lead.	Tin.	Antimony.	Melting Point, Degrees, Fah.
D'Arcet . .	8	5	3	-	Below 212
	2	5	3	-	Below 212
Walker . .	8	5	4	1	-
Onion . .	5	3	2	-	Below 197

By adding to the last given, mercury 1 part on taking the metal from the fire, an alloy will be obtained, which is liquid at 170° Fah. and only solid at 140°. Used for anatomical injections.

French cliché molds are made of the Walker alloy.

Electrotype molds of d'Arcet's and Walker's. Also for metallic pencils and laboratory baths.

Fig. 1121.



Fusible Plug.

Fu'si-ble Plug. One placed on a steam boiler or in an electric circuit (fire alarm), which melts when subjected to a heat exceeding the point for which the alloy is constituted. See FUSIBLE ALLOY.

The plug shown is covered with fusible metal and the spaces filled with the same. Water from the boiler circulates in the tube around the plug; the latter being screwed into place is readily removed, refilled, and replaced.

Fu'sing Disk. An invention of Jacob Reese, of Pittsburg, for cutting round steel bars.

It consists of a disk of soft steel 3-16″ thick and 42″ diameter, making 240 revolutions per minute, which gives a travel of about 2500′ to the edge of the saw. The round bar travels in the same direction 200 revolutions per minute, so that the edge of the disk and the surface of the bar move in opposite directions.

A round bar of steel 1¾″ in diameter is fused in two in 10 seconds without being at any time in contact, the kerf being 5-16″ wide. The disk remains cool; the bar is heated.

"*Engineer*" . . . . * i. 259.
"*Scientific American Supplement*" . . . 4138.

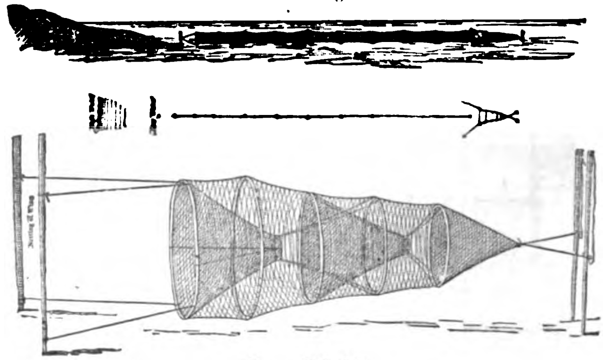
The circular saw for the removal of the fag ends of rails and bars while yet hot from the rolls is an apparatus used in many rolling mills. See HOT IRON SAW, *infra*.

Fyke Net. (*Fishing.*) A bag net with distended mouth and succession of funnel-shaped compartments.

In the upper part of the illustration a long *leader* is shown conducting the fish along shore into the fyke net. The netting of the wings is not shown, but extends from the stakes to the mouth of the *fyke*, and the end of the leader enters between the displayed wings, which are perhaps 5′ high and 20′ long. The leader, 100′ long, 5′ deep. The fyke has 5 hoops, 9′ to 15′ in circumference.

Under NET will be found a list of names of various pounds and traps, some of which embrace the same feature.

Fig. 1122.



Tyson Fyke Net

G.

Ga'bi-on. A basket, or frame of open work, used in hydraulic and harbor works to form a bar, dyke, or jetty. Cognate contrivances, as fascines, mats, etc. (which see), have a similar purpose; forming a nucleus for the holding of broken stone, gravel, or sand; or for the collection of sand or silt brought by the current, tides, or waves. See list under HYDRAULIC ENGINEERING.

The gabions of the Galveston jetty works are thus made: A bottom of 2″ planks is bored for the reception of upright pine poles, which have the bark left on them and these are held in position by a frame fastened to their tops. They are then wattled with the southern cane, which is so abundant. The gabions are stayed with cross braces internally, a ballast of concrete laid over the bottom and rammed, the top stayed by planks, the stakes nailed to the planking above and below, and the top and bottom planks tied together with ¾″ iron bolt rods. The gabion then receives two coats of cement and is allowed to dry for two weeks; such a gabion is 12′ × 6′ and 6′ high. The gabions are sunk upon a foundation mat of canes wattled on a frame of wood, and fascines of cane are thrust into the intervals between the standing gabions, which are planted by means of guide poles and are sunk by pumping them full of sand. Mats, fascines, and concrete blocks are arranged upon and around the group of gabions by divers.

See JETTY, *infra*, where the system adopted by the Dutch is represented. See also * "*Scientific American Sup.*," 245.

Ga'bi-on-ade'. A structure consisting of a number of gabions filled with sand or stone and sunk in lines upon fascines or hurdle mats, as a core for a sand shoal in harbor improvements. See "Works in Galveston Harbor."

"*Engineering*" . . . . * xxiv. 235.

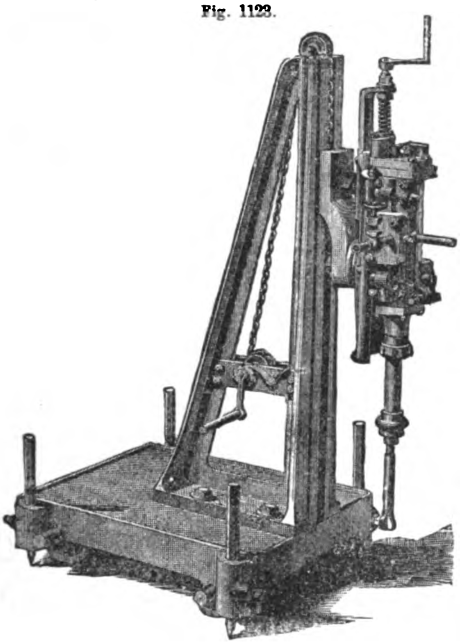
Gad'ding Car. (*Quarrying.*) One arranged to carry a drilling machine so as to present it to drill a series of holes in line. Used especially in getting out dimension stone.

See also CHANNELING MACHINE, Fig. 1246, p. 526, "*Mech. Dict.*;" the latter, however, works with chisels and makes a groove instead of a series of holes for as many *gads*, by driving which the stone is riven on the line of holes.

Fig. 1123 shows the drill mounted on car for gadding. It may be presented horizontally for heading, and lowered or raised on the column so as to make the horizontal holes at any altitude or at any angle.

The name is derived from the *gads*, or wedges which are used to rive the block after the row of holes has been drilled or jumped. The *gad* is shown in Fig. 2140, page 932, "*Mech. Dict.*" Another mode of splitting dimension stone upon the line of a row of holes is by means of the *plug-and-feather*, Fig. *a*, 3834, p. 1749, *Ibid.* In this case a wedge is driven between two oblique-faced plugs previously introduced into the hole. Each hole of a linear series being thus furnished, the wedges or gads are tapped in order down the line, again and again, until the stone parts on the line thus weakened and strained.

Fig. 1123.



Gadding Car and Drilling Machine.

Gaff. (*Fishing.*) A hook on a staff used in landing heavy fish; for salmon, halibut, cod, dory, etc.

The *pewgaff* is used in handling and pitching fish.

Gaff-top'sail Hook. (*Nautical.*) A mousing hook for a gaff topsail with rope sheet.

Fig. 1124.

Gaff-topsail Hook.

Gag. (*Surgical.*) An apparatus for distending the jaws during examination of or operation upon the mouth, fauces, etc., or in reducing lock-jaw. *Speculum oris.*

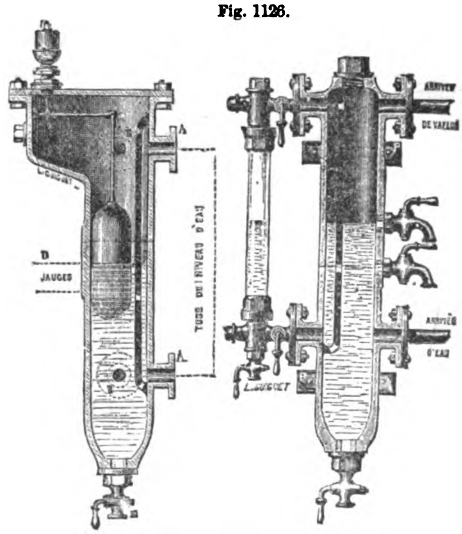
Gage Glass. A glass placed on a boiler to show the water level therein.

Fig. 1126 shows the gage glass of Damourette, Paris.

The instrument on the left is intended to be placed directly upon the boiler and has a float operating an alarm whistle when the water sinks below a given level. The dotted lines show the position of the glass tube.

The instrument on the right communicates with the boiler

Fig. 1126.



French Gage Glass.

by two pipes for water and steam, and has all the fittings, gage cocks, glass, tube cocks, sediment cock, etc.

The interposition of the chamber makes a slack-water between the boiler and gage glass which prevents the effect of ebullition manifesting itself in the latter, and the chamber also acts as a sediment catcher, keeping the glass clean.

Gage glass fittings, *Blake*, Br. . * "*Engineering*," xxix. 186.

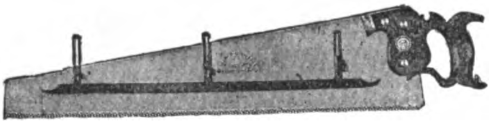
Gage Lathe. A lathe for turning work to size: handles of all kinds, chair legs, pillars and rounds, bedstead rails, beaded work and *nulled* spindles are turned to patterns also, but this speciality constitutes the machine tool a *nulling* lathe.

In the more perfect forms of gage lathes for turning exceptional shapes, three cutting-tools are used: one for turning the stick to a rough cylindrical form; a second to rough out the irregular outlines wanted; and a third to smooth-finish it. The second cutter is caused to approach or recede from the line of centers by a templet, against which the tool-holder rests and along which it slides. The roughing-tools are of the usual V-shape. The finishing-tool is a long blade, set at an angle with the center line of the lathe in order to take a smooth shaving. Its edge is given such a shape that it finishes the work accurately.

The piece to be turned is supported between centers by a ring, and the workman is thus enabled to turn a comparatively long and slender stick. The movement of the slide-rest which actuates the cutters is checked at the end of its throw by a self-acting stop.

Gage Saw. A hand saw with a gage bar adjustable to determine the depth of kerf.

Fig. 1127.



Gage Saw.

Gage Wheel. (*Agricultural.*) A wheel on the forward end of plow beam, to limit the depth of furrow. Fig. 850, p. 267, *supra*, shows a plow with a pair of gage wheels.

Gage Ta'ble-shears. A machine for cutting straw and mill boards to a regulated width, for book covers, box making, etc. See BOARD CUTTER, *supra*, and Fig. 739, p. 311, "*Mech. Dict.*"

Gag'ger. (*Molding.*) A piece of iron in a mold to hold a core in place. A *chaplet*.

Gaiffe Bat'te-ry. (*Electricity.*) There are several forms of batteries by this inventor.

Watson . . . . . . * "*Scientific American Sup.*," 524.

The lists commencing on the next page include all that is important in galvanic batteries up to date, so far as covered by patents.

Gal-van'ic Cur'rent. (*Electricity.*) The direct current from the galvanic battery. The primary current.

Gal'van-i-zing. Treated on p. 939, "*Mech. Dict.*"

"Pickle the article six or eight hours in water containing about 1 per cent. of sulphuric acid held in wooden vessels; the acid requires to be renewed from time to time, according to the quantity of iron pickled. After pickling, scour and wash well in clean water. Keep the article under clean water (in which a little freshly burnt lime has been stirred) until ready for the next process. Immerse in chloride of zinc for one or two minutes until a skin of fine bubbles is formed on the surface. Chloride of zinc may be formed by saturating hydrochloric acid with metallic zinc until effervescence ceases, then decanting and adding a little sal-ammoniac. Dry the article on a heated iron plate, then immerse it in a bath of molten (not glowing) zinc until it acquires the temperature of the zinc bath. The surface of the molten zinc should be protected by sal-ammoniac, or some other substance. In some cases there is a partition at the surface of the bath, one portion of the surface being protected with sal-ammoniac, the other with a layer of charcoal. Beat the article while hot, to remove the excess of zinc." — *Molesworth.*

Galv. electric bath, *Potin* . . * "*Scientific Am.*," xxxiv. 54.

A carefully written and full article on the zincing of iron surfaces, "*Scientific American Supplement*," 2798.

Iron . . . . "*Iron Age*," xxiii., Jan. 16, p. 9.
"*Manufacturer & Builder*," ix. 157.
Bath . . . . * "*Scientific American Sup.*," 2560.

Gal'van-i-zing Fur'nace. The bath of molten zinc in which iron is plunged to coat it.

The galvanizing furnace of Thum, of Laubach, Germany, is a reverberatory in which the zinc bath is heated from above. It has a fireplace and a chimney at each end, the part of the hearth connecting the two being arched over. The rest of the rectangular hearth is perfectly open above, so that the heat-conducting power of the metal is relied upon to keep it at the proper temperature in that part of the hearth. The slabs of fresh zinc are introduced through doors communicating with the hot ends.

Hill, J.	103,331	merc. and zinc.	-	-	-	cop. wire cloth.	Zn. in annular glass suspended from rim of outer cup. Cu. above zn.
Chutaux, T.	105,042	zinc.	-	-	-	carbon.	Plunging and inverted magazine. Liquid falls from cell to cell.
Chutaux, T.	105,043	zinc, iron.	-	sand.	granulated coke.	carbon.	Zinc in lower; iron in upper cells.
Robertson, O. W.	105,252	-	-	-	-	-	Insulator cell support.
McCracken, E. D.	106,383	-	-	-	-	-	Switch for connecting.
Kidder, J.	108,602	zinc.	-	-	-	platinum.	Neg. electrode coiled around suspended core. Elastic plug.
Farmer, M. G.	109,603	-	-	-	-	-	Thermo-electr. Pairs in curved tiers around heat.
Cook, D. M.	110,206	-	-	-	-	-	Several porous cups in one cell.
Cook, D. M.	113,399	-	-	-	-	-	Several porous cups in one cell wrapped with paper and wire.
Farmer, M. G.	113,864	ant. and zn. alloy.	-	mica.	-	Ger. silver cu.	Thermo-electric.
Hill, E. A.	114,005	zinc.	-	-	-	-	Quoit-shaped zinc suspended from rim of cell.
Hill, E. A.	114,006	zinc.	H_2SO_4.	-	sulp. cop.	copper.	Zinc suspended from rim of cell. Central tube supplies sulp. copper.
Klinkerfues, W.	114,950	zinc.	-	-	-	carbon.	Gas lighting auxiliary flame from gas of battery.
Powel, J. W.	115,519	-	-	-	-	-	Plunging. Trough-plates slide through elastic cover.
Little, G.	115,936	-	-	-	-	-	Automatic switch: alternating batteries.
Kidder, J.	116,451	zinc.	-	-	-	copper.	Separate binding post for each cell, with switch connection.
Drescher, L.	117,057	zinc.	-	-	-	carbon.	Grenet form modified.
Prevost, E.	119,175	conical zinc.	-	carbon cup.	nit. sod.; bichr.	carbon	Insulating collar round carbon opposite top of zinc.
Bastet, L.	119, 98	zinc.	H_2SO_4.	porous cell.	pot. H_2SO_4.	carbon.	Perforated partition in porous cell.
Himmer, V.	119,763	zinc.	H_2SO_4.	small cup; half	sulp. cop.	copper.	Sulp. in short cup saturated by tube from inverted globe.
Kidder, J.	119,855	-	-	height.	-	-	Plates in one leg of L-shaped cell. Plunged by tipping.
Callaud, J. A.	120,034	zinc.	sulph. zinc.	-	sulp. cop.	copper.	Gravity. With positive vertically adjustable.
Robbins, J. A.	120,327	tin.	-	-	-	carbon.	
Leland, E. J.	120,651	zinc.	sol. sulp. ac.	porous carb. cup.	sulp. merc.	platinum.	
Kidder, J.	120,750	-	-	-	-	-	Sliding cell coupler. Trough battery.
Klinkerfues, W.	122,389	zinc.	-	-	-	carbon.	Gravity; gas lighting; cell around gas pipe; turning on gas excites bat.
Robbins, J. A.	128,660	zinc plates.	-	porous cell.	-	carbon plates.	Elements duplicated.
Linke, C. A.	129,148	zinc.	-	-	-	carbon.	Negative depolarized by jet of steam.
Davis, A. G.	129,465	-	-	-	-	-	Insulating cell support.
Phelps, G. M.	130,593	zinc.	-	-	-	copper.	Gravity; zinc of peculiar shape and adjustable.
Wilder, W. J.	132,997	corrug. zinc.	-	porous cup.	-	copper.	Outer surface of zinc varnished.
Davis, A. G.	134,364	zinc.	-	-	-	copper.	Star-shaped elements; central tube; perforated cork stopper.
Thomas, J. H.	136,191	-	-	-	-	-	Insulating support collects leakage.
Lockwood, R. M.	137,556	zinc.	sol. sulp. acid.	-	sulp. cop.	spiral cop. wire.	Gravity.
Bastet, L.	138,602	zinc.	nitr. hyp. sulp.	porous cell.	nit. sod. and H_2SO_4	carbon.	Zinc for magazine, with gauze bottom. No amalgamation.
Wolf, A. L.	142,052	zinc.	sod.	-	ozone.	carbon.	Air or ozone injected through tubes.
Edison, T. A.	142,999	zinc.	sulp. zinc.	-	sulp. cop.	copper.	Gravity. Hor. copper plates between liquids to protect zinc against cu.
Ashcroft, E. H.	145,143	-	-	-	-	-	Non-freezing battery.
Lockwood, R. M.	149,320	zinc.	sol. sulp. acid.	felt.	sulp. cop.	copper.	Gravity. Zinc supported by insulating columns from copper.
Breslin, M.	149,635	zinc.	sulp. zinc.	-	sulp. cop.	copper.	Gravity. Negative in pyramidal form.
Clamond, C.	151,568	zinc.	-	-	-	antimony.	Thermo-electric.
Nolf, A. L.	153,841	zinc.	-	-	-	carbon.	Carbon cell with impervious coating.
Snow, W. D.	155,209	zinc.	earth.	earth.	-	carbon.	Several plates. Obtains intensity as well as quantity.
Arthur, R.	157,778	zinc fragments.	H_2SO_4.	porous cell.	HNO_3	carbon.	Perforated earthen jar holding zn. Has a cavity in floor for mercury.
Bryan, J. C.	160,152	zinc.	sulphur, earth.	-	-	copper.	Plates partially imbedded in sulphur.

Leiter, J.	161,246	-	-	-	-	-	Two-story. Pl. above. reserv. below. Forces liq. up. Autom. water feed.
Davis, W. M.	162,806	zinc.	sulp. zinc.	porous cell.	sulp. cop.	copper.	Bell rung when salt is exhausted.
Keegan, V. E.	163,318	zinc.	water.	sulp. acid in porous cell.	nitr. ac.	carbon.	Outer porous cell surrounded with coil of wire conn. to zinc.
Dechert, H. P.	165,312	-	-	-	-	carbon.	Neg. broken carbon in perforated tube of cop., lead, clay, gutta-percha.
Leclanché, G. L.	165,452	zinc.	chl. amm.	-	conglom. grap per ox. mang.	-	
Kidder, T.	166,012	-	-	-		-	Plunging. Adjustable plates, shallow cell; partitions for rapid filling.
Hill, E. A.	167,173	zinc.	H_2SO_4.	leaden plate.	sulp. cop.	copper.	Sulp. copper introduced through central leaden tube. Gravity.
Dawson, B. F.	167,510	zinc.	-	-	-	copper.	Agitator between negative and perforated positive.
Duhem, C.	169,529	zinc.	sulp. zinc.	-	sulp. cop.	copper.	A suppl. positive plate attachable to the zinc.
Lockwood, R. M.	170,864	zinc.	sol. sulp. ac.	porous cup.	sulp. cop.	copper.	Zinc in porous cup which rests on cu. supported by sulphate.
Kinemund, F. C.	175,112	-	-	-	-	-	Portable; plunging; trough; sliding cell connector.
Warden-Muirhead	175,884	slotted zinc.	chl. amm.	perforated cell.	graph. mang.	graphite.	Battery sealed.
Bliss, G. H.	176,270	zinc.	sulp. zinc.	-	sulp. cop.	copper.	Gravity; adjustable zinc; aux. copper disk above copper solution.
Brunelle & Mohr	177,066	zinc.	sulp. zinc.	-	sulp. cop.	copper.	Receiver att. to feeding tube between zn. and cu. to catch zn. residue.
Pulvermacher, J. L.	177,273	zinc.	vinegar.	fibr. absorbent.	-	copper.	Voltaic pile. Disk-shaped elements.
Einbigler, R.	177,996	-	-	-	-	-	Float regulates supply to service pipes of cells.
Watson, J. E.	178,215	zinc.	sulp. zinc, acet. lead, water.	-	sulp. cop.	perforated lead.	
Byrne, J.	182,101	-		-	-	plat. plated cop.	
Kidder, J.	182,293	zinc.	-	-	-	carbon.	Portable. Plunging. Two sets of cells, induction coils, etc.
Cerpaux, J.	182,802	zinc.	earth.	wood.	-	copper.	To be imbedded in earth
Parrish, M. W.	183,201	zinc.	-	-	-	copper.	Zn. supp. by copper hangers which compl. circuit when zn. is removed.
Byrne, J.	183,748	zinc.	-	-	-	cop. coated with lead and plat.	
Dechert, H. P.	184,005	-	-	-	chl. calcium.		
Van Tenac, C. L.	184,932	zinc wire.	chl. zinc.	blot. pap. or sand.	chl. silver.	silver foil.	Hard rubber ends; soft rubber sheathing.
Bastet, L.	185,160	zinc. [nit.-chr. ac.	bi-chr. pot. H_2SO_4.	porous cell.	nit chr. ac. H_2SO_4	carbon.	
Brush, C. F.	185,288	zinc.	sod. chloride.	-	oxychl. lead.	lead.	Gravity.
Parrish, M. W.	189,779	zinc.	-	-	-	cop. in two sec'ns.	Double connecting spring clips. Siphon connecting from cell to cell.
Jennison, C. R.	190,684	zinc.	acid.	-	-	carbon.	Portable battery. Commutator, etc.
Hussey, C. A.	195,762	zinc cup.	-	-	-	copper.	Plunging. Rotating plates.
Wray & Wray	197,196	-	-	-	-	-	Thermo-electric.
Hussey, C. A.	291,924	bottomless zn. cup	-	por. cell perf. bottom.	-	carbon.	Absorbent material surrounding plates.
Boekel, W.	203,405	zinc.	bichr. pot.		-	carbon.	Grenet form. Cup held by spring catches.
Cutten, E. B.	206,166	zinc.	sulp. zinc.	cloth, paper, sponge, pulp.	sulp. cop.	copper.	Tray battery; pressed together by a spring.
Griscom, W. W.	207,270	-	-		-	-	Perfluent battery. The plates form the partitions.
Lander, G.	208,614	met. sulphuret.	-	fibrous material.	-	perf. plate.	
Kreis, A. C.	210,460	zinc.	-	-	-	carbon.	Leclanché arr. Impd. clamp for carbon.
Bartlett, F. C.	210,835	zinc.	-	-	-	carbon.	Plunges by lifting trough. Water-tight cover.
Bastet, L.	211,213	zinc.	salt water.	porous cell.	mixt. carb., ant.	antimony.	
Drawbaugh, D.	211,322	zinc, felt.	earth.	-	coke.	copper.	Zinc in felt and copper in coke.
Ehrenberg, C. A.	215,899	-	urine.	-	-	-	
Wilson, W. S.	216,774	zinc, sulph. sod.	sand, per-ox. and sod. nitrate.	porous cell.	sod nitr. H_2SO_4.	carbon.	Porous cup.
Rogers, W. H.	217,023	-		-	-	carbon.	Amalgam between carbon and yoke.
Jablochkoff, P.	219,056	fused nitrates.	-	-	carbonaceous	matter.	Closed receiver for gases emitted.
Hopkins, G. M.	219,477	zinc.	-	cell porous half way down.	-	copper.	Liquid raised by plungers into contact with plates.
Fitch, D. H.	219,631	zinc.	merc'c, merc's, or amm. chl.		-	carbon in merc.	Gravity.
Thomson-Houston	220,507	zinc.		copper.	-	copper.	Intermediate plate for depositing positive metal.
Anderson, R. C.	223,212	zinc.	chl. amm.	porous cell.	oxal. chrom.	carbon.	Adjustable magazine. Perforated platinum bottom.
Converse, G. A.	224,378	zinc cup.	-	cloth.	-	platinum.	Flexible cap. Zinc fits inner surface of cell.
Maynard, W.	224,343	zinc.	-	-	gran. retort carb.	platinum.	
Doyle, J.	224,404	-	-	-	-	-	Automatic supply from magazine by clock-work.
Tommasi, F.	227,076	zinc.	-	-	-	carbon.	Two-story; liq. raised by displacement; ann. groove with merc. supp. zn.
Schlumberger, R.	227,448	zinc.	sulp. ac.	-	sulp. cop.	copper.	Gravity. Inverted reservoir with two connecting pipes.
Lockwood, W. V.	227,805	zinc.	sal. am.	porous cell.	per ox. lead, H_2SO_4	carbon.	
Watts, J. H. C.	227,865	-	-	-	-	-	Battery case.
Bartlett, S. H.	228,972	-	-	-	-	-	Plates in upper cell sep. from lower chamber by plugged partition.
Bartlett, S. H.	328,973	-	-	-	-	-	Cell slides vertically in a reservoir and has valves below.
Hardy, M. A.	229,122	-	-	-	-	-	Liquid forced up into cells by pneum. pressure from reservoir below.
Cheever, J. H.	233,601	zinc.	hydr. chl. ac.	porous cell.	chl. calc., coke.	carbon.	The coke and chl. calc. in alternate layers in the sealed porous cup.
Leclanché, G. L.	234,413	zinc.	chl. am.	-	per ox. mang.	carbon.	Conglomerate negative containing salt.
Delafield, A. F.	237,830	zinc box.	-	-	-	copper spiral.	Negative rotated by a crank. Single fluid.

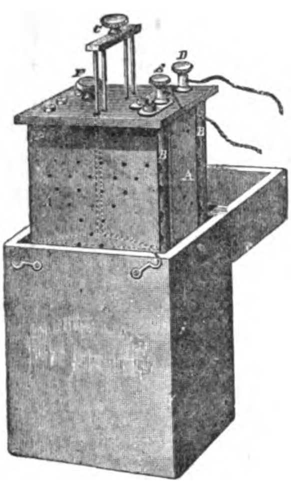
Gal-va'no Caus'tic. (*Electricity.*) An electro cautery. See p. 179, *supra*.

Gal-va'no-cau'te-ry Bat'te-ry. (*Surgical.*) For performing cautery by means of the heated platinum wire.

Fig. 1128 is Dr. Dawson's depolarizing battery, which is composed of two cells, in each of which are two positive (zinc) and one negative (platinum) plates, all measuring 4½" by 6". The zincs (*A*) are perforated, and adjusted ½" apart, and between them a platinum plate is placed and held in position by uprights (*B*). On each side of the platinum plates are hard rubber or celluloid pumps or agitators (*C*), worked by means of a small knob. *D* and *E* are the connecting screws, and *F* a knob for lifting the elements out of the cells. The battery requires 2¼ pints of fluid, the action being prolonged by the moving up and down of the pumps (*C*), more or less quickly, according to the intensity of the heat desired. By this action the old and exhausted fluid between the plates is thrown out through the perforations, and fresh fluid is made to take its place.

Fig. 1128.



Galvano-Caustic Battery.

Gal-va-nom'e-ter. An instrument for measuring the force of an electric current.

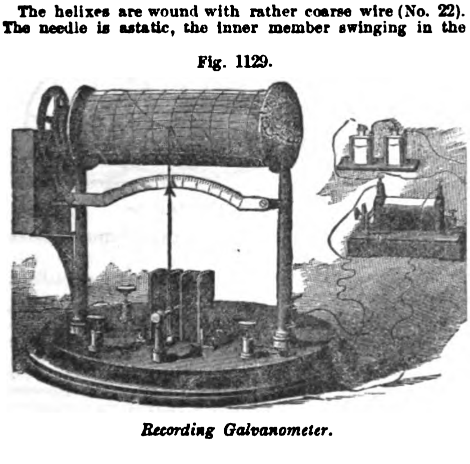
The reflecting galvanometer of Sir William Thomson is used in working submarine cables. In the astatic form it is used as a receiving instrument, placed in a box or curtained apartment, and the receiver calls off each word to an attendant who writes it down. The spot of light wanders over the scale in an apparently aimless manner, but the operator, by practice, interprets the motions.

The *siphon recorder* is a substitute for the reading of the vibratory pencil of light.

The recording galvanometer of Hopkins, shown in Fig. 1129, proceeds by the application of a disruptive spark from an induction coil.

The helixes are wound with rather coarse wire (No. 22). The needle is astatic, the inner member swinging in the

Fig. 1129.



Recording Galvanometer.

central opening in the helixes in the usual way, the outer member being located behind the helixes. The arbor supporting the needle has very delicate pivots, and carries a long aluminium index, which is counterpoised so that it assumes a vertical position when no current passes through the helixes, and the needle is unaffected by terrestrial magnetism.

The upper end of the index swings in front of a graduated scale, and is prolonged so as to reach to the middle of the cylinder carrying a sheet of paper upon which the movements of the needle are to be recorded. This cylinder is of brass, and its journals are supported by metal columns projecting from the base upon which the other parts of the instrument are mounted. The scale is supported by vulcanite studs projecting from the columns, and to one of the latter is attached a clock movement provided with three sets of spur wheels, by either of which it may be connected with the arbor of the cylinder. One pair of wheels connects the minute-hand arbor of the clock with the cylinder, revolving the cylinder once an hour; another pair of wheels connects the hour-hand mechanism with the cylinder, so that the latter is revolved once in twelve hours; while a third pair of wheels give the cylinder one revolution in six days.

This instrument is designed especially for making prolonged tests of different batteries in order to determine the characteristics. It is provided with four binding posts, one of which connects the wires of the batteries under test with the helixes. The other binding posts are connected respectively with the posts supporting the needle and with the journals of the recording cylinder. These posts receive wires from an induction coil capable of yielding a spark from ⅛" to ½" long.

The induction coil is kept continuously in action by two Bunsen elements and a stream of sparks constantly pass between the elongated end of the index and the brass cylinder, perforating the intervening paper and making a permanent record of the movement of the needle.

The paper upon which the record is made is ruled in one direction into degrees and in the other into hours and minutes. Refer to: —

Gal-va'no-plas-tique'. 1. (*Bronze.*) A particular kind of bronze work produced by depositing a heavy coating of bronze by the galvanic process upon a plaster of paris model, and afterward removing the model.

2. (*Glass.*) M. Alexander's process rests on the application of electro-metallurgy to the decoration of glassware, mirrors, etc., either for the exterior or interior decoration of houses, furniture, etc.

The substance which serves for tracing the design on the glass is a metallic paste of good conducting power, mixed with a solvent and thinned with an essential oil. The design once executed on the glass, the latter is submitted to the action of fire in either a muffle or a furnace, and is not withdrawn until perfectly cold.

The glass is then immersed in a metallic bath and a galvanic current passed over it; by this means the metal in suspension in the bath is precipitated on the design. The glass is withdrawn as soon as the coating becomes as thick as required. Finally, if necessary, the metallic design is finished up by chiseling or other means, and is left thus; or, indeed, another layer of a like or different metal may be deposited on it. — "*Moniteur de la Céramique*."

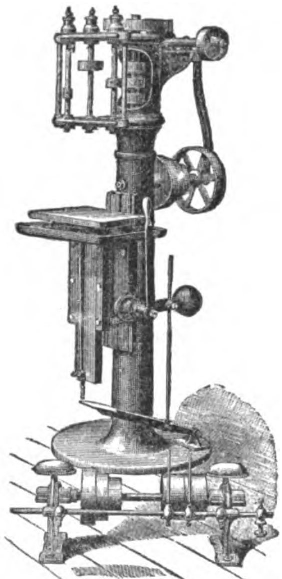
"*Scientific American*" . . . . xxxix. 136.

Gang. (*Sawing.*) *Round* and *live* gang are synonymous, one being the Eastern and the other the Western term for the same thing. It means such an arrangement of the saw-mill as causes the whole log to be cut up into boards at one operation. A *slabbing* gang is one by which from only the two sides of a log slabs are cut off, while the middle part remains as a thick beam. When the log is carried forward on a carriage termed a *saddle*, it is called a *saddle slabber*. After a beam has been flattened by passing through the *slabber* gang, it can be sawn into boards of equal width in the *flat* gang, when it will be straighter than if sawn only on a *round* or *live* gang. A *pony* is a single or small flat gang, used for sawing thin boards out of the best quality of timber.

Fig. 1130.



Gang Drill.

Gang Drill. A machine-tool having a number of vertical drills in a single head, each with its own belt and pulley from a common shaft, and with speed pulleys common to the gang.

The Pratt & Whitney gang drill is shown in Fig. 1130, without bands to the drill spindles, which are three in number. The counter shaft is shown detached, lying in inverted position upon the floor. The bench has vertical adjustment, and a certain amount of traverse by means of a treadle.

* *Thurston's "Vienna Report,"* ii. 223.

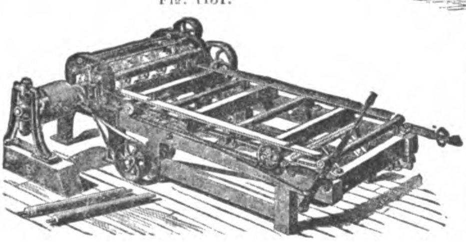
Gang Edg'er. A machine with a number of circular saws on a common mandrel, and adjustable as to relative distance, so as to split wide planks, etc., into boards or scantling of the desired width. The saws are from 3 to 6 in number.

In the Lane & Bodley gang edger the saws are not held on the mandrel by grooved collar and fork but by guide fingers on opposite sides of the saw; the guides have adjusting screws at the opposite ends of a yoke.

The stuff is fed between upper and lower rolls, the former being adjustable to admit varying thickness of stuff.

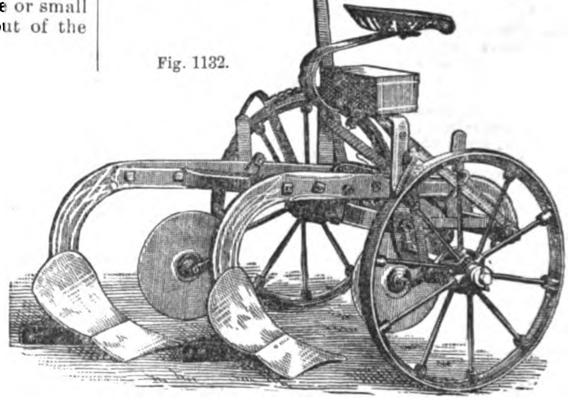
* *"Manufacturer & Builder"* . . . xi. 53.

Fig. 1131.



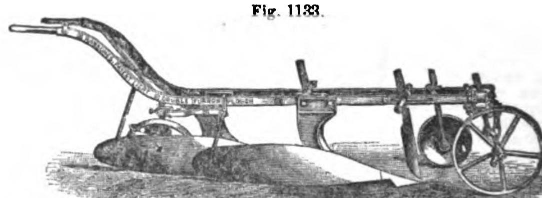
Gang Edger.

Fig. 1132.



Moline Gang Plow.

Fig. 1133.



British Gang Plow.

Fig. 1134.

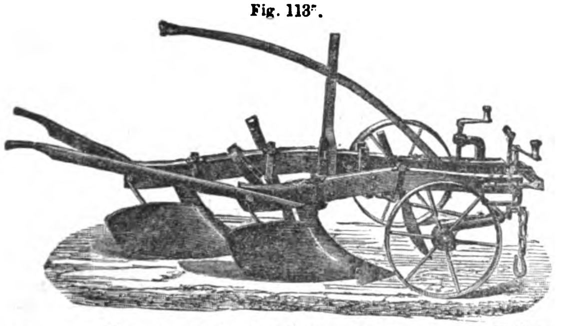
Ransome's Multiple Plow.

Gang Plow. A plow with two or more shares and mold-boards.

That shown in Fig. 1132 is the Deere gang-plow (Moline), which is all of iron and steel.

The plows are rigidly connected, rock upon the axle, and are operated by one lever. It is run by either three horses abreast, or four horses strung out in pairs, or any larger number in pairs, one wheel in the furrow. The plow is operated entirely by one lever, which locks the plows in the ground at various depths; and the same lever, in connection with a lug on the hub, lifts the plow clear of the ground for turning at the ends, without any effort of the operator. The tongue and clevis are attached to the beams by a swivel bolt,

Fig. 1135.



Meixmoron de Dombasle's Gang Plow.

giving it a free vertical motion, relieving the horses' necks of all pressure, and affording a natural draft from the ends of the beams, and from the end of the tongue.

It received a gold medal at the Paris Exposition of 1878, after the trial at Marmont, near Paris, the same summer.

Fig. 1133 is a British gang-plow, shown in two positions; the lower one illustrates the means for allowing it to travel on the surface of the ground without penetrating, in moving to and from the field and turning at the ends of the lands. Of its three wheels, one is for gage of depth; one to run in the furrow and support the plow behind the share, reducing the friction; and the third is only used to support the fore end of the plow in turning, while the rear end is supported by the stirrup-shaped piece.

Fig. 1134 is Ransome's multiple plow with three shares. The body is of the usual British type, an open frame of bar iron to the beams of which the plow standards are bolted. A single handle projects at the rear, and the depth of the furrows, or the complete removal of the plows from the soil is accomplished by a lever which governs the crank-axle of the carrying wheels, elevating or depressing the plow frame and bodies simultaneously.

Fig. 1135 is the *bisoc* of Meixmoron de Dombasle, of Nancy, France. It is composed of two plows attached to a single frame (*avant train*), which is supported by wheels, and carries the clevis, which has adjustments for land and for depth. The axle of the fore-carriage carries a long lever, projecting upward and rearward, and by the depression of the upper end the crank axle is rotated, throwing the wheels forward and lifting the front end of the plow, so that the shares leave the ground. This is used in turning at the end of a furrow, and also as a means of setting the plow for any given depth, pins on the vertical post holding the lever at any inclination. It received a gold medal at the trials at Marmont, near Paris, Exposition of 1878.

Gang Press. One for operating upon a pile or row of objects in a gang.

Seen in some forms of oil and stearine presses; see also FILTER PRESS, where the cases are in gangs. See also CHEESE PRESS; HOT-PRESS; HYDRAULIC PRESS.

Gang Saw. Several saws in a frame or on a spindle, acting simultaneously, either gate or circular. See Fig. 2157, p. 942, "*Mech. Dict.*" See GANG.

"The vast systems of roller gang mills in America have no parallel in the world." — *Richards.*

"A circular saw for edging and squaring, with a gang for slitting the stocks at one operation, is the equipment of a modern saw-mill. This outfit is, of course, duplicated many times in a large mill. At St. Anthony, in Minnesota, there are as many as 12 such mills in a single establishment."

"The speed of the teeth, or the number of teeth that operate in a given time, is the exponent of the performance of saws. The rate of feed varies with the timber; and saw-mills, like other machinery, are governed by mechanical laws, which admit of theoretical demonstration.

"A single reciprocating saw of 30″ stroke, 180 a minute, has a cutting movement of 450′ in the same time. In a gang of 20 saws, making in a minute 150 strokes of 24″, the cutting movement in the aggregate is 6000′ per minute." — *Richards.*

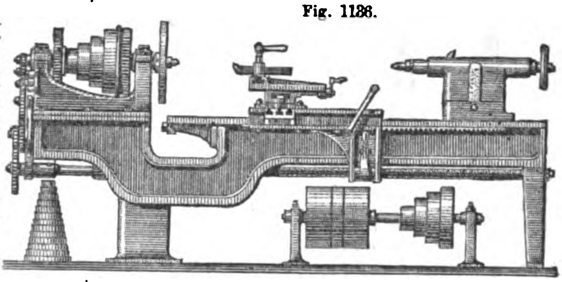
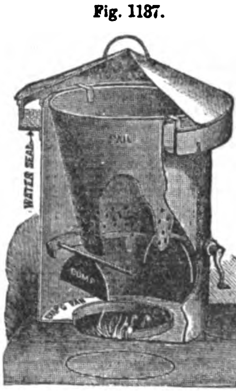
Fig. 1136.



Gap-bed Engine Lathe.

Gar'bage Burn'er. A self-sealing pail for holding kitchen garbage. It is suspended within an outer cylinder adapted to be placed on a stove, so that the garbage may first be dessicated and then dumped into the stove.

Fig. 1137.



Garbage Pail.

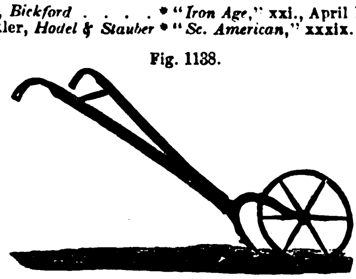
Pavement garbage box, *Jonas*, Br., * "*Engineer*," xlix. 190.

Garbage furnace, *Foote*, * "*Scientific American*," xl. 198.

Gar'den En'gine. A pump for watering the garden. See AQUAPULT, HYDRONETTE, IRRIGATOR, etc.

Pump, *Bickford* . . . . * "*Iron Age*," xxi., April 11, p. 5
Sprinkler, *Hodel & Stauber* * "*Sc. American*," xxxix. 370.

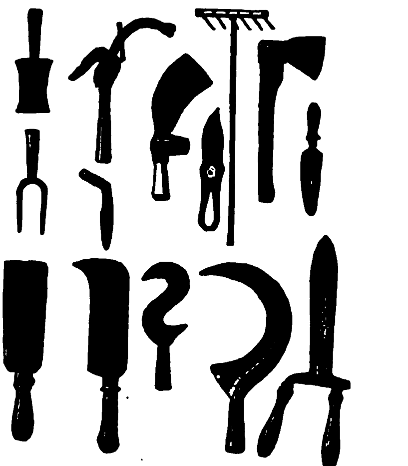
Fig. 1138.



Garden Plow.

Gar'den Net. One placed over fruit trees or vines to guard against depredation by birds.

Fig. 1139.



French Garden Tools.

Gar'den Plow. A small hand plow for cultivating vegetables in rows. It has a variety of hoes. See Fig. 1138.

Gar'den-ers' Tools. Fig. 1139 shows a variety of French garden tools: for digging, cultivating, trimming, pruning, and transplanting.

Gar'den Syr'inge. See AQUAPULT; IRRIGATOR; SPRINKLER, etc.

Gas'a-lier'. An arrangement of standard or drop, with branches and burners, adapted for the consumption of illuminating gas. The word is a clumsy imitation of *chandelier*.

Gas An'a-ly'zer. An instrument for determining the presence and quantity of the gases obtained by the destructive distillation of coal.

The following gases are produced: —

Ammonia (NH_3).	Acetylene, etc. (C_2H_2).
Sulphureted hydrogen (SH_3).	Carbonic oxide (CO).
Carbonic acid (CO_2).	Light carbureted hydrogen (CH_4).
Air, or oxygen and nitrogen.	Hydrogen (H.)
Bisulphide of carbon (CS_2).	
Olefiant Gas (C_2H_4).	

The first four of these gases on the list, although often present in well-made gas, are generally considered impurities, and by right should not be there.

The first analysis is qualitative to ascertain presence, to determine the order of precedence in the removal. The apparatus admits the gas to be bubbled up through the liquid charged with reagent.

The following reagents are used in the various tests: —

1. Dilute sulphuric acid.	8. Solution sub-chloride copper in hydrochloric acid.
2. Solution nitrate silver.	9. Lime water.
3. Solution arsenious acid.	10. Red litmus water.
4. Solution iodine.	11. Solution acetate lead.
5. Bromine	
6. Solution caustic potassa.	
7. Solution pyrogallate potassa.	

See "*American Gas-light Journal*," reproduced in part in * "*Scientific American Supplement*," 1767.

Gas and Air Mix'er. An instrument designed to mix a given proportion of air with gas made from petroleum, or its residuums, or tar, oil, rosin, or any rich hydro-carbon, so as to produce the best results from the combustion of either, through ordinary gas burners. Gas 60, air 40, is the usual proportion.

Gas and Coke Fur-nace. Many attempts have been made to obtain at the same time and operation gas for lighting and coke for metallurgical operations, by coking the coal in closed furnaces, from which the gas was conducted to the hydraulic main.

Pauwels, in 1849, established an apparatus of this kind at Ivry, in the suburbs of Paris, and his plan was subsequently improved by Pérate, resulting in the arrangement now used at Vilette, Paris, and elsewhere. See Plates XVI., XVII.

The distillation chamber is constructed of brick, and is of sufficient size to contain 6000 kilos of coal. It is open at each extremity, and the sole is horizontal. The coal is brought in wagons, which run on rails placed above the battery of parallel chambers, in order to be discharged into the chamber at an opening provided in the arched ceiling. Workmen spread it evenly over the floor to the height of the springing of the arch, equal to 0.60 to 0.70 m. of depth.

The sole of the furnace is heated by the circulation of flame beneath it, and serves, while the chamber is being recharged, as a reservoir of the heat produced during the latter part of the preceding operation. There is but one fire to each chamber.

The chambers are placed side by side and are closed at each extremity by an iron door, working in fixed iron guides on the jambs of the furnace mouth, and luted with fire-clay during the operation.

The gas escapes by a pipe *T*, which pierces the vault and communicates with a general conduit, a hydraulic valve *H* preventing back-lash of gas when the chamber is opened for recharging.

The distillation of a charge, containing 5 or 6 tonnes, occupies 72 hours. When it is terminated, the doors are unclamped, the luting removed, and the hydraulic valve fastened down. The free gas in the chamber escaping around the doors is lighted, and the doors are lifted by means of a winch, which travels on rails above each face of the battery of chambers. These rails are founded on the iron stay-structure of the furnace front.

The coke is removed by a pushing apparatus which, entering at one doorway, — that to the right in the longitudinal vertical section, — crowds the coke out at the other door on to a stone or iron floor which is on a level with the sole of the coke chamber. This floor is subdivided by walls in prolongation of the divisional walls between the respective chambers, and which are about the height occupied by the coke when in the chamber. These walls form a sort of cell for the coke into which it is pushed and where it is smothered by a covering of cinders and allowed to cool for 24 hours.

The figures in Plates XVI., XVII., represent the Pauwels-Pérate system as applied at Villette, Paris.

Fig. 1140 is a vertical transverse section on the line *A' B'*, Fig. 1143, and passing through the axis of the charging hole *G* by which coal is introduced into the chamber *C*. Above it is seen the wagon *W* in which the coal is brought, and which runs upon the rails.

Fig. 1141 is a transverse vertical section following the line *A, B, C, D*, Fig. 1143. It passes through the furnace *F*, and shows the diving flues *V V*, to the flues *X X*, leading to the chimney *Y*, which is common to all the furnaces in the battery. Dampers are placed in the diving flues to regulate the draft.

Fig. 1142 is a front elevation at the end where the coke pusher is operated, the right hand in the longitudinal vertical section.

Fig. 1143 is a vertical longitudinal section through the center of the chamber and the furnace beneath. It shows the entrance conduit *G* for the coal; the pipe *T*, by which the gas escapes from the chamber and the hydraulic valve *H* which isolates the gas conduits from the chamber when the latter is recharging. *W* shows the coal wagon on the track and *W'* an empty wagon on another pair of rails. The winches, *K K*, move on their respective tracks above the front and rear faces of the battery, and serve to lift the heavy iron doors which close the ends of the chambers of distillation.

Fig. 1144, Plate XVII., is a plan passing on a line just beneath the sole of the chamber and above the furnace. It indicates the circulation of the flames under the sole. The draft passes along the center and reverts back along each side, as shown by the arrows at the end of the division walls, *M M*. *V V* are the diving flues leading to the flues *X X* and chimney, *Y*, previously mentioned. The brick pillars *a a* support the sole, like those in the Roman *hypocaustum*, which, in fact, the furnace arrangement much resembles. See Fig. 2629, p. 1160, "*Mech. Dict.*"

Figs. 1145 and 1146 show the coke discharger, the first-named figure being a plan view and the other an elevation. The discharger has two principal portions; the lower one, *P'*, resting upon several pairs of wheels, *R R*, of which one pair only is shown in the views, in order to bring the illustration within reasonable space. By means of these wheels and the rails, *T*, the coke-pusher is brought opposite to any one of

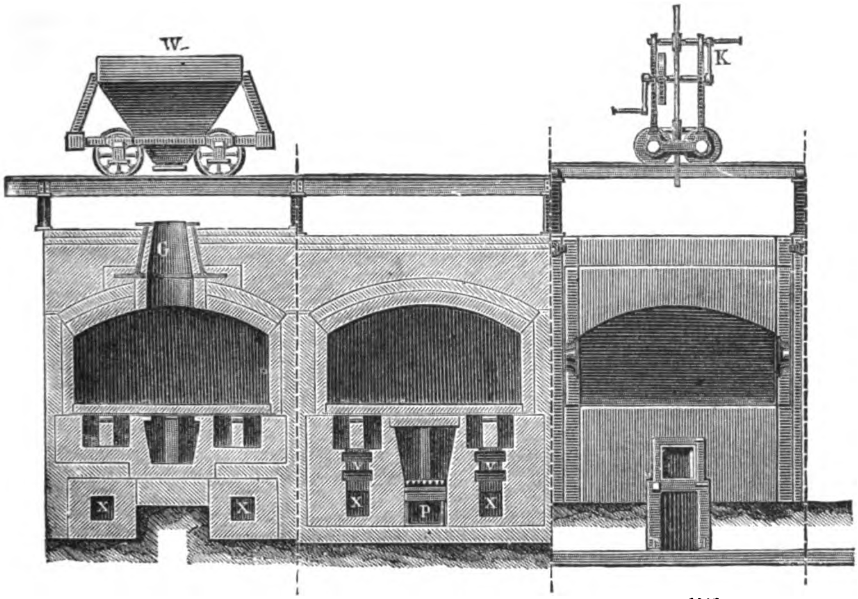

FIG. 1140. *Front Elevation*

FIG. 1141. FIG. 1142. *Transverse Vertical Sections.*

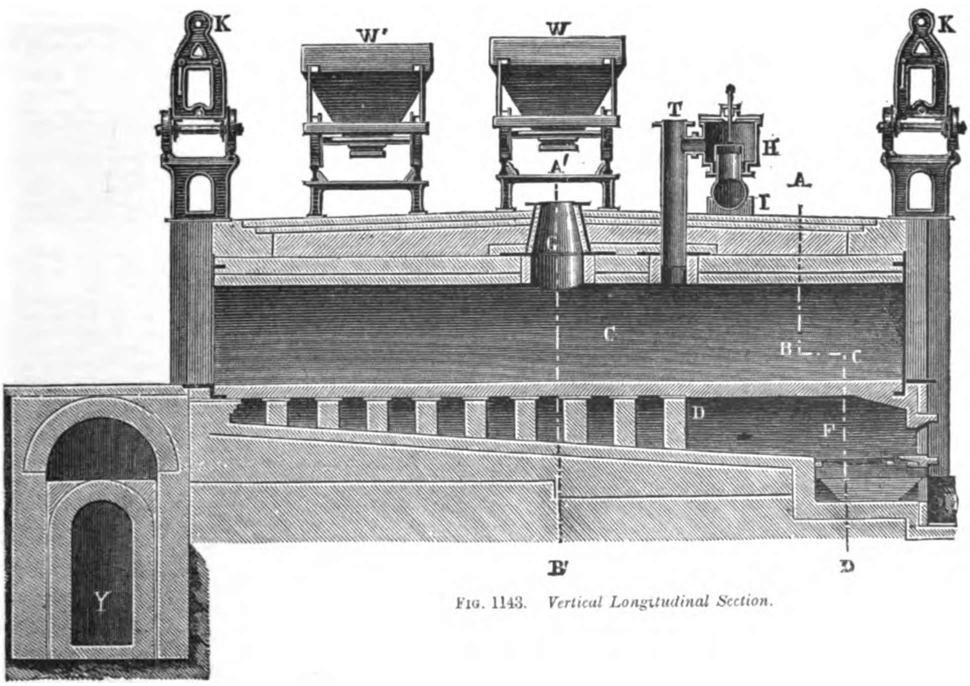

FIG. 1143. *Vertical Longitudinal Section.*

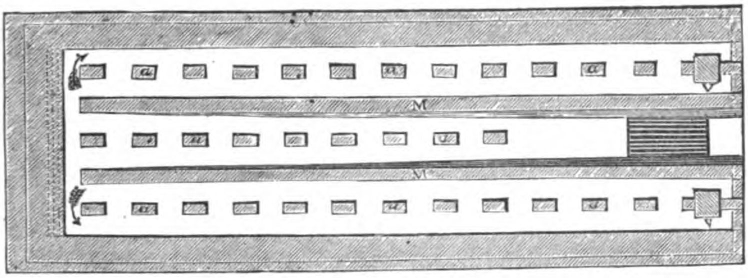

FIG. 1144. *Horizontal Section through Furnace.*

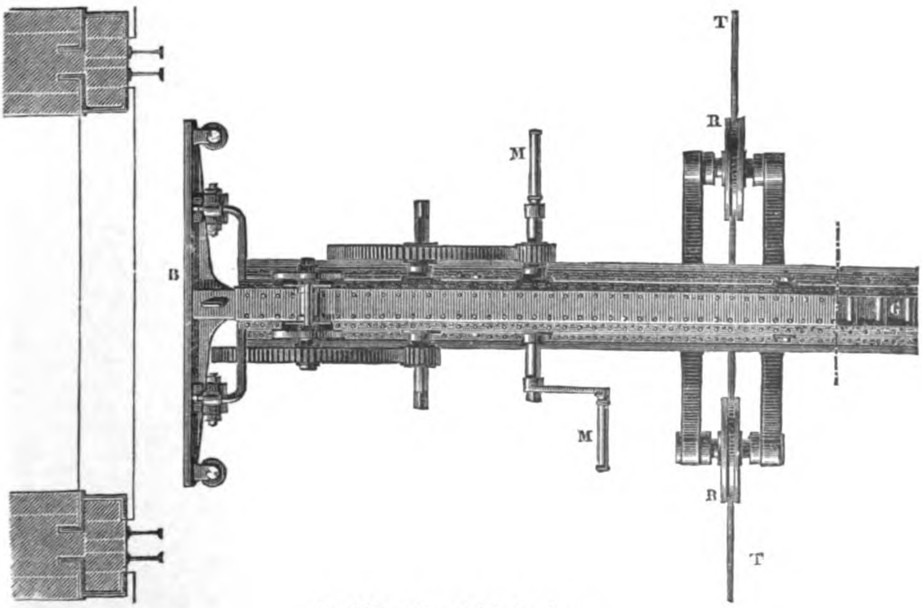

FIG. 1146. *Plan of Coke Discharger.*

the coke chambers, and, the doors of the latter being open, the upper portion, *P*, of the apparatus, armed at the end with a shield, *B*, is projected by means of the cranks, *M M*, and the gearing, acting upon a rack, *G*. The pusher, *P*, slides upon rollers on the carriage, *P′*, and the shield, *B*, has rollers at its ends which guide it in the coke-chamber to prevent its injuring the walls.

The coke oven of McLanahan & Co., Hollidaysburg, Pa., seems to be somewhat on this plan. Each chamber or oven is 22′ × 3′ and 7′ high, and a row of them looks like an arcade. The bottom and sides of the ovens are combustion chambers, in which is burned the gas liberated from the coke. The ovens are closed by iron doors at the ends.

The ovens are charged by hopper-filling trucks, which run on rails above the ovens; two filling holes to each oven aid in distributing the coal. The discharge is effected by a steam ram, which moves to and fro on a railway in front of the ovens. At the end of a long rack is a head which fits the oven, and this is pushed by powerful gearing, and expels the coke at the opposite doorway, the coke being left on the cooling ground at the other side of the oven. The ram being then withdrawn, the doors closed, the covers taken from the filling holes, the oven is recharged before it has had time to cool. The charge of an oven is 8 tons, and it is coked in 72 hours, the time occupied by the ovens at Villette. The produce is 6 tons of coke.

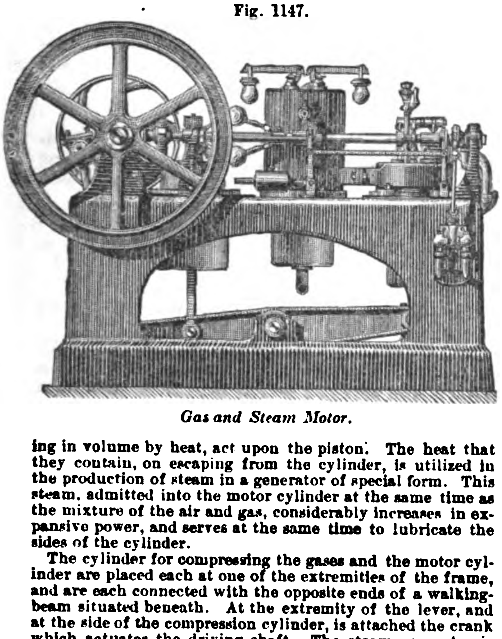
Gas and Steam Mo′tor. A machine operating through the combined forces of compressed gas and steam.

Simon's motor combines air, compressed gas, and steam The two former are aspirated and compressed in a cylinder, where they are mixed, and whence they pass into the motor cylinder above a jet of gas kept constantly burning. There they burst into flame, burn without explosion, and increas-

Fig. 1147.



Gas and Steam Motor.

ing in volume by heat, act upon the piston. The heat that they contain, on escaping from the cylinder, is utilized in the production of steam in a generator of special form. This steam, admitted into the motor cylinder at the same time as the mixture of the air and gas, considerably increases in expansive power, and serves at the same time to lubricate the sides of the cylinder.

The cylinder for compressing the gases and the motor cylinder are placed each at one of the extremities of the frame, and are each connected with the opposite ends of a walking-beam situated beneath. At the extremity of the lever, and at the side of the compression cylinder, is attached the crank which actuates the driving shaft. The steam generator is situated in the center, between the motor and compressing cylinders.

In the great variety of motors acting by expansible gases and air, the three — air, gas, and steam — have been combined in numerous ways. The history of the subject has been sketched in GAS ENGINE, pp. 947-949, "*Mech. Dict.*" See also GAS ENGINE, p. 881, *et seq.*, *infra*.

Gas and Wa′ter-tight Cloth.

A large, smooth piece of so-called gutta-percha paper is placed between two pieces of shirting, and then passed between heated rollers. The outer pieces of shirting combine in the most intimate way with the inclosed gutta-percha to form a material which is impenetrable by gas and water. It may be made still denser and more resistant by being coated on both sides with copal lac. The substance is conveniently flexible, and will remain proof against variable influences of weather and external temperature. It can be applied to all those purposes for which water-proof material is used, and it is well adapted to form gas-tight membranes for regulators of pressure of compressed gas, bags or sacks for dry gas meters, as also dry gas reservoirs. — *Dr. Hirzel*, of Leipsic.

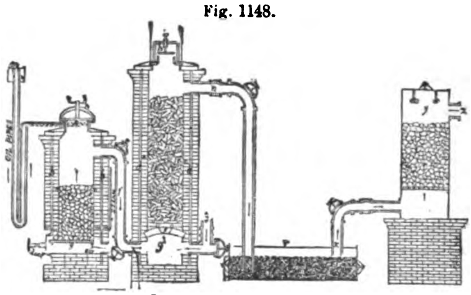
Gas Ap′pa-ra′tus. The Lowe gas-producing apparatus is shown in Fig. 1148.

Beginning on the left, the consecutive apparatus are — the generator, super-heater, washer, and scrubber.

The operation is as follows: —

The generator is kindled through door at base; charged

Fig. 1148.



Lowe's Gas Apparatus.

with anthracite from top and closed; the valve at top of super-heater being opened, and outlet at right of same closed.

Blast is applied below grate bars of generator, which, passing upward through same, and downward by connecting pipe, enters base of super-heater and passes upward through the perforated arch and the mass of loose fire-brick out into smoke-stack.

The gases thus carried from the coal into bottom of super-heater are met there and ignited by an air-blast, evolving an intense heat. When the anthracite is at cherry red, the second is white hot.

The blast is then shut off, top of super-heater closed, and its outlet opened. Hot steam is introduced below into the incandescent coal, while crude petroleum, led through trapped pipes, is simultaneously dropped thereon from above. The resulting gases pass off together into and through the super-heated fire-brick, by contact therewith being made permanent, and thence go through washer, scrubber, etc., to holder.

Melville's process, 1805-1813, is among the earliest in the history of the industry, and is shown in "*American Gas-light Journal*," • July 3, 1876, p. 9.

See CARBURETOR, GAS MACHINE, etc. See list under GAS, *supra*.

Gas Bag. (*Gas.*) A device to stop the flow of gas in a pipe or main during repairs or alterations. A hole is tapped, the collapsed bag inserted, and then inflated by means of the service cleaner or other air-pump. They are made with or without valves, either of rubber or of cloth.

Gas Bath. See BATH HEATER, Figs. 243, 244, pp. 82, 83, *supra*.

Gas Bat′te-ry. (*Electricity.*) One which has two platinum or other electrodes, one in oxygen, and the other in hydrogen, in two inverted cups, their edges submerged in acidulated water.

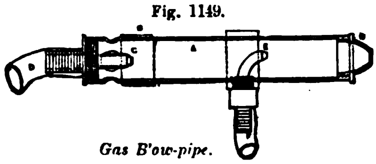
Gas Blow′-pipe. Fig. 1149 shows Wenham's gas blow-pipe, as adapted for the mouth blast or foot bellows.

D is the elastic pipe connecting with an ordinary gas burner, and *F* the elastic tube carrying air from the mouth or bellows. *A* is a brass tube into which the gas nipple *C* and air-jet *E* intrude. *G* is a split ferrule which slips on the tube *A* and regulates the area of air opening according to the supply of gas.

When there is a full supply of gas, and these orifices are quite open, with a strong mouth blast, the spire of flame issuing from the end at *B* will be 4″ or 5″ in length, perfectly

Fig. 1149.



Gas Blow-pipe.

stationary and quiet, and ending in a fine point. If the heat be too great for the purpose required, and the gas supply has to be turned down, the air-regulating ferrule *G* must also be drawn back, else the flame will be extinguished. When properly adjusted, either for maximum or minimum heats, this instrument in either case gives the required pointed flame, and as the orifice of the air jet at *E* is rather smaller than that generally used in an ordinary mouth blow-pipe, a continuous blast can easily be kept up without intermission.

Diameter of nozzle orifice at *B*, .23″; four openings at base, .23″; diameter of orifice gas at nipple at *C*, .07″; orifice of air or blow-pipe jet *E*, .02″.

Gas Boil'er. 1. A form of steam boiler in which coal gas is used as fuel. In the coal and petroleum regions, especially the latter, there are instances of the escape of natural gas which are largely used in steam boilers and metallurgic furnaces. See p. 944, "*Mech. Dict.*"

Otherwise, the gas boiler is usually a small vertical boiler in which gas is used instead of other fuel, for various reasons: compactness, cleanliness, saving in insurance, convenience of starting fire, easiness of regulation. To keep the boiler at a uniform working temperature, or just to keep up steam, or draw the fire, very small amount of attendance is necessary.

Fig. 1150.

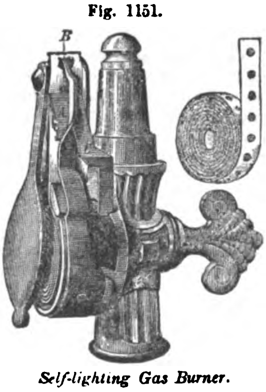
Portable Gas Boiler.

Under CROSS-TUBE BOILER, VERTICAL BOILER, suitable forms of boilers are shown.

2. A small boiler for bath, conservatory, or domestic uses. When used for green-houses it is fixed outside the house, and the upper and lower portions of the boiler are connected by wrought-iron pipes in which the water circulates, as in the ordinary water heater. In the form shown the boiler is portable, and has an enamel lining.

Gas Burn'er. Fig. 1151 is Stockwell's self-lighting gas burner. It has a chamber with a coiled strip of paper, on which are dots of fulminating compound. By turning the key, the paper coil is partly unrolled, and a pellet exposed to the action of a spring hammer at *B*, which causes a flash and thus ignites the gas instantly.

Fig. 1151.



Self-lighting Gas Burner.

A is a bent piece of metal, the lower portion of which enters a slot in the rear wall of the chamber, and has a projection below at right angles, which enters a circular hole in the disk, so that the rotating of the latter, in one way or the other, by the key, causes said piece to ascend or descend. The square upper end of the piece presses against the tape, and consequently raises and unwinds the same, as the key is turned vertically. At the same time, the piece *A* pushes back the spring hammer *B*, until the bend in the former at *C* is reached, at which point the hammer is released and carried forward by the spring, strikes one of the dots of fulminate, explodes the same, and so lights the gas. The arrangement of parts is such that the hammer does not fall until just as the key is placed so as to turn the gas fully on, which insures ignition. Each roll of tape contains 135 fulminate dots.

Chaussenot's gas-burner, adjudged the prize de la "Société d'Encouragement," 1836, is described in *Laboulaye's* "*Dictionnaire des Arts et Manufactures,*" ed. 1877, article "*Eclairage,*" tome iv.

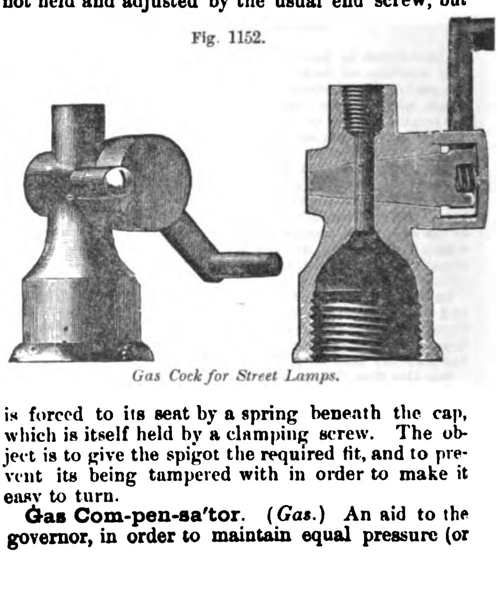
Gas Cock. Fig. 1152 shows Peck's gas cock for burners of street lamps. It is conical in shape, is not held and adjusted by the usual end screw, but

Fig. 1152.



Gas Cock for Street Lamps.

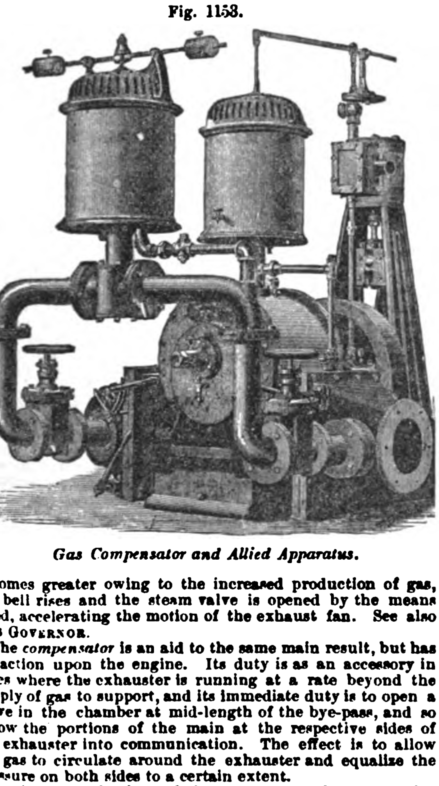
is forced to its seat by a spring beneath the cap, which is itself held by a clamping screw. The object is to give the spigot the required fit, and to prevent its being tampered with in order to make it easy to turn.

Gas Com-pen-sa'tor. (*Gas.*) An aid to the governor, in order to maintain equal pressure (or vacuum, as the case may be) in the action of the exhauster. The latter is assumed to be of a capacity in excess of the possible need, and its action under the circumstances of the varying production of gas, in different seasons, portions of the day, during the changing of retorts, etc., requires automatic compensation. For this purpose it has a *governor*, *compensator*, and *bye-pass*.

Fig. 1153 shows a convenient disposition of the whole apparatus arranged in compact form upon a single bed plate. Made on a scale for works of moderate size it occupies but 6′ × 5′ space in the exhauster room and includes engine, exhauster, governor, compensator and bye-pass.

The exhaust fan is driven by the engine on the right, the fly-wheel shown in the cut being upon the fan shaft. Above the case is the governor, in which is a bell raised by the pressure of gas beneath it and by means of the vertical stem and counterbalanced lever operating the throttle valve of the engine. When the pressure under the bell in the governor

Fig. 1153.



Gas Compensator and Allied Apparatus.

becomes greater owing to the increased production of gas, the bell rises and the steam valve is opened by the means cited, accelerating the motion of the exhaust fan. See also GAS GOVERNOR.

The *compensator* is an aid to the same main result, but has no action upon the engine. Its duty is as an accessory in cases where the exhauster is running at a rate beyond the supply of gas to support, and its immediate duty is to open a valve in the chamber at mid-length of the bye-pass, and so throw the portions of the main at the respective sides of the exhauster into communication. The effect is to allow the gas to circulate around the exhauster and equalize the pressure on both sides to a certain extent.

Passing into the base of the compensator is seen a pipe carrying gas. The weight of the bell within is compensated by the lever arms above, the weights being slipped towards or from their fulcra according to the adjustment required.

Gas Com-press'ing Pump. Pumps for condensing gas for car-lighting purposes are used by the Pennsylvania Railway, storing the gas in tanks 9′ 11½″ long, 12″ diameter, with cubic capacity of 12,995″. The gas is obtained from the city main and condensed to a pressure of 300 lbs. per square inch. From these it is conducted to reservoirs under the cars.

See also GAS LIQUEFACTION APPARATUS.

Gas Con-den'ser. (*Gas.*) The multitubular condenser is an apparatus for condensing the tar from the gas.

It consists of a cast-iron box, or series of boxes, with two horizontal diaphragms or partitions, one near the top, and the other near the bottom; the upper and lower spaces thus formed are connected by cast-iron pipes, usually about 4″ in diameter, placed as closely together as possible. The middle space of the box is filled with water, surrounding the pipes.

A series of boxes is thus arranged side by side, the gas is admitted into the lower space and passes up through the pipes to the upper space; from there it goes to the top space of the next box, down the pipes to the bottom space, thence into the next box, up the pipes, and so on, thus traveling up one set and down the other until the temperature of the gas is reduced sufficiently low by the water surrounding the pipes to cause the tar, etc., to be deposited in the lower space, from which the tar is run off into cisterns constructed for the purpose. The water surrounding the pipes is admitted from the end of the series of boxes opposite to that at which the gas enters, so that the water surrounding the pipes through which the gas first passes is the warmest (the heat having been acquired by the flow of gas), and that at the end where the gas leaves the condenser is the coolest. In this way the cooling of the gas goes on gradually, and is not too sudden in its change of temperature at any point, and the rapidity of cooling is easily controlled by regulating the amount of fresh water admitted to the condenser.

This form of condenser is largely used in this country, but is almost unknown in Europe, where, as a general thing, the temperature of the air is relied upon to cool the gas, which is passed through pipes exposed to the air out of doors for the purpose. The great advantage of the multitubular method is the control it gives to the rate of cooling.

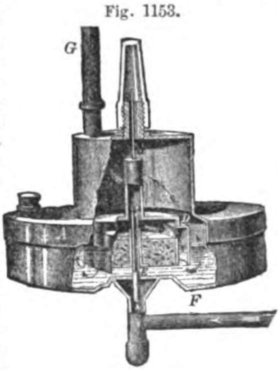
Gas Con-duct'or. (*Metallurgy.*) The downcast shaft at the side of a blast furnace, leading the heated gases from the top of the furnace to the hot-blast oven (*B*, Fig. 2588, p. 1134, "*Mech. Dict.*"), for heating the feed air of the furnace. Four such downtakes are shown in Fig. 5222, p. 2223, *Ibid.*

Gas De-tect'or. (Fr. *cherche-fuites.*) A torch for detection of leaking joints in pipes or gas apparatus.

Gas Drip Pump. A plumber's hand-pump, for removing water of condensation collected in gas piping.

Gas E-con'o-mi-zer. A carburetor for enriching gas by passing it through a hydrocarbon liquid. *F* is the pipe from the meter, and *G* the pipe leading to the burners. A float, *D*, slides upon a tube, *E*, and rests upon the hydro-carbon liquid in the chamber *A*. The gas is driven in the direction of the arrows, through the hydro-carbon, being enriched in its passage, and has always the same quantity of liquid to rise through, as the edge of the float *D* is equally submerged whatever the depth of liquid.

Fig. 1153.



Gas Economizer.

Gas saver, *de Palos* . . . "*Scientific American*," xlii. 164.

Gas En'gine. Gas engines are divisible into two systems: —

1. That system in which the expansive force of the gases acts directly upon the piston and, through this, upon the other moving parts, as in the Lenoir and Hugon engines, and

2. That in which the force of the explosion urges the piston (which for the moment is free) until a partial vacuum is created below it, when the atmospheric pressure is brought to act, and at

the return stroke produces the effective work. This includes the Otto and Laugen engine.

The upright Otto-Langen gas used at the Centennial Exhibition of 1876 has been superseded by the *Otto* horizontal gas-engine.

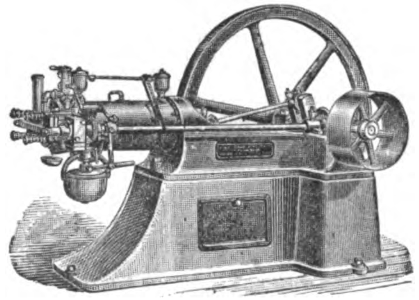
In the *Otto-Langen* engine coal gas and air are mixed in such proportions as to give a mildly explosive compound, and are admitted under a piston which slides air-tight in a vertical cylinder open at top.

The piston-rod urges the shaft only in an intermittent manner; it is geared to a pinion on the shaft which engages the shaft by means of a friction pulley only on the down stroke. On the up stroke the piston is driven violently by the expansive force of the gases till the pressure of the mixed products equals the atmospheric pressure, and is carried beyond this point by acquired momentum. It stops only when the work of the atmospheric resistance has absorbed the accumulated work in the piston. There results a rarefaction under the piston, so the down stroke is urged by atmospheric pressure aided by the weight of the piston. This descent is the effective stroke of the engine, for it is only then that the piston-rod is connected to the driving-shaft.

A variable automatic governor is attached. The piston-rod has teeth on one side working in a pinion, and is steadied by slides on the other side.

"This method of employing the effects of the explosion only indirectly has yielded good results economically; affording one-horse power for a consumption of one cubic meter of gas per hour, in place of 2.7 m., as in the Lenoir and Hugon engines. But the noise of the engine, as in the former cases, is quite unendurable, and has led to its rejection." — "*Armengaud.*"

Fig. 1154.



Otto Gas Engine.

The Otto gas engine consists mainly of a jacketed cylinder, with piston, slide valve, and governor, having a cut-off mechanism to regulate the supply of gas according to the varying load on the engine. The pressure utilized for the production of the power is generated in the cylinder, and at once used therein to propel the piston. This pressure is due to the combustion of a mixture of common coal gas and air, which is ignited by a small flame, carried from a burning gas jet outside into the cylinder by the motion of the slide. A small part only of the charge is combustible, which, on ignition, serves to expand the remainder, thus avoiding the shock, due to explosion of the whole charge.

In the Otto engine (as also in the Simon) the mixture of air and gas is compressed before explosion, so that the initial pressure at the moment of ignition is 12 atmospheres.

"The two ideas of previous compression of the mixed gases and a gradual combustion, instead of a violent explosion, distinguish the improved engines from the old forms. [Hugon and Lenoir.]

The Otto engine resembles externally a single acting steam engine. It has a single horizontal cylinder, open at one end and closed at the other, with a head furnished on the inner side with a conical cavity. The piston is connected by a crank with the shaft of the fly-wheel. Behind the cylinder is the supply chamber, which is furnished with a direct connection with the main shaft. The piston at the in-stroke does not reach the end of the cylinder, but leaves a space equal to about two fifths of the capacity of the cylinder. This is the compression chamber.

"The cylinder serves the double purpose of compression pump and working cylinder, which is perhaps not the least of the characteristics of the new system.

"The complete cycle of motions in the Otto engine is accomplished only by two complete revolutions of the working shaft, or four strokes of the piston. It comprehends the four following phases, namely: —

"1. The piston makes an up-stroke, drawing in the explosive mixture of gas and air;

"2. The inlet cock closes and the piston returns, compressing the gaseous mixture;

"3. At the moment the down-stroke is completed, and while the tension of the gases is somewhat above two atmospheres, the mixture is inflamed, and the consequent expansion causes the piston to make an up-stroke.

"4. The piston returns, driving out the expanded and cooled gases.

"Thus, of four strokes of the piston, only one (the third) conveys motive force to the shaft.

"The second consumes power; the other two have no appreciable effect.

"Such a method of working calls for a heavy fly wheel, the accumulated work of which accomplishes the compression of the gases.

"A special regulator to the engine intercepts the supply of gas and delays the ignition whenever the velocity becomes too great. Furthermore, the engine works without noise — a great advantage over the Otto and Langen motor.

"The effective working power of the engine is of course the difference between that afforded by the expansion of the gases and that absorbed by the compression. The indicator diagrams show a regular curve of pressures very different from the line of abrupt changes exhibited by the Lenoir engine.

"The regular decrease of pressure in the Otto engine is due to the method of burning the mixed gases The combustion is retarded, so that the heat developed is absorbed by the gases at a rate that is in better accord with the motion of the piston.

"M. Otto has accomplished this by his method of mixing and admitting his gases. He employs two different mixtures; one of fifteen parts air to one of illuminating gas, which he calls his 'feebly explosive mixture:' the other of seven parts air to one of gas, is called his 'strongly explosive mixture.'

"During the working of the engine, and at the moment when the gases are about to be ignited, the contents of the cylinder are: products of the preceding explosion, atmospheric air, hydrogen and hydro-carbon gases. These are not uniformly diffused, but owing to the position and action of the valves, the most combustible portion is at the bottom of the cylinder at the point of ignition, and the combustibility probably decreases quite regularly from the bottom of the cylinder to the piston

"The result of this condition is a *prolonged* explosion, and the force of expansion is less of the nature of a shock than in the previous engines.

"In order to insure combustion with proper rapidity, a jet of 'strongly explosive mixture' is made to traverse the mass at the critical moment." — *Armengaud.*

The Gilles gas engine combines the two plans of action in the same engine.

The pressure produced by the ignition of an explosive gaseous mixture in the cylinder of the engine is applied to propel two pistons in opposite directions, that is to say, a working-piston and a loose piston, the former of which is connected by crank with a driving-shaft, and the latter of which is free, but is temporarily held by a clamp after its propulsion by the explosion of the gaseous compound, to secure the return action of the working piston under atmospheric pressure as against a reduced pressure between the two pistons, thereby obtaining a motive power for the working piston in both directions of its stroke.

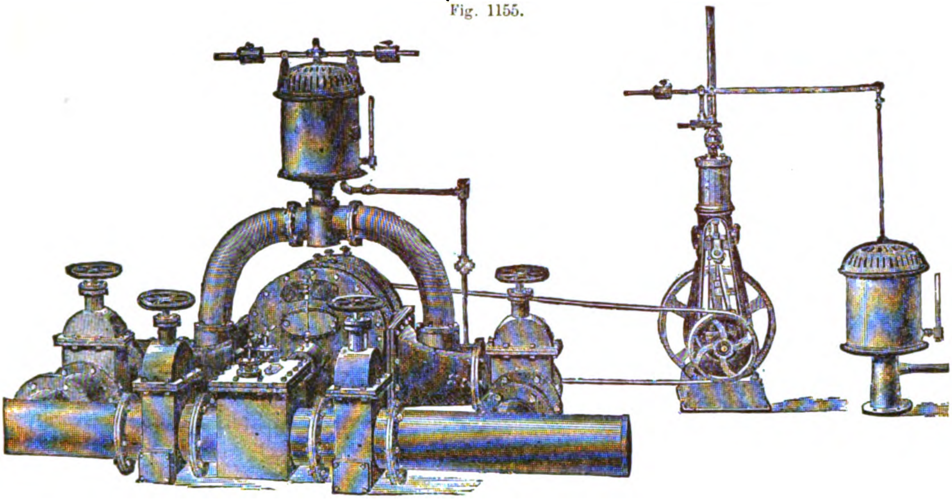
The principle of action of the Simon engine is essentially the same as the Otto, but there are some notable differences in the details. The compression is performed in a separate cylinder: upon the admission to the working cylinder the mixture is ignited by a gas flame kept constantly burning. The cylinders are vertical, and the two piston-rods connect with the same horizontal shaft.

The admission of the explosive mixture and the escape of the products of combustion are managed by valves worked by cams on the working shaft. The mixed gases are admitted in a series of small charges and inflamed successively, thereby insuring a gradual expansion.

Simon uses steam in connection with the gaseous mixture; a jet of steam from a boiler heated by the escaping gases, the water supplied to the boiler being first used to cool the working cylinder. The steam lubricates the piston.

The Bisschof engine belongs to the class that utilize the effects of an explosion to drive the piston. The cylinder is vertical, and the piston-rod connects with the shaft in such manner as to utilize in the fullest degree the effect of ex-

Fig. 1155.



Gas Exhauster.

pansion. No water is employed for cooling the cylinder; the result is secured by constructing the cylinder with projecting ribs or flanges, so as to expose an abundance of radiating surface.

Engines of small size only have thus far been constructed on Bisschof's system. Most of those made have been designed to run sewing machines, with a capacity of 1-15 to ⅛ a horse-power. The working of these costs, in Paris, two cents an hour for the former, and only five cents for the latter size.

The report on gas engines at the Vienna Exposition of 1873, vol. iii., § A, pp. 162 *et seq.*, includes notices of

Lenoir, Fr,	* Brayton, U. S.
Leavitt, U. S.	* Otto-Langen, Ger.
Hugon, Fr.	

The report by M. Armengaud, Jr., at the Conference at the Trocadéro, 1878, was printed in the "*Revue Industrielle*," and reproduced in "*Van Nostrand's Magazine*," xx. 148. It includes notices of the following: —

Gas, steam, and air engine.
Simon, Br. . . . . * "*Engineer*," xlvii. 43.

Gas Ex-haust'er. A rotary fan in the gas main of the works, drawing the gas from the retorts and sending it to the holder.

Another form of exhauster is McKenzie's, which acts by means of a steam jet in the manner of an ejector in a portion of the pipe of diminished area. See STEAM-JET EXHAUSTER.

The apparatus in Fig. 1155 shows an arrangement of *exhauster* in the main-pipe circuit, a *bye-pass* arched above the exhauster, and itself surmounted by the *compensator*. To the right is a vertical *steam-engine* for driving the exhauster, and itself regulated by the *governor* on the extreme right, which is actuated by gas admitted by a pipe from the main.

Pressure of gas in the inverted bell within the governor raises the bell, and by means of the stem and the counter-balanced lever raises the valve of the engine and puts on more steam. The increased pressure in the governor is thus made to accelerate the motion of the fan in the exhauster, and remove from the retorts the gas generated. The exhauster itself may be said to be upon a sort of bye-pass, as it is a U loop lying laterally from the direct line of main shown in the foreground. In this direct line are two stop valves, and between them is a chamber with a pair of butterfly valves which act automatically in a certain contingency; that is to say, if the gas exhauster should cease to operate by the stoppage of the engine or the running off its belt, for instance, the pressure of the gas coming from the retorts would open the butterfly valves and prevent the stoppage of the circulation, which might otherwise burst the retorts. The stop valve on each side of the safety-valve chamber is to cut the latter out of the circulation when it may be necessary to examine or remove it.

The principal bye-pass, on which the exhauster is situated, has also its stop-valves by which it can be cut off, when necessary. The bye-pass shown in arched form above the exhauster is in order to keep a certain equal pressure in cases where the exhauster may be working at a speed beyond the power of the retorts and subsequent apparatus to supply. It is common to provide an exhauster of somewhat more than the necessary capacity, and the bye-pass, the valve of which is actuated by the compensator, establishes a switch connection between the mains on the respective sides of the exhauster, when the difference between the pressures in the two exceeds a certain limit. The compensator is shown above the bye-pass, and is described under GAS COMPENSATOR: where is also shown another arrangement of exhauster, compensator, steam engine, exhaust-governor, bye-pass, pipes and valves.

Gas Ex-haus'ter Gov'er-nor. (*Gas.*) An apparatus to regulate the engine driving the exhauster, so that the speed of the engine is in proportion to the pressure of the gas coming from the retorts, in order to keep the pressure in the latter (or the vacuum, as the case may be) equable. See GAS EXHAUSTER.

Goodwin "*American Gas-light Journal*," * July 3, 1876, p. 4.

Gas Fire-pot. An iron chamber heated by gas and artificial air blast, used for heating soldering irons.

Gas-fit'ter's Pump. One for discharging pipes of air, or blowing away obstructions in gas pipes.

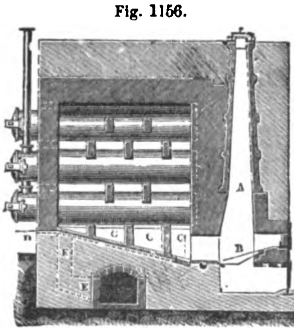
Gas-fit'ter's Torch. A form of lamp usual in the trade. It has a thick wick, and is used to detect escape of gas by applying it to suspected places.

Gas Fur'nace. 1. A furnace for distilling gas from coal, or other form of carbon.

The application of the Siemens and Ponsard furnaces to the distillation of coal in gas-works is shown under GAS-GENERATING FURNACE, Figs. 1159-1162, pp. 385-387, *infra*.

The subject of gas production is considered on pp. 944, 955, 956, "*Mech. Dict.*" An additional illustration may be

Fig. 1156.



Muller & Eichelbrenner's Gas Furnace.

given in the furnace of MM. Muller and Eichelbrenner, which has a magazine charger, *A*; grate bars, *B*, on which the carbonic oxide produced by the burning of coke is carried into flues *C C*, and mixed with air entering at *D*, while the waste products of combustion after the circuit of the retort chamber are conducted by the flue *E E* to the chimney.

2. A furnace in which coal gas from the main furnishes the combustible. See GAS HEATER; GAS STOVE; BATH HEATER; BUNSEN BURNER, etc.

Hoffmann's gas combustion furnace.
Griffin's gas furnace, for heating tubes, and for combustions in organic analysis.
Griffin's blast gas-furnaces are shown in Griffin's "*Chemical Handicraft.*"

3. A furnace in which gas from the combustibles is substituted for the combustibles themselves in the furnace proper. See GAS-GENERATING FURNACE; GAS PRODUCER, etc.

4. A steam-boiler furnace heated by gas; either coal gas from the main, or gas produced in the grate, as in the gas generating furnace.

The gas-fired steam-boiler furnace of Haupt, of Brieg, Germany, is shown in Fig. 1157.

The principle of firing is the same as in Fig. 1159, *infra*, the coal being fed at the hopper *A* into the furnace *G*, where it rests upon the grate in such thickness that the carbonic acid produced by the lower layer of fuel resting immediately upon the grate is compelled to pass through the layer of fuel above it, and there combines with an additional amount of carbon. *K* is a Koerting air injector which supplies air, previously heated to 190 C. in pipes which are built into the walls of the producer and boiler, and a portion of which are shown below the ash-pit *B*.

The volume of combustible gases passes by the fire-brick arches *z z*, and uniting with a volume of air coming in from the side is diverted into a mixing chamber, from which the combined volume issues, and is ignited at the points *a a*.

Some trouble was experienced in lighting the gas at starting in such a manner as to prevent explosion, but there seems to be no radical reason why the plan so successful in the producers of Siemens, Ponsard, Casson, and Bicheroux, should fail in the special application to steam boilers.

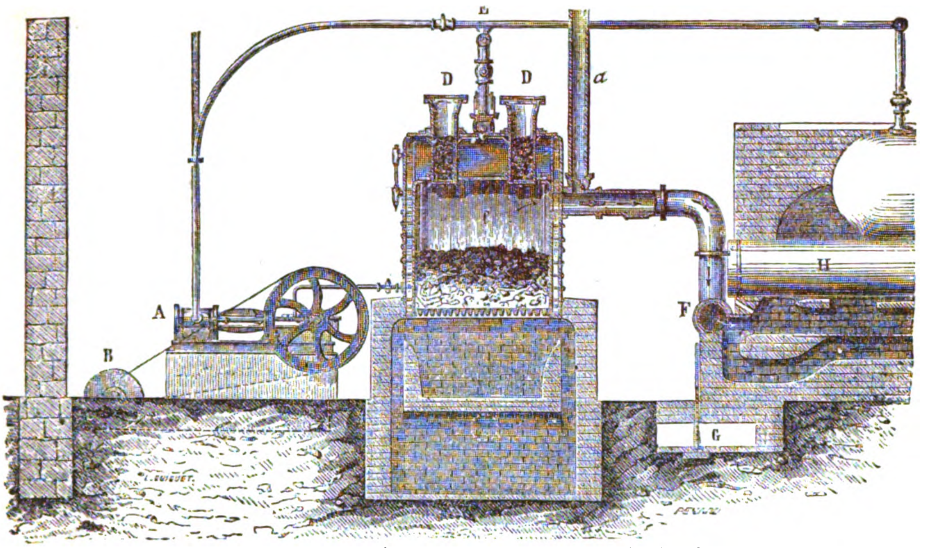
The furnace of Casson uses screened slack, supplied in a hopper and drawn down into the grate. Through the back of the grate it is blown by hot air drawn from the incased sides of the nearest stack. Hot air is likewise taken in at the top, and also at the bottom of the furnace, and makes its way to the exit of the gas from the gas furnace before it passes over the bridge of the puddling furnace, and the hot air fires the gas. The fierceness of the flame can be regulated by the quantity of air admitted, and the air is under the control of the furnace man.

See references under GAS-GENERATING FURNACE.

Gas-gen'er-a-ting Fur'nace. One in which gas from combustibles is substituted for the combustibles themselves in the operative chamber.

It is sometimes called the *Regenerator gas furnace* because in the Siemens, Bicheroux, and other systems, it is connected with the use of a *regenerator*. The Siemens (see Fig. 1159) has two pairs of chambers, each pair alternately being heated by the outgoing gases from the furnace, and forming a heating

Fig. 1158.



Beaufumé's Gas-generating Furnace. (*Section and partial elevation.*)

chamber for incoming gases for combustion and air respectively.

The Ponsard (see Figs. 1161, 1162) has a single regenerator chamber in which the draft of waste gases in one set of conduits, and of inflammable gases in the other conduits, are constant, and only divided by brick walls through which the heat of the waste is conducted to the air and carbonic oxide.

In a sense, all grate-firing may be considered as *gas generating*, inasmuch as the solid parts of the fuel are converted into gas and then burned. Thus coal parts in the grate with about 30 per cent of its weight in the form of hydro-carbon gases, and the remaining coke is also converted into carbonic oxide, and burnt into carbonic acid.

The distinction, however, which constitutes a grate-firing furnace a *gas-generating furnace*, is that the coal is in such thickness that the carbonic acid produced by the combustion of the fuel in the lower layer next to the grate is compelled to pass through the incandescent fuel above it, and thus again combine with carbon, preventing also, it may be added, the passage of unconsumed oxygen. This necessitates the admission and admixture of atmospheric air at another point besides that through the grate.

One of the first attempts in this line was the English patent of Juckes, No. 7858, Nov. 8, 1838. This had a magazine, and the coal was thrust into the fire by a piston which traversed in a hollow chamber in which the hydro-carbon gas was expelled from the coal before it reached the bed of coal on the grate. All the air was, however, admitted through the grate, so that this did not come under the present denomination, but was evidently intended as a smoke-burner or smoke preventer.

Price's English patent, 8,462, of 1873, has a magazine but no mechanical feeder, and the air is supplied only through the grate. The coal, however, in the expulsion chamber is heated by waste heat.

An early form of gas-generating furnaces was that suggested by Ebelman, but much improved by Beaufumé, under whose name it is well known in France.

The apparatus is shown in Fig. 1158. It has a furnace, *C*, with a grate enveloped in a double casing of boiler iron, like a locomotive furnace. Water circulates in the interval between the casings, and above is a steam dome. Steam passes by a pipe from the steam dome to a steam pump, which supplies water to the jacket. Fuel is introduced by means of two chargers, *D D*, which have valves above and below to prevent the exit of the hot gases from the furnace *C*. The upper valves being lifted, coal is placed in the chargers *D D*, and these valves being then closed the lower valves are opened and the fuel dropped on to the fire. The same device for feeding fuel to the furnace may be seen in Bennett's steam engine, U. S. patent, August 3, 1838 (Fig. 52, p. 21, and Fig. 81, p. 39, "*Mech. Dict.*"), which has several other points of similarity to the Beaufumé furnace.

The small engine *A* also drives a blower *B*, which forces air under pressure beneath the grates, and the ash-pit is necessarily hermetically sealed. This combustion under pressure and the sealed ash-pit are found in the Bennett patent, above cited, and also in the following patents: —

Washburn, U. S., Sept. 5, 1865.

Stillman, U. S., Aug. 9, 1864, and several others mentioned under AËRO-STEAM ENGINE and AIR ENGINE, "*Mech. Dict.*"

A portion of the air is inducted, as has been said, beneath the grating of the furnace *C*, but another part is destined for the consumption of the combustible gases beneath the steam-boiler shown at the right hand in the figure. The quantity of air devoted to the respective objects is regulated by registers.

The body of combustible in the furnace *C* is designed to be about sixty-five centimeters in height, in order that the requisite chemical combination may take place, the carbonic acid produced in the red coke-fire beneath, being converted into carbonic oxide in traversing the superior stage of fuel, combining with another equivalent of carbon to form an inflammable gas when mixed with air beneath the steam-boiler.

Steam, in regulated quantity, is injected beneath the grate, and ascending with the air is decomposed in the mass of burning fuel. The use of the steam is said to reside in serving to regulate the heat of the gas producer, and also in assisting in keeping the grate surface clear. The generation of the gases by decomposition of the steam is admitted to be at the expense of heat, but its introduction has a practical value in working, and is adopted by Siemens and others.

The hot gas passes by a lateral pipe to the space beneath the steam-boilers, being mixed with air from the chamber *G* in the pipe *F*, from thence circulating in the furnace passages beneath the boiler. *a* is a chimney used in starting fires in the furnace *C*, or upon other occasions as may be necessary; valves at the point of juncture of the respective pipes determine the course of the air

The Siemens' gas-generating furnace is the most noted of the class, and is used for many purposes. Invented in 1856, it was applied in 1864 to the production of steel by the Siemens-Martin process, and received the grand prize at the Exposition in Paris, 1867. Since that it has been used in glass-making, gas-works, etc.

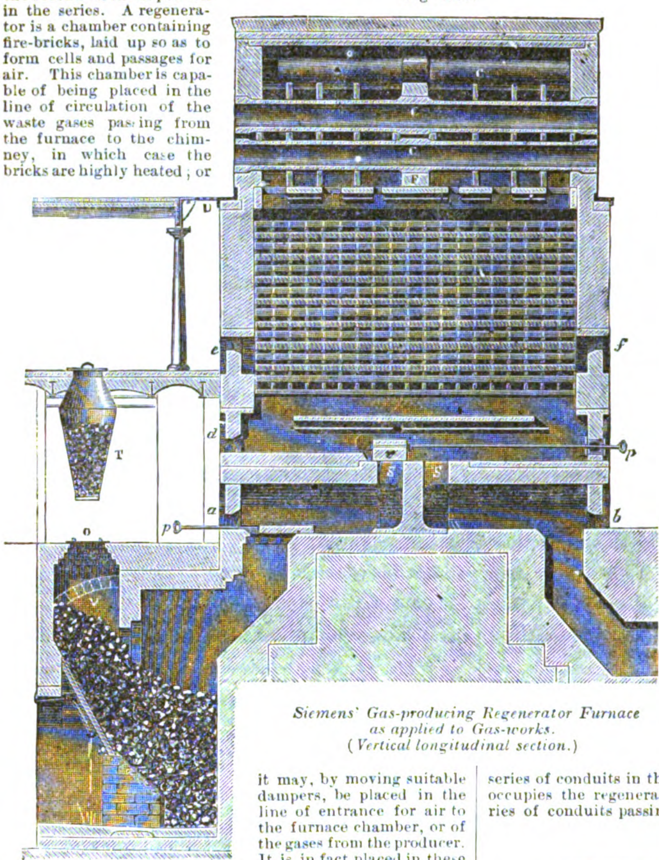
It consists of three parts: the gas producer; the regenerator; the furnace chamber. The latter may be an open metallurgic hearth, a siege full of glass pots, or a nest of gas retorts, as the case may be.

It is distinguished from the preceding by the notable absence of a forced current of air, and of the heating of the incoming air in tubes.

The furnace of the gas producer is fed through a hole above, which is closed by a cover at other times. The fuel descends an inclined plane of bricks made of refractory clay, and thence slides on to a grate surface, also inclined. The resulting gases pass upward into an exit pipe, the chemical conditions being much as in the Beaufumé furnace just described. The result of the combustion of coke, carbonic acid, passing upward through the mass of heated fuel, receives another equivalent of carbon and passes to the exit pipe as carbonic oxide, diminished in its heat by the cost of its transformation into oxide of carbon, which heat is, however, restored when the ignition takes place subsequently.

The current of heated gas passes by flues to the *regenerator*, the second essential portion in the series. A regenerator is a chamber containing fire-bricks, laid up so as to form cells and passages for air. This chamber is capable of being placed in the line of circulation of the waste gases passing from the furnace to the chimney, in which case the bricks are highly heated; or

Fig. 1159.



Siemens' Gas-producing Regenerator Furnace as applied to Gas-works.
(Vertical longitudinal section.)

it may, by moving suitable dampers, be placed in the line of entrance for air to the furnace chamber, or of the gases from the producer. It is in fact placed in these two lines of draft alternately: the first to be heated; the second to heat the aëriform matters passing through it. To secure continuity, two of such chambers are required, alternately heated and imparting heat, and in the Siemens' practice each of them are in pairs, as it is found advisable not alone to superheat the gases from the *producer* but also the air to inflame them, and to do these separately, and combine them after they are heated in the *regenerator*. Meanwhile the other pair of chambers is being heated by the gases flowing from the furnace chamber towards the chimney.

The action in the furnace chamber is according to the circumstances: whether the flame descend upon the ore or metal in the bosh, or circulate around glass-pots, or envelop crucibles filled with coal.

Figs. 1159, 1160, show the Siemens' regenerator-furnace as applied to the purpose of distilling coal for lighting gas. While his invention was first applied in steel furnaces, it has for some time been in use in gas-works, first of all in the "*Usine de Vaugirard*," belonging to the Parisian Gas Company.

The *gazogene* or *generator*, V, otherwise known as the *gas producer*, is placed below the ground level, and the gas produced, drawn by chimney draft, passes first to the *regenerators* and thence to the combustion chamber in which are the retorts *C C*. The regenerator, as has been said, is an assemblage of refractory bricks built up in such a manner as to leave between them interstices which are traversed by the waste gases from the combustion chamber on their way to the chimney.

The regenerator in the case in question has four compartments shown at $a\ a^1\ a^2\ a^3$ in Fig. 1160, which is a vertical transverse section, in a line at right angles to that shown in Fig. 1159.

At the bottom of these conduits are the dampers $R\ R^1\ R^2\ R^3$, by which the direction of the current is controlled.

Supposing the furnace to be in operation: the conduits $a\ a^1$ receive respectively, one the carbonic acid from the gas-producer, and the other the air for its combustion, the two united forming the flame beneath and around the retorts *C C*, in the combustion chamber. The proceeds of combustion descend by $a^2\ a^3$. At the end of an hour, the direction of all these currents is reversed; the air and carbonic oxide traverse the conduits $a^2\ a^3$, the bricks in which have been heated to redness, and the waste heat passes downward in $a\ a^1$, to heat that chamber in turn.

One gas producer heats 8 to 10 furnaces.

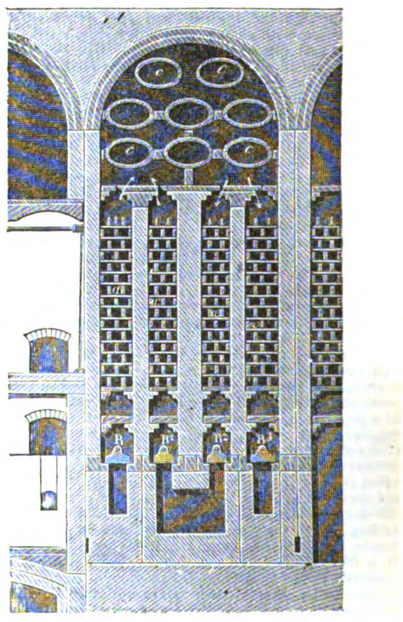
In the apparatus shown in Figs. 1159, 1160, the furnaces are fed with coke, that being the convenient fuel in gas-works, and the retorts are heated by burning the carbonic oxide.

The coke is fed into the furnace from a charger *T*, the furnace cover *O* being removed when the shutter at the foot of the charger *T* is moved aside to drop the charge into the furnace *V*. Water is shown trickling from a pipe on to the ash floor beneath the grates. *a b d e f*, Fig. 1159, are orifices, which may be opened or adjusted to verify or regulate the draft in the interior of the furnace. The dampers $R\ R^1\ R^2\ R^3$, are coupled two and two, and are operated by the draw-rod *p* to open one set of openings *s* and close the other, when the direction of draft through the generators is to be changed, as has been already explained.

The Ponsard furnace, which is shown in Figs. 1161, 1162, as applied to the same object, distilling gas in gas-works, has the same general features as the Siemens, with two exceptions to be noted. This proceeds upon a somewhat simpler plan.

1. The reversal of the direction of draft is avoided in the Ponsard regenerator furnace. The waste products of combustion follow constantly the same direction, descending from the combustion chamber and coursing through the series of conduits in the structure of hollow fire-bricks which occupies the regenerator, while the air follows another series of conduits passing upward in contact with the bricks,

Fig. 1160.



Siemens' Gas-producing Regenerator Furnace as applied to Gas-works (vertical transverse section).

Fig. 1161.

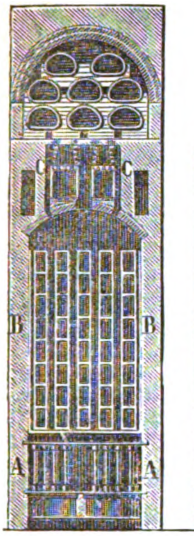


Fig. 1162.

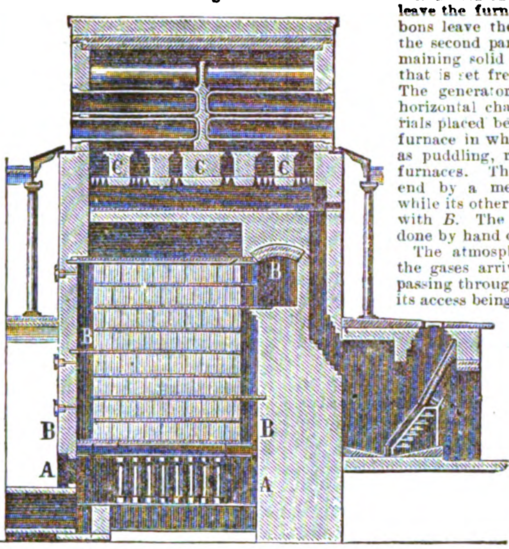

Ponsard's Gas-generating Furnace applied to Gas-works.
(Vertical transverse and longitudinal sections.)

A is heated by the waste gases after they leave the furnace, and the expelled hydrocarbons leave the chamber *A* highly heated. In the second part, *B*, the conversion of the remaining solid parts takes place, all the heat that is set free being utilized in the furnace. The generator consists of one, two, or more horizontal chambers, made of fire-proof materials placed below, above, or by the side of the furnace in which the gases are utilized; such as puddling, reheating, zinc, glass, and other furnaces. The chamber, *A*, is closed at one end by a mechanical feeding arrangement, while its other end is open and communicates with *B*. The feeding of coal into *A* can be done by hand or by machinery.

The atmospheric air necessary for burning the gases arrives highly heated by previously passing through channels heated by waste heat, its access being regulated by valves. The waste heat, after passing through the flues, round *A*, to expel the gases from the fuel, and heating the resulting coke to a bright red heat, may then be used under boilers, etc. See also: —

Gas producer.	Regenerator.

the other surfaces of which are heated by the descending waste current.

2. The carbonic oxide from the gas-producer proceeds directly to the combustion chamber, where it unites with the air which has entered at *A*, and passed from top to bottom around the heated air-ducts in the regenerator *B B*. The air occupies the space around these fire-brick ducts, while the waste heat passes horizontally through them. *C C* represent portions of the vault of the regenerator, through openings in which the heated air rises to the combustion chamber. The particular form and disposition of the air-ducts is attributed to M. Lencauchez. Ponsard's regenerator is also shown under REGENERATOR, which see.

The gas-generating furnace of Minary, of Besançon ("*Publication Industrielle*," 1868), has admission of air subsequent to the departure of the heated gases from the producer, see Fig. 3, p. 4000, "*Scientific American Sup.*," where is also shown Brook & Williams' Gas Generator, Fig. 4.

Gröbe's Gas Generator has been used at the Osnabruck Iron and Steel Works, since 1849; at the Vieille Montagne Zinc Works, and at several other places in England, Belgium, and Hanover. This furnace is founded upon the principle that the processes of expelling the hydro-carbon gases, and converting the resulting coke, require entirely different conditions. To expel the gases from the fuel, not atmospheric air is required, but only heat; while for the combustion of the coke into carbonic oxide, atmospheric air is essential. The latter process requires no heat, but on the contrary throws heat off, which is ordinarily employed for expelling the gases from the fuel, and having thus become latent, it cannot be used in the combustion chamber.

The gases contained in the coal are expelled in one chamber, *A*, and the solid remains (coke) are converted in another, *B*, and both gases so produced are burned in the combustion chamber, which is not visible on the figure.

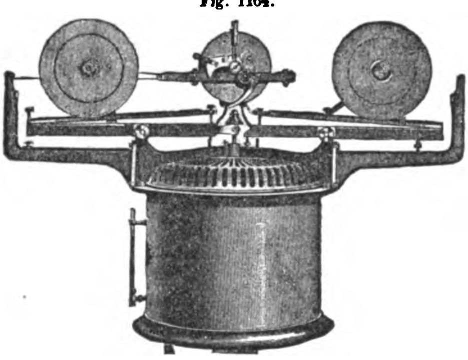
Gas Gov'er-nor. (*Gas.*) *a.* An apparatus of the nature of a regulator, to equalize the flow of gas in a pipe.

The usual method is to cause the pressure of gas to impinge upon a diaphragm to which is connected the stem of a valve, and the valve opening is diminished in proportion to the increase of pressure, and conversely.

Fig. 1164 shows Isbell's automatic gas-governor, for regulating the pressure of gas in street mains, proportioning the pressure to the necessity of the varying consumption at different periods of the 24 hours; as, for instance, a day pressure of $\frac{7}{10}''$, a night pressure of $2\frac{4}{10}''$, continued until 10.30 P. M., and then gradually diminished to a midnight pressure of $1\frac{1}{10}''$, and then gradually back to day pressure.

Fig. 1164.



Isbell's Automatic Gas Governor.

The rolling weights are governed by the clock in the center, and as they roll towards or from the clock they depress the levers on which they track, and actuate accurately balanced valves in the chamber below; the valve-rods will be seen depending from the end of each lever.

The rolling weights are connected by a chain to a sliding bar, working between friction rollers, and driven by a cam, on the main spindle of the powerful clock contained in the case. As the weights are moved in, at the proper time, by the action of the clock and cam, the valve below is opened and the pressure gradually increased to the desired point, held there, until the time set for it to be diminished, by the rolling back of the weights and the consequent gradual closing of the valve. The cam is easily and quickly secured in any position on the spindle, and has stamped upon it the hours of the day, as shown by the index.

It will be at once apparent how any desired effect can be obtained, by changing the position of the cams, or by putting on cams of different proportions.

The *Kidder-Noyes* gas governor acts by means of a balanced holder which fluctuates upward or downward upon any increase or decrease respectively of gas pressure above or below the mean for which it is set, to close or open the valve in the main.

Cox's (Br.) gas governor has the same general feature of balanced holder operating a valve.

Goodwin has a similar arrangement; and also a governor on the aneroid principle of an expanding diaphragm chamber.

Foster's governor, for tanks of compressed gas for railway cars and steamboats, has also the expansible diaphragm arrangement.

White (Br.) has a swinging flap-valve weighted with shot.

Foulis (Br.) has a double-cone valve and float.

Jones (Br.), a conical valve in perforated diaphragm.

Wharton has gravitating valves in a section forming a part of the line of pipe.

b. An apparatus on a gas exhauster to regulate by gas pressure the quantity of steam admitted to the cylinder of the engine driving the exhauster, so as to regulate the speed of the engine, and thus maintain any desired pressure or vacuum on the exhaust side. See GAS EXHAUSTER.

Goodwin's consumer's governor, "*American Gas-light Journal,*" * July 3, 1876, p. 6.
Goodwin's governor, *Ibid.*, p. 7.
Stott, Br . . . . * "*Engineering,*" xxix. 308.

Gas Grate. A contrivance of Dr. Siemens, in which the consumption of coke in the grate is aided by a row of gas jets; illustrating his theory of the economy of separating fuel into its constituents of coke and gas, and re-associating them at the grate or hearth.

Gas Gun. A signaling device, consisting of an explosion of gases in a pipe. Used at Howth Baily light station, Kingstown Harbor, Ireland. See Major Elliot's report, U. S. Engineers.

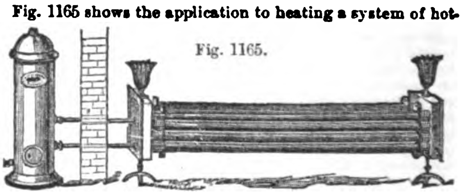
The gun is a tube of iron connected with the gas holder by a $\frac{1}{2}''$ pipe. The charge is a mixture of oxygen (3), coal gas (3), and air (2).

See also FOG GUN, Fig. 1079, p. 352, *supra*.

Gas Heat'er. 1. An application of gas as a means of heating water for domestic purposes: culinary, lavatory, conservatory, etc. See GAS BOILER, *supra.*

Fig. 1165 shows the application to heating a system of hot-

Fig. 1165.



Conservatory Heater.

water pipes for a green-house. See also BATH HEATER, Figs. 243, 244, pp. 82, 83, *supra*.

2. A form of burner for heating kettles or baths, and for laboratory purposes.

See also BUNSEN BURNER, Figs. 471–475, pp. 146, 147, *supra*, and references *passim.*

Fig. 1166.

Gas Heater.

3. A substitute for a forge in tempering drills, punches, and other small tools.

Put on a sufficient head of gas to prevent the flame from descending into the tube. For heating larger pieces, the flame should be nearly 3'' wide. The upper ends of the curved side pieces should not be more than $\frac{1}{2}''$ apart. The articles to be heated should be held in the upper part of the flame, above the central blue part and parallel with it. The larger the piece to be heated the further it should extend into the flame. The heater should be located in a dark place, and supports may be provided for greater convenience in heating heavy articles.

Gas Liq'ue-fac'tion Ap'para'tus. For the liquefaction of gas by pressure and cold.

Cailletet's apparatus is shown in Fig. 1169. A tube, *T*, of very fine bore toward its upper extremity, *P*, and capable of supporting a pressure of 500 atmospheres, is partly filled with the gas to be liquefied. The lower portion of the tube expands to form a capacious bulb, *T*, which is filled with mercury, and inserted in a reservoir containing mercury and water. The walls of the reservoir, *B*, are of steel, and sufficiently thick to allow pressures of 800 atmospheres to be used with perfect safety. The water is forced in by a strong pump, and, according as it enters, the mercury rises in the capillary tube, compressing the confined gas at the same time. A pressure of 200 atmospheres is attained by a few strokes of the pump, and is recorded by a metallic manometer, *E, M*. By means of a plunger, *V*, the pressure may be very gradually increased up to 500 atmospheres. Meanwhile the capillary tube may be surrounded by a freezing mixture, or by water at any desired temperature.

In the case of most gases, the manometer remains stationary when a certain pressure has been reached. This phenomenon, which is at variance with Boyle's law (a law absolutely true only for a perfect gas), occurs as soon as liquefaction begins. When an appreciable quantity of the gas has been liquefied, upon gradually diminishing the pressure the liquid begins to boil, and returns to the gaseous condition. But if the valve *V′* be suddenly opened, the gas will as suddenly expand, and, undergoing a very considerable reduction of temperature, a portion of it will be liquefied, filling the upper part of the tube with a sort of cloud or mist. These effects are readily seen with nitrous oxide and acetylene.

The proceedings of Pouillet, Faraday, Thilorier, and Cagniard-Latour, and the results of their experiments are related by *Laboulaye*, "*Dict. des Arts et Manufactures*," tome iv., cap. "*Liquefaction des Gaz*," ed. 1877.

Gas Prov'er. (*Gas.*) *a.* A means for testing the quality of gas. This is a chemical operation, (1.) turmeric or red litmus paper, or (2) acetate of lead paper being used to detect ammonia and sulphureted hydrogen respectively. See GAS TESTING APPARATUS; SULPHUR TESTING APPARATUS; GAS VERIFIER.

b. A test for pressure of fire-damp in mines. See GRISOUMETER; CARBUROMETER; FIRE-DAMP DETECTOR.

c. A means for measuring accuracy of meters. See METER PROVER; CONSUMERS' TEST METER.

d. A means for testing the illuminating quality of gas. See JET PHOTOMETER; PHOTOMETER; TEST METER.

e. A means for testing the levity of gas. See SPECIFIC GRAVITY APPARATUS.

Goodwin, "*American Gas-light Journal*," * July 3, 1876, p. 4.

Gas Pu'ri-fi'er. In Mackenzie & Isbell's apparatus and process for reviving and deodorizing the material in the purifying boxes of gas-works, the air is drawn through the openings in the covers, and through the material in the boxes, by the action of a steam-jet exhauster. No steam engine or rotary device of any kind is needed. The air passing through the purifying material takes up the ammonia and sulphur compounds; mingles with the steam; passes through a condenser or washer, where the steam is condensed and the foul matter removed; the air escaping practically pure.

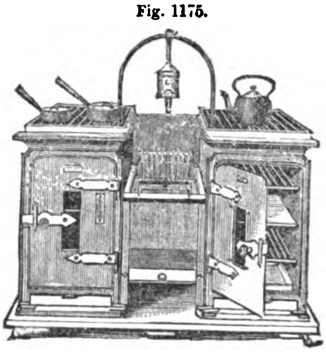
Gas'si-ot's Cas-cade'. (*Electricity.*) A beaker, internally coated with tin foil to within a short distance from the top, is placed on a glass disk resting on the plate of an air-pump. The whole is covered with the glass receiver, from the top of which depends a glass-covered conductor reaching nearly to the bottom of the beaker, the end of the conductor being exposed. Upon passing a high-tension current from the said conductor to the plate of the machine, and exhausting the receiver, a continuous electrical discharge takes place, passing up out of the cup, and in a cascade form, to the supporting plate.

"*Philosophical Magazine*" . . . . vii. 854.

Gas Range. A form of cooking-stove heated by gas jets, and having the conditions of the range

Fig. 1175.



Gas Range.

as distinct from the stove. It is fitted with 2 ovens, with thermometers attached; also with 5 burners on top for boiling, preserving, stewing, and broiling. See also GAS STOVE, and references *passim*.

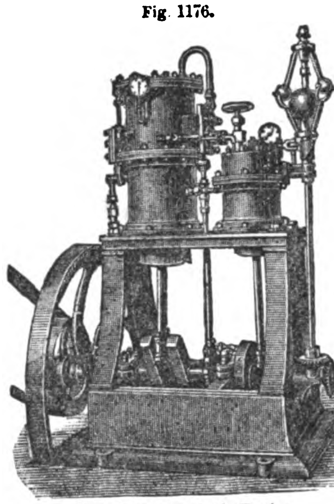
Gas, Steam, and Air En'gine. An aëro-gas engine with steam added. The gas is not used explosively but for the rapid expansion of atmospheric air previously compressed in a cylinder forming part of the engine. A small steam generator is heated by the combustion of the gas and the hot exhaust gases from the power cylinder, the steam being used in the latter to increase the power of the engine.

Simon's engine has two cylinders, one in which air is compressed in mixture with a determinate quantity of gas, and the other into which the mixture passes and is ignited by a constantly maintained flame, the air reëxpanding from the pressure due to its compression, and under the influence of the heat of combustion of the gas and partial combustion of the air.

Fig. 1176 is a perspective view, and Fig. 1177 a sectional elevation of the engine.

In Fig. 1176, *A* is the pumping or compression cylinder; *B* the piston working therein; *C* the connecting-rod, connecting it direct with the crank shaft *G*, on which is the fly-wheel *H*, and bevel wheels *Y*, which by means of the shaft *X* work the governors *O*, connected with which is a sliding cam, *D*, sliding on a feather in the shaft *X*, and connected with the governors, so as to be drawn upwards when, owing to the increased speed of the engine, the balls fly apart. The effect of this is to allow the runner at the end of the slide valve *E* to fall on the narrower part of the cam *D*, and thus to open the air passage *F*, and the gas passage *K*, for a shorter time, admitting less gas and air until the pressure falls, and the speed of the engine is reduced, when the runner of the slide valve *E* again rides on the wider part of the cam *D*. A spring, not shown in the drawing, gives the return motion to the slide valve *E*, and maintains the runner in contact with the cam *D*. After passing through *F* and *K* respectively, the air and gas pass into the chamber *L*,

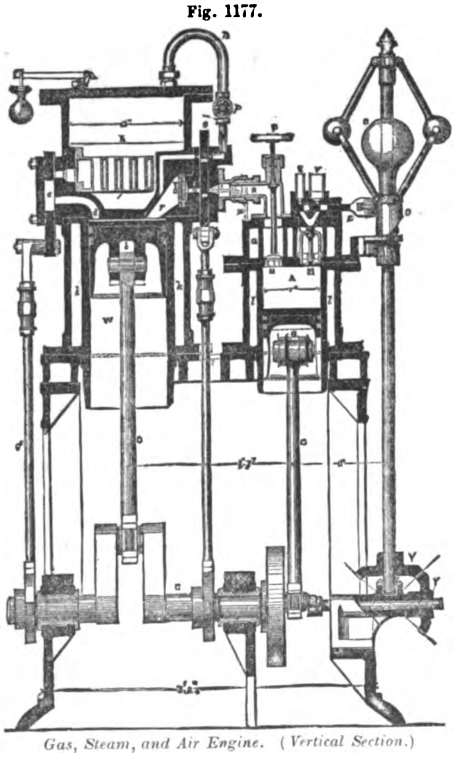
Fig. 1176.



Gas, Steam, and Air Engine.

whence they are drawn through the valve M into the cylinder A by the down-stroke of the piston B. By the return stroke of the piston B the gas and air are compressed and discharged partly through the pipe R into the combustion

Fig. 1177.



Gas, Steam, and Air Engine. (Vertical Section.)

cylinder, and partly into a receiver, Q, from which the internal constant flame at T is supplied; N is a back-pressure valve: P is a stop valve. When this is screwed down the compressed mixture cannot pass into the pipe R, and the motion of the engine is arrested; R being a tube through which the compressed contents of the air-pump A pass to the slide valve S, worked by the rod g, and which admits the mixture through perforated brass disks and wire gauze at T into the interior of the working or combustion cylinder W. A small pipe, Z, also proceeds from the receiver, Q, to the interior of the cylinder W, opening at the point indicated by the black spot under T; b is the piston in the cylinder W, and c the rod connecting it with the crank shaft G; d is the outlet for the exhausted gases to the slide valve e, actuated by the connecting-rod f, which admits them to an arrangement of tubes in the water chamber h from which they are afterwards led away through the exhaust port indicated into the center of the tube space. The water in h is in communication with the water in the jacket or casing, k, surrounding the cylinder W. This water is also in communication with a similar casing or jacket, l, surrounding the cylinder A. The heat of the combustion in the cylinder and the heat of the exhausted gases generate steam in the chamber h, which passes by the pipe n, opened or closed by the stop valve p, and a port, V, in the slide-valve S, into the passage r, and thus into the cylinder W. The water employed is first admitted into the jacket of the compression cylinder, where it keeps that cylinder sufficiently cool, and is at the same time slightly heated. From this jacket it passes to that of the working cylinder, and gains in temperature while it cools the cylinder, and thence passes to the steam generator h. To start the engine it is first turned a few revolutions so as to compress air and gas in the cylinder A, some of which passes into the space Q. A small cock in the pipe Z is then opened, and a plug opposite the spot under T is withdrawn and the gas ignited. The plug is then replaced, and the pipe Z sustains a constant flame in the interior of the cylinder W at T, through which flame the mixture of gas and air compressed in A passes, and in thus passing is ignited. The consequent expansion causes the piston b to make a down-stroke, imparting motion to the crank shaft G, and at the same time the piston B of the cylinder A compresses and discharges into the pipe R and the receiver Q a fresh supply of gas and air. The momentum acquired by the fly-wheel brings the piston b of the cylinder W back to its highest position, and the above described action is repeated.

Gas Stove. Fig. 1178 is a parlor or office stove. It is of cylindrical form, and is fitted with a highly polished copper reflector, and is designed to use illuminating jets only. The heat is thrown into the room by reflection from the copper reflector, also by radiation from the hot-air chamber, the heated air passing into the room through outlets in top of stove.

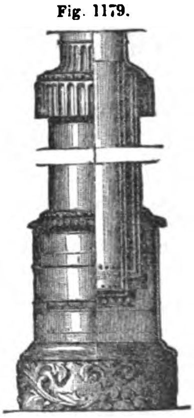
This stove is designed for use in bath and hall rooms where a connection cannot be made with flue.

A stove 27″ high, 8″ diameter, requires 8″ cubic of gas per hour.

Fig. 1178.

Parlor Heater.

Fig. 1179.



English Gas Stove.

Fig. 1179 is a view of an English office gas-stove, partly in elevation and partly in section.

It has an annular pipe pierced with numerous holes for the exit of gas, and situate in an ornamental cylindrical casing to which the air has access. This circle of lights is surmounted by a system of cylinders in cast-iron which absorb the heat developed by the combustion of the gas, and part with it to the surrounding air.

Fig. 1180 shows an adaptation for cooking-stoves. The joint is in the roasting oven, and the heat is reflected from the congeries of gas jets above it.

The baking oven is heated from below and by the heat passing through the flues around it, to the boiler plate above.

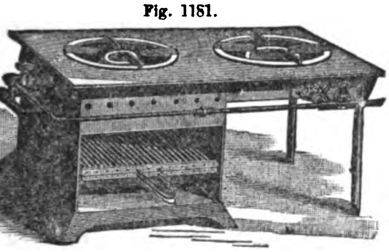
Fig. 1180.

Gas Cooking Stove.

Fig. 1181 is a combined furnace and sub-flame broiler; requiring no special description.

Gas heaters of various kinds are described and shown under specific heads, such as BUNSEN BURNER; BURNER; GAS BLOW-PIPE; GAS HEATER; GAS BOILER; BATH HEATER, etc.

Fig. 1181.



Furnace and Broiler.

Gas Tar Pump. A device to enable the tar pump to be constant in its stroke and action, but limiting the amount of tar raised to the quantity running into the well; keeping a constant level in the well, though the product of tar be irregular.

"*Scientific American Supplement*" . . . . . * 1412.

Gas Test'ing Ap'pa-ra'tus. *a.* The test for ammonia in illuminating gas is to allow a jet of the gas to blow upon a piece of turmeric or reddened litmus paper; for the detection of sulphureted hydrogen use similarly acetate of lead paper.

Hugh Young's apparatus is founded upon this method, pieces of turmeric and acetate of lead papers being suspended in a small glass receiver over an inlet of gas passing to a burner. This testing apparatus is only qualitative.

Dr. Letheby's quantitative sulphur testing apparatus has a meter, governor, and tube leading to a Leslie burner, under which is a beaker containing the requisite quantity of standard liquor ammonia, over the beaker is a glass funnel passing up through the burner, and covering the burner is a trumpet-shaped glass tube which discharges into a large glass condensing cylinder with bent glass tube at an angle of 45° at its farther end.

The *Gas referees' apparatus*, London, has points of similarity to the Letheby apparatus, but uses carbonate instead of liquid ammonia, and its condenser is vertical and contains marbles and has a sealed discharge pipe for liquid of condensation. See SULPHUR TESTING APPARATUS.

The apparatus for taking the specific gravity of illuminating gas is a modification of the Bunsen method (*Bowditch*, 1867, p. 237) by efflux through a fine opening in a thin plate of metal. See SPECIFIC GRAVITY APPARATUS.

In the use of Goodwin's apparatus for the analysis of coal gas, the proceeding is first by qualitative analysis to determine the presence of certain gases: this will decide the order of precedence in their removal. See GAS ANALYZER.

The apparatus consists of graduated glass tubes through solutions in which the gas is bubbled. The re-agents, formulæ for making them, and the directions for procedure in analysis, are in a pamphlet. W. W. Goodwin, Philadelphia, 1877.

b. The gas tester used by the city of Paris is an arrangement of meter, time counter, balance, and photometer. A given amount of gas, passing in a given time, and having a certain gravity, is lighted at a burner and this is compared with a carcel burner of given power, the two lights being simultaneously observed through a tube, the field of vision of which is divided by a vertical plate. See PHOTOMETER.

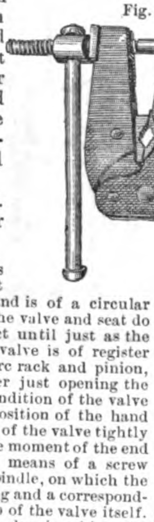
Gas Trap. A device to prevent the reflux of gas from the sewer. See SEWER TRAP.

Gas Tube Vise. One specially designed for work upon wrought iron tubes, collars, and couplings. It stands on the floor and has serrated jaw-pieces; the jaw-stock rotatable in a vertical plane.

Fig. 1182.



Universal Gas Tube Vise.

Gas Valve. A stop valve for gas mains.

In Root's gas valves the valve seat is cast solid with the case and is of a circular form. In closing, the valve and seat do not come in contact until just as the valve is shut. The valve is of register form moved by an arc rack and pinion, one turn of the latter just opening the valve, so that the condition of the valve can be told by the position of the hand wheel. The closing of the valve tightly against its seat at the moment of the end of its motion is by means of a screw cut on the central spindle, on which the movable valve is hung and a corresponding screw on the hub of the valve itself. Fig. 1185 shows a valve in which the parts involved in friction do not come in contact with gas. Fig. 1186 shows the Eddy valve, which is seated by a rocking bar at the back, operated by the plunger screw.

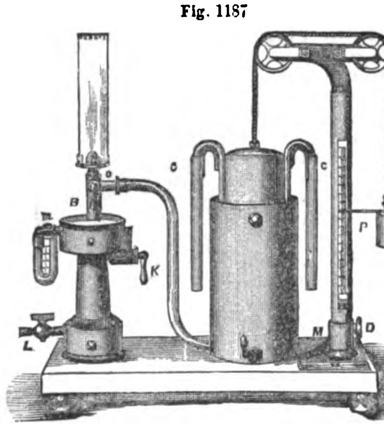
Gas Ver'i-fi'er. An apparatus intended to verify whether the gas comes up to a given standard. Giroud's apparatus is shown in Fig. 1187.

Fig. 1187



Apparatus for Estimating the Value of Gas.

It consists, first, of a reservoir or gasometer, of which the movable part is balanced by a variable counterpoise *P*, to which a needle is attached moving along a scale, so as to measure the amount; 2d, of a burner inclosed in a glass chimney, and in the foot of which are three cocks, *L*, *K*, and *A*, and also a pressure-gage, *m*. It is proposed to be used in the following manner: The gas is entered at *L*, and ignited, and the height of the flame regulated by the cocks *L* and *K*, so as to be 4″ high. The cock *B* is a two-way cock, which, if the handle is turned to a horizontal position, sends the gas into the gasometer. This is then done for the space of exactly one minute, and if the gasometer is raised 5″, the gas is equal to the standard of Paris; if it has risen less it is better, if more it is inferior.

It will be seen that this manipulation is based upon trying how much gas will be consumed in one minute in order to produce a flame of given constant size, and this trial again is based upon the fact that the more inferior a gas is the more it will shorten a flame, and consequently the more be required to produce a flame of given length, and the richer a gas is in carbon the longer will be the flame, and less will be required to give a flame the standard length.

The test is thus independent of photometric experiments, by which the amount of luminosity is determined.

See also GAS TESTER, *supra*; and PHOTOMETER, *infra*.

Gas Vul'can-i'zer. A small muffle heated by gas and used in vulcanizing dental bases. The cover is secured by three set-screws, which play in a movable screw collar, and produce direct pressure upon the packing joint. The thermometer bulb is immersed in a mercury bath outside the steam chamber. Fig. 1188.

Gas Wash'er. (*Gas.*) A tall cylinder in which the gas is brought in contact with a falling stream of water in order to precipitate the tar.

Gear. 1. A combination of parts to effect an object, as lifting-gear, hauling-gear, draw-gear, valve-gear.

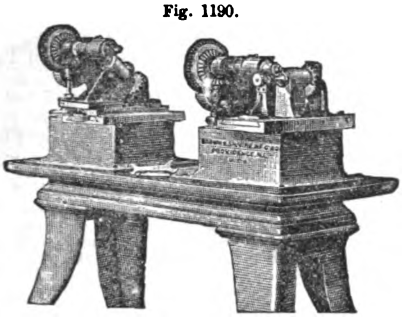
It is a useful word, serving as a substitute for "arrangement" or "apparatus." It is distinct from "machine" or "engine," in one direction, and from "tool" or "implement," in the other. See GEAR, p. 960, "*Mech. Dict.*"

2. (*Fishing.*) A term synonymous with *tackle*: the special rig or arrangement for a given kind of fish or fishing, such as —

Deep-sea gear.	Bottom gear.
Short hand-gear.	Flounder gear.
Shark gear.	Cod hand-line gear, etc.

Gear Cut'ter. Fig. 1190 is the Brown & Sharpe automatic bevel and spur gear-cutting machine. Two machines are shown on the same stand; one is designed for cutting spur and the other bevel gears. They are specially intended for the gears of sewing-machines and other light work.

Fig. 1190.



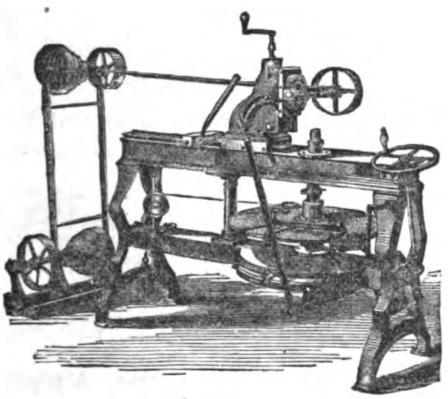
Gear-cutting Machine.

The machine is automatic to the extent of revolving the wheel from tooth to tooth, cutting through for each tooth, and stopping when the wheel is completed.

Upon the machine for bevel wheels, the movement of a lever places the wheel in position for making the second cut, when the same movements are repeated, completing the wheel. The spindles run in anti-friction boxes, provided with means for compensation for wear.

Fig. 1191 is another form of machine, adapted to cut spur, spiral, and bevel gears up to 54″ diameter.

Fig. 1191.



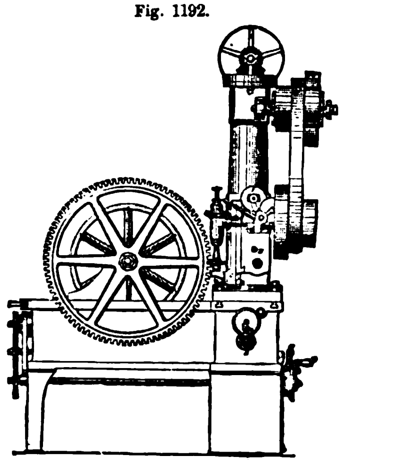
Gear Cutter.

The cutter is mounted upon shears like those of a lathe, and driven by counter gearing. The index-wheel is placed horizontally beneath the shears, and is worked by a lever.

Fig. 1192 shows Sellers' gear-cutting and wheel-dividing machine.

It is arranged for cutting both spur and bevel wheels, has a capacity up to 54″ diameter of wheel, 12″ face, and will cut a number of small spur-wheels of same size at one time. It is entirely automatic, performing all its work after adjustment, without attention of workman, to the completion of the wheel being cut or divided. The division is obtained by a tangent wheel and worm, and the designated number of teeth is obtained by use of change wheels, and the turning of the handle for change 1, 2, or 3 times, as may be called for on the schedule of division. This turning of the handle, however, and all other motions, are done by the machine itself. Thus, a blank wheel being put in place, and the proper cutter adjusted to depth of teeth, length of stroke of cutter-head, etc., the cutter will pass across face of wheel, cutting space between two teeth, will then return at a quick pace to the starting side of wheel, the blank will then be turned to present a second space to be cut, and the cutter will start its proper motion, all the changes being made by the machine itself, not by the attendant workman. The range is from 10 to 360 teeth.

Fig. 1192.



Gear Cutter.

The Corliss bevel-gear cutter, shown at the Centennial Exhibition, was used in cutting the large bevel wheels in the underground train of gearing by which power was distributed from the large engine. These motor-wheels are 6′ in diameter, weigh 3,000 pounds, have 14½″ face length of tooth, 4″ depth. The machine was illustrated in "*Harper's Weekly*," July 29, 1876.

The machine is an application of the planing machine to the purpose of gear-cutting. It has the appearance of a large quadrant, the vertical arm 14½′ high, and has also a horizontal arm, which is a mandrel carrying on its end the wheel to be cut. Midway between the vertical and the horizontal — when cutting bevel-gear having a face angle with its shaft of 45° — is an oblique arm which carries the cutter. It looks large enough to be a piece of ordnance with an elevation of an angle of 45°. This arm has beneath it the cutting tool, which is reciprocated by rack and pinion, its effective stroke being the downward. The arm oscillates on a center coincident with the axis of the pinion which drives the planer bar.

The angle of this arm in the frame depends upon the angle of bevel to be cut, and the capacity of the machine may be said to range from 15° to 75°, though these are unusual ranges.

The bevel-wheel, having been cast in the sand with its teeth approximately the shape required, is bored out and slipped on to the mandrel, where it is secured. On the rear end of this mandrel is the wheel, 15′ in diameter, and graduated so that any proportion of a circle can be turned at a time, according as the wheel may be desired to have 60, 64, 120, 200, or any other number of teeth. In the particular instance of the miter wheels for the train of the machinery building at the Philadelphia Exhibition, the number of teeth required on the wheel was 54, and one row of holes in the face of the wheel is 216 in number, so the wheel must be moved four holes for each successive tooth, and rigidly secured by pin and clamp before cutting.

A flat plate of steel is made of exactly the contour of tooth required, certain invariable rules being observed in the shape, while certain other elements of proportion are variable, and must be determined by the *pitch*, or distance from center to center of cogs measured on a certain line, the radius of the wheel, and what not, so that the teeth shall roll nicely upon each other and not rub. This is a complex matter to determine, and then a delicate one to execute. This pattern of tooth is secured in the quadrantal or arch-shaped member of the frame, a mandrel on the end of the arm lying against it, and slipping down against the pattern as the cutter is fed along down the tooth after each stroke, the pattern swerving the arm laterally to the necessary extent. This is the adjustment for *shape of teeth*.

The *cut of the tool* is adjusted by regulating the position of a pin of the feed motion to or from the center of oscillation of an arm. At the end of each down stroke a shifting gear ships the belts and a quick *gig-back* motion results, which is again shifted to the *feed* as the planer reaches the upper end of its stroke.

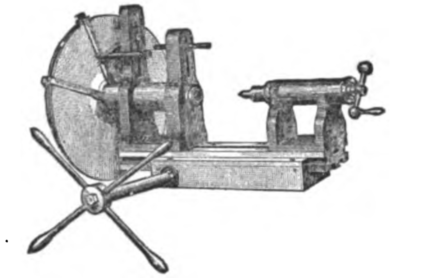
In Comly's process for making pressed gearing the wheels are made of wrought iron or steel, the teeth being forged or pressed by the action of a die revolving in contact with the heated blank wheel, which also revolves at the same time.

Grube's bevel wheel cutter (German), was shown in the German section of the Machinery Hall, Philadelphia, 1876.
Ingold (Chaux de Fonds, Switz.), exhibited at the same time and place his cutter for dressing the teeth of watch and clock wheels to give the epicycloidal form.

Gear-cut'ting At-tach'ment. Fig. 1193 shows Pratt & Whitney's gear-cutting attachment to the Universal Milling Machine.

It is designed for cutting larger and heavier wheels than can be cut with the ordinary apparatus belonging to the machine. It swings 13″, and is furnished with a 20″ index

Fig. 1193.



Gear-cutting Attachment.

containing 4,294 holes. It will divide all numbers to 75 and all even numbers to 150. Arbors fitted to the universal milling machine can be used in this attachment. The screw with set-nuts over the spindle supports the wheel while being cut.

Geared Brace. A boring tool in which the drill or bit is rotated by hand crank and bevel gear.

Geared Lo'co-mo'tive. A locomotive in which the motion of the engine is conveyed by gearing to the traveling wheels. Such is common in road-rollers and traction engines. *Vide* Figs. 4360, 4361, 4363, 4364, pp. 1952, 1953, "*Mech. Dict.*" The same plan has been adopted in locomotives for ascending heavy grades.

Geared locomotives, built by Lewin, Poole, England, for Guinness & Co., Dublin, are shown in the British journals. They are for use in the brewery yard. The width of the engine is 4′ over all.

The engine has but one cylinder, 6¼″ in diameter, and with a stroke of 8″. The motion of the engine is conveyed by steel gearing to the traveling wheels, which are also of cast steel. When running at 280 revolutions per minute the speed of the traveling wheels is six miles per hour. A wrought iron clutch gear is arranged on each engine, so that they can be used for driving other machinery on the premises. The piston, valve-rods, and all pins are of steel. The engine is carried on a strong bed-plate, fixed to wrought iron brackets riveted to the boiler, and suitable provision is made to allow of the expansion of the boiler. The regulator and other gear are all on the outside. The boiler is made with double riveted longitudinal seams. The ordinary working pressure of steam is 140 lbs. per square inch. At the front end of the engine two buffers are fixed in the ordinary way, but the back or foot-plate end is made semi-circular, and is provided with a radial draw, to enable the engine to pass with the wagons round the very short curves which are frequently met with on the brewery premises; the sharpest of these is 12′ radius; the gage is 22″. There are also several inclines on the line, the steepest being 1 in 30, and up to this a load of 16 tons is frequently taken, the engines being capable of pulling a load of about 40 tons on the level. * "*Scientific American*," xxxvii. 247.

Geared Scroll Chuck. A lathe or drill chuck in which the motion of a scroll plate acts upon gears on the jaw-pieces to cause the jaws to advance and recede concertedly, preserving equal distance from the axial center of the lathe. See *g, i, k*, Fig. 1287, p. 548, "*Mech. Dict.*," and Figs. 874–876, pp. 275, 276, *supra*.

Gear Tooth Gage. A scribing and testing gage, used in connection with a gear cutter for marking the depth to which the cutter should penetrate. Gages are made for all regular pitches, from 4 to 32 pitch, inclusive, one answering for each pitch.

When using a gage for any given pitch, a slight mark can be made on the wheel opposite where the first space is to be cut, and the cutter set just to the right depth by it.

Ged'des Har'row. A field harrow made of two V's inverted, and hinged to a central bar, so as to give flexibility to the tool when passing over ridges and inequalities.

Fig. 1194.

Geddes Harrow.

A and V harrows are well-known forms and are shown under Harrow, "*Mech. Dict.*," and, compounded with circular sections, under Harrow, *infra*.

Geis'ler Tube. An instrument in which light is produced by an electric discharge in rarefied air and gases. The colors are varied by using different gases.

Prof. Morton's Lecture, "*Electric Light*."
* "*Scientific American Sup.*," 2404, 2645.

Gel'a-tine, Blast'ing. An explosive invented by Nobel, composed of

Nitro-glycerine	94 to 95
Collodion	6 to 5

It is viscous, can be cut with a knife or scissors; is not affected by water, like dynamite, and its power is much greater,

Gelatine dynamite . . "*Iron Age*," xxii., Nov. 28, p. 5.
Blasting . . . . . "*Scientific American Sup.*," 2598.
"*Scientific Amer.*," xxxviii. 210.

*See Blasting Gelatine, 105, *supra*.

Gel'a-tine Cop'y-ing Pro'cess. A popular process for copying letters or orders, as a substitute for manifolds, is as follows: —

The original is written or drawn with thick aniline ink, generally Poirrier's "Violet de Paris," on ordinary smooth paper. Lay the writing upon an elastic cake of a special preparation contained in a shallow tray, press the paper on and take it off after two minutes. The greater part of the writing will be found to have been absorbed by the elastic cake, from which a number of reprints may be obtained, generally from 40 to 50. The cake must be wiped with a wet sponge if it has not been used for a length of time, and should always be kept in a cool place. As soon as the necessary number of copies has been taken, the writing must be at once removed from the cake by washing with cold or warm water, according to its nature, there being two different compositions, the preparation of which is described by Prof. Dr. V. Wartha, as follows: Warm a mixture of 100 grams of the finest gelatine with 400 to 500 cubic centigrams of a pasty precipitate of sulphate of baryta, and then add 100 grams of dextrine and from 1,000 to 1,200 grams of glycerine. The mass is allowed to cool until it is just possible to pour it, when it is transferred into shallow tin trays. If the cake be too hard, glycerine must be added. Another composition, which is said to yield sharper copies, but with which it is necessary to use warm water to remove the ink after use, is the following, preferred by Professor Wartha: 100 grams of gelatine, 1,200 grams of glycerine and 500 cubic centigrams of sulphate of baryta.— "*Dingler's Journal*."

Various names have been given to the process, some of them acceptable and others absurd: hectograph, polygraph, copygraph, lithogram, etc., etc.

An excellent ink, which will yield 100 copies, is readily prepared by dissolving rosaniline in a cold, saturated solution of oxalic acid. It must be allowed to dry spontaneously.

The pad may be made of 4 oz. gelatin dissolved in 6 oz. water, and 20 oz. glycerine, sp. gr. 1.26, previously warmed, stirred in. Any air bubbles in the gelatin are removed before the addition of the glycerine. A cheaper compound which answers equally well, but is rather darker, consists of Scotch glue, 6 oz.; water, 8 oz.; glycerine, 20 oz. These qualities make a slab 10 × 13 × ½″.

Any number of colors may be used in the original drawing, and Mr. Norman Lockyer has suggested that it would be of much use in laboratories, for the multiplication of original sketches of biological specimens, and even for spectra charts, and so save much of the time spent in making duplicate copies.

Herr Adler's gelatine printing process is as follows: —

"Use for writing or drawing a concentrated solution of alum, to which, in order to render the writing or drawing visible upon the paper, a few drops of some aniline color is added. Before laying the writing or drawing upon the gelatine surface, pass a damp sponge over the latter, and allow the moisture to sink in for a few minutes, so as to have a greater effect upon the alum. Then lay the written side downward upon the gelatine, and after the lapse of a few minutes, on removing it, the writing will be found reversed and eaten into the gelatine film as if it were engraved. By means of an india-rubber roller a little common printing ink is spread over the plate and absorbed by the lines sunk by the alum, and rejected by the moist gelatine. The paper is laid down upon it and smoothed over it by the flat hand. When removed, this paper will have upon it the impression of the writing or drawing. For each succeeding impression the plate must be inked, as in lithography, by the india-rubber roller. A considerable number of impressions can be taken."

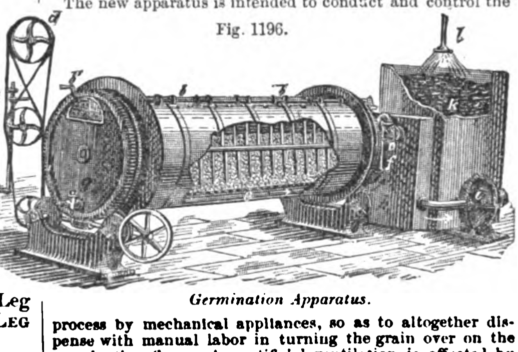
Ger'man Steel. (*Metallurgy.*) A metal obtained from spathose or bog ore by treatment with charcoal.

Ger'mi-na'tion Ap'pa-ra'tus. An apparatus invented by M. Gruber, in which the malting of grain is conducted; including the steeping, couching, and flooring; the kiln drying is a subsequent process. See MALT DRYER; MALT MILL, etc.

The new apparatus is intended to conduct and control the

Fig. 1196.



Germination Apparatus.

process by mechanical appliances, so as to altogether dispense with manual labor in turning the grain over on the germinating floor. An artificial ventilation is effected by means of a current of humid air passing downward through the grain. This ventilation keeps the mass at a relatively low degree of temperature (54° F. to 56° F.), and at the same time draws off the carbonic acid gas as fast as it is produced. Moreover, the thorough turning over of the grain, and its complete division by the periodical rotation of the cylinder, in which the germination takes place, insure a most regular and uniform development of both rootlets and plumule.

Fig. 1196 shows the apparatus. It consists of an iron cylinder, which by means of an endless screw receives a slow rotatory movement. The letters refer to the following parts:

b. Longitudinal openings for charging and emptying the apparatus.

b'. Handle for opening and closing the above.

c. Sheet-iron gratings for admission of moistened air.

d. Mechanical appliances for giving motion to the cylinder.

e. False bottom of perforated sheet-iron supporting the grain, and through which the air is drawn downwards.

f. Pipe for drawing out the air.

g. Tap for admitting and drawing off the steep water.
h. Exhaust chest.
i. Fan.
k. Chamber for moistening the air by filtering it through porous substances kept constantly saturated with water.
l. Shower of water on the moistening chamber.
o. Valve for regulating the draft of air.
p. Rake for dividing the layers of grain during the rotation of the cylinder.

Gruber . . . . * "*Scientific American Supplement*," 2686.
* "*Scientific American*," xxxvii. 152.

Ges'ten-ho-fer Fur'nace. One in which the burning of the sulphur from the powdered ore accomplishes its calcination.

The sulphurous vapor is used to make sulphuric acid, and the acid employed to make soda from common salt.

See notices under CALCINING FURNACE, p. 152, *supra*.

Gibbed Lathe. A lathe the carriage of which has a bar which grips beneath the overhang of the bed, beneath which it is secured by a wedge known as a *gib*, to prevent the riding up of the carriage.

In a *weighted* lathe, on the contrary, the carriage is held down upon the shears by a weight suspended beneath the carriage.

Gif'fard In-ject'or. See INJECTOR.

Gild'ing Press. A book-binder's press, for gilding covers and edges of books.

The edges of books, and hand-work on backs and covers, is done while the book is clamped in a press, 3, Fig. 1578, p. 668, "*Mech. Dict.*"

On a larger scale the full-arch or half-arch press is on the principle of 1, Fig. 1577, *Ibid.*

Gild'ing. Attaching an overlay of gold.

Gilding by dipping. — Dissolve 10 grams of gold in 40 grams of hydrochloric acid, and 15 grams of nitric acid; throw down the gold as fulminating gold by means of spirits of ammonia; filter, and wash. In the mean time dissolve 100 grams of cyanide of potassium in as small a quantity of water as possible, and then dissolve the gold upon the filter with the cyanide solution. Pour this solution again and again over the filter until all the brown particles are dissolved, when the gilding solution is prepared by the addition of 1 liter of distilled water. Into this solution, while warm, dip the metallic object to be gilded, and when drawn out it will have all the appearance of polished gold. — *Ebermeyer.*

Gilding on Glass. — Gold, chemically pure, is dissolved in aqua regia (1 part nitric, and 3 parts hydrochloric acid). The solution effected, the excess of acids is evaporated on a water-bath till crystallization of the chloride of gold takes place; it is then taken off and diluted with distilled water of such quantity as to make a solution containing 1 grain of gold to 200 cubic centimeters of liquid: a solution of caustic soda is then added until the liquid exhibits an alkaline reaction. The solution of gold is now ready for reduction. As a reducing agent, an alcoholic solution of common illuminating gas is used. This is prepared by simply attaching a rubber tube to a gas-jet and passing the current of gas for about an hour through a quart of alcohol. This liquid (which should be kept in a closed vessel) is added in quantities of from two to three cubic centimeters to 200 cubic centimeters of the alkaline solution of gold before mentioned: the liquid soon begins to turn to a dark green color, and at length produces the metallic layer of gold of known reflecting power. — *Dodon* in "*Moniteur de Ceramique.*"

Designs or ornaments of any kind can be produced on glass or ivory, by painting, with a very fine camel-hair pencil, nitro-muriate of gold over the designs. Hold the glass or ivory thus painted over a bottle, in which hydrogen is being generated; in a short time the design will shine with considerable brilliancy, and will not tarnish upon exposure to the air. The thickness of the coating of gold is not more than the ten millionth part of an inch. Another method, in which the use of hydrogen is dispensed with, is to mix gold powder with borax and water; then paint the lines and ornaments with it. When quite dry, the glass is to be put into a stove, heated to a high temperature. The borax is vitrified, and cements the gold with great firmness to the glass. — "*English Mechanic.*"

Gill Net. (*Fishing.*) A flat web net fastened at one or both ends, and arranged by floats and weights carefully proportioned to float near the surface of the water, at an intermediate depth, or at the bottom.

When it floats with the tide it is called a *drift* net.

The gill-net captures a fish by entangling it in its meshes.

The gill-net of Lake Michigan, and salmon-net of the St. Lawrence, are shown on pp. 256, 257, "*Report of U. S. Commissioner of Fish and Fisheries*," vol. i., Part I., 1873.

The *stake*-net is a form of gill-net.

The gill-nets for white fish, used on the Great Lakes, may serve as an instance.

"The gill-netting in use on the Great Lakes is knit from linen thread, two and three ply (25-4, 2-cord, and 30-50, 3-cord), from eleven to twenty-two meshes in depth, 3¾ to 5″ mesh. The nets, when hung or mounted for use, contain from one to three pounds of webbing, and range in length from 60 to 120 yards, and in depth from 4½′ to 6′. They are set in gangs of from three to five nets, and three to five gangs are laid out in one setting usually by aid of sail-boats or steamers.

"For floating the upper line, round or octagonal floats of bark, or wooden pickets about 2½′ in length, are used. Sinkers are of lead or stone. The nets are set in from 20 to 100 fathoms of water, the lead-line resting upon the bottom. They are taken out once a week and dried.

"They are used principally for the capture of the white-fish (*Coregonus albus, etc.*), and the lake trout (*Salmo namaycush*), though most of the common lake fishes are taken in these meshes. Sea-Island cotton (3, 4, 5, and 6 thread) is being largely substituted for linen in their manufacture.

"The weight of the twine preferred by fishermen varies in different localities, that used in Green Bay being the finest, that in Lake Erie next, then Lakes Michigan and Superior, and heaviest in Lake Huron. Lake Ontario consumes about 5,000 pounds of netting annually, Erie 7,500, Huron 6,000, Michigan 20,000, Green Bay 2,500, and Lake Superior 5,000. The aggregate length of this netting is probably about 4,575,000 yards." — *Bulletin U. S. National Museum.*

Gin. Cotton gins are of four principal kinds, the *roller*, *comb*, *saw*, and *needle* gins. The comb is Spanish (*almarraes*), and has mechanical importance.

The roller gin is found throughout India, Malaysia, and China, and has received its proximately perfect development in the Macarthy gin and its relatives.

The Macarthy double roller gin made by Platt Bros., of Oldham, England, has, as its name implies, two rollers instead of one, the feeding hopper being between the two. In the familiar Macarthy gin a reciprocating blade is employed in conjunction with a fixed blade and roller, but, in this later form of gin, two reciprocating blades come into action alternately. A simple contrivance regulates the feeding, making it uniform, and another regulates the pressure of the knifes, called in the American Macarthy gin, *stripper blades*, so as to adapt them to the work of the moment, and allow an obstruction to pass through without clogging or arresting the machine, or breaking the knife or stripper-bar.

The rollers are covered with walrus leather, far more durable, and, from its peculiar texture, superior to sole leather. Each roller rotates in contact with a fixed knife, dragging by its rough surface the fibres of cotton between itself and the knife. Besides these parts there are moving knives, to each of which is attached a grid, or series of fingers. At each elevation of the moving knives, which rise alternately, the grids attached thereto lift the cotton to the elevation of the fixed knife edge and of the exposed surface of the rollers. On the descent of each moving knife the seeds which have been separated from the fiber are disentangled by the prongs of the moving grid passing between those of the lower or fixed grid about 750 times per minute, and are, by this rapidity of action, flirted out.

The turn-out is from 120 to 190 pounds of cleaned cotton per hour. The machine was shown in operation at the Paris Exposition of 1878. It was there stated that 10,000 of the double Macarthy gins were in use in India; and 5,000 of the single Macarthy in Egypt.

The double action knife roller gin is made by Dobson and Barlow, of Bolton, England.

It is entirely self-feeding and self-acting, and the motion for detaching the cotton from the seed differs from that in any other make of gin. The leathern roller is solid, being composed of round disks of walrus leather with a square shaft through the center. These disks are pressed together mechanically with so much force that when withdrawn from the pressure they form a perfectly solid body. The knife-roller consists of a number of disks fitted obliquely on a wrought iron shaft; it revolves continuously in one direction, the knives gently moving the seeds to and fro while the leathern roller draws the cotton from them until the seeds are perfectly stripped, when they fall unbroken into a receptacle provided for them on one side of the machine, while the cotton is delivered in a continuous fleece at the other side.

When worked at the prescribed speed, a 40″ knife-roller gin is capable of ginning the following quantities of seed cotton per hour. —

Dhollerah, 300 lbs.
Candeish, 333 lbs.
Madras, 307 lbs.
Dharwar-American, 230 lbs.
American uplands, 329 lbs.
Egyptian, 690 lbs.
Sea Island, 387 lbs.
Brazilian K, 460 lbs.
Tinnevelly Madras, 500 lbs.
Broach, 348 lbs.
Native Indian (various), 820 lbs.

These results were obtained from this knife-roller gin, at the trials in Manchester and India under government auspices. The double-action knife roller gin can be adapted for any kind of cotton by a change of the grid through which the seeds have to fall, and it has the merit of simplicity in construction and adjustment, large turn out of clean cotton uninjured, and having neither crank nor cam motions.

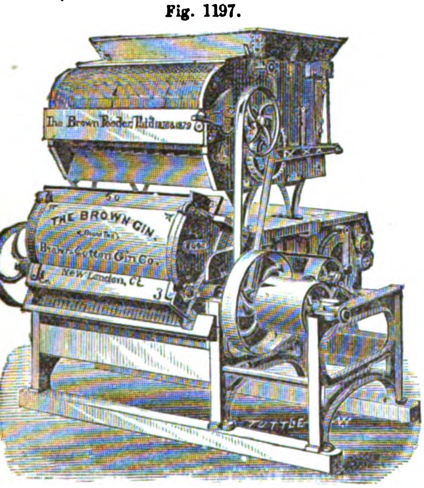
These gins are made of various sizes, with rollers 10″ long, to be worked by hand; 20″, 30″, and 40″ wide, to be driven by power.

The cleanness of work, and avoidance of damage to the staple secured by the Macarthy gin, and the large turn out of the saw-gin, are claimed to be united in this knife roller gin.

Fig. 1197 shows the Brown Saw Gin, with feeder and condenser.

The cotton is dumped into the hopper of the feeder, and is taken up by teeth on a revolving drum that runs in the semi-circular front, carried over and dropped into the hopper of the gin upon the saws that are revolving at a speed of 375 revolutions per minute. These saws run between grates or

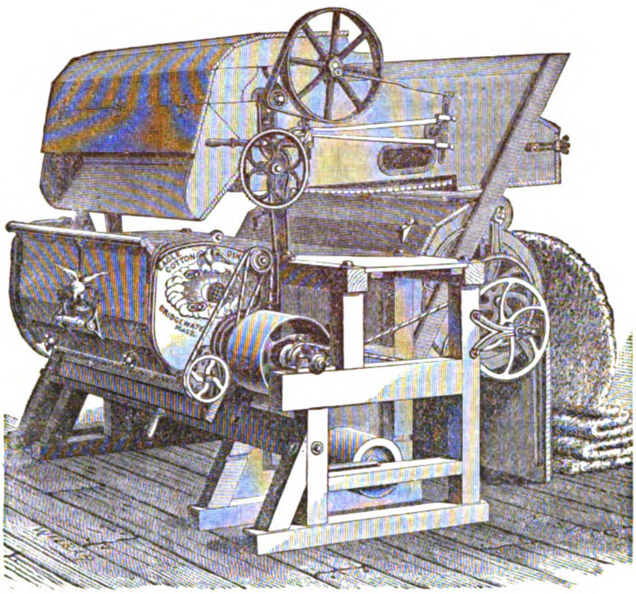
Fig. 1197.



Cotton Gin Feeder and Condenser.

bars that are set say $\frac{1}{8}$″ apart, and pick the cotton from the seed, carrying the lint cotton between the bars, where a brush is revolving at a speed of about 2,400 turns per minute. This brush wipes the cotton from the teeth of the saws, and it is carried by the current of air (caused by the revolving brush) into the condenser at the rear, when it passes between two wooden rollers and is dropped upon the floor in a pile. The saws number from say 30 to 80 in a gin, the average being about 50.

Fig. 1198.

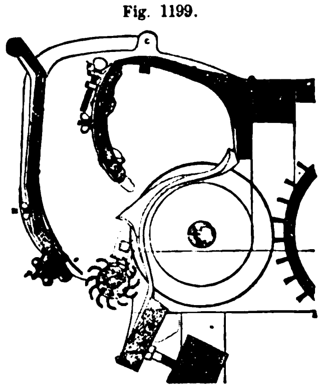


Eclipse Hulling Gin.

Fig. 1198 shows the Eclipse Hulling Gin, for working upon cotton gathered with the bolls. It consists of three parts, feeder and breaker, gin, and condenser.

The feeder and breaker, which is the upper member of the complete machine, is used to break the bolls apart before ginning, as well as to feed the gin. It has a strong, rapidly revolving cylinder with blunt points, to bring the cotton to the breast. This runs parallel with another cylinder, moving more slowly, and having wires in it bent backward. Between the two cylinders the cotton is well opened, and all the whole bolls are broken apart, putting them in such condition that the gin will easily discharge them, and at the same time knocking out a large amount of leaf and dirt. This machine picks its cotton on the under side instead of the top, as has heretofore been done.

Fig. 1199.



Eagle Cotton Gin. Sectional View.

The principle of action is described, and several illustrations are given of cotton gins, on p. 969, "*Mech. Dict.*" Fig. 1199 shows a sectional view of the breast, huller, gin-saw, and brush of the "Eagle" Cotton-gin.

The cotton is fed into the outer breast and drops upon the huller roller (*B*), and is carried by it constantly to the saws. The hulls are stopped by the projections from the ribs and the cotton is carried between them and into the inner breast, where it is ginned.

When the gin is fed by hand the inner breast is kept covered with a hinged flap so that the cotton may be pulled over it from the top of the gin. When a feeder is used, as in the perspective view, Fig. 1198, the flap is turned back so as to leave the breast open.

The Clement gin cards from the boll without breaking or tangling the fiber; avoids the separate ginning, and passes the lint from the seed to the condition of thread. Much stress is laid upon the avoiding of twisting and mixing the fiber heterogeneously, and the damage due to pressure in the bale.

The Gullett "Magnolia" Gin claims as a specialty a stationary beater consisting of 6 parallel bars in close proximity to the brush. This beater consists of thin straps of steel, running the whole length of the saws, and to which the cotton is carried, after leaving the saws, and over which it is thoroughly whipped and cleaned of dust and dirt by the brush.

The Scattergood needle-gin has needles instead of saws. The circles of needles consist of 10 segments, each removable for replacement.

Gin Block. A simple form of tackle-block, having one wheel over which a rope runs.

It has local names, such as *whip-gin*, *rubbish-pulley*, *monkey-wheel*. See Fig. 2225, p. 969, "*Mech. Dict.*"

Ging'ham Loom. A typical form has 2 harnesses and 4 boxes at each end of the lathe. Works pick and pick, and from 1 to 7 colors of filling; any shuttle can be brought into action, and any box can be skipped. Shuttle-boxes can be operated 135 to 145 picks per minute. Stop motion devices on each end stop the loom when any filling is exhausted. —*Crompton.*

Gin Pow'er. An adaptation of the horse-power to the working of a cotton gin. Usually in a story below the gin-house floor.

Gin Pul'ley. See GIN WHEEL.

Gin Wheel. (*Mining.*) A pulley for the lifting cord of the bucket used in sinking shafts. It has a swivel hook and wrought-iron frame.

Gi-raffe'. (*Mining.*) A form of cage or truck used on inclines in mines of the Pacific slope.

Gird'er Riv'e-ter. A form of riveting machine, preferably hydraulic, and suspended so as to work along the girder.

See RIVETING MACHINE, *infra*. Also, Fig. 4851, p. 1949, "*Mech. Dict.*" See KEEL RIVETER, *infra*.

* "*Scientific American Supplement*" . . 2225.

Girth Stretch'er. A frame in which saddle girths are suspended and held taut "to take the stretch out of them," as it is called.

Spring saddle girth, Br. . . * "*Engineer*," xliii. 78.

Gla'ci-a'ri-um. A skating rink, with ice artificially frozen.

That at Chelsea, London, is described, with the refrigerating apparatus, in "*Engineer*," * xli. 378, 381.

Gla'cis. A glancing defense on the deck of a monitor or turret vessel to deflect a ball. See TURRET.

Window glass.
Zaffer.

A glass has lately been made with phosphate of lime, by M. Sidot. He states that it is perfectly transparent and very refrangent (its index of refraction is 1.523, that of common glass being 1.525); and it can be worked like ordinary glass. It does not, like ordinary glass, dissolve all metallic oxides, but it dissolves very well oxides of cobalt and chromium. It is attacked by boiling acids, as also by potash; it is not attacked by hydrofluoric acid; and this property may render it valuable in connection with telescope glasses, for workmen who are exposed to these vapors, and who have to work in the art of engraving on glass.

According to Mr. Robert Hunt's experiments, on the effect of colored glass upon plants, the germination of seeds is prevented and young plants soon die when exposed to yellow light. With careful attention, red glass induces a sickly growth, but the leaves become partially blanched. Young plants seem to avoid the red by bending away from it, but as they arrive at the flowering stage, prefer it to blue or yellow. Blue promotes the germination of seeds and the growth of young plants, but after a certain time seems to increase the bulk rather than the strength.

Oxide of manganese when present in glass tends to correct the coloring action of the iron usually found in the sand, but allows a greater amount of heat to pass than does common glass and is consequently injurious. Mr. Robert Hunt, therefore recommended that glass be tinted with oxide of copper, which was done in the case of that employed for glazing the palm-house at Kew, with advantageous results.—"*Curiosities of Art and Literature.*"

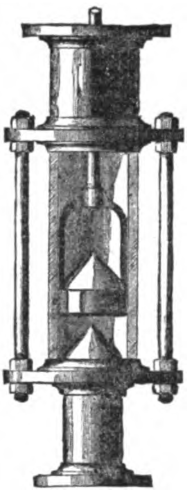
Glass Bar'rel Pump. A pump made by Appleby, and used in breweries for raising hot wort, in gas works for ammoniacal liquor, in tan-yards for tan liquor, in drainage works or farms for sewage, in paper-mills for paper pulp and bleach, and in chemical works for strong acids, etc.

Fig. 1201.



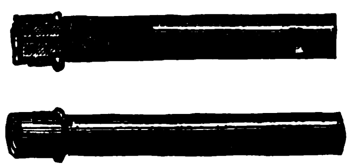
Glass Barrel Pump.

To suit the various circumstances under which it has to work, the mountings of the pump are made either of cast iron, lead, or gun metal, whichever may be best suited to the liquor to be dealt with. The glass working-barrel is accurately bored and highly polished. The mountings are arranged with flanges for coupling up to the suction and delivery pipes, and are held together by wrought-iron screwed bolts or stretchers, with double nuts at each end. The valves are solid india rubber, with lips which open and close. When it is intended to pump hot liquids it will be necessary to place the pump below the liquor, otherwise the steam evolved will prevent the creation of a vacuum in the cylinder. For thin liquids the pumps may be run at a high speed, but for dealing with thick fluids it is advisable to adopt a low speed.

Glass-blow'ers' Pump. A device for injecting air into a glass globe or cylinder while being formed; a substitute for the breath and the power of the lungs.

It was invented by *Robinet*, of Baccarat, and is shown in Fig. 1202. It consists of a small cylinder of sheet brass, closable at one end, in the interior of which is a steel spring;

Fig. 1202.



Glass-blowers' Pump.

at the lower end is a wooden piston, with an opening faced with leather, and held by a bayonet-joint thimble. The mouth of the *ponty*, the pump being held vertical, is placed in contact with the piston, the air contained in the cylinder is by a sudden blow injected through the ponty into the piece of glass being fabricated, and expands therein by the heat of the glass.

Glass-blow'ers' Tools. (*Glass.*) Ponty (blow-pipe), pinchers, shears, calipers, marver (iron plate), bench, and a few other primitive tools.

Glass tools, nickel plated, *Clémandot*, "*Man. & B.*," viii. 258.

Glass Carv'ing. A mode of ornamenting glass by etching and chiseling. The most remarkable instance is the "Portland," otherwise known as the "Barberini," vase. Long supposed to be an onyx, then considered ceramic.

A modern remarkable success in the same line is the "Dennis Vase," by Webb & Sons, shown nearly complete, at the Paris Exposition of 1878.

See "*Report on Paris Exposition*," 1878, vol. iii., pp. 237, 274.

"The body of this vase is of a very dark blue and coated outside with opal glass. The subject chosen by the artist, Mr. Northwood, is the Triumph of Galatea and Aurora. The cover represents a winged horse, not yet finished. The two handles represent horses' heads, one of which is finished. The subjects shown upon the sides, the base, and foot, are ornamented with leaves in opal. The immense difficulty of producing such an article will be understood when it is considered that all the designs in relief have to be carved and chiseled out of the white outside coating; the artist is required to produce a semi-translucid effect, showing the blue glass through the opal, carving out this glass and making it thin enough to show the blue through and yet retain perfect and correct relief forms. This beautiful effect was reproduced in several parts of the vase. The blowing of the vase itself must have been a difficult piece of workmanship, since the horse on the cover and the horse-head handles must have been so put on as to enable the artist to carve correct subjects and introduce the semi-transparent tints I have alluded to. This glass carving is necessarily a very slow work; the vase is not yet finished, some parts being polished and others yet in the rough state. The artist has already devoted two years to the vase, and it is estimated it will be worth $15,000 when finished. It is simply a '*tour de force*.'" —*Colné* (1878).

Glass Ce-ment'. See Recipes, CEMENT, p. 182, *supra*.

Glass Cut'ting. (*Glass.*) There are four kinds of wheels used in cutting or engraving glass: —

1. Cast or wrought-iron wheel.
2. Stone wheel of close grain.
3. A wooden wheel.
4. Cork wheel.

The iron wheel, being mounted in a frame, is rotated, and over it is a drip hopper containing sand and water, which run on to the glass object being cut. The sand cuts away the glass roughly.

The glass is then applied to the stone wheel, which removes the asperities caused by the roughness of the previous process.

Next the glass is applied to the wheel of poplar or willow wood, treated with wet pumice-stone powder. This removes scratches.

The polish is given by the cork-wheel, with *tin putty* (p. 1836), or *colcothar* (p. 593), "*Mech. Dict.*"

A simple way of cutting glass is to crack it with a very fine needle-like gas flame Start the crack with a file, and then apply the flame, which may be produced through a minute perforation in a glass connected with some rubber piping so as to allow of the flame being conveniently carried from point to point. The crack will run before the flame in any desired direction.

Glass Dec'o-ra'ting.

Carving.	Incrusting.
Coloring.	Painting.
Cutting.	Platinizing.
Enameling.	Silvering.
Gilding.	Etc.

See list under GLASS, p. 400, *supra*; also pp. 975, 976, "*Mech. Dict.*"

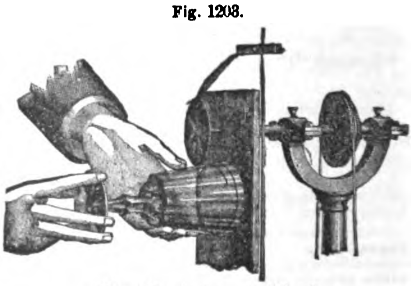
Glass En-grav'ing. The Figs. 1203, 1204, show the lathe and manner of using in lining and lettering glass ware, respectively.

As to the former, a wooden gage is placed behind the cut-

Fig. 1203.

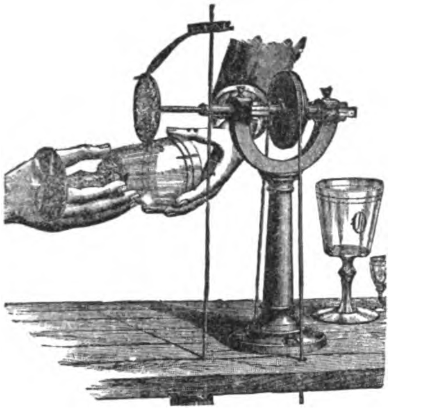


Glass Engraving. (Lining.)

ting wheel to regulate the distance of the line from the edge of the vessel. A little washed flour emery, mixed with olive oil, is applied to the periphery of the wheel, the latter being revolved at a moderate speed. By pressing the goblet against the gage, and at the same time holding it lightly against the wheel and turning it slowly, a line will be formed around it. The wheel is occasionally retouched with emery and oil.

In lettering and ornamenting, the design is first drawn with a pen or brush, charged with a mixture of gum-water

Fig 1204.



Glass Engraving. (*Lettering.*)

and whiting; the lines are then followed by the appropriate wheel charged with emery flour and oil. Small wheels are used for small work and for short curved lines, while the larger wheels will be used in making large curves and straight lines. The engraved work may be polished with leaden wheels, applying pumice-stone and oil.

"The surface of a plate of glass or crystal having been covered with a concentrated solution of nitrate of potash, and a horizontal platinum wire, connected with one of the poles of an electric battery, being placed in the liquid along the edges of the glass, any design may be easily drawn on the glass by touching it with the point at the other end of the platinum wire. The wire forming the 'pencil' is insulated, the tip alone remaining uncovered, and by simply using the wire as an ordinary pencil and tracing imaginary lines on the surface of the glass, the design is permanently reproduced and distinctly engraved thereon. Flat surfaces may be easily treated in this manner, but the difficulty of keeping convex surfaces covered with the nitrate of potash is likely to prove an obstacle to the general adoption of the system. By means of a specially constructed bath, however, it may be possible to overcome the difficulty" — *Planté.*

Mastic . . .	7
Sandarac . .	8

Terquem, "*Journal de Physique.*"

An elaborate article on grounds transferring and etching was reproduced from "*Dingler's Polytechnic Journal*" in the "*Scientific American Supplement*," p. 103.

The fluoric acid process is described in *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," cap. "*Verre*," tome ii., ed. 1877.

Glass Eye.

The workman is provided with a number of thin glass rods, of the colors required Heating the end of one of them by means of a blow-pipe, he gathers from it sufficient for his purpose, on the end of a wire. This first gathering is generally of white or colorless glass, to form the white of the eye. He then takes the rod required to form the iris, and gathers from it on the white, and lastly, a little spot from a black rod is added to form the pupil. During the process the bulb on the end of the wire is rotated in the flame of the blow-pipe and occasionally pressed against a smooth surface to obtain perfect evenness of outline.

Glass Floor'ing. Glass tiles

Flags or slabs of rough-cast glass are manufactured in pieces 6′ broad, 1$\frac{1}{2}$″ thick, 11″ long, and weigh 165 lbs. per square meter; the upper surface is generally molded in diamonds. Pavements of glass are made in the same style as the slabs, with the upper surface molded in diamonds, but are much thicker, and are intended for slabs for carriage-ways. They are made of cubes of about 6″ × 6$\frac{1}{2}$″, and weigh each 19.80 lbs. Rough slabs are also made of 6.56′ × 2.65′, varying in thickness from 9-16″ to 1$\frac{1}{4}$″; weight, from 213 to 492 lbs.

Glass Fur'nace. The use of Siemens' furnace in glass furnaces has proved a great success. The principles of the furnace are described under GAS-GENERATING FURNACE and REGENERATOR FURNACE.

Fig. 1205 shows the application to glass-making. *A* is the furnace, on the siege of which the pots *B B* are placed. *C* are the openings through which the contents of the pots are reached. Under the furnace floor are disposed 4 regenerators, of which but one, *D*, shows in the longitudinal section These, as is explained under the heads cited above, are used in pairs alternately: (1) heated by the gases passing from the furnace to the chimney, and (2) serving to heat the inflammable gases from the gas producer, and the incoming air, which mingle just before reaching the pot furnace *A*.

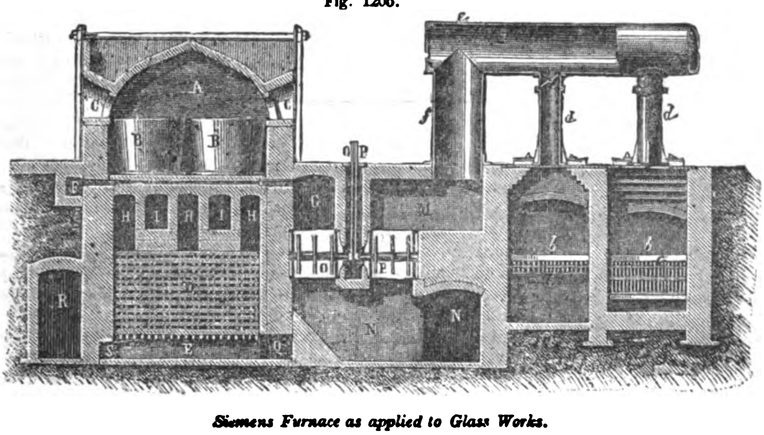
The vaulted roof of the regenerator is the floor of the pot furnace, and is traversed by the longitudinal flues *H I H I*, which communicate on one part by conduit *F* with the open air, and in the other with the flue *G*. Speaking as to any one of the four regenerator chambers, that shown at *D*, for instance, when it is to be *heated* the waste gases from furnace *A* discharge into *H H* and pour downward through the cellular brick structure *D*, through the grated floor into *E*, and thence by *N N* to the chimney; when the regenerator has been sufficiently heated, the valves *O P* are moved and the conditions are changed; the heated gases in *M* coming from the gas producer descend into *E* and pass up through the heated regenerator, to be united with air entering at *G* and passing through a similarly heated regenerator, the two being ignited at their point of junction and filling the furnace *A* with flame.

As one pair of regenerators become heated and the other cooled, the valves which transpose the course of the currents are changed by the motion of a lever, and the functions of the regenerators are changed, and so on alternately.

b b are the grates of the gas-producing furnaces; *d d*, the pipes of ascension for the gases; *e f*, flues communicating with chamber *M*, whence the gases are emitted to one or the other regenerator, as the case may be. See GAS-GENERATING FURNACE.

In the works of Lloyd & Summerfield, Birmingham, England, the application of the Siemens furnace to glass-works was first made, with the result of changing the consumption of fuel from 35 tons of superior coal, to 16 tons of inferior coal, per week.

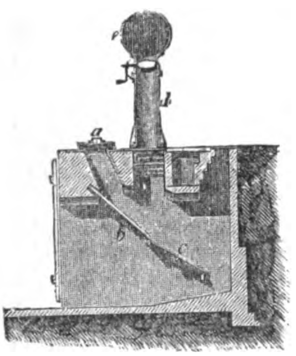
Fig. 1205.



Siemens Furnace as applied to Glass Works.

Fig. 1205 is a vertical section through one furnace in a line at right angles to the view given in Fig. 1206.

Fig. 1206.



Siemens Regenerator. Glass Furnace.

"The Siemens furnaces have been used quite extensively in metallurgy with great success; in this country we find but three glass-houses using them, viz., Burgin & Sons, of Philadelphia, the Lenox Plate Glass Company, and the Crystal City Plate Glass Works. In Europe we find quite a number of firms using them; in England, five plate-glass works, twelve window and bottle houses, and one flint house; in France, seven plate works, ten window and bottle works, and nine flint factories; in Germany, three plate works, eight window and bottle houses, and twelve flint works; in Belgium, four plate works, one window house, and one flint factory. These furnaces have also been introduced in Russia, Portugal, Hungary, and Austria." — *Colné.*

The Boëtius gas furnace, without the regenerating principle, has been introduced among European manufacturers. It is much simpler in construction than the Siemens. The gas generator is somewhat similar to that of Siemens, but the gases, instead of passing through regenerators, are conducted directly to the furnace with a sufficient quantity of air, and there ignited. The air, by passing through passages under the bottom of the furnace, serves to cool the bench, and thereby receives a certain degree of heat extracted from the hot bricks. The furnaces do not cost as much to construct as a regenerating furnace, they are easy of management, and the heat can be readily regulated.

The Ponsard furnace is also used in glass works, and has been described elsewhere. See GAS-GENERATING FURNACE, Figs. 1158-1162, pp. 385-387, *infra*.

In it the heat escaping from the fire-chamber, after having done its work, is conducted to a regenerator under the furnace, made somewhat in the same style as the Siemens. Instead, however, of one of the regenerators receiving the gas from the generator and the other the air to be mixed in the furnace, and having four regenerating chambers, the Ponsard system uses but one chamber. This regenerating chamber is made up of a number of passages adjoining one another, one series of which receives the hot gases after combustion, and the other receiving the air to be heated by the absorption of heat from the adjoining hot canals. This system is, therefore, continuous, and simpler than the Siemens.

The Siemens compartment furnace is a substitute for the bench with pots, the furnace being a tank divided into three compartments by means of transverse floating bridges. In the first compartment the batch is melted, in the second compartment it is refined, while the third compartment is the receptacle for the thoroughly purified glass, from which it is worked out *continuously*.

"The principal advantages resulting from the use of the continuous melting furnace are:—

"1. An increased power of production, as the full melting heat may be employed without interruption, whilst, with the old method of melting, nearly one half of the time is lost by cooling and settling the metal, the working out of the same, and the re-heating of the furnace.

"2. An economy in working, as only one half the number of men are required for the melting operations.

"3. A greater durability of the tank or furnace, owing to the uniform temperature to which it is subjected.

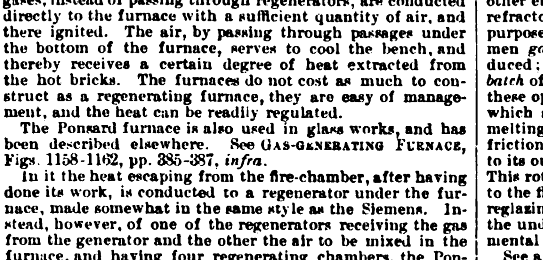
"4. A much greater regularity of working, and more uniform quality of the product than in other furnaces.

"5. For the manufacture of window glass, the compartment may be so arranged that the blowers can work without interfering with the gatherers: this does away with the separate blowing furnace now in use.

"The reason of the greater durability of the tank is not only due to the uniform temperature maintained, but also to the circumstance that the batch is filled in, in such quantities as not to come into contact with either the sides or the bottom of the tank, which consequently are not suddenly cooled or eaten away by the mixture; also to the fact that each compartment of the tank is subjected only to the requisite amount of heat necessary for the purposes carried on therein.

"The difference in the specific weight of the glass at the different stages of melting is used for keeping the metal separate in the several compartments, and the operation of charging the melting compartment with raw material causes the necessary onward pressure." — *Siemens*

Fig. 1207.



Tank Furnace.

Atterbury's tank furnace is shown in Fig. 1207. The tank is shaped like an oval dish, and the arch has the same form; in order to expose a large surface of the glass, relatively to the quantity, and secure a favorable reverberatory form to the arch. The division enables different colored glasses to be worked from the heat and furnace.

Duryee's glass furnace is a revolving cylinder with a blowpipe flame fed with petroleum and steam jet.

Franke's glass furnace is a revolving cylinder having perforated ends for the entrance of the flame from any desired form of fuel chamber, and for its exit to the chimney at the other end. The jacket is lined throughout with a lining of refractory fire-clay, and has openings on its sides for the purpose of access to the glass, and through which the workmen *gather* the glass for the different articles to be produced; another opening is provided, through which the *batch* of materials of which glass is made is introduced. All these openings are provided with doors lined with clay, and which are bolted shut during the *melt* or period when the melting is being done. The cylinder is mounted on anti-friction rollers, and is rotated on its axis by a rack secured to its outside surface and a pinion driven by steam power. This rotation causes the entire mass to be uniformly exposed to the flame traversing the cylinder, also causes the constant reglazing of the sides and ends of the furnace, and prevents the undesirable action of the *gall*, which has proved so detrimental to stationary tank furnaces.

Glass Press. The subject of the principles and practice involved in the making of glass objects by pressure in molds is carefully and lucidly treated by M. Colné in his Report on Glass at the Paris Exposition of 1878, vol. iii., pp. 378 *et seq.* The various requirements of special forms and complicated structures are there given *in extenso.*

Glass Ring. (*Microscope.*) A circle of glass for forming a cell in which a thick object is mounted.

Glass Silk. A product obtained by winding fine threads of glass in fusion on rapidly rotating and heated cylinders.

In the microscope the threads are as fine as those of silk or the fibrillæ of cotton. They break more easily than the latter, but are excessively supple. From the inalterability of the substance, it is very well suited for filtering acid or alkaline solutions, even concentrated, and various other substances, such as nitrate of silver, albumen, collodion, Fehling's liquor, etc. It affords great rapidity of flow, with good filtration. It is preferable to amianthus, which from the arrangement of its parallel fibers cannot be formed into a flexible ball, and which lets fragments pass that float in the liquid. For analysis it is very advantageous, allowing of a ready determination of insoluble matters deposited; also, by calcination and fusion of the glass may be found the volatile principles fixed in the passage of the liquid, unmixed with empyreumatic products.

Glass is capable of extremely fine filiation either by the winding process, cited above, or by means of a blast, in which latter case it assumes a flocculent quality. See MINERAL WOOL.

Glass Sil'ver-ing. Silvered plate glass is produced by causing a slight coating of mercury to adhere to the glass. To obtain this result mercury must be retained by a metallic medium; it is, therefore, amalgamated with tin. Mercury has been chosen owing to its power of reflecting light very brightly.

The process has been described on pp. 982, 983, "*Mech. Dict.*" See also pp. 2184, 2185, *Ibid.*

A solution of silver has been largely substituted for the mercury amalgam. The Pettitjean process is as follows: —

"The operation is very similar to silvering with mercury. The table, instead of being a stone, is a hollow sheet iron table, made quite smooth on its upper surface, and containing inside water capable of being heated by means of steam, to bring the temperature to 95°-104°. Preparatory to silvering the glass it should be thoroughly cleaned. The table being ready, a piece of oil-cloth is spread over it, and upon this is laid a piece of cotton cloth. The plates are now put singly upon these cloths, and the following solutions are poured over them: —

"*Liquor* No. 1. Dissolve in a liter of water 100 grams of nitrate of silver; add 62 grams of liquid ammonia of 0.880 density; filter and dilute with 16 times its volume of water. Then pour in this liquor 7.5 grams of tartaric acid dissolved in about 39 grams of water.

"*Liquor* No. 2. This liquor is precisely the same as the other, with the exception that the quantity of tartaric acid is doubled, say 15 grams.

"First pour liquor No. 1 upon the plates, as much as will remain upon the surface without running over. The heat of the table is now increased gradually to 95°-104° Fah., and in about thirty minutes the glass is covered over with a metallic coating. The table is now inclined and the plates washed with water, which carries off the surplus silver. The table is again raised, and liquor No. 2 is now poured over; in about a quarter of an hour another coat is deposited, which covers the glass completely. The plates are again washed; then they are carried to a slightly heated room, where they are gradually dried.

"This operation, as will be seen, is quite simple, and is generally performed by women. The silver carried off in washing and that contained in the cloths is recovered again. Since glass silvered by this process is liable to be altered when exposed to the air, and the coating may become easily detached if not covered over with a protecting coat of paint, the silver pellicle is covered with an alcoholic copal varnish, put on with a brush, and when this is dry a coat of red-lead paint is put on.

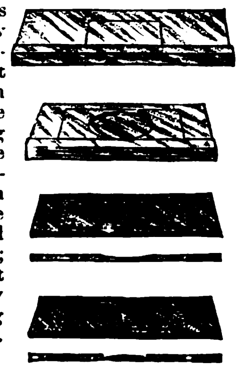
"Plates silvered by this means have more brilliancy than with mercury, but as there is a slight tinge of yellow given to objects reflected by these mirrors, they were at first objected to. This objection has passed away, however, to a great extent, and the yellow reflection has been obviated by giving a slight coloration to the glass. The new silver process costs about 36 cents per square meter. Inasmuch as such works as the St. Gobain have adopted it, and as the terrible disorders caused by mercury may be thus avoided, there should be no hesitation in adopting this new process everywhere." — *Colné.*

Glass Slip. (*Microscope.*) For mounting objects: usually 3′ × 1″ in size, made of crown or plate. See Fig. 1208.

Glass Stage. (*Microscope.*) A platform in the microscope, used instead of brass on account of cleanliness.

Glass, Tem'pered. Siemens' process consists in heating, then suddenly cooling the glass to be hardened and tempered; but when the articles are such as are usually molded, the hardening and tempering are accomplished at the same time as the pressing — that is, the molten glass is run into suitable molds, and while still highly heated, is squeezed; the molds having the effect of giving the necessary cooling without resorting to the liquid bath of M. Bastie.

Fig. 1208.



Glass Slips.

a. Glass slip with ledge.
b. Glass slip with hollow ledge and lip.
c. Glass slip with hollow.
d. Weber's slip with convex cell.

The material employed for these molds depends on the nature and thickness of the glass. In ordinary practice, however, it is found that cast-iron molds maintained at a temperature of about 212° Fah., and earthenware molds kept quite cool, yield very satisfactory results. The liquid glass may be conveyed direct to the molds, or may be taken from the melting furnace on the blower's pipe, and shaped in the mold, but it is preferable to heat the articles after shaping, before pressing and cooling them.

2. A spherical glass for a lamp or burner.

"It is not generally known what a very large proportion of light is obstructed by the glass globes or moons so frequently used over gas flames. From experiments, all made with a light equal to fifteen standard candles, I find the following results: —

	Illuminating Power.	Percentage of Light lost.
Naked flame	15.00	–
Clear glass globe	12.80	14.65
Ground glass globe	11.40	24.00
Opal globe	9.00	40.00
Another opal globe	8.16	45.60
Another opal globe	8.00	46.70
Another opal globe	6.64	55.90
Another opal globe	8.00	46.70
Another opal globe	7.48	50.10

The advantage arising from the use of these moons is that they diffuse and soften the glare of the naked light, which is sometimes oppressive to the eyes. Of the opal globes the dead white semi-opaque one should be avoided. A very good form of globe is that with a wide opening at the bottom, which allows a considerable amount of light to be reflected downwards from the white surface of the inside of the globe." — *Pattison.*

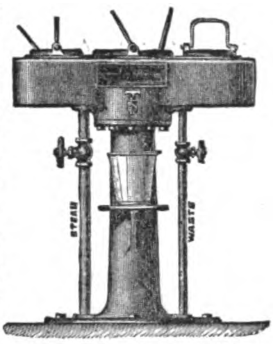
Glue Heat'er. A glue boiler.

In the figure, the walls of the steam chamber are double throughout, so that the pots do not come in contact with the steam or water. The steam chamber is also cast in one piece, preventing leakage of steam or water, there being but one joint, and that a plain flange which can be made perfectly tight.

Fig. 1213.



Glue Heater.

The glue pots, three in number, rest on turned flanges which are air-tight, to prevent the escape of heat. The center pot holds one gallon, and the two at the ends one-third gallon each.

Each heater is provided with a water pot, also with steam and waste-cocks, so attached by nipples to the steam chamber, that the connecting pipes may pass down through the base, as shown in the engraving, or in any direction from the heater — *Richards*.

Glue Wa'ter Core. A dry sand core in which common glue dissolved in water has been used for giving adhesiveness and strength to the core when dried. For this core a sand containing no loam at all may be used.

Glu'ten Test'er. See ALEUROMETER.

Glu'tine. A preparation by Dr. Bering for stiffening and rendering glossy, calicoes, wall paper, etc.

Freshly precipitated caseine is well washed, dried at 212°, and reduced to a moderately fine powder. This is levigated with a 59 per cent. solution of sodium tungstate. The mass becomes very thick as soon as the solution is added. It is now placed in a boiler and fully liquefied by heat. If it be too dry, a sufficient quantity of water is added. When it has acquired a completely homogeneous consistence, a little carbolic acid or salicylic acid is added to prevent its putrefaction. On cooling, the mass becomes nearly solid.

This preparation, when not completely hardened, is very soluble in water and very adhesive. It also adheres on metal, and may, therefore, be used for labeling tin cans, also bottles and jars. When entirely dry it resists for some time the action of water, but is soluble in glycerine. A mucilage formed by a solution of glutine in water and a small proportion of glycerine forms an excellent flexible varnish for wall paper.

Dissolved in glycerine alone a tough clear mass is formed, which, spread on paper and passed through a solution of alum, acquires the firmness of good batter.

On account of the large quantity of wolframic acid contained in it, it may receive all different tints and colors by the addition of the decoctions of various dyewoods. If, for instance, cotton or linen, soaked in a solution of glutine and dried, is passed through a decoction of logwood, it is dyed violet.

By soaking cottons or linens in glutine solutions, drying, and passing them through solutions of the mineral acids or salts of the same, they are dyed in various colors, resisting the action of soap and water and even that of alkalies. — *Chemiker Zeitung.*

Glyc'er-ine Ce-ment'. For metals and packing joints: glycerine and litharge; made of any consistence to suit. It withstands a temperature of 275° C. Is useful for galvano-plastic purposes, as it reproduces a surface with delicacy and accuracy.

Gold Al-loy'. An alloy resembling gold. Sometimes the composition has the color and specific gravity of the genuine metal.

Meiffren's. — 800 parts of copper, 28 of platinum, and 20 of tungstic acid are melted in a crucible under a flux, and the melted mass poured out into alkaline water, so as to granulate it. It is then melted together with 170 parts of gold. It resembles 750-1000 fine.

Another. — Pure copper, 100 parts; zinc, or preferably tin, 17 parts; magnesia, 6 parts; sal-ammoniac, 3 6 parts; quicklime, 1.8 parts; tartar of commerce, 9 parts, are mixed as follows: The copper is first melted, then magnesia, sal-ammoniac, lime and tartar are added separately and by degrees, in form of powder. The whole is next briskly stirred for about half an hour so as to mix thoroughly, after which the zinc is added in small grains by throwing it on the surface and stirring it till it is entirely fused; on this being done, the crucible is then covered and the fusion maintained for about 35 minutes, after which the surface is skimmed and the alloy is ready for casting. This alloy has a fine grain, is malleable, and takes a splendid polish. It does not corrode readily. *Schmitte's.*

Another: Copper	. . . .	8
Tin, 1½		
Zinc, ½	. . . .	1
Lead, 5-16		

Gold Lacq'uer. An imitation of the celebrated Chinese gold lacquer may be prepared by melting two parts of shellac and one of copal, so as to form a perfectly fluid mixture, and then adding two parts of hot boiled oil. The vessel is then removed from the fire, and ten parts of oil of turpentine gradually added. To improve the color an addition is made of a solution in turpentine of gum gamboge for yellow, and gum dragon for red. These are to be mixed in sufficient quantity to give the desired shade. The Chinese apparently use tinfoil to form a ground upon which lacquer varnish is laid.

Gold Pow'der. Put into an earthenware mortar some gold leaf, with a little honey or thick gum-water, and grind the mixture till the gold is reduced to extremely minute particles; when this is done, a little warm water will wash out the honey or gum, leaving the gold behind in powder.

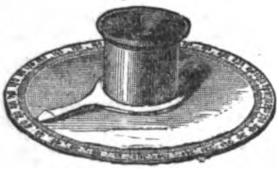
Go'ni-om'e-ter. An instrument fitted to the eye-piece of the microscope; used for determining by means of a double-image prism the angles of crystals.

Fig. 1215.

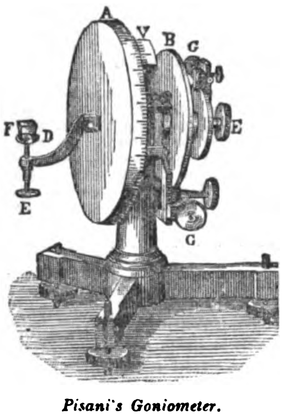


Leeson's Goniometer.

The goniometer of M. Pisani, for measuring the dihedral angles of crystals, is shown in Fig. 1216.

It consists of a circle *A*, divided into degrees and half degrees, and having a vernier, *V*, marked to minutes. The circle is turned by the disk *B*. A second disk moves the axis carrying the piece *D* independently of the circle. This piece is movable normally to the plane of the circle, and supports the platform on which the crystal is placed. *G* and *G'* are adjusting screws for the parts already mentioned.

Fig. 1216.



Pisani's Goniometer.

In order to measure an angle the crystal is secured by wax on the platform in such a position that the ridge of the dihedral angle passes through the axis of the crystal. This position is approximately obtained by movements of the stem *F E*. The goniometer is then placed on a table at some 15' distant from a candle fixed to the wall. After having determined by the plumb line the foot of the perpendicular passing through the luminous point, two points of view are obtained which are in the same vertical plane. The plane of the circle is then adjusted to the plane of these points. By turning the disk *C* the observer rotates the crystal until he notes on one face the reflected image of the flame. Then continuing to move the crystal he notes whether this reflected image coincides with the lower point of sight regarded directly. If this coincidence does not occur, if the luminous point appears to the left or right of the point at the lower end of the plumb line, it is made to coincide by the screw *E*. The coincidence being thus obtained for one face, the other face is adjusted, and when the two images on each face respectively coincide it remains only to measure the angle.

The circle is placed at zero, and by means of disk *C* the circle is turned until the coincidence of the two points of sight is obtained on the face on the same side as the observer. The eye is kept fixed, and the circle is turned by the large disk *B* until coincidence is obtained with the second face. The angle through which the circle is turned is the supplement of the dihedral angle, and it remains only to substract the measurement now from 180° to obtain the required result. See also Fig. 2267, p. 996, "*Mech. Dict.*"

The beaks of the forceps have a gouge shape.

Gov'er-nor. A device to regulate the speed of an engine or machine.

Steam Engine Governor, p. 997, *et seq.* "*Mech. Dict.*"

Gas. See GAS GOVERNOR, *supra*.

Water-wheel. Fig. 7126, p. 2646, "*Mech. Dict.*"

The *Condé* automatic safety stop-governor is shown in Fig. 1217, Plate XVIII. The valve has a number of ports giving a large sum of opening with a small motion of the valve.

The steam chamber *A* is fitted with a valve, *B*, composed of rings, stayed together by vertical ribs cast on its inside. The spaces between these rings form ports, through which the steam passes from corresponding ports made in the chamber. The valve is *double-acting*, governing on the downward stroke, and cutting off entirely on the upper stroke when the balls drop to their lowest point.

A sleeve and hand-wheel, *C*, are fitted to the upper part of the frame *D* by a screw connection. This sleeve supports the head *G*, which passes down through it to the driving gear, and is raised or lowered through the screw, thus changing the position of the valve in the chamber, increasing or diminishing the speed of the engine at will. Within the head *G* is fitted the cam gearing for transmitting the motion of the balls to the valve. This gearing increases the travel of the valve in proportion as the balls approach a horizontal line.

H is a throttle, with angular connection for attaching steam pipe without elbows. The valve and seat are of brass, and are removable. The valve rod has its traversing screw outside from the packing box, and passes through the outer end of the gland, which acts as the nut. This arrangement prevents steam acting on the thread, and allows a refitting of the valve in its place, simply by removing the gland.

The valve seat is set into the throttle with a taper joint, so as to be removed for repairs, without taking the throttle apart from the steam pipe.

The *Judson* governor is shown in Fig. 1218, Plate XVIII. The illustration shows the governor, governor valve, and stop-valve combined ; the speeder for altering speeds, Sawyer's lever and automatic stop-motion.

In the *Tremper* variable cut-off and governor, shown in Figs. 1219, 1220, 1221, Plate XVIII., the governor is employed not to open and close a valve directly, but merely to determine the point of time at which the cut-off valve shall be closed. This duty requires but little effort on the part of the governor, and its action can therefore be made very sensitive. The cut-off valve is moved by direct attachment to the engine, and is opened and closed at each half-stroke. The time of its opening is fixed and invariable, but its closing is determined by the governor, and varies with the duty to be performed. When the proper amount has passed the valve, the flow of steam into the cylinder is abruptly cut off by the sudden dropping and closing of the cut-off valve, and the volume admitted expands in the cylinder as the piston recedes, the pressure constantly diminishing until the exhaust port is opened and steam released.

Figs. 1219, 1221 are respectively perspective and sectional views of the cut-off governor, and Fig. 1220 is an enlarged view of some of the important parts. In this illustration *G* is the lower end of the governor ball stem, fastened to the wedge *W*; *L L* are the lifters; *C*, the bell crank ; *H*, the cork holder ; *R*, the ring of rubber or cork, upon which the beater *B* falls, after the steel plates *P* of the lifters are disengaged from those of the beater, by the wedge *W*; *V* is the valve stem, to the upper end of which the beater is attached, and to the lower end the cut-off valve. The movement of the beater is, therefore, identical with that of the valve. The rock-rod imparts a rocking movement to the bell-crank which moves the lifters upward and downward alternately, a given distance. The hardened steel plates, fitted into the lifters, project so far as to engage with corresponding plates in the beater. When the cone is raised by the governor balls to its full height, one of the lifters will carry the beater

upward, opening the cut-off valve; and as the steel plates are not, under these circumstances, disengaged by the wedges, but remain in contact, the valve remains open until it is closed by the lifter in its downward movement. It is then reopened by the lifter on the opposite side, which represents the return-stroke of the piston. When this condition exists, the engine is said to be "*carrying full stroke.*" The steam is not being cut off, but is freely admitted to both ends of the cylinder, and the full power of the engine is being developed. If a less amount of steam is sufficient to maintain the speed of the engine, the wedge *W* is moved downward by the operation of the governor balls and the lifter, sliding outward as it moves upward, is disengaged from the beater, and the valve is allowed to drop instantly into its seat, cutting off the passage of the steam into the cylinder.

The duty of the governor, therefore, is only to determine the position of the wedge *W*, the power required to move the valve being derived directly from the engine itself, operating through the lifter.

The engine governor of *Waters* is shown in Fig. 1222, Plate XVIII. The action of springs is supplemented to that of balls.

The balls are attached to the ends of curved springs, and supported from the ends of bell-crank arms which are pivoted to the revolving sleeve of the governor. In the axis of the sleeve is the upward extension of the valve-stem, and tappets on the inner part of the bell-crank work in the groove of a collar on the valve-stem, so that when the balls fly out by access of speed the tappets force down the stem, and so operate the throttle-valve in the chamber. One end of each of the springs is bolted to the sleeve and the other end connected to a suspended ball, the whole arrangement of balls, springs, and sleeve revolving around the stem. The end of the valve-stem is extended through the top of the composition collar and furnished with a handle with which to turn it and a check-nut to hold it in place. Screwing this stem down causes the engine to run slower, screwing it up causes it to run faster.

Fig 1223, Plate XVIII., shows the *Bourne* high-speed governor (Br.) The whole is made of polished brass. The spindle carries two bent springs, at the center of which two brass weights are situated, and the spindle, springs, and weights are rotated by a small pulley driven by a cord from the shaft. The spindle carries a double-beat valve which is closed or opened by the centrifugal action of the weights or the centripetal action of the springs. The latter is a constant quantity, but is overcome more or less by the centrifugal force as the speed of the engine varies, thus regulating the admission of the steam. The double-beat valve acts also as a stop-valve, its position being governed by the hand-wheel at the end of the spindle, while the periphery screw prevents this wheel from moving from the position at which it is set. On the top of the governor there is a grease cup, by which oil or grease is continuously fed in with the steam. The thumb-screw at the end serves to regulate the speed of the engine, or to stop and start the latter. The governor takes up but little room, and is an improvement on the somewhat similar arrangement long used by Mr. Bourne.

The variable cut-off governor of the "Buckeye" engine is shown at Fig. 1224, Plate XIX.

The cut-off mechanism consists of a light cut-off valve, working on the inner face of the main valve, the stem passing out through the hollow steel stem of the main valve, and being driven from a loose eccentric on the shaft with a special motion derived from the compound rock shaft. This loose eccentric is controlled by the governor, Fig. 1224, which is a shell fast upon the shaft and revolving with it. In this shell are pivoted two weighted levers, the outer ends of which are linked to the flange on the elongated sleeve of the loose eccentric The centrifugal force developed in the weights throws them outward, and two steel coil springs furnish the centripetal force. The system being coupled is independent of gravity, and the speed determines the position of the weighted arms, which, in turn, determine the angular advance of the eccentric and the consequent point of cut-off, the range of which is from zero to nearly three quarters of the stroke

Fig 1225 shows a *Hartnell's* governor (Br), in which an arrangement similar to that shown in Fig. 1224 is adopted. The entire governor is carried by a disk keyed to the crank shaft The purpose is to regulate the admission of steam to the engine cylinder without in any way throttling it, altering the stroke of the eccentric without altering the lead of the slide valve.

The figures show the weights extended and collapsed, respectively.

A^1 and A^2 are the weights, a^1, a^2, the pins on which they swing *R* the link connecting the weights with each other at r^1 and r^2 *E* is the eccentric, having a slotted eye, through which the crank shaft passes; it is fastened to the carrier, *C*, by the bolts b^1, b^2, b^3, and swings from the center e^1 *Q* is the quadrant fastened by the screw *q* to the weight A^2, the arm of this quadrant slides through a swivel pivot *P*, on the eccentric carrier *C*. S^1, S^2, are the springs which control the expansion of the weights, s^1, s^2, the adjusting screws for the springs.

On the engine being put in motion the centrifugal force tends to drive the weights, A^1, A^2, outwards, but they are prevented from flying out too readily by the restraining force of the spiral springs, S^1, S^2. The quadrant *Q* is so fixed upon the weight A^2 as to form an angle inclined to its path of motion, by sliding through the swiveled pivot *P*, and acts as an incline to shift the eccentric, which it does in correspondence with the movement it derives from the governor weights as they fly out or come in, giving more or less eccentricity to the eccentric, and consequently more or less stroke to the slide valve, and steam to the cylinder.

The construction of the *Allen* governor, Figs. 1226–1228, Plate XIX., is as follows: —

Within a corrugated cylinder, which has small projecting ribs on its interior periphery, and which is partially filled with oil, a paddle-wheel is caused to revolve by a spindle passing through one end of the cylinder, driven by a belt communicating with the fly-wheel shaft. The tendency of the revolving paddle-wheel is to cause the cylinder to move in the same direction. On the opposite side to the revolving spindle is a trunnion or short spindle fixed to the cylinder, attached to which is a wheel carrying a set of movable weights suspended by a chain, the speed of the engine being regulated by the number of weights. Attached to the wheel and keyed on the end of the short spindle is a pinion revolving with the cylinder, and working in a toothed sector, the arm of which, being fixed on the spindle of the throttle-valve, opens or closes it as the oil cylinder moves with the paddle, according to the variation of load thrown on the engine. When used with variable cut-off engine, the arm is attached direct to the cut-off.

Fig. 1229 shows the engine governor by *Runqvist*, of Sweden. Its principle is to develop a pressure produced by frictional resistance depending upon the velocity.

To the rapidly revolving main spindle of the governor is rigidly attached a bracket which carries on one side a set screw, and on the other a segment of an iron ring, *C*, in which are mounted three blocks of hard wood. This segment is so attached to the bracket that the faces of the three wooden blocks can readily adjust themselves to form one plane with the point of the set screw, however the latter may be adjusted This plane is not at right angles to the revolving spindle, but is more or less inclined

A heavy ring, *B*, is so attached to the body of the governor by a universal joint that it cannot revolve, but can freely oscillate. This ring is adjusted closely against the wood-blocks and set-screw mentioned before; and the latter forming a plane inclined to the spindle, rotation must transmit an oscillating movement to the ring *B*. This oscillation brings into play the inertia of the mass of the ring, reacting against the wood blocks, and producing, by friction, a resistance against the rotation of the shaft, evidently increasing with the speed.

The governor is driven from the engine by the pulley *A*, whence the motion is transmitted by the pinion *L* to the wheel *G*, which revolves loose on the main spindle of the governor. This wheel gears into a pinion fastened to a spindle, to which the wheel *H* is keyed; and this wheel finally transmits the motion to the main spindle by the pinion *K*. The lever *F* is forked at its fulcrum, that is formed by the main spindle, and it is extended beyond this fulcrum, carrying the spindle of the wheel *H*. From this it will be seen that the combination of wheels forms a differential gear; and here is where the resistance offered against the rotation of the main spindle meets its opponent — the tension of a vertical spiral spring — that will be elongated more or less according to the speed The lever *F* carries on its front end an adjustable saddle, to which the valve rod can be attached.

Fig 1230 is Heebner's speed regulator, for railway horse-powers

The rim or circle is fastened to the power behind the belt wheel, and leaves the shaft exactly in the center. The hub with its attached arms, weighted balls, and friction blocks, has a stud with small coiled brass spring secured by a thumb-screw at the end to regulate the amount of speed. As the speed increases the balls are thrown out by centrifugal force, and press the friction blocks against the rim, thus acting as a brake; but as soon as machinery is applied, and takes the power, the balls fall back and relieve the braking.

2. (*Gas.*) *a.* An instrument or apparatus to regulate the flow of gas. See Gas Governor; Gas Regulator.

b. An attachment to a gas exhauster which causes the pressure in the main to determine the speed of the engine running the exhauster. See Gas Exhauster Governor.

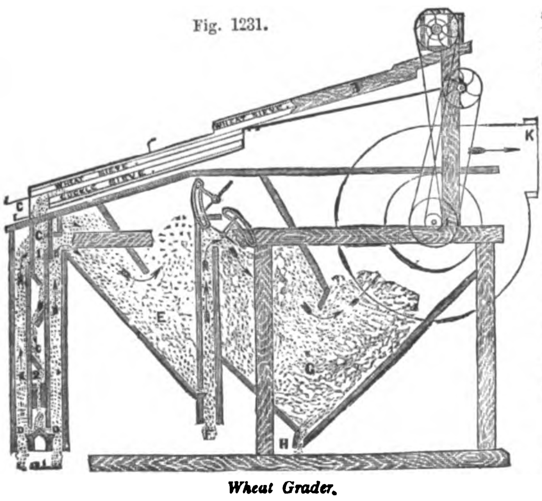
Gra'der. 1. (*Railway.*) A temporary track is laid, and from a platform and caboose car on this track a double plow is rigged out to throw up a track. — *Harden.*

2. An earth scraper.

3. (*Milling.*) A machine for separating grain into lots of varying qualities. Barnard & Lea's wheat grader acts by the combination of sieves and suction blast.

The wheat is received on a broad inclined sieve, *B*, and thence to a second or cockle sieve, and passes to the separating trunk *C*, where it meets the up-blast of air which enters at *D'*. The force of the blast is regulated to perform the separation required: the heavier grain falls at *D'*, second-grade grain is carried up and deposited in *E*, whence it reaches a second separating trunk *F* with up-blast of air, and parts with the screenings, which falls into *G* while the dust goes to the fan and is blown out. See also GRAIN SEPARATOR.

Fig. 1231.

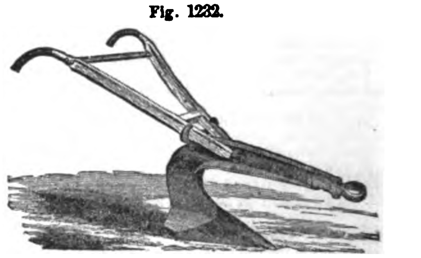


Wheat Grader.

Gra'di-ent'or. A form of surveyor's compass especially adapted for leveling and grading.

Gra'ding Plow. A heavy and strong plow used in road-making and road-working; plowing up the neighboring sod or soil to be removed by the scraper.

Fig. 1232.



Grading Plow.

Gra'ding Scra'per. An earth scraper. See SCRAPER.

Grad'u-a'ted Spring. (*Railway.*) A round-bar single-coil spiral-spring, with two conical india-rubber springs on the inside, one attached to the spring-seat and the other to the spring cap. When the spiral spring is extended, there is some space between the two rubber springs. The weight is first supported by the spiral spring until this is compressed far enough to bring the two rubber springs in contact, when they support part of the load. — *Forney.*

Grad'u-a'ting Sight. (*Fire-arms.*) One graduated for distance, wind, etc. See VERNIER SCALE SIGHT, for the former; WIND GAGE SIGHT, for the latter.

Graf'i-to. (*Fine Arts.*) Italian *Sgraffito*. A style of picture in which a thin light ground is cut, chipped, or scraped away to expose a dark under surface. See Fig. 1233.

It is principally used in artistic ceramics, *pateræ*, etc. See Prof. Blake's Report, " Paris Exposition Reports," 1878, vol. iii., for numerous examples, in which the designs are incised in a thin layer or covering of white slip over a dark red-colored coarse clay body.

In grafito, the figure is outlined by a sharp steel point, and then for the background and shadows the slip covering scraped away to give various depths of color. The design is thus left upon the surface in flat relief, being a mere film not much thicker than a card. The whole surface is then enameled with a fusible hard glaze which incorporates itself with the body and slip, and gives a mellow softness and finish to the work.

Graft'er. A fine-toothed, pointed, narrow-bladed hand saw, used in sawing off limbs and stocks for the insertion of grafts.

Grafting tool. . . * "*Scientific American*," xl. 212.

Graft'ing Scis'sors. (*Surgical.*) A skin grafting scissors, for cutting off and holding a piece of skin. Fig. 87, Part V., *Tiemann's " Armam. Chirurgicum."*

Grain Car. (*Railway.*) A box car, with light door, used for conveying grain in bulk.

Grain Clean'er. A device to remove imperfect or blasted berries, chaff, weed seeds, dirt, dust, or other trash from grain.

The grain separator does as much, but also sorts the grain into qualities. As the cleaning and sorting belong to the separator the subject is there considered. See GRAIN SEPARATOR; GRAIN SCOURER; SMUT MILL; BRUSHING MACHINE, etc.

Commercial wheat is rarely pure. Besides dust, sand, sticks, clods, chaff, and straw, there are numerous seeds, etc., which must be separated from the wheat before grinding. Such are several varieties of wild onions, vetches, peas, parsley, beans, radishes, mustard, chess, oats, grass-seed, cockle; besides blasted kernels of wheat, rust, ergot (smut).

Shriveled or blasted berries are in milling resolved into bran, and the flour discolored and rendered less nutritious. Some foreign seeds impart unpleasant taste, some are unwholesome, others discolor the flour.

Many mechanical devices are used to separate the offal from the pure grain; acting by gravity, meshes of varying size, rolling over a surface, exposed to a blast, a percussive impulse, pockets of varying size and shape, etc. See GRAIN SCREEN; GRAIN SEPARATOR; SMUT MILL. Also list under GRAIN, etc.

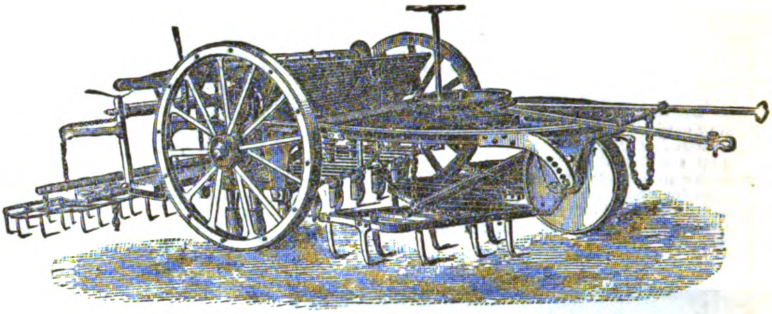
Bodin's Grain Crusher (French).

Fig. 1236.



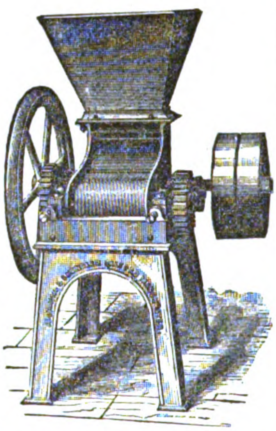
Fowler's Combined Drill and Harrow (Steam Culture.)

Grain Crush'-er. A machine for mashing grain for feed, in order to render it more easily digested. It is largely used in Britain and in France, especially with beans; oats are, however, roughly broken or ground in many cases.

The bean crusher is known as a *kibbler* in England; the grain crusher as a *concasseur* or an *aplatisseur* in France.

Fig. 1234 shows the *aplatisseur* of Bodin, of Rennes. The grain issues from the hopper in quantities regulated by the feed-wheel, and falls between the flat surfaces of the two large rollers (0.70 meter diameter), one of which is driven by hand or pulley, while the other is moved by contact. A set-screw regulates the distance between the two rollers, and a spring permits them to separate should a stone or foreign body intrude between them.

Fig. 1235.



Grain Crusher. (*British.*)

The work by hand is 22 gallons per hour.

The grain crusher of Richmond & Chandler, of Salford, England, is shown in Fig. 1235. The rollers are ridged so as to make it a rough grinding operation. It is used for beans, peas, oats, barley, maize, flax-seed, or malt.

The "set" of the rollers is regulated by means of two thumb-screws in front of the machine, so that the grain may be crushed to the required degree of fineness. The feed of the grain to the rollers, according to the force applied to the machine, is determined by a small regulating wheel.

Machines for crushing oil-cake for cattle and sheep feed are very commonly used in Europe. See Fig. 498, page 152, *supra.*

Grain Damp'-er. An apparatus or attachment to dampen grain before grinding. It is done by wetting or steaming. See Wheat Steamer.

Grain Door. (*Railway.*) A close-fitting inside half-door for the doorway of a grain car.

Grain Dress'er. A machine for cleaning and dressing grain before grinding.

See Grain Separator; Grain Scourer; Bushing Machine, etc. See list under Grain Cleaning and Grinding.

Vangelder . . . . * "*Scientific American Sup.*," 1620

Grain Drill. A machine for sowing grain in rows. See Wheat Drill, Figs. 7163–7168, pp. 2761–2763, "*Mech. Dict.*"

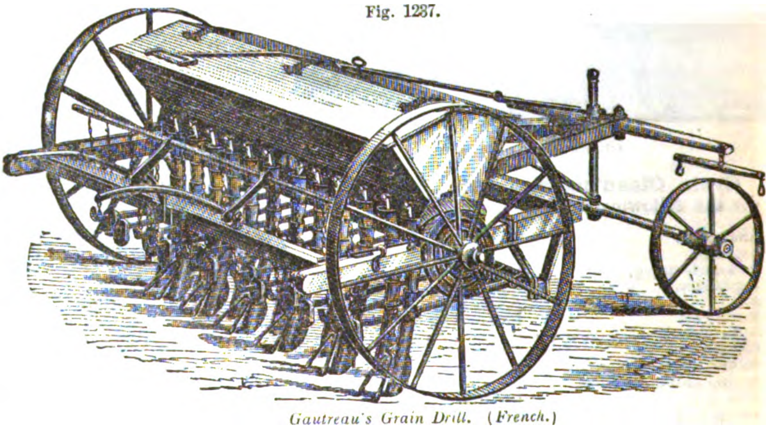
The combined drill and harrow, Fig. 1236, is one of the implements of the British steam culture.

It has a light cultivator or heavy harrow in front of the seeding colters, and a light covering-harrow following the same. The seed-drill itself, even of the largest width, requires but so small a fraction of the power of the engines, that it has been combined with the harrows. The drill has a width of 9'. In turning around, the heavy harrows are lifted by the power of the engine, and the whole implement moves at once on to new ground. The automatic lifting and turning action is described in connection with the turning cultivator, Fig. 739, p. 234, *supra.* See also "*Paris Exposition Reports*" (1878), v 87.

The Gautreau drill (Fr.), Fig. 1237, has a fore carriage (*avant-train*), which is controlled by the workmen at the rear of the machine, and serves to guide the drill. The steering-lever is seen trailing backward and resting on the top of the seed-box. In the English drills this duty is frequently allotted to a man in advance of the hopper-box, walking between it and the fore carriage.

The European shovels, for the English and French agree in this, are nearly vertical, trailing a little backward in fact, and are forced into the soil by means of a weighted lever of the second order attached to each. One or more cast-iron weights are placed on the end of the lever, according to the hardness of the ground, and the result is no small addition to the weight of the machine, and would be needless were the shovels made *hooking* so as to draw into the soil, the

Fig. 1237.



Gautreau's Grain Drill. (*French.*)

point ranging forward in the manner of the ordinary plow, which keeps itself in the ground by virtue of the mode of presentation of its point.

Smyth's telescopic drill-tube (Br.) shown in Fig. 1238, is a substitute for the caoutchouc tube, which is not so popular in Europe as it deserves to be.

Fig. 1238.

Telescopic Drill Tube.

It consists of three parts, slipping easily one within the other. The material is sheet-iron, and the conductor proper may be said to consist of two tubes, b^1 b^2, discharging into a spheroidal cup, *c*, which rests on the bar *d*, and discharges behind the share which opens the furrow. The tube b^3 suspended by chains *g g*, is merely an envelope to prevent the entry of rain, clods, or wind into the tube, to clog it or disturb the fall of the grain from the spout *a*.

See also CORN DRILL, Fig. 691, p. 222, *supra;* GRAIN DRILL, 5 figures, pp. 1002–1004, "*Mech. Dict.*," and WHEAT DRILL, pp. 2761, 2763, *Ibid.*

The English garden plow and drill, Fig. 1239, consists of one light steel shovel, for marking out rows to plant, or for loosening up the ground after the plants are up. Also a drilling attachment; a small steel plow for hilling up the rows; a cutter for exterminating weeds, and a rake for pulverizing the ground. The tools being optionally attached to the stock.

Dr. Knight's report on Class 76 at the Paris Exposition of 1878, contains notices and views of the following:

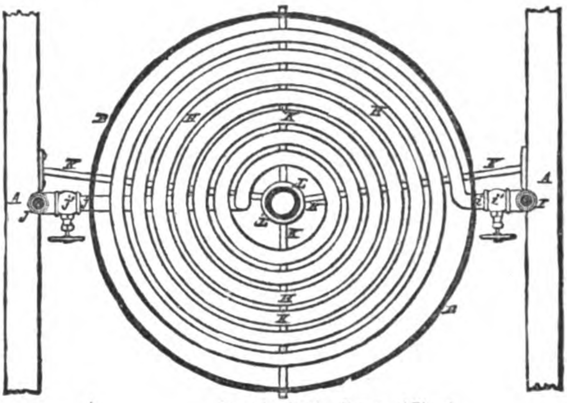
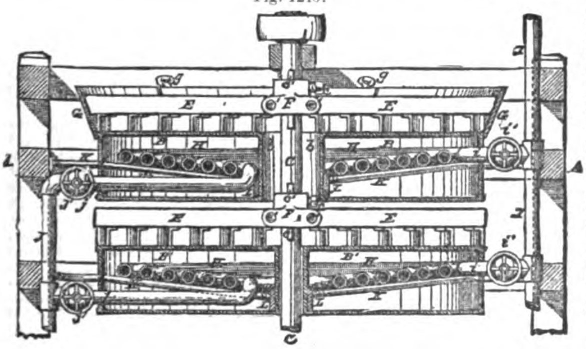
Fig. 1241.



Roper's Grain Dryer. (*Plan.*)

Fig. 1240.



Roper's Grain Dryer. (*Vertical Section.*)

Grain Dry'er. An apparatus or machine for artificially drying damp or heated grain.

Figs. 1240, 1241 show Roper's apparatus. *A* is the frame of the dryer, supporting the drying-pans *B B'*, through the center of which passes the driving-shaft *C*, carrying the rakes *E*, the teeth of which are so inclined as to carry the grain inward and outward on alternate pans. The grain is carried inward on one pan and discharged through a central opening, *b*, and is carried outward in the next pan of the series and discharged over the edge into the pan beneath.

H is a coil of steam-pipe, one of such coils being provided for each of the pans.

The grain or other material is supplied to the upper pan near its periphery, and carried inward to the central discharge, where it drops on to the pan *B'* beneath, on which it is carried outward and drops from the periphery of the pan on to the flaring edge *G*, and top of the pan beneath.

On the estate of Baron Horsky, in Bohemia, is a granary, provided with an elevator for the purpose of carrying the grain to the uppermost of a series of perforated floors or shelves, by means of which the grain can be made to fall in numerous slender streams through successive air spaces to the hopper at the bottom, from which the grain is again carried in the buckets of the elevator to be discharged on the upper shelf, and so made to go round and round until the desired dryness is attained.

Coignet's apparatus is designed to dry grain and seeds without destroying the life of the germ. For this purpose the articles to be dried are placed upon perforated stages and traversed by a current of air from above, downwards, heated to the proper temperature, from 104° to 122° Fah., which he finds best to answer his purposes. A still higher temperature (namely, from 300° to 310°), applied in the same apparatus, enables him to dry certain animal matters, intended as manures, without causing the loss of their nitrogenous material; but, as such a temperature of dry air would be apt to cause combustion, he replaces this by superheated steam.

There are many typical forms of grain dryers: fan, pans, screens, chutes, traveling aprons, etc. See several instances, pp. 1004, 1005, "*Mech. Dict.*"

Grain El'e-va'tor. An apparatus for lifting or transferring grain. See ELEVATOR.

"The pneumatic grain elevator of Renhaye consists of a centrifugal ventilator, the suction pipe of which is carried to a receiver placed upon the level to which the grain is to be carried. From the same receiver the supply pipe runs to the place from where the grain is to be lifted. Between the openings of the suction and the supply pipe of the receiver is an inclined plane, which throws the grain downward. A screen prevents the grain from entering the suction pipe, through which only the dust is carried off. A piston regulator at the lower end of the supply pipe acts in such a manner upon an adjustable nozzle that the proper proportion between the amounts of air and grain admitted is automatically maintained. The principle upon which this pneumatic elevator acts is that when solid particles in movement in a pipe are mixed with air, a semi-fluid is formed in which the pressures vary in accordance to the laws governing ordinary fluids." — "*Revue Industrielle.*"

Rennie, Br. . . . . * "*Engineer*," xlix. 28.

Grain Fan. See FANNING MILL; WINNOWING MACHINE.

Grain'ing. (*Leather.*) Giving to leather a granular appearance on the grain side by either the graining board or pebbling machine. The term originally meant raising the natural grain or marking of the leather on the hair side; but now is also applied to making artificial markings in imitation of morocco, hog-skin, etc.

Grain'ing Board. (*Leather.*) A rectangular piece of wood, the upper surface a plane; the lower one is convex, and fluted with parallel grooves, which run perpendicular to its length. The grooves are coarse or fine, as occasion requires.

Grain Meas'u-rer. See GRAIN REGISTER; GRAIN SCALE.

Grain Mill. See GRINDING MILL.

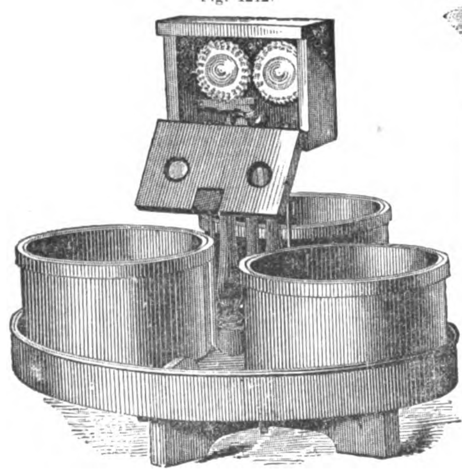
Grain Reg'is-ter. An apparatus to keep count of half-bushels moved away from the delivery spout of a threshing machine.

The half-bushels are moved consecutively under the spout, and as an empty one replaces the full one removed the register tallies one. The count is kept by the usual system of wheel, as in the gas meter. The shutter of the tally chamber is shown down, but the count may be observed through the windows of the closed shutter.

Fig. 1242.



Grain Register for Threshers.

Grains. An eel spear. One is shown with five prongs. Fig. 1243.

Grain Scale. A machine for weighing grain in commercial quantities and keeping tally of drafts.

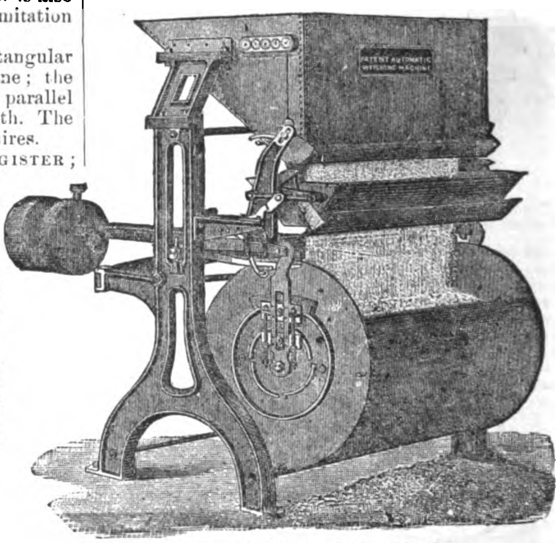
Fig. 1243.

Grains.

The machine shown in Fig. 1244 is by Baxter, of London. It is placed under a chute or spout, which delivers the grain with regularity.

Having determined the quantity that shall be registered at each tip of the cylinder, and adjusted the weight accordingly, the operation of weighing may commence. The grain being led into the hopper, descends into the compartment beneath, until the quantity nearly equivalent to the weight indicated on the steelyard has fallen; the diminishing valve then reduces the stream of falling material to such an extent that its momentum is not sufficient to influence the beam; the actual weighing here commences, and as soon as a correct balance is attained the cut-off instantly stops the supply to the cylinder; at the same moment the cylinder is released; it then turns and discharges its load. Being lightened, it rises, presenting the next compartment to be filled, opens the cut-off (letting out the grain collected therein), and the diminishing valve actuates the index, and the operation is repeated.

Fig. 1244.



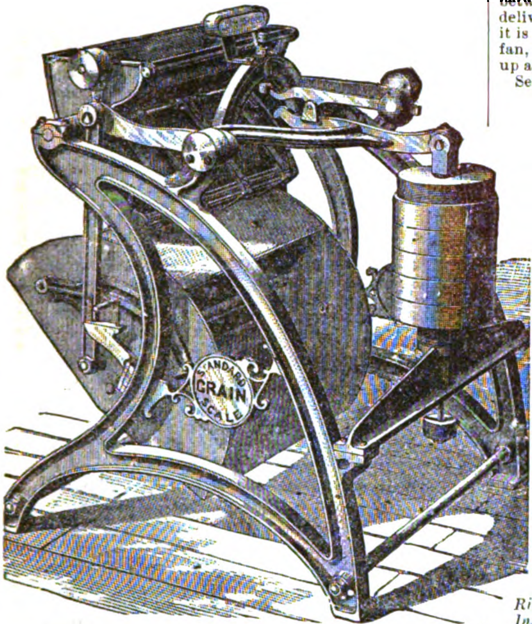
Baxter's Grain-weighing Machine.

The "Standard" grain-weighing machine is shown in Fig. 1245.

It consists of a balance beam, from one end of which, upon knife-edge pivots, is suspended a tilting grain-bucket. The bucket is divided into two equal compartments, and is held in position to receive grain by means of gravitating latches, pivoted to the suspenders which hang upon the knife-edge bearings and sustain the bucket. From the opposite end of the beam is suspended the balancing weight. The balancing weights are so arranged that the lower or main weight, in conjunction with the small weight on the supplemental beam, exactly balances the empty bucket, and the grain weight balances the weight of the grain to be taken in the bucket at each dump. Immediately above the grain bucket is placed the spout, which is gradually tapered to the mouth at the lower end, through which the grain is delivered into the bucket. Mounted upon the side of the spout are two long, narrow plates, the larger of which is known as the main, and the smaller as the supplemental cut-off, which are operated by means of fixed clutches upon the shaft.

When the grain-bucket is at the highest point of its travel, both the cut-off and the drip-plates are entirely withdrawn from under the mouth of the spout, and the grain flows freely into the bucket. When so much grain as is represented by the difference between the supplemental weight and the grain weight is taken into the bucket, the bucket and forward end of the beam descends a short distance, until the supplemental weight rests upon the beam, when the

Fig. 1245.



"Standard" Grain Scale.

bucket lacking grain to the extent of the supplemental weight is checked in its downward movement, and pauses until the requisite quantity to complete the load has been taken. The main cut-off plate is now closed, leaving open only a narrow slit, through which passes the final quantity of grain, necessary to complete the load. The bucket then descends until the latches holding it in position are released by check-pieces on the frame of the machine, when it turns on its shaft, discharges the weighed load of grain, and returns to repeat this operation as long as grain is supplied to the scale. The discharge of the grain from one compartment of the bucket presents the opposite compartment for the reception of grain as it rises under the spout.

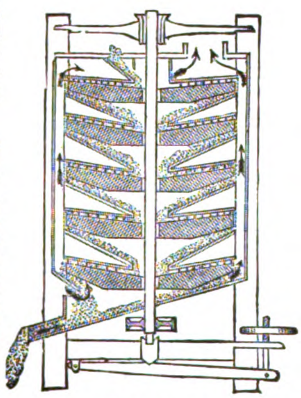
Grain Scour'-er. A machine for removing the fuzz from, and polishing the berry. Used for wheat, rye, and buckwheat.

The grain follows a circuitous passage; falling down a funnel to the center, it is caught upon the rough sandstone disk and thrown out centrifugally, to repeat the action again and again till it reaches the bottom and the discharge spout. The blast which carries off the fuzz ascends through the machine, passing in a contrary direction to the grain.

Fig. 1246.



M'Neil's Grain Scourer.

In Ingraham's machine, Fig. 1247, the wheat descends between the brush cylinder and the rough concave, and is delivered with all the fuzz and offal into the chamber, where it is exposed to the current of air passing to the aspiration fan, and is sorted into two grades while the dust is carried up and blown out.

Grain Sep'a-ra'tor. 1. The more common form of machine for ridding grain of chaff, husks, dirt, and dust is still the fanning-mill or winnowing machine, but late years have introduced a number of more speedy and excellent methods. The French especially have attained a degree of accuracy in sorting grades of grain, different grains, and grain from offal and dirt. Both in Britain and in France the farmer's implements for cleaning grain are in great variety. In milling implements our variety is the greater.

These machines may be summarized as acting by

a. *Blast.*	*d.* *Adjustable cylindrical sieve.*
b. *Aspiration.*	*e.* *Perforated and dented plates.*
c. *Graduated sieve.*	*f.* *Percussion.*
	g. *Projection.*

a. (*Blast.*) See FANNING MILL, p. 825, "*Mech. Dict.*" WINNOWING MACHINE, p. 2787. *Ibid.*

b. (*Aspiration.*) See ASPIRATING WINNOWING MACHINE, Fig. 119, p. 51, *supra*. Also, GRADER, Fig 1231, p. 410, *Ibid.*

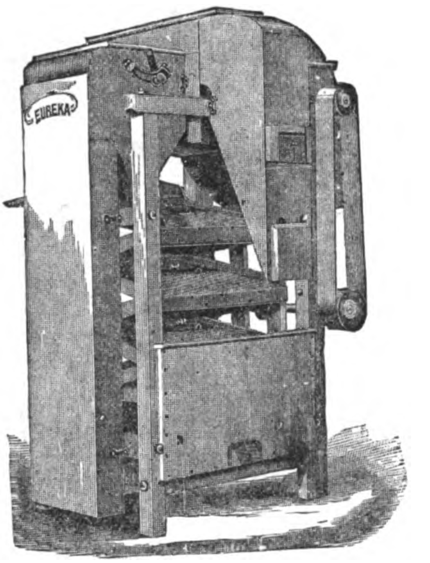
The "Eureka" separator, Fig. 1248, acts in large degree upon the aspirator principle, although it embraces many other features, shaking screens, etc. It has zig-zag arrangement of screens, combined with a lateral shake movement, and is intended to rid wheat of oats and other impurities.

The wheat is first fed into a suction separator, which removes the dust and light impurities, the dust passing to the fan, while the chess (cheat) and such other seeds as are of some value for food are discharged separately. The wheat then falls on to a shaking screen and distributor, which throws off straws, heads, sticks, etc., and distributes the grain evenly the entire length of the upper screen. It then passes over a series of screens which rid it of oats. It then passes to a cockle-screen which also rids it of sand and small seeds, and thence passes to a separating leg, where the operation is completed.

c. (*Graduated Sieve.*) An instance of this is afforded in Fig. 1249 of Plate XX., which represents the grain cleaner and separator of Boby, Bury St. Edmund's, England.

The machine has a wooden frame and a long inclined

Fig. 1248.



"Eureka" Separator.

sieve, which receives at its upper end the grain from a hopper. The grain issues in a thin sheet from the hopper, and first falls upon a separator, which arrests stones and large trash, allowing the grain to pass down and be discharged in a sheet as wide as the inclined sieve beneath. This sieve receives a longitudinal agitation by means of a pitman from a crank on the horizontal axis, which is revolved by hand-crank or belt, as the case may be.

The longitudinal wires of the shaking sieve are carefully stretched, and are spaced so as to retain plump grains and allow broken or thin grains to pass, and the meshes are kept open by thin blades, which also rectify the positions of the passing grains and bring them into parallelism with the wires along which they pass in their descent from the stone-separator to their point of ultimate discharge.

The machine is particularly intended for the cleaning and sorting of barley for malting, and the necessity of a perfect action in this respect is set forth in the statement following:

1. It is essential that, in advance of the payment of the impost duty (internal revenue or excise tax) on the steeped malt, the entire mass must be rid of matters which produce deficient quantities of saccharine extract.

2. It is necessary to separate all light grains before making the malt, for otherwise they will become too damp or saturated in the time necessary for the sufficient steeping of the good grain.

3. The thin or light grains must be absolutely separated from the full-sized grains before making the malt, for otherwise the thin grains pass unbroken between the rollers in the process of crushing the plump grains.

The operating surface of the Boby sieve is stated to have six times the area of the usual rotary sieve, and, the grain being spread over so great a surface, each light grain is sifted out in passing from the hopper to the discharge; in the rotary sieve the acting surface is only at the lower side, estimated as only embracing, at any one time, one-ninth of the peripheral.

d. (*Adjustable Cylindrical Sieve.*) A peculiar character of sieve, of cylindrical form, and capable of having the meshes made of any desired interval, within certain limits. The machine of Penney & Co., of Lincoln, England, is shown in three Figs., 1250, 1251, 1252, of Plate XX.

It is made of various sizes and prices, and there are also special constructions for certain purposes, such as the cleaning and grading of malt, the cleaning of peas and beans, etc. The latter-mentioned articles require such a very different range of adjustability that the machines cannot be economically made to suit the wide ranges of work.

The machine can be adapted for all species and qualities of grains (within profitable limits, as stated) by means of varying the distance between the wires.

The cylindrical screen may be said to consist of one continuous wire laid spirally around the longitudinal bars which form the skeleton of the screen. One of the heads is adjustable longitudinally of the axis of rotation, slipping thereon, and as it is drawn toward the extremity, the spaces between the laps of wire become larger, and, conversely, the intervals are diminished as the heads are approached by the reverse adjustment. Spiral springs mounted upon the exterior rods, as in Fig. 1251 (*ressorts extérieurs*), or within the cylindrical screen, as in Fig. 1252 (*ressorts intérieurs*), keep the screen extended longitudinally.

The different kinds of brushes used for cleaning the meshes of the screen are shown in Figs. 1251, 1252.

Regularity of passage through the length of the screen is secured by a spiral flange or rib projecting inward from the cylindrical surface, which tumbles the grain along until it pushes it out at the end. Dry and broken grain is retarded, while damp grain is expedited in its passage, the rate being thus made uniform, though the condition of the grain may vary.

The machine shown in Fig. 1250 is composed of two parts, of which the second and lower has screen openings of greater interval than the first part. It is intended for grain which contains stones, ordure of vermin, or other matters larger than the wheat or the grain to which the machine is for the time adjusted. The stones and other large matters pass clear through the screen and into a spout, which ejects them at the side; the good grain passes over the meshes of the first part of the cylinder and is divested of the small and broken grains which pass the meshes; it then itself falls between the meshes of the second portion of the cylinder, and is discharged by a spout at the end, while the stones pass on, and so to the side spout as stated.

e. (*Perforated and Dented Plates.*) The riddle-sorter of Pernollet, Paris, shown in Fig. 1253, Plate XX., is made in several forms, some adapted for the ordinary uses of the farm in cleaning grain, and others for special service, such as cleaning green peas, beans, lentils, coffee, cacao; for sorting different kinds of barley for brewers, etc.

The machines, in some cases, are specially constructed for a given purpose, but in others the change of the perforated iron plates for others of larger or smaller apertures is sufficient to adapt the machine to the required purpose.

The grain is placed in the hopper, its rate of feed depending upon the slide in the bottom. An oblique spout conducts the grain fairly within the rotating cylinder, whose four compartments, being clothed with punched iron screens of different apertures, sort the different kinds and drop them into boxes beneath. The respective screens have round holes of different sizes, or long holes, to detain or to allow to pass, as the case may be, seeds of varying sizes and shapes

Marot's grain cleaner, shown in section in Fig. 1254, Plate XX., shows a new feature in grain-cleaners, namely, *indented plates*, which form pockets to carry up seeds on the inside of the cylinder and drop them into a tray, which carries away the seed thus segregated from the other contents of the rolling cylinder.

The *indented plates*, of which detached portions are shown in Fig. 1255, Plate XX., are sectional cylindrical jackets, like the perforated covering of the Pernollet machine just described, but instead of holes they have pockets or cups, made by punching or drilling, and form cylinders around the axis of rotation.

As in the case of the Pernollet machine, and others of its class, the enveloping cylinder has perforations in its four sections, of varying sized apertures, according to the special work to which it has to be applied; so in the case of the Marot machine, the indented jacket, with its recesses facing inward, has pockets of such size and shape as to catch and hold special kinds of grain or of seeds which it may be required to abstract from the mixed or foul material fed into the machine.

The new mode of screening compels the long grains to pass through round holes equal in size to their diameter, a result vainly sought until now, and which can be readily understood in looking at the perforated cell, the entrance to which is three times as large as the perforation, being in fact funnel shaped.

It will be well to enter into a detailed statement of the functions of the different parts for the better understanding of the process and operation, and the perfection attained.

The grain-sorter is composed of a dented cylinder inclosed in a wooden frame, which is surmounted by a hopper, *T*, and in prolongation thereof is a double inclined riddle, agitated by connection with a wheel.

The upper riddle, *g*, retains all the impurities and large round grains; the lower riddle, *g'*, allows passage to the rye-

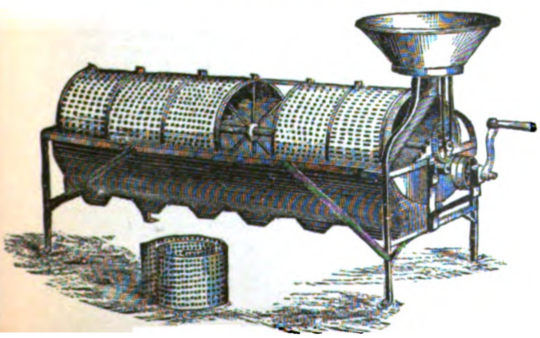

FIG. 1253. ***Riddle Sorter.***

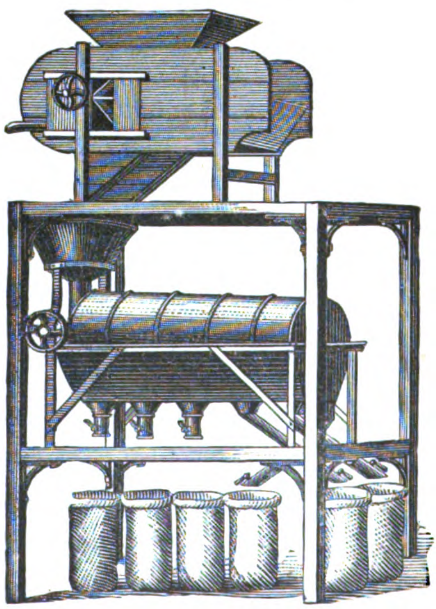

FIG. 1258. ***Cleaning and Separating Machine.***

grass seed, small seeds, and refuse, which fall into a tray, *h*, placed athwart the frame.

The wheat falls off the end of the riddle into a hopper, *E*, and thence into a spout, which conducts it into the interior of the cylinder *C*. In a central position in the cylinder beneath the axis *j* is a trough, *R*, in which is a conveyor, *r*, rotated by a pinion, *i*, from a wheel, *i'*, on the axis *j*.

The first part of the cylinder *C* is studded with indentations (concave interiorly, but not perforated), as shown in the left portion of Fig. 1255, Plate XX., which is a portion of one of the plates.

These depressions are of such diameter that the wheat and round grains may lodge in them, and in the movement of the cylinder their contents are lifted and dropped into the trough *R*, while the barley and oats are prevented, by their length, from lodging in the cups, and, following the slope of the cylinder, are discharged at the opening *o*, at its midlength.

The wheat and round grains, carried up the cups and caught in the trough *R*, are carried along by the conveyor *r*, and fall into the cylinder through an opening, *s*, at a point beyond the discharge, *o*, of the oats and barley. Here they come under the action of the second part of the cylinder, the inner surface of which has depressions of smaller diameter, suitable for carrying up the round grains, such as tares, but rejecting the wheat. The tares, etc., are dropped into the trough *R'*, which is a continuation of *R*, and, being pushed by the conveyor, are forced out at the end and led by a spout (not shown) into the box 1.

The wheat, deprived of oats, barley, and round grains (tares, mustard, rape, etc.), follows the slope of the cylinder to the point *t*, where it falls into the cylinder *C'*. It passes backward along the whole length of the cylinder, pushed by the helicoidal wings which form a conveyor on the periphery of cylinder *C*.

At the point *w*, beneath the place of first entry into the cylinder, the wheat, with some other grains not yet eliminated, falls into cylinder *C''*, which consists of plates both dented and perforated, concavity inward. The grain is caught in the cups and carried up, and, while the diameter of the holes is not sufficient to allow good wheat to pass, the shrunken grains, cheat, rye, rye-grass seed, etc., pass through the openings indicated by the lower row of vertical arrows, and fall upon the floor, while the clean wheat is discharged at the end into box 2.

Another machine is especially constructed for the separation of *crescute* from clover or lucern seed.

Marot's machine for the special use of maltsters and brewers, and shown in Fig. 1256, Plate XX., has substantially the same features in the main, but, in addition, it has three circular riddles at the delivery end of the machine, to separate the barley into three grades according to the diameter of the grains.

The object of the separation is to secure an even germination, as it is found that the different development or condition of the grain causes the sprouting to be more or less rapid; and, consequently, to mix different grades of barley is to obtain an uneven quality of malt, as the plumules and radicles are unevenly developed, indicative of different stages in the resolution of the components of the grain.

The sifting-sorting separator (*cribleur-trieur-diviseur*) of Caramija-Maugé, of Paris, is shown in Fig. 1257, Plate XX. It acts in the same general way as that of Marot, Fig. 1254, previously described, but carries the principle of separation to a fuller extent. It is intended to separate mixed wheat, barley, rye, oats, peas, vetches, cockle, cheat, etc.

The grain in the hopper on the left passes through a gate and by a tube to the interior of the rolling-screen. The first section removes small seeds and waste (*déchets*), and then the dents in the first portion of the cylinder raise the wheat and round grains and drop them into the interior tray, where the spiral blade drives them toward the second section of the cylinder. The long grains, oats and barley, are pushed along in the first section of the cylinder until they reach the exterior holes, at which they issue.

The wheat and round grains being conducted into the second section of the cylinder, as stated above, the round grains are picked up by the dented surface and raised so as to drop into the second interior trough, wherein a spiral works to thrust them out at the end, where they fall into the box shown at the right.

The second section of the cylinder has portions of differing fineness of mesh, sorting the wheat into qualities for seed and for market.

The result of the operation is five grades; reading from the left to the right, they are as follows: Waste, oats and barley, seed wheat, merchantable wheat, round grains.

Fig. 1258, Plate XX., is the separator of Pernollet, of Paris. It consists of a winnowing machine above and a cylindrical screen below, discharging the grades of grain and offal into separate bags.

The cleaning is done above and the separating below, the latter differing in no essential respect from some of those previously described. The machine is also by special adjustment adapted for sorting coffee, the product of the ground cacao, etc.

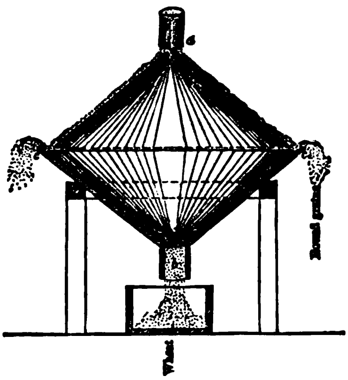
f. (*Percussion.*) This machine seems to be used but little out of France. Several ingenious forms of it are made by Hignette, Paris. It is especially intended to remove clods, and is shown under CLOD CLEARER, Fig. 637, p. 201, *supra*.

The tray has a rocking motion on pivoted legs, at the rate of 115 double strokes per minute. Grain falls from a hopper into the tray, and is bounced from side to side, angular blocks directing it to different discharge apertures.

g. (*Projection.*) A machine used in Austria, for the separation of round seeds from grain, is shown at Fig. 1257, in which advantage has been taken of the spherical form of certain of the foreign seeds to effect their removal.

The wheat, with its mingled mustard-seed, wild pease, and other round grains, is discharged through a tube upon the

Fig. 1259.



Conical Grain Separator.

apex of a varnished wooden cone, the slopes of which are inclined to the perpendicular at an angle of about 55°. The elongated wheat-grains slide to the bottom within a certain time, being retarded by friction. The round grains, however, rolling down the side of the cone, acquire very much greater velocity, and leap across a narrow opening at the base of the cone; while the wheat-grains, moving much more slowly, fall into the opening, and are received into a separate receptacle.

The spout *a* is adjustable. The round grains, striking the slender ledge at the base of the cone, bound or leap across the openings *c c*, while the long grains of wheat, moving at a slower rate, fall through and descend the incline to *b*.

The Vienna steam-mills have an endless apron stretched upon two equally inclined cylinders. The apron has a transverse inclination, and receives the grain at one end in a thin stream. The round grains roll off while the wheat grains travel to the end and are discharged into a box.

The principle of projection is also used in grading products of milling. See MILLING, *infra*.

2. A threshing machine, which see.

* "*Scientific American Sup.*," 2404.

Grand Feu. (*Ceramics.*) A French term, but frequently used in English treatises, signifying that the articles are baked in very highly heated kilns or muffles.

Gran'ite Ware. 1. (*Ceramics.*) A trade name (*w. g.*, white granite) of a kind of stoneware.

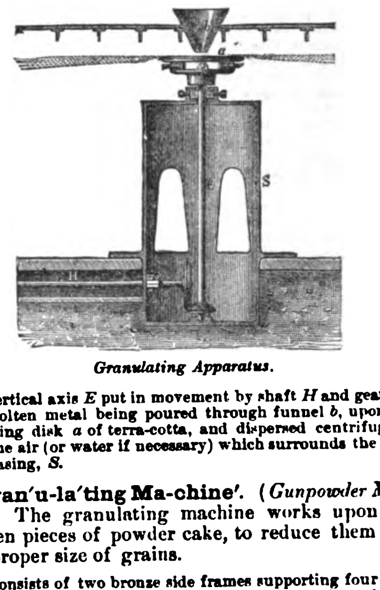
2. An enameled iron ware made by the St. Louis Stamping Company. It has a stone-like enamel of a gray color and remarkably adherent to iron, free from poisonous qualities and very durable.

Gran'u-la'ted Steel. (*Metallurgy.*) Melted pig-iron is run into a cistern of water; the grains put in a crucible with sparry iron ore, which yields oxygen to remove the carbon. The fragments are melted, and cast in ingots. *Uchatius steel.*

Gran'u-la'ting Ap'pa-ra'tus. An apparatus for the granulation of metals is shown in Fig. 1261. The object is to reduce the metal to fine powder or small particles so as to multiply the surfaces and facilitate oxidation, in their attack by acids.

The apparatus shown in Fig. 1261 is used for iron, copper and its alloys with zinc, lead, and tin. It consists essentially

Fig. 1261.



Granulating Apparatus.

of a vertical axis *E* put in movement by shaft *H* and gearing, the molten metal being poured through funnel *b*, upon the revolving disk *a* of terra-cotta, and dispersed centrifugally into the air (or water if necessary) which surrounds the cast-iron casing, *S*.

Gran'u-la'ting Ma-chine'. (*Gunpowder Making.*) The granulating machine works upon the broken pieces of powder cake, to reduce them into the proper size of grains.

It consists of two bronze side frames supporting four pairs of bronze toothed rollers placed on different levels and having their axes parallel and horizontal.

The first set is at the top of the machine, about 20′ from the floor, and the press cake, broken up between them, falls on to an inclined screen which conducts the fragments to a second pair of rollers. A succession of vibratory screens sorts the powder into grades and dust.

In the Petersburg arsenal the powder cake is broken into grains by placing it in sieves which contain a certain number of bronze balls. These sieves are attached to a vibratory frame, crushing the cake, the pieces falling through the bottom of the sieve into drawers beneath. The grains are subsequently dusted, glazed, and assorted. See Fig. 19 accompanying Appendix L, "*Ordnance Report*," 1877.

Fig. 1262.

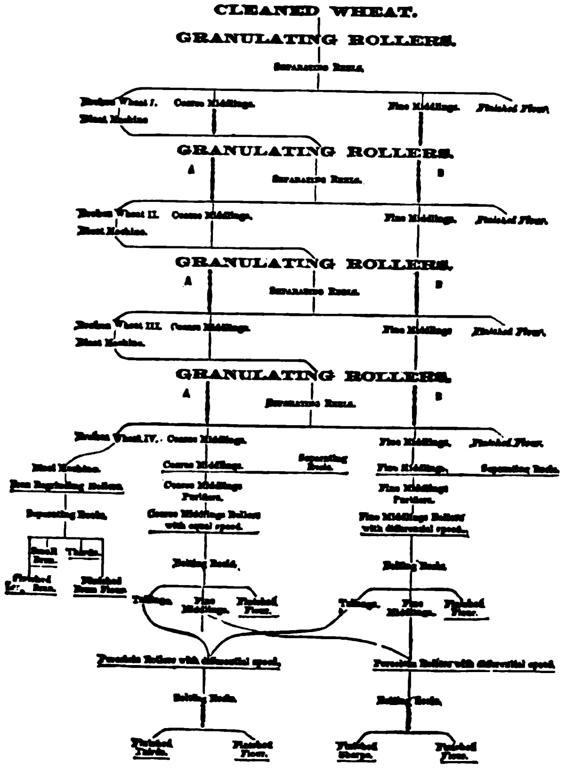

Diagram of Wegmann's Granulating Process.

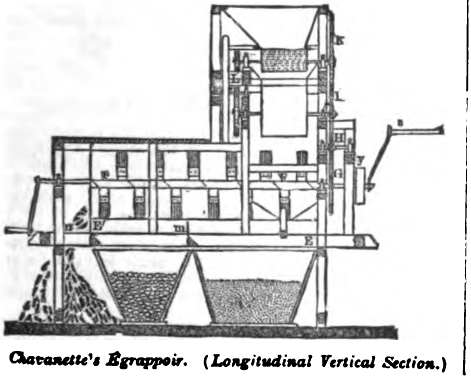
Gran'u-la'ted Wood Pow'der. The invention of Captain Schultze, of the Prussian army.

Wood is sawed into fine veneers across the grain. These veneers are chipped into small cubes. The acids and soluble substances are removed, and the little cubes are treated with a mixture of 40 parts by weight of nitric acid (of 1.48 to 1.50) and 100 parts sulphuric acid (of 1.85), and set aside to cool. Six parts of wood is added to 100 parts of the acid, stirring constantly for 3 hours. The grains are dried in a centrifugal machine, washed in running water, boiled in a weak solution of carbonate of soda; again washed and dried. The grains are then heated with potash or baryta nitrate, dried at a temperature of 90° to 112° Fah. for 12 hours.

Grape Mill. Figs. 1263, 1264 show Chavanette's (Paris) machine, for crushing, pressing, and de-stalking grapes.

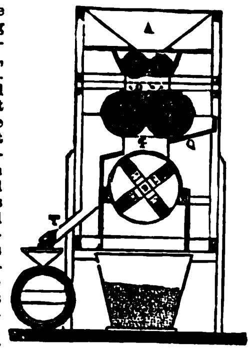
Fig. 1263.



Chavanette's Égrappoir. (*Longitudinal Vertical Section.*)

It is intended to do the whole duty of crushing the grape, expressing the juice, and removing the stalks, skins, and pips. Great stress is laid upon the perfect separation, on the supposition that the effect of fermentation upon the seeds and stalks is injurious to the wine, and the relative quantity of the skins in the fermentation-vat should be under control, as it is the fermenting skin which confers the color upon the wine. The value of the *dégrappage*, however, is disputed. In the *Côte d'Or*, for instance, it is claimed that the *rafle* (stalk of the bunch) contains the ferment, bitartrate of potassa, and tannin in notable quantities, and its presence in the fermenting vat adds quality to the wine and assists in its conservation.

Fig. 1264.

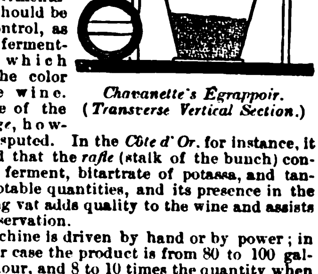


Chavanette's Égrappoir. (*Transverse Vertical Section.*)

The machine is driven by hand or by power; in the former case the product is from 80 to 100 gallons per hour, and 8 to 10 times the quantity when driven by an engine of 1-horse-power.

A is the hopper into which the grapes are thrown. From this they fall between two cylinders, *B B'*, the outer surfaces of which have conical-headed nails, which move in close proximity, but without contact. The cylinders are separated by a distance of 5 to 6 millimeters. The crushed mass falls upon a pair of cylinders covered with sheet caoutchouc, which has a uniform thickness of 7 millimeters. The pips, stalks, and skins are drawn through, but deprived of juice, which passes out through perforated plates, *O*, at the ends of the cylinder-box, and then, by the inclined plate *Q* and spout *T*, is discharged into a funnel and barrel. The pips, skins, and stalks drop into a chute, *P*, and then into a long cylindrical horizontal chamber, in which is a revolving helical brush, *F F'*, which drives the contents against the exterior, the lower part of which is covered with wire cloth, while the upper is of wood or sheet metal. The meshes of the portion from *E* to *m* are of such a size as to let the grape seeds fall through: from *m* to *E'* the skins pass out and the stalks are ejected at the end, *n*, of the cylinder. *G*, *H*, *I*, *K*, *L* are gear-wheels for transmitting motion derived from the crank *Z* or pulley *y*. *V* is the fly-wheel.

Fig 1265.



Grape Crusher.

The crushing of the grape is still performed by the feet in many parts of France. Earnest efforts are making to induce the small proprietors to adopt the *écrase-raisin* or *fouloir*.

The grape-crusher, Fig. 1265, of Meixmoron de Dombasle, of Nancy, is a light machine, driven by hand, and placed above the vat. It has two wooden rollers, and rods upon them which act as teeth to draw in and crush the grapes which are thrown into the hopper. The keys allow the juxtaposition of the rollers to be regulated. The work performed is 2,000 kilos of grapes per hour.

The American grape-mill is upon the same principle as that shown in Fig. 1265, a pair of rollers; toothed or spiked, to tear and crush.

The grape mill of Mabille Frères, of Amboise, is shown in Fig. 1266. The teeth on the rollers are spiral, and the action is one of tearing as well as cutting. It is the "*usage du Midi*," a great and important grape region.

See Wine Press.

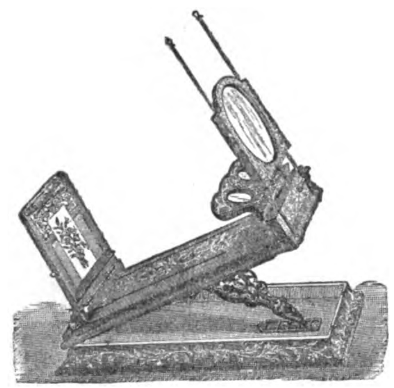
Grape Mill.

Graph'ite Bat'te-ry. (*Electricity.*) 1. A term used in England in reference to a battery, having platinized carbon plates and amalgamated zinc plates in dilute sulphuric acid.

2. A battery in which mineral graphite is used as the negative element. See instance in list under GALVANIC BATTERY.

Graph'o-scope. (*Optics.*) A mounted glass for viewing pictures or photographs. The lens mounting is usually hinged to a frame which forms the picture holder.

Fig. 1267.



Graphoscope.

Graph'o-ste're-o-scope. (*Optics.*) A frame with mounted lens, for viewing stereoscopic pictures.

Grap'nel. 1. A boat's anchor with four claws.

2. A grappling hook, for recovering submerged property.

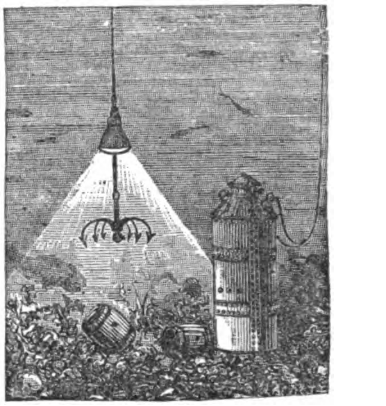
Fig. 1268 shows Toselli's (taupe marine) for directing the search for objects of value at the bottom of the sea. Suspended in the vicinity of the diving-bell is a spring grapple and an electric light with reflector, directing a bright light over a circular area of the bottom. Also used in coral, pearl-oyster, and sponge fishing.

3. A grapple for submarine cables.

The kind of grapnel ordinarily employed in picking up submarine cables for repairs is that known as the *centipede* grapnel. It resembles a compound fish-hook in shape, the stem or shank being set round with several prongs or flukes which catch the cable as the grapnel is dragged across it over the sea bottom. The flukes are rigidly welded to the stem, and one disadvantage in this form of grapnel is its liability to have its flukes broken off if it catches in submarine rocks or other obstructions on the bottom. To prevent the escape of the cable from the claw a fluke has been designed to close upon the cable and prevent its jumping out again.

Jamieson's cable grapnel, shown in Fig. 1269, is self-relieving when it comes in contact with rock or other obstruc-

Fig. 1268.

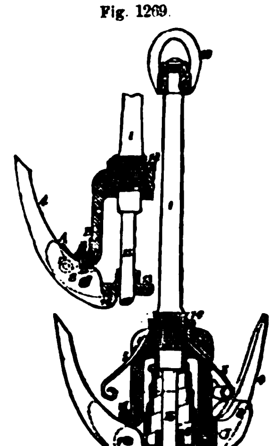


Toselli's (Taupe Marine).

tions on the bottom, and closes on the cable when once encountered.

At the lower end of the grapnel shank, 1, there is fixed a boss, 2, for containing a spring, 6, which exercises a pressure upon the inner ends of the grapnel toes, 4, as the outer portions of the flukes, 8, are called. The toe portion of each fluke is free to move round a center or fulcrum carried by the joint of the fluke, which is rigidly fixed to the boss, so that when the toe encounters a rock or other obstacle of the kind it yields to it, turning round on its fulcrum, 7, and thereby exercising a compression upon the spring until the obstruction is cleared, when the recoil of the spring restores the toe to its former position. When, however, the grapnel meets the cable, the latter, 18, lies in the joint of the fluke, where it is attached to the boss, and it is retained there by a spring, 5, which juts out from the boss and arches over it so as to hold it in.

Fig. 1269.



Submarine Cable Grapnel.

The grapnel operates in the following manner: The toes when engaged by rocks or other obstructions are pressed outward and rotate round their respective fulcra, their inner ends bearing against the movable piston 13 on the reduced portion 15, of the shank, which compresses the spring up the boss; a movement which may continue until the toes move round to the angle shown by dotted lines on the left hand, an angle amply sufficient to relieve the toes from the obstruction. As soon as the toes are released, the piston is forced down again by the reaction of the spring, and, bearing against the toes, restores them to their initial working angle. This angle is fixed for each grapnel by the shoulders 17 on the boss 2 which act as stops between the boss and toes, preventing the latter from bending in toward the shank.

The fragmentary view shows a grapnel with an arrangement of cutting shears for severing a cable or torpedo line. In this figure *A* and *B* are two steel knives or shears mounted on respective fulcra, *C* and *D*, and capable of rotating round them. These knives are ground sharp in their upper edges, on which the cable 18 rests. When a strain is produced on the cable by hauling in the grapnel, these knives shut on each other and shear the cable in two.

The upper shackle 10 is the means of attachment for the grapnel line, and 11 is for the length of chain which is always trailed after a grapnel to keep it from skidding and jumping.

2. A pair of claws grasping a beam or rafter as a means of suspension of a tackle for hoisting hay in a barn, or merchandise in a warehouse. See Grapple, p. 1011, "*Mech. Dict.*"

Grap'ple Dredg'ing Ma-chine'. A dredge with hinged jaws or claws which inclose or clasp the object.

Grap'ple Hay Fork. That form of fork with hinged jaws which mutually approach to clasp the hay; a form of horse hay-fork. Figs. 2027, 2080, p. 907, "*Mech. Dict.*"

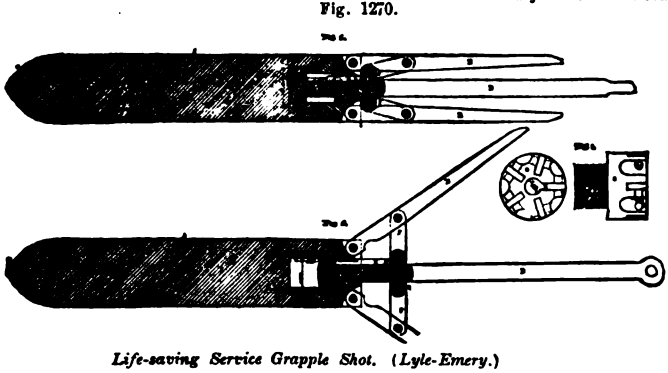
Grap'ple Hook. 1. (*Fishing.*) One with guard to prevent fish from getting loose from the barb. See Fig. 2000, p. 872, "*Mech. Dict.*" Also list of U. S. Patents, 1846–1872; Report of U. S. Fish Commissioners, Part I., 1873.

2. (*Hoisting.*) A pair of hooks to clasp the object to be hoisted. See Bale Hook, Fig. 181, p. 68; and Barrel Hook, Fig. 221, p. 78, *supra;* and *c* Fig. 2302, p. 1011, "*Mech. Dict.*"

3. A grapple attached to a beam as a means of suspension of hoisting tackle, etc. See *a, b, d, e,* Fig. 2302, p. 1011, "*Mech. Dict.*"

Grap'ple Shot. A shot used in the life-saving service on the sea-coast. Being fired across a ship, it catches in the rigging and serves as a means of establishing communication with shore. The flukes lie parallel in the barrel, but spring out when the cable is hauled in.

Fig. 1270.



Life-saving Service Grapple Shot. (*Lyle-Emery.*)

Grap'pling Gear. (*Fishing.*) Used to recover lost trawls. See Grapnel; Grapple.

Grap'pling Hook. (*Surgical.*) An instrument with a pair of claws at each end, used in post-mortems and dissecting to retain an opened flap in position.

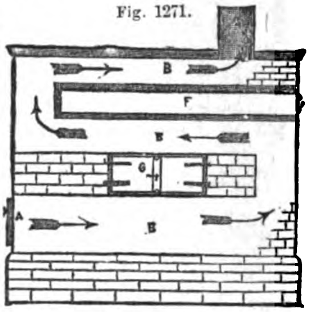
Grap'pling For'ceps. (*Surgical.*) A tweezers with double claws on the end of the prongs. Used in skin-grafting. — *Piffard.*

Grap'pling Tongs. (*Fishing.*) Broad-mouthed tongs for gathering oysters. Oyster tongs.

Grass-burn'ing Stove. A stove for burning prairie grass where coal and wood are scarce.

It is built of brick, stone, or concrete.

Fig. 1271.



Mennonite Stove.

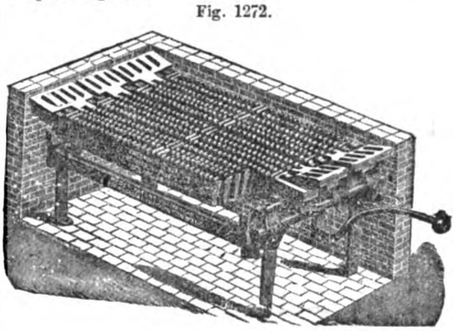
A. Furnace door to fire-box.
B. Draft.
C. Pipe.
F. Chamber with iron shutter (hinged) to let out heat. This chamber has doors on both sides of furnace.
G. Oven or cooking place on kitchen side of furnace.

Grate. 1. An open fire as in the open stove, Fig. 5009, p. 2410, "*Mech. Dict.*"

2. The iron bars containing the fuel in a furnace or fire-box. A collection of grate bars. A grid.

Fig. 1272 shows the Ryder reciprocal grate.

Fig. 1272.



Ryder Reciprocal Grate.

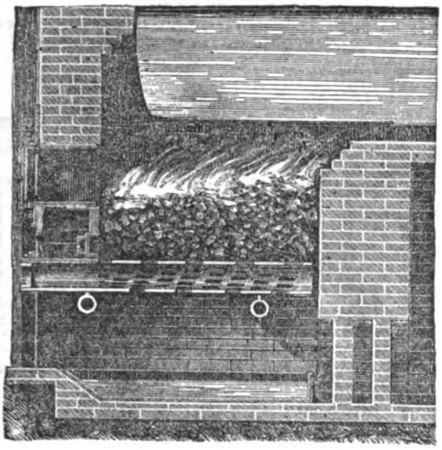
The grate consists of a series of alternate movable and stationary bars. The movable bars are moved backward and forward several inches by a lever in front of the boiler, through the ash-pit door. The movable bars, resting on friction rolls, are raised above the stationary bars a little, and have a corrugated surface for friction, which disturbs the coal, destroys the clinkers, and removes the ashes, thus opening up a uniform draft over the fire surface.

Fig. 1273 shows Schmitz's French furnace, having grate-bars which are hollow to allow passage of air, and turn on their axes to prevent burning out or having clinkers attached to them.

Fig. 1274 shows the Tupper sectional grate for steamboats, locomotives, and furnaces. The sections are laid on truss bars, but not fastened, so that they can expand and contract without strain. The openings in the bars are V-shaped.

Fig. 1275 shows the Hawley-Adams grate. The shaking grate-bars are rocked back and forth by a lever, so as to break up the slag or clinkers which would block them.

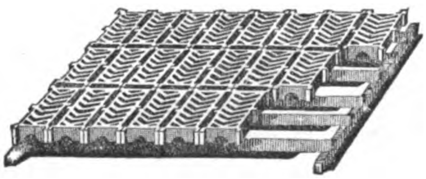
Fig. 1273.



Furnace, with Turning Grate-bars.

Fig. 1276 shows the grate of the "Calorific" cooking-stove. It has a sliding grate which is

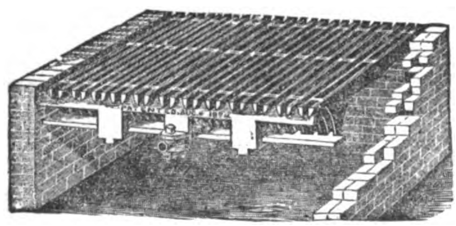
Fig. 1274.



Tupper Grate.

pulled forward to allow the clinkers at the back of the fire to drop out, and the clinkers in front are then picked out.

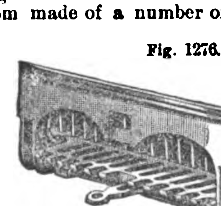
Fig. 1275.



Rocking Grate-bars.

Fig. 1277 is Bissell's radiator shaking grate, the bottom made of a number of parallel bars, which

Fig. 1276.



Anti-clinker Stove Grate.

are shaken in concert by means of the handle on the side. Numerous examples are shown under GRATE, GRATE BAR, on pages 1012, 1013, "*Mech. Dict.*"

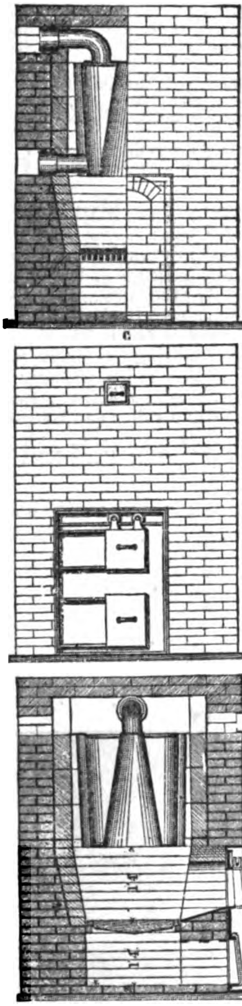
Fig. 1278.



Greenhouse Furnace and Boiler.

Green'house Furnace. The boiler for hot water heating apparatus for conservatories is usually a ribbed or corrugated iron, or sectional ring boiler, set in brick-work, and having departure and return pipes in which the water circulates through the greenhouse.

Burbidge & Healy's greenhouse heater is shown in Fig. 1278; three views, a combined half-vertical section, and half-front view; a front view and a transverse vertical section. The bells for the attachment of the pipes are shown on the left in the upper of the three views.

"*Scientific American Sup.*," 2250, 2394.

Green'house Syr'inge. A hand irrigator. See Aquapult; Hand Pump; Irrigator, etc.

Green'house Ven'ti-la'tor. A window-lifting apparatus for the glazed roofs of conservatories.

Green Ware. (*Ceramics.*) Articles just molded or otherwise shaped, before drying and baking.

Gre-nade'. The modern hand-torpedo, used in the British navy, is a compressed ball of gun-cotton, attached to a long cord, by means of which the torpedo is exploded with a force sufficient to shatter a five-ton block of granite when it has been pitched into position.

Gren'a-dine. (*Fabric.*) A French worsted dress-goods, woven with a gauze or open taffeta armure, and having a silk *grège*, organzine or cotton warp and an English combing-wool weft, which is highly twisted and gas-singed.

It is a kind of close barége.

Gre-net' Bat'te-ry. (*Electricity.*) A single-fluid bichromate battery. A bottle-shaped vessel has a stopper from which two carbon plates depend into the liquid. A zinc plate, *Z*, between the carbons *K K*, by means of a rod passing through a central aperture in the stopper, can be immersed at will in the liquid, to set the battery in action.

Fig. 1279.

Grenet Battery.

Niaudet, Amer. transl., * 222.
Trouvé's improvement on Grenet compounds a number of pairs of removable elements. *Niaudet, ut supra*, * 224.

Grid. 1. A grate, grate-bar, or furnace bottom.

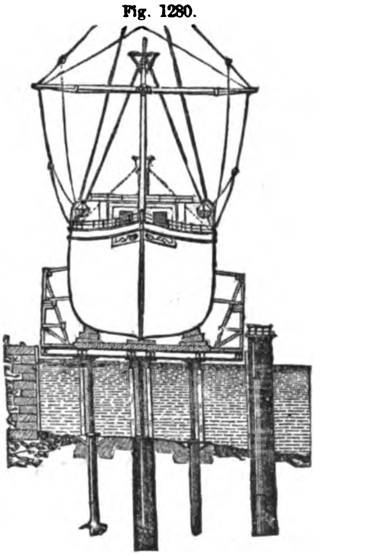
2. A grille or grated opening.

3. (*Hydr. Eng*). A structure of beams — lying in parallel open order they resemble a gridiron — on which a ship rests in building, lifting, or repairing.

Fig. 1280 shows a hydraulic grid of Clark, Standfield, & Co., whose depositing dock is a grid of the largest and most admirable construction, and is shown in Plate IX., Depositing Dock, *supra*.

In using the dock the grid and presses are lowered to the bottom, and the keel of the vessel is brought directly over

Fig. 1280.



Hydraulic Grid.

the center and secured in position by the bilge blocks and side shoring frames, the presses are then worked and the vessel lifted till the grid is above high-water mark. When in this position a number of struts or swinging frames (which were previously held up in a horizontal position under the grid) are liberated and allowed to hang in a vertical position. The grid is now lowered a few inches until the whole of these struts rest on raised bearings cast on the head of the presses, and the whole weight of the vessel and grid rests on them. The rams are now allowed to sink down into the presses, where they remain in fresh water, and are consequently less disposed to rust. The supports are hinged or swung at the top so as to fall accurately into their places, and suitable means are provided for raising and lowering them simultaneously by means of chains and shears. These frames are of considerable breadth, and some of them swing transversely and others longitudinally, so as to obviate any tendency of the grid to move in either direction. There are also, in addition, strong cast-iron columns, with guides, against which the grid slides as it rises and falls. The pumps, pipes, and valves are similar to those used in ordinary hydraulic docks.

See also Hydraulic Hoist, *infra*.

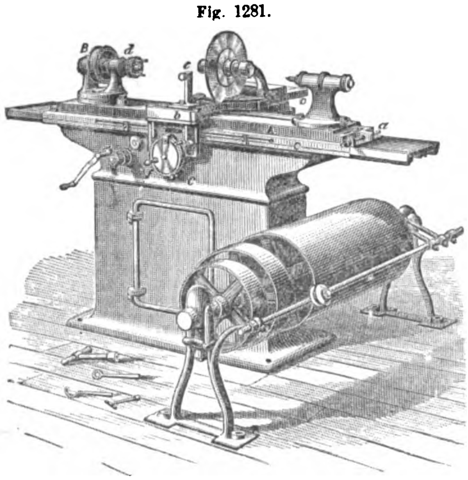
Grind'ing Lap. A grinding machine with a revolving wheel for cutting surfaces. See Lap, p. 1252, "*Mech. Dict.*"

Grind'ing Ma-chine'. A machine adapted for the execution of circular grinding, such as the grinding of hardened plugs, arbors, spindles, reamers, standards, cutters, etc. It will grind straight and tapering, either inside or outside, and is especially useful in grinding out holes in hardened cast-steel boxes and bushings.

Fig. 1281.



Grinding Machine.

Brown & Sharpe's grinding machine. Fig. 1281, operates by a solid emery or corundum wheel. The work can be revolved upon dead centers or otherwise. The grinding wheel can be moved over the work at any angle, by which means any taper can be produced. Wheels from ½" to 12" in diameter can be used either with or without water. The feed-works and slides of the machine are protected from grit and dust. The grinding of taper holes and angular cutters is provided for by graduated arcs. A special chuck is provided, for holding work to have holes ground. An additional movable table, capable of adjustment by a tangent screw and graduated arc, admits of straight and curved taper grinding with the centers of the machine always in line.

Grind'ing Mill. The subject is considered under many heads assembled in list under Grain Cleaning and Grinding, p. 411, *supra*.

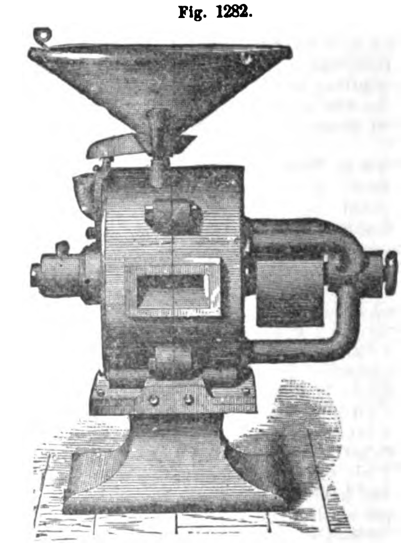
The purposes and construction of machines differ greatly; they are adapted for grain, ore, fertilizers; are made vertical or horizontal; edge rolling (Chilian); grinding on the flat; upper, under, or both stones moving; made of iron, buhr, glass, etc.; are made like cages, working by impact; grind by a tearing action between two surfaces, or a crushing between a roller and concave, or flattening between two rollers, etc. See numerous examples of forms and principles, Plate XXII., "*Mech. Dict.*," opp. p. 1020.

The principal heads under which they will be found are:

Aplatisseur.
Aspirator
Bean mill.
Bone mill.
Cake grinder.
Cement mill.
Concasseur.
Corn mill.
Cylinder mill.
Fertilizer mill.
Granulating mill.
Kibbler.
Ore mill.
Roller mill.

See also list under Mills, *infra*.

Fig. 1282.



Grinding Mill. (*Elevation.*)

Figs. 1282, 1283, show the Harrison portable mill with a pair of stones, one being a runner.

Fig. 1282 is an end or face view. The case and pedestal are cast in one piece. The heads containing the bed and runners are bolted to the rim of the case.

Fig 1283 shows the pedestal and case, with a dressing-frame bolted on and the buhrs turned out upon it for dressing. The frame is made in two parts, and fastened, one on each side of the case, by tap bolts, and when the dressing is done the frame is removed.

Gris-aille'. (*Fabric.*) A French fancy dress goods woven on a taffeta loom. It has a cotton chappe or fancy warp and an English combing wool weft. Warp is printed or *chiné*.

Gri-sou'me-ter. (Fr. *grisou*, fire-damp.) A fire damp detector invented by M. Coquillon.

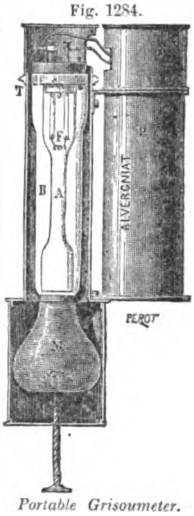
It is based on the property of palladium wire when heated, to burn the last traces of hydrogen contained in any carburet when supplied with sufficient oxygen for its combustion.

The reduction in volume resulting from this combustion is proportionate to the quantity of the protocarburet, so that a properly graduated gage furnishes at once the proportion of gas consumed.

The same principle is found in Coquillon's *Carburometer*.

The portable grisoumeter consists of a central tube, *A*, called the burner, narrowed in the middle and graduated into spaces of equal capacity; the lower end is open, the top closed by an india-rubber stopper carrying two holders for the conducting wires, and the lower branches of which press down the palladium wire. A third opening is left in the stopper to receive a small wooden plug or a glass rod. This first tube is surrounded by a glass sheath or cylinder, *B*, closed at the top by a rubber disk having an orifice which closes by means of a plug. To the lower portion is adapted a diaphragm containing water, which is elevated or depressed by means of a screw, on the principle of the Fortin barometer. Next to this first portion of the instrument is placed a second one, which consists of a Plante's condenser, the poles of which are attached to the two holders of the burner. A lateral screw acting by pressure starts the current and heats the wire at the desired moment. When an analysis is to be made, the inner tubes being full of water, the screw is lowered, so that as the liquid descends it is replaced by the air of the mine. The volume is so adjusted that the levels of both the tube and sheath are on the same horizontal line opposite the zero of the scale.

Fig. 1284.



Portable Grisoumeter.

The burner is now closed while the outer sheath is left open. The electric current is started and the wire heated to redness. The gas is rapidly burned, and after giving time for cooling, the water is seen to rise more or less in accordance with the quantity of gas burned. The two water levels are readjusted by means of the bottom screw to equalize the pressure; and the division of the scale opposite the surface level read off. This instrument gives in one reading the amount of protocarburet in hundredths, but does not apply to quantities of the same exceeding five to six per cent. This would be useless practically, as at this point the miner's lamp is full of fire and he himself in the midst of a detonating compound.

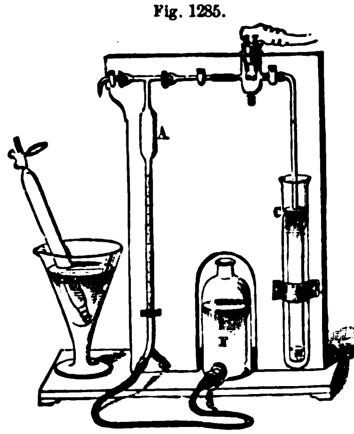
M. Coquillon has since replaced the palladium by platinum.

The principle of the stationary grisoumeter is based on Professor Deville's double flash, and is shown in Fig. 1285. It comprises, first, a vertical glass tube, *A*, or gage, the top of which is branched in T shape, two cocks being adapted to the horizontal branches of the T. The lower portion of this tube is constricted and carries ten divisions, each of which may be subdivided into ten others; it is bent at right angles and attached to a rubber tube fastened to a flask used as an aspirator or blower. The capacity of the tube measured from the cock is 25 cubic centimeters, and the zero of the scale is indicated at the bottom. This is the point that must be reached by the gaseous volume when no protocarburet is contained in the instrument; 10 is marked near the bulge, each division being equal to ½ cubic centimeter. The second portion of the apparatus is the burner *B*, formed by a small thimble-shaped tube closed by a rubber stopper pierced by two holes into which are introduced the holders for the palladium wires.

Laterally are adapted small capillary tubes which by means of rubber tubing allow of an attachment on the one side to the gage, on the other to the following bell glass. This last, *C*, is capped by a capillary tube bent at right angles and surrounded by a glass cylinder or sheath closed at the bottom and filled with water. The whole apparatus, as well as the corks, is in glass, and is mounted on a stout wooden board so as to protect it from accident. A small box containing 10 small tubes filled with water is accessory to the apparatus, these being filled when desired with the air collected in the various levels of the colliery and destined for analysis.

The use of the stationary grisoumeter is very simple. The bell glass surrounded by its cylinder is filled with water to a

Fig. 1285.



Stationary Grisoumeter.

determinate or fixed point: the gage tube is also filled with water. The burner and capillary tubes are left full of air. One of the small tubes from the box is now attached in such a manner that one end plunges into a tumbler full of water while the other or taper end is connected by means of a rubber tube to the anterior end of the gage. One of Mohr's forceps closes this rubber tube at the desired height

In order to introduce 56 centimeters of gas into the gage, the left cock is opened and the forceps pressed by the right hand, while the left hand holds the flask so as to be able to raise or lower it at will. The gas passes from the conico-cylindrical tube into the gage, and must be made to coincide with the zero of the scale as indicated by the water level. This being done, the left cock is closed and the right opened, and at the same time the palladium wire is heated to redness. The gas is made to circulate two or three times over the palladium by the motion given to the flask. After the burner has cooled down, the gas is returned to the gage, and the scale read off. This last is so graduated as to indicate at sight hundredths and thousandths of protocarburet or of bicarburet.

Grist Tol'ler. This machine operates through the periodical presentation of a toll spout with its attendant valve. Each time the spout is presented under the falling grain it takes in a portion which is carried down and out of the machine as toll.

The amount of toll taken is governed by a device in which the position of a wrist in a slotted crank regulates the amount taken.

Grits. (*Milling.*) Cracked fragments of wheat smaller than *groats*. An incident to the HIGH MILLING process, which see. See also GROATS.

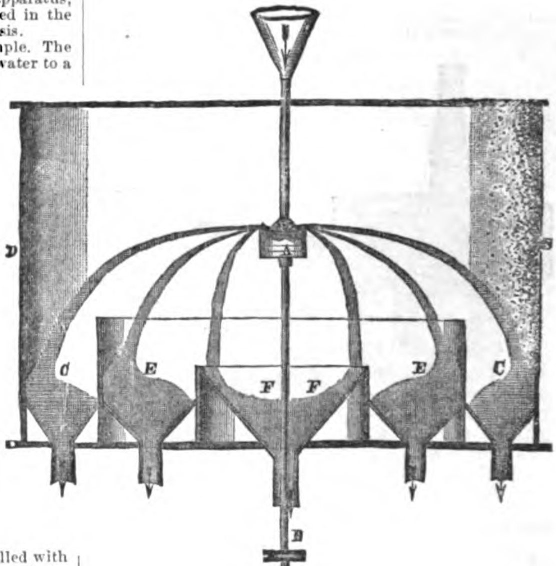
Grits Gra'ding Ma-chine'. (*Milling.*) A centrifugal apparatus for grading grits after the separation of the fine flour by the process of bolting.

The grits passes by a spout to the top of a rapidly revolving wheel, *A*, and is projected centrifugally; the larger particles fly to a greater distance and fall at *C*, while the others reach *E F* respectively, according to relative levity.

Grits Mill. The grits mill with one cylinder is used in the St. Georgen manufactory of St. Gallen.

W is the cylinder with steel shell and *S* the steel concave. It is used for the cracking of wheat and the production of grits, leaving further milling to be done with a run of stones.

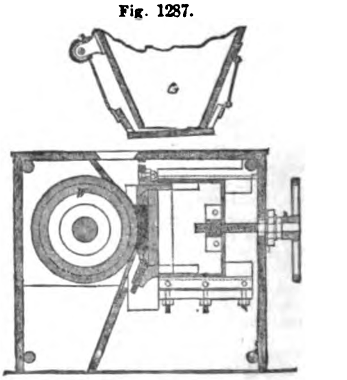
Fig. 1286.



Grits Grading Machine.

Grits Pu'ri-fi'er. A machine for separating bran scales from grits. It is of Austrian origin, the originator being Ignaz Paur, the inventor of

Fig. 1287.



Cylinder Mill of St. Georgen, St. Gallen, Switzerland.

the high-milling process. Paur's and Escher Wys's grits-purifiers are shown by Kick in his report on Group IV. to the Austrian Government, 1873, and in Prof. Horsford's report, "Vienna Bread," Vienna Exposition, 1873, vol. ii., § B.

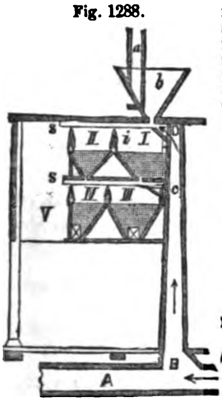
The machine, Fig. 1288, acts by a blast of air upon the materials of different gravity.

The *bran* is a thin flat scale of the wheat shell. The grits are irregular fragments from the interior of the grain, relatively heavier than the bran.

a is a supply tube introducing the mixed bran and grits. *b* is a hopper with a slit at the bottom. At *D* a current of air enters and encounters the falling stream of bran and grits. The grits being heavier fall into division *I*, the bran is carried to *V*, and the intermediates fall into *I I*. A second current of air entering at *c* subjects the matters to a farther separation.

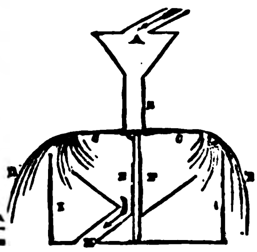
Another form is shown in Fig. 1289, and is used at Pesth. *A* is a hopper receiving the meal; *B* a cylinder fitting the spout from the hopper, and admitting of raising and lowering; *b* is a circular smooth metallic plate revolved by a vertical shaft attached below. The meal as it issues from the foot of the hollow cylinder is carried to the periphery and shot outward into the current of air produced by suction through spout *H*. The rounded grits, having greater weight in proportion to the extent of surface, reach the space *D*; the bran-flakes, having least material to surface, are drawn to *F*; and the fine flour falls between to the receptacle *H*.

Fig. 1288.



Paur's Grits Purifier.

Fig. 1289.



Grits Purifier. (*Pesth.*)

Griz'zly. (*Cal. Hydraulic Mining.*) *Grizzlies* are heavy iron grates which catch the bowlders and through which the gravel is sifted; they are placed at the point where the washings fall into the sluice.

Groats. (*Milling.*) *a.* Bruised or cracked fragments of wheat with bran attached; larger than *grits*. An incident to the process of HIGH MILLING, which see. This is the technical meaning of the word; adopted in the search for specific words to indicate conditions of fineness or quality.

b. Hulled and broken grain, used as an article of food. May be of wheat or oats. This is the domestic meaning of the word *groats* (pr. *grits*).

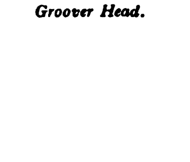
Groom'er. An application of the flexible or jointed revolving shaft to rotate a brush used in the grooming of horses. The flexible shaft is thus used in drilling, by dentists, for sheep shearing, horse clipping, hair cutting and brushing, and horse grooming.

Fig. 1290.

Horse Groomer.

Groov'er Head. A circular cutter used on a wood-planing machine to cut the grooves on one edge of matched boards. The cutters have spurs, and are held in slots by tapered compression bolts.

Fig. 1291.



Groover Head.

Groov'ing Ma-chine'. A form of lathe for making grooved or scroll work, such as table legs, balustrades, etc.

Ground Cock. A basin cock, ground into its seat, as distinguished from *compression* cock.

See Fig. 672, p. 216, *supra.*

Ground'ing Ma-chine'. (*Wall Paper.*) A machine for giving the requisite body to receive the colored pattern.

While passing over a roller the paper is covered with a mixture of clay (that used contains about 18 per cent. of alumina), glue, and water, and if the surface is to be finally polished — or satin finished — a percentage of lard oil is added. After the mixture is applied it is evenly distributed over the paper, first by two reciprocating brushes, then by a rotating brush roller, and lastly by two brushes like the first.

See cut, Fig. 1, p. 226, "*Scientific American,*" vol. xxxvii.

Group Spring. *Railway.* One formed of a number of separate springs in a cluster. See *u*, Fig. 1143, "*Mech. Dict.*"

Grous'er. (*Hydraulic Engineering.*) A heavy iron-pointed oak timber which passes through the hull or down the side of a boat for the purpose of anchoring.

"*Report of Chief of Engineers,*" 1876, vol. ii., Part II., p. 408, and A, Fig. 1.

Grout Wall. One made of béton or similar material.

"Grout (or concrete) as building material, is composed of lime and coarse gravel mixed with water, in the same manner as ordinary mortar, and of about the same consistency.

"A small proportion of cement — say, one tenth — may be mixed with lime, and will add to the strength, durability, and finish of the walls.

"To give solidity, quarry chips can be used by being imbedded in the composition while forming the walls.

"The walls of buildings are formed of this material by making boxes or molds of 2″ plank, of uniform width, placed on edge horizontally, as wide apart as the desired thickness of the walls, and held in place by cleats. Into these boxes or molds thus formed the grout is put, and allowed to remain a sufficient time to harden; when the boxes are removed, and again placed at the top of the layer just formed, and again filled with gravel and stone; and so on until the wall is of the required height.

"If the planks of which the boxes are made are, say, 12″ wide, the grout will harden in about 24 hours sufficiently to allow the boxes to be removed without injury to the wall.

"The gravel used may be mixed with a moderate proportion of sand advantageously.

"The partition walls can be built more cheaply and rapidly of lumber than of gravel; as where inside walls are constructed it is difficult to fit and manage the boxes without injuring the outside walls."

The boxes and method of construction are similar to those used in pisé walls. The difference is only in the material used. — *Report of Lieut. Rogers, U. S. A.*

Grove Bat'te-ry. The nitric acid battery, the invention of Mr. Grove, now Justice Sir W. R. Grove. It eliminates the hydrogen by oxidizing it so as to form water, and so prevents the polarization of the negative plate.

It has the amalgamated zinc in sulphuric acid, and its platinum in nitric acid, with an intervening porous cell.

Grow'ing Cell. (*Optics.*) Beck's. A plate of glass into which is fitted an annular zinc trough upon the upper surface of which a cover of plate-glass is screwed. On the top of this glass the object to be kept alive is placed, and over it is laid a thin glass cover.

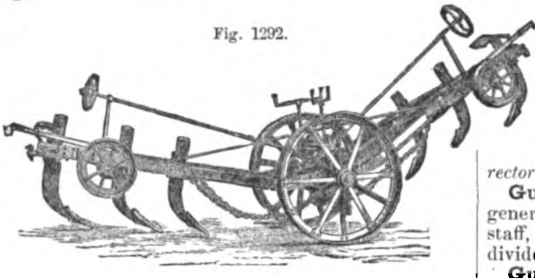
The action of this growing cell is as follows: The trough is filled with water, the plate-glass is screwed down, the thin cover placed upon it. The plate-glass cover has two holes pierced in it, one of which comes under the covering glass, and through which the water will flow by capillary attraction, feeding the object. The other hole is outside and will admit sufficient air to replace that lost by the capillary action under the covering glass.

Grub'ber. An implement for deep cultivation.

An implement for tearing through soils infested with grubs, stumps, stones, and roots. A clearing plow.

The steam grubber, Fig. 1292, is one of the set of steam cultivation implements. It is especially intended for working in stiff clay land, to stir and aërate the subsoil without

Fig. 1292.



Fowler's Steam Grubber.

materially disturbing the surface. For this purpose it is made with 1, 2, or 3 tines, and is worked 2′ deep. It is also used for stirring up the subsoil of old grass lands, and, with 1 or 2 tines, to a depth of as much as 30′′ in removing stones or tree-roots. It is known as a "knifer."

It may be called a renovating or reclaiming implement, and under all circumstances of its use is a powerful assistant in the matter of drainage in strong soils.

Grub'bing Ma-chine'. A special gun-tool. The work has a semi-rotary motion against a fixed tool.

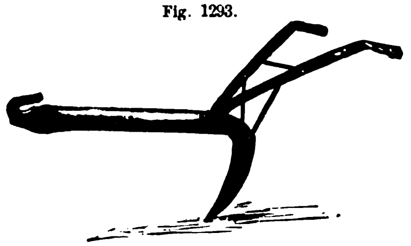
In the special grubbing machine the tool has a motion on a segment of a circle, and an automatic feed. — *Pratt & Whitney.*

Grub Break'er. (*Agric.*) A form of heavy plow used in recently cleared land, and having a strongly braced colter and share for uprooting grubs and breaking roots.

Grub Hoe. An implement something between a hoe and an adze, used in cutting and digging up brush, saplings, etc.

Grub Hook. An implement drawn by a team and used in rolling out stones and tearing out roots, stumps, and logs.

Fig. 1293.



Grub Hook.

Grum'met. (*Nautical.*) See GROMMET, p. 1025, "*Mech. Dict.*"

Guard. A fence, fender, screen, canopy, etc., as the case may be: —

A dash-board, or step-guard in cars.

A fender in grates.

A piece to receive the jar of an opening door.

A screen to keep the heat of a fire from a person, wall, or furniture.

A grating to a window to preserve it from blows.

(*Fire-arms.*) The bow which protects the trigger.

Guard Bolt. A flat-headed screw-bolt, fully counter-sunk, for fastening the guards of mowing machines to the bars.

Guard'ed In'stru-ment. (*Surgical.*) Said of an instrument the point or cutting edge of which is concealed or guarded during introduction, and uncovered when at the place where it is to become effective. As *guarded blunt-hook, guarded bistoury, guarded trephine.*

Bistoury caché expresses the same idea.

Gui'bal Fan. A ventilating wheel on the exhaust principle, receiving the air around its axis and forcing it by wings centrifugally to the exit shaft.

Guide. (*Surgical.*) A stiffening stem, withdrawable, in a soft rubber catheter.

A cannulated stem affording a means of direction to a flexible instrument. A *director.*

Gui'don. The flag of a commander of horse; generally of damask and fringed, 3′ broad on the staff, and lessening towards the bottom, where it is divided into two peaks.

Guil'lo-tine In'stru-ment. (*Surgical.*) An instrument for excising the tonsil or uvula. It has a cutter sliding in guides and a loop to hold the object.

See TONSILOTOME, *e*, Fig. 6525, "*Mech. Dict.*"; UVULATOME, *d*, Fig. 6886, *Ibid.*

Home-made . . . . * "*Scientific American*," xlii. 295.

Gui-tar'. (*Music.*) An instrument played by the hands, having 6 strings tuned in fourths and thirds. The three lower strings are of silk, covered with silver wire; the three upper of catgut. The three former are usually played by the thumb; the three latter, G, B, E, by the fore, middle, and third fingers respectively, the little finger resting on the instrument.

Gum De-pres'sor. A dentist's tool, used in holding the gum down from the tooth in filling cavities close to or under the gum.

Gum Lan'cet. (*Surgical.*) A pocket lancet in shell handle. See *a*, Fig. 2795, p. 1249, "*Mech. Dict.*"

Gum'mer. A tooth for gulleting saws. See SAW GUMMER.

Gum'mer Grind'er. A tool for holding the cutter of a saw gummer while being ground.

Gum Spring. One made of caoutchouc — india rubber.

Gun. See CANNON; RIFLE, etc.

"Duilio," *Armstrong* gun.

Bore	17.72′′.
Shot	2018 lbs.
Maximum charge powder	511 lbs.
Ordinary charge powder	355 lbs.

See CANNON, RIFLE, etc., and various specific heads.

Gun'-cot'ton. Cotton rendered explosive by treatment with sulphuric and nitric acids. See p. 1036, "*Mech. Dict.*"

Modes of manufacture and considerations of its stability, in "*Report of the Chief of Ordnance, U. S. A.*," 1877, p. 458, *et seq.* See also *Ibid.*, 1879, Appendix I., pp. 130-132.

On cannon, effect of . . * "*Scientific American Sup.*," 2618.

Punchon's improvements in the manufacture of gun cotton are thus described: —

"The cotton is first thoroughly cleansed by boiling it in an alkaline solution and exposing it to a current of air, and then again boiling it in clean water. After the second boiling it must be again thoroughly dried, first by a centrifugal machine, and afterward by being passed over a current of hot air, the wet meeting the cold current, and as it dries rising to a temperature of about 120° F. The cotton, in charges of one pound each, is then steeped for five minutes in a bath containing three parts of sulphuric acid and one part of nitric acid, after which it is taken out and placed in an iron cylinder, and a perforated piston, about 8'' in diameter, is forced down upon it by hydraulic pressure. The excess of acid pressed out of the cotton passes through the perforations in the disk and is pumped off. The cotton is then placed in glazed earthenware jars, which are covered in order to prevent any heating taking place, the jars being placed in a current of cold water, where they are allowed to remain for 24 hours, after which the cotton is taken out and again thoroughly washed, and while yet damp is passed between rollers until it is reduced to a very fine powder; this process being gone through while the compound is damp, prevents any possibility of its explosion. The powder is then mixed with a certain quantity of sugar, nitric acid, and water, into a pulpy mass, which, after being strained through a fine sieve, is carefully dried in a temperature never exceeding 120° F. The manufacturing process is finally completed by passing it through rollers under very high pressure, by which means it is compressed into a hard substance and rendered almost impervious to damp. The gun-cotton intended for blasting purposes is made into thin cakes, broken and irregular in size, but for rifle cartridges it is made in small pellets, similar in form and size to rape seed." — "*Universal Engineer.*"

Gun Hand'-tools.

Ball seater.	Intrenching spade.

Gun'pow-der Pa'per. A substitute for gunpowder. *Powder-paper* consists of paper impregnated with a mixture of potassic chlorate, nitrate, prussiate, and chromate, powdered wood-charcoal, and a little starch. The powder-paper is rolled into the shape of a cartridge of any required length or diameter. It is said that no explosion can take place except by way of contact with fire. Also that the powder paper leaves no greasy residue on the inside of the gun, produces less smoke, gives a less violent recoil, and is less impaired by humidity than gunpowder. With equal charges, by weight, of gunpowder and powder-paper, the penetrating power of the latter is 5-16ths greater than that of the former. — "*Pop. Science Monthly*," x., p. 253.

Gun Stock'ing Ma-chin'e-ry. Includes machines for

Bedding the barrel.	Placing the butt plate.
Bedding the lock.	Turning the stock, etc.
Bedding the guard.

H.

Hai-tha'o. A species of gelatine used in giving body to tissues and paper.

It resembles Irish moss, and may be derived either from the *Gehelium corneum*, a seaweed of Java, or from the *Phearia lichenoides*, peculiar to Mauritius. It is treated with hot acetic acid, afterwards with water, and finally with ammonia. The residuum dissolved in boiling water furnishes, on cooling, a jelly which is dried, and forms the commercial article. It was first used for alimentary purposes, and is now used as a size, and also as a substitute for gold-beater's skin. When placed in water it takes up about 500 times its own weight of the fluid. It is only soluble in boiling water, and insoluble in weak or diluted acids, alkaline solutions, and ether, but is attacked by sulphuric and other concentrated acids.

Half Back Saw. A hand-saw having a back stiffened to a distance about half the length of the blade from the handle.

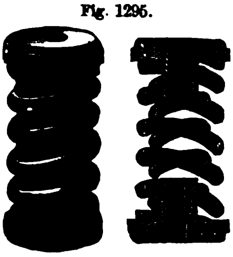
Half Clear. (*Glass.*) Said of glass, a portion of the surface of which has been depolished by any means, such as acid, grinding, etc.

Half-crys'tal Glass. (*Glass.*) A French term for *lime*-glass. *Crystal* answers to the English *flint* glass.

Half-el-lip'tic Spring. A carriage spring composed of one set of plates, like a half ellipse. See Figs. on p. 143, *supra*.

Half Hatch'et. A hatchet with one straight side, all the projection of the bit being on the side toward the hand. A shingling hatchet.

Fig. 1295.



Half-round-bar Spiral Spring.

Half Hose Coup'ling. A coupling having at one end a corrugated tubular portion on which the hose is bound, and at the other a sleeve internally threaded to receive an iron pipe.

Half-round'-bar Spi'ral Spring. (*Railway.*) A coil spring made of half-round steel rod. Fig. 1295 shows it in a double nest form.

Fig. 1296.

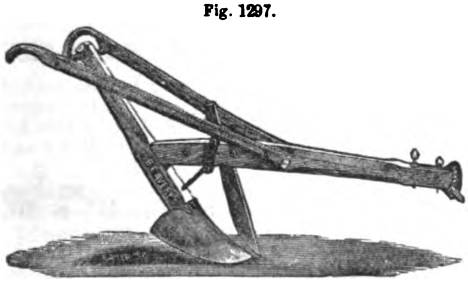
Flanged Half-S Hopper Trap.

Half-round' Spade. (*Whaling.*) Used in cutting the blanket-piece free from the carcass as the lifting tackle and blubber hook draw upon the piece in flaying.

Half-S Hop'per Trap. A sewer trap with a single bend; half the letter S in form. Fig. 1296 shows the form, and also a man-hole with cover.

Half-shov'el Plow. (*Agric.*) A plow intended for rooty land. The blade is of steel, and

Fig. 1297.



Half-shovel Plow.

has one straight side; it is braced by a lay to prevent its being broken or bent. A broad iron plate is attached to the beam, and the colter may be changed from a jumping to a cutting colter.

Half Spring. A spring with but one set of leaves; like a half-elliptic spring, shown at *d*, Fig. 1136, p. 480, *"Mech. Dict.,"* and Figs. 450–452, p. 143, *supra.*

Half Trap. A sinking bend in a sewer pipe, like a half-S, not having the rising portion. See Fig. 1296.

Hame. A curved piece of wood or metal, two of which are fitted to the collar; they have draft eyes to which traces and chains are attached.

The attachments are: —
Hame clip; a metallic link by which the tug is attached.
Hame link; at the lower end of each hame, for the hame strap to pass through.
Hame ring; on the hame, for the rein to pass through.
Hame strap; to couple the hames around the collar.
Hame terret; a rein ring in coach harness.
Hame tug; the forward loop on the trace; attached to the clip.

Ham'mer. (*Stone Working.*) Stone hammers are of various kinds, with faces or edges, plain or notched. Sometimes one end has a point (the *peen*) which is practically a pick, and used in *pointing* ashlars. See STONE DRESSING.

See Bush hammer.	Mallet.
Cavil.	Patent hammer.
Crandall.	Peen hammer.
Double-face hammer.	Pick.
Face hammer.	Stone hammer.
Hand hammer.	Tooth axe.

(*Surgical.*) Used in osteotomy. The percussor used in auscultation is also a hammer or mallet.

See under the following list, which includes also other striking tools, including sledges, mauls, hatchets, axes, and picks: —

Adze.	Mason's hammer.
Axe.	Mattock.
Ballast hammer.	Mill pick.
Ball-peen hammer.	Miner's pick.
Beating hammer.	Nail gun.
Bench hatchet.	Nail hammer.
Blacksmith's sledge.	Napping hammer.
Blocking hammer.	Patent hammer.
Brad driver.	Pavior's hammer.
Brad hammer.	Pavior's rammer.
Bricklayer's hammer.	Peeling axe.
Broad axe.	Peen hammer.
Bull-head axe.	Percussing hammer.
Bung start.	Pick.
Bush hammer.	Pick-axe.
Calking beetle.	Pick hammer.
Calking mallet.	Pick mattock.
Carpet hammer.	Plugging mallet.
Cavil.	Quartering hammer.
Claw hatchet.	Railroad axe.
Coal sledge.	Rammer.
Crandall.	Ring mallet.
Cross peen hammer.	Riveting hammer.
Dental mallet.	Set hammer.
Dog-head.	Sharp-peen hammer.
Double face hammer.	Shingling hatchet.
Drift hammer.	Ship's axe.
Driving hammer.	Sledge.
Electro-magnetic mallet.	Spalling hammer.
Engineer's hammer.	Spike maul.
Face hammer.	Steak hammer.
Farrier's hammer.	Stone axe.
Fireman's axe.	Stone-cutter's hammer.
Flaking hammer.	Stone pick
Flanging hammer.	Straight-peen hammer.
Geological hammer.	Striking sledge.
Half hatchet.	Swaging mallet.
Hammer pick.	Tamping pick.
Hand-drilling hammer.	Tinner's hammer.
Hand hammer.	Tooth axe.
Hatchet.	Top maul.
Hawsing beetle.	Trimming hammer.
Horse-shoe hammer.	Turning hammer.
Knapping hammer.	Turning sledge.
Lathing hatchet.	Welding hammer.
Mallet.	Wood chopper's maul.

Refer to: Cushioned hammer, *Bradley.*

Power hammer, *Hasse-Simon*, * *"Engineer,"* xlviii. 412.

Ham'mered Ar'ti-fi'cial Stone. An artificial stone compacted by means of blows.

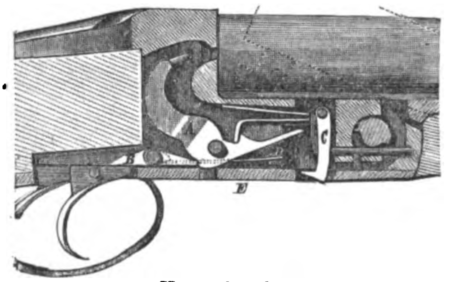
The ingredients and proportions vary with the facilities of the place of manufacture. *Béton*, as made by M. Coignet, is made of sand 5, lime 1, hydraulic lime 0.25, which are mixed with a shovel, water being sparingly used, and the compounded materials violently ground in a tempering mill and rammed in molds. See p. 278, *"Mech. Dict."*

The material to which the name of *hammered artificial stone* has been given is made by the application of the stroke of the steam hammer upon properly mixed proportions of hydraulic and common limes, hydraulic cements, pulverized iron slag, sand, broken stone, marble or granite, clays and minerals, inclosed in properly constructed molds and dies. It is made by proper disposition of the ingredients, to imitate marble, and, by carving the interior faces of the molds, to assume any ornamental configuration.

Ham'mer-less Gun. One without exterior hammer; usually fired by concealed spring-pin. The term may include the needle and bolt guns.

That shown in Fig. 1298 is by Greener, of Birmingham, England. It is shown by longitudinal section. The barrels are hinged to the breech-frame in the usual manner, but in-

Fig. 1298.



Hammerless Gun.

stead of the ordinary gun lock with outside hammers, the tumblers A are made nearly in the form of an elbow lever. These tumblers have their upper ends curved forward, and are provided with a small rounded point, which is arranged to strike through a small hole at the center of the breech piece instead of the ordinary firing pin. The lower front portions of the tumblers A are extended forward in the form of a flat arm, and these arms are curved laterally inward, so that their inner ends nearly meet at the center, each arm terminating with a small rounded projection on its lower side. The tumblers are in a recess which also contains the mainspring. (Referred to in the plural, as the gun is double barreled.)

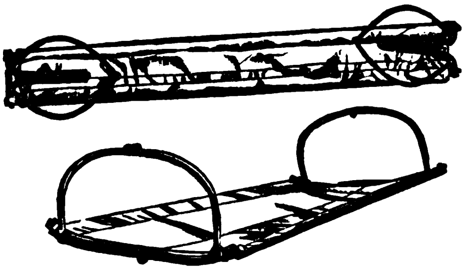
To one of the projections in rear of the joint is pivoted a pendant C, which plays loosely in a vertical slot in the center of the front arm of the breech frame, directly in front of the converging arms of the tumblers. This pendant has a hook-shaped projection which engages under the front ends of the arms of the tumblers, so that when the rear ends of the barrels are raised the hook raises the arms of the tumblers far enough to permit the dogs B to engage in a notch in the tumblers, thus automatically cocking the arm.

To hold the hook C back far enough to engage with the arms of the tumblers, a pin extends through a projection on the under side of the barrels. The triggers operate upon the rear arms of the dogs for firing the arm.

Ham'mer Pick. A stone-mason's tool having a hammer face and pointed peen at the respective ends of the head. A *pick-hammer.*

Ham'mer Strap. An iron strap stapled at its rear end on a wagon tongue, and having an eye at

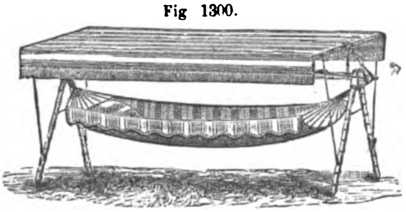
Fig. 1299.



British Navy Hammock.

its forward end which rests on the double tree. The handle of the *hammer*, so called, goes through

Fig 1300.



Lawn, or Tourist's Hammock.

the eye, the double-tree, and the tongue, and bears the strain in pulling.

Ham'mock. A suspended netting for reclining or sleeping.

Fig. 1299 is Stone's (Br.) portable swinging bedstead with canvas sacking. It is capable of being folded up and stowed,

Fig. 1301.

"Ashantee" Hammock.

being especially intended for a customary hammock arrangement on board ships of war.

Fig. 1300 is the Gwynfè (*Leycester*, Br.) self supporting hammock tent which stands by itself independently of ropes, trees, or pegs. The awning can be moved to any position.

Mosquito net frame, *Volle* . . . * "*Sc. Amer.*," xxxviii. 339.

Fig. 1301 shows the "Ashantee" hammock on slinging apparatus.

Ham'mock Clews. (*Nautical.*) The gatherings at the ends of a hammock formed by a *grommet* and *knittles* at each end, and by which it is suspended.

Ham'mock Cloth. (*Nautical.*) Canvas to protect the hammock from wet when stowed in the nettings on deck.

Ham'mock Net. Open-work or netted hammock.

Ham Try'er. A long bodkin for probing a ham, to detect by smelling the condition as to soundness around the bone.

Han'cock In'spi-ra'tor. See INSPIRATOR.

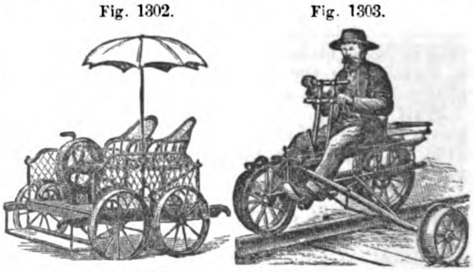
Hand. (*Fire-arm.*) The part of the stock gripped by the hand, and which may be either *straight* or *pistol-gripped.*

Hand Blow'er. A blower or bellows worked by hand. See Figs. 347, 348, pp. 111, 112, *supra.* Also Fig. 3891, p. 1768, "*Mech. Dict.*"; also list under BLACKSMITH'S TOOLS, p. 291, *Ibid.*; and list of AIR APPARATUS, pp. 25, 26, *Ibid.*

Hand Bolt'-cut-ter. A bolt-cutting machine, worked by hand-power. See Fig. 367, p. 117, *supra.*

Hand Car. (*Railway.*) A light car, driven by hand-crank and gearing, operated by those riding

Fig. 1302. Fig. 1303.



Inspection Hand-car. *Three-wheeled Hand-car.*

on the car. See various kinds in *Forney's* "*Car-builders' Dictionary,*" Figs. 43–47. See also INSPECTION CAR.

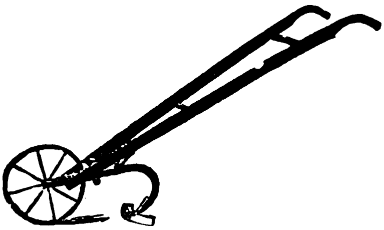
Hand Clamp. A species of vise for holding parts in apposition while nailing, glueing, or fastening by other means. See Fig. 1310, p. 560, "*Mech. Dict.*" See list of CLAMPS, p. 199, *supra*.

Hand Corn-plant'er. A hand implement forced into the soil and dropping corn into the opening. See Fig. 1470, p. 627, "*Mech. Dict.*," Fig 2383, p. 1057, *Ibid.*

Hand Cul'ti-va'tor. A garden cultivator, which runs with a wheel in front, and carries a

Fig. 1304.



Hand Cultivator.

hoe, the penetration and direction of which are governed by means of the handles.

Hand Drill. 1. A drilling machine or tool run by hand. See instances, Fig. 2374, p. 1055, "*Mech. Dict.*"

Refer to: —

Quick-speed	* "*Engineer*," xliv., 454.
Bellamy	* "*Scientific Amer.*," xxxix. 115.
Wiley & Russell . . .	* "*Iron Age*," xxi., April 11, p. 3.

2. A machine for drilling seed in rows. See HAND SEED-DRILL, *infra*.

Hand-dril'ling Ham'mer. (*Stone.*) One used with the chisel in jumping holes in rock for blasting or splitting by plug and feather. The hammer is of steel, and weighs from 3 to 8 pounds.

Hand Hoist. A lifting apparatus worked by hand, as in some species of winch. Specifically, an arrangement of pulley-blocks known as the *differential*. See Fig. 821, p. 257, *supra*, and Fig. 1647, p. 701, "*Mech. Dict.*"

Hand'-hole Trap. A sewer-trap, made with a hand hole, through which may be reached any obstruction which has caught in the bend. See HALF-S HOPPER TRAP, *supra*.

Hand Joint'er. A small machine for trueing the edges of boards or staves. A *buzz-planer*. See HAND MATCHER.

Han'dle Net. (*Fishing.*) A dip-net stretched on a hoop, with a handle.

Han'dlers. (*Leather.*) The vats in which the hides brought from the beam house are first placed, hanging lengthwise and parallel to each other. The vats have a weak infusion of oak bark. Otherwise known as *stringers*.

Hand Line. (*Fishing.*) A line, hooked and baited, and held in the hand, a *trawl* line, for instance; in contradistinction to a *set* line, or a *fly* line.

The hand-line has one or two hooks baited and sunk near to the bottom, or thrown to any desired distance by means of a weight, and managed from the shore or a boat.

Or, it is drawn rapidly over the surface of the water behind a boat, either with a bait attached or a shining object, such as a spoon.

Han'dling. 1. (*Leather.*) Taking the sides or skins out of the vats into the air, smoothing them out, and piling them on one side to drain, after which they are returned to the *stringers*. Each time they are handled they are returned to a stronger ooze.

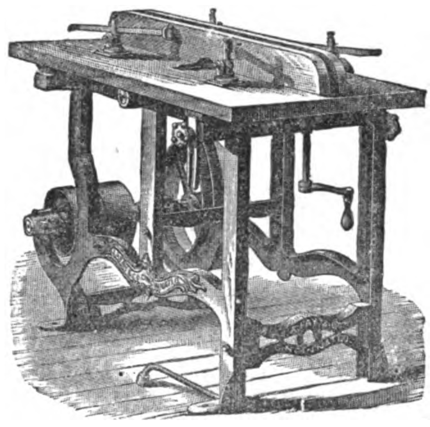
(*Ceramics.*) The operation of putting handles on ware, such as ewers, etc. The handles are molded separately.

Hand Mag'ni-fi'er. (*Optics.*) A series of 3 lenses giving various magnifying powers, whether used separately or in combination, and usually made to carry in the pocket. See LENS HOLDER.

Hand Match'er. A machine for tongueing and grooving short stuff for boxes, furniture, wagon boards, etc.

That shown has two heads, one for tongueing and one for grooving, running on the same arbor below the platen, which is raised or lowered to suit the required depth of work.

Fig. 1305.



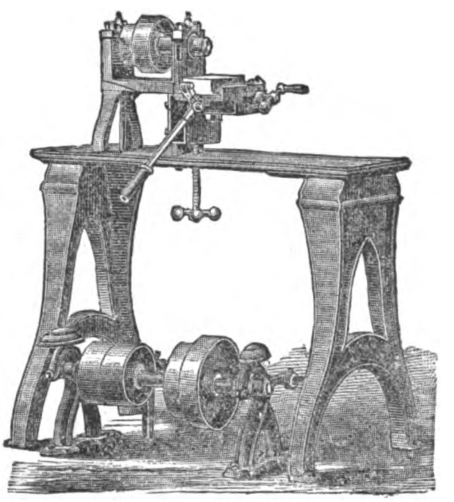
Hand Matcher.

The platen is furnished with movable fence and spring rollers, which are adjustable for different thicknesses of stuff which is passed over the heads edgewise, between the rollers and guides, both edges of the stuff being worked without change in the position of the operator.

Hand Mil'ling Ma-chine'. A machine tool, small of its class, the slide adapted to be run by hand.

Fig. 1306 shows a hand machine which is adapted for taking short milling cuts. The adjustment screw for the table passes down through the bed-plate, and is operated from the

Fig. 1306.



Hand Milling Machine.

under side. The cross-slide is adjusted by a screw that projects in front. The sliding table on which the work is placed is operated by a hand lever, and the motion is gaged by an adjustable stop. The spindle is steel, having gun-metal boxes and a taper-hole to receive the shanks of arbors.

The motion of the cutter is by power, that of the work by hand.

In a somewhat larger machine of this class, by *Kelly, Howell, & Ludwig*, and to which power-feed may be applied, the slide has a tool-post attached for the purpose of cutting up stock, facing nuts, or shaping up work from the solid bar or single pieces to be held in the chuck. The tool-post can be removed from the sliding table, and index centers, milling vise, or any milling fixture put on, required for milling, — taps, reamers, nuts, splining shafts, and any milling suitable to be done on a machine with a screw and level feed The table has a rack-and-pinion feed, operated by a hand-lever attached to the pinion shaft for a quick motion, and a screw feed so attached that either can be used when required; it also has a cross feed for adjustment or butt milling, drilling, etc The body of the machine is a large cupboard base with shelves for tools.

Pratt & Whitney . . * "*Thurston's Vienna Rep.*," ii. 225.

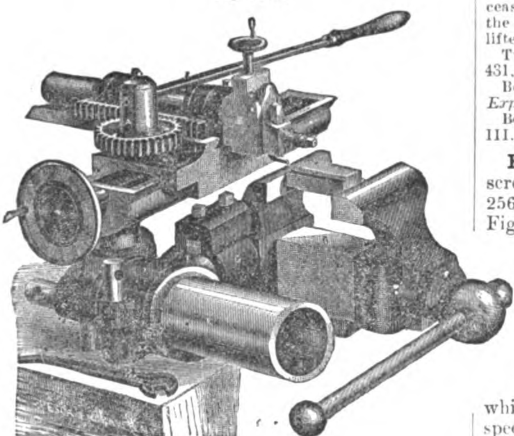
Hand Mor'tis-ing Ma-chine'. A machine in which the force of the blow of the chisel is given by hand. Fig. 3234, p. 1481, "*Mech. Dict.*"

Hand Pla'ner. 1. (*Wood.*) See HAND MATCHER.

2. (*Metal.*) A planing machine, small of its class, and adapted to be worked by hand.

Hall's hand planer is shown in Fig. 1307. The vise is

Fig 1307.



Hand Planer.

made expressly for the planer, which latter is attache by a socket, and has various adjustments to suit the tool to the piece held in the jaws of the vise. The pinion may be set to suit the length and convenience of the stroke. The tool-head swivels on its center, and may be set forward or back by the adjustable joints. The tool has a perpendicular feed of 2¼″. The motion of the lever rotates the pinion, and gives rectilinear motion to the rack which carries the tool-head.

Wood-planer, hand-feed,
Richards, * "*Eng'ing*," xxiii. 274.

Hand Pump. A pump for use in conservatories, washing carriages, etc. Specifically a light implement held in one hand and worked by the other.

See AQUAPULT, Fig. 104, p. 44, *supra*, and HYDRONETTE, *infra*.

The *proof* pump and *gas-drip* pump of the plumber are other instances.

Carr . . . . * "*Manuf. & Builder*," ix. 177.
Holland . . . . . . * "*Iron Age*," xxiii., June 5, p. 1.
"Reliance," Br. . . . * "*Engineer*," xliii. 170.

Hand Rake. (*Agric.*) A term applied to that class of harvesters in which the gavel is removed from the platform by a rake in the hands of a man who rides on the machine. The automatic or self-rake has superseded the hand rake in this country, but not yet in Europe.

Hand Rock Drill. A smaller form of stone drilling machine, differing but little except in size from the Rock drills, pp. 1956–1958, and Diamond drills, p. 697, "*Mech. Dict.*"

Fig. 1308.

Hand Seed Drill.

Hand Seed Drill. A garden tool, for planting seeds in rows.

The seed is deposited in the hopper, and by simply pushing the drill along the ground, the traveling wheel gives a motion to a slide at the bottom of the hopper, and the seed at once falls through a tube situate behind the colter and drops into the soil. The seed ceases to run through, the moment the drill is lifted off the ground.

Two forms of the broad-cast seeder are shown in Figs 430, 431, p. 136, *supra*.

Beet-drill, Figs. 132, 133, 135-137, Knight's Report, "*Paris Exposition Reports*," 1878, v., 118 *et seq*

Beet-drill, Fr., "*Dept. Agric. Sp. Report*," No. 28, Plate III.

Hand Stock Dies. Cutters for making screws, bolts, and threading pipes. See DIE, p. 256, *supra*; and Fig. 4739, p. 2069, "*Mech. Dict.*;" Fig. 4754, p. 2074, *Ibid.*

Hand'-strap Ap'pa-ra'tus. The dependent lever of the counter shaft gearing, by which the strap is run from the loose to the tight pulley, or *vice versa*. A *belt shifter*.

Hand Thresh'er. A threshing machine driven by hand; formerly common in the United States, and yet numerous in Europe. Fig. 1309 shows an excellent French form in which the machine is overshot, and the requisite speed is given to the beating cylinder by the aid of multiplying wheels.

Hand methods of threshing still survive in many countries; the sled shod with flints, the roller sled, and tramping by cattle are shown on p. 2555, "*Mech. Dict*" The roller is still used in Lombardy. and the *ripple*, in Europe for removing flax seed from the bolls, and in Africa for threshing *dhura*.

Fig. 1309.

Worker.
Worm auger.
Wrench.
Wrench and pipe cutter.
Wrench handle.
Wringer.
Y.

Hand Wheel. 1. The brake-wheel on a car platform.

2. The throttle-wheel of a large marine or pumping engine.

Hand Winch. A hoisting apparatus worked by hand. See pp. 2776, 2777, "*Mech. Dict.*" A *crab.* Fig. 1499, p. 640, *Ibid.*

Hang'er Bolt. A screw-bolt, coarse-threaded at one end to enter wood, and threaded at the other end for a nut.

Hang'ing Block. (*Nautical.*) A block through which the *top-sail* tye is rove, then through the tye-block on the yard, and the standing part made fast to the mast head.

Hang'ing Cut'ter. A colter depending from the plow-beam. See Colter, Fig. 662, p. 210, *supra.*

Hang'ing-leg Boil'er. The Galloway boiler, which may be called a form of Cornish in which the large single flue is traversed by vertical water-pipes, which are thus exposed to the horizontal course of the products of combustion.

See Fig. 5626, Plate LXI., opp. p. 2326, "*Mech. Dict.*" Also *p*, Fig. 5621, p. 2327, *Ibid.*

Hang'ing-tube Boil'er. One having water-tubes depending in the flame space; closed at the lower ends and the upper ends secured in the crown-sheet of the fire-box. The flame circulates among these tubes, sometimes directed in its course by a baffle-plate, and passes to the chimney through a straight central flue.

See Figs. 5629, 5633, Plate LXI., opp. p. 2326, "*Mech. Dict.*" Also Figs. 2684, and *B*, Fig. 2685, *Ibid.*

Hang'ing Wall. (*Mining.*) The layer of a rock or wall over a lode.

Hank-dry'ing Ma-chine'. The hanks are placed on perforated rotating rollers or winches, and the lower ends hang in the dye of the beck. The yarn is thus alternately steeped and aired. — "*Textile Manufacturer.*"

See also Wincing Machine, "*Mech. Dict.,*" and * "*Scientific American Sup.,*" 1763.

Han'o-ve'ri-an Bit. (*Manége.*) A straight or curved cheek bit, with two or more loops for reins upon the lower or long arm; also a loop at the end of the short cheek, for receiving the leather cheek, and a rein-ring at the cheek-piece.

Han'o-ve'ri-an Chif'ney. (*Manége.*) This differs from the regular Hanoverian by having a short movable arm attached, in the same manner as the Chifney; the curb-chain is attached to the stationary cheek.

Har'bor Gas'ket. (*Nautical.*) A broad gasket, one on every other seam of the sail, to show a well-furled sail when in port.

Har'dened Glass. Glass treated by the process of M. Siemens, at Dresden.

It is formed under hydraulic or other pressure which gives the desired hardness independent of any tempering. By means of this process larger glass panes can be formed than was possible before. The glass is stronger than the tempered glass of De Bastie in the proportion of 5 to 3. The fracture is fibrous, not crystalline like the ordinary glass. At an examination instituted by the "Gewerbeverein," a leaden bullet, weighing 120 grains, was dropped upon plates of ordinary and pressed glass, supported at the four corners. The ordinary glass was fractured by a fall of the bullet from a height of 300 millimeters, while the pressed pane fractured at a height of 2,000 millimeters. A second specimen of the latter was subjected to a fall of 3,000 millimeters without breaking.

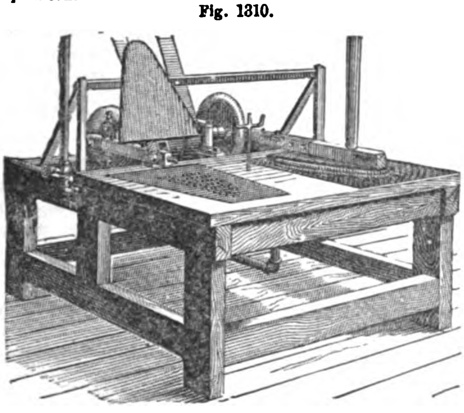
See Glass, Tempered, *supra*, for references.

Hard'en-ing Ma-chine'. A machine for rubbing and pressing hat bodies in order to felt the materials, increasing the density, diminishing the size, and making the material hard and compact.

The machine for hardening wool hat bodies operates by means of a reciprocating rubbing board. It is placed upon a strong wooden frame which serves as a table on which the hat-body rests. Into this table is fitted a steam box which is perforated on top to allow the steam, which is admitted by a pipe, to penetrate the hat bodies to be hardened.

Fig. 1308 shows a machine with two rubbing boards which receive a rapid reciprocating motion from two adjustable wrist-pins fitted to the fly-wheel disks on each end of the driving shaft. One of these rubbing boards, the nearer one, is shown thrown back and out of work. The other one is in operation.

Fig. 1310.



Hat-body Hardening Machine.

The hat bodies are built into a pile and laid upon the steam-box, coarse hardening cloths being sandwiched between each and pieces of cloth of suitable size and shape being laid inside each hat body. The object of these interposed cloths is to prevent the adherence of the hats, one to another. Two of them laid in immediate contact and rubbed while hot and wet would soon coalesce and be impossible to divide. The rubbing board, which is also covered with coarse cloth and is somewhat smaller than the hat-body, is then lowered upon the hat bodies and held down by a post which is hinged to a spring on the ceiling of the room and has a yielding pressure upon the rubbing board.

Three to five hat bodies are thus partially hardened at one operation; the projecting portions, however, not having been acted upon, the hat bodies are removed and so disposed as to bring under the rubbing board at the next operation the portions which were formerly the edges.

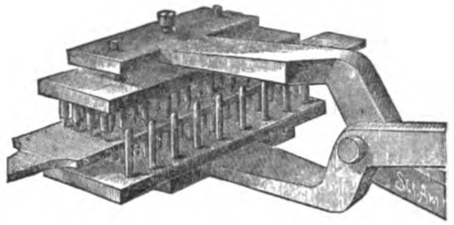
This operation completed, the hat bodies are ready for the *sizing kettle*, or battery, when to be made by hand, or to be fulled in a fulling mill if they are to be farther treated by machinery.

In some factories a separate machine is used to harden the tips of hat bodies. It consists simply of a rubbing board which acts upon a round steam chest of suitable size, upon which the hat body is placed after the sides have been hardened in the ordinary hardening machine.

Hard'en-ing Tongs. A tool to hold steel articles during the process of tempering.

A pair of tongs having T-shaped jaws is provided with pointed pins which bear upon opposite sides of the article, and prevent it from twisting out of shape when it is plunged into the water to cool, while it allows the water to com-

Fig. 1311.



Hardening Tongs.

pletely surround the article. One of the jaws is movable and is capable of adapting itself to tapering surfaces.

Hard Paste. (*Ceramics.*) A name applied to the material of real porcelain, which abounds in silex, and is so vitreous as to break with a fracture like glass. See Porcelain.

Hard'ware, House, Car'riage, Wag'on, etc. See under the following heads:—

Har-mo'ni-um. An English name for the parlor reed-organ. Distinguished from the *harmonicon*, which has bars.

Har-mon'o-graph. An instrument invented by Mr. Tisley, by which Lissajou's and Melde's figures may be drawn upon paper by a capillary glass pen containing a colored ink.

The ingenious instrument, which was originally employed merely to make curious curves, far exceeding in variety and eccentricity those of the rose-engine lathe, has now attain d great use and interest in producing graphic representations of sound vibrations from tuning forks or the voice. According to the circumstances, the curves are traced on a paper, smoked glass, or traveling ribbon, or are merely projected by mirrors upon a screen.

In a simple form the harmonograph consists of two pendulums vibrating in planes at right angles to one another, and having their rods continued above their centers of oscillation. One of these rods carries a small flat table upon which is fastened the paper upon which the figure is drawn, and the other actuates a rod which carries the pen. The center of gravity, and therefore the time of oscillation of the latter pendulums, can be altered to any required amount, so that the proportions between the periods of vibration of the two pendulums can be brought to any desired ratio to represent harmony, unison, discord, or indeed to illustrate all the harmonic combinations of waves of sound and music. The curves and figures traced out by this instrument are of great beauty, and by a recent addition to it, whereby the paper may be slowly rotated by a clock-work movement, while the vibrations are going on, very extraordinary figures are produced, some of which illustrate in a remarkable degree the laws of interference and of the polarization of light.

Har'ness. Diagrams, showing the principles of the disposition of heddles and harness for various kinds of weaving, may be found in *Laboulaye's "Dictionnaire des Arts et Manufactures,"* article "*Tissage,*" vol. iii., edition 1877.

Har'ness Grease.

Whale or neat's-foot oil	8 quarts.
Castor oil	1 pint.
Ivory black	¼ pound.
Rosin	¼ pound.
Beeswax	¼ pound.
Burgundy pitch	¼ oz.
Prussian blue	¼ oz.

Mix. Boil for half an hour.

Harness blacking . . "*Scientific American,*" xxxvi. 81.

Har'ness Hitch. (*Nautical.*) A kind of hitch for securing harness casks. See *h*, Fig. 2513, p. 1105, "*Mech. Dict.*" See also LIFTING TACKLE, *infra.*

Har'ness Snap. See SNAP HOOK, 23 illustrations, Fig. 5246, p. 2229, "*Mech. Dict.*"

Harp. (*Music.*) A stringed instrument played by the hand and having a compass, formerly, of 5½ octaves, but increased by Erard to 6½. It is written on two lines for the two hands. The lower line usually has the F clef, the upper the G. Erard's *double-action harp* is tuned in C♭; it has 7 pedals by which the strings may be raised a semi-tone or a whole tone. See Berlioz's "*Treatise on Modern Instrumentation and Orchestration,*" p. 62, *et seq.*

Har-poon'. A barbed javelin.

The harpoon employed in the capture of the sword-fish off the New England coast consists of a barb with jointed ears, and fastened to one end of a rope of several hundred feet in length, to the other end of which is attached an empty, well-bunged barrel, to serve as a buoy. The end of a long handle carries a pointed iron stem, over which the socket of the harpoon head referred to, usually called the *lily-iron*, is slipped. The fisherman stationed at the end of the bowsprit of a sloop drives the harpoon into the back of the neck of the fish; and if the lily-iron is fastened in the flesh, it slips off from the stem of the handle, which is pulled out as the fish darts away, and the rope and buoy are thrown overboard. The fish swims off, but becoming fatigued by the drag of the buoy, comes again to the surface, when it is drawn up by the rope and killed by a lance.

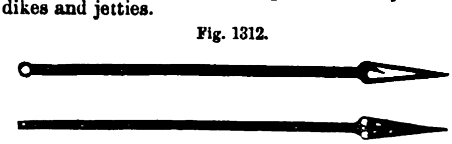
List of patents on harpoons, projectiles, rockets, bomb lances, etc., used in fishing and whaling: —

2,195	*Carsley*, Twisted flukes.
3,490	*Moore*, Vial of explosive mixture in the harpoon.
4,764	*Allen*, Bomb lance.
4,865	*Holmes et al.*, Harpoon with movable flukes.
4,872	*Randall*, Pivoted expanding flukes.
5,949	*Allen*, Gun harpoon.
7,410	*Brown*, Gun harpoon; mode of attaching line.
7,572	*Brown*, Gun lance; mode of attaching line.
7,610	*Brown*, Harpoon; mode of attaching line.
7,777	*Albertson*, Harpoon with hinged shank.
8,703	*Burt*, Exploding harpoon.
8,843	*Sonnenberg et al*, Electric whaling apparatus.
8,862	*Stillman*, A lance in a harpoon. Movable flukes.
9,047	*Brand*, Gun harpoon or bomb lance Wings on shank.
15,577	*Schofield*, Gun lance, spiral wings.
16,819	*Scholfield et al.*, Bomb lance, spiral wings.
17,178	*Sibley*, Gun lance with wings taken from the gun.
17,312	*Brand*, Bomb lance with folding spiral wings
17,370	*Grudchor et al.*, Bomb lance with percussion arrangement.
17,407	*Sibley*, Gun lance with wings.
18,848	*Kelly*, Harpoon with movable flukes.
18,568	*Bates*, Bomb lance with spiral tail.
18,824	*Scholfield*, Gun lance with wings.
19,363	*Harkness*, Harpoon with lance.
21,219	*Sibley*, Bomb lance with wings.
21,278	*Scholfield*, Gun lance with barbs.
21,949	*Doyle*, Harpoon with pivoted head.
22,064	*Andrews*, Bomb lance with interior fuse tube.
23,827	*Comins*, Bomb lance with folded wings.
24,371	*Brown*, Bomb harpoon, expanding flukes.
25,020	*Goodspeed*, Bomb lance with wings.
30,869	*Briggs*, Bomb harpoon with expanding flukes.
31,190	*Roys*, Shoulder gun for harpoons and lances.
32,830	*Goodspeed et al.*, Guide for bomb lance.
35,474	*Roys*, Rocket harpoon and bomb.
35,476	*Roys*, A whale raiser. A barbed instrument led down the harpoon line to a sunken whale.
38,207	*Adams*, Harpoon, with semi-revolving head.
40,387	*Allen*, Bomb-lance, with perforated fire-proof diaphragm.
46,437	*Barker*, Exploding harpoon.
49,548	*Pierce*, Harpoon and bomb lance.
54,211	*Roys et al.*, Rocket harpoon.
64,045	*Smith*, Gun harpoon, grooved head, to receive the pivoted barb.
71,763	*Kelley*, Gun harpoon with pivoted head.
78,675	*Kelley*, Bomb harpoon, pivoted flukes.
90,868	*Pierce*, Bomb lance.
97,693	*Rechtens*, Harpoon with bombs.
126,388	*Freeman*, Bomb harpoon.
171,553	*Cunningham*, Bomb lance.
201,793	*Kelleher*, Gun and bomb lance.
201,794	*Kelleher*, Bomb lance.
206,694	*Taylor*, Harpoon with expanding flukes.
211,777	*Pierce*, Harpoon gun.
211,778	*Pierce*, Bomb lance.
214,707	*Roys*, Bomb lance.
222,003	*Brand*, Bomb lance.

Har-poon' Gun. A small cannon, or a shoulder gun, for hurling harpoons or lances. See list, *supra.*

Har-poon' Shut'tle. (*Hydraulic Engineering.*) The standard tool for sewing mats for hydraulic dikes and jetties.

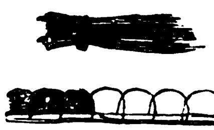
Fig. 1312.



Harpoon Shuttle.

Its weight is about 10 pounds. It is wound with 200 feet of No. 14 wire, and in operation is used by three men, two above and one below the mat. Two men pass the shuttle back and forth and around the pole in stitches 12″ to 18″ long, while a third tramps down the brush and holds the wire while the next stitch is being made. The shuttle may also be used in making an overhand or back stitch, the pole being omitted.

Fig. 1313.



Shuttle Fastening.

It was also the method employed in sewing to a wire; 2 shuttles were used in the harness-stitch, and a short shuttle in the chain stitch, and in combination with a hook needle it is used as a bobbin in making the lock-stitch. Of these methods the sewing to a wire and the lock-stitch turn the wire too short; the chain-stitch is of difficult manipulation, and the harness-stitch is expensive to make, and has great backslip when broken.

Har'ris-Cor'liss Engine. A form of Corliss engine. See Fig. 5666, p. 2341, "*Mech. Dict.*"

Engine works . . . . . * "*Sc. American*," xli. 175.

Har'row. (*Agric.*) An implement with teeth, lying flatly upon the ground, over which it is drawn to level the soil or cover seed.

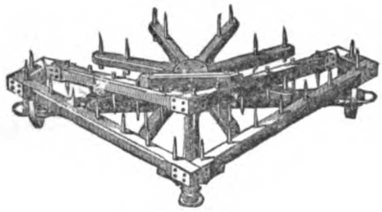
The following are shown on pp. 1067, 1068, "*Mech. Dict.*":

Brush harrow.	V-harrow.
Jointed harrow.	Double harrow.
Folding harrow.	Share harrow.
Rotary harrow.	Spiked-cylinder harrow.

See also *Chain* harrow, Fig. 589, p. 188, *supra*.
Disk harrow, Fig. 831, p. 261, *supra*.
Disking machine, Fig. 832, p. 261, *supra*.
Geddes harrow, Fig. 1194, p. 396, *supra*.

The "Penn" harrow is a Protean instrument consisting of a rotary portion revolving in a V-shaped section, and adapted to be used either single or double, and in various forms: (*a*) the rotary portion with one V, or (*b*) with two V's, forming a square; (*c*) upset and resting on its sled during removal from place to place (Fig. 1314); (*d*) the single V, or (*e*) the

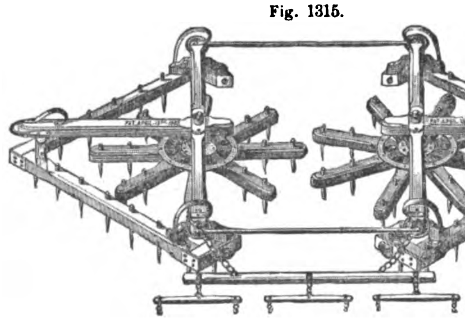
Fig. 1314.



"*Penn*" *Harrow*. (*In position to move on its sled.*)

double V, without the rotary; (*f*) the single V upset, the

Fig. 1315.



"*Penn*" *Harrow*. (*As a Gang.*)

three sled-bows acting as a corn-marker; (*g*) the complete tool (Fig. 1315) with the two V's and two rotary portions.

Fig. 1316 shows the Norwegian harrow. It is carried on

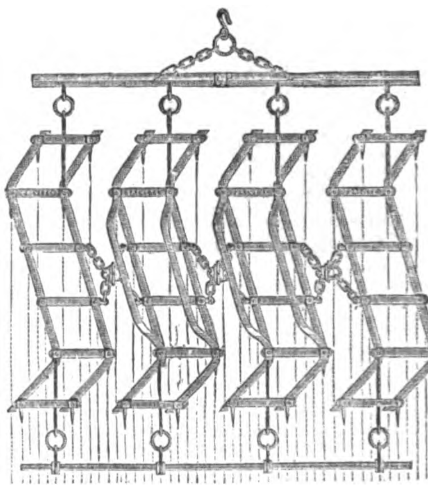
Norwegian Harrow.

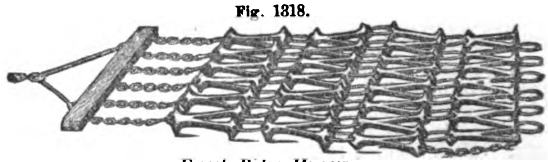
Fig. 1317.



French Articulated Harrow.

three wheels, by the forward one of which it is guided. It carries two spiked rollers, the depth of penetration of which is adjusted by means of a screw, operated by a crank from

Fig. 1318.



French Ridge Harrow.

the rear, the effect being to raise or lower the sleeve at the apex of the frame upon the pillar of the caster-wheel. The spikes are in fact star-disks, slipped upon an axial rod, and free to move thereon independently

The French articulated harrow (Puzenat, Bourbon-Lancy) has an equilibrium bar, and is made in jointed sections, from 3 to 6 in number, according to the breadth required. The arrangement of the teeth is such that with a given line of draft the surface of the ground is marked by equidistant lines. Fig. 1317.

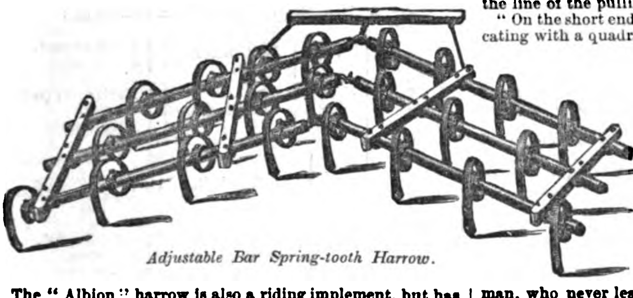
Fig. 1318 is the French *herse à billons* (*Souchou-Pinet à Langeais*), or ridge harrow; so called from its flexibility enabling it to lap over a ridge or upon the sides of a cleaning-out furrow; serving to break clods and level minor inequalities upon undulating ground. The *chain harrow*, Fig. 589, p. 188, *supra*, has the same adaptation.

Fig. 1319 shows the adjustable bar spring-tooth harrow, in which the teeth are permanently seated upon and coiled around the round bars of the frame; the bars being held in position by friction clamps, but adjustable therein so as to give the required presentation of the tooth to the soil, to regulate the depth of tilth. This without changing the position of the tooth on the bar. By rolling the bars to which the teeth are attached, forward or backward, the faces of the teeth are placed on an angle with the line of draft, by which they more readily scour, and also produce when at work a vibratory motion in addition to the coil motion, by which they more perfectly pulverize the soil, and free themselves from rubbish.

The two frames of the harrow are connected by a swivel coupling, so that the bars can be changed in either direction without affecting the working of the coupling.

Nishwitz, "Acme" pulverizing harrow is intended to combine the action of a clod-crusher, leveler, and harrow in one implement. A diagonal leveling bar runs upon the ground and carries at its rear edge a series of sword-shaped projecting colters. To the rear of the leveling bar is hinged another bar, from the rear of which projects another row of spring-steel colters, curved in form, beveled to an edge, and set at an angle with the line of draft and also at an angle with the horizon. A lever within reach of the driver (who rides) is held in position by a ratchet, and enables the operator to control the angular position of the crusher and at the same time raise or depress the colters on the hinged bar at the rear.

Fig. 1319.

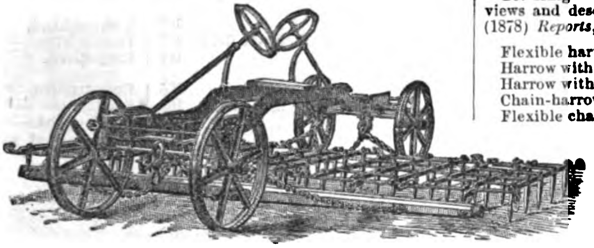


Adjustable Bar Spring-tooth Harrow.

The "Albion" harrow is also a riding implement, but has wheels and shafts. It has spring teeth depending from a bar jointed to the axle. These are curved like those of a horse-rake, but are flat, and their angle of presentation is adjustable to regulate the depth of penetration. This comes very closely to the class of cultivators.

In Europe, Britain and France especially, there is quite a variety of implements embraced in the general class of harrows, and used for cultivating or renewing the surface of ground. They may fairly be called harrows with handles, and are especially used for dragging out the twitch-grass which is such a nuisance in wheat-fields. See Fig. 1822.

Fig. 1320.



Steam Harrow.

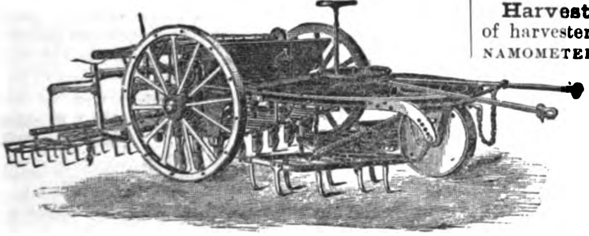
Figs. 1320 and 1321 show the adaptations of the harrow to steam cultivation.

The ordinary steam-harrow (Fig. 1320) covers a breadth of from 12′ to 18′, so that from 40 to 60 acres may be gone over in a day.

The harrow moves in either direction, and can be driven at high speed. The under frames can be removed and rollers or clod-crushers substituted for them.

The machine, Fig. 1321, has a light cultivator or heavy harrow in front of the seeding-colters and a light covering harrow following the same. The seed-drill itself, even of the largest width, requires but so small a fraction of the power of the engines, that it has been combined with the harrows. The drill has a width of 9′. In turning around, the heavy harrows are lifted by the power of the engine, and the whole implement moves at once on to new ground. The lifting and turning action is automatic.

Fig. 1321.



Steam Grain Drill and Harrow.

"The long end of a draft-bar or turning-lever is provided with two arms to which the two ends of the rope are attached. The arms are set at an angle for keeping the tail-rope clear of the implement. The lever itself is held by a vertical stud fixed to the frame considerably behind the steering-wheel. This position of the draft-stud gives the necessary liberty and power to the steering-wheel and enables it to lead the implement at almost any angle out of the line of the pulling-rope.

"On the short end of the turning-lever is a chain communicating with a quadrant on the crank-axle, and as the lever is pulled round, the chain, acting on the quadrant, turns the axle, lifts the frame, and raises the tines out of the ground.

"The plan of operation is as follows: As soon as the cultivator is brought up to the headland, the reverse pull brings the lever around, turns the quadrant, rotates the bent axle, and lifts the tines out of the ground, in which position the implement is held up by a catch; when lifted the required height, the lever strikes against a stop, and the implement turns into new ground. The man, who never leaves his seat, releases the catch, the tines drop into the ground, and the implement is re-drawn across the field." —*Knight's* "*Paris Exposition* (1878) *Reports*," * v., 85, 87.

Flexible chain-harrow .	*Howard*. England.

Har′row Cul′ti-va′tor. An implement like a harrow, but supported on wheels which limit the penetration of the tines. The distance apart of the tines suits the width of rows of the drilled crop. It is used in Europe in cultivating the intervals of drilled wheat, and in killing the weeds in summer fallows. The frame is vertically adjustable by means of the lever at the rear. (Fig. 1322.)

CLASSIFICATION OF HARVESTERS: BY STRUCTURE.

- **Connection of Cutting Apparatus with Frame.**
  - **Finger-bar rigidly connected.**
    - 1 To main frame.
    - 2 To hinged coupling frame.
    - 3 To vertically sliding frame.
    - 4 To flexible coupling arms.
  - **Finger bar hinged.**
    - 5 To arms rigid with main frame.
    - 6 To two arms; one rigid, the other jointed.
    - 7 To two arms, both jointed.
    - 8 To a single swiveled bar.
    - 9 To coupling frame jointed to main frame.
    - 10 To coupling frame jointed to secondary hinged frame.
    - 11 To coupling frame vibrating on main axle.
    - 12 To sliding arms.
    - 13 To pinioned shaft moving in vertical rack-ways.
  - **F.-bar reversible.**
    - 14 Endwise.
    - 15 Axially.
- **Model of Driving Cutter.**
  - 16 By simple gearing.
  - 17 By friction gearing.
  - 18 By planetary gearing.
  - 19 By gyrating gearing.
  - 20 By screw gearing.
  - 21 By changeable-speed gearing.
  - 22 By cams.
  - 23 By belts.
  - 24 By piston moved by compressed air.
- **Style of Cutters.**
  - **Reciprocating.**
    - **Rectilinear.**
      - Longitudinal.
        - 25 Single blade.
        - 26 Transversely divided blade.
        - 27 Double blades.
      - 28 Inclined.
      - 29 Transverse.
    - **Curvilinear.**
      - Longitudinal.
        - 30 Curved blade.
        - 31 Blade hung upon hinged arms.
        - 32 Series of pivoted knives.
      - 33 Inclined.
      - 34 Transverse.
  - **Rotary.**
    - 35 Cutters upon single vertical shaft.
    - 36 Cutters upon single horizontal shaft.
    - 37 Cutters upon series of vertical shafts.
    - 38 Cutters upon endless chain or belt.
    - 39 Cutters upon horizontal worm.
- **Style of finger-bar.**
  - 40 Stiff.
  - 41 Flexible.
- **Track Clearers.**
  - 42 Rigid.
  - Adjustable.
    - 43 Vertically.
    - 44 Horizontally.
  - 45 Vibrating.
  - Yielding.
    - 46 Vertically.
    - 47 Horizontally.
    - 48 Axially.
- **Dividers.**
  - 49 Rigid.
  - Yielding.
    - 50 Front to rear.
    - 51 Side to side.
    - 52 Up and down.
  - Adjustable.
    - 53 Vertically.
    - 54 Horizontally.
  - 55 Vibrating.
- **Draft.**
  - 56 Rigid with cutter frame.
  - **Jointed.**
    - 57 Upon main axle.
    - Upon cutter frame in rear of axle.
      - 58 Above.
      - 59 Below.
    - 60 Upon cutter frame in front of axle.
  - 61 Independent of tongue.
- **Discharge of grain.**
  - **Endless Apron.**
    - 62 Rear delivery.
    - Side delivery.
      - 63 On a level.
      - 64 Elevated.
  - Surface movement of platform.
    - 65 Rollers.
    - 66 Screw conveyors.
  - **Droppers.**
    - **Positive movement of platform.**
      - Tilting.
        - 67 To one side.
        - 68 To the rear.
      - 69 Swinging and tilting.
      - 70 Swinging.
      - 71 Revolving.
    - Receivers.
      - 72 Vibrating.
      - 73 Rotating.
      - 74 Dumping.
- **Automatic Rakers. — Stationary platform.**
  - **Operated from below platform.**
    - 75 Teeth upon endless belts or aprons.
    - 76 Teeth upon heads hung on belts.
    - Teeth upon reciprocating heads.
      - 77 Straight path.
      - 78 Curved path.
    - 79 Superposed heads on endless belt.
  - **Operated from above platform.**
    - **Reciprocating.**
      - Rectilinear.
        - 80 Front to rear.
        - 81 Side to side.
      - Curvilinear.
        - 82 Horizontal path.
        - 83 Vertical.
        - 84 Irregular.
    - **Rotary.**
      - Endless belt.
        - 85 Upon horizontal pulleys.
        - 86 Upon vertical pulleys.
      - About an axis.
        - 87 Horizontal.
        - 88 Vertical.
        - 89 Inclined.
  - 90 Reciprocating and rotary combined.
  - 91 Hand rakers.
- **Reels.**
  - 92 Revolving beaters on horizontal axis.
  - 93 Revolving beaters on vertical or inclined axis.
  - 94 Revolving beaters carried on endless belts.

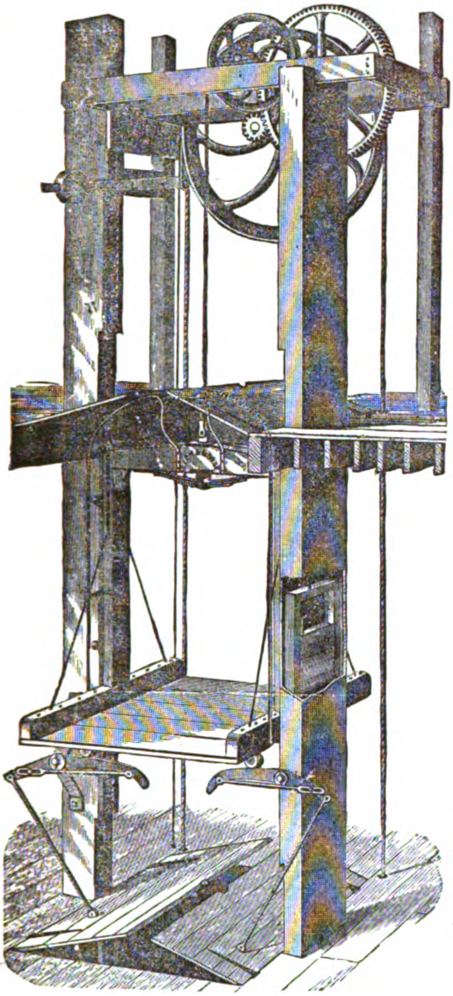
Hatch'way. The opening in a floor through which goods are lifted or lowered. Fig. 1323 shows automatic hatch doors in connection with a hand-

Fig. 1323.



Automatic Hatchway.

power elevator. The doors are always closed except while the platform is passing through, the platform in its ascent or descent opening the doors which close of themselves when the platform has passed. This is a guard against accidental falling down the hatchway, and also against the spread of fire by the elevator shaft. The rising rods lift the doors in ascending, and the platform actuates levers to lift the doors in descending.

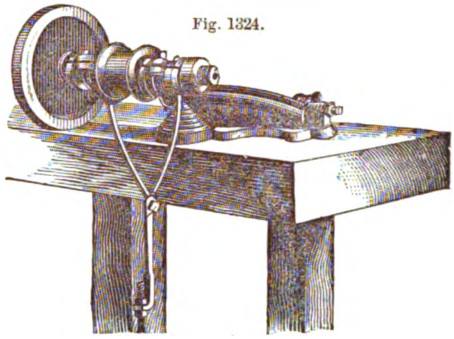
Hat-fin'ish-ing Lathe. A machine introduced by John T. Waring. It has a chuck fitted to a lathe spindle and carrying the hat, which, while rapidly revolving, is rubbed with sand or emery paper held against it. This is regarded as a very great advance in the art of hat-making machinery. Previous to this time the wool hat-body, after being sized, was rubbed with pumice-stone and then put on a block to be ironed off and touched up with sand-paper.

The finishing-lathe illustrated in Fig. 1324 is one of the forms yet in use, although in its first purpose, that of sand-papering hats, it has been superseded by later inventions. It

Fig. 1324.



Hat-finishing Lathe.

is now used to retouch the hat after it has been put on the finishing-block, and also to lay the nap with a piece of felt pressed by hand upon the surface while the hat upon the chucked block is revolving.

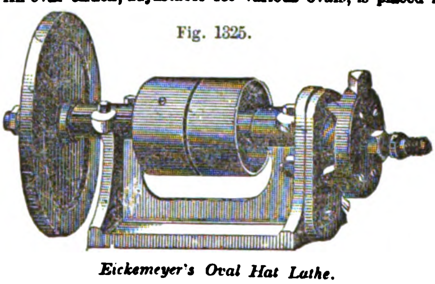
The spindle has its bearings in an adjustable frame which is held up by a helical spring. The lathe spindle is driven by a belt from a pulley above, and when the spindle is elevated by the spring, the loose belt slips on the spindle pulley. When the spindle is depressed by the foot of the operator on the treadle, the pulley is tightened against the belt, and the spindle receives rotation.

When wool hats came into more general use, oval blocks conforming more closely to the shape of the head took the place of the round blocks before in use, and this change made it necessary to use a lathe which turned in an oval path, to be able to finish the oval part of the side crown.

Fig 1325 shows the Eickemeyer oval hat lathe, the machine in most general use

An oval chuck, adjustable for various ovals, is placed in

Fig. 1325.



Eickemeyer's Oval Hat Lathe.

front of a lathe spindle, and is provided with a screw to receive the chuck in the hat-block, while an adjustable nut on the chucking screw is used to bring the hat-block into proper position to the oval.

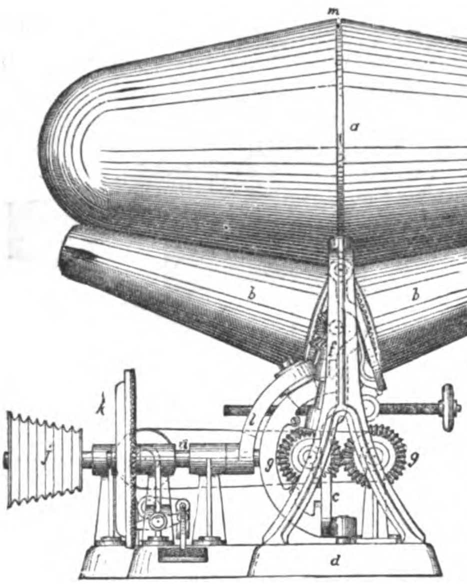
This lathe is used to finish the side crown and brim while the tip is still finished on a round lathe.

Hat-form'ing Ma-chine'. A machine for setting up hat-bodies. The wool and fur body machines are essentially different.

The first improvement in hat-making over the ancient hand processes was the hat-forming machine of Mason, followed by the patents of Grant. These machines consisted of a conical block upon which a web of wool was wound as fast as it was delivered from the carding machine.

Fig. 1326 is a front view of a wool hat former with a double cone upon which the web is wound. This double cone *a* is supported upon four conical rollers, *b*, two of which only are seen in the view. The rollers are pivoted upon a frame *c*, which is supported on a step in the bed-plate *d*, and is also pivoted on the upper end of the standard *f*. The pivot line of the frame *c* is coincident with the pitch line of the two bevel wheels *g g'*; it is at right angles with the crank-shaft *i*, and in a position close to the front of the double cone *a*.

Fig. 1326.



Wool Hat Forming Machine.

The cone pulley *j* is driven from the carding machine, and gives rotation through the gears *g g'* to the rollers *b b*, and thus to the double cone *a*. By means of a cone and pinion on a suitable countershaft, motion is given to the bevel-wheel *k*, shaft *i*, and crank *l*, which give to the supporting frame and forming cone a vibratory motion in a horizontal plane while the cone is revolving slowly on the rollers, the web from the carding machine winding on to the cone.

When a sufficient quantity of wool has been wound upon the double cone to make two hats, the *bat* is cut in two by the operator, who sets one blade of his shears into the equatorial groove which serves as a guide, and separates the two bodies while the cone is revolving.

It is of the utmost importance to lay the woolen web evenly upon the cone, and also to cross the wool fibers so as to make the hat body of equal strength in every direction; and it is also necessary to be able to adjust the supporting rollers to form cones of various shapes, and to adjust the speed to the different sizes of hats to be formed. All the woolen hat formers are therefore made adjustable in these various ways, and answer the requirements in greater or less degree, as the mechanism is more or less perfect.

The hat-forming machine for fur bodies is very different from that used for woolen bodies. Instead of a fine fleece from the carding machine wrapped upon a revolving former, the fur body former is a perforated cone with an interior exhaust blast and a fur picker which sends a fine cloud of hairs toward the cone on which they collect in a bat.

The machine is the invention of Henry A. Wells, who accomplished for the fur hat-body trade what Grant had previously done for the woolen hat-body. Wells's machine, improved by Taylor, Burr, St. John, and others, has disposed of the hatter's bow for ever. With an improved Wells machine 400 hat-bodies of superior quality can be made per day, and these, by dipping in a suitable bath, are made sufficiently firm to be sized into proper shape.

The machine is shown at Fig. 2431, p. 1075, "*Mech. Dict.*" As now used it consists of a feeding apron and a suitable picker which throws the fur upon a perforated cone.

The feeding apron and feeding rollers are upon a frame which furnishes also support for the bearings of the picker cylinder and the main driving shaft. A trunk or covered way is closely fitted to the frame and the cover which encloses the upper part of the picker cylinder. The trunk or conductor has a sectional shape corresponding somewhat with the shape of the former cone, and is adjustable in height by a supporting screw. The former cone is placed centrally upon a revolving table which has an opening in its center communicating with the inlet of the suction blower. The operator who weighs out the quantity of fur required for each hat-body places it evenly upon the feed apron, which is then started; the fur is delivered to the picker and guided by the conductor to the cone, where the fur is held by the pressure of air created by the fan which exhausts the air from the inside of the perforated cone.

When the fur for a hat has all been deposited upon the cone, a wet cloth is thrown over the tip, another cloth wrapped around the sides, and a hollow cap corresponding with the former cone is placed over the whole. The cone, with the hat-body thus held between it and the cap, is removed, another cone placed on the turning-table, and another hat-body formed as before.

To make the fibers adhere to each other the cone with its cover is then put upon a platform which is suspended by balancing weights over the dipping-tub, and is gradually submerged in hot water. The outer cone is now removed, the cloths taken off, and the hat-body slipped from the cone ready to be sized. To avoid the dipping of the hat-bodies, a sprinkling-pipe which blows hot water upon the revolving hat-body has been to some extent used, but with indifferent success, as more time is required to accomplish the object by the last-mentioned method, and the work of the machine is to this extent diminished.

Hat-li'ning Sew'ing-ma-chine'. A machine for sewing the sweat-leathers into hats; invented by Eickemeyer.

It differs from the ordinary sewing-machine in the arrangement of the work-plate, which is curved to receive and support the side crown on one of its faces while the brim is supported upon a narrow strip. In the presser-foot is a gage which guides the edge of the sweat-leather to the needle. The machine itself is pivoted to the table and can be turned around its driving shaft to enable it to be adjusted at the will of the operator in such a manner that the hat is held up without any further assistance after it has been put under the presser-foot.

The feed is an ordinary four motion which acts in the corner formed by the junction of the brim and side crown, while the presser-foot is of a right angular shape and presses upon the exterior of this angle. The hat is thus carried around, guided by the angle, which insures a perfectly even stitching of the sweat near the edge. In most cases the leather is stitched fast to the hat, leaving the stitches visible, while in other cases the edge is stitched fast and the sweat turned over to hide the stitches. By a change of the presser-foot either style can be sewed on the machine.

Fig. 1327.

Hat-sweat Sewing-machine.

To make a perfectly smooth edge on the sweat-leather where it touches the forehead, it is desirable to turn the edge of the sweat in a sweat-rolling machine, which is composed of two rollers geared together and supported in a frame, the upper one held down by a rubber spring to allow it to yield to the varying thicknesses of the leather. After the introduction of the hat-sweat sewing-machine, another improvement in the same direction, namely, a machine to make the hat linings, was invented by Eickemeyer, and improved by Judson. It consists of a table having a round or oval motion, upon which a piece of silk or other material to make the tip is secured, while another piece is put in a folding gage in such a way that the stitching will fasten the edge of the piece that forms the side crown in a circular or oval line to the flat tip.

Judson added to this attachment a pair of rotary shears, and arranged the turn table upon a swinging lever, which enabled him to trim the tips before the side crown was sewed fast.

The use of the pouncing machine has, however, done away with the necessity of lining the hat crown inside, both the outside and the inside being now pounced and presenting a smooth, finished surface.

Hat Ma'king. The manufacture of felt hats in the United States has, by the introduction of improved machinery and methods, reached a high degree of perfection and importance.

Fifty years ago the business was carried on in small establishments in towns and cities and in very small shops, even in villages. In the latter case the implements were almost as simple as those of the shoemaker, and a boss hatter, with one or two apprentices, made the hats for the surrounding district.

Wool and fur, with other hatters' supplies, were furnished by city merchants. The wool was simply carded, and the hatter, with his bow, shaped it into a hat body and then finished it.

The best machinery for making felt hats is of American origin and much of it has found its way into Europe, superintendents and workmen having come to this country to study the American method and become acquainted with the uses of the machines which have been exported to Europe.

This invasion of American machines reminds one of the complaints of the hatters of London, nearly 150 years since, in a memorial to the British Board of Trade, at the extent to which the manufacture of hats was carried on in New England and New York.

Beaver fur hats were formerly considered the best, but as that animal became scarce other furs were substituted for the body, which was covered with beaver fur on the outside. This mode of manufacture has now disappeared, and both soft and stiff felt hats are made of wool or of fur as two distinct branches of manufacture, which are carried on in different establishments and use almost entirely different machinery.

In the wool-hat factories are used all those machines which are ordinarily employed in cloth manufactories to prepare the wool for spinning; while the fur-hat factories have a set of special machines.

The hatter of 50 years ago laid the fur or wool, which had been previously prepared, on a hurdle made of wood or wire, with openings to let the dirt fall through. He then, by means of his bow, scattered the fur in all directions. The bow was usually made of ash, 6′ or 7′ long, with a catgut string stretched between the two ends. With a stick this string was caused to vibrate, and the fur driven from one end of the hurdle to the other. The layer of fur was called a *bat*, was made in a triangular shape, and formed one half of a hat body. It had to be carefully joined to another piece of the same shape, the edges overlapping each other, and the two portions, so united, with a cloth of the right shape between them, were patted on a hot-plate, while water was sprinkled upon them until the fur became partially felted and the cone-shaped hat-body had become tolerably firm.

The hat-body was now taken to the *battery* to be felted. This process consisted of rolling the body between cloths, continually changing its position in the cloth, while it was kept as hot as possible by dipping it into acidulated water kept boiling in the *sizing-kettle* by a small fire underneath. Special care was taken to shrink the hat body alike all over, and to reduce it from the size of a conical bag almost three times the dimensions of the finished hat-body. When the body was made of wool, and was to be *napped*, a cone of fur, bowed as described, was laid over it and wetted down with a brush until the fur adhered to the body firmly enough to continue the rolling between the sizing cloths, the body being kept hot by dipping it into the sizing liquor, as before, and this was continued until the loose fur had penetrated and formed a part of the body.

To give the hat-body its shape was the next operation, and this was also done on the battery. Having been thoroughly soaked in hot water, the operator laid the hat body on the plank which forms the margin of the battery, with that part of the body which was to form the brim turned up, and while turning it around on the plank pulled out the tip to form the flat portion of the hat crown. The body was now pulled on to a block of the size and shape of the finished hat crown, a cord slipped over the crown, and drawn tight at the junction of the side crown and the brim. In this condition the brim was pulled out flat and smoothed with a piece of metal called the *trencher*. While firmly secured on the block the hat was put in the coloring liquid, and after washing, trying, and stiffening, it was finished by carding the outside when a long, flowing nap was wanted, or it was rubbed over with pumice-stone, when a smooth finish was desired. After the trimming had been put on, the hat was ready for use. All the various manipulations were done by one man who had learned the hatters' trade; and the separation of these, and the division of the hat-makers into *makers*, *blockers*, and *finishers*, did not become general until the *forming* machines had come into general use.

The first improvement in hat making was made by Mason, whose wool hat-body former consisted of a conical block upon which the web of wool was wound as fast as it was delivered from the carding machine. This machine was improved by Grant. See Hat-forming Machine.

At about the period of the introduction of the wool-hat forming machine, the hat-body *hardening* machine, with reciprocating rubbing board, came into use in hat factories See Hardening Machine. It consists of a cloth-faced rubbing board, which is rapidly reciprocated upon a pile of hat-bodies lying flatly beneath it, each hat-body having within it a hard cloth, and a cloth also interposed between each body. The pile lies upon the perforated top of a steam box, so that the whole of them are kept saturated with hot steam.

Sometimes a special machine is used to harden the tips of hat-bodies. It consists of a rubbing board acting upon the top of a steam chamber of such shape that the hat-body can be slipped upon it after the sides of the body have been hardened in the ordinary machine.

Wells' machine, improved by *Taylor & Burr*, is described under Hat-forming Machine. It may be simply stated here in a general way that it consists of an apron to feed the fur, a picker cylinder to loosen and scatter it, and a perforated revolving former or cone, beneath which is an exhaust fan. The fur fed in regulated quantities is finely divided by the picker and sent whirling in the direction of the cone, upon which it collects as the air passes through the interstices and the hairs collect on the outside.

With the more extended use of the machine for forming fur hat-bodies, it became necessary to have better appliances to separate the fur from the hair and to prepare it for the former. This was accomplished in *Rotch's* fur-blowing machine, in which the fur and hair are separated and other impurities removed. This consists of a feeding apron, pickers, and a screen. The fur is presented by feed-rollers to the picker, which combs it out and scatters it, the lighter part into an upper chamber, and the heavier into a lower one, where a screen separates the tussocks of imperfectly treated matter from the hairs and dirt. The latter are removed while the former are passed back to be re-treated. See Fur-blowing Machine. Fig. 1112, p. 362, *supra*.

After the forming of hat-bodies, both fur and wool, had been successfully accomplished, the sizing or fulling of hats received the attention of inventors, and numerous attempts were made to full hats, but only a few machines proved of any value. James S. Gaylor, of Danbury, Conn., however, invented and patented a four-roller sizing machine which came into general use in wool-hat shops. The hat-bodies were rolled up in a piece of cloth and put between four rollers, which were placed in a hollow casing with their axes at an angle with each other. This position of the rollers caused the roll of hats, which was introduced into the machine at one end, to travel slowly along while turning between the rollers, two of which have, in addition to their rotary motion, a slight vibratory motion sideways, and thus the hats were slowly felted. As stated above, this machine was extensively used in wool-hat factories, but it was superseded finally by the fuller mill, which is now universally used.

The first successful attempt at fulling hat-bodies was in the factory of the Seamless Clothing Manufacturing Co., Matteawan, N. Y., where the manufacture of wool hats was commenced about 1860.

Various styles of mills are now in use. One will be found under Fulling Mill.

The batches of hats are placed in the bed of the machine, and are subjected to the blows of a beater driven by a crank, or to the pounding action of falling stocks, which are lifted by cams or trips, as the case may be. In some cases acidulated water is used in the bed to facilitate the felting, but generally fullers' soap is used. The fulling of hat-bodies in the mill is confined to hats of wool. Fur hats are sized on the battery.

Following in due sequence of history, we cannot omit noticing the advent of Kossuth in the United States, which made soft hats and flowing beards fashionable. The demand for soft fur and wool hats increased very rapidly, but the latter could not compete with the former until *T. Waring* introduced the hat-finishing lathe. Before this time the wool hat-body, after it had been sized, was rubbed off with pumice stone, and afterwards put on a block to be ironed off and touched up with sand-paper. Waring made the hat-block with a chuck which fitted to a lathe spindle, and the operator, while the hat was revolving rapidly on the lathe, held sand or emery-paper on the hat, and thus finished the hat. The advances made in the manufacture of wool hats date from the introduction of this improvement. Prior to this time wool hats were made of the lowest grades, and could not compete with fur hats, but, by the use of the finishing lathe, it became possible to give hats made of the finer grades of wool a finish closely assimilating the appearance of the lower grades of fur hats, and from this time the wool-hat trade began to rival the fur trade. See HAT-FINISHING LATHE.

Shortly after the introduction of the finishing lathe, sewing-machines were first introduced to put the lining on the brim of the hat. See HAT-LINING SEWING-MACHINE.

Consequent upon this came the hat-sweat rolling machine, which turns the edge of the leather sweat-lining in order to prevent its marking or hurting the forehead.

Next in order came a machine, invented by Eickmeyer and improved by Judson, to make the hat-lining. The tip is secured upon a table having a round or oval motion, while another piece is put in a folding gage in such a way that the stitching will fasten the edge of the piece that forms the side-crown in a circular or oval line to the flat tip. Judson added to this a pair of rotary trimming shears, and arranged the turn-table upon a swinging lever.

The pouncing machine, however, now finishes the insides of hats almost equal to the outsides, and crown-lining is almost discontinued in felt hats.

Another addition to the machinery in the manufacture of hats is that used to put the stiffening into the hat-bodies. To give the bodies a permanent shape, some stiffening material is generally put into the body; in the better class of hats a solution of shellac; in those of cheaper character, Irish moss, glue, etc. The solution is put into a trough under a pair of rollers which are geared together and driven by a belt from a line-shaft. Two troughs and two sets of rollers are generally mounted on one frame, one trough containing a thin solution into which the whole hat is plunged, and the surplus matter pressed out by passing up the hat-body between the rollers. The other trough contains a heavier solution into which is dipped that part only of the hat which is to form the brim. The troughs are heated by steam to keep the stiffening in a fluid state, and the hat-bodies, after being stiffened, are ready to be blocked.

Up to this time the hat-body is yet of a conical shape; *forming*, *hardening*, *fulling*, and *stiffening* have followed each other *seriatim*; this series is in the case of the wool hat-bodies only. It has been already explained that the operation with fur bodies is upon a special set of machines.

The blocking of the hat-body is that part of the manufacture in which the cone-shaped hat-body is pulled out around the edge to develop the brim, and the upper part is widened out to form the flat tip and the side-crown. This is described under BLOCKING MACHINE, pp. 109, 110, *supra*.

The machine of Fenn may be described in brief to have had two pairs of rollers, one pair traveling somewhat faster than the other. The edge of the conical hat-body being nipped between the rollers, the pair in advance pulled upon it faster than it passed through the hind pair and so stretched it. It was thus gradually flattened out so as to form a brim, but did not act upon the crown or tip, and as its action was slow and incomplete it only came into partial use.

The first complete machine for stretching hat-bodies, wool or fur, was the corrugation stretcher of Eickemeyer, and these machines, in various modifications to suit the different kinds of work, are now used almost exclusively in the hat factories of this country. Described and illustrated under BLOCKING MACHINE (Fig. 335, p. 109, *supra*), it need not be considered at length here. It has a ribbed and recessed former which rises vertically and pushes the hat-body into a cap which has a number of yielding levers corresponding in number with the recesses in the former. The edge-rollers on the ends of the levers push the felt into the recesses of the former and stretch it. This is repeated again and again, the hat being moved on the former between each operation. The brim and tip are thus developed.

Next in order comes the blocking machine to make the *band*, as the sharp angle formed by the junction of the brim and side-crown is known in the trade. This is done by a rising spindle which carries the hat on its block, in the first place against a clamping plate which holds the brim flat and then pushes the crown into a cylindrical banding shell whose lower edge forms the *band* or angle. See BLOCKING MACHINE, Fig. 337, *et seq*.

To adapt the principle of stretching by corrugation to fur hats a number of modifications were required. It was found advantageous to separate the *brim stretcher* from the *tip stretcher*, and to substitute round-edged bars for the round-edged rollers.

These machines are considered in their places. See BRIM STRETCHER, Fig 427, p. 135, *supra*; TIP STRETCHER, *infra*.

Eickemeyer's finishing blocking machine, known as a *hat-shaping machine*, is considered and illustrated under SHAPING MACHINE. The hat placed upon an expansible block (which has been previously contracted to its smallest diameter) and a circular series of 38 tongs is made to grasp ⅜" of the edge of the brim all round. The banding ring is thrown over the hat and locked fast. The edge of the brim being firmly held by the tongs, the operator raises the block and expands it to the desired size. The hat is then cooled and taken off, and the operation repeated on the next hat.

All the adjustments — size of band, height and diameter of crown, and width of brim — are made by gages attached to the different levers, so that the operator can set each part in a few moments, and all sizes of hats can be shaped on the same machine. A good operator will block from four to six dozen per hour. See SHAPING MACHINE.

The introduction of these machines for the stretching and blocking of hats has had a marked effect both upon the quality and facility of production of the hats so treated. When but imperfectly done, hats will in a short time lose their shape and "go to seed," as it is called in the trade, but when properly blocked on a machine, the felt is so well and equally stretched and shaped that the hat is much more durable.

Next in importance to the machine for blocking and shaping are the pouncing machines, for sand-papering the surface of the hat-body or the hat after it has been blocked.

The hat-finishing lathe, used in the wool-hat factories, was never successfully introduced in the fur-hat manufactories, owing to the fact that fur hats were usually made in small shops where power was not used, and also on account of the difference in the material.

The pouncing machines now in general use are constructed on two principles.

A rapidly rotating cutting or rubbing cylinder, which operates upon the hat-body or hat while it is fed along upon a yielding bed, is used in one class of machines. In the other class, a reciprocating motion is given to the cutting surfaces to rub in two directions.

For wool hats, and the lower grade of fur hats, the rotating cutter machines are exclusively used.

Under their own captions are described machines for pouncing hat-bodies, special machines for pouncing the brims, and for the crowns of the common grades of blocked hats, and also the reciprocating machine for the finer classes of felt hats. See POUNCING MACHINE.

The foregoing account comprises the most important machines used in the hat factories of the United States, but mention may be made of some machines used in the final finishing of the hat.

Joyce's hat-brushing machine is frequently used to remove the dust left in the hats by the pouncing machine.

Stewart's sewing-machine, adapted to sew ribbons on hats, has lately been extensively used in wool-hat factories.

Hydraulic presses to press hats into molds of proper shape, so extensively used in Europe, have not proved successful in this country, although a great many attempts have been made, and many machines patented by different inventors.

India-rubber blocks, made in the shape of the hat-block, have, however, been used in molds which surround the crowns only of the hats. See HAT PRESS.

Various styles of ironing machines are also in use, one of which is shown under IRONING MACHINE, which see.

But little improvement has been made in the finishing process of fur hats, and although many different machines have at times been used, and some with considerable success, none have been able to supersede hand labor. The use of the fulling mill to felt fur hats has also been frequently attempted, with but moderate success.

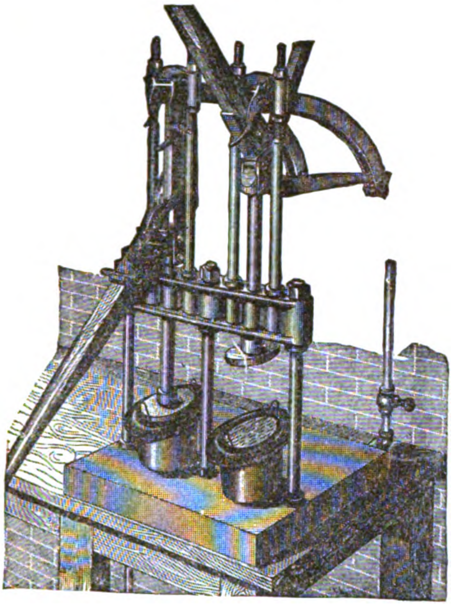
Hat Press. A machine in which pressure is brought against the inside of the hat to cause the latter to expand while hot and soft against the inside of a mold of the required shape.

Hydrulic presses are used in Europe for this purpose, but have not proved so satisfactory in the United States for some reason.

India-rubber blocks, however, made in the shape of the hat, are used in molds which surround the hat-crown only. Fig. 1328 is *Osterheld & Eickemeyer's* machine for that purpose. Three wrought-iron columns which support a cross-head are fitted into a metallic bed-plate, which is hollow and is heated by steam. A mold of brass of suitable shape is

Fig. 1328.



Hat Press.

put under a plunger operated by a hand-lever. When the mold is heated to a certain degree a hat is put into the mold, and a rubber die provided with two handles is placed inside the hat. The plunger, which has an oval flange fitting the mold loosely, is now lowered and by means of a toggle lever, which presses against the upper cross-head, the rubber is compressed, and thus the hat pressed against the hot mold. In the illustration one hat is shown as under pressure while the other is ready to press down the lever. The hat is left in this position for from 3 to 5 minutes, and it has, when removed, a smooth and glossy finish.

San Domingo mine, Spain	* "*Engineer*," xlvii. 316, 321.
Horizontal, *Tangye*, Br. .	* "*Engineer*," l. 103, 119.

Haul Seine. (*Fishing.*) A long net depending from a cork line and leaded at its lower depending edge, used to sweep large areas of water. The ends of the land line are carried ashore and being hauled upon the beach, the net assumes a V-shaped form; the bag of the net in the bend is the last to come ashore. See also SEINE.

Haul-up' Gear. 1. A portion of the saw-mill machinery devoted to drawing logs up from the yard or bay to be sawn.

2. Capstan or other machinery for hauling in the seine. Used on the Chesapeake and Potomac.

Hausse. A lifting breech-sight of a gun.

Figs. 1329, 1330, 1331, show that of the Mauser rifle, the piece adopted by the German government. It is short and at the same time adapted for long range firing.

It comprehends the following dispositions and range: —

Nick on the breech, 200 meters.

The small rear leaf lifted (Fig. 1329), 300 m.

The small leaf folded down and the forward *hausse* raised: the bottom nick (Fig. 1330), 400 meters.

The slider raised so that its lower end corresponds with figure "5" on the left, 500 meters.

Slipping to mark "6," 600 meters.

And so on up to "10" (Fig. 1331), 1,000 meters.

The sight then shifts to the upper opening in the slider, the latter being slipped down.

The bottom of the upper opening, 1,100 m.

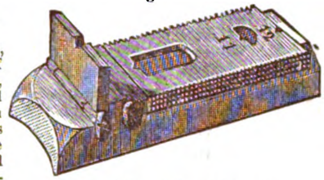
The top of the hausse, 1,200 meters.

The slider lifted to expose "13" on the right, 1,300 meters.

And so on up to "16" 1,600 meters, which is the position shown in Fig. 1331, which is shown as set for 1,000 or 1,600 meters, by using the lower or the higher notch, for the respective distances.

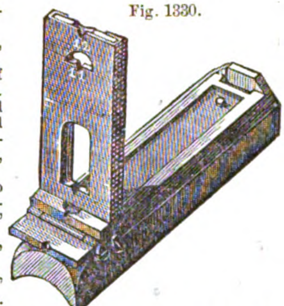
Other forms are given under SIGHT.

Fig. 1329.



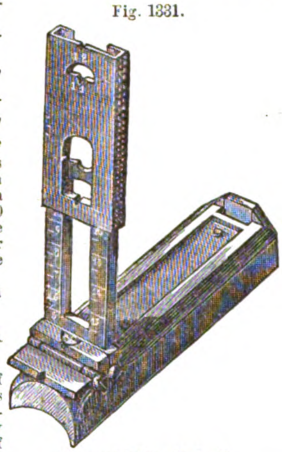
Hausse (Small Leaf Lifted).

Fig. 1330.



Hausse (Forward Hausse Raised).

Fig. 1331.



Hausse (Slider Raised).

Haw'ser. A cable.

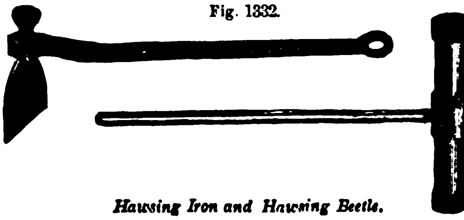
The steel hawsers of the large British ships of war are 8″ in circumference, doing the duty of hempen hawsers of 25″. 120 fathoms of 24″ hempen cable weighs 7 tons 16 cwt. 8″ wire cable 2.5 tons. The wire rope is equal in strength to a 25″ chain, the weight of which would be 16 tons.

Haw'ser Bend. (*Nautical.*) A kind of hitch shown at *l*, Fig. 2513, p. 1105, "*Mech. Dict.*"

Haw'ser Pipe. (*Nautical.*) A lining or bushing for a hawse-hole, through which passes the chain cable.

Haw'sing I'ron. A calking chisel.

Fig. 1332.



Hawsing Iron and Hawsing Beetle.

Haw'sing Mal'let. A hawsing beetle used with chisels, known as *irons*, in driving oakum into seams. Fig. 1332.

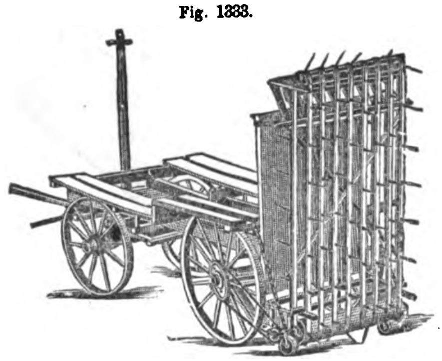
Hay Car'ri-er. A device used to suspend the horse hay-fork in a barn and travel along a bar to remove the load to a distant position, where it may be dropped. See Fig. 2449, p. 1081, "*Mech. Dict.*"

Hay Fork. (*Add.*) 3. A horse hay-fork for elevating large bunches of hay into a mow or on to a rick. See FORK, pp. 907, 908, "*Mech. Dict.*" HARPOON FORK, Fig. 2409, p. 1065, *Ibid.*

Hay Load'er. A rake with continuous elevator attached at the rear of a wagon and traveling along a windrow to load the hay on to the wagon. Foust's hay-loader is shown in Fig. 1333.

It has a wheeled frame attached by eye-bolts to the wagon and having an incline on which continuously travels a slatted

Fig. 1333.



Hay Loader.

belt having prongs which gather the hay collected by the rake. The belt is traversed by means of a sprocket wheel on the revolving axle of the trailing frame. See also Figs. 2456, 2458, p. 1083, "*Mech. Dict.*"

Hay Ma'ker. 1. An apparatus invented by Gibbs, and used in England for curing hay in catchy weather. It consists of a stove, fan, and a chute, through which the grass passes to be dried.

"A portable stove made of plate iron is surmounted by a fan, which is driven by a belt from a three-horse power portable steam engine; the fans draw all the heated air and gases from the coke fire together with a volume of warmed air, which passes through a chamber surrounding the inner chamber of the stove, and blows the hot current, at a temperature of 360° Fah. or more, into the dryer. This resembles in general shape a straw elevator, consisting of a sheet-iron trough 6' in breadth, 20' long, if mounted on wheels as a portable carriage, or 40' or 50' long, if a fixture. The trough is raised at one end at a low angle, so that hay fed in at the upper end furthest from the stove shall slowly travel to the lower end near the stove — this being assisted by a slow reciprocating motion given to the bottom of the trough. A ridge of triangular section running along the middle of the trough divides it into two almost semi-circular channels, so that the hay passes down in two streams; the hot air issues through two split apertures, one on each side the base of the middle ridge, and from the entire length of the machine; and the hay is kept continually stirred and lightened up over the hot blast by a number of small iron stirrers cleverly contrived to imitate the action of forks worked by hand."

2. A machine for stirring grass in the field, to expose it to sun and air. See HAY TEDDER, Fig. 2460, p. 1083, "*Mech. Dict.*," *et infra*.

Hay Press. The subject is considered under BALING PRESS, "*Mech. Dict.*," where the varieties are separately considered under captions derived from points of construction. See list under BALING PRESS, p. 218, *Ibid.* See also Fig. 183, p. 68, *supra*. Also *ration* press, Fig. 184, *Ibid.*

The hay presses of Dederick and Dodge make bales continuously, a compressed bale being tied and discharged while another is being formed.

The Dederick press has a plunger or piston, acting in connection with a reciprocating feeder, which drives a bunch of hay within the range of the plunger between each stroke of the latter.

In the Dodge machine the hay is thrown loosely on the feed-table or troughs in front of the press, whence iron teeth carry it right into the open mouth of the machine,

Fig. 1334.

Dodge Hay Press.

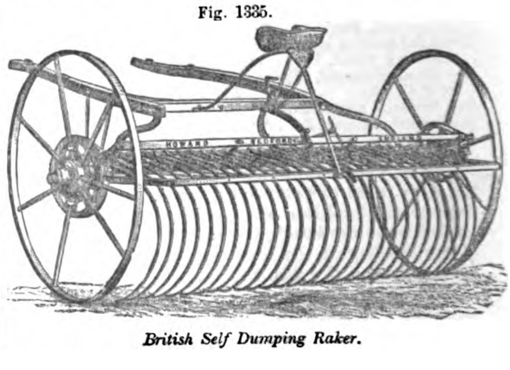
when it is seized by the revolving cones in the head-piece and drawn in from the feed-table in two continuous streams, and built up into a bale 26'' in diameter. The diameter of the bale is never increased, but the bale grows longer as layer after layer is built up. In doing this, the density of the bale is regulated by the friction-clutch, which has been previously made tight. After the bale is built such length as desired, the action of the compress-screw is brought into play by simply shifting one cog-wheel, and in a few seconds the bale is compressed endwise and shortened from about one fourth to one fifth its length without increasing its diameter. While the compression is going on, the man attending the press is passing around and fastening the two wires. When this is done, the pressure is released, the bale dropped out, and the press set for another bale.

Hay Rake. Various forms are shown in Figs. 2453–2458, pp. 1082, 1083, "*Mech. Dict.*"

The additional figure (1335) represents the Howard self-dumping riding horse-rake (Br.).

The wheels are of wrought iron and the teeth of fluted steel. When used as a riding rake the load is dumped by a foot-lever, which brings a friction-brake into action, causing the rake-head to make a portion of a revolution around

Fig. 1335.



British Self Dumping Raker.

the axle, tipping up the gang of rake-teeth and discharging the load. The clearer-rods, six in number, reach from the axle to the rear horizontal bar, on which the hind leg of the seat is supported.

When the operator is walking behind, the brake is operated by a hand-lever.

The self-dumping feature is also found in a large number of American horse hay-rakes, some of which use a clutch arrangement. In the French rake of Lhuillier, of Dijon, the same friction band is used, as just described.

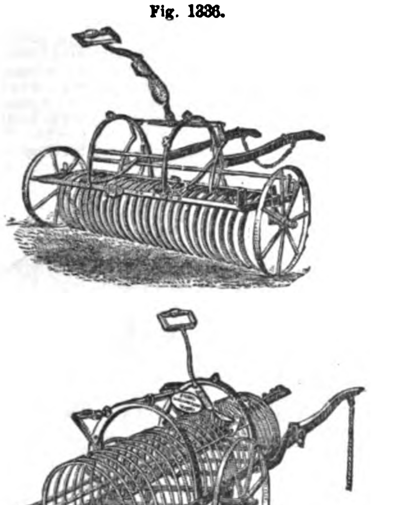
In some simple forms of American rakes the teeth are only operatable by hand lever, not using the draft power of the horse to dump the load. In one, the teeth are independent, and may be set any distance from the ground by slipping them endwise, each being held by its own jam-screw. They are thus set up for gleaning and set down for meadow work. This also admits of drawing the end teeth forward of those in the center, so as to gather the hay inward and prevent its scattering out at the ends. The upper end of each tooth plays upon a spiral spring, which allows the point to rise and pass an obstruction. It is operated by hand and foot lever.

A turning rake on a wheeled axle is made in England. The discharge is made by pressing a foot-lever at the right of the seat, when the tooth-axle is disengaged and the loaded rake revolves to the rear, discharging the load. Having accomplished half a revolution, the foot being removed from the lever, the other rake is arrested at its working position and the work is resumed. The absence of shock as the rakes fall into position is particularly urged as an advantage.

In France is made a reversible rake, in which the length of the rake can be thrown in line with the shafts to enable the machine to pass narrow gateways and doorways.

Fig. 1336 shows the two conditions.

Fig. 1336.



Reversible Rake.

Dr. Knight's report on Class 76 at the Paris Exposition of 1878, gives views and descriptions of the following. See "*Paris Exposition* (1878) *Reports*," vol. v., pp. 160-163.

Steam reaper. *Aveling & Porter*	England.
Horse rake. *C. Guilleux*	France.
Riding horse-rake. *Lhuillier*	France.
Self-dumping riding horse-rake. *Howard* .	England.
Walking hay-rake	England.
Turning rake. *Riches & Watts*	England.
Reversible horse-rake	England.
Hollingsworth horse-rake. *Dodd*	United States.
Double-acting hay-tedder. *Guilleux* . . .	France.
Hay tedder. *Howard*	England.

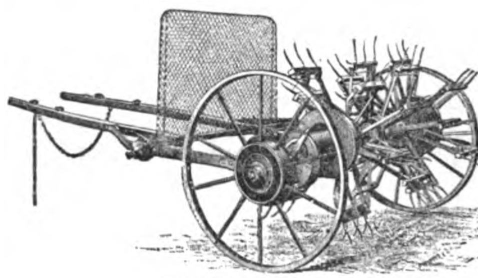
Hay Rope. Used in making large cores to wind about a core barrel before the application of loam. It permits the passage of the gases toward the perforated barrel, and as it carbonizes before the casting is cold, it facilitates the withdrawal of the barrel.

Hay Sweep. A form of rake for gathering hay, either from the windrow or the cock, to the place where it is to be stacked or ricked. It is quicker work than hauling by wagon, where the distance is small, and is used where hay is stacked in the meadow.

Hay Ted'der. An implement for stirring hay on the stubble to expose it to the sun and air and thus hasten curing.

Fig. 1337 shows the hay tedder built by Howard, of Bedford, England; the forks are disposed in zigzag order, four

Fig. 1337.

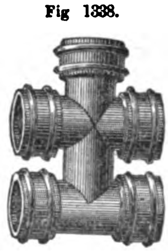


British Hay Tedder.

series of three teeth each, so that the work is practically uniform. The throwing in and out of gear is by means of a lever placed on the side out of danger of contact of the forks with the arm of the operator. The two systems of forks are regulated at such height from the ground as may suit the condition of the crop. The fork-heads revolve at a rapid rate, and the wire netting is to catch the hay and prevent it from covering the horse. By an eccentric movement of the main axle the rakes can be changed from a forward to a backward action, or *vice versa*.

Hay Un-load'er. A movable frame is placed on the wagon, and this is loaded in the field. Being drawn to the barn, tackles are secured to 4 eyebolts on the frame and the load elevated at one lift. When required to dump, the tackle at one side continues to lift, and so tips off the load.

Fig 1338.



H-Branch.

Ha'zel Hoe. A grubbing hoe for working in brush and bushes.

H-Branch. A main or pipe coupling having the form of the letter H, as in Fig. 1338.

H-Drill. A rock-drill, Fig. 1339, with a central and two end portions, resembling in section the letter H.

Head. (*Founding.*) Over the thickest part of heavy castings, a large *flow-gate* or *riser*, for the metal, is placed. Through this the contracting mass below is *fed* from time to time with hot metal, while a boy keeps the head open with a *feeding* or *working* rod.

Fig. 1339.

H-Drill.

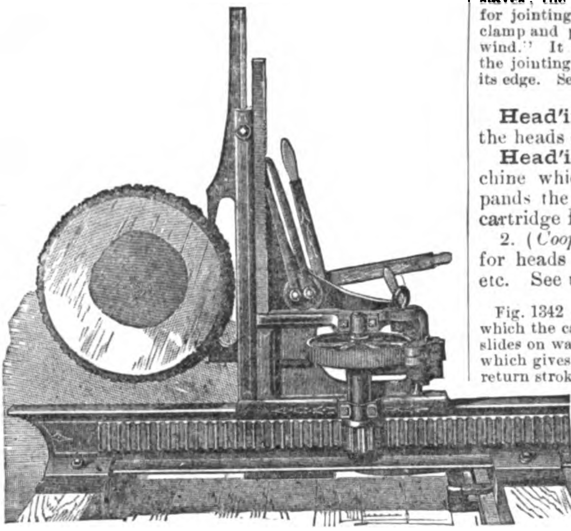
Head Axe. (*Whaling.*) For cutting off the head of the dead whale; opening the skull to obtain spermaceti; cutting off the baleen, etc.

Head Block. (*Saw-mill.*) A name which formerly signified the block which supported the head end of the log, while the tail-block supported the rear end.

Now, the device for holding the log upon the carriage while being sawn.

Gridley's head-block is shown in Fig. 1340. It exhibits a log hung up for sawing through and through, the boards being subsequently trimmed in the edger.

Fig. 1340.



Saw-mill Head-block.

Head-block. *Scofield* * "*Scientific American*," xxxviii. 291.

Head-block Plate. (*Carriage.*) An iron resting on the fore-axle and supporting the head block. It has projecting plates, one or two, for the attachment respectively of the single or double perch bars.

Head Dres'sing Ma-chine'. Used for leveling, facing, and smoothing barrel heads upon one side after the same have been jointed, doweled, and put together.

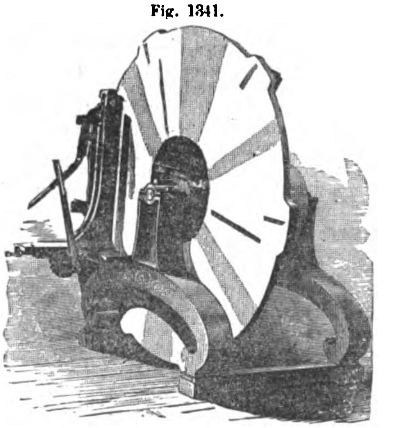
By passing the heads once through the machine they are fitted for the head rounder, and need no farther finishing. See Fig. 217, p. 77, *supra.*

Head Ear'ings. (*Nautical.*) The laniards to haul out the earings, which are ropes to fasten the upper corners of sails to their yards.

Head'ing. (*Mining.*) The vein above the drift.

Head'ing Chip'per. A machine for jointing head-staves. See HEADING JOINTER.

Fig. 1341.



Heading Jointer.

Head'ing Joint'er. A machine for planing the edges of pieces for heading.

On a heavy iron frame is mounted a large iron wheel in which are cutters for dressing and jointing the heading staves; the inner set of cutters for dressing and the outer for jointing. The piece of heading is locked in the sliding clamp and passed up to the cutters, which take it "out of wind." It is then taken from the clamp and placed upon the jointing rest, which gives a smooth and true surface to its edge. See also Fig. 218, p. 78, *supra.*

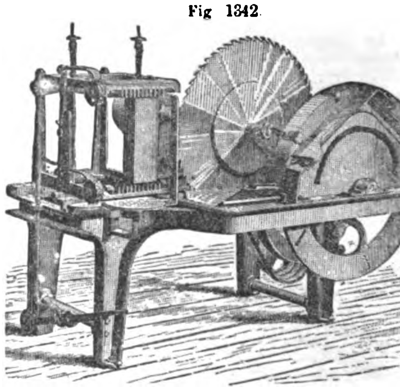
Head'ing Knife. (*Fishing.*) For cutting off the heads of halibut and other large fish.

Head'ing Ma-chine'. 1. (*Cartridge.*) A machine which presses the cartridge shell and expands the head to form a flange, which keeps the cartridge from slipping into the barrel.

2. (*Coopering.*) A machine for getting out stuff for heads of casks or barrels; dressing, turning, etc. See under various heads.

Fig. 1342 shows Lane's heading machine and jointer, in which the carriage, carrying the balk of wood to be sawn, slides on ways, and is moved by a compound crank motion, which gives a relatively slow forward motion and a quick return stroke. The feed works are driven by a single belt running from a cone pulley on the saw mandrel to a corresponding pulley on a counter-shaft carrying a paper friction pulley that in turn drives the iron friction pulley of the compound crank. The length of the stroke can be varied according to the width of the heading or shingles. The performance is 40 cuts per minute. The blocks are held in a perpendicular position and are set toward the saw between toothed rollers, the saw cutting into the side of the block. In front of the carriage is a round plate or table on which to rest the block while taking out the slab. Attached to this horizontal and partly revolving plate are the shipper handle, for starting and stopping the carriage, and an upright guard of wrought iron, that swings around in front of the saw whenever the carriage is at rest. The upper roll is raised by a treadle, enabling the operator to use both hands in taking out slabs and putting in new blocks. The saw mandrel is made of $2\frac{1}{4}''$ steel, with long bearings the full

Fig 1342.



Heading Machine.

size of the mandrel. The set rolls are adjustable to take in blocks from 11″ to 20″ long. The block is set while the carriage is moving about 1″ in passing the dead center. The iron box for catching the shingles is adjustable to the saw by screws and springs, so that should a splinter wedge between the saw and box, the box will spring away and let it pass through. A wheel-jointer, 40″ in diameter, is attached to the machine in such a position that the sawyer can stand at the saw and joint the shingles without turning his body. The jointer has two places for jointing, so that two persons can work at the same time, and it can be detached from the machine, and set in some other place, if desired. The jointer wheel is covered with an iron case, so as to prevent injury to the hands of workmen, and at the same time keep the shavings from flying.

Greenwood . . . . * "*Man. & Builder*," xi. 55.
Dressing machine, *Holmes* . . * "*Engineer*," xli. 430.
Turner, *Holmes* . . . . . * "*Engineer*," xli. 431.

Head'ing Pla'ner. 1. A machine for dressing down heads of casks, barrels, etc. See Fig. 217, p. 77, *supra.*

2. A small form of planing machine for dressing head staves, or made-up heading. See also STAVE DRESSER, p. 2314, "*Mech. Dict.*"

Head'ings. (*Mining.*) In placer mining, the mass of gravel above the head of the sluice.

Fig. 1343.

Head Light.

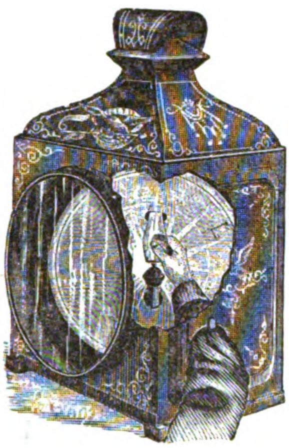
Head'ing Saw. 1. A stave saw. One for sawing head staves from the log or bulk. See STAVE CUTTER, p. 2313, "*Mech. Dict.*"

2. A saw for trimming heads to circular form. Fig. 219, p. 78, *supra.*

Head Knife. (*Whaling.*) For cutting off the head of the whale.

Head Light. In the locomotive head-light, Figs. 1343, 1344, the reflector, oil tank, burner, etc., rest on a revolving table of cast iron, and the engineer is enabled to clean both reflector and glass without removing the slide. The burner, being screwed to the oil chamber, can be removed without unsoldering and repairs made without sending the lamp to the shop.

Fig. 1344.



Locomotive Head Light.

Head Li'ning. (*Railway.*) The enameled ceiling-cloth of a car.

Head Ma-chin'e-ry. See HEADING MACHINE and cognate captions.

Head Rest. 1. (*Surgical.*) *a.* Used in torticollis, Fig. 6567, p. 2603, "*Mech. Dict.*" *b.* A tripod head-rest is used in post-mortem operations.

2. A support for the head on chairs used by dentists, photographers, barbers, etc.

Head Round'er. See BARREL-HEAD ROUNDER, Fig. 219, p. 78, *supra.*

Head Sheet. (*Nautical.*) A sail before the mast, or the foremast, in case of those vessels having more than one mast.

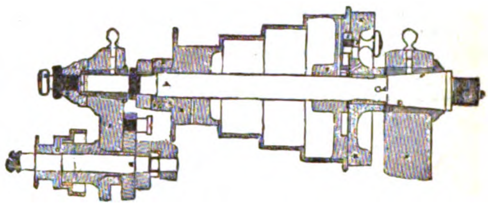
Head Spade. (*Whaling.*) Used in cutting off the head of the whale.

Head'stock. 1. That part of the lathe which carries the live spindle on which the work is chucked.

Fig. 1345 is offered as a specimen of good practice.

"The spindle *A A* is of hardened cast steel, ground perfectly cylindrical, *after having been hardened*, to avoid danger of change of form in the process of hardening, to secure absolute truth in size and shape, and to obtain perfect smoothness and the desired hardness. The box *B*, carrying this spindle, is subjected to all the strain thrown upon the latter, whether by the weight of the piece or by the force exerted by the tool. Here it is made of a single piece of steel, fitted approximately to finished size, hardened, and finally ground to exact form and to fit. The spindle bearing, *C C*, where it turns in the box, is conical, and capable of adjustment longitudinally, to take up the looseness occasioned by the wear, which takes place even with hardened steel journals running in hardened steel bearings. End-play is prevented by the nut *D D* and the set screw *E E*, which hold the spindle snugly in a position such that it may turn freely without either side or end-play. The back-end of the spindle is carried in the journal *F*, its box being held by the cap-screw *G G*. The cone-pulley *H H* turns loosely on the spindle when the back-gear is in action, and is clamped by the sliding-block *I* and screw *J*, when the spindle and the cone are to move together, the cone driving the gear *K K* directly, and the latter carrying the spindle, to which it is secured by keys. The pinion *L L*, on the cone-pulley, drives the back-gear. A spindle, *M M*, carried on the rear plate of the head-stock *N N*, carries the feed-cone pulley *O*. The belt-cone *H H* and the back-gearing are given broad bearings." — *Prof. Thurston.*

Fig. 1345



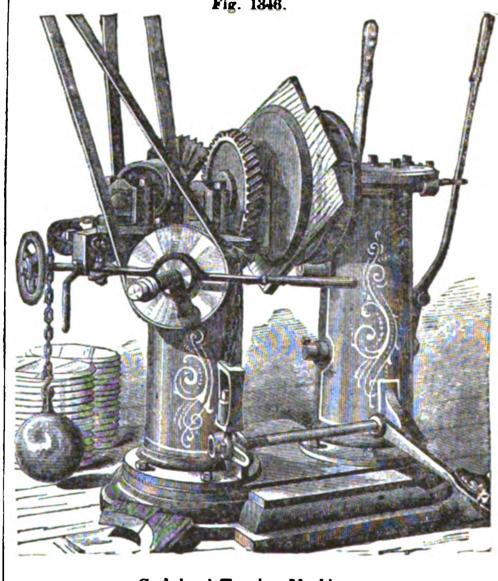
Lathe Spindle and Headstock. (*Worcester Free Institute.*)

2. (*Spinning.*) The stationary portion of a mule, containing the mechanism for effecting the different changes necessary in spinning. The other stationary portions are the creels for the bobbins and the rollers and roller-frames for reducing the thickness of sliver. See MULE.

Head Turn'er. A machine for rounding and beveling barrel-heads. Fig. 1346 shows a machine made by Holmes.

Before the unfinished head is put into the machine to be rounded, its center is found and marked by an apparatus for that purpose. When the head is put into the machine, the centering pin, which is jointed to the hand-lever beside the standard, is pushed forward by the use of the lever, and is brought in contact with the center mark on the head, thus centering it between two disks, one of which, that on the right in the illustration, is provided with a number of spring

Fig. 1346.



Cask-head Turning Machine.

pins near its periphery, which press the work against the opposite disk. The pin-disk is not connected with the driving machinery. Its spindle enters the standard on the right, in which is placed apparatus by means of which the disk is thrown forward and locked in that position, firmly holding the work. Through the rotation of the opposite disk, the pin-disk is also carried around, but for only one revolution, at the end of which stop-mechanism, in rear of the standard and not shown in the engraving, is actuated to unlock the clamp, so that the pin-disk springs back and allows the work to fall out. The disk on the left is rotated by mechanism by the driving pulley, which is thrown into or out of gear by the horizontal handle shown.

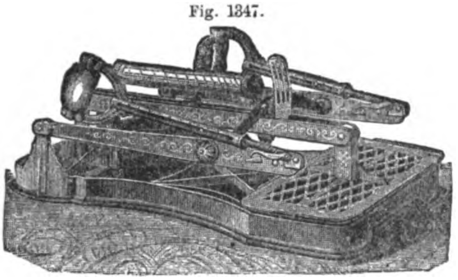
It will make round or oval heads. See also Fig 219, p. 78, *supra*. A French form is shown at BARREL-HEAD TURNING AND BEVELING MACHINE. Fig. 220, p. 78, *supra*.

Health Lift. A machine in which the patient or exerciser lifts upon handles against a graduatable weight or spring.

It originated with Dr. Windship, who devised a system of graduated yoke-lifting. Several forms have been devised: the dead-weight center-lift, the side-lift or reactionary.

The *Mann* reactionary lifter, shown in Fig. 1347, is adjustable from a power of 20 lbs. to 1,200 lbs. The handles are at

Fig. 1347.



Reactionary Lifter.

the side, and fall down to secure compactness of the machine. It has a series of compound levers lifting against the weight of the operator.

The *Marsh* and *Knight* health-lifts have an elastic resistance which reaches its maximum at the end of the lift when the knees are about straight. See also Figs. 2929–2930, p. 1306, "*Mech. Dict.*"

Hearth. (*Metallurgy.*) 1. A form of furnace in which malleable iron is obtained by direct process from the ore. A form of BLOMARY, which see.

2. An open hearth furnace in which pig iron is converted into malleable iron. The *open hearth* is in contradistinction to the reverberatory, which is domed in. The process in each is the same, it being to expose the melted iron to air to oxidize the silicon, manganese, carbon, phosphorus, sulphur, etc., present as impurities. In the hearth process the *blast* of air is driven upon the surface of the iron by inclined tuyeres in the side of the hearth, the iron gradually loses its impurities and is converted into a loup which is carried to the hammer or squeezer. The Walloon, Franche-Comté, and Lancashire are all modified forms of this idea.

3. The lowest part of a blast-furnace, generally cylindrical. It is lined with fire-brick, and the part below the tuyeres is the *crucible*, in which the iron and slag accumulate. The prolongation of the hearth towards the front of the furnace is the *forehearth*. The inclosure is the *dam*, covered by the *tymp-arch*. See Fig. 704, p. 293, "*Mech. Dict.*"

4. A form of steel furnace as distinct from the Bessemer convertor process. See OPEN-HEARTH FURNACE.

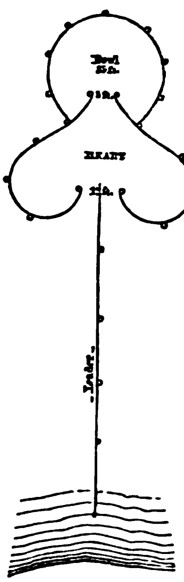
Heart. 1. (*Fishing.*) A net inclosure, into which fish are conducted by the leader, and from which they pass to an inner inclosure known as the *pound, bowl, pot,* etc. Fig. 1348. See POUND NET.

2. (*Nautical.*) A dead-eye with but one eye, and having scores for a lanyard.

Heart Net. (*Fishing.*) A net with a *leader* and a *bowl* or *pound*, between which is a heart-shaped funnel. See POUND NET.

Heart Seine. (*Fishing.*) A species of seine, with a leader, heart, and pound secured by stakes so that the upper edge is floated at the surface and the lower touches bottom.

Fig 1348



Heart Seine

Heat'er. A name applied to a stove or furnace arranged to effect the warming by convection, as with warm air, steam, hot water.

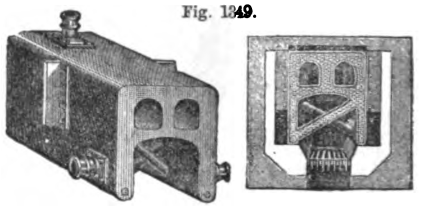
The *stove*, contrariwise, heats by radiation.

The term heater is a very inclusive one, and the subject is considered under various heads. See the list under HEATING AND LIGHTING APPLIANCES, p. 1309. and also STOVE, pp. 2409, 2410, "*Mech. Dict.*" Also list, p. 453, *infra*.

See also MAGAZINE STOVE, Figs. 5914–5922, p. 2411, "*Mech. Dict.*," and VENTILATING STOVE, Fig. 5909, p. 2410, *Ibid.*

The French furnace shown in Fig. 1349 is designed for domestic purposes and for conservatories, to be heated by circulation of hot-water pipes. The boiler is in rolled sheet-metal with riveted joints, and contains

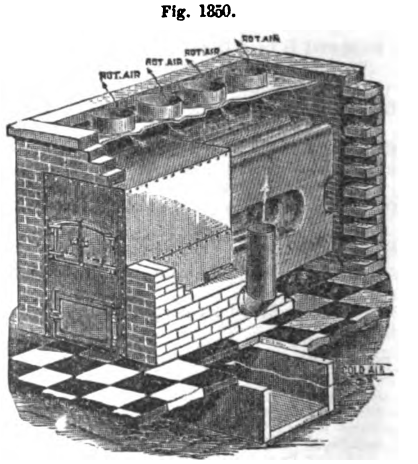
Fig. 1349.



French Green-house Heater.

the furnace, ash-pit, water-legs, and the longitudinal return flues. The boiler is in a brick structure, a space be-

Fig. 1350.



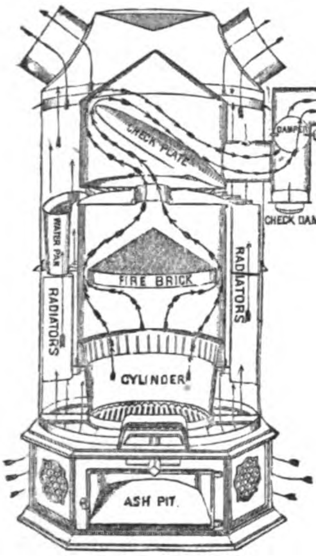
"*Simplex*" *Hot-air Heater.*

tween the two forming the re-return flue to the chimney. The water connections are shown in the perspective view.

Fig. 1350 shows Chase's "Simplex" furnace, in which the heating surface is a rectangular box, made of sheet-iron 1-10″ thick, and riveted. Its size for domestic purposes is 50 × 33″, height 52″ and heating surface 83 square feet. The top and bottom are of single plates, bent so as to rivet to the side sheets. The fire-box occupies a position in the boiler, being lined with fire-tiles, and so supported as not to touch the heating surface.

Fig. 1351 is a sectional view of what is known as a portable heater, from the fact that it is removable as a whole,

Fig. 1351.



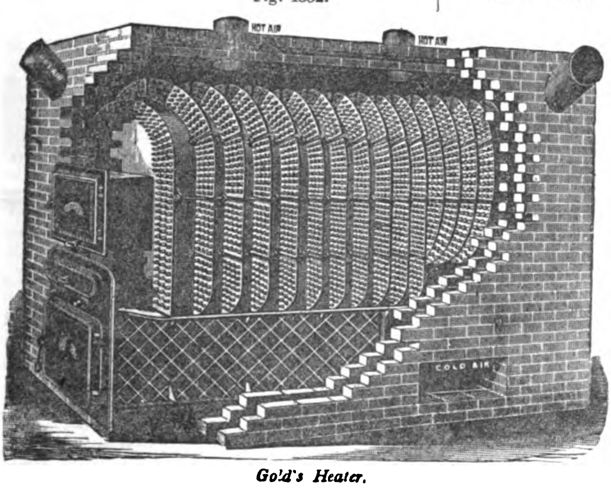
Air-tight Heater.

the brick erection forming no part of the arrangement. It has a riveted sheet-metal case.

The various parts are indicated in the figure. The flame spreads around a fire-brick which is suspended over the fire, passing through a ⅜″ space; thence to the radiator over the fire-brick, a check-plate causing it to make the circuit of the chamber before exit. Between the outer casing and the body of the heater is an annular space with corrugated lining, against which impinges the upward current of air, which is heated by contact therewith.

Fig. 1352 shows Gold's heater, which has a riveted plate-iron cylinder covered with points which greatly increase the radiating surface. Around it is a chamber of brick, inside of which and around the stove the air circulates.

Fig. 1352.



Gold's Heater.

Heat'er Cock. See Jet Valve.

Heat'er Coil. A prolonged pipe containing steam or hot water, and conducted through apartments or passages to heat them.

Coils assume many different shapes. A list may be found at Coil, on p. 207, *supra*.

Heat'ing Ap'pa-ra'tus. It has been proposed to supply heat to domiciles and factories by mains and pipes, as in the manner familiar with water and gas.

The following is the proposition, now in course of fulfillment: —

From the central station the mains will run through every street. One line of iron pipes from 3″ to 6″ in diameter, placed about 3′ below the pavement, packed around with some non-conducting material and inclosed in a wooden box, will be the conducting mains from which the hot water will be carried by means of smaller iron pipes, ½″ to 1″ in diameter, into the houses. Auxiliary or return pipes of about the same size as the conducting mains, will be laid alongside, through which the water, after it has passed through the houses, will run back to the reservoir.

The water heated in the reservoir to from 350° to 400° Fah., will be forced out through the conducting mains, and through the pipes which connect with the houses, and to each connecting pipe will be attached a water meter. The return pipe will also be provided with a water meter. Each house is to be provided with a steam convertor, which in general terms is simply a small metal chamber inclosed in a larger chamber. The water leaves the reservoir at about 400° Fah., and as soon as it enters the inner chamber it will expand into steam. The chamber is so constructed that a pressure of ten pounds will close a valve and shut off the supply of water. The steam will force its way through a valve into the outer chamber, whence it can be conducted through steam pipes to any part of the house and used for heating, cooking, or power, and returned through the auxiliary pipe back to the reservoir.

The steam cooking ovens are coils of pipe through which the steam passes inside of the ovens. Some of the steam will be condensed in the bottom of the convertor, and can be drawn off and used as hot water.

The system as pursued by Holly has an expansion junction service-box at intervals of 100′ to 200′ to provide for contraction and expansion of the mains, and from this box service-pipes are carried to the houses to be heated. A regulator is at each house and the steam used by each consumer makes its own record upon a slip of paper moved by the clock-work of the meter. The pencil-mark denotes the quantity of steam used, and the time of day at which each radiator in the house was put on or off.

Heat'ing Fur'nace. The term *heating* furnace may be held to include the whole range of furnaces, a list of which is given on page 926, "*Mech. Dict.*," and another, p. 362, *supra*.

The *Gas-producing furnace* and *Regenerator Furnace* have usually features in common, although the regenerator is not a necessary concomitant of the method of using the fuel shown in GAS-GENERATING FURNACE, pp. 384-388, *supra*.

See also HEATER, and list under HEATING APPARATUS.

Heat'ing Pan. (*Oil.*) A pan for heating flax or other seed which yields oil by expression.

The pan has a steam bottom for heating by steam. Horizontal stirrers driven by vertical shafts, and balanced so that they can be lifted clear for charging or discharging, keep the charge continually stirred. A gate is provided to each pan, through which the charge is drawn. The seed, after having been heated, is filled into bags, which are placed separately between horse-hair bags, covered with leather. The same kind of bags and hair are used whether the oil is expressed by stampers, screws, or hydraulic presses.

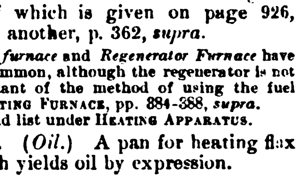
Other forms of pans for use in various other industries: sugar, confections, etc., are found under their appropriate heads in the "*Mech. Dict.*," and herein. See EVAPORATING PAN; CONFECTION PAN; VACUUM PAN; CLAY HEATER; DESSICATOR; DRIP PAN; FRUIT DRYER, etc.

Hea'ton Steel. (*Metallurgy*) Steel produced by air-blast through molten pig-iron; crude nitrate of soda, with other material, being used. See p. 2365, "*Mech. Dict.*"

Hea'ver. 1. A bar used as a lever.

2. (*Nautical.*) The tool, Fig. 1353, used by the sail-maker and sailor in marling, serving, etc.

Fig. 1353.



Sail-maker's Heaver.

Hec'to-graph. A process of dry-copying of writings or plans by reversing the freshly-written copy upon a gelatine film and subsequently applying clear sheets *seriatim* to the gelatine. See COPYGRAPH; COPYING PENCIL; and GELATINE PROCESS, *supra*.

Hed'dles. The cords governing the disposition of the warp-threads in the tissue.

See, for disposition of heddles and harness for various kinds of weaving, article "*Tissage*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," iii., ed. 1877.

Heel-spring, *Pease* . * "*Scientific American*," xl. 36.

Heel Plate. (*Fire-arm.*) The solid or skeleton plate at the butt-end of the stock. Sometimes the top and bottom are merely tipped.

Hel'i-cal Nee'dle. (*Surgical.*) A needle with a helically twisted stem to introduce a ligature around an artery or in case of ruptured perineum.

Hel'i-cal Tank Coil. A steam or hot-water heating coil of helical or flat-spiral form

He'li-o-gra'vure. The systems of heliogravure, or sun-engraving upon copper, as employed in the Austrian Military Geographical Institute, are thus referred to in *Petermann's "Mittheilungen"*: —

"The sheets of the new Austrian Ordnance map are carefully drawn on paper, on a scale of 1 : 60,000. They are then reduced photographically to a scale of 1 : 75,000, transferred upon copper, touched up, and printed. In this manner each sheet of the map can be produced in nine months, while the same amount of work engraved in the usual manner requires nearly 46 months for its completion. The whole of the Austrian staff map, consisting of 715 sheets, will thus be completed in 10, 11, or 12 years. No less than 271 have been published since 1874. The advantages of this process, as regards cost and rapidity of publication, are evident, and they fully compensate for any slight inferiority in the appearance of the work."

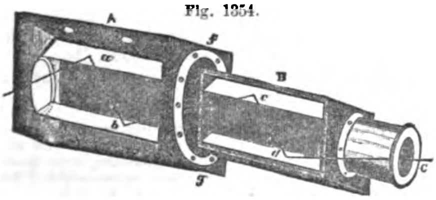
See also Heliotype, p. 1097, "*Mech. Dict.*"

He'li-o-scope. An instrument for viewing the sun.

The instrument shown in Fig. 1354 is the invention of Herr Merz, of Munich.

It is based on the law of polarization of light. If a ray of light strikes at an angle of 35° 25′ on a mirror which is mounted so that it may be turned on its axis, and the reflected ray is thrown on a second mirror placed at right an-

Fig. 1354.



Merz Helioscope.

gles to the first, the light is polarized. The polarized ray is perfectly bright if the two mirrors are parallel, but it becomes more and more faint when the upper mirror is turned, until at a right angle it disappears altogether, so that the field of vision in the second mirror is perfectly dark

In the two cases, *A* and *B* of the apparatus, are mounted four heavy mirror glasses, *a*, *b*, *c*, and *d*. The case *A* is screwed to the telescope through which the sun is to be observed. The light falls on the first mirror at an angle of 35° 25′, and is reflected to the second, from whence, by means of the mirrors *c* and *d* in the case *B*, it reaches the eye of the observer at *C*.

To effect the necessary diminution of the sun's light, the case *B* is arranged so that it may be turned around the axis of the apparatus by the ring *f g*. When the mirrors in case *B* are parallel to those in *A*, the image of the sun appears perfectly white, but the light can easily be diminished to any desired degree by simply turning the case *B*, which can be done without removing the eye from the ocular lens.

To prevent the air in the apparatus from becoming heated too much, the upper side of the case *A* is provided with a couple of holes for ventilation.

A simpler arrangement by Dr. Van der Weyde is described by him as follows: —

"I take a piece of plate glass of the same width as the diameter of the objective, and about three times as long, ground at the back so as to destroy the exterior reflection of that surface, and coat it with black varnish. I attach this before the objective under an angle of 35° 25′ with the axis of the telescope, so that the solar rays entering the instrument are polarized by the reflection of the polished surface. To the eye-piece I simply attach as analyzer a Nicol prism, and by turning the latter round its axis I reduce the intensity of the solar light to any degree desired."

Refer to "*Scientific American*," * xxxviii. 163, 186; xlii. 389.

He'li-o-tel'lus. An orrery embracing the sun and earth in its scheme. — *Hommatt*.

See also Geoscope; Orrery; Cosmoscope, etc.

He'li-o-trope. A geodetical instrument used to reflect a ray of light to a distant station. First adopted in surveying about 1821, by Gauss, a Hanoverian, for the purpose of rendering the vertices of the triangles visible in the triangulation of the kingdom of Hanover. Capt. Drummond's heliostat was used in the ordnance survey of Great Britain.

As now used, it is a stand bearing a 10″ mirror, swung like the ordinary toilet looking-glass, except that besides swinging horizontally, it is also pivoted, so as to move vertically as well. Behind the mirror, in the very center, a little of the quicksilver has been removed, so that the observer can go behind his instrument and look through a tiny hole in it toward the station he desires to signal. Having sighted the station by adjusting the mirror, he next proceeds to set up in front of the heliotrope a rod, and upon this rod is a movable stud. This stud is manipulated like the foresight of a rifle, and the observer, again standing behind his instrument, directs the adjustment of this stud until the hole in the mirror, the stud, and the distant station are in a line. The heliotrope is then ready to work, and in order to flash signals so that they can be seen at a distance, the operator takes care that his mirror reflects the sunshine on the stud just in front of him. Such signals are visible from 30, 50, to 100 miles, according to circumstances of elevation, atmosphere, etc.

In another and simple form, two opaque screens are placed about 18″ apart upon a strip of wood forming a base, and screwed or nailed fast. A hole about 1″ in diameter should be cut through each screen, the one in rear being a little larger than the other, and across each there should be drawn two fine wires or threads, so as to intersect each other. About 6″ in rear of the screens there should be placed a small mirror — 3″ in diameter would be sufficient — so mounted as to have the two motions horizontal (or in azimuth) and vertical (or in altitude). The crude instrument is then ready for operation. To throw the ray upon any given object visible to the unaided eye, turn the mirror down out of the way or remove it altogether, and sight across the wires, moving the base until the line joining the intersections of the cross wires passes through the object. Then replace the mirror carefully, so as not to disturb the line of sight, and turn it in either or both directions until the shadow of the edge of the hole in the first screen is concentric with that in the second. The reflected ray will then be visible to an observer at the given point. — *Haupt*.

The *heliotrope* is known to the British military world as the *heliograph*, which is a misnomer. The word *'trope* is the more appropriate, as it *turns* to the sun like the *helianthus* and the pretty little *heliotrope* (*H. peruvianum*) — called also *turnsole* or *girasole* — are supposed to.

The word *heliograph* and its cognate *heliogravure* have reference to writing or drawing. The word *heliometer* has its use also, indicated by the termination. The word *heliostat* has also its specific meaning, which is true of each of the following: —

'graph.	'scope.	'trope.
'meter.	'stat.	'type.

The apparatus used with the British army is known as *Mance's* heliograph.

"The signals made by it, under favorable conditions of position and atmosphere, have been read as far as 80 or 100 miles. It consists of a specially prepared mirror, with ingeniously-constructed adjusted mechanism for reflecting the sun's rays with absolute precision to any required spot, notwithstanding the sun's apparent movement. By the pressure of a finger-key the flashes are made of short or long duration, thus adapting the instrument to the Morse code of telegraphy. A second mirror is provided to permit of signaling being carried on irrespective of the sun's position. The instrument intended for field service weighs from 6 lbs. to 8 lbs., and is mounted on a light tripod stand. The working parts are protected from injury during transit, and the complete apparatus admits of being easily carried, as it is also efficiently worked, by one man.

"The apparatus has been in use for some time in India, where its working has been attended with very great success. In the winter of 1877-78 the Jowaki-Afridi expedition gave the Indian Government an opportunity of submitting it to the test of war. The two columns, under General Keyes and General Ross, operating in the Afridi hills were supplied with volunteer signalers. The instruments were simply invaluable, and helio[tropes] were supplied to each division of the subsequent Afghan expedition With Gen. Donald Stewart's column telegraphic communication was maintained by means of these instruments from the Khojak Pass to Girishk. General Roberts, from Khost, flashed his messages to the fort at Bannu, a distance of 60 miles; while Sir Samuel Browne, from the heights above Ali-Masjid, announced the capture of that fort to the expectant garrison of Peshawur by means of the Mance helio[trope]." — London "*Times.*"

Permanent heliotrope stations are now established between Tangier, Tarifa, Ceuta, and Algeçiras, and between certain W. I. Islands. It is used in the armies of the United States, France, and Belgium.

He'lix. (*Electricity.*) The coil In electromagnetic or induction machines the helix is composed of two or more coils. The inner or primary coil being of coarse wire and connected direct with the battery, and the outer or secondary coil being finer wire wound upon but completely insulated from the primary coil, and receiving its electric influences by induction from the core and inner coil.

Help'er Ring. A ring on the edge of a street-car platform for the attachment of the hook of the single-tree of the *helper horse* during the ascent of a grade.

Hem'a-cite. Bullock's blood mixed with finely comminuted mineral and vegetable substances; dried, molded under pressure, varnished. Uses for knobs and ornamental articles. — *Dibble.*

See Bois-durci, "*Mech. Dict.*," p. 320, and list of Compositions, p. 212, *supra.*

"*Iron Age*" . . . . xxiii., Feb. 20, p. 9.

Hem'i-ple'gi-a Ap'pa-ra'tus. (*Surgical.*) Supporting apparatus for a partially-paralyzed limb. *Paraplegia*, for both limbs.

Page 84, Part IV., *Tiemann's* "*Armam. Chirurgicum.*"

Hem'i-plun'ger. A proposed form of sea-going vessel, in which the habitable or fighting portion is supported by posts upon an entirely submerged portion, which is supposed to be below the level of wave-agitated water.

Tomassi, Paris . . * "*Scientific American*," xxxvi. 115.

Hem'or-rhage In'stru-ments. (*Surgical.*) Acting to prevent effusion of blood. The term may include epistaxis instruments, compresses, tourniquets, hydro-hemostats, ligating instruments, etc.

Bates's instrument for arresting urethral hemorrhage after operation consists of a thin, soft rubber pouch, ¾" wide, and 8" long. The outer end has three openings, two of which are furnished with stop-cocks. The center is traversed by a gum elastic catheter, the end of which, after piercing the lower extremity of the pouch, is fastened, and then cut off; over which part of a soft rubber catheter is passed and secured. A stylet passes through the catheter, and renders introduction easy. The apparatus measures 25 mm. in its flaccid state, and admits of any desired distention. It is used as follows: After the division of the strictures, the instrument is introduced so that the end of the catheter rests in the bladder, or just outside, if preferred; the stylet is then withdrawn and a plug inserted in the end of the catheter. The instrument is then tied in. To one stop-cock is attached a fountain syringe; to the other is attached rubber tubing for the purpose of conducting the refuse water to a receptacle at the bedside.

Hem'or-rheu'mo-scope. (*Surgical.*) An instrument for observing the flow of blood in a vein. The bowl of the instrument resting firmly upon the trunk of a superficial vein the peculiar movement of the stream of blood beneath the bowl sets the sensitive fluid column within the graduated tube into sympathetic action.

Fig. 282, Part I., *Tiemann's* "*Armam. Chirurgicum.*"

Hem'or-rhoid'al Clamp. (*Surgical.*) An invention in which a clamp is combined with a cautery. The invention of *Amusat.*

Shown in Fig. 579, p. 121, Part III., *Tiemann's* "*Armamentarium Chirurgicum.*"

Other pile-clamps are shown in Figs. 567-568, *Ibid.*

Hem'or-rhoid'al In'stru-ments. (*Surgical.*) These consist of clamp, syringe, dilator, tenaculum, artery and needle forceps, insufflator, cautery, bistoury-caché, suppositories, etc. See under the various heads.

Hem'or-rhoid'al Syr'inge. A fine, puncturing syringe, with graduated glass barrel, like a hypodermic syringe, for introducing medicaments to suppress hemorrhoids.

See Fig. 622, p. 128, Part III., *Tiemann's* "*Armamentarium Chirurgicum.*"

Hem'o-stat'ic In'stru-ments. (*Surgical.*) Those acting as styptics to prevent effusion of blood. See Epistaxis Instrument; Hydro-hemostat, etc.

Hemp Knife. A hooking knife, shaped like a pruner, and having a long handle so as to reach the lower portion of the stalk without stooping.

Hemp Sof'ten-ing Ma-chine'. A hemp brake, operating upon the rotted and subsequently dried stalks. One made recently by the Mohawk & Hudson Manufac. Co. has two fluted rolls: the lower one is 12" in diameter and 6' long. The upper one is 24" by 6'. The lower one is driven by gearing from the back shaft, and in turn it drives the upper. The shafts are 6" in diameter. The upper roll and shaft weighed about 8,500 lbs., and the complete machine about 15,000 lbs.

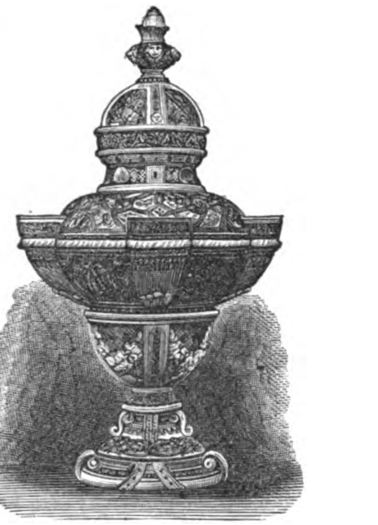
Henri-Deux Ware. (*Ceramics.*) Otherwise known as *faïence d'Oiron.* Fig. 1355.

The ware was made at Oiron, in the southwest of France, in the time of Henry II., of France, and is now very rare, but 37 pieces being known in France, according to M. Brongniart The emblems of Diane de Poitiers appear on the "Biberon," which was sold in March, 1865, to Mr. Malcolm, for £1,100. It is a little over 10" in height. The ware is very hard, quite white, and the ornamentation is inlaid, filling incisions or depressions in the body, though flush with the surface. The filling is generally ochery brown or yellow on the white background, though black, blue, pink, and green colors are known.

Hen'ri-et-ta Cloth. (*Fabric.*) A silk and wool French dress goods.

Her'a-kline. A blasting powder, invented by Dickerhoff, and used in the coal mines of France and Austria. It is composed of picric acid, saltpeter, nitrate of soda, sulphur, and sawdust. The gases produced by its combustion are said not to be injurious, and it burns comparatively slowly, so

Fig. 1355.



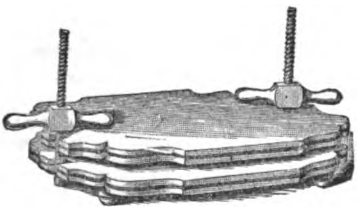
Henri-Deux Ware (Faïence d'Oïron).

that it tears apart the masses blasted, without hurling them violently about.

"*Scientific American*" . . . . . . xxxiv. 329.
"*Scientific American Supplement*" . . 134.

Her-ba'ri-um Press. A portable press consisting of a pair of boards with rising screws and

Fig. 1356.



Yale Botanical Press.

hand-nuts. The parts are all detachable so as to pack conveniently in one's valise.

Her'ni-a In'stru-ments. (*Surgical.*) For operating upon rupture; the protrusion of some part from its natural cavity, usually the abdomen. The instruments are numerous for reduction or operation.

For the former see Truss, Figs. 6700–6703, pp. 2636, 2637, "*Mech. Dict.*"; and page 9, Part IV., *Tiemann's* "*Armamentarium Chirurgicum.*"

Instruments for operation are needles, knives, directors, syringes, etc. See p. 126, Part III., *Ibid.*; Fig. 134, p. 44, Part I., *Ibid.*; Fig. 144, p. 48, Part I., *Ibid.*

Dr. White's instrument for the radical cure of hernia projects a pair of ligature needles.

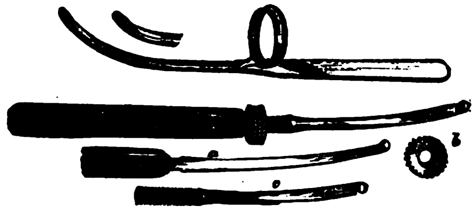
Dr. Warren's hernial ring injector is a graduated barrel with piston and with a needle which is a flat oval in section and twisted throughout its length. The needle is pierced with 10 openings on its side.

Dr Garmo's hernial syringe has a screw piston and a dome trocar needle.

Her'ni-a-tome'. (*Surgical.*) A knife for operating in cases of rupture of the bowels.

Dr. Allis's herniatome is a probe-pointed instrument with concealed blade, which is uncovered by turning the nut, after the constricting band has been reached. The Fig. 1357 represents the instrument when taken apart: *a*, the blunt-pointed blade; *b*, the nut that controls the movements of the shield; *c*, the shield that may be made to conceal or expose the blade by turning the nut *b*.

Fig. 1357.



Herniatome.

Dr. Warren's concealed bistoury for dividing the hernial ring has a saw concealed by a sheath and projected when the ring has been reached. The instrument serves as its own director.

He-veen'oid. Caoutchouc or its analogue compounded with camphor and sulphur, and vulcanized. Addition of lime or glycerine is sometimes made. — *Gerner.*

The proportions of the constituents to make a soft and hard heveenoid may be approximately given as follows: —

	Soft Heveenoid.	Hard Heveenoid.
Rubber	2 parts.	8 parts.
Camphor	2 parts.	2 parts.
Lime	1-16 part.	
Glycerine		½ part.
Sulphur	½ part.	8 parts.

Para caoutchouc is best for hard heveenoid, while Nicaragua rubber answers very well for soft heveenoid, and, in fact, is somewhat better adapted.

Hib'bard Spring. (*Railway.*) A spiral nest spring made of flat bars coiled one within another concentrically, to the number of four, wound in right and left directions, alternately.

High Grind'ing. A process of gradual reduction of the wheat by a succession of partial crushings, alternating with sifting and sorting the product. See High Milling; Cylinder Mill.

High Loom. (Fr.) *Haute lisse.* A tall tapestry loom of considerable size.

At the top and bottom of the framework composing the loom are horizontal cylinders. Around the upper one, the threads composing the warp are rolled, and around the lower one the tapestry, as it is completed yard by yard, is wound. Between these two cylinders is stretched the warp, upon the threads of which the artist marks in white chalk the outlines of the picture. To these he adds, for the purpose of fixing the light and shades, tracings from the pattern. Then, with this latter conveniently placed for reference, he stations himself against the back of his tapestry, and, with his many-colored worsteds and silks, commences the weaving of the picture. The vertical threads of the warp are divided by a heddle or cross stitch, which keeps half of them in advance of the rest; but those behind can be brought forward by means of small cords or *lisses*, one of which is attached to each warp thread. Between the two sets of threads the workman introduces his left hand and takes up as many of them as is necessary. Through these he passes his curiously-shaped wooden needle from left to right, and with its point piles the stretched thread, which in turn is passed back in the contrary direction through the space opened by shifting the front and back threads. The manipulation of the threads, the combination and proper use of the many colors and shades of worsted and silk, and the working out of the design, require a skill and delicacy only attained by long practice.

High Mil'ling. (*Milling.*) The wheat is reduced by a succession of crackings or of slight and partial crushings, alternating with sifting and sorting the product.

In *low milling* the reduction is effected in a single crushing, — the usual manner. The velocity is relatively high.

In high milling the velocity is low; the grinding surfaces at first remote, and made gradually to approximate, in successive grindings, as the products become smaller.

In high milling the reduction of the wheat is step by step, and the separation of the products is not alone according to the magnitude of the particles but also by specific gravity. See MIDDLINGS PURIFIER.

Kick, *Mehlfabrikation*, Leipsic, thus describes it: —

"If one rubs grains of wheat gently between mill-stones, which at first are 1-12″ apart, then one quarter less, and then one half less, and so on, there is obtained successively a finer and finer product. By the first operation, which we will call *clipping*, or *pointing*, a part of the shell or outside coat, the brush, and more or less of the germ, will be removed, and there will be produced grains, from which already many little particles which should not appear in the flour have been separated. The outer bran and hulled kernels coming together from between the stones may be separated from each other by passing them through a cylindrical sieve. The hulled grains, by passing them next through the stones brought nearer together, yield a cracked wheat, a product consisting of various finer particles, which may be graded by sifting. The products obtained are called *groats* (bruised or cracked fragments with bran attached), *grits* (smaller fragments), and finer particles, flour. The flour obtained consists for the most part of cells and particles from the outer portion of the grain, fragments of the bran, and of the gluten-coat, which make the flour dark. It is called *pollen*." — *Kick.*

"The *grits* will consist also of a mixture of fragments of outer and inner parts, and bits of bran of the same size, which go through the sieve with the grits. A product corresponding with this somewhat, used to be called *connell*, and is now known as *middlings*.

"The *groats* freed from the finer particles will be again ground, and this produces a second *groats*, *grits*, and flour; the second groats yield also groats, grits, and flour. Particles which are smaller than groats and larger than grits are called 'solutions;' such as are between flour and grits are called *dust;* and these must obviously be produced by cracking. By each succeeding cracking, the flour and grits produced will consist more of particles from the interior of the kernel of wheat, and as the interior cells, that is, the starch-cells, yield a whiter product, so the flour and grits will become more and more fair and white; and this, until the groats after the fourth grinding will possess the form of disks, having only a thin layer of starch-cells. In flour this phenomenon is very striking. The flour from the third groats is much fairer than that from the second or from the first groats; this is less striking in the grits, in that it is still largely mingled with particles of bran. The bran-particles are much lighter than the grits, and this property is taken advantage of to purify the grits by means of a current of air directed upon a thin sheet of falling grits. This work is accomplished by the grits-purifying machine, in which the air operates either by blast or suction.

"In the gradual grinding and purification of the grits lies the essence of the high or grits milling. This can be effected by various modifications. The wheat may be three, four, or five times cracked or bruised; the grits, which have been separated according to their size, may be more or less purified; and finally the purified grits may be either rapidly or slowly ground to flour.

"When the last traces of bran have been separated from the grits and the still finer dust, one obtains by grinding the pure grits and dust, the fairest, whitest flour, a product which it is impossible to obtain in any other way. Of this product there are several grades." — *Horsford.*

High Wines. Crude alcohol of higher proof than *singlings*.

Hill'side Plow. A plow with reversible mold-board and share for turning all the furrows down-hill in plowing hill-sides. Also known as a *turning mold-board* plow, and in Britain as a *turn-wrest* plow. See illustrations and remarks, p. 2173, "*Mech Dict.*"

There are 5 systems: —

1. Two complete sets of mold-boards and shares, right and left-hand respectively, and revolvable on the beam to bring either to working position. The Brabant system, known as *brabant double*, see Figs. 854, 856, pp. 268, 269, *supra*, and Figs. 25-28, vol. v., pp. 31-33, Knight's Report, "*Paris Exposition* (1878) *Reports*."

2. The old Scotch form: also known as the French *tourne-oreille*, or *charrue Wasse*. The sole and share are permanent; the mold-board is both right and left, either being brought into action as may be desired by means of a lever, the other one shifting into the line of draft on the land-side. The same colter serves for either. The share, mold-board, and land-side are made in one piece (or to move as one), and this is journaled on a horizontal axis at the lower edge. This is unlocked and partially rotated at the end of a furrow, converting what was the land-side into a share and sole, and presenting the mold-board in the other direction. See Fig. 22, p. 29, vol. v., *Ibid.*, and Fig. 6814, p. 2663, "*Mech. Dict.*"

3. A form used also in France, in which two mold-boards, which are united on a horizontal axis on the median line, are unlocked, and then turned half around, which brings the one now uppermost to the underneath position, both the mold-boards being then presented to the right hand as they are now to the left. Fig. 23, p. 30, vol. v., "*Paris Exposition* (1878) *Reports*."

4. A form which has a right-handed and a left-handed body placed back to back; that is to say, one presented forward and the other rearward. The beam and handles turn on a vertical pivot in the center of the body, and either the right or left-handed portion can be used by turning the beam and handles and presenting them in the appropriate direction. The rear portion of each mold-board is hinged, which allows the one in use to lap over the other, which lies back; this avoids the necessity for making the body the sum of the lengths of the two bodies.

An old English turn-wrest plow, known in its day as Hays's, was constructed on the same principle, but without the hinged wings to the mold-boards. See Fig. 24, p. 30, vol. v., "*Paris Exposition Reports*."

5. A system in which two sets of mold-board and share are used, right and left-hand respectively; the one in use lowered into the furrow while the other is elevated clear of the soil without deranging its position other than the clear vertical movement. A British form shown in Fig. 2509, p. 1103, "*Mech. Dict.*"

Hind Sight. The rear sight of a gun; *open*, *California*, *peep*, *vernier*, etc., which see. See also HAUSSE, and list under SIGHT.

Hinge. See under the following heads: —

Awning hinge.	Loose-pin hinge.
Ball-joint hinge.	Plate hinge.
Butt.	Port hinge.
Butt hinge.	Screw hook-and-eye hinge.
Coach hinge.	Screw hook-and-strap hinge.
Crate hinge and hasp.	Spring hinge.
Hasp.	Strap hinge.
Hook-and-eye hinge.	T-hinge.

Hinge Burn'er. A burner the chimney ring of which is hinged to the lamp-top.

Hip'-joint Splints. (*Surgical.*) See MORBUS COXARIUS SPLINT.

Hitch. A fastening made by passing a light line around a rope, or a rope around a mast or post, so that the line, or rope, crosses its own body and binds.

For list of hitches see KNOT.

Hob. A hardened steel mandrel with a threaded portion which is fluted. Used in cutting screw tools and chasers. See HUB, * Fig. 2600, p. 1139, "*Mech. Dict.*"

Hodge Brake. (*Railway.*) A lever car-brake, invented by N. Hodge, for operating upon all the wheels of a car simultaneously from a single wheel. Fig. 642, p. 426, *Forney's* "*Car-builders' Dictionary.*"

Hoe'ing Ma-chine'. (*Agric.*) See HORSE HOE.

Hog Ring'er. A special instrument for placing anti-rooters in the snouts of hogs. The *ring* is usually a wire or plate, with prongs which are thrust through the cartilage of the nose, and bent over to prevent retraction. The ringer is a pincers which holds the *ring* and thrusts it into place.

Hogs'head Ma-chin'e-ry. See list under BARREL MACHINERY.

Hoist'ing, Shaft'ing, Gear'ing, Grap'pling, etc. See under the following heads: —

Abutment crane.

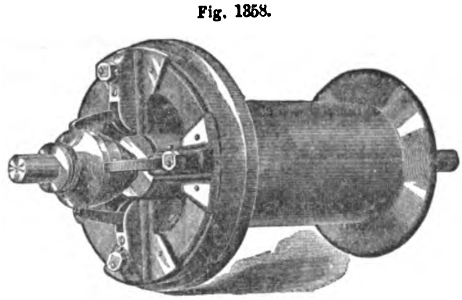
Hoist'ing and Con-vey'ing Ap'pa-ra'tus. A system for lifting and transporting buckets used in mining, grading, loading, and discharging vessels, transporting ores, minerals, etc., from positions difficult of access

Two forms are shown: one under WIRE WAY, Fig. 7006, p. 2798, "*Mech. Dict.*"; the other under CABLE CARRIER, Fig. 494, p. 150, *supra*.

Hoist'ing Drum. A pulley on which the hoisting-rope winds. In Fig. 1358 it is shown in

Fig. 1358.



Friction Hoisting Drum.

connection with a friction clutch which conveys the motion of the shaft to the drum. The cone slips on a feather on the shaft and so locks the parts together as to revolve the drum.

Frisbie's device is also shown in section in Fig. 1097, p. 857, *supra*.

Hoist'ing En'gine. Fig. 1359 shows Frisbie's hoisting machine, operating by means of the friction-clutch in Fig. 1358. As shown, it is especially intended for pile-driving. The rope is not detached from the hammer, but unwinds from the drum, which runs free on the shaft when the friction is removed and the hammer descends to do its work.

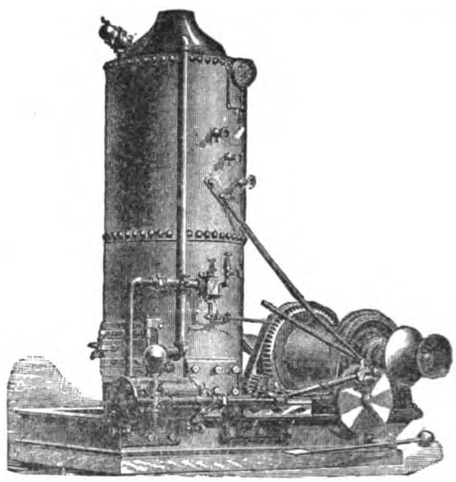
In the Lidgerwood hoisting machine, the engine is rotary and connected directly to the drum-shaft by spur-wheel and pinion. For platform elevators the machine has double or compound gearing, a brake which rests on the fly-wheel when the machine is stopped, and is lifted when the machine is started. The drum is large and has grooves for the wire cable.

In the Carr hoisting engine the engine runs constantly in the same direction, and the connection with the drum is by internal friction gearing.

See also FRICTION DRUM HOIST, Fig. 1009, p. 357; CELLAR LIFT, Fig. 573, p. 180; and ELEVATOR ENGINE, Fig. 958, p. 310, *supra*.

See also HYDRAULIC ELEVATOR; HYDRAULIC LIFT, "*Mech. Dict.*," *et infra*.

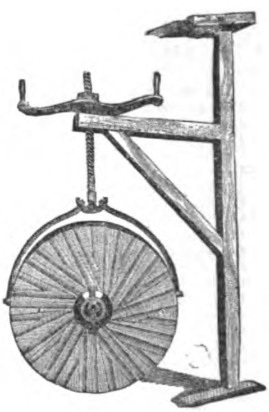
Fig. 1359.



Hoisting Engine.

Hoist'ing Screw. (*Milling.*) An elevating arrangement for lifting the runner from off the bed stone when it becomes necessary to dress either of them. The bail engages studs on the side of the stone which is then revolvable on the studs as centers in order to invert it and expose the working surface upwardly.

Fig. 1360.



Hoisting Screw.

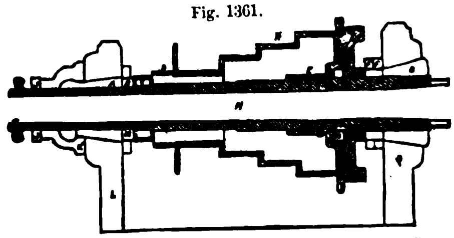
Hole Gage. A tapered metallic slip graduated to show the diameters of holes into which it may be thrust. See BARREL GAGE, Fig. 216, p. 77, *supra*.

Hol'low Plun'ger Pump. A pump made for mining and quarrying purposes, to remove water from the workings. Plunger pumps are shown in Fig. 3845, p. 1752, "*Mech. Dict.*" The tubular plunger is considered to have an advantage in muddy water.

Hol'low Spin'dle Lathe. A lathe with a head stock, the spindle of which is hollow.

P is the spindle; *H*, the hole 1¾″ diameter; *L* and *Q*, the standards of the head stock which have tapering holes to

Fig. 1361.



Section of Hollow Spindle Lathe Head with Taper Boxes.

receive the round boxes, *A* and *G*. These are turned to fit and then cut in half, being secured by the nuts, *F F* and *B*, *K*. *O* is the large spindle gear which is kept in place by the nut, *N*. *R* is a four-section cone pulley; *E*, the cone head; and *D*, the small gear on the cone. *C* is the feed-gear on the spindle. The end thrust is taken by a step held by the bracket *K* and check-nut *J*.

* "*Iron Age*," xxii., Nov. 28, p. 1.
* Fig. 2588, p. 1113, "*Mech. Dict.*"

Hol'low Spoke Wheel. (*Railway.*) A car wheel with spokes cored in casting, Figs. 166, 167, *Forney's "Car-builders' Dict."*

Hol'o-phote. (*Whole Light.*) A lamp which by refraction or reflection collects wandering rays, so that the whole of the beams are directed in the requisite course for the purpose required.

See CATOPTRIC LIGHT; DIOPTRIC LIGHT, "*Mech. Dict.*," *et supra*. Also p. 1113, "*Mech. Dict.*"
The *holophote* of Mr. Preece is a lamp for illuminating the depths of the sea. Its purpose is to detect advance of an enemy's torpedo, "*Scientific American*," xl. 358.

Ho-mo-ge'ne-ous Steel. Steel without blows (*acier sans soufflures*), *M. Euverte, Terre Noire, Fr.*

Hone. The Cinghalese hone is made of *capitia* resin combined with corundum in a state of impalpable powder, the resin rendered liquid by heat, and the corundum well incorporated. The mixture is poured into a wooden mold, and its surface leveled and smoothed while it is hot.

Oil-stone making, *Beach* . . . * "*Sc. Am. Sup.*," 293.

Hon'ey Ex-tract'or. A rotating cage in which comb honey is placed and the honey extracted by centrifugal action, the cage moving at high speed. A form of centrifugal machine. See also HYDRO-EXTRACTOR.

In Emmons's honey extractor an up and down motion is given to the comb to assist in breaking the cells.

"*Scientific American Sup.*" . . . . * 731.
"*Scientific American*" . . . . * xl. 179.

Hon'ey Knife. One with a thin blade bent at an angle to the handle.

Hood. (*Manége.*) That part of a horse blanket which covers the horse's head and neck.

Hoof Boot. (*Manége.*) A leathern boot made to fit the hoof of a horse, with an iron shoe attached; used as a protection to the hoof in case a shoe is lost, or where the hoof is in a condition that will not permit the nails being driven in it.

Hoof Cush'ion. 1. A pad in the hollow of the hoof to keep the sole moist: curative or preventive of dry cracking.

2. A roll attached to the fetlock and encircling the corona of the foot to prevent interfering.

Hoof Pick. (*Manége.*) A claw to remove stones jammed between the sole and the shoe; or the frog and the shoe.

Hook. A curved prehensile instrument. See list, pp. 1114, 1115, "*Mech. Dict.*"

1. (*Surgical.*) A frequent form in instruments, *e. g.* Hooked gorget used in supra-pubic lithotomy. Tonsil hooks, single and double; blunt hook for fistula or for parturition; tenaculi, etc.

2. (*Nautical.*) Among these are: —

Bench hook.	Match hook.
Block hook.	Self-mousing hook.
Boat hook.	Sister hook.
Clip hook.	Tackle hook,
Gaff-top-sail hook.	etc.

3. (*Fishing and Whaling.*)

a. Blubber hook.	Line hook.
Clam hook.	Lip hook.
Drail.	Lock hook.
Fly hook.	Pew gaff.
Gaff.	Spinner.
Grapple hook.	Spring hook.
Junk hook.	Squid jig.
Lance hook.	Tackle.
Lever hook.	Trawling hook, etc.

See FISH-HOOK, *supra*.

b. The backward curved portion of a wing net which constitutes it a space nearly inclosed. See STAKE NET.

4. A means for suspension. BARREL HOOK, Fig. 221, p. 78; BALE HOOK, Fig. 181, p. 68, *supra*.

A small hook for suspending calendars and what-not. *Heyl's* suspension hook; an ornamental plate with adhesive back surface and a wire loop-hook.

5. A means of handling: *e. g.*, BALE HOOK, Fig. 182, p. 68, *supra*.

The word *hook* appears in various and numerous compounds: —

Hook and eye screw-bolt.	Hook and eye turn-buckle.
Hook and eye hinge.	Hook and swivel block.

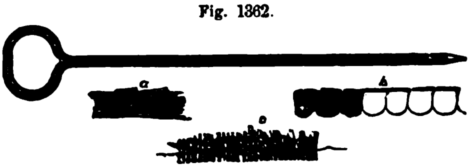
Hook and Lad'der Truck. A carriage for conveying ladders and hooks for engaging in extinguishing fires. The former useful in rescuing persons and in giving firemen entry into and points of advantage in fighting fire in buildings. The latter for pulling down dangerous walls, or buildings, which add to the extent of the conflagration.

The carriage being long, the forward truck turns under the carriage, and the hind truck is also swivelled, and is guided by a steering wheel.

Hook Nee'dle. (*Hydraulic Engineering.*) A hook-ended needle used in sewing mats for lining river banks or making levees. It is used in making the lock-stitch and also in the hook needle fastening.

The method of working is as follows: The wires are laid upon the ground, straight or crossways, as the case may be, and the material for the mat laid over them. The needle is passed through the mat, and engaging the wire pulls a loop

Fig. 1362.



Hook Needle Fastening.

up through the mat; through this loop a bobbin is passed in the lock-stitch or the butt-end of a brush in the hook needle fastening. A man at the end of the wire pulls all down very solid, and a third man stands on the wire where it crosses the brush or toggle to prevent back-slip, and presses the brush down while the next stitch is being made.

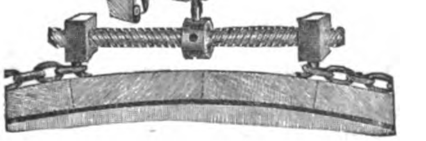
Hook Net. (*Fishing.*) One with an L-shaped continuation forming a sort of pocket. See STAKE NET. Also known as a *trap*-net.

Hook Plate. A supporter for RADIATORS, which see. See also COIL PLATE, Fig. 656, p. 203, *supra*.

Hoop. A band of metal or of wood around a cask, bale, or box.

Zollers' provisory hoop, Fig. 1363, for setting up large vats, has a right and left coupling screw, to heads on which are hooks engaging the ends of the straining chain.

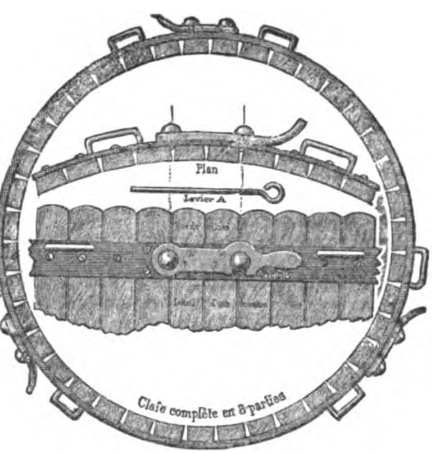
Fig. 1363.



Provisory Hook.

Fig. 1364 is a French hoop for cider and wine presses. It is made in three sections, and may be taken off when the pomace is well pressed in order to remove the exhausted material more readily.

Fig. 1364.

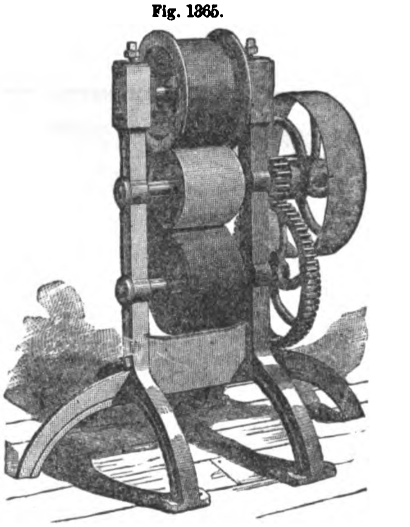


Hoop for Cider-press Vats.

Hoop-bend'ing Ma-chine'. A machine for giving flexibility to the rived sapling, for forming a hoop.

The machine has an iron frame in which are three turned

Fig. 1365.

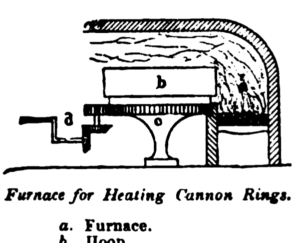


Machine for Bending Wooden Hoops.

iron pulleys. A belt is so placed upon the pulleys as to drive them all when one is put in motion. The hoop is ntered between the belt and the middle pulley, which is carried around the pulley and held close to it by the belt, which prevents its breaking.

Hoop-heat'ing Fur'nace. One for expanding a steel ring which is to be slipped on to a cannon on the building-up, or reinforce principle.

Fig. 1366.



Furnace for Heating Cannon Rings.

a. Furnace.
b. Hoop.
c. Revolving Table.
d. Crank and Gear.

When the hoop has a blue heat it is removed and slipped into place on the gun, which has been turned to a size to receive it. See ARMSTRONG GUN, "*Mech. Dict.*"

Hoop-ma'king Ma-chine'. A machine for riving hoops from the pole and finishing them.

It consists of a *splitter* and *finisher*.

A large splitter is used for heavy, that is to say, for three, four, six, or eight-part poles (which will yield that number of hoops), and a smaller splitter for smaller poles. The splitters cut through the center of the poles, and in a single rapid thrust divide at one operation each pole into all the splints which it contains.

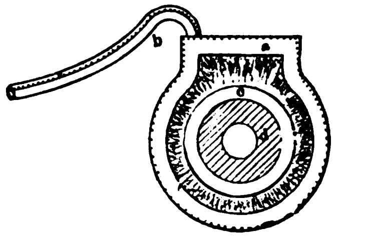
The finisher, in one rapid operation, cuts off the knots, takes out the core, finishes the face of the hoop, crimps it, and delivers it a perfect hoop, exactly even in thickness from end to end.

The splitter will split 12 to 15 poles per minute. The smaller finisher will run through 12 hoops of 6' length per minute. The larger finisher will run through 10 hoops of 7½' length per minute. — *Hart.*

Hoop-punch'ing Ma-chine'. A machine having rollers for flaring, and punches for punching and riveting respectively, the hoop-iron for making cask hoops.

Hoop-shrink'ing Ap'pa-ra'tus. An apparatus for shrinking a steel hoop which has been

Fig. 1367.



Apparatus for Cooling Hoops.

a. Watering Pot. *c.* Hoop.
b. Hose Pipe. *d.* Body of Gun.

heated to "blue" and slipped on to the core of a cannon, in the building-up or reïnforce method. It is a sort of circular watering-pot which bathes all portions of the exterior of the hoop equally.

The system of reïnforce rings is shown in the 100-ton gun, Fig. 526, p. 160, *supra*.

Hop'per. A funnel-shaped tank, spout, or vessel, either bottomless or with a movable door or flap beneath.

A coal hopper, grain hopper, etc., for discharging into cars or otherwise.

A soil hopper in a water-closet.

A car hopper, or bottom discharge of a coal car.

A weighing hopper; the cistern holding the grain and discharging below. See GRAIN SCALE.

Hop'per Barge. A barge used in dredging operations, to receive the silt from the dredger, convey it away, and drop it at any suitable place for deposit.

Hawks, Crawshay, & Co. • "*Engineering*," xxix. 354.
Dredger "Willunga," Australia . . . . . . • "*Engineer*," xlvii. 60.
Dredge, twin screw, Newhaven, Br. . . . . . • "*Engineer*," xlviii. 84, 88.

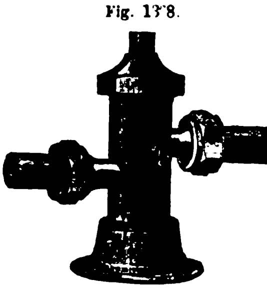
Hop'per Clos'et. A water-closet for public uses, in which the pan stands upon an S-trap and periodical flushing is depended upon for cleanliness.

Hop'per Cock. A faucet belonging to the hopper of a water-closet, so arranged as to give a wash when the seat is relieved of weight. See Fig. 1368.

Hop'per Scales. Elevator scales. See GRAIN SCALE.

Hop Pick'er. A device resembling a clothes-wringer and propelled by a treadle.

Fig. 1358.



Hopper Cock.

It consists of two rubber rollers, so constructed as to draw in the branch, while two steel rollers, having an opposite action, pick the hops from it. From the picker the hops run into a sack, which, when filled, is taken to the separator, which sorts the hops from all leaves or stems which may have gone into the sack, and thence to the hop house.

Cultivator, *Howard*, Eng. * "*Scientific Amer.*," xxxvii. 163.
Knight, Br. . . . . * "*Engineering*," xxiv. 98.

Hor'i-zon'tal Bor'ing Ma-chine'. 1. A machine with a horizontal table on which work is chucked for boring.

See HORIZONTAL LATHE, Fig. 2562, p. 1121, "*Mech. Dict.*," and Fig. 389, p. 122, *supra*.

2. A machine with horizontal boring-tool stock.

See HORIZONTAL DRILL, Fig. 2560, p. 1120, "*Mech. Dict.*"; BORING MACHINES, 811, 817, 818, 820, pp. 340, 341, *Ibid.*; UNIVERSAL BORING MACHINE, Fig. 392, p. 123, *supra*; ANGLE CAR-BORING MACHINE, Fig. 75, p. 85, *supra*.

Hor'i-zon'tal Check Valve. One arranged in a horizontal pipe, as in Fig. 609, p. 192, *supra*.

Hor'i-zon'tal En'gine. One, the piston of which works horizontally.

Hor'i-zon'tal Mor'tis-ing Ma-chine'. One, the auger and bit of which act in a horizontal direction.

Fig. 3339, p. 1483, "*Mech. Dict.*"; CHAIR MORTISER, Fig. 594, p. 189, *supra*.

Hor'i-zon'tal Pump. One, the barrel of which is horizontal.

A convenient form of lever handle-pump, and the usual position in steam pumps: instances (9) on pp. 2357–2359, "*Mech. Dict.*" See list under PUMP, p. 1827, *Ibid.*

Hor'i-zon'tal Saw Mill. One, the saw of which traverses horizontally: not a frequent position, but found in some special saws.

Horn. 1. (*Railway.*) One of the projecting parts of a pedestal, between which the journal-boxes work.

Horn-block in British parlance. See PEDESTAL, Fig. 3595, p. 1647, "*Mech. Dict.*"

Horn-block facing-machine, Lond. & N. W. Ry., * "*Engineering*," xxviii. 261.

2. (*Music.*) A brass wind instrument, with a mouth-piece, made in great variety. The name characterizes a family. Speaking in the most general terms, it may be said that they are of all sizes, and consequently of pitch, as the larger tubes vibrate more slowly. The pitch is also varied by

movable crooks. Some horns have keys, other pistons, cylinders, or slides. They have also a capacity for another variation of sound, known as the *open* or *closed;* the latter produced by closing more or less the *pavilion* or bell by means of the hand.

See CORNET, p. 222, *supra*. Also instances (11), Fig. 2564, p. 1122, "*Mech. Dict.*"

Horn Block. The casting with two dependent branches, between which the axle-boxes of a car work as the springs expand and contract. A *pedestal.*

Horn'er. A tool for breaking off the awns of barley. *Awner.*

Horn Ma-chine'. A machine for sewing soles to shoes.

The shoe being slipped on a *horn*, gives name to the machine. A *horn* is shown in Plate LX., opposite p. 2162, "*Mech. Dict.*"

Horn Press. A power press for closing the side-seams of cans and boxes, which are for the purpose slipped upon a horn protruding from the standard of the machine.

Ho'ro-graph. An instrument for making a multitude of perforations on a line, as guided, through a thin paper to be used as a stencil.

It resembles the Edison electric pen in the result, but the means of driving the *Newton, Wilson & Co.* horograph is a spring and clock-work.

"*Engineer*"	* xlvii. 813.
"*Scientific American*"	* xl. 377.

Horse Bar. The lever of a horse-power. A sweep.

Horse Bis'cuit A food for campaigning horses; adopted in Prussia and Russia. Also known as *oat comfit.*

It consists of: —

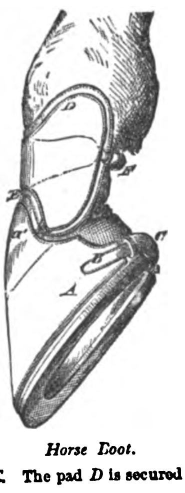
Oat flour	30
Dextrinated pea meal	30
Rye flour	30
Linseed meal	10
Or:	
Oat flour	40
Dextrinated pea meal	40
Linseed meal	20
Or:	
Pea meal	20
Wheat flour	20
Corn meal	20
Rye flour	20
Grated bread	10
Linseed meal	10

Or analogous mixtures.

$3\frac{1}{2}$ lbs. of the oat comfit are estimated to have a value equal to 12 lbs. of oats.

A daily ration is $3\frac{1}{2}$ lbs. comprising, say 26 biscuits, 4 to 5″ in diameter and 4-10″ thick. The biscuits are fed broken, dry or wet; 7 in the morning, 12 at noon, 7 in the evening.

Fig. 1369.



Horse Boot.

Horse Boot. (*Manége.*) An attachment designed to protect the hoof, pastern joint, and fetlock joint from being cut or injured by the over-reaching or interfering of the horse when being driven at high speed.

The lower portion, *A*, covers the hoof, and is secured by strap *B*, which passes around the heel. The portion *a′* covers the corona, and a tube, *C* on *B*, prevents the boot from slipping. *D* is the upper or speedy-cut boot, which is concaved in front to fit the portion *a′* of the hoof-boot, to which it is secured by straps *E E*. The pad *D* is secured by strap *F*.

Horse Car. (*Railway.*) *a.* One fitted to carry horses.

b. A street-car drawn by horses.

See "*The Horse in Motion,*" *Stillman*, J. R. Osgood & Co, Boston, 1882.

Horse Groom'er. See GROOMER, p. 427, *supra.*

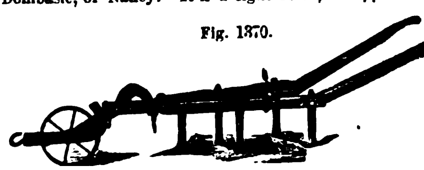
Horse Ham'mock. Used in shipping, transporting, and disembarking horses. In slinging, the canvas hammock is carried beneath the body of the horse and the cringles of the ends are carried to rings which engage the tackle-hook. Breast and breeching bands keep the horse from plunging out of the hammock.

On ship-board, the hammock is so suspended as to pass beneath the body of the horse, so as to catch him when he loses his feet in rough weather, and hold him till he recovers footing.

Horse Hoe. An implement for cultivating the ground between crops drilled in rows.

Fig. 1370 is a French horse hoe made by Meixmoron de Dombasle, of Nancy. It is a light form, an approximation

Fig. 1370.

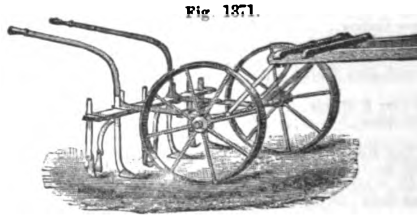


French Horse Hoe.

to the American, except in the shape of the hoes, which follows the English. The wheel in front regulates the depth, and the double adjustment by means of the perforated bars and pins gives command of the level or inclination of the frame. The latter is adjustable for different widths.

The implement shown in Fig. 1371 is also intended to follow drilled wheat, the hoes being carefully adjusted to the

Fig. 1371.



French Horse Hoe.

proper relative distance in accordance with the shares of the drill. The whole row of hoes is lifted or depressed by means of the handles.

See HOEING MACHINE, Fig. 2521, p. 1107, "*Mech. Dict.*"
See also SCARIFIER.

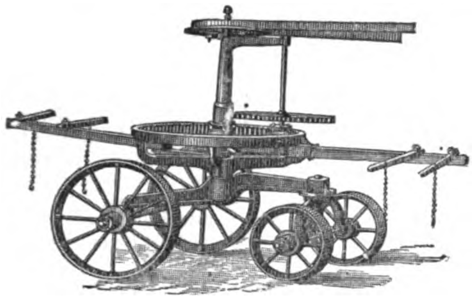
Horse Net. A net to protect a horse from flies.

Horse Pow'er. An apparatus for transferring the draft power of the horse to any machine.

Figs. 1372, 1373, 1374 show several French horse-powers, of moderate size. See also Figs. 2568-2571, pp. 1125-1127, "*Mech. Dict.*"

Fig. 1372 is a horse-power by *Girardin*, of Étampes (*Seine-et-Oise*). It is designed for two horses, and is used without dismounting.

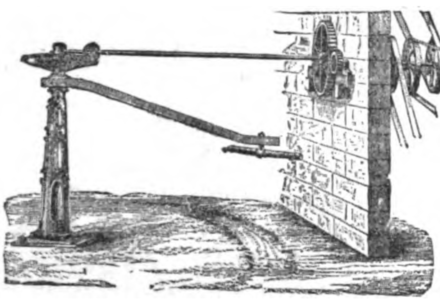
Fig. 1372.



Girardin's Mounted Horse-power.

The small horse-power with shafting, Fig. 1373, by Gautreau, of Dourdan (*Seine-et-Oise*), France, is founded on a column, the connecting-shaft going overhead. The horse-power stands on the outside of the building, and the power is transmitted by a bevel master-wheel and pinion, spur-

Fig. 1373.



Gautreau's One-horse Power.

wheel, and pinion to the pulley-shaft, which latter has a speed of 60 revolutions per minute with an ordinary speed of the horse which is attached to the sweep.

From the shafts in the building different *instruments d' intérieur*, as they are termed, are operated. Such are the straw-cutter, root-washer, root-cutter, grain-bruiser, etc.

The column is simply bolted to a foundation-plate or pillar, and the wall-gearing and shafting to a wall-plate, with but little expense of fitting, the work being simply to line and level the shafting in boxes already prepared and easily attached in place.

Fig. 1374 is another form of columnar horse-power, adapted for one or two horses. It is one of the lightest and cheapest forms.

The head is movable on the neck of the column, so as to direct the band-wheel in any radial direction from the column as an axis. It may thus be made to do duty with either one in turn of a numerous series of machines in a circular arrangement around the horse-power as a center, such as a chaff-cutter, root-cutter, corn-sheller, cider-mill, churn, or what not.

The speed-multiplier is an arrangement of spur-gears and pinions on the cruciform foot-frame, which is anchored or staked to the ground, or bolted to a floor.

The pulley revolving in a vertical plane has one advantage over the horizontal pulley, as it allows the endless band to reach a machine whose driving-pulley is much below that on the column, whereas the horizontal pulley requires that the machines shall have a relative height.

It is transported by sufficiently elevating it to enable wheels to be slipped upon the spindles, which are shown projecting from the ends of two opposite bars of the cruciform frame. To one of the bars at right angles to the last stated is attached the tongue to which the team is geared for transporting the horse-power; or the tongue is attached to the rear of the thrasher.

The pulley-shaft may be prolonged by means of a coupling, so as to penetrate the wall of a building for the conveyance of power.

Horse'-pow'er Com-pu'ting Scale. A pocket sliding scale for computing from the usual data, the indicated horse-power, size for power, etc.

The instrument consists of a simple double slide-rule, and will give the power of any cylinder from 4″ to 100″ diameter, working at from 1 lb. to 100 lbs. mean pressure, within about ½ per cent. of accuracy. By placing the scales in the necessary relative positions, they give, without calculation (1), the indicated horse-power from the usual data; (2) the size of engine for any given power; (3) the piston speed due to any stroke and number of revolutions per minute; (4) the ratio the high and low pressure cylinders of compound engines bear to each other; (5) the proportion the *mean* bears to the *initial* pressure, with the steam cut off at any given point in stroke. The instrument is 4½″ × 2¼″.

Horse'-pow'er Jack. The intermediate motion of a horse-power, whereby the motion of the tumbling rod is transferred to a band-wheel shaft.

See JACK; INTERMEDIATE MOTION.

Horse'-pow'er Pump. A pump driven by animal power, as at *D*, Fig. 2569, p. 1126, "*Mech. Dict.*" The Oriental and Spanish Norias (Na' Ura) are usually driven by cattle; the wheel with pots, as in Fig. 3333, p. 1533, "*Mech. Dict.*"; or the wheel with rope and pots, *a*, Fig. 3334, *Ibid.*

Horse'-pow'er Reg'u-la'tor. A device to limit the speed of the horse-power when work is suddenly withdrawn.

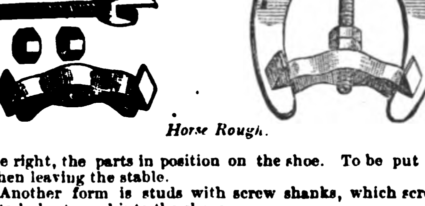
See GOVERNOR, Fig. 1230, Plate XIX.

Horse Rake. See HAY RAKE.

Horse Rough. A removable calk or stud to be attached to the shoe of a horse when traveling upon frozen ground or ice.

The Fig. 1375 shows, on the left, the pieces detached; on

Fig. 1375.



Horse Rough.

the right, the parts in position on the shoe. To be put on when leaving the stable.

Another form is studs with screw shanks, which screw into holes tapped into the shoes.

Horse Shoe. A horse shoe of raw hide is composed of three thicknesses of cow-hide compressed into a steel mold and then subjected to a chemical preparation. It is light, lasting, elastic, and requires no calks, even on asphalt.

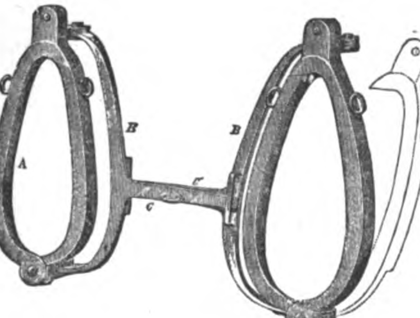
Horse'-shoe Ham'mer. See FARRIER'S HAMMER; TURNING HAMMER; TURNING SLEDGE, etc. See list under HAMMER; SLEDGE.

Horse'-shoe'er's Ma-chine'. A foot-vise with treadle and toggle. The shoe is gripped by

Fig. 1376.



Horse Yoke.

placing the foot on the treadle, and the vise falls open when the foot is removed. The dies in the jaws of the vise are so shaped to give the right form to the calk as it is hammered. An anvil attachment is used for trueing up the shoe; it carries a steel die with four different-sized slots for welding on calks. See ANVIL VISE, Fig. 97, p. 42, *supra*.

Horse'-shoe Stud. A calk secured into the horse-shoe.

Horse Yoke. (*Agric.*) A pair of hames, *A A*, Fig. 1376, slipped upon the usual collars, and each consisting of two hinged portions to clasp upon the neck; the two hames connected by sections *B B* and a brace, *C*; the latter having a ring to which the draft chain is attached. Practically, a return to the most ancient method of harnessing. See Fig. 1251, p. 528, "*Mech. Dict.*"

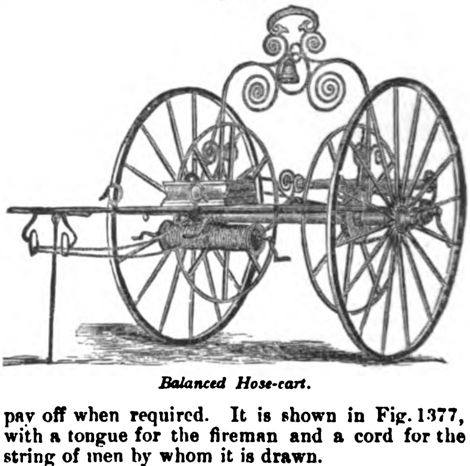
Hose Cart. A two-wheeled vehicle for transporting hose. It has arrangements for winding the hose upon the drum, and allowing the hose to

Fig. 1377.



Balanced Hose-cart.

pay off when required. It is shown in Fig. 1377, with a tongue for the fireman and a cord for the string of men by whom it is drawn.

Hose Clamp. A band which can be tightened upon a hose to sustain a weak part or stop a leak.

Fig. 1378.

Hose Clamp.

Hose Nip'ple. A short pipe, externally threaded at each end; on to one end the hose is firmly bound by lashing, the other affords junction for another section of hose or for the nozzle.

Hose Screw. The brass or gun-metal coupling for hose sections. See HOSE COUPLING, Fig. 2582, p. 1132, "*Mech. Dict.*"

Hose Sprink'ler. A rose on the end of a nozzle to give a fine spray of water.

Hose Truck. A small hose-carriage for carrying hose for domestic and garden use, washing carriages, etc.

See Fig. 2575, p. 1132, "*Mech. Dict.*"

Hose Un'ion. See Hose Coupling, "*Mech. Dict.*," Fig. 2582, p. 1132.

Another name for the screw coupling.

Hose Un'ion Cap. A cover to close the end of a hose; a cap screwed upon the coupling at the end of the line of hose.

Hose Wrench. A spanner for coupling and uncoupling sections of hose.

Ho'sier-y Seam'ing Ma-chine'. A machine for sewing together knitted goods.

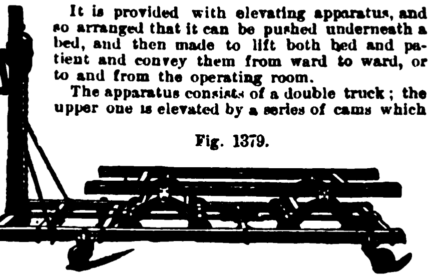
The loops of the respective pieces are slipped on to holding pins and are sewn together by a chain-stitch. The reciprocating eye-pointed needle puts a loop of yarn through the loops of the knitted fabric, the needle-yarn being caught by a reciprocating hook, which detains it while the needle retires; the goods are then fed along the distance of a stitch and the needle repeats the movement. The feed is by a rack-movement

Hos'pi-tal-bed El'e-va'tor. A truck, devised by Dr. Morton, for surgical wards especially.

It is provided with elevating apparatus, and so arranged that it can be pushed underneath a bed, and then made to lift both bed and patient and convey them from ward to ward, or to and from the operating room.

The apparatus consists of a double truck; the upper one is elevated by a series of cams which

Fig. 1379.



Hospital Bed-elevator and Truck.

run upon a narrow iron track: a long right-and-left screw, worked by an endless chain upon a crank at one end, raises and depresses the cams 400 lbs. can be lifted quite free from the floor in 4 seconds: and without difficulty a water-bed, which weighs about 700 lbs., with patient, can be elevated and readily moved. The elevation of the bed an inch or so from the floor is all that is required.

Invalid bed, *Graff*. . . * "*Scientific American*," xl. 403.

Hos'pi-tal Ward Car'riage. An invention of Dr. Morton for conveying all the necessary appliances for dressing the wounds or sores of the patients in a surgical ward.

It is a truck on 3 gutta-percha rimmed wheels, carrying a table, elevated water reservoir, and hose, the necessary pans, etc. On either side of the water-can appropriate places are partitioned off for the bandages, charpie, oiled silk, adhesive

Fig. 1380.

Hospital Ward Carriage.

plaster, and jars for holding the lint soaked in the various solutions commonly used for ward applications; drawers are placed in each end and serve as receptacles for towels, instruments, etc., etc. One large bucket, with a projecting lip, occupies one half the space under the table, into which all the refuse dressings, poultices, soiled water, and oakum, from each patient, are emptied. Another can, with two compartments, adjoins the bucket; into one of these the soiled bandages are thrown, while the other carries the fresh oakum, cotton batting, muslin, and old linen, used for the ordinary ward purposes.

One good-sized basin serves for the entire ward or series of communicating wards, since it serves merely as the receptacle for the water and discharges flowing from the part during the process of dressing. A can for hot water, for heating the adhesive plaster, completes the apparatus, which is pushed to the foot of each bed; the length of the gum-elastic tube and the elevation of the supply of water allow the stream to be carried to any part of the patient which requires cleansing, in either the recumbent or sitting posture.

Hot'-air En'gine. The subject of hot-air engines falls under several heads, as inventors have chosen names which have been accepted and become established. In the "*Mechanical Dictionary*," 11 pages have been devoted to Air Engines, nearly all of which work by increase of pressure derived from increment of heat.

The *caloric* engine of Ericsson was described in pp. * 40, 41, "*Mech. Dict.*," and a later very compact form at Figs. 510, 511, p. 155, *supra*. See references *passim*.

The *compression* engine of Rider is shown at Fig. 674, p. 216, *supra*.

One of the earliest, and certainly simplest, though not important, except as one may care to gather up all the items in the history of an art, is the English patent of Joseph Hately, 1775 of 1790, in which he proposed to utilize the force of a current of rarefied air escaping from a chimney against vanes. A smoke-jack.

Cooling arrangements for cylinder, Engl. Pats., Boulton, 1,636 of 1864; 501 and 827 of 1865.

C. W. Siemens, Engl. Pat., 2,074 of 1860, uses 4 working cylinders with communication through regenerators. A mixture of air and inflammable gas is introduced into the chambers through pipes. Cylinders cooled by currents of cold water. See 326 of 1852; 1,363 of 1856.

Woods's Engl. Pat., 739 of 1859. Air heated by passing through pipes conveyed to a cylinder under pressure.

See also Engl. Pat., Young & Kirk, 227 of 1864. Two displacing cylinders above the engine. The upper parts heated by steam jackets; the lower cooled by water. The pistons drive the air alternately from one to the other.

Mennon's, 218 of 1862. The piston of a single-acting engine is adapted on one side to draw in air and force it to the heating surface; on the other side is exposed to the motive power of the heated air. The capacity of the cylinder on each side is proportioned.

Wenham's hot-air engine (English) The air is heated in a closed combustion chamber by direct contact with the fuel, and passes with the gases evolved into the cylinder. The cylinder is single acting, the upper part of it being arranged to serve as an air pump, and there is the usual regenerator for economizing fuel.

The feature of burning under pressure and sending the gaseous products of combustion to the cylinder is found in the U. S. patents of Bennett, 1838, and Washburn, 1865. In fact it was the feature of Oliver Evans's "volcanic engine," about 1786.

The hot-air engine of Woodbury, Merrill, Patten & Woodbury is shown in elevation in Fig. 1381 and in vertical section in Plate XXI.

The essential features are a heater, regenerator, and cooler, which three, in combination, are termed a *reverser*, and in conjunction with a working cylinder, constitute a single-acting engine. The illustrations represent a double-acting engine, with two reversers and two working cylinders. These in a machine of the size represented are of the following sizes:

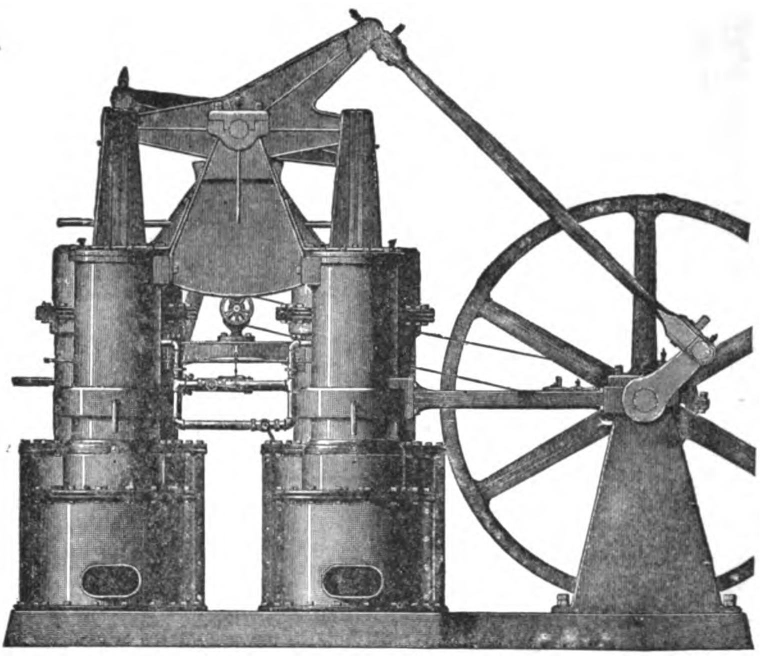
Working cylinders . . 10″ diameter . . 2′ stroke.
Reverser cylinders . . 20″ diameter . . 1′ stroke.

The air is heated and cooled on each revolution; and the rapidity with which this is effected is one of the chief objective points in machines of this character. The cooling process is performed by the circulation of water around small thin copper tubes through which the air passes.

The following statement explains the principle of the machine in the words of the inventors: —

In a machine of the size above referred to, "the displacer pistons or reverser pistons change 4,000 cubic inches of air from the hot end to the cold end by one displacer, and 4,000 cubic inches from the cold end to the hot end by the other displacer, each stroke of the engine, the engine being a double cylinder, or practically a pair of engines. In this way 8,000 cubic inches are heated and cooled by each stroke of the en-

Fig. 1381.



Hot-air Engine.

gine, or 16,000 cubic inches moved at each revolution, and of this amount 8,000 is heated and 8,000 cooled at each revolution, or at 100 revolutions per minute, which was the speed of the engine in its regular work in the Institute Fair [Mass Manuf. & Mech. Inst. Fair, Boston, 1881], 800,000 cubic inches are heated to a differential temperature of at least 400° Fah, and this is probably lower than actual practice. It is well known that atmospheric air at 30″ barometric pressure requires 13 cubic feet to weigh one pound avoirdupois, hence 800,000 cubic inches equals 470 cubic feet; 470 divided by 13 equals 36 lbs., which are heated to 500° Fah. every minute when working under 1 atmosphere of pressure, and at 4 atmospheres pressure 144 lbs. of air are heated to the same temperature. Actual experience with this motor has proved that the actual consumption of coal has not exceeded 400 lbs. in 10 hours, or 40 lbs. per hour. Per minute the consumption is one sixtieth of forty or two thirds of 1 lb per minute, and 144 lbs. of air is heated to a differential temperature of at least 400° Fah., with the combustion of two thirds of 1 lb. of fuel. It may take somewhat more heat to heat the air working under 4 atmospheres density, but it has not been realized in actual practice, or in practical work, and this practical experiment has proved that so long as the air is confined in a given space the rapidity and facility of its heating is not approximately different whether 1 atmosphere is worked or 4 atmospheres are worked; but the power developed by 4 atmospheres is enormously different in dense air from that obtained by using air under simply the natural atmospheric pressure. With 1 atmosphere the engine indicates 8 horse-power; with 4 atmospheres it indicates 26 horse-power, and in either case three quarters, at least, of the indicated horse-power is transmitted by the fly-wheel, the balance being absorbed in the friction of the engine, passing the air through the parts and running the water and air pumps. The cooling requires some 15 gallons of water per minute, the water weighing 8 lbs. 3 oz. per gallon; 15 gallons weigh 123 lbs., and this amount is required to cool 36 lbs. of air when working 1 atmosphere, and in working 4 atmospheres' density 144 lbs. of air are required, and the cooling water is raised in temperature about 20° Fah. above its normal temperature in passing through the coolers."

In Fig. 1381, which is a side elevation of the engine, the working cylinders (the smaller) are seen in front and the reverse cylinders behind.

In Plate XXI. the section passes through one working and one reversing cylinder, the connections, fire pit, bridge wall, and flue being one half of the engine as shown in Fig. 1381, the other half being precisely similar, making up a full double-acting engine with 4 cylinders having 2 working cylinders and 2 reversers. *A* is the fire-box or furnace mounted upon a bed plate and provided with the grate, ash-pit *C*, and the usual fire door. The fire-box casings extend to the rear of the combustion chamber, sufficiently far to serve as supports for the working cylinder, *D*; the rear portion being partially separated from the combustion chamber by the bridge wall *E*, above which the products of combustion pass through the flue *E′*, across the chamber *F*, and thence escape into the chimney through the passage *F′*. The working cylinder *D* is cast open at both ends and provided at its lower end with broad flanges, the outer portion of which rests upon and is securely bolted to the casing *A*, while to the inner portion of the same flange of the cylinder is bolted the fire-pot or heater. The lower portion of the cylinders, *D*, is made of somewhat greater diameter than the upper portion, and has fitted thereon the short secondary cylinder or shield *f*, the lower end of which extends down into the heater to within about an inch of the bottom, leaving space sufficient for the air to pass by under the piston in the working cylinder. The object of this is to force the air against the surface of the heater. The head at the upper end of the cylinder *D* has an opening for the passage of the piston-rod *I*, and two cupped packing rings to prevent the escape of air around said rod, the upper end of which is connected by the link *J* to one end of the beam *K*, which is also connected to the crank upon the driving shaft, mounted in bearings upon standards carrying the driving pulley *L*. The two chambers above the pistons are connected by the pipe *H*².

N is the cylinder of the reverser, provided with a broad flange, *j*, at its lower end, the outer portion of which rests upon the furnace casing *A*; to the lower end of the cylinder is bolted a curved heater, *O*, which is placed directly over the fire-grate for the purpose of receiving the direct radiation of the fire against its sides and bottom. *P* is the reverser cylinder, made of somewhat less diameter, and placed within and concentric with the cylinder *N*, with its lower end extending down into the curved heater within about an inch of the bottom, in such a manner as to form an annular chamber between the cylinders *N* and *P*, to serve as a regenerator. The upper ends of the cylinders *N* and *P* are closed by the head *Q*, which is firmly bolted to the cylinder *N*, and rests upon a rubber packing ring placed in a groove in the upper end of the cylinder *P* to form an air-tight joint and allow for unequal expansion.

The head *Q* has, set therein and projecting upward therefrom, a series of ∩-shaped pipes, one end of each of which communicates with the space between the cylinders *N* and *P*, and the other end with the interior of the cylinder *P*, above the reverser piston *R*, and is also provided with a central upwardly projecting tubular hub through which the piston rod *R′* passes, and to the upper end of which is secured the upper end of the cooler casing *S*, the lower end of which is firmly bolted through the head *Q* to the cylinder *N*, thus forming a cooling chamber inclosing the ∩-shaped pipes, which chamber is to be filled with circulating cold water.

The upper end of the piston rod *R′* is connected by the link *T* to the beam *V*, upon one side of the standard, in which said beam has its bearings, while said beam is connected upon the opposite side of said bearing by another link and piston rod to the reverser piston in the second reverser cylinder, which is constructed in all respects like the one just described.

The pistons *H* and *R*, of the working and reverser cylinders respectively, are each cast in two parts and screwed together so as to form hollow air-tight chambers therein, the lower portion of each of which is filled with fire-brick *r′*, and the upper portion with asbestos, *r′*. The beam center has firmly secured to its outer end the pendent arm *V*, provided with a pin *V′*, by means of which the beam and the reverser pistons may be worked by hand to start the engine, or by means of a hook connecting-rod and crank the beam and pistons may be worked by the power.

Air may pass freely by pipe *p q* from the interior of the reverser cylinder to the annular space, in the working cylinder and down against the heater of the working cylinder, to the space beneath the working piston *H*, and *vice versa*, as the motion of the piston may be either up or down.

An automatic bye-pass valve in a pipe, the ends of which open into both reverser cylinders, is used to equalize the pressure between the two reverser cylinders, and regulate the motion of the engine in proportion to its load.

An eccentric on the main shaft of the engine drives a small air-pump for the purpose of compressing air up to any density required; and connecting by means of r^1, with two vertical check-valves self-operating, which admit the air under pressure into the engine as required.

The water for circulation in chamber *S* to cool the air in the ∩-shaped pipes, is driven by a plunger pump, shown erect over pipe *p*. It enters *S* by means of pipe *n′*, and issues by pipe *o* to an annular chamber around the cylinder *D* at n^2, where it serves as a cut-off for the heat ascending the working cylinder, above that point against which the piston moves.

The operation is as follows: The beam being in motion, the effect is that the pistons in the reversing cylinders displace the air contained therein, by driving the air in the cold end of one of the said cylinders through the ∩-shaped tubes in chamber *S*, and the regenerator space between cylinders *P* and *N* into the heater; at the same moment driving the air in the hot end of the other reverser cylinder through the heater and the regenerator space into the tubes *n*, thereby greatly increasing the pressure on one reverser cylinder, and in the lower end of one working cylinder, and correspondingly diminishing the pressure in the other reverser cylinder and the lower end of the other working cylinder with which it communicates. The increase of pressure beneath one of the working pistons causes it to be worked upwards till it reaches the extreme of its upward stroke, when the reverser pistons change their position, thereby diminishing the pressure beneath the working piston which has just completed its upward stroke, and increasing it beneath the one that has just completed its downward stroke, thus creating a differential pressure beneath the two working pistons, by means of which the engine is driven, the pressure alternately changing from one cylinder to the other.

The power of the engine will be determined by the difference in the pressure alternately created in the reverser cylinders by the movements of their pistons, heating the air in one reverser cylinder and cooling it in the other, thereby at each stroke of the engine increasing the pressure beneath one working piston and diminishing it beneath the other working piston.

Hot′-air Pump′ing En′gine. The application of the hot air engine to pumping is the particular purpose of some of the small motors of this class. See Fig. 510, p. 155, and Fig. 674, p. 216, *supra*. See also Hot-air Engine.

Hot′-air Reg′is-ter. A valve, usually a centrally pivoted circular plate with openings, moving upon a perforated plate at the opening of a hot-air flue. By bringing the openings in the two plates into correspondence or otherwise, the air is allowed to pass, or is shut off, respectively.

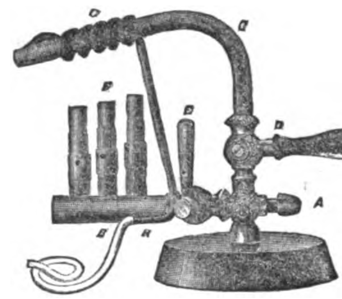
Hot′-air Stove. See Heater; Stove.

Hot′-air Syr′inge. A syringe with a chamber which heats the passing air. Used to dry cavities in teeth before filling. See Cavity Dryer, Fig. 572, p 179, *supra*.

Hot′-blast Blow′-pipe. A substitute for the ordinary blow-pipe.

The gas tubing is attached at *A*, allowing the gas to pass into both the upper and lower tubes, *B C*, and the supply can be regulated by the stop-cocks *D E*. The burners *F* heat

Fig. 1382.



Hot Blast Blow-pipe.

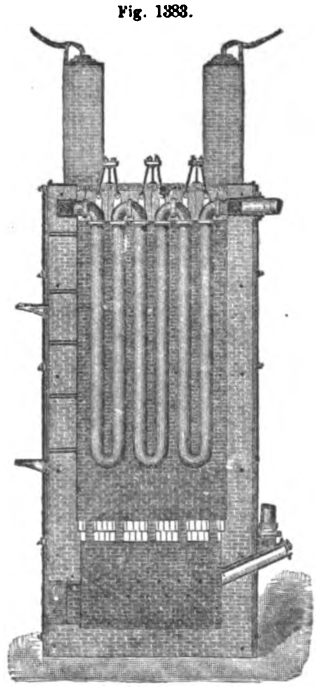
up the wire coil *G*, through which the breath passes, and it is thus thrown upon the surfaces to be acted upon in a heated condition. The mouth tubing is attached at *H*.

Hot′-blast Ov′en. (*Metallurgy.*) The Siemens' system, and modifications by Cowper and Whitwell are superseding the Player stove. *B*, Fig. 2588, p. 1134, "*Mech. Dict.*" See Gas Furnace, where the Siemens' regenerator is shown, Cowper's and Whitwell's are referred to, on page just stated. See Hot-blast Stove.

Hot′-blast Stove. Weimer's hot-blast stove, Lebanon, Pa., is shown in Fig. 1382. Its most important features are the suspension of the pipe from the roof of the stove, and the absence of the usual bed-pipes or mains.

The pipes are V-shaped, the cross section an ellipse 4″ × 12″ internally, and united by end flanges. The inlet main rests on the top end wall of the stove, and is provided with an inlet branch and three pipe branches; three rows of U pipe (three to a row) convey the air to be heated from the

Fig. 1383.



Hot-blast Stove. (*Lebanon, Pa.*)

inlet main through the first heating chamber to the transfer main, resting on the opposite side of the stove, where it is transferred to a similar lot of pipe, which convey it through chamber No. 2 to the outlet main. Each stove has two independent combustion chambers communicating each with its separate pipe chamber for the purpose of enabling the attendant to throw as much gas, and consequently heat, into the "cold" side of the stove as may be desirable, and to check a too great accumulation on the hot side. Each pipe is suspended by means of two key bolts to a 15″ wrought-iron beam, three of which traverse the top of the stove resting on wall plates. Four draft chimneys on the corners of the stove control the action of the upper pipe chambers, while the usual gas valve regulates the flow of gas to the combustion chamber.

The oven contains 18 pipes, 20′ long, the heating surface of each pipe 109 square feet.

The fire-brick stove of Whitwell, of Stockton-on-Tees, England, is intended to heat the blast of iron furnaces, and is shown in Plate XXII.

Fig. 1 is a vertical section.

Fig. 2, a horizontal section.

Fig. 3, an enlarged vertical section of the hot-blast valve, *B*, and its adjuncts.

Fig. 4 shows by an enlarged section the chimney valve, *C*, and cold-blast valve *J*.

Fig. 5 shows two ovens in elevation and the furnace in vertical section.

Fig. 6 is a plan of four ovens and a blast furnace.

The stoves are designed to replace the ordinary iron pipes used for heating the blast, substituting for them a series of fire-brick chambers and passages, which are heated by the direct contact of the flames of the burning gases taken from the furnace in the usual way. When the mass of brick is sufficiently heated the gas is shut off and the blast is admitted, and this, in passing through the same heated chambers, acquires the temperature of the bricks. The brick-work gradually cools down, but, by the time the last chamber begins to be too cool another stove has been heated up, and the blast is made to pass through that. The stoves are thus alternately heated by the burning gas and cooled by the blast. The advantages of this system are numerous. One of the greatest is uniformity of temperature of blast, which cannot be counted upon with iron pipes. The bricks are a great store-house of heat, and cool gradually. Iron pipes cool suddenly when, from any cause, the supply of burning gas is stopped. The air being brought into direct contact with the surfaces previously heated by the gas, absorbs the heat quickly and with little loss. The apparatus is simple, is easily erected, and is being extensively introduced. For cupola-furnaces, making 600 tons a week, two stoves, 12′ square by 21′ high, and with 2,270 superficial square feet of heating-surface in each, are necessary.

In heating the stove, the hot-blast valve, *B*, and the cold-blast valve, *J*, being closed, the gas-valve, *A*, is opened, through which the gas enters the stove, traverses up and down the spaces between the upright walls, and enters the chimney-flue by the valve, *C*. Heated air is supplied to the gas by means of the air-valves *a* and *c* and passages *b* and *d*, by which a most intense combustion is gained. The internal heat of the stove, as well as the combustion of the gas, is observed by the eye-pieces *e e*.

In heating the blast, the chimney-valve *C* and gas valve *A* being closed, and the hot-blast valve *B* being opened, the cold blast is admitted through the cold-blast valve *J*, and issues from the stove by the valve *B*, red hot, all other valves being closed perfectly tight.

In cleaning the stove, the top cleaning-doors, *F*, are opened and the walls scraped with the cleaning-tools, when the dust deposited on the heatin gsurfaces falls to the bottom of the stove, and is removed by the bottom cleaning-doors, *D*.

The general duty of one stove is 100 tons of pig iron per week: the average temperature of the blast, 1400° Fah. by Siemens' pyrometer.

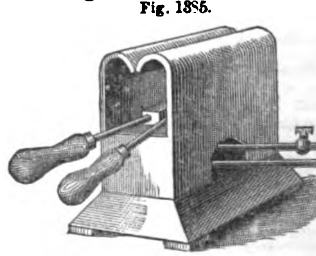
Hot Plate. A gas stove for heating copper bits for soldering.

Fig. 1385.



Hot Plate.

Hot Press. A machine in which pressure is aided by heat, either in calendering or expressing; the former for paper and fabrics, the latter for stearine and oils.

The stearine hot press of Morane, Paris, is shown in Fig. 1385. It has a hydraulic cylinder and pressure piston at one end, and a movable abutment at the other. The bags of material are sandwiched between hollow plates of iron, steam-heated by means of the pipes and flexible connections, the said pipes also serving to suspend the heated plates when the pressure is slackened in order to remove the cakes of

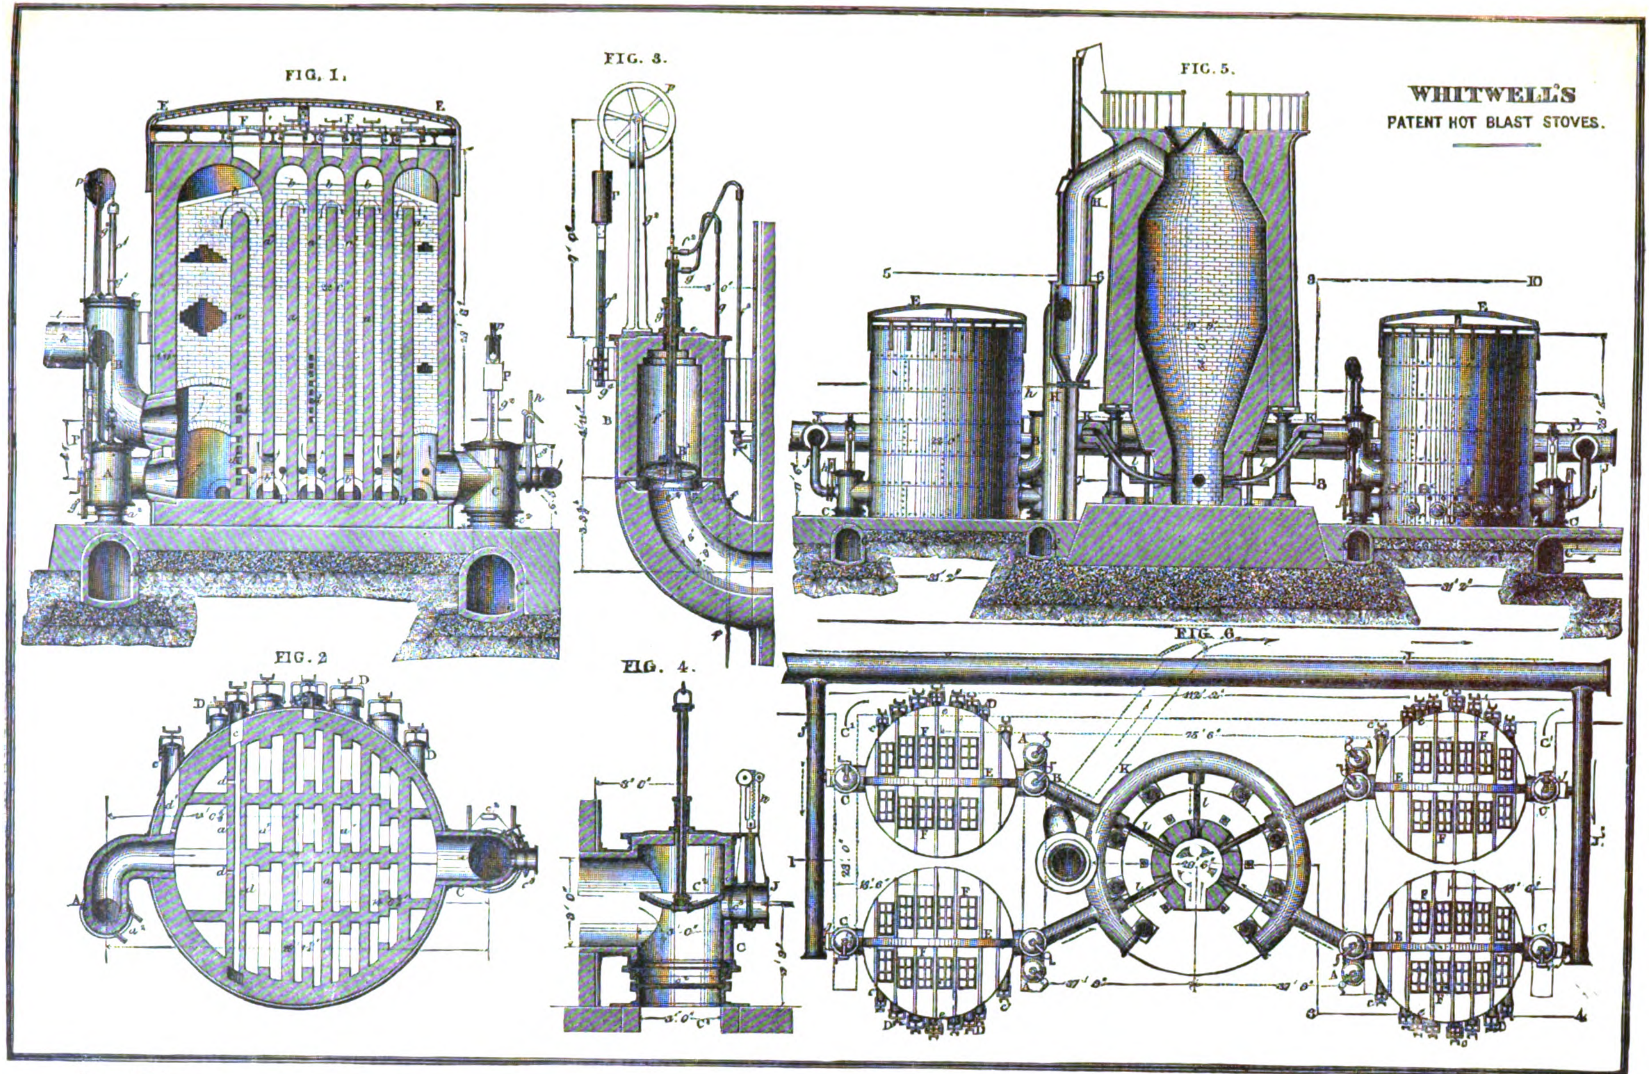


PLATE XXII.

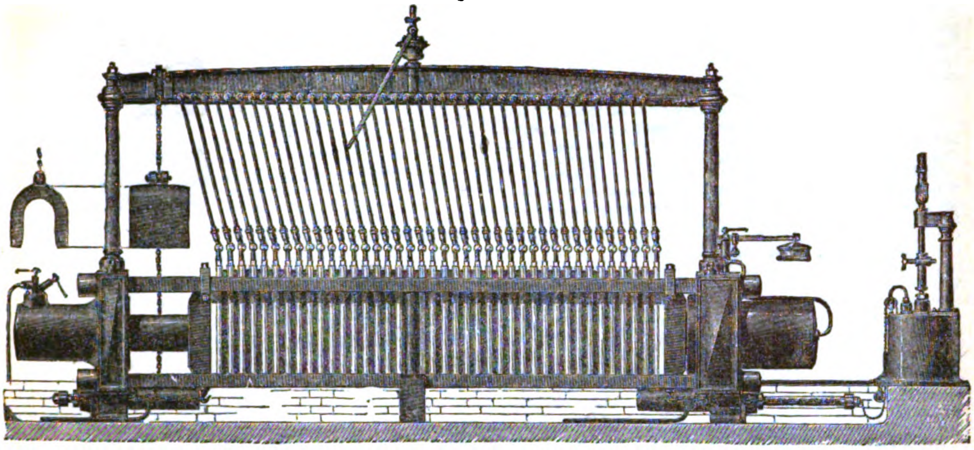
WHITWELL'S HOT BLAST STOVES.

See page 470.

Fig. 1386.



Stearine Hot Press.

stearine. Forty bags form a charge. The slack pressure (*suppression des espaces nuisibles*) takes 3 seconds; the completion, 17 seconds; total, 20 seconds. The pressure, 800 kilos. Production, 600 kilos. stearine saponifiée. The press is self-arresting when the required pressure is reached.

Hot Saw. See HOT-IRON SAW; IRON SAW.

Hot Straight′en-ing Ma-chine′. An apparatus to receive rods or bars from the rolls and straighten them perfectly by stretching before cooling.

At the end nearest to the rolls is a clamp-head or head-stock, which slides in a U-shaped groove. At the other end of the bed, which is long enough to allow the working of bars about 80′ in length, is another sliding head, the tail-stock, which can be moved by hand along the whole length of the bed, as may be required by the various lengths of the bars to be straightened. It runs on two wheels on a rail.

The machine is operated as follows: One end of the hot bar, as it comes from the rolls, is firmly clamped in the head-stock, while the other end is secured in the tail-stock, which is so constructed that simultaneous with the clamping of the bar the tail-stock is firmly fastened to the bed-plate so that it cannot slip. Power is then applied and the slide is dragged forward with an intermittent, jerky motion, which rapidly straightens the bar and stretches it, the proper limit being determined by the operator. The clamps are released and the bar is slipped on to the adjoining hot-bed, where it is allowed to cool.

Baldwin . . . . . * "*Iron Age*," xxiv., Oct. 16, p. 1.

Hot Water Heat′er. A device for warming buildings, conservatories, etc., by means of a circulation of hot water in pipes. See HEATER, *supra*, Also p. 1136, "*Mech. Dict.*"

Hound Plate. A bracing plate at the junction of the fore end of the wagon hounds with the coupling.

Hour Glass Coil. A heating coil larger at the ends than at the mid-length, resembling an hour glass in exterior outline.

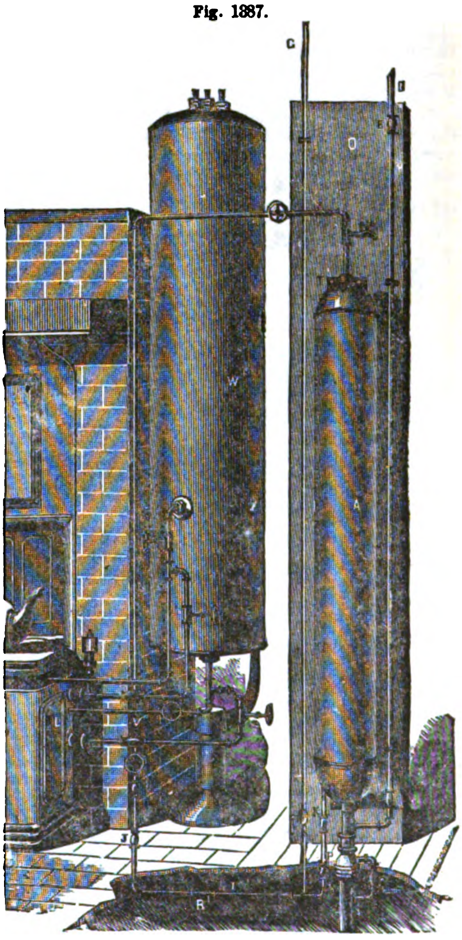
House Car. (*Railway.*) A box car, or closed freight car.

House Pump. One for the supply of a house when the pressure in the city mains is not sufficient for the high service in the house; or, when no urban water-works exist, to supply the house from ordinary wells or cisterns.

Houghton's automatic house pump is worked by the fire in the kitchen range. The cylinder *A* is a receptacle alternately for steam and water; its bottom is below the steam generator in the range, and its top not more than 25′ above the water supply, which is reached by a pipe extending from the bottom of the cylinder. The pipe has two valves, one near the near cylinder and one near the foot of the pipe. The steam generator is a back or cheek of the range furnace and has two nipples, for steam and water pipe connections respectively. The generator connects by pipe *F* with the top of the cylinder; the pipe has a cock to draw off steam or water when necessary, and a spring safety valve to obviate danger of explosion.

The pipe *G* conducts water from the tank above to supply

Fig. 1387.



Automatic House Pump.

the steam generator L through the branch I, and to condense steam in the cylinder through the branch K. In these branches are valves opening upward and towards the steam generator and cylinder, permitting water to flow into them, but closing downward by their own weight, and preventing the steam from driving the water up the pipe G, the pressure of the steam holding the valves in the pipes I and K to their seats against the weight of the column of water in the pipe G, which is pressing against the under side of them.

The cylinder and steam generator being filled with water, and a fire kindled, the water boils in the generator. The steam passes along the pipe F and expands in the top of the cylinder, and forces the water out of it up the outlet-pipe D, which rises above and empties it into the tank at the top of the house. In this pipe is a valve which prevents the water from falling back in it, and air from entering the cylinder through it. This outlet, or rising pipe, is of such diameter that the steam will drive the water before it, leaving the lower end of the pipe empty of water and filled with steam. The top of the column pouring out into the tank, it becomes shorter and correspondingly lighter, and as the weight of this column of water determines the pressure of steam, the lighter the column the lower the pressure becomes. When the pressure of steam is too low to hold the valves in the pipes I and K to their seats, the water in the pipe G flows by them and refills the generator with cold water, and jetting into the cylinder, condenses the steam in it, producing a vacuum, which is instantly filled with water forced up from the well or cistern by the pressure of the atmosphere.

This operation will repeat itself as long as the fire is kept up, and requires no attention.

Hous'ing Box. (*Railway.*) The axle-box which moves up and down in the *housing* or *pedestal.*

Hov'er-er. A warm chamber for young chickens, used in connection with an incubator to give to the young chicks an artificial protection in place of the brooding hen. An *artificial mother.*

How'el-ing Ma-chine'. (*Coopering.*) See CHAMFERING MACHINE.

How'it-zer. A relatively short and large bored cannon for certain uses at short range.

Fig. 1387 shows a Spanish howitzer of 21 centimeters, système Barrios, with its carriage.

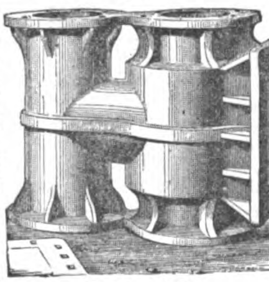
Fig. 1389.



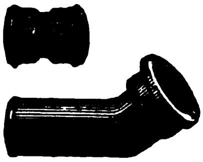
H-piece and Door.

H-piece. The section containing the valve-chamber of a Cornish engine.

By it is the door which closes the square opening by which access is had to the valve and chamber.

The door piece for a single pipe is shown at Fig. 841, p. 264, *supra.*

Fig. 1390.



Hub.

Hub. (*Add.*) 5. A short connecting pipe with a bell end for coupling pipes in line.

With two bell ends it is a *double-hub.* With one of the ends smaller than the other, it is *reducer double hub*, and connects two pipes of varying diameter. See REDUCER.

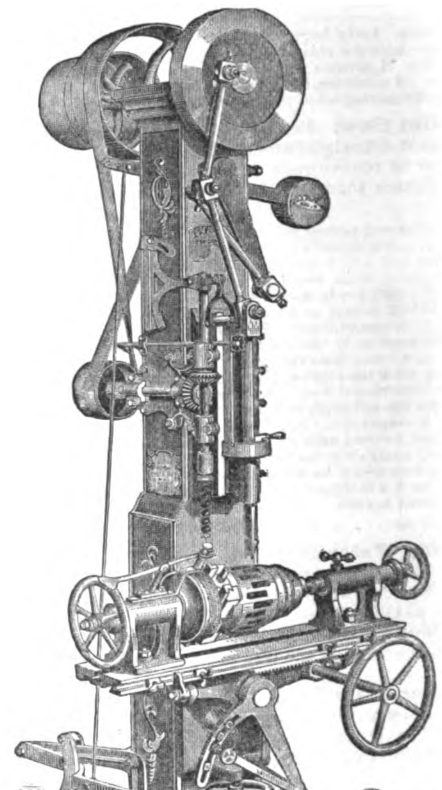
The lower figure in the illustration is a *bevel hub.*

Hub Bolt. (*Railway.*) The bolts by which the wheel plate is fastened to the hub, in the construction of paper-web car wheels.

Hub Mor'tis-er. A machine for making the spoke holes in hubs of vehicles.

The mortising and boring apparatus may both be driven by one belt from the counter shaft, or independent of each other, as may be desired.

Fig. 1391.



Hub Boring and Mortising Machine.

The hubs are confined in a screw chuck, the arms on its face being operated at the same time and by a single screw. It has a graduating wheel, spaced for 10, 12, 14, 16, and 18 spokes, thus obviating the necessity for setting out.

The dish of the mortise is regulated by a lever, having a crank and connections attached to the table. The lever has a handle with a spring stop, which works into adjustable poppets in a slot on the same circle as the lever handle describes. The lever support with the slotted piece are rigidly fixed to the center, upon which the table swings, and convenient to adjust the angle of the mortise instantly.

It has a graduated stroke, commencing at a still point above the extreme upper throw, and working gradually down into the mortise with but slight jar; the chisel mandrel is vibrated only when the chisel is brought down to the work.

Hurst. The frame on which a run of mill-stones is placed. A *husk.*

Hy'a-lithe. (*Glass.*) An opaque glass, usually black, and of remarkable strength. Used as a substitute for porcelain for vessels for boiling liquids, for coffee and tea-pots, etc.

To the usual white-glass compound add powder of calcined bones, iron scales, and charcoal.

It is made black, green, brown, red, by suitable additions to or restriction of elements in the compound.

See *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," article "*Verre*," vol. iii., ed. 1877.

Hy'dra. A self-registering thermometer with a compound head or bulb for holding the spirits; for increasing the surface exposed to the air and thereby causing the instrument to work very rapidly.

Hy'drant. A street connection to a water-main, to obtain water at the surface for extinguishing fires or watering streets.

Holly's fire-hydrant is shown in Fig. 1392. The axial vertical screw operates the main valve, which closes as it ascends. The main valve-seat is a leathern gasket, which serves also as a packing for the lower joint of the inner pipe. The hydrants are removable without disturbing the position of the shell in the soil. The extra frost jacket and drip-valve obviate freezing. The main valve closes with the current. The drip-valve is positive in its action, being held open by the main valve when the latter is closed, and closing as soon as the main valve is opened.

The gate at the base is for the purpose of cutting off the hydrant from the main when it is necessary to remove the former.

Fig. 1393 shows interior and exterior views of a street fire-hydrant. A key on top of the axial rod rotates the screw, which opens or closes the valve connecting with the main. The portion of the hydrant protruding above the surface has three connections for hose.

Fig. 1394 consists of two or more practically independent fire-hydrants secured to a common base, and permits the concentration of a number of independent fire-streams with a minimum amount of hose. A single casting acts as a washer, and also as a nut for all the operating screws. Either hydrant is readily detachable. — *Birkinbine.*

Fig. 1395 is another form in which the depression of the main valve uncovers the waste-pipe, and conversely.

Von Pauwel . . . . * "*Manuf. & Builder*," ix. 142.

Hy-drau'lic Bal'ance. A governor or regulator placed between a water-wheel and a driving-shaft to maintain a steady motion under circumstances of changes of work by throwing machinery on or off. See HYDRAULIC REGULATOR.

Hy-drau'lic Bend'er. A hydraulic jack used in bending and straightening rails and bars. See E, Plate XXV., opposite p. 1150, "*Mech. Dict.*"

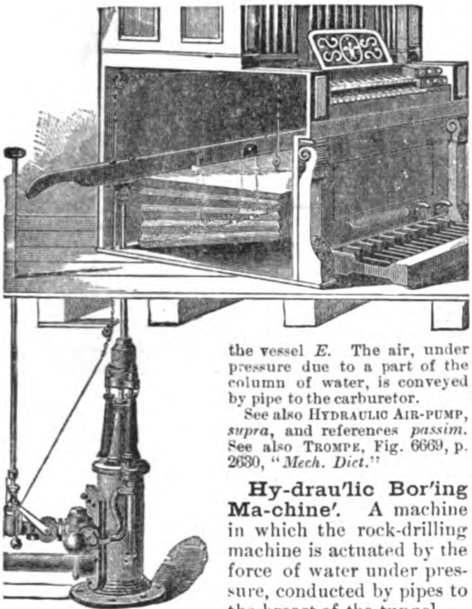
Hy-drau'lic Blow'er. An application of the hydraulic motor to the working of bellows.

Fig 1401 shows it as a reciprocating engine, worked by water from the main and oscillating the lever of the ordinary organ blowers. It is made self-regulating by attaching the upper valve of the organ by cords to the valve-lever, so as to proportion the induction of water to the condition of inflation of the bellows.

See also Figs. 3426, 3427, p. 1576, "*Mech. Dict.*"

Fig. 1402 is an application of the *trompe* to the purpose of forcing air to an apparatus for carbureting air. The injection-pipe brings water from a spring or a city main, and is fitted with a nozzle, through which the water rushes, falling through the larger pipe *C*. In so doing, air is drawn in at the suction-pipe *D*, and both air and water fall together into

Fig. 1401.



Hydraulic Organ Blower.

the vessel *E*. The air, under pressure due to a part of the column of water, is conveyed by pipe to the carburetor.

See also HYDRAULIC AIR-PUMP, *supra*, and references *passim*. See also TROMPE, Fig. 6669, p. 2630, "*Mech. Dict.*"

Hy-drau'lic Bor'ing Ma-chine'. A machine in which the rock-drilling machine is actuated by the force of water under pressure, conducted by pipes to the breast of the tunnel. The nature of the machine is in accordance with the action required, the percussion of the chisel, or the rotation of the diamond drill, — the latter, in the instance of the machine shown in Fig. 1403, made by Sulzer Brothers, of Winterthur, Switzerland.

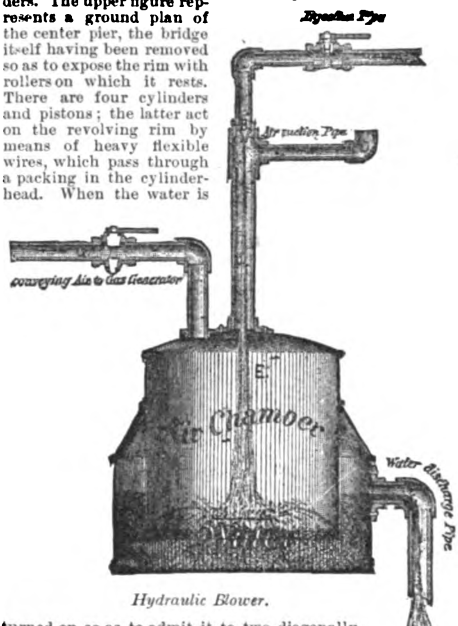
The machine for drilling the rock in the tunnel of Mont Cenis is shown in Fig. 6777, p. 2654, "*Mech. Dict.*"; the air-compressor, by which the drills are driven, is shown in Plate X., opposite p. 602, *Ibid.* The use of compressed air is much more frequent than that of water for running the drills. See pp. 2654, 2655, *Ibid.* The same may be said of the use of steam; see ROCK-DRILL, pp. 1956-1958, "*Mech. Dict.*"

Hy-drau'lic Brake. See HYDRAULIC RAILWAY BRAKE.

Hy-drau'lic Bridge Op'er-a'tor. An application of the hydraulic press to the moving of a pivot draw-bridge on its pintle, to open the waterway. See Fig. 1404, p. 476.

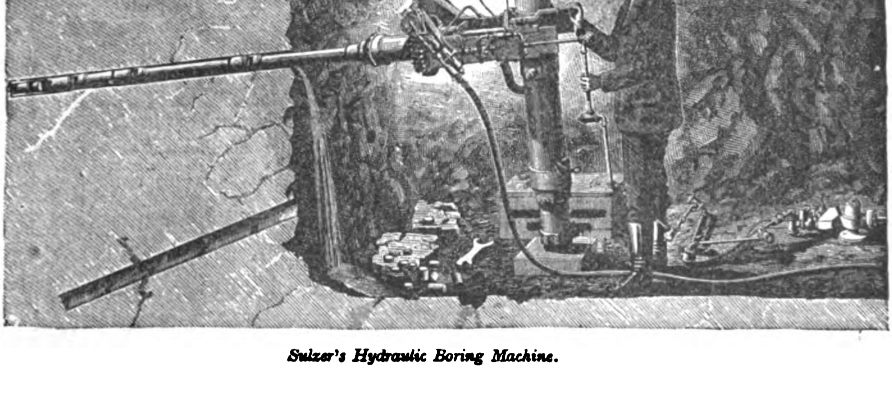
The motion is produced by the hydraulic pressure of the water on pistons in cylinders. The upper figure represents a ground plan of the center pier, the bridge itself having been removed so as to expose the rim with rollers on which it rests. There are four cylinders and pistons; the latter act on the revolving rim by means of heavy flexible wires, which pass through a packing in the cylinder-head. When the water is turned on so as to admit it to two diagonally opposite cylinders, its pressure will produce a pull on the wires, and these, being fixed to the revolving rim, will rotate it, and with it the whole draw, which rests on it. When the bridge has to be closed again, the water is turned on into the two opposite cylinders, while the same

Fig. 1402.



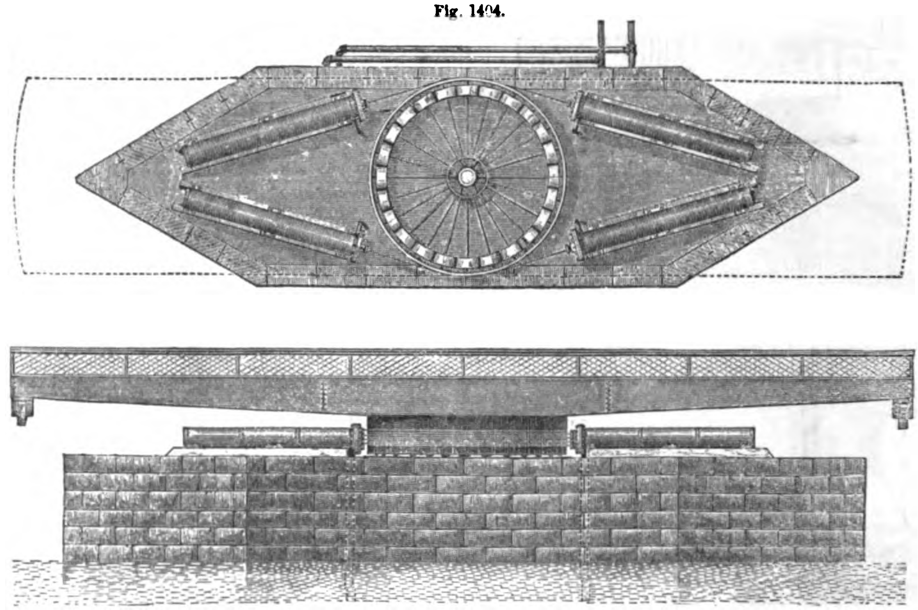
Hydraulic Blower.

Fig. 1403.



Sulzer's Hydraulic Boring Machine.

Fig. 1404.



Draw-bridge Moved by Hydraulic Pressure.

motion which turns on the water in two of the cylinders gives an exit to the water which has filled the two others. The water pipes are shown in the upper figure, one pipe for carrying the water to the pressure cylinders, which serve for opening, and the other pipe to those for closing the draw. The lower figure represents the bridge when open, resting entirely on the center pier, which is here seen longitudinally.

Hy-drau'lic Buf'fer. An arrangement of a piston in a cylinder to check the recoil of a cannon. The piston rod is made fast to the top carriage and moves in a cylinder filled with oil. The latter escapes through holes in the piston head, but with such difficulty as to impede the motion of the piston and thus act as a buffer.

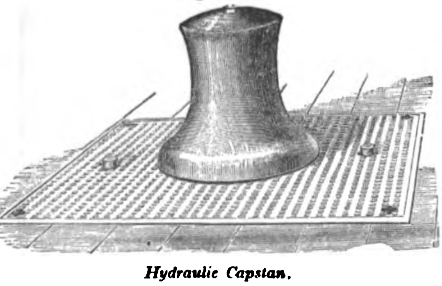
A quantity of air in the cylinder serves as a cushion to reduce the violence of the shock. The quantity of oil to be used, and the depth at the filling hole is marked on each cylinder. Otherwise known as a *recoil-check*.

See Fig. 83, Appendix L, to "*Ordnance Report*," 1877.
Plate VI., Appendix II, to "*Ordnance Report*," 1876.

Hy-drau'lic Cap'stan. One used ashore and operated by water under pressure.

Figs. 1405, 1406, show Brotherhood's three cylinder hydraulic capstan. It is a horizontal application of their familiar

Fig. 1405.

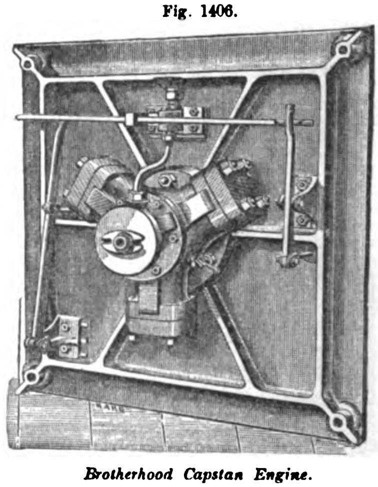


Hydraulic Capstan.

engine to the rotation of a capstan whose pintle is the common triple crank shaft of the trinary engine. Fig. 1402 shows the capstan on the plate beneath which the engine is fixed. Fig. 1406 is a view of the engine as it would appear if the plate were tipped up on edge and the bottom exposed.

The engine is very compact and is very simple. It is self contained and has but few working parts. There is but one valve in the engine, no glands, stuffing-boxes, or oscillating joints. The moving parts are subject to strain in one direction only. See also Fig. 531, p. 162, *supra*.

Fig. 1406.



Brotherhood Capstan Engine.

Hy-drau'lic Car Pro-pul'sion. A mode of propelling street cars by a hydraulic motor on each car, water being stored in each car under pressure of air at 20 to 30 atmospheres in a receiver.

The principle is the same, in most respects, as the plans proposed for air propulsion, stations at intervals refreshing the reservoir of the car. See notices under COMPRESSED-AIR ENGINE, p. 215, *supra*, and references *passim*. The water simply acts as the vehicle of transmission of the pressure of the air, and the benefit, if any, is in dealing with water rather than with air in the parts of the engine.

Hy-drau'lic Ce-ment'. Cement which will harden perfectly so as to exclude water. Cement which will harden under water.

Some limestones yield a perfect hydraulic cement, and in other cases materials are artificially united in proper proportions. See HYDRAULIC CEMENT, p. 1144, "*Mech. Dict.*"

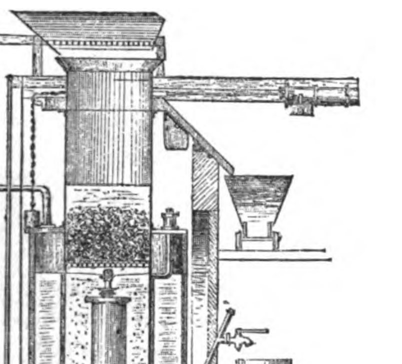
The English Portland cement, which has acquired a world-wide celebrity, is an artificial production, the special features of the manufacture of which are the following: Chalk and clay are ground together in water, the fine particles are floated away to other vessels and allowed to settle as a paste, which is thereupon collected, molded, dried, burnt, and finally ground. Certain porous, earthy, disintegrated rocks are found to be capable of cementing with lime in the natural state; that is to say, they do not require any preliminary preparation by burning as do the ordinary clays, it being simply necessary that they should be finely ground, in order that a thorough incorporation with the lime may be effected. These natural cements are generally of volcanic origin. The so-called pozzuolana and the trass are the best known of these deposits, both of which have been used from very ancient times. The pozzuolana, occurring on the coast of the bay of Naples — a species of tufa — was known on account of its cementing properties to the Romans, and by them largely employed. Vitruvius and Pliny both describe it, and state that it was mixed with an equal quantity of burnt lime for building under water. The same substance is very largely employed in the same manner at the present time. — "*Polytechnic Review.*"

See also TRASS.

Hy-drau'lic Clas'si-fi-ca'tor. (*Coal*) A coal dressing apparatus by M. Evrard, of St Etienne.

It consists of a vertical, hollow prism, either cylindrical or rectangular, 3 meters deep, the bottom of which is formed

Fig. 1407.



Evrard's Coal Dressing Machine.

by a movable piston-like inclosing rim, covered with a perforated plate, which can be raised to any height desired, as far up as the rim of the vessel, by means of a piston-rod attached to the under side and an upright hydraulic cylinder working upon it.

The vessel is prolonged beneath the piston in an open pipe of the same width and about 4 meters long, and both are submerged in a wider water-cistern, closed above and below and steam-tight, the cover being closely riveted to the outer covering of the vessel, and provided with a steam supply-pipe. By means of an intermittent supply of steam from the boiler, through the cover, into the upper part of the outer holder, the water therein receives an oscillating jerking motion, and works upon the minerals which are fed into the vessel and become heaped about 1 33 meters high upon the piston-sieve, just as with a jig-sieve. The only difference is, that the hydraulic strokes are much stronger at the start, being given with a lift as high as 20 centimeters, and then decrease to a few millimeters so that the action which follows at first just as with a slime separator, changes gradually to the action of a fine-jigging machine.

In this way a pause of one or two minutes is given, in order that the finest slime may properly settle on the piston-sieve, and then this piston is raised intermittently to the upper edge of the inner vessel, in order to scrape off the jigging-stuff over the edge in different layers, according as they lie upon the piston after sorting, and to obtain them separately as special products. The whole operation lasts about five minutes.

Hy-drau'lic Coal Mi'ner. An apparatus for breaking down coal *in situ.*

The breast of coal is undermined as usual and a hole drilled in it to hold an expanding plug of a cylindrical form worked by means of hydraulic pressure The plug is composed of two halves, which have a little wedge-shaped space between them, and are jointed at the end to the extremity of a hydraulic cylinder, and receive between them a wedge-shaped extension of the hydraulic ram or plunger, fitting exactly the widest part of the wedge-shaped space, and extending about half its length when the ram is withdrawn into the hydraulic cylinder. When the pressure is applied to the ram, the wedge-like extension is driven further along the space between the two halves of the plug, which are forced apart, so that the plug is expanded in one direction beyond its original diameter, and by lifting breaks off the mass of coal.

See HYDRAULIC BORING MACHINE, *supra.*

Hy-drau'lic Com-pres'sor. A device in a gun carriage to check the recoil of the piece by receiving the impact upon a piston which condenses air in a chamber.

See also GUN CARRIAGE; HYDRAULIC BUFFER, *supra.*

Krupp . . . .
Rendel . . . . } * "*Engineering*," xxviii. 87.
Vavasseur . . . . . .

Hy-drau'lic Crane. One in which the elevating chain is wound by hydraulic power.

The first crane worked by hydraulic power was put up on the quay of Newcastle-upon-Tyne by Sir William Armstrong, in 1846.

Fig. 1408 gives two views of a British crane of this kind. It is shown by side and end elevations, and is fixed against the wall of a warehouse in connection with a swing crane jib on the outside. The apparatus is used in connection with an accumulator, which is a vertical cylinder, proportioned in diameter and height to the number and power of the cranes or other machines to be employed. This cylinder is fitted with a leathern collar or gland, through which works a ram or plunger with a massive cross-head on the upper end, to which is attached an annular weight-case surrounding and sliding over the above-named cylinder. The weight-case is filled with ballast until the total weight on the ram is equal to (usually) 700 lbs. per square inch; water is then forced into the cylinder or accumulator by the hydraulic pumps, until the ram, loaded as above described, reaches the top of the accumulator. At this moment a self-acting arrangement arrests the motion of the engines, but immediately the ram begins to descend, in consequence of some of the stored power having been used, the engines and pumps are set in motion automatically, and the ram is again lifted.

The water passes from the accumulator to the cylinder of the ram, and, driving out the piston, draws upon the chain and lifts the load. The principle is shown also in Fig. K, Plate XXIV., p. 1157, "*Mech. Dict.*" The jibs are frequently of greater sweep than that shown, built up of plate and angle-iron, and fixed in a central position between two tiers of doors, one crane being thus made available for both sets of doors. The top pair of cylinders, shown in Fig. 1408, are used for slewing or turning the jib, and the bottom cylinder and ram for lifting the load.

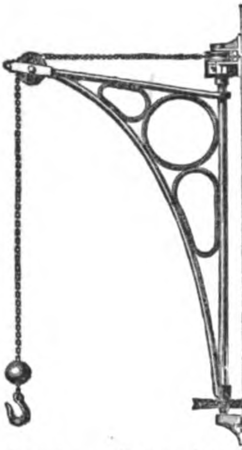
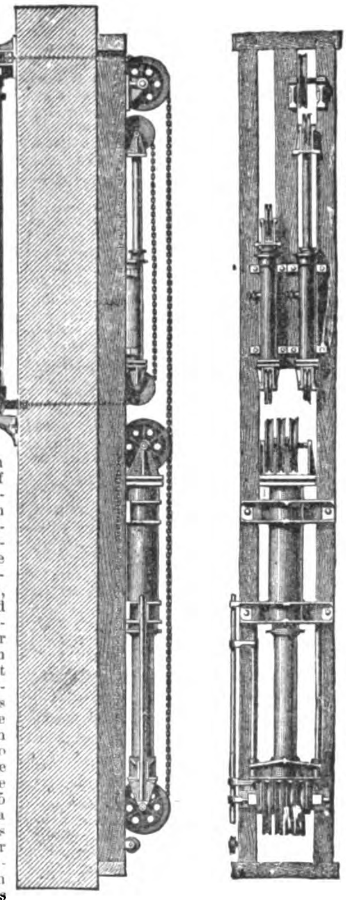
Hy-drau'lic Dump'ing. A tip for coal wagons to discharge them on to the chute.

As in similar constructions, the car or wagon is rolled on a platform, which, in most cases, rests with one end on the edge of the quay and swings around a horizontal axis,

Fig. 1408.





Hydraulic Crane.

situated at a distance from the quay of about one third of the entire length of the platform. The other end rests on a piston, moving in a cylinder filled with water, the resistance of which must be overcome during the downward journey of the platform, by which the water is forced from the cylinder into an accumulator. As soon as the car has reached its proper position on the platform, the front wheels act on a system of levers, which raise two clutches engaging the front axle of the car and holding the same in position. The car is then also secured at the rear end. The platform exerts now on the piston a pressure of about 25 atmospheres; by opening a valve, communication is opened with an accumulator of a pressure of about 20 atmospheres. The difference in pressure of five atmospheres forces the accumulator upward; this upward motion increases in rapidity as, by the change of position of the center of gravity of the car, the pressure in the cylinder is gradually increased to 40 atmospheres. As soon as the platform has attained an inclination of 45°, the accumulator has risen high enough to touch a lever, by which communication between itself and the cylinder is interrupted. Meanwhile the contents of the car have been dumped over the scoop-shaped end of the platform into the hold of the vessel below and the pressure in the cylinder has been reduced from 40 to 16 atmospheres. Connection with the accumulator having now been restored, the platform is brought into its original position by the overpressure of 20 — 16 = 4 atmospheres. Should the cargo of the car not weigh enough, a little water may be drawn from the accumulator by a separate stop-cock. Hereby the pressure is reduced and the platform lowered far enough to produce the necessary pressure by a change of position of the center of gravity of the car. Glycerine may be substituted for water when the apparatus is exposed to very low temperatures.

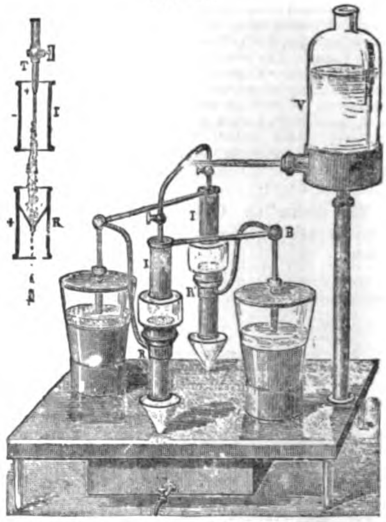
The principle involved in this apparatus is the storage of the weight of the cargo in an accumulator, and its employment for raising the empty car and platform after discharging the load.

See also references under DUMP CAR, p. 280, *supra*.

Hy-drau'lic E-lec'tric Ma-chine'. A machine in which electricity is excited by a flowing stream of water. — *Machine Électrique à Écoulement.*

The principle is illustrated in the small figure to the left in Fig. 1409, in which *T* is a metallic tube with a stop-cock, through which a small stream of water runs in drops from a reservoir, while it is electrically connected with the earth. It is surrounded by an isolated metallic cylinder, *I*, which induces a positive electrical conduction in the tube *T* and in the stream of water, by being itself once for all charged with negative electricity by contact with a piece of rubbed gutta-percha, hard rubber, sealing-wax, or equivalent substance. The cylinder *I* is called the *inductor*. These charges are indicated by the — and + signs. The falling drops of water being positive electric, communicate their charge to a funnel placed in the metallic cylinder *R*, which therefore, also, becomes positive electric, and is called the *receiver*. As electric charges always go to the outer surface of cylinders, the water flowing out of the funnel will be neutral, and all the positive electricity left behind in the outer cylinder *R*. Its charge increases continually,

Fig. 1409.



Hydraulic Electric Machine.

until the charge of the drops of liquid falling from *T* is in equilibrium with the loss, or until electric sparks fly over between the lower cylinder *R* and the upper one *I*, or until the drops from the tube *T* no longer fall down in the funnel *R*, being repelled sideways and thrown outward by the equally positively charged cylinder *R*.

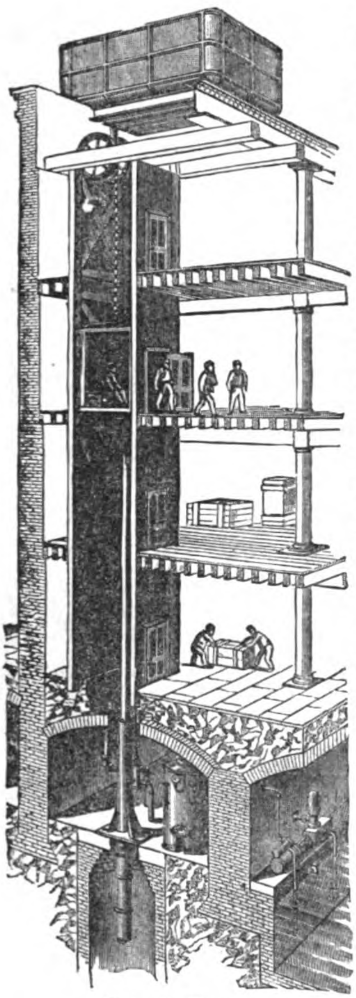
If nothing more were added to this arrangement, it would be necessary to renew the negative charge of the cylinder *I* frequently; but Fig. 1409 represents a double apparatus on this principle, invented by *Thompson*, and so arranged by duplication of parts, one set next to the other, that the electricity of the lower cylinder *R* of one charges the upper cylinder *I* of its other, of which then the electric charges will be reversed, the upper cylinder *I* will be positive, and the lower one *R* negative.

The reservoir *R* of the nearest set of cylinders is connected with the inductor *I'* of the farther set, while the receiver *R'* of this set is connected with the inductor *I* of the nearest set. The drops falling from the second inductor *I'* are then negatively charged, and give this charge to the second receiver *R'*, which increases the charge of the first inductor *I*. Added to the connections, of which, of course, one is always positive and the other negative, are two Leyden jars, *A* and *B*. The jars are truncated cones, of flint glass of good isolating quality, coated exteriorly with tinfoil, and interiorly containing a quantity of strong sulphuric acid, into which dip the lead rods, which at their lower ends have lead plates; the rods are surrounded by a glass tube and pass through the center of a cover of hard rubber. This is done to secure for the interior of these jars a perfectly uniform dry atmosphere.

The dynamic value of the electricity thus produced is derived from the power of the falling liquid: it would be equal to the work performed by gravitation on the drops of liquid during their downward route, if the drops arrived in the funnels after having lost all their velocity, and it corresponds exactly to their loss in *vis viva*. The loss of electricity is so weak in this apparatus, that the charge can be kept up for years by means of an insignificant discharge of liquid; a single drop, for instance, falling from each stop-cock every three minutes, has been found sufficient to keep up a constant charge.

The matter is considered more at length in "*Manufacturer and Builder*," * ix. 252.

Fig. 1410.



Hydraulic Elevator.

Hy-drau'lic El'e-va'-tor. A lift operated by hydraulic pressure.

Several methods of application of hydraulic force to this purpose are given in Plates XXIV., XXV., pp. 1150–1157, "*Mech. Dict.*"; and WATER ENGINE, Figs. 7101, 7102, p. 2738, *Ibid.* See also references at ELEVATOR, p. 309, *Ibid.*, and ROPE ELEVATOR, Fig. 4437, p. 1979, *Ibid.*

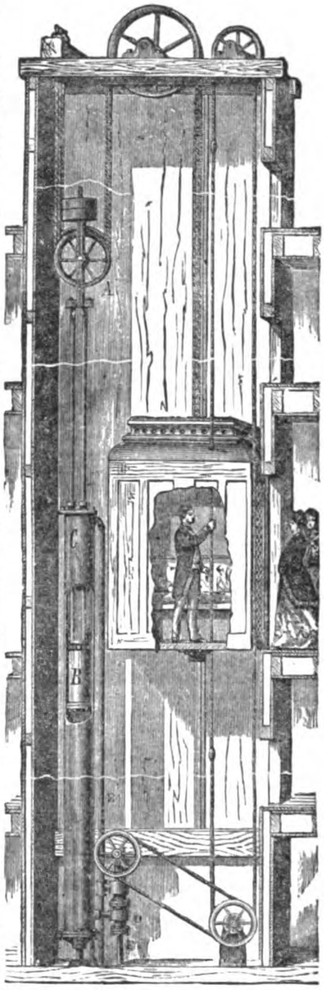
The Ascenseur Édoux is shown in Fig. 1410. It is regarded as the safest of all methods, and is remarkably smooth and noiseless in action.

It consists of a hydraulic cylinder equal in length to the height of the desired lift (sometimes 70′ and upward), placed vertically in a well or bore-hole, and a ram of area proportionate to the work to be done and the pressure of water available. The cylinder is fitted with a gland or leathern collar, and on the head of the ram rests the cage or ascending room, which is guided by suitable guide timbers. The motion is regulated by an equilibrium valve, admitting the water into the cylinder or letting it run to waste. The valve can be controlled from a rod which passes down one corner of the lift, and only requires a gentle pull to stop at any desired floor or to start again.

These lifts are always fitted with compensating counterbalances, exactly equal to the weight of the cage and the ram, insuring the utmost economy of water in working. The water pressure is obtained in various ways, from an accumulator, from the city main, or from an elevated cistern, as in the illustration, Fig. 1409, in which is a steam pump to keep the cistern supplied.

Fig 1411 is *Hale's* hydraulic elevator, in which the ram *B* in the cylinder *C* is made to draw upon a pulley, *A*, and so wind up the suspending rope of the cage. *D* is the pump, *F* water supply, and *E* pipe leading to ram cylinder *C*.

Fig. 1411.



Hydraulic Elevator.

While it is impossible to eliminate all chances of danger in lifting machinery, and preference has been expressed for the ascenseur Édoux on account of its avoidance of the use of a lifting cable, it must be acknowledged that it has one weak spot, and that is the parting of the connection between the cage and the lifting tube, in which case the counterbalance carries the cage violently upward and breaks the connection at the top, allowing the cage to drop. This was the cause of the fatal accident at the Grand Hotel in Paris, in 1878.

Hy-drau'lic En'gine. An engine operated by pressure of water.

Two forms of hydraulic engines are made by *Pratt & Whitney*. One with a rotary movement; it is a simple reciprocating engine worked under a water pressure of 20 pounds to the square inch or upward. It is intended for furnishing limited power for working printing presses, for small shops, etc., and the stroke is adjustable from 4″ to 10″.

The hydraulic engine for blowing pipe-organs works noiselessly and without thump, as the stroke of the piston connects directly with a partially rotary movement. It works under all pressure with equal facility.

See HYDRAULIC BLOWER, *supra*, and Figs. 3426, 3427, p. 1576 "*Mech. Dict.*"

The *Stannard* hydraulic engine resembles a small horizontal steam-engine, and is intended to be used, in any locality where a head of water can be obtained, to act as a light motor. The length of the stroke is adjustable at will, from 4″ to 8″, according to the quantity of water available, or power required. Diameter of cylinder, 5″.

White's dental engine is shown in Fig. 795, p. 250, *supra*.

The Valley Machine Co.'s engine is a small compact upright form for a domestic motor, or use in small shops.

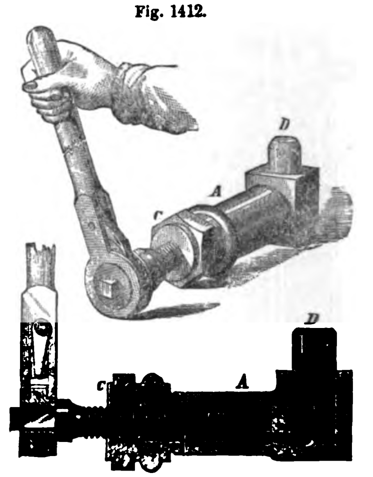
Hy-drau'lic Jack. An application of the hydrostatic press to a portable lifting or pushing instrument.

Several forms are shown at M, M', M'', M''', O, Plate XXV. p. 1157, "*Mech. Dict.*"

Fig. 1412 shows a jack for forcing crossheads out of piston rods, bolts from engine frames and cylinders, crank pins out

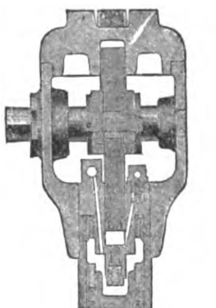
Fig. 1412.



Hydraulic Jack

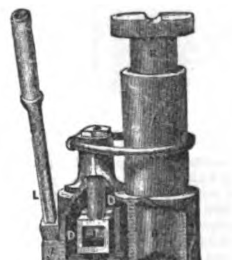
of locomotive driving-wheels, and for performing similar work in which it is necessary to employ a tool of large power in a small space. It consists of a long tube, *A*, in which works a piston, *B*. The latter is provided with suitable packing, and its rod is a screw working in the cover *C*. *D* is the ram of the jack. The handle has click and rachet so as to work by a vibratory movement.

Fig 1413.



Hydraulic Jack.

Fig. 1414.



Hydraulic Jack.

Fig. 1413 is Justice's hydraulic jack. It is filled with a liquid.

Water	1
Whiskey	6
Oil	0.5

Well shaken together before being filled into the jack. The pump-piston works in guides at top and bottom; the jack will work with any wrench or spanner, the socket of which will fit the square on the pump-shaft. The transference of the liquid from the upper chamber to the space beneath the piston is the cause of the elevation of the head and cylinder on the stem of the foot-piece.

Fig. 1414 represents the Dudgeon hydraulic jack. The vibrating lever *L* operates the plunger *D* by means of a cam, taking oil or glycerine from the chamber and forcing it by passages to the space *C* beneath the ram *B*, which rises in cylinder *A*.

The hydraulic jack has many applications, in machines bearing special names. See, among others: CRANK-PIN JACK, * Fig. 720, p. 229, *supra*; CAR-WHEEL PRESS, * Fig. 7189, p. 2768, "*Mech. Dict.*," etc. See list under HYDRAULIC MACHINERY, *infra*.

Compound, *Harrison*, Br. * "*Engineer*," xlii. 21.

Hy-drau'lick-ing. (*Mining.*) Washing down a placer claim by the use of hose or *giant nozzle*.

"The water is sold by the inch, that being the customary quantity which escapes through an orifice one inch square with the water 6″ deep above the top of the orifice; as measured, an inch of water is considered equal to 2¼′ cubic per minute. The mining ditches of California (1871) carry at least 100,000″, or about 2,500,000,000 gallons in 24 hours. This water is carried in open canals, in wooden frames, and iron pipes. The latter are used now invariably in crossing deep ravines, and the necessities of the positions have led to the adoption of heroic engineering precedents in regard to the thickness of metal, coupled with diameter of pipe. Thus the Swartsville pipe, 16″ diameter, under 180′ pressure, of No. 18 sheet iron, was laid in 1861, not painted inside, but painted on the out. San Juan, 30″ diameter, Nos. 12 and 14 iron, 55′ head, coated inside and out, laid in 1861. Chinese camp, Nos. 12, 14, 16, and 18 iron, maximum head 800′, was laid in 1868. The pipes are double riveted on the longitudinal seams, put together like stove-pipes and riveted, and coated with coal tar.

"Most of the water thus distributed is used, as is said, *to hydraulic*, that is, to wash banks of auriferous earth by throwing a stream of water upon them through a hose and pipe. Hydraulic claims are usually in hills. The water is brought to the bottom of the hill by an iron pipe or by a hose. The hose is of heavy duck, and from 4 to 10″ diameter, sometimes surrounded by iron rings 2″ wide and 3″ apart, connected by 4 ropes. It is important to preserve as great a head as possible, with flexibility of hose. The nozzles are like those of fire-engine hose, sometimes as large as 8″ diameter, with a discharge of 300 to 800″ of water. The miners usually turn the stream upon the banks near the bottom until a large mass of earth tumbles down. They then wash all this away into the sluice, and then cut the bank again at the bottom. The water usually costs 10 cents per inch per day, and dirt in this way has been in some places excavated at a profit when it contained one cent's worth of gold in a cubic foot. The same hydraulic process has been used for excavation merely."

See FLUME, Fig. 2041, p. 891, "*Mech. Dict.*"

Hy-drau'lic Lift. Lifting apparatus operating by pressure of water. See HYDRAULIC ELEVATOR; HYDRAULIC HOIST; HYDRAULIC PRESS.

Hy-drau'lic Lo'co-mo'tive. A device for traveling up a flume by power derived from the flow of water.

Leaman . . . . * "*Scientific American*," xxxvi. 79.

Hy-drau'lic Ma-chin'e-ry. Companies are now established in England for the production and renting of hydraulic power, distributed by mains. Such are the Chester and the Hull (Br.) Hydraulic Engineering Co.'s.

The application of hydraulic power to the lifting of passengers in hotels and stores, goods in warehouses, and factories; and also to the working of cranes, dock-gates, swing-bridges, elevating and tipping coal-wagons, etc., has become quite common in Britain and America. In the latter, either local pumps or the city mains are used; in Britain the same occurs, but there are also companies which rent power.

The subject has been considered, as to its history and the elaboration of its methods and applications, in a paper read by Sir W. G. Armstrong, before the *British Instit. of Civil Engineers*, 1877, reproduced in "*Iron Age*," xix., June 28, p. 3.

"In Hull (Br.) the system does not differ essentially from an ordinary water service, in which the necessary head of water is obtained by pumping direct into the mains against the pressure in an air-vessel or stand-pipe. The difference consists in the higher pressure employed — generally from 600 lbs. to 800 lbs. per square inch — and in the use of dead weight accumulators for maintaining a uniform pressure, and allowing for the variation in the rate of consumption of the water. In nearly all towns where a good pressure in the water main exists, the force due to the pressure is being utilized with great advantage for the working of cranes and hoists and other purposes, and the water is generally paid for at a rate per 1,000 gallons consumed. The pressure in the ordinary water mains of a city rarely exceeds 60 lbs. on the square inch, and it is obvious that if the pressure were increased to 600 lbs. on the square inch only one tenth of the water would be used to do the same amount of work, and the machinery employed to utilize the power need be only one tenth the capacity. The higher pressure also gives a greater speed and certainty of action.

"What the Hull Hydraulic Power Company have done is to lay a main of about a mile in length through the streets bordering the Old Harbor at Hull, in which are built most of the public wharves and warehouses of the city. This main is charged at a pressure of 600 lbs. on the square inch by pumping engines erected at a convenient spot on the line of main. Not the least important point in the value of such an undertaking is that the water being used exclusively for working machinery does not require to be of a quality necessary for domestic purposes, and there are but few towns where the supply of pure water is so ample that the utilization of inferior supplies is a matter of no moment.

"Any person on the line of main requiring to use cranes, or hoists, or printing machines, hydraulic presses, etc., has thus at his door a simple and economical power available at any moment by paying only for the amount he actually uses. In fact, the consumer can buy his power in the same way as he buys his gas, and with no more trouble in the one case than in the other. There are several other advantages in the system which will at once occur to the reader, such as the reduction of the risk of fire in warehouses through the substitution of water for steam power, and the saving of room effected by dispensing with boilers and engines. The water mains required for the system, though of great strength, are not of large size. The main laid at Hull is 6″ in diameter, which will be ample for all requirements there, and would probably be seldom exceeded should the system ever come to be adopted in the largest cities of the kingdom. Two pairs of pumping engines, of 60 horse-power each, have been erected, and the engine-house has been built to accommodate two other pairs of the same size, which will be added as the demand for the power increases. The engine-house is covered by a cast-iron tank, into which the water is pumped in the first instance from the river, and allowed to settle before being pumped into the main. A minimum charge is to be paid by consumers according to the size of the machinery to be worked, amounting for an ordinary river-side warehouse crane to about £52 per annum; and the cost of working will amount to about ½d. for each ton lifted 40′."

Figs. 1416, 1417 show two forms of rail punches by Dudgeon. Fig. 1416 is for punching holes through the webs of rails, for the passage of the bolts of fish-plates. Fig. 1417 is for punching notches on the edge of the foot flange for the driving of the spike.

Fig 1416.

Rail Web Punch.

Punch and shears, Toulon, Fr. * "*Sc. Am. Sup.*," 1183.

Hy-drau'lic Rail'way Brake. A form of railway brake in which the rubbers are brought against the wheels by hydraulic power. Barker (Br.).

The brake in its early form was worked by a set of pumps in the guard's van driven by a friction wheel. As now used on the Midland Railway, a steam pump, fitted under the foot-plate of the engine, supplies a pressure which can be varied between 5 lbs. and 360 lbs. on the square inch. The pump starts of itself when the pressure falls below a certain point, and its duty consists in always keeping an accumulator filled, the load on the accumulator being supplied by the pressure in the boiler. The brake blocks are operated by small hydraulic presses.

2. The piston of a hydraulic press.

The span of the Rock-island draw-bridge is rotated by two hydraulic rams, each of 10' stroke and 8" diameter of piston. These are placed over the circular girder of the turn-table, one on each side of the span in a vertical position, and are worked by a double-cylinder engine, each cylinder 6" × 8". The force-pumps are four in number, each with 1½" piston. The rams are reciprocal, each being the reservoir for the other, and the office of the pump is to transfer the liquid (water .50, glycerine .50) from one ram to the other. Both the rams are thus under the same pressure at all times, and hold the span in equilibrium, except during the process of turning.

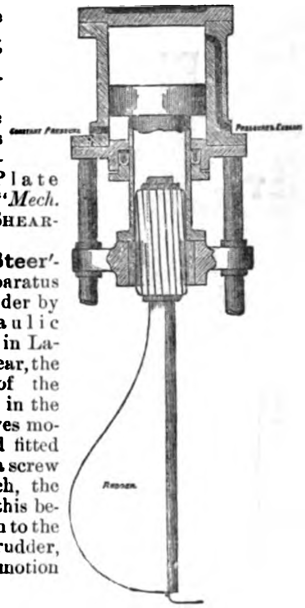
The power of the rams is transferred to the pier by means of a wire rope 1½" diameter, arranged as in an Armstrong crane. See Hydraulic Bridge Operator.

Hy-drau'lic Riv'et-ing Ma-chine. A machine riveter worked by hydraulic power. See Figs. 4351, 4354, p. 1949, "*Mech. Dict.*"
See also Riveting Machine.

Hy-drau'lic Shears. Shears worked by hydraulic power. *O*, Plate XXIV., p. 1157, "*Mech. Dict.*" See also Shearing Machine.

Hy-drau'lic Steer'ing Gear Apparatus for working a rudder by means of hydraulic power. As seen in Lafargue's steering gear, the vertical action of the plunger contained in the power cylinder gives motion to a crosshead fitted with a nut having a screw cut of a quick pitch, the collar working in this being firmly keyed on to the upper end of the rudder, gives the circular motion required.

Fig. 1418.



Lafargue's Hydraulic Steering Gear.

Hy-drau'lic Tip. A device for discharging coal wagons.

The invention of D. Thomson, of London. A vertical skeleton frame is provided with arrangements for lifting and tipping the wagons. A single hydraulic cylinder is used, the tipping being done by a chain attached to the end of the rising platform, that end of the platform being detained during the latter portion of the hoisting movement.

Thomson, Br. . . . . * "*Engineering*," xxviii. 204.

See also Hydraulic Dump.

Hy-drau'lic Valve. The valve for controlling the flow of water to and from the cylinder in hydraulic elevators; starting, stopping, and holding the car at the different floors. A wire shipping cable runs inside the hatchway from top to bottom, passing around the wheel on the valve stem, for opening or closing the valve, and the cable is under control of the attendant in the cage or on the platform. The valve is moved by pinion and rack and discharges below.

Hydro-carbon Engine.

Hy'dro-ac-cu'mu-la'tor. See ACCUMULATOR, HYDRAULIC ACCUMULATOR, *supra*.

Hy'dro-car'bon En'gine. An engine in which mixed petroleum and air are burned to furnish power by the expansion due to combustion.

Fig. 1420 shows Brayton's single-acting hydro-carbon engine. *A* is the working cylinder of the engine, which is jacketed by a water cylinder. *B* is an air-pump actuated by the working cylinder, and employed to compress air into the two reservoirs *C C*, constituting the base of the frame. *D* is a pump, which supplies the petroleum or other suitable fuel, as fast as it is needed for combustion. The double-acting engine is furnished with a beam, the column carrying the beam center being employed as the reservoir for water. The air-pump is also double-acting, and is placed over the motive or working cylinder; the latter having a diameter of 10″ and 15″ stroke. The engine is constructed to stand a pressure of 100 lbs. on the square inch, and to make 200 revolutions per minute. The oil reservoir is formed in the frame supporting the crank shaft; but if the use of a reservoir of oil is objected to, the oil pump can draw its supply through a pipe from an oil tank placed at any convenient distance. One volume of crude oil can be burnt with 25 volumes of highly compressed air.

The action of the engine is as follows: The oil pump feeds a few drops of liquid fuel through a small tube into an annular chamber containing felt; here the petroleum encounters a supply of compressed air by which it is vaporized, the mingled air and vapor are forced in proper proportion into the working cylinder, where the combustion takes place, communication with the annular chamber being cut off and the products of combustion being left to work expansively, driving the working piston downward; towards the end of the stroke the compressed air supply to the working cylinder is cut off, thus extinguishing the combustion therein; the opening of the exhaust valve permits egress to the products of combustion, and the stroke is completed. An independent jet of hydro-carbon, burning continuously in a suitable chamber, lights the hydro-carbon in the working cylinder at the commencement of each stroke. The supplies of air and oil are adjustable, thus giving to the engines all the advantages of a variable cut off, and effecting an important saving in fuel when the engine is not required to work up to its full capacity. Ordinarily but one of the compressed air reservoirs *C C* is employed, the other being kept charged in order to allow of the immediate starting of the engine at any time.

The engine is made in sizes for small factories, for yachts, and launches: 3 to 10 horse power.

In the small horizontal petroleum engine of Julius Hock, of Vienna, the oil is pumped into one end of a cylinder, mixed with air, and then exploded, the piston is driven outward and returns by the momentum of the flywheel, forcing the gas out of an exhaust valve in the backward stroke. One end of the cylinder is open, like the Otto gas-engine.

Hydronette.

Hy'dro-pneu-mat'ic Ac-cu'mu-la'tor. An apparatus in which compressed air is made the reservoir of power; especially adapted for using in connection with hydrostatic presses and lifts. See ACCUMULATOR.

Hy'dro-pneu-mat'ic Gun. One in which the recoil is used to compress a volume of air, which, being subsequently brought to act upon the gun, shall raise it to the firing position.

The invention of Capt. Jas. B. Eads. Independently invented or adopted by Major Moncrieff. See description, pp. 506 *et seq.*, "*Ordnance Report*," 1877, and Plates XXXIX., XL.

Moncrieff's system. Described and illustrated in Barnard & Wright's report on "*Fabricating of Iron for Defensive Purposes*," Engineer Department, U. S. A., 1871.

Hy'dro-py-rom'e-ter. One in which the temperature is ascertained by exposing to the action of the heat which is to be measured a definite weight of some metal, as platinum, steel, copper, etc., and then quenching the same in a known weight of water, and noting the rise in temperature of the latter.

The plan was first adopted by Clement Desormes & Schwartz for the measurement of heat in furnaces; then by Regnault in the determinations of the specific heat of various substances, and by Dr. Siemens in experiments upon the varying electrical conductivity of telegraph wire under different degrees of temperature.

Byström's (Swedish) hydro-pyrometer, "*Ordnance Report*," 1878, Appendix R, 8, Plates IV., V., and p. 375.

Hy'dro-rhe'o-stat. An apparatus to vary the intensity of the electric current by passing it through water.

Fig. 360, Part I., *Tiemann's* "*Armam. Chirurgicum.*"

Hy'dro-stat. (*Electricity.*) Water stopper. The cell cover, which prevents the spilling or slopping of the exciting fluids, and which makes the battery portable, and enables the operator to convey it from place to place safely, without removing the liquid.

Hy'dro-stat'ic Joint. A leaden joint for mains, calked by hydrostatic pressure. A circular groove inside the bell of the main is occupied by a ring of lead. A threaded hole is made on the exterior, leading into the groove. Tar is poured in around the ring and force applied, which drives the lead into every crack. The hole is then fitted with a screw plug.

* "*Scientific American Supplement*" . . . . 1725.

Hy'dro-stat'ic Reg'u-la'tor. 1. The hydrostatic regulator, as applied by M. Cheret to the arming press (*balancier*) of the French mint, is described in *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," i., art. "*Balancier*," Fig. 189 *bis*.

2. An apparatus for controlling the water pressure in the mains and pipes of water-works in the Holly system of water supply.

The hydrostatic regulator is provided with a piston, placed within an upright cylinder, and having a rod extending upward which is connected to a cross-bar, having heavy weights, which by means of suitable contrivances bear down upon the piston with a force that increases as the piston rises. A small pipe connects the water mains with the cylinder below the piston, and any change in the water pressure (which would be increased or diminished by opening or closing service-cocks) at once communicates motion to the piston, and the force below the piston is always met by an equal resisting force from the increasing weight. By means of simple appliances, the changes in the position of the piston are utilized to operate on the steam-valves of the engine (or the gates of a water-wheel, if works are run by water-power), and change the point at which steam is cut off in the cylinders of the engine, thereby increasing or decreasing the power of the engines, the speed of the pumps, and the quantity of water supplied. Thus it will be seen that if the piston moves either higher or lower in the cylinder than the point at which it may have been set to maintain the desired pressure, it will automatically bring the speed of the engine to the rate required to supply the demands for water, and permit the pressure to vary only within the limits needed — two or three pounds — to reverse the action of the cut-off moving mechanism of the regulator.

"*Scientific American Supplement*" . . . . 2220.

Hy'dro-stat'ic Weigh'ing Ma-chine'. An apparatus for ascertaining the weight of an object *in transitu*, during the operation of hoisting. Figs. 1423–1425.

The upper loop is placed over the hook of the crane chain, and the object slung to the ring beneath. To the upper loop is attached the cylinder,

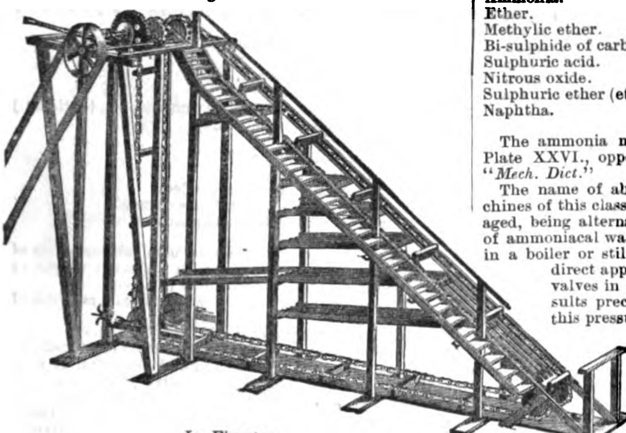
Ice El'e-va-tor. Fig. 1427 is an inclined plane for endless chain elevator.

Fig. 1427.



Ice Elevator.

It is so placed that its foot is in the water of the ice-pond and its several chutes connect with the stories of the ice-house, or successive elevations of the ice stored therein. An endless chain provided with slats runs over pulleys at the angles of the triangular frame; the foot, vertex, and at the angle of the right-angled triangle. The inclined planes consist of a series of gratings, filling its various panels, and the block of ice caught by one of the slats on the continuously moving chain, slips up the grating as far as the latter extends, which may be to any required distance according to the elevation acquired by the stored ice at any given time. On attaining this elevation, which, in the illustration, has been assumed to be at the second chute, say 20′ from the base, the grating having been removed, the block, no longer supported on its slippery track, passes between the inclined beams on to the chute, which, being inclined, conducts it to the ice-house.

Another form of inclined plane ice elevator is shown in Fig. 2641, p. 1163, "*Mech. Dict.*" See also Ice Screw, *infra*. See also Ice Elevator Chain, Figs. 956, 957, p. 309, *supra*.

Ice Ma-chine'. All artificial refrigeration proceeds upon the general principle of compressing a gas, removing from it when in this compressed state the heat generated by compression, by means of running water, and then permitting the reëxpansion of the compressed gas in a series of pipes or chambers so disposed as to abstract heat from the water to be frozen.

Three cubic feet of atmospheric air at the normal pressure of 15 lbs. per square inch and a temperature of 75° F., being compressed into an iron vessel containing one cubic foot, will show a temperature say of 225° F. Being cooled as above, until its temperature is 75°, and then permitted to expand, the result will be say 3 cubic feet of air at 25°.

Various gases are substituted for air as being more powerful refrigerating agents.

Such gases as can be liquefied by pressure possess manifest advantages for this purpose. Perhaps the most convenient agent known is ammonia.

Machines may conveniently be divided into two classes: —

Absorption machines; in which gas (ammonia) is set free from its watery solution by heat, is condensed, refrigerated, worked, and then reäbsorbed by the water.

Compression machines; in which the gasses are forced to make the circuit by means of pumps.

The absorption machines are those of

Tellier	*Boyle.*	*Stanly-Reece.*
Carré.	*Reece.*	*Mignon & Rouart.*
Rankin.	*Krupp.*	*Kropff.*

The following materials have been used in compression machines for the manufacture of ice: —

Ammonia.	Anhydrous sulphuric oxide.
Ether.	Chymogene (petroleum ether).
Methylic ether.	Atmospheric air.
Bi-sulphide of carbon.	Gasoline.
Sulphuric acid.	Carbonic acid.
Nitrous oxide.	Alcohol.
Sulphuric ether (ethylic).	Ethylo-sulphurous dioxide.
Naphtha.	Rhigoline.

The ammonia machine of Ferdinand Carré is shown in Plate XXVI., opposite p. 1164, and described on p. 1165, "*Mech. Dict.*"

The name of absorption machine has been given to machines of this class from the manner in which the gas is managed, being alternately distilled and reabsorbed. A charge of ammoniacal water or aqua-ammonia having been placed in a boiler or still, the gas is driven from the water by the direct application of heat; the gas being retained by valves in a receiver or series of pipes, pressure results precisely as in a steam boiler. While under this pressure, running water passes around the receiver or pipes, and the temperature of the gas is sufficiently reduced, so that it liquefies under the pressure which is derived directly from the still. This liquefied gas, after expanding in a chamber or in a series of pipes, for the purpose of reproducing refrigeration by absorbing heat from substances surrounding the pipes, is then reabsorbed by the water which originally held it in solution.

In these machines mechanical force is dispensed with, excepting in the slight power required to pump the water back into the still pipes, after it has reabsorbed the ammoniacal gas.

Plate XXIII. shows a small Carré ice machine of domestic size in which an ammonia solution serves indefinitely. It requires for operation nothing but fire and water, and, as soon as one block of ice is congealed it is ready to commence another. It is specially intended for ices, caraffes, sorbets, etc., but has its uses also in the laboratory.

In the Rankin Ice Machine, shown in Plate XXIII., the distillation of ammonia is effected by passing the aqua-ammonia through a series of 6″ or 8″ pipes, and finally taking the weak water from the lowest pipe, that is, the last one of the series of small still pipes. The number of these pipes varies from 8 to 18, according to the capacity of the machine. The ammonia passes from each still pipe at the rear end at the same time that the water passes from the front end to the next pipe below. A small pump forces the exhausted water back from the absorber into the still pipes. The absorbers are made of 8″ or 4″ pipe, jacketed for the cooling water to pass the reverse way of the heat. The same arrangement is applied in the construction of the condensers, equalisers, and cooling coils, so that the hottest meets the hottest and the cooler the cooler, in all the interchanges of the machine. Steam-pipes inserted in the still pipes is the preferable mode of heating.

In the Rankin machine the parts are numbered as follows: —

1. Still front.
2. Boiler.
3. Water pump.
4. Ammonia pump.
5. Still pipes
6. Weak water receiver.
7. Stand pipe.
8. Equalizer.
9. Gas receiver.
10. Strong water receiver.
11. Pipe from absorber to strong water receiver.
12. Gas expansion pipes.
13. Pipe to cooling coil.
14, 15. Pressure gages.

16. Header.
17 Pump suction.
18. Gas conductor to condenser.
19. Gas conductor from condenser to gas receiver.

The apparatus of Mignon & Rouart, Paris, is also on the Carré principle.

Pictet reduces temperature by expansion of anhydrous sulphurous oxide. The liquid, contained in a refrigerator, is vaporized under the ordinary atmospheric pressure by a double-acting pump, furnished with conducting pipes, and which compresses it under a maximum of three atmospheres after circulation into a condenser, where it is liquefied anew to be brought back to the refrigerator. The heat produced by liquefaction is absorbed in the condenser. The circulation of a solution of magnesium chloride, between and around ice-molds, is effected by the motion of a helix, which revolves constantly in the bath. The heat of the tropics and that of the arctic regions are found contiguous to each other in the conducting pipes of the pump.

The machine of M. Pictet, shown in perspective and section in Plate XXIII., uses anhydrous sulphurous acid. In the use of this, there is the advantage that at 80° Fah. its tension does not exceed four atmospheres, while it may be liquefied at 25°, and its tension then is only equal to the pressure of the atmosphere. It has no action upon metals when kept free from water; and in order to obtain it in a perfectly anhydrous condition, M. Pictet prepares it by the action of heat on a mixture of oil of vitriol and sulphur, the gas being dried by oil of vitriol. The condensing and refrigerating apparatus consists of tubular vessels similar to those employed with other liquids, such as ether.

A machine capable of producing 550 pounds of ice per hour is thus described: —

"A cylindrical tubular copper boiler has a length of 2 meters and a diameter of 35 centimeters; 150 tubes of 15 millimeters traverse its entire length, and are soldered by their extremities to the two ends. This first boiler is the refrigerator. It is placed horizontally in a large sheet-iron vat, which contains 100 tanks of 20 liters each. An incongealable liquid, salted water, is constantly circulating in the interior of the refrigerator by means of a helix. This liquid is re-cooled to about — 7° C. in a normal course, and it licks on its return the sides of the tanks which contain the water to be frozen.

"In the space reserved between the tubes of the refrigerator, the sulphurous acid liquid is volatilized, and its vapors are drawn up by an aspirating force-pump, which compresses them without the condenser. This condenser is a tubular boiler, the same as the refrigerator: only a current of ordinary water passes constantly into the interior of the tubes to carry off the heat produced by the change of the gaseous into the liquid state of the sulphurous acid, and by the work of compression. A tube furnished with a gage-tap, adjusted by the hand once for all, permits the liquefied sulphurous acid to return into the refrigerator to be subjected anew to volatilization.

"Sulphurous acid has the exceptionally advantageous property of being an excellent lubricant, so that the metallic piston which works in the cylinder of the compressing pump requires no greasing. Thus the introduction of foreign matter into the apparatus becomes entirely impossible.

"The work necessary to manufacture 250 kilograms of ice per hour is at the most seven horse power. A cold of 7° C. in the bath is amply sufficient to obtain in the tanks a rapid and in every way economical congelation. The cost of production is about 10 francs per ton of ice." — "*Nature*."

The perspective view represents a machine on a small scale. A larger apparatus is shown in "*Scientific American*," * xxxvii. 336.

Beneath is a diagrammatic view of the Pictet machine. At *A* is the compression pump, the valves of which are so arranged that at one stroke the gaseous oxide is aspirated through the tube *B*, and on the return it is compressed through the tube *C*. Tube *B* connects with the refrigerator *D*; tube *C* with the condenser *E*. The oxide is introduced at the plug lock *F*, and is drawn by the pump in the direction of the arrow into the copper tubular refrigerator *D*, the liquid filling the space between the tubes. Here vaporization and consequent production of intense cold takes place, and the temperature of the non-congealable mixture of glycerine and water which surrounds the refrigerator is so far reduced that water placed in the metal boxes *H*, immersed in the tank, becomes rapidly frozen. The propeller wheel, shown on the right, determines a current of the glycerine solution through the tubes, and thus hastens the refrigeration. The vapor of the oxide is drawn out of the refrigerator, as already noted, by the pump, carried through the latter, and forced into the space between the tubes of the condenser *E*. Through the tubes a cold stream of water is constantly pumped, which determines the condensation of the vapors, and the reliquefied oxide passes into the admission pipe and once more enters into circulation as already described.

Mignon & Rouart, Paris, use in the domestic machine the solution of ammonia, requiring but the addition of water and heat, alternately. In their larger machine a pump is added.

Sulzer Frères (*Linde*), Winterthur, Switz., operate by the evaporation and recondensation of ammonia, produced by the action of a double-acting suction and force pump.

Siddeley & Co. (Br.) use sulphuric ether. This ether is vaporized in a partial vacuum, and absorbing heat from brine during its vaporization, the vapor thus produced is subsequently condensed and liquefied, to be again vaporized, and so on. The water-vessels are exposed in the brine bath. The excess of heat in recondensation of the ether is carried off by contact of surface exposed to a flow of water.

Harrison, in his original apparatus, used ether.
Prof. Twining used sulphuric ether.
Liebe (Br.) used sulphuric ether.
Tellier, methylic ether.
Prof. Paersh, chymogene (petroleum ether) and carbon bi-sulphide.
Prof. Vander Weyde, chymogene.
Prof. Lowe, carbonic acid.
Prof. Seely, liquefied sulphurous acid.
du Motay & Rossi employ ethylo-sulphurous dioxide obtained from ordinary ether by saturating the latter with sulphurous gas.
du Motay & Beckwith, ethylo-sulphurous dioxide.
Boyle, ammonia.
Atlas Engine Co. (Br.), ether.
Duvallon & Lloyd, ether.
Holden, ether, methylic ether, chymogene, etc. (optional.)
Linde (*Sulzer Frères*), ammonia.
Kropff, ammonia.
Edmond Carré, sulphuric acid.
Johnston & Whitelaw, ammonia.
Kirk, air condensed and then expanded.
Winhausen, air condensed and then expanded.
Gorrie, air condensed and then expanded.
Vincent, methyl-chloride.
Toselli's machine for domestic uses, uses sub-carbonate of sodium or nitrate of ammonium, with an equal weight of water, in the interstices between tubes in a nest.

Glacière *Delpy* employs hydro-chloric acid and sulphate of soda.

Mansfield uses a deliquescent salt.

The principles involved in the various orders of procedure: vaporization, radiation, liquefaction, and reduction of pressure, have been considered on pp. 1164-1169, "*Mech. Dict.*"

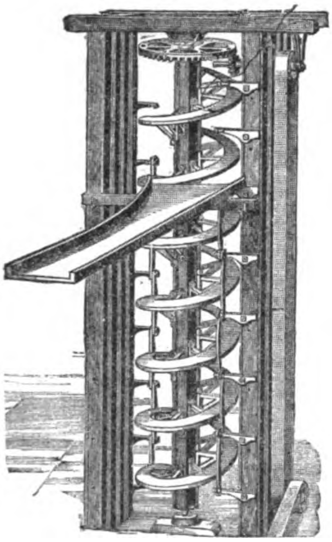
Ice Mold. A metallic case in which cream or custard is frozen so as to acquire a certain shape, which it retains for a while when deposited upon a dish.

Ice Screw. A machine for elevating ice from the pond to the ice-house, or from one level

Fig. 1428.



Ice Screw.

to another. The block of ice rests against vertical bars, and, as the screw revolves, is pushed up, rising vertically till it reaches the level where it is wanted. Here the block is no longer detained by the vertical bars, and slips off on to the chute which has been disposed to receive it and conduct it to the window of the ice-house.

Ich′thy-o-col′la. The preferable name for isinglass.

Classification by *Danilewski* in "*Technologiste*," xli. 515.

LIST OF UNITED STATES PATENTS.

Jan., 1834, *Norwood et al.*, Sounds are cut, digested, run into strips and dried.
2,474 *Paulsen*, Boiling under pressure.
5,978 *Rowe*, Rollers cooled by circulation of water.
29,596 *Hunter*, Glue from whale-blubber scraps.
40,933 *Herreshoff*, Menhaden fish-water as a dye.
53,686 *Lewis et al.*, Purifying the materials by boiling.
59,331 *Steart*, A "pure" bath of digested fish in treating fiber.
78,016 *Robinson*, Gelatine from fish-heads.
106,212 *Rowe*, Cooling rollers in isinglass manufacture.
134.690 *Manning*, Cooling rollers in isinglass manufacture.
148,317 *Müller*, Sturgeon sounds; solution saltpeter followed by sulphur fumes.
149,165 *Stanwood*, Alcohol and isinglass.
167,123 *Rogers*, Fish-skins scaled, de-salted, digested.
177,764 *Stanwood*, Fish-skins soaked, dried, digested, dried.
219,667 *Alsing*, Albumen from fish spawn.

Il-lu′mi-na′ted Sign. The number-signs of houses in Paris are in numerous cases illuminated by the following contrivance: —

"It consists of a hollow triangular prism 9″ long, two of whose sides are formed of panes of blue glass, on which the number of the house is picked out in white. This prism-shaped lamp-glass rests against the front of the house, so that the two sides with the numbers on them can be plainly seen by the passers-by. In the interior of the prism is a gas jet, fed by a pipe from the house." — "*Telegraphic Journal.*"

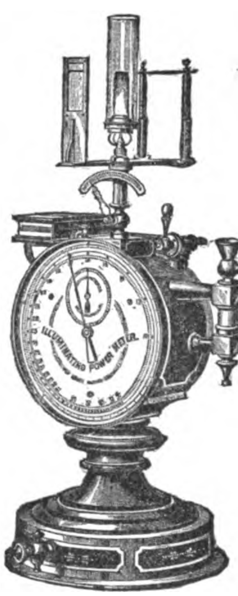
Phosphorescent signs and dials have been used to some extent. See DIAL, p. 254, *supra*, where are several recipes, and numerous references.

See also DIAL, *Morton*, "*Scientific American*," xl. 180, 232.

Il-lu′mi-na′ting Pow′er Me′ter. (*Gas.*) An instrument, by Sugg, of London, designed as a ready means to ascertain the exact illuminating value of gas, in terms of sperm candle values; it can be used in the office or any desired place, as it does not require a darkened room.

After adjusting the height of flame to 3″, the correct reading of any test can be made by an observation of one minute. It occupies a space of about one foot square, and consists of an experimental meter and clock. The dial of the meter is 12″ diameter, its outer circle being divided into spaces of varied lengths, each representing one candle, these spaces being subdivided into tenths of candles. Above the center of dial is a circle having 60 divisions, each representing one second of time, *i. e.*, one minute the whole revolution. A long hand traverses the outer circle and a shorter one the small one. On the side of the meter is a water-box with glass, showing true water-line, and on the top is a governor, three-way cock, pedestal, a quadrant with 45 equal divisions, an argand burner with chimney, and a sighting frame to enable the operator to adjust the flame to exactly 3″. To operate the instrument, start the clock, then adjust the height of flame to 3″, when the gas is passing through the meter, stop the hand at 16 by turning the cock so that the gas passes to the burner without going through the meter, then wait till the clock-hand moves to 60, at this instant turn the gas through the meter and let it pass through till the clock-hand again reaches 60, at this instant turn off the gas from the meter, and the long hand (or pointer) will indicate the quality of gas.

Fig. 1429.



Illuminating Power Meter

Il-lu′mi-na′ting Tile. One with glass bull's eyes for sidewalks over cellars and areas, or pavement over basements.

Il-lu′mi-na′tion.

The following is a London test of the illuminating value of the materials named: —

Material.	Value. 24 cents equal 1 shilling.	Duration of 1 cent's worth in one sperm candle values.
		h. m.
Standard sperm candles, per lb. .	$0.48	1 7
Best wax candle, per lb.	.48	1 6
Sperm oil in moderator, per gal. .	2.28	1 12
Belmont sperm candle, per lb. . .	.30	1 27
Stella or Burmese wax, per lb. . .	.30	1 37
Petroline candle, per lb.	.36	2 15
Composite candle, No. 1, per lb. .	.22	2 5
Composite candle, No. 3, per lb. .	.16	2 45
Common dip candles, per lb. . .	.12	2 52
Almond oil, in moderator, per gal.	2.22	3 –
Colza, per gal.	1.20	4 37
Paraffine oil, in lamp, per gal. . .	.72	9 35
Common London gas, per 1,000′ .	.90	26 –

It may be noted that the price of gas, 90 cents per 1,000′′ is scarcely more than one third of the exorbitant prices usual in the United States.

Il-lu′mi-na′tor. 1. (*Surgical.*) *a.* A lamp with lens used as a means of directing a strong light, in examination by the laryngoscope, ophthalmoscope, speculum, etc. Pages 78, 79, Part II., and Fig. 545, Part III., *Tiemann's "Armamentarium Chirurgicum."*

b. An instrument for illuminating an internal cavity by means of incandescent platinum in a glass envelope.

3. A glazed opening; such as floor-light, deck-light, side-light, bull's-eye, etc., which see.

4. (*Microscope.*) A special attachment for throwing light upon an object under view. See list under ILLUMINATOR, * 2660, p. 1171, "*Mech. Dict.*"

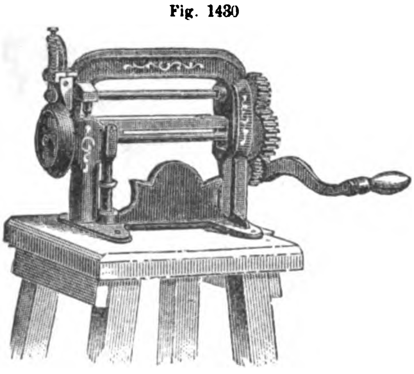
Im-pe′ri-al Silk Serge. (*Fabric.*) A silk and wool French goods.

Im′preg-na′tion. (*Mining.*) Metallic deposits having undefined limits and form.

Im-pres′sion Ma-chine′. (*Cartridge.*) A machine for making an impression in the head of the cup, which is done by a horizontal die pressing it into a pattern, so that, when vented, the holes will not be on the top but on the side of the impression.

Im-pres′sion Stitch Ma-chine′. (*Leather.*) A machine for crimping the upper edge of welts of a boot or shoe to give it the appearance of sewed work.

Fig. 1430

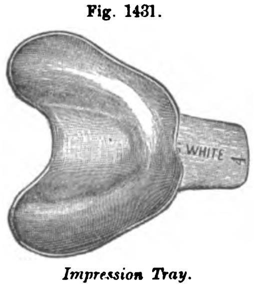


Impression Stitch Machine.

The machine shown in Fig. 1430 makes a stitch impression of any desired width or size.

Im-pres′sion Tray. A tray of Britannia metal to hold the gypsum in taking impressions of the mouth for the making of dentures.

Fig. 1431.



Impression Tray.

They are made of various sizes, and specifically for upper and lower jaws. They are light enough to allow of alteration by pliers or mallet to suit peculiar formations of the maxillary.

Incan-des′cent Light. (*Electricity.*) A form of electric light as distinct from the *voltaic-arc* light. In the *incandescent* light a strip of carbon or platinum is heated to whiteness, *in vacuo*, or in a rarefied atmosphere of an inert gas, nitrogen, for instance.

In the voltaic-arc light, the current leaps the space between two pencils of carbon.

"The incandescent systems are far less numerous than those which employ the voltaic arc, and hence their classification is less complex. They are divided into

"1. Incandescent lamps with combustion.

"2. Lamps purely incandescent.

"The former are represented by Reynier's, Weidermann's (Napolio's modification), Joel's, and Tommasi's apparatus. All of these consist of a carbon rod resting lightly on a lump of carbon or an irregularly-shaped piece of metal, thus producing imperfect contact.

"Pure incandescence is represented in four systems: those of Edison, Maxim, Swan, and Lane-Fox. In all of these we have incandescence of carbon, and this carbon consists of a very fine thread placed *in vacuo* or in a highly rarefied atmosphere of some inert gas.

"The nature of the current is a matter of indifference with incandescent lamps; they work with either continuous or with alternating currents. Those lamps in which there is incandescence with combustion require a great *volume* of current, and rise in *tension*, while those with pure incandescence require small *volume*, and usually rise in *quantity*.

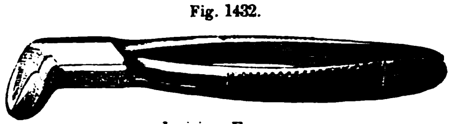
"To pure incandescence we must also refer Jablochkoff's, Kavlin's, Trouvé's platinum wire polyscopes and Geissler's tubes; but properly speaking these are not electric-light apparatus at all, but only objects to be used for study or for experiment." — "*Electrician.*"

Inch. The "miner's *inch*" is the amount of water that will flow in 24 hours through a hole 1′′ square with 6′′ pressure — about 2,000 cubic feet.

In effective hydraulic mining there should be at least 1,500 inches, each one of which will move from 3 to 5 cubic yards of gravel per day. See statement by Mr. Thomas, reported in "*Scientific American,*" xl. 314.

In-ci′sing For′ceps. (*Dental.*) An instrument for separating, cutting between teeth, splitting and excising salient prongs or parts.

Fig. 1432.



Incising Forceps.

In-ci′sor For′ceps. (*Dental.*) An instrument with narrow single prongs for extraction of the incisors.

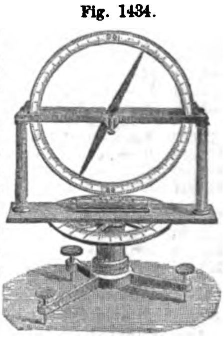
Fig. 1433.

Incisor Forceps.

In′cli-na′tion Com′pass. A magnetic needle with vertical circle to indicate the *inclination* or *dip*, one of the three elements of magnetic force registered at the observatories. The invention of *Norman*, of London.

See DIPPING NEEDLE, Fig. 1659, p. 705, "*Mech. Dict.*" The illustration, Fig. 1434, shows the instrument with a leveling stand and horizontal circle with magnetic needle.

Fig. 1434.



Inclination Compass.

In-clined′ Plane. An artificial slope for ascent of vehicles or objects; the term in its most important signification concerns railway grades. Many of them, traversed by locomotives, are very bold; some are only surmounted by means of stationary engines and cables.

The subject is treated on pp. 1174–1177, "*Mech. Dict.,*" references being made to the inclined planes of

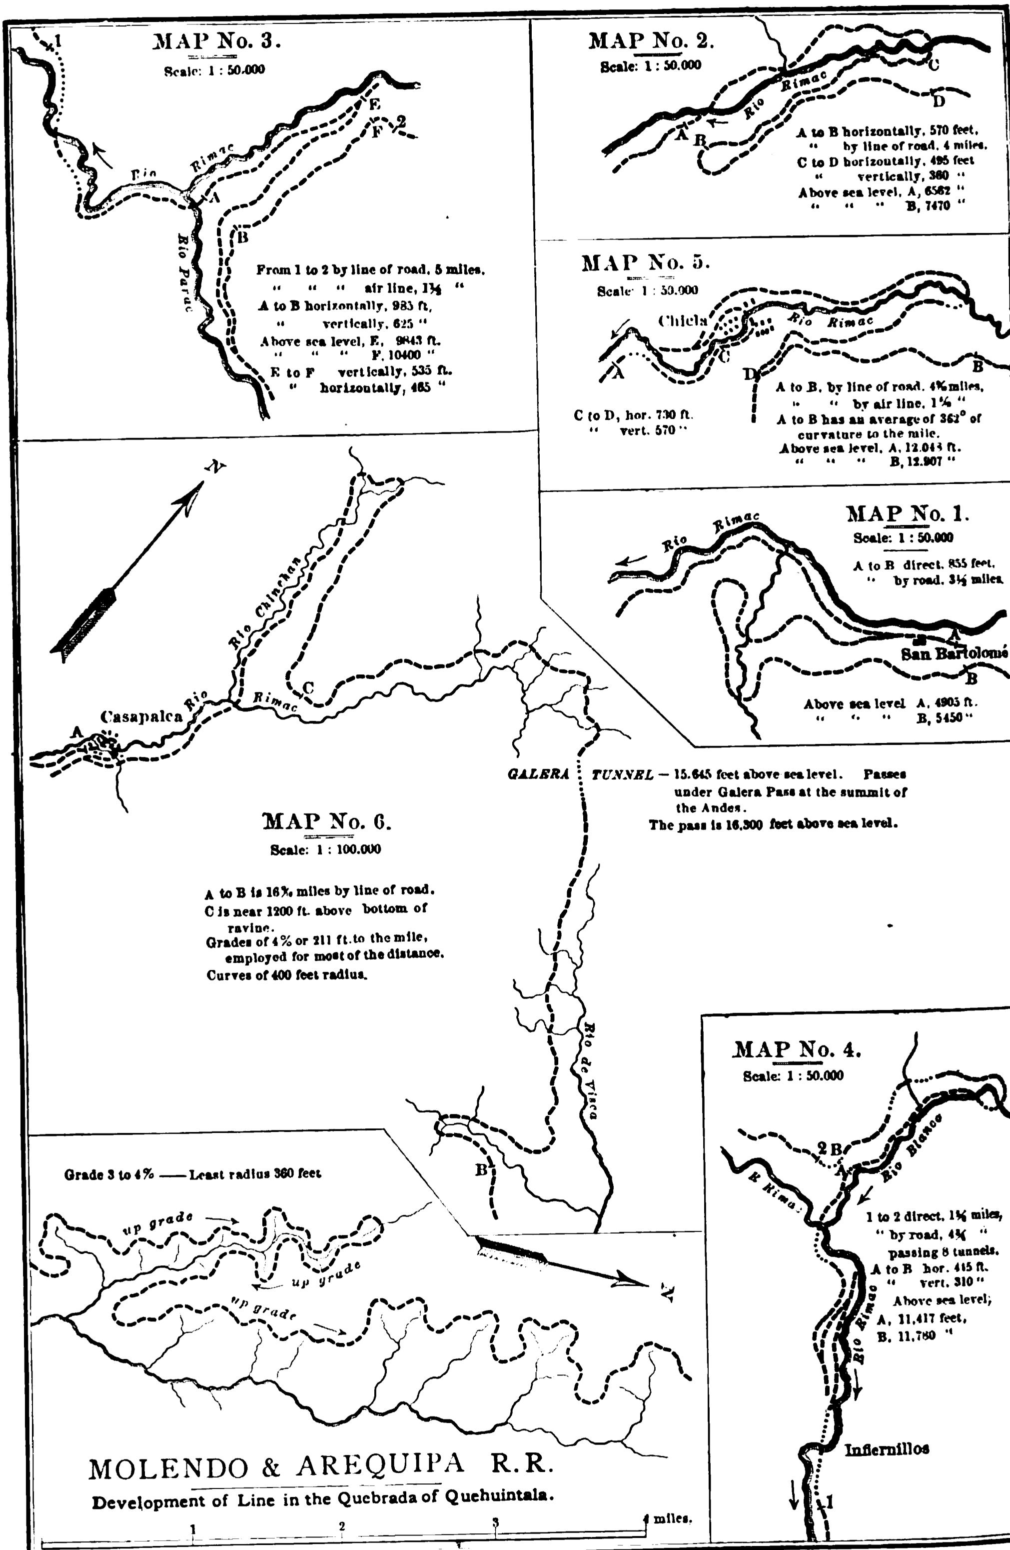


PLATE XXIV. DEVELOPMENTS OF INCLINED PLANES ON PERUVIAN RAILWAYS. *See page* 491.

Reduced from the Surveys in the Office of Señor Henry Meiggs, Lima.

Mount Cenis.	Morris and Essex Canal, N. J.
Holidaysburgh (former) route of Pennsylvania Railway.	Callao, Lima, and Oroya Railway, South America.
Portage, Pennsylvania canal.	Furka pass, Switz.
Mahanoy, Pennsylvania.	Konkan, Bombay.
Mount Washington.	Righi, Switz.

The publication of some engineering data of the Callao, Lima, and Oroya Railway, South America, (Fig. 2664, p. 1175, "*Mech. Dict.*") coming to the notice of Mr. Henry Meiggs, of Lima, Peru, Mr. Jno. McGee of his staff was so obliging as to send careful reductions of the maps of the most interesting developments of the road, which have been reproduced in Plate XXIV. These have all been completed and are numbered in the order the localities are reached in going from the sea.

The descriptions are printed in the panels with each map. In regard to the summit development, No. 6, it may be said that a 60-ton engine takes 60 tons, net load, over the road at 12 miles per hour with ease.

Near the beginning of p. 1176, "*Mech. Dict.*," it was stated that "the longest inclined plane on an artificial road is said to be that from Lima to Callao, which is about 6 miles, and has a descent of 511′, or about 1 in 60." It must now be added from information furnished by Mr. McGee that "the Oroya railway has an average incline for 75 miles of about 1 in 30."

The map of a development on the railway from Molendo to Arequipa, Peru, shown also in Plate XXIV., exhibits the approach to the pampa of Islay, which has a general level of 4,000′ to 5,000′ above the level of the sea.

The subject of inclined planes ascending by cogged gear on locomotive is considered incidentally under INCLINED PLANE, "*Mech. Dict.*"; also RACK RAIL, p. 1852, *Ibid.* Righi Railway, * Fig. 4124, p. 1862, *Ibid.*, and various systems cursorily mentioned on p. 1861, *Ibid.*

The following high grades in Switzerland are mentioned in the journals: —

"A road recently opened up Mt. Uetliberg, Switzerland, overlooks, at a height of 1,300′, Lake Zurich. The total length is 5¼ miles. The lowest grade is 232′ per mile, but 59 per cent. of the whole exceeding 264′ per mile. The curves are 500′ and 450′ radius, the latter coinciding with a grade of 327′. The track is standard gage, and the rails, of iron, weigh 60 lbs. There are three tank locomotives of the Krauss pattern, with six drivers coupled, each 38″ diameter, and with a wheel base of 6′ 8″. They weigh 41,800 lbs. empty, and in service, from 52,800 to 55,000 lbs. The heating surface is 770′ square, diameter of piston 12½″, stroke 21½″. At the first ascent the engine pushed up three cars with gross load of 30 tons, at from 8 to 10½ miles per hour, with steam pressure of 170 lbs. The descent is made with compressed air, by means of an apparatus used on the engines of the Righi road; speed 15½ to 18½ miles per hour.

"Another Swiss mountain road, the Righi Kulm and Lake of Zug, is 7 miles long; 6 miles are worked with a peculiar cogged wheel arrangement, by which grades of 1,056′ per mile are surmounted; radii of the curves, which are uniform, 600′."

PENNSYLVANIA IRON REGION.

Planes.	Total Length of Planes.	Height of Head above Tide.	Height of Foot above Tide.	Total Elevation.	Length of Main Rope required.	Diameter of Main Rope.	Weight per Foot.
	Ft.	*Ft.*	*Ft.*	*Ft.*	*Ft.*	*In.*	*Lbs.*
Mahanoy	2,410	1,478.42	1,124.70	353.72	2,900	2¼	8½
Gordon, 1	4,650	1,519.00	1,200.50	318.50	5,105	2¼	8½
Gordon, 2	4,755	1,206.00	802.00	404.00	5,225	2¼	8½
Big Mine Run. .	1,245	1,274.8	1,013.8	20.65	1,550	2	–

The Mahanoy has steel wire rope 2¼″ diameter with independent steel wire rope center. The others 2¼″ diameter iron wire rope (Big Mine 2″) with independent iron wire rope center.

A new locomotive for use on Ithaca Hill, N. Y., is thus described: —

"The incline has five tracks, of which the outer two are of the usual width, used in the ordinary manner. When the engine starts up the hill it rests upon a pair of rails just within the usual track and upon a set of double-flanged small driving-wheels which are upon the same axles with the big drivers, they being only about 30″ in diameter; this inside track is raised about 15 to 18″ above the outer one, and so high that the big drivers do not touch the track at all; the engine rests now upon the small drivers, and is independent of the outer ones; then in the center of the track is placed a wide cogged rail, which meshes into the cog-wheel, which is between these small drivers, directly under the center of the locomotive. By applying power to the big drivers, in the ordinary way, the power is applied to the cogged-wheel, which does the climbing. The cogs are about 3″ from tip to tip, and the wheel is 8″ wide."

CINCINNATI INCLINED PLANES.

	Mount Auburn.	Price's Incline, Mill Creek.
Vertical height . . .	275 feet.	346 feet.
Length of track . . .	840 feet.	758 feet.
Angle of incline . . .	°	24°.
Wire rope	1⅜″ diameter.	1¼ inch.
Wire rope weight. . .	–	39 tons.
Drum	9′ diameter	9 feet.
Actual strain on rope .	–	6 tons.
Number of winds . .	27	
Time in winding . . .	1 to 1½ minutes.	1′ 12″ to 1′ 15″
Engines	2, double act.	Same.
stroke	24″	
diameter	12″	
Made by John Cooper	Company, Mount	Vernon, Ohio.

The inclined plane of the Jeffersonville, Madison, and Indianapolis Railway at its landing on the Ohio River, has an ascent of 300′ in a mile, or 1 in 17. Wire rope is used.

When a locomotive ascends a grade and then winds up the train to its own level, either of two means may be employed. In each, a rope and winding drum is employed.

1. The winding drum is attached to the engine, which is detached from the train at the foot of the incline, attaches the rope to the forward car, and mounts the incline alone, is anchored to the rails, and then draws the car up after it. It may be anchored part of the way up, draw the cars to itself, the cars be anchored at this point, and then the engine ascend and repeat.

2. The winding drum is at the summit; the engine ascends and so places itself that its driving-wheels are over other wheels of the winding drum. The engine being anchored, its wheels in motion wind the drum, and draw upon the rope.

In each case the train is let *down* the grade by a brake on the drum.

The locomotive of Henry Handiside, of Bristol, Br., is constructed for this purpose. It has a gripping lock which holds the rails, and a drum beneath, operated by another cylinder, for winding the wire cable which connects to the front coach of the train. The locomotive ascends a piece, paying out the cable; then locks itself and hauls up the cars. These are then locked, and the locomotive makes another ascent and repeats. On a level, the locomotive acts in the ordinary manner: shown in Paris, in 1878.

COMPARISON OF DIFFERENT METHODS OF DESIGNATING GRADES.

Engineer	English.	American R. R.
.5 in 100	1 in 200	26.4 feet per mile.
1 in 100	1 in 100	52.8 feet per mile.
1.5 in 100	1 in 66 2-3	79.2 feet per mile.
2 in 100	1 in 50	105.6 feet per mile.
2.5 in 100	1 in 40	132 feet per mile.

100	14.9	300	4.2
110	13.6	350	3.3
120	12.4		

In-clined' Plane Car. (*Railway.*) One for ascending inclined planes; the support of the bed being so arranged that the bed shall be level when the car is on the incline. The Righi, Mt. Washington, and others afford examples. See INCLINED PLANE, "*Mech. Dict.*," *et supra*. RAILWAY, "*Mech. Dict.*," pp. 1061, 1062, and references *passim*.

In-clined' Press. One of which the bed and die are inclined, for convenience of insertion of the blanks. Cutting, drawing, and stamping presses are sometimes thus built, and sometimes are adjustable so as to have either level or inclined table.

In-cline' Drift. (*Mining.*) An inclined passage under ground; still known as a *level*, but having an inclination to carry off water, or following the dip of a strata.

In'com-bus'ti-ble Wood, etc.

See FIREPROOFING, p. 339, *supra*, for preparations for

Wood.	Canvas.
Theatrical scenery.	Cordage.
Fabrics.	Straw.
Cloth.	Paper.

In-con'stant Bat'te-ry. (*Electricity.*) A single fluid battery is usually termed *inconstant*, to distinguish it from a two-fluid battery.

In-cor'po-ra'ting Mill. (*Gunpowder.*) A mill on the Chilian principle; two-edge wheels revolving in an annular pan. The materials are ground in water; say 1 gallon to the batch of 50 pounds from the mixing-mill.

See "*Ordnance Report*," 1879, Appendix I., Plate II., Fig. 5, and description on pp. 99–101.

For gunpowder, Br. . . . . . * "*Engineering*," xxv. 37.

In-crust'ed Work. (*Fine Art Metal-working.*) Relief work in metal: from the *crustæ* of the Romans; small ornaments in relief attached to vessels. Distinct from *repoussé*, in which the relief is by beating out the metal.

When the figures were large they were removable and called *emblemata;* like instances seen in *Swami* work, of the Madras Presidency.

India shows many varieties of the work, as silver incrusted on brown copper, copper on brass, tracery, diapering, designs in one metal on another; engraved, chased, or stained by oxidation: tin soldered on brass and incised through in floriated patterns, the ground being in part filled with lac, somewhat like *niello*.

The modern French incrusted bronze, is a copper or bronze with gold and silver ornamentation. The objects are first painted in water colors, the principal ingredient of which is white lead. When several articles are to receive the same drawing, it may be printed in the same manner as in porcelain painting. The places which remain unpainted are varnished. The article is then laid in dilute nitric acid, which dissolves the color and bites the metal on the painted places to the required depth. After washing the article, it is placed in a silver or gold bath, where the free surfaces are electrotyped in silver or gold. The varnish is then removed, and the whole surface is polished so that the gilded and silvered parts are not unduly prominent. The article can then be bronzed. A fine effect is produced with black bronze by sulphuret of copper in the spaces between the gold and silver.

In-cu-ba'tor. An apparatus for the artificial hatching of eggs.

The Egyptian egg-hatching ovens, and the apparatus of M. Bonnemain, of France, are shown and described in the "*Mech. Dict.*," p. 1178.

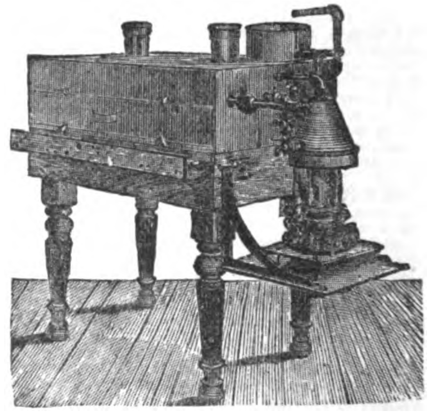
Several late apparatus may be noticed.

Probably each of the following patents has added something to the present approximately successful result.—

Axford.	*Dennis.*
Baker.	*Meyer.*
Day.	*Halsted.*
Cantello.	*Higgins.*
Carbonnier	*Graves.*
Corbett.	*Samuels.*
Weston.	*Thick.*

Fig. 1435 shows the "Reliance" incubator. A steatite radiator is placed over the egg-drawer and heated by hot water pipes imbedded in the steatite. The quantity of water is but

Fig. 1435



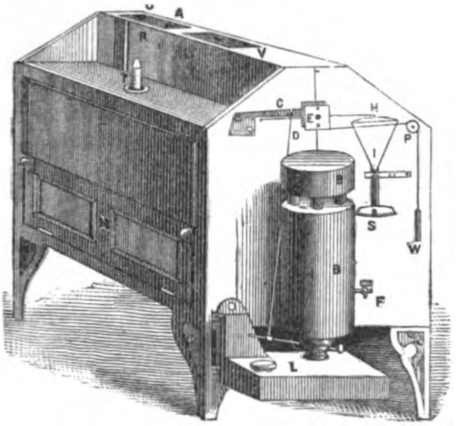
"*Reliance*" *Incubator.*

6 quarts for a 300 egg machine. The egg-drawers are separate, each has its ventilator, and receives moisture from an evaporating pan which gives an atmosphere approximating the condition of the natural nest: heat above, and cool, moist air beneath the eggs. The "Florence" oil-stove is used and the burner is so arranged as to obviate the need for other regulator or thermostat.

Halsted's "Centennial" incubator is shown in Fig. 1436, has a boiler, *B*, from which hot water passes to the tank, over which is the reservoir *R* with a glass water-gage. At *O* is the vent for air in filling, and at *F* the faucet for discharge of water when emptying. *V* is the ventilating flue opening into the egg chamber, the glazed door of which is at *N*. The egg drawer is of parallel bars just near enough together to keep the eggs from falling between them. A thermostatic bar in the chamber projects at *S* and operates the foot of the escape lever at *I*, the upper part of which is a spring wire with a narrow opening at *H*. *E* is a reel around which is wound a cord which passes over the pulley *P*, and is attached to the weight *W*. This reel carries four projecting arms, in pairs, the opposite ones of equal length, and a little shorter than the other pair. The ends of these are bent at right angles, so as to catch upon the curved wire section of the escape-lever *I*. This reel is firmly fastened to a shaft passing through to the ventilator flue, and there attached to the ventilator. On the back of this reel-plate are pins which raise or depress the lamp-lever *C*; this is connected with the lamp-trip by the connecting rod *D*.

The thermostatic bar is set or regulated by a set-screw in the opposite end of the machine. When regulated, the thermostatic bar, affected by the heat, acts upon the lever *I*, bringing the opening *H* over one of the ends of the arms, the force of the weight causes it to pass through and the next arm to catch, thus opening the ventilator and allowing the hot air to escape, and turning down the lamp. When the

Fig. 1436.

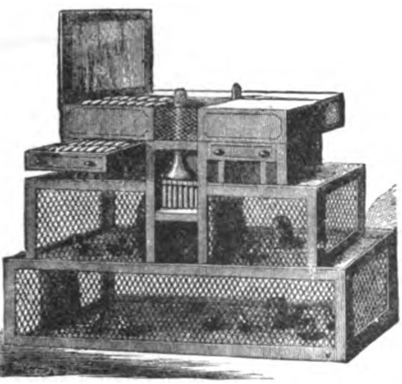


Halsted's Incubator.

drawer has cooled down one or two degrees, the reverse action of the thermostat again releases the end of the arm, and the ventilator closes and the flame is turned up. This is repeated automatically until the weight runs down.

Fig. 1437 shows the *Thick* incubator, which has a water reservoir of 10 gallons, heated by kerosene lamp. Air-carrying pipes pass through the heated water, and carry warm air to

Fig. 1437.



Thick's Incubator. (Br.)

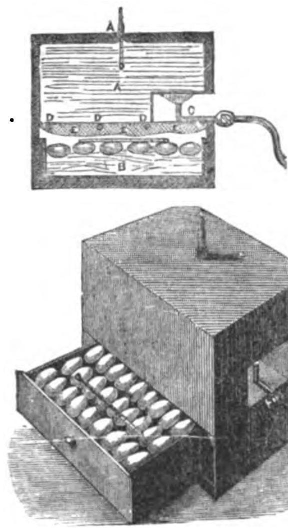
all parts of the hatching apparatus; hot-water boxes form part of the reservoir, under which the chicks, when hatched, are placed to receive the heat necessary for their health. The boxes are covered with a lamb skin, or a "wool mother," the cool, graveled flooring affords for the feet of the chickens a surface similar to natural conditions.

50 eggs are placed in each drawer. The heat of the water reservoir is about 120° Fah., which keeps the eggs at about 103°. The eggs are turned daily and left exposed for 15 minutes, and their relative positions in the drawers changed.

In *Voitellier's* apparatus, shown at the French Exposition of 1878, the heat of the reservoir is kept up by occasional renewals of hot water, and steam is occasionally allowed to escape to keep the atmosphere moist around the eggs.

An improvement on the incubator of *Carbonnier* (Fr.) is shown in Fig. 1438. The apparatus consists of a box, with a zinc case *A* filled with hot water fixed in the top, and underneath a drawer, *B*, to put the eggs in, and in which is spread a quantity of hay, so as to line the bottom of the drawer completely. *C* is a small gas burner sufficient to keep the temperature of the water at 110° Fah., for the eggs

Fig. 1438.

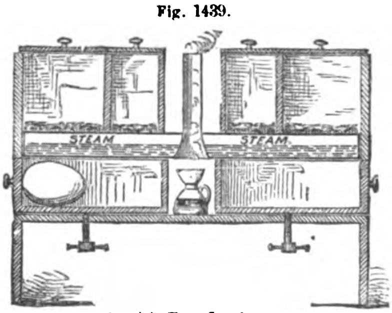


Carbonnier's Incubator.

to become warmed to a temperature of 105° or 104°, to show which a thermometer is laid on the top of the eggs The upper *A* is a pipe for supplying the basin with water and to receive the thermometer, which is immersed in the fluid, and shows the temperature. *D D* are three iron rods fixed in from back to front of the box as a support for the zinc case. *E* is a layer of sawdust, suspended by a piece of muslin (or some such thin material) fastened by a few tacks to the inner side of the box, through which the heat passes. The drawer is opened once or twice every day to turn the eggs, during the incubation of 21 days.

The "Leviathan" incubator, used in Africa in the artificial hatching of ostrich eggs, was exhibited in the Cape of Good Hope section at the Centennial Exhibition. The apparatus consists of a middle steam chamber of metal, which is kept constantly hot by a lamp or furnace beneath. Below this are drawers in which the eggs are first placed, and these, by means of the screws shown below, may be raised until the eggs are brought almost in contact with the warm surface above. In these receptacles the eggs are kept for two weeks at a temperature of 102° Fah. They are then removed and placed in the inner pair of compartments, shown above, for another fortnight, at a temperature of 100°. At the end of this period the eggs are carefully extracted, and a small hole is chipped in each shell at the point opposite the chick's head. They are next replaced and kept in the same compartments for two weeks longer at 98°, when the hatching takes place, and the young birds are placed in the outer upper receptacles, and there remain for two days. The compartments above have bottoms of lamb's wool, which come in contact with the steam chamber below.

Fig. 1439.



Ostrich Egg Incubator.

The egg is about 7″ in length, and the hatched chick about 18″ in height. The chick is fed on rice, and when it reaches the age of seven days is worth $50 in gold. Nearly 20,000 birds, it is said, have been hatched at the Cape of Good Hope by apparatus of this description. The machine is frequently made of sufficient size to hold 115 eggs at a time.

Day's machines are made for 220 and 320 eggs respectively. They are warmed by coal or gas, and the heat is regulated by a thermostat of two unequally expanding metals. This regulates the flame or the draft, as the case may be. An alarm is rung if a given heat be exceeded.

Halsted's "Acme" incubator is entirely of metal, is self-regulating as to heat, and has trays in which the eggs are simultaneously turned, without handling. It is a hot-air machine without boiler or tank. A copper drum is heated by oil lamp, and the warm air radiates from the drum, passing upward through the hot-air chamber where the evaporating trough divides the current and charges it with moisture. A plate deflects the air over the eggs in the drawers. A cool, moist air is retained beneath the eggs. The regulator is a thermostatic bar.

Axford's incubator has a lamp near the floor; circulation from above among the eggs, and exit downward; an electric thermostat and a turn-table holding the trays of eggs; and a special egg-turning arrangement.

Myer's "Perfection" Incubator is heated by the ordinary house-stove.

The *Corbett* incubator is placed on a pile of fermenting horse-manure, and more manure piled round if necessary. It is a cylindrical box with trays, each of which has a tier of eggs. The cover is removed and the trays lifted daily and the eggs turned. The apparatus subsequently acts as an artificial mother.

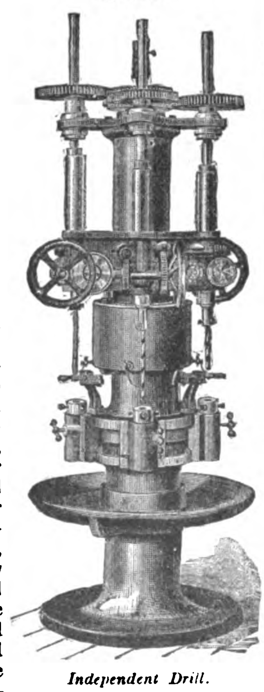
In'de-pen'dent Air Pump. One having no mechanical connection with the main engine: as distinct from a *connected* air-pump, which is a moving part of the engine. Being a steam-pump, operated independently, a vacuum can be formed for the engine before the latter is started, and the speed regulated according to the temperature of the injection water and the requirements of the engine.

In'de-pen'dent Car Wheel. One running free on the axle; as distinguished from the usual railway car wheel, which is chilled or keyed fast to the axle.

One form of independent car wheel, in which the two wheels are not essentially fast together, so that they can move independently in turning curves, is the *Miltimore* wheel, Fig. 532, p. 163, *supra*. See also CAR-AXLE, pp. 458, 459, "*Mech. Dict.*," and AXLE, pp. 198–201, *Ibid*.

Fig. 1440.



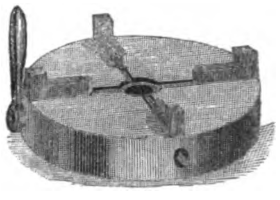
Independent Drill.

In'de-pen'dent Drill. A machine tool intended for work requiring four drills to finish a hole. Each spindle has independent automatic feed, so that one operator can attend to several machines. The four drills may be respectively a *starting* drill, *through* drill, *enlarging* drill, and *finishing* drill or *reamer*. The piece to be drilled is secured in a holder, indexed perfectly under the drills and finished before removing from its fastening. (*Pratt & Whitney.*)

In'de-pen'dent Jaw Chuck. A chuck in which each jaw is separately adjustable; as distinguished from the *universal*, in which the jaws move in concert. Fig. 1441. See also LATHE CHUCK, *infra*.

In'de-pen'dent Truck. (*Railway.*) One of the 4 or 6-wheeled trucks beneath a railway car on the American system. The car rests on the center pins of the trucks, which can therefore follow the track, swiveling by their own motion while the body of the car takes the position of a chord.

Fig. 1441.



Independent Jaw Chuck.

In the European practice the pairs of wheels are independent and their boxes work in hangers or pedestals on the main sill of the car frame. See Fig. 4126, p. 1863, "*Mech. Dict.*"

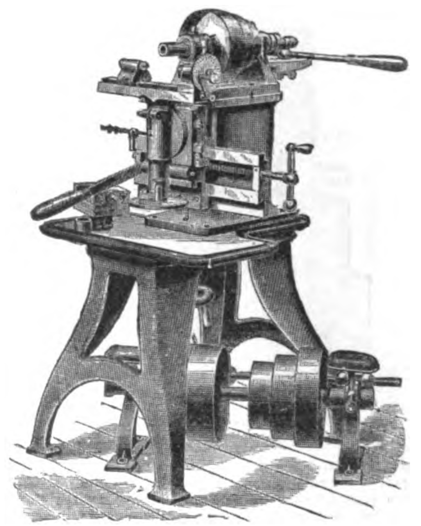
In'de-pen'dent Wheel. A term sometimes applied to a car wheel which runs free on its axle, in contradistinction to the customary wheel, which is chilled, or otherwise tightly fastened to its axle, in the usual railway practice where the wheels are rigidly attached to the respective ends of the axle.

See also a compromise arrangement in which the axle is divided, and each part carries its own wheel, Fig. 532, p. 163, *supra*.

In'dex Mill'ing Ma-chine'. A machine tool adapted to cutting rotary cutters in all varieties, spur and bevel gears, etc.

It receives ordinary work up to 6″ diameter, but will cut spur or bevel gears much larger. The index-plate is attached to the bottom of a hollow spindle having a graduated disk.

Fig. 1442.



Index Milling Machine.

The spindle is pivoted to a vertical slide, and with its attachments, as vise or centers, may be moved to and secured at any angle in a vertical plane of 180°, or 90° on either side of an upright position. This slide, carrying the index, spindle, etc., has a perpendicular traverse of 2″. The upward and downward movement of the main slide, to which the vertical is attached, is 6″, and its side traverse 12″. The centers are shown in the engraving as attached to the index-spindle. They will receive work 3½″ diameter and 8½″ in length. The cone spindle is of steel, and slides in a cast-iron sheath or shell, which runs in cast-iron boxes lined with babbitt-metal. The horizontal movement of the cone-spindle and the vertical movement of the slides is made by adjustable hand-levers, and limited by check-nuts. (*Pratt & Whitney.*)

In'dex. The following scheme for the filing away of valuable suggestions or data, of a miscellaneous description, or appertaining to any study, science, or what not, was devised some time since by Mr. M. T. C. Gould.

The scheme is for a book of 602 pp. The position of the slip or item is determined by its initial letter and next succeeding vowel, for instances: —

In'dex Wheel. 1. A graduated plate marked in circles of holes, for spacing in the cutting of gears. See INDEX PLATE; INDEX MILLING MACHINE.

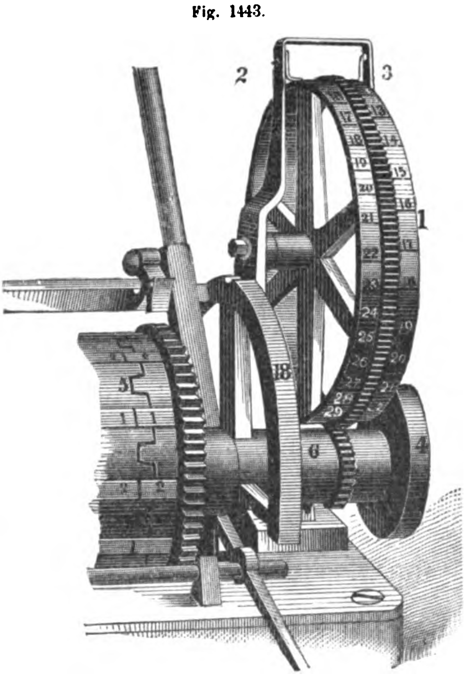
2. A graduated wheel in an instrument for dividing or measuring angles, or in some forms of calculating instruments.

An index wheel in the set works of a saw-mill is shown in Fig. 1442.
1 is the index wheel.
2 and 3, pointers.
4, coupling to which the set rod for working the knees is connected.
6, cog for working the index wheel.
18, support for the index wheel.

The object of the device is to tell at any time the exact number of inches in any log on the carriage, between the knees and the saw. Also, to tell how much slab must be taken off the first cut, in order to have the lumber in the remainder of the log all come out of the required thickness.

In'di-a Ink. The best India ink is still made in China, although its quality has deteriorated since glue made of buffalo instead of stag's horn has

Fig. 1443.



Index Wheel for Saw-logs.

been employed as the vehicle for the lampblack. Its first invention is reported to have been between A. D. 220–419. — "*Scientific American*," xxxvi. 26.

In'di-a Rub'ber. See CAOUTCHOUC.

In'di-a Rub'ber Spring. 1. (*Railway.*) A block of caoutchouc, usually cylindrical, and used in connection with steel springs, either as truck springs or for buffers and draw-springs. See Figs. 1142–1144, pp. 482, 483, "*Mech. Dict.*"

2. (*Carriage.*) A spring used in connection with the ordinary elliptic springs in the running gear, or as a bumper spring between the bolster and bed of a wagon.

3. A strap of rubber used for a return motion in many species of light machinery.

In'di-ca'tor. A marker of phenomena; time, place, number, distance, recurrent position or presence, etc.

There are many instruments cited as GRAPHS, METERS, SCOPES, etc. (see said titles in "*Mech. Dict.*"), which are indicators; such as, to cite one class of limited area, a *Gas Indicator*, of which *Fire-damp Alarm*, *Grisoumeter*, *Carburometer*, are specific titles.

See list of MEASURING, CALCULATING, AND INDICATING INSTRUMENTS, *infra*.

A list of speed, course, grade, and distance indicators and recorders is given on p. 282, *supra*.

Steam, electric, and other indicators are shown on pp. 1180, 1181, "*Mech. Dict.*," and the same work contains in their alphabetical places notices of the following indicators: —

Door.	Shoal.	Stream.
Leak.	Speed.	Street.
Leeway.	Station.	Weather.

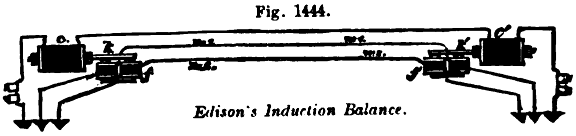
In-duc'tion Bal'ance. An instrument for the eradication of induction currents in telegraph lines.

Edison's induction balance, patented in England in 1877, and in the United States in 1878, was designed, in the terms of its specification —

"To compensate, neutralize, and destroy the extraneous or induced currents from contiguous circuits, so that the messages will not be in any manner interfered with by false

Fig. 1444.



Edison's Induction Balance.

currents. The invention consists, in the combination with the telephonic circuit, of an induction coil, connected with the contiguous circuits in such a manner that a reactionary induction is established in the telephonic line of a power corresponding and similar to the primary inductive action, but opposed to the same, so as to neutralize the action of the same."

Fig. 1444 is "a diagram representing one of the forms in which the compensation is effected. The large coils, *c c'*, are included in the telephonic circuit at each end of the line. In the coils are iron cores, surrounded by a primary coil, the ends of which may or may not be connected together, according to the compensation desired.

"The iron core extends outside of the coils some distance. The circuits, No. 1 and No. 2, running in close proximity to the telephone wires, induce a momentary current in it every time the circuits are opened or closed, the strength of which is proportionate to the proximity of the wires to each other and the number of miles that they run side by side. These induced currents are in one direction in closing the circuit, and the opposite direction on opening the circuit. To neutralize the induced current from, say, No. 1 circuit, electro-magnets, *e e'*, are placed at each terminal in the circuit of No. 1.

"These magnets are then adjusted to approach the iron cores, *k k'*, until the induced current thrown into the coils, *c* and *c'*, and telephone line by the action of the magnets, *e* and *e'*, is equal, but opposite to, the induced current from the circuit No. 1 thrown into the telephonic wire by running parallel to it. Thus a perfect compensation is attained.

"If the two lines run parallel for long distances the two ends of the primary coil on *c* and *c'* are connected together, and thus retard the magnetization and demagnetization of the cores, *k k'*, and consequently lengthen the induced currents thrown into *c* and *c'* by the action of *e'* and *e*.

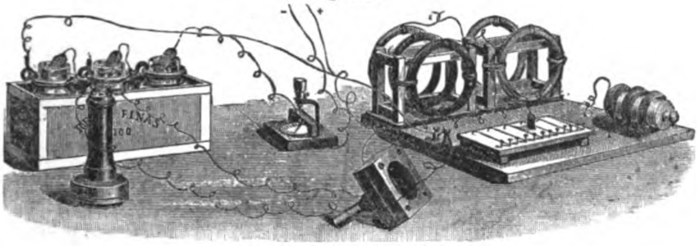
"Having thus compensated for circuit No. 1, the compensation for circuit No. 2 is exactly similar. If the latter circuit does not affect the telephone circuit as strongly as No.

1, the electro-magnets, *f* and *f'*, are placed a greater distance from *k* and *k'*; the latter may be elongated, and compensation attained from many circuits by employing separate magnets in each circuit which affects the telephonic circuit."

Fig. 1445 shows Prof. Hughes' apparatus. It consists of coils of wire, a telephone, a microphone, a three-cell Daniell battery, and a galvanometer, and was constructed by Prof. Hughes, to practically demonstrate his principle of compensation. The subject is carefully described, and the principles of the apparatus well treated in "*Engineering*," March 14, 1879.

"The five rings of insulated iron wire attached to the board — on the right, in the perspective view, Fig. 1445 — represent three lines of telegraph running parallel. The

Fig. 1445.



Hughes' Induction Balance.

two coils of each of the outside pair are joined so as to form one circuit, consisting of one black ring and one white one, each pair representing one line of a certain length, and between them is a single coil representing an intermediate telegraph line of a shorter length; this difference of length was adopted by Professor Hughes in his experimental model in order to represent a somewhat complicated case, and to show that no matter what the relative lengths and distances apart of telegraph lines, their mutual induction may be compensated by suitably constructed and adjusted compensating coils. The compensation portion of the apparatus consists of three rings whose distances apart can be adjusted by sliding in or out the cylinder to which each of the outer coils is attached. On the left front corner of the board is the commutator, consisting of six stiff elastic wires, which can be sprung against twelve brass nails, and the connections are so arranged that the battery circuit may be sent through any one of the lines, with or without the balance in the circuit, and each line can be made either a primary microphone circuit, or a secondary line in connection with a telephone, by simply placing the commutator wires against their proper contact pins. The microphone, and the clock (not shown), which is the source of sound, were, in the professor's experiments, placed in a distant room, and the direction of the currents throughout the whole apparatus was under perfect control by means of the commutator to which we have referred." — "*Engineering*."

In'duc-tom'e-ter. An invention by Dr. O. J. Lodge (England). A modified form of induction balance fitted for electric testing.

"*Engineering*" . . . . * xxx. 134.

In-duc'to-phone (*Electricity.*) A sounding instrument in which vibrations transmitted through the primary are reproduced by a plate and membrane. *Adams.*

In'fil-tra'tion. (*Mining.*) The theory that vein filling was introduced as mineral water.

In'fu-so'ri-al Earth. A species of earth, the remains of microscopic animals. It is used as an ingredient in dynamite. See p. 767, "*Mech. Dict.*"

Infusorial earth, uses of, "*Scientific American*," xxxv. 240.

In'grain. As applied to carpets, ingraining is the union, according to the necessity of the pattern, where an interchange of yarn occurs between the *plies* or webs. The more frequently this occurs the better the fabric is *ingrained.*

The ingrain carpet may be *two-ply, three-ply,* etc., according to the number of webs.

In-jec'tion. (*Mining.*) The theory that vein filling was introduced by an igneous fluid and solidified. See IMPREGNATION.

In-ject'ing Syr'inge. (*Microscopy.*) An instrument for injecting the minute arteries of animal tissues with colored chemical substances, thus filling the small blood-vessels and rendering them visible under the microscope.

In-jec'tor. 1. (*Surgical.*) An instrument of the nature of a syringe. The size and shape and the form and proportions of the nozzle vary with the object.

They may be classed as

Bladder.	Rectum.
Embalming.	Uterus.
Hypodermic.	Vagina.

Dr. Parker's injection tubes for the urethra are bulb-pointed, soft rubber, velvet-eyed.

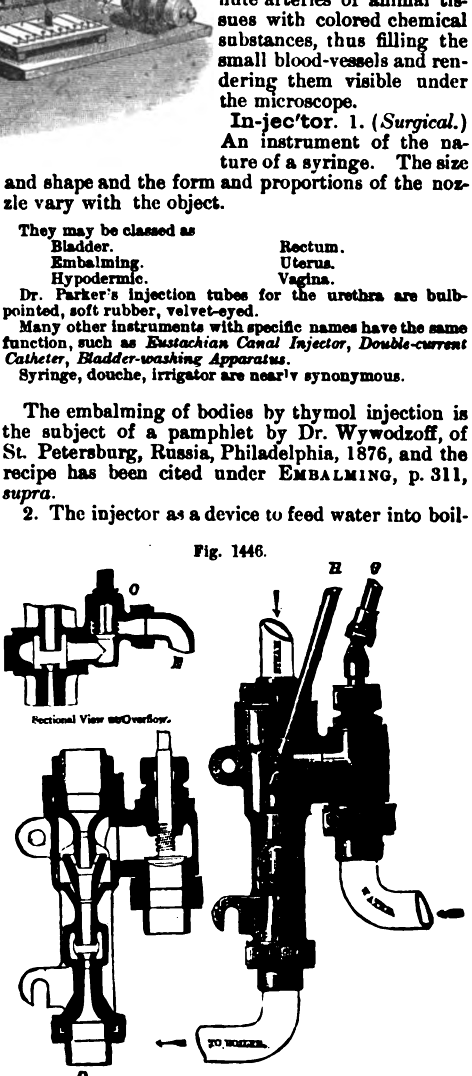
Many other instruments with specific names have the same function, such as *Eustachian Canal Injector, Double-current Catheter, Bladder-washing Apparatus.*

Syringe, douche, irrigator are nearly synonymous.

The embalming of bodies by thymol injection is the subject of a pamphlet by Dr. Wywodzoff, of St. Petersburg, Russia, Philadelphia, 1876, and the recipe has been cited under EMBALMING, p. 311, *supra.*

2. The injector as a device to feed water into boil-

Fig. 1446.



Friedmann Injector.

ers has been described on pp. 1185, 1186, "*Mech. Dict.*" *Giffard's*, and *Seller's* improvement on Giffard, are there shown, Fig. 2679.

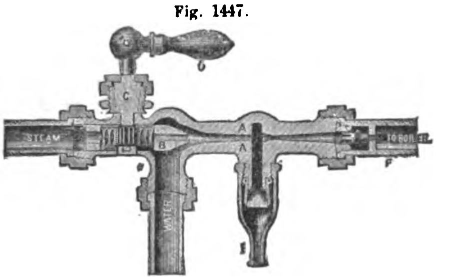
Various modifications and applications of the device are now found.

Fig. 1446 shows the Friedmann (Nathan & Dreyfus) non-lifting injector for locomotives. It is to be placed below the water line and can be used as a heating cock for the tender and water-tank by closing the overflow valve, the handle of which extends into the cab.

H is the handle of the overflow valve, to be used to close the overflow altogether or when the injector is to be used as a heater-cock to heat the water in the tender. *G* is the handle of the water valve; the latter is seen to the right in the sectional view. On the left, in the sectional view, is the intermediate nozzle by which the water supply is conducted in two annular streams to the condensing chamber of the injector when the steam jet is subjected to the action of both at separate points. The result is effective condensation of steam and the transfer of its velocity to the water.

Fig. 1447 is the "Keystone" injector. The form shown is used when the supply water is received from a pressure, such as street main or elevated reservoir. It is placed in a horizontal position, the steam pipe attached to highest part of the boiler, an ordinary globe valve being placed on the steam pipe, and a valve or water cock on the water pipe.

Fig. 1447.

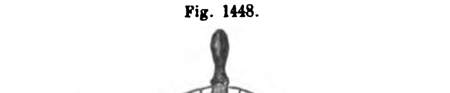


"*Keystone*" *Injector.*

Method of working: Open the steam valve to drive out any condensed steam there may be in the pipe, and close it again. Then open the water cock, then the steam valve, and move the plug *B* slowly forward with the handle *b*, until the water ceases at the overflow. If, while the injector is working, water should escape from the overflow, move the plug forward to reduce the supply of water. If steam escapes, move the plug backward, to give it more water. When the lever *b* is set so the injector works perfectly dry; if you wish to stop feeding, close first the steam valve, then the water cock.

Rue's "Little Giant" injector has an adjustable *combining-tube* moved by a lever. The motion to the left, as exhibited in the cut, Fig. 1448, gives more water, and contrariwise, less. The injector cannot be worked while the combining-tube is closed at either end. The injector lever should be in such position as to allow a sufficient quantity of water to condense the steam when the valve is full open. The combining-tube being open at each end slides in stuffing boxes *C C*, on the left towards the steam supply pipe which projects into the water chamber, and at the other end the tube projects into the discharge chamber to meet the discharge tube which leads to the boiler. The space around the tubes, what may be called the second chamber, has an overflow valve which allows escape of water in the direction of the arrows, when the force of the steam has not sufficient force to cause the water to open the check valve in the boiler supply pipe beyond the discharge plug. When the water has sufficient momentum to open the check valve it causes an indraft at the overflow pipe which closes the valve against the ingress of air.

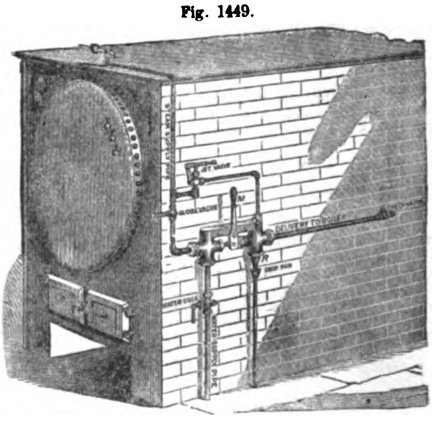
Fig. 1448.



"*Little Giant*" *Injector.*

Fig. 1449 shows the "Little Giant" injector attached to a stationary boiler. The parts are indicated in the cut.

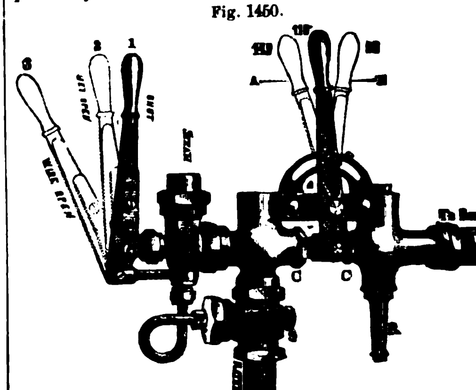
Fig. 1449.



"*Little Giant*" *Injector attached to Stationary Boiler.*

Fig. 1450 shows the arrangement of the *Rue* "Little Giant" injector as applied to locomotives. Directions for operating will sufficiently explain it in connection with what has been previously stated.

Fig. 1450.



Rue Locomotive Injector.

To start the injector: Open lever valve from 1 to 2; when water shows at overflow *R*, open valve to 3 where it must remain while the injector is at work. Regulate water by the combining-valve lever *M*.

To stop the injector, close the valve *A*.

To use as a heater: Close overflow by moving lever *M* to *A*. Then open lever valve on the left to 2 or 3 to admit steam required.

boiler, rising to admit the water under impulse of the steam jet, and falling to prevent back flow of water.

Ink.

Yellow: A little alum, added to saffron in soft hot water.

For tin or zinc plant labels: Copper, 1; nitric acid, 10; water, 10, subsequently added.

Stencil ink: Shellac, 2; borax, 1; soft water, 10; boil. Add gum arabic, 1; remove from the fire, and stir in lamp-black *ad suf.* Indigo added to tinge.

For tin or zinc: Sulphate of copper, 1; sal ammoniac, 0.5; acetic acid, 2; add lamp-black or vermilion.

Blue: Sulphate of indigo, diluted with water.

To restore faded ink: Brush over with a solution of sulphide of ammonium.

Or: Brush with solution of tannin, remove excess by current of water, and dry at 144° to 177° Fah.

Or: Brush over with solution of sulphocyanide of potassium 1 in 20, and dry in fumes of hot hydrochloric acid. Ferro-cyanide might answer.

To remove ink marks: Moisten with solution of cyanide of potassium, and then solution of oxalic acid. Apply with a camel's-hair brush alternately.

Japanese writing inks are very much like Chinese, and manufactured in a similar, though perhaps not quite identical way. The body of the ink is soot, obtained from pine wood or rosin, and lampblack from sesamum oil for the finest sort. This is mixed with liquid glue made of oxskin. This operation is effected in a large round copper bowl, formed by two spherical calottes, placed 1″ apart, so that the space between can be filled up with hot water to prevent the glue from hardening during the time it is mixed by hand with the lampblack. The cakes are formed in wooden molds, and dried between paper and ashes. Camphor, or a peculiar mixture of scents, which comes from China, and a small quantity of carthamine (the red coloring substance of safflower), are added to the best kinds, for improving the color, as well as for scenting the ink. There is a great difference in price as well as in quality between the various kinds of ink, the finest article being rather costly. The most renowned manufactory is in Nara, the old capital of Japan, in the province of Yamato.

Ink Cup. A vessel hermetically closed, to hold water color or liquid india ink, to preserve it from evaporation and from flies.

Fig. 1452.

India Ink Cup.

The stopper is removed, and the ground ink (or color) is placed in the cup through the tubular neck. Replace the stopper and tube. Pressure on the bladder cover causes the ink to rise in the tube, so as to be within reach of the pen.

Ink'er. The device on a recording instrument which makes the dot or trace.

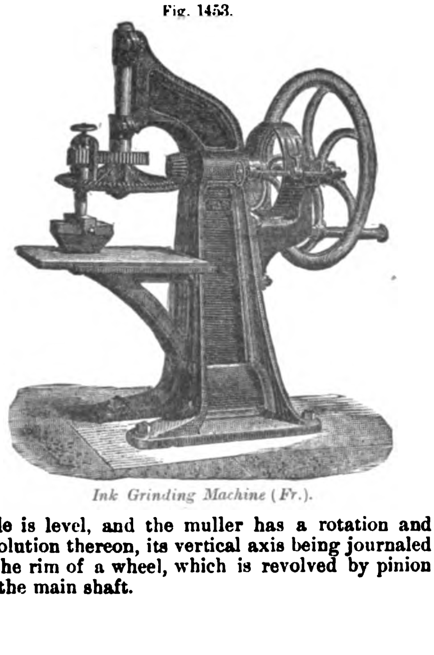
John inking disk, for telegraphic instrument, English, 1856.

Devos inker . . . . * "*Telegraphic Journal*," vi. 28.

Ink E-ra'ser. Take chloride of lime 4 ozs., dissolve in 1 quart of soft water. When dissolved, strain, and add a teaspoonful of acetic acid to each ounce of chloride lime-water. Apply to ink with a brush; absorb moisture with blotter, and dry.

Ink Grind'ing Ma-chine'. A machine having muller and table for grinding ink or color. The

Fig. 1453.



Ink Grinding Machine (Fr.).

table is level, and the muller has a rotation and revolution thereon, its vertical axis being journaled in the rim of a wheel, which is revolved by pinion on the main shaft.

Ink'ing Pad. A pad used to ink the faces of post-office canceling and office stamps.

The Yale pad has a metallic cup, a porous ink surface, and a cover to protect it when not in use.

Ink Pen'cil. A pencil giving a black mark which does not fade on exposure to light, and can be reproduced in the copying machine.

"The mass for these pencils is prepared as follows: 10 lbs. of the best logwood are repeatedly boiled in 10 gallons of water, straining each time. The liquid is then evaporated down till it weighs 100 lbs., and is then allowed to boil in a pan of stone-ware or enamel. To the boiling liquid nitrate of oxide of chrome is added in small quantities, until the bronze-colored precipitate formed at first is redissolved with a deep blue coloration. This solution is then evaporated in the water bath down to a sirup, with which is mixed well-kneaded clay in the proportion of 1 part of clay to 3¼ of extract. A little gum tragacanth is also added to obtain a proper consistence.

The nitrate of oxide of chrome is prepared by precipitating a hot solution of chrome alum with a suitable quantity of carbonate of soda. The precipitate is washed till the filtrate is free from sulphuric acid. The precipitate thus obtained is dissolved in pure nitric acid, so as to leave a little still undissolved. Hence the solution contains no free acid, which would give the ink a dirty red color. Oxalic acid and caustic alkalies do not attack the writing. Dilute nitric acid reddens, but does not obliterate the characters." — *Moniteur Scientifique.*

Ink Pow'der.

Aleppo galls	8 lbs.
Copperas	1 lb.
Gum arabic	½ lb.
White sugar	¼ lb.

Powder and mix. 1 pint boiling water to 2 oz. of this mixture makes a good ink.

Ink, Solid. One recipe for solid ink is: —

Honey	8 oz.
Egg	1 yolk.
Extr. galls	1½ pints.
Sugar candy	1 oz.
Gum arabic	3 oz.
Indigo	1 oz.
Decoc. logwood	½ pint.
Lampblack	2 oz.
Willow wood charcoal	2 oz.
Sulphate iron	3 oz.
Blue galls in powder	3 oz.

Another recipe is: —

Catechu	3 drachms.
Extr. hæmatoxylon	1 drachm.
Acetate and hydr. of deutoxide copper	10 grains.
Sulph. alumina and potash	1 scruple.
Gum arabic	1 drachm.
Sulph. of protoxide of iron	1 drachm.
Sulp. indigo, for color.	

Over all pour a decoction of Campeachy wood to form a paste.

Ink'stand. A solid-ink inkstand is one furnished with a block of ink which affords a writing fluid by addition of water. See *supra.*

In-lay'ing. (*Fine Art Metal-work.*) The inlaying of Japanese bronzes with gold, silver, and alloys is called *zogan*, and is principally carried on in the provinces of Kaga and Yechiu. The process by which the inlaid work is effected differs according to the nature of the material on which it is produced.

Cloisonné. The design is hollowed out to a certain depth with a graver or chisel, and the ornamenting metal, silver, gold, etc., generally in the shape of threads, is laid into the hollow spaces and hammered over, should the alloy be soft enough; the edges of these grooves are first slightly driven up, so that when the silver or gold has been laid in, they can be easily hammered down again, so as to prevent the inlaid metal from getting loose.

Or: The surface is merely covered in the required places with a narrow network of lines by means of filing, and the thin gold or silver-leaf fastened on to this rough surface by hammering. This last process is the one used mostly for inlaid iron-work. With *Niello*, instead of the usual black sulphureted silver and copper, a more easily fused alloy is used. Inlaid work of the above kind is made at Kanasawa and Takaoko, where the alloy used for the bronze casting is mostly composed of copper, tin, zinc, and lead.

In the European practice the inlaid enamel work which is performed by Oriental artists with so much skill and patience, and at the same time with such primitive appliances, is now executed by simpler and quicker means. The object to be inlaid is entirely covered with varnish, portions of which are removed by a graver so as to form the design; and thus prepared, it is subjected to the action of a galvanic bath of gold or silver, which deposits the metal in the places laid bare by the graver.

Another method is suggested by M. Morin. After the removal of the varnish, according to the pattern made by the graver, the object is plunged into a solution of cyanide of silver. The salt is deposited on the lines from which the varnish has been removed; the object is heated in a muffle furnace, and the metal appears on the black patina.

Inlaid patterns of gold and silver may be obtained, either of their natural brightness or with a dead surface, the latter being effected by different processes of oxidation; so that, on the same object, by making use of the protecting varnish, designs in gold and silver of various degrees of luster may be combined.

See also "*Manufacturer and Builder*" . . . . xi. 34.

Japanese *repoussé* work consists of small metallic ornaments for swords, tobacco pouches, etc., and larger pieces, such as tea-pots, scent-burners, vases, etc.; the inlaying of this kind of ware is sometimes of extraordinary delicacy and beauty. The dark blue color shown by a great number of smaller pieces is that of the Shakudo, composed of copper and 3 or 4 per cent. of gold.

India excels in inlaying, and has many styles, the names of some of which have been recognized in commerce, arts, or in treatises. The art, which was common in Europe, is said to have been introduced from Persia into India about a century ago.

Bombay inlaid work is used for boxes, desks, and similar articles.

Vizagapatam work is in ivory and stag's horn, and applied to articles similar to the Bombay work. The black etched scroll work on the ivory is in graffito.

Mynpuri work consists of boxes and salvers of a rich brown wood, inlaid with brass wire in geometrical forms and scroll patterns.

Agra work is a mosaic of semi-precious stones, copied in style from the exquisite Taj at Agra by Austin de Bordeaux.

See also Bidiri Work; Kuft Work.

In'ner-hung Brake. (*Railway.*) One in which the brake shoes and beam are hung between the wheels, under the car-bed. In contradistinction to *outer*-hung brake.

In Place. (*Mining.*) A vein or lode inclosed on both sides by fixed and immovable rock.

In'sect De-stroy'er. A means for destroying aphides, slugs, and bugs on roses or other flowers and plants; beetles on potatoes; worms on cotton, and so on.

See Sifter; Duster; Spraying Machine; Fountain Pump; Sprinkler; Beetle-Destroyer.

Comstock's "*Report upon Cotton Insects*," 1879, shows a great number of devices, which are listed under Cotton-worm Destroyer, p. 226, *supra.*

In'sect Pin. A delicate, thin pin for impaling entomological specimens.

In-sert'ed Joint. A form of pipe joint in which one member slips in the other, which forms a sleeve. A bell-joint.

In-side'-jaw Chuck. A chuck for holding drills, rods, or pipes. These pass *through* the chuck, the jaws of which have an inside hold instead of, as in a face-chuck, gripping the object by projecting jaws, as in the ordinary lathe chuck.

In-side' Mold'ing Ma-chine'. 1. A wood-planing, molding, or matching machine, the cutters of which are between the bearings of the cutter arbor; in contradistinction to a machine in which the cutter overhangs the frame.

2. A wood molding machine which has cutters protruding upwardly through the table, and adapted to work upon inner molding edges, as those of pic-

ture frames, etc. An edge-molding machine. See Fig. 3200, p. 1468, "*Mech. Dict.*"

In-sol′u-ble Ce-ment′.

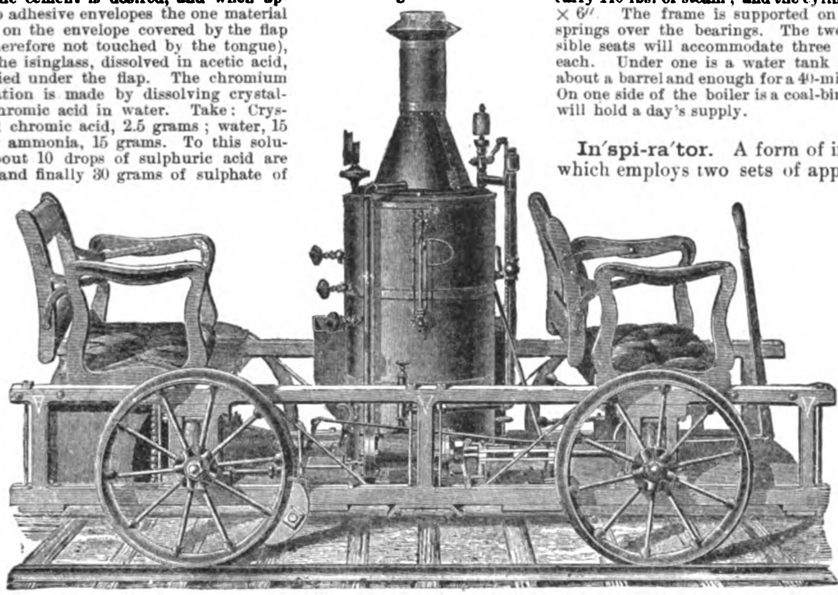
"A chromium preparation and isinglass forms a solid cement, which is not only insoluble in hot and cold water, but even in steam, while neither acids or alkalies have any action upon it. The chromium preparation and the isinglass or gelatine do not come into contact until the moment the cement is desired, and when applied to adhesive envelopes the one material is put on the envelope covered by the flap (and therefore not touched by the tongue), while the isinglass, dissolved in acetic acid, is applied under the flap. The chromium preparation is made by dissolving crystallized chromic acid in water. Take: Crystallized chromic acid, 2.5 grams; water, 15 grams; ammonia, 15 grams. To this solution about 10 drops of sulphuric acid are added, and finally 30 grams of sulphate of ammonia and 4 grams of fine white paper. — "*Dingler's Polytechnisches Journal.*"

In-spec′tion Car. One used by the officers of a railway while inspecting the track.

One made by Mr. Noble is shown in Fig. 1454. The platform extends under the axles and is within 10″ of the rails. The boiler is about 42″ × 18″, intended to carry 140 lbs. of steam; and the cylinder 3½″ × 6″. The frame is supported on rubber springs over the bearings. The two reversible seats will accommodate three persons each. Under one is a water tank holding about a barrel and enough for a 40-miles run On one side of the boiler is a coal-bin which will hold a day's supply.

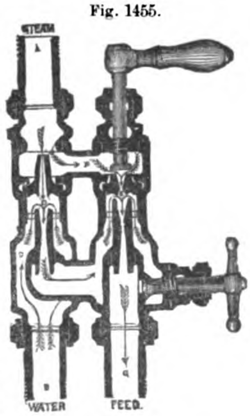
In′spi-ra′tor. A form of injector which employs two sets of apparatus contained each in a separate chamber, but working in combination, the first of which lifts and receives the water in the pump-chambers by the suctional action of a small jet of steam, and then conducts it to the injector or forcing-tubes contained in the second chamber. The water is then transmitted to the boiler by the aid of a second jet of steam, which constitutes the forcing element, and which impinges upon the stream of water as delivered by the pump, and forces it directly into the boiler.

Fig. 1454.



Inspection Car.

Fig. 1455.



Hancock's Inspirator.

The operation is as follows: Dry steam is admitted to the instrument by opening a valve at the point *A*. The water is drawn up from the well, or other reservoir, in the chamber *B* by the creation, at that point, of a partial vacuum, and rises through the channel *C* to the point *D*, when the jet of steam drives it into *E*, as shown by the line of arrows. The forcing jet of steam is admitted through *F*, and controls the feed-current at *E*, passing to the boiler down the feed-pipe *G*.

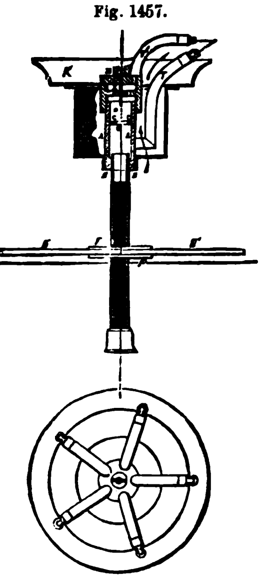
In-ten′si-ty. (*Electricity.*) Another name for tension; capacity to overcome resistance.

In-ten′sive Gas Burn′er. (Fr. *bec Mallet.*) A late French form of gas burner.

The burners, ordinary batswings, are placed in pairs on the circumference of a circle, so that their tubes of supply represent radii of the circle.

Fig. 1457.



Bec Mallet. (*Section and Plan.*)

In the burner shown in the section and plan in Fig. 1457 there are five pairs, or ten burners. The lower ones are inclined from the horizontal in an upward direction, so that the flames join together into one. The upper row is supplied from a chamber, *X*. The disk crossing the center of the chamber may be raised or lowered by the central screw, thereby giving less or more gas to the upper circle of burners. The chamber has a hollow thread cut in it, and screws up and down on the tube *A A*, so that the distance between the two circles of burners can be regulated. The lower burners are supplied from the tube *A A*. This tube has also a hollow screw cut in it and the main supply tube *H* screws into it. By screwing the supply tube *H* into the tube *AA* the supply of gas to the lower circle of burners is cut off as the end of the tube *H* approaches the diaphragm *C C* perforated with a hole *D*, while the supply to the upper burners is obviously unaffected. Thus the supply to either circle of burners can be increased or diminished or cut off entirely; and either can be lit, to the exclusion of the other. At *L* is represented a basket in wire gauze surmounted by a plate *K*. The air that passes through this is supposed to be somewhat heated, and supplies the flame through the interior of the apparatus, and the shield preserves the flame from currents of cold exterior air.

Fig. 1458 shows the general effect of the Mallet burner in a street lantern.

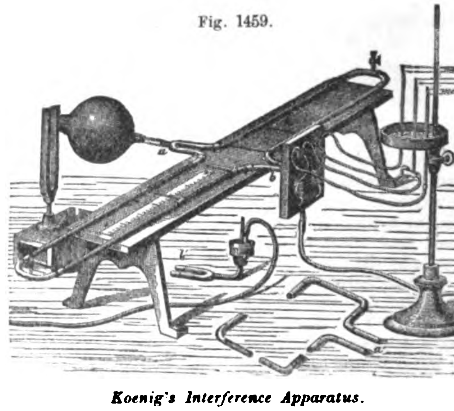
In′ter-fe′rence Ap′pa-ra′tus. An apparatus by M. Koenig for investigating the theory of sound. That shown in Fig. 1459 is for observing the interference of sonorous waves.

The apparatus consists chiefly of two U-shaped tubes, fixed horizontally upon a board, but so arranged that their length may be changed, on the same principle as the trombone with the well-known sliding piece: these allow the tubes to be made of the same length, or different according to any length desired. These tubes connect mutually by both ends; at one connection, *a*, a resonator is attached, serving to intensify the sound of a large tuning-fork, with which it is in unison, and to conduct it through both tubes to the other end *b*. When these tubes have the same length, the waves will arrive equally through both routes; but if we lengthen one of the arms until the difference between them amounts to half a wave-length of the note of the tuning-fork, the waves coming through the two conduits destroy each other at the other end of the tube, and if we allow this to terminate in a small cavity, above which is a manometric capsule, we shall see, on lengthening one of the arms, how the deeply cloven flames in the revolving mirror are gradually changed into bands of light when the difference of half a wave-length is reached, corresponding with the point where the two waves destroy one another by interference.

Fig. 1458.

Intensive Gas-burner.

Fig. 1459.



Koenig's Interference Apparatus.

See "*Manufacturer and Builder*," * viii. 12, and * v. 13, Fig. 3, also numbers for January and July, 1874, in regard to the application of resonators and mirrors in investigating the properties of sound.

See also CURVE INSTRUMENT; ELECTRICAL DIAPASON; FLAME MANOMETER; HARMOGRAPH, *supra*; and PENDULUM INSTRUMENT, *infra*.

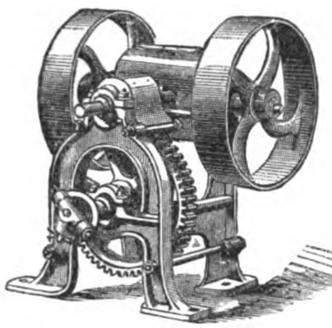
In′ter-me′di-ate Floor. (*Railway.*) A floor consisting of boards placed between the sills and floor-timbers of passenger cars and between the deafening or under floor and the upper or main floor. The purpose of the intermediate floor is to exclude noise and stiffen the floor-timbers. — *Forney*.

In′ter-me′di-ate Mo′tion. A device placed between a horse-power and a machine to be driven, to convert the motion of the tumbling-rod of the former into a band motion for the latter.

The tumbling-rod is coupled to the gimbal shown on the left, and the motion is communicated by master wheel, pinion and bevel wheels (in the case) to the band pulleys. The latter are two in number, to serve separate machines.

Also known as a *jack*; a jack serving 3 machines is shown at *E*, Fig. 2569, p. 1126, "*Mech. Dict.*"

Fig. 1460.



Intermediate Motion.

In'ter-me'di-ate Spin'ning Frame. In the series of spinning frames, consisting of *slubbing*, *intermediate*, *roving*, and *fine roving* frames.

In-ter'nal Gage. A gage for testing internal sizes; holes and other spaces. An internal diameter gage.

The *cylindrical* gage is a favorite form; see Fig. 772 (plain), p. 244, *supra*.
Also Fig. 994 (threaded), p. 322, *Ibid*.

In-ter'nal Pres'sure Gage. Lieut. Metcalfe's internal pressure gage, for testing pressures in exploding ordnance, is described and illustrated in the "*Report of the Chief of Ordnance*," 1877, * 361, and Plate accompanying Appendix 1, *a*. It uses a conical point, and the determination of the pressure is by measuring the surface diameter of its penetration into a copper disk.

In the same volume, p. 374 *et seq.*, and Plates I.-IV., is a description of Lieut.-Col. Benton's dynamometer, used for the same purpose. Also of Rodman's internal pressure gage, p. 387, and Plate V; the Adams circular cutter, p. 388, and Plate VI.; the national armory circular cutters, p. 389, and Plates VII. to X.
See DYNAMOMETER.
See also PIEZOMETER, *infra*; and CRUSHER GAGE, p. 283; CUTTER, p. 239, *supra*.

In-ter'nal Screw Gage. A steel external-thread screw made to an accurate size, for measuring internal-threaded screws.

See EXTERNAL AND INTERNAL GAGES, Figs. 993, 994, p. 322, *supra*.

In'ter-os'se-ous Saw. (*Surgical.*) A fine thin saw for working between bones, as those of the fore-arm, the lower leg, the ribs. — *Lente*.

In'ter-rupt'ed Cur'rent. (*Electricity.*) An intermittent current caused by the rapid action of a rheotome or vibrating armature. The primary and secondary currents are generally interrupted ones, and the galvanic or battery current can also be, if required.

In'ter-rupt'er. (*Electrical.*) An automatic apparatus, used in connection with the chronograph and wire-targets, to ascertain the velocity of flight of projectiles.

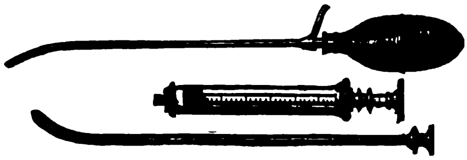
The *Russell* interrupter, used in connection with the *Schultz* chronoscope, is described on pp. 42, 45, and Plate I, "*Ordnance Report*," 1878.

In'tra-u'te-rine Syr'inge. (*Surgical.*) An instrument for injecting the uterine cavity.

The upper one in Fig. 1461 is *Molesworth's*. It consists of an elastic bulb and double canula; the fluid is discharged directly forward, towards the symphysis pubis, without danger of throwing the jet into the Fallopian tubes, and escapes as fast as thrown in, or may be retained as long as desired, and all withdrawn by relaxing the pressure on the bulb; the tube is silver, and the curve easily changed.

The lower one in the figure is *Gautillon's*. It has also the reverse flow, a graduated glass barrel, and a silver tube.
Intra-uterine and uterine electrodes, for introduction through the cervix and for clasping the neck of the uterus respectively, are shown in *Tiemann*, Part 1. page 106.

Fig. 1461.



Intra-uterine Syringe.

In-trench'ing Spade. One carried by troops for making earthworks.

See BURGOYNE, Fig. 77, p. 147, *supra*.
Harrison's, Fig. 2691, p. 1193, "*Mech. Dict.*"
Rice's TROWEL BAYONET, Fig. 6673, p. 263, "*Mech. Dict.*"
The Austrian intrenching spade has a jointed handle.
See also intrenching tool, *Buskett*, * "*Scientific American*," xl. 202.

In-ver'sion Bat'te-ry. (*Electricity.*) One in which the inversion, or upsetting of the battery, throws the exciting liquid against the plate or plates and sets the battery in action.

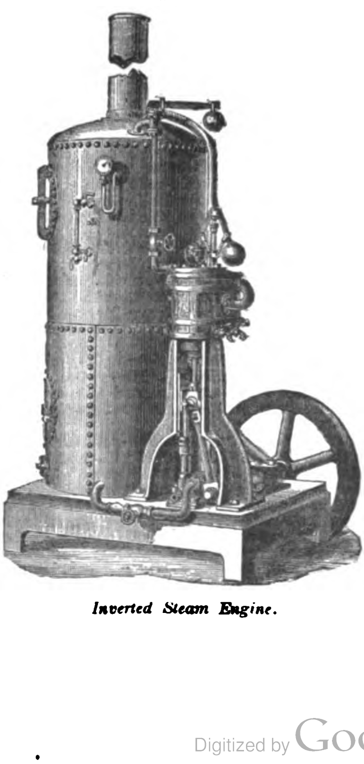
See that of M. Trouvé in connection with his electro-medical apparatus, * "*Telegraphic Journal*," vi. 475.
* "*Niaudet*," American translation, 147.

In-vert'ed Arch Bar. A wrought-iron bar bent into somewhat the form of an inverted arch, and which forms the tension member of a truss of an iron side-frame of a truck. The ends of an inverted arch-bar rest on the journal-boxes, and the arch-bar is on top of it. — *Forney*.

In-vert'ed Steam En'gine. A form of steam-engine useful in yachts and launches, as it allows direct connection to a propeller-shaft which has its bearings on the base-plate.

Several forms are shown in Figs. 2695, 2696, p. 1194, "*Mech. Dict.*" See also *Craig*, Br. * "*Engineer*," l. 3.

Fig. 1462.



Inverted Steam Engine.

In'wall. The lining wall of a smelting furnace; specifically, that part of it which is above the boshes.

I'on. (*Electricity.*) A product of voltaic decomposition.

Ir'i-dec'to-my In'stru-ments. (*Surgical.*) Instruments for operating upon the *iris* of the eye. See IRIDECTOME, p. 1195, "*Mech. Dict.*"

Iridectomy instruments include those for artificial pupil, dislocating the natural pupil, and incision. See KERATOME, p. 1223, "*Mech. Dict.*"

PUPIL, ARTIFICIAL, p. 1835, *Ibid.*

See also for knives, scissors, needles, forceps, sharp and blunt hooks, p. 30, Part II., *Tiemann's* "*Armamentarium Chirurgicum.*"

Ir'i-dec'to-my Scis'sors. (*Surgical.*) For operating upon the iris. See *Althof's*, *d* Fig. 4672, p. 2054, "*Mech. Dict.*"

I-rid'i-a'ted Glass. Glass, the surface of which has acquired opalescence or the iridescence familiar in mother-of-pearl, by exposure for a long period in the ground, or by artificial means for producing the same effect. See IRIDESCENT GLASS.

Iridescent lace, *Helouis*, Fr. . "*Sc. American*," xxxix. 184.

Ir'i-des'cent Glass. The cause of the change in the structure of the ancient glass, — the articles exhumed by General di Cesnola, at Idalium and Golgoi, in Cyprus, being the most brilliant specimens (see p. 973, "*Mech. Dict.*"), — is understood to be the combination of the alkaline components of the glass with carbonic acid, setting free the silicic acid. The alkaline carbonate, being washed away, leaves the surface in a laminated condition, adapted to refract light from a multitude of surfaces, giving the same appearance as the wavy structure of *nacre* or mother-of-pearl. It is said that analysis of some of the di Cesnola glass proves the fact of the changed chemical condition stated.

Specimens from China and Burmah indicate that means are in the possession of these Orientals for producing the rainbow tints, and Clémandot and Frémy have succeeded in producing the iridescence by placing the glass under a pressure of 2 or 3 atmospheres for 6 or 7 hours in a water-bath containing 15 per cent. of hydrochloric acid at a temperature of 248° Fah.

The wondrous beauty of the Cyprian specimens directed special attention to the subject, but it had long been noticed that Etruscan and Roman glass had acquired this property, and specimens in the European museums, in Italy especially, had made the appearance familiar. That the still more ancient glass of Egypt had not manifested the same peculiarity is accounted for by the dryness of the atmosphere of that country, although some Egyptian glass is not destitute of iridescence.

The process of Webb & Son, of England, is as follows: —

Chloride of tin or tin salt is burnt in a furnace, and the hot glass, while on the ponty in the last stage of the course of manufacture, is exposed to the fumes. To give greater depth to the tints, nitrates of bromine and strontium are used in small quantities.

Investigations of the Austrian and Bohemian iridescent glass show that the process there pursued is by heating the glass and causing the deposit of a metallic oxide on its surface by reduction. Bismuth is used, and M. Peligot has detected it by analysis.

Bohemian (lime glass) glass is thought to be the most suitable for this treatment.

Producing colors on glass by fuming vapors, forms the subject of a U. S. Patent to F. S. Shirley, Dec. 18, 1877. It is, however, a European invention, and was shown by Lobméyr, the pioneer in this line, in the Austrian section, at Philadelphia, in 1876.

Articles made with a beautiful iridescent surface are now common in shop windows, globes of this character having their effect enhanced by filling with water. It is perhaps more effective in partial shadow than in full light. Chandeliers and decorative bulbous plates of this kind of glass are extremely brilliant. Black beads, for trimmings of ladies' costumes, are now made as iridescent as peacock coal.

Clémandot's patented process produces beautiful effects. The main feature of the process is the application of acids to the glass, under a pressure of from two to five or more atmospheres. Water containing 15 per cent. of hydrochloric acid is used to bring out rainbow tints like mother-of-pearl; and artificial gems of various sorts have thus been manufactured. The glass prepared by these processes is quite as iridescent as that which antiquaries so much value, the pressure and the acids hastening a result that the ordinary agencies of the atmosphere would take centuries to produce.

To remove the tendency of window glass to show iridescent colors, it may be plunged as it is taken from the *leer* into a bath of water, with 2% of hydrochloric acid.

I'ris-a'ted Wire, etc. An invention of Nobile, improved by Becquerel and M. Hélouis, of France, in which metallic threads, lace, and ribbons are *irisated* by means of binoxide of lead, producing delicate fibers of binoxide in concentric rings, with varied colors, like those of soap bubbles.

Nobile used electro-chemical means. Becquerel devoted time to its elucidation, and substituted a solution of oxide of lead in potassa or soda.

M. Hélouis has succeeded in irisating ribbons, threads, and bands, objects in some cases of such tenuity as to have a length of 32,800 feet to the pound.

I'ris-a'tion. Conferring the tints of nacre.

To produce rainbow tints on metals: Dissolve 3 parts hyposulphite of soda in 30 of water and mix in 1 of sugar of lead. The mixture is precipitated on being heated to 70° or 80° Réaumur, depositing sulphuret of lead. In the presence of any metal this deposit is made upon it. According to the thickness of the deposited layer various iridescent colors appear on the surface of the metal. To produce this coloration uniformly the object should be heated throughout.

I'ron A-mal'gam. Sideraphthite: composed of 65 parts iron, 23 nickel, 4 tungsten, 5 aluminum, 5 copper.

It resists sulphureted hydrogen, is not attacked by vegetable acids, and only slightly by mineral acids. It is useful as a substitute for standard silver, while it can be produced at a cost not exceeding that of German silver. For alloys which have to be silver-plated to prevent oxidation, the inoxidizable iron, as the above is called, is stated to be a successful substitute.

Ir'on Bar'row. A wrought-iron wheel barrow for moving iron in pig, sheets, or bars.

I'ron Ce-ment'.

Dried and powdered brick earth	4
Peroxide manganese	1
Fine iron filings (free from rust)	2
Common salt	0.5
Borax	0.5

Mix, grind, and make into a paste with water. Apply when freshly made. Warm, and then expose to a nearly white heat.

Another: Sifted peroxide of manganese 1
Triturated zinc 1

Rub up into a pasty condition with common water glass. Apply while freshly made.

See also recipes, p. 182, *supra;* and pp. 507-509, "*Mech. Dict.*"

I'ron Clad. The Italian iron-clads are at present the most formidable.

"The new twin-screw double-turret vessel 'Dandolo,' belonging to the Royal Italian navy, excepting in the omission of the internal torpedo deck, resembles the sister ship 'Duilio' in her general arrangement, but has considerably surpassed her in speed. The 'Dandolo' was built at the royal naval arsenal at Spezzia, under the supervision of Director Borghi, at whose suggestion the whole of the bow plating is worked flush, instead of the plates overlapping as usual. The length of the vessel is 337′ 8″, the breadth 62′ 3¼″; the mean draft at the trials with armament on board was 28′ 9″, giving a total displacement of 11,225 tons. The battery is heavily armored, and is placed in the middle of the vessel; the two turrets rise above the weather-deck, and are placed diagonally in the battery, so as to enable all four guns to be fired fore and aft. The armor of the turrets is impenetrable to all except the heaviest modern artillery. Each turret contains two 100-ton Armstrong guns, made at Elswick, having a bore 17.72″, throwing a shot 2,018 pounds, with a maximum of 511 pounds of powder, the ordinary charge being 355 pounds. The turrets and guns are moved and worked by a complete system of hydraulic gear, made at Elswick. The loading is also done by the same means, the rammers being below the weather-deck, and arranged to enter the gun when the muzzles are depressed for the purpose. Between the turrets is situated the mast, which really assumes the function of a look-out tower, as there are no sails.

"The 'Dandolo' carries four large steam launches and eight other boats, all hung upon hinged davits which are worked from the steam capstan, and which will hoist them right on board. The 'Dandolo' is propelled by twin screws worked by two independent pairs of engines, which were contracted for to indicate a maximum power of 7,500 horses. These engines, together with the pumping and blowing engines, were constructed by Messrs. Maudslay Sons & Field, of London. Each set of engines is placed in a separate water-tight compartment, one at each side of the vessel; instead of being side by side, they are situated one in advance of the other, the alternate spaces being occupied by the magazines, which are placed immediately below the turrets. Each pair of engines has one high-pressure cylinder, 64″ in diameter, and one low-pressure, 120″ in diameter, with a stroke of 4′. Steam of 65 pounds pressure is supplied by 8 large oval and double-ended boilers, having 32 furnaces in all. Four boilers are placed forward of the engines, and the other 4 aft; but each pair of boilers is contained in a separate water-tight compartment. The chimneys, which are ample in size and height, are built of 1″ plate from the main deck to the flying deck above the turrets, so as to enable them to withstand the great shock produced by the discharge of the guns.

"The 'Dandolo' ran to Genoa and back without stopping, in 6 hours and 28 minutes, with a mean indicated horse-power of nearly 7,200, and a maximum of 7,415 horses, and the speed obtained was 15¼ knots, with a consumption of 51¼ tons of coal. On the measured knot trial a speed of 15.55 knots was obtained with 8,050 horse-power. No steam blast was used on any of the trials. The engines worked with perfect regularity throughout, giving a maximum number of revolutions of 74 per minute, the pitch of the screw being 23′ 6″." — *London "Times."*

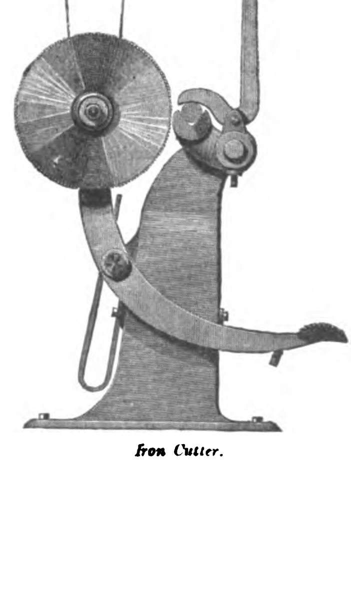
I'ron Cut'ter. 1. A machine for cutting iron in bar or sheet. See SHEARS, Figs. 4929-4934, pp. 2136, 2137, "*Mech. Dict.*"

2. A circular saw for cutting hot iron.

A number of the supporting brackets are fitted on a rod, 3′ to 4′ long, so arranged as to be set up in the position shown, or dropped down out of the way, as the length of the iron being cut may require. Adjustable gages for determining the length of the pieces cut are provided on the opposite side of the machine from the one shown in the engra-

Fig. 1463.



Iron Cutter.

ving. The belt coming down from a shaft above becomes slightly tightened as the saw is pressed forward to the iron, and loosened again when the saw returns to the position shown. The purpose of this arrangement is to avoid unnecessary strain upon the saw spindle when the machine is not in use, and to permit it to run continuously, a matter of convenience when a number of workmen use the same machine, as it saves stopping and starting each time a piece is to be cut. — *Richards.*

See also IRON SAW.

I'ron-ing Ma-chine'. **A machine for pressing clothes, fabrics, or hats, to smooth and polish the surface.**

Sanson's machine, Fig. 1464, is a pressing machine for tailors' use. By means of the swivel frame moving on friction roller, the iron can be moved in any direction. The lifting and depressing is parallel and evenly distributed over the surface of the board. The pressure is by treadle which is counterbalanced, and is adjustable up to 1,000 pounds. The machine has wide and narrow pressing boards, for optional use. The iron is moved by hand, and heated by gas from a flexible tube.

Fig. 1464.

Sanson's Pressing Machine.

Thurston's polishing machine for a laundry obtains the pressure by a spiral spring communicating with the iron by means of universal joints and levers. The table is stationary, and the pressure of the iron can be regulated by a lever to suit the work.

Walker's machine for tailors' use has an iron swiveled at the end of a double-jointed arm, free to turn about a vertical shaft, and raised or lowered by a spring and foot-lever. The iron is moved by hand and has an inserted iron heater.

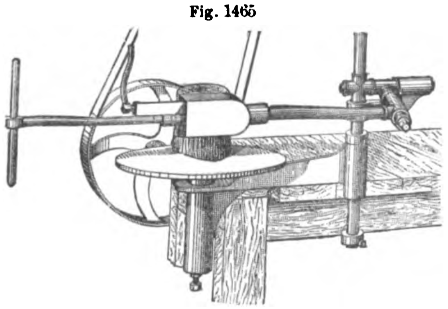
In the *Storrs* presser, the goose may be turned in any direction at the end of an arm, connected by a pivoted link with the upper end of a ⊃-shaped arm supported on a horizontal bearing. The pressure is by a foot-lever; the iron is heated by an inserted hot plate and is moved by hand.

In *Leopold's* ironing and polishing machine the article is laid upon a horizontally reciprocating and automatically reversible board. The iron is heated by steam, and has a short, rapid reciprocating movement by means of a short vertical shaft, rotated from a horizontal shaft held in an arm adapted to be vibrated horizontally. The iron support has a ball-joint and a handle which is grasped by the operator, and is moved over the material on the bed while being reciprocated mechanically.

Tyler's machine has a small polishing iron with a concavity in its upper surface, and is pressed down on the material by means of an adjustable spring on a hinged arm, pivoted at the outer end of a swinging frame. The table is adjustable.

Fig. 1465 is *Osterheld & Eickemeyer's* machine for ironing the sides, crowns, and tips of wool hats. An iron frame is secured on the edge of the finishing-bench; on it is a revolving table which supports the block on which the hat is drawn. The iron is heated by a Bunsen gas-burner fed by a flexible tube, and the lever which connects the iron with the joint is a wrought-iron pipe, and serves as a leader to the upright pipe and forms a chimney which produces sufficient draft to carry off all the gases and prevent the formation of soot and the soiling of the hats.

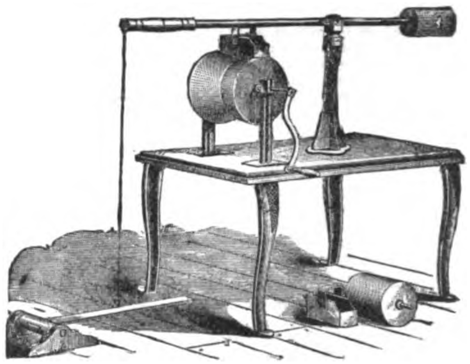
Fig. 1465



Hat-ironing Machine.

Fig. 1466 is a block ironing machine. The iron is of a shape to suit the object which is blocked, and the object is rotated beneath the counterbalanced lever which carries the iron. The pressure is by means of a treadle.

Fig. 1466.



Block Ironing Machine.

I'ron-ing Stove. A stove specially adapted for heating smoothing irons.

Fig. 1467 is a French *fourneau à repasser*, a cast-iron stove, adapted for 7 irons.

Fig. 1467.

French Ironing Stove.

I'ron-ing Ta'ble. A table specially adapted for use in ironing clothes.

Gilbert's table is capable of being folded, and when extended, affords a long board for use in ironing dresses, shirts, and trousers, which may be conveniently slipped on to it. (See Fig. 1468.)

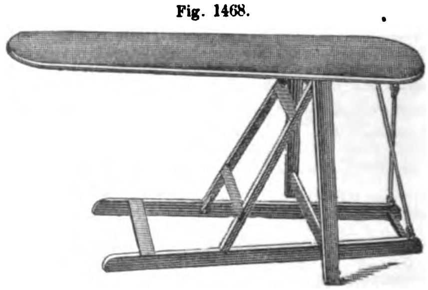
Fig. 1469 shows a French steam-heated table for pressing pantaloons or coats. It is a hollow iron arm projecting from the wall, and having the necessary pipe connections for steam and condensed water respectively. See also LAUNDRY.

Hogin . * "*Sc. Amer.*," xl. 194.

I'ron Pla'ting.

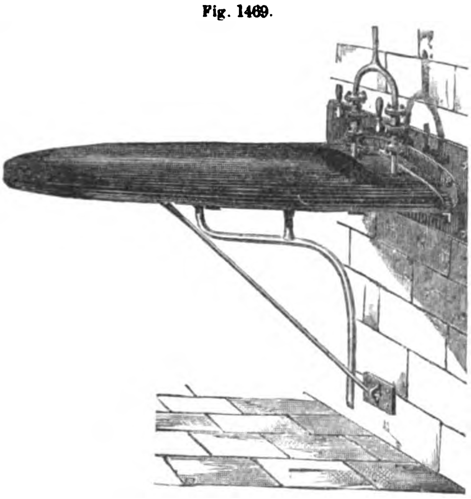
For coating copper plates with iron: Ten parts of ferrocyanide of potassium and 20 parts of tartrate of soda are dissolved in 220 parts of distilled water, adding a solution of three parts of sulphate of iron in 50 parts of water. Caustic soda solu-

Fig. 1468.



Ironing Table.

Fig. 1469.



French Steam Table for Pressing Coats and Trowsers.

tion is poured into the mixture until the Prussian blue formed is redissolved. — *Prof. Bottger.*

I'ron Pre-serv'ing Pro'cess. Barff's process consists in subjecting the surface of the iron to the action of super-heated steam at a high temperature. The result is the production upon the surface of the iron of a hard, smooth, and durable skin of black oxide of iron, which prevents rust, and is claimed to be more effective than any paint, lacquer, rubber, or other compound or process heretofore known.

Iron articles to be treated by this new process are first cleaned with dilute sulphuric acid, and afterward with bran water. They are then placed within a muffle, the temperature of which is 500° or 600° Fah.; dry superheated steam at a temperature of 1,000° Fah. is admitted, atmospheric air being carefully excluded. The formation of the black oxide skin rapidly takes place.

I'ron Pro'cess. Siemens' direct process briefly stated —

" Consists in smelting successive charges of ore in a rotary puddling furnace. A charge of about 20 cwt. of crushed ore mixed with the proper fluxing material is placed in the rotating puddler. When, by the flame from a regenerative furnace, it has been brought to a red heat, from 500 to 600 pounds of small coal is added and the speed of the puddler is increased. The reduction of the ore to the metallic state proceeds rapidly, the carbonic oxide evolved is burned within the chamber, and very little gas from the gas-producers is required. When the reduction is complete the puddler is stopped, and the fluid slag is drawn off. The puddler is then rotated rapidly; the iron is collected into two or three metallic balls, which are withdrawn and treated in the usual way. About two hours are required for a charge, and assuming that 1,000 pounds of iron are got out to each charge, the furnace would produce about 5 tons of puddled bar per diem. It is claimed to be feasible to push the operation so far within the rotator as to produce cast-steel. Mr. Siemens claims and undertakes to demonstrate that by this process a very great saving of fuel is effected. For the lining of the rotary puddler, after numerous trials, he has found a mixture of calcined bauxite powder with clay and graphite to be the best. Three per cent. of clay and six per cent. of graphite give the best results as binding materials. Bauxite is a ferruginous clay, containing from one to four per cent. of silica. The graphite, under the intense heat, reduces the oxide of iron in the bauxite to the metallic state. Linings so made have been found to be very durable, far more so than the best fire-brick." — *Blake.*

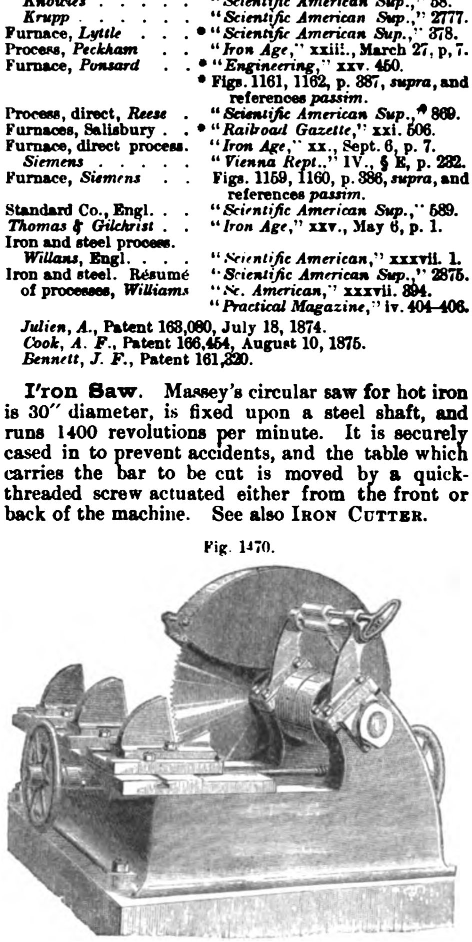
Bennett, J. F., Patent 161,320.

I'ron Saw. Massey's circular saw for hot iron is 30″ diameter, is fixed upon a steel shaft, and runs 1400 revolutions per minute. It is securely cased in to prevent accidents, and the table which carries the bar to be cut is moved by a quick-threaded screw actuated either from the front or back of the machine. See also IRON CUTTER.

Fig. 1470.



Circular Saw for Hot Iron.

I'ron Scale. A special heavy weighing scales with a bed of iron bars, used in weighing merchant iron, pig or castings.

I'ron Shears. Cutters, either hand or machine, for iron. See SHEARS, Figs. 4929-4934, pp. 2136, 2137, "*Mech. Dict.*"

See also IRON CUTTER; IRON SAW, *supra*.
Brown & Curtiss . * "*Iron Age*," xix., June 21, p. 1.

I'ron Steel. Metal composed partly of steel and partly of iron. In the process of manufacture a thin sheet of iron is introduced between the surfaces to be united.

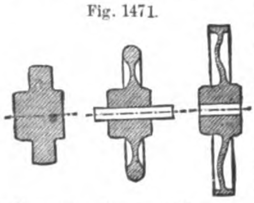
A mold for casting is divided into two compartments by a transverse metal plate, and the two metals previously refined are poured each into its compartment. The iron plate serves at the same time to prevent their mixing and to facilitate their union by becoming partly fused. — *Asbeck, Osthaus & Eicken*, Hagen, Westphalia.

I'ron Strapped Block. (*Nautical.*) One having a loop or band of iron, as contradistinguished from the rope band or strap, formerly exclusively and yet much employed.

I'ron-stone China. (*Ceramics.*) A variety of stone-ware.

I'ron Wheel. Iron wheels are customary with railway and street cars, some kinds of agricultural implements, parts of machines, etc. They are usually cast, composite wrought and cast, and more seldom all of wrought iron.

Fig. 1471.



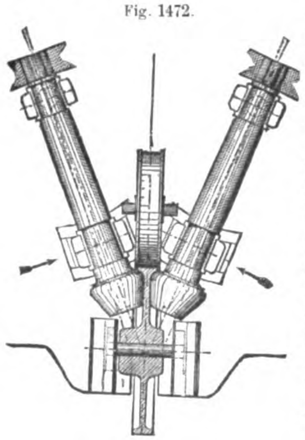
Successive Stages of Wrought Wheel.

A plan for rolling wrought-iron wheels in a single piece has been invented in Belgium.

The iron first receives the shape shown at the left hand, in Fig. 1471. Secondly that of the wheel to the right of it. Up to this point it may be an ordinary compression forging. A hole is then bored and a rod fitted in.

The right hand one of the three exhibits a section of the finished wheel. The machine by which the last transformation is made, is shown in Fig. 1472.

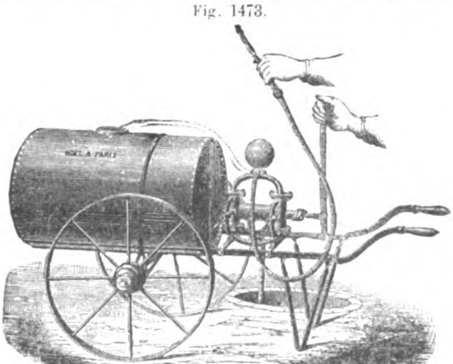
Fig. 1472.



Wheel-making Rolls.

It consists of two conical rolls, each mounted on a separate shaft, which is rotated by means of conical gearing, and which is placed in such bearings that the conical rolls at their extremity can be approached by moving them, as indicated by the arrows. The wheel to be finished rests with its axle in two bearings, and it is then exposed to the action of the conical rolls, which compress the material so that its diameter increases. In order to make allowance for this, the position of the bearings of the wheel are adjustable. The circumference of the wheel is worked by a cylindrical roll. The figure shows the rolling mill as required for finishing the shape of a wheel having the section exhibited. If another shape be required, the surface of the roll is turned accordingly. — *E. von Tarlo in "Annalen für Gewerbe und Bauwesen."*

Fig. 1473.



French Irrigation Barrel.

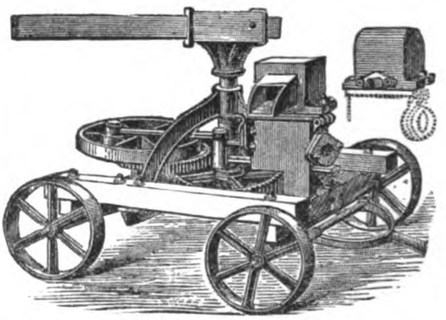
Ir'ri-ga'tion Bar'rel. A cask mounted on wheels and having an attached hand-pump for watering a garden or conservatory plants.

Fig. 1473 shows a French form in which the tonneau is in sheet iron and the pump is adapted to fill the vessel from a well or cistern and to discharge the contents of the vessel, as the case may require.

Ir'ri-ga'tion Pump. A pump for raising water for irrigation of growing crops.

Several forms are shown under various titles, such as the *Noria*, *Mental*, *Shadoof* of Oriental countries. See "*Mech. Dict.*" under these titles and references *passim*. See also list on p. 1827, *Ibid.*, and numerous examples on pp. 1825–1832, *ibid.*

Fig. 1474.



Cattle-power Pump for India.

A mounted cattle-power, a modern form of the Noria (see Fig. 3334, p. 1533, "*Mech. Dict.*") is shown in Fig. 1474, as made for the irrigation works in India.

See Irrigation in Ceylon.

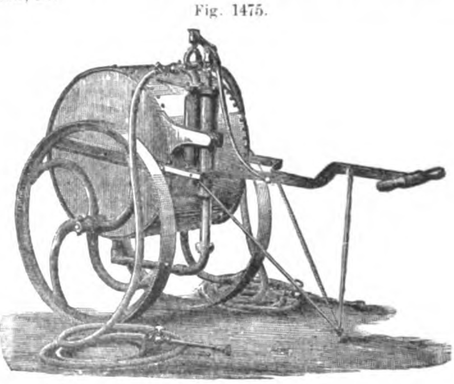
Irrigator, *Taylor* . . .	* "*Scientific American*," xxxv. 338.

Ir'ri-ga'tor. 1. (*Surgical.*) A douche. A means of applying a profuse washing to a part; rectum, vagina, uterus, etc. See Syringe, Injector, Douche, etc.

2. A watering-cart for growing crops.

In the form shown in Fig. 1475 it is a barrel mounted on wheels, and having a pump which acts as a suction-pump for supply, and a force-pump for discharge. — *Coleman & Morton*, Br.

Fig. 1475.



Irrigator.

I'sin-glass. Fish glue. *Colle de poisson.* See ICHTHYOCOLLA.

An interesting Japanese product is the *Kanten*, or vegetable isinglass, prepared from the *Gelidium corneum*. The seaweed called *Tengusa* is carefully washed and afterward boiled, so as to form a gluish decoction, which is strained off and put into square boxes. When cooled, it forms a stiff jelly, which can easily be divided into squares of a foot in dimension. The manner in which the surplus water is removed is ingenious and worthy of notice. The jelly prisms are exposed in the open air during a cold night, and allowed to freeze. During the day the sun melts the water, which runs off, leaving behind what one might term the skeleton of a white horny substance, which is extremely light, and easily dissolved in hot water; when cooled, it again forms a stiff jelly. This article, which is already to a certain extent known in Europe, can be applied to many uses, viz., for cooking purposes, for making bonbons and jellies, for clarifying liquids, as a substitute for animal isinglass, for making molds used by the plaster-of-paris workers, for hardening the same material; in short, as a substitute for all kinds of gelatines, over which it has the advantage of producing a firmer jelly. In Europe it is sold under the name of *Agar-agar*.

Another sea-weed, much used for industrial purposes, is the Fu, resembling the Caragheen moss, and applied to similar uses, such as, for instance, the sizing of the warp of silk goods. See also HAITHAO.

Is'tle Ma-chine'. A machine for preparing fiber from the leaves of the *lechugilla*, a Mexican *agave*. This fiber is used in the manufacture of hammocks, sacks, ropes, nets, cotton bagging, wagon-sheets, carpets, etc.

The machine (Welke's patent, No. 171,708) is a substitute for the slow and primitive process of hand-scraping.

The invention consists of devices by which the leaves are drawn by rollers through scraping-knives, which are made to yield to the thickness of the leaves. The leaves are placed between the scrapers up to a gage-piece, and then carried with the scrapers toward the feeding-rollers. Sliding and reciprocating scraper-jaws are operated by transmitting mechanism, by the forward motion of the scraper-frame, for scraping off the ends of the leaves which are conveyed to a receiving-platform, and dropped by the same to a receptacle below.

The word *istle* is Mexican, Spanish *pita*, the *Agave Americana*. Admirable specimens of the fiber were shown at the Centennial Exhibition, in Agricultural Hall. The fibers of a species of East India banana yield *Manilla*. The *cochorus capsularius* and *C. olitorius* yield the jute of commerce; the leaves of the *Phormium tenax*, New Zealand flax, yield an excellent fiber; the East Indian *Ramie*, *Bahmeria nivea*, one of the urticaceæ, has a stem, the inner bark of which yields a very useful fiber, used from time immemorial in China, and imported into Europe to mix with silk. *Tampico* is another fiber, the mechanical treatment of which offers the same problem. On the materials above stated, see RAMIE.

I'vo-rine Min'e-rale. A substitute by M. Roger, of Paris, for horn and ivory. It can be made to take various colors, and especially dark hues. By pressing the warm mass into forms, various useful articles, such as umbrella and cane handles, door-knobs, ink and pen-holders, buttons, etc., etc., are produced. — "*D. Industrie Zeitung.*," xix. 387.

I'vo-ry, Ar'ti-fi'cial. Various recipes are given on p. 1207, "*Mech. Dict.*," and a list of 22 patents.

Any white composition of a given mechanical consistence may pass for an artificial ivory, — white celluloid, for instance. See CELLULOID, pp. 180, 181, *supra*, where is given a list of 120 patents of celluloid, pyroxyline, xylodine, and allied compounds, and also a list of references.

See also the following under their alphabetical heads, *supra*. Hints may be taken from them, recollecting that the specialty *ivory* is a mere question of the color of the composition: —

Bonesilate.	Cellulose.	Ebony, artificial.
Bois-durci.	Coral, artificial.	Hemacite.
Boullnikon.	Ebonite.	

The question of color even is not all-important, as the practice is to stain ivory for various purposes, — billiard balls, for instance.

A general statement may be suggestive. Use, combined in suitable proportions, amber, Canada balsam, the Australian gum-kowrie, potato flour or fecula; and with these substances, or any of them, combine meerschaum, paper pulp, calcined bones, fluorate of gypsum or silicium, sulphide or sulphurets of mercury (vermilion), or of other metals, chlorides or carbonates of zinc, or other metals, sulphate of baryta, alkaline preparations, asbestos, fluxed or fritted colors, or finely powdered pumice-stone, sulphur, india-rubber, or similar gums.

See also PYROXYLINE, pp. 1839, 1840, "*Mech. Dict.*," where numerous patents and recipes are listed and described. To these may be added: —

Recipes: Papier-maché and gelatine; for billiard balls, moldings, and architectural decoration: add zinc white or other color. — *Dupré*, Paris. "*La Nature.*"

Ivory dust, 16, boiled in water to a jelly; add shellac, 16, dissolved in alcohol, and oxide of zinc, 1. Pour into forms, dry in the air, subject to high pressure; may be cut, sawed, or turned. — *Cohen*, London.

Calcined magnesia and caoutchouc; heated and pressed.

Cellulose, glue size, and alum water; press into molds; saturate with melted stearine and white wax; polish with a brush. More exactly —

No. 1.	No. 2.	No. 3.
Glue, 100	Alum, 100	Cellulose, 50
Water, 1,000	Water, 1,000	Water, 3,500

Take 75 of No. 1, 200 of No. 2, 200 of No. 3, and add 250 finely ground gypsum, and 100 water. Mix, fill into greased molds. Drain off superfluous water, and allow to solidify. Wash in hot water, dry, soak in equal parts of wax and stearine. Brush to develop luster. — *Harras*, Boehlen, Ger.

Also: Uses of ivory	"*Scientific American Sup.*," 2360.
Vegetable ivory, *Costes*	"*Technologiste*," xli. 823.

I'vo-ry Bleach'ing.

Clean the ivory by boiling it with a paste composed of burned pumice-stone and water. After cleansing place the article under a glass vessel, and expose it to the sun's rays until it assumes its original whiteness. The ivory should be kept moist with water while bleaching.

Mix a thin lime paste and heat over a moderate fire. Place the ivory in this paste, and leave it until it bleaches white, after which remove the paste, dry, and polish.

The ivory articles are placed in a solution containing 11¼ ozs. carbonate of soda in crystals and 45¾ ozs. of water, and allowed to remain in solution for two days. The articles are then removed from the solution, well washed in pure water, and then smeared for five or six days in a solution composed of 17 ozs. of sulphite of soda and 45¼ ozs. of water. At the end of five or six days there should be added to the solution containing the articles an ounce of hydrochloric acid diluted with 5¼ ozs. of water. The vessel containing the liquid should then be covered and left standing for from 24 to 26 hours, after which the ivory may be taken out, washed in clean water, and dried. — *Dr. Artus.*

I'vo-ry Dye'ing.

Black: Steep the article in a weak solution of nitrate of silver, and expose it to the light; or, boil the ivory first in a solution of logwood, and then steep it in a solution of sulphate of iron.

Red: Steep in an infusion of cochineal in liquid ammonia; the articles are first soaked in a water slightly acidulated with nitric or acetic acid.

Blue: Steep in a solution of indigo in sulphuric acid which has been diluted and neutralized with chalk or potash.

Green: Use a solution of verdigris in vinegar.

Yellow: Use a bath of chromate of potash, and afterward a boiling solution of acetate of lead.

Purple: Use a neutral solution of chloride of gold, and then expose to the light.

I'vo-ry Paste. (*Ceramics.*) The material of which ivory porcelain is made. The term *ivory* refers to the peculiar dull luster, made by depolishing the vitreous glaze.

I'vo-ry Por'ce-lain. (*Ceramics.*) A porcelain the vitreous surface of which has been depolished to remove the glaze, leaving the dull luster of ivory.

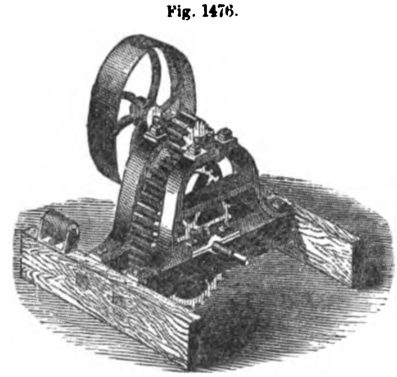
I'vo-ry Sil'ver-ing. Immerse in a weak solution of chloride of silver until of a deep yellow color; then take out and dip in water, after which expose to the sun's rays until black. On rubbing, the black surface will change to a silver.

J.

Jack. (*Add.*) 12. (*Leather.*) A machine to which may be fitted a steel, glass, or *lignum vitæ* slicker, a scouring-stone, or pebbling roller, according as the leather is to be slicked, smoothed, polished, stoned, or pebbled.

13. An intermediate motion, between a horse-

Fig. 1476.



Jack.

power and the machine to be driven. It converts the relatively slow motion of the tumbling-rod of the horse-power into a rapid pulley-motion, the latter communicating by belt to the thrasher, straw-cutter, mill, or what not.

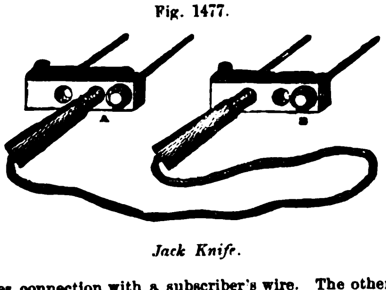
See also INTERMEDIATE MOTION.

Jack'et-ed Gun. (*Ordnance.*) One strengthened by bands fitted or shrunk on to the tube proper. It is now a common mode of making ordnance; a good instance may be seen in the *Broadwell* gun, * "*Engineering*," xxi. 16. Also the Armstrong gun, Fig. 527, p. 160, *supra*.

Jack'-knife. (*Electricity.*) A form of commutator used in telephone central stations. It is a square piece of brass fixed to an upright board by means of two bolts.

The cut shows two of such commutators. The left-hand bolt in each fastens the brass block, and at the same time

Fig. 1477.



Jack Knife.

makes connection with a subscriber's wire. The other bolt is in connection with the indicator wire, but is insulated from the jack-knife, and has a small, erect pin, likewise insulated, upon which the flat spring rests. The jack-knife is then at rest; the line in communication with the indicator, the other end of the latter being in the earth.

When the subscriber sends a current, the indicator notifies the central. The jack-knife has two holes, and the operator puts a pin in hole No. 2 at *A*, connecting by a wire with the telephone.

The pin raises a peg on the spring, and, consequently, breaks the contact between the mass of the jack-knife and the indicator. The simple introduction of the pin does two things: it detaches the indicator from the line, and attaches it to the telephone. The employee then receives his instructions from the subscriber. To connect the two jack-knives of the subscribers, right and left, a flexible metallic cord terminating in two pins is used. These pins are inserted in holes 1 and 2, as seen in Fig. 1477. If one of the indicators is wanted to be in derivation, the corresponding pin is inserted in hole to the left, the spring is not raised, and the mass of the jack-knife, which forms part of the line of correspondence, is connected with the indicator and the earth.

Jack Lamp. (*Sporting.*) One for still-hunting, *weequashing* or fire-fishing, and general camp use. It is sometimes carried on the hat or helmet, but is preferably supported by standard from the belt, so as to give freedom of motion to the head in peering and sighting. It burns kerosene without a chimney.

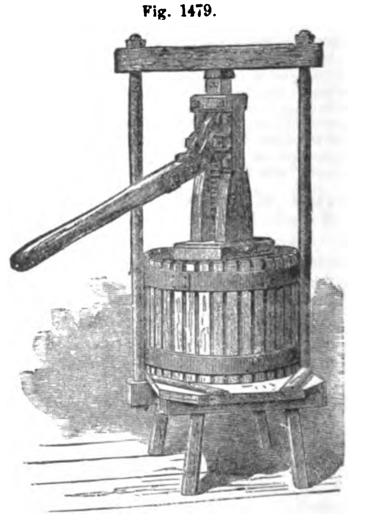
Fig. 1478.

Jack Lamp.

Jack Press. One in which a common lifting-jack arrangement is the means of applying the force. Fig. 1479 shows the ordinary lever-jack thus adapted to a wine, cider, or lard press.

Jack Screw. (*Add.*) 2. (*Dentistry.*) A small extensible instrument used in regulating the teeth;

Fig. 1479.



Jack Press.

to erect them or twist them into symmetrical order. (See Fig. 1480.)

Lifting-jack, telescopic, *Ball* . . . * "*Sc. Amer.*," xlii. 213.

Jac-quard'. See following notices:—

Barker's punching machine for Jacquard cards, noticed in "*Chambers' Journal*," "*Scientific American*," xxxiv. 183.

Double-shedding harness.

Ainley, Eng. . . . * "*Scientific American*," xxxvii. 258.

Jag'ger Spring. (*Vehicle.*) A spring beneath a seat and resting by its ends upon blocks or cleats, in the bed or body of the vehicle.

Fig. 1480.

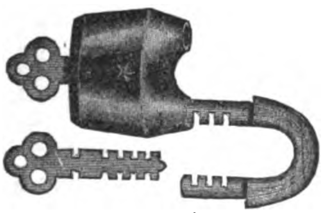
Dental Jack Screws.

Jail Lock. A form of lock used in securing shackles or hasps to staples. Sometimes called a Scandinavian lock, or Scandinavian padlock.

It is unlocked by a flat key, which loosens both branches of the shackle, so that they pull out, or, as in the case shown in Fig. 1481, one becomes free, and then the shackle rotates on the one which remains connected.

Page . . . . . * "*Iron Age*," xxi., January 8, p. 1.

Fig. 1481.



Jail Lock.

Jan'ney Coup'ler. (*Railway.*) A draw-bar arranged to couple cars automatically, and invented by Janney. See CAR COUPLER.

Ja'nus-faced Lock. One having duplicate faces, so as to go upon a right or a left hand door, the key entering at either side indifferently.

Ja-pan'. A kind of varnish, differing in its constituents according to the purpose required of the article treated with it, or of the nature of the process by which the article is manufactured. See LACQUER.

Baking Japans . . "*Iron Age*," xix., March 29, p. 15.

Jap'an-ese Bron'zes. These works of art are made by a process akin to those described on pp. 500 and 1462, "*Mech. Dict.*"

The models are made in wax; and in that material everything, down to the smallest feather of a bird's wing or the hair of a spider, is elaborated with scrupulous care. The wax model is then painted all over with a coating of extremely fine sand, held together by a fire-proof mucilage. The first coat is laid on with extreme care, so as to fill every tiny interstice. So with all following coats, which may number hundreds, until sometimes six months are consumed in the work of painting a cumulative mold three or four inches thick. When the latter is rendered sufficiently strong, the wax model inside is melted and removed. The bronze is then poured in, and the whole object completed in a single casting. The mold is subsequently removed with care only second to that employed in its construction, leaving the bronze without a crease or flaw. From this process emerged the magnificent incense bearer which stood at the entrance of the Japanese section at the Centennial Exhibition, 1876. It represents a vessel elevated upon worn sea rocks, inhabited by a dragon and surmounted by an eagle and flanked by flocks of birds. The price was $4,500, and it was purchased for the London South Kensington Museum.

"Statues of all sizes, bells, vases, water-basins, candlesticks, incense-burners, lanterns, etc., have been manufactured in large quantities for temples and their approaches. Portrait-statues, like the monuments erected in foreign countries to honor the memory of celebrated men, have never been made in Japan As articles for household uses, we may mention fire-pots, water-pots, flower-vases, and basins in which miniature gardens are made, perfume-burners, pencil-cases, small water-pots of fanciful shapes for writing-boxes, paper-weights, and small figures representing divinities. These bronze castings are either made in the simple and severe style of the old celebrated Chinese bronzes, or else are specimens of the peculiar character of Japanese art, which chooses its subjects from natural life, either combining them with lively scenes showing a great deal of humor together with the most minute copying of nature, or else using them to produce some artistical effect, sometimes in a somewhat capricious way, quite unexpected to the beholder. Occasionally the artist takes his subjects from Chinese and Japanese mythology, and produces all sorts of legendary animals, such as the dragon, the stork, the tortoise, etc., which are largely represented on the candlesticks and other castings used in temples, or in the domestic chapels. The bronze utensils of these latter are generally composed of 5 pieces — 2 flower-vases, 2 candlesticks, and one incense-burner." [From a Japanese author.]

Bronze castings of less elaborate design are made in the usual manner, the art being well understood in Japan where it is very ancient.

The plan adopted is similar to that now used in Europe, and described on p. 2312, "*Mech. Dict.*"

The bronze is cast in clay molds formed upon models made of a mixture of wax and resin, which is melted out from the finished mold previous to pouring the metal in. The artist who makes the model generally does the casting himself, and in most cases the work-people consist only of the master's family and two or three assistants. The melting furnaces are of exceedingly small dimensions, and generally made of an iron kettle lined with clay. After casting, the pattern is carefully corrected and worked out by chiseling, but the best bronze casters prepare the model, the mold, and the alloy in such a way as to produce a casting which needs no farther correcting or finishing.

The distinction between bronze (Jap. *Karakane* = Chinese-metal) and brass (*shin-chu*) is well understood in Japan. The spelter used in the latter is imported.

The coloring of the bronze is either for the sake of variety to suit certain tastes, or to confer the appearance of age. See BRONZE COLORING; PATINA.

Differences of opinion exist as to the nationality of the great bronze statue, the "*Daibutz*" (Buddha in Nirvana), now standing at Kamakura, Japan, and shown at Fig. 5578, p. 2312, "*Mech. Dict.*" The statue is 50' high and is there stated to have been cast at Tolon Noor, in Thibet, probably as much as 600 years since. The statement has high authority, and the very name of bronze in Japanese is a word equivalent to *Chinese metal*, as above stated. It is, however, but fair to state that other authorities mention the casting of a large bronze statue of Buddha in the position of serene contemplation, by the order of the Japanese emperor Shomu (724–749, A. D.). It was erected, the account runs, at Nara, 743–752 Damaged by earthquake and fire it was recast about 1300, and yet exists at Nara. A second, of a later date, at Kiyoto, was destroyed by fire.

See also BELL; BRONZE INLAYING.

Jas'per Ware. (*Ceramics.*) A form of ware invented by Wedgwood, in 1773. This paste he used in ornamental and cameo work, reliefs, etc., and the name was adopted after a series of improvements which left it proximately perfect.

It was imitated and copied throughout Europe Flaxman made designs for it, and antique works of all suitable kinds were borrowed to form molds.

Jaw Bit. (*Railway.*) A bar extending across the jaws of a pedestal underneath the axle-box.

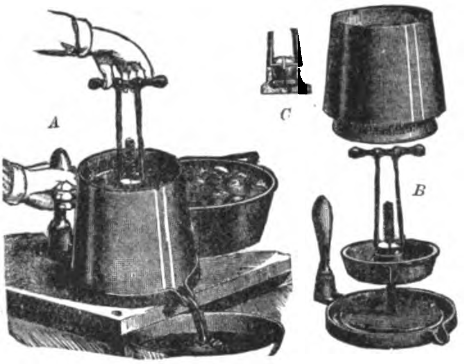
Jaw Chuck. One with movable studs on a face-plate adapted to approach and grasp the object, as in the screw and universal lathe chucks. Fig. 2833, p. 1263, "*Mech. Dict.*"

Jel'ly Pow'der. So called from its resemblance to calf's-foot jelly. It consists of 94% or 95% of nitro-glycerine and 5% or 6% collodion cotton, so mixed as to assume a gelatinous form. It is tough, but can be easily cut with knives or shears, and applied to cartridges and balls. It is water-proof, acts in the same way as dynamite, but is at least 50% stronger, and does not possess the great defect of the latter in parting with its nitro-glycerine when damp. — *Nobel.*

Jel'ly Press. A domestic hand-press for expressing juice from fruit, etc.

It consists of a guttered base upon which is an inner perforated cylinder into which the pulp is to be introduced, and an outer plain cylinder which serves to prevent any waste of the liquid pressed out. The plunger, which is shown at *B*, slides over the screw. The lower end of the screw handle, as will be seen at *C*, is split so that the han-

Fig. 1482.



Jelly Press.

dle can be pressed downward over the screw very rapidly, until the conical cap of the plunger bears so strongly upon the lower ends that they firmly clasp the screw. The greater part of the compression is thus quickly done. A few turns of the handle after it has been pressed down as far as possible, will complete the work. See also Fig. 872, p. 274, *supra*.

Jerk Net. (*Fishing.*) A folding net closed by a jerk upon a line.

Jerk Snare. A species of snare which is sprung by a line held by a party in ambush.

Jet. A solid black, glossy lignite, found principally near Whitby, in England. Also found in Spain. It is sawn, carved, bored, etc., and polished on wheels. Some cannel coal nearly approaches it. A dull kind is called *dazed jet*, as it will bear no polish.

"*Scientific American*" . . . . xlii. 23.
*"*Scientific American Supplement* . . . . 1571.

Jet Pho-tom'e-ter. An instrument for measuring the light of a burning gas-jet.

There are two modes of working:—

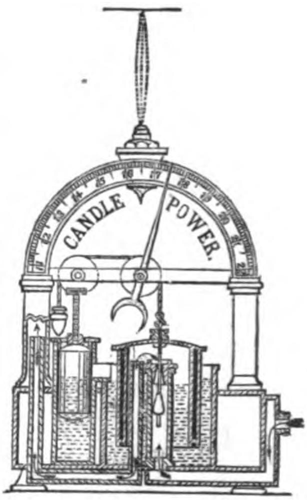
In one, the jet is regulated so as to reach a certain height, and the candle-power is shown by an index hand upon a graduated arc.

In another, it reads by an inverse method: the pressure being set at a regulated point, the height of the jet is measured as a determination of the candle-power.

The idea of ascertaining the candle-power of coal-gas by the height of the flame, while burning through a circular orifice under varying pressure originated with Mr. Lowe of London. The apparatus shown in Fig. 1488 is the American Meter Co.'s improved Lowe apparatus.

Gas is brought into and consumed from a small holder made so as to commence to rise from the water at .41 of an inch pressure, and cease at .71. The gas acting directly under the top of holder, which is of large area, causes it to rise through a space of nearly two inches by the increase of pressure from .41 to .71 of an inch, or in reality a rise of about .6 for every .1 pressure.

Fig. 1488.



Jet Photometer.

The holder, in rising, carries the pointer over the range of scale from 22 to 11, and as the gas burned at jet is taken directly from under the holder it is evident that any diminution or increase of pressure will give immediate motion to the holder and pointer, showing the exact candle power of the gas under such changes of pressure.

The height of flame is adjusted by the micrometer cock to exactly 7″.

With a flame 7″ high, ordinary coal gas, burnt at .41″ pressure, is equal to 22 candles, and at .71″ pressure, equal to 11 candles.

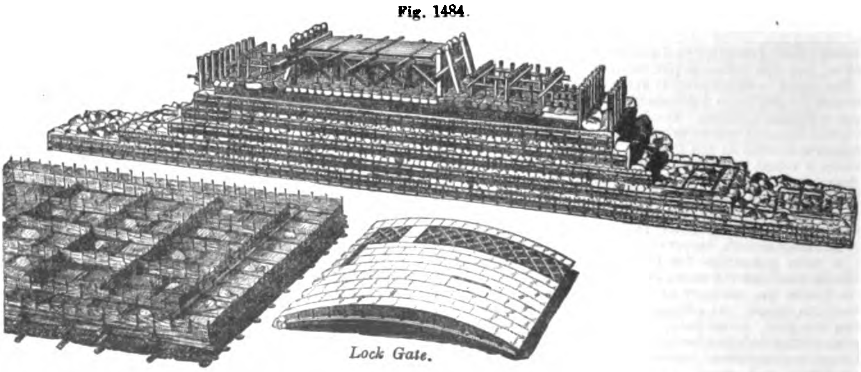
Jet'ty. Plans and sections of the jetties, rubble on mattresses, Charleston harbor improvements, are shown in the "*Report of the Chief of Engineers, U. S. Army,*" 1879, * i. 734.

Fig. 1484 shows details of the jetties of the North Sea entrance to the Rotterdam sea canal.

The principal feature is the use of the fascine mattress, common in dams and dikes on inland waters, but not before attempted in the open sea. The mattresses are made on the seashore at low water, so as to be floated off by the tide. They are made of willows and osiers, bound into fascines 10′ to 12′ long, the twigs remaining attached, making a bundle 17″ in circumference at one end and 14″ at the other. These are overlapped and tied together into long ropes called *wiepen*. To build a mattress the *wiepen* are laid parallel 3′ apart, crossed by others at the same intervals, and tied at the intersections with withes except at certain points where tarred ropes are used, to serve subsequently in binding other layers of *wiepen* to the foundation course and so on up. On this foundation bundles of twigs are laid, and then a second layer crosswise. This is followed by two layers of *wiepen* at right angles, like the former, and tied to the preceding by the tarred ropes. Stakes are driven in and baskets woven on the stakes to hold the ballast, and other stakes to form bollards for towing and mooring. The mattress is towed to the spot, anchored, and then sunk by simultaneously loading its whole surface with stone from small vessels all around it. 350 to 700 lbs. of stone to the square yard is the ballast for the mattress. Other mattresses are added until the required height is reached.

The head of the southern jetty is 82.5′ wide and 3.3′ height

Fig. 1484.



Jetty at North Sea Entrance Rotterdam Sea Canal, Netherlands.

above mean low water mark. 10′ above that level is a timber platform supported on piles. The platform is 25′ wide, and carries a railway track. The sides of the jetty are stone-faced.

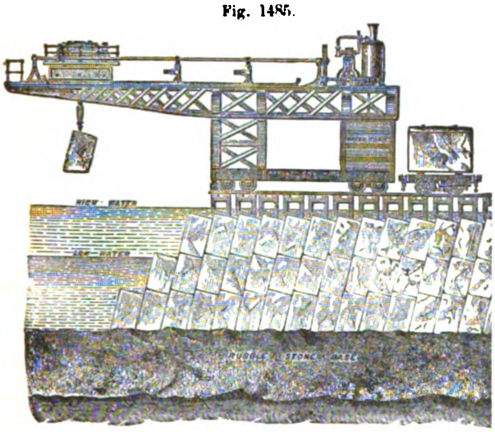
See also **Apron**, Fig. 103, p 44, *supra*.

Jet′ty Crane. A form of crane for building jetties of blocks.

That shown in Fig. 1485 is thus described by the engineers: —

"The object of the crane, appropriately called a *Titan*, is to lift blocks of from 20 to 30 tons' weight from the trucks

Fig. 1485.



The "Titan," Jetty Crane.

and place them in position *in advance* of the finished work, and thus to dispense entirely with the use of staging: it was first used for this purpose in the Manora Breakwater. The Titan, illustrated in Fig. 1485, fulfills all the conditions indicated when tenders were invited for the work.

"These conditions were, that the blocks, each weighing 27 tons, should be lifted, traversed out, and placed in position 25 feet in advance of the point of support afforded by the finished work. The main framing is made throughout of wrought iron, and travels on a pair of rails, 22′ gage, which were carried on blocking pieces up to the front face of the work, as shown in the engraving; the height from rail level to the upper side of the projecting girders is 20′. The lower members are of box-girder section, and are fitted on each side with two pairs of wheels placed close together, fore and aft, traveling on the rails above named, and the front group can be relieved of the strain due to the weight of the block, by powerful short-stroke hydraulic jacks placed under the front end of each girder.

The engines are two 7″ cylinders with link-reversing motion; the boiler is of the vertical type, and the several motions for lifting and traversing the load, and for moving the Titan, are transmitted by suitable shafts and gear with the necessary clutches and levers. The engine and boiler are mounted on a platform laid on the transverse girders, tying the two frames together; a pair of wrought-iron tanks, capable of holding 30 to 40 tons of water ballast are fixed over the trailing wheels, and form part of the framing. The cost of the *Titan* is £2,500, the weight 85 tons, and the duty, 6 blocks laid per day, allowing for the time required for the divers to place the blocks under water.

"The cost of the 10 trucks, which were required for bringing the blocks from the drying ground, was £180 each, and the weight 7 tons each.

"A convenient form of *Goliath* for lifting the blocks, after they are dried and are required for use, is one with a direct-acting hydraulic cylinder and ram of the stroke required to lift the block on the trucks, the ram and cylinder being mounted on a traveling jenny with an engine and boiler of sufficient power to give the traveling motions and to work the hydraulic pumps. The cost of this for 50′ span is £1,150, and the weight 30 tons.

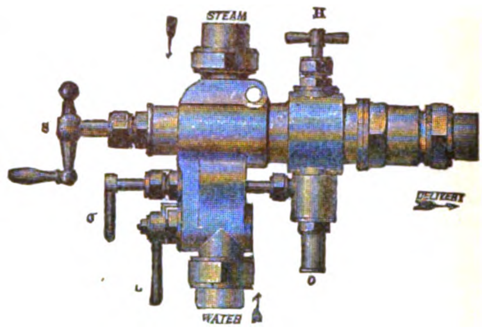
"Since the work above referred to was designed, it has been found necessary to use blocks weighing 40 tons, and the *Titan* for laying them has a swinging jib of about 50′ radius, carried on a frame somewhat similar to that already described; the jib is provided with swinging gear, and describes an arc of about 190°, and will lay stones across a face nearly 100′ wide." — *Appleby*.

Jet Valve. A valve in the lifting injector which is used in starting the injector.

In Fig. 1486, *J* is the jet valve; *S*, steam-valve; *L*, lazy cock; *H*, heater cock. To start, open jet *J*: when water appears at overflow *O*, open valve *S* and close *J*. To stop: close valve *S*.

To heat water in tender: close *S* and open *H*.

Fig. 1486.



"*Monitor*" *Lifting Injector.*

Jew′el-er′s Ce-ment′.

Turkish: Dissolve five or six bits of gum-mastic, each the size of a large pea, in as much spirits of wine as will suffice to render it liquid. In another vessel dissolve in brandy as much isinglass, previously softened in water, as will make a two-ounce vial of strong glue, adding two small bits of gum ammoniac, which must be rubbed until dissolved. Then mix the whole with heat. Keep in a vial closely stopped. When it is to be used, set the vial in boiling water. Known to the trade as *diamond* cement.

Jew′el-er′s Forge. A small forge with pedal blast and circular table; with charcoal grate or gas pot, according to circumstances. See references under Forge, p. 354, *supra*.

Jew′el-ing Rest. (*Watchmaking.*) A tool for setting jewels in plates or settings. It calipers each jewel separately, and turns a recess to fit.

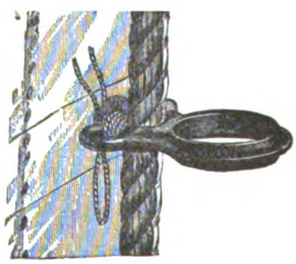
See Watchmaker's Lathe, where it is shown in connection with a universal head. See Jewel-setter, "*Mech. Dict.*"

Jib Crane. A crane with a projecting arm; as in Fig. 1408, p. 478, *supra*. See also Figs. 1504–1507, pp. 642, 643, "*Mech. Dict.*," and Fig. 1489, next page.

A convenient form for foundry use, has a mast of cast-iron and a jib of wrought plate iron in two pieces. A device retracts the jib when required, as when columns, belts, or other obstacles are in the way.

Pratt & Whitney.
* "*Iron Age*," xxiv., Sept. 11, p. 1.

Fig. 1487.

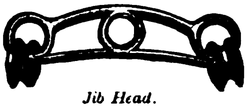


Jib Hank.

Jib Hank. (*Nautical.*) A ring on the leech of a jib and which slips on the stay.

Jib Head. An iron used at the head of a jib when the latter has been stretched too much. The jib is shortened at the head and the jib head attached to the sail; clew thimbles are at the ends.

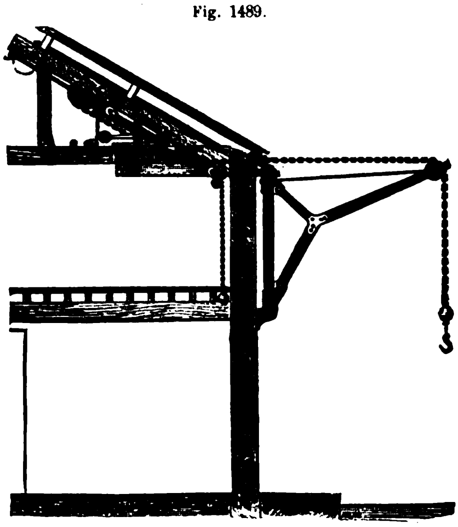
Fig. 1488.



Jib Head.

Jig'ger. (*Add.*) 7. A simple form of warehouse crane. The power is a hydraulic ram fixed

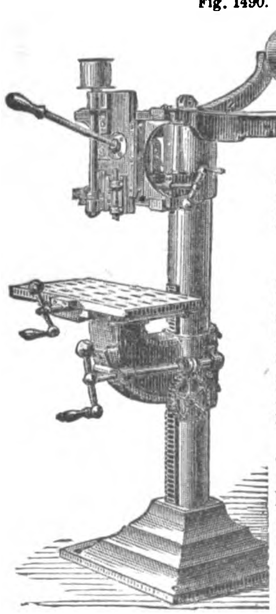
Fig. 1489.



Jigger.

to the timbers of the roof. A supplementary power is used to turn the jib when the load has been lifted the required height.

Fig. 1490.



Jigging Machine.

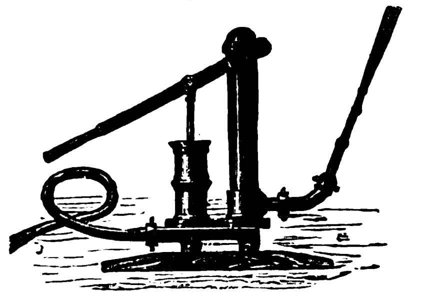
Hancock's copper-ore jigger, Moonta mines, S. Australia. * "*Scientific American Supplement*," 269.

Jig'ger Pump. A hand-pump on a portable stand. That shown in Fig. 1491 has a copper air-vessel, working lever, suction pipe, and delivery nozzle, all on iron base.

Jig'ging Machine'. A tool convertible into a drilling or profiling machine. It is especially adapted for first cutting or making duplicate dies, for light drilling and for single spindle profiling.

Jig Saw. A tool, the precursor of the band-saw. It is a fine reciprocating saw, cutting on the

Fig 1491.



Jigger Pump.

down-stroke, elevated by a spring, and kept taut between the latter and the pitman or crank-pin whence it derives its motion. See also SCROLL SAW.

Nitrate of potassium	75
Sulphur	10
Lignite	10
Picrate of sodium	3
Chlorate of potassium	2
	100

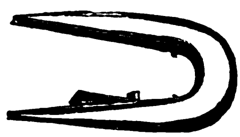
Join'er. A wood-working machine capable of a variety of work. See Fig. 2726 and description, p. 1217, "*Mech. Dict.*"

General, *Reynolds*, Br. . .	* "*Engineer*," xlv. 417.
Universal, *Rasse*	* "*Iron Age*," xx., Dec. 27, p. 1.

Join'er's Bench Stop. An abutment on the bench against which the work rests in planing. See BENCH STOP, Fig. 294, p. 96, *supra*.

Join'er's Clamp. A device for holding a piece while being worked; or holding parts together after being glued.

Fig. 1492.



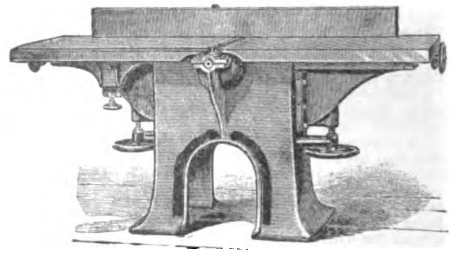
Clamp.

See BENCH CRAMP, Fig. 286, p. 95; CLAMP, p. 560, "*Mech. Dict.*"; CRAMP, p. 641; CARPENTER'S CLAMP; DOOR CLAMP, etc., *Ibid.*

The little clamp, Fig. 1492, is a two-fingered instrument adjusted in an instant, and fastened by a tap of the hand.

Joint Bolt. A bolt used for fastening two timbers, one end-wise to the other. A nut is inserted in one, and the hole bored through both. Used commonly as a fastening for a bed-rail to the bed-post. See JOINT-HOLDER BOLT.

Fig. 1493.



Smith's Stave Jointer.

Joint End. (*Vehicles.*) An iron piece with hole for a bolt; being united to the wooden portion, it forms the end of a carriage bow; or to a rod, forms the end of a stop-prop.

Joint'er. A machine for edging staves and headings.

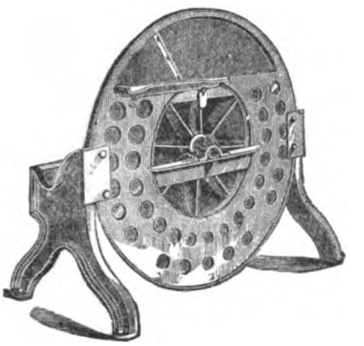
The old-fashioned jointer was a long plane, set obliquely with one end on the ground.

In the modern jointer the tool revolves and the stave is on a rest.

In Smith's jointer, Fig. 1493, the stave is run along the straight bed, against the fence, and the revolving tool planes the edge. The tool is a true planer, and has many shop uses besides jointing. By change of cutter the machine may mold, rabbet, chamfer, etc.

Fig. 1494 is Trevor's jointer. The plane bits are set ob-

Fig. 1494.



Stave Jointer.

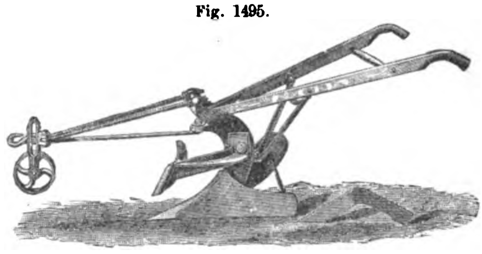
liquely in the face of the wheel, and the stave lies upon the horizontal rest.

See also Fig. 218, p. 78, *supra*.

Stave jointer, *Holmes* . . . . * "*Engineer*," xli. 431.

(*Add.*) 4. (*Plow.*) A small share in advance of the main plow body; designed to overturn weeds

Fig. 1495.

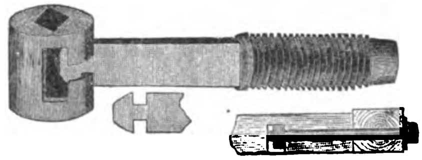


Gale's Jointer Plow.

and double them up so as to be more completely covered in the furrow.

Joint-hold'er Bolt. A furniture joint. Used in bedsteads, especially in fastening the rails to the posts.

Fig. 1496.

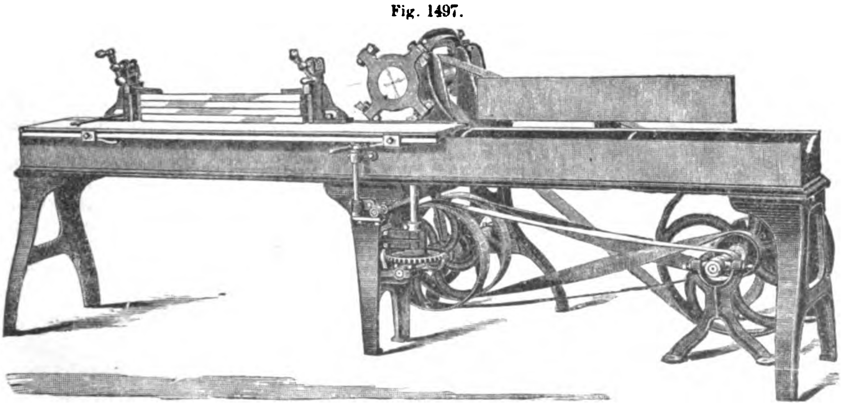


Joint Holder Bolt.

Two forms are shown: in the upper one, the socket is mortised into the side of one member of the frame and the bolt screwed into the end of the other. The notch-headed bolt being inserted into the channel of the socket and the latter rotated, the parts are indissoluble by direct draft.

The other bolt passes through both members and into a nut introduced at a side mortise.

Fig. 1497.



Cabinet Jointing Machine.

Joint'ing Ma-chine'. A planing machine adapted to a special class of work, as in furniture and piano factories, for instance.

The working parts of Rogers' cabinet jointing machine are: a table 6' long, on which the work is placed against a back gage and held firmly by adjustable screw-clamps; the feed then being thrown into gear by the lever in front, the work is carried against the revolving cutter head, the table reversing its motion, and stopping on its return automatically. The work is finished perfectly square and ready for glueing if desired. This machine leaves all the corners of work perfectly square and unbroken.

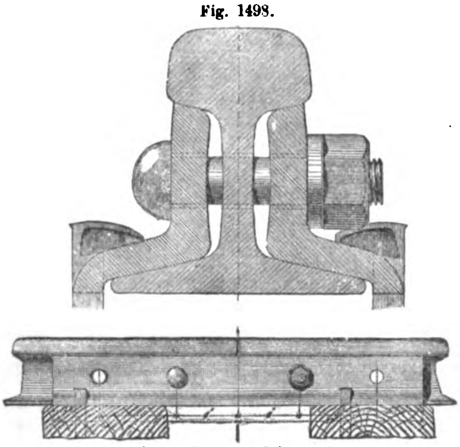
Joint Splice. A reënforce at a joint to sustain the apposed parts in true relation.

Fig. 1498 shows a standard rail section and fish plate of the Pittsburg, Cincinnati, and St. Louis Railway. The upper view is a vertical section, and the lower an elevation on a much reduced scale.

Jon'val Tur'bine. The turbine with *downward* discharge; in contradistinction to the Fourneyron *outward* flow, and others which are oblique, double, combined, etc. See Fig. 6784, p. 2657, "*Mech. Dict.*"

Jour'nal Bear'ing. The French *palier glissant* is shown at Fig. 3496, p. 1599, "*Mech. Dict.*" Bramah was the original inventor. See also Hydraulic Pivot; Water Bearing, "*Mech. Dict.*"

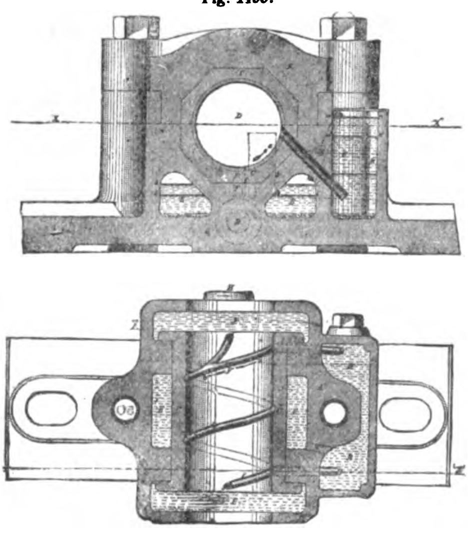
Fig. 1498.



Rail Section and Joint Splice.

The *palier graisseur sans mèche*, of Hignette, Paris, is shown in Fig. 1499.

Fig. 1499.



Journal Bearing.

A is the body of the bearing.
B, cap-piece.
C C, lining blocks.
G, helicoidal groove cut in the bearing linings.
A bifurcation assures the passage of the oil in whichever direction the shaft may run.
The reservoirs, lateral and lower, communicate by tubes with the grooves in the journal bearing.

Renewable, *Platt* . . . * "*Iron Age*," xxiv., Oct. 30, p. 11.
Marine engine . . . "*Scientific American*," xxxix. 216.
Cooler, *Dempsey* . . . * "*Scientific American*," xli. 323.

A material, a bad conductor of heat, invented by S. Coline, a French engineer, is designed for the bearing of all kinds of machines, wheels, and axles, and is stated not to require any lubrication. The following is the recipe for the composition : —

Take about 25 per cent. of asbestos, and the same of graphite, mix them very intimately and carefully ; add sufficient liquid silicate of soda or potash to reduce the whole to a half dry paste, which must then be submitted to the action of a hydraulic or other press, till it is converted into a solid mass, which is afterwards dried either in a furnace or by exposure to the air, until all moisture has disappeared. The bearings may either be turned out of the block or molded from the composition while in the moist state. When the bearing is finished it is steeped in hot melted paraffine, mineral wax, or in a solution of paraffine, benzole, or other mineral oil, until all the pores in the composition are filled.

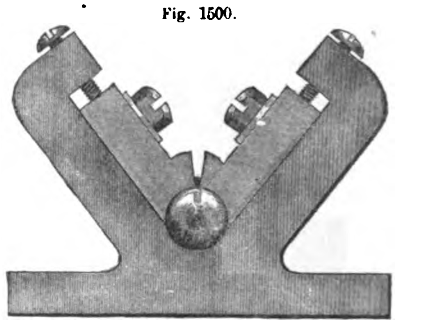
Jour'nal Bear'ing Key. (*Railway.*) A plate on top of axle box to hold the latter in plate. See 8, Axle Box.

Called also *wedge, liner, slide, saddle, keeper*, etc. — *Forney.*

Jour'nal Box. (*Railway.*) A metallic box which incloses the journal of a car-axle, the brasses and the key. See Axle Box.

Ellis's journal box is shown in Fig. 1500, and is made in three parts, the upper two of which are separately adjustable toward the journal, permitting the latter to be kept central and tight.

Fig. 1500.



Adjustable Journal Box.

Jour'nal Brass. The bearing or box of a journal or axle.

Jour'nal Pack'ing. (*Railway.*) Waste cotton or wool saturated with oil or grease and filled into an axle-box to lubricate the axle.

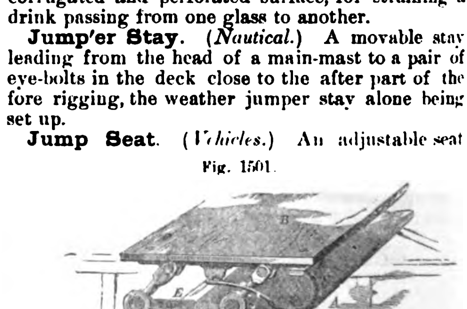
Jour'nal Spring. (*Railway.*) A spring which supports part of the weight of a car and is placed directly over the journal, and which usually rests on the journal box under the truck-frame. Such springs are sometimes placed above the truck-frame and supported by straps, and the weight of the car is transmitted to the journal box by a vertical pin or stirrup. — *Forney.*

Ju'lep Strain'er. A round or oval ladle with corrugated and perforated surface, for straining a drink passing from one glass to another.

Jump'er Stay. (*Nautical.*) A movable stay leading from the head of a main-mast to a pair of eye-bolts in the deck close to the after part of the fore rigging, the weather jumper stay alone being set up.

Jump Seat. (*Vehicles.*) An adjustable seat

Fig. 1501.



Jump Seat.

which may be brought into position for use when it is desired to convert a single-seated vehicle into a double-seated one.

In Fig. 1501 the seat *A* is shown out of use, in position below the seat *B*. When two seats are required, the seat *A* is thrown forward on its pivoted supports *C* and the seat *B* thrown backward on its pivoted supports which are braced together by the bar *E*. The supports of the front seat *A* are secured by a latch to the plate *D*, and the seat may be removed entirely if desired.

Junk Hook. (*Fishing.*) Used in hauling heavy pieces of blubber on deck.

Junk Vat. (*Leather.*) A large vat into which is pumped the tan liquor or ooze which has been deprived of a great part of its strength in the layers. The liquor is run into the stringers where a weak ooze is required.

Ju'nod's Arm. (*Surgical.*) A dry cupping apparatus. See CUPPING; ARM.

Ju'pon. (*Fabric.*) A French dress goods made on a taffeta loom. It has a simple cotton warp and carded wool weft.

Ju'ry Mast. (*Surgical.*) *Sayre's* apparatus for supporting the head by means of head and chin straps, and a spinal bar which rests below upon bands encircling the body. Fig. 194, Part IV., *Tiemann's "Armamentarium Chirurgicum."*

Jute. Fiber of the *Cochorus capsularis* and *C. olitorius;* an East India plant. Useful for many purposes in India. See p. 1221, "*Mech. Dict.*"

The product of the jute fiber by the Sachs process is known as *Kalameit*, which see. See also AGAVE; ISTLE; RAMIE; TAMPICO, etc., "*Mech Dict.*," and herein.

K.

Kal'a-meit. The name adopted for the fiber of jute as prepared by the Sachs process, for textile manufactures made by the Barrow Flax and Jute Co. (Br.), and shown in the shape of curtains, table-cloths, and dress goods at the Paris Exposition, 1878. See JUTE, *supra.*

Ka-lei'do-scope. An improved form has been made by M. Thomas, of Paris.

The two mirrors are, as usual, put in a tube; but the objects employed to produce the images are inclosed in a transparent case, which is separate from the tube. This case, almost flat and with its two faces formed of watch-glasses, is supported by a rod, which is fixed to the tube by a hinge. It can also receive a movement of rotation round its axis of suspension. In this way it can be inclined in any direction to the axis of the tube. A button, manipulated with the hand, enables one to turn it about its center, so as to change the positions of the objects within. A pasteboard disk, white on one side, black on the other, is placed behind the case. Transparent or opaque objects may thus receive light on one or the other side of the case and be displayed on the white or black background of the disk, according as it may be desired to observe them by transmission or reflection. — "*Société d'Encouragement*," *Paris.*

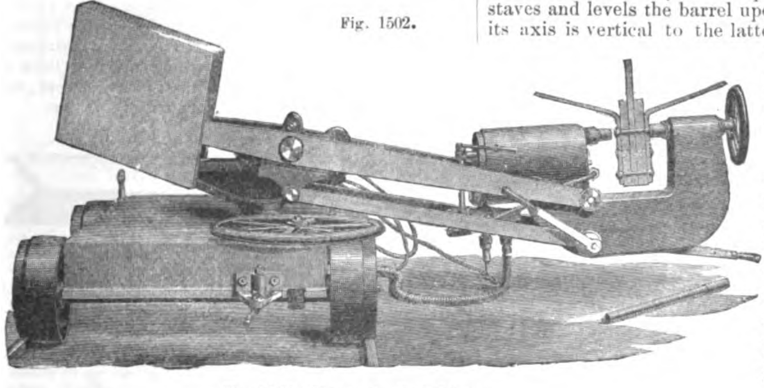
Kedge. (*Nautical.*) A small anchor used in warping; to keep a ship steady and clear of her bower when riding, etc.

Kedg'ing. (*Nautical.*) Tide-working in a narrow channel or river by kedge-hauling.

Keel Riv'et-er. A machine for riveting the keels of iron vessels upon the stocks.

Fig. 1502 shows Tweddell's hydraulic keel-riveter, as made by Fielding & Platt of Gloucester (Br.), and used at the Barrow Shipbuilding Co.'s works.

Fig. 1502.



Tweddell's Hydraulic Keel Riveter.

A short length of tramway is laid under the vessel and alongside the keel, and upon this travels a bogie or carriage carrying the riveter. This riveter is attached to one end of a pair of levers, and is balanced by a counterweight on the other end. Thus balanced, the riveter is easily moved up and down as required to meet not only the varying heights of the keel from the ground level, but also the different positions of the rivets themselves. The arrangement of levers is attached to a small carriage which is free to travel inward and outward along a pathway on a species of turntable, and this turntable is supported on a large pin which is free to revolve on a socket on the traveling bogie or carriage. By this means the riveter can be readily moved to or from the keel bar, which is sometimes necessary owing to the rails not being laid exactly parallel to the keel, and to other causes, while the whole apparatus can be turned round on its carriage.

A hand-wheel behind the cupping die on the *hob* of the riveter turns a screw, which takes the thrust of the die upon closing a rivet. By this means, when the hot rivet is put in, the screw being turned inward a slight pressure is brought to bear on the rivet head, and the machine is thus steadied in position. Keel rivets having very shallow heads, the rivets also being countersunk, some such contrivance as this is necessary to insure fair work. The riveting die is close to the top of the cylinder; this gives room when the garboard strakes come nearly at right angles to the keel.

The keels of the large steamships "City of Rome" and "Servia" were riveted by these machines.

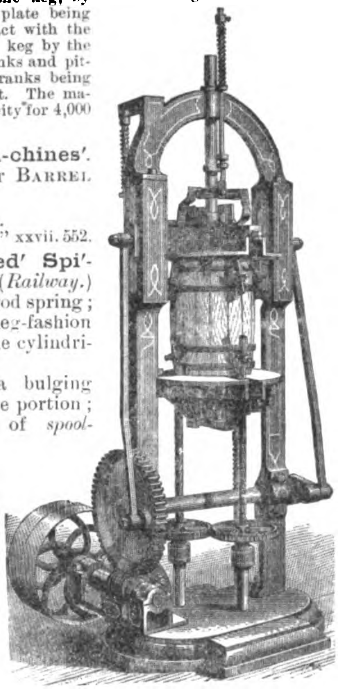
"*Engineering*" . . . . * xxx. 535.

Keep'er. (*Electricity.*) *Keepers*, also known as *shoes* (*Ganot*), are lateral projections from the polar extremities of a magnet to bring them in closest possible proximity to the revolving armature short of actual contact.

Keg Lev'el-ing and Trus'sing Ma-chine'. A machine which presses upon the ends of the staves and levels the barrel upon the table so that its axis is vertical to the latter; the staves being practically of a length, it also forces them endways, so that they are in range at the chine.

Holmes's machine is shown in Fig. 1503. The truss hoops are put on the keg in setting up, and the keg placed in the machine. The truss-hoop drivers are attached to two plates, one of which forms a stationary table and is adjustable for various sizes of kegs; and the other is moved to and from it perpendicularly. The drivers move automatically in and out, to allow the reception and discharge of the keg into and from the machine. The plates level and the drivers drive the truss-hoops at one and the same operation upon the keg, by the movable plate being brought in contact with the upper end of the keg by the action of the cranks and pitmans, the two cranks being on the same shaft. The machine has a capacity for 4,000 kegs per day.

Fig. 1503.



Keg Leveler and Trusser.

Keg Ma-chines′. See list under BARREL MACHINERY.

British, *Ransome*.
* "*Engineering*," xxvii. 552.

Keg-shaped′ Spi′-ral Spring. (*Railway.*) A coiled steel-rod spring; bulging — keg-fashion — from the true cylindrical form.

One with a bulging waist or middle portion; the opposite of *spool-shaped*.

Ker′a-tome Scis′sors. (*Surgical.*) Another name for *iridectomy scissors*. *d*, Fig. 4672, p. 2054, "*Mech. Dict.*"

See KERATOME, p. 1223, IRIDECTOME, p. 1195, "*Mech. Dict.*"

Ker′o-sene. (*War-light.*) From κηρός, wax, and a customary termination, as in camphene, paraffine, gelatine, etc.

The trade-mark name of the hydro-carbon oil, made for lighting purposes by the "Downer Kerosene Oil Company."

The distillation of petroleum gives a large number of products, which are known in a practical way by their gravity and flashing points.

	Gravity — *Beaumé.*
Gasoline	90° — 80°
Benzine	74° — 68°
Naphtha	65° — 62°
Kerosene	59° — 38°

Between the ranges 59°-38° the oil, when purified by chemical treatment, is sufficiently mobile and colorless to be suitable for burning in ordinary flat-wick lamps. The fire-test of the 59° B. is 90° Fah., and that of the 38° B. = 200° Fah.: between the stated limits are numerous grades capable of segregation, but for practical purposes they are combined, with a result of a fire test quality for the whole of 150° Fah.

The lighter grades of petroleum, having the gravity 90°-80° B., are used in the apparatus for carbureting air and gas. The grade known as *benzine*, 74°-80° B., is a substitute for turpentine in paint, and is largely used in scouring and cleaning. *Naphtha*, 65°-62° B., is used in paints and varnishes, and also as a solvent for caoutchouc.

The kerosene oil known as *Mineral Sperm* (Downer Kerosene Oil Co.) has a specific gravity of 36° B., and a fire test of 300° Fah. It is as safe as fatty oils, and is burned in lamps of special construction.

The still heavier products, 32° to 22° B., making in the mixture 24°-26° B., are lubricating oils, and yield from 20 to 25% of paraffine wax, which has to be removed in order that the oil may remain fluid.

Ker′o-sene Stove. See PETROLEUM STOVE, Figs. 3664, 3665, p. 1676, "*Mech. Dict.*"

Ker′o-sene Test′er. See PETROLEUM TESTER, Fig. 3666, p. 1676, "*Mech. Dict.*"

Ket′tle. A boiler. That shown in Fig. 1504 is a compact form of double-bottomed boiler, the space being heated by steam introduced through the trunnion on which the kettle may be tipped to discharge its contents. Used as an agricultural or laundry boiler.

Kier, boiling and bleaching. Br. . "*Sc. Amer. Sup.*," 1684.

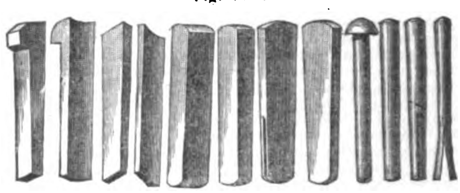
Fig. 1504.

Double-bottomed Bascule Kettle.

Key. A fastening piece to secure parts; a gib or spline, a forelock, a pin, a cotter, as the case may be. See the above definitions in "*Mech. Dict.*," and Fig. 2742, p. 1225, *Ibid.*

Fig. 1505 shows a number of forms: headed, plain, taper, stud, bracket, split, etc.

Fig. 1505.



Keys.

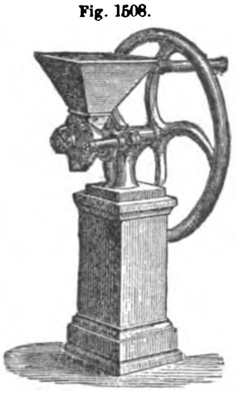
On cutting and fitting .	* "*Sc. American Sup.*," 888, 1255.
Drilling, *Sharp, Stewart & Co.*, Br.	* "*Engineer*," xli. 187.

Kib'bling Mill. A hand grinding-machine for mashing grain for stock. By it oats, etc., are flattened and broken, so as to insure more perfect digestion.

Kiln. A furnace for baking. fritting, calcining, firing, etc. See —

Brick.	Malt.
Faïence.	Pipe.
Porcelain.	Pottery, etc.

Fig. 1508.



Kibbling Mill.

King'-bolt Plate. 1. (*Railway.*) A plate on the floor of a car concealing the head of the king-bolt, which may be withdrawn when the cover is removed.

2. (*Carriages.*) A plate on the fore axle of a vehicle bushing the hole through which the king-bolt passes.

King'-bolt Tie. (*Vehicles.*) A saddle piece on a king-bolt, having opening at the ends for clip bolts.

Kite. A form of kite for lifting a person from the ground in order to reconnoiter an enemy's position, has been tried at Chatham, Br. The invention of Mr. J. Simmonds. A series of kites of relatively increasing size are flown, one attached to the other in series, the first assisting in flying the second, and so on. "*Iron*," viii. 300.

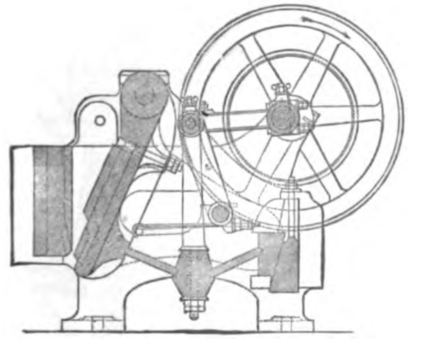
Knap'ping Ham'mer. A soft steel hammer, disk shaped or sharp edged, for breaking flint flakes into lengths for gun flints.

See *Evans' "Ancient Stone Implements of Great Britain*," p. 17, *et seq.* See GUN-FLINT.

Knap'ping Ma-chine'. A form of stone-breaking machine in which the stone is broken by a sudden blow, rather than by a sustained pressure, which is said to have the effect of more evenly cubing it, and producing less chips and dust.

The motion in the Baxter (Br.) machine, Fig. 1509, is obtained by a crank radius-link and lever. The blow is given by a quarter revolution of the fly-wheel shaft, the jaw remains stationary half a revolution, and retires during the remaining quarter.

Fig. 1509.



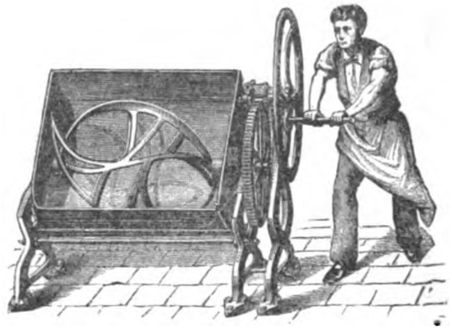
Knapping Machine.

Knead'ing Ma-chine'. A machine for incorporating the ingredients of dough.

See DOUGH BRAKE, Fig. 858, and DOUGH MIXER, Fig. 859, p. 270, *supra*.

Boland's kneading machine, shown in Fig. 1510, is an endeavor to approximate in machinery the action of human arms. The hand process has a dividing and rolling action; the hands in contact, and the arms bowed, a sweeping motion is made obliquely down through the mass of dough, which is divided, turned over, and thrown on top of the remainder. Until the mass attains a certain amount of solidity the action is principally as described, and may be compared to the beating of eggs with a spoon in a bowl, the mass being divided, and one portion flirted on top of the remainder. The action of the machine is a very close imitation of the human arm method.

Fig. 1510.



French Kneading Machine.

The subsequent pommeling of the tough dough can be dispensed with in great measure, as the capability of the machine for cutting and mixing the dough and slapping the masses together is much greater than that possible with large quantities by the human arms.

Knee Ap'pa-ra'tus. (*Surgical.*) Apparatus for fracture, luxation, weakness or deformity of the knee.

See ANCHYLOSIS APPARATUS, Fig. 202, p. 99, "*Mech. Dict.*"; PATELLA APPARATUS, Fig. 3567, p. 1636, *Ibid.*

Also, KNOCK-KNEE BRACE, BOW-LEG BRACE, etc., referred to under CURVATURE APPARATUS, *supra*.

See, also, GENU-VALGUM BRACE, p. 397, *supra*.

See, also, Patella Apparatus. Figs. 119-121, Part IV., *Tiemann's "Armamentarium Chirurgicum."*

Stillman's splint, *Ibid.*	Figs. 95, etc. Sup.

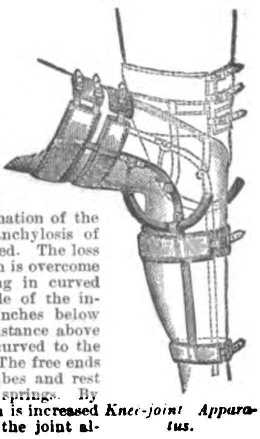
Knee Cap. (*Surgical.*) A water or ice-bag for topical applications to the knee.

Knee'-i-ron. An angle-iron at the junction of timbers in a frame.

Knee'-joint Ap'pa-ra'tus. (*Surgical.*) See KNEE APPARATUS, where a diversity of devices are referred to; including those for curvature, deformity, reduction, straightening, etc.

Dr. Hooper's knee-joint apparatus, shown in Fig. 1511, is an extension device to prevent the articulating surfaces from coming in contact, pending the suppression of inflammation of the parts. To prevent false anchylosis of the joint flexion is permitted. The loss of extension during flexion is overcome by placing a helix spring in curved tubes fastened on each side of the instrument shown, three inches below the joint. At the same distance above the joint are fixed rods, curved to the same arc as the tubes. The free ends of the rods fit into the tubes and rest upon the upper end of the springs. By this arrangement extension is increased by flexion. The play of the joint al-

Fig. 1511.



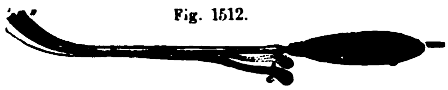
Knee-joint Apparatus.

lows the limb to be flexed at right angles. The action of the spring ceases when the limb is extended to its utmost, thereby preventing any undue pressure upon the joint in a direction contrary to the one in which it should be applied.

Knick'er-boc'ker. (*Fabric.*) A French all-wool goods, with irregular spots of different colors and materials.

Knife. A cutting implement wielded by the hand, and known by name indicative of material, shape, purpose, or mode of using.

Fig. 1512.



Knife and Tenaculum.

The following list includes many which are defined or illustrated under their alphabetical heads. See, also, list of 144 knives on p. 1233, "*Mech. Dict.*"

Bait knife.
Bait-mill knife.
Blubber knife.
Boarding knife.
Boat knife.
Border knife.
Bread knife.

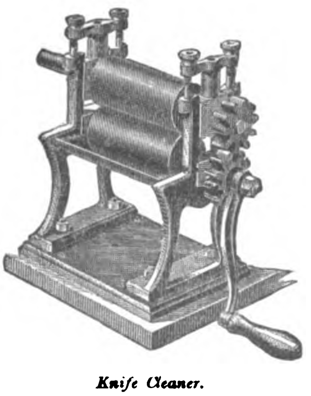
Urethratome.
Uvulatome.
Valentine knife.
Whaleman's knife

(*Surgical.*) The cutting implement has many uses and specific names in surgery. They will be found under specific heads herein and in the "*Mech. Dict.*" See list of knives, p. 1233, *Ibid.*

Fig. 1513.



Knife Cleaner.

The *dissecting* knife is made of various shapes for the more ready separation of the parts of animal and vegetable tissues.

The *section* knife is either a flat knife for slicing thin sections of various soft tissues, for microscopic purposes, or *Valentine's* knife, which has two parallel blades for cutting out a thin section at a single stroke.

Fig. 1512 is Dr. Skene's knife and tenaculum for uterine operations.

Knife Clean'er. An implement for removing stains from and polishing table-knives.

Two forms are shown in Figs. 1513, 1514. In the former the knife-blade is passed between two elastic rollers which

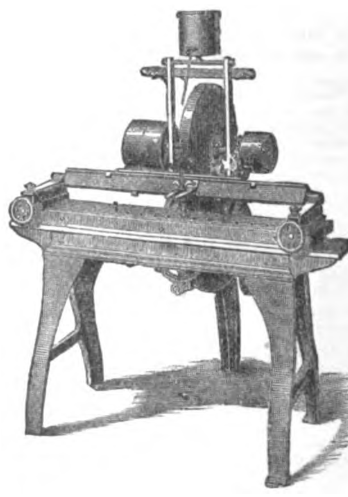
Fig. 1514.

Knife Cleaner.

have the abradant upon them. In the latter, the knife-blades are thrust into holes in the periphery of a round box, and are rubbed between the faces of two adjacent disks revolving in opposite directions, the distance between them being regulatable.

Knife-grind'ing Ma-chine'. An emery wheel mounted on a bench with a way upon which the

Fig. 1515.



Automatic Knife-sharpening Machine.

knife carriage is automatically traversed in front of the grinding wheel. Water is supplied from a trickling cup above.

See grinder, automatic .	* "*Scientific Amer.*," xxxviii. 371.
Grinding machine . .	* "*Scientific American*," xxxv. 367.
Manufacture	* "*Scientific American*," xxxvii. 88.
Polishing mach., *Chase*	* "*Scientific American*," xliii. 403.
Knife and tape line.	
Hastings	* "*Scientific American*," xxxv. 194.

Knife Guard. (*Cutlery.*) A pivoted piece on the back of a carving fork, to protect the hand should the knife slip in carving.

The guard is combined with a rest in the carver of the *Meriden Cutlery Co.*

Knife Head. That piece in the cutting apparatus of a harvester, to which the knife is fastened, and to which the pitman-head is connected. In the Harrison knife-head, rubber buffers are placed on each side of the pitman wrist, to take up the jar and keep the eye from being battered.

Knife Rest. A bench for holding a knife while being ground or filed. Such are used in connection with grindstones and emery wheels. See under the various heads and references *passim*. Also list under GRINDING.

The rest for harvester-knives, shown in Fig. 1516, is fold-

Fig. 1516.

Harvester Knife Rest.

ing, portable, and has a box for files. It has thumb-screws for holding the knife steady.

Knit'ting Ma-chine'. Considered at length, * pp. 1234–1238, "*Mech. Dict.*"

G. W. Gregory's Report on Knitting Machines, "*Centennial Exhibition Reports*," vol. vii., Group XX., p. 53 *et seq.*, describes the following: —

Weaver's knot.

Knot Ty'er. (*Surgical.*) An instrument for tying a ligature in a deep-seated situation.

See LIGATURE INSTRUMENTS, Fig. 2944, p. 1308, "*Mech. Dict.*"

Knurl'ing Tool. A tool to produce knurl work; such as that on the edge of a thumb-screw.

* "*Scientific American*," xl. 223, Fig. 2; Figs. 16–21, p. 223.

Kuft Work. (*Fine Art Metal-work.*) The name for the damasceening of Hyderabad: gold or silver wire let into undercut graved lines on a steel, iron, or bronze object, and incorporated by hammering.

A cheap *Kuft* work — a sham in fact — has gold leaf laid on a surface roughened by etching, while the gold wipes off the smoother surface.

Ky'ak. The Eskimo canoe, used in hunting and fishing.

Kys'to-tome. (*Surgical.*) See CYSTOTOME, "*Mech. Dict.*"

L.

L. A rectangularly bent pipe connection. An *ell*. See BEND, *c. d*, Fig. 295, p. 97, *supra*.

La'bel-ing Ma-chine'. A machine for attaching labels to cans, bottles, boxes, packages, etc. See Fig. 2781, p. 1242, "*Mech. Dict.*"

Bigelow's machine is adapted to labeling round cans and is adjustable to those of any circumference and length. The labels are applied either with marginal paste, or paste all over their backs. It is operated by two persons, one to lay the can on at one end and the other to take it off at the other end; the weight and velocity of the can passing down the inclined chute doing the work. Capacity, 40 per minute.

In *Russell's* machine the paste is applied all over the back of the label, the process is automatic, the cans being simply put in and taken out; the motion is by hand crank.

La'bel Ma-chine'. A machine for preparing and printing labels.

In *Hutchinson's* label machine, Fig. 1517, the ribbon of paper is wound upon reel *B*, from which it is drawn by a regular motion of the feed-rollers *J*. The guides *C C* steady it, in its onward course, in a direct line. The rollers *D* flange it and crease it. The guide d^1 turns the flange d^2 up at right angles. The reel e^1 has on it the tape e^4. In using the tape, carry one end down under guide e^6, through the mucilage e, up through scraper e^5, down again under roller *G*, then under guide g^1, where it is pressed down to the paper; and, as it passes forward, the flanged edge is folded down over it by the folder *H* and is pressed firmly down by spring presser-bar *h*. It then passes between feed-rollers *J*, and on between the plate *V* and stop s^1, and the hole is punched. At the proper interval of time, the inking-roller *N* passes under the type m^1, and recedes again. The type descends with the knife and prints the tag, and the knife *L* cuts off the tag complete. A piece of strong paper strips may be used instead of the tape, or the flanged edge may be gummed, without any tape being used; or a ribbon of paper and cloth, combined in one article, may be used instead of the paper ribbon.

Lab'o-ra-to-ry Forge. A compact form of forge for the work room.

That shown in Fig. 1518 is a French form, and has bellows, hearth, vise, and drilling arrangement.

See also CHEMIST'S FORGE, Fig. 610, p. 193, *supra*, etc.

Laboratory equipment, *Schacht* * "*Sc. Amer. Sup.*," 1578.
Laboratory furnace . . . * "*Sc. American Sup.*," 319.

Lab'o-ra-to-ry Fur'nace. A compact form of furnace for the work-shop.

For instances, see BLAST GAS FURNACE, Figs. 321–323, p. 105; BUNSEN BURNER FURNACE, Figs. 473–475, pp. 146, 147; CRUCIBLE FURNACE, Fig. 738, p. 283, *supra*, also p. 1242, "*Mech. Dict.*"

Lab'o-ra-to-ry Lathe. A form of lathe for dentists, jewelers, etc. Adapted for drilling and polishing.

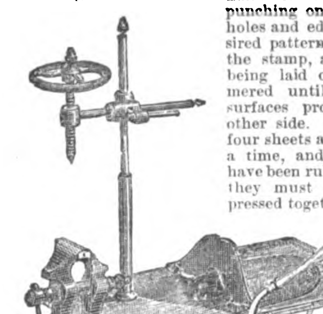
It is foot-power, stands on a tripod, and the head is thrown forward 5" from the perpendicular to allow a person to sit while using it. The height of the head is adjustable.

Lab'y-rinth. (*Metallurgy.*) An apparatus in which the slimes or finely stamped metallic matters and gangue are placed in an extended trough exposed to a current of water. The bottom of the trough has little trenches formed by slats, and the matters deposit according to relative fineness and levity, the lighter at the greater distance from the point of ingress.

Lace Paper. Paper surface-stamped and perforated to resemble lace.

The difficulty in manufacturing these papers is to produce a surface which will exhibit, as in real lace, the fine gradations of lines. Small leaden hammers are used for punching on stamps. The holes and edges of the desired pattern are raised on the stamp, and the paper being laid on it is hammered until the hollow surfaces project on the other side. From two to four sheets are stamped at a time, and unless they have been rubbed with talc they must be closely pressed together.

Fig. 1518.



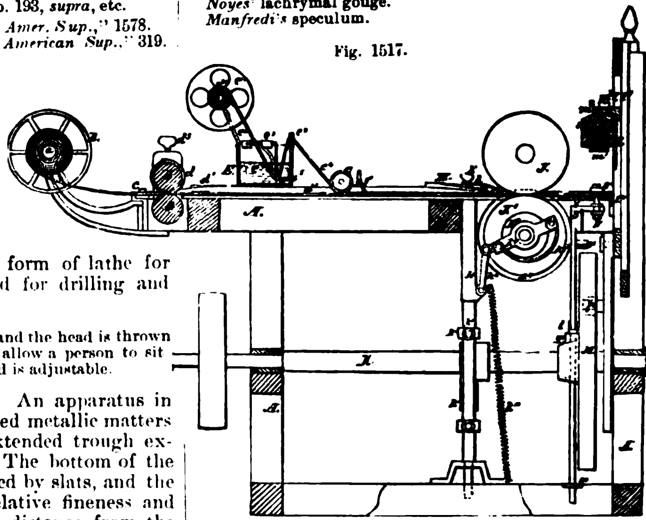
Laboratory Forge.

Lach'ry-mal Duct In'stru-ments. (*Surgical.*) These include syringes, dilators, probes, forceps, gouges, catheters, specula, knives.

See CANALICULA, also LACHRYMAL DUCT DILATOR, p. 1244, "*Mech. Dict.*"

See also pp. 6, 7, Part II., *Tiemann's* "*Armamentarium Chirurgicum*," for —
Anel's, *McFarland's*, *Liebold's*, *Agnew's* eye syringes.
Galezowsky's, *Weber's* canalicula dilators.
Anel's, *Bowman's*, *Williams's*, *Liebreich's*, *Levi's*, probes.
Liebreich's fistula knife.
Noyes' lachrymal gouge.
Manfredi's speculum.

Fig. 1517.



Label Machine.

Noyes' conjunctiva forceps.
Speirs' lachrymal catheter.

La'cing. (*Nautical.*) A cord to lace a sail to a gaff, or a bonnet to a sail.

La'cing Cut'ter. (*Leather.*) A knife with a gage, to preserve the width of the strip.

Lacing cutter, *Elliott* . * "*Scientific American*," xliii. 178.

La'cing Hook. (*Boot.*) Hooks on the margins of the upper, over which a lace is caught side by side alternately to close the opening in the shoe.

Fig. 1519.

Laboratory Lathe.

Lac'quer. From *lac* (*Hindu*), "the hundred thousand," alluding to the smallness of the insect, *Coccus lacca*, which produces the resinous exudation on certain Indian trees.

The Japanese lacquer, *urushi*, is from the sap of the *rhus vernicifera*, which is obtained by a process of tapping, similar to that employed in obtaining turpentine. The process is described and illustrated in the author's article on the subject in the "*Atlantic Monthly*," * vol. xl., p. 559, *et seq.* See also digest from report of Japanese Commissioners at Centennial Exhibition, 1876, in "*Scientific American*," xxxv. 89; and "*Scientific American Supplement*," 676.

The lacquer work of Japan is admittedly superior to that of China, which is attributed to the advantage possessed by the former in having a moister climate, and to the comparative absence of dust in the atmosphere. The Japanese lacquer itself is, however, more limpid than that of China, the latter having a yellow tinge.

The perfection of the Japanese and Chinese lacquer work does not altogether depend upon the excellence of the varnish or the preparation of the colors. The most elaborate pains are previously taken with the surface of the material to be embellished. The surface of the wood is carefully smoothed; joints, if any exist, are filled with fine tow, and covered with thin strips of silk or paper; the surface is then anointed with a vegetable oil, found in the mountains; when dry, the varnish is applied. On this surface the gold or silver ornamentation or relief work is applied, and the whole covered with another coat of varnish.

Recipes: —

For Brass Castings:	Seed lac	6 oz.
	Amber of copal	2 oz.
	Dragon's blood	40 grains,
	Extract red sandal wood	30 grains.
	Oriental saffron	36 grains.
	Pounded glass	4 oz.
	Alcohol	44 oz.

Expose articles to a gentle heat and dip in the lacquer, several times if necessary. Has a good color, is durable, may be cleaned with water and dry rag.

Gold Color Lacquer:	Copal	2
	Shellac	1
Melt and add:	boiled oil	2
	Mix gradually in oil turpentine	10

Color with gum guttæ in turpentine for yellow; dragon's blood for red.

For Brass or Bronze:	Shellac	16
	Dragon's blood	4
	Turmeric root	1
	Alcohol	332

Warm the article before applying.

Black Lacquer:	Shellac	9
	Methylic alcohol	50
Digest, and then apply asphaltum		10
	Dissolve in benzine	50
	Lamp-black, *ad lib.*	

Dilute with alcohol and benzine.

See also Brass Lacquering, p. 130, *supra*.

Lac'to-den-sim'e-ter. A specific gravity instrument by Quevenne.

It is of the hydrometer form, and has one spindle with two scales, — one to show the density of pure milk, another for skimmed milk; both scales expressing the specific gravity of the milk.

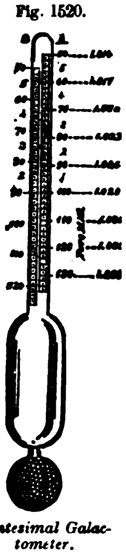
The greatest density of cow's milk is 1.035, produced under favorable circumstances. The usual density of pure good milk is 1.030, water being 1.000. A scale of 35° shows, therefore, the full range between water and the best milk, and serves to register all the information which a trial of the density can elicit.

See Lactometer.

Lac-tom'e-ter. An instrument for testing milk.

It is usually on the principle of the hydrometer, and determines the specific gravity.

Fig. 1520.



Centesimal Galactometer.

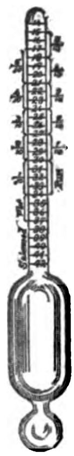
The centesimal galactometer is the invention of *Dinocourt*. It has two scales: one for pure milk, and colored yellow on the staff of the instrument; the other for skimmed milk, colored blue on the instrument.

"The first degree on the top of the scale is marked 50, which corresponds to the sp. gr. 1.014. The marks following extend from 50 to 100 (sp. gr. 1.029), and over. Each degree starting from 100, in mounting up to 50, represents a hundredth of pure milk; the degrees formed by a *line* are equal, as 50, 52, 54, etc.; the degrees formed by a dot are unequal, as 81, 83, 85, etc. To illustrate by an example: If the galactometer is sunk to the 85th degree, that will indicate 85 hundredths of pure milk, and consequently that 15 hundredths of water has been added to this milk; if sunk to 60°, that will indicate 40 hundredths of water, or four-tenths of water added.

"The skim-milk scale is, like the first, divided into hundredths (100°), of which the first 50 have been cut off as useless, as in the case of the other scale, each degree commencing from 100 to 50, and mounting upwards represents a hundredth of pure skimmed milk, consequently the manner of estimating the quantity of water added to skim milk is absolutely the same as for pure milk with cream." — "*Mott.*"

The instrument of *Bouchardat & Quevenne* is shown in Fig. 1521. It differs from that of *Dinocourt* in the division of its scale. The shaft bears three graduations.

Fig. 1521.



Lacto-densimeter.

Fig. 1522.

Board of Health (N. Y.) Lactometer.

The middle one comprises the figures between 14 and 42, answering to 1.014 and 1.042 specific gravity. For instance, if the instrument be sunk in a liquid up to the figure 29, this signifies that a liter of this milk weighs 1.029 grams, and that its density is consequently 1.029. The instrument has been graduated for the temperature of + 15° C. The scale on the right is employed when it is certain that the milk acted on is not skimmed. This scale shows what are the variations of the density of milk in proportion as water is added, and the figures .1, .2, etc., indicate that the liquid operated upon has been mixed with this proportion of water. The scale on the left contains the same indications relative to skimmed milk. Milk is marked pure on this instrument, between the specific gravities 1.030 and 1.034; skimmed milk is marked pure between the gravities 1.034 and 1.037.

In graduating the Board of Health lactometer, shown in Fig. 1522, the 100° is placed at the standard 1.029, and 0 at 1.000, the gravity of water, the intermediate spaces being divided into 100 equal divisions. The point to which the lactometer sinks in the milk under examination indicates the percentage of milk in 100 parts. Thus, if the lactometer sinks to 80, the milk must consist of, at least, 20 per cent. of water and 80 of milk. This assumes the original milk to have had a specific gravity of 1.029; but if the milk had originally a gravity of 1.034, it would require 16.67 per cent. of water to bring it down to 1.029, and 20 per cent more water to lower it to 80° on the lactometer. The temperature at which examinations are made with the lactometer should be 60 F.

The following is the rapid method of chemical analysis of milk, devised by Prof. Lehmann, of Munich.

A weighed quantity, say 9 or 10 grams of milk, is diluted with an equal weight of water, and poured out in a thin layer upon a porous plate of burnt clay, very dense and fine-grained. The water of the milk, as well as the milk sugar, albumen, and a portion of the salts dissolved in it, are absorbed by the clay plate, while the total amount of fats and caseine in the milk remain on the plate in the form of a thin skin or film. This film is easily removed with a horn spatula, and then dried and weighed. If it is desired to determine the fats alone, this film may be extracted with ether, and thus the two most important constituents of milk very quickly determined. In many cases it is sufficient to know the total weight of the principal solid constituents of the milk, hence also the amount of water, for which scarcely two hours are required. This method also possesses the advantage that a great number of samples can be tested at once without much trouble. It also does away with the use of numerous costly platinum dishes and troublesome water baths, which are always getting dry if not carefully watched. The operation is so simple that it can be used by any person who possesses an accurate balance and set of weights.

Comparing the milk of the cow, mare, and sow by composition, the latter is found very much the richest, as the following analyses show: —

	Cow.	Mare.	Sow.
Water	87.00	90.310	81.760
Fats	4.00	1.055	5.830
Albuminoids	4.10	1.953	6.180
Sugar	4.28	6.285	5.335
Mineral matter	0.62	0.397	0.895
	100.00	100.000	100.000

Rich as sow's milk is, it is remarkable that the lactometer shows no cream. Drying on the water-bath, it exhales the odor of roast pork, and on putrefying, that of putrid bacon.

Lac'to-scope. The lactoscope of Dr. Heusner of Barman is based on the opacity of pure milk.

It consists of two round plates of glass about the size of a watch crystal, placed parallel and held about ⅛″ apart by a metal strip, which passes between them, dividing the space between them into two sections. In the lower section is placed and secured some pure milk, or, better, some permanent white fluid of precisely the same opacity as pure milk. On one of the glass plates are some fine black lines. The upper section is filled with the milk to be tested, and secured by an elastic band. On holding the apparatus between the eye and the light, the black lines being on the side opposite the eye, the black lines will be seen more distinctly through the less opaque medium. If the milk to be tested is less opaque than the normal liquid, as shown by the lines being more distinctly visible through it, the milk has probably been watered or skimmed.

Compare DIAPHONOMETER, p. 255, *supra*.

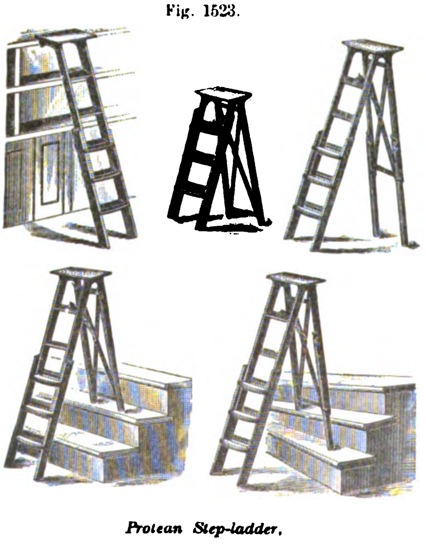
Lac Work. A very extensive industry in India. There are many styles: —

The surface of furniture, boxes, or trinquetry are covered with the lac, and this is laid on in colors, and the designs cut through to expose lower colors.

The surface thus prepared is etched or painted.

A drab ground, ornamented with geometrical flower forms, in colors.

Fig. 1523.



Protean Step-ladder.

These are but a few. The subject may be pursued in *Dr. George C. M. Birdwood's* "*Handbook to the British Indian Section.*" Paris, 1878; pp. 73, 74, 1st ed.

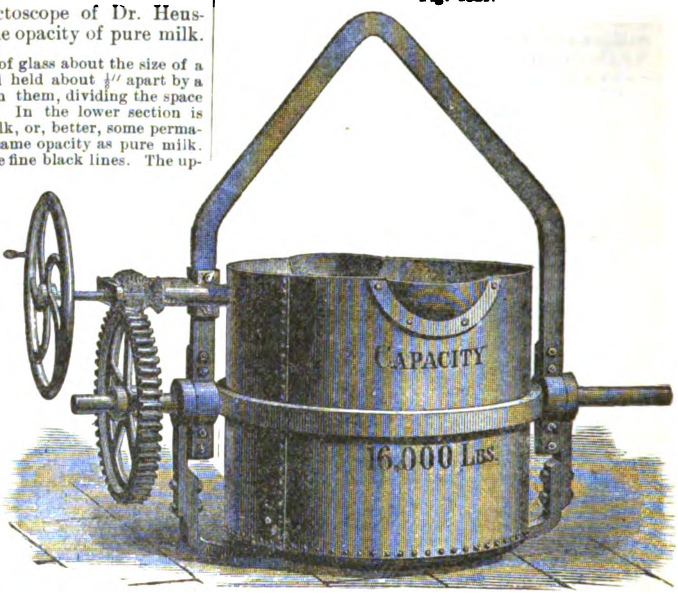
Lad'der. A portable frame with steps. A list is given on p. 1244, "*Mech. Dict.*"

A protean step-ladder is shown in Fig. 1523. It is shown closed, extended, on stairs, on winding stairs, etc — *Covert*.

Lad'der Truck. A vehicle for carrying fire-ladders and hooks. A hook-and-ladder truck. Furnished with (say) 5 ladders, 6 hand-hooks, 2 axes, 2 picks, 4 lanterns, rope-reel, drag-rope, and side-ropes, etc.

La'dle. (*Founding.*) A pan or kettle with a handle, to hold molten metal for pouring.

Fig. 1524.



Balanced Foundry Ladle.

The smaller are known as bullet or plumber's ladles, etc.; the larger, as *shanks*. The glass ladle is a *cuvette*.

Fig. 1524 shows a balanced foundry label of large size, with a capacity up to 8 tons. It pours from either side, and is tipped by gearing from the hand-wheel. It is slung by the bail above from the chain of the crane, and turns on pivots.

A nickel-plated concave disk may be attached to the handle of a foundry ladle to protect the workman from heat and reflect light upon the mouth of the flask.

La'dle Fur'nace. A gas furnace in which the metal to be melted is contained in a ladle over the Bunsen jet. Its capacity is (say) ladles of 6″ diameter, to melt 6 or 8 pounds of zinc, tin, lead, etc. See Fig. 1525.

Lag'ging. (*Mining.*) The timber over and upon the sides of a drift.

Lag Screw. An iron screw, driven by a wrench, but screwing into wood; securing the lagging around a cylinder or other object. See Fig. 1526.

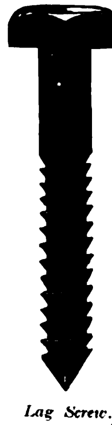
It has a square or hexagonal head, a wood screw-thread cut on it, and is round under the head.

Lake. A precipitate of hydrate of alumina, formed in a solution containing an organic coloring matter: as *madder* lake; *cochineal* lake, etc.

Fig. 1525.

Ladle Furnace.

Fig. 1526.



Lag Screw.

Yellow lakes for dyes are produced from quercitron bark, yellow berries, yellow wood and annatto.

Blue lakes are furnished by litmus derived from lichens found in Southern Europe, Africa, South America, and the East Indies, and indigo.

Red and violet lakes are obtained from cochineal, madder, Brazil wood, lac dye, and safflower.

Lam'i-na-ted Beam. One of the methods of forming a curved beam. They are as follows: —

The *Scarfed*,	*Flitched*,
Bent,	*Laminated*.

The latter is made of thin planks or boards, bent to shape, laid together and secured to form an integral beam, as in Figs. 312–316, pp. 138–139, "*Mech. Dict.*"

Lamp. A device in which a liquid oil or grease is burned in a wick.

Kendall's hydrostatic safety lamp is shown in Fig. 1527. The water is shown by horizontal shading, the oil by oblique. The water forms a seal for the oil, and forces the latter up the wick tube.

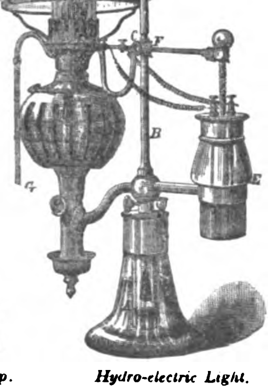
Lavendar's steam lamp (Br.) for collieries consists of a glass lantern 18″ square, with a funnel 24″ high. Into this is introduced a jet of steam, about 1-16″ in diameter, the object of which is to create a partial vacuum in the lantern. The consequence is, that the surrounding air is forced through the burner of the lamp, causing almost complete combustion of the oil. A very brilliant light is thus produced, the increase in brilliancy being partly owing to the products of combustion being continuously removed and a volume of fresh air introduced. The results obtained from a 4″ wick have been calculated as equal to a light of upward of 600 sperm candles.

See *Jobard*, Fr., * *Laboulaye's* "*Dictionnaire*," etc., iv., cap. "*Éclairage*," Fig. 3518.

Fig. 1527.

Hydrostatic Safety Lamp.

Fig. 1528.



Hydro-electric Light.

Zimmerman's hydro-electric self-lighting light is shown in Fig. 1528. The lamp has a Dobereiner apparatus and galvanic battery combined with any form of burner or kind of illuminating liquid.

The *Dobereiner* lamp *A* serves as the pedestal, and contains the acid, water, and zinc. The gas ascends the vertical tube *B*, passes through the valve at *C*, and escapes at an orifice just below the burner. *E* is a galvanic battery, which is normally out of action, but set in activity by pressing a knob, and has wire connecting with the hydrogen outlet near the burner, heating an electrode red-hot at the same moment that hydrogen is allowed to escape. The hydrogen is inflamed and the wick lighted by the single pressure on the knob.

Lamp Ce-ment'. For attaching the brass collar to the glass socket on the reservoir of a petroleum lamp: —

Boil 3 parts resin with 1 part caustic soda and 5 parts water. Mix with half the weight of gypsum. It sets in 45 minutes. Zinc white, white lead, or precipitated chalk may be substituted for the gypsum, but harden more slowly.

Lamp Fur'nace. One in which a lamp — in contradistinction to a gas jet, Bunsen burner, or charcoal — is used as a means of heating.

Used in laboratories: *Griffin's* for instance; see "*Chemical Handicraft*," * p. 123.

Lamp Jack. (*Railway.*) A hood over a lamp chimney on the roof of a car.

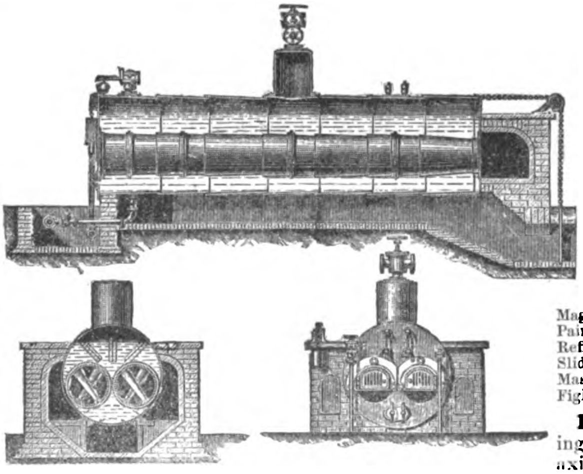
Lamp Stove. See PETROLEUM STOVE, Figs. 3364, 3365, p. 1676, "*Mech. Dict.*"

Lan'ca-shire Boil'er. The long horizontal two-flue boiler is an improvement upon the invention of the illustrious Smeaton, the originator of the flue traversing the boiler. Smeaton's boiler had a single flue; the common boiler used on our western rivers has two; but in neither case is the furnace or course of draft the same as in the Lancashire boiler, as it is called in England.

The front of each flue in the latter boiler, shown in Fig. 1529, constitutes the furnace, and the volatile products of combustion pass backward through the flues into a back chamber, revert along each side, dive under the front, and then pass underneath the length of the boiler and escape by a sub-flue to the stack.

The Cornish boiler has but a single flue and is sometimes mounted with side reverting flues; it usually carries a lower pressure than the Lancashire boiler and is of larger diameter. The Lancashire has some advantages, especially where great power is required. In large boilers, the two flue tubes form good stays for the flat ends; the fire grates can be made of the proportions which give the greatest economy. If the

Fig. 1529.



Appleby Bros. Lancashire Boiler. (*English.*)

flues are stoked alternately a more even temperature is maintained; the heat in one furnace is always at its highest when the other is at its lowest, and the two flues meeting in one combustion chamber, it follows that the gases from the hottest furnace ignite and consume the thick smoke from the other which is being stoked, so that no unconsumed products need escape from the chimney.

A range of large boilers is often fitted with lifting bridges, a flue connecting the two furnaces in the front, and, after a furnace has been newly fired, the bridge is lifted by a lever in front of the boiler, and the whole of the smoke is made to pass over the fire of the other furnace. In all large works there is at least one boiler more than is required for daily use, so that any of the boilers may be laid off for periodical examination and repair when it is required.

Lance. (*Fishing.*) A fishing spear used in killing captured whales, sword-fish, porpoises, etc. For list see HARPOON.

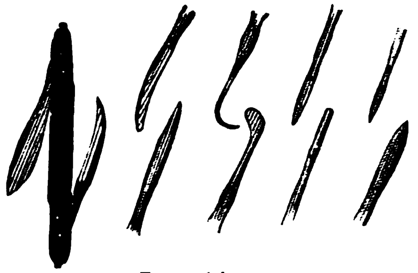
Lance Hook. (*Fishing.*) These are fastened on the boat's side to hang the lances upon.

Lan'cet. (*Surgical.*) A delicate cutting instrument which often bears a special name derived from its form or the place of its application.

Fig. 1530 shows several forms: —

Those on the left, in a handle, are a scalpel and spear bistoury.

Fig. 1530.



Forms of Lancets.

The next two are straight spear and curved probe bistouries.
The next two are a tenaculum and a gum lancet.
The next are sharp and blunt point tenotomes.
Next, tenotome and scalpel.

Land'ing Gaff. (*Fishing.*) A barbed spear for landing fish.

Land'ing Net. (*Fishing.*) A bag-net with hoop mouth for landing a hooked fish.

Land Line. (*Fishing.*) Line passing from the end of the seine to the shore.

Land Rol'ler. An implement for leveling land and breaking clods. See ROLLER. See also CLOD CRUSHER, Fig. 638, p. 201, *supra*.

Land'scape Mir'ror. A mirror which condenses or diminishes the view into a perspective effect. A *Claude Lorraine*.

Lan'tern. (*Founding.*) A perforated *core-barrel*, generally short, and of large diameter.

A portable case for protecting a light.

Fighting, Br. . . .		Fig. 1025, p. 333, *supra*.

Lap. 1. A wheel or disk used in grinding or polishing. Usually on a vertical axis. See p. 1252, "*Mech. Dict.*"

(*Watchmaking.*) Grinding and polishing laps are made of emery, copper, tin, boxwood, ivory, and Arkansas oil stone, of various dimensions.

The various kinds of wheels, and the abradants for grinding and polishing, are mentioned on p. 1253, "*Mech. Dict.*" Their relative hardness is given in a table, p. 1617, *Ibid.*

Japanese lapidary . . "*Scientific American*," xli. 298.

2. A fleece of wool or cotton. See LAPPING MACHINE.

Lap-doub'ling Ma-chine'. A machine which winds two fleeces of cotton upon the roller by means of two sets of rack gear and a top plain roller, which rests on two fluted calender rollers, and is lifted as the lap is formed. *Platt Bros.* (Br.)

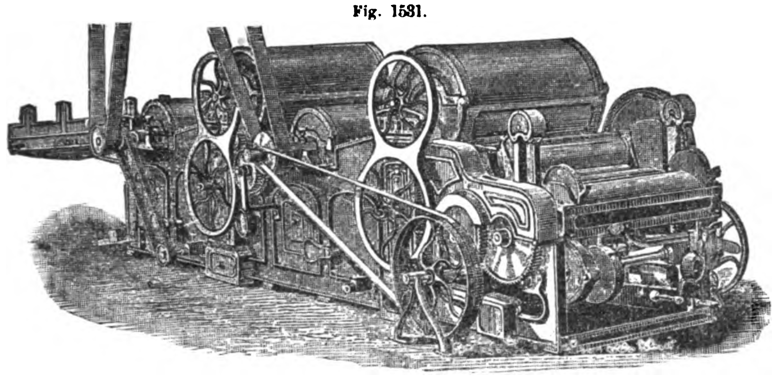
Lap Scale. A scale with a pan in which a given quantity of wool or cotton is weighed to be spread upon a given length of the traveling feeding apron of the lapper or carding machine, as the case may be.

Lap'per. Primarily, a machine for taking cotton from the opener and making it into a lap.

Fig. 1531 is a machine receiving bale cotton, to open, clean, and make it into a lap.

The machine, as shown in the figure, has in fact two open-

Fig. 1531.



Kitson Cotton Opener and Lapper.

ers, each separate and complete in itself, both delivering the cotton on to one pair of screens, when the two quantities unite and pass through the rest of the machine to form the lap. The aprons run slowly, and a draft of 12 to 1 is obtained.

A second operation may take place upon a *finisher lapper*. Clarke and Pelham's three-roll sectional evener is used on the Kitson finisher lapper to vary the speed according to the varying thickness of the cotton passing into the machine. This evener has two fluted bed-rolls above which are eight sectional rolls which are saddled in pairs. Each pair of saddles has a single saddle, and above there is one which thus bears upon the whole system beneath. In the center of the main saddle is a rack operating a pinion attached to a quadrant which communicates by a chain with the belt shipper on the concave and convex cone pulleys, so as to affect the rate of feed.

Lap Ta'ble. A sewing or cutting-out table, supported in or over the lap; a lap-board.

Lard Press. A domestic press for squeezing lard from cracklings.

A *screw-down* press is shown at Fig. 2811, p. 1256, "*Mech. Dict.*"

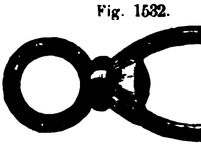
A *draw-up* press at Fig. 872, p. 274, *supra.*

Toggle motion, *Boomer & Boschert*, * "*Sc. Am.*," xlii. 242.

Lark's Head. (*Nautical.*) A form of bend; see 24, 25, Fig. 2777, p. 1240, "*Mech. Dict.*"

Lar'i-at Swiv'el. A coupling link for a lariat and picket pin, preventing the twisting of the rope as the animal wanders around the picket pin.

Fig. 1532.

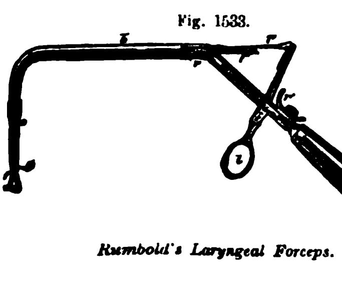


Lariat Swivel.

Lar-yn'ge-al For'ceps. An instrument for the extraction of laryngeal tumors.

The method of using the instrument is as follows: After the vertical portion *c*, being temporarily made as short as possible, has been introduced into the larynx, it is lengthened by the lever *l* pushing both rods *t'* and *f'* into the tubular portion *b c*, which causes both the smaller tube *t* and the forceps *f* to descend. As soon as the length desired is attained, the serrated rod *f'* is arrested by pressure made on the hook-shaped projection *r'* with the thumb, causing the claws to grasp and retain it. The forceps are closed by continuance of the pressure on the lever *l*, causing the rod *t'* to push the smaller tube *t* over the base of the forceps and close them upon the tumor.

Fig. 1533.



Rumbold's Laryngeal Forceps.

Lar-yn'ge-al In'stru-ments. (*Surgical.*) This includes a number of instruments, notably: —

Caustic carrier.
Powder blower.
Scoop.
Écraseur.
Electrode.
Forceps.
Inhaler.
Syringe.
Laryngoscope.
Mirror.
Lancet.
Scissors.
Tonsillotome.
Lantern.
etc.

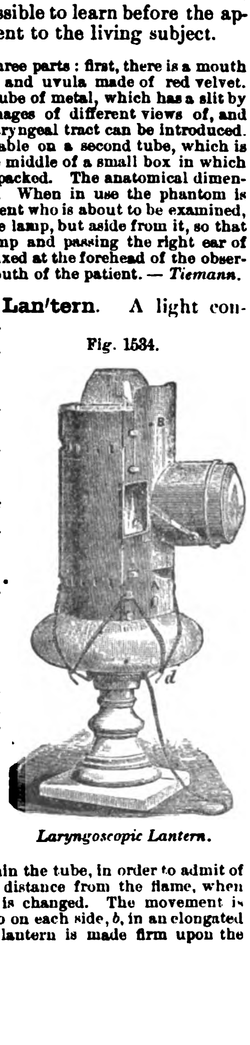
Lar-yn'go Phan'tom. An apparatus devised by Dr. Isenschmid, of Munich, and intended to familiarize medical students and practitioners with as many of the details connected with the use of the laryngoscope as it is possible to learn before the application of the instrument to the living subject.

The phantom consists of three parts: first, there is a mouth of thin metal, with tongue and uvula made of red velvet. This is fixed on a laryngeal tube of metal, which has a slit by which the thirty painted images of different views of, and different conditions of the laryngeal tract can be introduced. The laryngeal tube is movable on a second tube, which is tightly fixed on a peg in the middle of a small box in which the whole apparatus can be packed. The anatomical dimensions are taken from nature. When in use the phantom is placed like the head of a patient who is about to be examined, one or two feet in front of the lamp, but aside from it, so that the rays coming from the lamp and passing the right ear of the patient on to the mirror fixed at the forehead of the observer, are reflected into the mouth of the patient. — *Tiemann.*

Lar'yn-go-scop'ic Lan'tern. A light concentrated for use in laryngoscopic examination and operation.

Fig. 1534 shows Dr. Oliver's, which is designed for direct light, though the frontal deflector — shown in Fig. 2815, p. 1257, "*Mech. Dict.*," may be used if desired. It is an attachment to an ordinary lamp.

Fig. 1534.



Laryngoscopic Lantern.

The lantern is made up of three main portions — the front piece *A*, and two wings which hinge upon the front piece, and by which the diameter of the lantern may be increased to suit the diameter of the glass chimney. The wings are locked together at the desired point, as at *a a*. As the lens must be on a level with the flame, the tube containing it is attached to a slide *B*, which, moving in grooves in the front main piece, may be raised or lowered, as found necessary. The lens is also movable within the tube, in order to admit of its being retained at its focal distance from the flame, when the diameter of the lantern is changed. The movement is made by the sliding of a knob on each side, *b*, in an elongated opening in the tube. The lantern is made firm upon the lamp by a cord. At *c* is seen the little mirror for use in auto-laryngoscopy.

La-ryn'go-stro-bo-scop'ic Ap'pa-ra'tus. A method by Dr. Oertel, of Munich, of observing the vibrations of the vocal cords during the production of sounds.

The apparatus consists of a laryngoscope mirror, a strong light, and an arrangement by which the light shall be rapidly interrupted. The effect of the interruption of the light is to prevent the impressions made by the vibrations upon the retina from being modified before they can be perceived. The interruption may be conveniently produced by means of a perforated diaphragm revolving rapidly, and at a rate proportioned to the rapidity of the vibrations of the sounding cord; or it may be by a tuning-fork of the proper note. The interrupting apparatus must be placed between the light and the mirror, or behind the mirror, between it and the observer. By this means it is possible not merely to observe accurately the vibrations of one of the vocal cords, but also to compare the vibrations of one with those of another.

Lar'ynx, Ar'ti-fi'cial. A metallic instrument provided with vibratory reeds and attached to the upper surface of the tracheotomy tube. The removal of the natural larynx by dissection from the surrounding parts, and the invention and placing of the substitute were by Prof. Billroth, of Vienna.

Lash'ing. (*Nautical.*) For list of *whipping, seizing, lashing*, etc., see SEIZING.

Lash'ing Eye. (*Nautical.*) A spliced loop in the end of a rope by which it may be lashed fast to an object. Lower stays, block straps, etc., are thus fitted.

Lash'ing Knot. (*Nautical.*) A form of bend; see 31, Fig. 2777, p. 1240, "*Mech. Dict.*"

Latch. (*Fishing.*) A clamp for the inboard end of a fishing line.

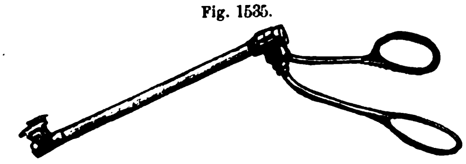
Stacey, June 2, 1868 . . . . . Patent, No. 78,546.
See also MACKEREL LATCH.

Lat'er-al Branch. A pipe with side connections. See several forms in Fig. 420, p. 129, *supra.*

Lat'er-al Cur'va-ture In'stru-ments. (*Surgical.*) A name applied to knock-knee and bow-leg braces, to some species of talipes instruments, wry neck, etc. See enumeration under CURVATURE APPARATUS, p. 236, *supra.*

Lat'e-ral Scis'sors. (*Surgical.*) A scissors

Fig. 1535.



Dr. Turnipseed's Lateral Scissors.

the blades of which approach like those of cutting pliers. Used in vesico-vaginal fistula, etc.

Lathe. See account and enumeration of 136 varieties, pp. 1261, 1263, "*Mech. Dict.*"

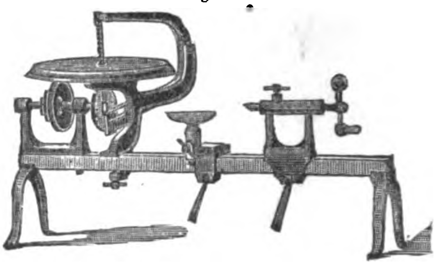
Lathe and Saw. A combination for light

Fig. 1536.



Lathe and Saw.

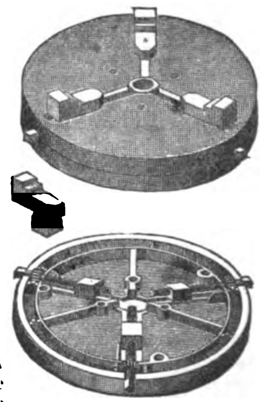
work, for amateurs and juveniles. The mandrel has a face plate with a wrist to which the lower end of the saw is attached; the upper end is connected with a spring arm.

Lathe Car'rier. A piece secured to the object in the lathe, and having a projection which collides with a stud on the face plate to cause the object to rotate in concert with the mandrel and face plate.

Fig. 1537.

Lathe Carrier.

Fig. 1538.

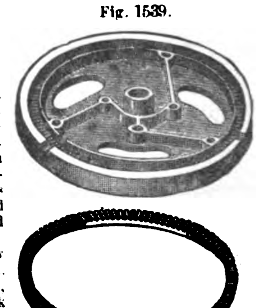


Inside Jaw Chuck.

Lathe Chuck. A device screwed to the mandrel of a lathe and grasping the object to be turned, bored, ground, polished, or what not.

Figs. 1538, 1539, show *Horton's* lathe chuck. The jaws are moved by geared screws and circular rack.

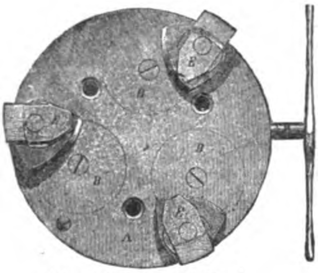
Fig. 1539.



The circular wrought iron rack is inclosed in the deep groove or recess in the back plate, the center faces of back and front plates are then turned true, which, when bolted together, makes a tight casing for the gearing, excluding dirt, chips, etc. When the rack is taken out, it makes an independent jaw chuck. The jaws are made solid, and forged of one piece of metal, and case-hardened.

Figs. 1540, 1541, show *Johnson's* universal chuck. Fig. 1540 is a face view, and represents the chuck ready for use. Fig. 1541 has a section through the edge of the body parallel with its face, the back part being removed to show the internal arrangement. Figs. 3, 4, 5, are details of construction; the jaw *E* revolves upon a steel pin in the arm of wheel *B*, to which it is also tongued and grooved, but

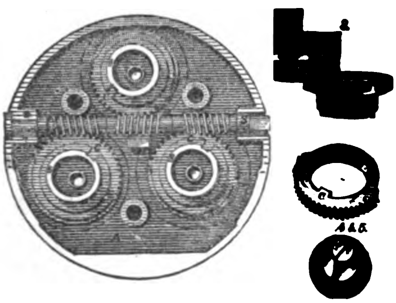
Fig. 1540.



Johnson's Universal Chuck.

which when turned to a certain position can be removed therefrom at will. The toothed ring *C* has a solid feather, and is accurately fitted and forced to its seat upon *B*. The

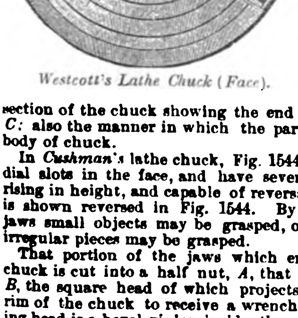
Fig. 1541.



Universal Chuck. (Section and Details.)

screw and plate *D* secure *B* in place. The worm shaft *S* is of cast steel. The toothed rings *C C C*, and jaws *E E E*, are of hammered iron, and case-hardened.

Fig. 1542.



Westcott's Lathe Chuck (Face).

Westcott's combination lathe chuck is shown in Figs. 1542, 1543.

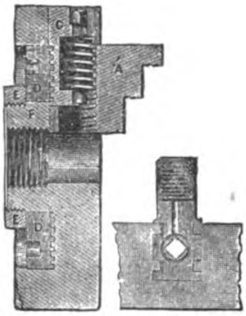
The jaws are reversible, can be made to act independently, or concentrically and simultaneously. May hold round, oval, or irregular shapes. Fig. 1542 is a face view of the chuck with one jaw reversed.

Fig. 1543 is a vertical section, showing the manner in which the ring *D* engages in box *C*; also showing the position of the screw *B*. The figure also gives a section of the chuck showing the end of the screw and box *C*: also the manner in which the parts are secured to the body of chuck.

In *Cushman's* lathe chuck, Fig. 1544, the jaws slide in radial slots in the face, and have several shoulders or steps, rising in height, and capable of reversal. One of the jaws is shown reversed in Fig. 1544. By a reversal of all the jaws small objects may be grasped, or by partial reversion irregular pieces may be grasped.

That portion of the jaws which enters the body of the chuck is cut into a half nut, *A*, that engages with a screw *B*, the square head of which projects through the face or rim of the chuck to receive a wrench. Below this projecting head is a bevel pinion inside the rim that engages with circular rack or toothed ring *C C*. Turning any one of these screws will actuate the rack and every other screw, and so far it is simply a concentric-jawed chuck. But the chuck is capable of transformation into one of eccentrically-placed jaws. The toothed ring rests upon a plain ring, *D*, *D*, the periphery of which is a screw-thread that engages with a similar thread on the inside of the shell, so that by turning the ring in one direction it is moved forward toward the face of the chuck, and by turning it the other way it is carried towards the back of the chuck. By this means the circular rack may be meshed in gear with the pinions in the screws, or disengaged from them. Should it be required to move one or more of the jaws farther from the center than the others, the spring catch is released by thumb-pressure, the supporting ring is turned out by a knob at the back of the chuck, and the circular rack unmeshed. In this condition it has the characteristics of an independent jaw-chuck. Then the jaws, one or more, may be moved singly into the position required, when the circular rack and the screw pinions may be again meshed, forming a chuck with eccentrically-placed but simultaneously moving jaws.

Fig. 1543.



Westcott's Lathe Chuck (Section).

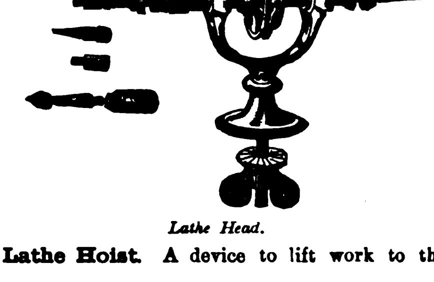
Lathe Dog. A piece to be attached to an object in a lathe to cause it to revolve with the lathe spindle. A *lathe carrier*.

See also CLAMP DOG, Fig. 625, p. 198, *supra*.

Lathe Head. The working part of a jeweler's or laboratory lathe; attachable to a lathe or stand, and driven by a cord from any pedal motor.

The illustration is White's dental lathe with burs, extension pieces, cone chucks for polishing cones, etc.

Fig. 1546.



Lathe Head.

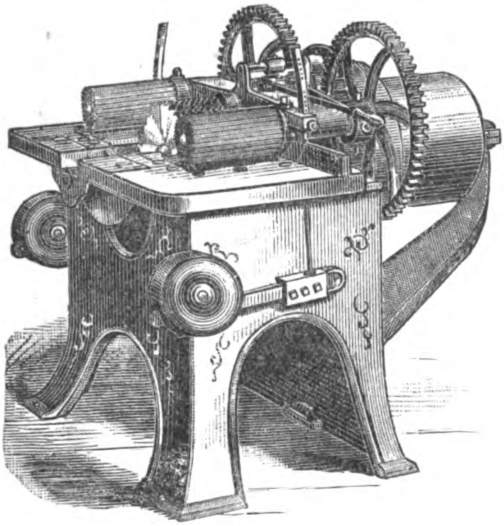
Lathe Hoist. A device to lift work to the height of the lathe centers in order to be placed in the lathe.

See Axle-lathe Hoist, *Thomas*, * "*Railroad Gazette*," viii., p. 289.

Lath Mill. A gang-saw, for sawing lath from the bolt.

The gang of saws in *Smith's* lath mill occupies a space 10″ in width, so that in cutting ⅛″ lath 16 saws may be employed. Plank of any width may be passed. The feed

Fig. 1547.



Smith's Lath Mill.

works consist of four rollers which may be started or stopped at will; the two upper rollers are weighted and driven by power. The rates of feed are 35′ to 45′ per minute. To prevent the lumber from springing and binding the saws a steel comb is attached to the bed, with teeth projecting upward, directly in the rear of the saws.

In the *Leonard & Silliman* machine the annular saws are separated by rings on a cylinder keyed on to the main shaft. The interior of the cylinder has spiral wings, which make a draft, and draw away the dust.

Lathing machine, *Trimble* * "*Scientific Amer.*," xxxiv. 131.

Lat'i-mer-Clark Bat'te-ry. (*Electricity.*) A battery designed as a standard, having a perfectly constant electro-motive force.

It consists of a combination of zinc in sulphate of zinc, and mercury in sulphate of mercury.

This battery has an electro-motive force of 1.4578 volts in absolute measurement.

"*Phil. Trans. Royal Society*," June 19, 1875.

Niaudet, Am. transl., 148.

Lat'rine. A water-closet for public use; the hoppers are flushed periodically.

Jennings . . . . * "*Manufacturer & Builder*," viii. 154

Lat'tice. A form of screen made of intersecting overlaid slats.

A form of girder having series of flat bars laid crosswise and riveted at the intersections, or at the junction with the upper and lower members, or both. See Iron Bridge, p. 120, "*Mech. Dict.*"

Launch. Formerly: the largest of the suit of boats attached to a man-of-war.

Now: a large boat with steam power.

The Thorneycroft (Br.) launches have acquired most distinction.

One of these attained at Cherbourg a speed of 19 knots per hour; and 18 knots for two consecutive hours, developing 220 horse-power. The dimensions were —

Length, 63.04′.
Beam, 8.53′.
Draft, 2′ (average).
Displacement, 15 tons.
Weight of hull, 9,900 pounds.
Weight of engine boilers and water, 16,060 pounds.
Power at speed of 18¾ knots, 220 horse.
Weight of machinery, 72.6 pounds per horse power.

The engines are condensing, two cylinder, on the compound system. The boilers are of the locomotive type, with the difference that the tubular surface is reduced about one half. This is the only sacrifice which has been made for the economic production of power; and it was necessary in order to reduce the weight of the apparatus. The safety valves are loaded to 132 lbs. The engine makes 430 revolutions per minute, which requires great mechanical excellence of the mechanism, and especially of the air-pump. The consumption of coal per horse power per hour is 3.52 lbs. The grate surface is 11.19 square feet. An artificial blast is conducted directly to the fire chamber instead of to the ash-pit.

The screw shaft is placed on a level with the keel, instead of being at a point half way between the keel and the waterline, as is usually the case. The screw then projects below the keel for nearly half its diameter, and consequently it acts upon a section of vein greater in area than the greatest section of the vessel. This arrangement doubtless contributes materially to the speed; while a sharp bend of the keel protects the propeller from damage.

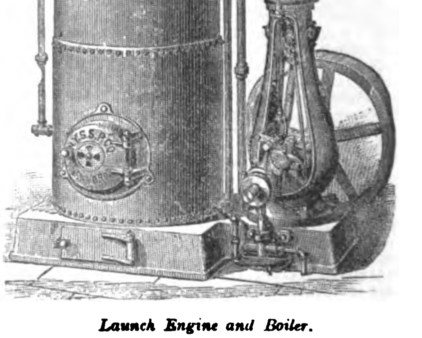
Launch En'gine. A relatively small engine, for use in launches, large boats acting as tenders, police boats in harbors, etc. A small class of surveying and pleasure steamers are also called launches.

The engine and boiler of the *New York Safety Steam Power Co.* are shown in Fig. 1548, and a section of the boiler in Fig. 1549.

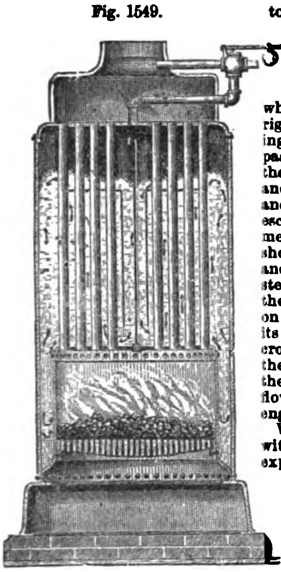
The engine is upright, having the cylinder mounted on

Fig. 1548.



Launch Engine and Boiler.

Fig. 1549.



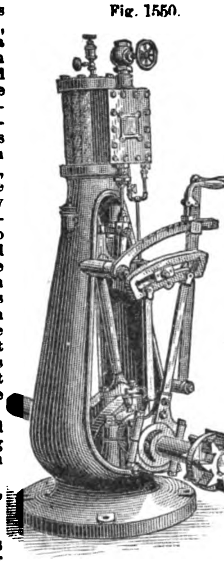
Launch Engine Boiler.

top of the bottle-shaped frame, which has two large openings at each side for access to the working parts. The fly-wheel, being at the base, secures steadiness. The engine has a plain slide-valve, and the slides are concave and cast with the frame. In Fig. 1548 the engine is shown combined with the boiler, both being placed on a cast-iron base which forms the ash-pit, and also contains the heater. An upright tubular boiler, Fig. 1549, is used, and, to prevent priming, a baffle-plate is introduced, through which all the tubes pass at or about the water-level. A large tube hangs from the center of this plate nearly to the crown of the furnace, and an annular space is left around the outside of the baffle and between it and the outer shell, sufficient for the easy escape of the steam and water. The effect of this arrangement is to stop the current of steam and water tending to shoot up between the tubes, and compel it to flow outward and escape between the baffle and shell, at which point the steam and water separate, most of the water flowing down the side of the shell, while the remainder of the water falls on the top of the baffle-plate and flows through the tube in its center, thus keeping up a current over the center of the crown sheet and among the tubes. It will be observed that the steam is taken off from the center of the boiler; and as the steam is delivered at the outer edge of the baffle it must flow inward between and around the tubes on its way to the engine and become dried and slightly superheated.

When designed for a steam launch the engine is provided with a link-motion for reversing, and notches for working expansively. The feed-pump is driven by an eccentric on the shaft.

Fig. 1550 shows the engine as detached from the boiler, and having the provisions just cited.

Fig. 1550.

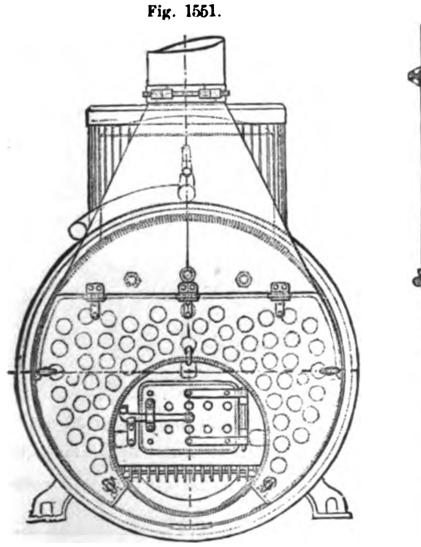


Launch Engine.

Figs. 1551 to 1555 show the launch engines of a United States cutter, having a length of 33′; beam, 8′ 7″; and depth, 3′ 9½″.

The boiler is of the ordinary multi-tubular type, and consists of a shell 3′ 4½″ in diameter outside, with a furnace 20½″ in external diameter, all the plates of the shell and furnace (including the tube-plates) being ¼″ thick. The boiler is provided with 60 return tubes 3′ 1½″ long over tube-plates, 58 of these tubes being 2″ in diameter outside and

Fig. 1551.



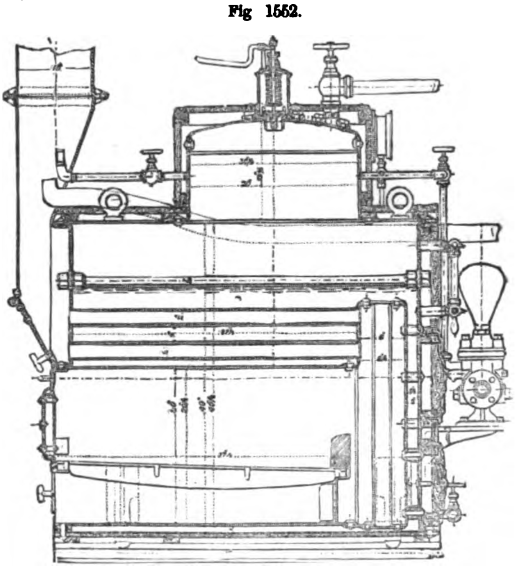
United States Launch Engine. (Cross Section of Boiler.)

the other two 1½″ in diameter. The fire-grate area is 4.5′ square, and the total heating surface 125′ square. A dome 20″ in diameter, and 13¾″ high, is fixed at the top of the boiler, and the latter is fed by a donkey pump bolted to it at the back end. The details of the boiler and its fittings will be readily understood from the figures, and the weight of the boiler complete, as shown, is 2,350 lbs. The general arrangement of the fittings is neat.

The cylinder is 8″, stroke 10″, and the engine weighs 725 lbs., the weight being rather heavy, owing to the somewhat singular arrangement adopted to obtain a long connecting-rod, and still keep the cylinder down tolerably close to the crank-shaft. The engine has a connecting-rod 26″ — or 2.6 times the stroke — in length, and its height from center of crank-shaft to top of upper cylinder cover is 38″ or 3.8 times the stroke.

As will be seen from Fig. 1555, the piston-rod, instead of being coupled direct to the connecting-rod, is screwed into a

Fig 1552.



Launch Engine. (Longitudinal Section of Boiler.)

cross-head from which a pair of side rods extend upward terminating in blocks working in guides formed at the sides of the cylinder. The connecting-rod is made with a wide fork, and takes hold of pins forged in one piece with the side rods and blocks just mentioned.

The link motion is used only for reversing and not for expansive working, the link being made with a straight slot, and provision being only made for fixing the block in extreme position by the arrangement shown. The valve is driven through the intervention of a rocking shaft and levers.

Laun'dry Ap'pa-ra'tus. Plate XXV. shows the interior of a French steam laundry with the apparatus in position and their names indicated beneath. It comprises the fittings made by Pierron & Dehaître, of Paris.

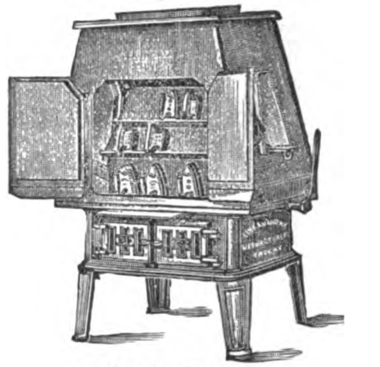
Laun'dry Boil'er. A water heater for laundry purposes. See figure in Plate XXV.; also KETTLE, *supra.*

Lav'a-to-ry. A wash-room.

Jennings . . * "*Manufacturer & Builder*," viii. 259.

Laun'dry Stove. One for heating water and smoothing irons for laundry purposes.

Fig. 1556.



Troy Laundry Stove.

The Troy laundry heater, shown in Fig. 1556, heats at one time 40 sad-irons or 80 polishing irons.

Another form has less capacity for irons, but has a large belt around it in which water is heated and whence it is conducted by pipes to the tubs.

See also IRONING STOVE, Fig. 1467, p. 506, *supra.*

Lawn Hose Cart. A small vehicle for garden and yard hose.

See HOSE REEL, Fig. 2585, p. 1132, "*Mech. Dict.*"

Lawn Mow'er. A machine for cutting sward.

Hill's archimedean lawn mower is mounted on a roller, the shaft of which has a spur pinion engaging a wheel which transmits a multiplied motion to the spiral knives which cut against a straight edge, and shear off the grass in the manner of scissors. Wheels in front gage the closeness of cut.

Fig. 1559 is the "Charter Oak" lawn mower, having two supporting wheels; multiplying gearing gives the rapid motion to the spiral knives. A larger size is made to run by pony. Some American and British forms have capacious boxes to catch the mown grass.

Fig. 1557.

Hill's Archimedean Mower.

Ohmer's machine has crank and reciprocating sickle.

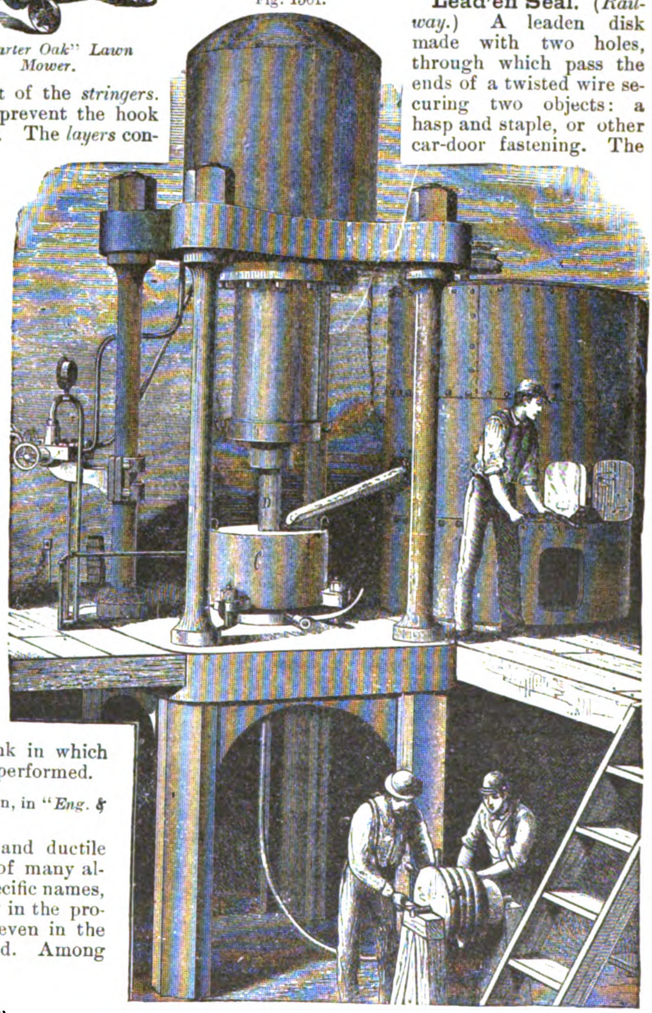
Lead'en Seal. (*Railway.*) A leaden disk made with two holes, through which pass the ends of a twisted wire securing two objects: a hasp and staple, or other car-door fastening. The

Fig. 1561.



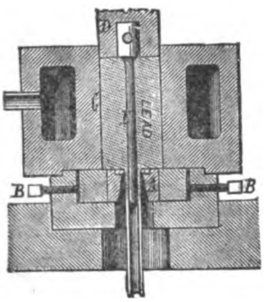
Lead Pipe Making.

lead is then pressed down by a stamp and the fastening cannot be detached without cutting the wire or defacing the seal.

Lead'er. (*Fishing.*) A net so placed as to intercept fish and lead them into a pound, weir, trapnet, etc. See POUND. It is a net fence that guides the fishes which attempt to get round it into the heart. It is usually made in pieces 10 rods in length. See HEART SEINE, *supra*.

Lead Pipe. The lead pipe press is shown in perspective in Fig. 1561, on page 533. Lead pipe is made by forcing the congealed lead through a die, in the axis of which is a mandrel, as shown in Fig. 1562. The hydraulic press is used.

Fig. 1562.



Lead Pipe Die.

The die *A* is a metallic disk which fixes the outside diameter of the pipe, and is adjustable by set screws *B B* to bring it in line. The lead receptacle *C* is heated by steam. *D* is the press plunger and from it depends the core or mandrel *E*, which occupies an exactly axial position in the die and determines the bore of the pipe. The plunger being raised, a charge of metal is run into the chamber; the plunger is then depressed and forces the metal out in the annular space between the core and the die. The pipe is reeled up as made.

Tin-lined pipe is made by a modified process. Before the lead is run into the chamber, a mandrel is inserted, which closes the die aperture and extends up through the receptacle. This mandrel consists of a central stem, around which are grouped dovetailed sections, so that when the central portion is removed the sections are easily taken out, leaving a hollow space in the lead, which is run in while the mandrel is in place. The sides of the mandrel are tapered, or rather crenelated, there being three or four shoulders and a different taper from each. The object of this is that after the mandrel is removed, the tin which is poured into its place may have several purchases against the lead which surrounds it. Before the tin is let in the core is inserted. Afterwards the pressure is applied in the usual manner, the result being that the pipe emerges with a thin lining of tin.

Protecting from corrosion by water: —

Treat for 15 minutes with a 2 to 5 per cent. solution of sulphuret of potassium or sodium at 212° Fah. *Dr. Schwartz*, Breslau, No. 1,519, British Patent Reports, 1863.

A boiling solution of sulphur in caustic answers the same purpose.

Or, "by causing a warm concentrated solution of sulphide of potassium to flow through the pipe for 20 minutes." "*Revue Industrielle.*"

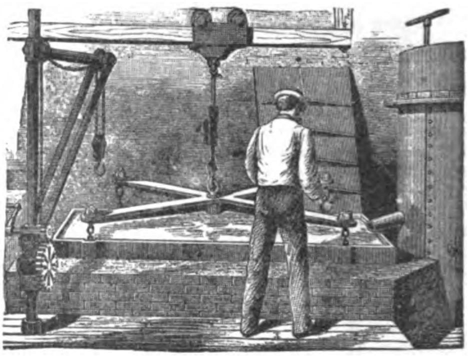
Lead Sheet. Sheet lead is made by running a flat ingot of lead repeatedly through a rolling mill until the required thickness of the sheet is reached.

The lead is run into a flat cake weighing about 4 tons, and having a size 7′ 10″ × 5′. After cooling in the mold, which takes some days, it is lifted out by the crane and carried by the overhead tackle to the mill, where, after the edges have been adzed true, it is passed and repassed between the rolls some 150 times, till it becomes 30′ × 7′ 10″, the original longer dimension being maintained, while the narrower dimension of 5′ has become 30′, more or less, according to the original thickness and the degree of tenuity or thinness of the rolled sheet, say a weight of 30 pounds to the square foot. The sheet is then cut up by vertical knives actuated by a screw, in a frame which is adjusted so as to cut across

Fig. 1563.

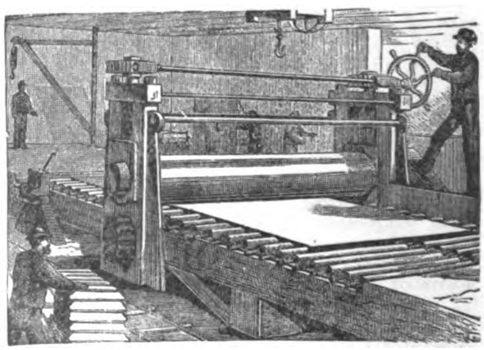


Melting the Lead.

the bed of the mill, and between two of the supporting rollers shown in Fig. 1564. The sections of lead are again rolled into 18′ lengths, varying in weight from 2½ to 10 pounds per square foot, according to the purpose for which they are required.

The mill has a cylinder 30″ diameter and 9′ long, and the bed is a double series of parallel rollers upon which the lead traverses. The vertical adjustment of the ends of the roll are performed simultaneously by hand-wheel at one end, com-

Fig. 1564.



Sheet-lead Mill.

mencing by gearing with the boxing of the roller at the respective ends of the latter.

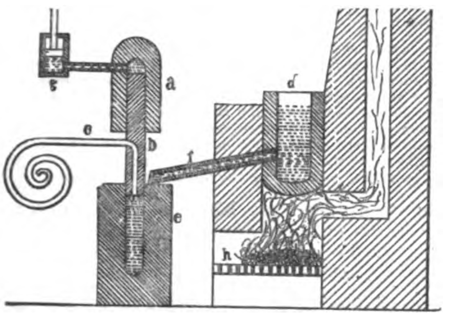
Chinese sheet-lead for lining tea-chests is made by pressing between tiles faced with several thicknesses of unsized paper. These plies act as a non-conductor.

Lead foil with tin surfaces is made by rolling an ingot of lead with layers of tin run upon each side, so as to sandwich the lead between the two. The compound ingot is rolled and re-rolled until the required thinness is attained.

Lead Soap. An insoluble oleate of oxide of lead; spread on cloth to form *diachylon* plaster.

Lead Wire. The apparatus for making lead wire is a copy in miniature of the lead-pipe apparatus.

Fig 1565.



Lead Wire Apparatus.

a. Hydraulic press.
b. Piston perforated with a hole for emission of the lead wire *c*.
f. Pipe for conducting melted lead from furnace *d* to compressor *e*.
g. Force-pump that supplies water to the hydraulic press.
h. Grate bars.

The lead is heated in a pan, conducted to the cylinder of the hydraulic press, forced thence in a wire having the size of the aperture through the plunger, and coiled on a shaft.

Leaf Sight. A form of sight having a hinged plate, known as a *leaf*, and erected for use, but lying flatly on the barrel for safety at other times.

The leaf is graduated for distance, say for from 100 to 1000 yards, and the slider with the sight notch is raised so that the upper surface coincides with the required graduation. See also HAUSSE, Figs. 1329-1331, p. 447, *supra*.

Fig. 1566.

Sporting Leaf Sight.

Leak'age Valve. A small valve used between the triple valve and the brake-cylinder in the Westinghouse car-brake arrangement, to prevent the leakage from the pipes from operating the triple-valve, and thus applying the brakes. See TRIPLE VALVE.

Leak Stop'per. An apparatus for the forcible application of a tampon against the side of a leaky shaft.

See * "*Engineer*," xlv. 373. A segment is forced against the breach by means of a hydraulic jack, then keyed up and wedged.

Leath'er. Tanned or tawed skin.

The principle of tanning: "Take the skin of an animal, remove from it the hair, fat, loose flesh, and other impurities, and immerse it in a dilute solution of tannic acid; the cellular and elastic tissues will gradually combine with that substance, as it penetrates toward the interior, and will form a compound perfectly insoluble, and which will completely resist putrefaction; this compound is leather." — *Lieut. Lyle*.

The treatment of hides and skins to make the various kinds of leather, including the work of the tan-yard and currying shop, is succinctly told in *Lieut. Lyle's* appendix K to "*Ordnance Report*," 1878, pp. 61-89, under the following heads: —

Sole leather.	Grain leather.
Harness leather.	Wax leather.
Bridle leather.	Polish leather.
Collar leather.	Oil-pebble leather.
Buff leather.	Trunk leather.
Splits.	Lace leather.
Mixed leather.	Bellows leather.
Skirting leather.	Belting.
Latigo.	Calfskins.

Leath'er, Ar'ti-fi'cial. A material made to resemble leather; it sometimes consists of leather waste and scraps agglutinated; or of paper or cloth treated with paints, resins, etc.

See LEATHER, IMITATION, and references *passim*.

Leath'er Board. Leather scraps and manilla of old rope, ground into a pulp, made up in the manner in straw board, and calendered. An article in very great use, not alone in the soles of cheap shoes, but for making drums, chair-seats, toys, etc.

Leath'er Ce-ment'.

Molesworth.	Gutta percha	16
	India-rubber	4
	Pitch	2
	Shellac	1
	Linseed oil	2

melted and mixed.

Water-proof Cement: Chase.

Ale	1 pint.
Russia isinglass	2 ozs.

Dissolve, and add common glue, 4 ozs.; then add slowly, linseed oil, 1¼ ozs., stirring well. Dilute in ale, put on hot with a brush, and weight the objects united.

To fasten Leather to Iron: Steep the leather in infusion of gall-nuts. Spread hot glue on the metal. Apply leather under forcible pressure, and allow it to dry without relieving pressure.

For joining pieces of leather: —

Bisulphide of carbon	10
Turpentine	1

Add gutta percha to thicken the composition. Free the leather from grease, and press the joint till the cement is dry.

Water-proof Cement. Moore: Gutta percha dissolved in bisulphide of carbon. Warm the parts, and maintain the pressure till dry.

Leath'er Cloth. An imitation leather. See Leather, Imitation.

Leath'er Dress'ing.

Castor oil.

An adhesive: printer's ink.

For belts:	Beef kidney tallow	1
	Castor oil	2

An adhesive, powdered chalk.

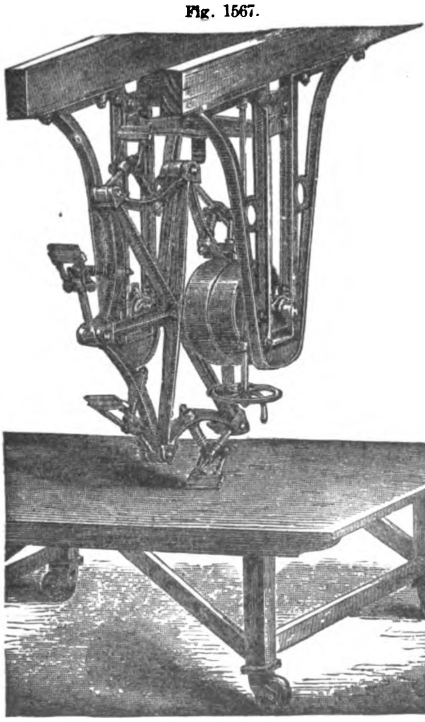
For belts:	Fish oil	4
	Lard or tallow	1
	Colophonium	1
	Wood tar	1
Or:	Tallow	2
	Bayberry tallow	1
	Beeswax	1

Heated to boiling, and laid on with a brush, and the beeswax driven into the belt by holding a hot iron plate against it.

See also Harness Grease, p. 439, *supra*.

Leath'er-ette'. An imitation of leather. A compound of fiber and some agglutinating materials, finished by passing between leather-covered rollers to give the surface imitation. See Leather, Imitation.

Fig. 1567.



French Leather Finishing Machine

Leath'er Fin'ish-ing Ma-chine'. A machine for giving the texture and surface finish to leather by means of a vibrating slicker or roller, according to the requirement.

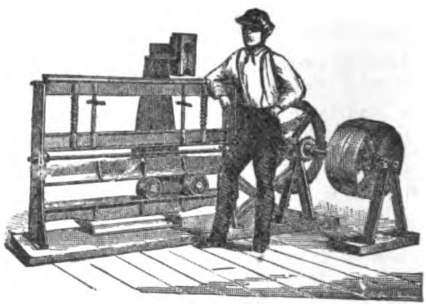
Graining, glossing, glassing, slicking, polishing, pebbling, dicing, are all terms within the definition of *finishing*.

The machine shown in Fig. 1567 has tools revolved by machinery, the pressure being due to a spring at the back of each tool-stock. The leather is upon a table on casters, so that a fresh surface of leather can be brought within the range of the tool by moving the table. The tool-head is a hexagonal frame, like a six-spoked wheel, and as it revolves each of the six slickers (for instance) in turn presses upon the surface of the leather. A hand-wheel adjusts the pressure by raising or lowering the boxing of the wheel.

Leath'er Gla'zing Ma-chine'. One for giving a surface gloss to leather. The glassing tool is reciprocated over the skin, compacting the surface, giving it a polish, and raising the grain.

The reciprocating tool, in imitation of the hand, is shown in Leather Finishing Machine, "*Mech. Dict.*," *et supra*. The *Baker* machine, shown at Fig. 1568, is a more compact form,

Fig. 1568.



Leather Glazing Machine.

and has all the strain within itself. It is shown without the table on each side on which the skin lies. The machine occupies a narrow space between two tables, and the skin passing across the interval rests on a bed, and its upper surface is subjected to the pressure of the *glass* which reciprocates above it, being effective on one stroke, and the pressure relieved on the return.

Leath'er Grease. See Leather Dressing; Harness Grease.

Leath'er, Im'i-ta'tion. See the following recipes: —

Paper treated with dilute sulphuric acid, so as to become toughened. Parchment paper.

Leather parings and caoutchouc worked by a machine into a homogeneous fibrous mass, gelatinized with ammonia water, and rolled into sheets, or pressed in molds. — *Sören Sörenson*, "*Deutsche Industrie Zeitung.*"

Leather fibers from leather offal, treated like paper stock; made into a pulp, mixed with flax fiber, and then treated as in paper manufacture. — *Rice, Kendall & Co.*

Sheets of carded wadding placed on polished heated metallic plates, and then saturated with a decoction of pearl-moss, fucus, or laminaria, and dried. The metal gives a polished surface to the material, which is then rolled between heated rollers, to give it compactness and the required thinness. It is then coated with boiled linseed oil and dried by artificial heat. When dry, coat with vegetable wax, and soften by passing between fluted rollers. It is then surfaced by rollers, which give it the appearance of morocco, pig-skin, or what not; or is varnished, bronzed, enameled.

Thicken decoction of fucus with cotton waste, and treat as paper pulp, or papier-maché.

Cocoa-nut fiber or waste of rope, hemp, or flax, treated with fucus, or any mucilage, and rolled into floor cloth.

Cork powder and caoutchouc. See Camptulicon, p. 435, "*Mech. Dict.*"

Cork powder incorporated with paper pulp. See Cork Board, p. 220, *supra*.

Caoutchouc or its analogue compounded with camphor and sulphur, and vulcanized. — *Gerner*. See Hevrenoid, p. 457, *supra*.

Heavy cotton cloth treated with dilute sulphuric acid, and then saturated with resinous compounds or paint.

Asbestos treated with gums, pigments, etc.

Leather ground into fiber, mixed with vegetable fiber, saturated with gummy solutions and paint. See BOULINIKON, p. 124, *supra*.

A number of compositions are given under LEATHER, ARTIFICIAL, pp. 1276, 1277, and LEATHER PAPER, p. 1278, "*Mech. Dict.*"; they consist of various materials compounded or associated: fiber, gums, resins, oils, gelatine, leather scraps, clay, gypsum, oxides, pigments.

Some compositions resemble leather in its more solid aspects as molded, but have not the pliability which is an ordinary characteristic of leather.

Such are *Bois-durci*, p. 320, "*Mech. Dict.*"
Bonesilate, p. 130, *supra*.

See also other titles under COMPOSITIONS, p. 212, *supra*.

"*Manuf. & Builder*," iv. 143; vi. 78, 192, 339; vii. 275.

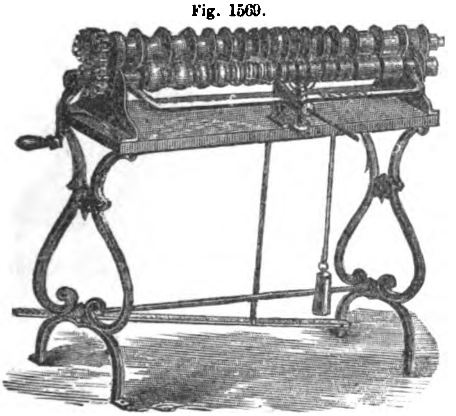
Millwood, "*Technologiste*," xli. 243.

"*Scientific American Supplement*," 185, 227, 692.

See also LEATHER BOARD; LEATHERETTE; LEATHER CLOTH; LEATHEROID; LEATHER WASTE.

Leath'er-oid. An artificial substance resembling leather in appearance, and serving as a substitute for it for some purposes. It is made in two varieties: one soft and flexible, the other like vulcanized rubber, and susceptible of a polish. See LEATHER, IMITATION.

Fig. 1569.



Raising and Creasing Machine.

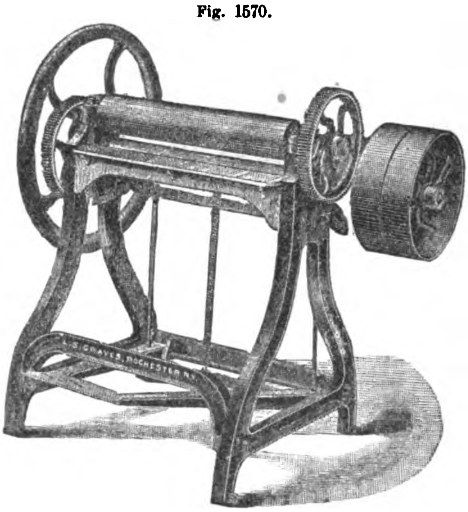
Leath'er Rais'ing and Creas'ing Ma-chine'. A machine for ornamenting straps, leather reins, saddle skirts, etc., by raising a ridge, giving a molded or wavy edge, or what not, according to the pattern of the rollers, between which the dampened leather is passed.

Fig. 1569 shows a machine with a numerous assortment of passes of varying widths and patterns, adapted to raising, creasing, stretching, polishing, and waving.

Leath'er Rol'ling Ma-chine'. A machine to compress and harden leather, as a substitute for the hammer and lap-stone.

The one shown in Fig. 1570 is a small-sized machine,

Fig. 1570.



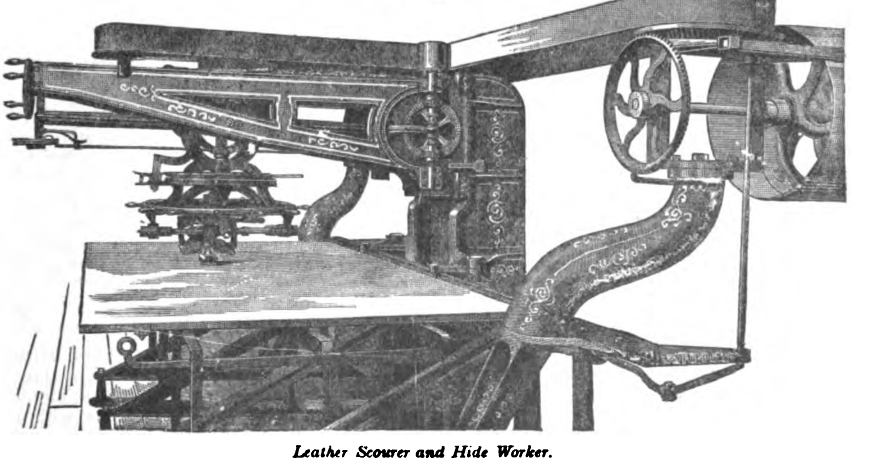
Leather Rolling Machine.

adapted to be run by hand or by power. The pressure, is given by the weight of the operator on the treadle, transferred by levers to the upper roll.

Leath'er Scour'ing Ma-chine'. A machine for working tanned and curried skins, bringing the pressure of a reciprocating tool upon the hide in successive strips as the skin is moved beneath it from time to time in a direction transverse to the motion of the tool.

The texture and elasticity, as well as the surface appearance of the leather depend upon this intermittent pressure, which glazes the surface and raises the grain, while also affecting the body of the leather. The machine simulates the

Fig. 1571.



Leather Scourer and Hide Worker.

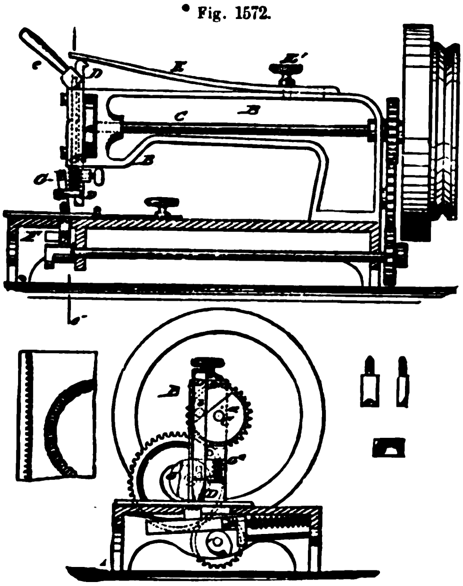
hand processes in reciprocating a comparatively narrow tool in direct lines over the surface, a strip at a time. Under LEATHER FINISHING, and LEATHER GLAZING, machines similarly actuated are shown. See also LEATHER MACHINERY, pp. 1277–1282, "*Mech. Dict.*"

Lockwood's machine, Fig. 1571, is capable of any required pressure, is universal in its movements, and so far automatic that the strength of the finger will guide its movements. It will scour, set out, or gloss; will take a slow or quick, a long or short stroke.

Leath'er Stamp'ing Ma-chine'. A machine for producing ornamental designs on leather for saddle flaps, carriage aprons, chair and sofa seats and backs, books, portfolios, etc.

Urner's machine is shown in Fig. 1572. The upper revolving shaft, *C*, works the stamp rod *D*, which moves in a guide in the arm *B*, and is acted upon by a band spring, *E*.

* Fig. 1572.



Leather Stamping Machine.

The spring may be adjusted by the clamp screw *E'*. The shaft *C* raises the stamp rod by means of a cam, *a*, which engages with a friction roller, *b*, on the rod; on being released from the cam, the rod is brought down forcibly by the spring. Either of the variously-shaped stamping bits may be clamped into the lower portion of the stamp rod *D*. The leather is fed by a vibrating feed mechanism, *F*, and retained by a presser wheel, *G*, which is attached to an arm on a presser rod, G^2, which is pushed down by a coiled spring, and raised or lowered by the lever *e*. A piece of leather, as marked by the machine, is shown at the side. The mechanism is operated by the belt wheel and gearing on the right.

Leath'er Waste. Utilized in the making of imitation leather by various processes. That of Sörenson, of Copenhagen, is as follows:—

The leather waste is first washed, after which it is reduced, by tearing, stamping, cutting, rasping, or rubbing, to a uniform and fibrous condition. When reduced to this finely divided condition, the leather is treated with ammonia water, by which it is converted into a gelatinized mass, which, when pressed into molds, or rolled out between rollers, and dried, makes a very hard and stiff product, having considerable cohesiveness, but without elasticity and soluble in water.

To make an elastic and water-proof fabric, the material is treated with caoutchouc dissolved in benzine, the mass kneaded, and then rolled or pressed into shape.

"*Bay. Industrie u. Gewerbe Blatt*" . . . viii. 140.

Leath'er Wa'ter-proof'ing.

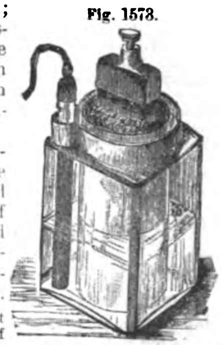
MacKenzie. Mixture of drying oil and oxides of lead, copper, or iron; or gummy resins in place of oxides.

Or: Caoutchouc shredded into and dissolved in warm copal varnish.

Or: Glue, 12 ozs., dissolved in water. Add Rosin, 8 ozs. Melt, and add Turpentine or benzine, 4 ozs.

Leath'er Whi'ten-ing Ma-chine'. (*Leather.*) A machine for doing the work otherwise performed by the knife at the beam; cleaning the hide by passing the knife with a fine edge lightly over the flesh side to bring it to a clean and fit condition for waxing.

Fig. 1573.



Leclanché Battery. (Porous Cup.)

Le'clanché Bat'te-ry. (*Electricity.*) One having its amalgamated zinc in a dilute solution of chloride of ammonium, and the carbon plate in a mixture of peroxide of manganese and coke. Fig. 1573.

In the Leclanché improvement the positive pole is composed of a plate of carbon inserted between, and in connection with two compressed prisms of peroxide of manganese and carbon (with a small cylinder of bisulphate of sodium in the center of the electrode), the three being held firmly together by rubber bands. The object of the acid salt is to prevent the formation of the oxychlorate of zinc.

Fig. 1574.

Leclanché Battery. (Prism.)

The negative pole is composed of a pencil of amalgamated zinc.

The two poles are set in a solution of sal-ammoniac and water contained in a glass jar, with a cover through which the carbon head and the zinc project.

As the zinc is indefinitely preserved without alteration in the sal ammoniac, and as the peroxide of manganese is insoluble in this liquid, no internal chemical action takes place when not in use.

Leech, Ar'ti-fi'cial. A form of uterine leech and aspirator by Dr. Reese, for depleting the engorged neck of the uterus, is a graduated glass cylinder 7½" long and ½" diameter, with a piston, through which is conducted a metallic rod with a spear point. The point is retracted by a spring after puncturing, and the blood aspirated by withdrawing the piston. — *Tiemann.*

Len-tic′u-lar Knife. (*Surgical.*) A scraper used in osteotomy. A sharp-edged disk is attached to the end of a staff, in a plane at right angles to the handle.

Let′ter Bal′ance. Scales graduated for letter postage. Usually in two sizes: one varying from ¼ ounce to 8 ounces; the other from ½ ounce to 4 pounds. The latter to include printed matter.

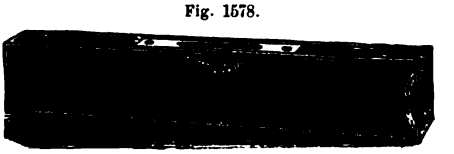
One form of letter balance has two beams, one graduated to ounces and fractions, and the other to metric weights.

Lev′ee. See Jetty.

Lev′el. 1. An instrument for determining horizontality. The subject is treated on pp. 1293 *et seq.*, "*Mech. Dict.*"

The machinist's level is shown in Fig. 1578. It has brass side-views, brass top and end plates, and corners, protected by ¼″ square rods extending the entire length of the rosewood staff.

Fig. 1578.



Machinist's Level and Plumb.

2. A level, used by Prof. Aita in the survey of Padua, for drainage and water service, was devised to overcome the difficulty of leveling in tortuous streets.

It consists of two glass tubes, doubly clamped to graduated staffs, and connected by a caoutchouc tube of any desired length. The two clamps are movable, the glass tubes being partly, and the connecting tubes wholly filled with water. The observers at the respective ends bring the clamps to the levels of the water in the respective tubes, and each enters the scale-reading in his note book. When the books are compared, the difference of readings give the difference of altitudes.

3. Attached to a gun to indicate its exact position.

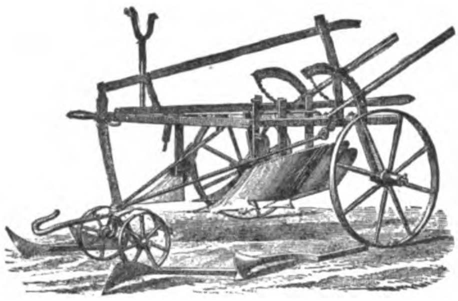
See *Simms'* "LEVELING."

Lev'el-ing Plow. One for plowing down ridges thrown up in some forms of row culture; beets, for instance.

Fig. 1579 is a French form by *Delahaie-Tailleur & Bajac*, of Liancourt, which is adapted for a still greater breadth. The shares are thrown into or out of the soil by a single lever, and their working depth is regulated by the two rear levers,

Fig. 1579.



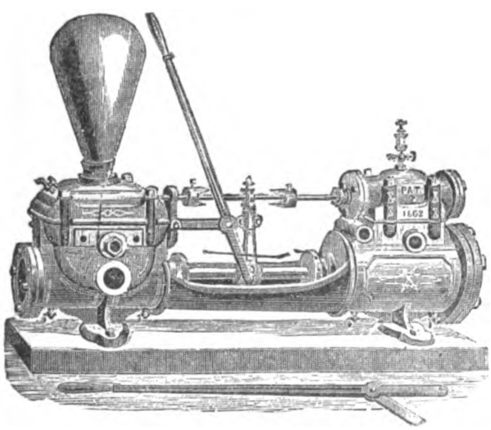
French Leveling Plow.

which actuate the bent axles of the hind wheels, so that the plows may penetrate the depth desired, or, as in the figure, be lifted clear of the soil in moving from place to place.

Lev'el-ing Screw. (*Milling.*) One in the hurst of a mill, acting against an iron plate in the back (beneath) of a bed-stone in order to adjust it vertically and bring it to an exact level. The runner is then *trammed* in accordance therewith.

Lev'er. (*Steam Engine.*) A hand-rod for moving the valves in the starting or reversing of an engine.

Fig. 1580.



Knowles' Steam Pump.

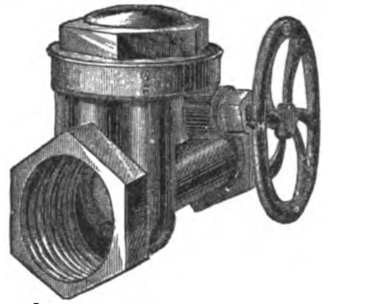
Fig. 1580 shows the hand-power lever of a steam-pump, and the lever detached.

(*Fire-arm.*) The piece by which the gun is opened or closed in some forms of breech-loaders. It may be *top, side,* or *under* lever. Examples are found in the Douglas, Henry, Maynard, and other rifles.

Lev'er and Cam Valve. A form of valve for gas or water mains.

The gate *A* moves on guides *B B*, which are arranged to

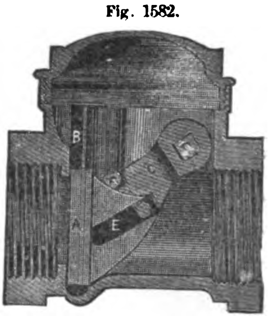
Fig. 1581.



Lever and Cam Valve. (*Perspective.*)

prevent friction by keeping the gate, when moving, from contact with the seat and wall of the valve chamber. The gate is opened and closed by means of the lever arm *C* attached to the rock shaft *D* and working in the slot *E*. When the gate is nearly down, the cam *F* forces it forward and down to its seat. One quarter turn of the wheel, which may be replaced by a straight arm or lever, opens or closes the valve.

Fig. 1582.



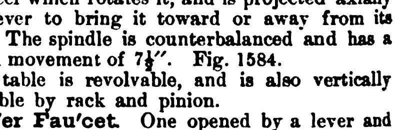
Lever and Cam Valve. (*Section.*)

Lever valve, *Young*, Br., * "*Engineer*," i. 494. * "*Sc. Am.*," xxxix. 19.

Lev'er Com-pres'sor. (*Optics.*) A means for applying pressure to an object whilst under examination with the microscope.

A screw is attached to a lever carrying a piece of glass and working on another plate in which a second glass is fixed and upon which the object is placed.

Fig. 1583.



Lever Compressor.

Lev'er Drill. A machine tool in which the tool spindle works with a spline in the socket of the wheel which rotates it, and is projected axially by a lever to bring it toward or away from its work. The spindle is counterbalanced and has a vertical movement of 7½". Fig. 1584.

The table is revolvable, and is also vertically adjustable by rack and pinion.

Lev'er Fau'cet. One opened by a lever and closed by a spring. See *a*, Fig. 232, p. 81, *supra.*

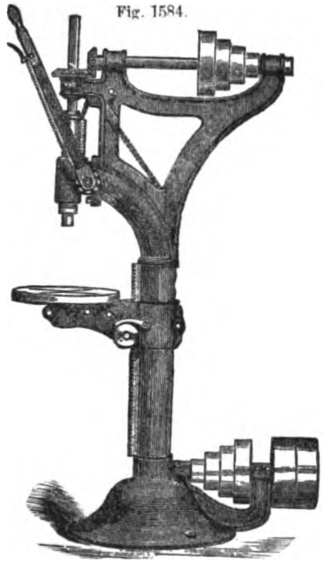
Lev'er Hand'-car. (*Railway.*) One worked by levers connected to cranks.

Lev'er Han'dle-cock. A faucet, the handle of which projects as a lever on one side only. See Fig. 234, p. 81, *supra.*

Lev'er Hook. (*Fishing.*) One so arranged that when the fish pulls at the bait, another hook strikes it and makes it fast. See list on p. 341, *supra.*

Lev'er Pla'ter. A form of calendering machine in which the force of compression is applied through the instrumentality of levers. See PLATER.

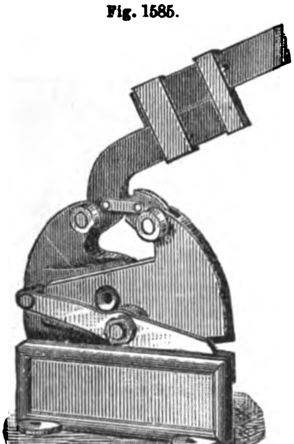
Fig. 1584.



Lever Drill.

Lev'er Press. A press for cutting or stamping tin ware, for instance, in which the punch or stamp is worked by a foot-lever; as distinct from a *pendulum*, *cam*, *screw*, or *fly press*.

Fig. 1585.



Lever Shears.

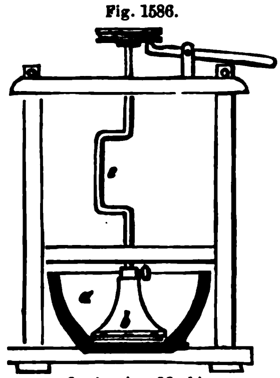
Lev'er Shears. A metal shears in which the power is applied by means of a lever; as in Fig. 1585, which is a French sheet metal shears having spur teeth on the contacting cams by which the motion of the lever is applied to the jaw.

Lev'er Valve. One moved by a lever.

See Lever; Lever and Cam Valve; Lever Cock.

Lev'i-ga-ting Ma-chine'. The porcelain levigating machine consists of a Thuringian porcelain mortar, *a*, with a flat-bottomed grooved pestle, *b*. This is attached to an iron crank, *c*, which is mounted in a strong wooden frame. There is a spout at the bottom of the mortar for running off the mixture when sufficiently ground.

Fig. 1586.



Levigating Machine.

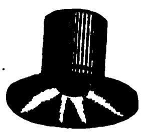
Ley'den Bat'te-ry. (*Electricity.*) A combination of Leyden jars presenting single positive and negative poles.

L. G. R. Large Grain Rifle powder.

Lid In'stru-ments. (*Surgical.*) See Eye Instruments; also Entropium forceps, Fig. 1877, p. 805, "*Mech. Dict.*"

Lieb'er-kuhn. A silvered cup, which slides or screws upon the front of the object-glass; light thrown upward by the mirror will be reflected by it down upon the object; by slightly varying the inclination of the mirror, every necessary alteration in the direction of the illumination can be obtained.

Fig. 1587.



Lieberkuhn.

Life. The endurance of a machine, or a part.

Compiled from the returns of 26 Illinois R. R. companies: —

	Years.		Years.
Locomotives . . .	$15\frac{1}{2}$	Pine ties	$4\frac{3}{4}$
Passenger cars . .	$15\frac{3}{4}$	Cedar	$5\frac{1}{2}$
Stock cars	10	Truss bridges . . .	$9\frac{1}{2}$
Freight cars . . .	$11\frac{1}{2}$	Trestle bridges . . .	8
Iron rails	7	Pile bridges	9
Steel rails	14	Joints and fastenings	7
Oak ties	7	Fencing	$8\frac{1}{2}$

"Locomotives 201, 202, 203, and 204 were placed on the Erie road in the months of June and July, 1854, and have run respectively 685,169, 532,548, 658,548, and 639,186 miles. The engines were equipped with new boilers in 1871, and are still considered good for 8 years more of good service. The locomotives are from the Rogers Works, Paterson." — *Hornellsville* (*N. Y.*) *Times*.

For endurance of car wheels, see p. 176, *supra*.

Life and Cur'rent Slide. (*Microscope.*) A slide in which are two oval cells with shallow connecting channel. By pressure on the cover the contents of a cell are caused to traverse the strait and the thin film is observed *in transitu*.

See Current Slide, Fig. 748, p. 236, *supra*.

Life Boat. Fig. 1588 represents a number of life boats in section and one in plan. They are derived from a lecture by Mr. Charles H. Beloe, read before the Liverpool Polytechnic Society.

Beginning at the left, above: —

a is the *Greathead* boat. *A A* are air-tight compartments, and *B* a water-tight deck discharging by tubes into the sea.

b is the Yarmouth sailing life boat, with air cases *A A*, and exterior cork fenders outside the gunwale. They are launched empty and the water then admitted to the well to the level of the water outside.

c, *h*, *i*, are views of the Royal National Life Boat. It is self-righting, and is the result of the experience in building the present fleet of life boats, numbering 235. It has side and end air chambers *C*, *D*, ballast *E*, relieving tubes *B* for the deck load of water.

e is *Lamb & White's* life boat. It is built of two thicknesses of plank with prepared waterproof material of an adhesive nature interposed.

f is *Woolfe's* boat.

g, *j*, are boats on the tubular principle.

k is *Hamilton & Co.'s* metallic life boat, which rids itself of deck water by discharge from the end of the boat which may be highest into a space between two bulk-heads, and then lowering it to outside level by means of a plug.

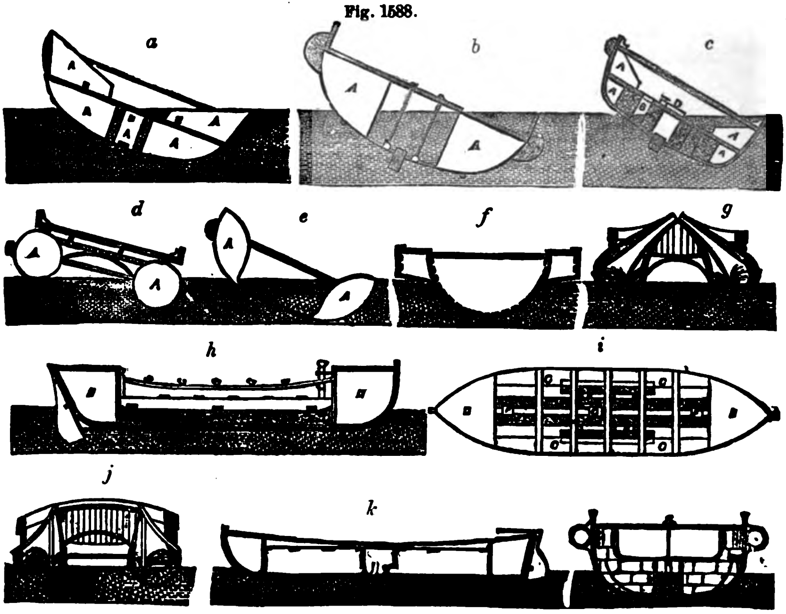
l is *Combe's* cork and cane life boat. It consists of two baskets, one placed within the other, secured to a deep wooden keel, and the intervening space filled with cork.

Fig. 1589 is the Royal Institution self-righting life boat, mounted on its carriage, and Fig. 1590 shows respectively a longitudinal section and a plan.

The boat has end and side air cases *f*, *g*, *b*. A water-tight deck with relieving tubes *a*. Spaces beneath the deck longitudinally amidships of the boat are packed with cork, forming a portion of the ballast. The extra buoyancy is obtained by the air-cases.

The self-discharge of water is provided for by the relieving tubes *B*, for, as the water-tight deck is always slightly above the level of the water outside, any sea that is shipped must flow out through these tubes, which are furnished with very simple self-acting balanced valves, that afford no obstruction to the free egress of water, but, closing by the pressure of the sea outside, effectually prevent the admission of any. The actual time occupied by one of these boats in freeing it-

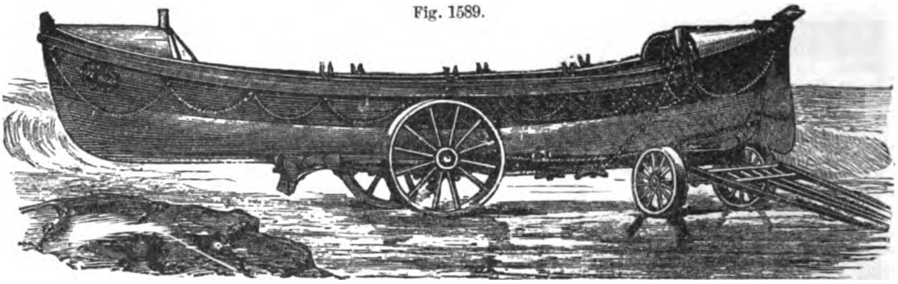
Fig. 1588.



British Life Boats.

self from water is about 80 seconds. A large portion of the ballast is composed of cork or wood. The really distinguishing feature of these boats is the property which they possess of self righting. The best proof of the safety of the boats is the fact that during the last 22 years the Institution has only lost from all causes, 29 persons from its own life boat crews, and many of these lives were lost by the men being crushed against wrecks, falling overboard, etc. The method by which this peculiar property is obtained is by attaching a heavy iron keel to the boat, and otherwise providing a sufficient weight of ballast, by giving a considerable amount of sheer, and by inclosing the bow and stern by air-tight chambers. These chambers have sufficient buoyancy to support the whole weight of the boat when upset, with the keel at a considerable height above the water; it is then floating on two points, with the ballast far above the center of buoyancy, thus forming an

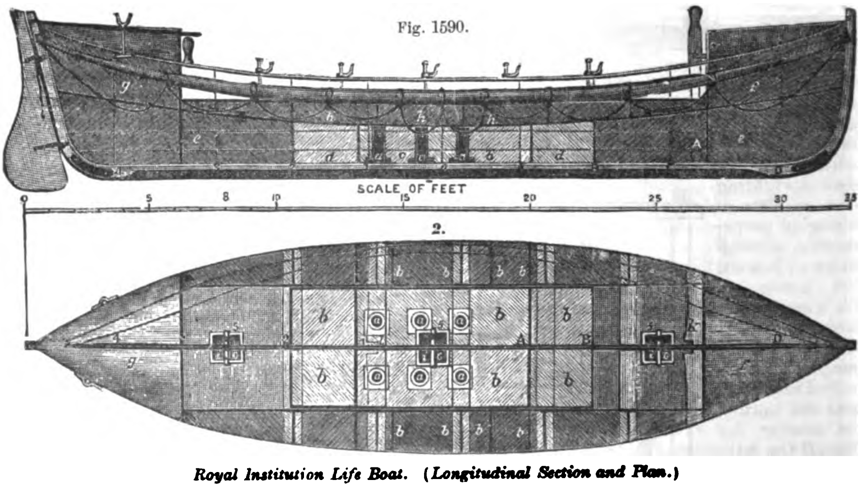
Fig. 1589.



Royal Institution Life Boat.

unstable equilibrium. In this position the boat cannot remain: and as soon as the keel falls to one side or the other of the center of gravity, the weight of ballast drags the boat round, the water escapes through the relieving tubes,

Fig. 1590.



Royal Institution Life Boat. (*Longitudinal Section and Plan.*)

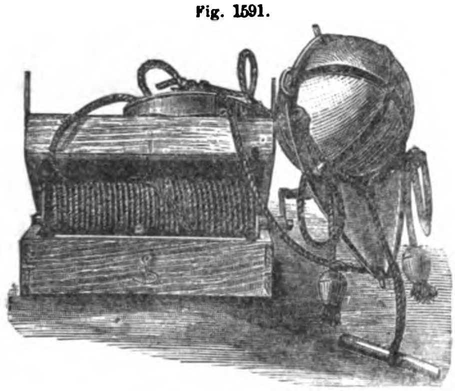
a, Delivering tubes; *b*, Air-cases; *c*, Well; *d*, Air-cases: *e*, Empty air-cases under deck; *f*, Fore air-compartment; *g*, After air-compartment; *h*, Air-cases; *k*, Mast-thwart; *s*, Scuttles for air.

and she is again ready for service. The following are the requirement requisite to insure self-righting: (1.) Ballast. (2.) Inclosed air chambers at the bow and stern, placed sufficiently above the center of gravity. (3.) Limited breadth of beam. (4.) Limited side buoyancy.

Life Buoy. One thrown to a man overboard.

The one in Fig. 1591 is Routourier's. It has two inflated canvas globes, a connecting strap, and winding-in line.

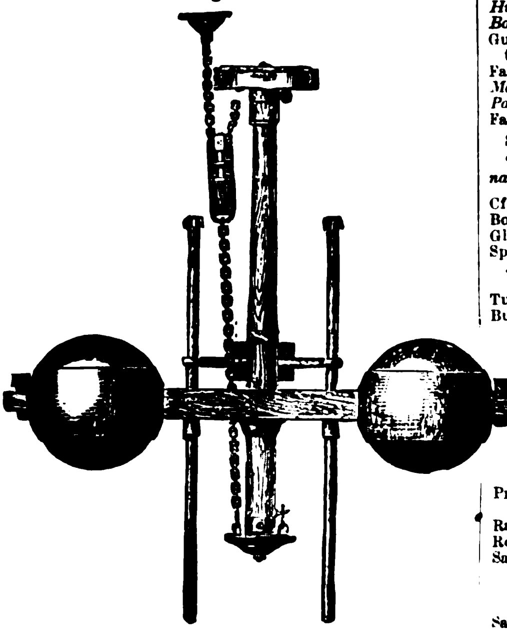
Fig. 1591.



Routourier's Life Buoy.

Fig. 1592 is Stone's improved form of Lieut. Cook's buoy (Br.). In this night life buoy, the act of throwing it overboard sets light to a port fire, which burns steadily on the surface of the water, and shows the situation of the life buoy to the party requiring its aid, as well as lighting the boat to the seaman in the water. This life buoy is in general use in the British navy.

Fig. 1592.



Stone's Night Life Buoy.

Life Pre-serv'er. An inflatable pillow, cushion, jacket, or what not. Fig. 1593 shows a number of forms.

Life-sav'ing Ap'pa-ra'tus. A lengthy and admirable report on life-saving apparatus, guns, projectiles, etc., by Lieut. D. A. Lyle, is to be found in "*Ordnance Report,*" 1868, Appendix P, pp. 177–334, and Plate LIV.

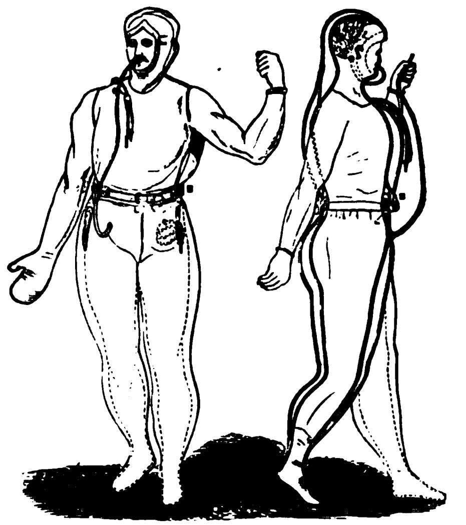
Life-sav'ing Suit. An inflatable dress to buoy up a swimmer or shipwrecked person.

Boynton's rubber life-saving dress is in two parts, tunic and pantaloons. The latter contains an air-chamber in each leg, which extends to the tops of the boots, while the waist is

Fig. 1594



Boynton's Life Suit.

girdled with a resisting steel band, on which is mounted a flange or ridge of heavy rubber. The jointure is made by lapping the tunic over the band, and a similar ridge drops into the groove formed. A belt thrown over the whole makes a tight joint. The tunic contains three air-chambers; one in the breast, back, and head respectively. When the latter chamber is inflated through the tube, it forms a pillow, raising the head of the occupant sufficiently to give him a complete range of vision. The suit is of delicate construction, and yet it will resist severe breakers and seas. The face is the only portion of the body exposed.

Fig. 1594 represents the swimmer in full outfit, and a sectional view to illustrate the construction.

Life Sig'nal. A provision on a life-saving buoy by which an inextinguishable light is given as soon as the buoy touches the water.

These chemical lights are now made in a variety of forms, and serve a useful purpose in giving a bright light upon the water when thrown overboard. One of the best of these contains chemicals that will not burn at any application of heat, but touched by water will evolve a bright flame. A small cylindrical box, ending above in a soft copper nib, is weighted below to keep it upright in the water, and filled with phosphate of calcium. When thrown into the sea, after the copper nib has been cut off, the water penetrates into the box, and the phosphureted hydrogen evolved escapes through a perforated tube leading to the open nib in a brilliant jet of light. Rain and spray only increases its brilliancy. Lieut. Cook's safety buoy is described under BUOY, p. 407, "*Mech. Dict.*" See also Fig. 2925, page 1301, *Ibid.*

Life Slide. See LIFE AND CURRENT SLIDE; CURRENT SLIDE. Fig. 748, p. 236, *supra.*

Lift. 1. The pump stock, or a portion thereof, of a deep well-pump. Perhaps especially one belonging to the Cornish system.

Fig. 1595 shows a portion consisting of a working barrel (11′), a door piece (6′) fitted with valve-seat and valve, an egg-ended wind-bore (9′) and the door-piece which has lugs for suspending it when the valve is to be examined.

2. A hand-hold attached to a window or window-blind, by which to raise or lower.

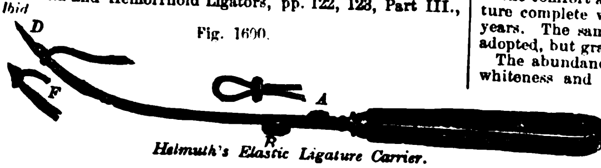
Fig. 1600.



Helmuth's Elastic Ligature Carrier.

Dr. Crooker's ligator for the gradual removal of tumors is shown in Fig. 1599. The spring is retained in a compressed state, until the ligature has been passed around the tumor, and its free ends secured to the cross-bar; it is then released, and the removal of the tumor is accomplished gradually and with little danger of hemorrhage.

Lig'a-ture Car'ri-er. Ligature carriers, knot-tyers, and ecraseurs are shown in Fig. 2944, p. 1308, "*Mech. Dict.*"

Helmuth's elastic ligature carrier, adapted for the treatment of complete or incomplete fistula, has two buttons, *A B*, Fig. 1600, close up to the handle of the instrument. By pushing forward the button *A*, the blunt end of the instrument, as seen at *F*, opens. The elastic ligature is then put upon the stretch, and, while thus drawn out, is slipped into the notch, and the button *A* drawn back to its place, and the needle (if the case is one of complete fistula) is ready for use.

If the fistula be incomplete, the blunt end is passed firmly up to the end of the sinus, the button *B* is pushed forward, which protrudes the sharp point *D*; in other words, transforms the blunt into a sharp point. The fistula is then made complete by piercing the tissues; as soon as this is done, the point is retracted again within its sheath, thus leaving a rounded extremity in the rectum. By elevating the handle with the left hand, and drawing the blunt end down by means of the index finger inserted within the rectum, the ligature is brought out at the anus, taken hold of and held, while the button *A* is pushed up, which entirely liberates the thread. The instrument is then withdrawn, the ends of the ligatures are passed through a leaden ring, which is slipped into position and clamped by forceps.

Light'er Staff. (*Grain Mill.*) A lever supporting and controlling the adjustable end of the bray-plank or bridge-tree, to which it is connected at one end by a stirrup while its other end receives the lighter screw, or sometimes, a counterbalance weight.

Light'house. The new Eddystone lighthouse is to be erected on the south rock of the group, about 120′ south of the present lighthouse, erected by Smeaton in 1757. The present lighthouse manifests no sign of weakness, but the "House Rock" on which it stands has been worn and probably undermined by the waves.

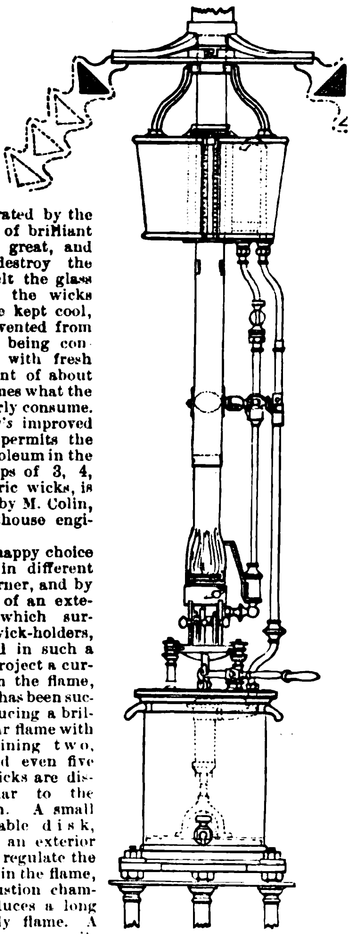
The Eddystone lighthouse is described on p. 1311 of the "*Mech. Dict.*" The new structure will be built to contain a light of more extensive radius and greater power. The old tower is 72′ above the level of high water; the new one is designed to be 130′ above the level of any spring tide, so that no matter what storm may rage, the light will be in no danger of being eclipsed. It will have a range of $17\frac{1}{4}$ miles, and is expected to overlap the electric light at the Lizard. Beside this, the tower will be considerably enlarged, giving nine rooms in place of the existing four, thus adding to the comfort and convenience of the keepers. The structure complete will cost £70,000, and be completed in four years. The same process of dovetailing the stones will be adopted, but granite is substituted for Portland stone.

The abundance and cheapness of petroleum oil, and the whiteness and brilliance of the flame it gives when consumed in properly constructed lamps, more than twenty years ago suggested its use for light-houses. The colza-oil lamps in use in light-houses have one wick for reflectors and small dioptric apparatus, and two, three, four, and even five wicks adapted to the different orders of dioptric apparatus, and the flames developed in these lamps are of greater size and brilliance than that of the four-wick lamps; for example, being nearly 4″ in diameter, by about the same in height, emitting a light equal to nearly 260 standard sperm candles. The heat generated by the four cylinders of brilliant flame is very great, and would soon destroy the burner and melt the glass chimneys, but the wicks and burners are kept cool, and the oil prevented from volatilizing by being constantly flooded with fresh oil to the extent of about three or four times what the lamp can properly consume.

Captain *Doty's* improved burner, which permits the burning of petroleum in the lighthouse lamps of 3, 4, and 5 concentric wicks, is thus described by M. Colin, a French lighthouse engineer: —

"It is by a happy choice of proportion in different parts of the burner, and by the application of an exterior cylinder which surrounds the wick-holders, and is arranged in such a manner as to project a current of air upon the flame, that Capt. Doty has been successful in producing a brilliant and regular flame with burners containing two, three, four and even five wicks. The wicks are distributed similar to the Fresnel system. A small central adjustable disk, combined with an exterior air cylinder, to regulate the currents of air in the flame, forms a combustion chamber which produces a long and very lively flame. A simple appliance permits the application of his system of burners to the ordinary overflow lamp, *i. e.*, the mechanical and moderator lamps."

Fig. 1601.



Funck's Float Lamp.

This invention at once places within the reach of lighthouse authorities lamps which do not require any structural rearrangement of the apparatus or lamps at present in use; new burners only require to be screwed or soldered on to the existing lamps, and the lighthouse management goes on as formerly, but with this difference, that the flames of the Doty burner show greater illuminating power.

Funck's float lamp for lighthouses is shown in Fig. 1601.

The float is in the chamber which is seen parallel with the burner and regulates the supply which descends from the elevated oil-chamber. The overflow passes into a lower chamber from whence it is again pumped into the elevated chamber, by means of a pump, the handle of which is shown protruding to the right.

Light Reg'is-ter-ing Ap'pa-ra'tus. An automatic device by Prof. Roscoe to keep a record of the amount of light that falls at any particular spot during small fixed intervals.

Clockwork drives the apparatus, photographic paper is the sensitive agent used, and by mechanical arrangements certain small portions of the paper are exposed to the action of light for fixed intervals, which can be regulated at pleasure. The tinted photographic paper is compared by the eye with a conventional scale of tints.

Lig'nose. A Silesian blasting powder made of woody fiber charged with nitro-glycerine.

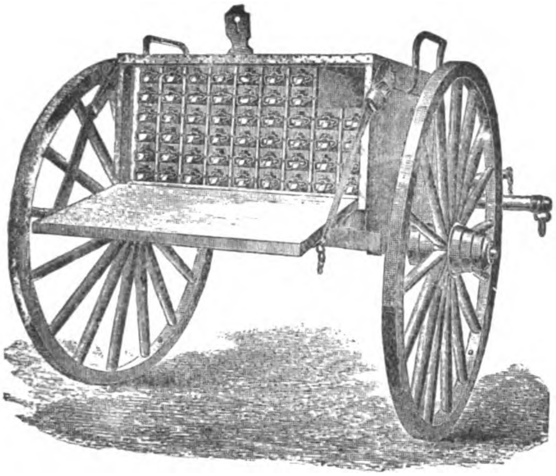
It is very light; burns slowly in a loose state; does not explode in contact with open fire; is three times as strong as an equal weight of black blasting powder, and less than one third the price. Mentioned in the "*Deutsche Industrie Zeitung.*" Made at Kieltsh by Baron von Trutzschbhler Falkenstein.

Lil'y I'ron. (*Fishing.*) The harpoon head, detachable from the stem, used in capturing swordfish. See also HARPOON.

Fig. 1602.

Lily Iron.

Fig. 1603.



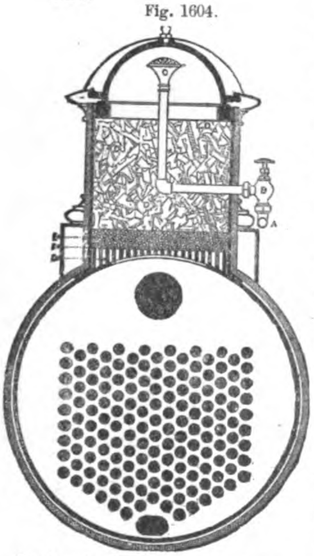
Limber for Gatling Gun.

Lim'ber. The ammunition carriage to which the trail of a field-piece is attached when in marching order.

Fig. 1603 shows the limber for the Gatling gun. The drawers hold cases of ammunition, 20 or 40 in a case; the case is slipped into the feed hopper of the gun, and the cartridges fall into the loading grooves of the gun as they successively present themselves when the barrels are rotated.

Lime Catch'er. A device placed between a feed-water pump and the steam boiler to intercept the lime.

Fig. 1604.



Feed-water Filter and Lime Catcher.

The device shown is in use on the Illinois Central Railway, and its purpose is to prevent the deposition of scale.

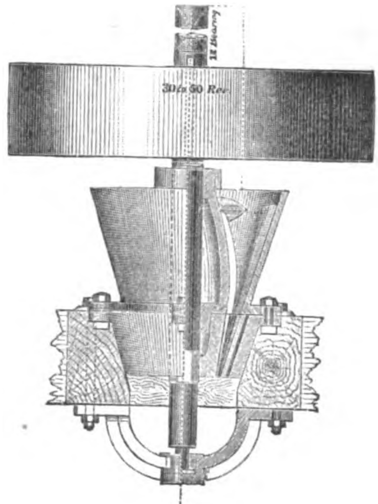
Instead of admitting the feed-water into the boiler in the usual manner (that is, on the side of the boiler, below the water level), the feed-water pipes are carried from the pumps, or injectors, to the top of the forward dome, either inside or outside of the dome, and deliver the water near the top of the dome from a rose, *C*, in the form of spray or thin sheets. From this point it falls into the body of the boiler by its own gravity, and in its descent is compelled to pass over and among pieces, *D D*, of metal, wood, charcoal, tile, oyster shells, etc., which are placed in the dome and are heated to the same temperature as the steam which surrounds them, and upon which the lime, magnesia, and other mineral impurities in solution in the water will deposit themselves. These pieces of metal, etc., are supported by a grating, *G*, over which is laid, if necessary, a piece of wire netting, *F*, to prevent the charcoal, *E*, from being washed through into the boiler.

The pieces of metal, etc., are renewed occasionally.

See also Feed Water Heater, Figs. 1000–1011, pp. 328, 329, *supra*.

Lime Crack'er. A mill for rough-grinding crude plaster and calcined limestone. The teeth

Fig. 1605.



Lime and Plaster Cracker.

are of chilled iron; those in the lower part of the pot are made in sections, which can be renewed separately when they wear out. The core is made in sections, also renewable. Used in cement works. With a motion of 30 revolutions per minute, a mill will reduce hard calcined water lime to a fineness suitable for grinding at the rate of 60 barrels per hour.

See also Cement Mill, Fig. 575, p. 183, *supra*; Fig. 1199, p. 510, "*Mech. Dict.*"; Mortar Mill, Figs. 3230, 3231, p. 1480, *Ibid.*, etc.

Lime Ex-tract'or. See Feed Water Heater, pp. 328, 329, *supra*; Lime Catcher, *supra*.

Lime'-glass. (*Glass.*) Known in England as *white* glass; not to be confounded with *flint*-glass, which has lead in it.

Bohemia is especially celebrated for its *white* glassware, making all articles usually made in *flint*-glass in England. The latter is the whiter and more brilliant; the *lime-glass* is the harder, and is blown into wooden molds. It is invaluable in the laboratory. Recipe: —

Pulverized quartz	100
Carbonate of potash	28 to 32.
Slaked lime	13 to 15.
Oxide of manganese	1
Arsenic	3

Saltpeter, borax, red lead, sometimes enter into the mixture in small proportions.

The French lime-glass, also known as *half-crystal*, is composed as follows: —

Sand	200
Carbonate of soda	66
Lime	50

Or —

Sand	3,000
Sulphate of soda	170
Slaked lime	75
Ground charcoal	10

A few hundredths of red lead are sometimes added.

Lime Kiln. Additional to what has been given on pp. 1319, 1320, "*Mech. Dict.*," some instances may be given of the calcination of lime combined with steam boiler heating, and the production of carbonic acid for use in sugar houses.

Cowan's (Br.) steam generating apparatus, combined with a kiln for calcining limestone, is shown in Fig. 1606.

The kiln is worked on the continuous principle, with coal and limestone alternately, and in regulated quantities. The escaping heat generates steam in boiler, which is partly jacketed around the kiln, and partly consists of a dome with vertical flues.

The plant for the purpose, to be added to the ordinary kiln, is included in the following schemes: —

Metallic fixture for lime-kiln of 175 cubic feet capacity.

Gas washer.

Blowing apparatus, with special motor, comprising 1 air-pump, 24½″ cylinder and 16″ stroke; 1 horizontal engine, with 9″ cylinder.

Tubing, for conveying gas from furnace to washer, the blowers and saturating-pans.

Simonneux's continuous kiln, * *Laboulaye's "Dictionnaire des Arts et Manufactures,"* vol. iv., ed. 1877, article "*Chaux.*"

Lime kiln heated steam boiler, *Cowan* * "*Sc. Am.*," xxxv. 307.

Lime kiln and steam boiler combined . * "*Sc. Am. Sup.*," 665.

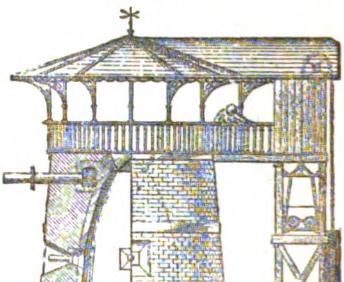
The calcination of limestone and chalk in kilns, for the production of carbonic acid, for use in the manufacture of beet sugar, is a prominent feature in European *sucreries*.

M. Derosne was the first to suggest quick-lime in the purification of the beet juice. His method was based upon three principal points: (1) the use of caustic lime; (2) the use of alum; and (3) the use of alcohol. The lime he adds to the fresh juice, of which he succeeded in expressing 63 per cent. of the weight of the root. The proportion added was 0.24 gram per liter of juice. After the addition of lime in a thick milk the juice was rapidly brought to boiling and the scums removed as they formed. The juice was then separated from the sediment, which settled and concentrated. It was then purified with alum and blood, and farther treated in the usual way. The proportion of sugar extracted by this method is stated to have been 4½ per cent., and was the highest result that had yet been attained. The beets from which this high yield was obtained were of the white Swedish variety, while the beets of the plain of Aubervillier did not yield as much by 2½ per cent.

Fig. 1607 shows a limestone calcining furnace specially devised for *sucreries*, and made by Chrétien, of Paris. It has steam elevator for the limestone, and a tube at the summit to conduct the carbonic acid to the pans in which the beet juice is saturated with the gas. This is described under CARBONATION PAN, p. 163, *supra*.

See also *Dr. McMurtrie's "On the Sugar Beet, and the Manufacture of Sugar Therefrom,"* Special Report, No. 28, Department of Agriculture, Washington, 1880.

Fig. 1607.



Lime Kiln for Beet Sugar Factories.

Lime Light. The Drummond light has been described at Fig. 1788, p. 757, "*Mech. Dict.*"

Fletcher's lime light consists of a block of lime, incased in a cylinder of porous ganister, and subjected to a flame from a Bunsen. At an opening in the pottery envelope the light is emitted. The ganister cover ismade of refractory clay 1 part; sawdust, 6 parts; burned; this makes a very porous material, like pumice; an excellent non-conductor of heat.

Line. 1. (*Fishing.*) *a.* The thread, twine, or cord used in baited-hook fishing. Known by various names indicative of size, quality, material, make, purpose, etc.; such as: —

Bottom set line.	Set line.
Braided silk.	Silk line.
China grass.	Silk-worm gut.
Cork line.	Silver gimp.
Cotton line.	Snood.
Float line.	Squid line.
Gut line.	Spilliard.
Hand line.	Surface line.
Harpoon line.	Tapered silk.
Land line.	Throwing line.
Linen line.	Toggle line.
Loaded line.	Trawl line.
Plaited line,	Trot line.
Rigged line.	Twisted silk line.
Seine line.	Waterproof.

b. Of a seine: —

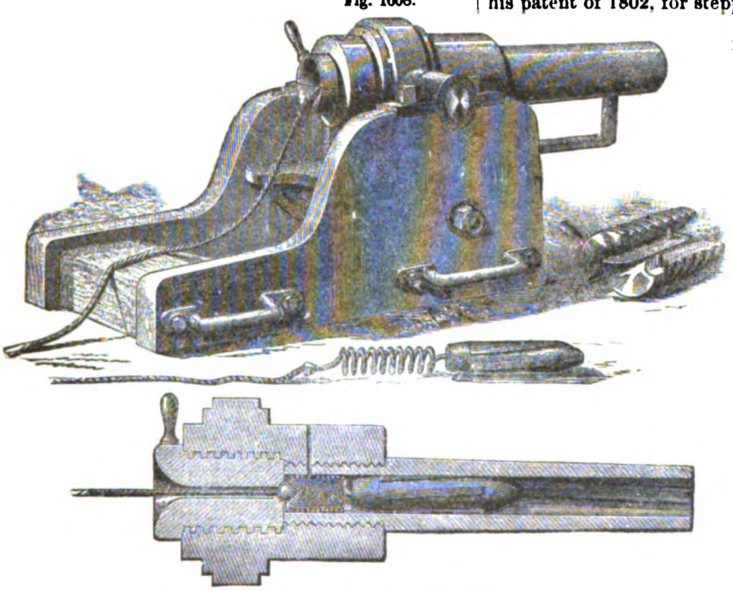
The *cork* line, or line of floats on the upper edge.
The *toggle* line, which in some seines runs along the line of leads.
The *land* lines, which pass from the ends of the seine to the sheave blocks on shore.

2. Mason's line, chalk line, etc.

Lin'ear Knife. (*Surgical.*) A delicate, sharp-pointed knife used in making the incision in operation for cataract. *Graefe's* and *Baader's,* straight and angular with the blade, are in *Tiemann's* "*Armamentarium.*"

Line Hook. (*Whaling.*) A hook for catching the harpoon line.

Fig. 1608.



Spencer's Line-throwing Gun.

Line-throw'ing Gun. A gun for throwing a line to vessels stranded or in distress off shore.

Fig. 1608 is Spencer's breech-loading line-throwing gun, which is mounted in the usual way, but has an axial aperture in the screw breech-plug for the passage of the line, which is attached by a spring to the base of the projectile to prevent the parting of the line at the instant of firing. The breech-plug is in two parts, divided longitudinally, to obviate reeving the line through the hole. The tail of the cord is attached to a life-line lying faked in a box near by. See Fake, Fig. 1000, p. 526, *supra.* See also Anchor Shot, Fig. 61, p. 33, *supra;* Grapple Shot, Fig. 1270, p. 421, *Ibid.*

Lin'ing Felt. A fabric of hair, or hair and asbestos, which may be saturated with a lime cement, and used as a non-conducting covering for steam boilers and pipes.

A mixture of fiber, animal or mineral, with cement wash, applied with the brush for the same purpose.

A felt inserted in a partition or siding, as a deadener of sound or non-conductor of heat.

Lin'ing Nail. A sharp upholstering nail with semi-spherical head, brass or nickeled.

Link Mo'tion. See * p. 1824, "*Mech. Dict.*"

Link-block, locomotion, *Alexander* * "*Sc. Amer.,*" xxxv. 230.

On the link motion, *Smith* . . * "*R. R. Gaz.,*" xxiii. 2.

Peaucillier was the first to discover that a straight line can be accurately described by a combination of links. See his parallel motion. See Fig. 3548, p. 1630, "*Mech. Dict.*"

Lint. 1. (*South.*) Ginned cotton before baling.

2. (*Fishing.*) A fisherman's name for the netting of a pound or seine.

3. (*Surgical.*) Raveled or scraped linen. See p. 1325, "*Mech. Dict.*"

Lip. The helical blade on the end of an auger to cut the chip. The *spur* makes the circumferential incision.

A lip auger has *pod* and *lip;* in contradistinction to the *screw*-auger.

Lip Hook. (*Whaling.*) A grapnel for catching in the lip of the whale, to tow it to the vessel.

Lip Pro-tec'tor. (*Dentistry.*) A saddle-shaped shield laid upon the lip to protect from abrasion or pinching during dental operations.

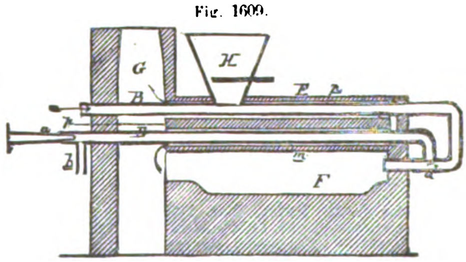
Liq'uid Bear'ing. Described by Bramah in his patent of 1802, for stepping vertical shafts. He went so far as to perform the vertical adjustment of the cutter spindles of his planing machine by pumping liquid into the step.

See Journal Bearing, Fig. 1499, p. 516, *supra.*
See also Palier Glissant; Hydraulic Pivot; Water-bearing, "*Mech. Dict.*"

Liq'uid Fu'el Fur'nace. A furnace utilizing petroleum or paraffine as the inflammable agent. (Fig. 1609.)

One form is shown in Fig. 2965, p. 1325, "*Mech. Dict.*" *Caldwell's* coal dust and petroleum furnace is adapted as a puddling or heating furnace, through the roof *E* of which, as well as through the chimney *G*, pass the two pipes *B* and *D*, the former for admitting air under pressure, and the latter for receiving a jet of steam from a nozzle, *a*, the jet inducting petroleum from an adjoining reservoir through the branch *b* into the pipe *D*. Both of the pipes *B* and *D* communicate with a short pipe or nozzle, *d*, which projects into the interior *F* of the furnace at the front end of the same.

Fig. 1609.



Coal Dust and Petroleum Furnace.

With the pipe B communicates a hopper H for containing coal-dust, more or less of which can be admitted to the pipe by means of a sliding damper. The petroleum injected into the pipe D in the form of spray by the steam-jet assumes a gaseous form before it reaches the nozzle d, where it unites with the supply of compressed and heated air which creates an intense heat in the furnace, and consumes the coal-dust which arrives by the air-pipe B, and is injected therewith into the furnace chamber F.

Fig. 1610 is Ramsden's hydro-carbon furnace (Br.), which is on the principle of the atomizer. Steam from a boiler is discharged in the form of spray from the outlets of horizontal tubes across the mouths of vertical tubes c, the lower ends of which are in a tank of petroleum. A vacuum is produced in the hydro-carbon tubes in the manner familiar in atomizers, and the consequence is a mingled spray of steam and hydro-carbon vapor which is conducted beneath the boiler.

Liq'uid Ma-nure' Cart. A vehicle for conveying liquid fertilizer and showering it upon the ground.

Fig. 1611 is a French form, made by *Bodin*, of Trois-Croix, Rennes. It is provided with a pump for filling the reservoir from cisterns in the barnyards or stables.

Fig. 1611.

Bodin's Liquid Manure Cart.

A British form is shown at Fig. 2919, p. 1826, "*Mech. Dict.*"

See also IRRIGATOR, *supra*.

Liq'uid Meas'ure. Liquid meters of several forms are shown on p. 1327, "*Mech. Dict.*"

See also WATER METER, Figs. 7110-7119, pp. 2740-2742, *Ibid.*, and SPIRIT METER, Figs. 2426-2429, pp. 2227-2278, *Ibid.* Also MEASURING APPARATUS: MEASURING FAUCET; MEASURING FUNNEL, pp. 1413, 1414, *Ibid.*, and list under MEASURING APPARATUS, etc., *infra*.

Fig. 1612 shows *Wilkinson's* oil-tank with hand-pump which discharges into a glass vessel graduated to quarts, pints, etc. When the stop-cock is opened to draw off the fluid, a valve is also opened, and air is admitted to the top of the receptacle. When the measure is being filled by pumping the fluid into it, the air will open the upper valve and escape, the valve afterwards closing and preventing evaporation.

Fig. 1612.

Oil Can and Liquid Measure.

Liq'uid Weigh'er. A device in which a vessel is placed on a scale beneath a faucet, weights in the other scale representing the quantity required and the tare of the vessel. As the scale descends it trips a lever and turns off the spigot. — *Watts.*

Lis'sa-jou's Curves. The method of combining rectangular vibrations to form beautiful and instructive figures consisted in the first place of a pen connected with a pendulum swinging in one plane, and tracing lines upon a platform which reciprocated in a plane at right angles to that of the pen pendulum.

Next came a pen connected with two pendulums swinging in planes at right angles to each other, the tracing being a line, the result of the two impulses.

Shifting to the merely visual; two tuning-forks carrying small mirrors and vibrating at right angles to each other, threw pencils of light upon a screen and it was soon seen, though not unexpected, that the consonances and dissonances of sounds were admirably shown by the optical method, visible in an auditorium.

In the original method the dying action of the pendulums as they sank to rest diminished the amplitudes of the curves; differences in their rates curiously complicated the curves described; the center of gravity and therefore the time of oscillation of the pendulums being adjustable to any required amount, the proportions between the vibrations of the two could be brought to any desired ratio to represent harmony, unison, discord, or indeed to illustrate all the harmonic combinations of waves of sound and music.

An addition, whereby the paper may be slowly rotated by a clock-work movement, while the vibrations are going on, gives extraordinary figures, some of which illustrate the laws of interference and the polarization of light.

To avoid the characteristics due to the decression of motion of the pendulums, Hopkins devised apparatus vibrated by electricity. In one case two reeds or tongues vibrated by an electric current and connected with a single mirror, which latter receives a beam from a lantern and reflects the errant beam through a lens and upon a screen; the play of the curve being the resultant of the two rectangular vibratory movements. See ELECTRICAL DIAPASON, pp. 293, 294, *supra*.

A simple form, using two spring slips with apertures, and vibrating in planes at right angles, is described by Hopkins, * "*Scientific American*," xliii. 259. The length and weight of the slips determine the period of their vibration, the force applied in snapping them the amplitude of the vibrations.

"If the two springs are set in motion by snapping them simultaneously with the thumb and finger, the square aperture formed by the intersection of the slits in the two cards will move so rapidly as to appear like a band of light, *i. e.*, supposing the operator to be looking through the aperture toward the light. If the two springs vibrate in unison the band will either be perfectly straight, bisecting the angle formed by the two springs, or it will be elliptical or circular. By changing the period of the vibration of one of the springs so that the periods of the two springs will be to each other as 1 : 2, the band of light will assume the form of the figure 8. Make the vibrations as 2 : 3, and the figure representing the fifth will be formed, and so on throughout the whole range of compound vibrations.

"To project these figures on a screen all that is required is to place a lamp at one side of the slitted cards, and a magnifying glass of about 6″ focus on the other side. An easy way to hold the magnifying glass in position is to place the handle in a hole in a board, the latter resting on the top of the box. This rude device admits of moving the lens forward or backward, and to the right or left, as may be required" — *Hopkins*.

The subject may be pursued by reference to the following captions, and citations *passim* : —

List'ing Plow. A double-moldboard plow, used in listing; that is, throwing up the soil into ridges. A plan adopted in some cultures, such as beet, and some garden crops.

Lith'o-gram. A name given to the gelatine copying process. See COPYGRAPH, p. 220, *supra;* GELATINE COPYING PROCESS, pp. 396, 397, *Ibid.*, and references *passim*.

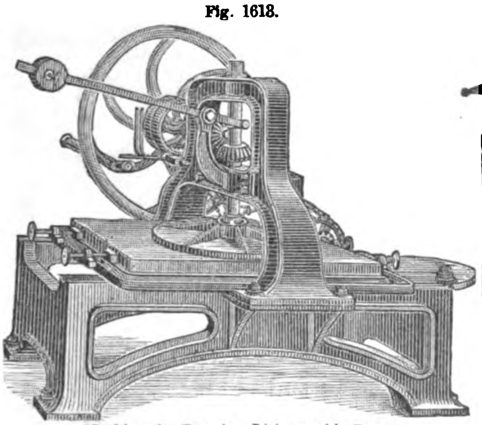
Lith'o-graph'ic Pa'per.

For Transfer Purposes: Chinese paper is much used, and is worked just as it comes from China, being rough in appearance, full of straws and imperfections. These imperfections are removed by the transferer while the paper is damp, as much as possible.

India Proof Paper: Chinese paper, smooth in appearance, different in shades of color or tints. These tints are selected by the lithographer according to the different subjects he may have to prove; for instance, a portrait of a lady of light complexion on light colored India paper; and the reverse when needed. It goes from China to France, and is there calendered and worked over, that the best printed results may be obtained therefrom, and is consequently much more expensive, costing at least three times as much as the Chinese transfer paper.

Lith'o-graph'ic Stone Dres'ser. A machine

Fig. 1613.



Machine for Dressing Lithographic Stones.

for facing lithographic stones. In *Jullien's* machine (Fr.), Fig. 1613, the stone lies upon the flat platen, face upward, and the circular wheel rotates above, while the stone is traversed backward and forward by means of a pitman connected to the platen and moved by wrist connection with a wheel beneath. The stroke of the platen is regulated by the adjustment of the wrist in a slot, towards or from the center of rotation, and the pressure of the wheel on the stone is regulated by means of a counterbalance weight on an arm which is seen projecting to the left.

In another form of machine, shown at the Vienna Exposition, for polishing off the faces of stone, preparing it for the engraver, the stone is laid upon a solid table, which is stationary, having a large iron platen suspended over it, and held by an arm extending back some 10′, and attached to a wheel lying horizontally and supported by a shaft 2′ long extending from below, where it is connected by cog-wheels to another shaft driven by pulleys and belting from the main shaft. This arm runs between two round blocks or loose pulleys placed in the center on either side of the arm, so that when set in motion this platen of iron moves backward and forward over the stone, while the blocks or pulleys in the center give it a side motion, at the same rate with that of the revolution of the wheel in the rear, thus making the iron platen travel more slowly over the surface of the stone, and giving it the same motion as when operated by hand. It covers the entire surface of a large stone with a uniform polishing. The stone is supplied with water from pipes properly attached, and an occasional supply of sand is furnished by the attendant.

Supply of lithographic stones "*Scientific Amer. Sup.*," 1292.

Lith'o-la-pax'y Ap'pa-ra'tus. (*Surgical.*) *Bigelow's* apparatus for rapid lithotrity with evacuation. It consists of a lithotritor and syringe, the former and the tube of the latter being introduced alternately through the urethra.

The lithotritor is shown at *a*, Fig. 2978, p. 1336, "*Mech. Dict.*" *Lithotritor* and *lithontriptor* seem to be synonymous terms. *Litholabe, lithoprione, lithoclast, lithorineur*, are terms belonging to special instruments of the same class, and approximately the same duty.

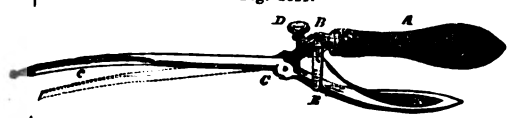
Lith'o-pone. Sulphide of zinc; used as a paint. P. Krupp's Patent.

Lith'o-tome. A bistoury or scalpel for making the incision in lithotomy. The instrument may have a special name derived from structure or mode of application: *gorget, bisector, bistoury-caché, cystotome.*

Hutchison's double-bladed lithotome is shown in Fig. 1614. The handle *A* holds a bistoury, *B*, curved on the flat, its cutting edge looking towards the right, the back being thick and terminating in a rounded probe-point to fit the groove of a lithotomy staff.

A second bistoury, *C*, is joined to the other by means of a screw, its beveled point resting against a section of the probe of the first one, and its cutting edge looking towards the

Fig. 1614.



Hutchison's Lithotome.

left. By this arrangement the blunt back of one blade conceals and protects the edge of the other, so that when the screw *D* is brought home the two blades become solid like a rounded staff. By approximating the wooden handle of the first and the steel lever of the second bistouries, the cutting edges are diverged, the extent of the incision being regulated by the screw *D* and measured by the index-plate *E*.

Li-thot'ri-ty and Li-thot'o-my In'stru-ments. (*Surgical.*) The list includes: —

Anklets and wristlets to secure the patient.
Forceps to grasp and crush the stone.
Lithoclast *b*, Fig. 2978, p. 1336, "*Mech. Dict.*"
Lithotrite *a*, *Ibid.*

Lit'mus Paper. Unsized paper colored with litmus (*Cryophora tinctoria*), and used as a test of the presence of acid or alkalies. It turns red with acids, blue with alkalies.

Lit'ter Cut'ter. A machine of the nature of a chaff-cutter, for cutting straw into lengths for bedding for animals.

Lit'tle Gi'ant. (*Mining.*) A jointed iron nozzle used in placer mining. See HYDRAULICKING, *supra.*

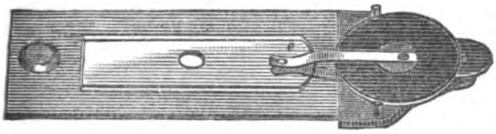
Live Ring. (*Bridge.*) A circular gang of wheels, as used in the turn-tables of draw-bridges, and in those for locomotives.

The *live-ring* of the Rock Island draw-bridge is composed of 34 wheels, each 30″ in diameter and 14″ face. The traveling weight borne by each of the wheels is 44,250 pounds.

Live Trap. (*Optics.*) A contrivance for keeping a live object in the field of a microscope without preventing its movement. This is done by making a hole in a piece of glass of the size of the field of view of the microscope and covering the same with two slips of thin glass. The parts of the apparatus can all be taken apart for purpose of cleaning.

It is accompanied with a glass trough into which one end of the live trap can be placed so as to supply the small aper-

Fig. 1615.

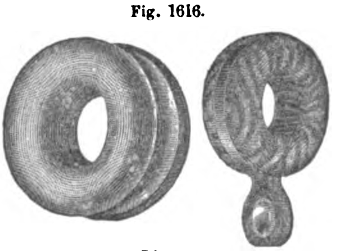


Live Trap.

ture with fresh water by capillary attraction when the object under examination is in water. The apparatus enables the object to be kept alive many days.

Liz'ard. (*Nautical.*) Otherwise known as a buntline bull's-eye. A large thimble worked into the foot-rope of a sail.

Fig. 1616.



Lizards.

a. Lizard.
b. Iron-strapped lizard for awning-blocks.

Lla'nos. (*Fabric.*) A French dress goods woven on a taffeta loom; it has a cotton warp and a weft of mohair, or mohair mixed with silk.

The warp is composed of 3 white threads; the weft is violet, blue, or black, which gives reflection to the stuff.

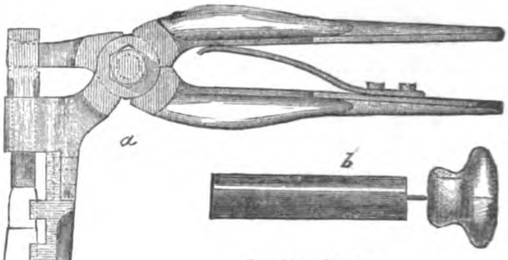
Load'er. An instrument for re-loading cartridge shells. (Fig. 1617.)

The instrument *a* has a prop for the shell and a plunger for the loading, the pressure being given by approaching the handles in manner of a forceps.

b is a powder or shot rammer, and at one end has a point which may be employed to dislodge the spent percussion shell.

a and *b* are manifestly not intended for the same shell. *a* is shown compressing the bullet into a bottle-shaped shell.

Fig. 1617.



Cartridge Loaders.

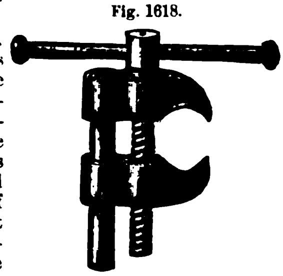
Load'ing Plug. A rammer for loading shells, which can also be used for extracting the caps from the spent capsules by changing ends with the removable head. *b* Fig. 1617.

Load'ing Ma-chine'. (*Cartridge.*) A machine for loading the shells of cartridges. The shells are fed in on a revolving wheel; 72 grains of powder are let in from above by a funnel from the can, and on revolving farther the bullet is pressed into the neck of the shell.

Loam and Sand Core. A dry-sand core, composed of sharp sand, loam, and horse manure. In these cores the loam is used in place of flour or other substances for giving strength and adhesiveness to the sharp sand.

Lob'ster Claw. A screw jack used in setting rigging. See RIGGER SCREW.

Fig. 1618.



Lobster Claw.

Lo'cal Ac'tion. (*Electricity.*) This takes place when the zincs require amalgamation. A hissing sound in the cells when the poles are not connected indicates a waste of battery material. It is remedied by re-amalgamating the zincs.

Lock. See for history and varieties, pp. 1338, 1342, "*Mech. Dict.*" A list is given on the last-mentioned page.

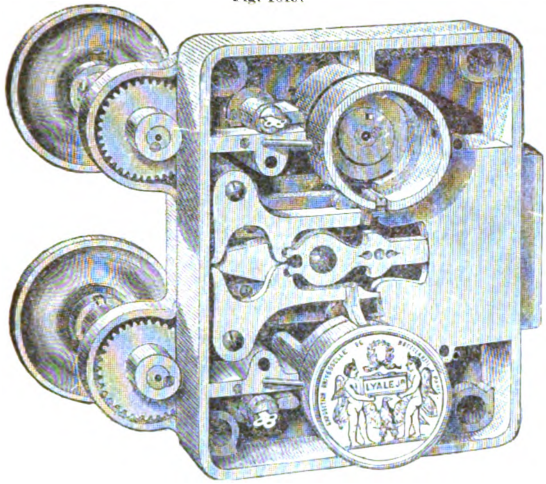
The Yale double-dial lock, Fig. 1619, is a double combination bank or safe lock having two dials, each operating its own set of tumblers and bolts, so that two persons, each in possession of his own combination, must be present in order to unlock it. It is evident that the two dials may be set on the same combination, or one person may possess the two combinations, if the double security be not desired, temporarily.

The *Time Lock* has a chronometer movement inside by which the bolt is permitted to unlock at predetermined times. Set to lock at 4 P. M., and to open at 9 A. M., for instance, the door being closed at the stated time (4), the unlocking mechanism cannot be operated until the 17 hours have elapsed. By a Sunday attachment, the recurrent 7th days an additional 24 hours is added to the 17 (=41 hours), during which the lock cannot be operated, nor the door opened.

Fig. 1620 shows the appearance of the lock, and enables its principles to be sufficiently explained.

The only parts of the lock which are not visible are the two chronometer movements which are concealed by the plate, and which cause the two dials to move in the directions indicated by the arrows. These dials are constructed with 24 pins representing the 24 hours, and colored white and black, to indicate the day hours and night hours. When these pins are pushed in they form a track on which the rollers of the yoke ride. The movement of the yoke up and down moves the lever, to which the yoke is pivoted, up and down also. It is necessary that both sides of the yoke should be pushed up by the revolution of the dials, in order

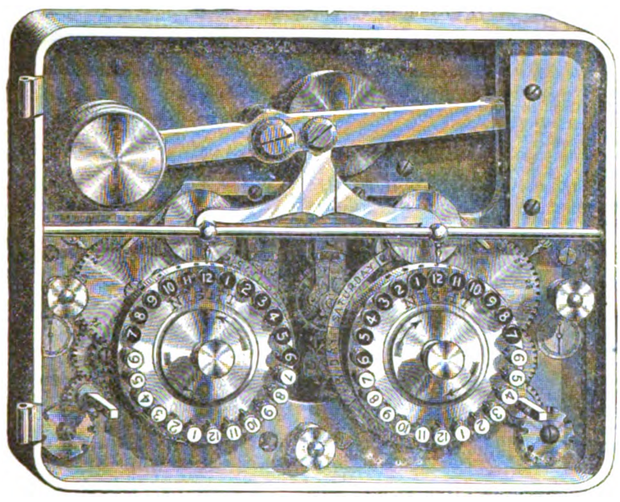
Fig. 1619.



Yale Double-dial Lock.

to push up the lever. When the pins of the dials are pulled out, the track on which the rollers of the yoke ride is broken away, and the yoke and lever are allowed to drop by gravity. At the left-hand end of the lever, as you look towards the cut, is shown a counterbalance weight, while the other end of the lever works in a slot in a movable dog or bolt. The sole object of the time lock is to cause this bolt to move up

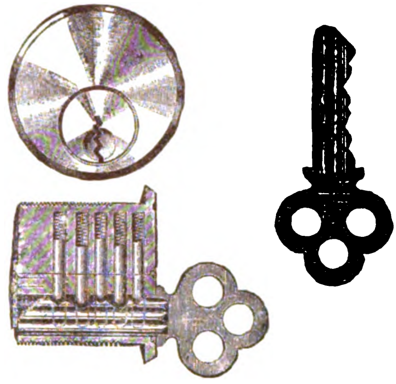
Fig. 1620.



Yale Time Lock with Sunday Attachment. (*Cover Removed.*)

and down at certain regular intervals. When the bolt is moved up it closes a hole in the case into which a projection on the string piece of the bolt work passes, when the bolt work is retracted. When the bolt drops the projection can pass freely into the hole and the bolt work be retracted. The construction of the bolt is such that pressure upon it causes no pressure whatever on the lever, but the pressure is resisted by a solid block backed up by the case of the lock. The operation of the lock is therefore as follows: The user selects the hour at which he wishes the lock to lock up, and pushes in that pin, and pushes in all the succeeding pins up to the hour when he wishes the lock to unlock, doing this on both dials, and setting the dials to the proper hour of the day by the pointer at the top of each. Now, so long as the movements are running, the pins, which are pushed in, will support the yoke, lever, and bolt, and keep the lock locked, while it will remain unlocked during all the hours represented by the pins which are pulled out. These periods can be varied at will. If the safe door is left open longer than usual, so that the projection from the bolt work is in the hole of the lock case when the hour comes at which the lock is set to lock, the rollers of the yoke will be raised, but the only effect will be to separate

Fig. 1621.



Yale Lock.

the yoke at the center, and to cause a spring which holds it together at that point to spread. When the bolt work is thrown forward, and the lever and bolt are free to rise, the spring will contract and push them up in the locked position. The lock is provided with what is called a Sunday attachment, that is, with a segment or track which comes under the rollers every seventh day and keeps the lock in a locked position over Sunday, during the hours when it will unlock on other days. This can be adjusted so as to lock up over a holiday also. To prevent the lock running down in the locked position so as to cause a lock-out, a supplemental unlocking device is provided, and consists of a coiled spring situated back of the lever. This is held coiled by two triggers which extend over the wheels, which indicate the number of hours that the movements are wound up to run. As the movements run down these wheels revolve with them, and just before either movement completely runs down a pin trips the trigger, and releases the spring which pushes down the lever and bolt, spreading the yoke apart.

Yale's pin lock, which is operated by a flat key, was a new departure, seen in position in the lock in the sectional view, Fig. 1621.

In the *Yale* lock the *escutcheon* or *tumbler case*, inclosing the pins upon which the bits of the key operate, is placed near the surface of the door, projecting slightly, so that a long key shank is dispensed with, the bow and bits brought closely together, and the depth of the escutcheon decides the length of the key, without regard to the thickness of the door.

The escutcheon cylinder is an exterior shell, containing in its lower part a smaller cylinder, from which rises a rib of metal containing the *pin chambers*, and within which is the *plug*, attached to the inner end of which is the cam that imparts motion to the bolt. This plug also contains the key hole.

The escutcheon contains five holes, or *pin chambers*, each formed partly in the shell and partly in the plug, therefore a pin which filled one of these holes would prevent the rotation of the plug, but, if the pin were cut in two, the joint corresponding with that between the plug and its hole, the plug could revolve freely, carrying with it one half of the pin, and leaving the other half in that part of the pin-chamber contained in the shell. Such is precisely the construction of the lock and its great element of security. The line of junction may be seen in the upper view, Fig. 1621.

Each pin is in two parts, — the upper termed the *driver*, the lower the *pin*, — and above each driver is a light spring, tending to press drivers and pins downwards. In this position the drivers intersect the joint between the shell and the plug, completely preventing the rotation of the latter. To open the lock, therefore, all the pins must be raised simultaneously to just the proper height, which can be done only by the right key, since a variation of one-fiftieth of an inch in the elevation of either of the pins will prevent the opening of the lock.

The width of the key admits of ten different *bittings*, or depth of notches, therefore a lock with but one pin could be variously *set up*, so as to be opened by ten different keys. In a lock with two pins the number of changes, or varieties of keys, will be 100; three pins, 1,000; four pins, 10,000; five pins, 100,000: six pins, 1,000,000; seven pins, 10,000,000. The least number of pins contained in any of the Yale locks is 4, as in drawer and desk locks; the night-latches have 5; the post-office, heavy store-door locks, etc., 6; and the "safe-deposit" locks — for inside doors of safes, vaults, etc. — have 7 pins.

The new Yale corrugated key consists of the original plate key altered by having its blade, or portion which enters the lock, corrugated in longitudinal lines. By special machines of great ingenuity, the lock has formed in it a key-hole of sinuous cross section conforming to that of the key. The key and its hole are interlocked throughout their entire length, and tilting of the key in its hole is impossible. The lock cannot be operated by any key but its own, nor can it be picked except by some tool which will raise the tumblers. The shape of the key-hole renders it impossible for any tool to raise the tumblers, because, even if one be made small enough to be inserted in the key-hole, it cannot be moved up and down.

Lock Bed'der. A machine for sinking a recess in a gun-stock for the lock.

The general appearance of this machine is similar to a revolving head gang drilling-machine containing five spindles with their cutters. The rifle stock is chucked in a fixed position; to the right of it, and also fixed, is an iron section of that part of the stock into which the lock is bedded: the iron section is used as a guide or former. The machine being started, the first operation is to drill two holes, the position of which is regulated by a pin which reaches the iron former a little in advance of the drill reaching the rifle stock, so that the position can be accurately determined. One hole being drilled, the spindles carrying the drill and the guide pin, which spindles are in the same frame and operate together, are raised, the machine head is swung one fifth of a revolution, and the first cutter comes in position to operate. On lowering the cutter spindle there descends with it, and slightly in advance of it, a guide pin in the iron former, and when the guide pin is well within the iron former the cutter reaches the surface of the wood, and is guided by the operator moving the head so that the guide pin travels all around the edge of the recess in the former. The motion of the guide pin and of the cutter being laterally identical, the operator has but to enter the cutter as far into the rifle stock as a stop provided for the purpose will admit, and then to move the frame carrying the guide pin and cutter so that the guide pin moves and touches all around the sides of the recess in the iron former. The recess in the rifle-stock will be then the exact counterpart, in size, form, and depth, of that in the pattern. The whole operation is but a repetition of the above, with the remaining cutters swung one after the other into position, the one iron former answering to regulate the lateral movement of them all. The speed at which the cutters revolve is about 8,000 revolutions per minute. As soon, however, as each drill or cutter is swung out of position, it stops running, which prevents wear and tear.

Lock Chain. A short chain by which a padlock is fastened to a door or car so as to be irremovable.

Lock Fau'cet. One the spigot of which can only be turned by a removable key.

Lock Gate. The gate of a bay in a canal lock.

Designs for hanging lock gates, and valve for locks. See Plates III. (*a*), III. (*b*), IV., "*Report of Chief of Engineers, U. S. Army*," 1876, vol. ii., Part II., p. 416 *et seq.*

A report "*On the Construction of Iron Lock Gates for the Harbors of the Weser River, Germany*" (translation), reproduced by the Corps of Engineers, U. S. Army, forms a quarto brochure, Washington, 1873.

Lock Hook. (*Fishing.*) A supplementary hook to spring upon and secure a fish which draws on the bait.

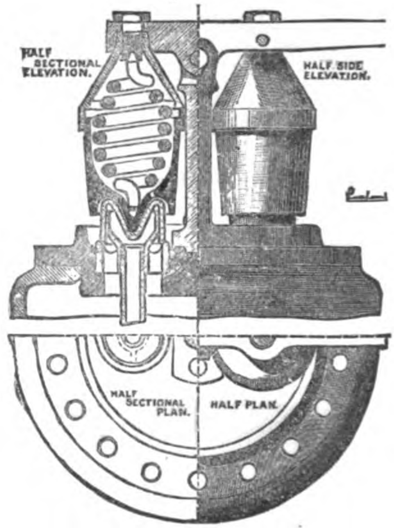
See "*Report of U. S. Fish Commissioners*," p. 275, Part I., 1873, and Fig. 2000, "*Mech. Dict.*" See also Fish Hook, p. 841, *supra*.

Lock'ing Plate. A nut-lock; see 45 illustrations, Fig. 3350, p. 1538, "*Mech. Dict.*"

In Finney's (Br.), a small pin is fixed a short distance beyond the nut. A circular plate, divided equally by 17 notches, fits easily over the nut in any of its six positions. The principle of the invention is the same as that of the vernier scale. As there are 17 notches in the plate it follows that three of them represent just one-seventeenth of one side of the hexagon nut; so that if the plate be moved round three notches, it will not fit unless the latter be moved round a distance equaling one-seventeenth of one side of the hexagon, or a distance which equals the one hundred and second part of a whole turn.

"*Iron Age*," xxii., August 1, p. 19.

Fig. 1622.



Lock-up Safety Valve.

Lock'-jaw In'stru-ment. (*Surgical.*) Apparatus for forcing open the jaws.

Goodwillie's operates by a screw which acts upon two hinged valves, introduced, wedge-fashion, between the teeth.

Westmoreland's has two parallel plates expanded by a screw.

Some of the heavier forms of *speculi oris* may be similarly used.

Lock Mor'tis-ing Ma-chine'. A machine for boring holes in the edges of doors to hold mortise locks.

The machine is clamped to the door, spanning the edge at the height desired to set the lock; a bit of the width of the lock body is placed in the bit-holder, which works in guides to secure verticality, and is rotated by hand-crank and gearing. An adjustable stop on the bit-stock determines the depth.

Lock Nut. See Fig. 3350, p. 1538, for numerous varieties.

Locking plate.

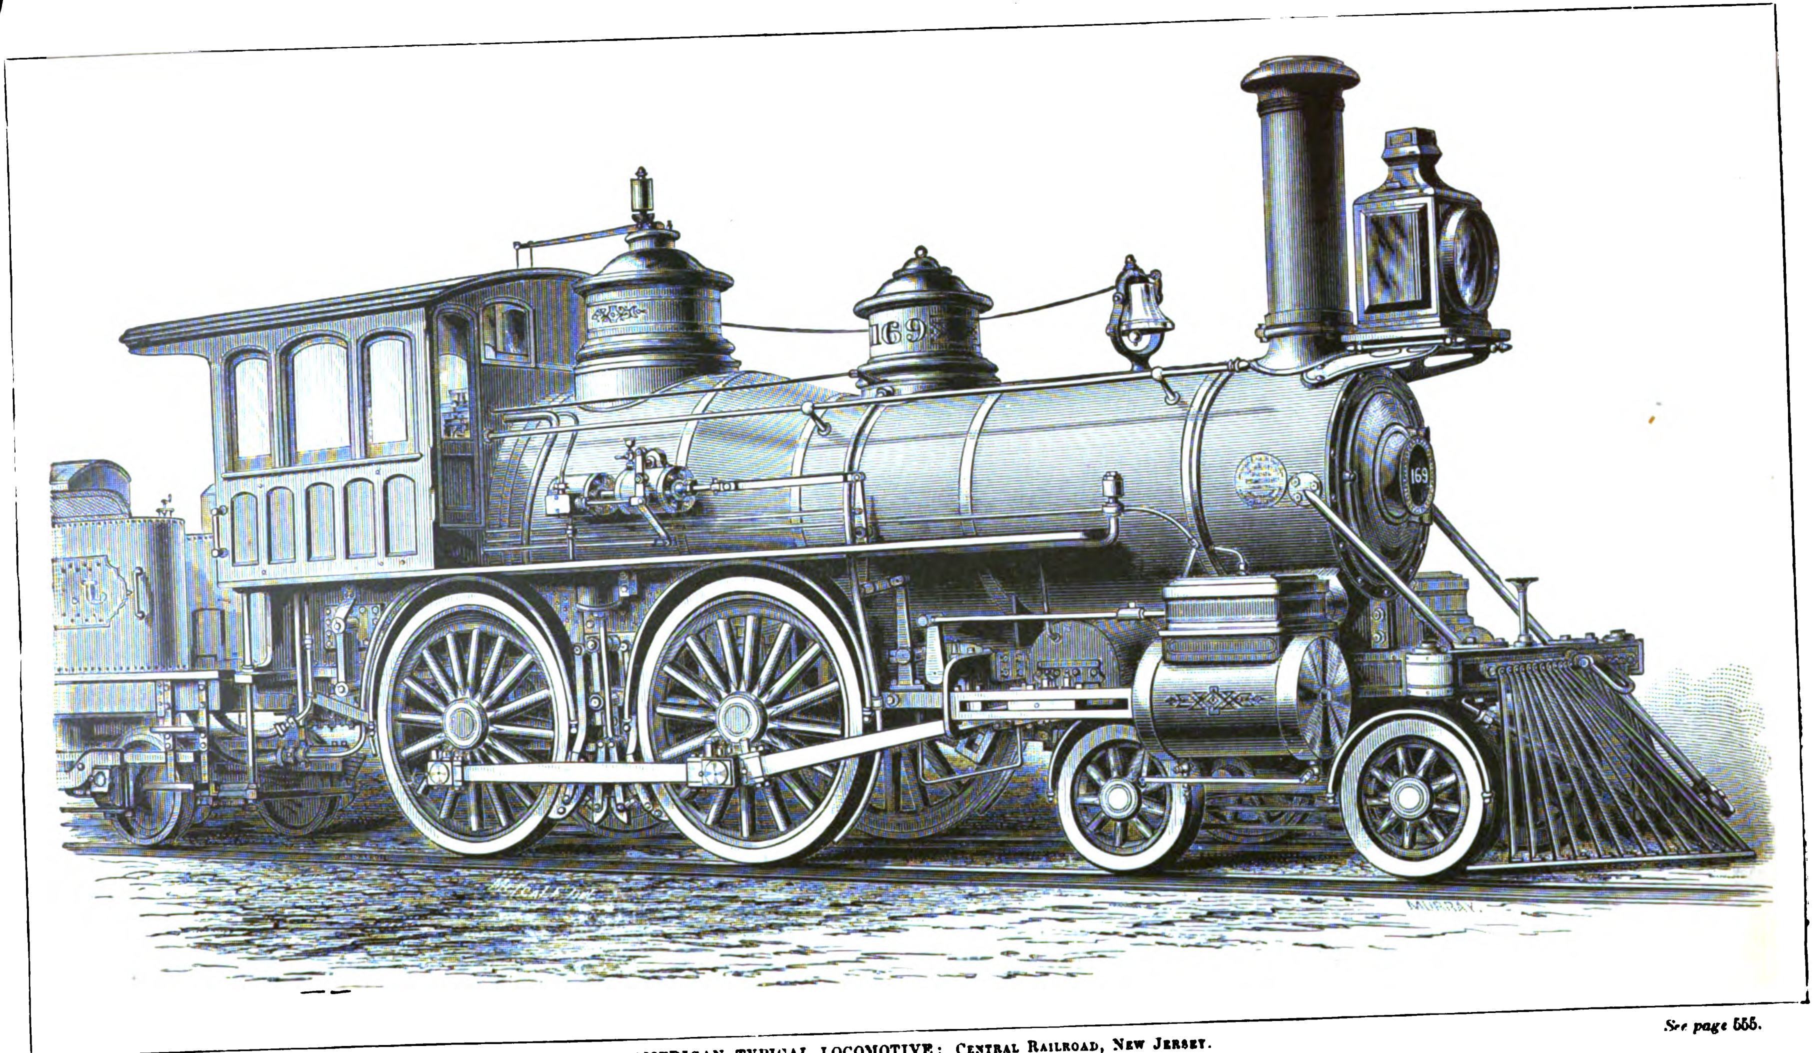
	* "*Engineer*," xlvii. 78.

Lock Seal. A piece of glass, lead, or paper over the key-hole of a padlock, so that the latter cannot be tampered with without defacing the seal. Used on cars containing goods *in transitu*, in bond, etc.

Lock Switch. A form of switch board used in telegraphy.



See page 555.

AMERICAN TYPICAL LOCOMOTIVE: CENTRAL RAILROAD, NEW JERSEY.

PLATE XXVI.

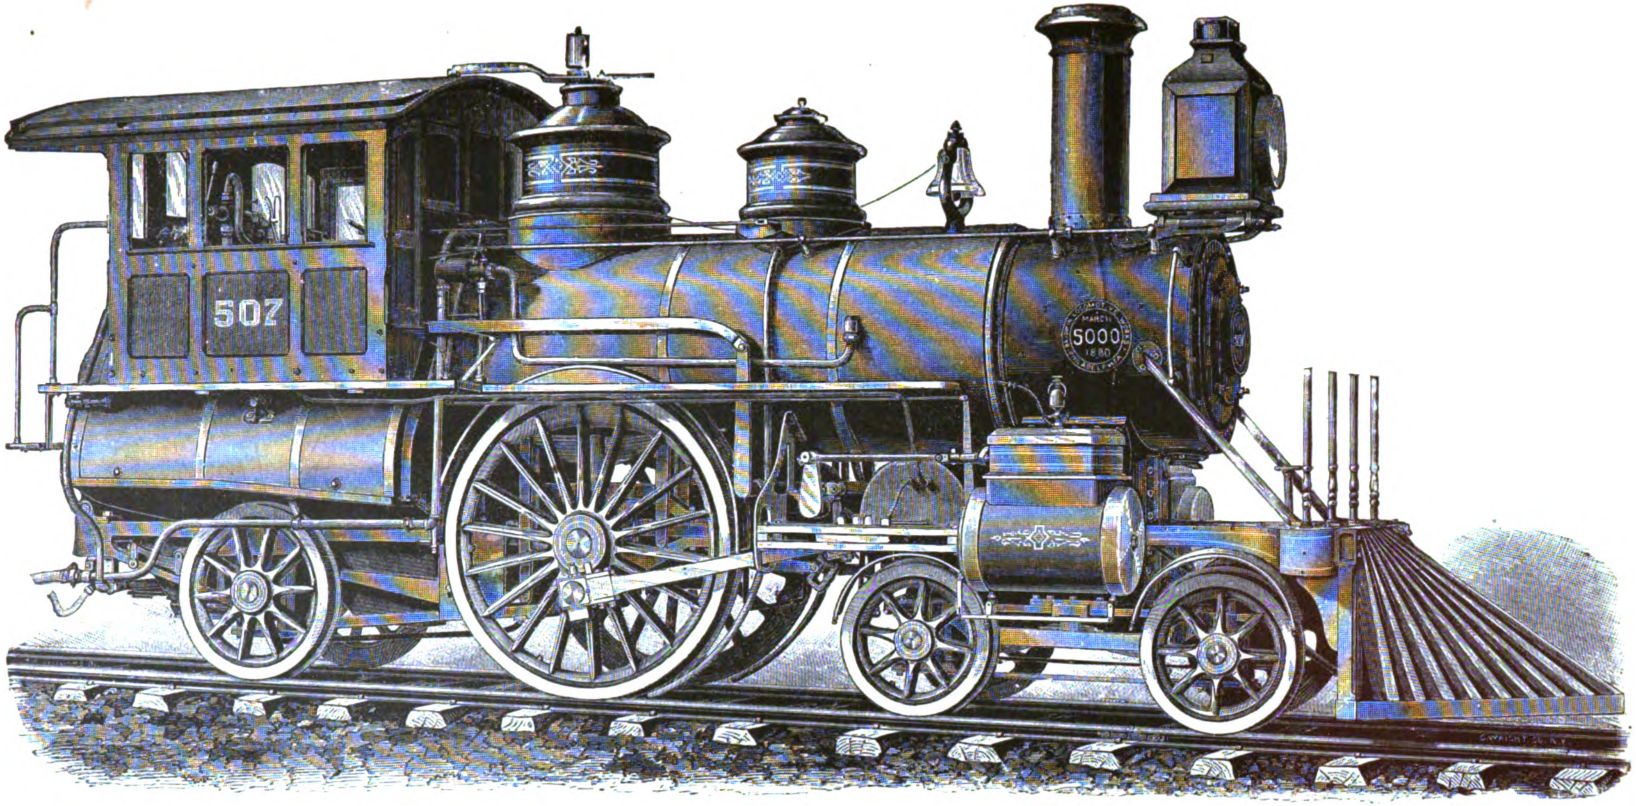


PLATE XXVII

FAST PASSENGER LOCOMOTIVE. BOUND BROOK LINE, NEW YORK AND PHILADELPHIA.

See page 555.

Two sets of brass bars are arranged at right angles to each other on opposite sides of a wooden frame. The connection is made between any two intersecting bars by a metallic peg, provided with a spiral spring, which, when the peg is inserted and secured in its place, presses against the two bars, forming an electric connection. See PIN SWITCH.

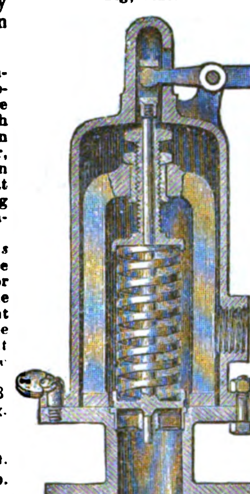
Lock′-up Safe′ty Valve. One in which the weight or spring is in a closed chamber which cannot be tampered with, or changed, except by one having possession of the key.

Fig. 1622 is *Wilson's* improvement on *Klotz's* safety valve. The springs are not accessible, although the engineer can ascertain by lifting the trying lever, whether the valves are in good order. Valve and seat are of gun-metal, having the same ratio of expansion.

Fig. 1623 is *Stone's* locked-up safety valve (Br.), in which the lever operates in a yoke on the valve-stem, being efficient in lifting, to prove the condition of the valve, but powerless to add pressure thereto.

See also Fig. 2983, p. 1343 "*Mech. Dict.*," and Fig. 4544, p. 2019, *Ibid.*

Fig. 1623.



Lock-up Safety Valve.

Lo′co-mo′tive. See "*Mech. Dict.*," pp. 1343–1348.

Plate XXVI. gives a view of a first-class, fast engine of the ordinary American type, with four connected driving wheels and a four-wheeled truck. It was built by the Baldwin Locomotive Works, for the Central Railroad of New Jersey, for fast passenger service. The special points of improvement in construction and proportion are carefully and elaborately detailed, accompanied by sectional views, in the "*American Machinist*," * v., pp. 1–3, January 7, 1882, to the publishers of which journal the author acknowledges his indebtedness for the plate.

"The train usually consists of five cars, viz., one baggage, one express, one Pullman drawing-room coach, and two ordinary passenger coaches. With this train, notwithstanding the fact that the smoke-stack is well inclosed within the smoke-box, to prevent throwing fire, plenty of steam is generated at all parts of the road. The regular schedule time between Jersey City and Bound Brook is 37 minutes. This distance has been run by No. 169 in 33 minutes. Three miles upon the route have been run in 2 minutes and 24½ seconds, — the same distance frequently covered in 2½ minutes. The quickest mile ever run by this locomotive was in 45 seconds, — timed between mile posts with a stop-watch." — "*American Machinist.*"

The following are some of the principal dimensions : —

Gage of road	4′ 8½″
Weight (running)	93,000 lbs.
Cylinder diameter	18″
Stroke	24″
Driving wheel, diameter	68″
Wheels, diameter	32″
Boiler, thickness, steel	⅜″
Diameter	52″
Fire-box, length	125¼″
Width	43⅜″
Tubes, number	200
Diameter	2″
Length	11′ 5½″
Grate, area, sq.	38′
Heating surface, box, sq.	145′
Tubes, sq.	1175′
Total, sq.	1320′
Steam power, normal	140 lbs.

A freight locomotive by Rogers, having four pairs of coupled drivers, is shown in Fig. 1624.

The original "Consolidation" locomotive was built in 1866 from the plans of Wm. Alex. Mitchell, at the Baldwin Works in Philadelphia. This type of locomotive has four pairs of drivers and a two-wheeled pony truck in front. It was originally built to overcome some steep grades on the Lehigh Valley Railway, and specially for the Mahoning Plain, which rises 133′ to the mile.

Plate XXVII., for which the author acknowledges indebtedness to the "*Railroad Gazette*," gives a view of locomotive 5000, built at the Baldwin Locomotive Works, Philadelphia, for the fast train between New York and Philadelphia on the Bound-Brook route. A careful description with sections and elevations is in the journal mentioned, * vol. xxiv., 246, 315.

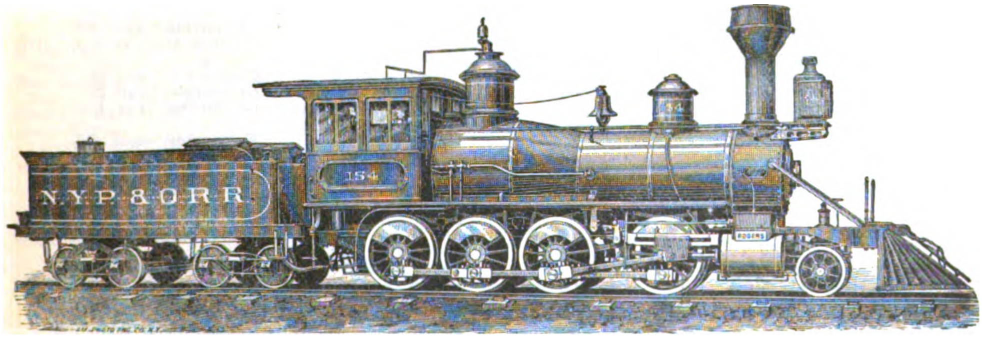
"This new locomotive has a single pair of driving wheels 6½′ in diameter, in place of coupled drivers of 5½′ in diameter. In the latter form of engines run at high speed there is danger that the coupling rods connecting the driving wheels will be broken by centrifugal force. The larger wheel also reduces the number of revolutions per mile of run. In the new locomotive the boiler has 1400′ square of heating surface and about 56′ square of grate surface. The dimensions are as follows : —

Diameter of cylinder, 18″.
Length of stroke, 24″
Diameter of driving wheel, 78″.
Wheel base, 21′ 1″.
Distance from center of driving wheel to center of trailing wheel, 8′
Boiler, 7-16″ steel . . . 52″ in diameter.
No. of tubes, 198 . . . 2″ in diameter and 12′ 2¾″ long.
Fire-box . . . . 96½″ by 84″.
Capacity of the tender . . . . 3,800 gallons.
When filled with water and coal, 70,000 pounds.

"The weight of the engine is 85,000 lbs., and is so disposed that by an alteration of fulcrum points additional weight can be thrown on the drivers at the time of starting.

"At a trial trip on May 14th, the engine was attached to a train of four cars, each weighing about 42,000 pounds, making the weight of the train complete, about 148 tons. The run was made at rates ranging from 27 miles an hour, between Ninth and Green and Wayne stations, to 62 miles an

Fig. 1624.



Freight Locomotive, "Consolidation" Type.

hour, between Trenton Junction and Bound Brook, the time from Ninth and Green to Jersey City (89.4 miles) being 98 minutes, or at the rate of 54¾ miles per hour. On the return trip the run was made in 100 minutes. In a former trip the engine developed a speed of nearly 79 miles an hour. In these trial trips the engine consumed 36 gallons or 300 pounds of water per minute." — *Le Van.*

Dimensions of Mogul Passenger Locomotive, No. 600, Built by Baltimore and Ohio R. R. Co.

Gage of road		4′ 8½″
Driving wheels, number		6
Diameter		60″
Truck wheel, number		2
Diameter		31″
Total wheel base		22′ 11″
Cylinders, diameter		19″
Stroke		26″
Steam ports		1¼″ × 15¼″
Exhaust		2¼″ × 15¼″
Throw of eccentrics		5½″
Boiler, diameter		50″

Number		165
Diameter		2¼″
Weight on truck wheels	13,850 lbs.	
Driving wheels	76,550 lbs.	
Total weight, running	————	90,400 lbs.

Locomotives for steep gradients are of several kinds, among which may be noticed the following: —

1. The Fell system, so called, in which a pair of horizontally rotating wheels or rollers embrace a central rail. This was used by him on Mt. Cenis and Mt. Washington. See also Vignoles and Ericsson's central rail (Fig. 1210, "*Mech. Dict.*"). This was patented by these parties in England in 1830, which is doubtless much older than Fell's invention. Kollman's English patent of 1836; Sellers' United States patent of 1835.

2. The Righi railway (Fig. 4124, "*Mech. Dict.*"), which has central rack engaged by spur wheel on the locomotive. This was patented in England by Blenkinsop in 1811, Snowden in 1824, Easton in 1825.

3. Coleman's (English patent 1845), in which a screw beneath the locomotive works into a line of rollers laid down midway between the rails.

4. James' (English patent, 1825), converting each wheel of the train into a driver. A horizontal shaft extending beneath the carriages from the locomotive throughout the train, rotated by the locomotive and having bevel wheel connection with the axle of each car. See p. 1861, "*Mech. Dict.*"

•5. Handyside's system, in which the locomotive, provided with a winding drum and wire rope, proceeds up the incline in advance of the train, and, after being anchored to the rails, draws up the train after it by the wire rope.

6. Appleby's system, in which a chain is laid between the rails and passed over by a chain wheel of the same diameter at the pitch-line as the wheels of the locomotive. The engine hauls by adhesion on the level and lays hold of the chain when going up or down steep grades.

For most of these engines vertical boilers have been used on account of the small foundation space they occupy, and because there is less uncovering of the flues when the boiler is on a heavy grade.

The locomotive attachment of *Wootten & Hazel* is designed to enable a locomotive on one track to impel an engine or car on another. A ram is pivoted to the locomotive and may be folded against the same or extended by an adjustable spring-brace rod, to a position to engage the car on a side track to move it forward.

The fast trip from New York to San Francisco was made in 83 hours, 34 minutes.

The "Uncle Dick" locomotive for the Atchison, Topeka and Santa Fé railway weighs 65 tons, and is 60′ long from the head-light to the rear of the tender.

Boiler, length	21′
Cylinder, diameter	20″
Stroke	26″
Drivers (8), diameter	42″
Restraining force of brakes	75 tons.

The largest locomotive at Vienna weighed 70 tons, and could draw 1000 tons at 30 miles per hour.

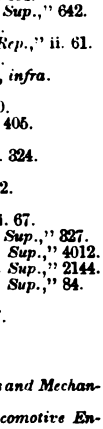
Lo′co-mo′tive Bal′ance. The spring on the safety valve beam of a locomotive. Preferred to a weight on account of steadiness and lightness.

Fig. 1625.



Locomotive Balance.

Lo′co-mo′tive Crane. A crane mounted on a car. A wrecking or construction crane. See RAILWAY CRANE, *infra*. Also, BALANCE CRANE, Fig. 176, p. 66, *supra*, and *j*, Fig. 1507, p. 643, "*Mech. Dict.*"

Lo′co-mo′tive Cup. An oiler for the cylinder of a locomotive.

Fig. 1626 shows the *Nathan & Dreyfus* oiler, which is self-acting.

While the engine is in motion, the steam passes up the tube to the upper part of the cup, where it condenses, and the water so produced, being heavier than the oil, sinks to the bottom and lifts an equal amount of the lubricant to the top, causing it to overflow through the side hole near the top of the tube to the parts where the lubrication is required.

At the end of the day, or when the oil or tallow is exhausted, water, acids, and other impurities which remain should be drawn off by the waste-cock, and the cup refilled with the lubricant.

Lo′co-mo′tive Pump. A self-propelling steam-power pump. The most familiar is a steam-driven fire-engine; a self-moving engine carrying a pump: the *locomobile pompe* of the French, with whom it is more common than with us.

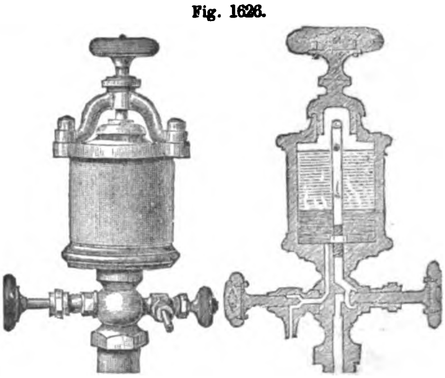
Lode. (*Mining.*) Aggregations of mineral matter containing ores in fissures.

Lodg′ing Car. A car fitted with bunks for hands at work on a railway line.

Log. A velocimeter; employed to ascertain the rate of a ship's motion. See p. 1348, "*Mech. Dict.*"

In Keelmay's electric log an electric circuit is applied to the ordinary patent log, so that a revolution of the vanes

Fig. 1626.

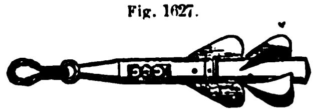


Cylinder Oiler.

will, by a make-and-break arrangement, actuate an indicator in the captain's cabin. The number of knots can be read off the indicator, and hauling in the log itself is not required.

Massey's log has spiral wings, propelled by the passing water, and the revolutions registered by wheel-work and dials inside.

Fig. 1627.



Massey's Log.

A French log is described as an instrument to be fixed either in the engine-room or in the captain's cabin. The water is conveyed to it by means of suitable valves, placed in the side of the vessel, and the impact of the water while the vessel is moving communicates motion to some clockwork, and the distance is recorded by means of a dial. There are four smaller dials within a large one which record the knots by units, tens, hundreds, and thousands, while the large dial tells the statute miles, so that measurement can be taken either in miles or knots.

Froude, Br. . . . . "*Van Nostrand's Mag.*," xviii. 344.
De Normanville, "*Engineer*" . . . . . * "*Scientific American Sup.*," 1522.

Log Beam. The traveling frame in which a log lies and travels in a saw-mill. Fig. 4629, p. 2043, "*Mech. Dict.*"

Log But′ter. A drag saw for *butting*, *i. e.*, cutting off square the ends of logs.

Log Frame. A name for a saw-mill, *i. e.*, DEAL FRAME, Fig. 1601, p. 680, "*Mech. Dict.*"; also Plate LIV., p. 2042, *Ibid.* Plate III, p. 72, *supra*.

Log′ging Lo′co-mo′tive. A light back-truck locomotive used on logging and plantation roads,

Fig. 1628.

Logging Locomotive.

where the track is usually uneven and the speed slow; also for shifting and switching, and for local passenger traffic on narrow-gage roads.

Log'o-graph. An instrument by Barlow (Br.) for giving a graphic representation of the vibratory motions of the air-waves of speech. It was thought possible it might become a substitute for short-hand writing. It depends for its action on the well-known fact, that, in articulating, the air is forcibly expelled from the mouth in jets of different character by different consonant sounds; this, irrespective of intensity, is due, in part, to the specific energy of expiration in the enunciation of the consonant; some of these, as is well known, commence with an energetic puff, and others in a much less decided manner. The instrument reproduces all these, and other peculiarities graphically.

It consists in a mouth-piece similar to that of a speaking trumpet, which is inclosed at one end by a thin india-rubber diaphragm about 2½″ in diameter. A small camel-hair pencil, moistened with ink and aniline dye, is attached to the center of the diaphragm so as to partake of its motions. A strip of white paper is caused to move uniformly past the point of the pencil-marker by clock-work. On speaking into the mouth-piece the diaphragm is violently agitated, and the hair pencil draws a fine, irregular line along the paper strip. This line is a delineation of the mechanical air motions produced by speech. The subject is considered, and illustrations of the sound tracings given, on pp. 2514, 2515, "*Mech. Dict.*"

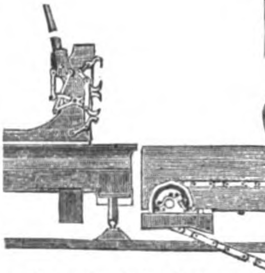
Cf. Paper by *Barlow* . * "*Jour. Soc. Tel. Eng.*," vii. 65.
* "*Scientific Amer.*," xxxvii. 376.
"*Scientific Amer. Sup.*," 1923.

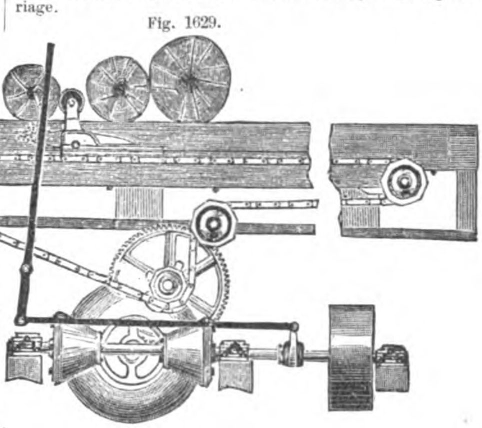
Log Rail'way. One the track of which is formed of logs, laid to a gage and parallel. The upper surface is rounded to suit the concave surface of the truck wheels; or, a square scantling is pinned to the log, and the ordinary flanged wheel used with engines and trucks. — "*R. R. Gaz.*," xxiv. 105.

Log Rol'ler. A device in a saw-mill to convey logs from the log-deck or the log-way skids to the head-block.

By the motion of the lever the friction-gear is thrown into action, the chain traverses and the knees come against and push the log upon the carriage, bringing it squarely against the knees of the head-block. Motion of the lever in the other direction throws the other friction cone into connection with the wheel beneath the track, and, the chain being moved in the other direction, the knees retire, being forced down as they pass beneath the next log and then erect themselves behind it ready to push it in turn upon the log carriage.

Fig. 1629.





Emery's Log Roller.

Log Scale. A table which gives the quantity of lumber, one inch thick, board measure, which may be obtained from a round log, the length and the diameter below the bark being given.

Log Turn'er. A device for turning a log on its carriage after slabbing, or to roll it on to the carriage. Fig. 1630.

A spiked bar on the end of a piston rod working in a steam cylinder beneath the log floor, is projected upward so that the teeth or spikes on its surface shall catch against the log and roll it. The steam cylinder can be oscillated on its gudgeons in order to act upon logs otherwise beyond its range, as seen in dotted lines.

B is a flexible steam pipe; *C* is the bar, with teeth *D*. *G* is a supplementary bar which is brought into action to hold the log from rolling back when the toothed bar retires for another hitch. The cylinder is caused to oscillate by putting the foot upon a treadle lever which acts against a transverse arm and tips the cylinder; the latter is restored to vertical position by the counter-weight *J*.

Long Rol'ling Splice. (*Nautical.*) A splice for lead lines, fishing lines, etc., in which the junction is very long and the splice rolled to make it round and symmetrical so as to run freely.

Long Splice. (*Nautical.*) The junction of two rope ends by intertwining the strands for a relatively long distance. See *h*, Fig. 5435; also *a e*, Fig. 5434, p. 2279, "*Mech. Dict.*"

Loom. See for history and instances Figs. 2996–3006, pp. 1351–1358, "*Mech. Dict.*"

Watson's "The Theory and Practice of the Art of Weaving by Hand and by Power."

Loop. (*Fire-arm.*) The projection under the barrel to which the fore end is fastened.

Loop Bolt. (*Vehicle.*) A bolt with ornamented head for securing the body-loop to the running gear of a carriage.

Loop Head. (*Vehicle.*) The swell and eye on the end of a body loop. See Fig. 358, p. 114, *supra*.

Loop Knot. (*Nautical.*) A form of hitch. See 27, Fig. 2777, p. 1240, "*Mech. Dict.*"

Loop Yoke. (*Vehicle.*) A loop for the strap by which the swaying of the body is limited. See *d*, Fig. 358, p. 114, *supra*.

Loose Box. (*Manége.*) A partitioned space in a stable where a horse may be confined without haltering.

Loose Hook Block. (*Nautical.*) A block the hook of which is secured by a loop to the eyes of the block-strap, instead of being rigid therewith.

Loose'-joint Hinge. One in which the leaves are detached by lifting the blind, door, casement-window, or what not.

Loose Pin Hinge. One in which the leaves are detached by lifting out the pintle.

Fig. 1631.

Loose Pin Butt-hinge.

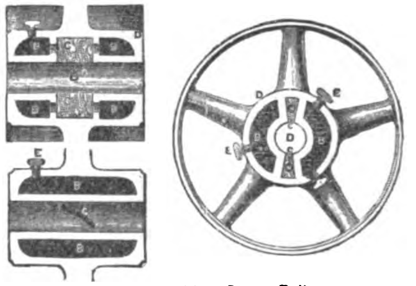
Fig. 1632.

Streit's Pulleys.

Loose Pul'ley. A pulley running free on a shaft, and to which the belt is transferred when the machinery is to be stopped.

The pulleys shown in Fig. 1632 are fast and loose, the latter being the smaller one which is loose on the shaft. From it extends a flaring flange which expands to the diameter of the fast pulley so as to enable the belt to be readily slipped from one to the other. The object is to have the belt run slack when not driving the machinery.

Fig. 1633.



Otis' Self-oiling Loose Pulley.

In the *Otis'* self-oiling loose pulley, Fig. 1633, the hub is cored out to form an annular oil chamber *B* surrounding the bore; this communicates indirectly with the shaft *D* by the intervening supply chambers *C*, which are filled with wick which leads the oil from the reservoir to the shaft. Oil is supplied by exterior opening closable by screw plugs *E*.

The *Oesterline* loose pulley has a somewhat similar arrangement.

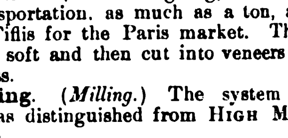
Davis, Br.	* "*Engineering*," xxx. 349.
Fay	* "*Scientific American*," xxxvii. 294.
Kitson	* "*Engineering*," xxvii. 243.

Lor'gnon. A single eye-glass, also known as a *quizzing* glass.

Lost Mo'tion. Looseness of fitting, incident to wear of parts.

Lou-chettes'. Spectacles, or rather goggles, for strabismus; to constrain the eyes to assume the normal position with eyes front.

Fig. 1634



Louchettes.

Loupe. Fr. A knot or burr on a tree from which veneers are cut for fancy furniture. Walnut, maple, oak, and other trees yield these curled excrescences. Remarkable specimens, some weighing, before dividing for transportation, as much as a ton, are shipped from Tiflis for the Paris market. They are steamed till soft and then cut into veneers by a shaving process.

Low Mil'ling. (*Milling.*) The system of close grinding as distinguished from HIGH MILLING, which see.

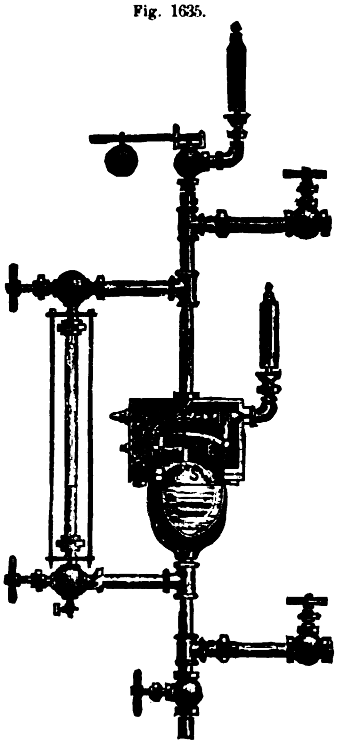
"The pointed or clipped grain is passed through stones at the nearest adjustment, by which it is at once ground to flour. It is practicable, however, by careful management of the working between the stones, to obtain a large part of bran and gluten-coats without disintegration, and to separate them from the flour by sifting, and this the more perfectly as by this process of milling finer sieves are employed. Still, it is not possible, at least it has not yet been shown, that this separation of the bran can be carried out so perfectly as to yield an *extract flour* of such fairness as is ordinarily obtained by the process of *high milling*. — *Horsford*.

See HIGH MILLING, pp. 457, 458, *supra*, where the question High Milling *v*. Low Milling is considered, and references are given to apparatus involved.

Low-wa'ter A-larm'. A device to sound an alarm when the water in the boiler sinks below the point of safety.

A number of devices, including those operating on the various principles, the float, the thermostat, and the fusible plug, are shown in Fig. 3008, p. 1359, "*Mech. Dict.*"

Fig. 1635.

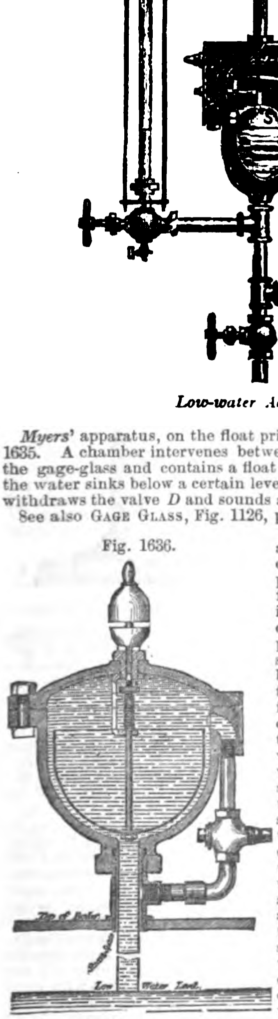


Low-water Alarm.

Myers' apparatus, on the float principle, is shown in Fig. 1635. A chamber intervenes between the boiler head and the gage-glass and contains a float *S* which descends when the water sinks below a certain level and by actuating levers withdraws the valve *D* and sounds a whistle.

See also GAGE GLASS, Fig. 1126, p. 365, *supra*.

Fig. 1636.



Kenyon's Low-water Alarm.

In *Kenyon's* low-water alarm, Fig. 1636, under ordinary conditions the pressure in the boiler forces the water up the inner pipe, and fills the outer vessel and suspended copper basin ; but should the water in the boiler get below the bottom of the pipe, the water falls out of the vessel excepting the portion retained within the basin, which, acting as a dead weight, overcomes the slight resistance of the upward spring and the steam pressure, and pulls the plug away from the opening to the whistle, when the steam, rushing up the pipe, sounds the alarm. The apparatus can at any time be tested by turning the handle of the steam-cock upward, which places the interior of the vessel in a state of equilibrium, when the water falls to the level of that in the boiler (excepting that contained in the basin, which cannot escape), and the whistle is sounded ; the vessel refills with water on closing the steam cock.

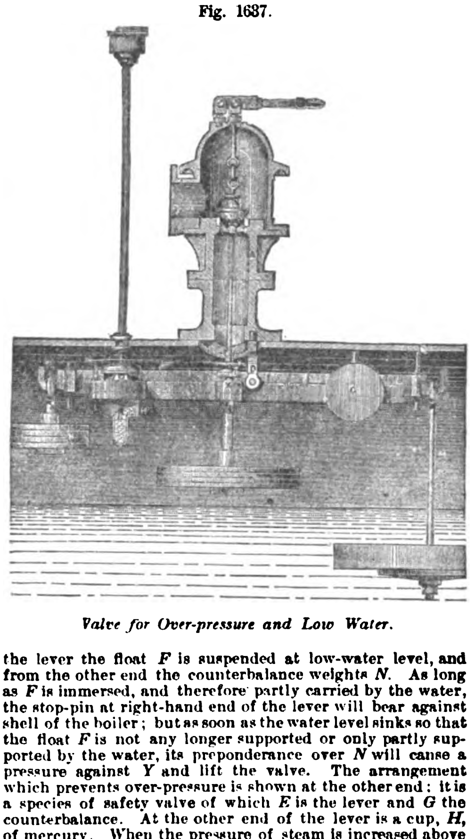
See also LOW-WATER VALVE.

Low-wa'ter Valve. A valve which opens when the water in the boiler sinks below the level of safety. See LOW-WATER ALARM, Fig. 3008, p. 1359, "*Mech. Dict.*," and Fig. 1636, *supra*.

In *Hopkinson's* valve, shown at Fig. 1637, the working parts are within the boiler. In the form shown, it is a combined over-pressure and low-water valve. From one end of

Fig. 1637.



Valve for Over-pressure and Low Water.

the lever the float *F* is suspended at low-water level, and from the other end the counterbalance weights *N*. As long as *F* is immersed, and therefore partly carried by the water, the stop-pin at right-hand end of the lever will bear against shell of the boiler ; but as soon as the water level sinks so that the float *F* is not any longer supported or only partly supported by the water, its preponderance over *N* will cause a pressure against *Y* and lift the valve. The arrangement which prevents over-pressure is shown at the other end : it is a species of safety valve of which *E* is the lever and *G* the counterbalance. At the other end of the lever is a cup, *H*, of mercury. When the pressure of steam is increased above a certain limit, a part of the mercury is displaced from the cup, and the lever, lightened at that end to that extent, rises and lifts the valve in the dome, allowing the steam to escape.

Lub'ber's Mark. (*Nautical.*) Of a compass. The black vertical mark in the compass-bowl in the direction of the ship's head, by which the angle between the magnetic meridian and the ship's course is shown.

Lu'bri-cant.

At a boiling heat stir together —

Petroleum	**1 liter.**
Graphite	**88 grams.**
Beeswax	**3 grams.**
Tallow	**9 grams.**
Caustic soda	**3 grams.**

Add to petroleum saturated solution of lime-water till the mixture becomes ropy, and then keep stirring till a drab color is acquired. 1 part may be added to the same amount of animal fat. — *Von Phul & Groat.*

Residuum of petroleum distillation, 160 ; compounded with pine tar, 15, boiled by steam heat and diluted with petroleum.

Petroleum, graphite, flour-sulphur, steatite, tallow, rock-salt, palm oil. — "*Amer. Manuf.*," "*Sc. Amer.*," xxxiv. 39.

Slaked lime, tar oil, resin oil, for slow-moving journals; caustic soda added for more rapidly moving objects. — *Newton*, Br.

Lu'bri-cant Al-loy'. An alloy of zinc, 7; copper, 4; tin, 1, resisted all turning tools till the edges were moistened with petroleum. The alloy then yielded readily. — "*Les Mondes*."

Lu'bri-cant Test'er. A machine to test the quality of oil used for lubricating purposes.

Most of the machines are founded upon the same principle. The better the oil, the less the frictional adherence of two surfaces moving relatively and in contact with a given pressure upon them.

This may be evidenced in either of several ways: —

By the power required to produce the motion.

By pressure in the nature of a Prony brake to bring the motion to a halt.

By heat generated by the friction.

Deprez & Napoli's apparatus gives for the various oils a distinctive trace on properly ruled paper.

It has a lower revolving plate and an upper one supported upon it in such a manner that when oil is placed between the points of support of the upper plate and the lower plate, the tractile force upon the upper draws upon a steel ribbon connected to a pulley mounted on points, and to the axis of which is secured a pendulum. The rod of the latter carries a roller which engages upon a vertical piece attached to a carriage mounted on wheels which traverse rails. The carriage carries a sheet of paper against which is pressed a pencil which has a very slow motion of translation proportioned to the number of turns of the lower plate before mentioned, and the direction of the said motion is perpendicular to that of the carriage.

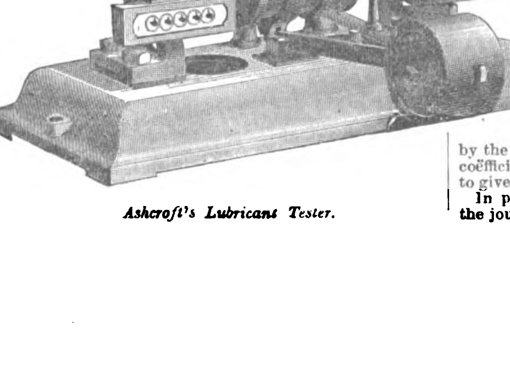
The curve traced on the paper by the composition of these two movements is the curve representing the value of the friction in terms of the number of turns made by the said lower plate.

The tractile force is so much the greater as the lubricating quality of the oil decreases. See "*Scientific American*," xxxvi., 214. A still better view of the same, or of a machine with similar functions, is given on p. 360, vol. xl., *"*Scientific American*." It appeared in "*Engineering*," and represents a machine employed by the Eastern Railway of France to ascertain the value of various lubricants, and was shown at the Paris Exposition of 1878.

An apparatus used by the Paris, Lyons, & Mediterranean Railway is shown at page 2794, *"*Scientific American Supplement*." Two pairs of wheels on their axles are mounted in a frame, one above the other. Axle-boxes having been charged with the lubricant to be tested, the springs are raised by an arrangement of screws and worm wheels so that the axles of the upper shaft are lifted from the load. The wheels being rotated the springs are brought down, and that lubricant is the best which allows the heaviest pressure without heating.

Ashcroft's lubricant tester, Fig. 1638, consists of a shaft mounted on centers, so as to rotate freely, upon which shaft a drum is fixed, and revolves with the shaft. To this drum brasses are neatly fitted, and held in position and pressed against the surface of the drum by levers and weights; and between the surfaces of the drum and of the brasses the oil is tested.

Fig. 1638.



Ashcroft's Lubricant Tester.

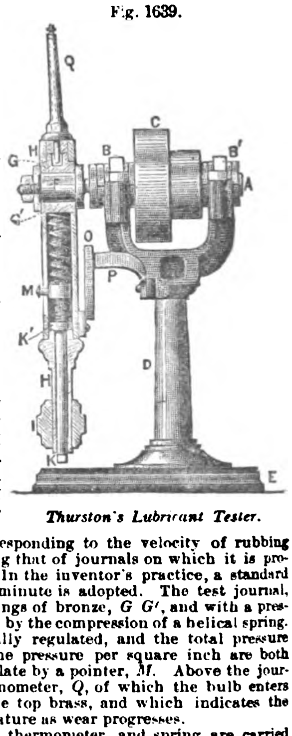
Upon the upper brass is a cup, which communicates with the surface of the drum, and into which the oil is dropped. The shaft is rotated by a belt and pulley, and the number of revolutions is registered by a counter device operated by gearing from the shaft. Attached to the upper brass is a reservoir of mercury, into which a thermometer is adjusted, which indicates the heat generated by the frictional surfaces as the trial of the lubricant proceeds.

The principle upon which this machine is based is that of submitting a given quantity of the lubricant to be tested to a frictional action between cylindrical concaved and convexed surfaces under a fixed pressure, and then measuring the quantity of motion required to use up the given lubricant, determining the time when this is accomplished by the temperature of the frictional surfaces, which increases rapidly as the lubricant becomes exhausted.

Four drops of the lubricant to be tested are dropped into the cup from a glass dropping-tube, the temperature noted, the machine set in motion and allowed to run until the thermometer indicates a given degree of temperature at which it would be safe to run the machine — say 200° Fah. — as a standard; when it is stopped, and the number of revolutions taken.

The better the quality of the oil, the longer the machine will run before reaching that temperature. After each experiment the machine is taken apart, thoroughly cleaned, and allowed to cool to the surrounding temperature.

Fig. 1639.



Thurston's Lubricant Tester.

In order to test the "gumming" qualities of the oil, it is allowed to cool before cleaning.

The speed is about 1,400 revolutions per minute. On tests of various kinds of oils, the revolutions given varied from 11,250 to 15,360 before reaching the given temperature.

In Professor Thurston's lubricant tester the oil or other lubricant to be tested is placed on the journal *F*, which is on the overhung extremity of a shaft *A*, mounted in bearings *B*, *B*, on a standard, *D*, mounted on a base plate, *E*. The shaft is driven by a pulley, *C*, at any desired speed. A counter may be placed at the rear end of the shaft to indicate the number of revolutions. The shaft is usually driven at a fixed speed, corresponding to the velocity of rubbing surfaces approximating that of journals on which it is proposed to use the oil. In the inventor's practice, a standard speed of 750 feet per minute is adopted. The test journal, *F*, is grasped by bearings of bronze, *G G'*, and with a pressure which is adjusted by the compression of a helical spring. This spring is carefully regulated, and the total pressure on the journal and the pressure per square inch are both shown on the index plate by a pointer, *M*. Above the journal is a thermometer, *Q*, of which the bulb enters a cavity in the top brass, and which indicates the rise in temperature as wear progresses.

The brasses, thermometer, and spring are carried in a pendulum, *H*, to which the ball *I* is fitted; and weights are adjusted in such a manner that the maximum friction of a dry but smooth bearing shall just swing it out into the horizontal line. The stem, *K K'*, of the screw, which compresses the spring, projects from the lower end of the pendulum and can be turned by a wrench. A pointer, *O*, traverses an arc, *P*, and indicates the angle assumed by the pendulum at any moment. This angle is very large with great friction, and very small with good lubricating materials. This arc is carefully laid off in such divisions that dividing the reading by the pressure shown on the index gives the corresponding coëfficient of friction. The machine can also be arranged to give the friction directly.

In practical use, a standard quantity of oil is placed on the journal. The bearings are slipped on and set up to the proposed pressure; the machine is started at the speed determined upon, and the observer notes the time, speed, pressure and temperature. These observations are repeated and recorded at regular intervals, and cease when a rapid rise of temperature to an objectionable or dangerous extent indicates that the lubricant has become destroyed.

See also Fig. 6330, p. 2539, "*Mech. Dict.*"

Another form, made by Bailey, of Salford, England, has a pendulum with a block on the end of a jointed arm, the block moving to and fro on a plate as the pendulum swings. The block and plate having been daubed with a definite amount of the lubricant, the pendulum is started in its oscillations, and the number of movements counted before it comes to rest. These will be fewer when the lubricant is the poorer.

Still another apparatus by Bailey is for testing the consistence of oils at given temperatures. A drop of oil is placed on the upper end of a slanting glass plate covering a heated tank. The distance which it will come down the glass is the measure of its consistence.

The form and size of a drop which drops from a pipette is an indication of quality at a given temperature.

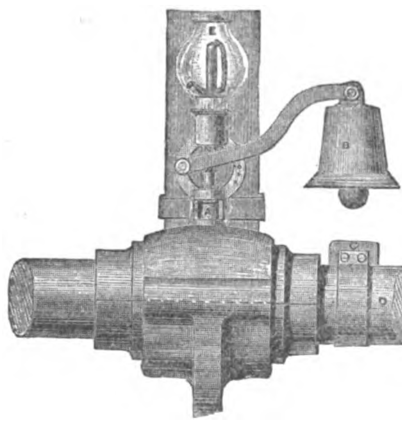
Lu'bri-ca'tor A-larm' Sig'nal. A device to give an alarm when a journal becomes heated from absence of lubricant.

Alley's alarm is shown in Fig. 1640. The mode of action is as follows: The bell *B* is held in an elevated position by the composition plug *A*. If the supply of oil ceases from

Fig. 1640.



Lubricator Alarm Signal.

any cause the bearing heats and melts the plug. The bell *B*, thus losing its support, drops into gear with kicker *C* on the shaft *D*, rings, and continues to ring until the bearing is cooled down, and the plug renewed. These plugs are formed of hard, fatty matter, which melts at 130° Fah., the lubricant not taking fire until the temperature of the metal reaches 300° Fah. The substance of the plug running into the bearings prevents the evil from increasing before steps can be taken to reduce the heat.

Luff Tac'kle. (*Nautical.*) A tackle with a double and single block and a fall. *d*, Fig. 6159, p. 2480, "*Mech. Dict.*"

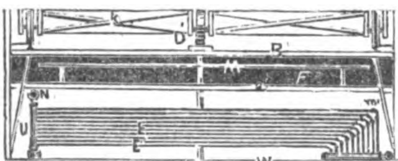
trucks *D* is run upon rails. Underneath floor *B* of the lumber chamber is a dead-chamber, *F*, and still lower is the chamber heated by steam-pipes and coils *N, P, U, U′, E.*

Fig. 1642.

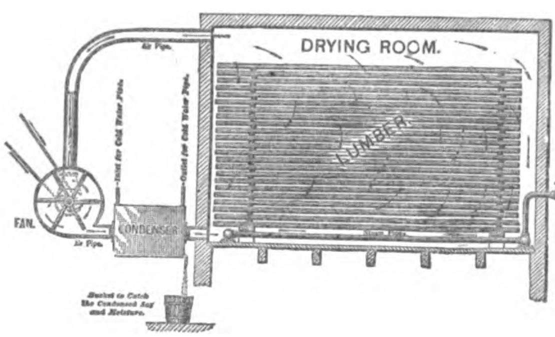


Lumber Dryer. (*Transverse Section.*)

The drying is by circulation of heated air which carries off the evaporated moisture.

Fig. 1643 shows Fuller's apparatus for drying lumber, in which the moisture is condensed; the room being tightly

Fig. 1643.

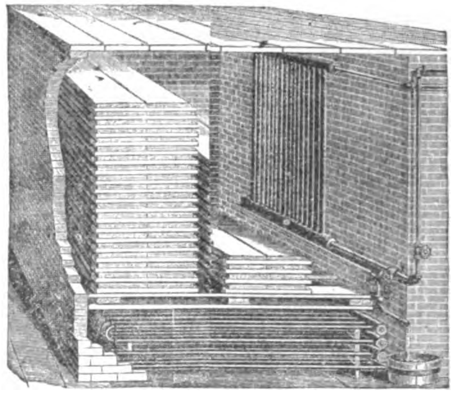


Fuller's Apparatus for Drying Lumber.

closed and steam-heated. The boards are placed in parallel rows with intervening spaces. A coil of steam-pipes is supported just above the floor of the room. From a point near the ceiling an air-duct leads to the fan; air is exhausted from the room and blown by the fan to the condenser, which is kept cool by a stream of cold water. The same air, deprived of moisture, is again driven into the lower stratum around the steam-pipes, and repeats its hydrophoric office.

Woods' lumber dryer, shown in Fig. 1644, has the artificial heater and the condenser in one tightly closed apartment, heated to 160° Fah., which in the illustration is shown as of very limited dimensions, but may hold ten or a dozen piles of lumber on the grated floor above the system of steam-pipes and coils in the basement. On the wall is seen the vertical system of water-pipes on which the moisture of the apartment condenses, and down which it trickles; being caught in a trough, it is conducted away. A stream of cold water constantly passes through the condenser pipes arranged against the wall.

Fig. 1644.



Woods' Lumber Dryer.

Lu'mi-nous Di'al. Recordon, of Paris, illuminates watches and clock dials by passing an electric discharge through a Geisler tube filled with a gas which yields a bright light. For a watch; a thimble cell of Trouvé is, together with a small induction coil, hung at the watch-chain. Pressing a spring completes the circuit and illuminates the dial.

A number of compositions of phosphorescent salts are given under Dial, p. 254, *supra.*

Lu'mi-nous Buoy. 1. One which is luminous by night, to warn mariners from shoals.

2. One which is thrown into the sea and is self-lighting, or covered with a phosphorescent substance, as a guide to a person overboard.

A mode of automatic electric lighting of buoys, invented by M. de Lussex, of Belgium, consists in the employment of a Ruhmkorff coil in connection with a vacuum tube on the buoy as a lantern. The battery power is furnished by large plates of zinc and carbon, the sea-water acting as the exciting liquid. The induced current thus generated is said to be sufficient to light up the tube lantern so that it renders the buoy useful at night. — "*Engineering News.*"

Pintsch's buoy, for the same purpose, has a reservoir containing a quantity of condensed rich gas. Electric lighting apparatus is used. See Buoy, p. 147, *supra.*

Lieut. Cook's safety buoy is mentioned, p. 147, *supra*: also in "*Mech. Dict.,*" p. 407. See also Life Saving Apparatus, *supra.*

Lu'mi-nous Paint. A phosphorescent paint to render an object visible at night.

English Patent 4,152, of 1877. Method of rendering paints, whitewashes, and temperings luminous, consists in introducing into ordinary paints, varnishes, or washes, a phosphorescent substance, with or without colors. The compound consists of lime and sulphur, or carbonate of lime and sulphur heated together. It is then mixed with colorless varnish, and may be applied to various articles by brush or by dipping, and to protect from weather is glazed over with a flux, as in enameling. Inventor mentions clock faces, thermometers, mariner's compass, cards, insides of railway cars, etc.

W. A. Caron, 121,703, Dec. 12, 1871. Door-plates having the letters of the name surrounded by an opaque surface, themselves being transparent (or *vice versa*). A stick of phosphorus held against the rear of the plate by a spring, and packed in cement, so as to admit but a limited amount of air for the slow combustion of the phosphorus. Plate luminous by night.

Jules Peiffer, French *brevet*, Aug. 22, 1877. Certificate added Aug. 19, 1878. Application to various articles, under the name of "*Fulgore,*" of phosphorescent substances to produce various colors in the dark after having been exposed to natural or artificial light. The *Fulgore* is made from the sulphides of barium, strontium, calcium, etc.

An English patent has a composition of carbonate of lime, phosphate of lime, hydrate of lime, sulphur, sea salt, and almost any mono-sulphuret. Another has calcined shells, sulphur, arseniate of baryta, gum tragacanth, or sulphides of strontium, or barium with magnesia. See "*Sc. Am.*," xli. 248.

W. Trotter, No. 246,841, Sept. 6, 1881. Paint or composition of sulphide of calcium, and a vehicle consisting of a varnish made with gum mastic or other resinous body, and turpentine or other spirit, or gelatine. May be mixed with various colors; is translucent and phosphorescent, and is intended to be applied to windows, to emit during the night the light stored up during the day.

Balmain's paint is a preparation of sulphide of calcium. See "*Engineering and Mining Journal*," xxix. 408.

On photographic paper weights. See "*Scientific American*," xlvi. 249. See also DIAL, p. 254, *supra*.

Lump. (*Fire-arm.*) The iron piece soldered on to the barrel, and which descends into the action (in break-joint breech-loaders) where there is a recess prepared for it.

Lu'na-tel'lus. An orrery showing the astronomical relations of the earth and moon.

Lung Test'er. A spirometer: an instrument for testing the capacity of the chest. Fig. 5431, p. 2279, "*Mech. Dict.*"

Burt . . . . . * "*Scientific American*," xxxv. 242.

Lus'ter. 1. (*Ceramics.*) Lusters are thin metallic surfacings to pottery which require no burnishing and in some cases have iridescent effects. They are placed on the ware with camel's hair pencil and the ware is fired in a muffle. They offer a cheap and brilliant effect with but little permanence. The following are the more usual: —

Gold luster is prepared by precipitating with ammonia the regal solution of gold, diluting the humid precipitate with turpentine and applying it without flux.

Platinum luster is obtained by a concentrated solution of chloride of platinum mixed with an essential oil.

Mother-of-pearl luster is obtained by precipitating by a weak acid a double sulphate of gold and potassium and grinding the precipitate with a little flux and essence of lavender.

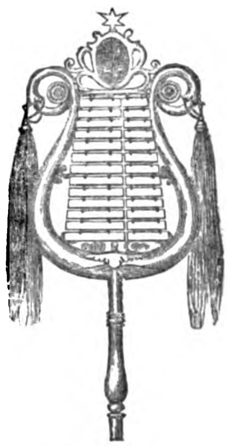
The *copper luster* of Spain is supposed to be produced by the silicate of the protoxide of copper; it is conjectured that the oxide is thrown into the furnace when the ware is fired.

Cantharides luster is obtained with a mixture of lead-glass and a little oxide of bismuth and chloride of silver. It is put on with the brush, the ware fired in the muffle from which it is withdrawn while red hot.

2. (*Fabric.*) A taffeta woven goods with cotton chain and long luster wool weft. A grade of alpaca.

Ly'ra. (*Music.*) An instrument with jingling plates. That shown in Fig. 1645 has two sets of steel bars, embracing two chromatic octaves. For references to the various instruments which have bars in series sounded by percussion, and consisting of wood, metal, glass, stone, etc., see MARIMBA.

Fig. 1645.



Conn's Lyra.

Ly'sim'e-ter. A rain gage; pluviameter; ombrometer; udometer. See pp. 1871–1873, and Figs. 4145, 4146, "*Mech. Dict.*"

The lysimeter is designed to determine the amount and quality of the water which percolates through a certain depth of soil. By it a certain body of soil is so isolated without disturbing its natural condition that all the water percolating can be measured, and the heavy rains which in part flow over the surface of the soil may also flow over the lysimeter and not enter into the measure of effective rain. It consists of a box inclosing an undisturbed cube of earth, and a light bottom with a slant which directs the water to a measure placed below the drip, in a pit excavated at the side of the box. This method is in use at Rothamstead, England, and at "Houghton farm," Orange Co., N. Y.

Gage for temperature of rain, *Colladon* . . . * "*Scientific American Sup.*," 2746.
Rainfall . . . . . . * "*Scientific American Sup.*," 1606.
Rain gage . . . . . * "*Scientific American*," xxxvi. 257.

M.

Ma-chine'. As distinct — on the one hand — from an engine: An instrument which fashions, or operates mechanically upon, objects or materials, and does not contain its own motor. It is driven by an engine or other motor, or by hand.

As distinct from a tool: It contains its own guide for operation.

A tool is a manual instrument depending for its efficiency upon the strength and skill of the operator.

A machine-tool is one which supersedes the hand tool formerly employed.

Instrument is a qualitative term, applied to tools and apparatus of delicacy and precision.

Some irregularities exist in the placing of these terms.

Ma-chine′ Bolt. A bolt with a thread, and a square or hexagonal head.

A machine *screw* is similar except as to the head, which has a slit for the insertion of the screw-driver.

Ma-chine′ Gun. One in which the loading and firing are executed by mechanical means; the power being usually applied by means of a hand-crank.

The subject is considered under BATTERY GUN, * pp. 249-251, "*Mech. Dict.*," where the following are described or referred to: —

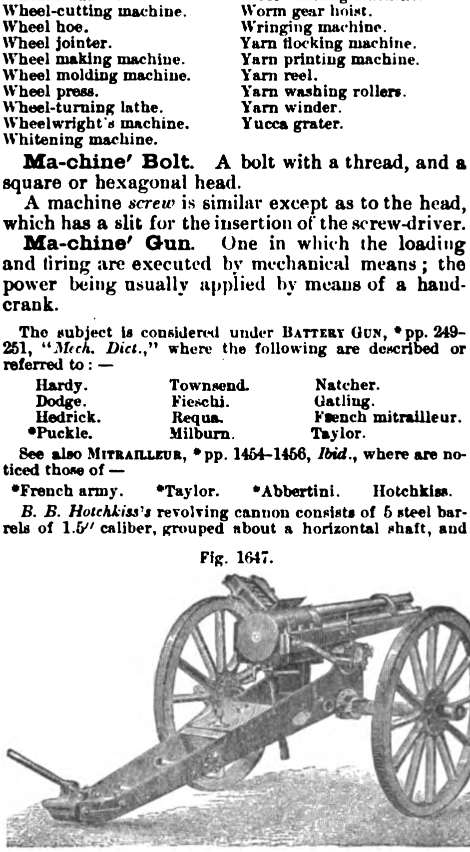
Hardy.	Townsend.	Natcher.
Dodge.	Fieschi.	Gatling.
Hedrick.	Requa.	French mitrailleur.
*Puckle.	Milburn.	Taylor.

See also MITRAILLEUR, * pp. 1454-1456, *Ibid.*, where are noticed those of —

*French army. *Taylor. *Abbertini. Hotchkiss.

B. B. Hotchkiss's revolving cannon consists of 5 steel barrels of 1.5″ caliber, grouped about a horizontal shaft, and

Fig. 1647.

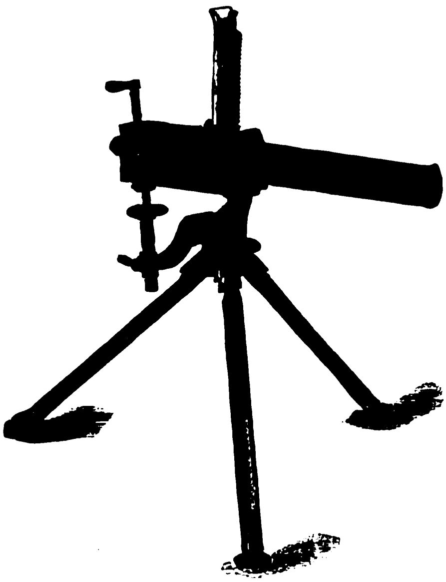


Hotchkiss Cannon Revolver.

revolving in front of a breech-block, which has openings to receive the cartridge and empty shell. The gunner, by turning a crank extending from the stationary breech, causes the shaft and barrels to revolve, and, while this rotation is in progress, mechanism is operated which shoves fixed ammunition into the rear of each barrel, and then, as the loaded barrels continue their revolution, a spring plunger strikes each cartridge in succession, and each barrel is thus discharged in turn. The projectiles are percussion conical shells, weighing about one pound each, and the rapidity of fire has exceeded 100 shots per minute. As each shell on striking bursts into an average of 17 effective pieces, the above volley is equal to 1,700 bullets striking within an area of 260 square feet in the above period of time. The range far exceeds that of any small arm. The revolving cannon is made by the inventor for the French government at St. Denis, near Paris, and is stated to be effective and accurate at 5,000 yards.

The *Gardner* machine gun (Fig. 1648) is mounted upon tripod or upon carriage; is automatic, transferring the cartridge from the feed-port to the barrel, firing, extracting, and ejecting the empty shell, consecutively to each barrel.

Fig. 1648.

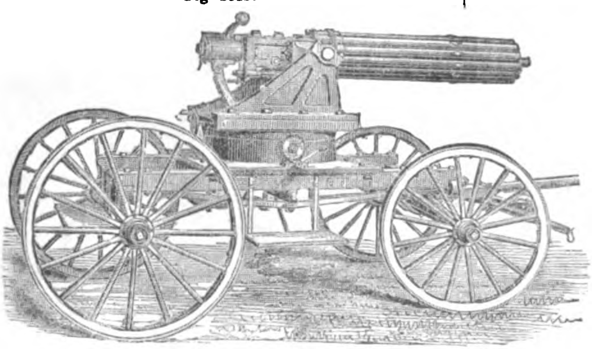


Gardner Machine Gun.

The barrels are stationary. The mechanisms for feeding and firing each barrel are independent; those for loading cartridges and ejecting shells are positive. The cartridges are fed automatically from a vertical magazine: the movements are derived from a hand-crank. The gun has traverse motion on its vertical axis in the stand, and adjustment for altitude by hinge and screw.

The *Taylor* machine gun has 12 barrels of 2″ caliber, each having a magazine capable of holding 12 cartridges. The magazines revolve, the loading is automatic, and the gun worked by one person by means of the lever on the tail-piece.

Fig. 1649.



Taylor Machine Gun.

The *Bailey* gun has a circular cluster of parallel barrels, and is worked by a revolving crank, the cartridges descending in a case which is stuck into the hopper so as to feed automatically. It has one lock, made in two pieces, which works all of the barrels.

See also *Parkhurst's* machine gun. Patent No. 228,777.

Coloney's patents:	225,461.	225,466.
	225,462.	231,652.
	225,465.	231,653.

Farwell's machine gun consists of 10 steel barrels of .45″ caliber, arranged parallel to each other in a metallic frame. From center to center of the outer barrel is 3′. Each barrel is charged separately from a magazine containing 50 rounds of ammunition. The charging, firing, and extraction of exploded shells are all accomplished by the turning of one crank, at each revolution of which the whole 10 barrels are discharged, emptied, and reloaded. A system of cog-wheels connects the firing crank with an automatic traverse.

It differs from the Gatling gun in the simultaneous loading and firing of 10 barrels, the latter loading each barrel through the same magazine aperture and firing but one shot at a time, though with almost incredible swiftness.

The *Requa* battery has 25 barrels lying horizontal and parallel on a carriage. It is a breech-loader, and the barrels are fired simultaneously.

The arrangement of the barrels is similar to that of the "infernal machine" of Fieschi, with which he fired upon Louis Philippe and his staff, killing several persons, but missing the king. In Fieschi's device the barrels were separately loaded, laid on a bench, clamped, and a train of powder laid over the touch-holes

In Requa's battery the paper cartridges are driven into all the barrels simultaneously by a sliding breech-block traversing at the rear of the whole platoon, and operated by a lever. Priming leads to each of the cartridges, and the charges are fired by a cap.

Two forms of the *Taylor* battery gun have the horizontal parallel (or converging) arrangement of barrels.

See also REVOLVING CANNON.

Ma-chine' Twist. A kind of silk thread, made three-cord, and twisted from right to left. Made specially for use in the sewing machine. Sewing silk is two-cord, and twisted from left to right.

See account in *J. L. Hayes'* "*Centennial Report*," v. 96, 97.

Mack'in-tosh Steel. (*Metallurgy.*) Steel made from malleable iron by a stream of carbureted hydrogen directed upon the bath of metal in a furnace. C. Mackintosh patent, 1825. Also known as the Baron process.

Mack'e-rel Latch. (*Fishing.*) A cord-clamp which holds the inboard end of a mackerel line.

Mack'e-rel Plow. (*Fishing.*) Also known as a *fatting-knife*, for creasing the sides of lean mackerel to make them resemble No. 1.

Mag'a-zine' Bat'te-ry. (*Electricity.*) One in which a magazine contains the crystals which are supplied to the liquid as exhausted, to keep the liquid saturated: —

As in the *Daniells'* battery, which has a magazine of sulphate of copper crystals; and the *Anderson*, which has a magazine filled with bichromate of potassium crystals.

Anderson's battery, U. S. Patent, "*Scientific American*," * xliii. 115.

Mag'a-zine' Gun. A gun containing a supply of cartridges, mechanically furnished to the chamber of the barrel, seriatim.

The subject is considered on pp. 1367-1369, "*Mech. Dict.*," where the following systems are described or referred to: —

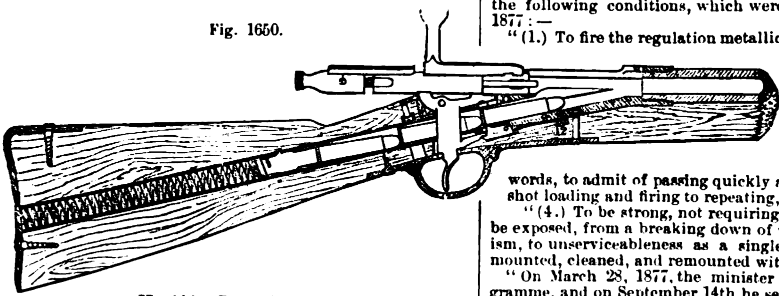
*Winchester.	*Callen.
*Ward-Burton.	Swiss.
Spencer.	Meigs.

Also on pp. 853, 854, *Ibid.*, and Plate XVIII.

The Hotchkiss repeater is a bolt and needle magazine gun. The magazine in the butt contains six cartridges which are forced forward by a spring. The gun is shown in Fig. 1650.

The cartridges are inserted one at a time, to the number of five, pressing each backward into the chamber until a click

Fig. 1650.



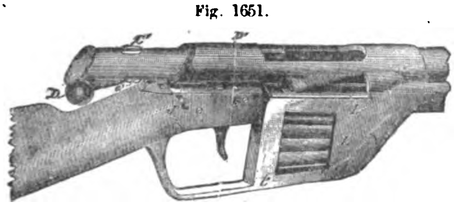
Hotchkiss Repeating Arm.

is heard, due to the head of the cartridge passing the cartridge stop. A sixth may be placed in the chamber. To load, turn the bolt and retract it. The bolt engages a cartridge, and the return motion forces the load into the chamber and cocks the piece. The piece has the usual 4 motions: Twist, draw, return, lock. The cocking being automatic, the piece is ready to fire.

Lieut. A. H. Russell's (U. S. Army) magazine gun is shown in Figs. 1651, 1652. The magazine is at the side and can be filled whether the piece be loaded or unloaded, the opening for insertion of the cartridge being accessible at all times.

The loading is on the bolt system, but no turning of the bolt is required. Fig. 1651 shows the bolt pushed forward

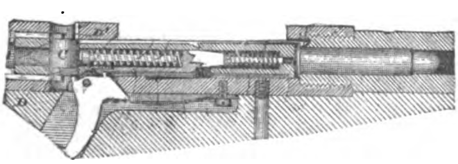
Fig. 1651.



Russell's Magazine Gun. (Elevation.)

slightly, forcing before it a cartridge just introduced into the receiver from the magazine *L*, which holds 5 or 6 cartridges, side by side. The magazine is at the side of the receiver and extends downward to the bottom of the trigger guard. The mouth of the magazine is at the side of the receiver, and the cartridges are forced upward by a spring so as to bring them in succession to the action of the bolt. A spring-gate pre-

Fig. 1652.



Russell's Magazine Gun. (Section through barrel and bolt.)

vents the escape of cartridges except to the receiver, while it allows them to be inserted sidewise into the magazine from without. They may be inserted singly, or the magazine may be filled quickly from a cartridge-box applied to the mouth of the magazine, the cartridges being forced in by the finger, the gate of the magazine yielding to the pressure from above and closing after the cartridges have entered.

The action of the bolt is rectilinear. It is drawn out by a handle which unlocks a pivoted catch-piece, *C*, to free the bolt, and relocks the piece *C* when the bolt is thrust home in loading. The forward motion of the bolt compresses the firing spring and the trigger catches in the hook of the firing pin. The breech mechanism is simple, and the operation requires merely a forward and back motion of the hand.

See also *Trabue's* magazine gun, patents Nos. 223,414; 223,660.

Report of trial of magazine arms for the French navy: —

"The French authorities have recently made a careful trial of repeating arms with a view to adoption should one be found which, while serviceable in other respects, fulfilled the following conditions, which were put forth in March, 1877: —

"(1.) To fire the regulation metallic cartridge of the army.

"(2.) To have the same trajectory and the same accuracy as the rifle model, 1874.

"(3.) So constructed as to be used as an ordinary single shot arm, or, in other words, to admit of passing quickly and simply from single shot loading and firing to repeating, and *vice versa*.

"(4.) To be strong, not requiring too tender care, not to be exposed, from a breaking down of the repeating mechanism, to unserviceableness as a single shooter; to be dismounted, cleaned, and remounted without difficulty.

"On March 28, 1877, the minister approved of this programme, and on September 14th he sent orders to Cherbourg to experiment with three types of repeaters, with detailed instructions as to the trials. These three arms were: —

"(1.) The *Hotchkiss*.

"(2.) The *Kropatschek*.

"(3.) The *Krag*.

"To these three the board confined themselves.

"The result of these trials showed that the magazine of the Hotchkiss was most quickly charged. The Hotchkiss also fires most rapidly; both in repeating and single shot fire the Kropatschek was not far behind it. The Krag does not seem to have been well understood and manipulated by the men.

The Kropatschek — modified — with eight cartridges in its magazine beat the Hotchkiss which had only six, while the Krag with nine cartridges was best of all. The time necessary to discharge this latter arm's magazine of nine rounds was 24.85 seconds, in which time the Kropatschek had on an average fired 8.9 cartridges per arm, and the Hotchkiss 7.9 starting with the magazine closed; with the magazine open 25 seconds were occupied, in which time the Krag fired 9, the Kropatschek 9.3, and the Hotchkiss 8.25 rounds on an average. Single shot fire proved better than recharging the magazine and repeating continually. The minimum times taken to fire off the magazines, at the conclusion of the experiments, when the men were expert, were as follows: Hotchkiss, 6 rounds, in 10 seconds; Kropatschek, modified, 8 rounds, in 14 seconds; Krag, 9 rounds, in 17 seconds; giving an average time per round of 1.66, 1.75, and 1.88 seconds respectively.

"Finally, it was concluded that the Hotchkiss rifle is the easiest and quickest in charging the magazines; then the Kropatschek: and last, Krag. As to rapidity of fire, the Hotchkiss and Kropatschek are about equal. Large magazines have a great advantage; the magazine once empty, it is best not to attempt to refill it till leisure gives the opportunity." — "*Engineer*."

The following United States patents may be consulted: —

Appendix T to the "Report of the Chief of Ordnance," 1878, describes the official trials of magazine small arms for the United States service. It gives drawings and descriptions of the following magazine guns: —

No.	Name.	Plate.	Descriptive Page.
9.	Hotchkiss	I.	27
19.	Hotchkiss	II.	31 (adopted)
17.	Remington	III.	33
	Remington (modification)	IV.	
8.	Sharps	V	39
1.	Franklin	VI	40
2.	Ward-Burton	VII	42
11.	Burton	VIII	44
4.	Hunt	IX.	45
13	Winchester	X.	46
22.	Burgess	XI.	49

List of Magazine Guns at trial (*continued*).

No.	Name.	Plate.	Descriptive Page.
21.	Tiesing	XII.	52
26.	Chaffee	XIII.	53
7.	Buffington	XIV.	54
15.	Miller	XV.	56
24.	Clemmons	XVI.	59
6.	Lewis-Rice	XVII.	58
14.	Lewis-Rice	XVIII.	60
	Russell, magazine for Hotchkiss gun	XIX.	63
	Guer, modification of Hotchkiss bolt.	XX.	

The tests were as follows: —

Preliminary test, for safety; fired by the exhibitor.

1. Rapidity with accuracy.
2. Rapidity at will.
3. Endurance, by continuous firing 500 rounds without cleaning.
4. Firing defective cartridges.
5. Exposure to dust and firing without cleaning.
6. Exposure to rust by sal-ammoniac and two days subsequently in the open air.
7. Excessive charges.

Supplementary tests of various kinds.

The following classification give the peculiar points of each relatively to the method of feeding the cartridge.

CLASSIFICATION OF MAGAZINE ARMS.

FOUNDED ON THE METHOD BY WHICH CARTRIDGES ARE FED FROM THE MAGAZINE.

Magazine arms, supply chamber with cartridges from —

- 1st, butt-stock
  - 1st, by a spring
    - 1st, direct . . . . Hotchkiss. Lewis-Rice. Spencer.
    - 2d, indirect . .
      - 1st, by rotating barrel about axis parallel to it into line with magazine. . Scott and Triplet.
      - 2d, to position opposite receiver . . Clemmons.
  - 2d, by a rachet, which is —
    - 1st, automatic . . . . Chaffee.
    - 2d, operated by hand. . . . . Springfield-Miller.
  - 3d, by a spiral cam (screw motion) . . . . Evans.
- 2d, tip-stock by a spring — on a carrier which is—
  - 1st, sliding at right angles to axis of bore Winchester. Henry. Hunt. Vetterly.
  - 2d, rotating —
    - 1st, to position oblique to axis of bore . . . . Burton. Ward-Burton. Sharps. Remington.
    - 2d, to position parallel with axis . . . . . Tiesing. Burgess.
  - 3d, sliding and rotating — . . . . Buffington.
- 3d, magazine on top of barrel . . by a spring — to position parallel to axis of bore and above receiver — and by gravity into line with axis of bore. Franklin.
- 4th, magazine below bolt. by a spring (vertically) — to position opposite center of chamber. . . . . Lee.
- 5th, revolving chambers . . . . Hodges. Colt's repeating rifle. Revolving pistols.

FOUNDED ON THE MOTIONS OF THE PRINCIPAL PART BY WHICH THE BREECH IS OPENED AND CLOSED.

Breech-loading small-arms have — fixed chambers closed by — movable breech-blocks which are —

- 1st, sliding. in line of axis of barrel by —
  - 1st, direct action, *i. e.*, bolt-guns having —
    - 1st, concealed locks . . Hotchkiss. Remington. Burton. Ward-Burton. Franklin. Lee. Sharps Rifle Company.
    - 2d, center locks . . . Hunt.
  - 2d, indirect action, *i. e.*, moved by levers from — below . . . . Winchester. Burgess. Tiesing.
- 2d, sliding and rotating . . . . Buffington. Chaffee.
- 3d, rotating about an axis — at 90° to axis of barrel, and — horizontal lying —
  - 1st, above axis of barrel, and in — front. . . . . Springfield-Miller. Springfield-Clemmons.
  - 2d, below axis of barrel, and in — front, moved from — below (by a lever) Lewis-Rice.

The following detachable magazines, etc., are described in "*Ordnance Memoranda*," No. 15, Washington, 1873: those of—

Col. Benton's,	Springfield,
R. T. Hare,	Elliot.
Ira Merrill,	

C. B. Norton's "Appendix to American Inventions; Small Arms and Heavy Ordnance," Osgood, Boston: 1882.

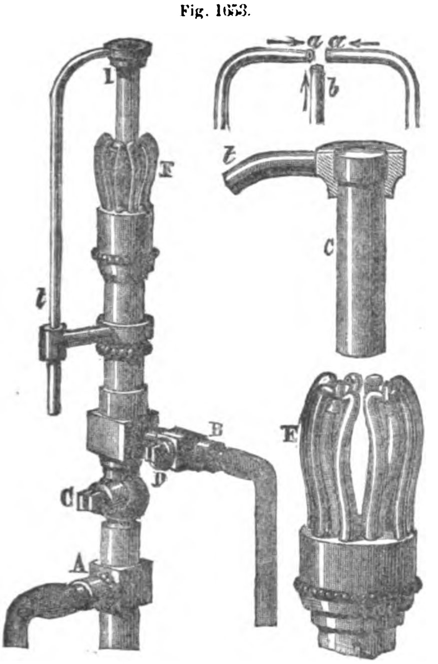
Mag-ne′si-a Light. A modification of the Drummond Light, in which a ball or crayon of carbonate of magnesia is substituted for chalk. See DRUMMOND LIGHT; LIME LIGHT, "*Mech. Dict.*"

The *magnesia* light is not to be confounded with the *magnesium* light, in which latter the metal is burned, either in strips or powder. See MAGNESIUM LAMP, p. 1370, "*Mech. Dict.*"

The substitution of magnesia for chalk is the invention of Sig. Carlevaris, an Italian physician.

In the apparatus of M. Tessié du Motay, as at first devised, a cylindrical crayon of compressed magnesia, prepared by

Fig. 1653.



Tessié du Motay's Magnesia Light.

the *système Caron*, was placed vertically above the burner, at which issues a melange of oxygen and ordinary illuminating gas. The design was afterwards modified, a change being made in the burner, so that the carbureted hydrogen arrived by two opposite pipes, *a a*, while the oxygen issued from the orifice of a vertical pipe, *b*, at a slightly lower level. Fig. 1653 shows the burner complete; on the right the respective oxygen and carbureted-hydrogen tubes, *A B*, with cock *C D* and the stem *t* of the holder *I*, from which the crayon *c* of magnesia is suspended, and by which it is vertically adjusted in the cluster of pipes *F*. On the right hand of the figure the *bec du Motay* is shown on an enlarged scale, and the arrangement of the pipes is also shown in a diagrammatic manner.

Mag-ne'si-um Light. A light made by burning the metal. See p. 1370, "*Mech. Dict.*," and Fig. 3684, p. 1689, *Ibid.*

Prof. Thurston's lamp is made by the American Magnesium Co. The strips of magnesium are rolled up on cylinders in the upper part of the apparatus. These strips are unrolled by clock-work in the lower part of the apparatus, and are carried between two small rollers, the uniform motion of which feeds them regularly into the lamp, where they are ignited. The ashes are cut off at intervals by means of eccentric cutters, and collect in the bottom of the apparatus. A small chimney is added, which is very important, as producing a draft of air directly through the flame. A portion of the products of combustion is thus carried away, and the flame becomes very intense, while it is less so without a draft. This lamp has been found very efficient, especially for marine signals. At trials made at sea, on two vessels stationed eight miles apart, the signals could be readily distinguished.

Larkin's lamp is based on a different principle. The magnesium is not employed as wire, or in strips, but as a powder. By this means the clock-work, or other mechanical device, has been dispensed with. The metallic powder is contained in a reservoir, which has a small opening in the bottom. The magnesium powder flows through this like the sand in a sand-clock. It is intimately mixed with a certain quantity of fine sand, in a manner diluted; first, in order to be able to make the opening sufficiently large; furthermore, to produce a continuous flow of the material. The mixture falls into a metallic tube, through which the illuminating gas is led from the upper end. The light is very brilliant, and the remaining sand falls into a vessel placed below, while the smoke passes away by a chimney.

The chess board with magnetized pieces, for use in railway traveling, is a Prussian invention.

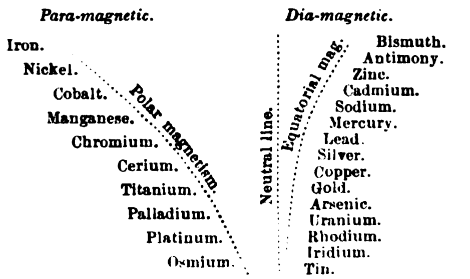
Mag-net'ic Bat'te-ry. (*Magnetism.*) A number of magnets joined together by their similar poles.

Mag-net'ic In-duc'tion. (*Electricity.*) The influence of a magnet through space, either to produce other magnets or to induce electric currents in metallic circuits.

Mag-net'ic Scale. A table or diagram exhibiting the para-magnetic and dia-magnetic metals in the order of their strengths respectively. The order given is from *Gordon's* "*Treatise on Electricity*," London, 1880. The diagrammatic illustration, in two hypothetical curves tangential to a neutral line, is by G. H. Knight. The dia-magnetic curve requires, it may be added, great exaggeration to make it visible. *Gordon*, ii. pp. 15–17.

In para-magnetic bodies the magnetism is strong and polar. In dia-magnetic bodies the magnetism is weak and equatorial. For example, the polar magnetism of the strongest known para-magnetic substance (iron) is estimated to be forty thousand times that of the equatorial magnetism of the strongest dia-magnetic substance.

MAGNETIC SCALE.



Mag-net'ic Sep'a-ra'tor. An instrument or apparatus for separating iron from other matters: as iron filings from those of brass; scraps of nails or wire from wheat, etc.; iron particles from ore in powder.

Mag-ne'to Call'-bell. The sounder of a telephone circuit. See Fig. 508, p. 155, *supra*.

Mag'ne-to-e-lec-tric'i-ty (*Electricity.*) Electricity produced by magnetic induction.

Mag'ne-to-e-lec'tric Ma-chine'. The modern accepted definition of this is about as follows: —

That class of devices for translating motion into electricity in which the magnetic field is formed by permanent magnets or electro magnets energized by a current of electricity independent of the current generated by the machine itself.

Under DYNAMO-ELECTRIC MACHINE, pp. 283–286, Figs. 890-905, and Plates XI., XII., the subject is considered. The distinction between *Dynamo-electric* and *Electro-magnetic* represents a real difference in action; but this differentiation of terms is comparatively recent. See definition of the DYNAMO-ELECTRIC MACHINE, p. 283, *supra*.

The Gramme & Ivernois and Pacinotti electro-magnetic machines are shown in Plate XI., opp. p. 283, *supra*.

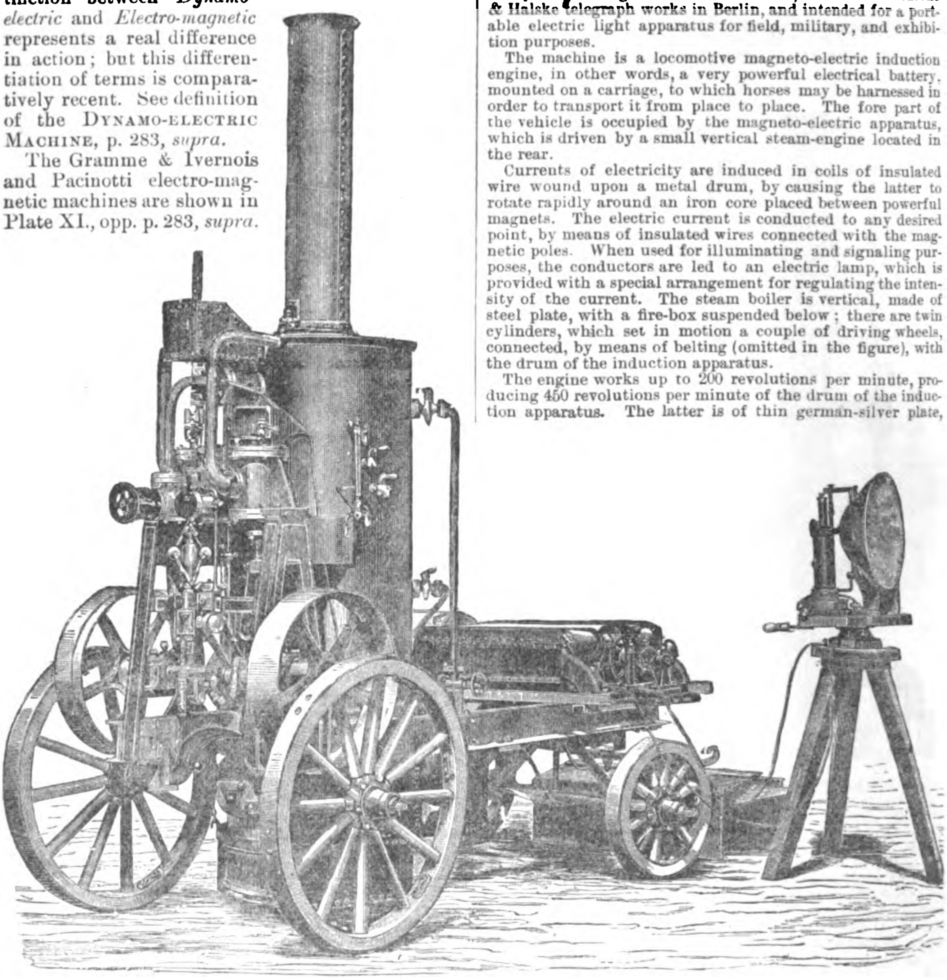
Fig. 1654 is an illustration from the "*Practical Magazine*" of a powerful magneto-electric machine, built at the Siemens & Halske telegraph works in Berlin, and intended for a portable electric light apparatus for field, military, and exhibition purposes.

The machine is a locomotive magneto-electric induction engine, in other words, a very powerful electrical battery, mounted on a carriage, to which horses may be harnessed in order to transport it from place to place. The fore part of the vehicle is occupied by the magneto-electric apparatus, which is driven by a small vertical steam-engine located in the rear.

Currents of electricity are induced in coils of insulated wire wound upon a metal drum, by causing the latter to rotate rapidly around an iron core placed between powerful magnets. The electric current is conducted to any desired point, by means of insulated wires connected with the magnetic poles. When used for illuminating and signaling purposes, the conductors are led to an electric lamp, which is provided with a special arrangement for regulating the intensity of the current. The steam boiler is vertical, made of steel plate, with a fire-box suspended below; there are twin cylinders, which set in motion a couple of driving wheels, connected, by means of belting (omitted in the figure), with the drum of the induction apparatus.

The engine works up to 200 revolutions per minute, producing 450 revolutions per minute of the drum of the induction apparatus. The latter is of thin german-silver plate,

Fig. 1654.



Portable Magneto-electric Machine.

covered with eight separate coils of copper wire of 0.28″ gage, and rotates between two very powerful horse-shoe magnets. At full speed, the current induced is sufficiently intense to heat a copper wire, 0.04″ in diameter and 38′ long, to redness, and, photometrically, is equal to 14,000 wax candles. The draft of the apparatus is about 2¼ tons.

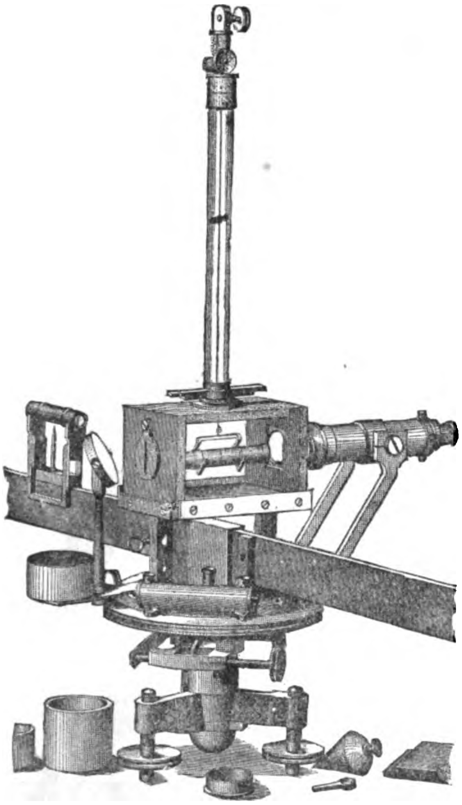
Mag′net-om′e-ter. The furnishing of a magnetic station includes instruments for dip or inclination, variation or declination, and intensity.

The subject of the discovery of the variations of the compass by the Chinese, and subsequently by Columbus; the detection of the dip, and the invention of the dipping needle by Norman, of London; the determination of the *agonic* lines, eastern and western; various voyages of observation for the determination of magnetic phenomena; and the world-wide system of magnetic observatories, are referred to on pp. 1873, 1874, "*Mech. Dict.*"

"There are two forms of unifilar magnetometers in use: those with a complete astronomical theodolite, or alt-azimuth, mounted to the magnetic north or south of the box in which the collimator-magnet is suspended, and on the *same* stand with it; and those which have the box with suspended magnet mounted centrally over, and firmly connected with an azimuth-circle, the reading-telescope being mounted eccentrically on supports. The first form (devised by *Gauss*) is the preferable one in field use; it admits of greater expedition, allows of greater ease in observing, and is almost indispensable when the astronomical meridian has to be determined. With the magnet to the south of the theodolite, it

Fig. 1655.



United States Coast Survey Magnetometer.

readily admits of observations of the sun, for the determination of time and azimuth (also of latitude, if required) without interfering with the magnetic work proper. Deflections are read off on the scale of the collimator magnet, and must be converted into angular measures. The second form (see Fig. 1655), by *Dr. Lamont*, is capable, perhaps, of greater accuracy, and is better suited for a fixed observatory, especially when declination disturbances also are to be observed, or at stations where there is a large daily range in the declination. The angles of deflection are at once read off. In order to observe the azimuth-mark, the magnet and box have temporarily to be removed, which is unnecessary in the first form of the instrument. When observing deflections, the bar, and consequently the deflecting magnet, remain fixed in the magnetic prime vertical, in the magnetometer, with attached theodolite: but in the second form of the instrument the deflecting and deflected magnets always remain at right angles to each other. Improvements have been made at the Coast Survey Office in the construction of magnetometers, with a special view of making them more portable than the older instruments, which were found unnecessarily large and heavy. A 3'' Casella theodolite was utilized for this purpose. The magnet (3'' long and ¼'' in diameter) and light box, with glass tube, were first attached to the upper frame of the theodolite; afterward to its stand, by which greater steadiness was secured. The relative horizontal intensity only could be measured by means of oscillations. Subsequently, a similar instrument was fitted up with 2 magnets, inertia ring, and deflecting bar for absolute measure, the magnets being only about 1¼'' and 1½'' in length. Several instruments were constructed with 4'' theodolites and magnets, 1.50 and 1.84'' in length, respectively; diameter, 0.3''. One of these instruments is presented in Fig. 1655. The upper part of the theodolite can be removed, and the magnet-box placed on its azimuth-circle." — *Prof. Hilgard.*

Maize Cut'ter. A large form of chaff cutter. More especially one for cutting green corn for ensilaging.

See ENSILAGE CUTTER, Fig. 971, p. 315, *supra*.

Ma-jol'i-ca. (*Ceramics.*) A species of fine pottery with opaque enamel and brilliant colors. The name is derived from Majorca. See p. 1376, "*Mech. Dict.*"

See also MEZZA MAJOLICA, a ware with a leaden glaze in which the colors run so as to give a softened or mezzo effect.

Mal'le-a-ble Bronze. A simple method of rendering bronze as malleable as copper or iron, has been announced by Dronier.

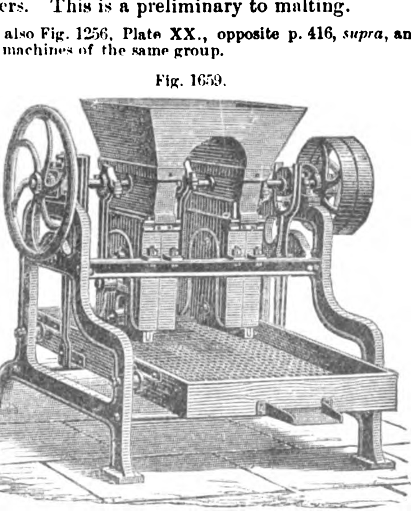
It consists in the addition of ½ to 2 per cent. of mercury. The mercury seems to act mechanically rather than chemically, and may be combined with one of the metals of which bronze is made, before they are combined, by pouring it into the melted metal and stirring well, or it may be put into the melted copper along with tin, or just after the latter has been added, or an amalgam of tin is stirred into the melted copper.

Mal'le-a-ble I'ron Pro'cess. (*Metallurgy.*) A process of decarburizing cast or pig iron by heating in an ordinary oxidizing atmosphere below the fusing temperature. It proceeds gradually from the surface to the center. Articles are packed in oxide of iron in boxes and exposed in ovens to a red heat for 5 or 6 days. See pp. 1376–1377, "*Mech. Dict.*"

Malt Clean'ing Ma-chine'. A machine of the nature of a grain cleaner, in which barley is freed from all extraneous matters, such as seeds of other grain, grass and weed seeds, dust and foul matters. This is a preliminary to malting.

See also Fig. 1256, Plate XX., opposite p. 416, *supra*, and other machines of the same group.

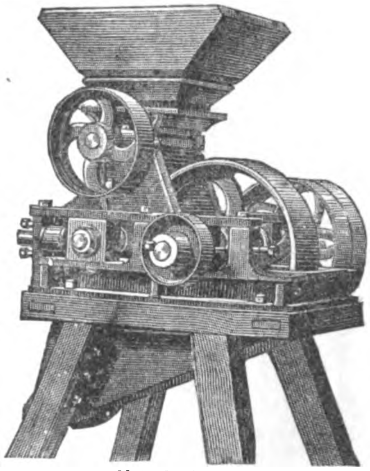
Fig. 1659.



Malt Cleaning Machine.

Malt Crush'ing Mill. A machine for grinding malt preliminary to mashing. Fig. 1660 is a French machine, by Duprez, of Rheims, which has an ingenious mechanical arrangement to throw out stones and nails. By the rapid motion of the machine the fecula of the malt is completely divested

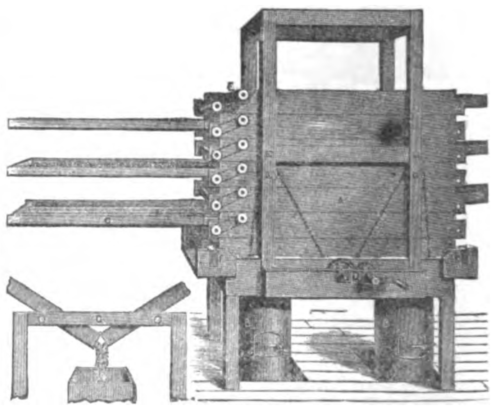
Fig. 1660.



Malt Crushing Mill.

of its natural envelope, which secures complete maceration and perfect infiltration in the vat during the mashing process.

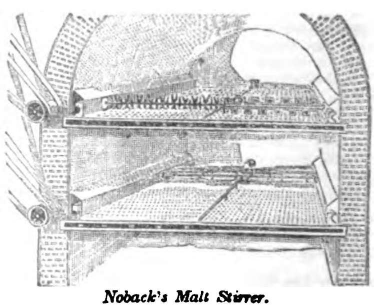
Fig. 1661.



Reynolds' Malt Dryer.

Malt Dry'er. A machine or apparatus in which malt is artificially dried in order to arrest the pro-

Fig. 1662.



Noback's Malt Stirrer.

Malt Dryer. Noback Frères.

cess of germination and the chemical change in the constituents of the grain.

The malt-kiln is the older form of apparatus and exposure in the *oast* succeeded the previous operations of steeping, couching, and flooring. See Fig. 3036, p. 1380, "*Mech. Dict.*"

Reynolds' machine, Fig. 1661, has a vertical series of wire-bottom trays on which the malt is spread, and furnaces beneath, which send a heated current of air upward through the chamber in which the trays are placed.

A is a sectional chamber, with three compartments; each section contains rollers on which the trays *C* move backwards and forwards through the hot and cold air alternately as desired, the center being only partially heated by the two heaters *B B*; *C* are folding trays, twice the length of the chambers; *D* crank and gear wheels attached to movable frame *F* by chains, which serve to raise the entire sectional chamber and trays 10″, to admit a fresh tray when desired. Below is shown a table with rollers, showing the manner of discharging the malt from the trays when finished.

The malt kiln of Brüder Noback and Fritz, Prague, Bohemia, is shown in Figs. 1662, 1663, 1664. Fig. 1662 shows two floors in the upper section of the tower, Fig. 1664.

The malt is spread evenly on the floor, the latter being made of slats, of wires or wire cloth, so as to allow of the passage upward of the heated air from the stove shown at the lower apartment of the tower. Some differences of arrangement of the heating apparatus in the towers will be noticed in the Figs. 1663 and 1664 respectively. Each has a stove in the lower story, a flue which has a rectangular deviation to a flue built in the wall and a return to the chimney which crowns the whole. The heat generated by the stove suffuses the chamber and passes upwardly through the perforated floors, and the layers of malt, and escapes by the annular space around the central smoke flue in the chimney. In one of the figures, two malt floors are shown, and in the other as many as six. Each has the traveling stirrer, shown more in detail in Fig. 1662. This is a shaft which is armed with paddles and extends across the width of the malt chamber and has at the same time a movement of translation lengthwise of the chamber; so that it moves *along* the floor, stirring up the malt the whole *width* of the floor. The two movements are by gearing and rack in the covered side chambers which run lengthwise of the floor. When the stirrer has reached the end of its course, the belt is automatically shifted and the return course commences. See MALT TURNER, Fig. 1666, *infra*.

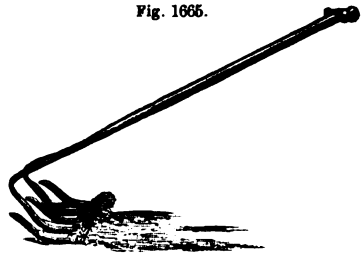
Malt Rake. A hand tool used in stirring malt on the kiln floor. The hoe portion scrapes the floor and allows no grains to escape being raised, and the fingers at the rear allow the grains to escape as the object is simply to stir and not to give a movement of translation. (Fig. 1665.)

Malt Screen. A device for cleaning extraneous matters from barley or from malt. See Fig. 1248, Plate XX., opp. page 416, *supra*.

Malt Turn′er. A mechanical arrangement for turning the malt while being heated in the kiln. (Fig. 1666.)

The floor of the kiln is made of wire, and the turning apparatus consists of a shaft having four arms projecting radially from it, on the ends of which are wire brushes clamped between two scrapers. This shaft has two motions, one rotating and the other longitudinal. When it arrives at

Fig. 1665.

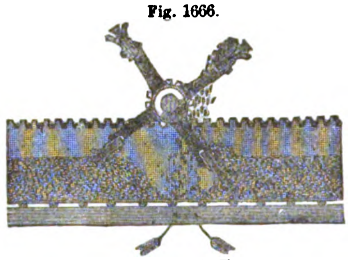


Malt Rake.

the end of the floor it shifts the driving belt, and returns over the same course.

Malt'wood's Find'er. (*Microscopy.*) A means for registering the position of an object on a slide.

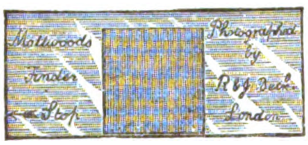
Fig. 1666.



Bergner's Malt Turner.

It is a slide with numbered rulings, 100 × 100. A slide containing an object of considerable area, and a point of special interest in the field being observed, the slide is removed and the finder substituted; the exact square is noted, and this being marked upon the slide of the object, the particular point of interest in the field of the slide can be at once brought into view, by placing the finder on the stand and bringing the number square into the field, and then substituting the slide with the object.

Fig. 1667.



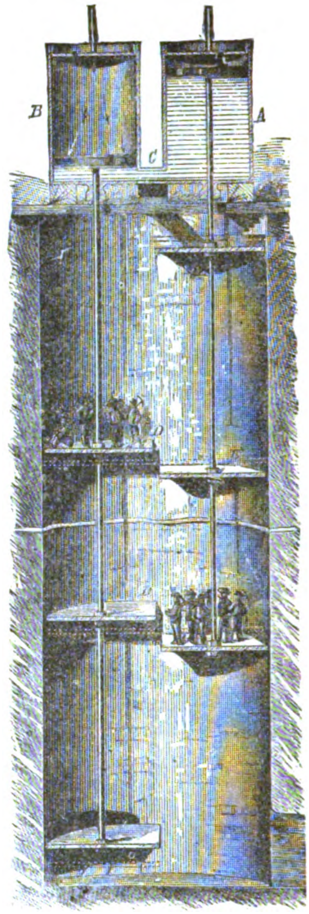
Maltwood's Finder.

Man En'gine. An apparatus for raising and lowering men in mines. Two forms are shown in Fig. 3042, p. 1382, "*Mech. Dict.*"

A more elaborate and capacious apparatus is used in the collieries of the *Sociétés des Charbonnages de Mariemont et Bascoup*. These large corporations own an area of some 500 square miles of coal fields, and employ 9,000 men, producing, from 14 mines, 7,000 tons per day. The apparatus for lowering and elevating the miners to and from their work is shown in Fig. 1668. *A* and *B* are two steam cylinders, connected by the pipe *C*, and containing water in the spaces below the pistons. The latter are attached to platforms *D* and *E*. A miner about to descend will step upon upper platform, *E*, when it is at the top. Steam admitted above the piston in cylinder *A* will drive the piston down the length of one stroke, and bring it even with a platform, *D*. Steam is then admitted above the piston in cylinder *B*, forcing said piston down, and hence driving the water into the other cylinder. This of course lowers *D* and raises platform *E*, and, as is evident, again brings two platforms on a level, when the piston in *A* is at its highest, and that in *B* at its lowest point. The miner now steps from platform *D* to a lower platform, *E*. Steam is again admitted, this time above the piston in *A*; platform *E* sinks, and eventually comes on a level with a third platform, *D*, and so on. This operation is continued, the workmen entering at the top and stepping from one platform to another until the bottom is reached. The ascent is by the inverse method.

Ma-neu'ver-ing Wheel. One of the wheels on the top carriage of a gun, on which it runs in and out of battery on the chassis.

Fig. 1668.



Man Engine.

Man'ga-nese' Bat'te-ry. A galvanic battery using the peroxide of manganese. See LECLANCHÉ BATTERY.

Man'ga-nese' Bronze. An alloy made by P. M. Parsons, England, in 1877, by adding from 1 to 2 per cent. of manganese to the proper proportions of copper and zinc, as used in making brass.

The average tensile strength of the metal when forged or rolled is 30 tons per square inch, with an elastic limit of from 11 to 18 tons, and an elongation of from 20 to 45 per cent. when in the annealed state. When cold-worked, the breaking strength in bars or plates rises to 40 tons per square inch, with an elastic limit of over 30 tons, and an elongation of about 12 per cent. When drawn into wire, the strength goes up to 70 tons per square inch.

The effects of forging are remarkable, raising the strength to such high limits, and practically giving a new and most valuable metal to the world. In some respects, indeed, it resembles aluminium bronze, but is superior in resistance to this alloy, which does not exceed 22.6 tons, and is also inferior in elongation and elasticity. Manganese bronze will find an application wherever gun-metal is used, while the facility and benefit of forging will render it still more useful in construction.

It is already much used in armor and sheathing for vessels, the making of torpedo boats and launches, bearings, pins, brasses and piston rings of steam engines.

It is said to be 60 per cent. stronger than gun-metal, and wears 3 or 4 times as long.

Parsons' manganese bronze: trials at the government gun factories, Woolwich, Eng., in comparison with Muntz-metal and gun-metal, gave the following. "*Engineering.*"

Material.	Strain per sq. inch. Elastic Limit.	Strain per sq. inch. Breaking Strength.	Ultimate elongation 2''.
	tons.	*tons.*	*per cent.*
Mang. bronze, cold rolled	34.4	39.6	11.6
Forged and annealed	16.6	30.7	20.7
Hot rolled and annealed	15.2	27.4	12.8 *
Cold rolled and annealed	14.5	29.1	18.3
Hot rolled (mild quality)	11.0	29.0	45.6
Muntz metal, rolled and annealed	7.8	24.0	54.6
Gun-metal. Cast.	7.0	16.0	16.6

* Broken, owing to a fault in turning.

In carrying out the invention, the copper should be first melted in a crucible or other vessel in the ordinary manner, and the spiegeleisen or ferro-manganese, either with or without the addition of wrought-iron scrap as sometimes practiced, should at the same time be melted in a separate smaller furnace capable of generating a high temperature in a graphite crucible under powdered charcoal, and when it is completely fused, and the copper is also fused, and at a boiling heat, the ferro-manganese should be poured into the copper and the two well mixed together by stirring with an iron rod previously made red-hot; the tin, or zinc, or both, should then be added in the usual way and in the requisite proportions, according to the kind of alloy it is desired to produce. After the tin and zinc are added the metal should be again well stirred with a red-hot rod and skimmed; it may then be either poured into ingot molds for future use, or it can at once be cast in molds to produce any articles required.

Four kinds of manganese bronze are at present manufactured, varying somewhat in their qualities: —

1. For forging and rolling into plates, sheets, and drawing into wires and tubes.
2. For casting into bars and plates subjected to strain.
3. For casting into bearings and brasses.
4. For casting into valves, faces, piston rings, slide blocks, top and end connecting rod brasses, etc.

The following U. S. Patents may be consulted: —

203,266 *Hale*, May 7, 1878.
206,604 *Parsons*, July 30, 1878.
178,490 *Ward*, June 6, 1876.

Prof. Genti publishes an analysis or a specimen of manganese bronze from a Transylvania factory. It is nearly of the color of brass, is tenacious and ductile under the hammer, and contains sulphur, manganese, copper, zinc, iron, with traces of silica, tin, and carbon. The essential ingredients are 15 parts of copper, 4 of manganese, and 1 of zinc. — "*Revue Indust.*"

Technologiste "	xxxvii. 168; xli. 489.

Man'ga-nese' Cop'per. An alloy made at Isabellenhuette, near Dillenburg, Germany.

Copper	70
Manganese	30
	100

It is used as an addition to brass, bronze, etc., for increasing the density, tensile strength, and ductility of the metal, as the formation of oxides of tin or copper, which impair the physical properties of the material, is prevented by the great ease with which manganese is oxidized.

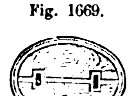
For bearings the following is recommended: —

Copper	80
Manganese copper	9
Tin	6
Zinc	5
	100

Larger amounts of manganese — for instance, 2.3 to 6 per cent. — make the metal particularly hard, and it is stated that bronze can be made in this manner to assume a hardness approximating that of steel.

Man Hole. An opening by which a city subway or sewer is reached from the street.

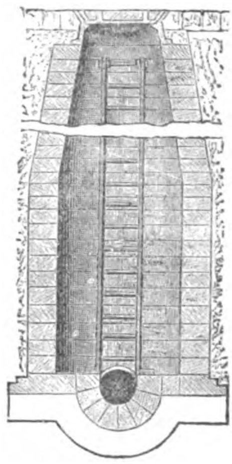
Fig. 1669.



The sub-ways of London and Paris are spacious and far-extending. See Fig. 6040, p. 2462, "*Mech. Dict.*"

The man-hole and manhole cover in Figs. 1669, 1670 are those used in London, carefully built in masonry, with standing iron ladders and with elm blocks in the cover rim, or an iron plate, in the respective figures.

Batten, Br., *"*Engineer*," l. 343.



London Man Hole.

Man'i-fold. 1. (*Heating.*) The chambers with nozzles into and from which the pipes of a radiator lead. Fig. 1671 shows two manifolds, a set of bent tubes with couplings, and a pair of coil plates to hold up the system.

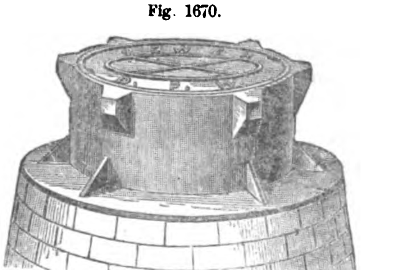
Manifolds are: back outlet, side outlet, double, etc.

2. A method of multiplying copies of a writing.

Man'i-fold Writer.

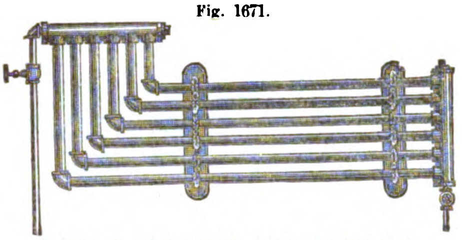
One French manifold writer consists of a metallic *slate* covered with tallow, mixed with one of the purple or red coal-tar colors. A sheet of tissue paper is laid thereon and written on with a hard pen without ink. On taking up the tissue paper the writing reversed is found upon the other side. The tissue paper is now laid (inky side up) on several folds of wetted blotting paper; the writing paper intended for the reception of the impression is moistened (sponged over) with an aqueous solution of gum tragacanth, laid upon the

Fig. 1670.



Stone's Man-hole Cover. (*London.*)

Fig. 1671.



Radiator for Wall, with Manifolds and Coil Plates.

matrix, and placed for a few seconds in a copying press. By these means 20 or 30 good copies can be obtained.

Another method has sheets of varnished paper to write on, with an ink by which the varnish is destroyed and the paper rendered porous. This is then placed on an ink pad, and the writing paper to be employed upon the top. On squeezing, ink is forced through that portion of the paper from which the varnish has been dissolved, and an impression is produced. An indefinite number may be so obtained.

E. De Zuccato's facsimile process for multiplying MSS. by chemical means is as follows: —

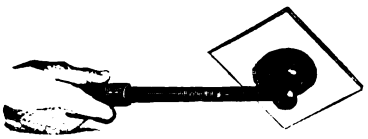
A sheet of thin paper is first prepared with a resinous varnish and dried. Upon one side of this the writing is executed with an ink consisting of a colored solution of potash or soda. The soluble compound formed by the alkali and resin is next removed by water, leaving the paper pervious to fluids where the ink lay upon it. This sheet is now placed face down upon a pad damped with a solution of persulphate of iron, and upon its back or upper side is laid the sheet to be printed upon, stamped with a dilute solution of ferrocyanide of potassium. After the pressure of a copying press has been applied, the facsimile writing will be found in blue (Prussian blue) upon the blank sheet. By substituting other sheets similarly prepared a large number of copies may be obtained from the same matrix.

Man'i-graph. A name for a method of multiplying copies of writing.

See Copying Process; Gelatine Copying Process; Hectograph, etc.

Ma-nip'u-la'tor. 1. An intermediate contrivance for handling plates without exposing the hands to injury. Useful in working with photographic plates and negatives. At the end of the handle is a suction disk of caoutchouc.

Fig. 1672.



Negative Manipulator.

2. A machine for shampooing or pummeling the body; rubbing the arm, legs, back, kneading the abdomen, etc. A substitute for exercise with the bed-ridden; and a useful adjunct in gymnastic training. See Exercising Machine.

Ma-nom'e-ter. An instrument for measuring the elastic force of a gas or of steam. See Fig. 4039, and references to Boyle and Ramsden, page 1684, "*Mech. Dict.,*"

Koenig's flame manometer . . . . Figs. 1046, 1047, page 344, *supra*.

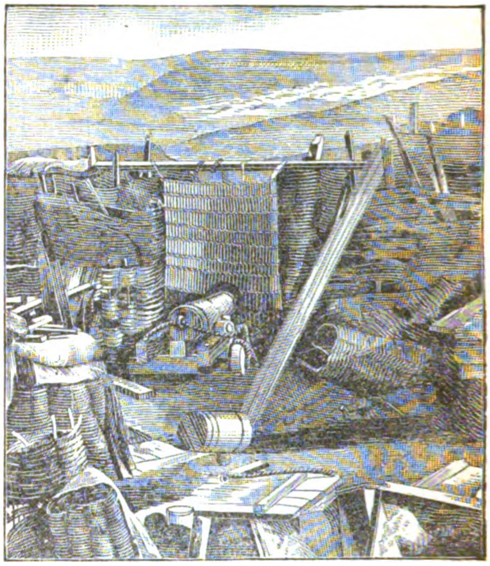
Man-te'an. (*Fabric.*) A fine French worsted stuff made of carded wool, both warp and weft; taffetas armure, which see.

Man'te-let. A bullet-proof screen to protect gunners serving a piece from the fire of the enemy. It is usually woven of rope. Fig. 1673 shows a mantelet in an embrasure of the Malakoff tower, before Sebastopol, in the Crimea.

Fig. 1673.



Mantelet, in the Malakoff Battery.

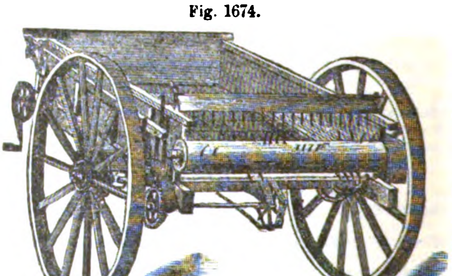
Mantelets are also used in front of rifle-pits; also to protect pioneers and sappers, and those working or passing in the trenches and approaches of an invested work.

Ma-nure' Drag. (*Add.*) 2. A fork with bent tines to unload manure by dragging it off the wagon.

Ma-nure' Spread'er. A cart having a bed of traveling slats, and a spiked roller at the tail gate, to distribute the load while the vehicle is moving over the surface of the ground.

It can be attached to the fore-wheels of any ordinary farm wagon. The floor of the cart is a revolving apron, which is carried backward by the gearing, bringing its contents against a rapidly revolving beater, which breaks up and distributes the manure. It is thrown into gear by a single lever at the left hand of the driver's seat, and throws itself out of gear when the load is spent. In running to and from the field none of its machinery is in motion, and it may be used through the season the same as an ordinary cart.

Fig. 1674.



Kemp Manure Spreader.

Man'y-light Reg'u-la'tor. (*Electricity.*) An order of regulator for voltaic-arc lights which allows a number of lights on one circuit. See POLYPHOTE REGULATOR.

Mar'ble, Im'i-ta'tion. See recipes, p. 1390, "*Mech. Dict.*"

Statuary: Coat a plaster-of-Paris or papier maché figure with white dammar varnish and dust with pulverized glass; it then resembles *alabaster*. It may be varnished a second time and dusted with coarsely pulverized glass or mica and it will resemble *Carrara marble*. May be veined with a delicate blue pigment between the coats.

To give to sandstone the appearance of marble: Impregnate the well dried stone with soluble silica and alumina. For colors, add mineral pigments to the liquid.

Marbleizing limestone: Work the stone to form and then put it in a boiler, submerged in water and bring a steam pressure of 75 to 100 lbs., according to the size of the object. Allow the object to cool; remove the object and submerge it in an alum bath, colored or otherwise. — *Hosmer.*

Mar'ble-ized Glass. (*Glass.*) Made by immersing hot glass in water, reheating and expanding by blowing. The incipient fractures become joined but show in the article like veins in marble.

Mar'ble-iz-ing I'ron. First coat with a thin layer of plaster-of-paris and alum, made to adhere by previously roughening and oxidizing the iron. This coat being well leveled and ground smooth, the paint used will readily adhere.

Mar'bling Pa'per. Described on p. 1391, "*Mech. Dict.*"

Elaborate description and directions from "*Paper World*," reproduced in "*Manufacturer and Industrial Gazette*," iv. 2, pp. 6, 7.

Woolnough . . . "*Scientific American Sup.*," 1889.

Marc. The residuum of grapes after pressure therefrom of the *must*. Corresponds with the *pomace* of apples, the *grains* of malt.

Ma'rie-Da'vy Bat'te-ry. (*Electricity.*) One in which the zinc stands in pure water and the carbon in a paste of moistened proto-sulphate of mercury in a porous cup. See MERCURY BATTERY.

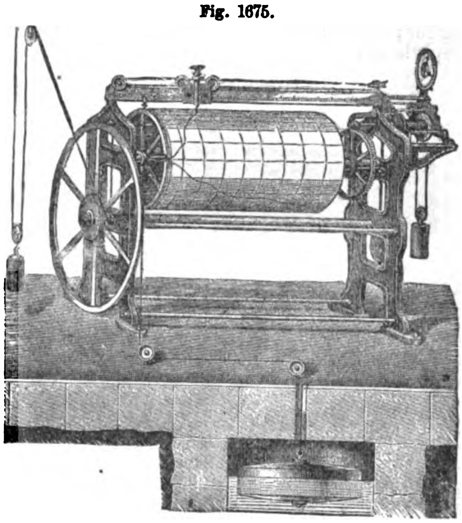
Sabine, London, 1867	229
Niaudet, American translation	* 140

Ma'ri-graph. A registering tide gage; by an extension of the meaning it may be held to mean an instrument for registering the fluctuations of height in sea, harbor, river, or canal. Other terms are used for some of these: such as *fluviograph*, etc. See also, TIDE GAGE, Fig. 6426, p. 2566, "*Mech. Dict.*"

The French Marigraph shown in Fig. 1675 is operated by an endless cord which connects with a float located in a suitable reservoir, into which the sea water enters. The changes of level of the water are registered on a large horizontal cylinder which is rotated by clock mechanism once in 24 hours. The cylinder is covered with a sheet of paper, changed fortnightly or monthly, and which is divided into longitudinal divisions, giving, on a reduced scale, the heights of the tides in meters and centimeters. A carriage, mounted on rollers upon a steel rule above the cylinder, carries a pencil which is pressed against the paper by a spring. The carriage communicates by an endless cord with a small grooved wheel mounted on the shaft of the larger wheel which receives the motion of the float previously referred to.

On a third wheel, of medium diameter, is wound a cord, which is drawn by a weight in an opposite direction to that of the cord of the float. When, therefore, the float rises, the effect of the weight is to remove the shaft so as to take up the slack of the cord so that the latter is always kept taut. The pencil carriage is similarly actuated, and traces on the cylinder a mark of which the extremity is the maximum height of the water. If the level is constant, the carriage remains motionless, and the pencil traces on the cylinder a line parallel to the transverse divisions.

Fig. 1675.



Marigraph.

A dial placed above the mechanism shows the hour, and at the same time serves to regulate the changing of the paper, and to indicate the moment at which the apparatus should be started on its daily motion. An electric indicator serves to give warning of any desired level being reached by the water. The indicator is movable, and is set on a special rod on the rule at the point corresponding to the height of water to be noted. When the carriage, on reaching that point, comes in contact with the indicator, the effect is to sound a bell.

Ma-rim'ba. A musical instrument of percussion, consisting of bars which yield various tones when struck. A *sticcado* (from the Italian).

The instruments are frequently called by names which indicate the material of which the bars consist.

Marimba is Portuguese, and the instruments of Angola have been introduced into European museums under that name. The instrument is common over a large part of the African Continent, and also in Malaysia. It is found in Guatemala but is probably of negro introduction. One from Central America is in the National Museum, Washington, D. C.

See author's article on "*Crude and Curious Inventions at the Centennial*," 1876, '*Atlantic Monthly*," * vol. xxxix., pp. 523–525, where may be found the marimbas of Angola, Central Africa, of Malaysia (*gambang*) and Siam (*Ra-naht-ake*).

The subject may be pursued by reference to DULCIMER; HARMONICA; LAPIDEON; * WOOD-HARMONICON; XYLOPHONE; "*Mech. Dict.*" Also, STEEL-BAR PIANO, * Fig. 3689, p. 1695, *Ibid.* Also, * LYRE; METALLOPHONE, *supra et infra*.

All the above have bars in series arranged according to a musical scale. The scales vary; diatonic, pentatonic, and those of the African and Asiatic, not quite in harmony with either.

See DRAG-ANCHOR, Fig. 1738, p. 737, "*Mech. Dict.*"

Ma-rine′ En′gine. The engines of the steamships of the American line, "Pennsylvania," "Ohio," "Indiana," and "Illinois," were built by the William Cramp & Sons Ship and Engine Co., of Philadelphia. The vessels are of 3,030 tons, have a length of 355′ over all, and a beam of 43′. The engines are shown by longitudinal and transverse vertical sections in Plate XXVIII., and by plan in Fig. 1677.

"The engines are independent, compound, and surface condensing, with the crank set at right angles. The cylinders are 57¼″ and 90⅛″ in diameter, respectively, and the stroke of pistons is 4′. The main slide valves are on the outside of the high and low-pressure cylinders, which are both inclosed in a jacket connecting them together, and forming a receiver. The high-pressure cylinder is also steam-jacketed, but the low-pressure cylinder is not. The pistons are 16¾″ deep; the rod for the high-pressure cylinder is 8″, and that of the low-pressure 8½″ in diameter, and both are carried upwards through the cylinder heads. The cross-heads are of wrought iron, with cast-iron slides bolted to their ends. The main slide valves have double ports, each is fitted with an independent cut-off valve on the back, no provision being made for counterbalancing the pressure on the valve faces. The weight of the main valves is counterbalanced by the steam pressure in a cylinder on the top of the steam chest. Both main valves are driven by motion of the double bar-link type.

"The engines are reversed by direct-acting steam gear, the reversing cylinder being 20″ in diameter, with a slide valve on top, which is thrown open by hand, and closed by the motion of the piston-rod in any position. A screw is also provided which can be clamped to the piston-rod of the cylinder so as to move the links by hand if there is a want of steam.

"Relief valves are fitted at the end of each cylinder with gear to use them as starting valves. The connecting rods are forked by the cross-heads and are fitted with strap ends. The cross-head journals are 10½″ in diameter and 10½″ long, and the crank-pins are of steel 15½″ in diameter and 20″ length of journal. The crank-shafts are built up in two lengths, and are made interchangeable; the main journals are 15½″ in diameter and 30″ long, except the forward journal, which is 24″ long. The cranks are counterbalanced.

"The bed-plate is made in two parts and is bolted up to the condenser. This latter is in two pieces and contains 1,492 tubes, ⅞″ in diameter and 14′ long, the surface exposed being thus 4,786 square feet. The water from one circulating pump passes through them three times and from the other twice. The pumps are worked from the main cross-heads through wrought-iron levers as shown. Each air and circulating pump is cast separately and bolted to the condenser. A feed and a bilge pump are bolted to each air pump. The latter are 26″ in diameter, the circulating pumps are 18″ in diameter, and the feed and bilge pumps are each 6″. The stroke of all is 26″.

"A vertical turning engine is bolted to the side of the condenser and gears into a worm-wheel fastened to the intermediate shaft coupling between the two cylinders. The propeller shaft is 15½″ diameter, and is sheathed in the stern pipe. The propeller is four-bladed, with the blades cast separately and bolted to the bars; the diameter is 17′ and the pitch 24′.

"The boilers are double-ended, three in number, and fired fore and aft. The diameter of each is 12′ 3″ and the length 17′. There are three furnaces in each end 2′ 10″ in diameter, with grate bars 5′ 4″ long. There are 316 tubes 3″ in diameter and 7′ long in each boiler."

The compound has become the most popular, as it is the most economical, of marine engines. Reference has been made to 52 examples in COMPOUND STEAM ENGINE, p. 215, *supra*.

Fig. 1677.

ENGINES OF THE STEAMSHIPS "PENNSYLVANIA" "OHIO," "INDIANA," AND "ILLINOIS,"

CONSTRUCTED BY THE WILLIAM CRAMP AND SONS' SHIP AND ENGINE BUILDING COMPANY, PHILADELPHIA.

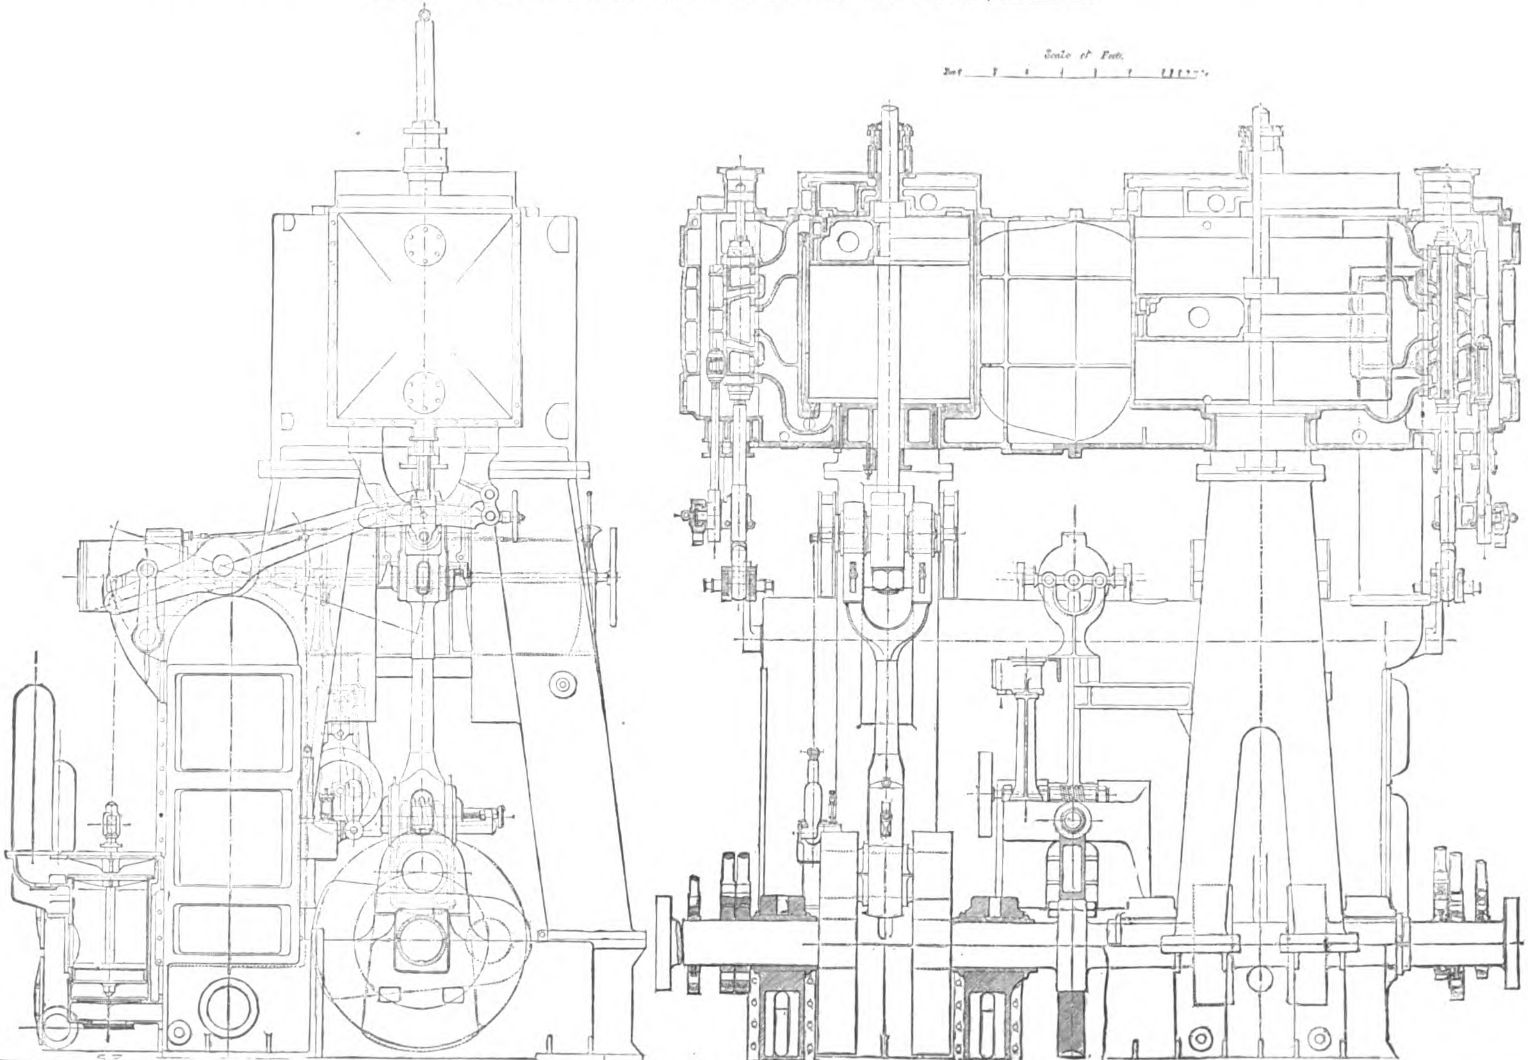

PLATE XXVIII. MARINE ENGINE. (*American Transatlantic Line.*) See page 582.

"The running of the Ohio during the voyage from Queenstown to Delaware Breakwater on her second voyage, was as follows: —

Date.	Knots Run by Screw.	Knots Run by Observation.	Running Time.		
Oct, 1873.			*hours.*	*min.*	
17	246.8	226.0	18	59	
18	323.8	280.7	24	23	
19	333.5	322.0	24	15	
20	335.7	294.0	24	23	
21	331.0	No obser.	24	0	15 minutes detention.
22	341.5	No obser.	24	24	
23	336.7	946 in 3 days	23	43	18 minutes detention.
24	339.5	333.7	24	22	
25	343.2	321.0	24	21	
26	142.0	140.0	10	30	
	3,075.7	2,863.4	9 days, 7 hours, 20 min.		

"The slip of the screw amounted to 212.3 knots, or 6 8 per cent., while the average speed was 12 8 knots. The weather was calm. Average indicated horse power, 1,977.54.

"That the performance of the engines we have described has been most satisfactory is proved by the great regularity of the passages made by the vessels to which they are fitted, while their workmanship and general finish well deserve praise." — "*Engineering.*"

The change from *paddle* to *screw* has revolutionized the forms of marine engines. The necessity for placing the propeller shaft near the keel has placed the engine above it, and the proximity of the keel and consequent short radius of the crank has reduced the stroke of the piston.

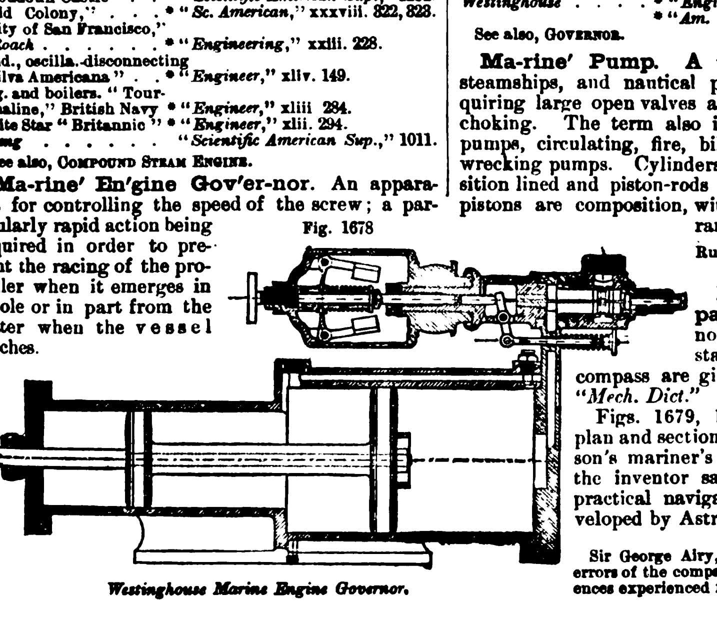
Ma-rine' En'gine Gov'er-nor. An apparatus for controlling the speed of the screw; a particularly rapid action being required in order to prevent the racing of the propeller when it emerges in whole or in part from the water when the vessel pitches.

Fig. 1678



Westinghouse Marine Engine Governor.

The subject has been considered in the "*Mech. Dict.*," and the following referred to at the pages noted: —

Huntoon, * *q q'* Plate XXI., opposite p 998.
Huntoon, * Fig. 4750, p. 2073.
Silver, * Fig 3066, p. 1394.
Cathcart, * Fig. 3067, p. 1394.
Duff, * Fig. 3068, p. 1395.
Wolcott (electro-mag.), p. 1395.
Mosman (chronometric), p. 1395.
Osborne, p. 1394.

The principle embodied in the Westinghouse marine engine governor is the employment of steam pistons as the medium for operating the throttle-valve or link, and the only duty of the governor is to actuate a small piston valve which controls the pressure of steam on opposite sides of these pistons, thus varying their position, and also that of the throttle-valve or link to which they are attached.

The apparatus consists of two parts, a differential cylinder and a regulator; the former contains a piston-rod, one end of which is connected to the starting valve of the engine, and the other passes through a long tube or sleeve, carrying at either end a piston fitting the differential cylinder just mentioned

The apparatus is shown in Fig. 1678; its operation is as follows: —

Steam is admitted into the large and small parts of the cylinder so that the pressure on each side of the larger piston is equalized, while the pressure on the smaller piston keeps it at the end of its stroke, that is, to the left in the cut, the opening in the end of the smaller cylinder leading to the air or condenser. This position keeps the engine valve open and this is the normal running condition. The portion of the regulator containing the weights is driven by a strap from the engine, and, as soon as racing commences, the increased speed given to the revolving weights causes them to fly outward and depress the regulator spindle which acts upon a piston valve and allows the steam to escape from the right hand side of the larger piston, to the atmosphere, reducing the pressure on that side of the piston. The pressure of steam on the larger piston then instantly overbalances that on the smaller one and the pistons fly to the right and thereby close or partially close the valve admitting steam to the engine. The speed is by this means instantly reduced, the piston valve returns to cover the port in the regulator chamber, and the pressure is restored to equality on each side of the large piston.

Durham's screw engine governor acts also on the principle of the combination of a governor with a steam cylinder and piston.

Ma-rine' Pump. A pump for steamboats, steamships, and nautical purposes generally, requiring large open valves and passages to prevent choking. The term also includes boiler feeding pumps, circulating, fire, bilge-water, and perhaps wrecking pumps. Cylinders are preferably composition lined and piston-rods solid composition; the pistons are composition, with spring rings, or arranged for leather.

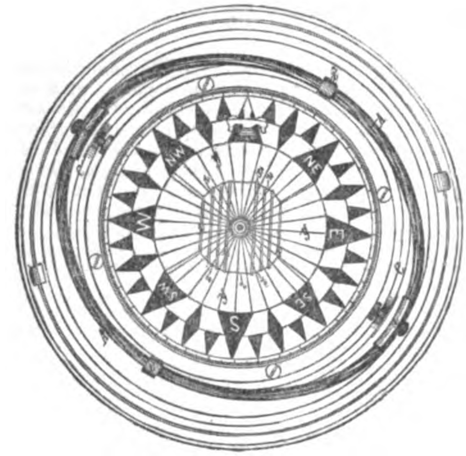
Russian navy. * "*Engineering*," xxi. 326.

Mar'in-er's Com'-pass. The history, early notices, and modern instances of the mariner's compass are given on pp. 1395–1398, "*Mech. Dict.*"

Figs. 1679, 1680 are respectively plan and section of Sir William Thomson's mariner's compass, designed, as the inventor says, "to carry out in practical navigation the principles developed by Astronomer-royal Airy.

Sir George Airy, in 1840, showed how the errors of the compass, depending on the influences experienced from the iron of the ship, may be perfectly corrected by magnets and soft-iron placed in the neighborhood of the binnacle. The system has become universal. The principal difficulty in practice "has been the size of the needles in the ordinary compass which

Fig. 1679.



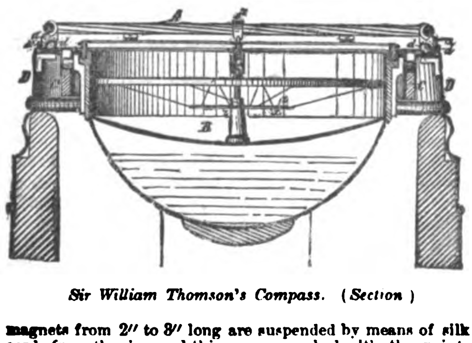
Sir William Thomson's Mariner's Compass. (Card.)

renders one important part of the correction, the correction of the quadrantal error for all latitudes by masses of soft iron placed on the two sides of the binnacle, practically unattainable; and which limits, and sometimes partially vitiates the other chief part of the correction, or that which is performed by means of magnets placed in the neighborhood of the compass.

See paper by Sir William Thomson, United Science Institution, * Feb. 4, 1878. See United States Patent No. 232,781.

In size and outward appearance this compass (with binnacle, etc.), does not differ from those hitherto in use; but the patent card is constructed on an entirely new principle. It consists of a central aluminium boss and an outer aluminium rim connected together by fine silk cords. Small

Fig 1680



Sir William Thomson's Compass. (Section)

magnets from 2″ to 3″ long are suspended by means of silk cords from the rim, and thin paper marked with the points of the compass and degrees is attached to the rim and partially supported by the silk cords between the rim and the boss. By this arrangement the principal part of the weight is in the aluminium rim, and is consequently as far as possible from the center on which the card moves. This gives a very long period of free oscillation, and, consequently, great steadiness.

The card with the needles is extremely light, the 10″ compass weighing 178 grains, which is about one twentieth of the weight of an ordinary compass of such dimensions. The *frictional error* is thus reduced to a very small amount.

The *quadrantal error* in this compass is corrected by a pair of soft iron globes fixed one on each side of the binnacle. When the quadrantal error has been thus once accurately corrected, the correction is perfect, to whatever part of the world the ship may go, and requires adjustment at no subsequent time, except in the case of some change in the ship's iron, or of iron cargo or ballast sufficiently near the compass to introduce a sensible change in the quadrantal error.

The *semi-circular error* is corrected by applying two adjustable magnetic correctors, one for neutralizing the thwart-ship component, the other for the fore-and-aft component of the ship's magnetic force.

The *heeling error*, chiefly experienced in iron sailing ships, is corrected by the application of an adjustable magnet below the compass in a line through its center perpendicular to the deck.

Mar'lin-spike Hitch. (*Nautical.*) A form of bend. See *g*, Fig. 2513, p. 1105, "*Mech. Dict.*"

Mar'tin Bit. (*Manége.*) A stiff-bar bit, having a spoon-shaped port, from 4¾″ to 6″ long and ½″ wide; the top is convexed and polished; when in use, this long piece rests against the roof of the horse's mouth, and when necessary it becomes unusually severe, yet it does not injure the mouth as much as other port bits.

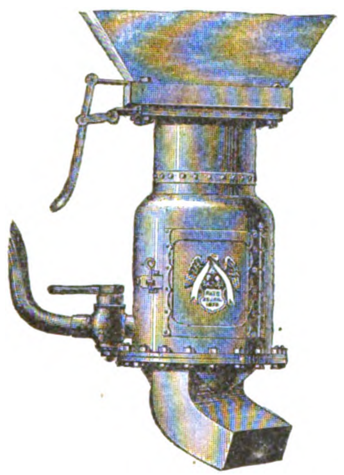
Mar'tin Steel. (*Metallurgy.*) Steel made by adding malleable iron to a bath of pig-metal in a reverberatory. P. and É. Martin, Patents, 1865–1867. A Siemens-Martin ingot, weighing 120 metrical tons, was cast by the Terre Noire Company, in 1878.

Ma-ryn'go-tome. (*Surgical.*) A fine hastate pointed instrument of incision; used in operations on the ear. — *Buck.*

Mash Ma-chine'. A machine for pulping mash before discharging it into the tun where it is steeped.

Siebel's device, shown in Figs. 1683, 1684, is a sparger used to soften and pulp the mash on its way from the hopper to the

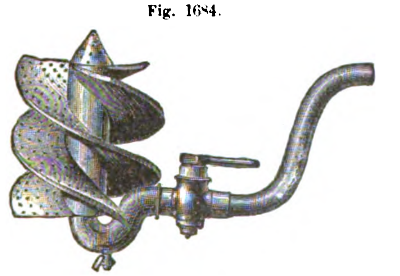
Fig. 1683.



Siebel's Malt Pulper.

tun. Fig. 1683 is an exterior view of the apparatus, and Fig. 1684 a view of the interior sparger. It consists of a hopper, sparger chamber, and spout, and a pipe and worm with perforations to eject water to suffuse the passing malt. The gate valve at the bottom of the hopper being withdrawn, the ground malt in the hopper commences to descend; hot water is admitted to the sparger by turning the spigot. The

Fig. 1684.

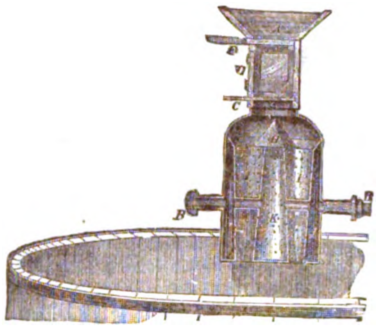


Sparger.

vertical portion and the spiral of the latter are hollow and perforated, to discharge jets of hot water arriving by the pipe. The descending malt is spread by the cone, and, passing down the face of the spiral is reduced to a soft pulp before being discharged by the chute into the tun beneath.

In *Trageser's* self-acting mashing machine the malt enters from the hopper *A*, strikes the cone *H*, and passes down

Fig. 1685.



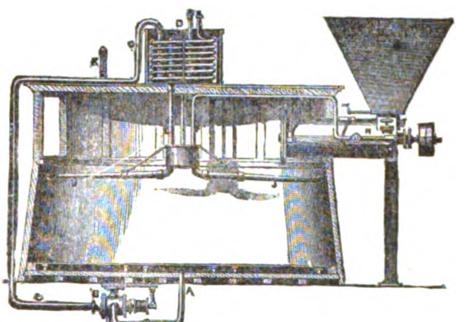
Trageser's Sparger.

an annular space *I* between two cones *J K*. Water from pipe *B* surrounds the outer cone and fills the inner one, and is sparged through perforations upon both sides of the malt passing downwards into the tun.

Mash Tun. A vat in which ground malt is steeped and stirred to make wort. See Figs. 3077–3080, pp. 1402, 1403, "*Mech. Dict.*"

Fig. 1686 is *Boby's* mash-tun (Br.), which is adapted for mashing at a low temperature, and subsequently increasing the heat, avoiding the use of successive amounts of hot water; called in England *piece liquors.*

Fig. 1686.



Boby's Mash Tun.

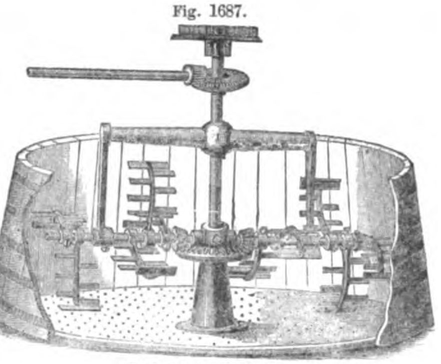
In the figure —

A. Pipe provided with stop-cock, to convey wort from bottom of tun to pump.
B. Pump with rigger, to be driven by means of a strap.
C. Pipe which conveys wort from pump into copper cistern with coil
D. Copper cistern containing coil for heating wort.
E. Tube from coil cistern to sparge.
G. Tube with cock for the purpose of emptying pump and pipes after the operation.
J. Sparge arms.
K. Thermometer, indicating temperature of wort in tun.

The peculiarity of *Feiderlein's* mash tun (Fig. 1687) is in the mechanism. It has a strong perpendicular driving shaft, by which the whole system of rakes is revolved in a horizontal plane The rakes revolve in vertical planes, and are journaled upon a horizontal shaft which itself has a rotary sweep in addition to its axial rotation. The double-armed rake lifts the malt on both sides of the tun at once.

Fig. 1688 shows *Schimper & Immen's* mash machine, a portion of the side of the tun being broken away to exhibit the apparatus and interior The stirrer consists of a spiral which rotates with its horizontal shaft, and partakes with the latter of a sweeping movement in a horizontal plane around the vertical axis to which it is attached. The movement of rotation of the screw is given by the meshing of a pinion on the horizontal shaft with a bevel wheel on the floor of the tun. The mash is heated by a steam coil above

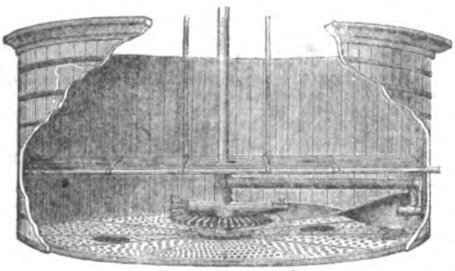
Fig. 1687.



Feiderlein's Mash Tun.

the agitator. The arrangement prevents the accumulation of the solid contents at the bottom of the tun: the currents created by the compound motion of the screw — of translation about the vertical axis and of rotation about its own horizontal axis — maintains a constant circulation between the center and the perimeter of the bottom of the tun; a vertical circulation taking place at the outer walls of the tun and also in the center.

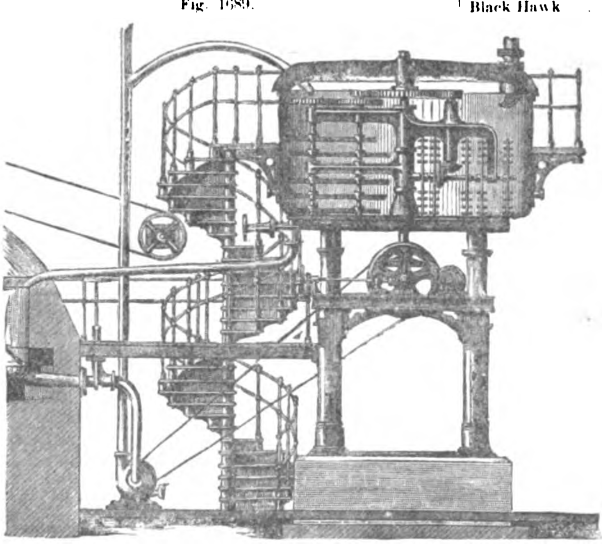
Fig. 1688.



Mash Machine.

The mash tun of *Noback, frères*, of Prague, is shown in Fig. 1689. The figure shows the boiler, pump, tun, and mechanism for stirring; also the pipe and band connections. The stirrer has a revolution of translation in a horizontal plane around the vertical axis. The arms on the sides of the axis have respectively rakes revolving in horizontal and vertical planes so as to leave no corner or surface of the mash tun unvisited.

Fig. 1689.



Mash Tun. (Noback, Prague.)

Ma'son-ry. The various kinds may be found under —

Ashlar	Range.
Dimension stone.	Rubble.
Random.	Squared stone.

For list of masonry, varieties, tools, etc., see list under STONE-WORKING, *infra.* Also, list MASONS AND BRICKLAYERS' TOOLS AND WORK, p. 1405, "*Mech. Dict.*"

The column of Trajan is of Parian marble, constructed of circular blocks placed one above another, like so many immense mill-stones, so large and high that each makes the circumference of the pillar, there being but 17 in the shaft of the column; in all, 24, including the base and the capital, reaching 24 toises of elevation, — 152 feet.

The windows and the steps of the spiral staircase are carved out of each block.

"The most valuable pillars about Rome, for the marble of which they are made, are the —

"Four columns of oriental jasper in Ste. Paulina's chapel in Ste. Maria Maggiore.

"Two of oriental granite in Ste. Pudenziana.

"One of transparent oriental jasper in the Vatican library.

"Four of Nero-Bianco in Ste. Cecilia in Transtevere.

"Two of Brocatello and two of oriental agate in Don Livio's palace.

"Two of Gallo-Antico in St. John Lateran.

"Two of Verdi Antique in the Villa Pamphilia.

"These are all entire and solid pillars, and made of such kinds of marble as are nowhere to be found but among antiquities, whether it be that the veins of them are undiscovered, or that they were quite exhausted upon the ancient buildings." — *Addison.*

See also paper on "*Ancient Roman Works*," by Nash, read before the "Architectural Association" of England. Published in "*The Builder*" and republished in "*Van Nostrand's Eng. Mag.*," xvii. 464-472.

Cf. Gillmore's "Building Stones."

Ma'son's Ham'mer. A steel hammer weighing from 3 to 8 pounds, having a square face, and an edge peen, the line of the latter in the plane of the sweep of the handle.

Mast. The following list gives the full height of the masts of a number of vessels, excluding those under 130′: —

Cf. *Fincham's "Masting Ships and Mastmaking."*
Kipping's "Treatise on Masting and Rigging."
"Treatise on Sails and Sailmaking."

Mast Head. (*Nautical.*) The upper part of a mast above the rigging.

Mast-head' Lamp. (*Nautical.*) A signal and sailing lamp swung aloft as a caution to other craft.

Fig. 1690.

Mast-head Lamp.

Mast-head' Pen'dant. (*Nautical.*) A short piece of rope fixed upon the head of a mast under the shrouds, having at its end an iron thimble spliced into an eye, to receive a hook of a tackle.

Mast Hinge. (*Nautical.*) A socket for setting up a boat's mast, and allowing it to be struck by unstepping it at the keel.

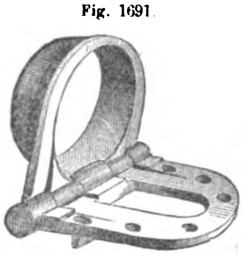
Mast Lin'ing. A thickness of cloth on a sail to prevent chafing against the mast.

Mat. 1. (*Nautical.*) A plaited rope fabric used to bind on shrouds or spars to prevent chafing. It is made of strands of old rope, spun yarn, foxes, sennit, etc.

See: Paunch mat. Sword mat.
Sennit. Thrum.
See list under SEIZING.

2. (*Hydraulic Engineering.*) 1. A woven structure of willows, weeds, or brush, secured by ropes or wires into a continuous mat, and used as a revetment for river banks. See MATTRESS.

Fig. 1691.



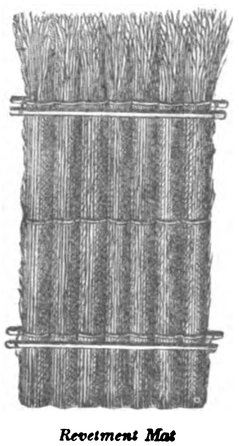
Mast Hinge.

One laid by the U. S. Engineer near Covington, Nebraska, was 2,000′ long and 69′ broad, and from 6″ to 12″ thick. It was built on a mattress boat, which gradually receded as the mat was constructed, letting the mat slip into place in the water. See "*Report of U. S. Engineers,*" * 1880, p. 1455.

Fig. 1692 shows a mat made of 6 or 7 fascines laid side by side, and lightly bound between 4 poles tied together in pairs at the ends and middle with lath yarn. Such a mat is about 12′ × 5′ 8″.

Full description of making may be found in "*Report of Chief of Engineers, U. S. Army,*" 1876, * vol. ii., Part II., p. 404. Mats are used to anchor with stones in making dams or jetties: as a revetment to banks, to prevent scour of river bottoms, etc.

Fig. 1692.



Revetment Mat

3. A species of rug, for the feet.

Felt mats are made by the following process: A piece of felt of suitable thickness is cut into strips ⅜″ to ¾″ in width, and as long as the mat is to be wide. These are laid side by side on edge, and holes are made through them, and through these holes cords of fine wire are passed, and the strips are then drawn tightly together and fastened in place at each end of the wires. This gives a fabric as thick as the strips are wide, and of a light, flexible, and elastic character. The strips may be in various colors and may be disposed in any desirable pattern. When finished, the mats have a good face on either side.

4. A floor covering, or substitute for carpet.

The ordinary Japanese mats are made of the materials mentioned below and lined with rice straw, are more than 1″ thick, and throughout Japan are all of the same size, viz., 6′ by 3′.

The surface of the mats in rooms, and mattings of better quality in general are made of the *Juncus effusus*, — the pith of which is used for candle- and lamp-wicks, — in the province of Oomi; of the *Isolepis*, in Bingo, and of the *Cyperus rotundus*, in Satsuma and Bungo. For the commoner mattings rice straw and also different kinds of rushes are used; for instance, *Scirpus lacustris*, *Hydropirium latifolium*, and typha, which plants grow almost everywhere. Rain cloaks are also made of certain kinds of grass or of palm-leaves.

Fluted portable matting . . . * "*Man. & Builder,*" xi. 43.
Malakoff mantelet . . . . Fig. 1673, p. 580, *supra.*

Mat Boat. (*Hydraulic Engineering.*) A frame of ways supported on scows, on which mat for revetment is woven, and from which it is launched into place to act as a preventive of scour on a river bank or elsewhere.

Match. Considered on pp. 1408, 1409, "*Mech. Dict.*"

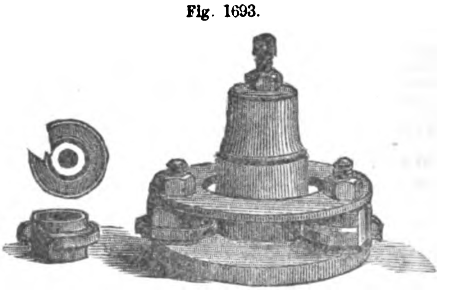
Process of match-making in France described under article "*Allumettes,*" *Laboulaye's "Dictionnaire des Arts et Manufactures,*" vol. iv., ed. 1877.

American process . . . "*Harper's Weekly,*" June 22, 1878.
"*Scientific American Sup.,*" 1832.

Match'er Head. (*Wood-working.*) The head in a planing machine which carries the cutting tool.

Fig. 1693 shows a form in which the cutting tool — either the grooving or the tongueing cutter — is a solid circular disk secured between the plates of the head by a bolt running through its center, and projecting from the periphery of the plates a sufficient distance to cut the groove and clear the edge of the board. The cutters are 2¼″ diameter and afford about 7″ cutting surface, being filed back as they wear.

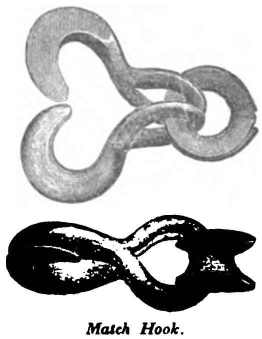
Fig. 1693.



Matcher Head.

Match Hook. A tackle hook, consisting of two portions which shut together, each forming a mousing for the other. A *sister* hook.

Fig. 1694.



Match Hook.

Ma-te-lasse'. (*Fabric.*) A silk-and-wool French dress goods.

Mat Hook. A long pole with an iron hook, used to hook on to the binding pole of a mat. Used also in handling the mats in floating into place and holding while being anchored with stones. See under JETTY, p. 512, *supra*. c

See Figs. 10, 12, "*Report of Chief of Engineers, U. S. Army*," 1876, vol. ii., Part II. Appendix X. 4, pp. 408, 409.

Mat Pole. (*Hydraulic Engineering.*) A pole 20′ long, 3″ in diameter, smoothly shaved and iron pointed, used in placing mats of brush for shore protection, jetties, etc. See MAT HOOK.

Fig. 1695.

a. Mat Hook.
b. Mat Pole.

Ma'trix. 1. (*Mining.*) The rock or earthy matter containing a mineral or metallic ore.

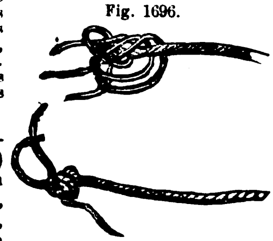
2. (*Dentistry.*) A mold used in filling proximal cavities in teeth. The matrix is a slip driven between the teeth, its wedging side against the abutting tooth and its concave side against and agreeing with the cavity to be filled. — *Dr. Louis Jack.*

Ma'trix Rol'ling Ma-chine. A machine which in large establishments takes the place of the beating table and brush. Fig. 5800, p. 2380, "*Mech. Dict.*" The work of the machine is to force down the prepared matrix paper into the type in taking a cast thereof by the paper process; described on p. 2380 above cited.

Mat'thew Walk'er. A form of knot something like a double wall knot.

To make it: Unlay the rope for 10″ or 12″; pass the first strand around the rope and bring the end up through the bight thus formed; pass the second strand around the rope and bring the end up through both bights; pass the third strand around the rope, and bring the end up through the three bights; haul the ends gently until the knot is in shape, then haul tight, and finish with a crown. The cut shows the strands laid through the bights and also hauled tight.

Fig. 1696.



Matthew Walker Knot.

Mat'tress. (*Hydraulic Engineering.*) A mass of woven withes, poles, brush, willows, or what not, used to place on a bank or shore to preserve it against the impact of water and prevent erosion by the current.

There are many modes of building, and among the most remarkable instances to be found are the maritime and interior dyke works of Holland and the Eads' improvements of the southwest pass of the Mississippi. Good illustrations of methods are to be found in Plates I. to XIV. opposite p. 1380, vol. ii., "*Report of Chief of Engineers, U. S. Army*," 1880.

See also mattresses of Galveston jetty, same work and volume, * p. 1228.

A good account of all the tools and methods used at Nebraska City is given in the "*Report of the Chief of Engineers U. S. Army*," 1879, * ii. 1074.

It includes the following: —

Harpoon shuttle.	Shuttle fastening.
Brush jack.	Hook needle fastening.
Brush jack needle.	Mattress fastening.
Hook needle.	Curved needle fastening.
Curved needle.	Various kinds of sewing.
Jack fastening.	

Drawings and descriptions of elaborate mattress work on the Mississippi River may be found in the "*U. S. Engineers' Report*," 1879, * ii. 1111, 1118.

Charleston harbor . .	* *Ibid.*, i. 736.
Savannah river . . .	* *Ibid.*, i. 742.
Arkansas river. . . .	* *Ibid.*, 1878, ii. 658.
Mississippi jetties . .	* "*Scientific American Sup.*," 332.

Among the various tools used in making revetment mattresses are the following, which are described under their various headings, *supra*: —

Brush jack.	Harpoon shuttle.
Brush jack needle.	Hook needle.
Curved mattress needle.	

To these may be added the following names of types of revetment work, which see: —

Apron.	Mat.
Curtain.	Revetment.
Floating brush dike.	Sand fence.
Floating wire dike.	Willow curtain.
Hurdle.	

Mat'tress Boat. (*Hydraulic Engineering.*) A boat on which a mattress is built and from which it is launched. Such mattresses are used in revetments of banks or the prevention of scour of bottoms, also in making dikes to act as dams, chutes, or breakwaters.

Views and details of mattress boats as used on the Mississippi are to be found in "*Annual Report of Chief of Engineers, U. S. Army*," 1880, * ii., pp. 1418, 1439.

A mattress boat consists essentially of a set of 8 trussed ways supported by two scows. The ways upon which the mattresses are made form the upper chords of the trusses. See also Plate I., and p. 1074, vol. ii., "*United States Engineer's Report*," 1879.

May'nooth Bat'te-ry. (*Electricity.*) In a cast-iron pot containing nitro-sulphuric acid is placed a porous jar which contains the amalgamated zinc and dilute sulphuric acid.

Niaudet, American translation	175.
"*Scientific American*"	xl. 123.

Meal Cool'er. A process in which the meal from the millstones is conducted along a passage in which is a current of air induced by a fan, in order to remove the heat generated by attrition between the stones.

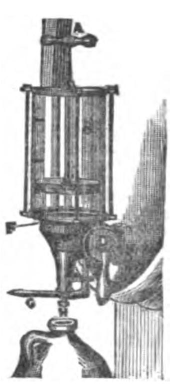
Meas'ur-ing Fau'cet. One which shows by means of a graduated vessel of marked quantities, the amount of liquid passing from a tank to a vessel, for instance, or a meter arrangement by which a given quantity is forced through an opening.

Fig. 1697.



Measuring Faucet.

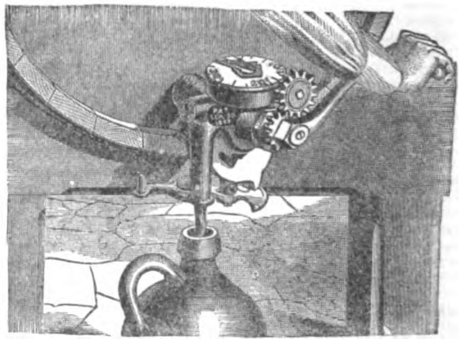
Fig. 1697 is an illustration of the first-mentioned kind; the liquid, being allowed to flow from the barrel into the graduated glass vessel *B*, is forced from the latter by pressure on piston handle *A* at opening *H*, the subsidence of the level in *B* being noticed. *G* is the gate.

Fig. 1698 is a force feed measuring faucet for heavy oils, molasses, etc. The chamber, of known capacity, is emptied at each revolution of the crank, and the pointer on the dial registers the revolutions.

Meat Cut'ter. A meat slicer, for dried beef especially. See BEEF SHAVER, Fig. 256, p. 86, *supra*.

Hittenger's round knife meat cutter has a rotary meat pan and two sets of circular knives that, as the pan rotates, cut the meat. A scraper is attached to the frame by which the sides of the pan are cleared of meat.

Fig. 1698.



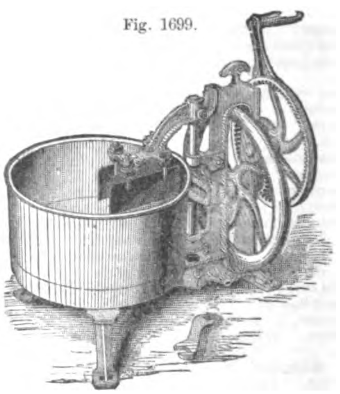
"Enterprise" Measuring Faucet.

See also forms of machines, Figs. 3106–3110, pp. 1415, 1416, "*Mech. Dict.*" See also SAUSAGE MACHINE, *Ibid.*

Meat Chop'per. A mincing machine for reducing meat to fragments for sausage, hash, or croquettes, salad, pates, etc.

Fig. 1699 is a small-sized machine for the above purposes; also useful chopping fruit and vegetables. The knives are reciprocated vertically with rapidity and the pan turned on its base.

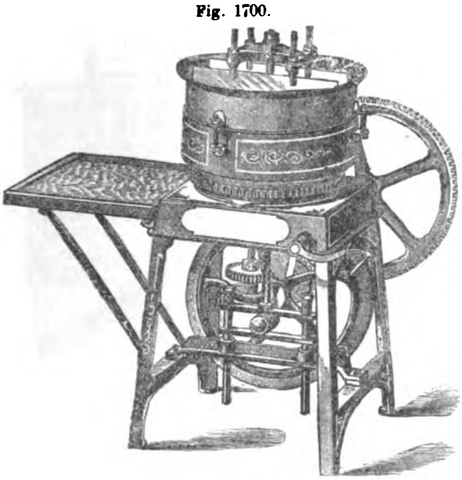
Fig. 1699.



Domestic Meat Chopper.

The *Nittinger* meat chopper is on a larger scale, being driven by power, and having automatic turning motion for

Fig. 1700.



Butcher's Meat Chopper.

the pan. The knives are moved vertically by means of an axial rod passing down through the center of the chopping block and attached to a crank-pin beneath. The block has an intermittent motion in the interval between the cuts.

Me-a'to-scope. (*Surgical.*) A speculum for observing a natural passage. Specifically a urethral speculum. The term *endoscope*, from ἔνδον, within, is applied to instruments having a similar purpose.

See Part III., *Tiemann's "Armamentarium."*

Gouley's, Fig. 19, Part III., *Tiemann's "Armamentarium."*

Meat Rock'er. A mincing knife having a handle at each end, and worked by a rocking motion.

Fig. 1702.

Meat Rocker.

Me-a'tus In'stru-ments. (*Surgical.*) 1. Instruments for the examination of, or operation on the external meatus auditorius.

Bistoury.	Forceps (see list).
Caustic holder.	Furuncule knife.
Cotton holder.	Marygotome.
Curette.	Otoscope.
Ear hook.	Polypus forceps.
Ear mirror.	Polypus snare.
Ear scoop.	Powder blower.
Ear speculum.	Probe
Ear syringe.	

2. Instruments for the meatus urinarius. See Urethral Instruments.

Me-chan'i-cal Bat'te-ry. (*Electricity.*) One in which the plates are moved or shaken to prevent polarization, and to bring them in contact with fresh liquid.

Me-chan'i-cal Ex'er-ci-ser. See Exercising Machine.

Me-chan'i-cal Fin'ger. (*Microscopy.*) A device used in segregating from a mass of minute material on a slide a minute object, such as a diatom, for instance, and placing it solus upon a slide.

It consists of a wire, bristle, or hair on a stage forceps, the end projecting to the center of the field. The stage is then manipulated by the mechanical movements until the object is beneath the hair. The slide may then be raised by the parabola fixed in the sub-stage so that the minute object becomes attached to the hair. Remove the slide and substitute a clean glass slide, and raise it so as to detach the object from the hair.

Me-chan'i-cal Fir'ing. A mechanical arrangement for the supply of fuel to a furnace.

See * Furnace Feeder, Figs. 1116, 1117, p. 363, *supra*.
* Puddling Furnace, *infra*.
* Smoke-consuming Furnace, "*Mech. Dict.*"
* "*Scientific American Supplement*," 1218.

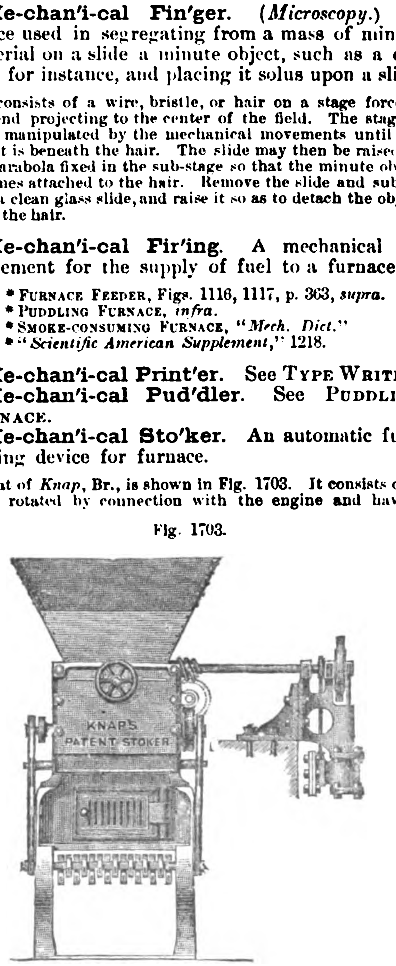
Me-chan'i-cal Print'er. See Type Writer.

Me-chan'i-cal Pud'dler. See Puddling Furnace.

Me-chan'i-cal Sto'ker. An automatic fuel-feeding device for furnace.

That of *Knap*, Br., is shown in Fig. 1703. It consists of a shaft rotated by connection with the engine and having

Fig. 1703.



Mechanical Stoker.

wings in the bottom of the fuel hopper so as to allow an amount of fuel to drop into the furnace, proportioned to the rate of revolution of the shaft and the size of the opening.

Belt connection to a lower shaft gives a periodical lifting to the grate bars so as to disturb clinkers and drop the ashes.

See also Figs. 1116, 1117, p. 363, *supra*; Fig. 5229, p. 2226, "*Mech. Dict.*," "*Sc. Amer. Sup.*," 1423.

Meer'schaum, Ar'ti-fi'cial. The chips and waste of meerschaum pipe making, hardened by pressure.

Gypsum, boiled with stearic acid or paraffine, much resembles meerschaum. The resemblance may be increased by coloring the mixture with solution of gamboge and dragon's blood.

"*Scientific American*" . . . . xxxiv. 383.

Meg-al'o-graphe. A French name for a form of camera-lucida, made by Secretan, of Paris.

It is used for microscopic drawing and pattern drawing for industrial purposes.

It differs from the ordinary camera-lucida, inasmuch as it admits of drawing directly from objects under the microscope, or from designs produced by the turning of the kaleidoscope. It is provided with three tubes: one microscopic, one kaleidoscopic, and the third simple. A prism on a detached tube of its own is adjustable to either of these, and by means of mechanical contrivances the point of view may be changed as occasion demands.

"*Scientific American*" . . . . xxxv. 345.

Meg'a-phone. An instrument for assisting hearing, invented by T. A. Edison.

It consists of two large funnels 6′ 8″ long and 27.5″ diameter at the pavilion, with elastic conducting tubes from their apices to the aural orifice. Conversation in moderate tones has been heard and understood at a distance of one and a half miles.

"*Manufacturer and Builder*" . . . . x. 278.

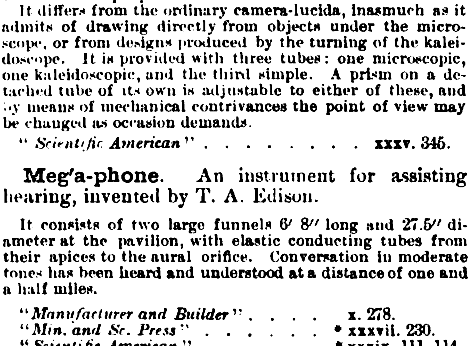
Meg'a-scope. A species of camera-obscura for throwing a reflected magnified image upon a screen. In one invented by Dr. Curran, the image is projected by a large compound objective lens 7″ in diameter. The light from the lantern is thrown upon the object itself and is thence reflected to the screen.

In a French form of the instrument, represented in Fig.

Fig. 1704.



Megascope

1704, especially designed for making enlarged copies of designs, medals, statuettes, and engravings, the instrument consists of a screen, a magnifying lens, a shelf to hold the object, and a mirror to project the light upon the surface presented towards the lens.

The object is placed on the shelf at such distance from the mirror that the reversed image on the screen shall have the desired size. The image being magnified will have less brilliancy than the object, since the rays reflected from it are spread over a larger surface. To avoid this, the mirror reflecting solar light, or a pair of calcium lights, as used by Dr. Cresson, are employed to illuminate it. The screen is of glass, and the draftsman places himself behind it, and follows with a pencil the lines of the image.

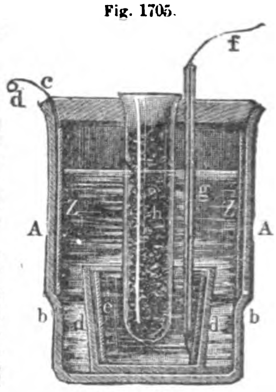
Me-gass' Dry'er. See Bagasse Dryer.

Mei'din-ger Bat'te-ry. (*Electricity.*) A modification of the Daniell battery, having no porous cell.

Fig. 1705.



Meidinger Battery.

The glass vessel, *A*, has a shoulder, *b*, on which rests the zinc element, Z. In *A* is placed a small glass cup, *d*, lined with copper, *e*, on the lower end of which an insulated copper wire, *g*, is riveted. A glass cylinder, *h*, having a hole at the lower end, is suspended from the wooden lid, and contains the sulphate of copper crystals, which keeps the liquid in the cup *d* saturated with that salt. The remainder of the space in vessel *A* is filled with a solution of sulphate of magnesium.

Prescott's "*Electricity*" . . . . * p. 53.

Niaudet, Amer. transl. . . . . * 124.

The Meidinger *balloon* battery has a flask magazine for supply of crystals.

Niaudet . . . . * 127.

Meg-ohm'. (*Electricity.*) A measure of electrical force or resistance equal to 1,000,000 ohms.

Mé-lange'. (*Fabric.*) A French dress goods of cotton chain and woolen weft.

Me-lan'o-scope. Invented by Lommel. It consists of a pair of spectacles, made of two kinds of glass, one on top of the other; the first glass is dark red, the second light violet. This combination admits only red rays, so that all green plants appear black. It may thus be used to recognize the flames of substances which show red lines in the spectroscope, such as potash, strontium, etc.; its use is limited to substances which give red lines.

Me-lan'o-type. A photograph on a background of japanned metallic plate. Invented by Smith & Neff. The name was originated by Peter Neff.

Me-lo'di-o-graph. A contrivance to record the notes of tunes played upon an instrument.

In the melodiograph of Zigliani, a double flat spring placed under each key is connected with a battery and with a recording apparatus, which consists of a comb provided with insulated teeth gently resting on a copper cylinder. A strip of ruled and chemically prepared paper is drawn over this roller by clock-work, and receives the impressions or marks of the teeth of the comb. This clock-work can be regulated so as to cause the paper to move in conformity with the time kept by a person playing the instrument. Every time a key is depressed the circuit is closed, and the electricity, passing through one of the teeth of the comb, makes a mark corresponding to the key that has been depressed.

That of M. Carpentier is described in * "*La Nature*," and the account is reproduced in "*Scientific Canadian*," * x. 106, 107. It was exhibited at the International Exposition of Electricity, Paris, 1881.

The subject has been considered in the "*Mech. Dict.*," Music Writer, p. 1502, where the following instruments are referred to: —

Creed, Br., 1747.	Hennersdorf, Ger., 1748.
Freke, Br.	Unger, Ger.
Hohlfield, Br.	

See also Music-recording Instrument, *Ibid.*, same page.

Besides the use of the melodiograph for composers and transcribers of music, the purpose of Carpentier's apparatus is the perforating of sheets for *melophones* and other apparatus for the automatic playing of music. See also "*Scientific American*," xli. 166.

In the apparatus of M. Carpentier the harmonium is one part and the melodiograph another. 50 wires concealed beneath the floor put the two instruments in communication. 50 keys of the harmonium are provided with devices, so that the depression of each makes contact with the corresponding wire. The currents operate a series of perforators, which act upon a band of paper, each one being operated by the movement of its appropriate key. The band of paper is carried along in the melodiograph by clock-work.

In the use of the perforated paper band for playing, 50 small brushes of silver wire placed in the instrument make contact through the holes with a cross-piece against which they press the paper. When a contact is made by the contact of a brush, through a hole, with the cross-piece, a current circulates in it, operates the opening machine of the corresponding key and causing the reed to speak, sustaining the sound so long as the brush makes its contact through the hole, which may be long or short.

Mel'o-graph. See MELODIOGRAPH.

Melt'ing Fur'nace. (*Glass.*) A furnace in which the *frit* for glass is melted, being then transferred to a *blowing* furnace from which it is worked. This is the better practice. In America it is most frequently worked from the *melting* furnace direct.

Melt'ing Point of Al-loys'. See ALLOYS, "*Mech. Dict.*," p. 66, *et supra.*

Melting points of gold and silver alloys: —

Silver 100 (pure)	954° C.

Mer'cu-ry Fur'nace. The mercury furnace of M. Hippolyte Berrens, at Barcelona, Spain, is thus described in the "*Correspondance Scientifique:*"

"It consists of a horizontal or vertical furnace, charged periodically, as its action is not continuous. It connects with a transmission chamber, from which the gases pass into condensers, 17 to 25 in number, the shape of which resembles that of two cones united at their base. The lower cone is buried in the ground, the upper, made of sheet iron, is cooled by a continuous stream of water. Each condenser has a capacity of about 30' cubic. They communicate with one another at their lower parts. The last one of the system is connected with a chamber containing charcoal, destined to remove the last traces of mercury from the gases. There is no chimney, but an aspirator instead, which permits accurate regulation of the furnace. The walls of the apparatus are coated with a layer of a mixture of equal parts of charcoal powder and cement. The furnace at Barcelona was charged with 15,717 pounds of 2.76% ore. Theoretically, therefore, the yield should have been 455.89 pounds of quicksilver, but in fact it was 450.96, which proves a loss of 0.79%, although the carbon of the last receiver was not examined. Gold leaf placed at the end of the apparatus did not show the least trace of amalgam. In a second trial, — made in summer, at a time when work at Almaden is entirely suspended on account of the too heavy loss of quicksilver, — the exhauster was run at so high a speed that the ore in the furnace was glazed; the time of the operation was decreased by 25 hours, and yet the yield from a charge of 15,790 pounds of 2.82% ore was 434.51 pounds, the loss amounting to 3.67%. A horizontal furnace is now building at Anfondeguilla capable of working 20 to 30 tons of 1% ore per day."

See also references to Mercury furnaces under MERCURY, *supra.*

Mer'cu-ry Hold'er. (*Dentistry.*) A vulcanite cup with cover, for the convenient preparation of amalgam.

Me-rid'i-an Cir'cle. Refer to: —

Me-ri'no. (*Fabric.*) A fine wool French dress goods woven with a twill on both sides. It is made from 8 to 50 picks to the inch, and is piece-dyed.

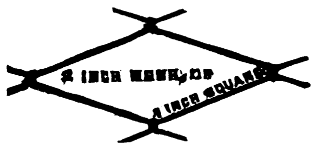
Cashmere resembles it, except in the respect of being twilled on one side only.

Me-ri'no Tulle. (*Fabric.*) An all-wool French goods.

Mesh. The loop in the texture of a net.

The measure is stated by the width of the mesh stick on which it is made; or by the length of one side of the quadrilateral loop. Fig. 1708.

Fig. 1708.



Mesh.

Mesh'ing Net. (*Fishing.*) One which entangles the fish by their gills in the meshes. Seines, and many other nets with specific names, are included with the term *meshing*. See NET.

Mes'sage Cop'y-ing Press. (*Telegraphy.*) A press for taking a copy of a message received before remitting to the sendee.

A duplicate is taken, for filing, by laying a sheet of dampened unsized paper upon the message, and passing the two through a copying press. The latter consists of a pair of rollers, which are turned by steam power, an electro-motor, or by hand, according to circumstances. In large offices, usually by a Phelps electro-motor.

Manifolds are used for press news, of which a large number of copies are required.

Met'al-ized Glass. An ornamental glass having flakes of gold, platinum, mica, etc., distributed through the glass. It is made by the "Aurora Glass Co.," of London, but much resembles the *Aventurine* (which see), of which it is perhaps but an imitation.

The metals used are principally white and yellow. It is presumed these metals are reduced to powder or thin leaves, and when the article is in process of manufacture the glass is rolled in this metallic dust, which then adheres to the glass, and, by re-heating, the article is finished in the usual way. A piece of broken glass of this variety showed the metals to be near the outer surface and slightly sunk into the glass.

Another mode of working imprisons a metalized surface between two layers of glass.

An object is first blown in glass of the desired color; metallic flakes are then rolled on to it, and a new layer or envelope put on this. The flakes are thus inclosed between two layers of glass. Vases shown in Paris, in 1878, had black interior covered with white mica, others with golden flakes.

Me-tal'lic Chain. The chain of square iron links with clasps. Invented by *Vaucanson*.

Me-tal'lic Pack'ing. Tubes of lead, or some soft metallic alloy, filled with hemp, cotton, or some other suitable vegetable material. These tubes can be prepared of great length and cut to fit any given requirement. The ends may be either soldered together or forced into close contact. The convenience, durability, and cheapness of this packing are especial recommendations. — *Strieder*, "*Dingler's Pol. Jour.*"

Me-tal'lic Shin'gle. A plate of metal with ridges on the face for ornament, and beneath the overlap for joint; a substitute for shingles, tiles, or slate.

Me-tal'li-kon. An English architectural surface decoration for consoles, brackets, casings of pillars, etc.

It consists of ornamental glass, or ceramic slabs, or forms mounted by cement on glass plates which are secured in place. "*Building News*," 1876. "*Scientific American Supplement*," 745.

Me-tal'lo-phone. A keyed instrument with outside resemblance to a piano, but having metallic bars instead of strings. See Fig. 3689, p. 1695, "*Mech. Dict.*"

The subject of musical instruments of percussion possessing bars tuned to a scale is considered under MARIMBA. See also references *passim*.

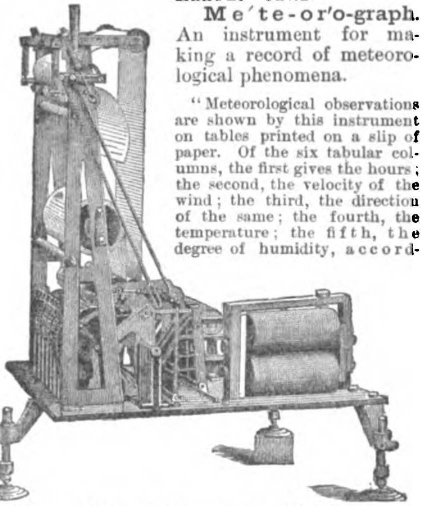
Zinc plating.
Zinc powder.

Met'al Saw. The band saw — *scierie à ruban* — has been adapted in France and England for cutting thin plates of metal into curved forms, for ornamental or constructive purposes. Such plates form escutcheons, hinges, overlays, and inlays.

Met'al Seal. See LEADEN SEAL.

Me'te-or'o-graph. An instrument for making a record of meteorological phenomena.

Fig. 1709.



Theorell's Printing Meteorograph. (*Swedish.*)

"Meteorological observations are shown by this instrument on tables printed on a slip of paper. Of the six tabular columns, the first gives the hours; the second, the velocity of the wind; the third, the direction of the same; the fourth, the temperature; the fifth, the degree of humidity, according to August's method; and the sixth, the atmospheric pressure, which is given in millimeters. The degrees of the thermometer employed are those of the Centigrade scale, and negative degrees are expressed by their complements of 100. The direction of the wind is indicated by figures from 1 to 32. The numbers expressing the velocity of the wind signify meters in a second.

"The registration takes place by means of electrical currents, which are closed in the barometer and both the thermometers by contact between the quicksilver and steel wires that descend into their tubes, and at the weather-cock and anemometer by contact between a metal knob, which is put into motion by the current, and a wheel which is in a direct mechanical combination with each of these instruments.

"The steel wires in the barometer and in both the thermometers are connected, each by its respective system of brass wheels, with numerical types engraved on the edges, in such a manner that the rotation of the wheels causes an upward or downward motion of the steel wires, so that the point of the scale on which the lower extremity of the wire is situated is necessarily that indicated by the number appearing at the same moment uppermost on the corresponding wheels. The two other brass wheels with engraved figures are likewise combined, by means of electric currents, with the above-named metal knobs in the weather-cock and the anemometer, in such a manner that the figure which is uppermost on the periphery of the wheels at the moment it is about to be registered indicates the direction of the wind at the same moment, and its mean force during the preceding quarter of an hour.

"The wheels containing the figures are governed by an electro-magnetic motor, which for each observation sets the five systems successively in motion until the corresponding wires have reached the quicksilver in the barometer and the two thermometers, and caused a contact between the above-named metal knob in the weather-cock and the anemometer, and the wheels, which are in a mechanical combination with each of these instruments.

"The numbers, therefore, that are uppermost on the numbered wheels are just those which indicate the height of the barometer and of the two thermometers, as well as the direction and velocity of the wind. And now the same electro-magnetic motor operates upon a printing apparatus, which, after having deposited color on the types, presses the above-mentioned slip of paper against them.

"This being done, the steel wires are drawn up again by the motor, which stops as soon as a certain distance from the quicksilver is attained, and all is ready for the next observation. The interval between the observations is a quarter of an hour.

"As the clock which determines the time of the observations does not require winding up, the instrument itself restoring the tension of the mainspring every quarter of an hour, it continues going as long as the impellent force, *i. e.*, the electric current, is maintained; and as the slip of paper applied lasts for fully three months, that is the period for which the instrument may be left to itself." — *M. Sörenson.*

In the meteorological recording instrument of Von Baumhauer, of Utrecht, Holland, shown at the Centennial, the instrument was run by weight and clock-work, the stylus making its marks or dots upon a revolving vertical cylinder with blackened surface.

See also ANEMOMETER, *supra*.

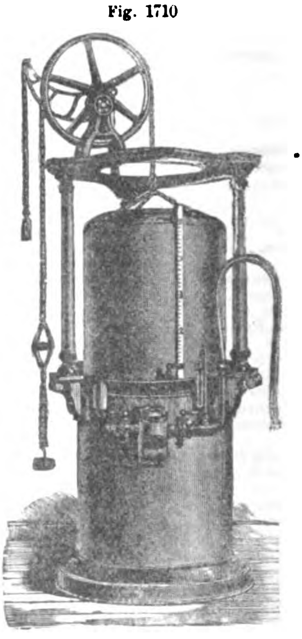
Me'ter. (*Fishing.*) The strengthening line of a seine or gill net, to the upper one of which the floats, and to the lower the weights, are attached. The *seaming* is the marginal line of the net, to which it is seized by meshes, and the *meter* is an outside line seized at intervals of a yard.

Me'ter and Am-mo'ni-a Sat'u-ra'tor. (*Gas.*) An experimental instrument, used in the proving of the quality of gas. — *Goodwin.*

Me'ter Prov'er. (*Gas.*) A holder of known capacity used in testing the accuracy of the indications of a gas meter.

The prover is accurately counterpoised and adjusted so as to give a uniform pressure from top to bottom. The water must be uniform in temperature with the air of the room in which the experiment is conducted. The meter is connected to the holder, and a small quantity admitted to bring the pointer on the index to any figure desired. Next adjust the pointer on the holder to 0°. Turn on the gas and make one or more complete revolutions of the pointer on the dial. The quantity registered by the meter should

Fig. 1710



Meter Prover.

correspond with the indications on the vertical scale of the holder. Per centage of error is readily calculated.

Met'ric Sys'tem. In addition to the remarks on page 1428, "*Mech. Dict.*," METRIC SYSTEM, in regard to the constitution of the French commission of 1798 to report upon the selection of a natural standard of measurement; and on p. 1554, ODOMETER; p. 173, ASTRONOMICAL INSTRUMENTS, in reference to early measurements in Egypt and Mesopotamia of an arc of the meridian, and by Fernel, physician to Catharine de Medici, 1550: —

Cassini (*b.* 1625; *d.* 1712), the discoverer of the diurnal periods of Jupiter, Mars, Venus, and the Sun; of four satellites of Saturn, of which Huyghens had previously discovered one, and the first observer of zodiacal light, gave great attention to the measurement of an arc of the meridian. Cassini was invited to Paris by Colbert, and he and his descendants of three generations presided over the Observatory of Paris.

President de Brosses, "*En Italie*" (1739), tome i., p. 237, *et seq.* (Didier, Paris, 1858), mentions the church of San Petronio in Bologna and its curiosities: —

"Mais ce qu'il y a de principal est la fameuse ligne méridienne tracée sur le pavé par Cassini, laquelle, tant qu'elle existera, servira de règle aux astronomes à vener pour measurer l'obliquité de l'écliptique Elle est ménagée fort adroitment dans la plus grande longeur de l'église, passant avec obliquité entre deux piliers. *La longueur de cette ligne fait la six-cent-millieme partie de la circonference de la terre.*

"Elle est de marbre, devisée dans sa longueur en deux partis égales, par un filet de cuivre qui marque précisement le méridien; et sur le marbre sont gravées toutes les chose qui peuvent avoir rapport à l'ouvrage pour le rendre parfait. L'endroit de la voûte où est le petit trou par où l'image du soleil va se porter à midi précisément sur la ligne de cuivre s'étant un peu affaissé, on fut obligé, sur la fin du siècle dernier, de restaurer l'ouvrage. Il passe maintenant pour le plus parfait de tous ceux qui sont en ce genre, et ses bonnes qualités sont inscrites sur une pierre incrustée dans le mur. J'ai été choqué de voir qu'on la foulait aux pieds sans respect, ce qu'en efface beaucoup les caractères."

New standard . . . . . "*Sc. Am. Supplement*," 764.
To approx. yards and meters . "*Scientific Am.*," xxxviii. 41.

Me-tror'ga-non. (*Surgical.*) A uterine knife with a guard blade. — *Newman.*

Mex'i-can Bit. (*Manège.*) A stiff cheek bit, having a high port, to which is attached a large ring, which, when the bit is in the horse's mouth, encircles the jaw. The cheeks are long, and have rein rings at the lower ends; they are also wide and quite ornamental; chains and small drops are attached to various parts for the purpose of ornamentation; it is the most severe bit in use.

Mex'i-can Cloth. (*Fabrics.*) A silk and wool French goods.

Mez'za Ma-jol'i-ca. (*Ceramics.*) Pottery with a lead glaze and decorated with colors, in which the running together of the glaze and color gives a mingled or softened appearance to the outline of the ornamentation.

The Italian *mezza majolica* of the 15th and 16th centuries was made in great quantity, and some pieces were of great beauty.

It may be said that it preceded the stanniferous glaze (used by the Saracens in Spain and Majorca) and that the secret of the tin glaze was rediscovered by Luca della Robbia, who thus initiated the majolica ware.

Mi'ca. Some of the mechanical and ornamental uses of mica are enumerated on p. 1430, "*Mech. Dict.*"

Spectacle glasses of mica, used in Germany, are concaved in the shape of watch glasses, and are about 1·25″ in thickness. They are mounted in simple brass wire frames, and are made sufficiently large to fit closely around the eye sockets. The advantages gained by this utilization are very great.

Murray's ornamental process for treating mica: —

The mineral is first cut to the desired thickness, then coated with a thin layer of fresh isinglass diluted in water, and the gold or other surface applied, after which it is allowed to dry. A copper pattern of the desired design is next placed on the reverse side of the sheet, and any superfluous parts of the gilding are removed by means of a small brush, the design remaining on the parts not brushed. Colors are then laid on as desired, and the whole is coated with a solution of liquid glue, diluted in alcohol. The sheet is then fastened with glue permanently in position.

Puscher's process, Nuremberg: Treat thin plates with strong sulphuric acid and then silver as with glass. Cut into shapes for inlaying.

Heat to redness to give a dulled look; for inlaying, —

Scatter powdered mica on sheets of gelatine and varnish.

Mix powdered mica with dissolved gum arabic for a silver paint.

Powdered mica, boiled in hydrochloric acid, washed, and sorted for fineness: used in dusting over artificial flowers, fancy papers, passementerie; articles of wood, metal, glass, paper, papier-maché, gypsum, etc. The articles are painted in bronze colors; then receive a binding coat of gelatine, and the mica is dusted on.

See for colors, etc., BRONZING, p. 138, *supra*.

Dusted over articles coated with asphalt varnish imitates granite.

See also MARBLE, ARTIFICIAL, *supra*.

Mi'co-lon Steel. (*Metallurgy.*) Steel made by the process suggested by Réaumur, 1722, by adding wrought iron to cast iron to reduce the mixture to the proportion of carbon to form steel.

Martin's process is a successful application of the same suggestion.

It may be applied either in the crucible or the cupola. In the former, the proportions of iron and steel are placed in the crucible with such an amount of spiegeleisen as may consist with the character of steel required.

The cupola process, in which coke alone is used as fuel, proceeds in the same way, but the proportions chosen by the inventor have been preferably such as to give a good casting steel for bells, but one which will not weld.

M. Debette thinks "that we have heard the last of this."

Mi'cro-bat'ter-y. A very small galvanic battery, used in testing the delicacy of instruments; as, for instance, a cell of thimble size, with a fraction of a teaspoonful of exciting liquid.

Mr. Collet wrote from Heart's Content, Newfoundland: —

"I have just sent my compliments to Dr. Gould, of Cambridge, who is in Valentia, Ireland, with a battery composed of a gun cap with a strip of zinc, excited by a drop of water the size of a tear."

See also Micro-battery for telephone, "*English Mechanic*," * xxvii. 602.

Mi'cro-far'ad. (*Electricity.*) The millionth part of a farad. The practical unit of capacity; being the trillionth part of the absolute electromagnetic unit = $\frac{1 \text{ volt.}}{10.000}$. — *Gordon.*

Mi-crom'e-ter. (*Microscopy.*) A piece of glass ruled into 100ths and 1000ths of an inch, and used to measure objects in the field.

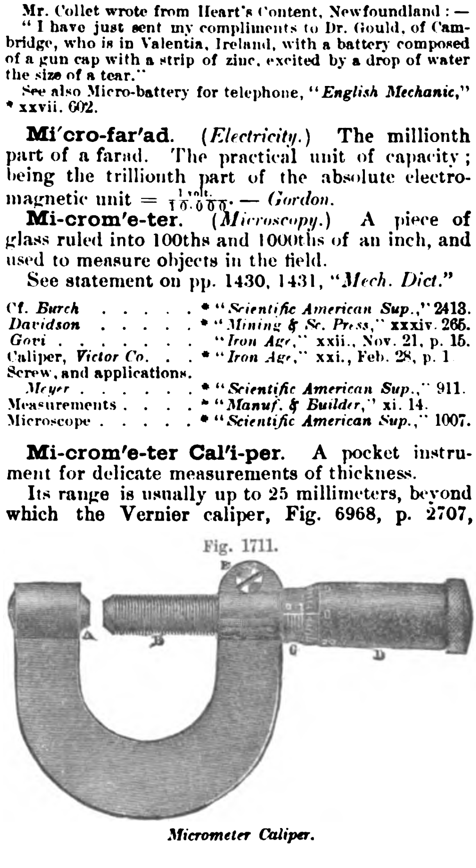
Mi-crom'e-ter Cal'i-per. A pocket instrument for delicate measurements of thickness.

Its range is usually up to 25 millimeters, beyond which the Vernier caliper, Fig. 6968, p. 2707,

Fig. 1711.



Micrometer Caliper.

"*Mech. Dict.*," is regarded as the preferable instrument.

The micrometer caliper is graduated to read to 40ths of millimeters, but 80ths are readily obtained. Binding and adjusting screws furnish ready means for compensating for any wear resulting from use.

The instrument is also made to read in fractions of inches. The one shown has a capacity of 1″, and can be set to ½ and ¼ thousandths.

Mi-crom'e-ter Screw Con'tact Cal'i-per. Mr. A. S. Kimball describes a method used by him to detect the contact of micrometer screws.

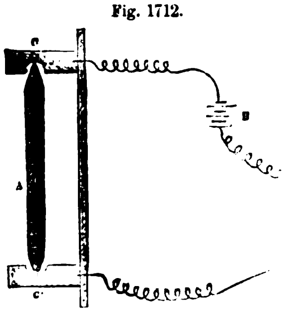
In the case in question the micrometer screw had 60 threads to an inch, and its head was graduated to 300 parts, so that the unit of measurement was the 1-18,000th″. The iron bar, micrometer screw, and a telephone, were put in the circuit of a weak Leclanché cell. When the screw was turned up to loose contact with the bar, the familiar boiling sound of a too sensitive microphone was heard, which ceased the instant firm contact was made, the change to silence being abrupt and sharply defined.

Mi'cro-phone. An instrument which is simply a telephonic transmitter of peculiar form, but which owes its name to the fact that it plays the same part in acoustics in regard to feeble sounds that the microscope does in optics in regard to small objects. It is an amplificator of mechanical vibrations of weak intensity, which it changes into undulatory currents.

Its action depends upon the property possessed by some substances of varying their electrical resistance under varying physical conditions; stress, temperature, division, etc.

The name was given by Mr. Hughes, whose instrument is shown in Fig. 1712, and a view of Ducretet's model is given in Fig. 1713.

Fig. 1712.

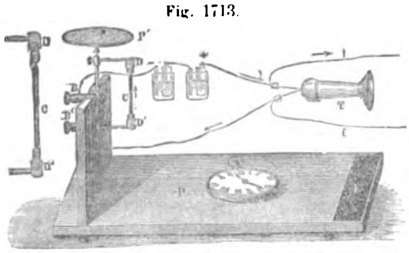


Hughes' Microphone.

"It is formed of a small charcoal crayon, *A*, pointed at both ends. It is lightly held in a vertical position between two cups hollowed out of two small carbon blocks, *C C*, which are fixed to a thin sounding-board. This last is laid on a firm plate. The blocks *C C* are connected by wires with the pile, and the line wire that leads to the telephone.

"Not only words and musical notes, but the faintest vibrations, and even imperceptible sounds, are converted by it into sonorous repetitions. The slightest stroke on or touch against the plate will produce a loud, grating sound in the telephone." — "*Electrician*."

Fig. 1713.



Ducretet's Model of Hughes' Microphone.

Referring to the question, Hughes *vs.* Edison, *in re* microphone, the "*Electrician*" remarks: —

"It is now easy to understand the slight differences that exist between Edison's carbon transmitter, and the microphone in the simple form given to it by Mr. Hughes.

The telephonic or microphonic action is produced in both instruments by the *variations of electric resistance*, which result from the vibrations that are communicated to the transmitter

"In Edison's carbon telephone these vibrations act on a plate, that produces variable pressures on a disk. In Hughes' microphone, the vibrations change the points and surface of contact; one is arranged for transmitting words only, while the other is more specially adapted for sending feeble sounds.

"There has been every reason, therefore, from the beginning to consider the inventions of Edison and Hughes as perfectly distinct, both as regards the methods employed, and the effects produced. A whole series of instruments have since bridged over the dividing line between the two original inventions. It is not easy to draw distinctions between the two systems, with the new transmitters of Blake, Boudet, Paris, Ader, etc., before us, but all the microphones and microphonic speakers can be designated under the generic name of *carbon transmitters*."

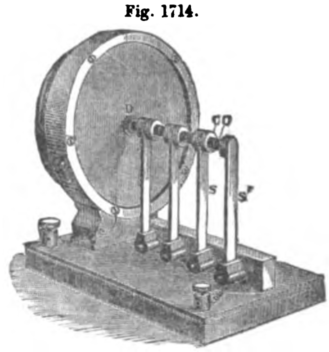
"The small model of a microphone by Ducretet, Fig. 1713, reproduces most of the experiments. A small graphite or coke crayon is pointed at both ends, and kept in a vertical position between two coke carbons, *D D'*. The bearer of the upper cup, *D*, is so arranged that the equilibrium, and the play of the crayon between the cups, can be readily regulated, and consequently the sensitiveness of the microphone The two cups are in direct communication with the two boundaries, *B B'*. The whole is fixed to a small board and a wooden upright, *P*. Two india rubber tubes, underneath, serve as feet to the board, and isolate any foreign vibrations. A slip of emery paper provides a rough surface, *E*, for producing frictions to be transmitted by the instrument.

"A pile of two or three Daniell or Leclanché elements, and a telephone, *T*, *placed at a distance*, form a complete circuit, in which is comprised the crayon *C*, with imperfect contacts." — "*Electrician*."

Edison discovered that carbon varied its electrical resistance with variation of pressure, and upon this is based his articulating telephone. Subsequently, this property was found to be inherent in other instances, even the atmospheric medium itself.

Edison's plan was to use several pieces of semi-conductor

Fig. 1714.



Edison's Microphone.

instead of one. One of his earliest may be seen in Fig. 1714 Some pieces of charcoal are supported each by an upright spring Fig 1715 has two carbons separated by a plate of metal. Another form has 10 plates of silk prepared by saturation in dextrine and lamp-black. Edison's *pile telephone* has alternate plates of zinc and copper with a bibulous medium between pairs.

Prescott's "*Speaking telephone, Electric light*," etc., gives many forms, including the above, and also —

The *condenser*, in which the plates are arranged, as in the ordinary form of condenser.

The *microphone* with graphite rods.

Microphone with pendants.

Microphone without carbon.

The name microtelephone was given by Julian Ockoswicz.

See also STETHOSCOPIC PENDULUM, *infra*.

Coke microphone: Blyth. Articulate sounds can be received, as well as transmitted, by an instrument made of an ordinary earthenware jar, about 3½″ in diameter and 4″ deep, half filled with

Fig. 1715.

Microphone with Carbon disks.

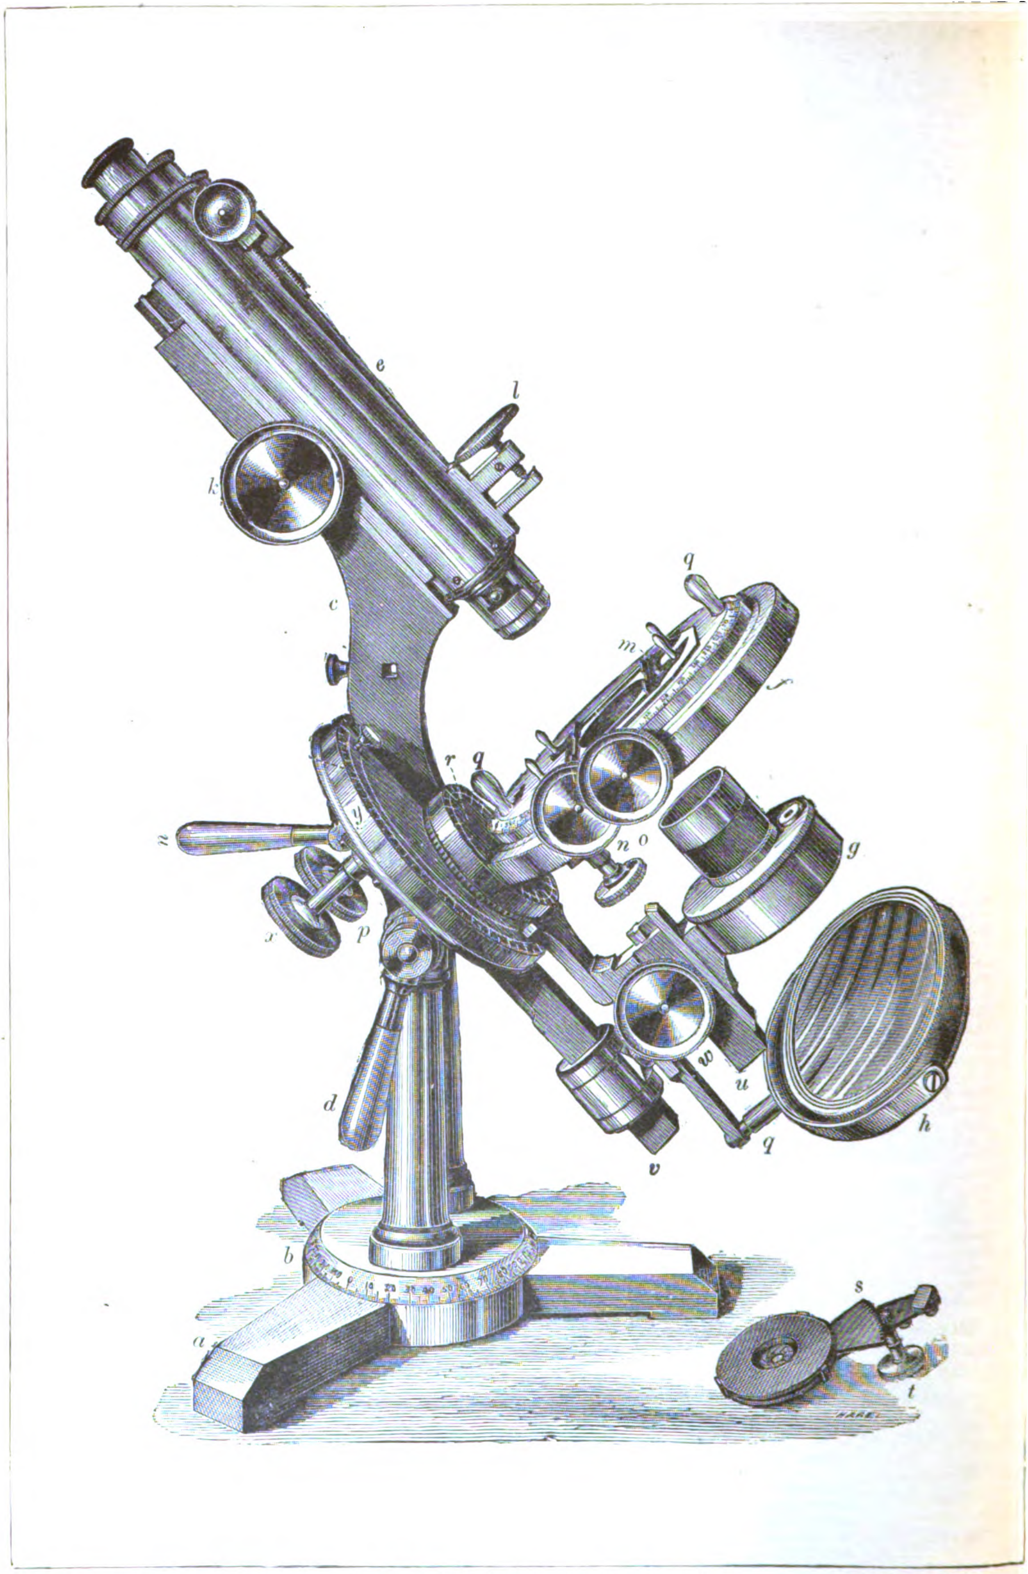


PLATE XXIX. BECK'S "INTERNATIONAL" MICROSCOPE. *See page 599.*

gas coke broken into coarse fragments The electrodes are two strips of tin about 2″ wide, slipped down on each side between the pot and the coke, bent over the edges, and fastened with a cord. When a pair of these are put in circuit with two strong Grove cells the arrangement is complete. — "*Nature.*"

Pocket microphone: Trouvé. It resembles a small dark lantern, with a carbon crayon substituted. Even when a person speaking stands from 75′ to 100′ from the microphone, it transmits his voice very well to a receiving telephone. The instrument can be used for revealing the movement of a clock, the heart or lungs. — "*La Nature.*"

The instrument is sensitive to the slightest noises in a building: a whisper, a footstep, a creak, mice, the ticks of clock, and what not A watchman with a most delicate ear.

Pendulum telephone: An upright bar of carbon suspended from a support, so that its lower end rests gently against a sharp contact piece of carbon

Mi′cro-phone Re′lay. A delicate microphone attached to the plate of the receiving telephone as a relay.

As contrived by Houston & Thomson. See "*Telegraphic Journal,*" * vi. 343.

The microphone as a relay for itself. * "*Telegraphic Journal,*" vi. 361.

Mi′cro-scope. Beck's "International" Microscope, shown in Plate XXIX., has a tripod, *a*, for its base, upon which is placed a revolving fitting *b*, graduated to degrees, by which means the microscope can be turned around without its being lifted from the table, and the amount of such rotation registered; upon this fitting two pillars are firmly fixed, and between them the limb *c* can be elevated or depressed to any angle, and tightened in its position by the lever *d*. The limb carries at one end the body *e* (binocular or monocular), with eyepieces and object-glasses; in its center is the compound stage *f*, beneath which is the circular plate, sliding on a dove-tailed fitting, and moved up and down by the lever *z*, and carrying the supplementary body or sub-stage *g*; and at the lower end a triangular bar carrying the mirror *h*.

The binocular body consists of two tubes, the one fitted in the optical axis of the microscope, and the other oblique. At their lower end and immediately above the object-glass there is an opening, into which a small brass box or fitting, *i*, slides: this box holds a prism so constructed that when slid in it intercepts half the rays from the object-glass, diverts them from their direct course, and reflects them into the additional or oblique tube. When the box is drawn back to a certain distance the prism in no way interferes with the field of view, and all the rays pass up the direct body, and the microscope is converted into a monocular one.

The upper or eye-piece ends of the tubes are fitted with racks and pinion for varying the distances between the two eye-pieces, to suit the differences between the eyes of various persons.

This body is moved up and down with a quick movement by means of the milled heads *k*, and with a very delicate and fine adjustment by the milled head *l*.

The compound stage is of new construction; the object is most frequently merely placed upon it, but, if necessary, it can be clamped by carefully bringing down the spring-piece *m*; the ledge will slide up or down, and the object may be pushed sideways; this arrangement forms the coarse adjustment. Finer movements in vertical and horizontal directions are effected by means of two milled heads, *n* and *o*. The whole stage revolves in a circular ring by the milled head *p*, or this can be drawn out, and then it turns rapidly by merely applying the fingers to the two ivory studs *q q* fastened on the top plate, which is divided into degrees to register the amount of revolution. The stage is attached to the limb on a pivot, and can be rotated to any angle, which angle is recorded on the divided plate *r*, or can be turned completely over, so that the object can be viewed by light of any obliquity without any interference from the thickness of the stage.

Beneath and attached to the stage is an iris diaphragm, *s*, which can be altogether removed, as shown in the illustration, from its dove-tailed fitting, so as not to interfere during the rotation of the stage The variations in the aperture of this diaphragm are made by a pinion working into a racked arc and adjusted by the milled head *t*.

Beneath the stage are two triangular bars, *u v*, the one revolving around and the other rigid in the optical axis of the instrument. On the former the sub-stage *g*, carrying all the apparatus for illumination and polarization, fits, and is racked up and down by the milled head *w*: the mirror also, if desired, slides on the same bar; the revolving motion to this bar is given by the milled head *x*, and the amount of angular movement is recorded on the circle *y*, while the whole of this part of the stand is raised and lowered concentric with the optical axis of the instrument by the lever *z*, and the amount of such elevation or depression registered on a scale attached to the limb. This bar can be carried around and above the stage and be thus used for opaque illumination.

The lower triangular bar *v* carries the mirror *h*, or a right-angle prism, when the illumination is required to be concentric with the optical axis of the instrument, and independent of the movements of other illuminating apparatus.

The mirror-box contains two mirrors, one flat and the other concave; it swings in a rotating semicircle attached to a lengthening bar, which enables it to be turned from one side to the other, and revolves on a circular fitting for giving greater facilities in regulating the direction of the beam of light reflected, the whole sliding on either of the triangular bars, and made to reverse in the socket so as to bring the center of the mirror concentric with the axis of the microscope in either case.

As the mirror alone is insufficient for many kinds of illumination, some provision has to be made for holding various pieces of apparatus between the object and the mirror. For this purpose a supplementary body, or sub-stage, *g*, is mounted perfectly true with the body, and is moved up and down in its fitting by rack and pinion connected with the milled heads *w*. This sub-stage is now regarded as one of the most important parts of the achromatic microscope: in it all the varied appliances for modifying the character and

direction of the light are fitted But a few years since it was considered sufficient for this part of the stand to be constructed so as to move up and down perfectly coincident with the optical axis of the instrument, and for that purpose it was racked in a groove planed out on the same limb as that on the upper end of which the optical portions were carried. But lately microscopists have shown the desirability of affording every facility for lateral angular adjustments; and this has led to the sub-stage being attached to an arc working in the circular plate *y*, and moved by a rack and pinion, *x*, while the amount of such angular movement is recorded on the upper surface of the plate *y*. Having once fixed the angular direction of the light, the focusing of it depends upon the lever *z*, which moves the circle up and down, and with it the arm carrying the illuminating apparatus, *in the optical axis of the instrument.*

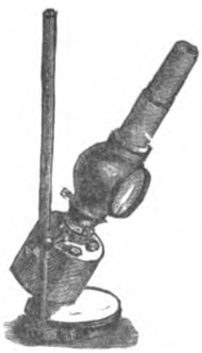
Microscopic photography	"*Scientific Amer.*," xxxvi 226.

Mi′cro-scope Il-lu′mi-na′tor. (*Optics.*) A convenient form of lamp adapted to the use of the microscope. The metallic chimney is telescopic, the condenser fits into the cell in front. The reservoir is of brass. The lamp slides vertically on a pillar, and may be inclined to direct the rays. The chimney is lined with gypsum.

Fig. 1716.



Microscopic Illuminator.

Mi′cro-scope Lamp. (*Optics.*) A lamp for convenient use with the microscope. Several have been invented, the great desiderata being: —

1. Ease of elevation or depression of the lamp by attachment to a long upright rod.
2. A flat wick, so as by turning either the edge or broadside of the flame to get intensity or volume.
3. Absence of great heat.

In a special form of lamp, on a bull's-eye stand, the lamp is attached to a bull's-eye lens, the position of which can be varied at pleasure for varying the character and direction of the rays.

Mi′cro-scope Ta′ble. (*Optics.*) A pillar and claw table, employed in connection with the microscope which stands upon it.

The top is mounted on a strong iron center which enables the observer to revolve the microscope at pleasure without vibration.

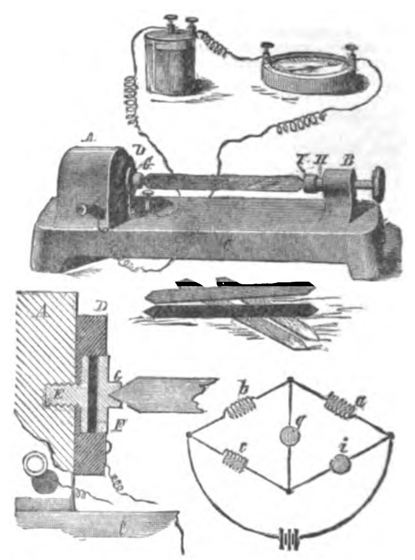
Mi′cro-spec′tro-scope. (*Optics.*) See SPECTROSCOPIC EYE-PIECE.

Mi′cro-ta-sim′e-ter. An instrument, by Edison, for the detection and measurement of infinitesimal pressure. The instrument consists essentially of a rigid iron frame for holding a carbon button, which is placed between two platinum surfaces, one of which is fixed and the other movable, and in a device for holding the object to be tested so that the pressure resulting from the expansion of the object acts upon the carbon button.

The instrument is represented in Fig. 1717 by perspective, sectional, and plan views.

A B are posts rising from plate *C*. To post *A* a vulcanite disk is attached by the platinum-headed screw *E*, which rests in a cavity in the disk. On the head of the screw is the carbon button *F*, and upon its outer face is a disk of platinum foil which is in electrical communication with the battery. A metallic cap, *G*, receives one end of the bar to be tested, the other end being in a cup, *I*, on the end of a screw, *H*, on the other head, *B*. The post *A* is in connection with a galvanometer, in turn connected with the battery. After the strip has been subjected to a small initial pressure, which deflects the needle of the galvanometer, the slightest expansion or contraction of the strip will be indicated by the needle. The warmth of the hand held a few inches from a hard rubber strip caused an expansion which was indicated by a deflection of a few degrees of an ordinary galvanometer, which was not affected in the slightest degree by a thermopile facing and near a red-hot iron. The principle of this apparatus is to be applied to delicate thermometers, barometers, and hygrometers.

Fig. 1717.



Edison's Microtasimeter

Fig. 1718 shows the apparatus as constructed for more delicate operations. The instrument is connected with a Thomson's reflecting galvanometer, and the current is regulated by a Wheatstone's bridge and a rheostat, so that the resistance on both sides of the galvanometer is equal, and the light pencil from the reflector falls on 0° of the scale. The principle is illustrated in the plan view in Fig. 1717, where *g* is the galvanometer, *i* the instrument. At *a b c* the resistance is the same. An increase or diminution of the pressure on the carbon button by an infinitesimal expansion or contraction of the substance under test is indicated on the scale of the galvanometer.

The carbon button may be compared to a valve, for, when it is compressed in the slightest degree, its electrical conductivity is increased, and when it is allowed to expand it partly loses its conducting power.

The heat from the hand, held 6″ or 8″ from a strip of vulcanite placed in the instrument — when arranged as last described — is sufficient to deflect the galvanometer mirror so as to throw the light-beam completely off the scale. A cold body placed near the vulcanite strip will carry the light-beam in the opposite direction.

Pressure that is inappreciable and undiscoverable by other means is distinctly indicated by this instrument.

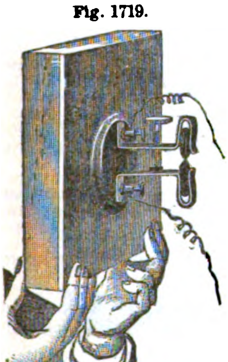
Mi'cro-tel'e-phone. The name given by its inventor, Julian Ockovowicz, of Lemberg, Gallicia, ("*Telegraphic Journal*," vii. 132) to a Bell telephone in which the current generated by the vibration of the diaphragm is caused to pass through the diaphragm as well as the core before it enters the line.

Fig. 1719.



Hopkins' Microphone.

The communication of the current with the vibrating plate is effected by means of two small springs which are lightly pressed by the membrane, and which act as a microphonic contact. 3 mm. above the iron diaphragm is a membrane of caoutchouc, so that the two inclose a film of air between them.

Dr. Hopkins' instrument consists essentially of two springs secured to a small base piece, and each supporting at their upper end a piece of ordinary battery carbon. These two pieces of carbon are placed in light contact, and the two springs are put in an electrical circuit in which there is also a receiving telephone of the Bell form. In Fig. 1719 it is shown as secured to a small sounding-board. The two carbon supporting springs are fastened to a single base by the binding posts which receive the battery wires. An adjusting screw passes through one of the springs at or near its center, and bears against a rubber button projecting from the other spring. This simplé device when placed on a table indicates in the receiving telephone the slightest touch of the finger on the table or on the instrument. Blowing on it makes in the receiving instrument a deafening roar; drawing a hair or a bit of cotton across the carbon is distinctly audible in the receiving instrument.

Mid'dlings. (*Milling.*) Coarse particles of the kernel from immediately adjoining the skin of the berry, and now appreciated as the most valuable part because consisting largely of *gluten*, while the interior of the kernel is composed of the *starch*, which, when dry, readily becomes a pearly powder.

Under the method of *straight grinding* almost universally practiced until within a very few years, the prime object of the miller was to make as few middlings as possible, considering them only fit to be ground into an inferior grade of flour, or high grade of feed. Consequently the grinding was done very *close* with keen, sharp burrs; shaving into powder as far as practicable all this compact horny part of the kernel, which thus became incorporated with the interior or starchy part, and through the bolt was separated from the bran or skin of the berry. The coarser particles, known as middlings, remained mixed with small particles of bran and other foreign substances, also a fine fuzz, which is found on the skin of the berry.

The new process consists in manufacturing a flour out of the middlings, having larger and more uniform granules than the flour which is made from the central part of the berry, and free from the fine impurities mixed with the first grinding.

The middlings are passed through a machine called a purifier, so arranged that a properly regulated current of air may be sucked or driven through them, separating all the fuzz and small specks, which have less weight than the particles of the kernel thus freed of impurities. The purified middlings are then reground, with care, so that the grinding may be even and the angular shape of the particles retained. After grinding, it is bolted as usual through proper numbers of cloth, and the larger particles passing over the tail of the reel are returned to the purifier and stone.

This is a general synopsis of the process, which is of course varied to suit the judgment and experience of skilled millers, some using many purifiers for frequent separations and different methods of manipulating the returns and re-grinding.

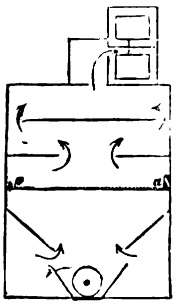
The middlings flour being sought after as superior to the straight grade, it is desirable to *grind high*, and make as much middlings as practicable, — frequently 35 to 40% is made into middlings flour.

See also HIGH MILLING, p. 458, *supra*; and references *passim*.

Mid'dlings Pu'ri-fi'er. The separation of middlings by air currents and by shaking are old devices.

The employment of the hand sieve and natural current of air, as in the ancient mode of winnowing (Fig. 7256, p. 2786, "*Mech. Dict.*"), but on a smaller scale and in more confined situation, was the natural resource before reels and bolting chests came into use. The middlings purifier proper is something more than a mere bolt; properly speaking, it is a machine for separating minute bran scales from grits by causing a broad stream of air either by blast or suction, to pass through a slightly-inclined plane sieve of meshes sufficiently large for both the bran and grits to pass through; the force of the blast being so gentle as to permit the grits to drop, while the particles of bran are kept afloat to be discharged at the lower margin of the sieve. The sieve is sometimes disposed around a cylinder, and the action promoted by a brush acting upon the surface of the sieve in connection with the blast or suction. Of this class, several of most ingenious construction, under the name of middlings-purifiers, have been recently invented and brought into use in this country.

Fig. 1720.



Principle of Middling Purifier

The accompanying figure illustrates one of the simpler forms.

a a, is the slightly-inclined sieve, through which the air is carried upward by the exhaust-fan, by which the fine bran is prevented from passing through, while the heavier grits are dropped to the trough below.

The subject has been considered on pp. 1436, 1437, "*Mech. Dict.*," where the machines of

* *Lacroix*, * *Huntley & Holcomb*,
* *Smith*, * *Wilson*,
* *Mowry*,

have been adduced as illustrating five modes, having certain points of difference in operation.

Several systems of grading middlings and bolting are described in *Rollet's* French work on milling (Paris, 1847), including those of

* *Lanturelu*, * *Benoist*.

Reference is made to the above also in "*Scientific American Supplement*," where are also shown the apparatus of

* *Westrupp*, Br., 1854. * *Cabanes*, Fr., 1855.
* *Perrigault*, Fr., 1862.

A slight, general sketch of the distinctive methods may be given, and reference for particulars can be made to the publications cited in the subsequent list: —

La Croix's device consists in the combination with the reciprocating screens of traveling air tubes under the screen placed 5″ on centers, and moving backward and forward 5″. These tubes are supplied with air at high pressure by means of two small but powerful blast fans. The air is discharged in thin sheets the entire width of the cloth, which cleans the meshes, and raises the light fibrous matter from the middlings so that it may be readily drawn off by the suction fan, which is employed on top of the machine as usual.

Walker. A distributing feed shoe: an inclined, shaking, suction blast separator suspended and vibrated upon links, and divided into sections, each of which consists of a series of slightly inclined shelves, extending to the side-boards of the suspended separator; a brush and concave arrest the middlings at their mid-passage, and they fall upon a shaking sieve where they are sorted and certain portions returned for re-dressing.

Collin's "Garden City." A succession of inclined sieves of gradually coarser quality, and suction blast of increasing strength in the descending order. The matter passing through each sieve is spouted away to its own receptacle.

Smith. Has feeding rollers, shaking bolt, traveling brushes to clean meshes of the cloth, and upward current of air to carry off impurities.

Reel & Seyler "Champion." Has a spout and rotary reel for separating the finer particles: thence to a chute where the fuzz is withdrawn by a suction fan; then to a series of grading sieves with upward blast.

Huntley, Holcomb, & Heine "Excelsior." Middlings are fed through tubes to disintegrators, two in succession; the dust and fiber are carried off through wind-trunk, and go to a feed hopper and reel to be sorted; the middlings pass to shaking sieves with upward draft.

Hunter. A blast machine with percussion sieve.

"Phœnix" has suction fan, sloped sieves, and a succession of hoppers for graded product.

"Keystone." Succession of zigzag inclined sieves and suction draft.

Affleck. The middlings are subjected to a current of air before going on to the sieve, where the purification is finished and the floury matter drawn off into a suitable bolt.

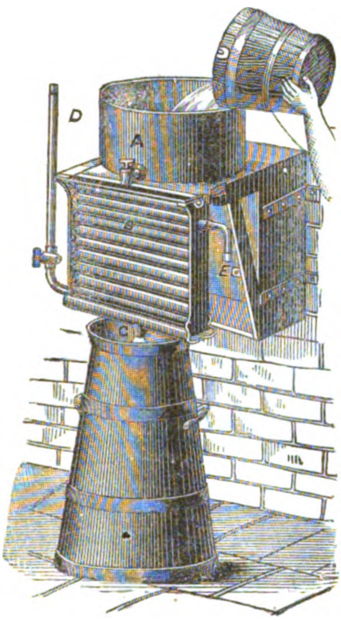
Milk Car. (*Railway.*) One for carrying milk in cans. It is usually made with end platforms like a baggage car, and has the springs of a passenger car. — *Forney.*

Milk Cool'er. An apparatus for removing the natural warmth of fresh milk. Two forms are shown.

Fig 1721 is Lawrence's capillary refrigerator (Br.), which is also adapted to cooling wort. Milk as soon as milked is poured into the strainer *A*, whence it passes into a chamber

Fig. 1721.



British Milk Cooler.

which is occupied by a system of convoluted pipes, *B*, in which cold water circulates, passing by pipe *D* to *E*, and exit. The milk flows into the churn *C*. The front end of the cooler chamber is removed to expose the interior.

The Austrian cooler, Fig. 1722, is very simple, and consists of a vat or tub through which cold water is constantly circulating. On the surface of the water floats a circular

Fig. 1722.

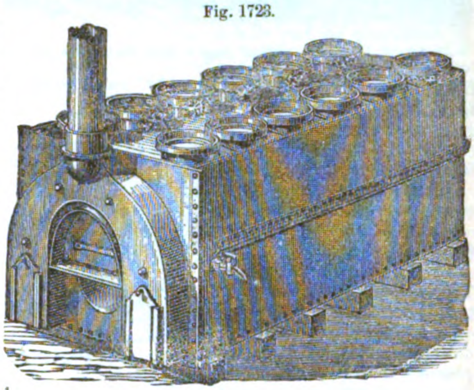
Vienna Milk Cooler.

wooden plate, provided with a number of round holes into which are inserted the vessels containing the milk. These are made of sheet zinc, two feet long, and each, according to the "*Wiener Landw. Zeitung*," contains a little over a gallon of milk.

It takes about fifteen minutes to cool the milk down to a temperature slightly above that of the surrounding water. When not in use the cylinders are turned upside down on a wooden rack to drain and dry.

Milk Glass. A semi-translucent glass used in some graduated glass instruments to contain the scale in order to render it more legible. See also CRYOLITE; HOT CAST PORCELAIN, etc.

Fig. 1723.



French Milk Heater.

Milk Heat'er (*Dairy.*) A furnace arrangement for heating milk for cheese-making.

That shown in Fig. 1723 is a French form in which the deep cans set in a water bath above a furnace. The furnace and tank are of sheet iron.

See also MILK PAN.

Fig. 1724.

Milking Tube.

Milk'ing Tube. A tube inserted into the via lactea of a cow's teat in order to overcome the muscular contraction and allow the milk to flow without the use of the hands. The tubes are of silver, four to a set, and are telescopic to suit varying lengths of teats.

Milk Pan. A pan in which milk is set to allow the cream to rise; or in which it is heated or cooled as the circumstances may require, for churning or for cheese-making.

Figs. 1725, 1726 show the "Iron Clad" milk pans arranged in battery and having double bottoms in which by means of pipes a flow of hot or cold water is obtained. In Fig. 1725 the water proceeds from an elevated reservoir and is supplied to either or all of the pans by means of faucets. In Fig. 1726, *A* is the pipe from the boiler leading to pans. *B*, the hot water pipe spigot. *F* is the waste-water pipe, *G* the sour milk pipe. *H H* are thermometers for indicating temperature.

Mill Driver.

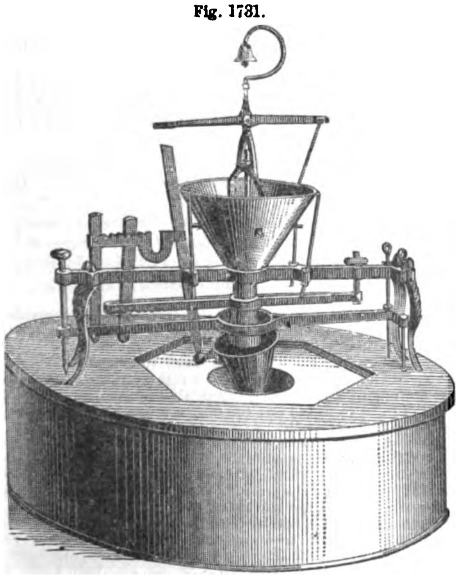
Mill Dri'ver. The apparatus immediately concerned in giving motion to the runner millstone.

The figure shows the spindle, slip-driver, set-screw, tram-pot, lever, lighter screw, bail or balance-rynd, damsel, back-lash spring, fulcrum, pinion and pinion jack. See glossary, pp. 1019, 1020, "*Mech. Dict.*"

Mill Feed'er. The customary feed of a mill-stone is by a damsel on the spindle which agitates the shoe beneath the hopper and causes the grain to dribble into the eye of the runner.

Fig. 1731 shows a self-regulating silent mill feeder which also gives an alarm by the ringing of a bell when the feed runs short. The device rests by four legs upon the husk and has an arrangement of compound levers supporting the funnel which acts as a feed hopper and discharges into the lower funnel which distributes the grain around the eye of the buhr.

Fig. 1731.



Mill Feeder.

Mill File. A thin flat file used in machine shops for lathe work and draw filing.

Mil'ling. 1. (*Grain Grinding.*) In the comparison of the advantages of high and low milling respectively, it is stated by J. J. Wyngaert, editor of the German journal "*Die Mühle,*" that the Austro-Hungarian process of *high milling,* consisting of a disintegration of the tissues by successive crackings, is especially adapted to a hard and brittle wheat, such as that in the markets of Vienna and Pesth, and not to the softer varieties, more abundant in North Germany, Britain, and the United States, and which have a tougher shell and friable interior.

"The advocates of high milling rest upon the claims of the scientific solution of the problem: the reduction of the wheat-grain by a succession of alternate crackings and sortings, in which disintegration is effected by successive steps of such slight individual advance, and the graduations of the successive products are so fine that the heat produced is inconsiderable, and the ultimate product of flour free from specks and of absolute fairness is much larger than by the low-milling process. The significance of this peculiarity of the process cannot be easily over-estimated. It leaves the integrity of the cells of gluten unimpaired. They have, therefore, their natural investment of cellular tissue to protect the sensitive nitrogenous constituents of the interior from the oxygen of the air, and from the spores of microscopic vegetation always afloat in the atmosphere. Having escaped destructive crushing, they have also escaped the heat attendant upon it, and the loss of water and chemical decomposition due to it. As the chemical changes consequent upon this exposure of the gluten bring with them products of disagreeable taste and smell, the flour produced by the high milling has escaped the deterioration consequent upon the destruction of the texture of the gluten-cells."

"The physical impracticability of producing lumps from the friable interior of the soft wheat shows at a glance the inferior adaptation of this kind of wheat to the production of the numerous grades of grits which characterize the Austro-Hungarian milling. The toughness of the shell of the soft wheat makes it practicable to obtain a product in low milling in which the fine particles of bran are relatively few, and from which a flour of high order of whiteness may be obtained. The dry, brittle Hungarian wheat, subjected to the low milling process, would, by reason of the brittleness of the shell, yield a product in which the small particles of bran would be numerous, and, being of the same size, would pass through the bolt with the flour, and make it impossible to produce a flour of perfect whiteness." — *Prof. Horsford.*

By the processes of low milling, we have the following scheme of low milling treatment: —

Cleaning.

Clean wheat. Refuse.

Pointing.

Pointed wheat. Poorest flour. Coarse bran

Grinding.

Flour No. 3, or { No. 1. No. 2. No. 3 } Dust. Fine grits ground. Hulls ground.

Flour No. 2. Dust. Flour No. 6. Bran

Dust ground.

Flour No. 1. Black dust ground.

Flour Nos. 4 or 5

A much more elaborate table, by Wyngaert, may be found in Prof. Horsford's "*Report on Vienna Bread,*" "*Vienna Exposition Reports,*" ii., § B, table opposite to p. 56.

The scheme of treatment of the "Fife" spring wheat of Minnesota is shown in the same report, p. 57.

In the process of high-milling, which is a step by step reduction of the grain, started with the pointed kernels, three products are obtained at each grinding:

Coarse fragments with much bran attached.
Less coarse fragments with less bran attached.
Minute fragments with little or no bran.

These are separated from each other by the sifting and purifying machine. Each of the several products is again subjected to grinding, and the product in each again sorted into grades, and so on until the last traces of the white interior of the berry have been separated from the dark hull and graded. See MIDDLINGS.

The table on the following page exhibits the products yielded in a comparatively primitive high milling establishment: —

HIGH MILLING PROCESS.

1) *Cleaning.*
2) *Pointing.*

Pointed wheat. — Bran. — Black flour, No. 6

3a) *First cracking.*

Groats flour. — Dust (flour). — Grits. — 1. Groats.

3b) *Second cracking.*

4) *All the grits purified and ground to dust (flour) give*

Flour No. 1. — Dust (flour).

5) *All the dust (flour) purified and ground gives*

Flour No. 2. — Black dust flour No. 5.

6) *Grinding the hulls.*

Flour Nos. 5 and 6. — Bran.

A very much more elaborate scheme may be found in Prof. Horsford's report above quoted, table opposite to p. 59.

	There were produced from wheat of average weight.	83 to 84 pounds per metze.
		per cent.
A	Lady-groats	
B	Table-groats, fine	4.25
C	Table-groats, coarse	
0	Extra imperial flour	
I	Extra fine flour	5.53
II	Ordinary fine flour	5.76
III	Extra roll or semmel flour	5.51
IV	Common roll or semmel flour	6.48
V	First pollen flour	7.12
VI	Second pollen flour	13.30
VII	First dust-flour	11.85
VIII	Second dust-flour	9.95
IX	Brown pollen flour	4.36
X	Foot-flour	6.32
F	Fine bran	8.94
G	Coarse bran	6.87
H	Chicken-feed, loss, and dirt	3.76
		100.00

The terms to indicate certain results or conditions of the material in the process of grinding grain have been multiplied since the introduction of the *high-milling* process.

Prof. Horsford in his "*Report on Vienna Bread*," Washington, 1876, uses the following: —

Groats (Ger. Schrot). Broken and bruised kernels.

Middlings (Ger. Ueberschlag). Unpurified grits.

Grits (Ger. Gries). Purified groats.

Besides these are many terms known in the trade, such as *farina, semolina, cracked wheat*, etc.

Farina. A kind of grits, finely purified.

A number of terms have comparatively lately come into milling: —

Low milling is the ordinary system of mashing and repeated scraping and squeezing and a single bolting. It is attended with heating of the product, which injures the flour.

The *high milling* is a system of successive crackings with alternate removal of the finer particles and the bran as fast as produced. It is attended with but little heating of the product. There is some cracking in low milling and some mashing in high milling.

The *half-high milling*, as its name imports, partakes more of the cracking than low milling, and more of the scraping and squeezing than high milling.

The *cylinder milling* is a system of pressing and cracking, and, where the cylinders are grooved and move with unequal velocities, of tearing. Like the high milling, it produces little heat. See under each head.

Disintegration: A system in which there are neither stones nor cylinders, but in which the pulverization is effected by means of the friction of the grain upon itself, being kept in motion by beaters revolving at a high velocity in a hollow cylinder. *Carr's* process, Fig. 1665, p. 707, "*Mech. Dict.*"

See also under the following heads: —

Aspirator.	Exhaust purifier.
Cylinder grinding mill.	Grain cleaner.
Cylinder mill.	Grain dryer.
Grain separator.	Pointing.
Granulating process.	Purifier.
Grits grading machine.	Roller mill.
Grits mill.	Smut machine.
Grits purifier.	Stone separator.
High milling.	Unbranning machine.
Low milling.	Wheat cracker.
Middlings purifier.	Wheat scourer.
Mill stone.	Wheat separator.

2. (*Fine Art Metal-working.*) Giving an ornamental ridged or ribbed surface to an object by holding it against a ribbed tool which revolves in a lathe.

3. (*Metal Working.*) The cutting of metal, etc., by means of revolving cutters. See MILLING MACHINE, "*Mech. Dict.*," *et infra.*

4. (*Leather.*) Treatment in a large wooden drum or cylinder, about 8′ in diameter, and 4′ in height, water-tight, and having wooden pins projecting radially from the interior concave surface towards its horizontal shaft. The drum is revolved by a pinion, from 8 to 20 times per minute.

The mill is used for stuffing light leather, and for other purposes. After stoning, skiving, and shaving, the sides are put in the mill with some tan liquor to soften them and make them porous.

5. A mode of finishing some descriptions of goods by means of vertical fallers. See BEETLING MACHINE.

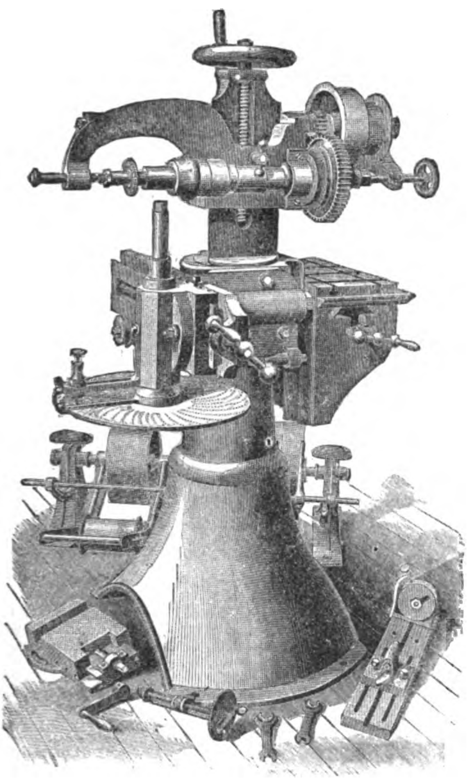
Mil′ling Ma-chine′. The subject is considered on pp. 1441, 1442, "*Mech. Dict.*," Figs. 3151, 3152. The form shown in Fig. 1732 is Lawrence's Combined Index and Plane Milling Machine.

On the circular portion of the standard is a sleeve capable of being clamped in any position, and carrying on one side the index cutting arrangement, and on the other the plane-milling table. By this arrangement of the sleeve the index can be swung round to the opposite side from the cutter, and this movement carries the milling-table under the cutter in position to be operated on, and only a moment of time is required to make the adjustment.

From the top of the sleeve, upward, the front of the standard is flat with beveled sides, and on this top part the spindle-carrier is fitted, with spindle and lateral adjustment of spindle, gears and pulley for driving the spindle, and rack-gear and handle on the back side.

The cutter-spindle carrier has a traverse of 9″, and can be operated either by a screw and hand-wheel at the top or by the lever and rack behind. On the left-hand box of the cutter-spindle is a pipe-box, bored tapering, and into which a composition-bush is fitted. Through this bush the spindle passes. On the outer end of the bush a check-nut is fitted for drawing the bush in on the taper and contracting the hole. By this method the wear of the bearing is taken up. The index is 16″ in diameter, and is drilled to cut all numbers up to 80, and all even numbers up to 150. Spur, bevel, or right or left worm-gears can be cut. It will cut gears up to 16″ diameter accurately, and by swinging the index away

Fig. 1782.



Combined Index and Plane Milling Machine.

from the cutter will cut 24″ diameter. The number of degrees in a circle are cut on the edge of the index-plate. The plane-milling table is dovetailed and gibbed into the top part of a knee-piece, which knee-piece is gibbed to one side of the sleeve, and has a traverse of 5″ on the sleeve. It is operated up or down by a hand-wheel with bevel-gears and screw. The table is 18″ × 10″, and has T-slots running both ways in the top. It has a longitudinal traverse of 18″, with a lateral adjustment of cutter-spindle across it of 5″, obtained by a screw and hand-wheel at the right hand of the cutter-spindle. It has self-adjustable, automatic feed. The extreme distance between the top of the table and the center of the cutter is 14″. The table can be set at any angle with the cutter, and, with the help of a pair of rotary centers, twist-drills or spiral-cutters can be milled. By means of the swinging sleeve true circles of greater or less diameter can be milled on the face of the work.

Mill′stone A-larm′. A device to give notice when the supply of grain to the stone runs out or runs short.

See Fig. 3150, p. 1441, "*Mech. Dict.*" MILL FEEDER, *supra*.

Mill′stone Bush. See MILL BUSH, *supra*.

Mill′stone Crane. A device for lifting the runner off the bed-stone. See HOISTING SCREW, Fig. 1360, p. 460, *supra*.

Mill′stone Curb. The covering of the stones. A *husk* or *hurst*.

Mill′stone Dres′ser. 1. A machine for forming millstones; bringing them to shape. A species of stone-turning lathe.

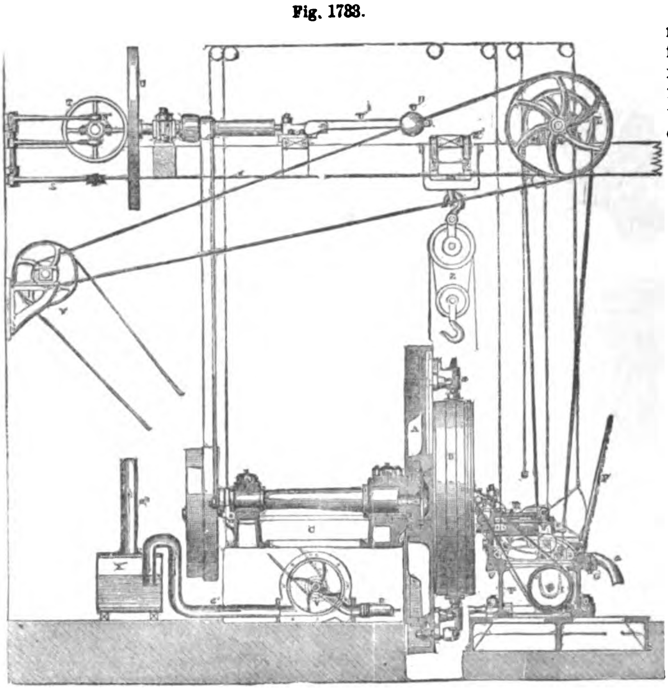
Figs. 1733–1736 show a *Rogers'* diamond tool millstone dressing machine, illustrated in the "*Bulletin de la Société d'Encouragement pour l'Industrie Nationale.*"

A is a face plate, to which the stone *B* is secured by the four clamps *a*. *C* is the bed, resting upon a masonry foundation. *D* is the rotary tool, carrying eight diamonds and revolving 3,500 turns per minute. It is mounted on a carriage, *E*, which travels across the face of the stone on slides *G*, on the support *F*. The movement of translation of the carriage is effected by the screw *H*, the rate of motion of which is proportioned to that of the stone's revolution. The diamond tool is actuated from the pulley *I* by the belt *I′*. *K* and *K′*, respectively, are fixed and loose pulleys imparting motion to the drum by means of a belt passing over the pulley *L* of the main shaft *M*. A lever, *P*, acting on pinions *P′* and *P″*, which engage in racks *Q* and *Q′*, enables the whole tool-carrying apparatus to be moved toward or from the stone, as desired. *N* is a shaft placed against a wall, which serves to set the lathe mechanism in motion, as described hereafter. On this shaft is a pulley, *T*, which transmits motion by friction to the disk *U* mounted on a shaft which is belted to the lathe arbor below. A lever, *U′*, having a counterweight, *U″*, always gives the necessary pressure to cause the contact of disk *U* and pulley *T*. This mode of transmission by friction pulley and disk imparts to the lathe arbor a variable velocity according as the tool operates upon the stone at a portion nearer to or farther from the center, so that in this way whatever part of the stone is presented to the tool, the velocity is nearly constant.

The position of the wheel *T* with relation to the disk *V* is regulated by means of the lever *S*, operated by cords *s*, which are attached to the ends of the tool carriage. A ventilator, *V*, operated by the special gearing *V′*, removes the dust produced through the tubes *v*. The air from the blower is led into a water reservoir *X*, and thence, after depositing its dust, escapes by the pipe *v″*. The traveling tackle *Z* serves to adjust the stone in the machine.

The diamond tool is separately represented in Figs. 1735 and 1736. *A* is the tool, *P* the driving pulley. Eight diamonds are mounted on the surface of the cylinder in sleeves,

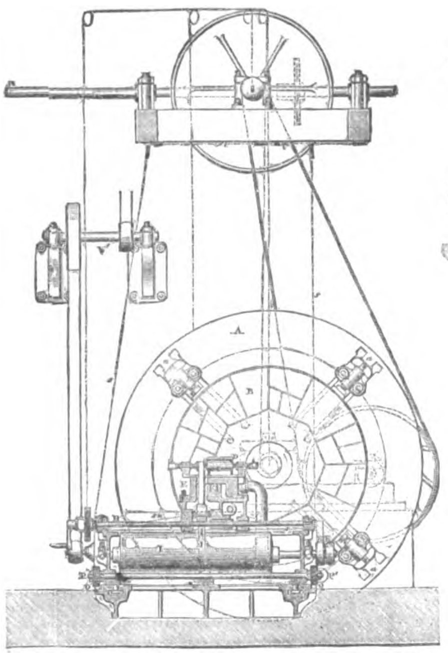
Fig. 1733.



Rogers' Millstone Dressing Machine. (*Side Elevation.*)

and in such a way that they may be caused to project more or less by means of a regulating screw. *B B'* are lubricating

Fig. 1734.



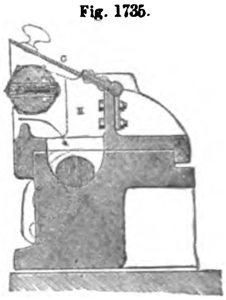
Rogers' Millstone Dressing Machine. (*Front Elevation.*)

cups, and *U* is the conduit whence dust is drawn by the ventilator from the chamber *E*, as shown by the arrows. Access is had to the tool by lifting the cover *C*.

2. A machine in which a millstone is placed while being faced. The French machine for dressing millstones by the revolving traversing diamond is shown in Fig. 1737. The cutter has a rotary motion, and also a movement of translation, on the face of the stone, parallel with the furrows; the lining being parallel on each pane.

The cutting pitch of the diamond

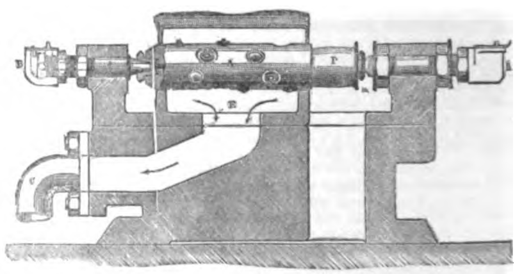
Fig. 1735.



Section of Diamond Mandrel.

is regulated by an inclined slide *H*, fixed to the cast-iron framework of the machine *I I* by the bolts *K K*. The incline of the slide is in the direction of the center of the stone, which secures uniformity in the cutting, and the inclination is regulated by means of adjustable wedges; an arrangement which secures mathematical exactness in the depth of the cut The action of the machine is similar to

Fig. 1736.



Millstone Dressing Machine. (*Enlarged View of Diamond Mandrel.*)

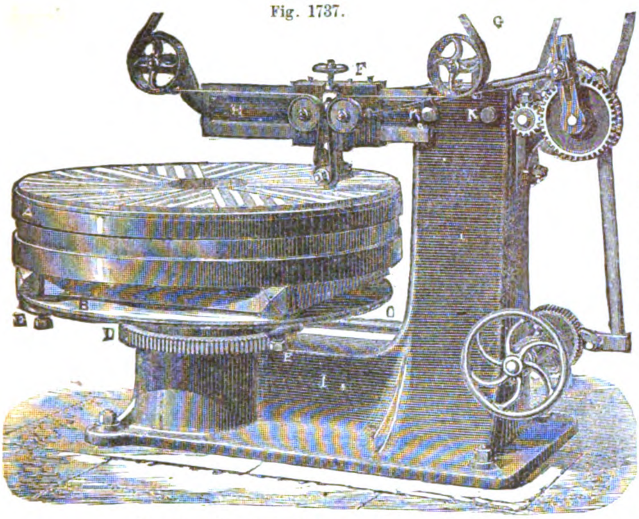
that of a milling cutter, and the course of the diamond is from the circumference to the center, and *vice versa*, the face produced on the millstone by means of the machine being partially granulated. The movement of the platform is by automatic intermittent feed connecting with pinion and master-wheel *D*. *E E* are leveling screws in the plate *B*.

The *Hodgeboom* millstone dresser is shown in Fig. 1738. The post of the machine is keyed in the eye of the millstone; whereas, in the last-mentioned instance, the stone is placed on the rotatable table of the machine. The Hodgeboom machine, however, uses wheels of 8″ diam. made of corundum with a cementing material. The wheel makes 2,000 revolutions per minute. The cross head carrying the wheel runs in covered slides with steel gib and friction rollers, and so constructed as to be impervious to the dust. The idle pulleys run on hollow spindles which are self-lubricating. The standard is in the form of a tripod and easily trammed. The cross bar is fastened to the standard by means of a face plate collar, and may be raised or lowered at will. The automatic feed is a rack bar and pinion, driven by belt, and is strong, simple, and accurate

The machine of *Hignette*, of Paris, shown at the Paris Exposition of 1878, is similarly supported on the stone, but has a rotative diamond.

Coplin's machine is on a similar principle.

Fig. 1737.



Dupety's Diamond Millstone Dressing Machine.

3. A portable machine which is laid upon the stone, and the tool reciprocated thereon to dress the working face of the stone.

The *Harris* machine employs one or more revolving diamond cutters, which are run at a speed of about 3,000 revolutions per minute, making 125 cuts to the inch the entire width of furrow, leaving the natural grit of buhrs, and the furrow true and smooth. Provision is made for dressing furrows in buhrs that run either with or against the sun, and at any angle or pitch of furrow required.

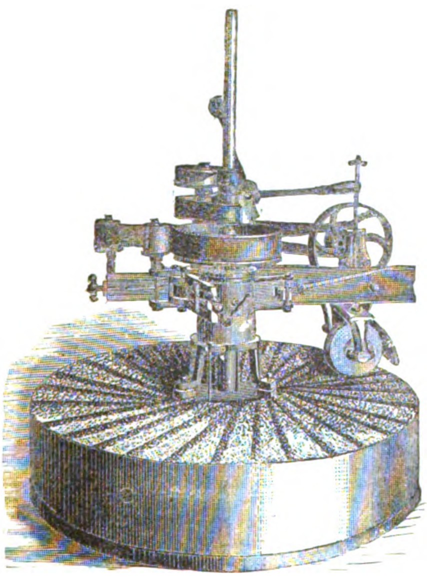
The automatic feed can be set to cut any number of cracks to the inch, from 8 to 125.

The *Larer* dressing machine has also a diamond on a carriage moving on guides.

Orff's and *McFeeley's* machines for facing and furrowing use the diamond in reciprocating carriage.

The *Griscom* buhr-dresser, Fig. 1739, shows a method of operating the diamond, which is in a carriage moving on a track, which latter occupies a segment panel in a frame which lies flatly upon the face of the stone, and is fastened by a bolt passing through the eye of the stone. Any panel on the face of the stone can be reached by the adjustment of the frame on the central bolt, and the track can be brought into parallelism with the furrow by adjustment of the central end, as a tangent to a larger or a smaller circle of which the axis of the stone is the constant center.

Fig. 1738.



Emery-wheel Millstone Dresser.

Benton's diamond millstone dresser, Fig. 1740, is designed to furrow, face, or crack, and its carriage moves in guides on a platform which is laid upon the face of the stone.

The *Harris* dresser, shown in Fig. 1741, has a carriage carrying a mill pick. This, being hinged, will make a row of cracks as the car is pushed along, and a parallel line is made by readjusting the base-piece *A*. The fore-arm of the operator rests on the pusher, and the hand grasps the pickhandle at *K*.

4. A hand tool used as means of sharpening the furrows, clearing the surface of gloss or gum, restoring the cutting quality of the buhr, etc. A *facing tool.*

Frequently a block of cemented corundum. See CORUNDUM HAND-TOOL, Fig. 701, p. 224, *supra;* FURROW RUBBER, Fig. 1120, p. 363, *Ibid.*

Mineral Dresser.

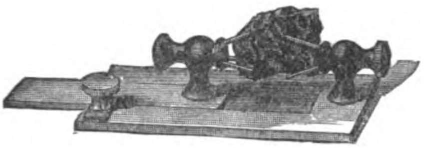
specimens with certainty, in removing superfluous portions, or exposing crystals or fossils.

The bed, *A*, has a chisel head, *B*, fastened by a link; the other chisel is on a head, *K*, moved by bar *H* and lever *L*. The screw, *M*, gives a shearing action.

Canfield . * "*Engineering and Mining Journal*," xxii. 188.
* "*Iron Age*," xvii., June 8, p. 1.

Min'e-ral Hold'er. (*Microscopy.*) A means for holding a rough piece of mineral so that it can

Fig. 1747.



Mineral Holder.

be readily revolved while under examination with the microscope.

Min'e-ral Wool. (*Glass.*) Filamentous slag made by a steam blast on a falling stream of melted slag from an iron furnace.

The "hair of Pélé," the effect of the eddying gusts of wind upon the spray pellets of the masses of slag ejected from the crater of Kilauea, is a natural and constantly produced material of the same character as the artificial slag wool.

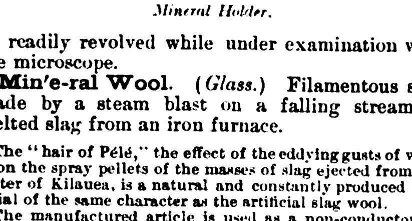
The manufactured article is used as a non-conductor, to prevent freezing of water-pipes, tanks, etc.; to prevent cooling of steam-pipes, boilers, cylinders, etc.; to prevent dampness, to keep out vermin, and to prevent the spread of fire, it being incombustible. It is formed by allowing a blast or jet of air or steam to impinge upon the surface of molten slag, which is thereby blown into filaments, producing a light material having a glassy fiber.

Player's U. S. Patent, May 31, 1870. Re-issued February 1, 1876.

The method of manufacture at the Krupp Works, Essen, Prussia, is as follows: The pig-iron furnace is provided with a tap an inch in diameter, out of which a continual stream of slag is allowed to flow, and to fall a distance of 2′ 6″, at which point the falling stream of slag is met by a strong blast of cold air, the effect of which is to separate the slag into myriads of hair-like threads, as white as snow, resembling the finest wool.

Fig. 1748 shows the method adopted at the Clove Furnace, Orange Co., N. Y. The wool-house is 100′ from the furnace.

Fig. 1748.



Mineral Wool Apparatus.

The slag is run into box cars, rolled to the wool-house, and there tapped. A small stream issues on to the runner, falls 3½″, and is then encountered by a jet of steam which scatters it in threads into the house, which is 30′ × 40′, and 21′ to the comb. A sheet-iron extension 10′ long reaches to the slag car. The size of the nozzle has an important bearing upon the formation of *shot*, as the pellets of slag are termed.

Mi'ner's Bar. A crow-bar with narrow and relatively wide chisel ends at the respective extremities.

Mi'ner's Forge. A portable forge for use in a mine, to dress picks, etc. See PORTABLE FORGE, and references *passim*.

Mi'ner's Inch. The term is somewhat arbitrary, the value varying in different localities.

Customary: The amount of water flowing in one second through an orifice an inch square, under a head of 6″, measuring from the upper line of the orifice. Approximately, 9 to 10 ounces by weight per second.

"In round numbers, the miner's inch is equivalent to a discharge of 95 cubic feet per hour; one cubic foot is 7½ gallons. A miner's inch would equal a discharge of 712.5 gallons per hour." — "*Mining and Scientific Press*," xxxvii. 152.

Diameter of drivers	22″ to 28″.
Wheel base	4′ to 5.25′.
Length over all	10′ to 15.1′.
Height	5′ to 0.5′.
Weight (running)	7,000 to 20,000 lbs.
Hauling capacity on level . .	175 to 500 tons.

See list under LOCOMOTIVE; NARROW-GAGE LOCOMOTIVE.

Mi'ning Wedge. A gad for driving into a natural seam, or a channel cut or bored, to split off a mass of coal, or what not.

A wedge for bringing down coal, on the principle of the plug-and-feather, is shown in * "*Scientific American Supplement*," 1907.

Min'now Pro-pel'ler. A bait for trolling, having a bright *spoon* which rotates by contact with the water. Behind the propeller is a feather bait with hooks. Fig. 1750 shows Chapman's minnow propeller.

Fig. 1750.

Minnow Propeller.

Min'ute Clock. A stop clock used in making tests of gas.

Goodwin's "*Amer. Gas-light Journal*," * July 3, 1876, p. 7.
Minute clock, comb. with meter and gas index, *Ibid.*, p. 7.

Mir'ror. See pp. 1452, 1453, "*Mech. Dict.*"

(*Surgical.*) To reflect light into a cavity, as the larynx, the meatus auditorius, the eye, the rectum. The laryngoscope, endoscope, ophthalmoscope, etc., use mirrors.

Mirror telegraph . . .	"*Scientific Amer.*," xxxix. 310.

See also POLEMOSCOPE.

Mir'ror Gal'va-nom'e-ter. An instrument for measuring the deflection of the astatic needle under conditions of electric excitement. A mirror is attached to the needle, and the reflected pencil of light becomes as it were a pointer traversing a scale.

The first use of a mirror attached to a moving body to indicate angular displacements was by Galileo in a pulsometer, the small mirror being laid on the pulse, the beam of reflected light was received on a wall or screen. See *Sphygmograph*.

"*Engineering*," vol. xxiv., p. 346, refers to the application of the idea by Gauss, in a telescope or eye-piece, and by Tyndall in his lectures, in throwing upon a screen the image of a dial and needle of an ordinary astatic galvanometer. See also "*Engineering*," xxii. 115.

Mr. Charles Brook used the mirror in his photographic self-recording galvanometers, in 1851, to reflect a spot of light upon a moving strip of sensitized paper.

Sir William Thomson used the spot of light, thus reflected, on an index traversing a scale, in his sub-oceanic telegraph instruments, *b*, Fig. 2150, p. 939, "*Mech. Dict.*"

See also instruments by W. J. Wilson and Prof. Silvanus P. Thomson, described in "*Engineering*" above cited. Also paper by Judd, "*Journal Society Telegraphic Engineers*," v. 248.

Mi'ter. A scribe or guide for an oblique cut. The term *miter* may be held to include only the angle of 45°, the half of the rectangle, and the *bevel* to refer to chamfers or oblique angles generally. The custom, however, is not absolute.

Fig. 1751 is a combination instrument consisting of a rule, square and miter, capable of many uses.

Fig. 1751.

Iron Frame Miter and Square.

Mi'ter Board. A miter box in which a piece is laid while the saw reciprocates between guides which cause it to make the kerf at the prescribed angle.

In Stevens's miter-board, Fig. 1752, one of the guides is adjustable on a graduated quadrant so as to set the guide to saw at any required angle with the base.

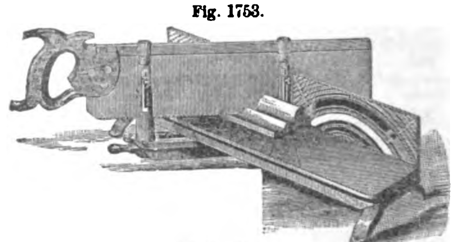
Fig. 1752.

Miter Board.

Mi'ter Box. A tool with a bed and a fence, against which, as a base, an object is held, while a saw working in guides makes a kerf at any determined angle.

In the Langdon miter box, Fig. 1753, this angle is adjustable, one of the guides being set in accordance with the scribe lines on the bed.

Fig. 1753.

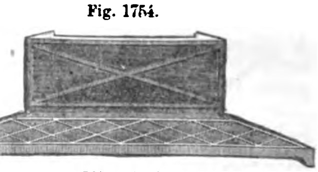


Miter Box.

Mi'ter-box Saw. A wide-bladed tenon saw for cutting miters. See Fig. 1753.

Mi'ter Jack. A templet used in making and fitting all kinds of small miters on moldings. Fig. 1754.

Fig. 1754.



Miter Jack.

Mi'ter-ing Ma-chine'. A machine on which stuff is sawed to a determined angle. Its most frequent use is to saw off the ends of pieces obliquely in order that they may be united to form a frame. The uses are very various. See p. 1453, "*Mech. Dict.*"

The mitering machine, Fig. 1755, has a table, a circular saw, and two fences adjustable to any angle, and capable of a movement of translation across the table, in order to saw off the end of a piece of stuff held against the fence and moved toward the saw.

Mitering Machine.

Mi-trail-leuse′. The subject has been considered on pp. 1454–1456, * "*Mech. Dict.*," where the French army, the Abbertini, and the Taylor systems are shown. See also MACHINE GUN, pp. 569, 570, *supra.*

Mixed Clay Ware. (*Ceramics.*) Ware made of portions of clay of different colors, to give various marbled or mottled effects; or to give the parts of a vase or other object different colors.

See of the former order, SCRODDLED WARE and TORTOISE-SHELL WARE.

Pâte changeant is a porcelain which has a peculiar changeable color as viewed by solar or gas-light, or at different angles.

Mix′ing Ma-chine′. 1. A machine for compounding. See list under MILL, *supra.* Also DOUGH MIXER, *Ibid.*

2. (*Gunpowder.*) A revolving hollow copper drum with interior spokes to mix a batch of the dry materials; say 50 lbs. in all, at one operation.

See "*Ordnance Report*," 1879, Appendix I., Plate II., Fig. 4; and description on p. 99.

Gunpowder, Fr.	* "*Engineering*," xxxv. 37.
And grinding pan, *Mather*, Br.	* "*Engineering*," xxix. 205.
And knead., *Pfleiderer*, Br. .	* "*Engineering*," xxviii. 483.
Pottery clay	* *Laboulaye's* "*Dict.*," iii., "*Poterie*," Figs. 2163–2166.

Mod′el-ing Clay. Dry clay kneaded with glycerine.

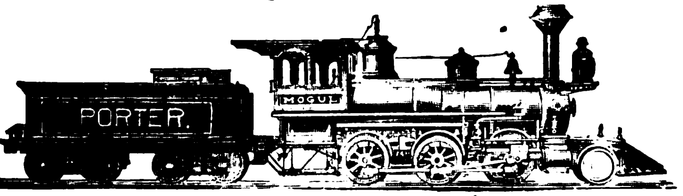
Plastilina: Clay, 3; sulphur, 6; oxide of zinc, 1; fatty acids, 2; fats, 10. First saponify the zinc white with oleic acid, which then mix with the other fatty acids, add sulphur in flowers, and the clay in a dry powder.

Or: Glue, 8, with zinc oxide, 1; add oleic oil, 4; wax, 2; sulphur, 6; clay, 3.

Mo-gul′. The name of a class of locomotives adapted for heavy freight traffic. It originated in the Baldwin Locomotive Works with the "E. A. Douglas," built in 1867. It is made in several sizes, but with the typical three pairs of connected drivers and a swinging pony truck in front.

Utilizing, as it does, nearly the entire weight of the engine for adhesion, the main and back pairs of driving wheels being equalized together, as also the front driving wheels and the pony wheels, and the construction of the engine, with swing truck and one pair of driving wheels without flanges, allowing it to pass short curves without difficulty, the *Mogul* is generally accepted as a type of engine especially adapted to the economical working of heavy-freight traffic.

Fig. 1756.



Mogul Locomotive.

Mo′hair.

"Mohair, the fleece of the Angora [Asia Minor] goat, is not a mere substitute for wool, but occupies its own place in the textile fabrics. It has the aspect, feel, and luster of silk, without its suppleness. It differs materially from wool in the want of the felting quality; so that the stuffs made of it have the fibers distinctly separated, and are always brilliant. On account of the stiffness of the fiber, it is rarely woven alone; that is, when it is used for the filling, the warp is usually of cotton, silk, or wool, or the reverse. The distinguishing qualities of the fiber are luster, elasticity, and durability. These qualities fit the material for its chief use, — the manufacture of *Utrecht velvets*, commonly called *furniture plush*, the finest qualities of which are composed principally of mohair, the pile being formed of mohair warps, which are cut in the same manner as silk warps in velvet." — *Hayes'* "*Centennial Reports*," v. 78.

See also *Hayes'* "*The Angora Goat: its Origin, Culture, and Products*," published in vol. xi. of the "*Proceedings of the Boston Natural History Society.*"

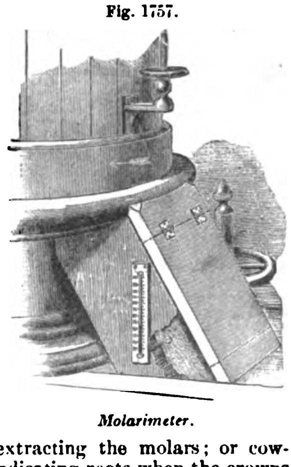
Mo′hair Gla-cé′. (*Fabric.*) A goat's-hair and cotton French dress goods.

Mo′hair Lus′ter. A black dress goods, resembling alpaca, consisting of mohair woven with cotton warp. Also called *brilliantine.*

Moist Bat′te-ry. (*Electricity.*) A battery invented by M. Trouvé, consisting of a pile of zinc and copper plates separated by paper disks; the paper in contact with the copper being saturated with a solution of sulphate of copper, and that in contact with the zinc serving to hold the zinc sulphate produced during the action of the battery.

"*Scientific American*," * xxxvii. 323.
"*Telegraphic Journal*," * v. 78.
Niaudet, Am. transl., * 112.

Fig. 1757.



Molarimeter.

Mo′lar For′-ceps. (*Dentistry.*) Heavy forceps for extracting the molars; or cow-horn forceps for eradicating roots when the crowns have decayed below the alveolar process.

Mo-la-rim′e-ter. (*Milling.*) An instrument invented by E. Campbell, for ascertaining the temperature of the meal as it flows from the mill spout. Fig. 1757.

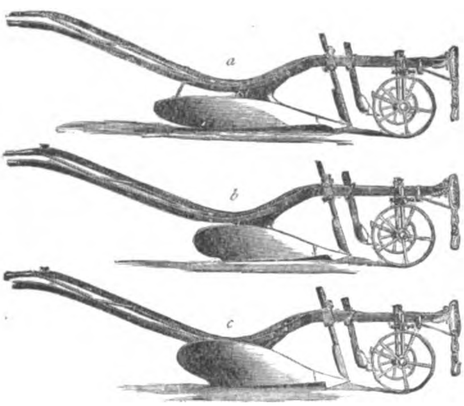
It is a thermometer with a bent leg; the bulb exposed to the flow of meal in the spout, and the graduated limb exposed to observation on the outside of the spout.

"*Leffels' Milling and Mech. News*" . . . . * viii. 85.

Mold'-board. The spiral wing on the side of a plow body, to raise, curve, and press over the furrow slice cut by the share and colter.

The following are recognized in Britain and France: —

Fig. 1758.



Mold-boards.

a. Long breast: *versoir allonge*.
b. Short breast: *versoir court*.
c Deep breast: *versoir profond*.
Medium breast: *versoir mixte*.
The latter is not shown in the illustration.

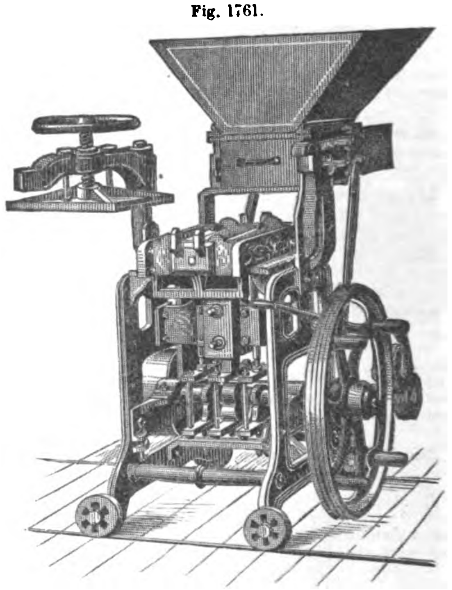
2. (*Foundry.*) A machine for making loam molds from patterns. See Figs. 3195, 3196, 3202, pp. 1466–1468, "*Mech. Dict.*"

Aiken & Drummond's machine is shown in Fig. 1761. The ordinary snap or iron flask is used. The pattern is forced

Fig. 1761.



Foundry Molding-machine.

down into the sand, making a compact face, and a soft back for the escape of the gases. The flask being put in place, the sand is dropped into it from the hopper, the pattern adjusted, platen brought over, pressure applied, relieved, the pattern withdrawn, flask closed and removed.

The match machine, for foundry use, is made with a plunger and follower, the patterns being attached to an independent head, which is fitted to rest on the plunger head. Metal plates are fitted to surround the patterns, and are attached to the follower-head. The follower and pattern-heads work independent of each other in a box, which serves as a guide and gage for the proper amount of sand to supply the reduction in compression. On this box adjustable pins and sockets are placed to hold flasks. The sand hopper is furnished with a drawer having an independent bottom. When the drawer is pulled out, it leaves the bottom at the edge of the flask, where it passes over and deposits the sand. It is then retracted, striking off the surplus sand, and engaging the bottom at the proper place, carries all back into the hopper. A swinging binder-plate is then brought over, and holds the flask in place to resist the pressure, while the revolving of the shaft, on which is a series of cams, raises the pattern-head and follower simultaneously, forcing the patterns and sand into the flask, and as the shaft continues its revolution the patterns are withdrawn from the mold, while the molded sand is protected by the follower plate, which is afterward withdrawn, leaving the mold complete and ready to be carried away. The match molders are intended to mold for such castings as gas, steam, and water-pipe, fittings, cocks, valves, and other plumbers' goods, household and carriage hardware, etc.

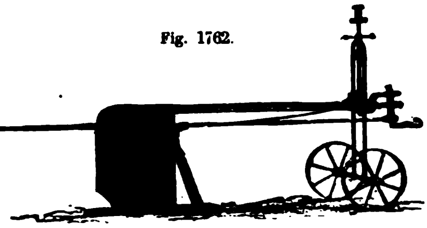
Mole Plow. (*Agriculture.*) An implement which makes an underground channel for water to follow and relieve the soil.

Instances are shown on p. 1469, "*Mech. Dict.*" The French mole plow, shown in Fig. 1762, has a wide, deep, and thin

Fig. 1762.



French Mole Plow.

plate which connects the mole with the beam and makes but a narrow incision in the soil.

Mon'o-gram Ma-chine'. A foot press for stamping monograms, initials, sizes, etc., on paper or manufactured articles.

Mon'i-tor Car. (*Railway.*) One with a clear-story or central elevation above the surrounding portions of the roof.

Monk'ey Wheel. A simple tackle-block over which a hoisting rope runs. A *whip-gin, gin-block,* or *rubbish pulley.*

Mon'ni-er Pro'cess. (*Metallurgy.*) A process of reduction of auriferous copper ores.

It consists, substantially, as follows: 1. Calcination of the metallic sulphides with a portion of sulphate of soda, or other similar salt. 2. Lixiviation of the calcined ore. 3. Evaporation and crystallization of the sulphates. 4. Reduction of the sulphate of copper. 5. Smelting into ingot copper. 6. Amalgamation of any gold residuum. The working details are explained at length in "*Mining & Sc. Press.*"

Mon'o-lith. See statement and instances, "*Mech. Dict.*," p. 1473.

A block of sandstone at the Dark Hollow Stone Quarry, near Bedford, Ohio, was lifted April, 1880. It was 40' by 60' square, 30' deep. Estimated weight, 6,000,000 pounds. 185 slip wedges were used in detaching it. It was cut up into building stones, loading nearly 300 cars.

A block of granite, 59' long by 5½' square at the base and 3½' at the top, has been taken from the quarry of Vinalhaven. It is for the shaft of the General Wool Monument, at Troy, N. Y.

Mon'o-phote Reg'u-la'tor. (*Electricity.*) A voltaic-arc regulator adapted to but a single light on a circuit: as distinguished from *polyphote* regulator.

The current is regulated by its intensity. Traversing an electro-magnet and a voltaic arc, should it grow weak the electro-magnet weakens also, and allows the carbons to approach each other.

Foucault's and *Duboscq's* apparatus have springs to maintain the normal distance between the carbons. In *Siemens'*, *Maxim's*, *Jasper's*, *Crompton's*, *Carré's*, and others, the positive carbon holder acts by its own weight to preserve the normal distance. The regulating is done by electro-magnet or by solenoid; currents continuous or alternating, in different systems.

Mon-tag'nac Coat'ing. A fabric named from its inventor, M. Montagnac, of Sedan; also known as *cloth velvet.*

The pile of the surface is usually furnished by fibers of cashmere wool, incorporated in the yarns of the fabric, and they are straight and perpendicular to the surface, the cloth having the aspect of a silk-velvet, but with a softness peculiar to the cashmere fiber. The pile is developed on the surface by *battage*, or beating the moistened cloth with elastic rods.

Moon Knife. (*Leather.*) A circular knife, 10″ or 12″ in diameter, having a round 4″ or 5″ hole in the center to introduce the hands in working it. It is concave, presenting the form of a conical zone. The concave part is applied to the skin. The edge is turned over a little to prevent it from entering too far into the leather. It is used for shaving off the coarser, fleshy parts of the skin.

Moor'ing Swiv'el. (*Nautical.*) A link of iron in a mooring chain to allow turning without kinking. See Swivel, Fig. 6137, "*Mech. Dict.*"

Mooring anchor, *Protheroe*. Br. . . "*Engineer*," xliii. 392.

Mor'bus Cox-a'ri-us Splint. (*Surgical.*) One for diseases of the hip joint. It requires an extension apparatus, and in some approved forms consists also of a pelvic band, perineal strap, knee cap, and foot-piece.

Fig. 1763.

Morbus Coxarius Splint.

Sayers' short hip-joint apparatus, Fig. 82, p. 42.
All in *Tiemann's* "*Armamentarium Chirurgicum.*"
Dr. *Stephen Smith's* morbus coxarius apparatus throws the extension or weight upon the gluteal muscles. See also Leg Support, etc.

Mor'tar. 1. A cement. See p. 1477, "*Mech. Dict.*"

Black brick and Black mortar. — Brick becomes black through the process of baking when the brick clay has been mixed with either the protoxide of iron, the oxide of cobalt, or the peroxide of manganese; 1 part of the iron or manganese to 10 of clay is sufficient. Sometimes two or three of these ingredients are used together. To make black mortar, mix the lime with fine anthracite coal-dust instead of sand.

Sawdust instead of hair used as a bond in French mortar: cement, 1, lime, 2; sawdust, 2; sharp sand, 5.

Selenitic Mortar: Sulphate of lime or sulphuric acid is mixed with the water, and ground to (for 4 minutes) a thin paste; add sand or burned clay, and continue the grinding for 10 minutes. The mortar sets quickly; is very tenacious; resists great pressure. — *Col. Scott.* London "*Mech. Magazine.*"

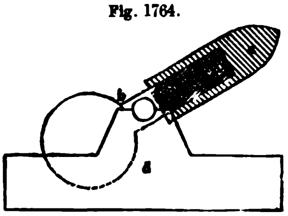
2. A form of ordnance, p. 1488, *"Mech. Dict."*

Fig. 1764.



Mortar.

a. Projectile in section.
b. Mortar.
c. Powder chamber.
d. Bed.

Fig. 1764 is a section of a small Austrian rifle mortar in which the projectile covers the outer part of the mortar. The embraced portion is a hexagonal spiral, like a Whitworth bolt, and the projectile is of corresponding shape, and fits it like a cap, and slips off when fired. The counterbalance, *b*, is to give preponderance to the rear of the trunnions.

Prussian rifled mortar of 21 cm. *"Ordnance Report,"* 1878, Appendix L., p. 93, and Plate VII. *a*, Fig. 8.

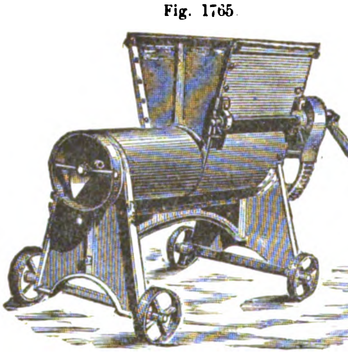
Mor'tar Car'riage. (*Military.*) The distinction between cannon and mortar carriages has been less marked since the mortar has been lengthened, rifled, and used for direct and curved fire, with solid and hollow shot, as well as shell.

Mortar carriages of modern form, Austrian, German, Krupp's, and Russian, are to be found in Plates XLI.-XLV., *"Ordnance Report,"* 1877.
Russian rifled mortar and carriage, *Ibid.*, p. 521, and Fig. 12.
See also: *"Scientific American Supplement"* . . 514.

Mor'tar Mix'ing Mill. A mill for intimately mixing the ingredients of mortar. Figs. 3230, 3231, p. 1480, *"Mech. Dict."*

Reynolds, London, portable mortar mill is shown in Fig. 1765. It is hand-worked, and is moved to the building spot.

Fig. 1765.



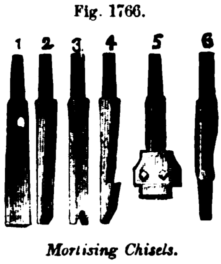
Mortar Mixing Mill (English).

The hopper being filled with the materials, the spindle in the center of the cylinder, having 14 wrought blades, is set in motion by the handle, and the mortar is ready for use when discharged from the outlet.
Mortar machine at Dunkerque and Gravelines. *"Vienna Exposition Report,"* chap. viii., Plate XVII., vol. iii., § C., p. 59.
See also Béton, Cement, Concrete, Mortar, etc., *"Mech. Dict.,"* *et supra.*

Mor'tis-ing Chis'el. The chisels used in mortising machines are known as follows: —

1. Core punch.
2. Ordinary chisel.
3. Sash chisel.
4. Lip chisel.
5. Blind stile chisel, with removable cutters.
6. Hollow chisel, for making sash and door pins.
Corner chisel (not shown).

Fig. 1766.



Mortising Chisels.

Mor'tis-ing Ma-chine'. Mortising machines are divided into *reciprocating* and *rotary.*

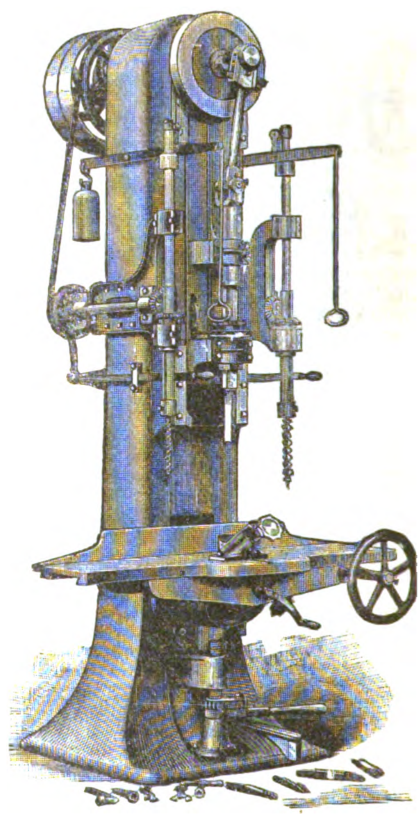
1. Reciprocating: —

a. Graduated Stroke. The chisel bar has a graduated reciprocating motion commencing from a still point, and progressing downward into the timber, returning to the starting point at each return stroke. This differs from a variable eccentric inasmuch as it requires a stroke but little longer than the depth of the mortise.
Variable cranks and eccentrics that operate the chisel-bar by an increased throw in both directions, also come under this category.
b. The chisel has a continuous motion, and the reciprocating parts, including the crank wheel, chisel-bar and connections, are brought down towards the timber, the chisel having a continuous motion, with a uniform range and positive eccentric.
c. The chisel-bar or its connection is elongated to give the stroke, the bar and chisel having a continuous reciprocating motion, but capable of being extended to the required depth of mortise.
d. Machines in which the wood is moved up to the chisel, which has a continuous reciprocating motion. The latter is the most simple when the work is light.

2. The European machines are usually rotary, the action being a species of routing, the auger cutting on the side.

The car mortising and boring machine of *H. B. Smith* is shown in Fig. 1767. It has an auxiliary boring attachment,

Fig. 1767.



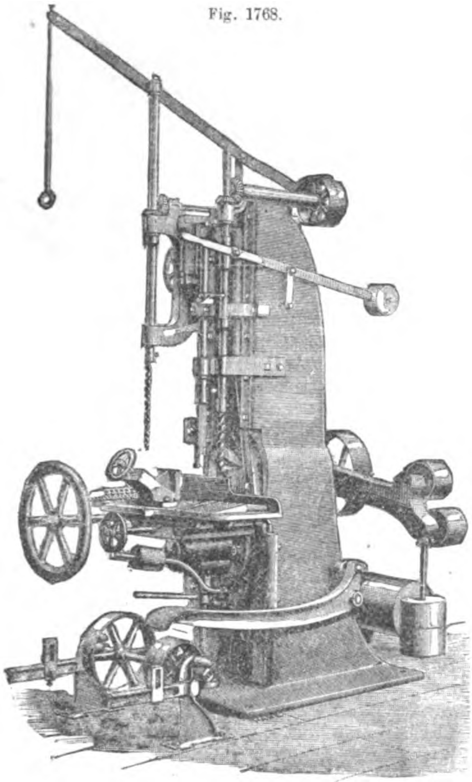
Reciprocating Car-mortising Machine.

and is intended for car and other heavy work, being capable of making a $2\frac{1}{2}''$ mortise through $12'' \times 12''$ stick of timber.
The head-stock, carrying the crank-shaft and chisel-bar, is fed down to the work by power, and has a quick return movement. Power for this purpose is taken from the crank-shaft, a lever at the base of the machine serving to apply the power for starting a screw in either direction for raising or lowering the head stock. The head-stock is stopped auto-

matically when it reaches its highest point, and an adjustable cam is provided for limiting its downward motion; so that the chisel may be made to penetrate any desired depth to 6″, an index on the frame showing to what depth it is cutting.

The table is adjustable vertically by means of a powerful screw and double ratchet lever. A rack and pinion feed is

Fig. 1768.



Reciprocating Car mortising Machine.

provided for moving the lumber horizontally under the chisel, an adjustable clamp holding it securely to the table. The table also adjusts to and from the machine and tilts for bevel work.

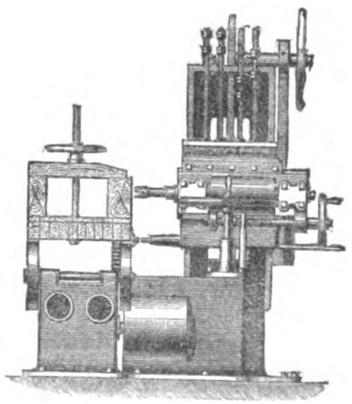
The reciprocating mortising machine of *Richards, London, & Kelley* is shown in Fig. 1768. It has also a boring spindle and auxiliary boring attachment for joint bolt-holes. It is a strong, heavy machine, especially adapted for railway-car work and similar duty. It receives chisels to any width, and has two boring spindles, one fixed and the other to traverse 12″. The feed movement is operated by treadle, and may be locked to avoid jarring the foot of the operator. The joints are compensating and operated without noise. The crank-shaft is placed in the base of the column, and the machine stands upon its base without top bracing.

See also HUB-MORTISING MACHINE, Fig. 1391, p. 472, *supra*.

Figs. 1769, 1770 are respectively side elevation and transverse vertical section of one of the rotary chisel class of mortising machines built by *Richards, London, & Kelley*, and adapted for boxing, facing, recessing, and mortising.

In machines of this class no laying out of the work is needed. A templet is placed upon the machine, and the stops are set for the position, length, and width of each mortise; after which any number of pieces are worked with-

Fig. 1770.



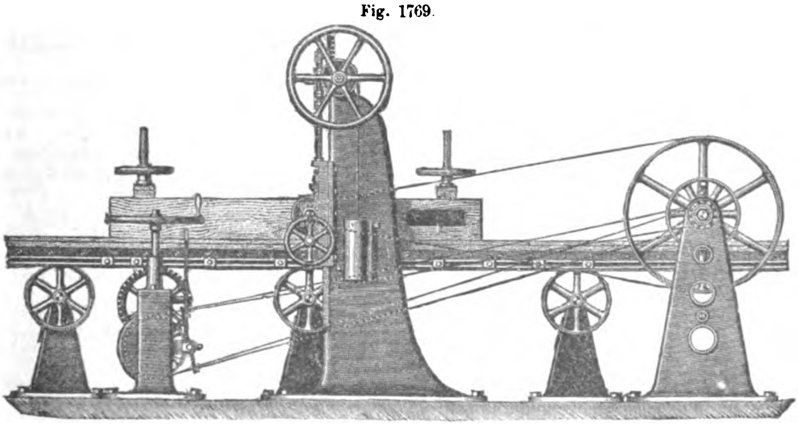
Rotary Chisel Mortising Machine. (*Transverse Vertical Section.*)

out a single mark of any kind on the timber, and without any danger of mistakes. The boxing, or facing, can be done at the same time, and with the same tools.

Fig. 1771 is an end elevation of another machine of this class, built by Ransomes (Br.). The work is clamped in a carriage which has a longitudinal reciprocation on ways for length of mortise. The chisel is a router with side-lip, and the chisel spindle passes through the driving pulley, which is splined thereon. The motion of the timber carriage is by means of the lever, which is shown erect in the view, and that of the chisel is effected by the hand-wheel which is brought conveniently near to the work.

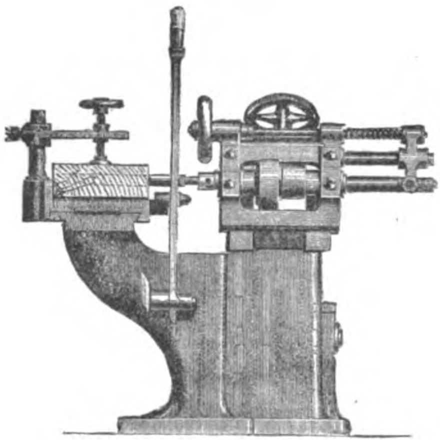
Fig. 1772 shows a combined mortising and tenoning machine. The work is dogged, as in the last-mentioned example, to a bench, which has, however, in the present case, an adjustment in either of two directions, longitudinally or transversely; the latter for the especial purpose of bringing the work within the range of the rotary tenoning cutters.

Fig. 1769.



Rotary Chisel Mortising Machine. (*Side Elevation.*)

Fig. 1771.



Horizontal Mortising Machine. (Rotary Movement.)

These rotate on horizontal spindles in the upright frame, being capable of a movement of vertical translation to adjust their distance apart for making tenons of varying thickness. The lever shown in front is that by which the chisel is projected and withdrawn. The lever on the right of the one mentioned gives the longitudinal traverse of the carriage for length of mortise; or, for traversing the work past the tenon cutters, as the case may be.

Fig. 1772.

Mo-sa'ic Gold. 1. A yellow metal for cheap jewelry. A factitious gold. See recipes, MOSAIC GOLD, p. 1484, "*Mech. Dict.*," and ALLOYS, JEWELERS, p. 63, *Ibid.*

2. A sulphuret of tin used in bronzing frames and as a gold color for printer's work. Two recipes for the dry process are:—

Tin foil	40
Sulphur	35
Sal ammoniac	25

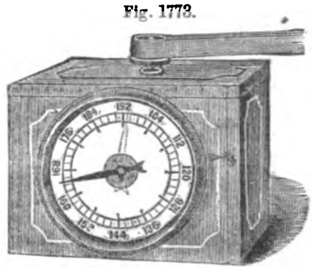
Zinc putty	80
Sulphur	60
Sal ammoniac	30

In the wet process a solution of chloride of tin is treated with sulphureted hydrogen gas.

Moth'er. The hen-mother at Baker's Cresshill poultry farm is of hollow zinc, filled with hot water and lined on the under side with blanketing.

Mo'tion In'di-ca'tor. An apparatus to indicate upon a dial the rate of revolution — per minute, for example — of the machine to which it is attached. It does away with the element of time in observation, in this respect differing from the mere *counter*. The finger on the dial stands at the figure representing the beats per the unit of time for which it is calculated and constructed. Fig. 1773 shows the Bowsher motion indicator.

Fig. 1773.



Motion Indicator.

See's motion timer, a modification of the metronome, * "*Scientific American Supplement*," 181.

Mo'to-graph'ic Re-ceiv'er. An invention of Edison, by which the volume of sound is increased in a telephonic receiver.

Called also ELECTRO-MOTOGRAPH, which see.

The vibrations of a mica diaphragm are communicated to a metallic rod, one end of which rests on a revolving cylinder with a chemically prepared surface. The contact of the cylinder and rod gives rise to friction which draws upon the diaphragm, but when an electric current passes, the friction is lessened and the diaphragm moves towards its normal position.

The current is governed by the sound waves and the motion of the receiving diaphragm also, and thus the sound waves are reproduced by the receiving instrument in augmented force.

See ELECTRO-CHEMICAL TELEPHONE, Figs. 947–950, pp. 305, 306, *supra*.

See * "*Engineer*," . . . . Nov. 23, 1877.
* "*Engineer*," . . . . xlvii. 213.
* "*English Mechanic*" . . . . xxv. 276.

Mo'to-phone. A name given by its inventor, T. A. Edison, to a small machine driven by the voice. The phonographic vibrations of a diaphragm are caused to rotate an axle by means of a stylus and ratchet wheel.

Mo'tor. A prime mover. An engine. See under various heads: AIR; STEAM; ELECTRO; HOT-AIR, etc., etc.

See: Small "Simplex."

Transmitting, paper on.
Robinson, Engl. . . "*Scientific American Sup.*," 1078.

Mo'tor Print'er. A small electro-motor running a press for copying messages. An electro-motor printer. "*Scientific American Sup.*," 367.

Moul'le-ton. (*Fabric.*) A fine wool French dress goods, with a satin weave.

Moun'tain Gun. (*Ordnance.*) A light cannon capable of being transported on mule back. For this purpose it is detached from its carriage and the weight distributed among several animals.

The Ashantee gun is shown in Fig. 8242, p. 1485, "*Mech. Dict.*"

The new Woolwich mountain guns, made from the designs of Sir William Armstrong, instead of weighing merely 200 lbs., like the mountain gun used in Abyssinia and Zululand, will weigh 400 lbs. each. As, however, an essential condition of mountain artillery is that every part of it shall be carried on the backs of mules, these guns are made in two pieces, screwed together, and strengthened at the joint by a third piece in the shape of a ring or collar. The breech end of the gun when disjointed weighs 200 lbs., and the barrel with collar amounts to about the same weight, which is regarded as a fair burden for a mule over hilly country. These guns, like their smaller namesakes, are of the small caliber adopted for 7-pounder projectiles, but their greater length and weight enable them to do much more effective work.

* "*Scientific American Sup.*" . .. . 2521.

Moun'ted Pow'er. A horse power adapted to be used without dismounting. See Horse Power.

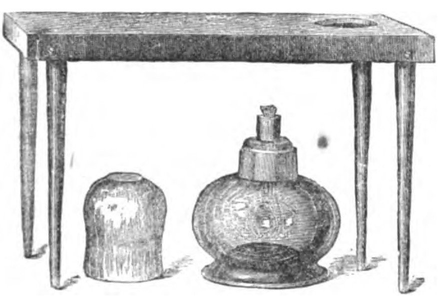
Mount'ing In'stru-ment. (*Optics.*) An instrument for pressing down glass covers on microscope slides.

Fig. 1774.

Mounting Instrument.

Mount'ing Stand. (*Optics.*) A small table sliding up and down on a brass rod or stand, or independently on its own legs, and supplied with a chamber below for holding sand for equalizing the temperature when the lamp accompanying it is applied beneath. The stand shown in Fig. 1775 has folding legs, so as to go in a microscopist's traveling case.

Fig. 1775.

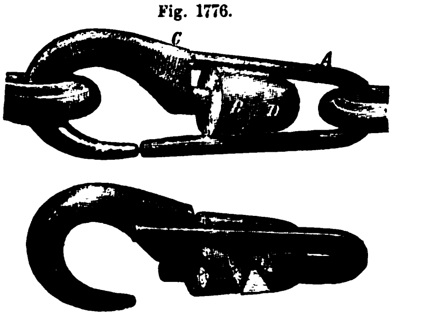


Mounting Stand.

Mouse Mill. A small electro-magnetic engine and electro static induction machine used in the siphon recorder. *Sir William Thomson, "Journal Soc. Teleg. Engineers,"* * v. 185.

It is propelled by a battery and its purpose is two-fold: (1) to generate statical electricity by means of induction wherewith to highly electrify the ink so that it may flow through the delicate capillary siphon pen. To generate the necessary electricity the drum is caused to rotate by electro-magnets, and this rotation is taken advantage of to (2) draw the paper past the point of the siphon.

Fig. 1776.



Self-locking Hook.

Mous'ing Hook. A hook having a member which normally closes the opening.

In the *Raines* mousing hook a draft upon the hook brings the mousing-arm in apposition with the point of the hook. The parts *B D* slide on each other, being respectively attached to *A* and *C*. The cut shows the device closed and open.

Mousse-line'. (*Fabric.*) A fine wool French goods, taffeta woven. *Moulleton* is woven with a satin armure.

For muslin see "*Report of East Indian Section*," Paris Exposition," p. 84.

Mousse-line' de Bège. (*Fabric.*) A French dress goods.

Mousse-line' Glass. (*Glass.*) A very thin blown-ware with ornamentation resembling the patterns of lace or printed goods.

The process is as follows: —

After carefully cleaning the surface of a plate of glass, an even layer of vitrifiable color is laid over it, with the aid of gum water. The glass is then submitted to a gentle heat until the water has evaporated, when a stencil of the desired pattern is laid over the surface, and with a stiff brush the pigment is removed from the parts which are to be transparent. The glass is next inclosed in a frame, and above it is extended a piece of tulle, or, if desired, embroidered lace, the embroidery in the latter case being so disposed as to harmonize with the ground pattern previously made. The whole is then hermetically closed in a box which contains in its lower portion a reservoir holding a certain quantity of dry color in the form of an impalpable powder. This is blown evenly upon the glass by an air-blast, adhering to it wherever the surface is not protected by the threads of lace. In this way the pattern of the latter is defined. In order to fix the powder the sheets of glass are exposed to steam, which moistens the gum and causes the powder to adhere. The color is then burnt in a special furnace. — *M. Aubriot.*

Mousseline glass was exhibited in Paris in 1878, in great beauty and variety by the "*Cristallerie de Clichy*," and by *Bandoux*, of Lodelinsart.

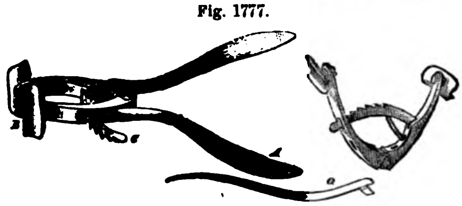
Lockert, on . . . . . . "*Technologiste*," xl. 51.

Mous-tache' Pro-tect'or. 1. (*Dentistry.*) A shield to keep the moustache out of the way of the operator during operations on the teeth.

2. A shield on a drinking cup, to keep the moustache from dipping in the liquid.

Mouth Gag. (*Surgical.*) For holding the mouth open during operations. *Speculum oris.*

Fig. 1777.



Dr. Weir's Mouth Gag.

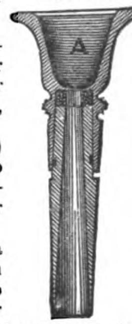
Dr. Weir's gag has two leaves with a spring catch. It is operated by two detachable handles. The illustration shows all parts and positions. See Gag, and references *passim*.

Mouth'ing Machine. (*Sheet-metal Working.*) A machine for crimping bottoms and swaging or mouthing the tops of open-top cans, to receive the covers.

Mouth Mir'ror. (*Dentistry.*) A small mirror to introduce into the mouth, to enable the observation of parts which have a rear presentation.

Mouth Piece. The lip of a wind instrument. That shown in Fig. 1778 is so constructed as to enable the performer to enlarge or contract the opening in the throat,

Fig. 1778.

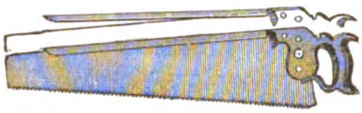


Conn's Mouth-piece.

or bottom of cup, at will, while playing, thus facilitating the reaching of the higher notes, and requiring less pressure of the lips to produce them. It has two metallic pieces with an interposed elastic ring.

Mov'a-ble-back Saw. A saw, the stiffening back of which can be removed so as to convert it from a tenon saw to an ordinary hand saw.

Fig. 1779.



Hand Saw, with Movable Back.

Mov'a-ble Dam. A barrage.

The Davis Island Dam, on the Ohio, near Pittsburg, is the first attempt to introduce the *movable* dam system into this country. The system is known as the *Chanoine*, and is in use on the rivers of France, especially the Seine and Loire. It consists of a dam formed from wickets, and so arranged that when the water is high the wickets are lowered, and boats can pass over the dam freely. When the water is low the wickets are raised, a pool is formed, and the boats pass through the locks. See BARRAGE, *supra*.

The entire length of the dam is 1200′, and two stone piers divide this into three sections of 400′ each. That section nearest the lock is called the Pass, and this, besides the other two sections, is to be closed by the movable wickets whenever the stage of water in the river is less than 6′. Each wicket is a little dam by itself, hinged so as to lift up and oppose the water, or lie down and permit the river to flow over it. Each wicket is 13′ long and 3′ 8″ wide, made of oak. They are to stand on end, side by side, across the river, with a space between each of 4″. One by one they are raised, and when raised, they are retained in rigid position by the pressure of water above and a wrought iron prop below, until a *tripping bar* is brought into play and the entire dam falls down flat on the sill.

The lock has a clear length of 600′ between the gates, and a clear width of 110′, and can hold 12′ depth of water. The gates that shut off the water at either end of this lock are each in one solid piece, 118′ long, $10\frac{1}{2}$′ wide, 14′ high, and weigh 80 tons. The openings in the lower part of the gate recesses, and for filling and emptying the lock, are $4\frac{1}{2}$′ in diameter. The filling culvert, a lofty, arched water-way, takes the water from these openings and conducts it to the lock, which is filled through 10 inlets, each 3′ × $3\frac{1}{2}$′, and 17′ below the coping. The lock has required over 11,000 cubic yards of cut stone and rubble, and 10,000 barrels of hydraulic cement.

The gates of the lock slide back into the gate recesses in the shore wall, and when in position across the lock, rest on a shoulder built in the river wall. They are operated by turbine water wheels. It is estimated that the gates can be closed or opened, and the lock filled or emptied in four minutes

Description of the new system of wickets adopted for the La Mulatière dam on the Saône, at Lyons, by A. Pasqueau, Engineer des Ponts et Chaussées. Translation in "*Report of Chief of Engineers, U. S. Army*," 1880, * ii., pp. 1753-1762.

Movable Point Plow.

Mov'a-ble Point Plow. One which has a long bar the forward end of which forms the plow-point, and can be thrust forward as it becomes worn. Made by Guilleux, Segré, France.

Mow'er. The subject of mower has been considered and the history detailed on pp. 1487-1493, "*Mech. Dict.*" Plate XXX. has diagrammatic views of 40 principles of cutting; and Plates XXXI.-XXXIII., have 36 illustrations. The classification of mowers is given on p. 1488, *Ibid.*

The McCormick iron mower is shown, in company with the McCormick single-wheel reaper, in Plate XXX. opposite. The mower is a front cut, jointed bar, iron frame machine, with inclosed gearing. The smaller size, 4′ cut, weighing 580 pounds.

The frame is of cast and wrought iron, and the gearing inclosed in a cast-iron case. The draft is directly upon the cutting apparatus through a draft-rod connecting the double-tree strap to the finger-bar brace. The cutter-bar has a rolling motion given to it by a roller on the end of the long connecting pin, which works up and down in the front end of the inside shoe; by this device the bar conforms itself to the unevenness of the ground, and always cuts a close stubble

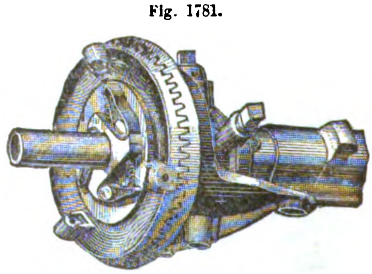
By means of the tilting lever, the points of the guards can be thrown up or down; and with the lifting lever the bar may be raised bodily from the ground, in order to pass over rocks or other obstructions; thus, through these two levers, the cutting apparatus is entirely under the control of the driver, and may be instantly changed, as occasion may demand, to suit the necessities of grass or ground.

The pitman box is light, strong, and durable; has no bolts, and yet can be quickly taken off and put on; the wrist pin has a screwed cover; the crank shaft box is bored large, so that a babbitt metal bushing is inserted, in which the shaft works; when worn, the bushing can be easily removed and replaced by a new one.

The Whiteley machine, "New Champion," is shown in Figs. 1781-1783. It is a front-cut machine, in respect of the cutter-bar being in advance of the gearing and carriage portion. The peculiarity of the machine is in the gearing.

There are practically but two pieces between the axle and the knife, one being a small bevel cog wheel secured to the axle, and the other a similar wheel made to gear into the former. This second wheel, or disk, does not rotate, however, but being hung on what is called a gimbal joint, like a ship's compass, it begins, on starting the machine, a succession of rapid serpentine vibrations around the face of the other wheel, much as a dinner plate or coin will act when rung down upon a table; and an arm extended from this vibrating disk down to the knife, gives it the required rapid, reciprocating motion. There is only one rotating bearing besides the axle on the machine, and that is not a part of the movement proper, but belongs to a small fly-wheel, which only assists in giving the required regularity and

Fig. 1781.



"New Champion" Mower. (Gearing.)

steadiness of motion. There are always 11 teeth in contact, and thus the wear is distributed over a large surface.

The finger-bar is operated and controlled by two levers, one for foot and the other for hand, and by the use of these levers either end of the finger-bar may be thrown up at any angle or to a vertical position without throwing the machine out of gear or stopping the knife. The finger-bar may also be folded and secured for transportation by the driver without leaving his seat, and by the use of the tilting lever the height of cut may be changed and controlled instantly. By the use of this lever the cut may be lowered and the points

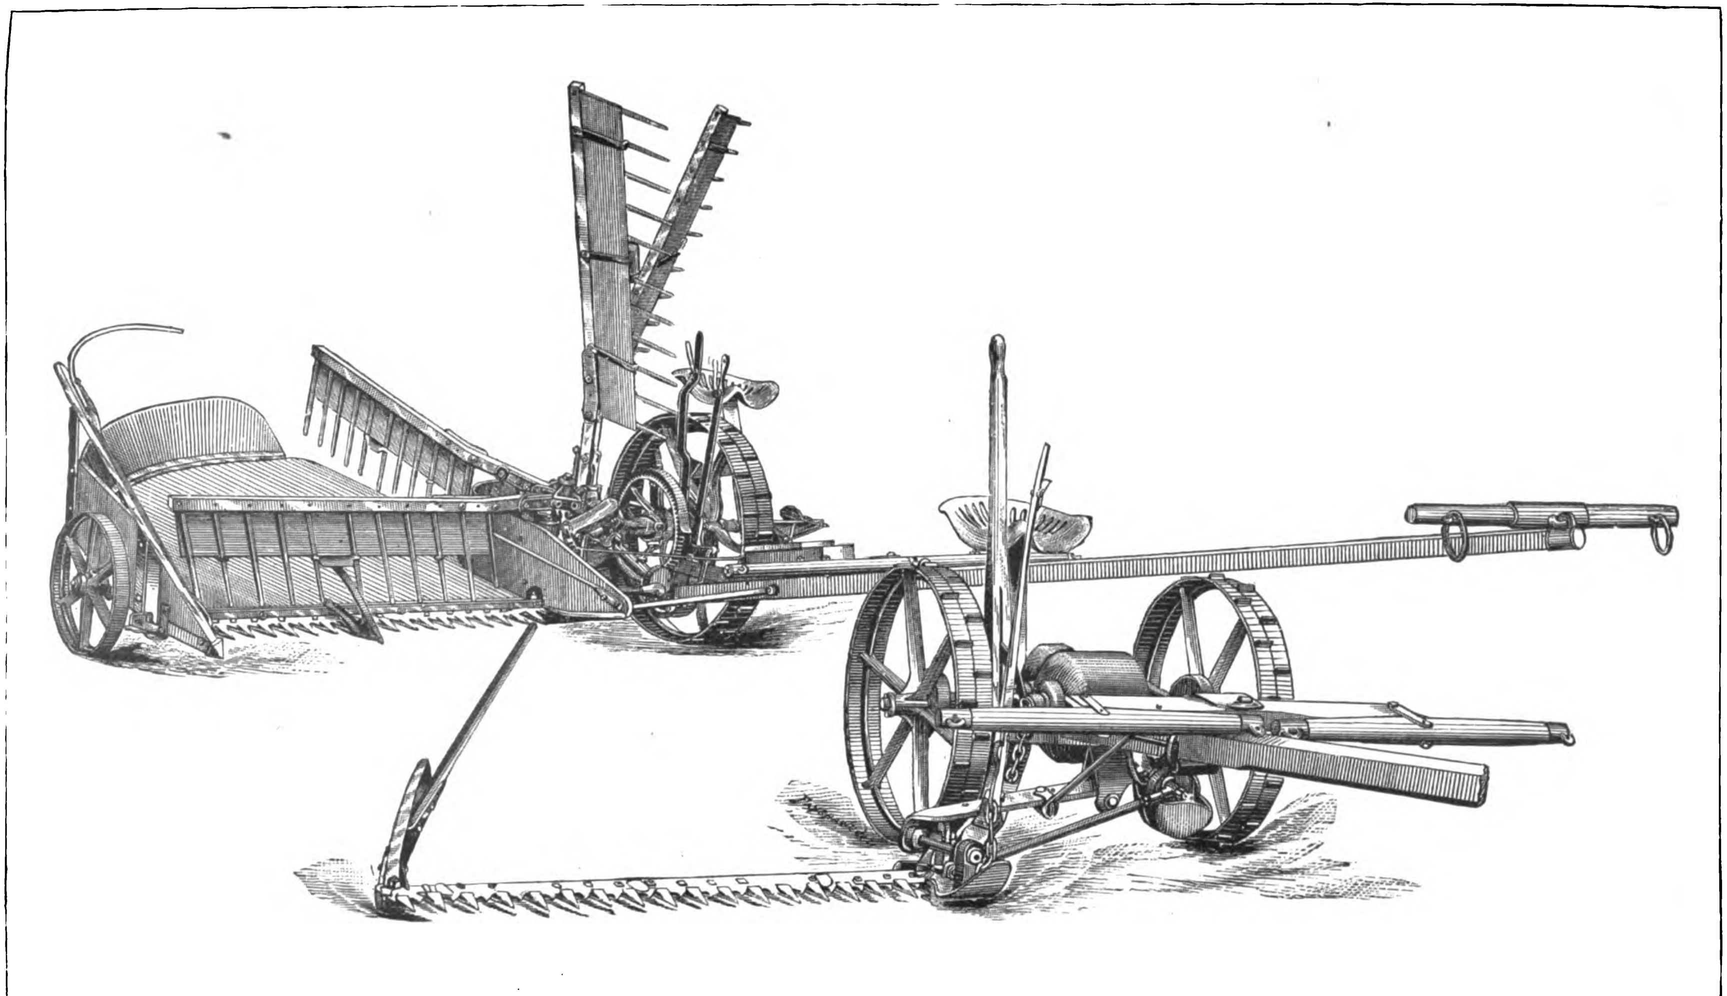


PLATE XXX. McCORMICK'S MOWER AND SINGLE-WHEEL REAPER. See page 620.

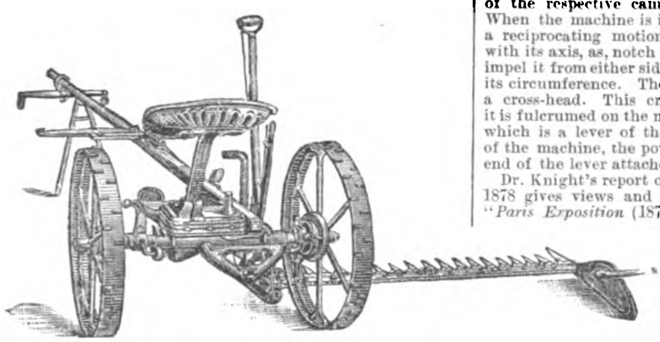
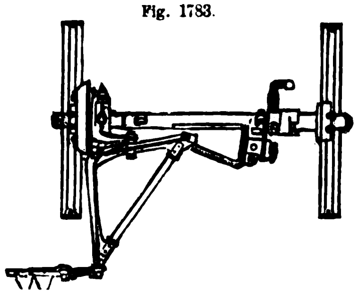
Fig. 1782.



"*New Champion*" *Mower*. (*Perspective.*)

of the guards turned down for picking up badly lodged grass, or the cut may be raised and the points of the guards turned up so as to cut high or readily pass over obstructions; or when desired, the tilting lever may be so arranged as to allow the finger-bar and guards to oscillate and perfectly follow the uneven surface of the ground. The gearing is inclosed within itself. The draft of the team is not upon the pole, but through a draft-rod directly connected to the

Fig. 1783.

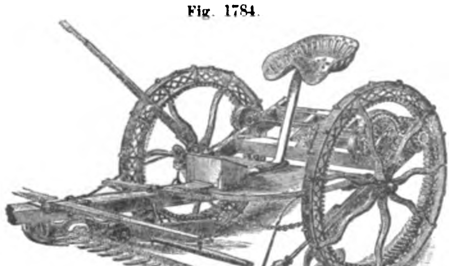


"*New Champion*" *Mower*. (*Plan.*)

cutting apparatus in such a way that a portion of the weight of the finger-bar is carried or suspended by the draft of the team.

Wilbur's "Eureka" mower is a direct draft front-cut, which cuts the grass behind the horses and in front of the running gears of the machine. One horse walks in the grass and the other upon the stubble, the double-tree being long, in order to throw one horse outside the swath, which is 6′ wide. The machine, being center-cut, is, of course, reversible, and may cut back and back, throwing the off and the near horse alternately upon the stubble.

Fig. 1784.



Eureka.

The peculiarity of the mowing machine motion of *Goodwin* is the method of converting the rotary motion of the driving wheels into the reciprocating movement of the knife without the intervention of spur gearing and without crank.

On the axle are two circular plates. These are fast to the axle, and have on their inner faces a series of inclined faces which may be termed *star-cams*. Between these two wheels is another *star-cam* which has faces on each side facing those of the respective cams between which it is sandwiched. When the machine is in motion the wheels rotate and give a reciprocating motion to the cam in a direction parallel with its axis, as, notch by notch, it slips past the cams which impel it from either side, all the faces bearing equally around its circumference. The cam is prevented from rotating by a cross-head. This cross-head is pivoted. At its butt-end it is fulcrumed on the main frame of the machine cross-head, which is a lever of the third order: fulcrumed on the frame of the machine, the power exerted by the cam and the outer end of the lever attached to the reaper knife.

Dr. Knight's report on Class 76 at the Paris Exposition of 1878 gives views and descriptions of the following. See "*Paris Exposition* (1879) *Reports*," vol. v., pp. 150-155: —

Whiteley . . . United States.
One-horse mower.
Walter A. Wood . United States
"New Buckeye" mower.
Aultman & Co. . United States.
"Eagle" mower.
Wm. Anson Wood, United States.
"Paragon" mower.
R. Hornsby & Sons . . England.
"La Française" mower, *J. Cumming* . . . . . France.

See also comparison of machines, Paris Exposition, *Knight*, "*Scientific American*," June 22, 1878.

For table of Dynamometrical tests, see p. 288, *supra*.

Mo′zam-bique′. (*Fabric.*) A French worsted dress goods woven on a gauze or taffeta loom. It has a cotton warp and an English combing wool weft.

Mu′ci-lage Brush. One with a reservoir in the handle, to keep the brush supplied.

Mucilage on government postage stamps: —

Dextrine	2 oz.
Acetic acid	1 oz.
Water	5 oz.
Alcohol	1 oz.
	9 oz.

Mucilage . . . . . "*Scientific American*," xxxv. 23.
"*Scientific American Sup.*," 2511.
Bottle. *Wight*. . . * "*Scientific American*," xxxiv. 246.

Muck I′ron. Crude puddled iron ready for the squeezer or rollers.

Fig. 1785.

Mucilage Brush.

Mu′cy-line. A sizing for woolen yarns.

It is composed of 18 pounds stearine, 18 pounds of soft soap, 10 pounds glycerine, ¼ ounce sulphate of zinc, and 50 pounds of water. The stearine is mixed carefully with the glycerine. The soap is then added. To this is added the water, in which the sulphate of zinc has been dissolved, amid constant kneading of the mass till a stiff and homogeneous paste is produced. For use, 32 pounds of this paste are taken and diluted with 36 pounds of water, which is used cold or warmed to 66° or 70° Fah., according to the season. The solution is filtered or clarified by decantation, and this clear liquid, which has a specific gravity of 1.025, constitutes the mucyline.

Mud′dler. A churning stick for chocolate. A smaller one for mixing toddies.

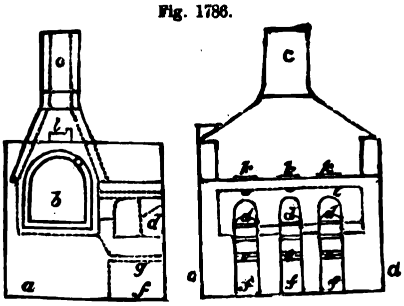
Muf′fle. (*Ceramics.*) A small furnace and chamber for baking metallic colors for pottery.

The figure shows two forms, one of them with a refractory clay chamber isolated from the fire. The other furnace has several chambers *d d*, with grating *e*, cinder holes *f f*, and openings *k k* to allow volatile matters to escape. See PORCELAIN MUFFLE, *infra*.

The other view has grating *g*, cinder hole *f*, charging hole *d*, muffle chamber *b*, escape for fumes *l*.

The fuel is exclusively wood or charcoal, the fire gentle at first and then intense. The heat is judged by practiced observation of the color of the fire or by the shades of color which the powder of cassius takes in the fire, being exposed on a removable slip of porcelain. See also PORCELAIN MUFFLE.

Fig. 1786.



Muffles for Vitrifiable Colors.

See: Faïence . . . . * "*Scientific American*," xl. 258.
For copper, *Silliman* . * "*Eng. & Min. Jour.*," xxii. 264

Muir'head Bat'te-ry. (*Electricity.*) A compounded Daniell's battery, in which the series of rectangular elements are inclosed in a tight box.

See Prescott's "*Electricity*," * p. 63; *Niaudet*, * p. 107.

Mule. A machine for drawing and twisting into yarn the roving from the roving-frame or jack-frame and winding it upon spindles in the form of cops automatically.

These machines are in two principal parts, the stationary and the movable.

The stationary parts comprise the head-stock, creels, rollers, and roller-beams for reducing the thickness of sliver. The part called the head-stock contains all the mechanism for effecting the different changes necessary for spinning.

The English mules exhibited by Dobson and Barlow at Philadelphia, were for coarse and fine counts respectively. The coarse mule contained 216 spindles, 1⅞" gage, and was arranged with double boss top rollers and single creels for spinning 1's to 50's. The fine mule contained 314 spindles, 1¼ inch gage, single boss top-rollers, creels for double roving, double speeds, supplementary stretch, roller turning motion to deliver yarn while twisting at the head-stock, faller motion to lift the fallers free from snarls, and is arranged to spin from 50's to 250's.

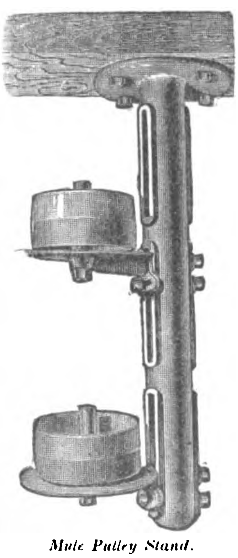
In the headstock each motion is separate and distinct from the others, is so placed as to be easy of access, and can be detached and removed without disturbing the other motions. The headstock stands very low, which gives steadiness to the working parts and enables a longer strap to be used, which is a special benefit in low mills.

The principal novelty in these mules is an improved method of working the changes, which dispenses with the well-known troublesome cam-shaft.

A long lever is placed lengthwise inside the head-stock framing and makes three changes.

The first change is made when the carriage arrives out by lifting a latch lever, the long lever rises to a second latch and detaches the drawing out motion. When the requisite turns of twist are put in, the backing off takes place, and the locking of the fallers again liberates the catch and allows the long lever to rise again, putting out of gear the backing off and putting into gear the drawing-up cone. The mule recedes inwards to the beam, and the long lever is again unlatched and falls down to its original position, disconnecting the drawing-up motion, and putting into gear the drawing-out motion.

Fig. 1787.



Mule Pulley Stand.

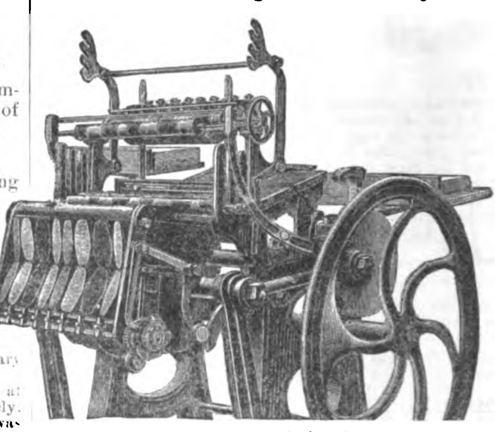
Lees, Br., "*Sc. Am.*," xxxvii. 211; *Spencer*, "*Engr.*," i. 437.

Mu'ley Axle. (*Railway.*) One without collars on the outer ends of the axle. See AXLE BOX.

Mule Pul'ley Stand. A form of stand for pulleys which revolve in planes at varying angles. In Fig. 1787, each pulley is on a plate which has a perfect adjustability on the post, either for height or for angle.

Mul'ti-coil Spring. One which consists of a number of coils as in *p, q, r, s, t, u*, Fig. 1143, p. 483, "*Mech Dict.*," in contradistinction to a compound spring in which several types of springs are united for a simple effect, as in *k, l*, Fig. 1142; *m, n, o, q, r*, Fig. 1143; and *d, d*, Fig. 1144, p. 483. *Ibid.*

Fig. 1788.



Multicolor Printing Press.

Mul'ti-col'or Print'ing Press. A chromatic printing press. Bacon's press, shown in Fig. 1788, is for printing in bands or stripes of color; not a press such as is used in chromo-lithography, for printing in over-laid colors by successive operations. See p. 545, "*Mech. Dict.*"

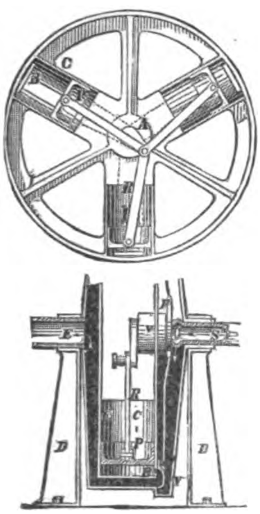
The working table, instead of being in a single piece, is composed of a number of narrow ovoid plates held in a frame, and so hinged as to move easily on each side at every revolution of the table. The end piece near the ink-trough is stationary. The various colored inks are placed in the ink-trough, which is divided into cells by metallic partitions. Directly over the trough is an iron frame carrying a set of screws and nuts. By tightening these screws, which are placed over the metallic partitions, the inks as they flow beneath are prevented from mixing. The inking rollers, instead of being fixed at a certain angle relative to the table, are arranged so as to run perfectly straight, the distribution being effected by a certain limited motion of the plates at each revolution. The different inks are spread on the multiple table in the usual way. Motion is communicated to the movable plates by a small lever which hangs under the table, and which rests on a small vertical iron plate affixed to a cross-stay of the machine.

Mul'ti-cyl'in-der En'gine. A steam engine with a plurality of cylinders; the term is, however, rarely applied to engines with less than three cylinders.

The Billing engine, shown in Fig. 1789, operates in a manner the reverse of that of ordinary motors, inasmuch as it is the engine that revolves while the shaft and crank are stationary. In the illustration three cylinders are employed, but as many may be used as can be grouped around the rim of the fly-wheel without causing too great complication of parts. Dead centers are avoided and the machine reduces itself to a self-rotating pulley-wheel.

A is the stationary crank, *C* is a light wheel, on which the three cylinders are grouped; the cylinders take steam at the rear end only, *B* being the steam-port and the dotted lines indicating the steam passages. The engine has bearings in the wheel-hubs, through one of which, *S*, the steam enters, as shown by the arrow, and through the other, *E*, the exhaust is had. The crank-shaft is merely a continuation of the steam-pipe, a suitable stuffing-box being provided at *Y.* On the pipe, also, and inside the steam chamber is fixed the eccentric *F*, which gives motion to simple valves *B* at the cylinder ends. The exhaust-pipe may be run through a stuffing-box and used as a shaft for pulleys. See Revolving Cylinder Engine, Figs. 4298-4301, p. 1931, "*Mech. Dict.*"

Fig. 1789.



Three Cylinder Engine.

See also Six Cylinder Engine; Three Cylinder Engine; also Fig. 890, Plate XI., op. p. 282, *supra.*

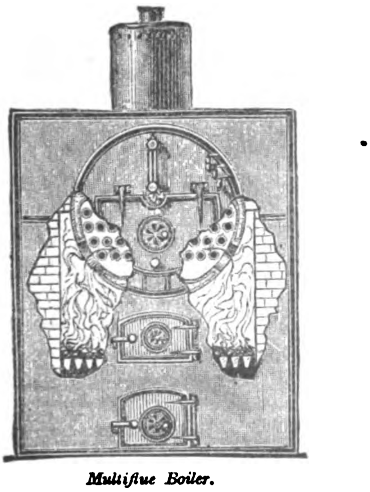
In the Payton & Holmes' multiple cylinder steam engine, (Br.), either two or four cylinders are used, the four cylinders being placed in pairs at right angles, one crank and eccentric answering for both. Steam is admitted only on the top side of the pistons of one pair of cylinders from the top port, and to the top of the other pair of cylinders from the bottom port. The engines can be reversed by a two-way cock for each pair of cylinders, placed behind the ports, and which, by moving a certain distance, reverses the steam current from the top of one pair of cylinders to the top of the other pair, or by sliding an inclined key fixed on a sleeve along the shaft within the eccentric.

Payton & Holmes, Br. * "*Engineer*," xlvii. 385.
Bacon . . . . . . * "*Scientific Am. Sup.*," 349.

Mul'ti-flue Boiler. The horizontal multiflue boiler has its principal exemplars in the boilers of locomotives and portable engines. See Fig. 2927, p. 1346, "*Mech. Dict.*," Fig. 5638, p. 2329, *Ibid.*

See also *A B C*, Fig. 5628, Plate LXI., "*Mech. Dict.*"
Observe the distinction between *flue* and *tube.*
The vertical multiflue boiler has flues or flame pipes traversing vertically the boiler space above the fire, being secured in their respective ends in the crown sheet or lower flue plate and the upper flue plate.
The *Lowe & Watson* multiflue boiler is shown by part elevation and part section in Fig. 1790. The furnace is beneath the front ends and the products of combustion pass from them by side openings into a combustion chamber which occupies a portion of the end of the boiler, then rearward by flues similar to those of a locomotive, and then beneath the boiler, and so to the stack.

Fig. 1790.



Multiflue Boiler.

SS. "Jason," *Cochrane*, Br. * "*Engineer*," xlix. 279.
Piedbœuf, Ger. . . . . . * "*Engineer*," l. 228.

Mul'ti-fur'row Plow. (*Agric.*) One having several bodies for plowing two or more furrows at once. See Gang Plow.

Mul'ti-ple Dril'ling Ma-chine'. A machine tool with a multiplicity of drills adjustable as to distance apart and adapted for drilling holes at a regulated distance apart on a number of bars which require exact conformity in all respects, as in bridge, trestle, and car work.

The London "*Engineer*" shows a machine especially adapted for drilling plates in position, on straight or hog-backed girders. The drills may be adjusted at any distance apart, and to suit varying pitches of holes, and while they may be brought together within 3¾", the driving wheels, by passing each other upon different levels, may be nearly 6" in diameter. The feed is automatic or independent at will.

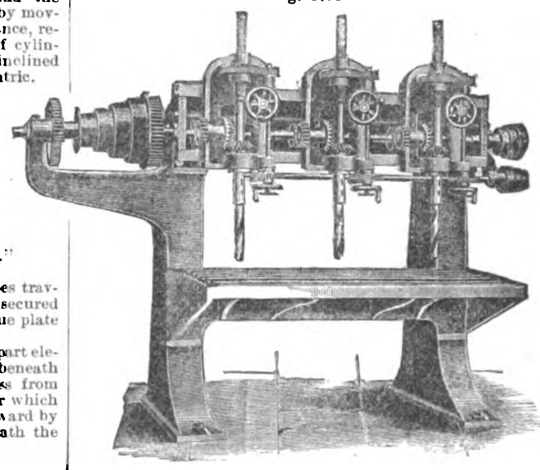
Boring mach., *Richards* * "*Engineering*," xxvii. 506.

Mul'ti-ple Tel'e-phone. A form of telephone by M. Trouvé, intended to increase the capacity of the Bell and render it available for long distances. It has been adapted to M. Trouvé's military telegraph.

Fig. 1791



Multiple Drilling Machine.

"Instead of the single vibrating diaphragm used by Prof Bell, M. Trouvé substitutes a cubical chamber, each face of which (with one exception) is a vibrating membrane. Each of these membranes, being thrown into vibration by the same sound, influences a fixed magnet and electric circuit, the same as in the Bell arrangement. By associating all these currents, a combined current of single intensity proportional to the number of magnets influenced is produced. Instead of the cube, a polyhedron having an indefinite number of vibrating membranes may be used, and thus intensity augmented as desired.

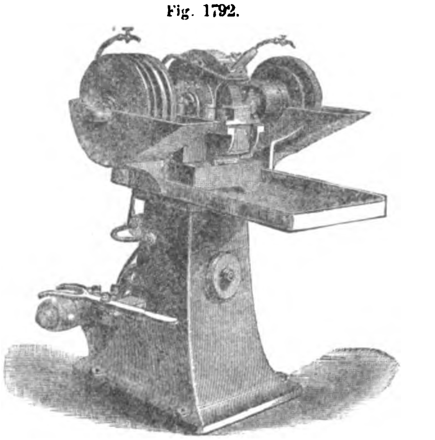
"Suppose now a line established on which is disposed a telephone constructed as above described, the membranes and magnets of which are divided into two series, and the circuits so arranged that, by pronouncing a word, currents are produced on the same wire in opposite directions. When a dispatch is received to be transmitted further on, the operator talks in the telephone in the usual way; and his speech, by the arrangement of circuits above noted, is heard both at the station to which he is forwarding the message and also at the one from which the message was sent, so that the possibility of error is thus rendered nil. M. Trouvé has adapted this apparatus to his military telegraph."

Mul'ti-ple Wheel Tool Grind'er. A grinding machine furnished with a variety of wheels, of differing qualities, fineness, size, shape, or what not, to suit varying requirements.

Fig 1792 is a tool grinder made with six emery wheels, by Thomson, Sterne & Co., of Glasgow, Scotland.

The wheels have different shapes and width of face, four being for gouges of varying size and for molding irons: one has a square face for straight edged irons (plane irons); one is a fine emery hone to replace the "water-of-Ayr" stone.

Fig. 1792.



Multiple Wheel Tool Grinder.

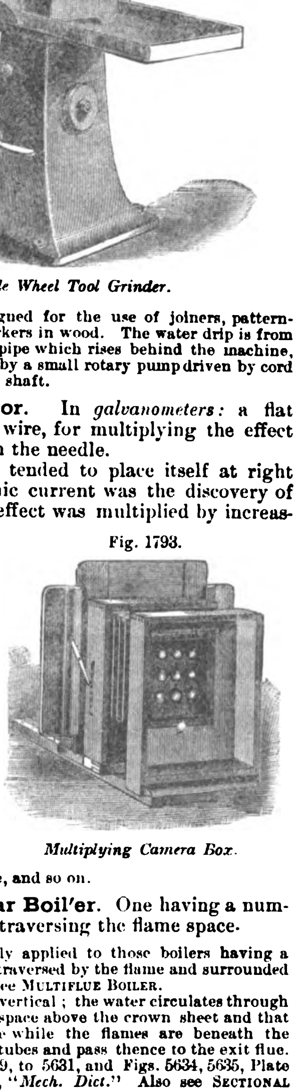
It is especially designed for the use of joiners, pattern-makers, and other workers in wood. The water drip is from branches of a vertical pipe which rises behind the machine, the water being lifted by a small rotary pump driven by cord from the emery wheel shaft.

Mul′ti-pli-ca′tor. In *galvanometers:* a flat coil of conducting wire, for multiplying the effect of the current upon the needle.

That the needle tended to place itself at right angles to a galvanic current was the discovery of *Oersted;* that the effect was multiplied by increasing the number of convolutions of the conducting wire, was the discovery of *Schweigger.*

Mul′ti-ply-ing Cam′e-ra Box. (*Photography.*) A chamber with numerous lenses all focalized by the same adjustment.

Fig. 1793.



Multiplying Camera Box.

For instance the nine-tube multiplying camera box will take 72, 36, or 18 gems on a 7″ by 10″ plate. 9 on a 5″ by 7″ plate, and so on.

Mul′ti-tu′bu-lar Boil′er. One having a number of water tubes traversing the flame space.

A term unfortunately applied to those boilers having a number of small *flues* traversed by the flame and surrounded by water. For these, see MULTIFLUE BOILER.

The boiler is usually vertical; the water circulates through the tubes between the space above the crown sheet and that below the steam dome while the flames are beneath the crown and around the tubes and pass thence to the exit flue. See also from Figs. 5629, to 5631, and Figs. 5634, 5635, Plate LXI., opposite p. 2326, "*Mech. Dict.*" Also see SECTIONAL BOILER.

Ormerod, Grierson & Co., Br. . * "*Engineer,*" xlii. 379.

Mun′cke Bat′te-ry. (*Electricity.*) One in which the elements are of horse-shoe shape, one arm copper and the other zinc, soldered together at the bow. These are laid mutually interlocking on a frame which is lowered into the trough of acidulated solution. *Niaudet,* * Am. trans., p. 18.

Mur′rhine. The agate cups of the ancient Cambay and Broach in India. Glass, and glass vases, in imitation of murrhine vases, are cited by Arrian in his Periplus of the Erythrean Sea, as exported by the Egyptian traders to southern African Red Sea ports.

Mur′rhine Glass. (*Glass.*) An imitation in glass of the celebrated ancient drinking cups, made probably of onyx or agate.

The reference by Pliny, "*Album et murrhina aut hyacinthos sapphirosque imitatum et omnibus aliis coloribus,*" is believed to describe the various kinds of glass so highly valued in his time.

At the Paris Exposition of 1878 were specimens of Roman murrhine glass, thus described:—

"There were silver goblets, or cups, with elliptical perforations half an inch long at the sides, through which an inner lining of sapphire or ruby glass protrudes like gems. The whole surface seems set with round cut and polished sapphires or rubies. The glass lining of the silver is perfect throughout, but bulges and protrudes through the openings. It is evident that the silver goblet is first made and polished, with the openings left in the sides, and then, being warmed, is lined with glass by blowing a bulb inside of it, the lining protruding through the spaces. These linings were, of course, very tight and close fitting, and could not be removed without breaking or melting the silver. These cups are copied from an original in the British Museum. Sapphires, emeralds, amethysts, and rubies were thus imitated.

"A cup in imitation of onyx — a copy of one in the treasury of St. Mark's — was mounted in silver gilt by Signor Castellani; another, also copied from one in St. Mark's treasury, and mounted in silver by Castellani, has the colors of topaz and emerald. A *pateræ* in murrhine colors, white, blue, and yellow, is a facsimile of the original in the National Museum at Naples." — *Prof. Blake.*

Mus′cle, Ar′ti-fi′cial. (*Surgical.*) An elastic caoutchouc band connecting two parts of an apparatus to draw them together, as in the case of club-foot apparatus, where a continuous strain is applied to correct deformity.

Mush′et Steel. (*Metallurgy.*) Steel made by fusing malleable iron with charcoal, graphite, or other carboneous matters in crucibles.

Mush′room. (*Electricity.*) An excrescence formed on the end of an electric-light carbon electrode. Such form from time to time, and becoming detached fall to the floor, or are caught in the glass globe. Also called *tack-heads.*

Mush′room Strain′er. An inverted dish strainer for cistern pumps, so named from its resemblance to a mushroom.

Fig. 1794.

Mushroom Strainer.

It will draw water from a level within 3″ of the bottom without disturbing the sediment. It screws on to the bottom of the pipe and is intended to rest on the floor of the cistern.

La Cour . . . . . * "*Scientific American Sup.*," 145.

Mu'si-cal Con-den'ser. A sort of telephone, invented by Varley, for the conveyance of musical sounds. It consists of receiving and transmitting apparatus. See description in "*L'Electricité*," reproduced in * "*Scientific American*," xl. 6.

Mu'sic Print'ing. Alisoff's (St. Petersburg) method of preparing clichés for music is as follows: —

The staffs, notes, and all signs are printed on fine paper, and kept in cases, like type. A glass ruled with vertical and horizontal guide lines on the reverse side, is used on which to set up the music. The gum on the face of the glass renders the paper transparent, so that the guide lines can be seen. When a page is set up it is removed, and is reproduced by photographic relief process. The cliché is made much larger than the negative required, to give facility in setting and sink small inequalities by reduction.

Mus'lin Glass. (*Glass.*) French, *mousseline.* Glass blown very thin. See MOUSSELINE.

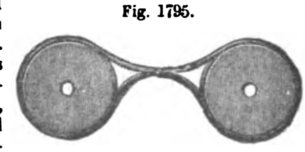
Muz'zle-piv'ot-ing Gun. A cannon which admits of firing through a very small embrasure, as the piece traverses upon a pivotal point at the muzzle.

Instance, Austrian piece, p. 537, and Fig. 43, Appendix L, "*Ordnance Report*," 1877.
Krupp . . . . . . * "*Engineer*," xlviii. 122.
Eads . . . . * Fig. 3411, p. 1566, "*Mech. Dict.*"

Muz'zle Sight. (*Rifle, etc.*) A front sight near the muzzle of the piece. It may be globe, open, etc. See list under SIGHT.

My'dri-a'sis Spec'ta-cles. *Mydriasis* is an exaggerated and chronic dilation of the pupil. Spectacles for its relief are blackened disks, pierced with small holes, which contract the area of light admitted. An affection just the opposite — the pupil being contracted to an exaggerated degree — is called *myosis.*

Fig. 1795.



Mydriasis Spectacles.

My'o-graph. An instrument for recording muscular movement.

M. Helmholtz appears to have contrived the first instrument of this character. One end of a muscle of a frog he fixed to an immovable point, and the tendon of the other end to a lever whose movements, excited by electricity, were traced on a turning cylinder. See Fig. 1, p. 51, "*Scientific American*," xxxvi. 51.

M. Marey, in his myograph, has replaced the weight which was placed on the muscle by a spring. The registering apparatus is substantially similar to that shown in M. Marey's *cardiagraph*, which see.

For other physical recording apparatus, see PNEUMOGRAPH; SPHYGMOGRAPH; PLETHYSMOGRAPH.

* "*Manufacturer and Builder*" . xi. 205.
Laboulaye's "*Dict. des Arts*," *etc.* iv., cap. "*Graphiques.*"

N.

Nach'et's Prism. (*Microscopy.*) A means for throwing and revolving an oblique pencil of converging rays upon an object under examination by the microscope. *a* Fig. 3963, p. 1803, "*Mech. Dict.*"

Næ'vus Nee'dle. (*Surgical.*) A cauterizing dermal needle for obliterating a nævus or birthmark. Heated by blow-pipe.

Nail. See, for history, and for list of varieties, pp. 1505, 1506, "*Mech. Dict.*"

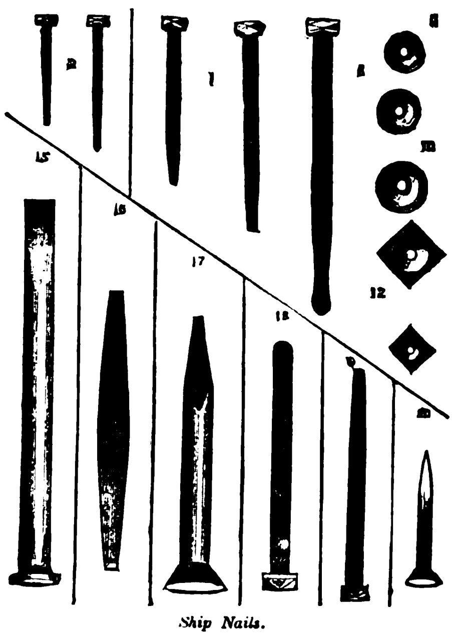
The Paris *pointes*, nails made from round wire, are now made channeled or polygonal by drawing or rolling. *Chelot.* The economy is 12 per cent. in material, and the efficiency is increased 20 to 35 per cent. according to the wood into which they are driven.

INDEX TO FIGS. 1796, 1797.

Wrought and Cut, Copper, Zinc, and Cast Metal Nails and Rivets used in Dockyards.

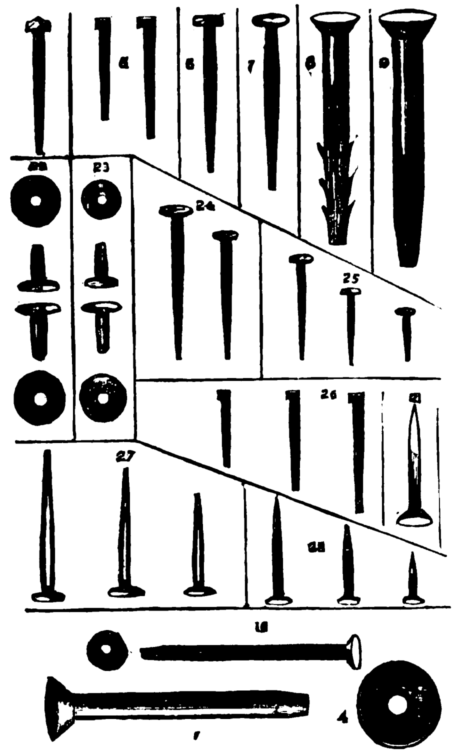
1. Rose-head copper boat nails (dumps or clench).
2. Rose-head copper flat points.
3. Deck-head copper flat points or spikes.
4. Cut copper clasp nails.
5. Cut copper brads.
6. Cut copper rose-head boat nails.
7. Cut copper flat-head boat nails.
8. Wrought copper lightning-conductor nails.
9. Wrought copper stem nails.
10, 11. Copper rose-burrs or round roves.
12. Copper square roves.
13. Wrought copper clench nails, countersunk flat-heads, round points.
14. Wrought copper clinker nails and washers.
15. Cast composition butt bolts.
16. Cast composition dowels.
17. Cast composition stem nails.
18. Cast composition spikes or flat points.
19. Cast composition dumps or boat nails.
20. Cast composition sheathing nails.
21. Cast composition slating nails.
22. Wrought copper hose and strap rivets.
23. Tinned copper hose and strap rivets.

Fig. 1796.



Ship Nails.

Fig. 1797.



Ship Nails.

24. Cut copper slating nails.
25. Cut copper or brass tacks.
26. Cut brass brads.
27. Cut zinc slating nails.
28. Wrought copper tacks.

The following varieties bear names indicative of material, application, shape, size, character of head, etc.

Band nail.
Barbed nail.
Barrel nail.
Basket nail.
Bessemer-steel nail.
Black nail.
Blued nail.
Blunt nail.
Boat nail.
Brad.
Brass nail.
Brush nail.
Brush tack.
Card tack.
Carpet nail.
Carpet tack.
Casing nail.
Chair nail.
Channeled nail.
Channel nail.
Charcoal iron nail.
Cheese-box nail.
Chisel-point nail
Cigar-box nail.
Clasp nail.
Clinch nail.
Clinker nail.
Clout nail.
Coated nail.
Coffin nail.
Coffin-lining nail.
Collar shoe nail.
Concave-head nail.
Conical nail.
Cooper's tack.
Copper nail.
Copper-plated nail.
Copper tack.
Countersunk-head nail.
Cut nail.
Cut tack.
Deck-head nail.
Diamond-head nail.
Double-pointed tack.
Drive nob.
Dump.
Escutcheon pin.
Felting nail.
Fencing nail.
Fine nail.
Finishing nail.
Flat-head nail.
Flat-head tack.
Flat nail.
Galvanized nail.
Gimp nail.
Gimp tack.
Glazier's point.
Hame nail.
Heel nail.
Hob-nail.
Hook-head brad.
Hungarian nail.
Japanned nail.
Lace tack.
Last nail.
Leathered tack.
Lightning conductor nail.
Lining nail.
Lining tack.
Looking-glass tack.
Machine finishing nail.
Miner's tack.
Nugget-head nail.
Oval-head nail.
Pail tack.
Picture-frame nail.
Plated nail.
Riveting knob.
Roofing nail.
Rose-head nail.
Saddle nail.
Serrated head nail.
Shank tack.
Sheathing nail.
Ship nail.
Shot-head nail.
Shoe nail.
Shoe tack.
Silver nail.
Slating nail.
Smooth nail.
Spike.
Steel nail.
Stem nail.
Swedes-iron nail.
Tack.
Tinned nail.
Tinned tack.
Tobacco nail.
Trimming nail.
Trunk nail.
Tufting button.
Tufting nail.
Twopenny to Twenty-penny.
Upholsterer's nail.
Upholsterer's tack.
White-metal nail.
Window-glass point.
Wire-nail.
Wrought nail.
Zinc nail.
Zinc-shank nail.
Zinc shoe nail.

Nail Gun. A device for nailing down flooring boards.

The nail is placed on the end of a tube and a rod slipped down within drives the nail home.

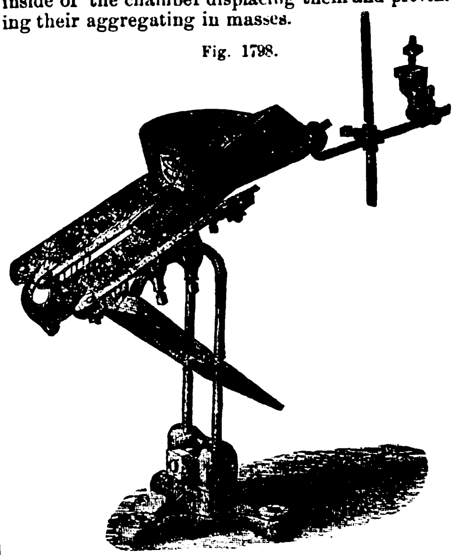
Nail In'stru-ment. (*Surgical.*) The list includes: —

Nail extracting forceps.
Sequestrum forceps.
Scalpel.
Nail cleaner and file.
Nail nippers.
Spring for inverted nails.
Splinter forceps.

It embraces the instruments of the chiropodist and the manicurist.

Nail Pol'ish-ing Ma-chine'. A tumbling box. A hexagonal chamber 19″ in diameter and 30″ long, with heads. In it the nails are placed and tumbled about against each other, points on the inside of the chamber displacing them and preventing their aggregating in masses.

Fig. 1798.



Nail Selector.

Nail Se-lec'tor. A machine, or an attachment to a nail machine, to pick out perfect nails from headless and ill-formed nails, slivers, and first cuts.

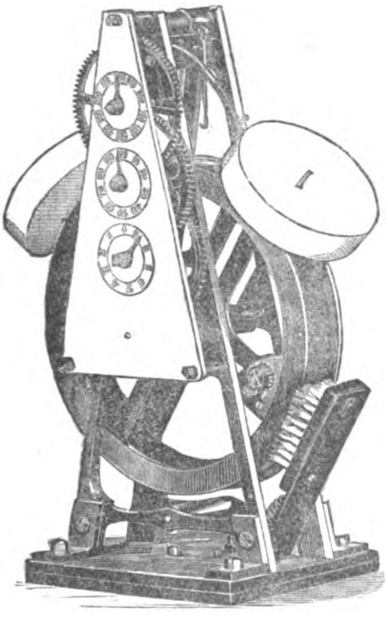
It consists of two pairs of parallel plates set at angles to each other and inclined to the floor, forming a sort of trough with a slot running the entire length of the plates. At the top and immediately under the bed plate of the nail machinery is a pan or receiver to catch the nails as they drop from the machine. The bucket is attached to the rear of the bed plate, while the upright rod is in the path of, and receives a stroke from, the griping lever. Thus every movement vibrates the selector and feeds the nails into these troughs, the plates of which are so set as to allow the points to drop into the slots, but not to permit the heads to pass through; that is, the nails are held by their heads as they are conducted down the slots in Indian file. The dirt and headless nails and slivers fall through the slot under the machine, into a receiver, while the perfect nails, held by their heads, slip to the lower end of the trough where the slot expands to a large oval, allowing the perfect nails to fall into the pan for removal.

The same plan is used in machines for feeding wood-screw-blanks.

Nap Me'ter. An instrument invented by Prof. Kittary and used for testing the wearing quality of cloth, by the Russian war office.

The instrument consists of a double-flanged wheel, faced with leather between the flanges, and having two rasps hung and weighted so as to bear upon that face; also an ordinary set of counting-wheels and dial-plates, to show the number

Fig. 1799



Russian Nap Meter.

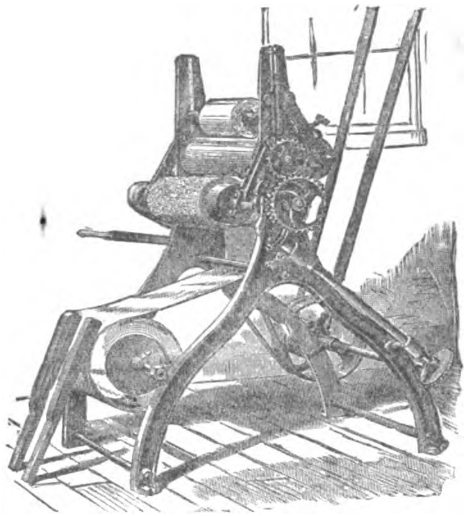
of revolutions of the flanged wheel. The cloth to be tested is wound in a narrow strip around the leathern face and secured, a light brush is provided to remove the dust, the rasps brought to bear upon the cloth, and the number of turns of the crank required to wear the cloth threadbare and smooth gives a comparative test of its durability and wearing qualities.

Nap'per. A machine for cleaning, napping, and surfacing hosiery goods.

It consists primarily of a roller on which the goods are flatly stretched, and a brush, consisting of card clothing, applied to the cloth. The machine takes in any width of cloth, from 24″ down, brushes the cloth in a flattened web, works on both sides at once, cleans off the specks, burrs, seeds, etc., raises a nap, restores the pliancy and softness — of which the washing has deprived the goods — and leaves the web in a smooth roll ready for the cutter.

The goods are smoothly stretched both in length and width over a roller having a firm and true surface. The brush cards are attached to a wooden roller, the bearings of which are adjustable parallel with the cloth roller. A lever on the left allows the pressure to be relaxed when a seam occurs.

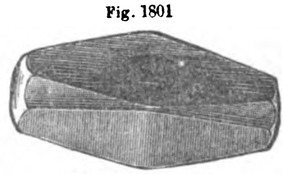
Fig. 1800.



Napper and Brusher.

Nap'ping Ham'mer (or *Knapping*). A stone-breaker's hammer, as for macadamizing, for instance.

Fig. 1801



Napping Hammer.

Naph'tha. A grade of petroleum obtained by distillation, and having a gravity from 65° to 62° *Beaumé*.

It may be considered the third in the series of products as practically utilized.

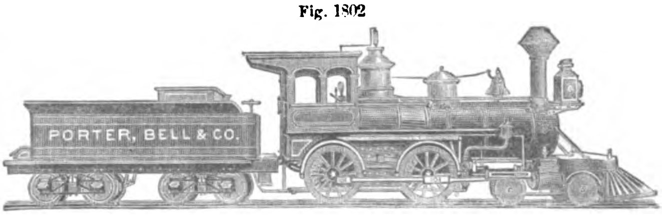
Gasoline, gravity 90° to 80° *B.*
Benzine, gravity 74° to 68° *B.*
Naphtha, gravity 65° to 62° *B.*
Kerosene, gravity 59° to 38° *B.*
See also KEROSENE; PETROLEUM.

Nar'row Gage Lo'co-mo'tive. Fig. 1802 shows a narrow-gage freight locomotive.

These engines are equalized between rear and center drivers: they also have a cross equalizer at front drivers. The center drivers are without flanges. They are easy on the track, and curve well up to a speed of 15 to 20 miles per hour. Having all their weight on drivers, and a short wheel base, they are specially adapted to hauling heavy loads on steep grades and short curves.

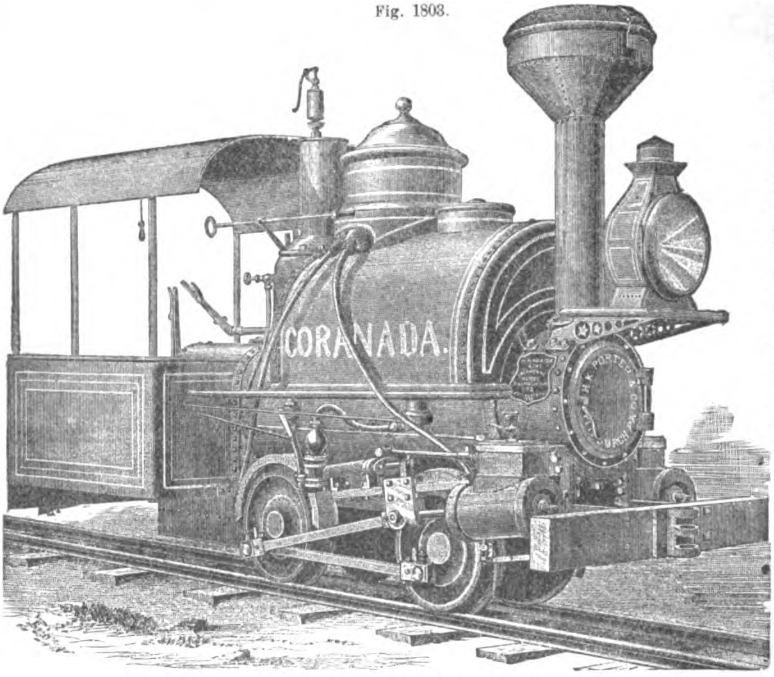
They are made of varying sizes and powers.

Fig. 1802



Narrow Gage Freight Locomotive.

Fig. 1803.



Locomotive for 20″ Gage Railroad. Arizona.

Cylinders, diameter	10″ to 12″
Stroke	16″ to 16″
Drivers, diameter	33″ to 36″
Wheel base	28′ to 29′
Weight working	28,000 to 36,000 lbs.

A locomotive for 20″ gage, built by Porter for the Longfellow Mining Company of Arizona, is shown in Fig. 1803.

The following is a description: —

Gage of track	20″
Cylinders, diameter	6″
Stroke	10″
Wheel-base	45″
Diameter of boiler at smoke-box end	23″
Number of flues	29
Diameter	1¾″
Length	72″
Fire-box, inside measurements, length	28″
Width	19″
Depth	27½″
Driving wheels, diameter	22″

Water supplied by one full-stroke pump and one number two injector.

Tank capacity, 200 gallons.

Fuel, wood; fuel room for about one fourth of a cord of engine wood.

Weight in working order, about 9,000 pounds.

Extreme width over all, 65″ at back bumper, 46″ at cylinders.

Extreme height, 100″.

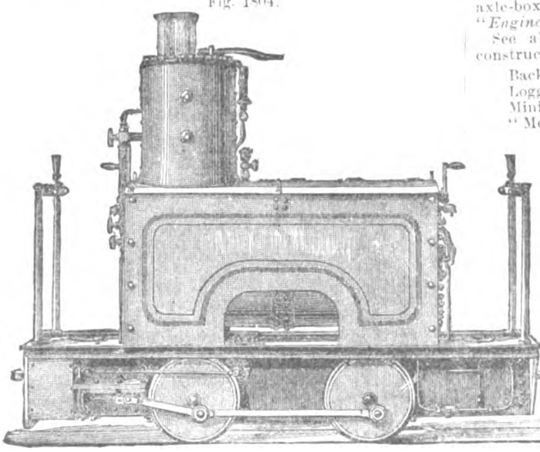
Extreme length, 158″.

Width in clear between frames, 13″.

Throw of eccentrics, 2⅝″.

The railroad is 5½ miles long, with maximum grades of 4½ per 100 and minimum curves of 90′ radius, with 16-lb. rails, and is used for the transportation of copper ore, the loaded cars coming down grade. The locomotive boiler is set on a slight incline, so that the water will be level when it is on an average grade, and the engine is intended to back up the grade. The locomotive was taken apart and boxed for shipment: as it had to be prepared for hauling by wagons several hundred miles from the railroad terminus. The frames, with cylinders and entire link motion, were all placed in a box about 8 × 4 × 3′, and weighed about 2,000 lbs.

Fig. 1804.



British 18″ Gage Locomotive.

Fig. 1804 shows a yard engine used on an 18″ railway in the Crewe Works of the London and North Western Railway, England.

The boiler is cylindrical, and is traversed by a hexagonal flue strengthened by small cross-tubes, which present very efficient heating surface. From the flue three chimneys pass up through the steam dome, each chimney being provided with its own blast nozzle. The flue is fixed on the barrel by bolted joints so that it can be readily taken out for cleaning the cross-tubes when necessary.

The cylinders are 5.5″ diameter, 6″ stroke; wheels 15″ diameter. The effective pull estimated at 1,089, steam being 90 lbs. A regulator handle as well as a reversing lever is provided at each end of the engine so that the latter can be driven from either foot-plate. The water is carried in tanks between the frames, and the boiler is fed by a simple kind of injector. The engine is carried on four cushion springs, which are simply placed in recesses cast in the top of the axle-box guide, and bearing directly on the axle-boxes. — "*Engineering*."

Chili	118	–
Bolivia	–	155
Brazil	20	411
Havana	–	–
Java	34	–

"*Mémoirs de la Société des Ingenieurs Civils,*" 1878.

" On the Denver and Rio Grande Railroad it is stated that 16 cars on the 4′ 8½″ gage unload and fill 20 cars on the 3′ gage. Thus, say —

Empty Cars, Weight.	Paying Load.	Total Dead Weight.	Total Paying Load.	Total Cars and Load.
	tons.	*tons.*		
16 cars, wide gage, 8½ tons	10	136	160	296
20 cars, narrow gage, 5 tons	8	100	160	260
Saving in total weight	–	–	–	36 tons.

Which is equivalent to 22 tons additional freight, or 23 per cent. more, assuming the cars loaded to the full capacity, and the comparison is more favorable when the cars are not filled. — *Capt. Galton's* report, "*British Reports on Centennial Exhibition.*"

Na′sal Feed′ing Ap′pa-ra′tus. One of the alternatives in case of lock-jaw, mania, choking paretics, paralysis of the throat, fractured jaw, etc.

The nasal operation may be by a simple funnel, a tube in the pharynx, or a tube directly into the stomach.

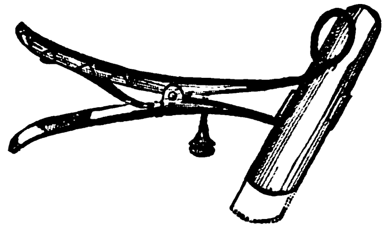
Dr. Newington's feeding device with two nasal tubes, used in Bethlehem Hospital, London, is described in * "*Lancet.*" See also * "*Scientific American Supplement,*" 2648.

Na′sal In′stru-ments. (*Surgical.*) Includes the following: —

Nasal speculum.
Nasal douche.
Nasal clamp.
Epistaxis tampon.
Laryngeal syringe.
Posterior nares syringe.
Nasal electrode.
Polypus forceps.
Polypus canula.
Epistaxis canula.
Rhinoscope.
Rhinoscopic mirror.
Nasal syringe.
Nasal feeding tube.

Na′sal Spec′u-lum. A bivalvular speculum for distending the alæ of the nose.

Fig. 1805.



Nasal Speculum.

In Dr. Shurly's nasal speculum one valve is a ring; the other a shell; they are made in pairs, rights and lefts.

See also *a, b, c c*, Fig. 5361, p. 2260, "*Mech. Dict.*"

Na-trom′e-ter. An instrument for estimating the quantity of soda contained in salts of potash and soda. *Pessier* has invented a standard form.

Nat′u-ral Steel. (*Metallurgy.*) 1. Steel made directly from the ore by the *blomary* process.

2. Steel obtained by the finery process; the carbon being removed from the molten cast iron by a blast of air directed upon the metal, which is covered with a layer of charcoal.

Nau'ti-cal Alarm. See under various heads: BUOY; FOG TRUMPET; SIRENE, etc. See also MARINE ALARM.

Nau'ti-gon. An instrument invented by Dr. Hill, of Harvard, for solving by inspection, without the use of tables, any problem in spherical trigonometry, with sufficient accuracy for the principal problems of practical navigation.

"*Scientific American*"	xxxvi. 85.
* "*Scientific American Supplement*"	314.

Nau'ti-lus. A name for the diving bell. See cap. "*Plongeur*," *Laboulaye's "Dictionnaire des Arts*, etc.," Figs. 3686, 3687.

Nav-i-ga'tion-al Sound'ing Ma-chine'. A machine for taking soundings *en route*. The invention of Sir William Thomson. See FLYING SOUNDER.

Nav'i-sphere. A nautical instrument, by M. de Magnac. It is designed to indicate, without calculation, the names of the stars above the horizon at a given moment (with altitude and azimuth), the angle of route for going from one point to another by the arc of a great circle, and the approximate distance between these points. Spherical triangles may also be solved with it. For a detailed description see the "*Comptes Rendus*" of the Academy; and for an abstract, London "*Nature*."

Nav'vy. A species of excavator, which see.

Steam navvy . . "*Scientific American*," xxxvi. 399.

Neb'u-li-zer. (*Surgical.*) A spray instrument. See ATOMIZER.

Ne-ces'saire. (*Optics.*) A circular base of polished wood, in which 6 re-agent bottles are arranged with ground capillary tube stoppers, and the whole covered with a low bell-glass to exclude dust.

Ne-cro'sis For'ceps. (*Surgical.*) An instrument for gnawing away portions of diseased bone. They are of various shapes: front cutting, side-cutting, curved on the flat, serrated, knee-curve, gouge-shaped, etc. See list under FORCEPS.

Nee'dle. The process of needle-making in 35 operations is described under cap. "*Aiguilles*," *Laboulaye's "Dict. des Arts et Sciences*," i., ed. 1877.

The following is the series of operations in the works of the *National Needle Co.*, Springfield, Mass.: —

Blank.	Brass brushed.
Reduced blank.	Eye-polished.
Reduced and pointed, blank.	First inspection.
Grooved.	Hard straightened.
Eye-punched.	Finish-pointed.
Hardened and tempered.	Finished.
Hard-bur dressed.	

See *Dr. Knight's* Report on "*Sewing Machine Needle Machinery*," at the National Needle Co.'s works, Springfield, Mass., "*Centennial Exhibition Reports*," vol. vii., Group XXII., p. 59, *et seq.*

Open-eyed needles for threading without reeving; numerous instances, Fig. 3305, p. 1517, "*Mech. Dict.*"

(*Surgical.*) The uses of the needle in surgery, for operation and suture are numerous. The names signify the material, construction, or application. Among them are the following, the greater number of which may be found under their alphabetical heads in this or former volumes: —

Acupuncture.	Hypodermic syringe.
Aneurism.	Iris.
Angular.	Ligature.
Artery.	Milium.
Canulated.	Nævus.
Cataract.	Open eyed.
Couching.	Paracentesis cornea.
Discission.	Perineal.
Eye.	Seton.
Fistula.	Staphylorraphy.
Harelip.	Stop.
Helical.	Suture.
Hernia.	Tattooing.

See also ACUS, *supra*; also NEEDLE. 2. SURGICAL, p. 1517 "*Mech. Dict.*;" NEEDLE FORCEPS, Fig. 3306, p. 1518, *Ibid.*

Making	* "*Scientific American Sup.*," 856.
	"*Scientific American*," xxxv. 403.

Nee'dle An-nun'ci-a'tor. 1. A form of optical telegraph in which a finger moving on a dial indicates a letter or a message. See DIAL TELEGRAPH, Fig. 806, p. 254, *supra*. Fig. 6238, p. 2506, "*Mech. Dict.*," Fig. 1667, p. 708, *Ibid.*

2. A form of annunciator in which several messages, numbers of rooms, or office departments may be placed on a board and a needle caused to point to either, at the option of the sender.

Nee'dle Car'ri-er. A *porte-aiguille*. A needle forceps. In the instance given, Dr. Turnipseed's clamp needle-carrier for operation in vesico-vaginal fistula, the needles clamped in the ends of the arms have a mutually approaching transverse

Fig. 1806.

Clamp Needle-carrier.

motion as the loops of the handle are partially rotated by pressing together.

Nee'dle For'ceps. An instrument to hold a needle in sewing up wounds.

In the instance, Fig. 1807, *Dr. Thornton Parker's*, the threaded needle is held by a screw clamp, and may have any

Fig. 1807.

Dr. Parker's Needle Holder.

convenient angle of presentation. The hollow handle holds needles.

Dr. Wight's needle forceps has serrated jaws, and a catch

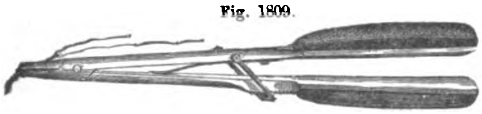
Fig. 1808.

Dr. Wight's Needle Forceps.

on each bow to lock the forceps shut. Used also in removing pieces of necrosed bone, in arresting arterial hemorrhage, etc.

Fig. 1809 shows the needle forceps of *Dr. Anatole de Gaine,*

Fig. 1809.

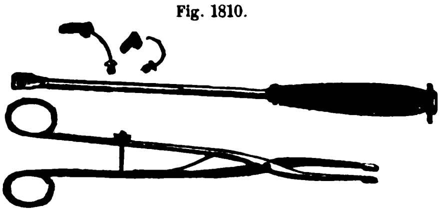


Dr. De Gaine's Needle Forceps.

of St. Petersburg. The needle is held at any angle, and the handles are locked by link and ratchet.

Dr. Turnipseed's needle holder, needles, and clamps, for uterine operations, are shown in Fig. 1810. The needles pro-

Fig. 1810.



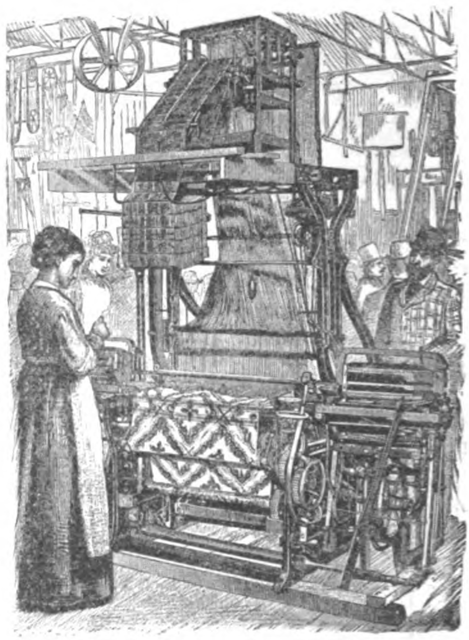
Dr. Turnipseed's Needle Forceps.

jecting transversely to the line of the handle, are thrust through the lips of the wound by a partial rotation of the handle, and the ends of the needles received in clamps, which are pressed down upon the needle, preventing retraction. The clamp closer is shown below.

Nee'dle Loom. A loom in which the weft is thrust through the shed by a rod, known as a *needle.* Fig. 1811 shows a four-harness Jacquard loom of Dienelt & Eisenhardt, for weaving ingrain carpets. It has a capacity for 16 weft threads of varying colors.

The pattern mechanism acts upon separate lifters, through which the 8 colored threads of the weft respectively pass. The colored yarn which is required for the next throw is

Fig. 1811.



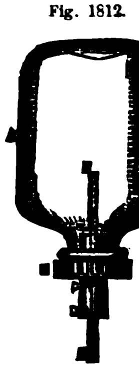
Ingrain Carpet Needle Loom.

elevated so as to be caught in the slot of the reciprocating needle and carried half way through the shed, where it is caught by a hook which has advanced from the other selvage to meet it, and the loop is drawn back to the selvage by the hook, laying two threads in the shed. The loop of the weft is then caught by a latch-needle, which is moved in a direction across the path of the weft and is knit in with the former loop.

See also Carpet Loom, p. 169, *supra.*

Nee'dle Lu'bri-ca'tor. A form of lubricator consisting of a strong globe of glass having a neck or outlet fitted with a stopper of wood, through which is a conical metal tube, forming the only exit for the oil. In order to regulate the supply of oil, a metallic feed-rod (needle) passes through the tube, and rests upon the shaft to be lubricated.

Fig. 1812.



Needle Lubricator.

Neg'a-tive. 1. (*Electricity.*) In the battery, the copper, carbon, or platinum plate.

See list in Negative columns, tables of Galvanic Batteries, pp. 367–373 *supra.*

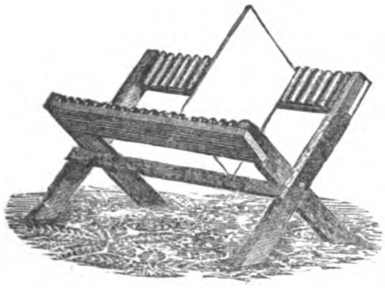
2. (*Photography.*) The cliché or picture in reverse; from it the *positive* is printed.

Neg'a-tive Rack. A frame for holding glass negatives to drip. See Fig. 1813.

Nerve In'stru-ments. (*Dentistry.*) Instruments for broaching, cleaning, filling, etc., the nerve cavity. Fig. 1814.

a. Spring tempered *nerve bristles*, for removing pulp, cleansing pulp-canals, introducing medicaments in the treatment

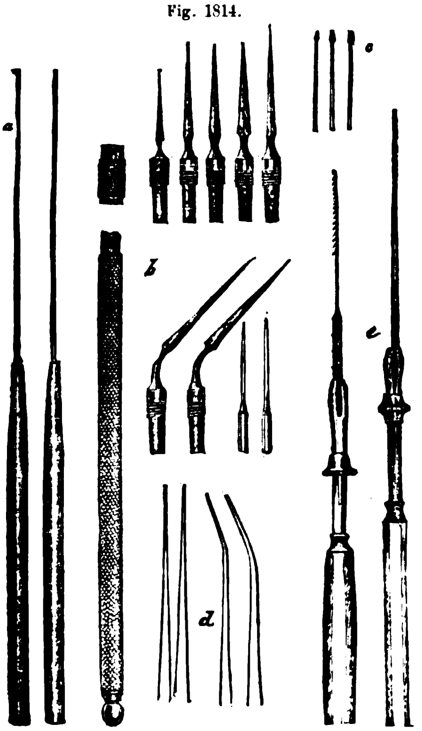
Fig. 1813.



Folding Negative Rack.

of alveolar abscess, etc. Some are roughened, some have minute hooks at the end. There are 10 in a set.

Fig. 1814.



Nerve Instruments.

b. Nerve-canal reamers, for cleansing and preparing nerve canals. A set consists of 14 triangular and 3 4-sided reamers.
c. Bur drills, used in drilling fangs preliminary to filling.
d. Nerve-cavity pluggers.
e. Nerve extractors. Barbed bristles.

Neurotome; excision of dental nerve * "*Sc. Am. Sup.*," 4114.

Nest Spring. A spiral spring of several concentric coils. *s. t.*, Fig. 1143, p. 483, "*Mech. Dict.*"

Net. For list of U. S. Patents, fishing nets, pounds, traps, seines, eel pots, etc., see FISHING NET, p. 342, *supra*.

Also: —

Garden net, over fruit trees.
Fly net.
Horse net.
Poultry netting, to limit their range. A sort of fence.
Spring net; one closed by trigger and spring; used in catching rabbits.
Banner netting, for painting signs or banners, to be suspended across a street, and avoid carrying away by the wind.
Clap net; one having hinged sections; used in bird-catching.
Hammock net; open-work netted hammock.
Vat net, for a strainer.
Quail or partridge net, for catching those birds.
Lawn-tennis net; used in the game.

Net'ma-ker's Knife. (*Fishing.*) A blade (2″) without a handle, and the heel of the blade curved so as to fit the finger like a ring.

Net'tle. (*Nautical.*) A small cord used for seizing or grafting, as the *nettles* (*knittles*) of a hammock.

Net'tle Stuff. (*Nautical.*) Small line used for seizings, worming, etc.

New Pro'cess Mil'ling. See CYLINDER MILL; ROLLER MILL; HIGH MILLING; MIDDLINGS PURIFIER, etc., and "*American Miller*," vi. 2.

Ni-au'det Bat'te-ry. (*Electricity.*) Otherwise known as the *chloride of lime battery*. The positive electrode is a plate of zinc in a solution of chloride of sodium; the negative element is a plate of coke surrounded by coke fragments and chloride of lime in a vessel of biscuit ware or parchment paper.

Nic'ol's Prism. (*Optics.*) A prism of Iceland spar so constructed as to transmit but one of the two rays into which light is divided in passing through this substance — polarizing the same.

Used in connection with the polariscope for the microscope. See POLARISCOPE.

Nick'el. See data on p. 1525, "*Mech. Dict.*"

The alloys of nickel are of considerable importance. It unites readily with iron, cobalt, copper, antimony, zinc, tin, etc.

The alloys of nickel with copper and zinc form German silver or albata (Eng.), *Argentan* (Fr.) *Packfong* (Ch). See list, p. 63, "*Mech. Dict.*"

Britannia metal is principally copper, tin, and antimony.

French recipes: —

	Copper.	Nickel.	Zinc.
1. Common *argentan*	16	4	7
2. White *argentan*	16	6	7
3. Electrum	16	8	7
4. Electrum	16	12	7
5. Tutenag	16	6	11

Solder for *argentan*; argentan (No. 1), 5 parts; zinc 4 parts.

At Krageroe, Norway, magnetic pyrites, holding on an average 1.25 per cent. of nickel, are worked by the following process: "The raw ore is smelted with slag from refining in a 13-foot 3-tuyere shaft furnace, the slag made being thrown over the dump while the raw matte, holding 3.5 per cent. of nickel, is roasted in stalls. This roasted matte is smelted in a low furnace with one tuyere, 4′ high. The slag, holding 1 to 1.5 per cent. of cobalt, goes to the ore smelting. The matte made contains 30 per cent. of nickel and 15 per cent. of copper, and is returned to the same furnace, which concentrates it to 60 per cent of nickel and 30 per cent. of copper. The sulphur is only 10 per cent. This matte is ground and roasted completely in a small reverberatory furnace, and the oxides are reduced with charcoal powder in graphite crucibles, yielding 68 per cent. of nickel and 30 per cent. of copper. By the addition of copper this product is smelted into an alloy of one of copper and one of nickel, which is marketable." — *Friedr. Bode in "Dingler's Polytechnic Journal."*

In Plazanet's nickel-plating process a bath is used of 87.5 grams of sulphate of nickel, 20 sulphate of ammonia, 17.5 citric acid, and two liters of water. A bath much used in France is formed of a solution of 4 parts of nitrate of nickel in 4 of liquid ammonia, and 150 water, in which 50 parts of sulphate of soda have been dissolved. Using a moderately weak current, the operation is at an end in a few minutes. There is no need to interrupt it by taking the objects out and brushing them. When the film of nickel is of sufficient thickness, the objects are withdrawn from the bath and dried with sawdust.

A new nickel-plating solution, said to yield beautiful results, is prepared by mixing the liquid obtained by evaporating a solution of $\frac{1}{2}$ oz. nickel in aqua regia to a pasty mass and dissolving it in 1 lb. aqua ammonia, with that obtained by treating the same quantity of nickel with a solution of 2 ozs. cyanide of potassium in 1 lb. of water. More cyanide renders the deposit whiter, and more ammonia renders it grayer.

Nick'el Bat'te-ry. (*Electricity.*) *Slater.* One form consists of a vessel with two interior porous concentric cells. In the central one is placed the plate of nickel with its excitant, dilute sulphuric or other acid; in the middle space is a solution of sesqui-carbonate of ammonia; in the outer space is a solution of sulphate of nickel, or the double sulphate of nickel and ammonia, together with suspended prisms or plates of carbon. The deposited salts are of commercial value.

Slater . .	"*Scientific American Supplement*," * 3341, 3790.
Wenzel .	"*Scientific American*," * xxxix. 150.

Nick'el Bronze. An alloy named from M. Jules Garnier, the inventor. The *garnierite*, an ore of nickel found in great quantity in New Caledonia, is worked in Nouméa, and the regulus shipped to Septemes, near Marseilles.

Here the pure metal is mixed with various proportions of copper, zinc, and tin, forming nickel bronze. Twenty per cent. of nickel suffices to give the desired tint, and to secure inoxidizability. All articles now made of brass or copper, nickel plated, can be produced in solid bronze by the same processes and with the same plant, and at practically the same cost. So made they are 20 per cent. stronger, and may generally be much lighter. Its great strength and the property of non-oxidization make this alloy eminently suitable for mathematical and musical instruments. It is used for:

Builders' fittings.	Harness trimmings.
Chains.	Arms.
Scientific instruments.	Clocks.
Art-metal work.	Bells.
Journal bearings.	Propeller journals.

Guillemin "*Technologiste*," .	xl. 364.

Nick'el-ine. The term given by Guillemin to nickel bronze. "*Technologiste*," xl. 364.

Nick'el Plat'ing. Nickel galvanoplasty for electrotypes and reproductions of works of art, has been much advanced by Boudreaux (*père et fils*), of Paris. The great difficulty attending the deposit in any considerable thickness, is owing to the tendency to exfoliate and curl, which is ascertained to be due to the absorption of hydrogen.

"This mode of accounting for the phenomenon will be readily accepted, if it be borne in mind that in this case the nickel crystallizes; that it is very porous as compared with ordinary cast nickel; and that in 12 hours it condenses 160 times its own weight of hydrogen, when it is attached to the negative pole of a rather powerful galvanic battery, in the electrolysis of water." — "*Electrician*," Feb., 1882, p. 24.

The advantage of nickel for type plates and art reproductions is evident from the fact that with about the same density (Cu., 8.90; Ni., 8.57) the resistance of nickel to mechanical pressure is about 3 times that of copper. Nickel is also much less affected by colored inks.

Prof. Stolba's Process: To a dilute solution of chloride of zinc (5 to 10 per cent.) enough nickel sulphate is to be added to impart a decidedly green color to it, and the solution is then to be heated to boiling in a porcelain vessel. The clouding of the liquid from a separation of a basic zinc salt need not be heeded, as it will not interfere with the effectiveness of the bath. The articles to be nickel-coated — first carefully cleaned of oxide or grease — are to be suspended in the solution from 30 to 60 minutes, the bath being kept at a boiling temperature. When articles are observed to be uniformly coated, they may be removed, washed in water in which a little chalk is suspended, dried and finally polished with chalk or other suitable material. By the substitution of a cobalt salt in place of the nickel, objects may be similarly coated with cobalt.

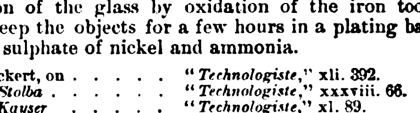
Nick'el Steel. An alloy of cemented iron and nickel. — *Boussingault.*

Nick'ing Saw. A small circular saw, used in nicking screw-heads, etc.

Fig. 1815.



Nicking Saw.

Ni-el'lo. (*Fine Art Metal-working.*) Formerly, a metallic plate was engraved and the lines run full of an alloy which became black by heat. The surface being scraped down, the effect was of a drawing in black on the gold or silver plate.

On a larger scale, brass monumental plates were similarly ornamented, and the alloy formerly used, which was of copper, silver, lead, etc., was substituted by enamel, and then by black wax.

The latter style lives in the shop and door-plates of our streets.

Artistic work is yet produced in this line, black enamel and red copper being used, the latter deposited in the electro-bath.

See also p. 1526, "*Mech. Dict.*"

One beautiful form of niello is a sort of enameling upon silver; with a paste consisting chiefly of the sulphide of the metal itself. The process is as follows: —

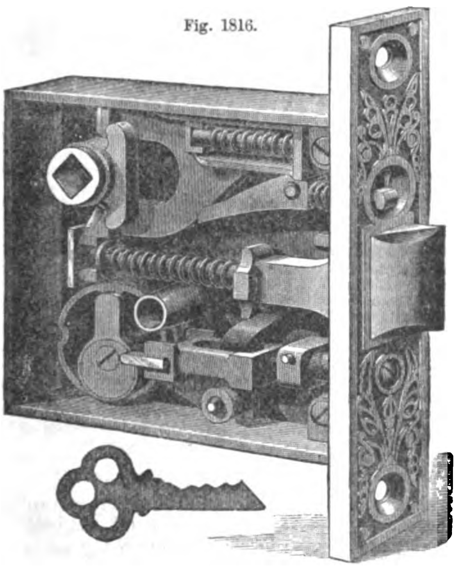
Take 4 drachms of silver, 2 oz. and 4 drachms each of copper and sal-ammoniac, 3 oz. and 4 drachms of lead, and 12 oz. of flowers of sulphur. Make a paste of the flowers of sulphur and water; put it into a crucible; afterwards melt the metals, and pour them into the crucible which contains the paste; re-cover this vessel in order that the sulphur may not take fire, then calcine over the fire until all the superfluous sulphur is driven off; afterwards finely pulverize the mass, and make, with the addition of a solution of sal-ammoniac, a paste, which introduce by means of rubbing, into the parts intended to be enameled; then clean the article, and place it in a furnace, where it is sufficiently heated to melt the paste which fills the engraved parts and makes it adhere to the metal. That done, moisten the article with a solution of sal-ammoniac, and heat it in a muffle to redness; after which you may rub and polish the article when it has become cold without fear either of altering or of detaching the enamel; it remains always of a very fine black color. — *Dr. Percy.*

Ni-el'lo Sil'ver. The composition of the Russian tula, or Niello silver, long kept secret, has been announced to be as follows: —

It consists of 9 parts silver, 1 part copper, 1 part lead, and 1 part bismuth, which are melted together and saturated with sulphur. This mixture produces the gorgeous blue which has often been erroneously spoken of as steel blue. — "*Berliner Tagblatt.*"

Night Latch. A lock operatable by key only from the outside, by handle from the inside; but capable of being fastened by a catch so that the bolt becomes immovable.

Fig. 1816.



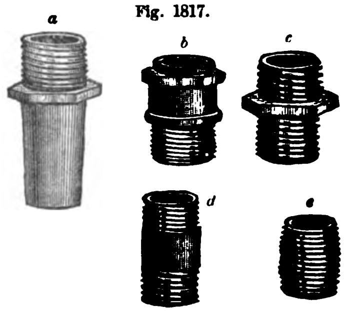
Night Latch.

The illustration shows a mortise lock, adjustable to right or left-hand doors.

Nip'pers. (*Nautical.*) An elastic hank made of strong yarns, laid parallel and marled from end to end. It is used for binding the messenger to the cable.

Nip'ple. A pipe coupling of reduced size, frequently threaded on the outside to allow the wire binding to compress the attached hose into the depressions of the thread.

Fig. 1817.



Nipples.

a. One end screw, the other solder.
b. Screw, and screw socket ends respectively.
c. Double screw.
d. Shoulder.
e. Close.

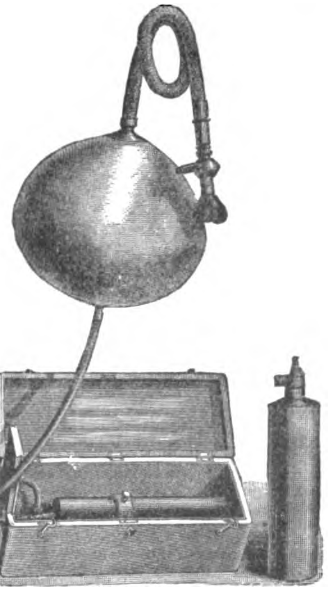
Ni'tro-gel'a-tine. An explosive agent invented by Nobel; formed by dissolving gun-cotton in nitro-glycerine, with camphor added in varying proportions, nominally 4 per cent. See BLASTING GELATINE, p. 105, *supra.*

Ni'tro-gly'cer-ine. The subject is discussed and numerous references given on pp. 1529, 1530, "*Mech. Dict.*"

See also "*Scientific American,*" xxxiv. 341; xxxviii. 58; "*Scientific American Supplement,*" 3874.

Ni'trous Ox'ide Ap'pa-ra'tus. This comprises a strong cylinder containing 100 gallons of gas compressed to a pressure of 80 lbs. to the square inch at 60° Fah. The case is provided with an iron ring and set screw, by which the iron cylinder is held in place during use, and its valve protected from injury; also, a rubber bag with rubber

Fig. 1818.



Surgeon's Case.

tube at one end for admission of gas; and a tube, terminating in an inhaler, at its opposite end.

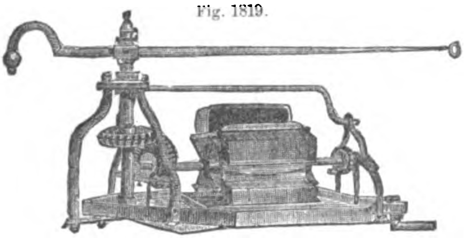
Nitrogen gas apparatus, *Blair,* * "*Sc. American,*" xxxix. 21.

Non′-con-duct′or. (*Electricity.*) Anything that does not freely transmit the electrical current, such as glass, hard rubber, dry wood, etc.

No′ri-a. (Arabic, *Na' Ura.*) A water-raising device consisting of a chain of pots or buckets. A very ancient device, still very crude in Syria and Egypt. See Figs., p. 1533, "*Mech. Dict.*"

Fig. 1819 shows a modern French form in which the main features of the ancient contrivance are preserved, but with

Fig. 1819.

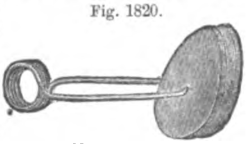


Modern Noria.

the aid of improved construction and materials. The animal, an ox usually, travels in the accustomed route; the interposition of a single pair of gears transposes the motion from the vertical to the horizontal, and upon the shaft are iron chains and buckets, the substitutes for the ropes and pots.

Nose Com′press. Pinchers for the nose, when administering gas from a *mouth*-piece, and not from a face-piece.

Fig. 1820.



Nose Compress.

Nose Glass. (*Optics.*) A *pince-nez*, or folding eye-glass, supported by grasping the nose instead of the temples.

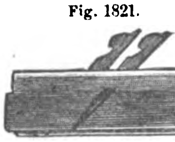
No′sing. The keeper of a lock, into which the latch or bolt engages.

No′sing Mo′tion. Refers to appliances for the perfect winding of yarn on the noses of the spindles, by an accelerating motion, to secure tightness of the yarn on the reduced diameter of the upper end of the mule spindle.

See article by Mr. Eli Spencer, of Oldham, in "*Engineering*," xxx. 510, Figs. 8 to 12.

No′sing Plane. A plane with hollow-rounded sole, for dressing the front edges of wooden treads of stairs.

Fig. 1821.



Nosing Plane.

Notch′ing Ma-chine′. 1. (*Sheet-metal Working.*) A machine for cutting the corners and notches for square boxes, hinges, etc. It has adjustable gages, works with a foot-treadle, and will cut several thicknesses at once: 12,000 notches in 10 hours.

2. A machine for cutting notches in blanks for paper boxes or envelopes. See Fig. 693, p. 222, *supra.*

Noz′zle. A discharge-pipe or ventage.

The nozzles of the placer mines in California are shown in Fig. 2616, p. 1149, "*Mech. Dict.*," and the subject also considered under Hydraulicking, p. 481, *supra.*

With the introduction of iron pipe, the nozzles were gradually enlarged, and the "Little Giant," a large cast-iron nozzle working on a swivel joint, was introduced.

Craig discovered that by rifling the Little Giant, the jet, instead of whirling and expanding, shot out straight, retaining its full force. Then Hoskins invented the second joint to the "Little Giant," which enables the raising or lowering of the nozzle, and under several inventions a nozzle has been perfected, the largest of which can be moved in any direction by a child; one of eight inches, with 200 feet head, capable of moving 3,000 cubic yards per day, being operated by one hand with ease. Thus one man, with perfect ease moves as much gravel in a day as 1,000 men could with shovels and cars.

Controlling nozzle, *Clemens*, * Fig. 685, p. 219, *supra.*

Nut Lock. A device to keep a nut from turning on the bolt. See Fig. 3350, p. 1538, where 46 illustrations are given.

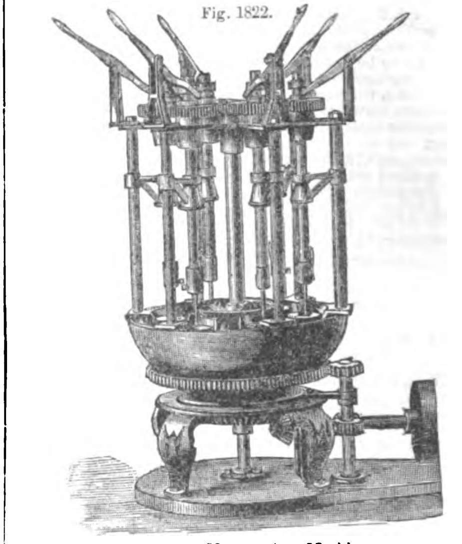
Nut-tap′ping Ma-chine′. A machine for cutting threads in punched nut blanks.

The machine shown in Fig. 1822 consists of a solid cast-iron platform, upon which rests a bowl which is kept nearly full of water; on the top of this bowl is a solid six-armed plate upon which rest six nut chucks; above this plate there

Fig. 1822.



Cleveland Nut-tapping Machine.

is a top plate supported by iron columns, in the center of which there is a vertical driving shaft, on the head of which there is a cog-wheel. Around this cog-wheel at regular distances apart are six spindles. The tap goes in at the lower end of the spindle, each spindle being over a nut-chuck on the bottom plate. The top and bottom plates being securely bolted together, have a rotary motion, and at the same time the gearing is so constructed that the six vertical spindles, being propelled by cog gear at the top, perform the work of tapping nuts as they pass around. One person can manage the machine. The water in the bowl comes up to the surface of the nut chuck or seat, and about a quarter inch of oil floats upon the water, coming over the nut (one quart of oil being sufficient for the tapping of a ton of nuts).

Each tap will hold from 8 to 12 nuts, which, fast as they are cut, rise to give place to the next one. When the tap is full, the attendant releases it, removes the nuts, and replaces the tap, which is ready to operate as before.

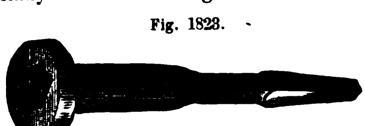
Horsfall, Br. . . .	* "*Engineer*," xliv. 148.
Boring, tapping, facing, & slotting, *Hartnell*, Br.	* "*Engineering*," xxi. 364.

Nut Wrench. A tool to be used in an ordinary brace, for the screwing on or off of bolt-nuts. Especially useful in carriage work.

Fig. 1823.



Nut Wrench.

Nut and washer gage, Fig. 7048, p. 2727, "*Mech. Dict.*"

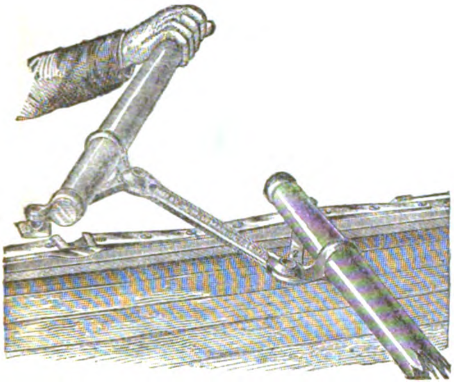
O.

Oar. The early notices of, and terms employed in, the handling of oars, are given on p. 1541, "*Mech. Dict.*"

The *Lyman* oar is a compound lever arrangement by which the oars are manipulated by a rower facing forward. Fig. 1824.

See also Rowing Gear.

Fig. 1824.



Lyman Facing Rowing Gear.

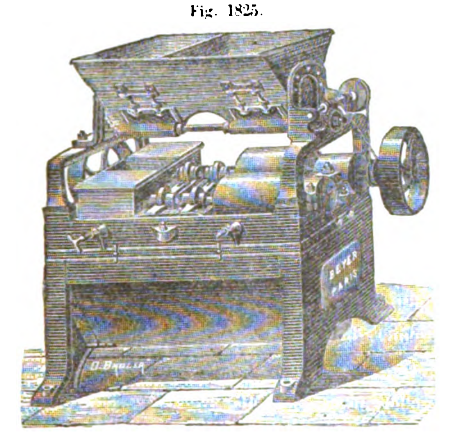
Oat Mill. A machine for coarse-grinding oats.

The machines are of two characters : —

1. For grinding horse-feed ; these are known as feed-mills or kibbling mills in England, and as *concasseurs d'avoine*, or *aplatisseurs*, in France. Their action is usually rather a crushing than a grinding operation.

2. Machines for the grinding of oats for gruel or porridge. The proper plan is to hull the oats, and then to pass them

Fig. 1825.



Oat Mill. (French.)

through a pointing machine which removes the fuzz on the point of the berry. This fuzz is said to produce an irritation of the skin which Byron mockingly calls "Sawney's violin."

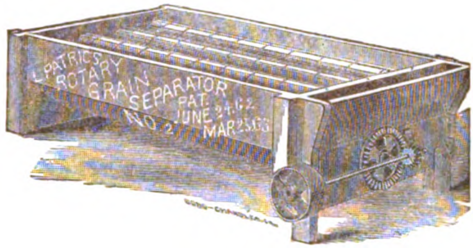
The French oatmeal machines (Beyer, Paris) proceed, however, directly upon the oats, by a double operation. The oats are passed between cylinders which simply flatten the grain without discharging any of the farina, and this product is then passed through the mill, which grinds it and discharges it into the sieves beneath, which sort it into qualities. See also • "*Scientific American*," xlii. 261.

A British form of oat-mill, *Biddell's*, is also double, but its duplicate parts are for simultaneous operation upon two grains for feed, — say oats and beans.

Oat Sep'a-ra'tor. A machine for removing from wheat the oats which are so frequently present in merchantable grain.

The grain is poured on to the slanting rollers which continually rotate and keep the berries in line ; the thinner oats escape in the intervals between the rollers.

Fig. 1826



Rotary Oat Separator.

See also Grain Cleaner, Plate XX., opp. p. 416, *supra*, where a number of devices for this purpose are shown.

Ob'e-lisk. The obelisk, to be erected to Gen. John E. Wool, near Troy, N. Y., is to be 59′ height, 5.5′ square at base, 3′ square at top. To be erected on a pedestal 15.5′ high, on a foundation of 16′. Total 90′.

Ob'tu-ra'tor. (*Add.*) 2. (*Ordnance.*) A gas check in a breech-loading piece; a Broadwell ring, for instance.

See remarks on the application of the obturator in an Austrian rifled cast-iron breech-loading howitzer of 21 cm. "*Ordnance Report*," 1878, Appendix L, p. 97, and Fig. 12.
Broadwell gas check, Fig. 1067, p. 448, "*Mech. Dict.*"

Oc'to-plex Tel'e-graph. (*Electric.*) One capable of sending 8 messages simultaneously over a single wire. An extension of the principle of the duplex, quadruplex, etc.

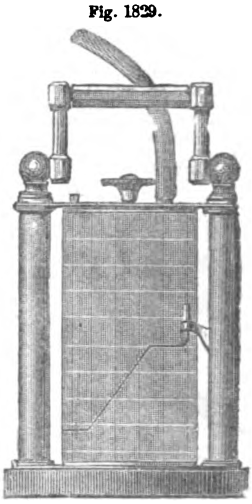
Klinkerfuss . . . . "*Scientific American*," xli. 306.

Oc'u-lists' Chair. One with special adaptations for operations on the eye.

The *seat* is adjustable for height.
The *back* for length, and for inclination.
The *head-rest* for angle.
The *cheeks* for distance, in clamping the head to hold it steady.
The *foot-rest* for length, height, and angle. *McIlroy.*

O'do-graph. An apparatus invented by M. Marey, for measuring the length and rapidity of man's strides in walking.

Fig. 1829.



Marey's Odograph.

It is a small instrument carried by the hand, and consists of a cylinder containing clockwork which causes the cylinder to revolve at the uniform rate of 2.36″ an hour. A pen is so arranged as to trace a line on paper rolled around the cylinder, and the track made by this pen shows the rapidity of the footsteps of the person to whom it is attached. An air valve is placed in the sole of the shoe, and it communicates with the instrument by means of a rubber tube leading up the trowsers' leg. Each time that the foot strikes the ground a slight puff of air is sent through the tube, causing the pen (which would otherwise mark only a horizontal line) to rise a distance equal to 0.004″. Thus a line is traced on the paper from left to right, rising at a greater or less angle with the horizontal according as the rapidity of the step is increased or diminished. If a man stepped exactly 3′ at each step it is evident that in going 3,000′ the pen would rise just 0.4″ but it was found in practice that the distance the pen was raised varied between 0.51 and 0.67″, showing that the average step varied in length from 2¼ to 2′.

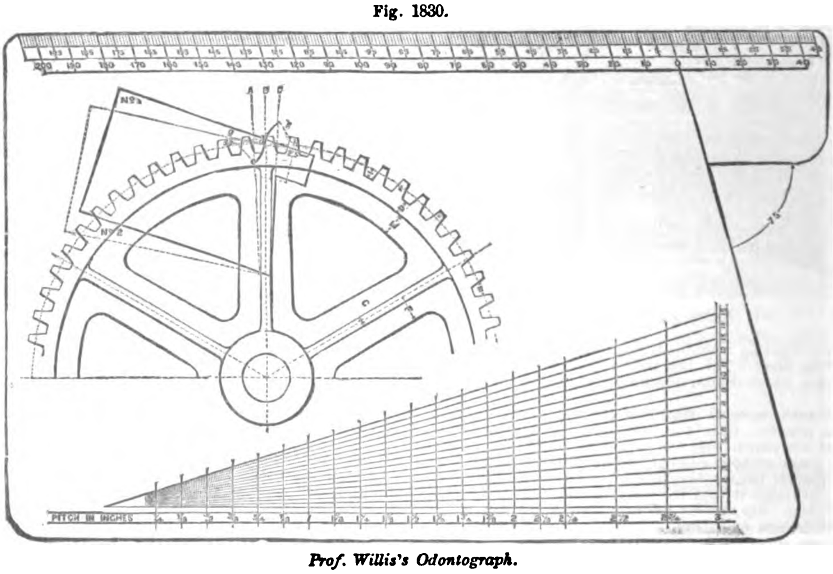
Odometer, *Gurley*, * "*American Man.*," July 25, 1879, p. 12.

O-don'to-graph. An instrument for setting out the forms of teeth of gear wheels.

By the use of Prof. Willis's instrument, shown in Fig. 1830, and tables of the *centers for the roots*, and *centers for the tops or faces*, the circular tops and roots of teeth can be readily drawn, and, considering the shortness of the arc, the shape of the tooth approximates very closely to the true epicycloidal form, and is quite correct enough for all practical purposes.

Fig. 1830 shows how the instrument is used. The wheel

Fig. 1830.



Prof. Willis's Odontograph.

selected as an example has 61 teeth, 3'' pitch. Having found the diameter of the pitch line of the wheel required, and this diameter being described, set out A C = to the pitch of the tooth, and draw the radial dotted lines as shown; bisect these by another radial line, B. For the root of the tooth, place the instrument as indicated in No. 1, and in the Table for the Roots of Teeth, which is the number nearest to that required, and in the column for 3'' pitch, will be found 37. This point must be pricked off at g, and the arc d e described. This gives the proper form for the root of the tooth. The instrument is then moved into the position indicated by the dotted lines No. 2; and 25 being the number given opposite to 60 in the column for 3'' pitch in the Table for Tops of Teeth, this point is pricked off as above described, and from the point h the arc k d is described. This gives the proper form for the top or face of the tooth.

When fixing the points g and h, it must be remembered that they will be found on *opposite* sides of the radial arm of the instrument.

***Internal Gear.* — In setting out internal gear the rule is inverted, the curve for the root becoming that which is given for the top in the foregoing instructions for using the instrument.**

***Rack Gear.* — For setting out racks the pitch line becomes a straight line, and the instrument is applied to perpendiculars drawn on it equal to the pitch.**

The numbers for pitches not given in the Tables may be found by doubling or dividing the numbers of a given pitch. As examples, if 4'' pitch is required, double the number given for 2'' pitch; or if ½'' pitch is required, take half that given for 1'' pitch.

The diagonal scale, at the lower part of the figure, gives the proportions of the various parts of wheels. These proportions give good results for wheels of ordinary dimensions; but modifications are required for very small or very large wheels. — *Appleby*.

Oil Cel'lar. (*Railway.*) A cavity in the lower part of a journal box for collecting the oil and dirt which runs off the axle at the dust-guard. — *Forney.*

Oil Cup. A lubricator placed over a journal or on a cylinder to oil the piston.

Fig. 1833.

Oil Cup.

The forms are various and may be found under: NEEDLE LUBRICATOR; OILER LUBRICATOR; TALLOW CUP, etc., in "*Mech. Dict.*," and herein.

The form shown in Fig. 1833 is a glass cup mounted on brass, provided with a hollow tube, inside of which is placed a loose-acting, solid or hollow wire, which rests upon the journal and acts as a feeder and regulator.

Oil En'gine. A name for the HYDRO-CARBON ENGINE, which see, Fig. 1420, p. 484, *supra.*

Oil'er. A LUBRICATOR. See TALLOW CUP; OIL CUP; OIL GLOBE, etc.

The oiler for wool is attached to the first breaker card.

Oil Gage. An instrument usually of hydrometer form for ascertaining the specific gravity of oils, and thereby obtaining data by which to estimate their purity.

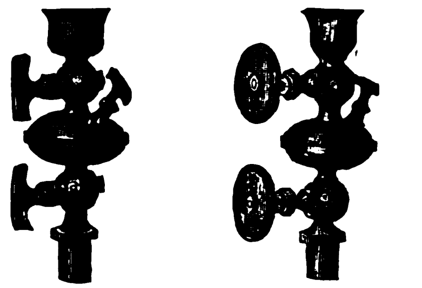
Plunge the instrument in the oil, give it time to acquire the temperature of the oil, and then observe the degree of the thermometer, as well as the degree of the hydrometer. If the thermometer is at x degrees *above* zero, an equal number of degrees must be deducted from the hydrometer degree. If the thermometer is at x degrees *below* zero, an equal number of degrees must be added to the hydrometer degree. The range of the hydrometer scale is from 22 to 50, and the following table shows the degree of certain common oils: —

Purified rape oil	38-39
Common rape oil	37-38
Olive oil	37-38
Dotter oil	32-33
Poppy oil	32-33
South sea train oil	33
Nut oil	32-33
Hempseed oil	30-31
Linseed oil	29-30

Mixtures of oils show a mean density. Oils that have been purified are rendered lighter, and show about 1° more on the instrument.

Oil Globe. A form of oiler having a globular oil chamber. In the instances shown, the devices have three cocks: one between the funnel and the chamber, one between the chamber and the steam cylinder, a third allows air to escape from the chamber when filling.

Fig. 1834.



Oil Globes.

Oil Line Pipe. A pipe laid for conveyance of petroleum. It was first introduced by S. Vansyckle, who laid a 2″ tube, 6 miles in length, in 1865. The United Pump Co. laid a 3″ pipe in 1873.

The following is the total mileage of iron pipe used for conveying oil in the oil regions of Pennsylvania: —

Lines.	Size of Pipe.		Total Miles.

The following is the mode of collecting the oil by means of the pipe lines and loading it into the cars: The pipe used is of wrought-iron lap welded, usually two inches in diameter, put together with a screw-sleeve joint. The main pumping line or lines are run from the center of production by the most direct route to the railroad station. The pipe is laid along the surface of the ground, except at road crossings or where protection is necessary. At the railroad large iron receiving tanks are erected varying from 5,000 to 20,000 barrels capacity each. These tanks are placed at a sufficient elevation above the railway to permit their contents to be run by gravity through pipes to the loading racks where the cars stand in sidings adjacent. At the necessary intervals along the pipe line, pumping stations are established for the reception and forwarding of the oil. The equipment of the main stations consists of a pump house, with two or more powerful pumps worked by steam: two tanks of from 500 to 2,000 barrels capacity each in a tank house; a telegraph office and a building to accommodate the employée in charge. From each such station, branch connecting lines lead off in every direction to the hundreds of wells that are tributary to it. At each well accurately gaged storage tanks are fixed to which the pipe line branches are attached. Before commencing to draw oil from these tanks their contents are measured and recorded; another measure and record is made after the pipe line ceases taking oil from them, and the difference in inches between the two measures forms a basis of credit to the well owner in the company's books. A memorandum receipt, known as a gager's ticket, is given to the well owner at the time the oil is run into the pipe line, and becomes a negotiable certificate. All petroleum received goes into a common store, from which deliveries are made in accordance with orders received from the owners.

"The average capacity per 24 hours of a single main of two-inch pipe may be considered as about 40,000 gallons. From 1866 to March 31, 1876, the oil passed through the Empire Transportation Company's pipes amounted to 375,810,551 gallons of crude petroleum. The quantity of petroleum held in store in tanks located in the Pennsylvania oil region may be stated as averaging from 80,000,000 to 120,000,000 gallons. In case of the conflagration of an oil tank the loss is shared by the owners, in the ratios of the relative quantities of the oil held for them at the time. From Karns City to the Alleghany Valley Railway the charge made for the use of the pipe line was 30 cents per barrel, an allowance of a little over two per cent. being made for leakage and waste." — *Capt. Galton.*

Oil Test'er. 1. A machine for testing the lubricity of oils. See LUBRICANT TESTER. See also Fig. 6330, p. 2539, "*Mech. Dict.*"

2. Apparatus for testing explosive points of burning oils. See PETROLEUM TESTER. See also Fig. 3666, p. 1676, "*Mech. Dict.*," Figs. 6317, 6318, p. 2536, *Ibid.*, and memorandum on p. 1558, *Ibid.*

A simple test for the presence of free acid in machine oils consists in pouring the oil to be tested over a layer of cuprous oxide contained in a glass. (The ash of the coppersmith answers the purpose, since it contains this oxide.) If the oil contains either free, fatty, or resinous acid, the same will attack the oxide and color the oil green in a very short time. Slightly heating accelerates the action, which manifests itself in less than half an hour. This test is said to be very delicate, and more satisfactory than any hasty test heretofore devised.

See also LUBRICANT TESTER.

Oil'-well Pump. A pump for deep wells of narrow bore. See references under OIL PUMP, *supra.*

In the *Douglas* pump, Fig. 1837, the stuffing box head has a branch pipe on which to connect the discharge pipe that leads to the tank. Forked metallic connections are screwed on to the short connecting-rod in the stuffer head and to the piston, and are themselves connected by a wooden rod to which they are attached. The piston has a brass ball valve. Threads are cut on the stuffing box head, and the lower cylinder, so as to screw on iron pipes between to lengthen out the pump to suit wells of any depth.

O-i'ron-ware. (*Ceramics.*) See FAÏENCE D'OÏRON; HENRI-DEUX WARE, *supra.*.

O'le-o-jec'tor. A name adopted by the inventor, Mr. Royle, for a new form of cylinder and slide valve lubricator.

The apparatus has an elevated reservoir from which the oil drips, drop by drop, into the cup. A valve closes against internal pressure, and at each recurrence of low pressure a jet of steam drives the oil in a spray into the chamber or cylinder.

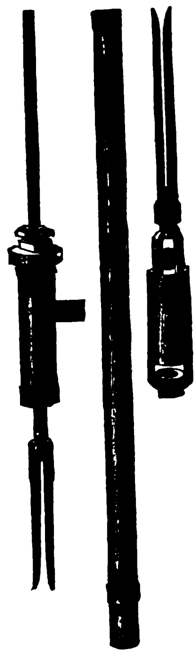
"*Engineering*"	xxx. 294.
"*Engineer*"	l. 281.

O-le-om'e-ter. An instrument on the Gay Lussac hydrometer principle, for testing the relative gravity of oils.

It has a weighted air bulb and graduated stem, and does not differ from other meters of its class, except in proportion and the index of graduations.

Another test of the purity of oils proceeds by observation of the tints of oils by adding a drop of concentrated sulphuric acid to 10 or 15 drops of the given oil on a glass plate, covering with white paper, and observing the tints produced: the method of M. Heydenreich, of Strasburg. The results obtained are affected, however, by the age of the oil; in some degree by the mode of its extraction; some oils give the same indications, and mixtures give curious combined results difficult to read.

Fig. 1837.



Oil-well Pump.

Flax seed	9.350	93.50	935.

See also tables and lists, pp. 1551-1553, "*Mech. Dict.*"

The instrument of Lefebvre, of Amiens, Fig. 1838, has a relatively large cylindrical air-chamber and a long stem. The latter is graduated for densities comprised between 9,000 and 9,400, which includes the principal oils of commerce. The figuration on the scale comprises actually only the two middle figures, the units and thousands not being shown.

For example: colza oil shows "15" on the scale. It is necessary to read 9(15)0 for the density; or 91.50 kilos for the weight per hectoliter: or 915 grams per liter.

On the left of the line of the graduations are the names of the oils. Thermometrical corrections are made by table. Adulterations give indications between the two oils so combined, according to their relative densities, and proportional quantities. The test is much complicated by the settling of the heavier oil to the bottom as the mixtures are unstable. Poppy-seed oil, mixed with olive oil, will form a lower stratum in 8 days of repose.

Earth-nut and olive oil have the same weight: hemp seed and cod-liver oil are also equal.

The oleometer of Laurot, of Paris, is for testing by means of ascertaining the density at the boiling point of water in a bath of which the vessel of oil is placed. At the temperature 100° C., the oils differ more in relative densities The instrument of Gobley, *Elaiometre*, is designed simply to test the presence and quantity of poppy-seed oil in olive and almond oils.

See *Laboulaye's "Dictionnaire des Arts et Manufactures,"* iii., "*Oléomètre.*"

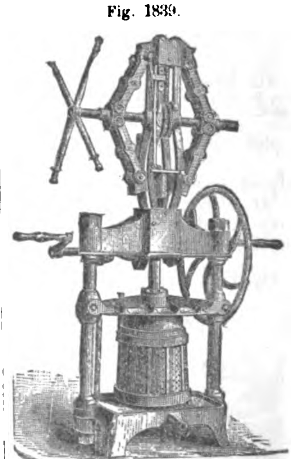
Ol'ive Press. A toggle-press for olive pressing was exhibited at the Paris Exposition, in 1878, by Samain, of Blois, France, and is shown in Fig. 1839.

It is capable of being worked by hand or steam, though the pulley is not shown in the cut. It is an eminently compact arrangement, even in that land of fruit and presses.

For the lower power the machine is worked by the crank, but when the higher power is required the upper handles are used to extend the arms of the toggle-levers. This flexor and extensor movement is found in some of our own presses, and is both powerful and compact.

A sheet-iron barrel is shown in the press, and the tampon is of a corresponding shape. Fig. 1840, however, shows a cast-iron square box or caisson for containing the olives; the wooden plug or tampon which enters the box and expresses the oil towards the side as well as downward; also the sheet-iron barrel with perforated sides.

Fig. 1839.



Toggle Press for Olives. (Samain of Blois.)

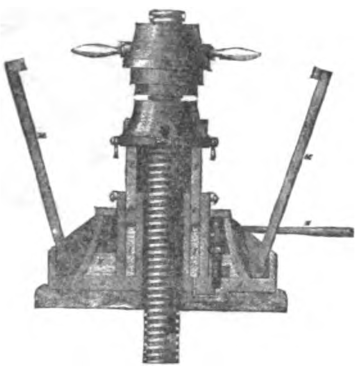
Fig. 1840.

Samain's Caisson, Tampon, and Barrel for Oil Press.

A very compact combination of the screw and hydraulic press is made by Cassan Fils, of Jallieu, near Bourgoin (*Isère*), the hydraulic mechanism being in the sole of the pressure-block beneath the nut on the screw of the press.

The vertical fixed screw has two nuts, *L* and *J*. When high pressure is to be applied, the tank *H* is filled with wa-

Fig. 1841.

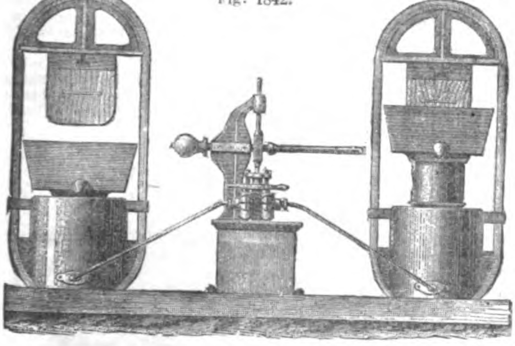


Combined Screw and Hydrostatic Press. (*Cassan, fils, Jallieu.*)

ter, the valve of egress closed, and the lever *E* of the pump worked. The sole *B* descends as the water from the cistern *H* is driven by the pump *D* into the cylinder *I* beneath the piston *C*. As soon as the circular mark *O O* appears, the course of the piston is complete.

To sustain the pressure, the props *M M* are brought beneath the nut *L*, which is adjusted in height to suit the occasion The exit-valve of the cylinder is opened, and the water returns into the tank *H*. The nut *J* and the piston *C* then descend until the latter is at the bottom of the cylinder. The valve is then closed, the pump worked, and the sole *B* driven down again as before.

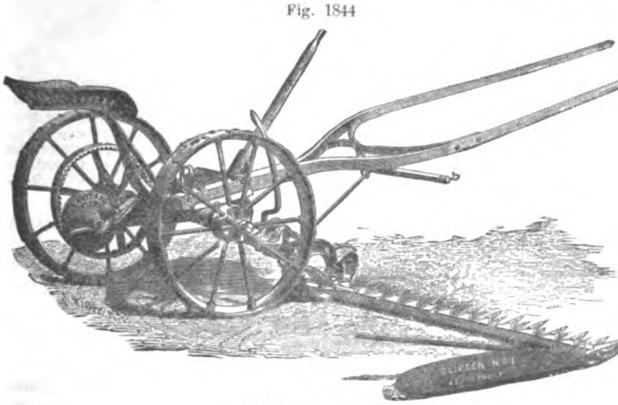
Fig. 1842.



Hydraulic Oil Press. (*Mannequin, Troyes.*)

Fig. 1842 shows a compact hydraulic press by Mannequin, of Troyes, France. It is intended for nut oil, colza, rape, and turnip seed.

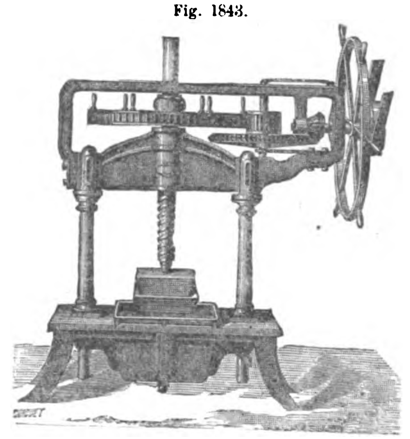
Fig. 1844



"*Clipper*" *Mower.*

The follower enters the basin, which is on the summit of the piston of the hydraulic press. The pistons are worked alternately by a single pump. The press is adapted for wine, for the extraction of the oils of seeds, nuts, olives, and fish, and also for use in sucreries, paper, and soap factories. Its power varies according to the purpose for which it is constructed, from 1,000 to 200,000 kilos.

Fig. 1843.



Press with Gearing. (*Mabille, Frères.*)

Fig. 1843 is a press operated by gearing, either by hand or power.

The press has two speeds: First by levers in the pins of the master wheel, and secondly, by the hand-wheel and system of gearing. The capacity is stated as yielding from 15 to 20 liters each filling, requiring 20 minutes for perfect extraction; 30 trips per day at 20 liters = 600 liters per 12 hours without reheating the cakes.

Olives . . . . . . "*Scientific American Sup.*," 1912.

One′-horse Mow′er. A mower of relatively small size, adapted to be drawn by one horse. That shown in Fig. 1844 has driving wheels 30″ high, and cuts a swath 3.5′.

One′-legged Rail′way. A railway supported on a single row of posts, adapted to be traversed by a saddle-shaped car.

Used in the Bradford oil region.

One form was shown in operation in Fairmount Park, at the Centennial. See also Figs. 1856, 1857, pp. 792, 793, "*Mech. Dict.*," "*Scientific American*," xxxviii. 22. See also ONE-RAIL RAILWAY; UNO-RAIL RAILWAY, *infra*.

One′-light Reg′u-la′tor. (*Electricity.*) An order of regulators for voltaic arc lights, adapted to a single light; as distinguished from a *many-light*, or *polyphote* regulator. Usually called a *monophote* regulator.

One′-rail Rail′way. One in which the car travels saddle-fashion upon a single rail. Instances are given in Fig. 1856, p. 792, "*Mech. Dict.*" See also ONE-LEGGED RAILWAY.

A one-rail railway in the oil regions of Pennsylvania is 6 miles long.

The car is not unlike an ordinary passenger car in appearance. It is 28′ long, 8′ 2″ wide, with seats running lengthwise of the car, as in street cars. Underneath the car, and running its entire length, are two sections or boxes, flush with the outer sides of the car, with sufficient space between them for the wheels and the rail they travel on. The sections serve to balance the car upon the rail, and also for the carriage of baggage. Transversely, below the floor at each end of the car are the axles of the 34″ double-flanged wheels, the upper portions of the latter being boxed in, while the lower rest on the rail. The rail is laid upon piles about 4′ high. Along the piles, on each side, about a foot below the running rail, are flat guide-rails. The inner sides of the two sections that come below the rail have friction rollers that run snugly on the guide rails. There are several points of similarity between this and the instances given on p. * 792, "*Mech. Dict.*"

See also Fig. 6872, p. 2683, *Ibid.*

O'nyx Glass. A revival of the art to which we are indebted for the Portland Vase, which is formed of a dark glass for the body and a white opal glass for the raised figures overlying it, but all in one piece.

To produce such vases it is necessary to first envelop the whole surface of the vase with a thick coating of white or opal glass, and then to cut away, down to the groundwork or body of darker glass, all that is not required to form the raised figures. These figures are sculptured and engraved in minute detail by steel points used as gravers, as stone cameos are wrought out of the solid onyx. The effects are the same.

Pieces of onyx glass were shown in the Paris Exposition (British section) in 1878.

See *Prof. Blake's* Report, "*Paris Exp.* (1878) *Reports*," iii. 286.

O'pal Glass. (*Glass.*) Calcined bones are added to the batch in the glass pot.

A Philadelphia company made a sort of opal glass under the name of *Hot-cast Porcelain*. It consisted of

Cryolite	10
White sand	20
Oxide of zinc	20

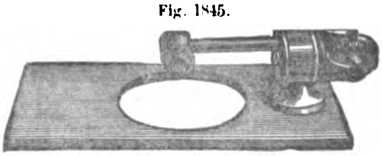
The dark discolored oxide answers the purpose very well. Fluor spar has also been used in making opal glass.

O'pal Glass Slip. (*Microscopy.*) An attachment placed on the stage of the microscope, under the object, to modify or diffuse the light passing through the latter.

O-paque' Disk Re-vol'ver. (*Optics.*) *Beck's.* A means for holding an object under a microscope so that five sides of a cube can be examined seriatim while under investigation.

The object being attached by gum to the surface of a small blackened metallic disk, this is fitted by a short stem pro-

Fig. 1845.



Opaque Disk Revolver.

jecting from its under surface into a cylindrical holder; the holder carrying the disk can be made to rotate round a vertical axis by turning the milled head on the right, which acts on it by means of a small chain that works through the horizontal tubular stem, whilst it can be made to incline to one side or to the other until its plane becomes vertical by turning the whole movement on the horizontal axis of its cylindrical socket.

The supporting plate being perforated by a large aperture, the object may be illuminated by a lieberkuhn if desired.

The disks are inserted into the holder, or removed from it with a pair of forceps constructed for the purpose.

O-paque' Il-lu'mi-na'tor. (*Optics.*) *Beck's.* See Vertical Illuminator.

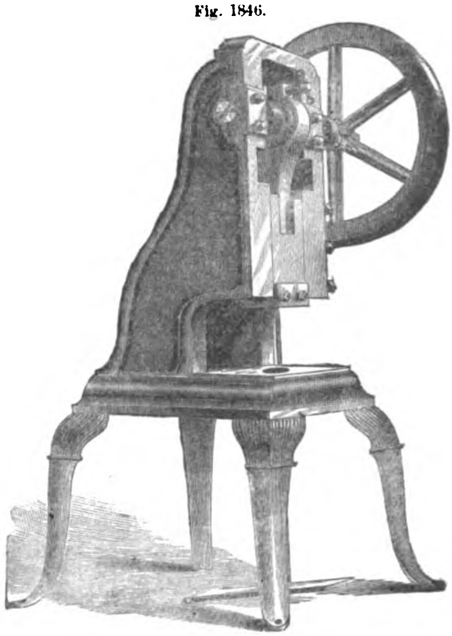
O-pei'do-scope. A phonoscope. An instrument for making sound visible. A mirror on a membrane vibrated by the voice throws a ray upon a screen. "*Scientific American*," xxiv. 5.

O'pen Back Press. One with standards set apart so that work can be put in or withdrawn, forward or rearward, and objects placed beneath the plunger, their length extending through the opening.

O'pen Bead Sight. (*Rifle.*) Also known as *aperture* sight. See Bead Sight.

O'pen Die Ma-chine'. A screw-threading machine with open die on the traveling head.

Fig. 1846.

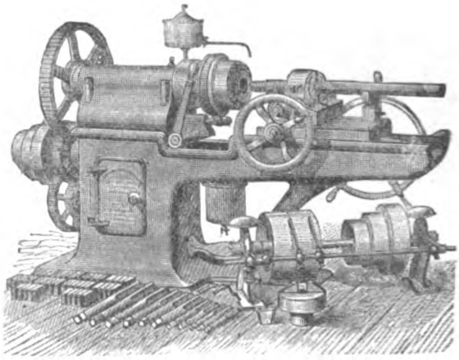


Open Back Press.

When the bolt or tube is threaded, the halves of the die are unclamped and the object removed.

The die head is constructed to receive finished blocks or cases, with inserted chasers, forming the dies, thus doing away with the labor of fitting each die or chaser to the head.

Fig. 1847.



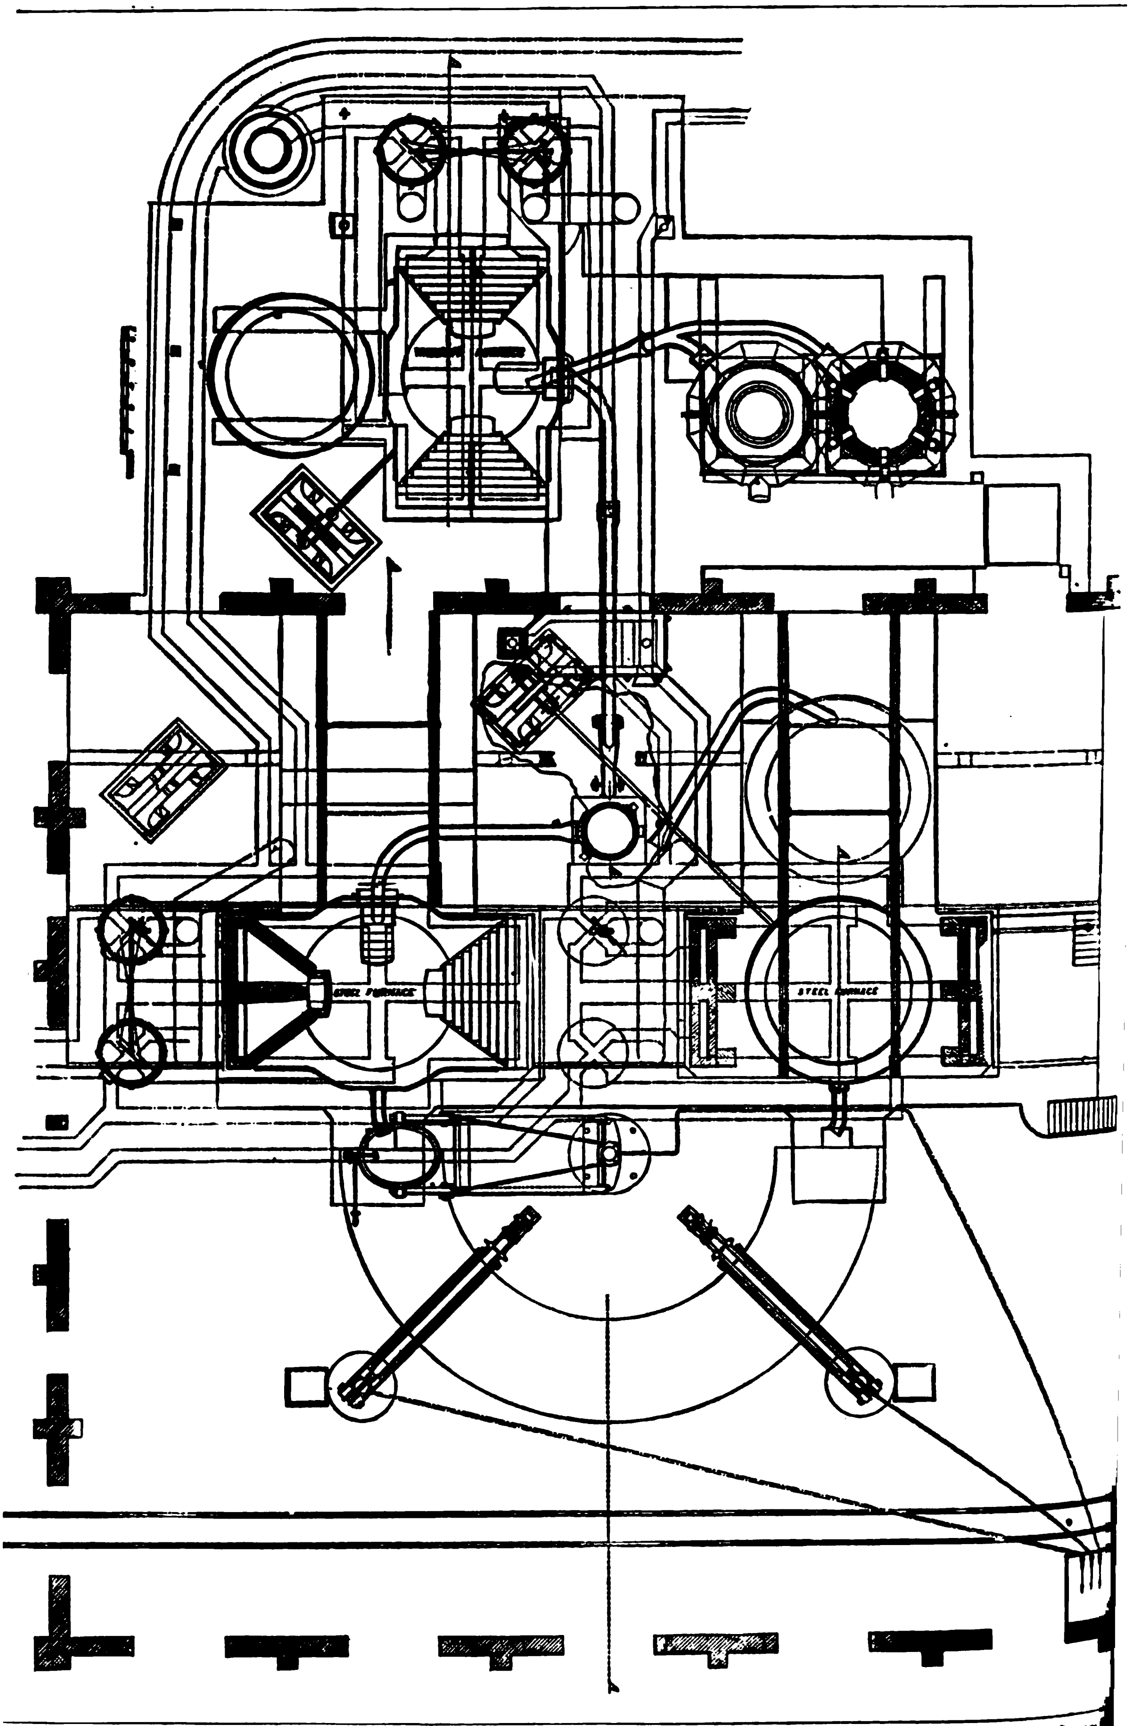
Open Die Machine.

The machine can be quickly converted into a nut tapper by removing the case dies and putting in their place a steel block to which is secured a universal chuck for holding taps. The locking device is positive and requires but one movement of the lever, by hand, or automatically, for unlocking and opening the dies, when the desired length of thread has been cut, or closing and locking. The hollow spindle allows a piece to be threaded any distance desired.

O'pen-er Lap'per. A machine for taking bale cotton, picking it, extracting dirt, and bringing it into a relatively clean and fleecy condition in a continuous lap, fit for feeding to the carding machine. See Lapper.

O'pen Hearth Fur'nace. (*Metallurgy.*) 1. A form of furnace for obtaining iron by direct process from the ore. See Blomary; Hearth.

2. A form of furnace of the nature of a puddling furnace; in the improved practice it has a remova-



XXXI. THE "PERNOT" OPEN HEARTH FURNACE, SPRINGFIELD IRON WORKS, SPRINGFIELD, ILLINOIS. See page

(General plan of open hearth plant.)

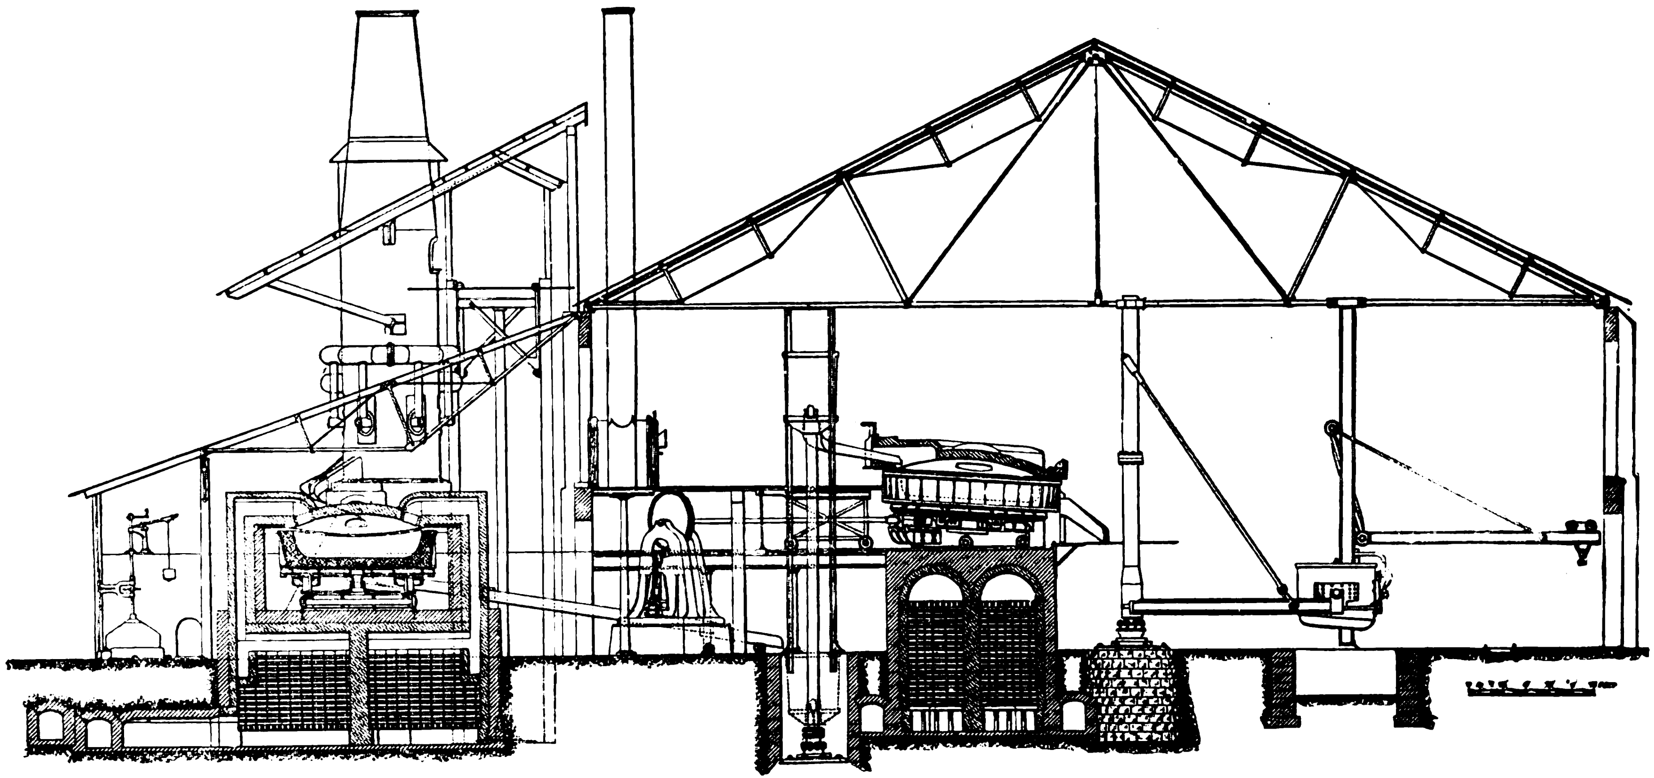


PLATE XXXII — THE "PERNOT" OPEN-HEARTH FURNACES, SPRINGFIELD IRON WORKS, SPRINGFIELD, ILL. — See page 645.

Vertical section on lines A A A, Plate XXXI.

ble hearth and is worked by the Siemens' regenerative furnace.

This regenerative furnace is shown in Figs. 1159, 1160, p. 386, *supra*; and the Ponsard regenerator in Figs. 1161, 1162, p. 387, *Ibid*.

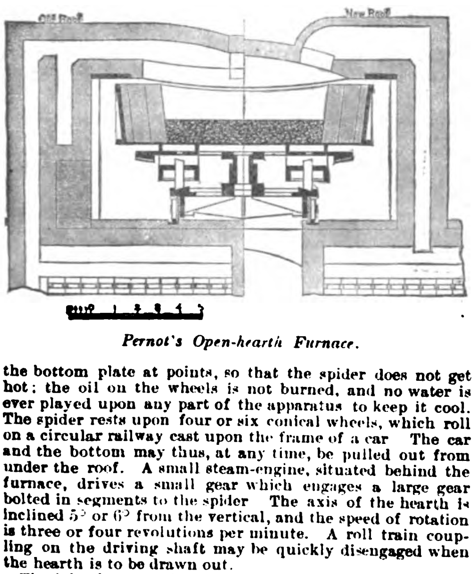
The materials employed are various: melted or unmelted pig with ore, and with or without scrap; pig iron purified from silicon and phosphorus, with or without scrap; pig iron and scrap, remelted together in a cupola, or charged hot or cold, together or separately, into the steel furnace; a pig-iron bath, and hot or cold steel or iron scrap, direct sponge or Catalan or puddled blooms charged into the bath.

The operation is, to a greater or less extent, according to the nature of the materials used, a desiliconization and decarburization of the pig iron and its dilution by already purified materials. Manganese is employed at the end of the operation to remove oxide of iron and silica, a regulated amount of manganese remaining in the product.

The Pernot hearth is shown in the engraving with its old form of roof on the left, and its new form on the right. The new roof is a flat dome, resting upon a continuous skew back, which is supported by the circular iron frame.

The hearth has a plate-iron bottom, the sides being cast-iron staves secured by an upper ring, and easily replaced. The hearth stands on a cast-iron spider, which only touches

Fig. 1848



Pernot's Open-hearth Furnace.

the bottom plate at points, so that the spider does not get hot; the oil on the wheels is not burned, and no water is ever played upon any part of the apparatus to keep it cool. The spider rests upon four or six conical wheels, which roll on a circular railway cast upon the frame of a car. The car and the bottom may thus, at any time, be pulled out from under the roof. A small steam-engine, situated behind the furnace, drives a small gear which engages a large gear bolted in segments to the spider. The axis of the hearth is inclined 5° or 6° from the vertical, and the speed of rotation is three or four revolutions per minute. A roll train coupling on the driving shaft may be quickly disengaged when the hearth is to be drawn out.

The joint between the revolving hearth and the stationary roof is simply a 3″ space filled with fire-sand, excepting a mere slit at the top, which forms a perfectly efficient packing.

The roofs and the sides of the hearth are made of silica brick. The bottom of the hearth is of fire-sand, rammed hard while the hearth is out. It is more durable and more easily set than the stationary bottom.

Each 8-ton furnace has four producers of the ordinary Siemens pattern and size.

The Pernot open-hearth of the Springfield Iron Company, of Springfield, Ill., is shown in Plates XXXI., XXXII.

This company, as Mr. A. L. Holley observed, was the first in the United States to adopt the Krupp process of washing phosphorus out of pig iron, and the second to introduce the Pernot revolving and movable hearth. The full plant of the open-hearth furnaces is shown in the plates, which are respectively a plan and vertical section.

The pig is melted down in the cupolas shown on the upper left hand, Plate XXXII., and run through a gutter to the revolving Krupp washing furnace near it. After being purified, the metal is tapped and transferred to the Pernot steel furnace. In this it is converted into steel, which is tapped into the ladle shown in position over the pit. The steel is finally cast into ingots.

The following description is by Mr. Holley: "The furnaces stand high enough to give a roomy and well ventilated floor all around them on a general level, and also a conveniently shallow casting pit. The upper part of the regenerators, and also the reversing valves, stand accessibly above ground. The charging floor and appurtenances are on the opposite side from the casting department.

"Casting is done by means of an ingot crane of large radius, rather than by the less convenient and less easily moved ingot car. There is a platform in front of the furnace for dressing the tap hole. The arrangement is such that the ladle may be moved over the ingot molds; or steel may be running into the ladle, and at the same time out of the ladle into a group of molds.

"The furnaces stand in a single line, and not in a double line, which gives a concentrated stock-yard and a producer-house (reached by the same elevated railway system) on one side, and a cool casting house and an ample ingot yard on the other side.

"The chief advantage of the revolving hearth is mechanical agitation, which facilitates the chemical reactions. The obvious and important advantage of the removable hearth is convenience and economy of repairs. The ordinary repairs do not, as in the case of the stationary hearth, interfere with the continuous production of steel.

"The sustaining and revolving gear of the hearth are not materially changed from M. Pernot's designs, except that a water-cooled center pintle has been provided to resist the lateral thrust of the hearth. The hearth must necessarily be run out for repairs, not only on the charging side, but through the charging floor. In order to avoid the trouble of taking up the charging floor when the hearth is run out, that part of the floor behind the hearth is placed on a carriage that rests on the same railway that sustains the hearth.

"The arrangement of the pig melting and washing apparatus is intended to promote the least handling of materials, and also good ventilation. It is not only economical, but it is humane, to arrange a plant so that men can comfortably perform the best work there is in them.

"The cupola furnaces are set 12′ from the open-hearth house, and their *débris* (drop bottoms) and slag discharge are directed away from other furnaces and operations. One hydraulic hoist raises materials with equal convenience to the charging floors of the cupola, the washing furnace, and the steel furnaces. The flow of fluid metal from the cupolas to the washing furnace, from the washing furnace to the ladle, and from the ladle to the steel furnaces, is short and direct.

"There is no lateral transference of melted metal in ladles; the washed-metal ladle stands permanently on a lift, and is once raised vertically. The system avoids the expenditure of time and labor attendant upon swinging, turning and drawing about heavy ladles on cranes, turn-tables, and cars.

"The hearths at Springfield prove large enough to convert 20-ton charges with facility. With cold pig (30 per cent.) and cold scrap, 24,000-pound heats have been made in 4 hours, and 40,000-pound heats in 8 hours. The regenerators prove abundantly large, and the burning gas plunges down upon and flows over the whole surface of the bath in such a manner as to heat it with the greatest efficiency. The importance of the removable hearth has been strikingly demonstrated; the hearth has been run out (by means of a chain from an ingot crane), its lining entirely replaced, and again run under the roof, in 17 hours from the tapping out of a charge. Meanwhile a part of the roof was renewed. It is now confidently expected that one of these furnaces will produce 100 tons of ingots per 24 hours from Krupp-washed material." — *Holley*.

O'pen-hearth Steel. (*Metallurgy*.) Steel made by open-hearth process, as contradistinguished from blister, puddled, Bessemer, cast, etc.

O'pen-ing Ma-chine'. See OPENER.

The *wolf* (Fr. *loup*, the action being known as *louvetage*), or French *opening machine*, is shown in Figs. 1322, 1323, article "*Laines*," *Laboulaye's* "*Dictionnaire des Arts et Manufactures*," ii., edition 1877.

O'pen Plate Wheel. (*Railway*.) A cast-iron single-plate wheel for street-cars, with openings cast in the plate between the ribs.

Fig. 1849.

Open Plate Wheel.

O'pen Re-turn' Bend. A **U**-shaped pipe-coupling having the branches open or distinct as in the letter **U**, and not close, or united by a fin.

O'pen Sheave. One having spokes, or mortised openings; in contradistinction to one turned solid, or with perfect web.

O'pen Sight. A sight, *through* which the object is viewed. See list under SIGHT, where many examples may be found, as also pin, fin, and globe sights which are not *open*.

Op'e-ra Flan'nel. A name given to a light flannel more highly finished than the ordinary article, piece-dyed uniformly in many fancy colors, and not pressed.

Oph-thal'mo-scope. 1. An instrument for the examination of the interior of the eye. The invention of Dr. Helmholtz; denoted on p. 1562, "*Mech. Dict.*" Dr. Knapp's auto-ophthalmoscope is Fig. 3403, p. 1563, *Ibid.*

2. An instrument for testing the form of the eye.

The metrical system of numbering the glasses has been adopted in preference to the statement by length of focus.

The dioptric unit, proposed by Prof. Donders at the congress of oculists in 1876, is a lens of 1 meter focal distance; and the following derivation: —

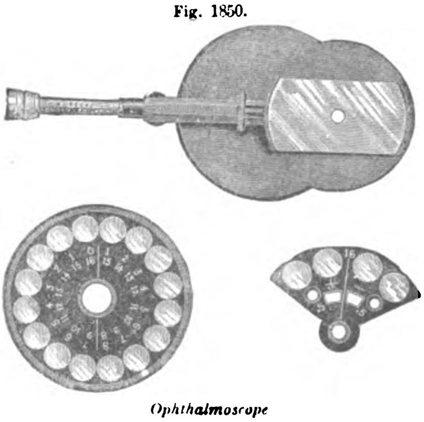
2 *d* (dioptric)	= 0.5 meter focal length.
1 *d*	= 1 meter focal length.
0.5 *d*	= 2 meters focal length.

The lens 2 *d* bears its relation to 1 *d* as having *double* the refracting power of the latter, and a lens of 5 *d* has one fifth the length of focus, or 5 times the refracting power of the lens 1 *d*, and so on.

The oculist's instrument for testing the focus of vision is a convenient arrangement of a series of lenses in a disk with numbers attached, so that after diagnosis the reading can be observed and the prescription for the optician readily given.

Dr. Loring's ophthalmoscope is shown in Fig. 1850. The single disk contains 16 glasses on the metric system, the plus being numbered in white, and the minus in red. The first row of numbers, or that just beneath the glass, shows the real value of the glass; the second or inner row shows the result of the combinations when the quadrant is in position. The quadrant rotates immediately over the disk and around the same center, and contains four glasses, — 5, — 16. and + 5, + 16 When it is not used the quadrant is beneath its cover The instrument then represents a simple ophthalmoscope with 16 perforations, the series running with an interval of 1 *d*, and extending from 1 to 7 plus, and from 1 to 8 minus. This is ample for all ordinary work, as the interval of 1 *d* is as close as even an expert usually desires, and can, with a little experience, be used for even very minute discrepancies For if in a given case the fundus is seen distinctly with 1 *d*, and a little to spare, while 2 *d* blurs the picture, we know at once that the refraction must be between the two, or 1.5 *d*. If, however, for any reason we wish to prove this conclusion, we can bring up 0 5 *d* From this glass we get successive half-dioptric from 1 to 8 plus, and from 1 to 9 minus. If the higher numbers are desired these are obtained by combinations with those of the quadrant These progress regularly up to 16 *d*, every dioptric being marked upon the disk; above this, up to + 23 *d*, and — 24 *d*, we have to simply add the glass which comes beneath the 16 *d*, turning always in the same direction.

Fig. 1850.



Ophthalmoscope

The mirror shown in the drawing is the *tilting* form.

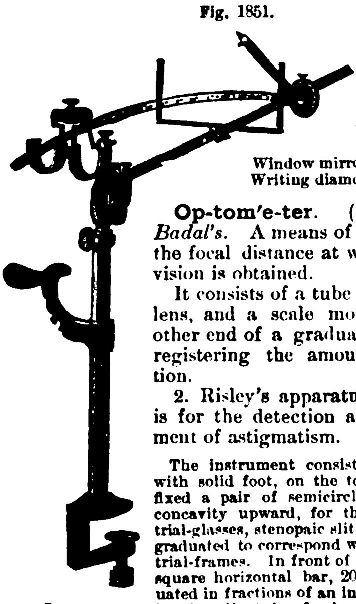
Fig. 1851.



Optometer.

Op-tom'e-ter. (*Optics.*) 1. *Badal's.* A means of ascertaining the focal distance at which perfect vision is obtained.

It consists of a tube containing a lens, and a scale movable at the other end of a graduated tube for registering the amount of variation.

2. Risley's apparatus, Fig. 1851, is for the detection and measurement of astigmatism.

The instrument consists of a stand, with solid foot, on the top of which is fixed a pair of semicircles, with their concavity upward, for the reception of trial-glasses, stenopaic slit, etc. They are graduated to correspond with the Nachet trial-frames. In front of the holders is a square horizontal bar, 20″ long, graduated in fractions of an inch. Upon this bar is adjusted a freely-moving carrier, designed to bear a series of cards containing test-types, and test-figures for astigmatism, including the system of radiating lines of Dr. Green, of St. Louis. The whole set is intended for use at 12″ instead of 20″. Some of the tests are cut in thin brass disks, and are to be used over an illuminated background, which is furnished by a plate of ground glass. A plate fitting the carrier has a central opening designed to receive these disks, and to permit their free rotation over a graduated scale corresponding to that upon the holders. One of this series of test-objects is a wire *optometer*, consisting of a brass rim, with two groups, each containing five wires, stretched one millimeter apart, the two groups crossing the center at right angles.

There is also an adjustable *perimeter*, which can be removed when not in use.

See also OPHTHALMOSCOPE, Fig. 1850 p. 646; AMETROMETER, Fig. 48, p. 29; ASTIGMATISM APPARATUS, Fig. 124, p. 53, *supra*.

O'pus Con-su'tum. Cut cloth-work or *appliqué*.

O'ral In'stru-ments. (*Surgical.*) See EAR INSTRUMENTS.

Or-ches'tri-on. (*Music.*) An instrument constructed on the principle of an organ, except that the tubes are caused to *speak* by means of a mechanical arrangement similar to that used in a *musical box*, instead of being operated by means of a key-board or manual. They frequently contain, in addition to the reed stops, metal pipes, bells, drums, etc., etc.; in fact, anything that will give forth a sound when you strike or blow it; but no strings.

See p. 108, Class XVI., vol. ii., Official Catalogue British Exhibition, 1862.

Ore Car. (*Railway.*) A small, narrow-gage car, with four wheels, used on tracks in mines for transporting minerals to daylight.

Ore Dry'er. A machine in which a vibrating screen furnishes the sand and metallic particles to the hopper, from which it is discharged in a regular stream, under the influence of the rotary agitators, into the drying cylinder below, that is kept heated by a furnace in the basement of the machine.

As the sand dries and becomes less cohesive, the rotary heated cylinder discharges it through its spout into a receptacle beneath.

Or'gan, Au'to-mat'ic. See AUTOPHONE, p. 57, *supra.*

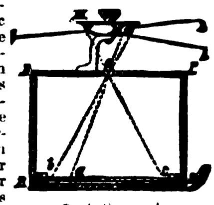
Or'o-graph. (ὄρος, a mountain.) An instrument for mapping undulating or mountainous surfaces.

As constructed by M. Schrader, the instrument consists of a circular paper-covered plate with central vertical axis carrying a sleeve which can turn round freely. On the top of the sleeve is a telescope on a frame, the movements of which in altitude are communicated to a pencil, and transformed by gearing into to-and-fro movements. If the telescope revolves in azimuth, the style describes a circle on the plate; a motion in azimuth compounded with one in altitude, gives an oblique line, an outward or inward curve; the trace produced being farther from or nearer to the central axis, as the movement in altitude increases or diminishes. A spirit-level is fixed to the telescope, and graduated scales give the value in height of any point on the tracing.

Or'o-he'li-o-graph. An instrument invented by M. Noë, and described in a memoir to the Photographic Society of France.

It consists of a camera, the sensitive plate forming the inner horizontal floor, and the lens looking up perpendicularly to the sky. Over the lens is placed a silvered mirror, half globe-shaped, completely circular on its plan and parabolic through its vertical section. The result is that an image of all surrounding objects reflected from this half-ball-shaped mirror is received by the lens, and transmitted thereby to the sensitive plate underneath, with its surface forming a right angle with the axis of the lens and circular mirror. By this means a circular panoramic view of the horizon is obtained, as seen from the station the oroheliograph occupies.

Fig. 1852.



Oroheliograph.

This instrument is described in "*Scientific American*," xxxviii., 40, * 116. See also PHOTOGRAPHOMETER, *infra.*

Or'tho-pe'dic Ap-pli'an-ces. Apparatus for talipes, eversion of the feet, etc.

See Report by *Dr. J. H. Thompson*, of Group XXIV.* in vol. ii., "*Centennial Exhibition Reports.*" *Darrach's* raw-hide appliances, *.
Dr. Stillman's "*Contributions to Orthopædic Surgery*," * "*Medical Record*," August 30, 1879.

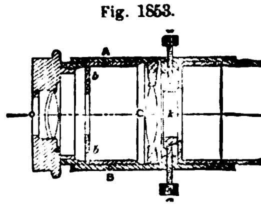
Or'tho-scopic Eye'piece. A combination of lenses used in an eye-piece, giving a very large field of view.

Kellner's orthoscopic eye-piece is achromatic, and has the advantage of an actually flat field and a straight, flat image of any object, correct in perspective, distinct in its whole extent. It consists of three lenses, the bi-convex collective lens *C*, the flatter curve of which is toward the object-glass, and the achromatic lens *O*, which is composed of two lenses, similar to the achromatic object glass. *b b* is a diaphragm.

Fig. 1853.



Orthoscopic Eye-piece.

O-ru'go. From Latin *Aurūgo*, the jaundice, referring to the yellow color induced by oxidation. The peculiar oxidation seen on ancient bronzes, and which gives character to the antique medals and statuary in that alloy.

See PATINA.

Os'cil-la'ting En'gine. Engines with oscillating cylinders are shown in Figs. 3430–3433, pp. 1578, 1579, "*Mech. Dict.*"; Screw Propeller Engines, * p. 2073, *Ibid.* See also MARINE ENGINE, *supra.*

The type of paddle engine, shown in Figs. 1854, 1855, has been more used in Great Britain than any other on account of the large power which can be provided in a very limited space; the piston rods working direct on to the crank pins, there is little loss by friction except that due to the friction of the trunnions. The steam enters the cylinders through the outer trunnions, and, when it has done its work, passes through the inner trunnions to the condenser. The air-pump is driven from a crank central between the two cylinders, and the two feed-pumps are driven by eccentrics on the paddle shaft. The bearings for the paddle shaft are carried on a strong entablature, which is supported on wrought iron stays or columns from a massive base plate.

Such engines are employed on the English channel and river steamers, and the form of the framing is such that, while light, it has strength to resist the strain caused by the work being suddenly thrown on one paddle, while the next moment the deep immersion is sufficient to greatly retard the normal speed of the engine.

O-the′o-scope. A form of radiometer devised by Mr. Crookes, which revolves, even though destitute of a glass envelope.

"The first form of otheoscope described by M. Crookes consists of a four-armed fly, each carrying a vane of thin clear mica. At one side of the glass bulb which incloses the apparatus there is a vertical plate of mica blackened on one face, and so placed that each vane closely approaches it as the mill rotates. If light be allowed to fall only upon the clear vanes, no motion is produced; but if the light shine upon the black plate the vanes instantly begin to rotate, as though repelled by a molecular wind blowing from this surface. The movement is therefore produced by pressure generated on a fixed part of the apparatus, by which the movable portion is propelled. As this driving-surface is stationary, it is not restricted in weight, size, or shape; and hence the modifications of which the otheoscope admits are well-nigh endless." — "*Chemical News*," May 4, 1877.

Out′crop. (*Mining.*) That portion of a vein appearing at the surface.

Out′er-hung Brake. (*Railway.*) One in which the brake shoes and beams are attached outside of the wheels.

Out′rig-ger Hoist. A hoisting apparatus rigged out from an outer wall; as distinct from the hatchway hoist. — * "*Scientific Amer.*," xxxviii. 223.

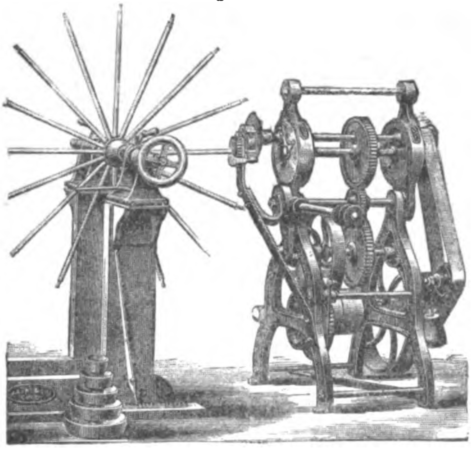
Out′side Mold′ing Ma-chine′. That form of wood-planing machines in which the cutter is on an overhung spindle; in contradistinction to the *inside* molding machines, in which the cutter is between the bearings of the spindle. See Fig. 3198, p. 1467, "*Mech. Dict.*"

Out′sole Tack′ing Ma-chine′. One which drives a headed nail with a clinching point, which buries itself in the insole, to secure the outsole to the insole for future sewing or pegging.

O'val Ten'o-ning Ma-chine'. A machine for making oval tenons, on the ends of spokes where they enter the felly. The diameter of the tenon is longer with the grain of the wood in the felly than across it. This form of tenon reduces the risk of splitting the rim in driving it on the tenon, and dispenses with wedging.

The wheel is held between the chucks, which receive the ends of the hubs, and the chucks are supported on a sliding frame, which can be adjusted to cut the spokes to the desired length. The spoke being operated on is held between

Fig. 1856



Oval Tenoning Machine.

two geared clamps, which open and close simultaneously, bringing the center of the spoke to the center of the revolving disks.

The upper part of the machine in which the disks revolve has a vibrating motion given to it by the weighted hand lever. By depressing this lever the cutter-head is brought forward, the saw cutting off the end of the spoke and bringing the cutter-head up to the spoke, cutting the oval, which may be varied in size to suit the work required.

Oval lathe . . . . *Heckendon's patent*, No. 222,901.

O-va'ri-ot'o-my In'stru-ments. (*Surgical.*) Instruments for the extirpation of ovarian tumors.

The list includes : —

Ligator.	Tissue and sac forceps.
Ecraseurs.	Tenaculum forceps.
Clamps.	Pedicle forceps.
Vulsellum forceps.	Polypus forceps.
Vulsellum hook.	Uterine fixator.
Tenaculi.	Polyptome.
Blunt hook.	

Pages 92-99, *Tiemann's "Armamentarium Chirurgicum."*

O'ver-flow' Gage. (*Gas.*) An attachment to a station gas-meter. It performs a double purpose : (1.) it maintains a true measuring water line on the inside of the drum, insuring accurate registration ; and (2) it produces a constant change of the water contained in the meter to keep it free from impurities, especially ammonia. See STATION METER.

O'ver-hand Knot. (*Nautical.*) A form of knot shown at 1, Fig. 2777, p. 1240, *"Mech. Dict."*

O'ver-head' Trav'el-ing Crane. These are of five descriptions : —

1. Those with the engine and boiler moving with the load.
2. Travelers having the engine and boiler fixed at one end of the beams.
3. Travelers driven by a line of shafting.
4. Travelers driven by a high-speed cord.
5. Travelers driven by a slow-speed wire rope.

See Fig. 3451, p. 1585 ; Fig. 5652, p. 2335 ; Figs. 6623, 6624, pp. 2618, 2619, *"Mech. Dict."*

O'ver-head' Work. Countershafting and gearing, when overhead.

O'ver-hung' Door. One supported from above, as the sliding door of barns and cars.

O'ver-hung' Head. A cutter on a spindle outside of the bearing, as in outside molding machines. Fig. 3198, p. 1467, *"Mech. Dict."*

O'ver-pick' Loom. One with a *picking* or shuttle driving arrangement above; in contradistinction to *under* or *side picking* motion.

O'ver-pres'sure Valve. A valve which opens when a predetermined pressure in a boiler has been reached. A SAFETY VALVE, which see. A special form by Hopkinson at Paris Exposition, 1878. * *"Scientific American Supplement,"* 2192.

O'ver-shot' Sep'a-ra'tor. (*Agric.*) One in which the sheaf grain is fed into the threshing machine *above* the cylinder.

O'ver-wind'ing Check. A device to cast loose a cage from the hoist when a certain height is attained, to avoid accident by carrying the cage over the drum.

In the device shown in Fig. 1857 a bar connects the cable with the chain attached to the cage in such a manner that

Fig. 1857.

Overwinding Check.

as the straight bar is drawn over the pulley or sheave, in case the cage is hoisted too high, this bar will separate and the cage be held in place by the safety clutches, while the rope or cable may pass over the sheave without taking the cage with it. This bar is formed in two pieces, having at one end a hook and at the other a socket into which the hook engages. Light rivets are driven through both hook and socket. As long as the cage is held by the cable the bar will remain as one piece ; but as soon as the cage is raised too high and the bar is drawn partly over the sheave, the bending action of the straight bar passing over the circular sheave breaks the rivets and throws the hook out of the socket.

In *Lane's* apparatus the hand of the dial does all the work of stopping the cage. When it moves round to the point which indicates that the cage is nearing the mouth of the shaft, the hand comes in contact with the end of a lever, which moves a second lever attached to the end of a rod which reaches to the engine, and there moves a third lever that gradually shuts off the steam and stops the machinery.

In the overwinder check at the Justice mine on the Comstock, at the depth of 100 feet below the top of the shaft, the cage moves a lever and half the steam is shut off at the engine. The cage then ascends at a moderate speed, passes the proper stopping-place, and moves on upward toward the sheaves. Just before it reaches the point of danger, however, the cage presses another lever, a powerful brake is ap-

PLATE XXXIII. FRENCH OYSTER IMPLEMENTS. See page 651

plied to the hoisting reel, and the cage, with its load, is instantly stopped.

Laboulaye's "*Dictionnaire des Arts et Manufactures*," iv., ed. 1877, article "*Parachute*," treating of safety apparatus for cages in mines, etc.

Ox'i-dized Sil'ver. "The color of so-called oxidized silver depends on sulphurization. The silver goods are dipped into a boiling-hot solution of calcium sulphide or hyposulphite of soda, or into ammonium sulphide, until they have taken the proper color. 'Old silver' is a coloration produced by laying on a mixture of graphite and oil of turpentine, or some fatty matter, and cleaning off with blotting paper until no more color comes away. Copper acquires a handsome look if treated in the same manner. If it is desired to varnish oxidized silver, take 18 parts alcohol, 3 red arsenic, and 1 castor oil, and a non-transparent varnish can be made, which may be diluted with its own volume of alcohol, if a particularly thin coating is wished." — "*Engineering and Mining Journal.*"

Oys'ter Cul'ture.

LIST OF UNITED STATES PATENTS.

125,470	Oyster basket of galvanized metal strips.
127,903	Oyster nursery.
130,631	Hoisting bucket, bottom of angle iron and bars.
149,921	Sunken net to keep off star-fish.
212,389	Tank for fattening oysters; may be lowered into the water.
217,558	Oyster float to keep oysters submerged.
221,326	Oyster feeder; two tanks with inclined bottoms.

Oys'ter Dredge.

LIST OF UNITED STATES PATENTS.

25,680	Dredge rope runs over a pulley; landed over roller. Reissued February 4, 1868.
27,213	Rake runs on sled runners.
35,324	Guards or fenders on dredge head.
38,436	Conical wheels to roller on gunwale.
45,904	Fenders rods to aid getting dredge over roller.
55,228	Flange on roller to aid in getting dredge aboard.
59,812	Davit on gunwale to raise dredge.
65,442	Screw roller on gunwale.
74,857	Aids in getting dredge aboard.
78,509	Construction of dredge head.
81,304	Adjustable rake, and clevis.
85,936	Guides for dredge rope to roller.
89,323	Guide bars on dredge head.
97,420	Wire basket behind dredge rake.
109,104	Winding apparatus for dredge rope.
120,463	Adjustable rake. Float to keep it vertical in sinking.
121,227	Open-arched cage to dredge.
121,249	Windlass.
122,423	Construction of dredge.
125,964	Automatic adjustment of rake.
132,668	Automatic adjustment of rake.
138,164	Construction of rake.
141,489	Bottom opens to discharge oysters.
144,169	A dredging scoop, with angular blade and prongs.
178,498	Windlass.
197,341	Windlass.
217,031	Hoisting drum and shaft.
220,827	Dredge winder.

Steam dredge, *Graves*. . "*Scientific American Sup.*," 3947.

Oys'ter Im'ple-ments. These are of various kinds, and the practices of countries and districts differ materially. See under the heads: Oyster Tongs, Rakes, etc.

Plate XXXIII. is a collection of the implements used in France, in the parks of St. Brieuc, Arcachon, and the Island of Ré on the coast of Bretagne: —

1. *a*, Wooden rake for cleaning oyster park.
   b, Rake for moving oysters.
   c, Rake for cleaning oyster parks.
2. Wooden rake for removing oysters from the parks.
3. *a*, Shovel for lifting oysters from the mud.
   b, Shovel for use in the parks.
   c, Wooden shovel for washing collectors after removal from the parks.
   d, Wooden rake for cleaning parks and basins.
   e, Iron shovel for lifting oysters from the mud.
4. Fork for hunting and destroying eels.
5. Shovel for throwing water on oysters after they have been taken from the beds.
6. Wooden rake for removing oysters from the parks.
7. Two-pronged hook for raising oyster basket.
8. Shovel to select oysters in boxes, taking only the large ones.
9. Knives for breaking up bunches of grown oysters.
10. Sifter for separating different sizes of oysters.
11. Trap for taking crabs.
12. Shovel for raking oyster beds.
13. Double hook for raising bunches of oysters.
14. Knife for breaking up bunches of grown oysters.
15. Tool for boring holes in tiles.
16. Tool for boring holes in tiles.
17. Knife for breaking up bunches of grown oysters.
18. Lock for letting water in and out of the parks.
19. Knife for breaking up bunches of grown oysters.
20. Caisson for raising oysters.
21. Caisson for breaking oysters after being taken from the tiles.
22. Iron rake for raking oyster beds.
23. Drag net with rake. (Prohibited in France.)
24. Galvanized wire basket for washing oysters.
25. Drag-net, used only under surveillance of the maritime guard.
26. Stationary nippers for separating the oyster from the tiles by breaking the tiles.
27. Hand-barrow for carrying oysters.
28. Crab-trap made of wood and galvanized wire.
29. Machine for separating oysters of different sizes.
30. Rotary rake for removing clay and slime from oyster beds.
31. Crab or lobster trap made of galvanized wire.
32. Sifter for separating oysters.
33. Machine for separating oysters and scraping them from the slates.

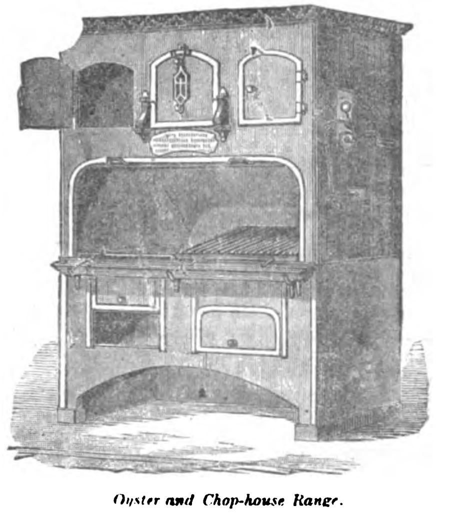
Oys'ter Rakes and Tongs.

LIST OF UNITED STATES PATENTS.

19,516	Grapnel jaws, with locking catch.
44,634	Barrel used as a drum in hoisting rakes.
58,426	Pair of rakes, with handles and lever catch.
75,550	Pair of rakes, with lazy tongs.
76,697	Hinged rake-heads.
105,495	Grapple tongs.
107,740	Grapple tongs.
135,167	Construction of rake.
201,559	Construction of tongs.

Oys'ter Range. A cooking arrangement, with the various appurtenances for stewing, broil-

Fig. 1858.

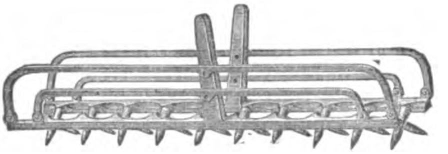


Oyster and Chop-house Range.

ing, roasting, frying, baking of oysters. To cite the possibilities would be to copy a page of a possible bill of fare.

Oys'ter Tongs. A pair of hinged claws which are approached to gather the oysters, and then form a tray in which they are contained while being lifted on board.

Fig. 1859.



Oyster Tongs.

O'zo-ke'rite. A fossil gum, found in Africa.

Cire fossil, Weil . "*Technologiste*," xxxviii. 308.
Refined . . . . "*Technologiste*," xlii. 430.

O'zone Ap'pa-ra'tus. In M. Bertholet's apparatus for the thermic formation of ozone, the gas is produced by means of the silent electric discharge.

It consists of a glass tube to which are connected two smaller tubes. A fourth tube is placed in the large tube. The apparatus is filled with a conducting liquid, water acidulated with sulphuric acid, and inserted in a test tube filled with the same. The electrodes communicate with the liquid in the interior tube, and with that in the test glass. The silent discharge takes place in the annular space between the tubes and acts on the oxygen which enters at one of the smaller tubes and escapes at the other. The gas is thus transformed into ozone through the influence of the current.

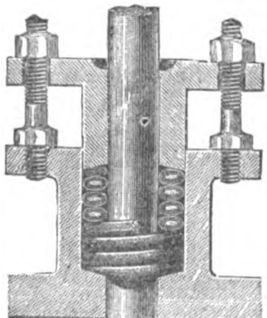
P.

Pa-chym'e-ter. A Viennese instrument which determines the thickness of paper to the 1-1000th of an inch. The micrometer caliper (which see) has much more delicate adjustment.

Pack'ing. A stuffing around a part to prevent leakage of a fluid.

Various materials and applications are given under PACKING, p. 1590; and PISTON PACKING (45 citations), pp. 1717, 1718, "*Mech. Dict.*"

Fig. 1860.



Steam Packing.

The packing shown is that of Ottenson, Hamburg. It is a wick-twisted hose stuffed with mineral and animal grease, and wound around the piston rod in a continuous coil. The gland being screwed down upon the packing expresses sufficient of the lubricant.

Wire cloth & caoutchouc.
Beardmore . . . . * "*Iron Age*," xxv., April 29, p. 9.

Pack'ing Ex-pand'er. A spring to spread the packing of a piston or valve against the surface upon which it traverses. See numerous examples in Fig. 3759, p. 1716, "*Mech. Dict.*"

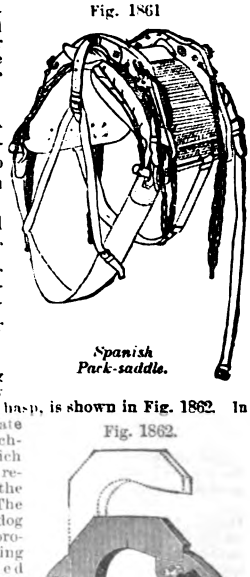
Pack'ing Gland. An annular piece, the cover of a stuffing box, which is screwed or otherwise forced into the stuffing box to expand the packing against the piston. See PACKING, *supra*.

Pack'ing Leath'er. A leathern ring on a piston or plunger, traversing against the cylinder or barrel to make a tight joint therewith.

Pack Sad'dle. The Spanish military pack saddle is shown in Fig. 1861.

The saddle has an adjustment of the sides relatively so as to fit the width of shoulders of the pack mule. The pommel and cantle afford points of attachment for the breast, buttock, and belly bands, and also for the chains by which the load is fastened on to the saddle. The body is sheet iron, with a covering of leather sewed with wire. The lining is of thicknesses of hair felt secured by clasps to the saddle and capable of being removed and opened so as to take out or add thicknesses to adjust the saddle to the shape of the mule's back.

Fig. 1861



Spanish Pack-saddle.

Pad Brack'et. A stable-wall bracket having a shape adapted to receive the saddle which rests thereon.

Pad'lock. Several forms of padlocks are shown on page 1575, "*Mech. Dict.*," and others may be found by titles in the list under LOCK, p. 1342, *Ibid.*

The *Miller* self-fastening lock, which operates by thrusting in the tang of the hasp, is shown in Fig. 1862. In the upper figure the outer plate is removed to exhibit the mechanism. *A* is the dog, which is so pivoted as to fit into a recess of the hasp *B*, when the latter is pushed down. The end of the lower arm of the dog is formed with an angular projection *C*, which, engaging against a properly shaped shoulder at the bottom of the recess, holds the hasp in the position mentioned in opposition to the upward tending force of one arm of the spring *D*. At *E* are the tumblers, either six or seven in number, according to the size of lock, all of which are pivoted on a single pin, and each provided with a bent wire spring, as shown. The upper portion *F* of one of these springs, instead of resting, as do the others, against the projecting part in the shell, is brought forward and under the straight arm of the dog, so as to force the lower arm of the latter against the tumblers, and causes the projection *C* to enter notches in the tumblers, when the same are brought into proper position.

Fig. 1862.

Self-locking Padlock

Owing to the angle of the

notches in the tumblers, and to the dog being in a solid piece, it is only when all the notches coincide that the projection can enter them. By means of varying the positions of the notches on the tumblers, a special key is required to operate each, in order to render all the notches coincident. The key having peculiarly formed projections and recesses at its extremity, acts on all the tumblers simultaneously, and lifts each the exact distance required.

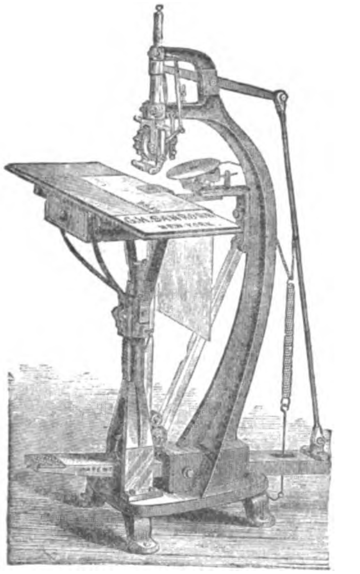
The key is merely pushed in the proper aperture, freeing the dog as above described, and allowing the hasp to be acted upon by the spring *D*, and so lifted upward into the position indicated by the dotted lines, in Fig. 1362. Motion in this direction is then limited by the catch *H*.

Lock, *Miller*. . . . * "*Iron Age*," xxi., April 4, p. 1.

Pa'ging and Num'ber-ing Ma-chine'. The principle of the change of numbers in paging machines is described under that head, p. 1596, "*Mech. Dict.*"

Sutcliff's paging and numbering machine is shown in Fig. 1863. It is adapted for paging blank books, for numbering bonds, checks, drafts, policies, tickets, etc.

Fig. 1863



Paging and Numbering Machine.

The cut represents the machine ready for numbering, with the table up, and the smut-band removed. For paging books, as large figures are used, it is necessary to change the head, and replace the smut-band to prevent smutting the pages. This machine is compact, has two inking rollers, both of which ink the figures, an adjustable gage, and an endless smut-band. With a four-disk head it will number or page to 10,000; with six disks will number to 1,000,000.

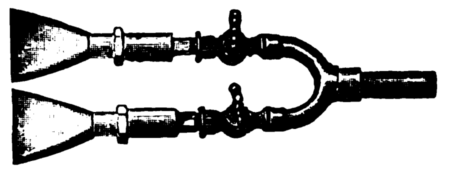
Pail and Tub Ma-chin'er-y. See Fig. 3484, p. 1596, "*Mech. Dict.*"

In Whitney's pail and tub machinery the wood is sawn into planks the breadth of the staves, then cut into pieces of the proper length; these are again sliced into staves by a stout cylindrical saw with the teeth formed upon its extremity; the staves are now baked in an oven, then have the edges planed by a suitable machine to the required form, the pail is set up with a temporary hoop and slipped upon a conical chuck, there held by an end-washer, plate, and bolt, and the hoop removed. A slide-rest tool is then passed along the exterior surface, the temporary hoop is again applied, and then pushed into a box chuck, another slide-rest tool is passed down the interior and finishes at one move. When at the bottom, the workman with the left hand in an instant moves another chisel to form the groove for receiving the chine of the pail-bottom and chamfers the upper edge. The boards for the bottom are planed on both sides in an ordinary machine, then sawn into squares; the squares are gripped between revolving plates and cut to the proper diameter by a parting tool, when a second tool bevels the edge to fit the pail.

Paint Burn'er. An instrument for softening paint by heat or gas, in order that it may be removed. Fig. 3188, p. 1597, "*Mech. Dict.*"

Reed's atmospheric paint burner, for softening paint with gas, is shown in Fig. 1864. The two burners are flattened out so as to present a wide sheet of flame.

Fig. 1864.



Paint Burner.

Acid proof paint	. .	"*Scientific American*," xxxv. 278.

Cleaning oil paintings	.	"*Scientific American Sup.*," 1994.

Paint'ing Ma-chine'. A machine for painting of laths or strips of wood, or iron, evenly and thoroughly on both sides and on the edges. — *Roberts*, Br.

There are two feed rollers, the lower of which is grooved spirally, and has at each end a paddle-wheel with floats so arranged as to dip into a tank of thin paint, and, carrying up the liquid, throw it on the rollers and on the strips which may be fed between them. The strip or lath is thus washed with paint on both sides, and it next passes between two long brushes which distribute the color evenly, and remove and return to the tank below any excess of paint.

The speed of the small machine, which takes in a lath 3″ wide and ¼″ thick, is estimated at 6,000 running feet, say 600 laths per hour, on both sides and both edges; requiring the attention of one man and two boys. The rollers and the brushes have a vertical adjustment by means of screws.

Paint Mix'er. A can with shaft and paddles, resembling an upright churn. Used to mix paint with the necessary oil, turpentine, varnish, or what not. The shaft is driven by hand-crank and gearing, and the outlet is by faucet with a gate.

Pa-lam'poor. (*Fabric.*) A bed cover. A highly decorated printed cotton goods of India. See PALLAMPOOR, p. 1599, "*Mech. Dict.*" Also p. 427, *Ibid.*

Pal'a-tor'rha-phy In'stru-ments. (*Surgical.*) For sewing up a cleft palate, synonymous with staphylorraphy. See Fig. 5563, p. 2309, "*Mech. Dict.*"

Pa'le-o-phone'. A writing telephone. *Cross.* "*Technologiste*," xl. 48.

Pa'li-er Glis'sant. A bearing where the journal runs on a film of lubricant or water.

See Fig. 3496, p. 1599, "*Mech. Dict.*" See also HYDRAULIC PIVOT; WATER BEARING, *Ibid.*; and JOURNAL BEARING, Fig. 1499, p. 516, *supra*.

Palier graisseur, *Béthouart et al.*	. . . . .	* "*Technologiste*," xl. 397.
Palier graisseur, *Delerm*		* "*Technologiste*," xxxix. 278.

Pa-lis'sy Ware. (*Ceramics.*) A faïence with stanniferous glaze and raised decorations made by Bernard Palissy, of Saintes, France, about 1555.

His work was principally representations of aquatic objects: fish, shells, lizards, etc., in relief.

Fig. 1865.

Palm.

Palm. The sailor's thimble: made of leather, with a hole for the thumb and an abutment over the palm of the hand for the needle.

Pan'el Pla'ner. 1. A planing machine for working on thin stuff for panels, dressing the surface, and feathering the edges to enter the grooves in the stiles.

2. A machine for rabbeting down the edges of panels in order to leave a raised central portion. A PANEL RAISER, Fig. 3502, p. 1602, "*Mech. Dict.*"

The boards are fed through the machine by two pairs of rollers, all of which are driven so as not, by slipping, to mark the surface. The cutters are secured to a wrought-iron adze block, and the pressure bars hold the board firmly on either side of the cutter head.

Fig. 1866.

Bonelli	"*Mech. Dict.*," p. 784.

Pan-tel'e-phone. A microphonic transmitter, so named by its inventor, *Prof. Leon de Locht*, Liège.

It is sensitive to sonorous vibrations emanating at a great distance. It is capable of transmitting words spoken at 45′ from the apparatus to a distance of several miles through the medium of receiving telephones. It is composed essentially of a movable plate carrying a carbon contact, which presses against a disk of carbon or metal, silver or platinum.

Pan'to-graph En-gra'ving Ma-chine'. A system of etching calico rolls by means of a pantographic apparatus.

A copy of the pattern to be engraved is enlarged by camera to any required size ; this copy is then laid on a table forming a part of the machine ; and over the lines of this copy the operator guides a stylus or tracing point, which, by being connected with suitable mechanism, causes a number of gravers or diamond points to come in contact with the roller, each point duplicating on its surface the exact copy, in miniature, of the original design. The roller is covered with a coating of varnish, and upon this coating the figures are etched. After this, the roller is immersed in nitric acid, where it remains till the metal has been eaten away to the required depth excepting where the varnish preserves the surface from the action of the acid.

Pan-to-graph'ic Cut'ter Form'ing En'gine. A milling machine for forming cutters for gear cutting.

An arrangement by which from a templet of the correct size, any required reduction may be made in the size of the cutter. preserving the correctness of shape. The gear cutter is turned nearly to the required form ; the notches are cut in it, and the duty of the pantographic engine is merely to give the finishing touch to each cutting edge and give it the correct outline. — *Pratt & Whitney.*

Pan-tom'e-ter. (*Surveying.*) An instrument by Fouquier, for obtaining angular measurements. It is composed of two vertical cylindrical drums of the same diameter, one superposed on the other axially.

The lower has a socket beneath which rests on a staff, and the upper one turns on the axis and has two planes diametrically perpendicular acting as alidades. An object is viewed through one and the angle determined by aid of an opening and wire in the lower drum, then bring on the other object the opening and wire in the upper drum. The angle sought is then equal to that of the diametric planes of the two drums, and is read directly by aid of the divisions with which they are furnished.

Pan-top'ol-lite. A German dynamite containing a small proportion of naphthaline dissolved in the nitro-glycerine. Intended to prevent the formation of disagreeable nitrous vapors during explosion.

Pa'per. The statement, adopted from Pliny, and given on p. 1604, "*Mech. Dict.*," as to the mode of making paper from the *papyrus* reed, requires correction.

Pliny said a great many things from knowledge and still more from information, and in this case is not correct. He describes the cutting of the reed stalks into lengths and separating " by splitting the successive folds of the stalk with a needle."

A critical examination of the papyrus stalk shows that it does not have successive folds, but its triangular stalks have a single envelope and the pith on the inside must have been divided into slices by a knife, either in strips of such width as the side of the prism admitted, or else shaved round and round (like the operation of cork making) making a long spiral slice, as practiced from time immemorial in China and Formosa in making what is popularly called, by us, " rice paper," which has no rice in its composition but is a spiral shaving, made as just described (of the papyrus), from the pith of the *Aralia papyrifera*, which grows wild in Formosa. See p. 1938, "'*Mech. Dict.*"

Materials for paper, shown or cited at the Centennial Exhibition, 1876 : —

Common and Botanical Names.	Exhibited from.
Maguey, *Agava Americana*	Mexico, etc.
Maguey, *Agava Mexicana*	Mexico.
Spanish broom (*Esparto*), *Macrochola tenacissima* .	Spain.
Banana leaves, *Musa*	Egypt.
Halfa, *Ligeum Spartium*	N. Africa.
China grass (Rhea), *Bæhmeria nivea*	Victoria.
New Zealand flax, *Phormium tenax*	New Zealand.

Agave, ***Fourcroya gigantea***	Tropical America.
Cow-itch tree, ***Lagunaria Pattersoni***	Norfolk Island.
Spanish bayonet, ***Yucca aloifolia***	Victoria.
Spanish bayonet, ***Yucca filamentosa***	Victoria.
Adam's needle, ***Yucca gloriosa***	Victoria.
Adam's needle, ***Sparmannia Africana***	Africa.
Adam's needle, ***Hibiscus heterophyllus***	Queensland.
Queensland hemp, ***Sida retusa***	Queensland.
Victorian hemp, ***Sida pulchella***	Victoria.
Queensland grass cloth, ***Pipturus propinquus***	Queensland.
Flame tree, ***Brachychiton acerifolium***	Queensland.
Bottle tree, ***Sterculia rupestris***	Queensland.
Tree nettle, ***Laportia gigas***	Queensland.
Mulberry (***Kuwa***)	Japan.
Wild cherry (***Hi-no-ki***)	Japan.
Sisal hemp, ***Agave sisilana***	Yucatan.
Pineapple, ***Ananassa sativa***	Jamaica.
Pineapple, ***Bromelia sylvestris***	Mexico.
Pineapple, ***Bromelia penguin***	Jamaica.
Mohant tree, ***Hibiscus arboreus***	Tropical America.
Okra, ***Malva***	Jamaica.
Yercum, ***Calatropis gigantea***	Jamaica.
Bow-string hemp, ***Sanseviera Zeylanica***	Jamaica.
Ife tree, ***Sanseviera Angolensis***	Angola.
Fig tree, ***Ficus speciosa***	Brazil.
Milk weed, ***Asclepias***	Brazil.
Diss, ***Cyperus dives***	Egypt.
Cat-tail, ***Typha latifolia***	Egypt.
Neilgherry nettle, ***Urtica heterophylla***	India.
Puyba (puya flax), ***Bœhmeria puoya***	India.
Kangra hemp, ***Cannabis sativa***	India.
Barriala, ***Sida rhomboida***	India.
Brown hemp, ***Hibiscus cannabinus***	Bombay.
Roselle, ***Hibiscus sabdariffa***	India.
Indian mallow, ***Abutilon Indicum***	India.
Sun hemp, ***Crotalaria juncea***	India.
Jubbulpore hemp, ***Crotalaria tenuifolia***	India.
Jute, ***Corchorus olitorius***	India.
Nettle, ***Urtica incisa***	Queensland.
Paper mulberry, ***Broussonetia papyrifera***	Queensland.
Hollyhock tree, ***Hibiscus splendens***	New South Wales.
Hollyhock tree, ***Abutilon venosum***	S. America.
Hollyhock tree, ***Abutilon mollis***	S. America.
Hollyhock tree, ***Abutilon Bedfordianum***	S. America.
Hollyhock tree, ***Abutilon striatum***	S. America.
Ribbon tree (lace bark), ***Plagianthus betulinus***	N. Zealand.
Club rush, ***Scirpus fluviatilis***	Australia.
Sedge grass, ***Carex appressa***	Australia.
Gallingall rush, ***Cyperus lucidus***	Australia.
Gallingall rush, ***Carex pseudo-cyperus***	Australia.
Sword grass, ***Gahnia psittacorum***	Australia.
Sword grass, ***Cyperus vaginatus***	Australia.
Sword grass, ***Lepidosperma elatius***	Australia.
Coast sword grass, ***Lepidosperma gladiatum***	Australia.
Slender sword grass (mat grass), ***Lepidosperma flexuosa***	Australia.
Black reed (cutting grass), ***Cladium radula***	Australia.
Stringy bark, ***Eucalyptus obliqua***	Australia.
Messmate, ***Eucalyptus fissilis***	Australia.
Swamp tea-tree, ***Melaleuca ericifolia***	Australia.
Swamp tea-tree, ***Melaleuca genistifolia***	Australia.
Swamp tea-tree, ***Melaleuca squarosa***	Australia.
Flame tree, ***Sterculia acerifolia***	New South Wales.
Bottle tree, ***Sterculia diversifolia***	Victoria.
Bottle tree, ***Sterculia lucida***	Victoria.
Bottle tree, ***Sterculia fœtida***	Malaysia.
Lye plant, ***Commersonia Fraseri***	Queensland.
Lye plant, ***Dombeya Natalensis***	Natal.
Wire grass, ***Ehrhasta tenacissima***	Australia.
Wire grass, ***Poa Australis***	Australia.
Plume grass, ***Arunda conspicua***	New Zealand.
River rush, ***Isolepus nodosa***	Australia.
Sea-coast rush, ***Juncus maritimus***	Australia.
Sea-coast rush, ***Juncus vaginatus***	Australia.
Sea-coast rush, ***Dianella latifolia***	Australia.
Sea-coast rush, ***Dianella longifolia***	Australia.
Dragon tree, ***Dracœna Draco***	Teneriffe.
Spear lily, ***Doryanthes excelsa***	Eastern Australia.
Bulrush, ***Typha angustifolia***	Australia.
Jaggery palm, ***Caryota urens***	Queensland.
Screw pine, ***Pandanus utilis***	Australia.
Common rush, ***Juncus pauciflorus***	Australia.
Tussock grass, ***Xerotes longifolia***	Australia.
Currijong, ***Pimelia axiflora***	Queensland.
Currijong, ***Dais cotinifolia***	Natal.
Currijong, ***Pittosporum crassifolium***	Natal.
Manila hemp (abaca), ***Musa textilis***	Philippines.
Baobab, ***Adamsonia digitata***	Tropical Africa.
Baobab, ***Strelitzia regina***	South Africa.
Baobab, ***Heliconia gigantea***	Tropical America.
Urania (*Ravenala*), ***Madagascariensis***	Madagascar.
Urania, ***Pterospermum acerifolium***	Mauritius.
Urania, ***Guazuma ulmifolia***	Mauritius.
Urania, ***Melochia liliacefolia***	South Africa.
Sago palm, ***Sagus ruffia***	Mauritius.
Sago palm, ***Sagus saccherifera***	Mauritius.
Sago palm, ***Livistona mauritiana***	Mauritius.
Sago palm, ***Sanseviera zebrina***	Mauritius.
Sago palm, ***Sanseviera latifolia***	Mauritius.
Sago palm, ***Sanseviera cylindrica***	Mauritius.
Sago palm, ***Colocasia antiquorum***	India.
Mulberry, ***Morus tartarica***	Tartary.
Mulberry, ***Alpinia magnifica***	Tropical Africa.
Mulberry, ***Cordia myxa***	Egypt.
Mulberry, ***Ixora corylifolia***	
Panama hat-straw, ***Carludovica palmata***	Ecuador.
Bamboo, ***Bambusa vulgaris***	Asia.

The Victoria collection at the Philadelphia Exposition embraced samples of paper made from plants growing in Victoria, Australia, were as follows: —

Paper made from Bark of

Paper mulberry tree, ***Broussonetia papyrifera.***
Salvia Canariensis.
Dais continifolia.
Stringybark, ***Eucalyptus obliqua.***
Messmate, ***Eucalyptus fissilis.***
Soft-leaved abutilon, ***Abutilon mollis.***
Veined lantern flower, ***Abutilon venosum.***
Currijong, ***Pimelia axiflora.***
Lye plant, ***Commersonia Fraseri***, **Queensland.**
Thick-leaved pittosporum, ***Pittosporum crassifolium.***
Queensland grasscloth plant, ***Pipturus propinquus.***
Common tea tree, ***Melaleuca ericifolia.***
Broom-leaved tea tree, ***Melaleuca genistifolia.***
Victorian bottle tree, ***Sterculia diversifolia.***
Flame tree, ***Sterculia acerifolia.***
Chinese grasscloth plant, ***Bœhmeria nivea.***
Victorian hemp, ***Sida pulchella.***
Queensland hemp, ***Sida retusa.***
Victorian yellow-wood, ***Melaleuca squarrosa.***

Paper made from Stems of

Victorian nettle, ***Urtica incisa.***
Ehrharta tenacissima.
Carex appressa.
Carex pseudo-cyperus.
Isolepis nodosa.
Few-flowered rush, ***Juncus pauciflorus.***

Paper made from Stems and Leaves of

Gahnia psittacorum, var. erythrocarpum.
Tall sword rush, ***Lepidosperma elatius.***
Tall palm lily, ***Cordyline indivisa.***

Jaggery palm, ***Caryota urens.***

De Naeyer & Co., of Willebroeck, Belgium, showed at the Paris Exposition of 1878, paper manufactured from the following materials, and furnished the statement of percentage of fiber yielded: —

Woods.

Common and Botanical Names.	Yield per cent.
Heath, ***Erica vulgaris***	27.14
Filbert trees, ***Corylus avellana***	31.50
Alder, ***Alnus glutinosa***	34.30
Bamboo, ***Bambusa thonarsu***	34.82
White pine, ***Abies pectinata***	34.60
Horse chestnut, ***Æsculus hippocastanus***	38.26
Oak, ***Quercus robur***	29.16
White poplar, ***Populus alba***	35.81
Red pine, ***Pinus sylvestris rubra***	32.28
Elm, ***Ulmus campestris***	31.81
Ash, ***Fraxinus excelsior***	32.28
Black alder, ***Rhamnus frangula***	37.82
Fir, ***Pinus sylvestris***	35.17
Osier, ***Salix alba***	29.50
Canadian poplar, ***Populus Canadensis***	36.88
Beech, ***Fagus sylvatica***	30.90
Pitch pine, ***Pinus Australis***	31.08

Walnut, *Juglans regia*	26.52
Willow, *Salix alba*	37.82
Birch, *Betula alba*	33.80
Italian poplar, *Populus Italica*	36.12
Acacia, *Robina pseudoacacia*	34.10
Lime tree, *Tillia Europea*	38.16
Rattan, *Calamus verus*	29.19
Aspen tree, *Populus tremula*	35.00

HERBACEOUS PLANTS, ETC.

Camelina, *Camelina sativa*	29.16
Bent grass, *Agrostis spica venti*	45.82
Buckwheat, *Fagopyrum esculentum*	30.60
Marsh rush, *Scirpus palustris*	41.70
Banana, *Musa ensete*	31.81
Mateva, *Hyphæne Thebaica*	26.08
Oats, *Avena sativa*	35.08
New Zealand flax, *Phormium tenax*	32.71
Asparagus stalks, *Asparagus officinalis*	32.56
Marsh grass, *Glyceria aquatica*	38.80
Maize, *Zea maïs*	40.24
Reed, *Phragmites vulgaris*	41.57
Canna, *Canna*	20.29
Rye, *Secale cereale*	44.12
Giant nettle, *Urtica dioica*	21.66
Sugar cane, *Saccharum officinarum*	29.15
Barley, *Hordeum vulgare*	36.21
Sedge, *Carex*	33.86
Wheat, *Triticum sativum*	43.14
Fromenteau, *Baldengera Arundinacia*	46.17
Blue flag, *Enodium cæruleum*	40.07
Hop, *Humulus lupulus*	34.84
Canary grass, *Phalari Canariensis*	44.16
Wild broom, *Spartium scoparium*	32.43
Dog's grass, *Triticum repens*	28.38

An *astronomical tower* 29′ in diameter was constructed of paper at the Polytechnic Institute, Troy, N. Y.

A *paper church* near Berlin has a capacity for nearly 1,000 persons. It is circular within, octagonal without. The reliefs outside and statues within, the roof, ceiling, the Corinthian capitals, are all papier mache, rendered water-proof by saturating in vitriol, lime water, whey, and white of eggs.

Bricks are made of paper pulp from rough materials in Wisconsin.

Barrels of paper are made in numerous factories in the United States.

Paper chimney-pots are made in Breslau, and are light and durable. Before the paper pulp is molded and compressed into the required shape, it is treated with chemicals which render it non-inflammable.

Pa'per Bar'rel. Barrels are made from molded pulp, formed in sections, and then united; or of paper in layers.

The process of preparing the paper consists in subjecting three layers of paper (called straw-board), cemented together, to a hydraulic pressure of more than 100 tons. This produces a compact, solid substance of great resisting power. These sheets are run through machinery which dovetails the ends, making them ready for joining, and turns the edges. It is passed through another machine, which gives the cylindrical shape. This saves 25 per cent. in packing space over the usual barrel. The outside of the barrel, after being ornamented and rendered perfectly air and water proof, is ready to put together. One operator can easily manufacture 150 per day, while from 15 to 20 have been considered a good day's work in making wooden barrels. Either wooden or paper heads can be used. The former are turned, and the latter are pressed out and stamped in dies. The hoops are strongly united bands of paper Each part of the barrel, hoop, head, and cylinder, is made complete. Empty barrels can be packed the one within another, and put together as required. The weight of a paper barrel is about one-half that of a wooden one. — *Thompson.*

By another method straw pulp is run into a mold made in the shape of a half-barrel, cut vertically. The ends are of paper, but are protected by wood. The staves are three-eighths of an inch thick.

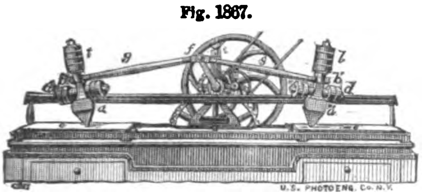
See also "*Manufacturer & Builder,*" xii. 149.

Pa'per Bur'nish-ing Machine'. A machine for putting a polish on paper. The action is more energetic than that of the calender, which depends upon mere pressure.

See CALENDERING MACHINE, Figs. 499, 500, pp. 152, 153, *supra.*

The substitution of glazed rolls for the burnishing of marbled and colored papers with polished agates, etc., has not equaled the previous result. Fig. 1867 is a machine by M. Alauzet, of Paris, for manipulating the burnishing stone, and thus economizing the cost without impairing the beauty of the imparted surface. This machine, which may be used for dyed and undyed paper, is double acting; the sheets of paper are represented by *e*, while *a* shows the burnishing stone guided and moved by the bar *b d t* and the rod *g*, which is

Fig. 1867.



Paper Burnishing Machine.

connected with the crank *f*. The weights *t* and *l* may be increased or diminished according to requirements.

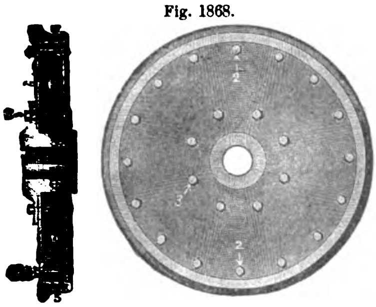
Fig. 1868.



Paper Car Wheel.

2. Tire-bolt. 5. Tire.
3. Hub-bolt. 6. Compressed paper.

Pa'per Car'bon Lamp. A form of incandescent electric lamp in which a slip of paper reduced to carbon is used as the illuminated agent in a glass globe with an atmosphere of nitrogen. The carbonized strip of paper is the substitute for other forms of carbon, such as rattan or bamboo bark, or the metal platinum. The mode of disposing the carbon arc and its connections is shown in Fig. 938, Plate XIV., opp. p. 300, *supra*.

Pa'per Car'pet.

Paper is rendered hard and tenacious by subjecting the pulp to the action of chloride of zinc. After it has been treated with the chloride, it is submitted to a strong pressure, thereafter becoming as hard as wood and as tough as leather.

"A paper carpet is now made in England, and designed to imitate parquet flooring, the paper being printed in patterns to imitate different woods from photographs, so that the resemblance is perfect. The floor is first prepared by being made perfectly level, and the crevices filled up with plaster-of paris ; over the surface, as thus prepared, *hession* (paper treated with chloride of zinc), is stretched, and on this first lining paper, and then the patterned paper, is pasted, the whole being finished with a coating of a peculiar hard and wear-resisting varnish." — "*Furniture Trade Journal*," Br.

See also LEATHER, ARTIFICIAL, *supra*, and references there cited.

The imitation of Japanese paper, for decorative purposes, is made by the Pavey Co., of London.

It is made of hemp and jute, with a small percentage of animal matter. It is used for lambrequins, window and bed curtains, tapestry, blinds, valances, upholstery, etc. It is made and printed in imitation of silk, woolen, cotton stuffs, the brocades of Lyons, reps, woolen and silk damasks of Paris and Bordeaux, and the cretonnes of Mulhouse, while it retains the peculiar Japanese characteristics.

The paper is first formed into an endless roll, and is perfectly white in color. Afterward it is taken to an embossing machine, which impresses it slightly, and then the design is printed from electrotype plates, first cast from the wood and formed upon a roller, as in wall-paper printing.

Pa'per Car'-wheel. (*Railway.*) A car wheel with steel tire and a web of compressed paper between plates which are bolted to the hub and tire. It is shown by section, and also by elevation, in Fig. 1868.

The central portion of the wheel is entirely of thicknesses of paper, united by paste and compressed by hydraulic machinery to the consistence of wood, but without the liability to split, which wood has more or less ; the hub and the tires are of steel. One of these wheels, used under a Pullman car, has run for eight years, and for a distance of 302,900 miles.

Pa'per Clip'ping Ma-chine'. A machine for trimming the edges of books, or of paper in piles. See PAPER CUTTER.

Pa'per Col'lar Ma-chine'. See p. 1619, "*Mech. Dict.*"

The Lockwood machine works from an endless web of paper, or of cloth and paper, the width of the web being slightly greater than the length of the collar required. The web passes over rollers, and then beneath an intermitting descending platen, which has two sets of dies by which the collars are cut, creased, button-holed, stitch-marked, and embossed with the name and number at the rate of 30,000 per day. The material is fed intermittingly and receives the button-holes, stitch marking, and embossed number by one set of dies, then is advanced beneath the cutting-out dies, both sets of dies descending at once, but operating consecutively upon the paper.

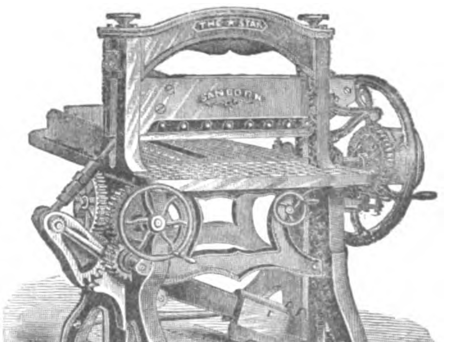
When paper only is used for the collar, three strips of gummed cloth are fed from spools, so as to be exactly over the places for the three button-holes. The patches are cut from these and automatically damped, deposited upon and fastened to the web in the places where the holes are to be cut.

A *forming machine* then bends the paper collar at the crease, taking them in endwise, and discharges them at the rate of 50,000 per day.

Pa'per Cut'ter. A machine for cutting paper in pile. In the Sanford cutter, Fig. 1869, the knife is brought down obliquely upon the pile and returns by a quick upward stroke. The table has rules and lines for cutting to measure. The paper clamp is moved independently.

Another form of paper cutter is that for scoring and cutting paper boards for boxes, notching the corners, and scoring the joints. — *Sanborn.*

Fig. 1869.



Paper Cutter.

See also BOOK TRIMMER, *Semple*, Fig. 384, p. 121 ; BOARD CUTTER, Fig. 354, p. 113 ; CARD CUTTER, Figs. 539–541, p. 166, *supra*.

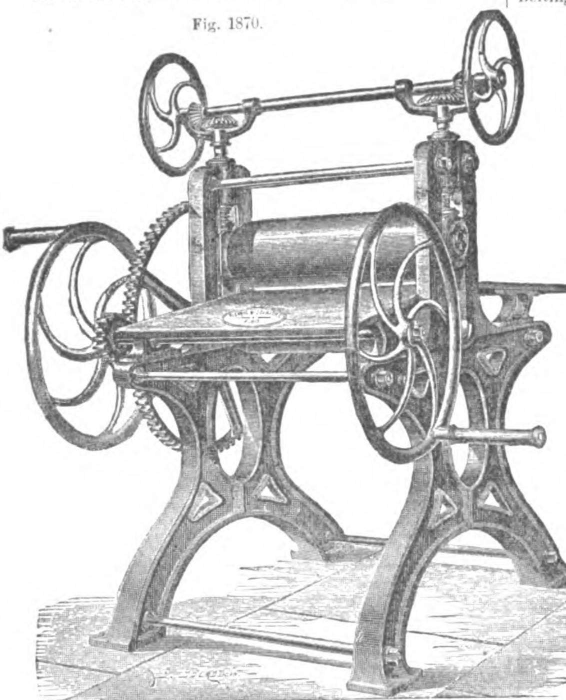
Pa'per E-nam'el. Enamel for paper cards and papeterie.

For white, and for all pale and delicate shades, take 24 parts by weight of paraffine, add thereto 100 parts of pure kaolin (China clay), very dry, and reduced to a fine powder. Before mixing with the kaolin the paraffine must be heated to fusing point. Let the mixture cool, and it will form a homogeneous mass, which is to be reduced to powder and worked into a paste in a paint mill with warm water. The enamel is then ready for application. It can be tinted to any desired color.

Pa'per Gla'zing Rol'ler. A machine through which paper or card is passed to give to it a burnished surface.

The machine shown in Fig. 1870 is that of Pierrin et Dehaître, of Paris. The paper is passed between two rollers, the lower one of which is driven, and the resistance of the upper one gives a sliding pressure which compacts the surface of the paper in the manner of a burnisher.

Fig. 1870.



French Paper-glazing Machine.

Pa'per Knife Sharp'en-er. The machine of Bell, of Lucerne (Switz.), is shown in Figs. 1871, 1872; it is adapted for knives up to 1.5 meter in length. The emery wheel is in fixed bearings, and the knife, secured to a slide rest, traverses in front of it. The wheel is .45 to .5 m. in diameter and makes 600 turns per minute. The knife is advanced to the emery wheel by hand wheel and screw. The motion of the grinding wheel is communicated to the slide rest which passes the knife to and fro by an alternate movement. See GRINDING MACHINE.

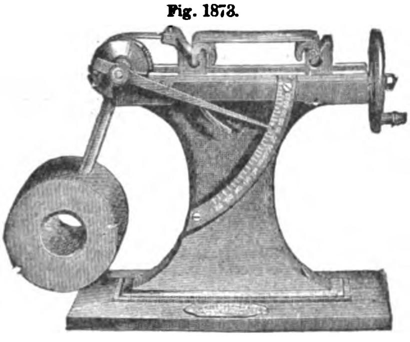
Pa'per Rol'ling Ma-chine'. See PAPER GLAZING ROLLER, Fig. 1870, *supra*; PLATES, *infra*; CALENDERING MACHINE, Figs. 499, 500, pp. 152, 153, *supra*.

Pa'per Test'er. A machine in which the tensile strength of a strip of paper of a given width is ascertained.

In Fig. 1873 the paper is tested by the direct action of a weight, avoiding the variations which arise in the use of springs.

The strip of paper is secured by cam clamps in the two holders. By rotation of the hand wheel the clamps are separated, and the strain is indicated by the finger against the graduated arc.

Fig. 1873.



Paper Tester.

Chavin & Marin-Darbel. . . * "*Sc. American*," xxxviii. 69.
* "*Sc. American*," xxxix. 211.

Pa'per Weight. (*Glass.*) Ornamental blocks or globes made in various ways. See CAMEO INCRUSTATION; FILIGREE; VITRO DE TRINO; MILLEFIORI; and list on pp. 975, 976, "*Mech. Dict.*"

Pa'per Wet'ting Ma-chine'. The bundle of paper is placed on the bank, and fed in quires, either open or folded, to guides on the feed table. At the proper time the table advances and enters the paper between two cylinders covered with felt, the lower one of which runs in a trough of water. As the paper issues from these cylinders, it passes between a top and bottom sprinkler, by which additional water can be put on, and the quantity can be regulated at pleasure. The paper is then conveyed by cords to a sheet-flyer, which lays it on a table suspended on springs. These springs are adjusted to suit the weight of the paper, so that the table falls as the weight increases, and thus keeps the top of the pile always at the same height. — *Hoe.*

Pa-pyr'o-graph. Known also by other names. See HECTOGRAPH; COPYGRAPH; MANIFOLD, etc. See also GELATINE COPYING PROCESS, and references *passim.*

Par-a-bol'ic Il-lu'min-a'tor. (*Optics.*) Beck's. A means of illuminating opaque objects under the microscope.

It consists of one half of the upper portion of a parabola made of polished silver, and slides by means of a fitting, up and down upon the outside tube of the object glass. All parallel rays falling upon the silver surface will be reflected to the focus of the parabola which is of necessity in the optic axis of the microscope, at the point where the object under examination is situated. See Fig. 3545, p. 1629, "*Mech. Dict.*"

Par'a-cen-te'sis In'stru-ments. (*Surgical.*) Instruments for tapping a cavity.

For Paracentesis abdominis: —

Drainage tubes.	Drainage canula.
Trocars.	Hollow trocar.
Aspirators.	Clamp forceps.
Aspirator needles.	

For Paracentesis corneæ: —

Trocars.	Needles.

For Paracentesis thoracis: —

Dieulafoy's Aspirator, Fig. 6665, p. 2629, "*Mech. Dict.*"

Par'a-chute Light. A device invented by General Boxer and used in the British military service as a means of revealing the enemy's position and movements at night.

It forms, when closed, a large shell, expanding into a huge umbrella, 15' high, when opened, the cup of composition which is suspended being designed to burn $4\frac{1}{2}$ minutes.

The star shell, which has been designed as a substitute, is much smaller and more portable, and of comparatively trifling cost. It can be fired into the air from a mortar at the required angle to show the enemy's works, and burns with a brilliant light for about half a minute, long enough to take an observation and lay a gun, but not long enough to allow an adverse wind to bring the light back over the firing point, and so turn the advantage in favor of the enemy.

Par'af-fine. The mode of manufacture of paraffine and some of its uses are referred to on pp. 1629, 1630, "*Mech. Dict.*"

Its use depends upon several qualities: It is inodorous, white, clean, tasteless, non-oxidizable, water repellant, a non-conductor of electricity, inflammable, plastic.

It is used as a water-proofing material for fabrics and paper.
Lining wooden and metallic vessels.
Saturating paper as a water repellant, and to preserve contents from becoming rancid, — butter, for instance.
Trays and tanks for acids and voltaic batteries.
Insulator (electric).
For covering splints and other paraphernalia subject to septic influences.
As a polisher under the iron in fine laundry work.
As a vehicle of the fulminate in matches.
As a covering for cartridges.
Paper saturated with paraffine is used to inclose saccharine or saponaceous materials, etc.
Matthews lines with paraffine the enameled metal reservoirs of his soda fountain.
Hoe lines glass electrotype baths with paraffine.
Staunton preserves fruit and vegetables by films of paraffine.
Makes boxes, cans, or vessels air-tight by lining with paraffine; for holding meat, vegetables, fruit, butter, spices, etc.
Tucker has a lard package made of paper soaked in paraffine.
W. B. Guernsey saturates with paraffine the pores of wooden cases for containing butter, etc.
Paper by *Grostowsky* . . "*Scientific American Sup.*," 1898.

Par'a-kite. A series of kites, the smaller in advance and increasing in area, are flown *en suite.* The largest and last in the series is 36' × 30', and is intended to raise a man from the ground to an elevation of several hundred feet to observe the position of an enemy.

Experimented with at Woolwich, England.

"*Manufacturer & Builder*" . . . . . viii. 18.

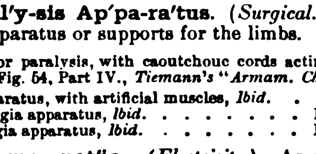
Par'al-lel Com-pres'sor. (*Optics.*) Beck's. A means for holding or compressing an object under the microscope.

Two plates of brass, upon each of which a piece of glass is fixed, are connected by four arms of brass of equal length,

Fig. 1874.



Parallel Compressor.

giving a parallel movement to the plates. These plates are gradually brought together by a screw at the end attached to one plate and working in a conical hole in the other.

Pa-ral'y-sis Ap'pa-ra'tus. (*Surgical.*) Electrical apparatus or supports for the limbs.

Glove for paralysis, with caoutchouc cords acting as extensors. Fig. 64, Part IV., *Tiemann's* "*Armam. Chirurg.*"

Leg apparatus, with artificial muscles, *Ibid.* . Fig. 70
Hemiplegia apparatus, *Ibid.* . . . . Fig. 71
Paraplegia apparatus, *Ibid.* . . . . Fig. 72

Par'a-mag-net'ic. (*Electricity.*) As opposed to dia-magnetic. Substances the poles of which, like iron, nickel, cobalt, etc., tend to move from the weak to the strong places of electro-magnetic force are called para-magnetic, or ferro-magnetic. — *Gordon.* See also MAGNETIC SCALE.

Par'cel-gilt. Meaning *partly gilt.* Silver ware gilt inside, as bowls, spoons, etc.

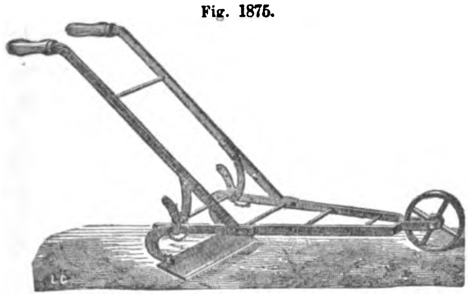
Par'cel Lift. A dumb waiter used in stores and warehouses.

Parch'ment Pa'per. Paper treated with dilute sulphuric acid. See p. 1633, "*Mech. Dict.*"

A new recipe is to use a bath of ammoniacal solution of copper, made by treating plates of copper with a concentrated solution of sal-ammoniac.

Par'er. A wide bladed hoe, drawn by a man or a horse, and used to pare the surfaces of walks in gardens and parks to kill weeds and grass.

Fig. 1875.



French Parer.

Pa'ri-an Bis'cuit. (*Ceramics.*) A fine-ware made by Minton and Copeland, of Stoke-upon-Trent, England. It is an ornamented semi-vitreous ware with a clear ring nearly like china, and is recognized as one of the best fine-wares introduced since the time of Wedgwood.

Par'ing Plow. See PARER, *supra.*

Park'e-sine. See CELLULOID, "*Mech. Dict.,*" *et supra.*

Par'lor Or'gan. A reed or pipe organ; generally the former, of small size, adapted to parlor, vestry, or school room.

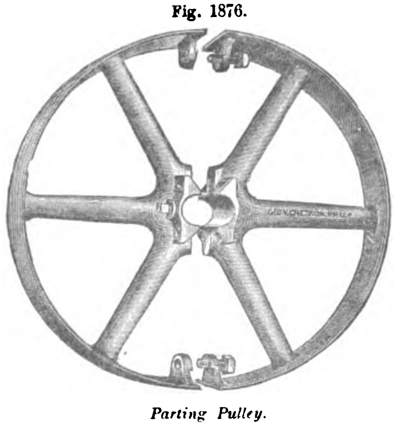
History of the parlor organ in report of *H. K. Oliver* on Group XXV., in vol. vii., "*Centennial Exhibition Report,*" p. 45.

Par'lor Skate. A skate on rollers.

Plimpton's improvement consists of an arrangement by which a skate is made to keep the floor without reference to the angle of the body or the sharpness of the curve turned. In the center of the sole of the skate is fixed a spherical spring of india-rubber, yielding to the slightest inclination of the foot, a mere change of motion by the well-known mechanical means causing the axles of the roller wheels to converge.

Part'ing Pul'ley. One capable of division, so that the parts can be attached to the shaft without dismounting the latter.

Fig. 1876.



Parting Pulley.

Part'ing Rail. (*Carpentry.*) A rail intermediate between the bottom and top rails of a door or partition.

Part'ing Strip. (*Carpentry.*) A narrow piece separating parts, as the strip between the upper and lower sashes in the window frame; or between the window and blind in a car.

Pas'sen-ger El'e-va'tor. See ELEVATOR.

Pass'ing Nip'pers. (*Nautical.*) A strong hank of untwisted but mailed yarn used in binding the messenger to the cable.

Paste. (*Ceramics.*) The material of porcelain and other fine grained pottery.

Known as *hard, soft, jasper, basalt, cream,* etc., names given to indicate relative quality or color, or names of fancy.

There are all gradations, from the soft paste of some *faïence,* which in many cases is so coarse as to be hardly deserving of the name, to the hard *china,* which resembles glass. See list under POTTERY.

Paste'board Cut'ter. See BOARD CUTTER, Fig. 354, p. 113; CARD-BOARD CUTTER, Figs. 539–541, p. 166, *supra.* Fig. 3665, p. 1636, "*Mech. Dict.*"

Paste Jag'ger. A pastry cook's convenience for notching the edges of cakes, pies, and pâtes.

Pas-tille'. An odoriferous pellet which emits an agreeable odor in burning. Its burning is due to the niter and charcoal in its composition.

French recipes: —

	Grams.
Oliban in tears	24
Storax in tears	24
Niter	16
Pulverized charcoal	124
Add for rose perfume: —	
Pulverized rose leaves	32
Essence of rose	2
For orange flower pastille: —	
Galbanum	24
Dried orange peel pulverized	32
Essence neroli	2
For vanilla pastille: —	
Galbanum	24
Girofle (cloves)	16
Vanilla	32
Essence cloves	1
Essence vanilla	16

Make into a mass with gum arabic, 4 grams; water two-thirds deciliter; mold and dry.

Pas-tille' Pa'per. Paper prepared with an odoriferous composition.

Take cascarilla bark 8 drachms, gum benzoin 4 drachms, yellow sanders 2 drachms, styrax 2 drachms, olibanum 2 drachms, charcoal dust 6 ozs., niter 1½ drachms, mucilage of gum tragacanth, sufficient quantity. Reduce the substances to a fine powder, form into a paste with the mucilage, coat the paper with this, and dry in an oven.

Pate Chan-geante'. (*Ceramics.*) A peculiar porcelain, made by Minton, which has changeable color according to the light or angle at which it is viewed, something like the changeable or shot silk. In daylight it has a grayish or celadon green color, and at night it appears pink.

This kind of chameleon paste was compounded by the chemist Regnault when director of the Sèvres establishment.

Pate de Bois. Wood pulped, and formed by compression into paper, carton, decorative cornices or panels.

Pa-tel'la Ap'pa-ra'tus. (*Surgical.*) Supports, braces, or splints for fractured patella. Fig. 3567, p. 1636, "*Mech. Dict.*"

Figs. 119–121, *Tiemann.* Dr. White's elastic patella hooks engage the upper and lower surfaces, and draw the portions together.

Pa'tent Ham'mer. (*Stone Working.*) The head holds a number of wide thin chisels held together by bolts.

It is used for giving a surface-finish to squared masonry. See Fig. 3160, p. 1444, "*Mech. Dict.*"

Pa'tent Plate. (*Glass.*) An English name for cylinder glass.

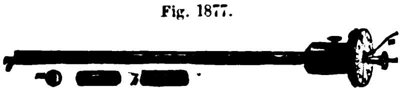
Pâte-sur-pate. (*Ceramics.*) A form of decorative work in which one colored slip is laid upon another in bands, fillets, figures, and what not; sometimes to the number of a dozen or more. Wedgwood's imitation of the Portland vase is an eminent instance of the art, and Solon has also executed some very remarkable work.

The body is usually dark olive-green, brown, turquoise blue, or black, and the paste white, and laid on in relief, the lights and shades partly due to the thickness of the slip, which is in relief. After laying a sufficient thickness the artist scrapes away portions according to the requirements of the design, the dark background showing through in parts. Re-firing renders all translucent.

It is a very old process, having long been used in China on porcelain, and in India for common ware; the Scinde and Punjab pottery, for instance. In Scinde the pattern is pricked out on paper, and drawn by laying it upon the surface of the jar and dusting along the prickings. The effect is good, and articles are sold at from eight to twenty-four cents. See "*Handbook to the British Indian Section, Paris Exposition,*" by Mr. George C. M. Birdwood, C. S. I., M. D. "*Paris Exposition* (1878) *Reports,*" iii., pp. 113, 136, 137.

Path'find-er. (*Surgical.*) An instrument by Dr. Eldridge, of Yokohama, for finding urethral strictures by means of filiform whalebone bougies placed in any position by the rotating disk and screw.

Fig. 1877.



Pathfinder.

Pa-ti'na. The peculiar color on antiques, bronzes, and medals, due to exposure and time. It is counterfeited by various processes, either by oxidation or painting. *Orugo.*

The patina given to the Japanese bronzes is a trade secret, having been handed down from father to son for ages. M. Morin has discovered that the patina of the celebrated black bronzes is due to the use of an alloy composed of copper, 80; tin, 4; lead, 10; zinc, 2; iron, 4; besides small proportions of gold, nickel, arsenic, and sulphur. Some of the bronzes analyzed show a proportion of lead varying from 10 to 20 per cent., added at the expense of the copper, and a quantity of 7 per cent. of tin. Molded in thin plates, this bronze is very easily worked, and the patina is developed by heat when the metal is subjected to a high temperature in a muffle furnace. It is, however, very brittle.

An imitation of patina can be produced by preparing a paint of carbonate of copper and any light alcoholic varnish, and applying it to the object with a brush. This green color penetrates the smallest recesses, and has, when dry, the appearance of patina. Carbonate of copper gives a blue patina, verdigris a light green, and intermediate shades of color can be obtained by mixing the two.

The French patina is effected upon bronzes of the ordinary strength by subsequent surface application. The process consists in preparing a ground by the action of chemicals having oxides and sulphides of copper as their bases. If different tints, black, brown, red, or green, be desired on the same object, it is sufficient to cover with a protecting varnish all portions of the surface except those to which it may be desired to give a certain hue; then when they have been treated for a sufficient time, they are covered with varnish, while the other parts of the surface now exposed are subjected to the action of the chemicals, and so on for as many tints as are required. See also MILDEW BRONZE.

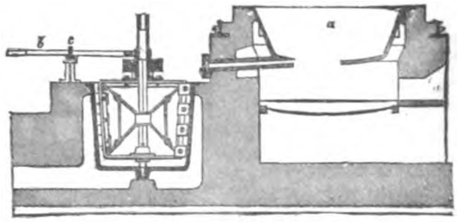
Pat'tin-son's Pots. A process for separating silver from lead by crystallizing the latter and removing it, the remainder being richer in silver.

The principle of the process is described and the apparatus shown on pp. 1638, 1639, "*Mech. Dict.*"

The improvement of Bourdehen, as practiced at Stolberg Hozappel, and Rouin, is shown in Figs. 1878–1880.

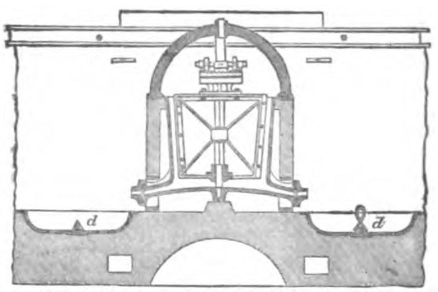
Fig. 1878.



Pattinson's Pots. (*Vertical Section on Line a B,* Fig. 1880.)

Each battery is composed of two kettles, the *melting* and *crystallization* kettles. The stirrer in the latter has two shafts, concentric, and moved in opposite directions. On the

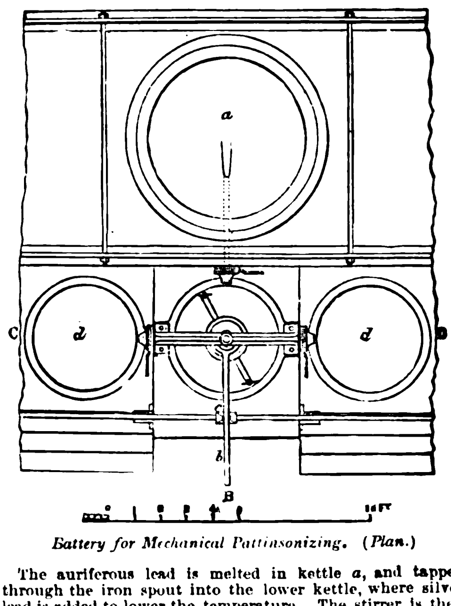
Fig. 1879.



Pattinson's Pots. (*Vertical Section on Line C D,* Fig. 1880.

outer shaft is a stirrup-like frame from the sides of which project flat-edged scrapers; on the inner shaft are flat arms, arranged spirally, and with oblique sides.

Fig. 1880.



Battery for Mechanical Pattinsonizing. (*Plan.*)

The auriferous lead is melted in kettle *a*, and tapped through the iron spout into the lower kettle, where silver lead is added to lower the temperature. The stirrer is then set in motion, and small jets of water thrown upon the molten alloy. At the end of two hours the mass will have become pasty, when the stirrer and water-streams are stopped and the mother-liquid is tapped into a heated pot, *d*. An iron hook is set in the lead while molten, and when the lead has cooled it is lifted out by means of a tackle. A fresh quantity of silver-lead, assaying about the same in silver as the remaining crystals, is added from the melting-kettle, *a*, to the crystallizing-kettle; during this operation the motion of the stirrer is reversed. The molten alloy soon liquefies the crystals, when the already-described operation is again performed. After this operation has been repeated 7 times, the poor lead contains but 0.0036 per cent. Ag. The crystals are melted, tapped off, taken to another kettle for re-melting and casting in pigs. An obstruction to the process is thus avoided. The mother-liquid is enriched in 8 operations. The mother-liquid resulting is then returned to the kettle and further enriched in 5 operations: it contains 2.4 per cent. Ag.

Pave'ment. The subject is considered on pp. 1639–1642, and Plate XXXVIII., "*Mech. Dict.*"

The Figs. 1881–1884 exhibit the latest Parisian method of laying asphalt pavement.

The asphalt paving is of two kinds: the *asphalte comprimé*, that is, beaten and compacted with hot rammers; and the *asphalte coulé*, in which the material is spread with trowels.

The *asphalte comprimé* is especially employed around the churches, schools, theaters, concert halls, banks, and public buildings, on account of its freedom from noise; and generally for the additional reasons of cleanliness and salubrity in the places mentioned, and also in the main streets of the city. In the fashionable drives macadam is preferred on account of its freedom from slipperiness, and on the quays and warehousing quarters of the city the granite block system yet remains a favorite.

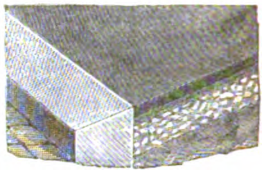
The first essential is a gravel foundation of sufficient thickness. Upon this a layer of concrete is placed to form a bed for the asphalt. There are but three materials used, and but three tools. The materials are: gravel screenings or sand; a silicious gravel in pieces, say from ½″ to 3″ in diameter; a gray hydraulic lime, usually Portland cement. The tools are: pointed shovels; two rakes with long bent prongs; two flat beaters, about 18″ square, and with handles set in obliquely. To this may be added 6 wheelbarrows, holding about a bushel each, and 18 water buckets, of 2½ gallons each.

Twenty men form a gang under a foreman, who work diligently in giving the final shape to the surface of the concrete, preserving the proper camber of the street, gage pegs being driven into the gravel foundation to work by, their tops representing the future surface of the asphalt.

The work now proceeds as follows: A man dumps a wheelbarrow load of sand, and another spreads it out to 4′ diameter. A bag of 3 pecks of lime is emptied on to it and spread evenly. On to this 3 barrow loads of silicious gravel are emptied, and the heap is trued up into conical form by shoveling from the foot of the heap and throwing it on to the apex. The materials are damp, and the lime clings to the gravel where it touches. The heap is torn down and built up in a spot alongside, the effect being to mix the materials of three different finenesses. The heap is presently flattened out to 6′ diameter, and a bucket of water distributed over it. As the middle is the wettest a cone is made at the center, so that a second bucket of water reaches the outside ring of the material. The conical heap is again constructed, and about a quarter of a bucket of water splashed by the hand upon the outside, — the outlying portions of the spread mass as it lay previously upon the ground.

It rests thus but a few minutes, and then is torn down, beginning at one side and throwing it, shovelful by shovelful, into a new location, a man with the three-pronged rake, like a manure hook, working it energetically and unceasingly as each new shovelful arrives at the heap. This mixing is a very important matter, as it insures that every particle of silicious rock shall be covered with the lime, and the heap now is, instead of the yellow of the flint gravel, a uniform gray. The water is only sufficient to cause the parts to adhere, and some little (without attempting to trace the chemical reactions) lost as such in the attack of the lime on the silex and in slaking.

Fig. 1882.



Section of Sidewalk. (Trottoir.)

The heap is ready in a few minutes to be removed in barrows and dumped on the line of working, where it is spread with shovels and with a second one of the three-tined rakes. Here the eye of the master is called for, and he gives it the final shape, so far as the shovels are concerned, due regard being paid to the gage pegs.

A man with the flat beater compacts and levels the surface by his blows, and the concrete is then surfaced with an inch thick coat of hydraulic lime mortar laid on with a trowel, and on this a coat of loose sand, which roughens it and forms a bond for the asphalt, which is afterward laid hot upon it, rolled and beaten. Of this presently. The sand appears to become partially imbedded in the yet soft mortar, and is in turn grasped by the asphalt. If the final asphalt were laid upon too smooth a surface it would be apt to fail in adherence and to flake off. Its mere adhesive quality is aided by a mechanical bind to the particles of sand which are, so to speak, riveted in the mortar, and it in the concrete.

Fig. 1883.

Section of Road.

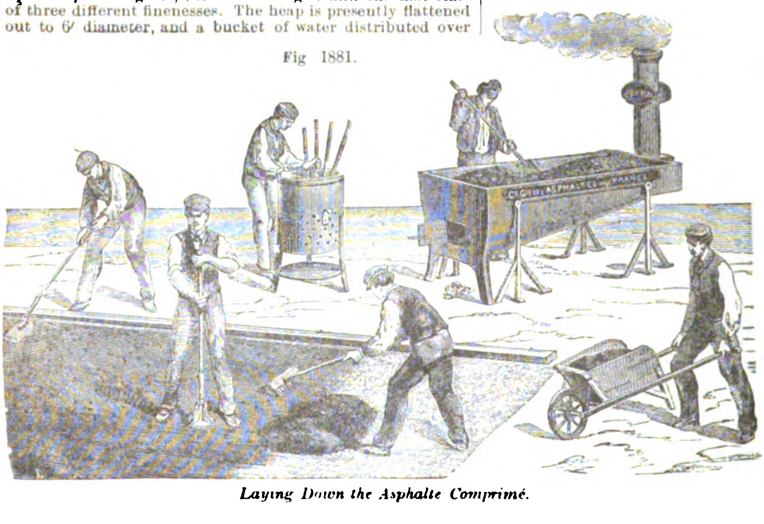
After a few days, the foundation — having been carefully guarded from disturbance by travel — having become fully set, the asphalt compound is brought hot in carts, and, being transferred to wheelbarrows, dumped upon the surface of the foundation concrete, and spread with rakes to a thickness of 4″. It is then lightly pounded with a very hot iron rammer with a circular face 10″ broad. A furnace is kept near by for heating the rammer. A second ramming with hard blows of the same rammer then takes place, condensing the asphalt to but little more than half its former thickness, and causing its intimate union with the rough surface of the layer beneath.

The final smoothing is given by a hot iron block, which is pushed and pulled over the surface, and burnishes down the elevations and the rough marks of the pounders.

The *asphalte coulé* is laid with a trowel upon the concrete basis, and is not pounded, as in the case of the *asphalte comprimé*. It is used for sidewalks, platforms and waiting saloons of railways, for prisons, skating rinks, baths, warehouses, breweries, and manufactories of all kinds.

To make a square meter of surface, 15 millimeters thick, it is necessary to use 1¼ kilos of bituminous minerals: 23 to 24 kilos of Seyssel

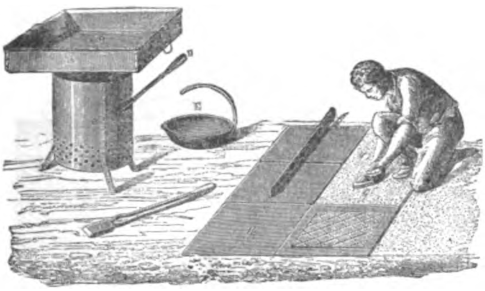
Fig. 1881.



Laying Down the Asphalte Comprimé.

mastic; and 13 to 15 kilos of washed, dried, and sifted gravel.

Fig. 1884.



Imitation of Tile Pavement in Asphalt Coulé (Carrelages).

The material is also wrought up into the form of tiles (carrelages), and laid upon a soft and level bed of concrete, melted mastic being poured into the joints and fashioned by the rule and jointing iron.

The following statement of the expense of maintenance of the pavements of Paris is taken from the "*Annales des Ponts et Chaussées*: —

"For cleaning streets, machine sweepers are employed drawn by a single horse, cleaning about 5,000 square meters an hour.

"The cost of keeping in repair is quite different for the different avenues.

"The asphalt roadways have a joint area of 225,120 sq. meters, to which should be added about 34,000 sq. meters for the walks through the macadamized streets. The price of construction varies from 12 fr. to 15 fr. per sq. meter.

"The repairing is done by contract for 1.10 fr. per sq. meter per year for the roadways, and 1.70 fr. for the walks.

"The mean cost of repairing roadways in Paris, which was 1.08 fr. in 1870, has been reduced to 0.82 fr. This reduction is due especially to a change in many places from macadam to paved roadways. The mean cost of repairing pavement never exceeds 0.60 fr., while macadam roadways cost 1.80 fr. per sq. meter. The latter should therefore be replaced, except where they serve as promenades and ornaments, as in the boulevards and avenues.

"The number of vehicles which pass daily through some of the principal thoroughfares of the city have been ascertained to be as follows: —

"Boulevard de Sebastopol	11,602
Avenue des Champs Elysees	11,734
Rue de Rivoli	13,898
Rue Royale	16,177
Boulevard des Capucines	19,043

"The paved roadways have an aggregate total area of 5,458,000 sq. meters; their maintenance requires the constant service of 431 men (*cantonniers*). The cost per sq. meter varies from 15.90 fr. to 20.40 fr., according to the gage (.10 to .16 meter).

"The cost of hand labor in keeping the pavements in order is 0.154 fr. per sq. meter.

"The macadamized roadways cover an area which, although less than in 1870, is still 1,900,000 sq. meters. The number of *cantonniers* required for their maintenance is 965.

"The steam rollers employed weigh about 30 tons each. The rolling is generally completed in a single night."

See ROAD-ROLLER, "*Mech. Dict.*"

A new pavement, composed of 85 % fine ground granite, and 15 % of bitumen, has been laid in Newgate St., London. It is stated to be free from slipperiness, and unaffected by the atmosphere.

It is laid in a heated, semi-fluid condition, 2″ thick, upon a foundation of Portland concrete 9″ thick.

Frusto pyramidal blocks of asphalt are used at Dordrecht, Netherlands.

Pave'ment Pipe. A protection for a gas or water pipe rising to the pavement, or forming a well at the bottom of which is the square of a cock in a water or gas pipe.

Pave'ment Ram'mer. A machine for performing the labor of ramming granite blocks in forming pavement for roadways.

See references on p. 1642, "*Mech. Dict.*," under PAVING MACHINE.

The *Johnson* rammer is shown in Fig. 1885.

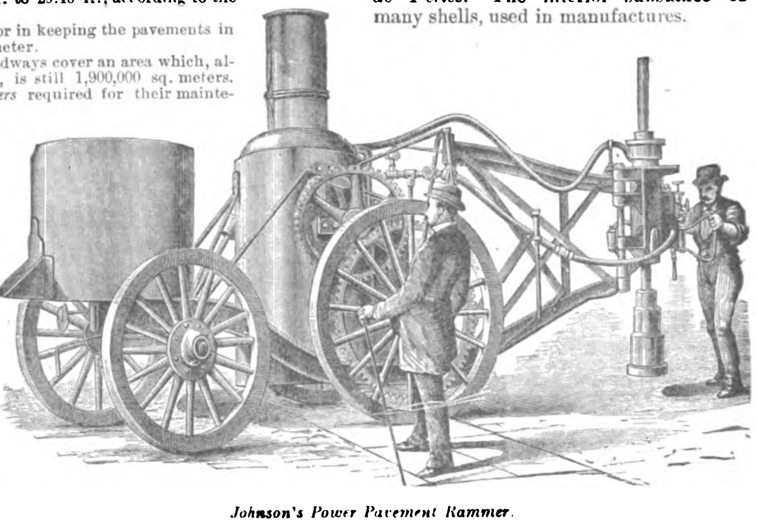
The machine is self-propelling. The crane, which projects forward, carries a steam cylinder containing a reciprocating piston, the rod of which is attached to the rammer. The piston reciprocates in much the same way as a steam hammer, and its movements are controlled by the attendant, who also moves the crane from one side to the other.

Two persons are required to work the machine, which has a power to strike from 1 to 2,200 pounds, at a rate of 160 strokes per minute.

Pav'ing. See PAVEMENT.

Pearl. (*Mother of Pearl.*) Fr. *Nacre de Perles.* The interior substance of many shells, used in manufactures.

Fig. 1885.



Johnson's Power Pavement Rammer.

The pearl oyster, *avicula margaratifera*, of the Indian seas, yields some of the best. It is hard to work, and is cut with fine saws and files, dressed with emery, and polished with calcothar.

The Sanskrit name for a pearl, *maracata*, was conveyed by *μαργάριτης* and *margarita* to the French *marguerite*, the daisy.

David Brewster was the first to explain the irisation of the surface of *nacre*, which is due to the fine ridges, which are more than 3,000 to the inch. This has been proved by taking a cast of the surface, reproducing the delicate inequalities, and producing a similar effect. See PEARL INLAYING; IRIDESCENT GLASS.

Pearls and pearl culture .	"*Scientific Amer.*," xl. 170.
Artificial	"*Scientific Amer. Sup.*," 156.

See also CAMEO CUTTING, p. 156, *supra*.

Pearl'ing. The decortication of barley; stripping the pericarp, except that portion in the crease of the grain, —

"The pearling of barley is accomplished by means of small horizontal mills made of sandstone or wood and having a diameter of about eighteen inches and a thickness of four inches. They revolve at a speed of 400 revolutions per minute, and each of them is enveloped with a covering of sheet iron which is punched with holes like a grater, with the edges of the holes turned inward. Between the sides of the mill and those of the sheet iron is a space of about half an inch. On leaving the winnowing machine the grains of barley fall, by means of a hopper, upon the upper surface of the mill, which, by reason of its rotary movement, throws them toward the circumference where they are rubbed alternately between the vertical surfaces of the mill and the covering of sheet iron. By this means they are pearled and are rounded off like balls of marble. The waste escapes without, and when it is seen that the grains are sufficiently rubbed by this action of the mill and its covering, they are made to pass out by a valve and are replaced by a fresh quantity of unpearled grain." — *Rollet.*

Pearl In'lay-ing. The kinds of pearl are: —

White pearl, so called; obtained from the shell of the pearl oyster.

Aurora shell, from the *haliotis*, sea-ear or sea-shell, as it is variously called, and is remarkable for its wrinkled appearance and iris colors.

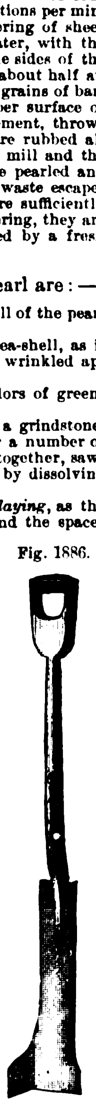
Green snail shell, which has changeable colors of green, yellow, and pink.

The shells are sawn, ground to thickness on a grindstone, cut to shape with scissors, punches, or dies, or a number of similar shape are made by glueing the films together, sawing them to shape, and then separating them by dissolving the glue.

Pearl inlaying upon metal is scarcely true *inlaying*, as the pieces of *nacre* are varnished to the object and the spaces filled with varnish. This is laid on in several coats, each being dried in the oven. The varnish is then scraped away from the pearl, and the surface leveled with pumice-stone and then polished.

Stems of leaves and veins of flowers are traced with varnish, flowers are colored, and gold added by placing leaf on varnished spots. The whole is then covered with white varnish. The process with papier-maché is similar.

Fig. 1886.



Peat Spade.

Peat Char'coal Kiln. A species of oven in which peat in blocks is dried and carbonized.

The ovens are brick arches, covered with sand to retain the heat, and are used in pairs, one being heated while the other is cooling to a sufficient degree to allow the peat to be withdrawn; if air be admitted too soon the peat will inflame. The peat is run into the kiln on trucks, the body being a sort of iron basket with wire netting bottom. The heating is by superheated steam and the heat required to carbonize the peat is 750° Fah. The flues are arranged to allow the diversion of the gases from the furnace when charring has been completed in a given oven. In some cases the peat is dried into blocks; in others it is compressed into *briquets* and dried. The peculiar processes depend upon special conditions.

Peat Spade. One having a side wing at an angle of 90°, so that a cubical prism of peat may be cut from the bank at one thrust.

Peau d'ours. (*Fabric.*) A Moscow coating made in Germany.

Peb'ble Pow'der. Gunpowder in large grains or masses. comparatively slow-burning. Cube powder; *poudre brutale.*

Pebble powder is usually formed from dense cake $\frac{3}{5}''$ in thickness by breaking it into rectangular prisms and then into cubes, by consecutive operations, the length of the faces being equal to the thickness of the cake. It is also made as large as 11-16'' to 2'' cube.

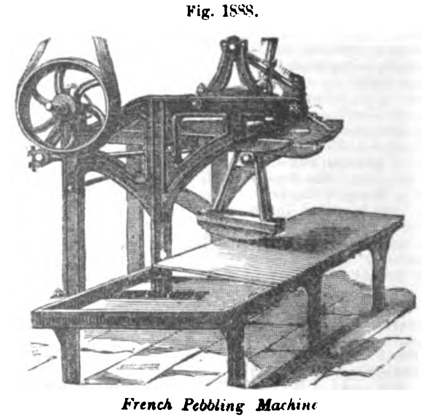
See "*Ordnance Report*," 1879, Appendix I., p. 128, and ENGINEER, September 16, 1870.

Peb'ble Pow'der Ma-chine'. A machine for making cube gunpowder.

The machine is composed of two fluted bronze rollers, each 6'' in diameter, placed about 0.5'' apart, their axes being horizontal and parallel. The teeth formed on the roller by fluting it are 0.5'' apart. The rollers revolve in opposite directions, and the corresponding teeth of the two rollers pass the place joining the axis at the same time. The cake is 14'' × 15'', and is fed vertically between the rollers which break it into right prisms 14'' long with square bases. These fall upon a board, and fed by strips on endless band to a second pair of toothed rollers which break it into cubes.

The result is sifted to remove crushed fragments and dust. The cubes are dusted and are rounded off in the glazing operation, which is done in barrels holding 400 lbs. each. The barrel makes 40 revolutions per minute, and 0.5 oz.

Fig. 1888.



French Pebbling Machine

black lead is added for each 100 lbs. 40 minutes is required for the operation.

Diagram of pebble-powder machine in "*Report of Chief of Ordnance U. S. A.*," 1877, Plate I., accompanying Colonel Laidley's report, Appendix K. See also Figs. 70, 71, Appendix L., same report, and p. 546.

See also Crispin & Baylor's report, "*Ordnance Report*," 1879, App. I., Plate VI., Fig. 18, and description on pp. 128, 1829.

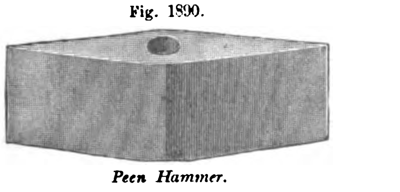
Peel. The portion of a cracker or biscuit machine beyond the cutter is known as the *peel-end*, and its capacity gives name to the machine, as *two-peel* machine. See CRACKER MACHINE, etc.

Peel'ing Axe. A double-bitted axe used in barking trees.

Peen Ham'mer. (*Stone Working.*) One which has two opposite cutting edges. It is used for making drafts around the arris or edge of stones and in reducing faces and sometimes joints to a level. Its length is about 10″ and the cutting edge about 4″. It is used after the point and before the patent hammer. See PEEN, p. 1647 "*Mech. Dict.*"

Fig. 1890.



Peen Hammer.

Peep Nick'ing Ma-chine'. A special gun tool which forms the peep in the leaf of a rifle sight.

Peep Sight. A form of hind sight for rifles. It has an opening through which the muzzle sight is lined upon the object.

The OPEN-BEAD SIGHT, Fig. 249, p. 84, *supra*, and the HAUSSE, Fig. 1329, p. 447, *supra*, are instances. See also GLOBE SIGHT, Fig. 1210, p. 406, for other instances, and list under SIGHT.

Peg'ging Ma-chine'. A machine for driving pegs into boot and shoe soles.

The subject has been considered on pp. 1648–1649, Figs. 3602–3606, "*Mech. Dict.*" Fig. 1891 shows a late form of the Varney foot-power pegging machine which operates upon a peg-strip; cutting off the peg, punching a hole, driving the peg, and feeding the boot sole to its place of apposition for the repetitive action.

Fig. 1891.

Pegging Machine.

Pel'let Pow'der. A form of British cannon powder in which each pellet is molded of a given quantity of mealed powder.

Various shapes have been tried: disks, prisms, and cylinders; the latter preferred. The shape is a right cylinder with a circular base and a small hemispherical cavity at one end. Size 0.5″ long, .75″ diameter; weight, 95 grains. The molds are bored holes in a bronze plate in which a gang of bronze pistons work by hydraulic power.

Pebble powder has superseded it, or largely so.

In France the following are the adopted sizes: —

14 centimeter gun from .275″ to .3937″.

19 to 24 centimeter gun from .51″ to .63″.

27 centimeter gun from .63″ to .787″.

See also "*Ordnance Report*," 1879, Appendix I., p. 126, and "*Engineer*," Sept. 16, 1870.

Pel'let-pow'der Ma-chine'. (*Gunpowder.*) A machine in which the powder is compressed into molds of determined shapes.

"*Ordnance Report*," 1879, Appendix I., Plate V., Figs. 11, 12, and described on pp. 126, 127.

Dr. John Anderson's machine for this purpose is shown at Figs. 11, 12, p. 198, vol. xxv., "*Engineering*." See also PEBBLE POWDER.

***Lead pencils* are now made in Germany by rolling paper around the core of graphite to the required thickness.**

***Paper treated to render Pencil Marks Indelible:* Any ordinary drawing paper is slightly warmed and then rapidly and carefully laid on the surface of a bath consisting of a warmed solution of bleached colophonium in alcohol until the entire surface is moistened. It is then dried in a current of hot air. The surface of the paper becomes smooth, but readily takes the impression of a lead pencil. In order to make the lead pencil marks indelible the paper is warmed for a short time on a stove. This method may prove very valuable for the preservation of working drawings when it is not convenient to finish them in ink.**

COLORED PENCILS, FABER'S PROCESS.

Black:	Lampblack	10
	White wax	40
	Tallow	10

White:	Zinc white	40
	White wax	20
	Tallow	10
Light Blue:	Prussian blue	10

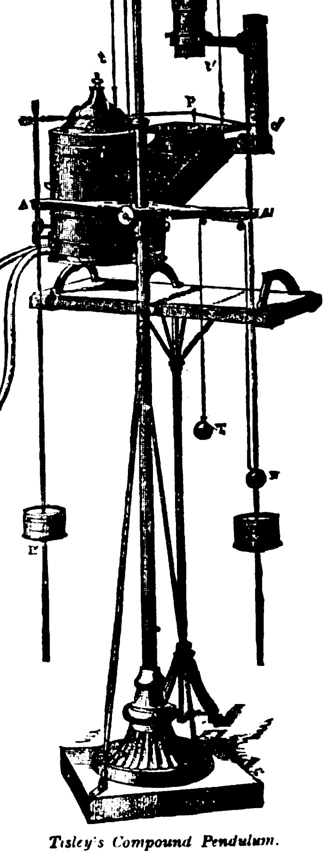
Pen'du-lum In'stru-ment. An instrument for tracing the *Lissajou curves.* In the compound form it is known as *Tisley's* compound pendulum. In the illustration, Fig. 1892, it is shown as adapted to use with the vertical lantern and reflector by which the effects are made visible and projected upon a screen to be viewed by an audience.

Reference has already been made under CURVE INSTRUMENT, p. 236, HARMOGRAPH, p. 439, and LISSAJOU'S CURVES, *supra*, to the instruments for making curves by means of a pen connected with two pendulums swinging in planes at right angles to each other; or a pen to one pendulum and a paper platform to another; also to the mode adopted by M. Lissajou of combining rectangular vibrations to form figures, by means of two tuning-forks carrying small mirrors and vibrating in planes at right angles to each other.

The peculiar curves, the resultants of two vibrations of tuning-forks, produce very instructive diagrams, illustrating definite acoustic relations, such as those corresponding, for example, to the ordinary musical intervals, making the harmonies of sound visible to the eye, and demonstrating visually the relation of the sounds which, united, produce harmonies or discords. — *Lecture of Prof. Bracket, Stevens Institute.*

Under HARMONOGRAPH, p. 439, *supra*, Prof. Tisley's instrument is described. Hopkins has a method of producing the

Fig. 1892.



Tisley's Compound Pendulum.

vibrations by electro-magnet so as to maintain the rate and amplitude of the vibrations, removing the incident of the dying motion of the pendulum without sustaining power.

The compound instrument shown in Fig. 1892 may thus be said to make visible curves representing the musical intervals, the gradual changes between unison and octave, octave and fifth, etc. The apparatus consists of two pendulums, *P P′*, balanced on knife-edges at *A A′*, and continued above their axis of suspension to *c c′*, from which points project two brass arms, *c p*, *c′ p*, which, when the pendulums are quiescent, meet at right angles, the apex being at *p*. Perfect freedom of motion is secured by connecting the arms to the pendulum at *c c′* by ball and-socket joints. Two threads, *t t′*, are fastened at their upper ends to delicate springs, attached to the brass arms, *c p*, *c′ p*, and at their lower ends to an adjustable screw, *d*, by means of which the tracing point *p* may be raised and lowered without in any way affecting the vibrations of the pendulums.

The brass plates, sliding upon the pendulums, are intended to receive the weights, which can thus be placed at different heights, and the relative rates of vibration of the two pendulums altered. The sum of the weights used should vary from 5 to 12 lbs. *W* is a weight sliding upon its pendulum, and counterpoised by a weight *T*. The object of *W* is to slightly change the rate of vibration while the pendulums are in motion. By this means the pendulums can be adjusted very accurately, or if desired, one can be given a small fraction of a vibration in excess of the other; it can be entirely removed, if desired.

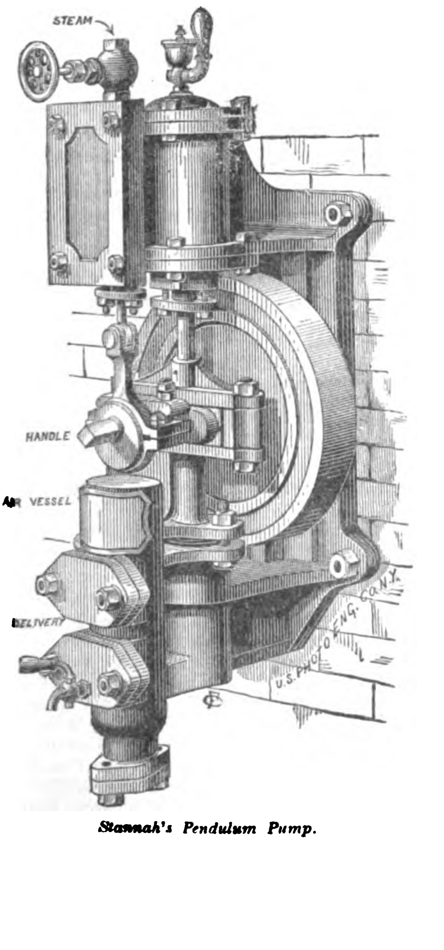
To exhibit these beautiful effects to an audience, a plate of glass blackened by burning camphor is placed upon the vertical lantern, as shown in the figure, the requisite weights are added to the pendulums, and these are set in motion.

Then if we want a curve corresponding to an octave, one of the pendulums must make two vibrations while the other makes one. Having ascertained this we start the pendulums together, then lowering the pen, the beautiful curves will be traced.

"It is not easy to imagine a more striking experiment than that afforded in the present instance, by the noiseless and gradually decreasing sweep of a pen-point gliding over its sinuous path, in obedience to the oscillations of two conjoined pendulous bodies, and tracing, before the eyes of admiring spectators curves of maze-like intricacy and yet of faultless symmetry. As in music, the simplest harmony is the most agreeable to the ear, so with these figures, the simpler the proportions between the vibrations of the pendulums, the more pleasing are the resulting curves."

See also Flame Manometer, pp. 344, 580, *supra*.

Fig. 1893.



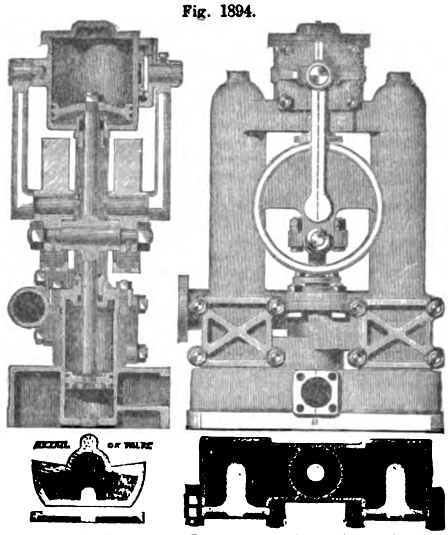
Stannah's Pendulum Pump.

Pen′du-lum Press. A form of press for sheet-metal work, in which the swinging treadle actuates the punch.

Pen′du-lum Pump. 1. A direct acting donkey pump in which the fly-wheels have an oscillatory motion in a vertical plane. Invented by Stannah, London.

The steam and water pistons are fixed on the same rod, and the action is therefore direct. A rotary movement is

Fig. 1894.



Stannah's Pendulum Pump. (Section — Elevation.)

employed to work the valves and limit the length of the pistons. The remarkable feature about the pump lies in the means adopted for causing the rotation of two fly-wheels, no dog link or connecting rod being employed. The crank-shaft is allowed to move sideways in slots carrying its bearings, and the crank pin is attached direct to a piston rod. In the pendulum pump the two fly-wheels are mounted on pins set in the ends of two hanging links, while a crank pin common to both fly-wheels passes through a suitable bearing in the piston rod. When the pump is at work the fly-wheels oscillate backwards and forwards while revolving, the motion being very moderate in range.

Fig. 1893 shows the pump in perspective, and Fig. 1894 shows it on a smaller scale, in front view and section.

2. A pump the handle of which swings each side of its center of suspension.

Perch. A pole connecting the fore and hind gears of a vehicle. See Reach.

The various irons, etc., are at the points of connection.

Perch plates are *head-blocks* and *bed* plates, above and below the perch at the king-bolt.

Perch iron is a term inclusive of the iron parts generally.

Perch loop; an iron attached to a perch, having loops for the straps which pass to the bed to limit the swinging of the latter.

Perch stays; side rods acting as braces, passing from the perch to the hind axle.

Per-chlo′ride of I′ron Bat′te-ry. (*Electricity.*) Invented by Duchenin.

Zinc in solution of sea-salt, carbon in solution of perchloride of iron.

Niaudet, American translation, 208.

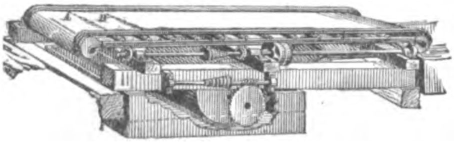
Per-cus'sion Fuse. One which explodes on impact.

The Russian pewter percussion fuse is described on p. 523, and shown in Fig. 17, "*Ordnance Report*," 1877. See also Br., * "*Engineer*," xlvii. 79.

Per-cus'sion Ta'ble. (*Ore.*) A device for sorting ores by exposing them to agitation on a slightly inclined traveling apron in a stream of water.

Frue's percussion table has a rubber belt 2′ broad, constantly shaken from side to side with a regular slow motion.

Fig. 1895.



Concentrating Percussion Table.

This belt is 27′ long, and has projecting flanges of elastic rubber along its outer edges, to keep the sand and water from splashing over. The progressive motion is communicated to the belt by a driving drum, which is connected by a small rubber belt to the front-end roller. The driving drum dips into a tank of water through which the endless apron travels in passing around. On leaving the water tank the belt passes over the tightener and guiding roller.

The ore sized, where the waste is present in larger size than the valuable material, being shaken with a small amount of water will divide evenly on the inclined plane, and the heavier and smaller ore particles will resist the down-flowing water sufficiently to be carried along by the belt over the upper edge into the water tank below; and the waste (lighter and larger particles) will pass over the lower edge. It is successful only on material classified in funnel boxes and of the size of one half millimeter or less.

Per-fect'ing Press. A press which prints both sides of the paper at once, or at a single passage. It acts upon a continuous web of paper, and is shown in several figures, pp. 1566–1568, "*Mech. Dict.*"

See also, PRINTING PRESS, *infra.*

Per-flu'ent Bat'te-ry. (*Electricity.*) One in which the exciting liquid flows through the cells or cell to keep the battery constant.

In one form of the nickel battery of Slater the exciting fluid

Pe-riph'e-ry Con'tact Key. A key having two disks, the peripheries of which come in contact to establish the electric connection. See Fig. 847, p. 266, *supra.*

Per'nette. (*Porcelain.*) A little spur or stilt to place between pieces in the kiln.

Also called (Fr.) *Pattes de coq*, or *colifichets*; Eng. *stilts* or *spurs.*

Per'not Fur'nace. An open hearth revolving furnace. See OPEN HEARTH FURNACE, *supra.*

Springfield, Ill. . . * "*Engineering*," xxix. 374.
* "*Amer. Manuf.*," April 25, 1879, p. 8.

Per'not Steel. In each furnace is a pan that can contain 20 tons of steel, which is revolved by a connection with the engine employed for that purpose. After the pan is charged, the gas flames playing over and around it bring the contents to the desired state of fusion, while the revolving of the pan causes the intimate intermixture of the ingredients, thus overcoming the objection to melting steel in larger receptacles than crucibles. The operation is completed in a little more than five hours. See OPEN HEARTH FURNACE, *supra.*

Per-ox'ide of Lead Bat'te-ry. (*Electricity.*) An invention of De la Rive.

The negative plate is imbedded in peroxide of lead in the porous jar, the salt acting as a depolarizer. — *Niaudet*, Amer. transl., 179.

Per-ox'ide of Man'ga-nese' Bat'te-ry. (*Electricity.*) One in which peroxide of manganese surrounds the carbon plate and depolarizes the same by oxydizing the hydrogen. The invention of Leclanché. — "*Teleg. Jour.*," iv. 213.

In one of *Gaiffe's* batteries, the positive pole has a carbon cylinder pierced with holes parallel to the axis filled with binoxide of manganese; a zinc rod forms the negative pole. The solution is formed of 20 parts chloride of zinc, free from lead, dissolved in 100 parts of water. — "*Teleg. Jour.*," vi. 185.

Per-spec'to-graph. An instrument for assisting in making perspective projections.

It consists of two fixed rulers, one horizontal and the other vertical, in form like a T-square; a sliding ruler which has a lateral movement right and left along the fixed horizontal member, and a graduated quadrant, which is adjustable up and down the vertical member.

The adjustments and mode of using are described by the inventor in "*Engineering*," * xxii. 223.

Pha-na'ro-gri-sou'me-ter. An apparatus invented by M. Gossiaux, of Gardanne (Fr.), for indicating the presence of dangerous gases in fiery mines. A lamp of peculiar construction and a pyrometer make up the instrument.

The lamp is covered with a cylinder of wire gauze. A wire spiral encircles this, and extends the entire length of the cylinder; the wires are held in place by grooves cut in vertical bars forming a frame to the lamp, and are fastened at the top to a ring attached to the cap of the lamp. The wire at the lower end terminates in a tube closed at one end. As the wire dilates under heat, the end of the tube moves a small lever terminating in a sector gearing into a pinion, on which a needle moving on a graduated semicircle is fixed. Constant contact between the end of the lever and the tube is maintained by a small spring, the indicating arrangement being protected by a glass. The heat generated by the presence of the burning gas in the lamp expands the coil and actuates the needle. To graduate the scale, the lamp is lighted in pure air, and zero is marked when the needle is stationary. A piece of iron, a fifth of the volume of the wire envelope, being brought to a red heat, is placed within the gauze, and as the gauze begins to redden — which represents the condition of the lamp burning in an atmosphere saturated with gas — the position of the needle is marked 100, after which the interval is marked off into a scale of 100 parts.

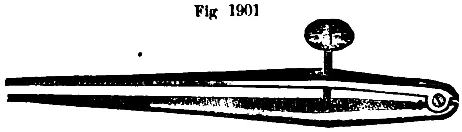
Phi-mo'sis In'stru-ment. An instrument to excise the inner inelastic mucous membrane of the prepuce without removing the normal skin.

The limbs, or blades, terminate in blunt points, and are deeply serrated on their outer surfaces, with points or teeth set backward, like fine saw-teeth, for the purpose of firmly holding the mucous membrane, without the risk of slipping when traction is made The blades are forced apart by a thumb-screw.

In operating, the blades, closed to a point, are introduced

Fig 1901



Phimosis Instrument.

within the prepuce up beyond the corona of the glans. They are then, by turning the thumb-screw, strongly separated, so as to render the mucous membrane tense. Traction is then made, and the outer elastic skin is drawn back fully, so as to be away from the portion to be excised, and excision is effected by transfixing the prepuce through the middle with the bistoury, and cutting laterally in both directions toward the blades of the instrument.

Phimosis forceps.	Rupturing forceps.
Phimosis scissors.	Circumcision scissors.
Frenum probe and spatula.

Phon'ic Wheel. Apparatus devised by M. Paul de la Cour.

It consists of a toothed wheel of soft iron turning round on an axis, so that the teeth pass very closely to but do not touch the pole of an electro-magnet. If a phono-electro current be caused to pass through the electro-magnet, so that the pole exerts a periodic series of attractions on the tooth nearest to it, then the wheel will be in stable equilibrium when at rest and also when it turns at definite speeds, as when the time of a magnetic impulse is equal to that of the turning of the wheel a distance equal to one tooth. The attraction tends to retard the wheel when it attempts to increase its speed, and to accelerate it when it lags.

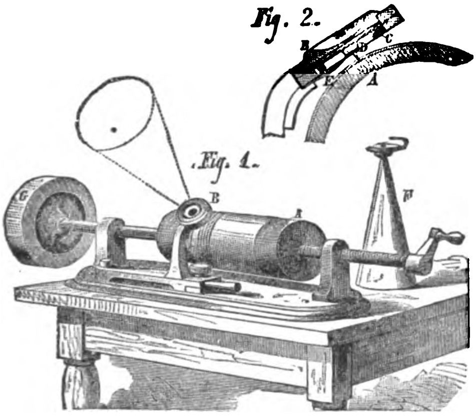
Pho'no-graph. 1. An apparatus for repeating sound. It consists, as shown in Fig. 1902, of a brass spirally grooved cylinder, *A*, mounted on a long, horizontal screw, the cylinder being rotated, and at the same time, moved laterally by turning a crank on the end of its axis. One diaphragm, *B*, serves the double purpose of vibrating in response to the voice, and so indenting by the diamond-tipped point *D* attached to the spring *E*, the tinfoil wrapped about the cylinder, and also revibrating in response to the movements mechanically imparted to it by

the indentations already made passing under the point.

"The exhibitor sang into the machine an entire verse, and it was repeated as often as the cylinder was readjusted. Sounds of coughing, clearing the throat, knocks, noises of

Fig. 1902.



Edison's Phonograph.

all kinds, were as accurately reproduced. A curious effect is produced by whistling, the apparatus giving forth every note clearly and fully; but more remarkable still is it to hear two voices at once come from the machine. The exhibitor first sang a verse which was registered, and then running the cylinder back talked so that the indentations produced by the speech vibrations came over those made by the song. The instrument repeated both utterances simultaneously, each, however, being clearly distinguishable. Another odd performance is turning the cylinder the wrong way, and making the machine talk the language backward."

A modification of the phonograph is called by Mr. Edison the *airophone*. In this machine the vibrating plate, which in the phonograph moves a sharp point over the revolving cylinder, operates as a valve to shut off and open a flow of steam through the pipe which leads from the boiler to a peculiarly-constructed tube. By this contrivance the steam, instead of producing a discordant whistle, pronounces words with considerable distinctness, and audible at a great distance.

Pho-nom'e-ter. An apparatus designed to assist the signal-man on steamships in marking the intervals of time at which the fog-horn or whistle is to be blown, and to regulate the sounds in such a way as to cause them to announce the ship's course.

It consists of a horizontal clock, placed, face up, in sight of the signal-man. The face is about 8″ in diameter, and indicates seconds only, the minute and hour figures and hands being upon a small dial near one edge. The second-hand has four arms at right angles with each other, and above the face is a movable disk, or dumb card, that obscures about three-fourths of the whole dial. Around the edge of the clock face are painted sections or segments. One of these covers ten seconds' space; four mark five seconds each, and between each are blanks of three seconds each. Outside of the clock is a flat brass ring, having the points of the compass marked upon it.

In using the phonometer, the disk is moved round till the open part comes opposite the ship's head and in line with her course. The segments on the dial that are then visible indicate the number of blasts to be given on the whistle. The second-hands, as they then come into view, give the duration in seconds of each blast and each pause. The signal-man merely watches the hands as they traverse the segments in sight, and sounds his whistle accordingly, announcing the ship's direction. For instance, one blast of ten seconds indicates that the ship is steering within the points north and east, quarter north. Two blasts of five seconds each, with an interval of three seconds between them, would announce the ship's direction as between east and south, quarter east. Three blasts, and two pauses of five and three seconds, would mean south to west, quarter south, while four blasts of five seconds, with the same pauses, would indicate the ship's course to be between west and north, quarter west, and so on. The disk employed is designed to prevent mistakes, and the four hands serve to save time in watching for their appearance and journey over the visible portion of the dial.

Pho-no-mo'tor. The machine has a diaphragm and mouth-piece similar to a phonograph. A spring which is secured to the bed-piece rests on a piece of rubber tubing placed against the diaphragm. This spring carries a pawl that acts on a ratchet or roughened wheel on the fly-wheel shaft. A sound made in the mouth-piece creates vibrations in the diaphragm which are caused to propel a fly-wheel.

"*Scientific American*" . . . . xxxix. 51.

Pho'no-phone. A term proposed for the phonograph, as the latter term had been previously applied to Scott's machine, which is of different character, and invented many years since.

See PHONAUTOGRAPH, p. 1678, and TELEPHONE, pp. 2514, 2515, "*Mech. Dict.*"

Pho'no-phote. An apparatus for the transformation of sound into light, devised by M. Coulon, Conservator of the Industrial Museum of Rouen.

Two Geissler tubes are put in quick rotation on an axis. The induction coil of the first is worked by an ordinary interrupter, and gives the deviation of a luminous cross. The interrupter of the second is replaced by a telephone. The figure presented by the second tube projects on the first one, which is colored by uranoxide glass, and exhibits the most rapid changes according to the height of the tone delivered in the telephone trumpet. The sensibility of the changes are said to be startling and most interesting. —"*Nature*."

"*Eng. & Mining Journal*" . . . . . xxviii. 147.

Pho'no-scope. An instrument invented by Henry Edmunds for producing figures of light from vibrations of sound. It consists essentially of three parts, an induction coil, an interrupter, and a rotary vacuum tube. The action of the instrument is as follows: —

"Sounds from the voice or other sources produce vibrations on the diaphragm of the interrupter, which, being in the primary circuit of the induction coil, induce at each interruption a current in the secondary coil similar to the action of a contact-breaker or rheotome; therefore, each vibration is made visible as a flash in the vacuum tube. This tube revolving all the time at a constant speed, the flashes produce a symmetrical figure like the spokes of a wheel, as in the *Gassiot Star*. The number of spokes or radii is according to the number of vibrations in the interrupter during a revolution of the tube, and the number of vibrations being varied to any extent, according to the sounds produced, the figures in the revolving tube will be varied accordingly. The same sounds always produce the same figures, providing the revolution be constant. In case of rhythmical interruption being produced in a given sound, as in a trill, most beautiful effects are noticeable, owing to the omission of certain radii in regular positions in the figure. The uses of this instrument are the rendering visible of sounds, and showing the vibrations required in their production, and it forms a mode of confirming by sight an appeal to the ear." — *W. Ladd.*

* "*Engineer*"	xlv. 421.

"*Scientific American Supplement*" . .	2182, 2308.

Phos'phide of Cop'per. See PHOSPHOR BRONZE.

Phos'phor Bronze. Invented by Montefiore & Künzel, the founder of the Val-Benoît nickel manufactory, near Liege.

"Phosphorus bronze is made by fusing phosphorus tin with copper or with phosphorus copper. It fuses at 1230° to 1250°; the finished product usually contains 0.053 to 0.76 per cent. phosphorus and 4 to 9 per cent. tin." — *Dr. Stammer.*

The result of analyses and observations indicates that the phosphorus exercises a double chemical action over the metals which compose the alloys. While reducing on the whole the oxide of tin contained in the mixture, it at the same time forms with the metals it has thus purified a perfectly homogeneous alloy, the hardness and resistance of which are subject to control by varying the proportion of phosphorus.

Experiments have established the superiority of phosphorus alloys over ordinary bronze, copper, coke-iron, charcoal iron, and steel. Under the influence of strains exceeding the limit of elasticity, or of violent shocks, their texture does not become crystalline. They are completely free from metals easily liable to attack, such as zinc. Sea-water, or diluted solutions of sulphuric acid, have only a very feeble action upon them, and in all cases much less than on pure copper. One of their most valuable qualities is, that recasting does not occasion loss in tin. Moreover, their degree of liquidity, which may be compared to that of mercury, renders it possible to obtain them without blisters, and to have perfect moldings. Their degree of fusibility is nearly the same as that of ordinary cannon bronze.

A number of phosphor-bronze alloys are now manufactured, varying in composition to suit the objects for which they are intended. The scope of their application is very great. For instance: —

Bearings.	Locomotive fittings.
Bell metal.	Nails.
Boiler tubes.	Oil cups.
Bolts.	Ornaments.
Buckles.	Printing rollers.
Busts.	Rivets.
Cannon.	Tools.
Cocks.	Tubes.
Engraving plates.	Tuyeres.
Fire-arms.	Valves.
Gun fittings.	Wire.
Hammers.	Wire rope.
Harness fittings.	Wrenches.
Keys.	Etc.
Locks.	

The great features of phosphor-bronze are that it can be made to any degree of hardness, toughness, or elasticity. It can be rendered more ductile than copper, as tough as wrought iron, or as hard as steel. It possesses great fluidity, its homogeneity is complete, and its grain is as fine as that of cast steel. It may be controlled with ease and accuracy to suit the particular purpose for which it is intended, and can be remelted as often as may be desired without any appreciable loss or material alteration of its quality. The phosphor-bronze alloy made for rolling, drawing, or embossing, will stretch more than copper or any of its ordinary compounds. Plates have been reduced by a single cold rolling to one fifth of their thickness, the edge remaining perfectly sound, and without cracks.

The following shows the results of tests made by Mr. David Kirkaldy, of London: —

CAST METAL.	Diminution of Section before Rupture.	Resistance in pounds per square inch. Elastic.	Resistance in pounds per square inch. Absolute.
	Per Cent.	*Pounds.*	*Pounds.*
Pure copper	3.30	4,400	6,975
Ordinary gun metal, containing 9 parts copper, 1 part tin .	3.60	12,800	16,650
Phosphor-bronze . .	8.40	23,800	52,625
Phosphor-bronze . .	1.50	24,700	46,100
Phosphor-bronze . .	33.40	16,100	44,448

Various Alloys. Phosphor-Bronze	102,759	49,851	6.7	89	37.5
" "	120,957	47,787	22.8	52	34.1
" "	120,953	53,381	13.0	124	42.1
" "	139,141	54,111	17.3	53	44.9
" "	159,515	58,853	18 3	66	46.6
" "	151,119	64,569	15.8	60	42.8
Copper	63,122	37,002	86.7	96	34.1
Steel	120,976	74,637	22.4	79	10.9
Iron, Galvanized best Charcoal E . . .	65,834	46,160	48.0	87	28.0

N. B. — The wire used for these experiments was No. 16, Birmingham wire gage.

"The following analyses of specimens of phosphor-bronzes show that phosphorus enters into them in very small proportion, though it has a most useful effect: —

Copper . .	93.68	94.11	90.86	94.71	90.34
Tin	5.82	5.15	8.56	4.88	8.99
Phosphorus .	.17	.21	.19	.55	.76
Zinc . . .	.34	.23	-	-	-

"Phosphorus may be introduced directly into the alloy in a state of fusion. In this case a great part of it is lost; only a small quantity combines chemically with the metal. The copper may also be melted in a crucible, lined inside with bone-ash, nitric acid, and charcoal. This mixture should surround the copper on all sides before the closing of the crucible." — *Revue Industrielle.*

Phos'phor Cop'per. An alloy used in the making of phosphor bronze.

"Phosphorus copper may be made by heating together four parts acid calcium phosphate, two of granulated copper, and one part of charcoal; the copper must be pure." — *Dr. Stammer.*

"A crucible is fettled with a mixture of bone ash, silicic acid, and carbon, granulated copper is laid in and covered with a quantity of the fettling mixture, and the whole is fastened down with a cemented cover. Soda and glass can be added to promote fusion. At a fusing heat, the silicic acid acts on the phosphate, the phosphoric acid is reduced and taken up as freed by the copper." — *Dr. Schwarz.*

Phos'pho-res'cent Di'al. Usually made of paper or thin cardboard enameled like visiting cards; covered with an adhesive varnish, or white wax mixed with a little turpentine, over which is dusted with a fine sieve powdered sulphide of barium. Sulphides of strontium and calcium possess the property in a lower degree. The dial loses its phosphorescence after a while in darkness, but is restored by sunlight or burning magnesium wire.

Illuminated sign . . .	p. 489, *Ibid.*

Phos'pho-res'cent Pho'to-graph. A plate coated with a mixture of dextrine, honey, and bichromate of potash is exposed under a negative, the result being that those portions which are exposed to the effect of the light through the transparent portions of the negative harden, while those which are protected from the light remain adhesive. The lines of the image retain any fine powder which is dusted over it, while the hard portions will not retain it. A phosphorescent powder — for instance — sulphite of lime, is dusted over the positive, and, after having been exposed to sunlight, or any strong artificial light, becomes luminous in the dark.

Phos'phor Tin. By heating 6 parts phosphorus with 94 parts moist tin sponge prepared from the chloride by reduction with zinc, the substance formed is Sn_9P, fusible at 370° C.

Made at Graupen tin works at Mariaschein, in Bohemia.

Useful in making phosphor bronze, as it removes the oxides, which tend to harden the latter. See —

Pho'to-col'lo-type. A photograph printed in natural colors.

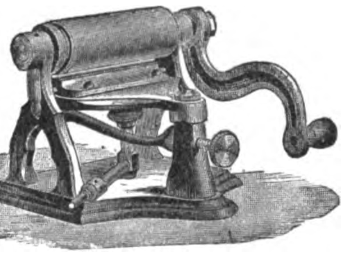
Herr Albert's method .	"*Scientific American*," xli. 260.
Mr. Bolas' method . .	"*Scientific American Sup.*," 2770.

Pho'to-drome. A scientific instrument for producing optical effects by flashes of light.

It consists of a strong rotator, carrying three disks of devices, each 30″ in diameter, painted on paper; and a small rotator carrying a smaller disk of card-board, with openings in it, to allow the light from a calcium, magnesium, or electric lantern to be thrown upon the first disk by flashes. Each rotator is revolved rapidly, producing curious effects upon the large disk. See PHENAKISTOSCOPE.

Pho'to-graph Bur'nish-er. A little machine in which a brilliant surface is given to a photograph by passing it under pressure over the surface of a burnishing tool. The feeding roller is slightly roughened; the picture is fed, face downward over the burnisher, which is heated by an alcohol lamp beneath.

Fig. 1903.



Schuyler's Photograph Burnisher.

Ewing	"*Scientific American Supplement*," 809.

Pho'to-graph'ic Ri'fle. A device to take photographs of birds in flight.

Capt. Vassel proposes a small dark rifle chamber of 2.27″ interior diameter, surmounted by a proper level and sight. By means of Muybridge's, Janssen's, or other contrivances for taking instantaneous pictures, he thinks that small views might be easily taken which could be subsequently enlarged. He also proposes a photographic revolver for taking a series of successive attitudes at a single operation — "*La Nature*."

Pho-tog'ra-phom'e-ter. An automatic apparatus to record the angular position of objects situated around a given point.

The objective is mounted vertically on a circular platform capable of rotating, by means of clock-work, in a horizontal plane.

The picture is formed, not in a vertical plane, as ordinarily, but in a horizontal; the rays, passing in through the objective, are deflected 90°, by means of a reflecting prism so as to fall on the horizontal sensitive surface, which is collodionized glass, and is placed in such a way that its center corresponds with the point at which the center point of the diaphragm would be represented. To prevent a number of confused images superimposed on each other being formed during the rotation of the objective, an opaque screen, having a narrow oblong opening, the medial line of which passes through the axis of rotation, is placed over the whole of the sensitized surface, and revolves along with the objective.

The result of this arrangement is the production on the sensitized plate of images of the different points that lie around the observer; the angles formed by lines joining the center of the plate, and the different objects being exactly the same as those formed by lines joining the center of the instrument and the objects themselves. The position of the objects thus accurately obtained may be transferred to paper, etc., in the ordinary way.

See also OROHELIOGRAPH, *supra*.

Pho-tog'ra-phon. A complete portable photographic apparatus for field-work.

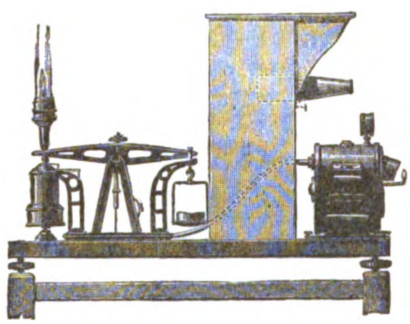
Brice's "English Mechanic" . . . . . . xxvii. 141.

Pho-tom'e-ter. A measurer of illuminating power. See instances pp. 1687, 1688, *"Mech. Dict."*

The official gas-testing apparatus used in the city of Paris is the result of consultations of the *Compagnie Parisienne du Gaz*, and *MM. Dumas* and *Regnault*, and is shown in Figs. 1904–1906.

The table has leveling screws. One extremity of the table has a meter with a dial, one hand registering units of 1-20 liter of gas, and the other hand fixable in any position as a

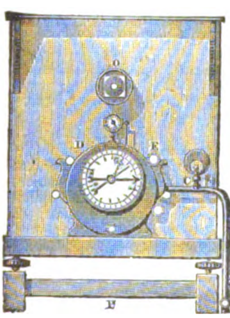
Fig. 1904.



City of Paris Photometer. (Side Elevation.)

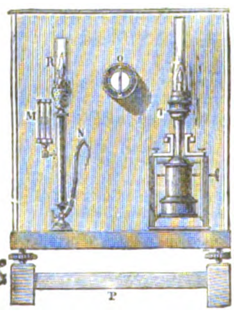
mark at the commencement of an evaluation, and in connection with the dial-hand of departure is a lever which sets in consentaneous movement the dial-hand of a seconds chronometer placed above the dial of the meter. Behind the meter is a hood beneath which the observer places his

Fig. 1905.



City of Paris Photometer. (Front End View.)

Fig. 1906.



City of Paris Photometer. (Rear End View.)

head, and looks through the tube which is shown projecting to the right. In the tube is placed a glass plate on which is a thin film of starch, and behind this a vertical plate, set edgewise so as to divide the field of view, and allow the light under evaluation and the standard light to be compared.

The chemical photometer of Herr Eden, of Vienna, is based upon the observation that chloride of mercury is very easily reduced to insoluble chloride in sunlight whenever it is mixed with organic substances.

The sensitive solution consists of two volumes of a solution of 40 grams of oxalate of ammonia in one liter of water, and one volume of a solution of 50 grams of sublimate in one liter of water. In sunlight turbidity is immediately produced, the action of the light being weaker as the solution is more dilute. Tables are furnished for the corrections necessary to allow for the influence of increasing dilution and varying temperature on the quantity of the chloride of mercury separated by the photo-chemical process of decomposition.

The pocket photometer of M. Schutte, of Paris, has the form of a small telescope.

Putting the eye to the narrow end and looking through at a light, one sees a small luminous circle, on which is detached some figure in black. On turning the wider part of the instrument, successive numbers are seen, and the higher the number the weaker is the light perceived, and at length it quite disappears. This effect is obtained by means of leaves of waxed paper, the number of which increases with the figures. Thus a weak, luminous source does not allow one to see the same number as a strong one, and the variation between the figures increases with the difference in intensity. The instrument can be used for determining the time of exposure in photography.

The same principle is involved in the actinometer, described on p. 11, *"Mech. Dict."*

"Popular Science Monthly" . . October, 1882, p. 864.

Pho'to-phone. An apparatus devised by Alexander Graham Bell and Sumner Tainter for the production and reproduction of sound by means of the undulations of light. Vibrations are conveyed between distantly separated diaphragms by a beam of light.

It is founded upon the sensitiveness of matter to light vibrations, and selenium offers the most promising results of the numerous substances experimented with. Professor Bell's description of one form of the apparatus is as follows: —

"The simplest form of the apparatus for producing the effect . . . . consists of a plane mirror of flexible material, such as silvered mica or microscope glass. Against the back of this mirror the speaker's voice is directed. The light reflected from this mirror is thus thrown into vibrations corresponding to those of the diaphragm itself."

"The beam is received at a distant station upon a parabolic reflector, in the focus of which is placed a sensitive selenium cell, connected in a local circuit with a battery and telephone."

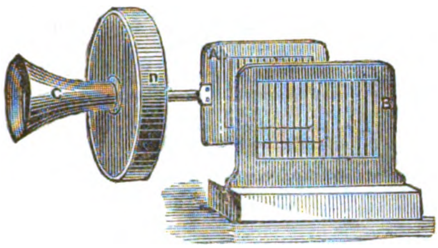
Articulate sentences have been conveyed 213 meters. See address by Professor Bell, at the annual meeting of the *"American Association of Science,"* August 25, 1880. Reported in Boston *"Daily Advertiser"* of that period, and reproduced in —

"Sc. American Supplement" . . p. 3921.
"Iron Age" . . . . xxvi., Dec. 2, p. 1.
"Manufacturer and Builder" . . xii. 255.

Fig. 1907 will illustrate an experimental instrument.

"In order to obtain a beam of light, the illuminating intensity of which at a distance could be directly controlled by, and bear a relation to, the sonorous vibrations constituting musical notes or articulate speech, Prof. Bell interposed in the path of a beam of sunlight a screen consisting

Fig. 1907.



Photophone (Illustrative Instrument).

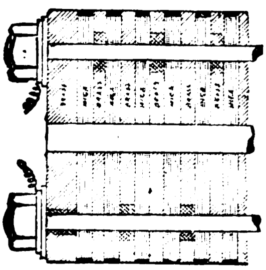
of two thin plates of metal, perforated with a number of fine slits, one of these plates, *B*, being fixed, while the other, *A*, was attached to the center of a diaphragm, *D*, which could be thrown into vibrations by the human voice at *C*, so that the motions of the diaphragm would cause the movable screen to slide backward and forward over the fixed plate, and in so doing alternately enlarge and contract the orifices through which the luminous beam was transmitted." — *Engineering.*

In the illustration the intervals are exaggerated, to render them more clearly visible. "The width of the slits, as well as their distance apart, are so determined with respect to the rigidity of the diaphragm that at no position in the amplitude of the motion is the passage of the beam entirely closed, a certain amount of light passing continuously to the receiver, the opening and contracting of the orifices of the screen merely varying the intensity, for although a rapidly intermittent beam of light would by this means transmit musical notes, it would be powerless to convey even an approximation to the complications of articulate speech." — *Ibid.*

The construction of the selenium cells of the receiver by Messrs. Bell and Tainter is one of the most interesting of the series of ingenious contrivances involved. There is but room here for a sketch of results; the references appended will furnish details omitted here.

Fig. 1908 is the cylindrical form of selenium cell employed by Prof. Bell. The sensitive portion is the cylindrical surface upon which the rays of undulatory light are thrown by a paraboloid reflector in the focus of which it is placed. It consists of a number of circular disks of brass about 2″ in diameter strung upon a rod passing through their common center, and separated by a similar series of disks of mica of slightly smaller diameter. When the compound series is built upon the mandrel a number of grooves occur around the mica, owing to the relatively smaller diameter of its disks. These grooves are filled with melted selenium. The bolts which pass through the disks form the connecting screws for placing the instrument in circuit with a telephone and battery. Every other disk of brass is in connection with the upper bolt, and the alternate disks with the lower bolt.

Fig. 1908.



Bell's Photopile of Receiver.

This alternate connection is shown by the diagram, Fig. 1909, the odd numbered disks being connected by wire *M*

Fig. 1909

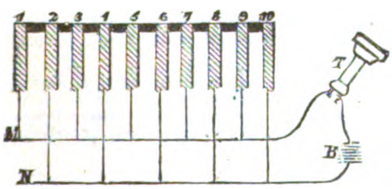


Diagram of Photopile and Connections.

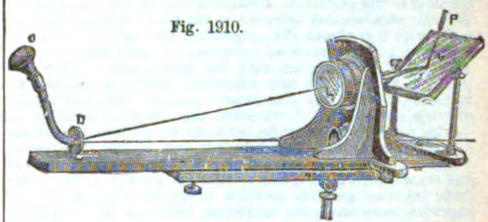
with the telephone *T*, and the even numbered by the wire *N* to the battery *B*, and thence to the telephone *T* in circuit.

Figs. 1910, 1911 illustrate the photophone, the former showing the transmitter, and the latter the receiver.

The transmitting instrument of the photophone (shown in Fig. 1910) consists of a long board, with suitable adjust-

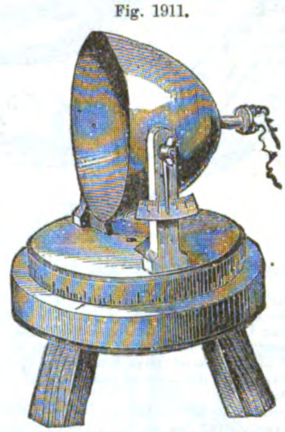
Fig. 1910.



Transmitter.

ments for directing it, within certain limits, in both altitude and azimuth. To the board are attached the various parts of the apparatus. *O* is the mouth-piece, with its reflecting diaphragm, *D*, of silvered glass or mica, and *M* is the mirror by which a ray of light from the sun, or any other powerful source of light, may be projected on to the diaphragm *D* by the condensing lens *L*, below which is fixed another lens, *E*, for the purpose of parallelizing the beam after reflection from the silvered diaphragm, and projecting it to the distant station, where it is received by the paraboloidal reflector of the receiving instrument shown in Fig. 1911, in the focus of which is placed one of the cylindrical

Fig. 1911.



Receiver.

photopiles, Fig. 1908, and in circuit with the latter is placed a pair of telephones and a voltaic battery, which in Professor Bell's experiments consisted of nine Leclanché cells.

The general arrangement and disposition of the whole installation is clearly shown in the diagram, Fig. 1912, in which the portion to the left of the figure is the transmit-

Fig. 1912.

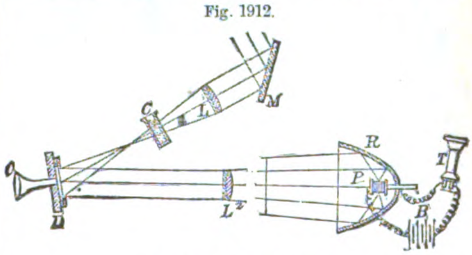


Diagram of Installation.

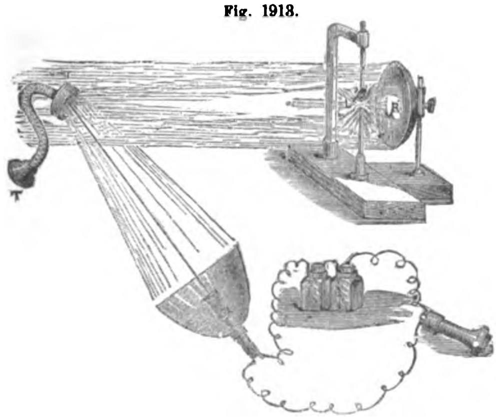
ting apparatus, and that to the right the receiving instrument. The rays from the sun, or from whatever source of light is employed, after being reflected by the plane mirror *M*, are concentrated upon the face of the reflecting diaphragm *D* by means of the lens *L*, and a small glass trough *C* containing a solution of alum is interposed in their path for the purpose of absorbing the heat rays which, by altering the figure of the diaphragm mirror and introducing other irregularities, might produce disturbing influences which are better eliminated. At L^2 is placed a second lens for the purpose of either parallelizing the rays and projecting them to the receiving apparatus, or of rendering them divergent according to the particular circumstances of the experiment. *R* is the paraboloidal reflector, in the focus of which and co-axial with it is placed the cylindrical photopile *P*, which is included in the circuit of a battery, *B*, and telephone, *T*. When words are spoken into the mouth-piece *O*, the diaphragm *D* is thrown into vibration, becoming thereby alternately more or less convex and concave with continually varying amplitudes of vibration, the effect of which is to confer upon the beam reflected from its surface a continually varying illuminating intensity and, as this undulatory beam is projected by the reflector, *R*, upon every portion of the sensitive surface of the cylindrical photopile, the latter is in the best possible position to produce by its varying electrical resistance the maximum effect in the telephone. — "*Engineering*."

Fig. 1913 is a diagram showing an apparatus by Prof. Bell, used in Paris in photophonic experiments, with electric light as the source of illumination.

Fig. 1913.

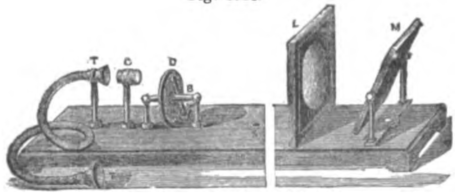


Photophone with Electric Light Illumination.

L is the electric lamp, the arc of which is in the focus of a paraboloidal silvered reflector, *R*, by which the divergent rays emanating from the arc are condensed and projected as a parallel beam to the reflecting diaphragm *T*, by which a certain small proportion of them is reflected to the receiving instrument through a distance of nearly 50′, as shown in the figure.

Fig. 1914 shows an apparatus devised by Messrs. Bell & Tainter in investigating the transmission of sounds from one

Fig. 1914.



Photophone without Electricity.

station to another without the aid of electrical arrangement, or of any thermopile. Almost all substances emit a sound when placed in the path of a beam of soniferous light, such for instance as is reflected from the vibrating diaphragm of the photophone in action, or as is produced by giving to the beam of light a rapidly intermittent character. In the instrument shown in Fig. 1914 rays of solar light are by the lens *L* condensed, after reflection from the surface of the mirror *M*, to a focus on the *D* disk, in which is perforated an annular series of some forty holes, and which can be set into very rapid rotation by arrangements not shown in the figure. By this means a beam of light projected by the lens *L* on to the tube *T* can be interrupted from a hundred to six hundred times in a second, which corresponds to the rapidity of vibration of a musical note of high pitch. When such an intermittent beam is allowed to fall upon diaphragms of different substances placed at the end of the tube *T*, they, with doubtful exceptions, are thrown into vibration, and the corresponding note is heard in the hearing-tube.

When the hearing tube *I* is removed, the apparatus shown in Fig. 1914 may be used as a transmitting instrument for the sending of photophonic signals on the Morse or any other prearranged system to a distant station. In this case, while the disk is in rapid rotation, a shutter operated by a key (shown in the figure) is made either to obstruct the light or to allow it to pass for longer and shorter periods of time corresponding to the dashes or dots in the Morse code. When the instrument is employed for this purpose a plano-convex lens is placed at *C* for parallelizing the beam of intermittent light.

MM. Bell & Tainter have also devised an apparatus for bringing about the variation of the intensity of a luminous beam, by the application of Faraday's discovery of the rotation of the plane of polarization of a beam of light in its passage through a magnetized field. Rays of light emanating from a source of light are parallelized by a lens and projected to a receiving photophone, passing successively through a polarizing Nicols' prism, a hollow coil of insulated wire and an analyzing Nicols' prism. — * "*Engineering*," xxx. 409.

Following in the same line of research is a new apparatus in which a beam of light from a lime light, or even a candle, is thrown upon a common glass flask having a long neck. To this is fastened a rubber speaking tube that may be placed to the ear, so that any sounds in the flask may be heard through the tube.

Between the flask and the light is placed a circular disk of metal, having narrow slots or openings, placed like the spokes of a wheel round the edge. When the disk is at rest, the beam of light may pass through one of the slots and fall on the flask.

If, now, the disk is made to turn rapidly on its axis, the light will reach the flask in a series of flashes, as it shines through the slots one after the other. Here the curious discovery comes in. When the flask is filled with a gas or a vapor, say the vapor of sulphuric ether, common street gas, oxygen, perfumes like patchouli or cassia, or even smoke, and the beam of light is made to fall on the flask in a series of alternate flashes, the operator, listening with the speaking tube at his ear, will hear strange musical sounds inside the flask.

The pitch of these tones will correspond exactly with the speed with which the disk is made to turn, and each kind of gas or vapor in the flask will give a different kind of note, some soft, some loud, and some very sweet and musical.

"This shows that light may be made the means of making sounds audible at a distance, even when the eye can see no difference in the light. It even suggests the idea that we may yet be able to hear the sounds of the fires raging in the sun. It may, indeed, be only a hint to yet more wonderful and unthought of relationships between light and sound, which may be utilized as a medium of communication."

Pho′to-print′ing Pro′cess. Numerous inventions, processes, and modifications are given in the "*Mech. Dict.*," a list being appended on p. 1686. Notices of the following methods may be found in the references cited. There are so many systems, and they anastomose in so intricate a manner, that it is not easy within allowable limits to make even a digest.

In the following list the term printing is used somewhat generally, including relief process, gelatine, and metallic, bichromate or acid processes; also printing from negatives either to make clichés, positive pictures, or transfers.

Pie'som'e-ter. See PIEZOMETER; PRESSURE GAGE; and references *passim.*

Pi'e-zom'e-ter. 1. (*Surgical.*) An instrument to measure the sense of pressure. It consists of a spring in a German silver graduated tube. The spring is pressed by a rod, on the end of which is a hard rubber disk $\frac{1}{3}''$ in diameter.

The sense of pressure is strongest on the forehead, tongue, and cheek; next in order come the fingers, back of hand, forearm, and arm; then the anterior portion of the thigh and leg, back of foot, and toes. The least sensitive portions are the back of thigh and leg.

Beard's Fig. 284, Part I., *Tiemann's* '*Armam. Chirurg.*" See also ÆSTHESIOMETER.

2. An instrument to ascertain the pressure set up in the bore of a gun when a charge of powder is fired.

"*Engineer,*" * Sept. 16, 1870; vol. xlvii., 83, 134, 170.
See "*Ordnance Report,*" 1879, Appendix M., pp. 228-256, and Plates I.-XI.
See also CUTTER; CRUSHER GAGE, *supra*; * PRESSURE GAGE *infra*.

The piezometer of M. Sebert consists of a metallic rod of square section fixed in the axis of a hollow projectile, and which serves as a guide to a movable mass. The latter carries a small tuning fork the prongs of which terminate in two small metallic pens which leave undulating traces of their passage on one of the faces of the rod, which has been coated with lamp black. It is designed to determine the laws of motion of a projectile in the bore of a cannon in order to deduce therefrom the law of the pressures developed by the combustion of the charge.

"*Scientific American*" . . . . xl. 1811.
* "*Scientific American Sup.*" . . . . 4042.

3. The same principle is adopted in obtaining measurements of depth in sounding. In *Thomson's* navigational sounding apparatus, shown and described on pp. 351, 352, *supra*, the observed condensation of air in a tube attached to the sinker and registering itself by the contact of sea water with a preparation lining the tube, is made the measure of depth.

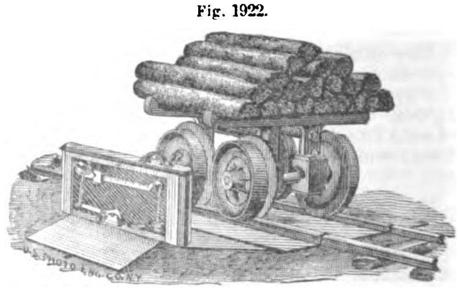
Buchanan . . . . "*Van Nostrand's Mag.,*" xviii. 61.

Pig and Ore Pro'cess. (*Metallurgy.*) A process of Dr. C. W. Siemens.

It consists in melting down a charge of pig-iron together with enough iron ore to make good the loss of pig-iron by oxidation. The ore facilitates the decarburization of the pig-iron. The pig and ore process is coming largely into use, and is in Great Britain, where it is well done on a large scale, a successful rival of the Bessemer process. — *Holley.*

Pig Met'al Scales. An iron truck to run on to a section of railway upon scale platform.

Fig. 1922.



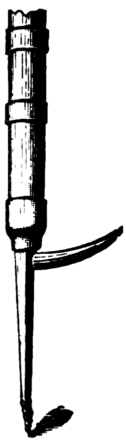
Pig Metal Scales.

The car is intended to hold a furnace charge. The beam is concealed, but has an indicator which passes through the top of the beam box.

Pike Pole. A tool used by lumbermen in driving logs in rivers. See Fig. 1923.

Pile Dam. A dam made by driving piles and filling in with stones. It usually has planking to protect the surfaces.

Fig. 1923.



Pike Pole.

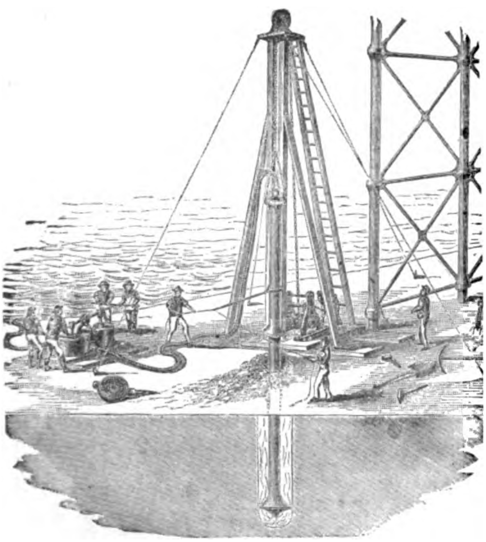
See Pile dam on the Little Kaukanna, Fox River improvements: "*Report of Chief of Engineers U. S. Army*," 1876, vol. ii., part 2, Plate II., p. 416.

Pile Dri'ver. The pile driver as a ramming engine to force piles into the ground is shown in Figs. 3717, 3718, pp. 1702, 1703, "*Mech. Dict.*" See also PILE-DRIVING ENGINE, *infra;* PNEUMATIC PILE, "*Mech. Dict.*," *et infra*, and references *passim*.

The method of driving piles by aid of hydraulic jet has been very successful in sands and soils which are free of logs and bowlders. The operation is shown in Fig. 1924. It is a device of British engineers, used at Morecombe Bay in India, in building a railway bridge crossing some treacherous sands and also used in the construction of Southport pier, England. The pile is in hollow iron sections and has a bulbous shoe.

"The columns, 9″ in diameter and of ¾″ metal, terminate in an extended base 18″ in diameter, with a contracted opening of 2½″. This disk is provided with toothed edges, and serrated flanges to scratch away any impediments, and cut through the layers of indurated mud and silt which here and there interpose and interrupt its progress. The column is clasped by moving guides on the face of an ordinary piling engine frame, and down the inside

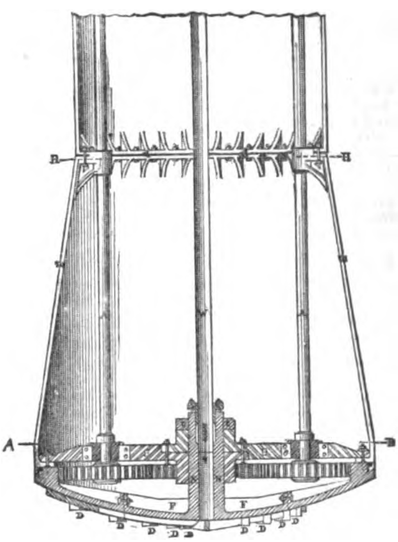
Fig. 1924.



Dickson's Hydraulic Pile Driving

is run an iron tube 2¼″ in diameter, protruding a few inches beyond the base. The upper end of this tube being brought round, is attached by screw couplings to a flexible hose, in connection with a steam pump. The whole being duly placed in position, a couple of men are told off to keep the column in reciprocating motion by means of a lever clasped round it, and all being ready the pumps are set to work. The issuing jet of water blows up the sand, which is thus kept continually agitated, and down goes the pile in the hole thus formed, steadily lowered by the men at the winch, the ascending stream keeping the sand above alive, and preventing it setting; but so soon as the requisite depth is attained, the pumps are stopped, and the tube rapidly withdrawn, and the whole in the course of a few minutes is firmly fixed. These columns, in the case cited at Southport, are all put down a depth of 15′ to 20′, the average time occupied in the actual process of sinking being but 20 to 30 minutes. Two or three were fixed in a tide, the bulk of the time being necessarily occupied in moving about the

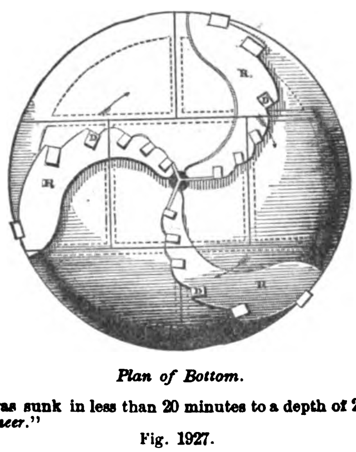
Fig. 1925.



Section through Axis of Pile.

apparatus and machinery. Some of the piles were sunk from a raft, the process answering equally as well under water as ashore. An experimental column with a reduced

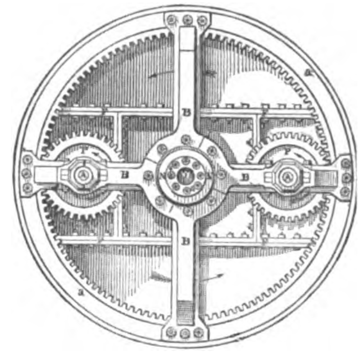
Fig. 1926



Plan of Bottom.

disk, was sunk in less than 20 minutes to a depth of 26′." — "*Engineer.*"

Fig. 1927.



Section through A-B.
(Showing Plan of Bridge-piece and Arrangement of Gearing.)

Figs. 1925–1927 show excavating shoes to be added to the end of the ordinary tubular pile when the soil is of such a nature as not to yield to the mere impact of water.

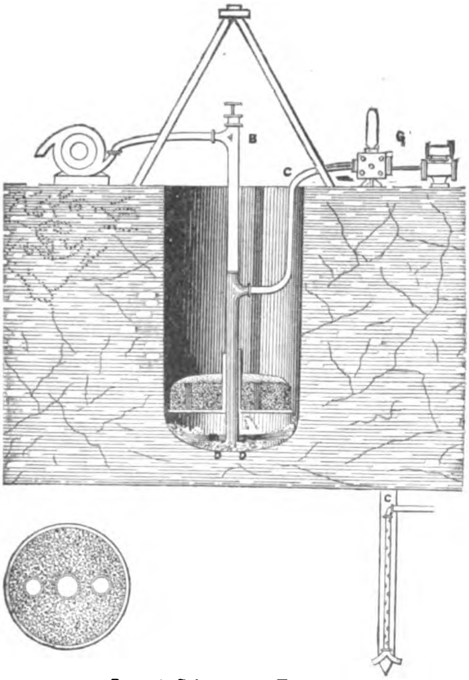
The cylinder itself is not rotated but is held upright over the spot it is to occupy and sinks as the earth is excavated beneath it. The sole of the pile is shown in section in Fig. 1925 and in plan in Fig. 1926, steel cutters *D* being placed on curved blades *R*, and driven by means of gears *P* on shafts *A* supported in sockets *R* and bridge *B*. The gears *P* mesh into an internal cog-wheel *A* which is a part of the sole *F*.

The shoe being rotated comminutes the soil which is driven away by a copious jet of water conducted down the interior of the cylinder. The required depth being reached, an air chamber is attached to the top of the pile and air forced in to empty the pile while the machinery of the bottom portion is all removed. The pile is then filled with concrete.

Pile Dri'ving. The methods of sinking piles and caissons by pneumatic methods or by combined pneumatic and other methods have been considered under * PNEUMATIC PILE, p. 1754; * CAISSON, p. 421; * AIR LOCK, p. 49; * SUBMARINE EXCAVATOR, p. 2439, "*Mech. Dict.*" See also PILE, *supra.*

Figs. 1928–1930 show views of the subaqueous excavator of Pontez, used for driving piles or making solid foundations in quicksands or unstable soils.

Fig. 1928.



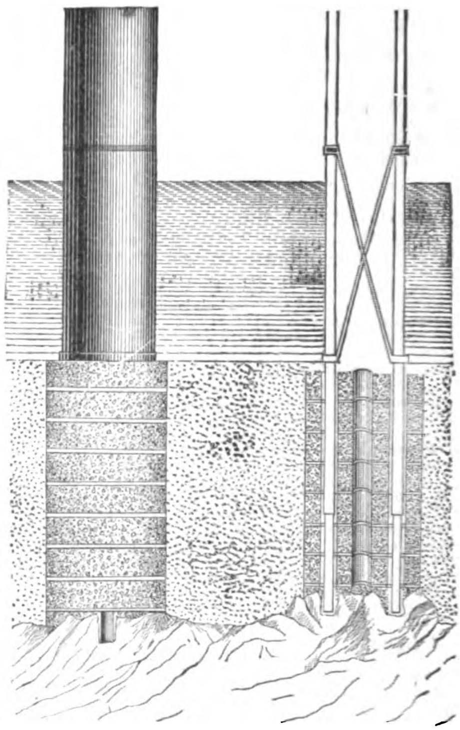
Pontez' Sub-aqueous Excavator.

Fig. 1928 is a vertical section showing the excavating cylinder in position, also the working apparatus. Beneath the view of the apparatus in situ are two detached figures: one a plan of the disk showing the central hole for the tubes, and other holes for piles which are to be driven through. On the right is a sectional elevation of the excavating cylinder, showing internal perforated tube *C*, and hydraulic jets *D D*.

The excavating cylinder *B* is formed of sheet iron, connected at its upper extremity with a powerful suction pump or air-tight receiver. The lower section of the excavator is connected with another pnmp, a force pump, by the hose *C* which passing through the side of the excavating cylinder, then feeds a pipe perforated with a number of small holes. This pipe, leading down near the open end of the cylinder *B* bifurcates and then projects outside the cylinder at opposite sides, forming two external hydraulic excavating jets *D D*.

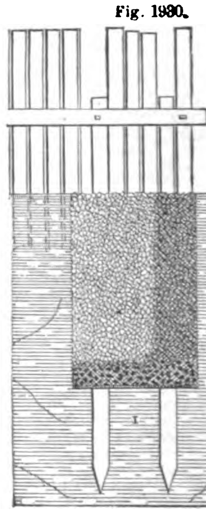
The operation for sinking a disk is as follows: The excavating cylinder is passed through the central aperture, and rests on the mud beneath; the connections are then made respectively with the force-pump and suction-pump or vacuum chamber. The first effect of the action of the suction-pump is to force the nozzle of the excavator, by atmospheric pressure, into the mud for some depth, thereby excluding the outer water. A column of permeable sand or mud now fills the cylinder; under the power of the suction it packs tightly, and the operation would cease, but simultaneously the force-pump *G* sends into the column of mud numerous small jets of water; the moment it becomes permeable it passes on in a continuous flow and is delivered by the pump, holding the maximum of solid matter with the minimum of water, or air if forced in instead of water. The diverging hydraulic or air jets acting over and beyond the area covered by the disk, excavate beneath and undermine it, the material passing into the excavator, the disk subsides. Bowlders or large stones encountered would be washed into the center of the excavation, where they could be broken through the aperture.

Fig. 1929.



Elevation and Section of Pile Foundation.

Fig. 1930.



Sheet Piling.

Fig. 1929 shows two forms of piles sunken by these means. One has a series of disks with intervening concrete or rip-rap. The sectional view shows the disks with central tube, and the side piles in position.

Fig. 1930 shows the plan as adapted to sheet piling.

Pile-dri'ving En'gine. An engine specially adapted for the working of the pile driving by monkey, and the lifting of piles into position for driving.

The lifting gear is single purchase, and is usually proportioned for working with a monkey not exceeding one ton in weight. The barrel is loose on the shaft, and is made fast to it by a powerful conical friction clutch, which is thrown in and out of contact with the barrel by the hand-lever; this lever is also connected by a rod to the throttle-valve, which automatically regulates the supply of steam.

The capstan-end is used for pitching piles or for hauling; the strap-brake is worked by the foot-lever, and is used for holding the load, or for preventing the chain from overhauling too much.

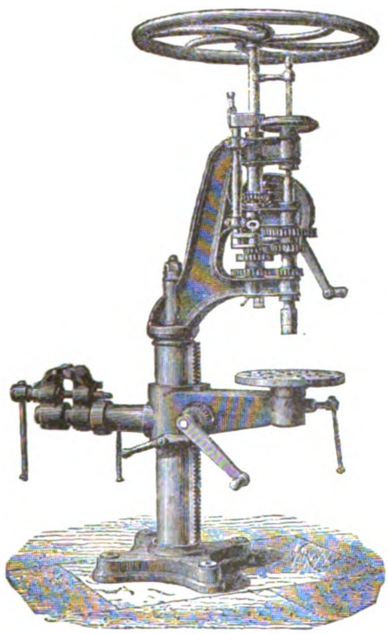
See Friction Drum Hoist, Fig. 1099, p. 357, *supra*. Also Figs. 454 and 1359.

Pile In'stru-ments. (*Surgical.*) See "Hemorrhoidal Instruments."

Pile Tel'e-phone. A telephone having a voltaic pile in the circuit.

In *Edison's* a piece of cork is fastened to the diaphragm and presses upon a strip of platinum, which is attached to a plate of copper; the latter is one of the terminals of an ordinary galvanic pile.

Fig. 1931.



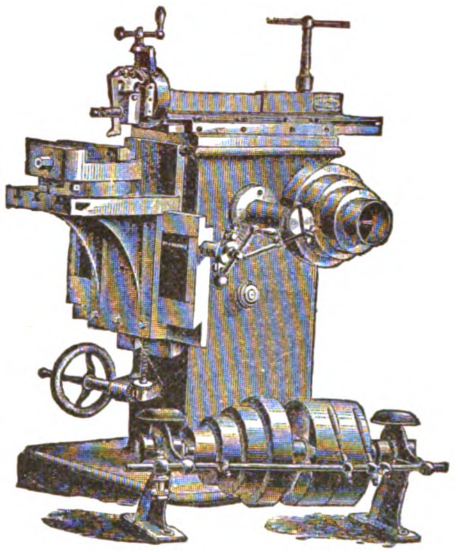
Treble-geared Pillar Drilling Machine.

* "*Scientific American Supplement*" . .	2591-2594.
* "*Engineer*"	xlvi. p. 425.

Pil'lar Dril'ling Ma-chine'. A machine tool which stands erect upon a pillar support on which the bench or platform is adjustable vertically by rack and pinion. The machine shown has treble speeds by means of sets of gearing.

Pil'lar Sha'per. A compact form of planing machine for metal.

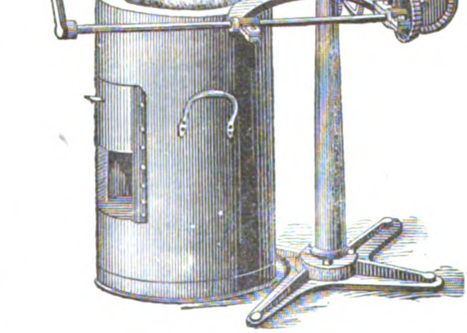
Fig. 1932.



Pillar Shaper.

The 10″ machine, for instance, stands on a hollow column, the base of which measures 36″ by 27″. The stroke may be graduated to any point within its extreme limit, the cutter-slide has a quick return, and the cross-feed is automatic and

Fig. 1933.



Pill Coater.

adjustable. The planer-vise has a slide base and operating screw; length of stroke, 10″, traverse of bed, 16″; distance between table-top and bottom of slide, 11½″.

Pratt & Whitney . . . . . . * "*Engineer*," xlii. 24.

Pill Coat′er. A machine like a comfit-making machine, in which pills are coated with sugar.

A regular rotary motion is given to the pan, which tumbles the pills over each other, exposing them to the saccharine matter which adheres to them, while the constant motion prevents mutual adherence. See Fig. 1933.

Pill coating, *Bull* . . . "*Sc. Amer. Sup.*," 2065.

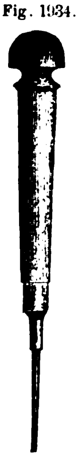
Pin′-ball Sight. (*Rifle.*) Another name for the *bead-sight;* also called pin-head sight. Left-hand illustration, Fig. 249, p. 84, *supra*.

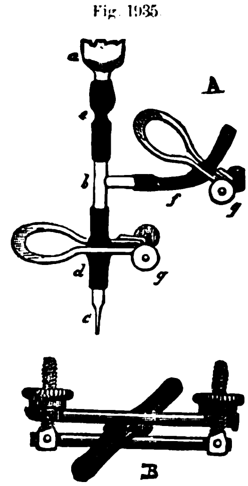
Pin Bush. A reaming or polishing tool for pin holes.

Fig. 1934.



Pin Bush.

Fig. 1935.



Pinchcocks.

A. Mohr's Pinchcock.
B. Bunsen's Pinchcock.

Pinch′cock. A clamp on a flexible pipe to regulate the flow of fluid or liquid, so as to keep up a constant action at a fixed rate.

Pinch′er. (*Glass.*) A nipping tool fitting the inside and outside of a bottle, in order to shape the mouth.

(*Metal.*) Compound lever * "*Iron Age*," xxiv., Sept. 18, p. 7.
Cutting, *Hall* . * "*Scientific Amer.*," xxxix. 388.

Pin′ion Jack. (*Milling.*) A jack for raising the stone pinion out of gear. This attachment works from below.

Another and simpler device for raising the pinion from above has a shaft worked by a hand wheel with ratchet stop, and having short chains and hooks, which are caught under the arms of the pinion, and raised by the turning of the shaft.

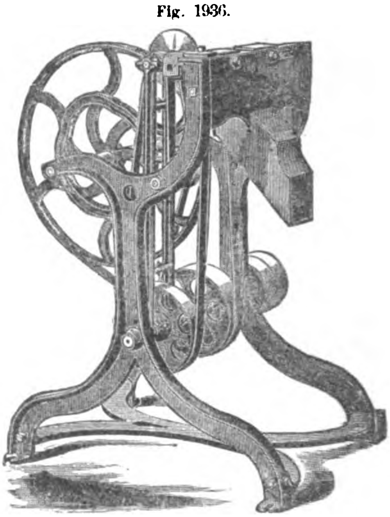
Pink′ie. A fishing vessel with a high, narrow-pointed stern. Used in the cod and coast fisheries.

Pin Ma-chine′. 1. Toilet pin. See p. 1705, "*Mech. Dict.*"

2. A machine for making wooden pins, for securing mortise and tenon joints, for dowels, etc. It is especially used in making the pins used in sash, blind, and door factories.

The square stuff is fed into the machine, rounded by passing through a hollow mandrel, and pointed by a rotary

Fig. 1936.



Wooden Pin Machine.

pointing cutter. The machine will cut off the pins at any desired length, and leave them round or square. Cuts and points 80 to 130 pins per minute; length, ½″ to 4″; diameter, ¼″ to 5-16″.

Pin Stick′ing Ma-chine′. A machine for sticking pins in paper.

The pins in bulk pass from a hopper into an inclined, slotted chute, down which they move, supported by their heads. At the bottom of the chute the pins are received singly between the projecting threads of a screw shaft, and are moved horizontally over a warped guiding and supporting surface shaped to gradually change the pins moved over it from a vertical to a horizontal position. Each pin, after it is placed in a horizontal position, is released from the control of the screw or feeding shaft, and is delivered under a spring presser or holder, and then a reciprocating driver strikes the head of, and projects the pin horizontally forward and through parallel, projecting, longitudinal ribs formed on a long strip of paper led from a suitable reel. The paper is ribbed or crimped longitudinally for the reception of the pins by the action of a foot and a wheel, between which the paper passes. The strip, with pins inserted, is then cut into proper lengths and wound on a mandrel to form rolls, which are then pressed between a concave and convex matrix into pyramidal form.

Pin Switch. (*Telegraphy.*) A simple and efficient method of connecting wires and loops with instruments, or changing from one line to another. The connections are made with pins or plugs, which give a rubbing or frictional contact when thrust into the holes on the board. See LOCK SWITCH.

Pi′o-scope. A milk test by Prof. Heeren.

It consists of a disk of black vulcanized caoutchouc, having in its middle a flat circular depression. A few drops of the milk in question, well mixed, are placed in the hollow and covered with the second part of the apparatus — a plate of glass painted with six shades of color radiating out from a

small, uncovered, circular spot in the middle. The colors range from white gray to deep bluish gray. The layer of milk is seen through the uncolored spot in the center, and its color can thus be compared with the radiating colors, and its quality judged according to the color with which it coincides. The whiter the color the more creamy the milk. See LACTOSCOPE **and references** *passim*.

Pipes, Valves, and Plumb'ing. Apparatus included under the following heads : —

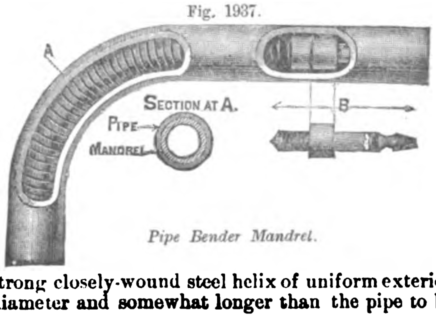
Pipe Bend'er, 1. A mandrel consisting of a

Fig. 1937.



Pipe Bender Mandrel.

strong closely-wound steel helix of uniform exterior diameter and somewhat longer than the pipe to be bent. This is thrust into the pipe and keeps it from becoming distorted. See FLEXIBLE MANDREL, Fig. 1058, p. 347, *supra*.

2. Miller's machine for bending stove-pipe elbows consists of sets of clamps in pairs which seize the pipe, and, turning on horizontal axes, force it to bend at each operation through a small angle. The pipe is then released and a new hold taken at a point a little farther along, and the operation repeated until the pipe has been given the required bend.

Pipe Coup'ling. A joint or piece to connect two pipes or a pipe with another object.

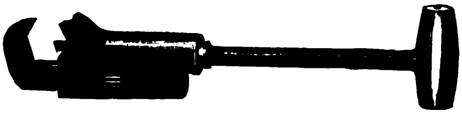
See:		
	Bell.	Hub.
	Bend.	Offset.
	Branch.	Reducer.
	Cross.	Sleeve.
	Elbow.	Tee.
	Expansion joint.	Y.

Pipe Cut'ter. 1. A machine for cutting pipe into lengths or trueing the ends. Associated with a threader in Fig. 1744, p. 1712, *"Mech. Dict."*

2. A tool for cutting off pipes. Four forms are shown in Figs. 3735–3738, p. 1711, *"Mech. Dict."*

Fig. 1938 is a form in which the body of the tool is threaded internally for the reception of the threaded end of the stem of the handle, and has at the rear a chamber for the reception and guidance of the stem of the movable jaw. This stem has a screw thread cut upon it so that it can be moved

Fig. 1938.



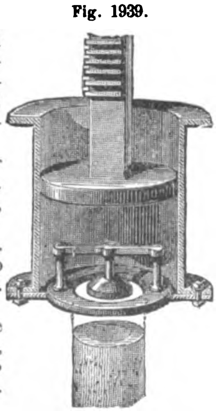
"Acme" Pipe Cutter.

in or out by means of a knurled nut. The pipe is cut by a chisel on the end of the handle stem which is fed into the pipe by means of the thread on the stem, while the tool is revolved around the pipe.

Pipe Die. 1. (*Ceramics.*) Pipes of stone-ware are made in a press, in the usual manner of pressing the plastic clay out of an annular hole made by suspending a cone in the circular exit. They are finished with a lead glaze and second firing.

2. The threaded nut for chasing a screw on a pipe. See Figs. 812–815, p. 256, *supra*.

Fig. 1939.



Clay-pipe Die.

Pipe Fit'ter's Vise. See PIPE VISE, *infra*, also Fig. 3752, p. 1713, *"Mech. Dict."*

Pipe Fit'tings. See list under PIPE TOOLS, etc., *infra*. Also GAS PIPES AND CONNECTIONS, Fig. 1174, p. 390, *supra*.

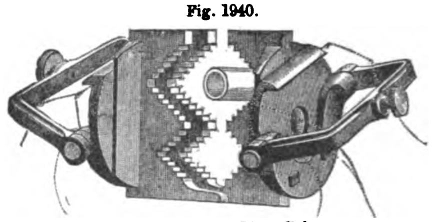
Pipe Grip. Toothed or stepped jaws, to be placed in a vise, to hold round objects, such as pipes and rods.

In Fig. 1940 the device adjusts itself to any size, one jaw slipping between the two apposed ones. A capacity for rotation in a vertical plane enables the jaw to grasp the pipe at any vertical angle. The dotted lines indicate the jaws of the vise. See also PIPE VISE, p. 1713, *"Mech. Dict."*

Pipe Kiln. The form of kiln used in France for baking clay pipes is shown in Fig. 1941.

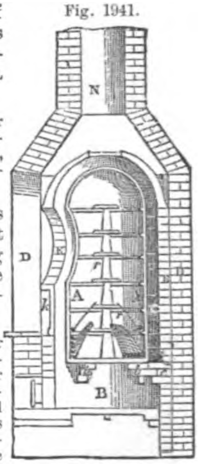
B is the furnace, *A* the chamber with pipe trays *r* of refractory material on a central stem. *N* is the chimney; *D* the walls; *E* the aperture for charging and discharging.

Fig. 1940.



"Challenge" Pipe Grip.

Fig. 1941.



French Pipe Kiln.

Pipe Line. A means of transporting liquids by pipes laid above the ground or beneath the surface. See OIL PIPE LINE, *supra*.

Description of pipe lines for transport of beet-root juice to factories, Dr. McMurtrie's report, 1880, in *"Dept. of Agric., Special Report,"* No. 28, pp. 131 *et seq.*

Pipe Mold. Primard's mold for iron pipe to be cast vertically is a metallic casing rolled in a spiral and capable of being expanded or contracted at will.

"A plunger attached to the lower end of a spindle, and having a diameter equal to the outer diameter of the pipe, passes through the interior of the casing, which is placed in the center of the mold. This spiral casing is placed in its contracted state into the center of the mold, and sand is run between them. The plunger, in passing through the spiral, enlarges it and compresses the sand uniformly. When it is withdrawn the spiral contracts and may be easily withdrawn. The casting of the neck and flange on one end of the pipe is provided by a simple contrivance." — *"Moniteur Industriel."*

Pipe O'ven. A hot blast oven in which the air passes through pipes exposed to the heat of the furnace. In contra-distinction to a fire-brick oven. See HOT-BLAST STOVE, *supra*.

Pipe Re-du'cer. A pipe coupling which is larger at one end than the other, to unite pipes of different diameters. *c*, Fig. 271, p. 92, *supra*.

Pipe Screw'ing. See PIPE THREADER, Fig. 3744, p. 1712, *"Mech. Dict."*

Pipe Stand. A frame to support radiator pipes. See COIL STAND; COIL PLATE, *supra*.

Pipe Stay. A device to hold a pipe in place; or to hang a pipe.

Pipe Stop. A spigot in a pipe.

Pipe Test'ing Ma-chine'. See PIPE PROVER, Fig. 3741, p. 1711, *"Mech. Dict."*

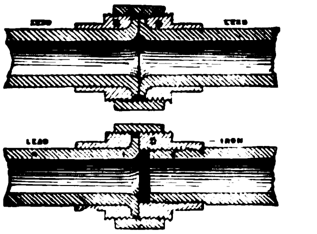
Pipe Turn′buck-le. A pipe or rod coupling, consisting of a pipe with internal threaded ends, having respectively right and left-hand threads. Into these the ends of other threaded pipes or rods are inserted, and by rotating the turnbuckle are drawn towards each other.

Its function is the same as that of the ordinary turnbuckle, but the latter is made of rods and a link, Fig. 6794, p. 2659, "*Mech. Dict.*"

Pipe Un′ion. A pipe coupling. See 18 varieties, Fig. 3734, p. 1710, "*Mech. Dict.*"

That shown in Fig. 1942 is for connecting lead, or lead and iron pipes without solder.

Fig. 1942.



Pipe Joint.

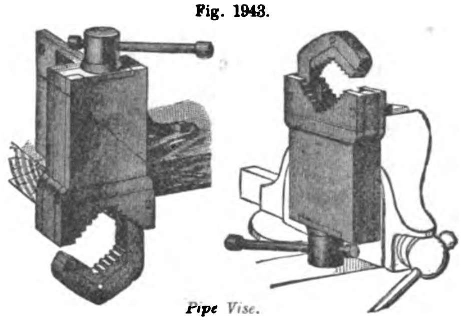
In connecting two lead pipes, the conical rings are placed loosely on the ends; the ends of the pipes are then forced out by a taper plug, the pipes being allowed to project above the rim; the ends are flattened over the edges of the conical rings with a small hammer until they form a flange, as shown on section; the outside hoop is then screwed on, and the whole tightened firmly together by screwing with two spanners in opposite directions.

In connecting a lead and iron pipe, the lead pipe undergoes the same operation as above described, the plain conical ring being placed on the end of the lead pipe, and the screwed ring on the iron pipe, the face of the ring being firmly screwed up to the face of the lead pipe.

Pipe Vise. A special vise for pipes. Attachments to vises, to enable them to grasp pipes and rods, are shown under Pipe Grip, *supra*. Pipe Vise, Vise, "*Mech. Dict.*"

The *Pancoast & Maule* vise, shown in Fig. 1943, can be used either as a permanent fixture to a work-bench, attached to an angle plate, or can be held between the jaws of any machinist's or blacksmith's vise. The movable jaw being open on the side permits work to be gripped at any desired point without slipping it in from the end; the box is made of mal-

Fig. 1943.



Pipe Vise.

leable iron, the screw of wrought iron, and the remainder of solid steel. The steel gripping jaws can be duplicated and replaced when worn out.

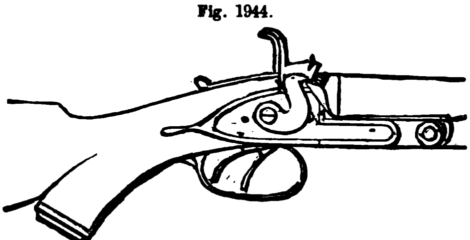
See also Fig. 3752, p. 1713, "*Mech. Dict.*;" Fig. 6986, p. 2713, *Ibid.*

Pis′ci-cul′ture. See Fish Culture, Oyster Tools, etc.

Pis′tol. See Revolver.

Pis′tol Grip. A protuberance shaped like the butt of a pistol beneath the *small* of a gun or rifle

Fig. 1944.



Pistol Grip.

stock, to be grasped by the right hand, to give steadiness to the grip in firing.

Pis′tol Ri′fling Ma-chine′. A standard machine cuts 5 grooves of an invariable pitch, in barrels 3.5″ to 5″ long, with or without feed for depth of grooves. See Rifle, p. 1939, "*Mech. Dict.*"

The twist may vary from 1 turn in 72″ to 1 turn in 12″. — *Pratt & Whitney.*

Pis′ton Pack′ing. See 22 figures illustrating different forms of piston packing, pp. 1715, 1716, "*Mech. Dict.*"

See also list of patents on pp. 1717, 1718, *Ibid.*

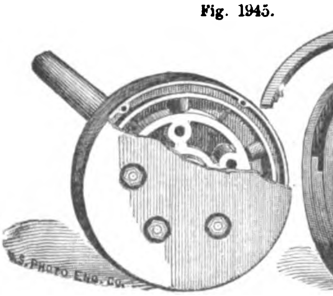
The Babbitt & Harries piston-packing is shown in Fig. 1945, which has three views.

One represents the packing in its place in the piston.

Another shows the chunk ring with two sections of the packing out.

A third shows two sections of the packing ring with its accompanying spring plate and spring.

Fig. 1945.



Piston Packing.

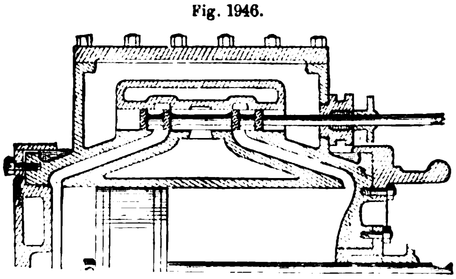
The operation of the packing is as follows: When steam is admitted into either end of the cylinder, the packing ring is carried by the steam over to the side of the grove in the chunk ring, making a joint there, and allowing the steam to pass down by and under the packing ring, thus placing it in equilibrium, when a very light spring is able to do the holding of the packing in contact with the bore of cylinder.

The piston-rod packing of Herr Gehrckens, of Hamburg (Philadelphia, 1876), is a wick-twisted hose stuffed with animal and mineral grease, and coiled around the piston-rod in the stuffing-box. See Packing, Fig. 1860, *supra*.

Pis'ton-pack-ing Ex-pand'er. A steel spring in a piston head, to expand the packing against the inside of the cylinder.

Pis'ton Valve. A circular valve moving in a cylindrical chamber. That used on the Norwalk Iron Works Steam Engine, consists of two peculiarly constructed pistons connected by a rod, and is

Fig. 1946.



Piston Valve of N. Y. Safety Steam Power Co. Engine.
(Section of Valve and Steam Cylinder.)

worked by an ordinary eccentric. By a simple arrangement these pistons always have the same pressure inside as out, which prevents any leakage or blowing through.

Pitch, Mu'si-cal. In addition to what was said on p. 1719, "*Mech. Dict.*," reference may be had to a late paper read before the American Association, "*On the Present Condition of Musical Pitch in Boston and Vicinity*," by Charles R. Cross and William T. Miller. It is summarized on p. 4041 of the "*Scientific American Supplement.*"

It recounts an extensive series of experiments carried on in 1880 at the "Massachusetts Institute of Technology," to determine the amount of variation of standard pitches in use by different makers of musical instruments in the neighborhood of Boston.

		No. of Vibrations. C 3.
Variations extended from	Koenig's physical pitch	256.1
	Chickering	268.5
	Covent Garden	270.3
	Weber	270.3
	Thomas	271.1
	Music Hall	271.2
	Steinway	272.2

Pitch'er Nose. Said of a faucet with a bent down lip.

Pitch Faced. (*Masonry.*) The arris is cut true, but beyond the arris edge the face is relatively rough and projecting, the *face* being merely dressed with a *pitching* chisel.

Pit Guide. A vertical bar forming a guide for the cage in mining shafts.

Pit Head Gear. The winding and emptying apparatus and framing for the transportation cars at the mouth of a mining or coal shaft.

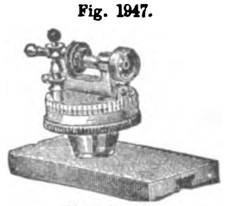
Pit'man Press. One working by pitman connection with a shaft, instead of eccentric or other equivalent. Used in drawing, cutting, stamping, and shearing presses.

Pit'ter. A device to take the pits from peaches, plums, and other stone fruit. See Fruit Pitter, Fig. 1107, p. 359, *supra.*

Piv'ot Pol'ish-er. An attachment to the watchmaker's lathe.

It is used for grinding and polishing conical pivots, snailing and drilling. The circular base being graduated into degrees, it can be set to grind at any angle. It has a finely graduated elevating screw to adjust the spindle above, or below, the center of the headstock.

Fig. 1947.



Pivot Polisher.

The spindle has a taper hole for drill chucks. This makes it very useful for drilling, either in the center or eccentric, and by using the graduations on the pulley of the headstock, an accurately spaced circle of holes may be drilled.

Piv'ot Span. (*Bridge.*) The draw span of a bridge. See Draw-bridge, *supra*, and references *passim;* Pivot Bridge, Fig. 3775, p. 1721, "*Mech. Dict.*"

Pla-cen'ta In'stru-ments. (*Surgical.*) For the removal of the after-birth. Forceps, hook, etc.

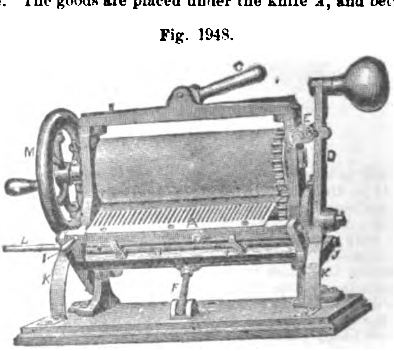
Pla'cer. (*Mining.*) A gravelly place where gold is found; includes all forms of mineral deposits excepting veins in place. Section 2,329, "*Revised Statutes of the United States.*"

Plain Sight. (*Fire-arms.*) A hind sight consisting of a simple notch in a raised plate or protuberance.

Plait'ing Ma-chine'. A machine for plaiting goods in piece or strips.

The roller is heated by gas or hot irons, and in the domestic size, it plaits strips up to 6″ wide, the plaits ⅛″ to 1″ wide. The goods are placed under the knife *A*, and between

Fig. 1948.



Plaiting Machine.

the rollers; then push down the handle, *C*, and the machine is ready. Move the lever *D* back and forth; this forms the plait, and presses it between the rollers. To change the width of plait, turn the nuts on the curved screw *E* back to the next notch on the screw, then lower the plaiting knife by adjusting the nut on screw *F*. There are 7 notches on each of these screws, answering to as many widths of plait.

See also "Crown" machine, * "*Iron Age*," xx., Nov. 29, p. 1.

Plane. A smoothing tool, having its cutter protruding from a throat in a stock.

See ADJUSTABLE PLANE, Fig. 7, p. 5, *supra*; CIRCULAR PLANE, Fig. 620, p. 197, *Ibid.*; BELL-NOSE RABBET PLANE, Fig. 460, p. 110, *Ibid.*; HAND MATCHER, Fig. 1305, p. 433, *Ibid.*; HAND PLANER, Fig. 1307, p. 434, *Ibid.*; PLOW, *infra*; SMOOTH PLANE, *infra*.

Description, illustrations, and list of varieties, pp. 1724, 1725, "*Mech. Dict.*"

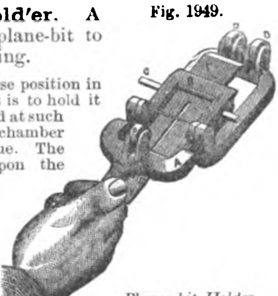
Rabbet plane, *Bonney* . * "*Iron Age*," xxii., Nov. 14, p. 5.
Rabbeting, grooving and turning mach., *Wood* * "*Manufact. & Builder*," x. 64.

Plane'-bit Hold'er. A device to hold a plane-bit to the stone for grinding.

Fig. 1949.



Planer-bit Holder.

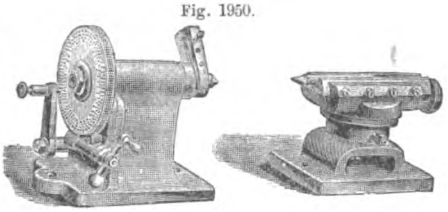
It is shown in reverse position in Fig. 1949. The object is to hold it firmly and squarely and at such an angle that the chamber shall be flat and true. The rollers *D D*, run upon the stone and it is impossible to grind the bit awry.

Pla'ner Cen'ter. A head and tail stock bolted to the table of a planer in order to hold objects centered while under treatment.

In the instance shown, Fig. 1950, the device is practically a pair of lathe stocks; the head stock has a dial with worm, gear, and index wheel. The foot stock has horizontal traverse by means of feeding screw.

See also Fig. 3788, p. 1726, "*Mech. Dict.*"

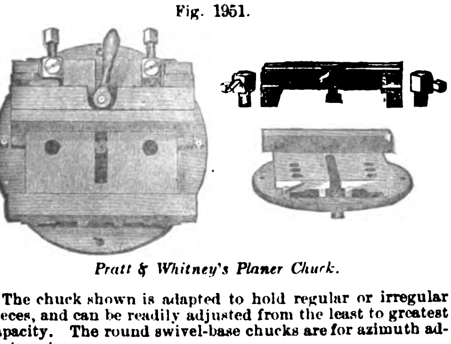
Fig. 1950.



Planer Center.

Pla'ner Chuck. A device bolted or keyed to the planer table, and serving to dog an article under the action of the plane.

Fig. 1951.



Pratt & Whitney's Planer Chuck.

The chuck shown is adapted to hold regular or irregular pieces, and can be readily adjusted from the least to greatest capacity. The round swivel-base chucks are for azimuth adjustment.

Pla'ner Knife Grind'er. An emery-wheel or stone, traversing on its mandrel in front of a knife dogged to the table or conversely.

See KNIFE GRINDER, Fig. 1515, p. 520, *supra*, and Fig. 2765, p. 1238, "*Mech. Dict.*"

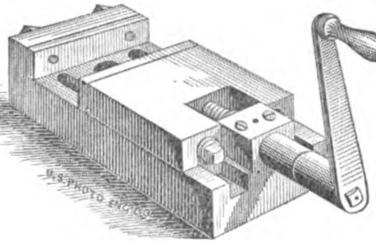
Pla'ner Vise. A device to hold work on the bed of a planing machine while under treatment.

Fig. 1952 shows a form in which the moving jaw is actuated by crank-handle and screw.

Fig. 1953 is Babbitt's planer vise.

In this chuck, instead of gripping the work with the vise jaws direct, two pivoted plates are interposed which incline

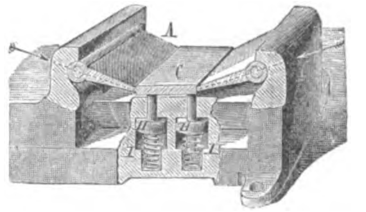
Fig. 1952.



Planer Vise.

from the pivots towards the work. *A* and *B* represent these plates, and *C* represents the work; the strain of the plates upon the work is in the direction denoted by the respective arrows, so that the work is forced downwards upon the tops of the pins. The plates are made to bear, at the back of the hinge, upon the hollow curve in the chuck jaws, as shown,

Fig. 1953.



Planer Vise

which relieves the pivot of the strain due to screwing the chuck tightly.

The pins are made adjustable for height to suit the work, being screwed into the disks *H* which are attached to spiral springs, which depress until the disks *H* meet the shoulder at *I*, resting solidly upon them.

Harris; Thomas . . . "*Sc. American*," xxxviii. 245.

Pla'ni-graph. An instrument invented by Marmet, of Versailles, France, for reducing or enlarging drawings.

It consists of a rule carrying two scales which have different graduations, and are placed end to end in opposite directions. At the common origin of the scales is a needle about which the rule can freely turn. Reading on one side the radii vector of the different points of a given figure, and marking on the other side the points designated by the same numbers, you obtain a figure reduced or enlarged in the proportion resulting from comparison of the scales. The scales are fixed to the rule by screws. There are five for each side, among which choice is made according to the reduction required.

"*Scientific American*" . . . . . . xxxvi. 328.

Pla-nim'e-ter. An instrument for measuring the area of plane figures.

Amsler's planimeter is shown in Fig. 3794, p. 1728, "*Mech. Dict.*"

Ljungström's circular planimeter consists, in its most simple form, of a circular plate of glass, through the center of which passes a vertical steel wheel that is to be placed at right angles to a radius which is etched in the pane and marked with a point. When in use, the plate of glass is brought along a rectilineal support (a ruler) so that said point accurately follows the border line of the figure once round. The reading is taken from the wheel, which is turned by friction against the paper. The instrument measures figures of a width equal to that of the whole ruler. If very large figures are to be measured (*e. g.* an ordinary map at once) the instrument is changed by a so-called *couple* into a kind of polar planimeter. The *couple* consists of a metal ring, which goes round the pane of glass, together with two legs, one of which is attached to the ring, and the other to the plate. The former moves about a fixed point, while a point marked on the other leg is moved along the border-line of the figure. The reading off is in this case also done from the steel wheel.

See also Pillar Shaper; Milling Machine, etc., *supra*.

Richards's classification of planing machines divides them into three classes: —

1. The *carriage planing machine*, in which the material is carried and guided on a carriage having its movement governed and regulated by extraneous guides and independent of its own surface or shape. — The *Daniel* planer, Fig. 3796, p. 1728, "*Mech. Dict.*"

The carriage planing machine requires a length double that of the material to be worked; that is to say, the track must be twice the length of the carriage, the movement of which is reciprocating.

2. The *parallel planing machine*, such, for instance, as have feed-rollers over which the material is fed and gaged from, forming a fixed gaging surface opposite to the cutters.

3. The *surface planing machine*, having its action gaged from the surface of the material, cutting a constant amount without reference to dimensions or to producing parallel lines.

Plan'ish-er. For photograph planisher, see Photograph Burnisher.

(*Photography.*) See Photograph Burnisher.

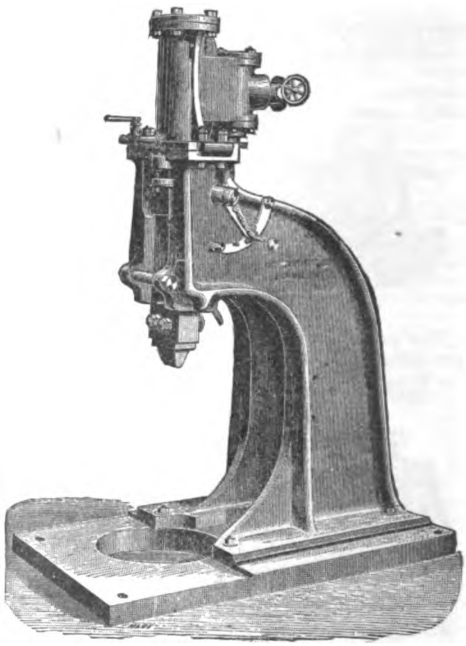
(*Paper.*) See Calender; Plater; Paper Burnisher; Paper-glazing Roller.

(*Metal.*) See Planishing Hammer.

Plan'ish-ing Ham'mer. A hammer for flattening, curving, or shaping sheet metal by properly disposing and graduating the blows upon its surface.

Saw blades are planished to straighten them. Buckling is removed by planishing, *i. e.*, giving a *plane* surface.

Fig. 1954.



Planishing Hammer.

Again: by the planishing hammer sheet metal is shaped to form kettles and what not. When the curve is regular and cylindrical the work is done by rollers. See Plate Bending Machine, *infra*.

When the object admits of being made by a stamping process, as a dish or pan, the work is done at a blow or by a series of blows.

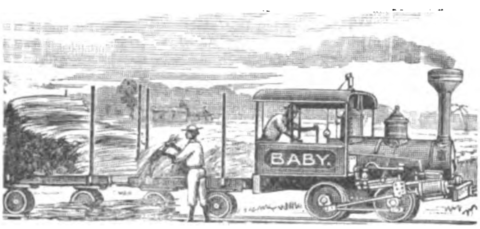
The old mode of forming the 60 gallon copper, sugar, or soap-kettle was planishing, the parts being subsequently united by brazing. The planishing hammer is yet a valuable tool and very effective, especially when worked by steam.

Plan'i-sphere. An instrument to assist in the study of the stellar heavens.

It consists of a card about 4″ square, carrying a circumpolar star-map, surrounded by a circle of the months subdivided for the days; and a smaller circular card, carrying the hours of the day, and an open space representing the horizon. These two cards are attached at the center, so as to turn one on the other.

Plan-ta'tion Lo'co-mo'tive. A four-wheeled locomotive, for use in plantation work. The tank is at the rear, beneath the floor of the cab, over which is a sheet-iron canopy. One pair of driving-

Fig. 1955.



Plantation Locomotive.

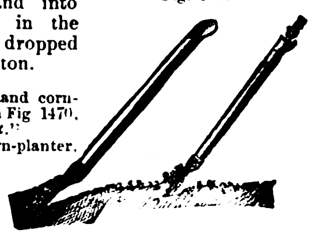
wheels is equalized across. The hauling capacity on a level is from 150 to 475 tons, with engines of from 5 × 10″ to 9 × 14″, and diameter of driving wheels, 22″ to 28″.

Plan'té Bat'te-ry. See SECONDARY BATTERY.

Plant'er. A tool or machine for planting grain or roots in hills.

Two French hand-planters are shown in Fig. 1956. In one form the seed is dropped by hand into the open end; in the other the seed is dropped by moving a piston.

Fig. 1956.



Hand Planters. (*French.*)

The American hand corn-planter is shown in Fig 1470, p. 627, "*Mech. Dict.*" The horse corn-planter. Figs. 1468, 1469, p. 627, *Ibid.* See also CORN PLANTER, Fig. 697, p. 223, *supra.* POTATO PLANTER. See Fig. 3919, p. 1776, "*Mech. Dict.*" Also see *infra.*

Plant Sprink'ler. A syringe for watering plants.

In the form shown in Fig. 1957 it is a caoutchouc bulb with valves. See also AQUAPULT; HYDRONETTE, *supra.*

Fig. 1957.

Plant Sprinkler.

Plaque. (*Ceramics.*) A decorated porcelain dish or plate.

Plas'ter. *Hard plaster:* Alum plaster, made in Paris for fine-polished walls. It does not, however, resist moisture thoroughly.

The gypsum in blocks is calcined in a reverberatory, cooled, placed in a wooden cage, and lowered into a bath with 10 per cent. of alum. After some minutes' immersion it is raised, allowed to drip into the bath, then laid on a floor to dry; again raised to a red-heat in a furnace, cooled, ground, and bolted.

Another plan is to mix the ground plaster with alum in powder and bake in a furnace.

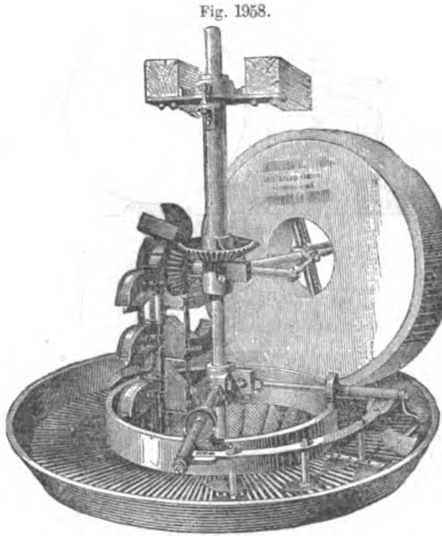
Plas'ter Mill. A machine in which crude plaster is ground to powder.

The form shown is by Jannot fils, Triel (*Seine et Oise*), Fr. It has the Chilian roller, followed by stirrers, scrapers, and hoes. The bottom of the annular trough is a grating,

Fig. 1958.



French Plaster Mill.

through which the powdered material passes. A series of cups on an endless band raise the material from a central well and discharge it into the trough.

See BONE MILL, Fig. 378, p. 119, *supra*; CEMENT MILL, Fig. 575, p. 183, *Ibid.*; MORTAR MILL, Fig. 2330, p. 1480, "*Mech. Dict.*"

Plas'tic Crys'tal. A variety of Portland cement remarkable for its plasticity, and consisting of —

Silica	86.42
Alumina	9.33
Oxide of iron	0.86
Lime	0.34
Magnesia	0.22
Alkalies	0.37
Loss on ignition	2.40
	99.94

"*Dingler's Polyt. Journal.*"

Plas'tic Etch'ing. (*Glass.*) The term given by Casset-Delas, of Paris, to his etched plate-glass. It is designed to give relief by etching away the glass, and to imitate plastic relief; basso, or *pâte sur pâte.*

Plas'ti-li'na. A kind of modeling clay, which remains damp, and does not require frequent wetting.

Glycerine has been mixed with the clay, but the following composition is preferred : —

Fatty acids and fats	10
Oxide of zinc	1
Sulphur	6
Clay (dried and powdered)	3

Or : —

Glue	8
Oxide of zinc	1
Oleic oil	4
Wax	2
Sulphur	6
Clay	3

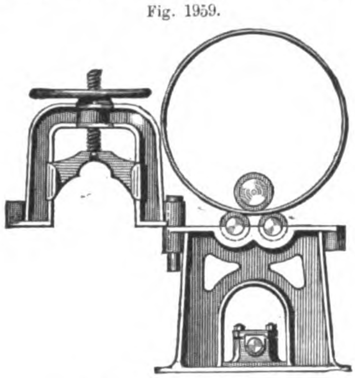
Plate. (*Fire-arm.*) The side of the lock.

Plate Bend'er. A round-bitted pinchers, for bending dental plates without showing the pinch marks.

Plate Bend'ing Ma-chine'. Machines for bending plates are shown under several specific heads. ARMOR PLATE BENDING, Fig. 296, p. 97, *supra*, and references *passim*.

In the plate-bending machine, Figs. 1959, 1960, the principal feature of the invention is, that tubular work, such as flues, cross-tubes, funnels, ship-masts, etc., can easily be removed from the machine, after they have been formed into the requisite shape and size, *without requiring to unship any of* the rollers. The plan hitherto adopted has been to draw out the top roller when releasing tubular work, which arrangement involves the labor of re-shipping the roller before the machine can be used again.

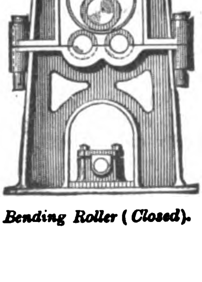
Fig. 1959.



Bending Rollers (*Arch Open*).

The whole of the driving gear of this machine is arranged at *one* end, and is made either double or triple powered, in accordance with the size of the machine. The other end is entirely free from driving gear. The framing is made in halves, held together by cotter bolts. After a plate has been formed into an entire circle, one of the cotter bolts is removed, the top part of framing is swung round out of the way, when the tube is easily drawn out, and the framing can be instantly readjusted for the following operation.

Fig. 1960.



Bending Roller (*Closed*).

Plate Glass. History and procedure on pp. 1737, 1738, "*Mech. Dict.*"

Plate XXXIV. has a plan and elevation of a French plate-glass factory.

The furnace for 12 crucibles is elliptical in form. The *siege* or crucible platform is in a single mass of fire-clay concrete work, and has a central elliptical funnel-shaped crater, at the bottom of which is the grating, and beneath the latter is the ash-pit in the sub-way of the glass-house, by which air reaches the furnace. Twelve openings, of which the sills are on the level of the crucible *siege*, serve as means of introducing and removing the pots, and each is closed with a large tile, *tuile d'ouvreau*, when the melting process is in course. Above each of these large openings is a small one known as a *pigeonnier*, through which the materials to be melted are introduced into the pots by means of a square tray on the end of a long handle. The hole affords means of judging of the progress of the melt, and is closed with a ball of fire-clay. The flame strikes against the vaulted roof, circulates around the crucibles and escapes into the little chimneys perforated in the pillars of the wall and thence to the conical sheet-metal chimney *A*.

The furnace is placed in a central position between ovens, *leers*, *B*, in which the glass plates are annealed. *D D* are cranes by which the crucibles or cuvettes *E* are lifted and moved, to carry the molten glass from the furnace to the tables *C C*, where the molten glass is rolled to a thickness, depending upon the upward projection of the rim of the table on which the roller runs. The table has wheels which run on rails so as to present the glass at the opening of either one of the annealing furnaces in the series. Each *leer* has three furnaces to heat it, a large opening in front to enter and remove the glass plates, openings for air to gradually reduce the heat, and a flue to lead the fumes to the chimney. See, also, description on p. 1738, "*Mech. Dict.*"

Plate Nip'pers. (*Dental.*) Nippers used in cutting out plate for dentures.

Plate Press. A copper or steel-plate press. Fig. 1445, p. 619, "*Mech. Dict.*"

Pla'ter. A paper calendering machine.

The weights and levers of the machine, Fig. 1961, exert a pressure of about 35 tons on the roll. The paper is packed between smooth plates of zinc or copper, and passed between the rolls back and forth till the desired finish is obtained; the motion of the machine being reversed at each passage of the pack.

Plate Shear'ing Ma-chine'. Examples are given under SHEARS in the "*Mech. Dict.*"

The Sellers plate-shearing machine, Fig. 1962, is specially adapted for cutting and trimming plates used in bridge and ship construction, and is adapted for trimming edges of long plates, or cutting off to length plates 5' wide. Will shear wrought-iron plates 1" thick. The upper blade is guided vertically in the frame of the machine, and driven down by a pitman as wide as the blade is long, this pitman receiving its motion from a long rocking shaft above it. The driving

Fig. 1962.

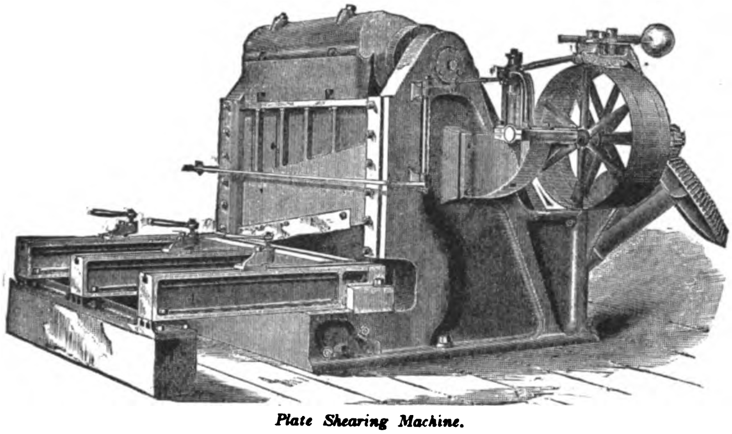

Plate Shearing Machine.

arm or lever of the machine is a rack segment engaging with the teeth of a spiral pinion, which is driven by bevel wheel and pinion and open and crossed belt, after the manner of planing machines. The cutting blade is adjustable in length of stroke, returning at double the speed of its down stroke.

The blade can be made to cut to any fixed point in its length and then stopped or raised. It is provided with an automatic adjustment to its belt-shifting motion, gaging the length of its stroke. It makes the down stroke, immediately reascends, and stops up, to wait for the readjustment of the plate.

Fisher's bevel-edge boiler and armor plate cutter is on an oblique frame so as to chamfer edge the plate presented to it. Of the jaws, one is horizontal and holds the plate, the other descends in an oblique direction and bevels the plate edge.

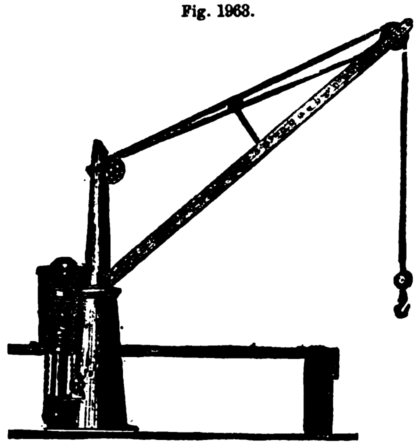
Plate Weld'ing Ham'mer. A peculiar form of steam hammer for welding plates, carried on the flat horn of a movable anvil beneath the hammer.

Adamson . . . . . . * "*Engineering*," xxx. 295.

Plate Wheel. (*Railway.*) A car-wheel, the web of which is a plate, instead of spokes.

Plat'form. (*Railway.*) Miller's platform is used in conjunction with his automatic car coupler, and is arranged so that the line of draft and the compressive strains on the car are in a direct line with the sills of the latter.

Fig. 1963.



Hydraulic Platform Crane.

Plat'form Crane. A crane upon a landing platform for discharging goods, etc., from cars or wagons.

In the hydraulic platform crane, shown in Fig. 1963, the machinery is easily accessible. The mast and jib are supported in a heavy foundation. The pipes and hydraulic cylinder are independent of the jib, and the only stuffing-boxes or working hydraulic joints are the glands of the hydraulic ram and ram spindles.

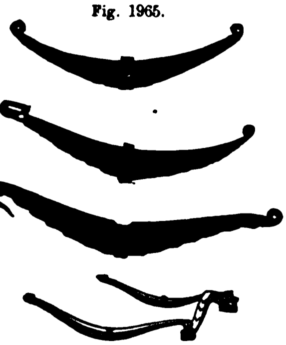
Fig. 1964.

Platform Spring Shackle.

Plat'form El'e-va-tor. One lifting a platform or cage. See ELEVATOR.

Plat'form Spring. A form of spring, Fig. 1965, used largely on city trucks; the *platform* is probably the bed of the truck and gave its name to the spring.

Fig. 1965.



Platform Springs

Fig. 1964 shows the peculiar shackle used in coupling together the springs, the ends of which meet at a right angle: as seen in the lower one of the four springs, Fig. 1965.

Plat'in-i-zing. (*Metals.*) The process of M. Dode, of Paris, is for the protection of the iron from the action of air, fire, and acid gases.

The iron first receives a coating composed of lead and copper, and then the platinum is applied. The first coating is prepared by mixing 22 parts of borate of lead and 4½ parts of cupric oxide in oil of turpentine, and is applied by means of a fine brush. The platinum coating is prepared by converting 10 parts of platinum into chloride mixed with 5 parts of ether, the latter being permitted to evaporate in the air. The residuum is mixed with a viscid combination of 20 parts borate of lead, 11 parts red lead, and some oil of lavender, and 50 parts of amylalcohol are added to the whole. Into this mixture the object to be platinized is dipped, allowed to dry in the air, and then heated to a moderate temperature.

"*Scientific American*"	xxxvi. 233, 407.
"*Scientific American Supplement*"	2818.

(*Glass.*) Platinum has been tried for a reflecting surface, but owing to the somber appearance of objects reflected by looking-glasses prepared with it, it has not met with a commercial success.

Pla-tin'o-type. A photographic print obtained upon paper in platinum in form of a finely-precipitated powder. In this state the metal possesses an intensely black color, and, as in its massive state, is wholly unalterable by atmospheric influences. — *Willis.*

A platinum alloy, melted and cast by Matthey, of London, "is so malleable and ductile that thread 1-2500th'' in diameter has been made of it. Its composition is: Platinum, 80.600 per cent.; iridium, 19.079 per cent.; rhodium, 0.122 per cent.; iron, 0.098 per cent.; and ruthenium, 0.046 per cent. Its density at a temperature of 32° F., is 21.614." — *Phillips.*

Ple-thys'mo-graph'. An instrument invented by Sig. Mosso, of Turin, for observing the variation of the circulation of blood in various parts of the body under natural or artificial causes: as in the two arms; the acceleration in the head in case of surprise, etc.

The forearm, for instance, is inserted in a glass cylinder, *B*, which rests on suspended plank *E*, and is filled with tepid water, a rubber ring, *A*, preventing the exit of water around the arm. There is an opening, *F*, leading from the cylinder to a measuring apparatus, *C*, which indicates the quantity of water admitted or expelled by the contraction or dilation of the volume of the forearm, due to the arterial action. See also SPHYGMOGRAPH.

The test tube *M* is equilibrated by the counterweight *N* and pulley *L*; *D* is a thermometer.

In plowing with dynamite a certain number of dynamite cartridges are buried at regular distances in the soil, and connected together by electric wires. The explosion is simultaneous; and, though nothing is thrown up, the field is effectually plowed.

The Sackett plow and pulverizer throws the soil into a cage which rotates at the side of the plow, and so pulverises the soil.

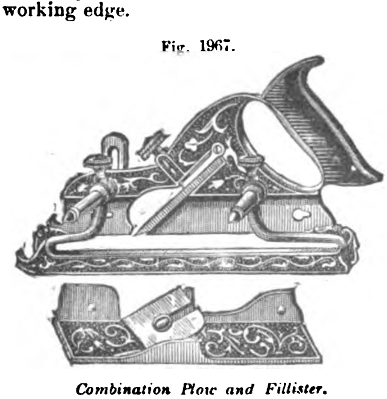
2. (*Joiners.*) A grooving plane, with adjustable fence to regulate the distance of the groove from the working edge.

Fig. 1967.



Combination Plow and Fillister.

The tool shown in Fig. 1967 embraces a combination of the carpenter's plow, an adjustable fillister, and a matching plane.

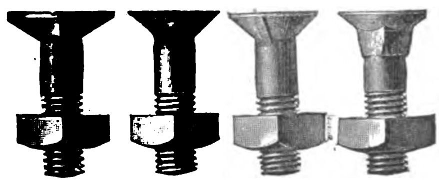
The engraving represents the stock of the tool, adjusted for use as a plow.

A metallic bed-piece, with cutter, can be attached to the stock of the tool by means of two screws passing through the slots in the base-piece of the stock. Over this bed-piece the gage, or fence, will move backward or forward, and when secured to the bars by the thumb-screw will constitute an adjustable fillister of any width required.

See also DADO; FILLISTER, "*Mech. Dict.*"

Plow Bolt. A bolt for securing the share, landside, or mold-board to the stock. It has a

Fig. 1968.



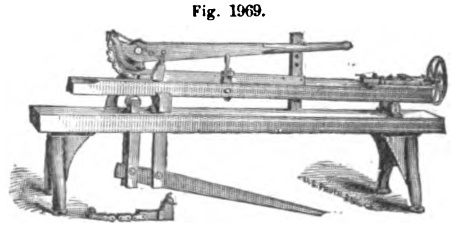
Plow Bolts.

chamfered countersunk head, and usually a square or fin to keep it from turning when the nut is screwed on.

Plow Grind'er. An emery machine specially adapted for grinding the faces of shares, mold-boards, and landsides.

Plow-han'dle Bend'ing Ma-chine'. A machine adapted for bending plow-handles after they are turned. The handle is steamed, it is locked to

Fig. 1969.



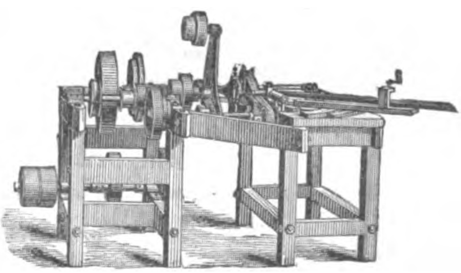
Plow-handle Bending Machine.

the bed of the machine, the grip-end attached to the lever, which is then brought down, bending the handle by means of a flexible chain on the outside. The end of the handle is then fastened by a rod to a cramp on the straight portion of the same, and the piece removed to season in drying.

See also WOOD-BENDING MACHINES, pp. 2803, 2804, "*Mech. Dict.*"

Plow-han'dle Pol'ish-ing Ma-chine'. A

Fig. 1970.



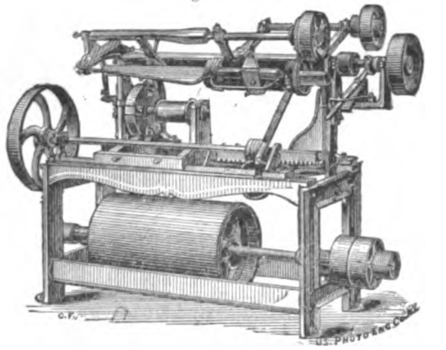
Plow-handle Polishing Machine.

machine for polishing or smoothing plow-handles after they are bent and sufficiently seasoned. It has a central shaft on which is a cast-iron frame, with pulleys and a smoothing belt. It is automatic. The handle is put in position and fastened, the feed is thrown in by the lever, which causes the frame with the polishing belt to revolve around the handle; at the same time the carriage holding the handle feeds slowly along until the bent or rounded part of the handle is finished, at which point it throws out the feed.

Plow-han'dle Lathe. A machine on the principles of the Blanchard lathe, adapted to turn plow-handles by patterns.

In the case represented the pattern-rest is adjustable so that it will turn different sizes from the same pattern without readjustment of the machine. The cutter head is so arranged and constructed that it reduces the stuff worked with great ease, leaving it in a smooth condition; it runs in a movable carriage, is automatic in its operation, and is protected by an iron cover from accident.

Fig. 1971.



Plow-handle Lathe.

Plow'ing Ma-chine'. See * STEAM PLOW, pp. 2354-2356, "*Mech Dict.*"

Knight's report of Group 76, "*Paris Exposition* (1878) *Reports*," v., pp. 53-89.

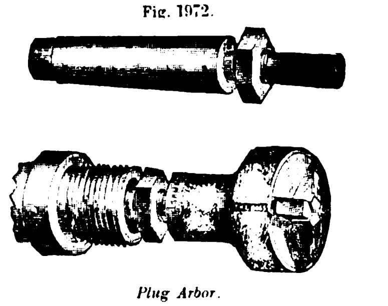
Plug. 1. A tap, made of a form intermediate. *Taper, plug, bottoming,* see Fig. 6211, p. 2495, "*Mech Dict.*"

2. A stopper screwed into the end of a pipe.

3. A short rod, split lengthwise, and the sections driven apart by a wedge known as a *feather;* for riving stone, Fig. 3834, p. 1749, "*Mech. Dict.*"

Plug Ar'bor. A lathe attachment for mounting drill chucks. *Cushman,* Fig. 1972.

Fig. 1972.



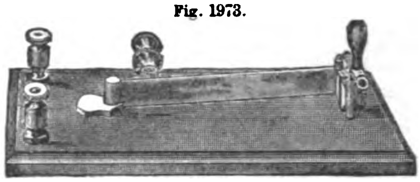
Plug Arbor.

Plug Ba'sin. A standing washbowl with plug hole at bottom for emptying.

Plug Cock. A faucet which is simply driven into the barrel, not screwed in.

Plug Cut'-out. (*Telegraphy*) Or *wedge cut-out;* a spring connected to one main-line binding-post, normally rests against a pin connected with the other main-line binding-post, thereby forming a spring-jack into which a wedge-shaped switch-loop-

Fig. 1973.

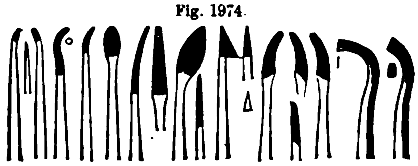


Plug Cut-out.

plug may be inserted for the purpose of connecting instruments in line without disturbing the continuity of the circuit. A set-screw bearing against the side of the spring is used for adjusting its tension.

Plug Fin'ish-er. (*Dentistry.*) A fine file for finishing the surfaces of tooth fillings.

Fig. 1974.



Plug Finishers.

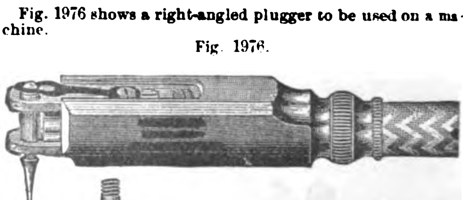
The sizes, shapes, and fineness of tooth, fit the instruments for special applications. Some are file-cut on one side and some on both.

See DENTAL FILE, Fig. 796, p. 251, *supra.*

Plug'ger. (*Dentistry.*) A tool for driving and packing filling materials into carious and excavated teeth.

Fig. 1975 shows a number of hand pluggers of various forms.

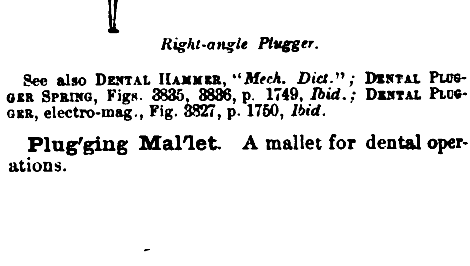
Fig. 1975.



Hand Pressure Pluggers.

Fig. 1976 shows a right-angled plugger to be used on a machine.

Fig. 1976.



Right-angle Plugger.

See also DENTAL HAMMER, "*Mech. Dict.*"; DENTAL PLUGGER SPRING, Figs. 3835, 3836, p. 1749, *Ibid.*; DENTAL PLUGGER, electro-mag., Fig. 3827, p. 1750, *Ibid.*

Plug'ging Mal'let. A mallet for dental operations.

The heads are *lignum vitæ*, soft steel, wood with metal core. See DENTAL MALLET, p. 251, *supra*.

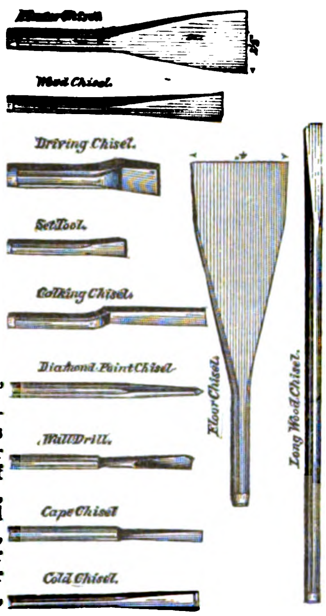
Plug Tap. One somewhat tapered at the end to facilitate its entrance in commencing to tap a hole. See PLUG, *supra*.

Plumb. The suspending string is wound upon a reel concealed in the interior, and the friction of the reel will keep the bob suspended at any point. On release of the cord it rewinds.

Fig. 1977.

Plumb Bob.

Fig. 1978.

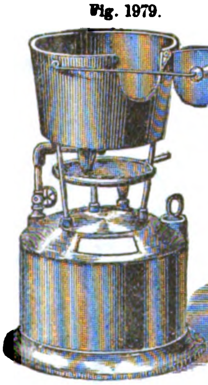


Plumbers' Chisels.

Plumb'ers' Chis'els. Various lengths and widths, for cutting walls of brick, plaster, and wood; cold chisels for iron, long chisels for boring holes for pipes or wires, etc.

Plumb'ers' Fur'nace. A portable soldering furnace. That shown is heated with petroleum elevated from the reservoir below and burned in the tray. The handle forms a rest for soldering bits.

Fig. 1979.



Plumbers' Furnace.

Plumb'er's Tools. See list under PIPES, etc., *supra*.

Plun'ger. (*Fire-arm.*) *a.* A pin struck by the hammer and exploding the priming by force of the communicated blow.

b. In other cases the plunger has the exploding point on its own end, as in the bolt gun.

Plun'ging Bat'te-ry. (*Electricity.*) One in which the positive or the positive and negative elements may be withdrawn from the fluid to render the battery inoperative, or to prevent the consumption of the plates when the battery is not required.

Grenet's bichromate battery is a familiar instance. *Prescott's "Electricity,"* * p. 72.

c c', Fig. 2148, p. 938, "*Mech. Dict.*," is an early form of plunging battery used by Sir Humphrey Davy.

See also Fig. 14, p. 2490, * "*Scientific American Sup.*"

It may be added that there are three principal modes: —

1. By plunging the elements into the liquid.

2. By raising the trough so that the liquid surrounds the elements.

3. By displacement of the liquid, raising it to the level of the elements.

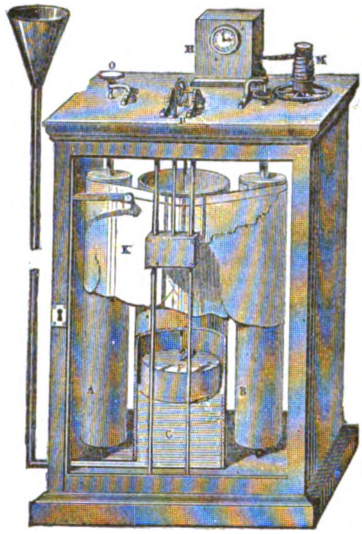
Plush. (*Fabric.*) The fabric known as *furniture plush* is a mohair fabric known also as *Utrecht velvet*. It is of mohair filling with cotton warp, or, in the better qualities, of mohair entirely. See MOHAIR.

Plush Bat'te-ry. A modification of the Callaud. Fr., * "*Engineer*," xlvii. 333.

Plu'vi-am'e-ter. An instrument used to measure the quantity of rain which falls over a given surface.

A new apparatus by M. Hervé Mangon is shown in Fig. 1980. A cylinder, *C*, receives the rain water led from the receiver *P*. In the cylinder is a copper float *F*, which, by means of a very fine cord passing over the pulley *N*, is connected to the weight *K* which is a little the heavier. The weight *K* slides on two guides of tightly stretched pianoforte wire, and carries a pencil, the point of which comes in contact with the

Fig. 1980.



Pluviameter.

exterior of the cylinder *C*. Inside the weight *K*, which is hollow, is a small electric interrupter, which, whenever a current is transmitted to it from the regulator, strikes against the pencil and produces indicated points on a curve, which serves to control the clock movement by which are actuated the two copper cylinders *A* and *B*. Over these last a belt of paper is passed, as shown; and the mechanism in *H*, which moves them, is provided with a regulating fusee *M*, so as to compensate for the difference caused in the diameter of the cylinder *B*, by the rolling thereon of several thicknesses of paper. *I* is a fixed pencil which traces a horizontal base-line on the paper. The latter, after first being rolled about the cylinder *A*, is carried over cylinder *C* and attached to cylinder *B*. In the middle cylinder sufficient water is then introduced to completely buoy up the float *F*. If rain falls, the float, by the addition of water beneath it, is lifted; and the weight *K* following the movement, the pencil thereon traces a curve on the paper, which gives in millimeters the corresponding depth of rain. If, on the contrary, no rain falls, the line left by the weight pencil is straight and parallel to that made by the fixed pencil.

Pneu-mat'ic Clock. A clock which is driven or regulated by air.

In the Parisian system, handsome public illuminated timepieces have been erected in the middle of the causeway of the leading thoroughfares of Paris. These are all in communication with the works of the new Pneumatic Clock Company, in the Rue St. Anne. By means of subterranean tubes this company receives the time direct from the Observatoire every morning, and regulates all the timepieces in connection simultaneously. In future it will be possible to have the correct time laid on in any house, like gas or water, at the trifling cost of from three to five centimes per clock per day.

To supply the whole of Paris, three or four central clocks are required, designated *Directing Normal Clocks*. These are placed at convenient centers, and connect with the ordinary or "Reception Clocks" of their system or district. Each of these central clocks is connected with a system of pipes, including, first, those running through principal streets; next, those branching therefrom into the minor streets; next, those running from the streets into the buildings; and, finally, smaller ones running as required in the interior of the buildings.

The central clocks are provided with a small engine, worked by steam or gas, which every minute sends a pulsation of compressed air through the entire system of pipes and acts upon every clock in the circuit, advancing the hands on the dial of the clock by one minute. The clocks are of simple construction.

Regulator, *Wenzell* . . * "*Min. & Sc. Press*," xxxviii. 281.

Pneu-mat'ic Con-duct'or. A fan blower and tube, to lead away air, foul air, fire damp, fumes, smoke, dust, shavings, etc.

Such are used in connection with stones which grind dry, such as in some departments of cutlery.

Shavings from a planing mill in Chicago are driven by air blast 700' through a 15'' sheet-iron pipe to a distillery, where they are burned.

See SHAVINGS CONDUCTOR, p. 2134, "*Mech. Dict.*"; FAN BLOWER, Fig. 1918, p. 825, *Ibid.*

Pneu-mat'ic Dis-patch'. A mode of conveying letters, parcels, etc., by sending them through a tube by force of air; vacuum or plenum systems. See PNEUMATIC TUBE.

Pneu-mat'ic Ex'ca-va'tor. A method of raising of sand, silt, or debris from a shaft in course of excavation.

Several forms are given in the "*Mech. Dict.*" under PNEUMATIC CAISSON, p. 1752; PNEUMATIC PILE, p. 1754; CAISSON, p. 421; AIR LOCK, p. 49, and Plate II.; SUBMARINE EXCAVATOR, Fig. 6028, p. 2439, etc.

The methods vary: 1. In the *Potts* system, the pile is a tube with the top closed, and the air being exhausted from within, the atmospheric pressure drives the cylinder into the sand. Used on the Goodwin Sands, England.

2. In the *Triger* system, the workmen are in the lower end of the chamber, and communicate with the exterior by air locks. See AIR LOCK, "*Mech Dict.*," p. 49. The system was used in sinking the caissons of the St. Louis and Brooklyn bridges. See references above quoted.

3. A mode of moving silt, mud, or sand by a pipe, the open end of which is exposed to the matter to be moved, and the air exhausted from the pipe. A vacuum system; a form of dredging apparatus.

4. The converse of the last mentioned; a pipe with blast of air, carrying with it detritus, silt, sand. Used in removing the matters from the caissons of the Brooklyn and St. Louis Bridges. See AIR LOCK, "*Mech. Dict.*;" PILE DRIVING, *supra.*

A form of pneumatic excavator which comes under the first cited of the four methods, is used in British harbor improvements.

It is chiefly used for sinking the cylinders for the piers of bridges in sandy soil. The apparatus consists of a pair of cast-iron cylinders 4' in diameter, carried on a staging and placed in connection at their tops with an air-pump, driven by a small steam engine. The connections are so arranged that the air can be exhausted either from one cylinder singly or both at the same time. The bottoms of the cylinders are connected with a suction tube 3¼'' in diameter, which leads down to the sand. Here again it is so arranged that the cylinders can be worked, either singly or in combination, by means of self-acting valves. The soil is discharged from each cylinder by a trap door placed in its front. The engine and air-pump are carried on the same framing, and the whole forms a very compact arrangement.

In operation, the engine being started, the air is exhausted from one cylinder: the sand and soil rushing up into the vacuum thus created soon fill the cylinder, the fact being indicated by a tell-tale. The connection is then made between the air-pump and the second cylinder, and that is similarly filled, during which time the contents of the first cylinder are discharged, and it is ready for the air-pump by the time the second cylinder is full, and so the process continues alternately until the desired end has been attained. The excavator has worked very successfully: a vacuum of 24'' was maintained during exhaustion, and the cylinders were rapidly filled with sand and water from a pit, the contents being quickly discharged.

Pneu-mat'ic Ma-chin'er-y. See AIR ENGINES, and list under AIR APPARATUS, p. 12, *supra.*

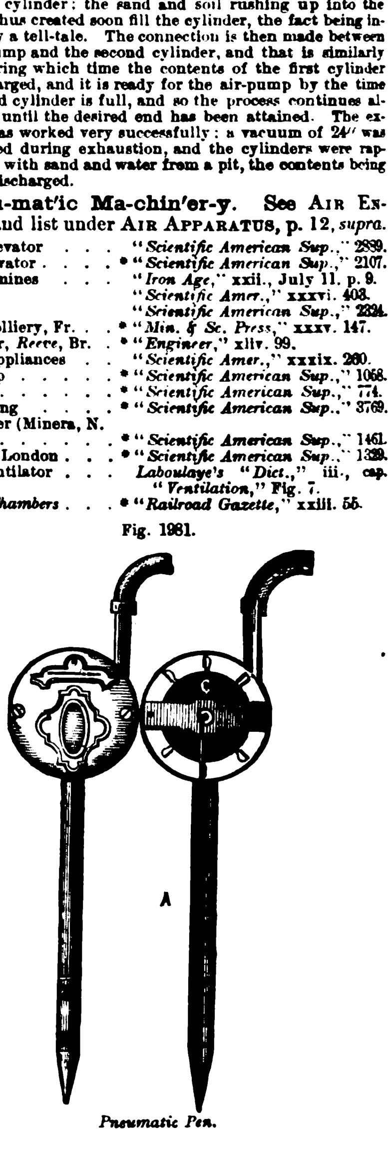
Fig. 1981.



Pneumatic Pen.

Pneu-mat'ic Pen. An instrument for obtaining a stencil for copying purposes. Fig. 1981. Numerous perforations are made through the paper by the instrument which follows the lines of the letters. See ELECTRIC PEN.

The instrument is guided as an ordinary pen. The tube *A* contains the needle *B*, which is connected to a crank on the axis of the fan-wheel *C*. Rapid motion is imparted to the fan by means of a blast of air either from the mouth of the writer or an air-bellows, through the flexible rubber tube *D*, connected with a foot-bellows or otherwise. On moving the point of the pen over a sheet of paper, it becomes pierced with very fine holes in lines of the desired pattern. Ink or color is then spread over the surface, which fills the holes, and passes through the stencil to as many sheets of paper as may be brought successively in contact with it.

Pneu-mat'ic Pile. See PILE DRIVING, *supra*.

Pneu-mat'ic Pile Dri'ver. See * PNEUMATIC PILE, p. 1754, "*Mech. Dict.*"; PNEUMATIC EXCAVATOR, *supra*;" see also PILE, *supra*, and * "*Scientific American Supplement*," 3769.

Pneu-mat'ic Pump. A pump in which the pressure of air upon a liquid is made the means of forcing or elevating. An application of the air pump.

The pump shown in Fig. 1982 is used for the discharge of the contents of casks, carboys, etc. It is a caoutchouc bulb

Fig. 1982.

Pneumatic Pump.

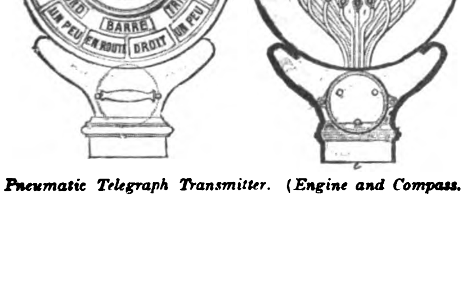
with valves. The pipe passes through the bung of the cask and condenses the air above the liquid in the latter. The liquid passes out by another pipe to the vessel placed to receive it.

Pneu-mat'ic Tel'e-graph. The pneumatic telegraph of Count Sparre, of Sweden, is shown and described on p. 1755, "*Mech. Dict.*" It acts by the impulse given to a column of water by pneumatic pressure.

Under PNEUMATIC CLOCK, *supra*, is described the method of running all the clocks of a district by means of an impulse of air, at definite intervals, carried by pipes to each clock in the district, and moving the hand on the dial one step.

The *télégraphe à air* of M. Walcker, of Paris, is shown in Figs. 1983–1986, as applied to the vessels of the French navy and transatlantic service.

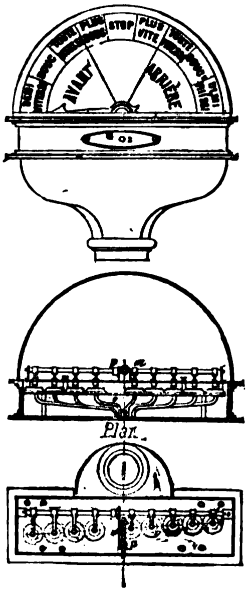
Fig. 1983.



Pneumatic Telegraph Transmitter. (Engine and Compass.)

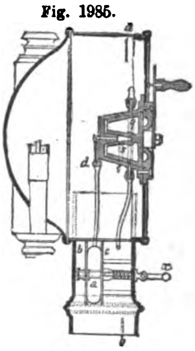
Fig. 1983 gives two views of the transmitter, — a front elevation and a vertical section on the same plane, a little behind the dial, on the line *a b*, Fig. 1985.

Fig. 1984.



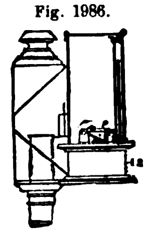
Pneumatic Telegraph Receiver. (Engine.)

Fig. 1985.



Pneumatic Telegraph Transmitter. (Transverse Section.)

Fig. 1986.



Pneumatic Telegraph Receiver. (Transverse Section.)

Fig. 1984 has three views of the receiver, — a front elevation, a vertical section in the rear of the dial exposing the machinery, and a horizontal section giving a plan of the acting parts.

Fig. 1985 is a vertical section on a plane transverse to the former.

Fig. 1986 is a vertical transverse section of the receiver.

The purpose of the apparatus is to convey to the engineer and to the steersman the directions of the captain or pilot on the bridge of the steamer.

The apparatus is double or single; in the former case, the dial has a full circle, the upper hemisphere concerns the engine, and the lower portion the rudder. In the single apparatus the engine or the rudder is alone concerned, — one single transmitting apparatus for each being placed on the bridge.

The operation of the apparatus is by compressed air, caused by a pressure brought upon the caoutchouc reservoir *a*, which is compressed between plates *b c* when the piston *x* is pulled. Air escapes to the chamber *d* and thence to passages *e f*, which, by devices to be described, sound a bell and move a pointer respectively in the receiver, which may be in the engine-room or the wheelhouse, as the case may be.

The operation is as follows: The needle being at zero, in the horizontal position shown in Fig. 1983, and the vessel supposed to be on her course, the officer on the bridge wishing to stop the engines, takes hold of the pointer (the handle is seen projecting to the right in Fig. 1985), and moves it to "*stop*," at the same time pulling the piston *x* and compressing the air in *a*. There are as many pipes to convey the air from the transmitter to the receiver as there are directions; for the engineer there are 9, — 1 for "*stop*" and 4 each for graduations of speed in "*forward*," "*astern*," respectively. In the example cited, "*stop*," the air passes in two bodies, one to the bell in the engine-room which calls the alarm, and the other by the special pipe which actuates the needle in the receiver, Fig. 1985, to bring it from its horizontal (zero) position to "*stop*" on the dial. The position of the pointer on the transmitter governs the choice of pipe openings, which are shown in a circular series in the sectional view Fig. 1983. The transverse section, Fig. 1985, shows the lamp at the rear which illuminates the glass dial on which the various indications are pointed.

The receiver is shown in Figs. 1984, 1986. It requires but a half-dial to hold its indications, and is but a single machine which belongs to the engine room. The fellow machine, which responds to the other half of the transmitter, is in the wheel-house. Taking the receiver in the engine-room: the pointer, when at zero, is horizontal, and the action of the air is to cause it to make a sweep within the range of a semicircle. The 9 air-tubes from the transmitter lead to as many levers in the receiver. As the levers are of different lengths an equal motion of the end of each will have a corresponding effect upon the axis *m*, with which they are connected, and upon the level gear *p* which actuates the needle. Thus the latter is moved less or more to bring it to the required place on the dial, which, in the example cited, "*stop*," is midway, that is, vertical. It stays at its indication until the engineer pulls on the button *z* and releases the air. The engineer then calls "*Aye, aye, sir*" through an acoustic tube. The same description, *mutatis mutandis*, applies to the steering.

Pneu-mat'ic Tube Dis-patch'. See the history and details, pp. 1755–1757, "*Mech. Dict.*"

The tubes of the Western Union Telegraph Co., New York, are 2¼″ interior diameter, with a capacity for sending 4 boxes a minute. The pipes, which are 18′ long, and joined by air-tight screw-joints, are laid 3′ under ground. The curves have a radius of 12′. The engine in use is a 30 horse-power compressing engine; and exhausting at the same time from two separate reservoirs. It has a capacity for 40 tubes.

The pneumatic dispatch service, of Berlin, Germany, embraces 26 kilometers of tube, and has 15 initial stations. The wrought iron tubes have a clear breadth of 65 millimeters, and lie about one meter below the surface of the ground. The letters and cards which are to be forwarded have a prescribed size, and are inclosed in iron boxes, or cartridges, each of which can hold 20 letters or cards. In order that they may pack closely, they are covered with leather. From 10 to 15 cartridges are packed and forwarded at a time; behind the last cartridge is placed a box with a leather ruffle, in order to secure the best possible closure of the tube. At four of the stations are the machines and apparatus needed for the business. The forwarding of the boxes is effected either through compressed or rarefied air, or through a combination of the two. Steam engines of about 12 horse-power are used for the condensation or exhaustion of the air. Each main station has two engines, which drive a compressing and an exhausting apparatus, the steam for each engine being furnished by two boilers. Large reservoirs are employed, both for the condensed and for the rarefied air. The former has a tension of about three atmospheres; the latter of about 35 millimeters of mercury. The air, which is heated to 45° C. by the compression, is cooled again in double-walled cylinders which are surrounded by water. The velocity of the boxes averages 1,000 meters per minute, and a train is dispatched every 15 minutes. Each of the two circuits is traversed in 20 minutes, including stoppages.

The service between Paris and the chambers where the sittings of the National Assembly were held at the Palais in Versailles, involved a line of 11 miles, and the packages were dispatched at an average of 8 minutes for the course. The tubes were 4″ in diameter, and required three steam engines of an aggregate of 50 horse-power. An apparatus called a relay acts as an accumulator, and comes in aid of the original impulse at points along the route. The air is forced in at one end and exhausted at the other, the messages are in boxes forming a train, and the relays come into action immediately that a train passes a station.

The French method of locating the position of an obstruction in a pneumatic tube is by firing a pistol into the tube. The resulting wave of compressed air, traversing the tube at the rate of 1,000′ a second, strikes the obstruction, and is then reflected back to its origin, where it strikes against a delicate diaphragm, and its arrival is recorded electrically upon a very sensitive chronograph, on which also the instant of firing the pistol had been duly recorded.

Pneu'mo-graph. The *cardiograph* of M. Marey is capable of being used also as a *pneumograph* by an adaptation of the apparatus of exploration.

This consists of a spiral spring inclosed in rubber and forming a hollow extensible cylinder of which the ends are closed. A lateral tube places the interior of the cylinder in communication with the registering apparatus, which is shown under CARDIOGRAPH. Each action of inspiration and expiration produces a movement of contraction or extension of the cylinder, which reacts upon the registering lever.

The elastic cylinder is placed with its end on the breast of the subject, and is included within an inelastic band which encircles the chest. As the chest expands and contracts in the act of breathing, the cylinder is condensed and dilated respectively, the air passing by the tube to the registering apparatus.

Laboulaye's "*Dictionnaire*," *cap.* "*Graphiques*."

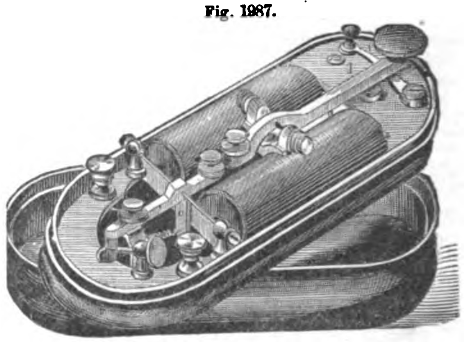
Pock'et. (*Mining.*) A rich spot in a vein or deposit.

Pock'et Mi'cro-scope. (*Optics.*) A portable microscope, to be carried in the pocket for field purposes; sometimes a set of single lenses; sometimes supplied with a compound body.

Pock'et Net. (*Fishing.*) One with a relatively small compartment in which the fish are collected. See TRAP NET. See also TRAMMEL NET.

Pock'et Re'lay. An instrument for making telegraphic connection at any point on a line, to communicate in case of accidents, etc. Also known, from its use, as a *wrecking instrument*.

Fig. 1987.



Pocket Relay.

Po-dom'e-ter. See PEDOMETER.

Po'do-scaph. A foot boat; one in which canoe-shaped floats are attached to or support the feet.

The one shown is that made by Mr. Fowler, of Bordeaux, and used by him in crossing the Straits of Dover.

The dimensions are: length, 3 meters.
Each podoscaph: width, 20 cm.
Above water: height, 30 cm.
Time of crossing: about 12 hours. Distance 21 miles.

Fig. 1988.

Fowler's Podoscaph.

Pog'gen-dorf Bat'te-ry. (*Electricity.*) 1. A Smee battery, in which pulverized copper is deposited upon the copper electrode.

Niaudet, American translation . . . . . . p. 59.

2. A modification of the Grove battery, in which

the platinum is in the shape of an S, and is fastened to a porcelain stopper, which nearly closes the porous jar.

Niaudet, American translation . . . . . . * p. 155.

Point Find'er. An instrument for finding the vanishing point in making perspective projections.

"*Engineering*" . . . . * xxii. 223.

Point'ing. 1. (*Milling.*) A preliminary in the preparation of grain for the mill in the modern process; it consists in rubbing off the points of the grain, *clipping* the *brush*, and removing the germ end.

This is done in a machine like a *smut mill* (which see), or by passing the grain between mill-stones separated from each other by a distance a little less than the length of the grain. The grain is only abraded when in a position vertical to the surface of the stones. This is the first operation in the *high-milling* process, *which see*.

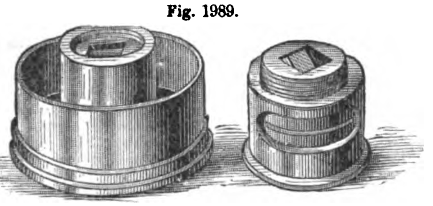
2. (*Metal Working.*) A machine for finishing the ends of nails, pins, or wire.

* "*Iron Age*" . . . . xxii., December 26, p. 1.

Po-lar'i-scope. (*Optics.*) An instrument for analyzing the light thrown through an object, whereby, in accordance with its varied texture, varied shades of the spectrum are given to its different parts. This is usually effected by two Nichols prisms of Iceland spar; sometimes by means of tourmalines. See TOURMALINE.

One of the prisms is placed beneath the object and above the mirror, and is called the *polarizer*. The other prism is

Fig. 1989.



Polariscope.

above the object-glass, and is called the *analyzer*. By revolving either of these prisms variations in the tints of the spectrum are produced.

The polariscope is an invaluable adjunct to the microscope for detecting the structure of miner ls, animal tissues, vegetables, crystals, etc.

Laurent's polariscope, used in determination of quantity of sugar in solutions, is described in Dr. McMurtrie's report on beet sugar, 1880, "*Dept. Agric. Special Report*," No. 28, pp. 84, 85.

Polar clock . . . "*Scientific American Sup.*," 505.
"*Mech. Dict.*," Figs. 3767–3769, p. 1759.
Lockyer's "*Spectrum Analysis.*"
Schellen's "*Spectrum Analysis.*"

Po'lar-i-za'tion. Broadly, the definition is thus given by a philosopher: —

"When a particle of a body possesses qualities related to a certain line or direction in the body, and when the body, retaining these properties, is turned so that this direction is reversed, then if, as regards other bodies, these properties of the particle are reversed, the particle, in reference to these properties, is said to be polarized, and the properties are said to constitute a particular kind of polarization." — *Clerk-Maxwell.*

1. (*Galvanic Batteries.*) The accumulation of hydrogen upon the negative plate, followed by the deposition of zinc from the said plate, by which the current is weakened.

2. (*Magnets.*) The establishment of magnetic poles in a piece of steel or iron, as of a compass needle or the soft iron core of an electro-magnet by means of a generated circuit.

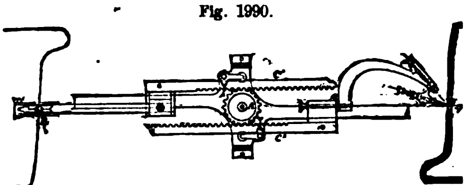
3. (*Light.*) The separation of a pencil of light into two rays, in planes at right angles to each other, known as the ordinary and extraordinary rays, which may be done by double refraction or by reflection.

4. (*Heat.*) A similar action with heat rays.

Po'lar Pan'to-graph. An apparatus devised by M. Napoli for copying on paper the profiles of worn railway-wheel tires.

The apparatus, shown in Fig. 1990, consists of a light frame, having mounted on it the toothed wheel *A*, into which gear the rack bars *C C'*, the former of these being

Fig. 1990.



Napoli's Polar Pantograph.

provided with a pencil-holder, *B*, while the latter is provided with a pointer, *D*. The arrangement of the parts is such that a line joining the center of the pencil at *B*, with the apex of the pointer at *D*, passes through the center of the wheel *A*, and is bisected by that center. The racks *C C'* are kept in gear with the wheel *A* by rollers mounted on bell-cranks, these bell-cranks being provided with springs which tend to force the rollers against the rack bars. The effect of the arrangement is that any movement in the plane of the wheel *A* imparted to the pointer *D* is exactly reproduced by the pencil *B*, and thus if the pointer *D* be moved over the profile of a tire the pencil *B* will draw that profile on a piece of paper placed under it. The whole apparatus is so mounted that it can be readily attached to the tire of which the profile has to be taken, provision being made for supporting the paper under the pencil *B*.

* "*Railroad Gazette*" . . . . . xxiii. 349.
* "*Engineering*" . . . . xxvi. p. 427, Fig. 8.

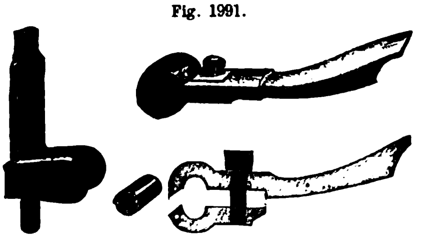
Pole. (*Electricity.*) The wire, plate, or cord leading from the battery. Their names are the opposite of those of the plates from which they lead; thus the zinc is the *positive* metal or plate of the battery, but the wire leading therefrom is the negative pole.

Pole Chan'ger. An instrument for shifting a current from negative to positive, or *vice versa*. See, for instance, the key at Fig. 847, p. 266, *supra*.

Pole Coup'ling. The connection of the pole or tongue with the front axle of a vehicle.

On the left is the clip, not yet bent to clasp the axle. To

Fig. 1991.



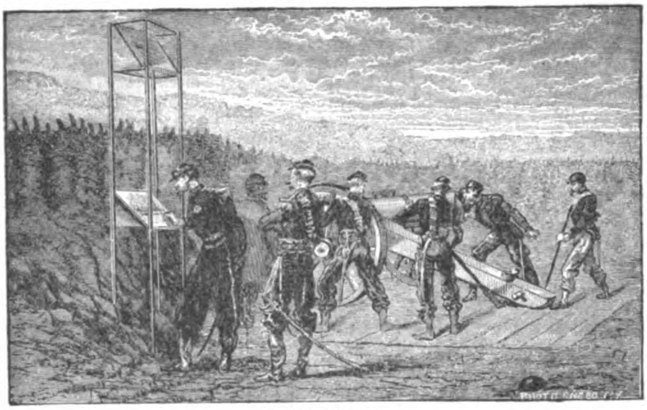
Pole and Shaft Coupling.

the right are the shaft-eye and rubber packing, shown complete and in sections detached. The rubber prevents rattling.

Po-lem'o-scope. A reflecting apparatus consisting of a combination of two plane mirrors, so inclined to each other as to enable the spectator, by glancing into one of them, to see the images of objects separated from direct view by intervening obstacles. It is used during sieges to observe the position and movements of the enemy, while the soldiers may remain in shelter behind a parapet.

A simple frame-work of wood supports at the top a plane mirror, with its reflecting surface directed towards the scene to be observed, at an angle of 45°; beneath this mirror is a second one, precisely similar, and with its reflecting surface inclined upward at the same angle as the upper one.

Fig. 1992.



Polemoscope.

The reflecting surfaces of the two mirrors are, therefore, opposite to each other, and parallel. The image received upon the first mirror is reflected directly upon the second, from which it becomes visible to an observer.

See * ALTISCOPE, Fig. 136, p. 69, "*Mech. Dict.*"; INDIRECT POINTING APPARATUS, p. 496, *supra.*

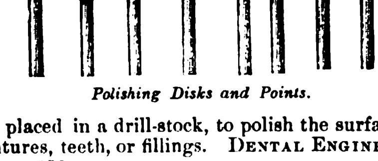
Pole Rail'way. One, the way of which consists of two parallel poles, the cars having tires with concave tread. Used for temporary purposes in the lumber regions in getting logs of a tract to the saw mill. See LOG RAILWAY.

Pol'ish-ing. Materials, tools, and machines are cited and described on p. 1762, "*Mech. Dict.*"

The forms of polishers are: —	Surfaces.	Materials.
Bands.	Bristles.	Borax.
Belts.	Brushes.	Chalk.
Cones.	Buff.	Colcothar.
Cylinders.	Catgut.	Corundum.
Disks.	Cloth.	Crocus.
Drums.	Cotton.	Emery.
Laps.	Felt,	Graphite.
Rings.	Leather.	Oxide of tin.
Sticks.	Metal.	Pumice stone.
Threads.	Stone.	Putty powder.
Wheels.	Thread.	Rotten stone.
	Walrus.	Rouge.
	Wire.	Tripoli.
	Wood.	
	Wool.	
	Yarn.	

Pol'ish-ing Disk. (*Dentistry.*) Small instruments carrying a fine powder and revolved by being placed in a drill-stock, to polish the surfaces of dentures, teeth, or fillings. DENTAL ENGINE, Fig. 795, p. 250, *supra.*

Fig. 1993.



Polishing Disks and Points.

Pol'ish-ing I'ron. A small laundry iron, sometimes curved on the face and used in putting the extra finish on shirt fronts, collars, cuffs, etc.

Pol'ish-ing Jack. (*Leather.*) A machine armed with a lignum-vitæ slicker; used for polishing leather when considerable pressure is required.

Pol'ish-ing Ma-chine'. (*Wood.*) A machine having an emery wheel which dresses the face of the work applied thereto.

See SURFACING MACHINE, Fig. 6083, p. 2458, "*Mech. Dict.*"

Speculum . * "*Sc. Amer. Sup.*," 699.
Wheels, *Rose* * "*Sc. Amer. Sup.*," 489.

Pol'y-chrome Print'ing. A process in which colors in blocks are built up together like type in a chase and themselves furnish the color to moistened paper laid thereon. A mosaic of color blocks. — *Johnson*, Br. See also British patent 14,078, 1852, and United States patent, *Laemmel*, July 4. 1871.

Pol'y-con'ic Pro-jec'tion. (*Geodesy.*) A development of the earth's surface in which each parallel of latitude is represented on a plane by the development of a cone having the parallel for its base, and its vertex in the point where a tangent at the parallel intersects a prolongation of the earth's axis.

Pol'y-gon'o-scope. (*Optics.*) An optical instrument for producing and displaying an infinite number of designs and patterns, which can be copied or photographed, and may be used for art manufactures, for amusement, or for other purposes.

The instrument consists of two mirrors fixed in a case and connected together by means of a universal hinge, which is so arranged that the mirrors can be set and fixed at any angle to produce any required design. One of the mirrors is loose in its frame, and can be moved toward or from the other, so that at whatever angle they may be fixed the edges of the mirrors can be made to touch each other, thus preventing the pattern or design from being broken in the center. The apparatus can be closed up in a portable form, similar to an ordinary pocket-book. Patterns having any number of angles or sides may be produced by varying the mirrors. The above has some resemblance to the kaleidoscope. — *Hatton*, Br.

Pol'y-graph. One of the names given to the gelatine copying pad. See GELATINE PROCESS; HECTOGRAPH; COPYGRAPH, *supra.*

In one modification of the process, instead of the gelatine compound in a tray, paper is coated with the material. Sized or unsized paper is coated on one side with a composition consisting of glue, or gelatine, glycerine, soap, and water, approximately in the following proportions, which have been found to give good results in practice: 80 animal glue or gelatine, 20 glycerine, 20 soap, 200 water.

The writing is made in aniline ink.

Then take a sheet of the polygraphic paper, lay it on a damp flannel, sponge with water containing a little alum, lay the writing thereon, ink to the gelatine, back with a sheet of paper, and put the pile in the ordinary copying press. — *Alisoff.*

Pol'y-mi'cro-scope. An adaptation of the principle of the revolving stereoscopic camera to microscopic purposes; the objects mounted on plates attached to a band are successively presented to the instrument.

Prof. Von Lenhossek, Buda-Pesth, * "*Scientific American Supplement*," 2267.

Po-lym'e-ter. An apparatus used for testing the distance between railway rails, and detecting inequalities of elevation.

An improved apparatus by M. Coutourier is mentioned in a paper in "*Bimensuel de la Société d'Encouragement*," 1878, p. 385, and republished in the proceedings of the "*Institute of Civil Engineers*," London.

It consists of an iron triangular ruler 6½" in length, having the long side for its base, furnished with a movable arm which is pressed against the rail by a spring. The arm communicates with a pointer, which stands at the zero of a finely divided scale when the rails are at their normal width apart (4′ 8½″ = 1.447 meters). Any deviation from this, more or less, is indicated on the scale.

At the side, a pendulum is attached to the ruler, which, when vertical, points to the zero of a circular scale; any change in the inclination of the ruler is communicated to an index sufficiently long to reproduce on the scale the actual amount of the super-elevation — or otherwise — of the rail. This communication can be made either by a toothed wheel or by a series of links from the pendulum to the index. See DYNAGRAPH, *supra*.

Pol′y-phote Reg′u-la′tor. (*Electricity.*) An order of voltaic arc regulators, also known as a *many-light* or *division* regulator, which allows several or many lights on one circuit.

Of this order are several forms, which see —
Differential.
Derivation.
Fixed interval (Regulators *à écart fixé*).

Po-lyp′tome. (*Surgical.*) A hook or écraseur for cutting loose a polypus in uterus, ovary, nasal cavity, etc.

Pol′y-pus For′ceps. (*Surgical.*) For removal of polypi by grasping and wrenching.

Allen's, Politzer's, Bumstead's, Avery's, Noyes', Hinton's, Pomeroy's, Tiemann's, and Wilde's ear forceps, pp. 45-47, Part II., *Tiemann's "Armamentarium Chirurgicum."*

Blake's polypus snares, *Ibid.*, p. 45.

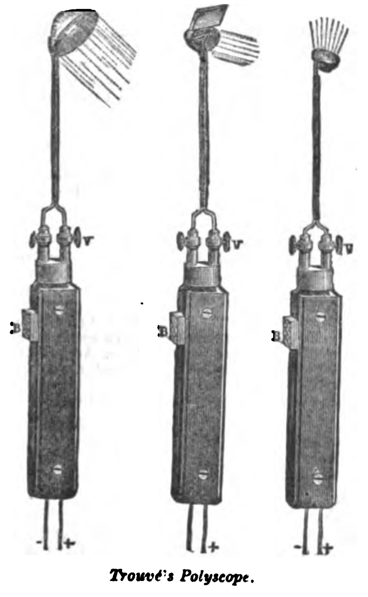
Simrock's, Gross's, and other nasal polypus forceps, *Ibid.*, p. 57.

Écraseurs and ligators, pedicle forceps and clamps, clamp and sac forceps, tumor forceps, tenacula, vulsellum forceps, etc., for uterine and ovarian tumors, *Ibid.*, Part III., pp. 92-99.

Pol′y-pus In′stru-ments. (*Surgical.*) Prehensile instruments for removing polypi from the nose, ear, uterus, etc.

They are forceps, snares, écraseurs, etc., for grasping, cutting, or tearing loose the sac or tumor, severing the pedicle, etc.

Fig. 1994.



Trouvé's Polyscope.

Pol′y-scope. Invention of M. Trouvé. Designed to illuminate cavities of the human body.

It consists of a secondary Planté battery, with rheostat for regulating the flow of the current, and a galvanometer with two circuits, in which the electro-motive force of the reservoir and that of the Trouvé-Callaud battery, intended to charge it, are opposed.

The instrument has a platinum coil and reflector fitted to a handle, and wire connecting it to the reservoir.

Edison has proposed a small electric light in a glass bolus to be swallowed, in order to illuminate the stomach interiorly.

" *Telegraphic Journal* " . . . . * vi. 313.
" *Scientific American* " . . . . * xxxix. 182.

An instrument to illuminate the cavities of the body has also been invented by Dr. Nitze, in Saxony. It consists of a platinum wire kept red hot by an electric current, and inclosed in a glass bulb.

One form is made by Coxeter & Sons, England.

Pol-y-zo′nal Lens. 1. A lens having several zones, as in the Dioptric arrangement for lamps and lighthouses.

See circular zones in Fig. 1096, p. 357, *supra;* and cylindrical zones in Fig. 1657, p. 704, "*Mech. Dict.*"

See also * "*Scientific American*, xli. 53.

2. A combination of a number of segmental lenses arranged in zones. Fig. 1376, p. 1763, "*Mech. Dict.*"

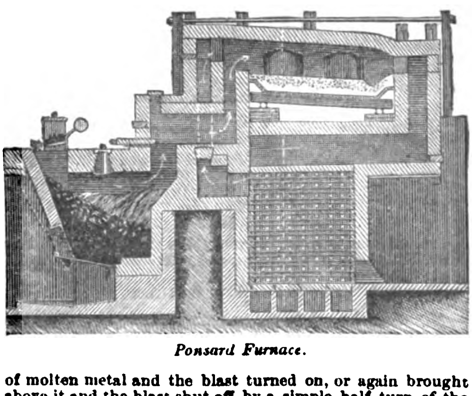
Pon′ci Bat′te-ry. Invention of Prof. Ponci. It consists of a glass jar and porous pot, the former containing a solution of ferric-chloride, in which is immersed a carbon-plate, and the latter containing a solution of ferrous-chloride, in which is immersed an iron plate. Each solution 35° B. "*Telegraphic Journal*," vi. 425.

Pon′sard Fur′nace. An open hearth furnace with a circular inclined and movable hearth, and considered to occupy an intermediate position between the Bessemer and Siemens in the range of its application to the raw materials.

The regenerator, shown beneath, is still more clearly indicated in Figs. 1161, 1162, p. 387, *supra*, where the *Ponsard* regenerator is shown as applied to gas works, and where the distinction between the *Ponsard* and *Siemens* regenerators is pointed out, the latter being shown in Figs. 1159, 1160, on p. 386, *supra*.

The open, circular, inclined and movable hearth of the *Ponsard* furnace is fitted with a pneumatic attachment, so arranged that the tuyeres can be plunged beneath the bath

Fig. 1995.

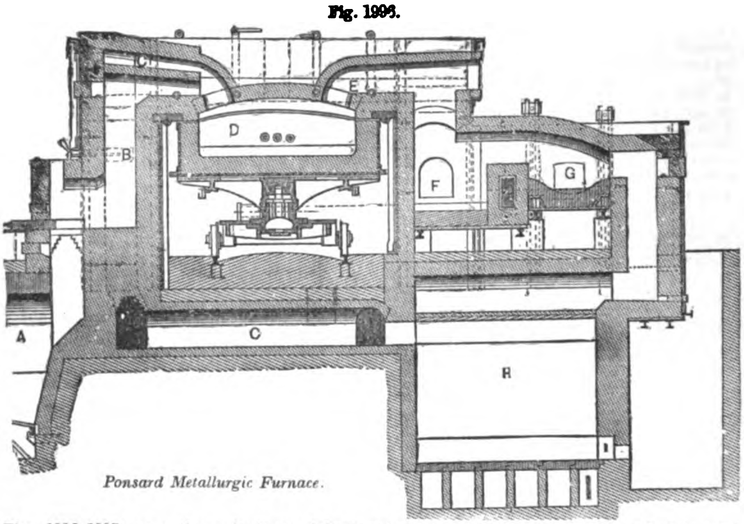


Ponsard Furnace.

of molten metal and the blast turned on, or again brought above it and the blast shut off by a simple half turn of the hearth, allowing the operation to be prolonged or shortened, or repeated at pleasure, without shutting off the heat or retarding the manufacture.

The hearth of the furnace can be readily detached and run out from beneath and away from the heat, affording facilities for repairing or renewing the lining as often as may be required. As the roof will generally outlast five or six hearth linings, the advantage of being able to have a second hearth ready to be run in without letting down the heat is great, particularly in the treatment of highly phosphoric pig by the new methods, in which the basic lining is rapidly destroyed by the reaction.

Fig. 1996.



Ponsard Metallurgic Furnace.

Figs. 1996, 1997, are sections of a Ponsard furnace in which the hearth is on a carriage and is run in and out of furnace, and is capable of rotation on its inclined axis. *A* is the producer; *B*, gas flue leading to hearth *D*; *E*, chimney; *R*, regenerator, *C F X*, flues; *G*, heater furnace.

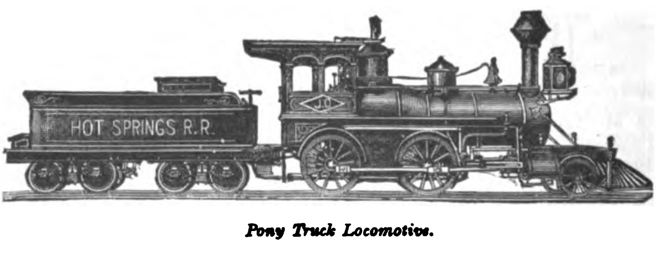
Pon'ty. The glass-blowers' tube.

M. Clémandot, of France, recommends nickel plating pontils and glass molds, to prevent coloration of the glass by oxidation of the iron. It is adopted in several French factories, the plan being to put the objects in a plating bath of a sulphate of nickel and ammonia for several hours.

Pony Truck. A truck with a single pair of wheels. Shown in Fig. 1998 as in advance of the drivers and just behind the pilot.

In Fig. 168, p. 65 *supra*, it is shown beneath the rear of the locomotive.

Fig. 1998.



Pony Truck Locomotive.

Po-poff'ka. A circular ironclad, the invention of Admiral Popoff, of the Russian navy.

The "Novgorod" and "Adm. Popoff," described in "*Iron Age*," vol. xix., June 7, p. 26.

See also references under "*Iron Clad*."

Por'ce-lain. (*Ceramics.*) A hard, partially vitrified, form of pottery, divided into two classes known as *hard* and *soft*, which names indicate the comparative hardness of the wares, due largely to the different quantities of silica in the composition. The porcelain of China (see p. 1765, "*Mech. Dict.*") is composed of *kaolin* and *petuntze*, one a peculiar clay and the other a feldspar. Silex (flint) is a form of silica commonly used in English porcelain, and entering as it does into some of the better forms of stone-ware and queen's-ware, they partake largely of the porcelain character.

Porcelain is translucent and breaks with a vitreous fracture, bright and clean, differing from the softer forms of pottery of which faïence forms the most attractive example.

Brogniart's classification, under the general head of "*Poteries à Pâte Translucent*," enumerates three kinds of porcelain: —

1. Hard porcelain: *porcelaine dure.*
2. Natural soft porcelain: *porcelaine tendre naturelle.*
3. Artificial soft porcelain: *porcelaine tendre artificielle.*

1. Hard Porcelain is distinguished by a fine, hard, translucid paste; it has a hard earthy glaze and a more vitreous character than other pottery, which accounts for its glassy fracture, and its sonority.

The elements which enter into the composition of hard porcelain are kaolin, feldspar, chalk, and sometimes silicious sand, plastic clay, and powder of broken porcelain.

Following in the description the practice at the manufactory at Sèvres: —

The kaolin of St. Yrieix yields both the argillaceous, flinty varieties. The feldspar is taken from a rock of pegmatite at St. Yrieix. The silicious sand is from Aumont, near Creil. The chalk is from Bougival. The plastic clay from Abondant, near the forest of Dreux.

The following is the composition at Sèvres: —

Silex	0.580
Alumina	0.345
Chalk	0.045
Potash	0.030
	1.000

The preparation of the paste is by means of careful grinding, levigation, sifting, incorporation, dilution, straining, ripening, and the subsequent operations upon the paste are by means of throwing or molding, or the two united much as in other species of pottery but with greater exactness and delicacy in proportion as the work is of a more delicate or elaborate description.

Owing, however, to the less plastic and tough character of the porcelain paste great care is necessary, and processes for condensing the paste by pressure in bags or wire cloth vessels have been employed, and are described by Brogniart and others as the invention of MM. Honoré, Grouvelle, Alluand, de Caen and others. See under "*Poterie*," Laboulaye, vol. iii.

The paste for articles of statuary which are not to be glazed but remain in biscuit form is composed of: —

Clay of the flinty kaolin	0.64
Feldspar	0.16
Sand of Aumont	0.16
Chalk	0.04
	1.00

The largest pieces are made of a much more plastic composition by M. Regnier: —

Clay of flinty kaolin	0.43 to 0.44
Pipe clay of Abondant	0.21 to 0.25
Feldspar	0.16 to 0.17
Quartzose sand of Aumont	0.16 to 0.09
Chalk	0.04 to 0.05
	1.00 1.00

The mode of fashioning is by throwing-wheel or mold, which see.

After a slight drying in the air, the pieces are baked in the waste-heat chamber at the upper part of the porcelain kiln, (see PORCELAIN KILN), where they are carefully preserved from soot by encasing in *casettes*, which are boxes of refractory clay like seggars, which see.

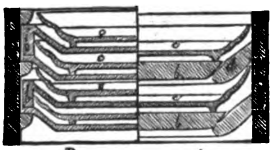
The glaze (Fr. *couverte*), is of the pegmatite of Saint Yrieix, the mean composition of which is: —

Silex	0.74
Alumina	0.18
Potash	0.07
Chalk and manganese	0.01
	1.00

The articles are dipped in the slip, which is the result of the most careful grinding and straining, and the quality is judged by the rate at which it will descend in still water in a cylindrical graduated glass vessel, in which it has been agitated so as to be in a state of suspension.

The firing of the ware is done at a high temperature so as to soften the compound, which is partially fused by the heat, giving it the vitreous and translucent character which belongs to porcelain. See PORCELAIN KILN.

Fig. 1999.



B A

Seggars for Sèvres Porcelain.

The encasing of the pieces in the kiln is a carefully arranged matter, and the accompanying figure shows two forms, one half of each being represented. In each case the rings *a* have spurs projecting inwardly on which are laid rondeaux, *b*, which serve to support the plates or dishes *c c*. The seggars (*casettes*) are of a special size and height for each description of ware. See PORCELAIN KILN.

2. NATURAL SOFT PORCELAIN. This is an English invention of which the Worcester porcelain may be considered the representative. The works at that city were started about 1751. The paste is a grade between fine faïence and hard porcelain. It is distinguished by having a base of kaolin and a large proportion of phosphate of lime obtained by the calcination of bones.

The following recipes show that great latitude of proportion is practiced: —

	Saint-Amans.		Aikin.
Argillaceous kaolin, washed	0.11	0.41	0.310
Flinty kaolin, crude and ground	–	–	0.260
Pipe-clay	0.19	–	–
Calcined flint	0.21	0.16	0.025
Phosphate of lime	0.49	0.43	0.405
	1.00	1.00	1.000

The paste is very plastic and is fashioned after the manner usual with fine faïence, yielding readily to the throwing-wheel or mold. The kiln is the same as that used for fine faïence (see FAIENCE) having fires *à alandier*. The glaze is lead and boracic acid glass, harder than that for faïence, but not so hard as the *couverte* of hard porcelain. It is laid on by immersion in the slip glaze.

The following is one example of glaze: —

	Saint-Amans.
Feldspar	0.48
Silex or quartzose sand	0.09
Borax, crude	0.22
Flint glass	0.21
	1.00

The glazing materials are fritted, and after grinding 10 to 12 per cent. of minium is added.

The firing of the glazed and decorated ware is at a moderate heat.

3. ARTIFICIAL TENDER PORCELAIN. — The porcelain made at Sèvres until 1804, when the difficulty of working in so little plastic a material caused it to be discarded.

The paste is marly, fine, dense, almost vitreous, hard, translucid, and fusible at a high temperature. The paste has but little adherence, and was always molded. After having acquired some little tenacity by the addition of a certain quantity of gum adragante, the dry pieces were finished on the lathe. The setting of the ware in the kiln or muffle was accompanied with great difficulty, as the objects required to be stayed and supported by pieces made in the same paste in order that they might exactly follow the contraction.

The composition was eminently vitreous. A frit was made as follows: —

Niter	0.220
Grey marine salt	0.072
Alum	0.036
Soda of Alicante	0.036
Gypsum of Montmatre	0.036
Sand of Fontainbleau	0.600
	1.000

The composition of the paste was: —

The frit, as above	0.75
Chalk	0.17
Calcarean marl of Argenteuil	0.08
	1.00

The glaze was put on by sprinkling. It was composed: —

Sand of Fontainbleau, calcined	0.27
Calcined flint	0.11
Litharge	0.38
Carbonate of soda	0.09
Carbonate of potash	0.15
	1.00

The materials are mixed, melted in a crucible, crushed, and again melted and crushed. The firing is at a lower temperature than that required for the biscuit. Care is taken to treat the interior surface of the seggars (*cazettes*) with the same glaze in order that they may not absorb that of the objects contained in them.

Por'ce-lain Ce-ment'. For mending china or glass ware.

Gelatine	5
Chromate of lime	1

Anoint the edges, press together, and expose in the sunlight.

Por'ce-lain Col'ors. (*Ceramics.*) Colored glasses which fuse upon the biscuit surface in firing. Fluxes with metallic colors; oxides generally.

Cobalt	Blue.
Chromium	Green.
Oxide of iron	Brown.
Oxide of uranium	Black.
Oxide of titanium	Yellow.
Chromate of lead	Yellow.
Chromate of baryta	Yellow.
Oxide of manganese	Black, violet, brown.
Sesqui-oxide of iridium	Black.
Oxide of cobalt	Black, blue-grey.
Proto-chromate of iron	Brown.
Purple of cassius	Purple.
Sub-oxide of copper	Red.
Oxide of copper	Green.
Oxide of chromium	Green.

Por'ce-lain E-lec'tro-pla-ting. Sulphur is dissolved in oil of lavender spike to a sirupy consistence; then chloride of gold or chloride of platinum is dissolved in sulphuric ether, and the two solutions mixed under a gentle heat. The compound is next evaporated until of the thickness of ordinary paint, in which condition it is applied with a brush to such portions of the china, glass, or other fabric as it is desired to cover, according to the design or pattern, with the electro-metallic deposit. The objects are baked in the usual way before they are immersed in the bath.

Por'ce-lain Kiln. The porcelain kiln is a high cylindrical tower with a dome, built of refractory bricks. It has two or three vaulted stages and is flanked at its base by several furnaces, from which the flame reaches the lower kiln chamber by horizontal passages, thence the upper chamber by vertical canals, and eventually the chimney at the summit.

See Plate XXXV. which is a representation of the porcelain kiln of Sèvres, France.

The upper chamber is for the baking of the green ware, bringing it to the biscuit stage, after which the objects receive the glaze (*couverte*) and then take their final firing in the lower story. The pieces are placed in refractory clay boxes termed (*cazettes*) seggars (which see), which are piled in the furnace forming high columns which reach almost to the vaulted ceiling. The door of the kiln (*laboratoire*) is then closed and luted, and the fires lighted in the furnace. The fires burn about 36 hours.

The chambers of the kiln are entered by arched openings which are bricked up when full and the kiln is ready to fire. The furnaces are 6 in number, around the base of the kiln, and the fire is direct, the air to support combustion entering by way of the ash-pot as usual.

The *couleurs de grand feu* are required to support an equal temperature with the paste but they are not so numerous as the other class of colors, *couleurs des moufles*, which are fired in muffles divided into stories and celles. See PORCELAIN MUFFLE.

Another form of porcelain kiln at Sèvres has furnaces *à alandier*, with a diving draft. Fig. 36, p. 20, *supra*, shows a three-story kiln with furnaces around them, but the section cuts through only one at each stage. The two lower ones are *a alandier*.

Por'ce-lain Mold'ing. (*Ceramics.*) In molding porcelain, if the hollow object is to have two exterior faces, the mold is in two parts, which, when joined, present an interior surface corresponding to the relief of the object; the paste is applied in each portion and smoothed on the exposed surface, which forms the interior of the vase (for instance). The parts of the mold are then brought together and the joint made by the hand, a spatula, or a smooth shell introduced into the interior.

A hollow shallow object such as a dish or tureen, is made by another method, termed *moulage à la croute*, the paste is rolled upon a marble table, in the manner of a pie-crust, hence the name, and is laid upon the mold, applying to the surface a sponge dipped in thin slip. See Plate XXXVI.

For thin hollow objects, the *moulage par coulage* is adopted, the thin paste being poured into the mold, which has a plug at the bottom, which is opened after a time to allow the superfluous slip to run out; the mold is porous, and the plug is withdrawn after a time determined by experience, when a sufficient thickness of the slip shall have adhered to the mold. The operation may be repeated for a greater thickness.

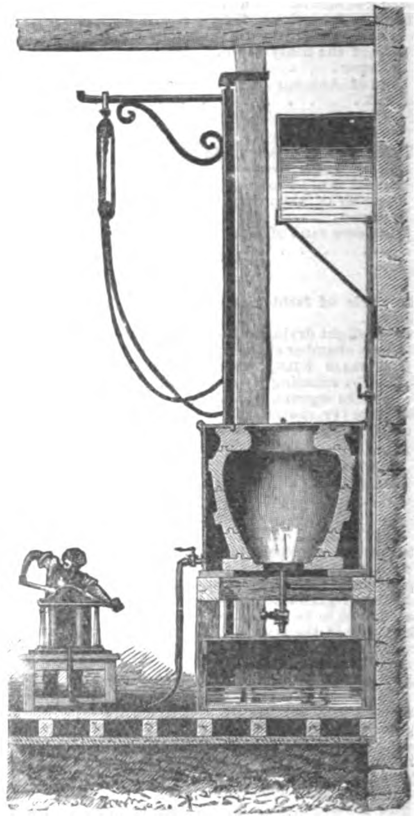
For a cup it needs but to pour a thin slip into a cavity of the right shape in a block of plaster. The water passing through the pores of the plaster allows the paste to gather on the sides of the mold, and the superfluous paste is poured out. This is the way in which very thin ware is made.

In making thin objects of large size by *coulage*, the aid of an air-pump is called for: either to compress the air inside the mold, or to remove the natural pressure of the air from the exterior of the hollow mold. See Plate XXXVI.

In the former case (compression) the slip is projected into the interior of the hermetically closed mold by a tube of caoutchouc, and the superfluous slip withdrawn by a faucet below; the compressed air introduced into the mold by another tube holds against the interior of the mold the paste which would be disposed to slip down.

In the latter case (exhaustion), the upper part of the mold is open to give access to the atmosphere and all the remainder of the mold is covered by a box of sheet-iron, as in Fig. 2000. The slip is injected and the excess drawn off by the

Fig. 2000.



Regnault's Apparatus for Molding with Air Exhaust (*Section*).

faucet below. The air inside the box around the porous mold is withdrawn by means of the air-pump, and the atmospheric pressure upon the paste adhering to the mold keeps the paste from slipping down, as mentioned in the previous case.

The molding completed, by means stated, the object is allowed to dry in position, by absorption of its moisture by the mold and the action of the air; the shrinkage renders it easily withdrawn and it is then finished. This may be upon the wheel, by scraping, by adding to or mending portions, hollowing out, stamping, adding molded portions, carving, and ornamenting in various ways with colors, designs, and what not.

To resume at the point of withdrawing the green ware from the mold, — the objects are dried in the air for several days, and then those which were fashioned upon the wheel are returned to it, and by means of sharp tools, of shapes and sizes, called *tournassins*, which have some resemblance to metal-turning tools, — the object is retouched, the angles sharpened, hollows deepened, the protuberances and moldings smoothed, the foliation repaired, and the whole object brought to the detail and thickness required. This operation is the *tournassage*.

Scraping (*grattage*) is adopted with objects not fashioned on the wheel.

The repairing or refilling (*remplissage*) which follows, consists in stopping up with paste defects in the molding, or holes produced in the subsequent *tournassage*.

The *evidage*, *estampage*, and *moletage* which follow, refer to the engraving, recessing, stamping, molding, and attaching molded ornaments, after which come the artistic sculpturing and the *garnissage*, which last refers to the surface artistic ornamentation. The next operation is firing. See PORCELAIN KILN.

Certain kinds of articles required in large numbers and of exactly equal size are molded by revolving wheel and templet, as in Fig. 7201, p. 2770. "*Mech. Dict.*"

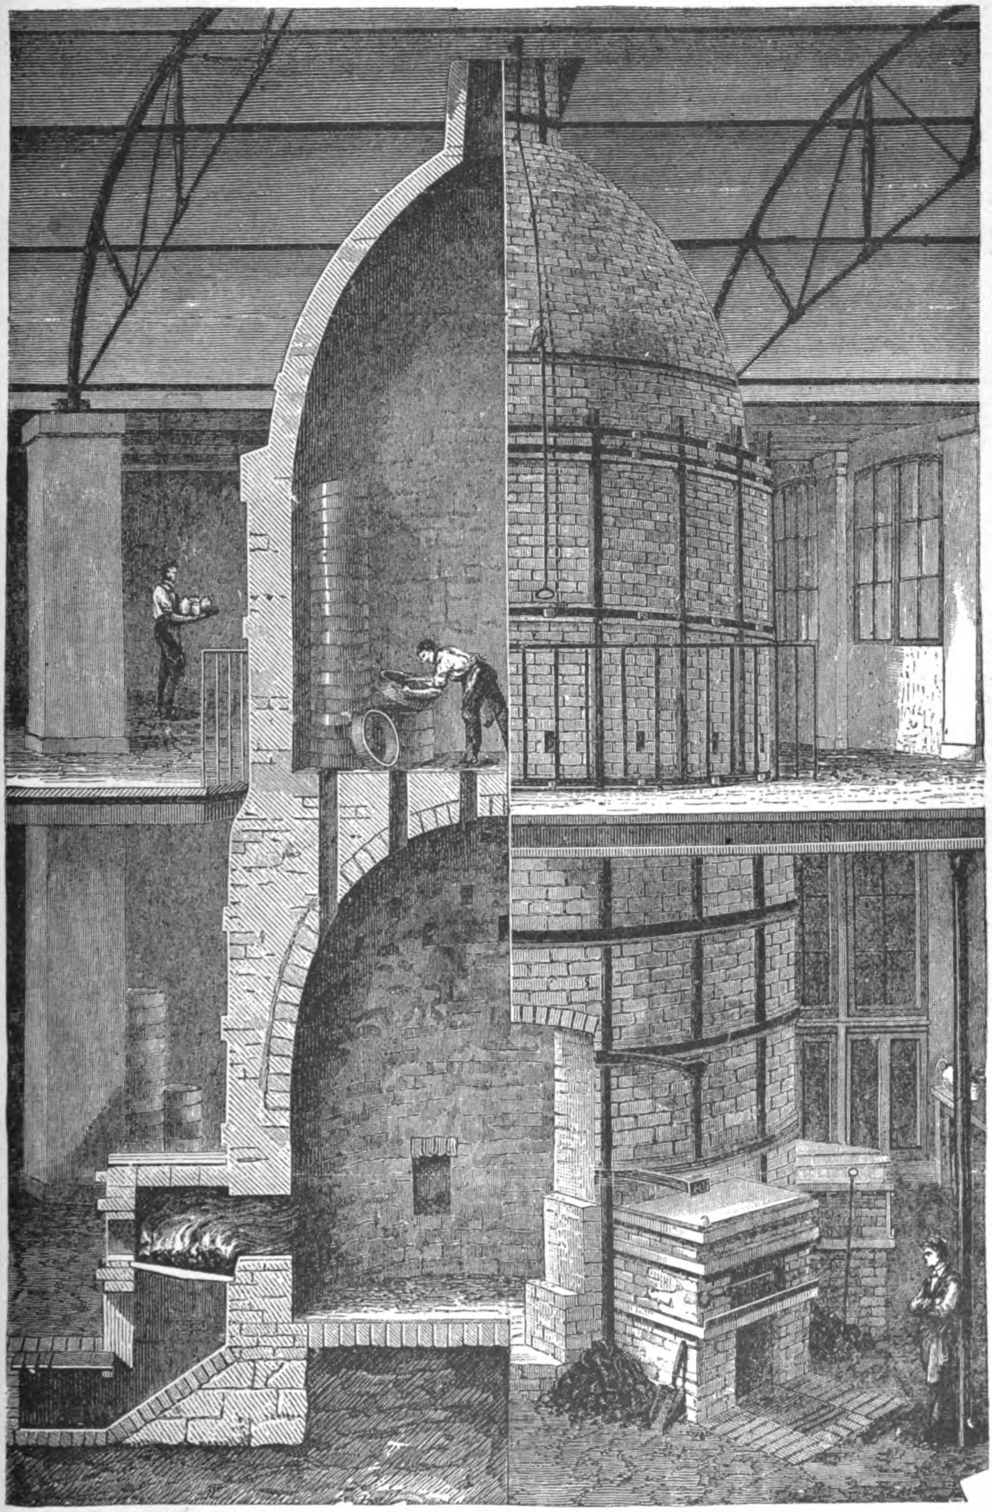


PLATE XXXV. PORCELAIN KILN, SÈVRES. (*Section and Elevation.*) See page 704.

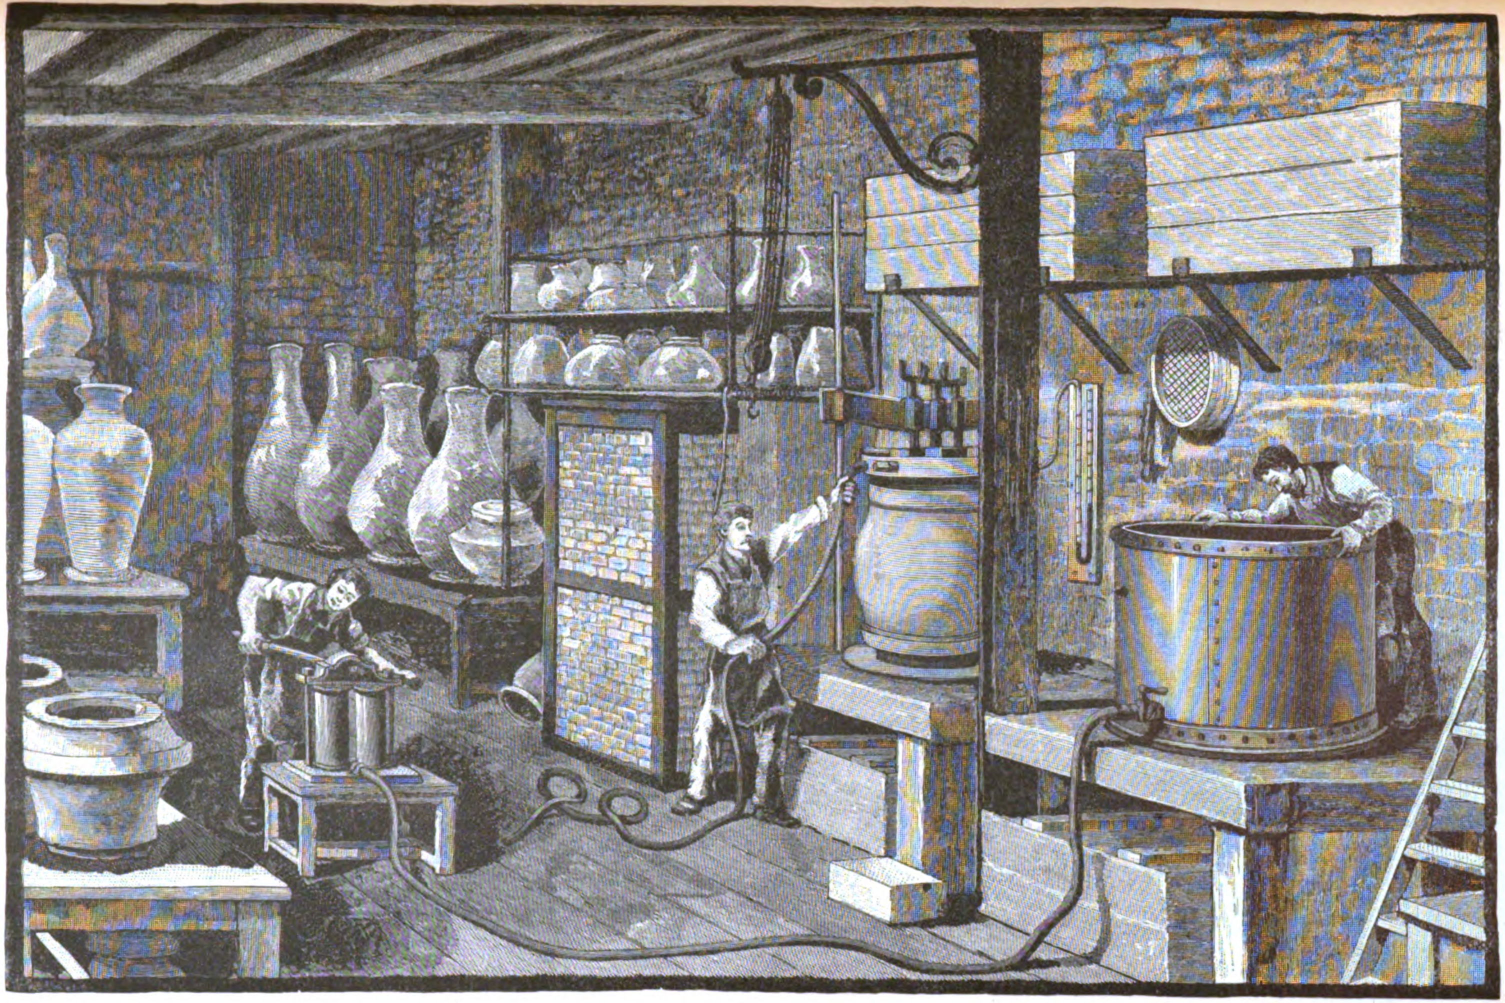

PLATE XXXVI.

MOLDING ROOM, SÈVRES.
WITH AIR COMPRESSION AND EXHAUSTION APPARATUS.

See page 704.

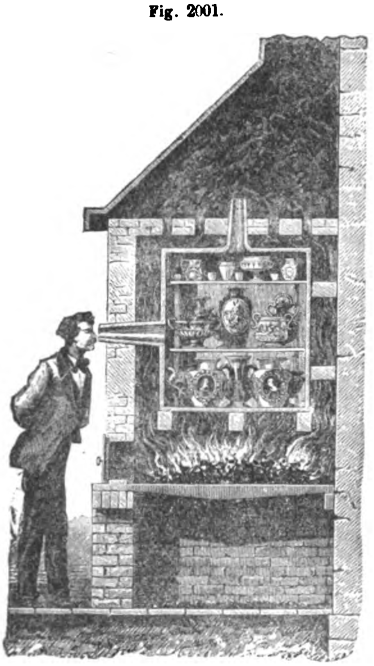
The templet, having at its working edge the exact half figure of one face of the object, is attached to a plate which is adjustable on an arm which has a center of motion to permit adjustment.

The plate is adjustable vertically and longitudinally on the arm, and a plate beneath the arm, secured by set screws, limits the downward drop of the arm, the latter is held down at the required distance by a set nut. By means of all these adjustments the required thickness is given to the plate, saucer, or other object, the top of the turning wheel giving the conformation to the interior surface of the article. The distance between the templet and wheel is the thickness of the article. Templets, for each different article required to be fashioned, are kept in stock, and are placed at pleasure on the arm; a suitable wheel-head also being attached to the vertical spindle to correspond with said templet.

Por'ce-lain Muf'fle. A kiln in which porcelain is fired to fix the colors which will not bear the great heat of the porcelain kiln. The colors are divided on this line into *couleurs de grand feu* and *couleurs des moufles.*

The muffle is a box of refractory clay, divided into stories and cells to contain painted porcelain, and is enveloped in the flames of the furnace, which, however, do not reach the interior, as the effect of contact of flame and smoke would

Fig. 2001.



Muffle for Firing Decorated Porcelain. (*Sèvres.*)

deface the objects. The inclosed ware is examined by means of peep-holes (*visières*), which are closed by a removable plug of baked clay. The condition of the ware is ascertained by the color and by the effect of the heat on slips which can be withdrawn for accurate examination.

Por'ce-lain Pâte Ten'dre. (*Ceramics.*) Soft paste porcelain. *Vieux Sèvres:* made there till 1804.

Por'ce-lain Plate Ma-chine'. The machines shown in Figs. 2002, 2003, 2004, are those used in the making of porcelain plates by M. Faure, of Limoges, France.

The hand process may be first described in brief:

"To produce the plate, three distinct operations are necessary — the forming, the molding, and the turning. The forming (*ébauchage*) consists in giving to the soft paste an approximate form. The workman taking a ball of the plastic mass places it on a wooden disk, the center of which coincides with that of his wheel. He then flattens the mass until it assumes a lenticular shape, the molecules being pressed to follow a spiral from the center outward. This is then put in a dry place for a short period. Molding consists in forcing the mass formed as above into a mold, which imparts to it the exterior form of the plate. By means of a dampened sponge the workman presses on the paste until it takes the imprint, working always from center outward, and leaving enough material wherewith to form the base portion. With a knife he removes the excess of material and then places the plate in a drying chamber, where it becomes sufficiently solid to be removed from the mold. It is then about twice the thickness to which it ultimately must be reduced.

"The turning operation brings the object to its proper dimensions. A cutting tool is used to remove the excess, and

Fig. 2002.

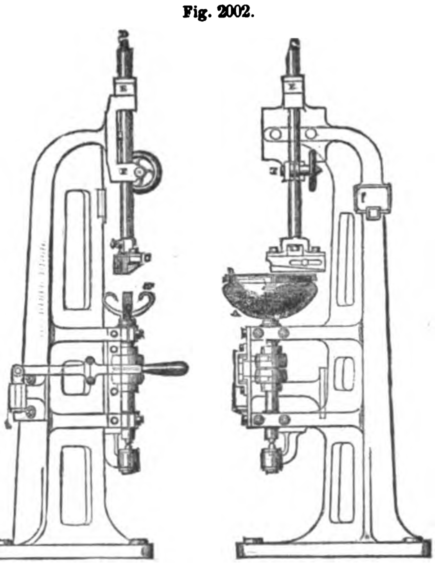


Plate-making Machine. Limoges (*Croûte Making.*)

the diameter of the plate being traced with a compass, it is removed and finished by thinning the edges. The plate is then ready for baking.

"The difficulty in the above is that peculiar to all handwork — variability.

Fig. 2003.

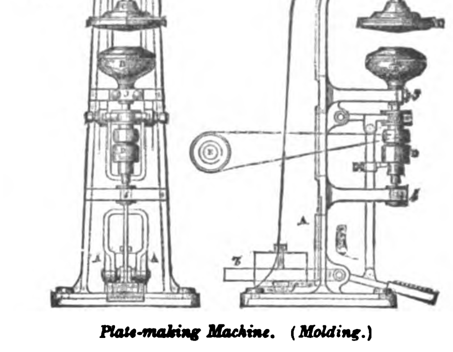

Plate-making Machine. (*Molding.*)

"Fig. 2002 exhibits side and front views of the apparatus for making *croûtes*, or thin flat disks of paste. *A* is the lathe head made of plaster mortar, formed on the iron armature *a*. *B* is a piece of sheepskin extended on a copper circle. *C* is the calibrating tool which spreads the paste. *D* is the tool arbor. This is lifted by a cord and pedal, and descends by its own weight. *E* is a stop limiting the descent, which is also adjusted by the device at *F*. The plastic material is placed in ball-shape on *B*, and the lathe set in motion by pressing a pedal. A second pedal-pressed tool descends vertically, with an accelerated velocity at the beginning, stops a few seconds for the operator to center the ball with the palm of the hand and hold it so as to resist the centrifugal force, and then continues its travel with slackened speed. At the end of its movement the tool has reduced the paste into a cake, of a surface and volume conforming to that which the plate ultimately is to possess. As soon as one *croûte* is prepared the tool rises, and a second ball of paste is inserted, and so on.

"The second apparatus, as shown in the front and side views in Fig. 2003, serves to replace the *croûte* in the axis of the lathe without deviation of the center, when turned over to be brought in contact with the mold. *A* is a cast-iron frame carrying four collars, 1, 2, 3, 4, the axes of which coincide. The pair above guide the tool arbor; those below, the lathe spindle. *B* is the lathe head surmounted by the mold. *C* is a platform to which is secured the sheepskin circle to which the *croûte* is attached. By carrying this platform down, the *croûte* is brought in contact with the mold. When the *croûte* is detached the platform and sheepskin is lifted by the counter weight *a*. *D* is a friction gear thrown into action by the counterweighted pedal *b*. This serves to throw the lathe into or out of motion at will. *E* is the motor.

"The third apparatus, of which a front view is given in Fig. 2004, consists of a vertical frame carrying the lathe below, a calibrating tool in the center, and the molding tool above. The *croûte A* coming from the second machine is secured to the lathe head. *B* is the molding tool moved by the handle *C*. *D* is an adjustable collar. *E* a carriage regulating the movement of the tool effected by the handle *F*. *G* is a gage for regulating the form of the plate. *H* is the calibrating tool. The *croûte* being on the lathe head the tool is caused to descend, and this meets the paste at the center, determining its thickness. Being restricted in its motion by the guide or gage *G* which represents the profile of the plate, and being submitted to a horizontal movement, it necessarily works the object according to the desired exterior form indicated by the gage.

Fig. 2004.

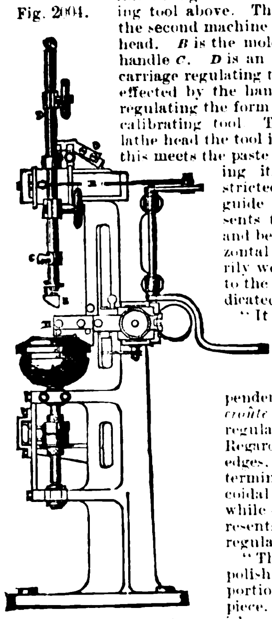

Plate-making Machine. (*Turning.*)

"It is evident that the tool should exercise, on the bottom and rim, certain relative pressures. These are, however, dependent on the section of the *croûte*: and this is perfectly regulated by the first machine. Regarding the shaping of the edges, the tool acting at a determined angle and with helicoidal faces cuts the paste while compressing it, and represents the work of the hand regulated and perfected.

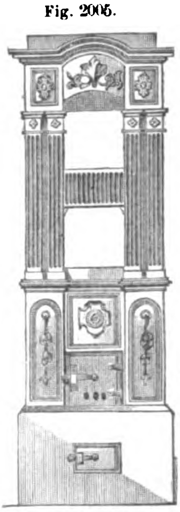
"The calibrating gives the polish, and produces the raised portions which decorate the piece. The tool merely polishes without pressing, and this terminated, a special tool removes the material which extends over the edges of the mold. The workman then lightly lifts the extreme edge so as to facilitate withdrawal, and removes the mold to a warm place for drying, as already explained.

"With regard to production, by hand work alone about 100 plates per day can be made. A single workman, aided by two children, can by the above machine average 450 per day." — "*Bulletin de la Société d'Encouragement pour l'Industrie Nationale.*"

Por'ce-lain Stove. The use of porcelain for stoves is very common in Germany, Austria, and Sweden. A number of such were shown in Paris, 1878. Figs. 2005, 2006, show two made by Joseph de Ceute, of Vienna.

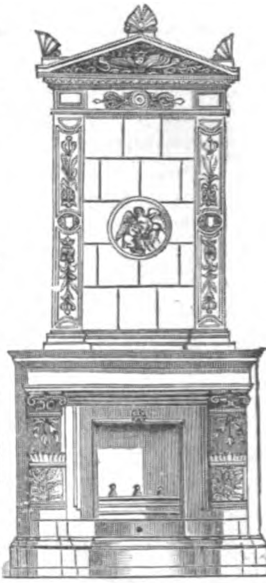
They are the artistic development of the Tartar *kang* and the Russian brick stove, each of which, however, is bedstead as well as stove. The former is heated by fermenting dung, and is a true hot-bed, while the Russian, one step, and a large one, in advance, is heated by burning wood.

Fig. 2005.



Porcelain Stove. (*De Ceute, Vienna.*)

Fig. 2006.



German Porcelain Stove. (*De Ceute, Vienna.*)

The advantages of the ceramic over the metallic material are several.

1. Not being good conductors of heat, they radiate it slowly and without sudden changes.
2. Being bulky, they hold heat equally and for a long time, even after the fire has burned out.
3. They do not scorch or "burn the air," or the floating particles of dust in it.
4. They have many of the advantages of the open grate.

"The mateɹial is earthenware molded into tiles or hollow bricks, about 6″ or 8″ square and several inches thick. They are made in a great variety of ornamental forms, and are generally glazed on the outer or exposed face, either white — which is most common — or brown, red, green, or black. Besides the ordinary flat-faced tiles, they are made with incised or raised designs, or are molded in high relief, so that when combined they form recessed panels or projecting fillets and moldings, in a variety of architectural patterns.

"The back portion of the tile exposed to the fire or heated gases rising from it is perforated and peculiarly shaped, so as to expose a large surface and make a series of tubular openings favorable to the absorption of the heat into the body of the tile.

"The shape of the stove formed of these tiles varies with the taste of the fabricant and the demands of the consumer. They are generally from 6 to 8 or 10 feet high, with a breadth of 3 or 4 feet. Usually there is a deep recess above the fire-space, or an opening quite through, the stove being divided in that portion into the parts united above by an entablature and cornice. Cylindrical or columnar stoves are also made; indeed, the modifications are numerous, to conform to the varying taste or fashion of the time. Lower and broader stoves are now coming into use with large openings in front, so that the fire may be seen and enjoyed as in an open fire-place, while the heat is much better utilized." — PROF. BLAKE.

Po'ro-type. A method of copying engravings. It depends upon the fact that the portion of the face of the print occupied by ink is non-porous.

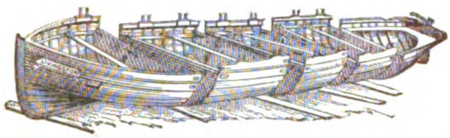
A gas which acts upon a certain chemical agent, and either bleaches or discolors it, is permitted to penetrate a copper-plate engraving or woodcut where possible, and, coming into contact, as it permeates, with paper which has been suitably prepared, brings about a reaction, — that is to say, wherever the gas has found means to penetrate, the color of the prepared paper alters, and a copy of the engraving is in this way produced. — "*Photographisches Archiv.*"

Po'rous Cup. An unglazed biscuit ware, used in batteries to prevent the mixing of two liquids, and yet not oppose the passage of the electric current.

Por'ta-ble Boat. One capable of transportation by land; over portages; sometimes sectional.

Fig. 2007 shows the sectional boat of the African traveler, H. M. Stanley, which he transported overland for the navigation of any rivers and lakes encountered during his researches.

Fig. 2007.

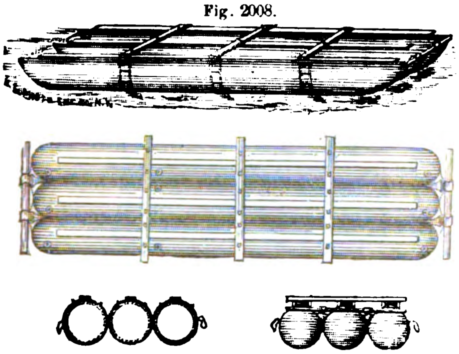


Stanley's Portable Boat.

The boat is, when put together, 40′ long and 6′ 4″ wide. It is composed of 5 water-proof sections, which may be firmly united by means of bolts and clamps. This craft, the "Livingstone," is the largest that has yet floated in the rivers of interior Africa.

Fig. 2008 is a boat, or rather *raft*, made of a number of inflated pontons bound together and braced with bars.

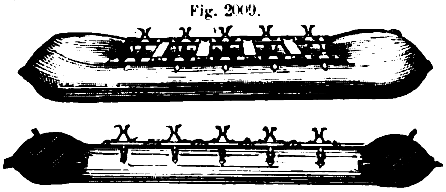
Fig. 2008.



Ponton Portable Boat.

Fig. 2009 is an inflated mattress with gunwale, rowlocks, and thwarts.

Fig. 2009.



Inflatable Portable Boat.

The United States Museum of Fisheries has models of portable and folding boats.

Colvin's. *Hegeman's.*
Fenner's.

Also of canoes, fishing-boats, coracles, etc.
See list of references under Boat, p. 114, *supra*, to *collapsing*, *folding*, and *sectional* boats.

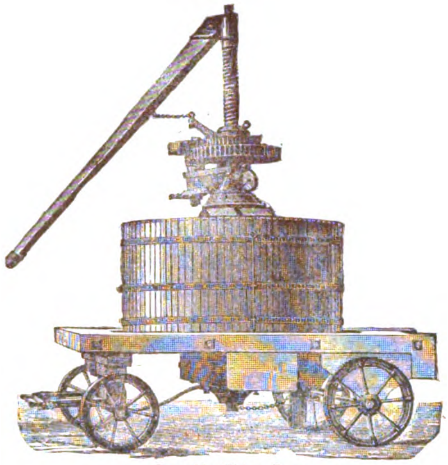
Folding boat	* Fig. 2057, p. 899, "*Mech. Dict.*"

Port'a-ble Ci'der Press. A press on wheels; much used in Normandy, where the apples are ground and pressed by machines taken from farm to farm, much as threshing is done in this country, and steam-plowing in Britain.

The press shown in Fig. 2010 is one made by Samain, of Blois (*Loir et Cher*). A horse is hitched to the end of the sweep, and the press has three powers of gradually increasing force, being shifted from to each in succession as the pomace becomes more compacted. A dynamometer is attached to indicate the pressure.

Fig. 2010.



Portable Cider Press.

Port'a-ble Crane. One which is transportable upon its base. The traversing crane and overhead crane move on their bases.

See Railway Crane, *infra*; Balance Crane, Fig. 176, p. 66, *supra*; Portable Steam-crane, *infra*; Portable Hand-crane, *Ibid.*

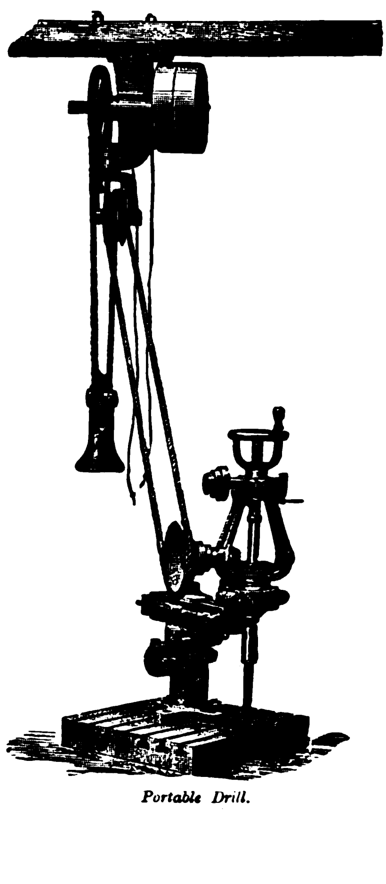
Fig. 2011.



Portable Drill.

Port'a-ble Drill. A drill capable of being moved to its work, instead of the converse. See Bench Drill, Fig. 287, p. 95, *supra*. Also list under Drill, pp. 750–752, "*Mech. Dict.*," and references under Drill, p. 275, *supra*.

The portable drill shown in Fig. 2011 can be placed as easily as a rachet brace, and will drill at any angle in any position, at any distance, and in any direction from the power. The driving apparatus is so arranged that the round belt which drives the machine passes through the center of a hollow stud, enabling the power to be taken off in any direction, while the weighted idler keeps the belt tight at whatever distance the machine is worked.

The machine is intended to be bolted or clamped by its base to the piece being drilled. It can be adjusted in height by drawing the post out of the socket, and radially by screw and handle on the arm. The arm can be swung on the pillar as a center by means of a worm and tangent wheel, thus providing delicate adjustments in every direction. The spindle-frame swings in a ball and socket bearing to any angle up to 30° from the base, and is also provided with means of fixing it in a vertical position. The whole of the machine, including the post, can be drawn out of the socket, and the post passed into the horizontal hole in the socket for drilling in a direction parallel with the base.

The feed motion is self-acting and variable.

Port'a-ble En'gine. One upon wheels, either to be hauled from place to place or self-driven. See Portable Steam Engine.

Among the portable engines may be classed —

Agricultural engines.	Traction engines.
Steam fire engines.	Portable steam pump.
Steam road rollers.	Portable steam hoists.
Steam plowing engines.	Portable steam cranes.
Railway crane.	(Which see.)

Port'a-ble En'gine and Pump. The portable engine pump for irrigating purposes is shown in Fig. 2012, as used upon the Nile. It is the modern substitute for the shadûf, mental, picotah, noria, wheel with pots, etc.

The pump is fixed on a staging over a stream, and is driven by a portable engine. The boiler has a fire-box considerably larger than the ordinary portable engines, and where coal is expensive, as in Egypt, and there is an abundant supply of cotton stalks, maize, etc., great economy is obtained by feeding this vegetable matter into the fire-box by the straw-burning apparatus, driven by a strap from the crank-shaft, as shown in the engraving. The traveling wheels are made entirely of iron, and are not affected by excessive heat or the attack of insects. The pump shown in the engraving has double suction pipes. The pipes are made entirely of wrought iron, with a view of saving weight, and avoiding the inconvenience caused if a pipe is broken. The disk is accessible for examination without disturbing any of the joints.

The apparatus has, however, various other uses, such as in drainage, sheep-washing, emptying docks and dams, etc.

See also Noria, Fig. 1819, p. 636, *supra*.

See also Centrifugal Pumping Engine, Fig. 1218, p. 516, "*Mech. Dict.*"

Port'a-ble Forge. A movable forge to be used in the field, on the march by pioneers, in the vicinity of temporary works, etc.

Two forms are shown in Figs. 2013, 2014. They are adapted to be driven by hand or power, having the necessary

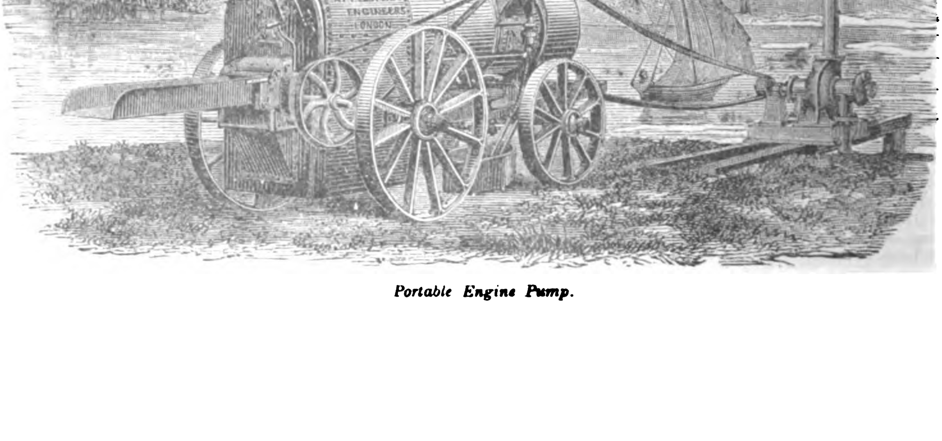
Forge, Figs. 1084, 1085, p. 354, *supra*, and references *passim*.

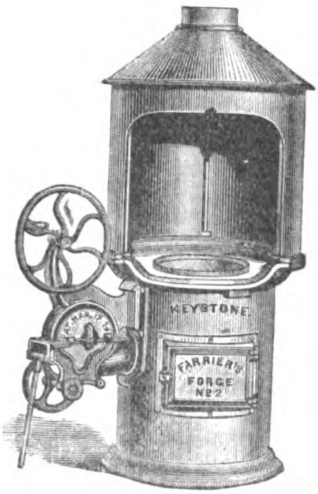
Port'a-ble Fur'nace. One which is transportable, as in the case of charcoal furnaces for domestic or plumbing purposes.

Fig. 2012.



Portable Engine Pump.

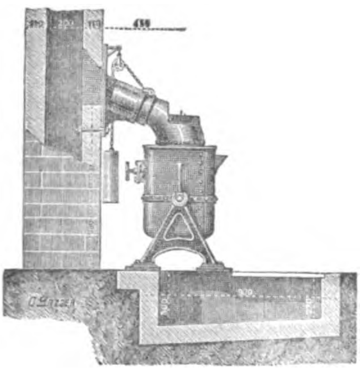
Fig. 2014.



Portable Forge.

A more important example, however, is the oscillating crucible furnace of M. Piat.

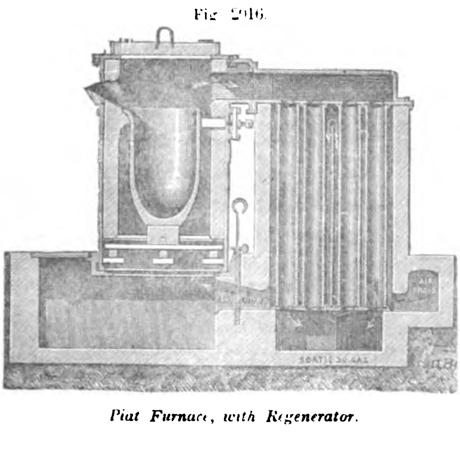
Fig. 2015.



Piat Portable Furnace.

It is shown in partial elevation and section in Fig. 2015, and in perspective under CRUCIBLE FURNACE, Fig. 737, p. 233, *supra*.

Fig. 2016.



Piat Furnace, with Regenerator.

The crucible is permanently inclosed within the furnace wall, and the two are moved together, whether to the furnace and chimney, or to the molds on the floor of the foundry. The mode of heating is either by combustible placed between the crucible and the furnace wall, the ashes from which fall through holes in the furnace when the crucible is over the draft, or the heated gases from a gas producer are led to the furnace (Fig. 2016), passing through the regenerator which is heated by the gases escaping from the furnace in the direction of the upper arrow.
