

The American

GAS LIGHT JOURNAL.

(ILLUSTRATED.)

DEVOTED TO THE INTERESTS OF

ILLUMINATION, HEATING, VENTILATION

AND

GENERAL SCIENCE.

VOLUME LII.

(THIRTY-SECOND YEAR.)

FROM JANUARY 1 TO JUNE 30, 1890.

A. M. CALLENDER & CO., Publishers,

OFFICE OF PUBLICATION, NO. 42 PINE STREET, NEW YORK CITY.

INDEX

—TO—

VOLUME LII.

January 1 to June 30, 1890.

- A**
- A Chapter of Don'ts, by W. H. Snow 393
*Addicks, W. R., Vaporization and Feed of Oil to Generator and Retort..... 356
Address, President's, New England Association. Robert B. Taber..... 278
Address, President's, Western Gas Association. Chas. R. Faben, Jr..... 766
Address, President's, Ohio Gas Light Association. Edward Lindsley..... 463
Adjournment of Ohio Gas Light Association..... 557
Advantages of a Combined Coal and Water Gas Plant, by Geo. A. Light..... 478
Advantages of Water Gas over Coal Gas for Small Works, by F. H. Parker..... 320
Advertisers. What They Say..... 354
Air Engine. A Hot..... 401
*Alavoine's Gas Washer..... 433
*Alexander & Paterson Process of Making Oil Gas..... 72
American Gas Light Association. Appointment of Committees at Meeting of Council..... 765
Amory, Dr., of Brookline, on Municipal Gas and Electric Lighting..... 281
Amendment to Constitution, New England Association..... 280
Ammoniacal Liquor. Economy of Fuel in the Distillation of, An Advance Budget from "Three Stars"..... 729
An Interesting Chapter in Photometrical Testing, and an Addendum by T. S. Cleminshaw..... 427
Annual Report (5th) of Massachusetts Gas and Electric Light Commissioners..... 140
Annual Meeting of the Springfield (Mass.) Gas Company.... 141
Another Loomis Patent in England..... 882
*Another Step in the Granger Process..... 71
A Point or Two in Regard to Illuminants During Condensation and Purification, by Geo. F. Goodno..... 391
*Apparatus for Manufacturing Gas. Close's..... 5
*Apparatus for Washing Gas. Dye's..... 698
Applications for, and Election to, Membership, New England Association..... 248
Appointing Special Committees, Western Gas Association.... 916
Appointment of Committees, Ohio Association..... 433
Aqueduct, Methods of Lighting Work on the New Croton... 74
Argument in Favor of the Municipal Ownership of Electric Lighting Plants, by Victor Rosewater..... 423
Assay of Coal..... 918
Associated Press Once More, The..... 801
Australia, Progress of the Electric Light in..... 699
- B**
- Badges, in the Matter of, New England Association. 355
Batch of Invitations, A. Western Association..... 912
Baths. Dangers of Gas and Geyser..... 735
Benson, Arthur W.—Obituary..... 2
*Blower. Steel Pressure..... 136
Boiling of Water is not a Guarantee of Purity, The..... 885
Boilers, Preventing the Incrustation of..... 249
Bowers, Geo. W., Combination of Gas and Electric Lighting in a Small Town..... 465
Brin's Process Company for New York, A..... 846
British Coal. The Possible Average Depth at which it is now Worked..... 214
British Gas Works, Water Gas for, by C. J. R. Humphreys... 210
Budget from "Three Stars," An Advance..... 729
Burners, Gas, for Illuminating Purposes..... 731
By-Products of Experience, by A. R. Foote..... 879
- C**
- *Carburetor for Gas Engines..... 40
Carcass Roofing, by J. Robinson..... 735
Car Lighting..... 172
*Charging Gas Retort Furnaces with Hot Residual Coke, Device for..... 210
*Charging Inclined Gas Retorts, Device for..... 428
Change of Interests in the Siemens-Lungren Company..... 801
- Cheapest Light, The..... 597
Chemistry of Illuminating Gas, by N. H. Humphrys..... 39
Chemistry of the Dinsmore Process..... 774
Chimney Proportion..... 44
*Chollar, B. E., Doubts Versus Dogmatism..... 485
Chollar, B. E., The Relative Value of Gaseous Fuels..... 802
Clark, Walton, The World's Fair and the Gas Associations.... 838
Claus' Method of Producing Water Gas and Obtaining Certain Bye Products..... 244
Cleminshaw, T. S., An interesting Chapter in Photometrical Testing, and an Addenda..... 427
*Close Gas Manufacturing Apparatus..... 5
Coal Industry, The Illinois..... 73
Coal Miners' Strike and London Fuel Supply..... 561
Coals in Western Canada, Notes on Some..... 662
Coal Fields of the State of Washington, by W. J. Wood..... 665
Coal, Assay of..... 918
Coke and Charcoal Compared..... 43
Coke Manufacture Utilization of Residuals from..... 104
Coke Brick for Furnace Linings..... 329
Combination of Gas and Electric Lighting in a Small Town, by Geo. W. Bowers..... 465
Combustion, Spontaneous, in Coal Ships..... 700
Competition, The Effect of Natural Gas, by Jas. Somerville.. 911
Conductors, Deterioration of Electrical..... 41
Connellsville Coke Trade, The..... 249
*Conroy's Cut-Off and Relief Apparatus for Gas Mains..... 558
Construction of Gas Holder Tanks..... 664
Controversy, The Incandescent Light..... 42
Conversion of Gas Globes into Regenerative Lamps..... 75
Corrosion..... 79
*Cash's Apparatus for the Manufacture of Gas..... 732
*Cowell's Device for Carrying off Leakage from Gas Mains.. 593
Cowdery, E. G., on Mixed Gases..... 910
Coze's System, Improvements on..... 178
Cushing, Oliver E., Death of..... 69
- COMMITTEES:—New England Association of Gas Engineers.—
Invitations, 248; President's Address, 280-391; Nomination of Officers, 281-326; Memorial, 281; World's Fair, 326-394; Badges, 326-394.
- Ohio Gas Light Association.—
Membership, 431; Executive, 431; Legislation, 431; Place of Next Meeting, 433; Nominations, 433-552; President's Address, 465; Location, 518.
- American Gas Light Association..... 765
- Western Gas Association.—
President's Address, 769-840; Board of Directors, 769; Membership, 769; On Examination of Books and Accounts of Secretary and Treasurer, 769; Visitors, 769; Nomination of Officers, 769-842; Resolutions, 769-916; Obituary Resolution, 769-808; Place of Next Meeting, 842-916; Gimper Paper, 842; Gas Companies' Accounts, 874; Arrangements, Louisville Meeting, 916.
- CORRESPONDENCE—
- Electric Lighting at St. Louis..... 969
Explosion at the St. Paul (Minn.) Gas Works. B. F. Ellisen..... 206
Dr. Wilkinson Objects to the Figures..... 70
Gas Companies Should Control the Introduction of Gas Stoves, by S. S. Stratton..... 705
The Lighting Situation at Fort Scott, Kas..... 145
- D**
- Danger, Fire, from Outside Electric Currents..... 397
Dangers of Gas and Geyser Baths..... 735
Dangers of Electric Lighting, by S. Z. de Ferranti and Francis Ince..... 138, *175
Death of Oliver E. Cushing..... 69, 101, 586
Death of Dr. Lull, President of the Dubuque (Iowa) Key City Gas Company..... 170
- Death of Alfred Arndt..... 808
Death of Arthur W. Benson..... 2
Death of Thomas A. Cosgrove..... 809
Death of Theobald Forstall..... 102
Death of Walter Burchard Houston..... 513
Death of James Henri Rollins..... 909
Death of Edward J. King..... 806, 808
Demand for More Light..... 139
Depth (the Possible Average) at Which Coal is Worked in England..... 214
Deterioration of Electrical Conductors..... 41
*Device for Charging Gas Retort Furnaces with Hot Residual Coke..... 210
*Device for Testing the Gradients of Pipes..... 212
*Device for Charging Inclined Retorts..... 428
Deville's, M. Sainte-Claire, Study of Coal Gas..... 207
Did Dr. Wilkinson Confine Himself to Facts? by James Somerville..... 695
Difference in the Eastern and Western Methods of Management of Gas Works, by E. G. Pratt..... 318
Dinsmore Process, The Chemistry of the..... 774
Dinsmore Process, The..... 9
Discharge of Steam through Orifices..... 633
Distributory Plant, Notes on..... 695
Don'ts, A Chapter of, by W. H. Snow..... 393
*Doubts Versus Dogmatism, by B. E. Chollar..... 485
Draft, Chimney, Note on Rankine's Treatment of, by Prof. J. B. Webb..... 171
*Dye's Apparatus for Washing Gas..... 698
- E**
- Economical Engine for Small Power, On the Most..... 217
Economy of Fuel in the Distillation of Ammoniacal Liquor.. 365
Education, Technical..... 213
Egner, Frederic. Practical Hints on Purification with Lime.. 462
Egner, Frederic. A Page from Experience with an Exhauster. 3
Egner, Frederic, On the Abuse of the Patent System, with a Remedy..... 770
Election of New Members, Ohio Gas Light Association..... 432
Election of Officers, Ohio Gas Light Association..... 552
Election of Officers, New England Association..... 326
Election of New Members, Western Gas Association..... 802
Election of Officers, Western Gas Association..... 842
Electing Mr. H. B. Leach to Honorary Membership, Western Association..... 802
Electric Lighting of Ships..... 75
Electric Wiring in Boston Buildings, Proposed Legislation in the Matter of..... 3
Electric Lighting, Dangers of, by S. Z. de Ferranti and Francis Ince..... 133, *175
*Electric Meters, Three Types of..... 176
Electric Tests, Influence of Temperature on..... 181
Electric Light at the British Museum..... 217
Electric Currents, Fire Dangers from Outside..... 397
Electric Units, Thoughts on..... 398
Electric Conductors, Deterioration of..... 41
Electric Ignition of Gas Engines..... 697
Electricians, The Vagaries of the..... 212
Engine, Hot Air..... 401
Engineers, Useful Memoranda and Information for..... 705
English Lighting Methods, President Peaty's Views on the Status of..... 390
Evans, C. H. Another Year with Fuel Gas..... 515
Exhaust and Pressure Registers and Pressure Gauges..... 71
Examination of Commercial Glycerine..... 7
*Experience with Subsidized Gas Mains..... 557
Experiments on the Relation of Electric Lamps to Combustible Bodies..... 38
Exhibition of Gas Apparatus, Western Gas Association..... 809
Excavating, The Poetsch System of, by E. L. Abbott..... 734
Experiments in the Photometer Room, by N. W. Gifford.... 317
- EDITORIALS—
- A Banquet Response..... 426
A Bad Verdict..... 730

GAS LIGHT JOURNAL

REDMAN & KENNY, N.Y.

PUBLISHING OFFICE NO. 42 PINE STREET

DEVOTED TO THE INTERESTS OF ILLUMINATION, VENTILATION, WATER SUPPLY AND DISTRIBUTION, & GENERAL SCIENCE.

VOLUME LIII.—No. 1. }
Whole No. 761.

NEW YORK, MONDAY, JANUARY 6, 1890.

{ \$3 PER ANNUM,
IN ADVANCE.

A. M. CALLENDER & CO., Proprietors. C. E. SANDERSON, Manager.
JOS. R. THOMAS, C. E., Editor. T. J. CUNNINGHAM, Asst. Editor.

ENTERED AT THE POST OFFICE AT NEW YORK, N. Y.
AS SECOND CLASS MATTER.

Published on each Monday of the year, at No. 42 Pine Street, N. Y.

Terms of Subscription, Including Postage.—For the United States and Canada, \$3 per annum. European countries, \$4.50 (19 shillings—22½ francs). All payments to be made in advance. Single copies, 10 cents.

Remittances should be made either by post-office order, registered letter, or bank draft on New York, payable to the order of A. M. Callender & Co.

Correspondence.—Wishing to make this JOURNAL a gazette of intelligent discussion to those of our readers who may wish to gain or give information on the subjects to which its columns are devoted, correspondence is solicited for publication from all who make the study of those subjects a pleasure or a profession.

The American News Company, Nos. 39 and 41 Chambers street, New York, are agents for this JOURNAL. Newsdealers will send orders to them.

Books.—We will forward by express, at publisher's lowest rates, any book—scientific or otherwise—to any address in the United States or Canada. No books will be sent C. O. D.

Collections are invariably made directly from this office, for subscriptions, advertisements, etc. We have agents to solicit the same, but they are not authorized to receipt for money.

BRIEFLY TOLD.

THE YEAR'S RECORD.—To American gas men the year just closed will in many respects remain sharply impressed on their memories as one worthy of recollection for the teaching that it conveyed. At the close of 1888 the advocates of the general adoption by gas companies of electrical supply were very glib and positive in their assertions about the necessity of entering on such a course. There was no middle ground upon which they were content to rest—it must be “combination,” or decay. Well, it seems to us at least, from diligent inquiry and an opinion formed from the revelations of such inquiry, that 1889 has acted as an eye-opener to the enthusiasts (self-dubbed, by-the-way) of the thick-and-thin division. In some places the combined plan has been continued with success, in others it has held its own, while in still other situations failure has been the result. In fact the experience of the past twelve-month in this regard all goes to show that local circumstances and influences are the simple factors that are to determine whether or not it is wise for a gas company to undertake the supply of electric currents. We might go a step further and say that as a rule the teaching of the twelve-month is averse to the operation of the dual system, and that this applies to large, populous and wealthy centers is beyond doubt. However, those who are now considering, or in the future will consider the adoption of the dual plan should be in no haste to reach a decision. The policy of watching and waiting is the safe one.

On the other hand, 1889 has also made plain the fact that gas can and does more than hold its own against all opposition. From output figures received from 42 different points in the country, the total sendout (annual) represented is 2,520 million cubic feet, which quantity compared with that sent out from the same places in 1888, exceeds that of the latter year by a percentage equal to 10.6. In none of the places that figured in this respect did the annual sendout exceed 125 millions cubic feet, and in eight of the places reported on the sendout was less than 30 millions cubic feet. The points chosen were representative ones in different sections of the country, and care was taken to exclude from the inquiry locations which were favored by exceptional growth in population or building development. At 12 of the points noted concessions in rates had been made during the year, and, as usual, in these places the increase in sendout was most marked. As the figures were obtained under the condition that the localities would not be disclosed, no further excuse for the “lump” manner in which they are presented is necessary.

But even if they are given in a general statement their teaching is none the less forceful, when it is attempted through their agency to time the pulse of the gas business in respect not to its rugged permanency alone but also to its bounding rate of progress. We submit that the average (10.6 per cent.) of increase is most gratifying; and that it also is beyond what we hoped it would be we are fain to confess. From the general tenor of the replies to our inquiries we are forced to the conclusion that the progress of the gas business in the present year will be at even a greater pace than that maintained in 1889.

This latter conclusion further takes on a decidedly definite shape from our knowledge that many important changes in the line of betterments and new construction are now being considered by the proprietors of several large plants. These will undoubtedly be ordered this spring,

hence the gas works constructors can share to the full in the satisfaction already the portion of the gas proprietors. From a business point of view, then, the old year leaves no unpleasant memories on its history.

Another important development of the twelvemonth was the approach made in the direction of a clearer understanding of the fuel gas problem. We think we are not far wrong in saying that we are now close to the beginning of the end in this respect, and we believe the thanks of the fraternity are due to Gen. Hickenlooper, Geo. Westinghouse, Jr., and Walton Clark for their utterances on this subject during the year. The General, we think, is entitled to great credit for insisting that the *people* have always had fuel gas at their command in the shape of a good article of illuminating gas—it only remaining for the gas maker to supply it at as economical a rate as possible, that his efforts should be intelligently seconded by the manufacturers of gas apparatus, and that the consumer should supplement the efforts of the others by a careful use of the product and appliances placed at his command. Mr. Westinghouse is to be commended most heartily for his manly acknowledgment that the Hickenlooper theory is the one now worthy of acceptance; and Mr. Clark should share in the approval for the admission that while his researches and those of his confreres although not crowned with success as yet, would nevertheless be continued to the end. To sum it up, the conclusions of the gentlemen mentioned point to the same moral—make intelligent use of that which is before you, for such use is but a spur to the perfecting of old systems and in no wise interferes with the search after that which is new.

The dark drapery to the twelvemonth has been adjusted by the hand of death, and that conqueror of man has made his presence sorely felt. In the death of J. O. King, of Jacksonville, Ills., the fraternity suffered a loss that many a day of time will lapse ere its depth be filled. And in it we are led to remark that the Western Association is the greatest sharer. A shining mark, indeed, did death select when the President of the Western Gas Association was stricken down; but time's merciful hand will in due season reconcile them to their loss, and the memory of his good and useful life will after all live with them and us to the end. Others, who bound the present generation of gas men to those of the olden days, to pass away were Philip Deily, of Philadelphia, F. M. Roots, of Connersville, T. A. Cosgrove, of Evanston, Ills., Jas. Wilbraham, of Philadelphia, A. W. Benson, of Brooklyn—but why enumerate them all again? They were with us and have gone before. That is all.

In conclusion, we have but to remark that, for the fraternity as a whole, the dead year was fruitful of material prosperity, and that the skies of 1890 are bright with good promise.

MAYOR NOONAN ROUTS THE ST. LOUIS GAS GRABBERS.—Following up our reference in the last issue to the infamous gas measure proposed in and indorsed by both branches of the municipal government of St. Louis, it is with great pleasure that we publish the fact that Mayor Noonan has refused to give the infamous proposition his official sanction. Not only so, but in a scathing message puts the conspirators in a proper light before the people. It was a sensible act that does much to blot out many of the "inequalities" of the Noonan administration, and was a peculiarly acceptable gift to the people, who were officially informed of the throttling of the measure on the morning of January 1st.

THE BROWNSVILLE (TENN.) WORKS TO BE REBUILT.—Some short time ago the gas works at Brownsville were badly wrecked by explosion and fire, and it was thought by some of the residents that the plant would not be restored. This was not well-founded, however, for Mr. W. B. McKinney, of Troy, O., who owns the plant, has decided to reconstruct the same, and on an enlarged scale. The contracts for the necessary work were awarded about a week ago.

THE new telescopic gasholder (capacity 150,000 cubic feet) at the Alameda (Cal.) gas works, is in satisfactory operation.

WE regret to have to say that Mr. Ralph Woodward, of the Waltham (Mass.) Gas Company, was recently the victim of a painful accident, that obliged him to remain for some days under treatment in the Waltham Hospital. On the evening of December 24th, while engaged in inspecting a service pipe that ran through a dark and littered cellar, he stumbled over a barrel, a rusty nail which protruded therefrom entering his leg at a point just below and to the side of the knee cap.

WE understand that the articles of incorporation, recently filed by Messrs. F. J. Chamberlain, J. H. Smith and W. H. Griffith, at Pueblo, Col., give birth to the Colorado Gas Light and Fuel Company, and that under the certificate the proprietors propose to manufacture water gas in

the Colorado counties of Arapahoe, El Paso, Pueblo, Las Animas, Chaffee, Lake and Pitkin. We understand that the first points to be attacked are Denver and Pueblo. There can be no doubt about the aims of the projectors of this movement, who are evidently intent on raiding invested capital.

OBITUARY.—Arthur W. Benson.—On the 27th of last month, Arthur W. Benson, formerly President of the Brooklyn (N. Y.) Gas Light Company, was stricken by death. As was his life, so was his death. Peaceful and conservative were his habits and manner in the former, in accordance therewith was the latter, the summons reaching him while seated in his boat fishing in the placid waters of Lake Monroe, an indentation of the St. John's river, bordering Enterprise, Florida, where Mr. Benson had been in the habit of evading the rigors of our Northern winter seasons. Deceased was born in Maine, in 1812, removing at an early age, with his parents, to Boston, at which place his education was completed. He finally located in Brooklyn, N. Y., which locality he saw grow from a village of 5,000 inhabitants to its present proportions of a city holding perhaps 800,000 people. He took great pride in improving its condition, and was foremost in urging and assisting that which was calculated to advance its interests. He engaged in the shipping business in New York, and retired therefrom with a competency in 1849, at an age when others as a rule are but beginning to feel safe of their footsteps over the avenues of commerce. About the time that he retired from the shipping business he was elected a member of the Common Council, representing his ward (the First) therein for one term. In the meantime his fortune, by means of wise investment in banking and gas stocks, had largely increased, and many a worthy charity can be traced to his liberal hand. In 1862 Mr. Benson (he had occupied the Vice Presidency of the Company for some years) was chosen President of the Brooklyn Gas Light Company, and remained so until 1882, when he positively declined to be put in re-nomination, or even to allow his name to be balloted for as a director. At this year he withdrew from active participation in business of any sort, but devoted his time to the relief of others. There was perhaps not a better exemplar of real, unostentatious charity in the city of Brooklyn, than the late Arthur W. Benson. For instance, it is matter of record, that his salary as President of the Brooklyn Gas Light Company was annually handed over by him to the Treasury of Grace Church, of which he was a vestryman for many years. His careful and intelligent administration of the affairs of the Brooklyn Company were fruitful of great results, and although he may not be well known to the fraternity of to-day, time was when Arthur W. Benson's name was a household word in the gas ranks of the East. Liberal, broad-minded, charitable, and blunt, deceased was guided by honor, influenced by charity, and controlled by justice in his dealings with his fellow men. The funeral services were celebrated in Grace Church, Brooklyn, on the morning of December 31st.

The Market for Gas Securities.

The market for city gas shares remained fairly even during the week, despite the fact that money was bid up to 12 and even to 15 per cent. Consolidated holds fairly well the advance scored shortly after the declaration of the dividend, and is to-day (noon, Friday) bid for at 92½. Perhaps a resume of the course of these shares on the Exchange during the past year may not be without interest. In the period noted the total sales recorded provided for the transfer of 194,406 shares; the opening price for the year was 82; the highest rate recorded was 94½; the lowest was 80½; the last for the year was 91¾. It is thus seen that the range was 14 points, and that the advance was 9¾ points. The closing price in 1888 was 82. The increase in the dividend rate, from 4 to 5 per cent., during the year, our readers were prepared for, and while a similar move this year would not surprise us in the least, we nevertheless are inclined to the belief that no such step will be taken. We look, however, to see the shares pass the par mark in 1890. And by way of the gossip that is going we might remark that a few days ago we heard a good authority estimate the value of the Company's real estate at 27½ million dollars.

Equitable shares are firm and higher. This Company is doing a good trade. Brooklyn stocks are about as before. Baltimore Consolidated is active and higher, at 48½. This stock looks to us a purchase. The dividend rate of the Hartford (Conn.) Company has been reduced to 3½ per cent. Cornelius Callahan, an owner of stock to the value of \$18,000 in the old Troy Citizens Gas Company, having refused to accept the valuation put upon it by the appraisers who attended to the consolidation of the gas interests of that city, has applied for a commission to revalue the same. J. C. Green, G. W. Greenman and Shepard Tappen have been named as such commission, and they will meet for the purpose indicated on Saturday next. The original valuation was 50 cents on the dollar.

A Page from Experience with an Exhauster.

By FREDERIC EGNER.

Some years ago it was counted a point against the professional character of a gas man if he ventured to express an opinion on any subject connected with the gas business—except, indeed, he did it within the precincts of the Company employing him, and then only to the accredited and constituted authorities, officially, over his particular department. Yet, as the Rev. Mr. Jasper, of Richmond, Va., remarked to his congregation about 12 years ago, "De sun do move, an' I knows it, 'cause de Bible says so;" and I believe we may also say that the world moves, because we see it has done so. And, as evidence of the latter fact, we know that whereas, when silence and secrecy were the peculiar virtues of the gas man, and a yield of 4 cubic feet of poor gas from a pound of good coal, and 4,500 cubic feet of the same gas per retort in 24 hours, was accepted as fairly good average work, that *now*, when we have a number of good associations of gas men, whose members frequently and publicly discuss their business and exchange opinions, 5 cubic feet per pound of coal, and 8,000 to 10,000 cubic feet per mouthpiece, is not at all an uncommon result at many gas works. Further, consumers and gas companies have been benefited by the change from the methods of the dark ages to those of progress and light.

Much more could be done if gas men everywhere would consent occasionally to write up items of their experience for publication in the papers devoted to the science of gas lighting. Doing this would not injure anyone, would make no one poorer—not even the giver of the information—and could not fail to result in good to some. If there be some who, on reading these lines, would say to themselves, "If I told all I know others would be as smart as I am," they might reflect upon the truth that if all teachers of man were inspired with such a spirit humanity would never have gone much beyond the instinct of the beast; and it could be that they themselves were most likely benefited by the published knowledge and experience of others. Possibly they still continue to be so benefited, and are perfectly willing that the benefit should yet accrue. Or, if one should be afraid to be considered as a 'fellow who writes too much,' let him only remember that it is not how much, but *what* he writes, that will win praise or condemnation. And those who still indiscriminately condemn everyone who, for the good of his kind or for his own pleasure, ventures to speak or write, let them carefully note the indisputable results of the old policy of secrecy and silence, and the outcome of the present more enlightened methods mentioned above.

The following experience with an exhauster is neither in the line of high art nor intricate science; it is only one of those everyday occurrences with some of us which, if they were generally made known, would not unlikely save time, trouble, and expense to others without the least injury to anyone.

A few months ago we bought a Number IV. Roots exhauster, intending to use it in connection with our water gas apparatus. When received the machine was in good order, and could be turned easily by hand, together with the engine, which was on the same bedplate. We commenced operations and everything moved smoothly, that state of affairs continuing for several hours, when, without seeming cause, the exhauster began to work irregularly, and at last stopped entirely. Two men could not pull it around, tugging with all their might at the fly-wheel of the engine. We were very angry over having a new machine act in that way, and telegraphed to the factory to at once send an expert to determine what was the matter with the apparatus, as we had not time to look it over, and would not bother with it if we had, because a new machine ought not to start out on its mission in such an eccentric manner—so we thought, and said.

The expert made his examination and gave it as his opinion that that exhauster was built for cold coal gas, and, with the latter, it would work all right, for, see (the exhauster had been opened, wiped out, greased, and was cold then), a child could turn it; and with only 20 pounds of steam and a little opening of the valve the exhauster whirled around with the speed of a buzz-saw, apparently. However, as we wanted the machine to pump very hot water gas, the expert placed a few thicknesses of drawing paper between the cylinder heads and the body of the exhauster, to allow for the extra expansion, but stated that he did not think it would work anyhow. What we wanted to get was one of those hot gas blowers, with water-cooled journals. We did not think so, because we were—and had been for years—using a larger Roots exhauster in our coal gas works. That machine was placed next to the hydraulic main, and was pumping very hot gas—as hot nearly as the Number IV. machine was to work on.

We started again. All worked well for over 24 hours, when the ex-

hauster acted as before. This time we did not send for the expert, for we had seen, when the machine was taken apart before, that it was whole and in good order; so we wanted to find out the real cause of the trouble this time, and remedy it if possible. We found it. On removing the pipe plates we found the heads of the exhauster coated with pitch, and the rollers or pistons were similarly affected. That was the trouble. The machine was well made; it was a close, neat fit everywhere. The thin coating of hard pitch on every portion of the inside of the machine had stopped it as effectively as a number of steel wedges could have done it.

But where did the pitch come from? The oil used in gas making contained none, as we could easily prove by evaporating a quantity of it. The coke used contained none; so where did we get it? Well, here it is. We had used as a lubricant of the exhauster some best, pure, natural, W. Va. 29° lubricating oil. In our coal gas exhauster we use no lubricant at all except on the journals, as the tar coming over with the gas makes this unnecessary; but we had no tar in our water gas, and therefore oiled the cylinder of the machine, through the oil cups on top of it, with the kind of oil mentioned. And that it was which caused the trouble, and in this way: The oil used was, as has been said, a good article of petroleum lubricating oil, which we have used with entire satisfaction on all kinds of engine journals and shafting, and also in a large Roots exhauster at our district station, 3½ miles distant from the works, where we pump, daily, cold gas. But our water gas exhauster had to pump very hot gas, and this gas in its passage picked up all of the lubricating oil except the very heavy portions of it, which were left in the shape of pitch, and this accumulated so slowly and evenly that it was bound to stop the machine at last.

Finding the cause, the remedy was quite simple. We removed the slips of drawing paper, which the expert had put in as previously stated. We cleaned out the machine thoroughly by sweeping, and washing with turpentine; and when we started again we used lard oil as the lubricant, and had no further trouble.

To make very sure of the cause of the exhauster acting as it did, we again tried the "pure, natural, lubricating oil," watching the machine very closely though. In two hours it began to act stiff, and we poured turpentine mixed with a little lard oil into it, whereupon the trouble grew less at once, until it ceased entirely. We continued to oil the machine with lard oil, using it quite sparingly. We have had no trouble with the exhauster since, and, notwithstanding the expert's opinion that it was a cold coal gas exhauster, and would not do for the hot water gas, it has done it, and is doing it right along as nicely as anyone could desire, thus proving that the exhauster was all right in the first place, and showing a cause for defective action which many would not have suspected. But as the remedy is given, and is simple and easy of application, we can now bring this paper to a close, with, it is hoped, satisfaction to the reader as well as to the writer.

Proposed Legislation in the Matter of Electric Wiring in Boston Buildings.

The following report has been made by a sub-committee of "representative citizens," of Boston, Mass., that was formed shortly after the recent disastrous fire in that city. This sub-committee, the report from whom is here appended, was appointed to formulate rules for the proper installation of electric wires in buildings, and the findings handed in are:

Your committee appointed to report upon "Electric Wires Inside of Buildings," would recommend the enactment of laws substantially as follows:

For arc light and power wires, or others designed to carry current of over 250 volts electromotive force.

That they shall not be placed so as to be concealed from view.

That they shall not be allowed in contact with wood or other inflammable building material that may become carbonized, but that they shall be separated from such material by at least ½-inch air space by use of non-combustible, non-carbonizable insulators, placed near enough to prevent contact of the wires by sagging or otherwise, but not further than 6 feet apart.

That with such construction wires of opposite polarity shall not approach each other nearer than 10 inches, except at the lamp and switch.

If the wires are incased in insulating tubing that is impervious to moisture, will not support combustion, and of sufficient mechanical strength to protect them from injury, the tubes may be laid as near as 3 inches to each other, and may be fastened to any building material by use of staples or such other means as will not injure the tubing.

All such wires must enter and leave the building at the same place in

order that a non-combustible hand-switch may be placed outside for the use of shutting off the current.

All insulating covering that will support combustion will not be allowed.

For incandescent light and power wires or others designed to carry currents of less than 250 volts electromotive force.

If such wires are concealed within partitions or like places they must not be allowed in contact with wood or other inflammable building material that may become carbonized, nor with any conducting material such as piping or other wires.

They must be rigidly separated from such material by at least $\frac{1}{2}$ -inch air space by the use of non-combustible, non-carbonizable insulators placed at intervals near enough to prevent contact by sagging of the wires or otherwise.

The wires must be kept at least 6 inches apart, except where they enter junction boxes, cut outs or the like.

Wires laid in plaster, cement or other similar building material will not be allowed, no matter what insulating covering may be used.

In lieu of construction by air space and non-combustible insulators, wires may be incased in insulating tubing that is impervious to moisture, will not support combustion, and of sufficient mechanical strength to protect them from injury, and such tubes may be laid side by side in plaster, cement or similar finish, or in any concealed space where they will not be subjected to injury, and may be supported by staples, or such other means as shall not injure the tubing.

No switch or safety cut out except those made of non-combustible material will be allowed.

For telegraph, telephone, messenger service and all other electric wires not heretofore mentioned, except public fire alarm and police wires and "series" electric light wires.

All such wires in any town or city in this Commonwealth where electric lights or power wires are being operated, must be provided at the entrance of any building (both ingoing and outgoing wires) with some safety device that shall instantly open the circuit or shunt the current out of the building in case the flow of current shall at any time exceed in quantity or electromotive force that which is normally used on such wires.

Such safety device must be located as near as possible to the place where the wires enter the building, and in some place easy of access.

When the safety device is placed inside of the building, the wire connecting it with the outside wire must be of equal or greater carrying capacity.

The device must be mounted on non combustible material.

All switches, cut-outs, insulators, insulation or tubing for use in electric lighting or power work, and all safety devices herein referred to must be approved by the committee or inspector in power before being used.

Prindle's Retort Lid.

On December 10, U. S. Letters Patent (No. 416,855) were granted to F. C. Prindle (of Wilmington, N. C.) for an improvement in retort lids. In the language of the specification the Prindle improvements relate to cylindrical retorts which are provided with doors for admitting raw material and for removing the residual products after heat has been applied to the retorts—as, for example, for the destructive distillation of wood. But the improvements may be applied to hollow cylinders of any sort.

In the accompanying drawings, Fig. 1 is an end elevation of a retort provided with a circular hinged door, and annular parts around its margin corresponding in function and relation to a common door jamb. Fig. 2 is a section on the line 2 2 of Fig. 1. Fig. 3 is a section on the line 3 3 of Fig. 1. Fig. 4 shows an annular end casting to which in practice the door is hinged. Fig. 5 shows an annular casting which constitutes the frame of the improved door. Fig. 6 shows a sheet metal ring to be secured in practice around the periphery of the annular end casting shown in Fig. 4.

Referring to the letters, *A* indicates a section of a hollow, sheet metal cylinder suitable for a retort; *B* an annular end casting having a cylindrical part *B'*, adapted to be secured to the end of the retort cylinder by means of bolts and rivets *C*, for example, passing through the part *B'*, or in any other suitable way. This annular end casting is formed with an inward annular projection *D*, provided with an annular packing socket *E*, for the purpose of receiving a packing ring *F*, which may be of asbestos or any other suitable material. It is also formed with an outward annular projection *D'* adapted to support the end of a retort. It is also formed with an opening or passage (indicated at *G*, and in practice located in the lower part of the casting), for the purpose of

drawing off any residual liquid products that may be contained in the retort. This passage may have applied to it any suitable cock for this purpose.

H indicates a sheet metal ring, which is bolted, as at *I*, or otherwise suitably secured to the outward projection *D'* of the end casting *B*, and serves to rest the retort upon the masonry, so as to leave an air space between the retort and the masonry to facilitate cooling and to prevent overheating the retort in use and injuring it.

K indicates suitable hinge-pivot projections of ordinary character, properly placed or formed upon the outer face of the end casting. The

end of the retort cylinder at *L* is preferably cut away so as to incline, as illustrated. A shoulder *M* is formed upon the inner part of the end casting *B*, inclining in an opposite direction to the incline of the end of the retort just mentioned. The object of this structure is to form a dovetail annular pocket for receiving packing *N*, which extends in practice all around the end of the retort and secures a gas-tight joint between it and the end casting.

O indicates an annular casting suitable to form a frame for the retort door and adapted to fit within the end casting *B*. The door is composed of this end casting and an outer sheet metal plate *P* and an inner sheet metal plate *Q* and suitable filling *R* between the two of a character to prevent rapid conduction and radiation of heat from the interior of the retort out to the open air.

Asbestos or some composition of asbestos may be used if desired; but any other substance preferred may also be employed. These inner and

outer door plates consist of concavo-convex metallic discs with their concave faces toward each other and adapted to fit the annular casting *O*, to which they are bolted—as, for example, by means of bolts *S*.

T indicates stay-pieces through which the bolts *U* pass to preserve the contour of the door plates which gives great strength to the door. Any suitable packing may, of course, be used, if desired, between the margins of the plates and the annular casting *O* to make gas-tight joints; but no such packing is illustrated, because it forms no part of the invention and is generally not necessary where the metal work is properly done.

V indicates a handle for the door.

W indicates an outward annular projection from the casting *O* hav-

ing an annular flange *W'*, adapted to fit into the annular socket *E* of the casting *B* and bear upon the packing ring *F* to make a gas-tight joint.

X indicates a series of projections from the end casting *B*, provided with wedge-holes to receive the wedges *Y*. These wedges bear at one end upon stumps *Z* on the end casting *B* and at the other upon stumps *Z'* upon the annular casting *O*, and serve to hold the door in place when closed, as is usual.

a indicates the door hinges, of usual construction.

By the instrumentalities described one is able to form end supports and closers for retorts provided with hinged doors, which are cheap, durable, gas-tight and convenient to use, and that will conserve the heat of retort ends, so as to render the interior of a long retort more uniform in temperature than is usually practicable. By this means he dispenses with clay lutings.

The Close Gas Manufacturing Apparatus.

U. S. Letters Patent (No. 416,825) were granted on December 10th to Mr. Thomas J. Close, of Philadelphia, Pa., who made an assignment of his invention to the Gas Improvement Company, of North America. In his specification the inventor says:

My invention relates to apparatus for the manufacture of gas; and it consists of certain improvements which are fully set forth in the following specification and shown in the accompanying drawings, which form a part thereof.

More particularly my invention relates to externally heated generating

of the retort and the inner compartment or chamber, and are thereby subjected to a large degree of heat, and are superheated and freed of their smoky constituents and made into a thoroughly fixed, pure gas, which escapes to the holder. This inner superheating space between the inner combustion chamber and the outer shell of the retort preferably extends entirely about the inner chamber, so as to form a space on all sides thereof, in order that the products of combustion passing from the inner chamber into this superheating space may be brought in contact with a large area of heating surface. In order to more thoroughly diffuse or scatter the products of combustion throughout this superheating space, I prefer to provide the superheating space with a series of dividing walls or ribs extending longitudinally.

The particular form or shape of the apparatus and the minor details of construction may be varied, as the essence of my invention lies in the formation of a superheating retort with an inner combustion chamber, and a superheating space or spaces between the outer shell of the retort and the inner combustion chamber, through which the products of combustion are caused to pass from the inner combustion chamber to the gas outlet, for the purpose of subjecting them to a large degree of heat to purify and thoroughly fix the gas, and also to protect the inner compartment from an excessive temperature, and thus induce perfect destructive distillation of the products without excessive disintegration and too rapid carbonization of the gas producing materials.

In the drawings, Fig. 1 is a sectional side elevation of the improved retort. Fig. 2 is a cross sectional view of the same upon the line *xx* of Fig. 1. Fig. 3 is a similar view upon the line *yy* of Fig. 1. Fig. 4 is a sectional side elevation illustrating a modification of my invention, and Fig. 5 is a cross sectional view of the same on the line *zz* of Fig. 4.

A is the furnace setting, provided with a grate *B*, above which the generating and superheating retort is supported. *C* is a grate door. *D* is the outer shell of the superheating retort, supported within the setting *A* above the grate *B*. *E* is the gas outlet, opening from the outer shell *D*. *F* is the inner combustion chamber, formed within the outer shell *D* and having a space *G* between the inner surface of the outer shell *D* and the outer surface of the inner chamber *F*. This inner chamber *F* is preferably shorter than the outer shell, and is open at its rear end to the superheating space *G* by a space or passage *H* between its end and the wall of the outer shell *D*, through which products of combustion from the interior of the chamber may escape into the superheating space *G*. This inner chamber *F* is preferably formed with a wall or flange *I* on its rear end to prevent the ashes falling out into the shell *D* and clogging up the lower part of the superheating space *G*. It will thus be seen that the retorts are made long, as compared with their diameter, so as to have as small cubical capacity with relation to the heating surface as is consistent with a proper adaptation to hold the material to be treated.

J is the door of the retort, opening into the inner chamber *F* only, and preferably having an asbestos or other suitable packing *j*, and clamped in place in any manner desired. For the purpose of more perfectly distributing and diffusing the products of combustion throughout the entire superheating space *G*, for the purpose of bringing them into contact with a larger heating area, I prefer to divide the space *G* into channels by a series of longitudinally extending ribs or walls *K K*. These ribs or walls are provided with notches, openings, or holes *k* at the front end to allow the gas to escape to the outlet *E*.

By the arrangement of the ribs the longitudinal passageways are so formed that they communicate with each other at both ends of the retort, receiving the gaseous products at one end and allowing their escape at the other end. The use of these walls or ribs, and the particular formation or construction of them, are not absolutely necessary to my invention, although I consider them an advantage.

In Figs. 4 and 5 is shown a modification of my invention, in which the inner or distillation chamber is formed with a fluted or corrugated surface, with the superheating space *G* formed of the passages made by these longitudinal corrugations. The spaces made by the corrugations open into an annular chamber *g*, communicating with the outlet *E*. In place of making the retort cylindrical, it may be made \square -shape, as shown in dotted lines in Fig. 3, or, in fact, of any form which may be deemed advantageous. The \square -shaped construction referred to would be found advantageous, as presenting a larger surface of the retort directly to the flame of the fuel on the grate *B*.

The operation of my invention is as follows: The door *J* is opened and a suitable quantity of fuel—such as wood or coal—is placed in the inner combustion chamber *F*. The door *J* is now closed and the heat from the furnace dissociates the fuel in the chamber *F* into its gaseous constituents, which escape out of the rear end of the chamber through the passage *H* into the space *G*. Here they are thoroughly subjected to contact with a large area of heating surface, and their smoky constitu-

and superheating gas retorts for the purpose of generating and immediately superheating and thoroughly fixing the gas before it passes to the holders, whereby the purity, quantity and illuminating power of the gas is increased.

In carrying out my invention I employ a retort having an inner compartment to contain the gas producing materials, open at both ends, and a superheating space or spaces between the surface of the outer shell of the retort and the inner compartment, a charging door to the inner compartment, and an outlet from the superheating space or spaces to convey the gas to the holder, as more clearly described hereinafter. The products of combustion from this inner compartment pass through the open end thereof into the superheating space or spaces between the outer shell

ents are fully gasified, and a thoroughly fixed gas of excellent quality is produced, which upon reaching the forward end of the superheating space passes through the outlet *E* to the holder without again entering the entrance or throat of the retort. It is evident that in this form of retort the heat of the outer shell is far in excess of that of the inner shell; hence anything which passes in contact with the said outer wall (through the spaces *G*) is going to be heated to a much higher temperature than that of the chamber *F*. This is utilized to superheat the gaseous products emanating from the inner chamber and convert into gases of the proper composition such carbonaceous vapors and gases not already fully dissociated into the required gaseous products, and such gases are then fixed in passing through the chamber *G'*. By performing the superheating and fixing operation in the same structure, and immediately upon the taking place of the destructive distillation of the gas producing materials (wood or coal), I am enabled to obtain a pure gas of high candle power and great non-condensability. The outer chamber *G* also guards the inner wall of the compartment *F* from becoming too hot, and thus interfering with the proper and perfect carrying on of the destructive distillation process.

It is evident that the retort may be made of metal or fireclay, as desired.

In my improvement the inner chamber *F* is permanently in the retort, and is charged with the material to be gasified through the door or cover *J*. The outlet *E* is not exposed by the opening of the retort, as the shell of the inner chamber seals it at the charging end of the retort.

Mr. Watson Smith on Naphthaline.

The London *Journal*, in commenting on a paper read by this gentleman on Monday week, before the London Section of the Society of Chemical Industry, entitled "Some Notes on Variations in the Products of Different Gas Coals Heated Separately in the same Retort and under Similar Conditions," says considerable attention was devoted to the subject of naphthaline deposits.* Mr. Smith did not appear to be aware that this subject is now interesting to gas engineers in a theoretical sense only, as the causes which lead to its formation are fairly well understood, and also the remedies that are necessary to prevent it; and it seems like going back some 20 or 30 years to find advice given as to the means to be adopted for preventing naphthaline. Briefly, it may be stated that since gas engineers have become alive to the necessity for proper and gradual condensation as distinct from a mere cooling of the gas, they are not troubled with naphthaline to such an extent as to render them anxious to hear of a remedy. With many it has disappeared altogether, and with the remainder an occasional service or main stoppage—usually attributable to the specially exposed position of the pipe in question—represents the sum total of their naphthaline experience. It may then be asked: "If this is so why has the subject of naphthaline any interest at all, even in a theoretical sense?" and the answer is simply that its illuminating value is very high. It is well known that when returned to the gas, in the form of "albo-carbon," a great improvement in the illuminating value is effected. The experiments made by Mr. Leicester Greville showed that 1 pound of naphthaline is equal in illuminating value to 17 pounds of sperm. The view that producers of artificial light should take of the question is not so much an uncompromising removal of such a valuable illuminating constituent from the gas, on account of its inconvenient proclivity to precipitate in the solid form, but a consideration of how it can be retained in the gas and delivered at the burner of the consumer. It is in this light that we approach the consideration of Mr. Smith's paper.

The various hypotheses which are to be found at the commencement may be briefly passed over as the consideration of a chemist rather than those of a practical gas engineer. As to the fact of "air and sun dried coal" receiving a more drastic carbonization than coal "in the usual condition of dampness," we may remark that the percentage of hygroscopic moisture in gas coal as ordinarily carbonized is too low to have any great effect on the temperature of carbonization. Any reduction in temperature sufficient to prevent or materially hinder the formation of naphthaline would also have an effect on the more important result of "make of gas per ton." It is well known that working at high temperatures causes the production of naphthaline; but this is only true within certain limits. With the introduction of generator furnaces the tendency has been to increase the carbonizing temperatures. Higher heats and quicker charges are the order of the day. But no evidence is forthcoming to show that any increased production of naphthaline is observable. The fact that the presence of light hydrocarbons—such as benzene

—in the gas is effective in retaining naphthaline and preventing its deposition was observed many years ago, and hence the old-fashioned practice of sweeping out the mains with charges of cannel gas, or of sprinkling the oxide in the purifiers with naphtha.

The likening of naphthaline to snow was a simile adopted by Mr. Lewis Thompson, in a letter to the *Journal*, 33 years ago; and in this connection Mr. Smith seems to have got into some confusion as to the existence of slow currents in the gas mains in summer and stronger ones in winter. The comparatively small consumption during the summer is not so much due to slower currents as to longer hours of daylight. In many districts there is a close agreement between the proportionate consumption of gas and the hours of darkness before 10 P.M. Thus, when there are only two hours (from 8 to 10 P.M.) the consumption will be about one-third of that experienced when there are six hours (from 4 to 10 P.M.). Therefore it does not appear probable that a stream of gas is likely to rush through the pipes at any time during the winter with sufficient force to stir up scales of naphthaline that have laid motionless during the summer. Many gas engineers agree in observing that trouble from naphthaline is experienced at times of changeable atmospheric temperature—such as warm days and cold nights; but we do not find that any have connected them with the velocity of travel in the gas mains. Further, if this theory is correct, the naphthaline should appear in the busiest districts, and at the services of the largest consumers, whereas the exact reverse is the case. The deposits are particularly liable to favor "blind" pipes, lamp services, and other localities where the current is slow. It may be well to observe that some gas engineers use naphthaline as a generic term for deposits of any kind from the gas in the supply pipes. But it frequently happens that the deposit is of a tarry nature, especially where rich gases are supplied, and in cold weather the stoppage may simply be due to freezing of moisture present in the gas.

Mr. Smith has conducted a series of experiments upon seventeen varieties of coal, representing the principal or typical cannel and gas producing coals in the northern coal fields of England. The results were given in a table, and they comprise yield and quality of gas, quantity and strength of liquor, quantity and specific gravity of tar; also percentage of naphthaline and number of gallons of light oil distilling below 180°, and light oil above 180°, per ton of tar. These results are greatly robbed of their interest by the fact that the author is so careful to conceal the names of the coals as not even to state if they are cannel or otherwise. This is, however, perfectly clear from the quality of the gas made. In the majority of cases the make is high—10,200 to nearly 11,000 cubic feet per ton—and the quality rather low—about 14½ or 15 candles. In six instances there is a comparatively small yield of high-quality gas, ranging from 24 to 29 candles. Mr. Smith does not appear to have directed his attention to the quantity of naphthaline present in the gas—a point on which gas engineers are especially desirous of information. The general impression is that the bulk of it does not escape condensation, and that the actual proportion present in the gas as supplied to the consumers is extremely minute. Many chemists have searched for it by means of the usual tests, and failed to find it; and have even been led to suggest that it is formed by synthesis under the conditions which lead to its deposition in the pipes. So we may take Mr. Smith's results as practically indicating the total quantity of naphthaline formed. The only connection to be traced between the proportion of naphthaline and the yield or quality of gas is that the high percentages appear to favor a large make. This may be due to the fact that the percentage of naphthaline agrees remarkably well with the specific gravity of the tar; and a high make of gas is usually accompanied with a yield of thick, heavy tar. The proportion of naphthaline ranges from 2.15 to 6 per cent. In the highest case there is a yield of about 7½ lbs. per ton of coal, equivalent to more than 120 lbs. of sperm, or somewhere about 25 per cent. of the total illuminating value represented by the yield of the gas. With the cannel this proportion is considerably less, and of course the total sperm value is higher; so that the value represented by the naphthaline is represented by less than one-tenth of the whole. Even at the lower rate, however, it is impossible to avoid an expression of regret that such a valuable illuminant should be allowed to go into the tar well. The general conclusion is that a coal which yields the lightest tar is the least likely to cause trouble with naphthaline. In other words, the coal should furnish a sufficient quantity of light oils to be capable of absorbing or scrubbing the naphthaline out of the gas. If these light oils are reduced from any cause, as by working at an abnormally high temperature, then the naphthaline is less likely to be removed, and therefore more likely to be carried on with the gas. So we are in the anomalous position that a sufficient quantity of one illuminant—viz., light oils, which have been shown by

* See JOURNAL, Dec. 20, 1889, p. 923.

Mr. Liecester Greville to possess an illuminating value nearly equal to that of benzene, or about 12 times that of sperm—should be left in the tar in order to secure the removal of another illuminant—viz., naphthaline. The manufacture of illuminating gas as at present conducted is therefore open to the charge of wastefulness; as it is an unavoidable feature that considerable quantities of illuminating matter must be allowed to pass into the tar well. Mr. Smith's advice, in effect, is either to use a coal that produces a sufficient excess of light oils to render the tar thin, or else to so carbonize it as to secure that result. It sounds more like the advice of a tar distiller than of a gas engineer.

The real question for manufacturers of illuminating gas to consider is not how much naphthaline they produce, but how to secure its complete removal, or better still, how to retain it in the gas. The quality of tar produced does not affect them so long as the tar remains fluid enough to flow off into the tar well. It may contain either 2 or 6 per cent. of naphthaline for all they know—the price received for it will probably be the same. Their point is to secure the highest possible illuminating value in the form of gas; and to prevent annoyance to themselves and their customers on account of stopped pipes. Possibly the circumstances which favor the formation of naphthaline may be just those which yield the best results from their point of view. If the proportion present—be it 2 or 6 per cent.—cannot be retained in the gas without being liable to deposit on the slightest provocation, then the question of means for its removal that will at the same time be thoroughly efficient, and as innocuous as possible in regard to other illuminating constituents, comes into view. Many practical men regard naphthaline in gas as present in the vaporous form, and therefore subject to the laws which influence the carrying of vapors by gases, as continually instanced by water vapor in the atmosphere. There is a "saturation point" beyond which any excess of naphthaline present would be deposited in the solid form; and this point varies according to the conditions of temperature and pressure. Assuming this to be correct, it follows that if the gas is reduced at the works to the lowest temperature to which it is likely to be exposed in the course of its subsequent existence, no further trouble from deposits will be experienced, as any excess of naphthaline present in the gas will be thrown down then and there. This vapor theory is substantiated by the careful experiments of M. Bremond, which do not appear to have attracted Mr. Smith's attention. M. Bremond found that the desiccation of the gas, by passing it through dry lime, was in practice a cure for any tendency to deposit naphthaline. This was explained by the statement that removing one vapor from the gas would leave it more free to retain another.

Mr. Smith's paper comes with singular aptitude immediately after the discussion of the Dinsmore process, at the recent meeting of the Manchester District Institution of Gas Engineers. Mr. Carr shows that it is possible to obtain higher illuminating value from the coal than that which is secured under the usual system of carbonization. Mr. Smith shows that a margin for such increased value exists. We have only to suppose that the conditions obtaining in the Dinsmore duct are favorable to the decomposition of naphthaline, with the formation of lighter hydrocarbons, in order to afford an explanation of the increased value claimed for the Dinsmore process.

It is well known that naphthaline is perfectly stable at the temperatures prevailing in the Dinsmore duct; but that is no reason why it should not be amenable to the influences of other hydrocarbons also present with it. The fact that the production varies in a wide ratio—from one to three, that is very much in excess of other results, such as quantity or quality of gas, or quantity and specific gravity of tar—indicates either that the circumstances which lead to its production are of a narrow character, confined within small limits of temperature; or else that, when formed, it is very liable to decomposition. So it is to be hoped that the further researches on the Dinsmore process, which Mr. Carr indicates as likely to be made, will include an examination of the resulting tar for naphthaline.

Incandescent Lamps on Buoys.

A recent report, made by Captain Millis, of the United States Light-house Board, in relation to the electric lighted buoys at the Gedney's Channel entrance to New York Harbor, states that a year's service shows that the system is a practical success. During the last nine months over 220 ocean vessels passed through the channel between sunset and sunrise. The buoys withstood the heavy storms of last September without drifting from their positions, and not more than two lamps out of six were extinguished at any one time. On one occasion a buoy was run down by a vessel and entirely submerged without

injury. Some trouble has been experienced from moisture getting through the lamp sockets and destroying the connections, but a new form of lamp has been devised which promises to be free from this objection. It has been found that the life of lamps made with red glass globes was much shorter than that of the uncolored ones, an effect which was attributed to the interception of a greater portion of the heat radiated from the carbon filament; and lamps with bulbs of clear glass are now used on all the buoys, lanterns lined with red glass being used to produce the red lights. Captain Millis notes the fact that a building on shore, very near the buoys, was twice struck by lightning while the buoys and their connecting cables were uninjured, and adds: "It is probable that the use of an earth return insures greater safety from damage by lightning than it would obtain if the circuits were entirely insulated."

The Examination of Commercial Glycerine.

Mr. J. H. Wainwright, F.C.S., of the New York branch of the U. S. Laboratory, has prepared the following valuable paper on this subject, which ought to be of great assistance to the gas chemist, if not the gas engineer. He remarks:

The tariff law of 1883 imposes upon "Glycerine, crude, brown or yellow, of the specific gravity of one and twenty-five hundredths or less at a temperature of 60° Fahrenheit, not purified by distilling or refining," a duty of two cents per pound; and upon "glycerine, refined," a duty of five cents per pound.

In view of possible attempts to enter, through the Custom House, a partially refined glycerine as the crude article, a sample of every importation of so-called crude glycerine is submitted to the U. S. Laboratory for examination as to whether it is properly invoiced, or is partially or wholly refined; in the latter case it should pay the higher rate of duty. It has been always considered by the chemists at this port that the extent of "refining" properly permissible in a glycerine in order to bring it within the definition of *crude*, is the allowing of impurities to subside by long standing, or removing them by a process of straining or filtering, and all samples showing evidence of having been treated further than this are reported as *refined* and subjected to the higher rate of duty.

For purposes of classification under the tariff law referred to above, *distillation* has always been regarded as the dividing line between crude and refined, and efforts have therefore been made to determine by means of physical and chemical tests whether this process of refining has been employed, since nearly all the glycerine imported as crude is bought by distillers for the manufacture of glycerine to be used in making dynamite (for which purpose distilled glycerine alone is used) and the white C. P. article used for medicinal and pharmaceutical purposes.

I will now call attention to some of the characteristics of crude and refined glycerine. Glycerine, crude, is defined by the tariff (T. I. new, A. 4) to be "brown or yellow, of the specific gravity of one and twenty-five hundredths, or less, at a temperature of 60° Fahrenheit, not purified by refining or distilling." Crude glycerine is the product obtained directly by stearine candle manufacturers from the saponification or disintegration of their fats and oils, and is a by-product in the manufacture of soap, being obtained from the waste lyes.

Its specific gravity is usually 1.25, or less, at 60° F., but the gravity of waste lye glycerines sometimes runs much higher, owing to the large amounts of chlorides, etc., present.

Its color is yellow, brown or black, but never white, sometimes light yellow, usually medium to dark yellow and often dark brown or black.

It possesses a strong characteristic odor of fatty acids, usually disagreeable, sometimes even foetid.

Reaction to litmus paper may be either acid or alkaline, never neutral.

Refined glycerine is usually the product of the distillation of the crude article, the distillation being repeated several times and the resulting glycerine concentrated and further purified by decolorization, etc., according to the uses for which it is intended. Its gravity is usually about 1.25.

Its color ranges all the way from dark brown or even black to white, according to the extent to which the process of distilling or refining has been carried.

If distilled it should have either no odor at all or a more or less burnt odor. This odor in a *distilled* glycerine is highly characteristic and suggests the odor obtained on burning gunpowder. If refined without distillation, as would be shown by other tests, the odor of fatty acids, if any, should be very faint. Distilled glycerine also possesses a characteristic taste faintly suggestive of garlic. This taste, however as well as the burnt odor, is only exhibited in distilled glycerine of inferior quality.

Reaction neutral or very faintly acid.

In determining the nature of a sample of glycerine a problem is often met with, inasmuch as it is often a matter of great doubt whether a sample has been distilled or not. The following tests, however, I regard as extremely reliable, and, with experience and practice, they afford results which admit of very nice distinction between crude and refined (or distilled) glycerine.

A 10 grm. sample is heated in a tarred platinum capsule until it inflames, the source of heat is removed and it is allowed to burn spontaneously; the residue is then weighed and its per cent. calculated. Distilled or refined glycerine will yield from 0. to 0.5 per cent. of "carbonaceous residue," rarely more than 0.5 and never as much as 1 per cent. (unless in the case of an otherwise apparently high grade article it has been adulterated, which would be shown by other tests), whereas crude glycerine yields as high as 10 per cent. I have found the per cent. of "carbonaceous residue" as determined by this test to admit of duplication within very narrow limits.

If desired, a determination of the ash may be made by igniting the "carbonaceous residue."

According to Sulman and Berry (Analyst, 11, 12) the determination of the ash will definitely decide whether the glycerine is crude or distilled; this is somewhat of an error, as it does not necessarily follow that a small proportion of ash alone would indicate that the glycerine had been distilled, since a large proportion of the glycerine manufactured is made directly from fats by "saponification" with steam, in which case the impurities would necessarily be organic and would be destroyed in the process of incineration, hence, other tests to show the presence of fatty impurities must be employed.

I have frequently found samples yielding as high as three per cent. of "carbonaceous residue" and less than 0.05 per cent. of ash. The proportion of mineral matter, however, affords a good indication of the character of the sample, since, in refined glycerine, the ash is never higher than 0.2 per cent. and rarely as high as 0.1, whereas, in crude glycerine made from soaps, lyes and other processes of saponification, the ash frequently runs as high as 14 per cent.

If deemed desirable, an examination of the ash may be made; this also will often afford an indication of the source of manufacture from which the glycerine was obtained (Allen's Com. Org. Anal., 2d ed., 2, 297). Of all the other tests which are recommended for the examination of glycerine the two most important are those made with solutions of silver nitrate and basic lead acetate in distilled water, the former being a two per cent. solution and the latter being made by adding 10 grams, of C.P. lead acetate and 8 grammes of litharge to 500 c. c. distilled water, boiling for some time and filtering. The tests are made as follows:

The silver nitrate test.—Dissolve 5 c. c. of the sample to 20 c. c. distilled water in a large test tube and add 5 c. c. silver solution, shake, allow to stand at rest for one hour. In refined glycerine a darkening of the solution may occur, with even a slight reduction of silver, after standing some time; it will be quite heavy if allowed to stand long enough, even in highly refined samples, but if it is not quite heavy at the end of one hour the result may safely be considered an indication of refined glycerine. In crude glycerine a considerable precipitation takes place, usually at once, and is nearly always *flocculent*. The precipitate may be of any color from black to white, according to the nature of the impurities present.

The lead test.—This test is made by adding to the lead solution in a large test tube, its own volume of a solution containing equal volumes of the sample and distilled water, and shaking and allowing to stand at rest for one hour, as in the silver test. Refined glycerine will remain unchanged or will show a slight precipitation or cloudiness, but never a *flocculent* precipitate, even on standing for a long time, whilst in crude glycerine there will always be more or less of a *flocculent* precipitate.

In applying these tests it is *never* safe to rely on either of them *alone*, as it will frequently happen that a sample will be met with which will stand one test and not the other; however, if it will not stand both of these tests it is perfectly safe to call it crude, and, with some experience, a fair idea of the value of the sample may be obtained. By boiling, the tests may be greatly hastened, although this is not recommended except in extremely doubtful cases, as the test thereby becomes much more delicate.

If deemed desirable other tests may be made, and among them the following will be found useful.

The addition of an equal volume of distilled water. Refined glycerine will remain clear. In crude glycerine if much oil or fat be present they may be separated from the glycerine in this manner:

Ammonia.—Refined, no change; *crude*, precipitate indicates presence of iron and alumina.

Ammonium Oxalate.—Refined, no change; *crude*, precipitate indicates lime salts.

Barium Chloride.—Refined, no change; *crude*, precipitate indicates sulphates.

Nitrogen Peroxide (Gas).—Refined, no change; *crude*, curdling indicates fatty impurities

Fehling's Solution.—Refined, no change; *crude*, shows the presence of glucose, etc.

For other tests recommended for the examination I would refer to the very able paper of Messrs. Sulman and Berry (Analyst, 11, 12 and 34), and to Allen's Com. Org. Anal. (2d ed., vol 2, 292 et seq.).

With a fair amount of experience a discrimination between crude or raw and refined or distilled glycerine will readily be accomplished by means of the foregoing tests, and, moreover, a fair idea as to the quality of the sample may be obtained, and it may be ascertained beyond a doubt whether it is fit for the manufacture of nitro-glycerine for which so much of the refined glycerine of commerce is used.

Steam Jackets, Their Mode of Action, and the Reasons of Their Economy.

Prof. Dwelshauvers Dery, of Liege University, writing in *Engineering*, says:

In the second volume of M. Hirn's book on the "Mechanical Theory of Heat" (Paris, 1876), the author devotes the first pages to the study, based on actual experiments, of the action of steam jackets. He compares two experiments made under practically the same conditions, with this single difference, that the steam jacket was not at work in the first, but was used in the second. It will, we think, be of practical utility to engineers, if we endeavor to give a brief summary of his analysis and conclusions.

Firstly, we give in the following Table the results of experiments in fractions of the total heat brought by the steam into the cylinder:

	Fractions of Total Heat brought by Steam into Cylinder.	
	Without Steam Jacket.	With Steam Jacket.
Heat given to the walls by partial condensation during the admission of steam—called(R_a)	0.459	0.380
Heat returned from the walls to the steam during expansion(R_d)	0.173	0.317
Heat passing from the walls to the condenser by evaporation during exhaust.....(R_e)	0.273	0.050
Heat lost by external radiation.....(E)	0.013	0.013
Heat furnished to the steam from the jacket.....	0.022
Heat equivalent to external work performed during expansion.....(T_d)	0.088	0.113

The heat given up to the walls by the steam during admission is afterwards (1) utilized during expansion to increase the external work; (2) wasted during exhaust in evaporating the water remaining in the cylinder, and sending it on to the condenser; (3) wasted in heating the surrounding atmosphere. We get therefore:

$$0.459 = 0.173 + 0.273 + 0.013$$

$$0.380 = 0.317 + 0.050 + 0.013$$

We see from this Table, first, that the jacket considerably diminishes the initial condensation, that is the heat given up by the steam to the walls during admission, since this is represented by 0.459 without the jacket, and only by 0.380 with it; secondly, the jacket increases the external work during expansion, the heat equivalent to this work being 0.088 without the jacket, and 0.113 with the jacket, in other words an increase of 28.4 per cent. If this increase is expressed as a fraction of the total heat expended, it will be 0.025.

Hitherto the action of the jacket has been considered merely as transmitting to the steam working in the cylinder a quantity of heat represented by 0.022. Even this small amount of heat has produced very great results. But the influence of the jacket does not stop there. We find that it actually reverses the proportions of the gains and losses of the heat stored up in the metal during admission. To prove this, let us compare the heat utilized during expansion and the heat lost during exhaust with the heat due to initial condensation, taking the latter as the unit of heat. We find the following figures:

$\frac{0.173}{0.459} = 0.378$	$\frac{0.317}{0.380} = 0.834$
$\frac{0.273}{0.059} = 0.596$	$\frac{0.050}{0.380} = 0.132$

	Without Steam Jacket.	With Steam Jacket.
Heat usefully employed during expansion.	0.378	0.834
Heat lost from the walls during exhaust by the cold condenser.....	0.596	0.132

Thus, without the jacket the heat stored up in the metal walls during admission can only benefit the work of expansion to the extent of 0.378. With the jacket the gain is 0.834. Without the jacket the loss in heat passing unutilized into the condenser is 0.596, while with the jacket this loss is reduced to 0.132. Here are the facts; we will now sum them up in a few words.

The steam jacket has transmitted 0.022 of heat through the metal walls, and this heat has been completely absorbed and utilized during expansion. But its action does not stop there. It has diminished the quantity of heat given up by the steam to the metal during admission by $0.459 - 0.380 = 0.079$; and as a consequence the wasteful cooling of the metal during exhaust has decreased by $0.273 - 0.050 = 0.223$, and the profitable cooling of the metal during expansion has increased by $0.317 - 0.173 = 0.144$. The physical explanation of these phenomena is given by M. Hirn, and he also adduces other facts no less worthy of attentive consideration. We will try to summarize these as clearly as possible.

The interior wall of a steam cylinder passes through successive phases of high and low temperature, in consequence of its contact with mixed steam and water, the pressure of which varies continually. There is a continual exchange of heat going on between the metal and the steam, sometimes in one direction, sometimes in another. For the fluid in action in the cylinder is not homogeneous; water and steam are not mixed in the same proportions in the center and in the neighborhood of the walls. Of course the interchange of heat only occurs in the strata in contact with the walls, for heat does not easily penetrate a gaseous body. The process of transformation from a liquid to a gaseous state, or the reverse, which is produced by this exchange of heat, certainly does not take place, because the entire mass has received or lost heat, but only the particles in contact with the walls. If at the same time the whole temperature happens to vary, this is in consequence of a change of pressure, occasioned by partial condensation or evaporation. In short, it is not a propagation of heat from one particle to another through the whole body of steam which is here meant, but a local exchange of heat in a limited portion, produced by direct contact with the walls, which condenses or evaporates the saturated steam or water. The first is always a slow process: the latter, because of the unstable equilibrium of these bodies, is extremely rapid.

During admission the steam in condensing heats the metal walls, and gives up to them R_a thermal units. This heat the metal returns to the steam; firstly, during expansion, R_d ; secondly, as wasted heat during exhaust, R_e . If we neglect the external radiation, we have

$$R_a = R_d + R_e.$$

Any method which tends to diminish R_a or to increase R_d at the expense of R_e is economical. The jacket and superheated steam, therefore, both produce a saving. The effect of the action of the jacket is to keep the metal walls at a higher temperature, and thus to diminish R_a ; but it also increases R_d by evaporating during expansion the greater part of the water which covers the inner surface of the metal. The result of this is useful, because the residue of water which is lost in evaporation during exhaust is diminished. But the steam in the jacket is far from furnishing all the heat necessary for evaporation. It only acts as an auxiliary to the steam condensed during admission.

The heat given by the jacket to the cylinder during exhaust has, so to speak, no influence, except, perhaps, to shorten the time necessary to evaporate the water adhering to the internal walls of the cylinder at the beginning of exhaust. At this moment there is a certain weight of water in the cylinder, and a certain amount of heat will be required to evaporate it, which will be neither more nor less, whether there is a jacket or not. The water once evaporated, any further heat the metal can transmit through the gaseous body is insignificant.

If the effect of the jacket were to evaporate all the water condensed during admission, just at the moment when this evaporation would be most useful, that is, during expansion, the loss through the influence of the walls would be reduced to external radiation only, that is, to its minimum. And the result would be obtained with very small expenditure of steam in the jacket.

Hitherto we have only spoken of single cylinder engines. Experiments have proved that a radical difference exists between the thermal

phenomena presented by a non-jacketed engine, according to whether it has one or two cylinders. In a compound engine the expanding steam is, in fact, almost entirely separated at each stroke of the piston from the steam flowing in from the boiler. Therefore the effect of the walls upon it must also be different. In a single cylinder non-jacketed engine the metal walls give up heat to the steam during expansion, although the quantity of heat surrendered is much less than with a jacket. In a compound engine, on the contrary, the walls, even during expansion, absorb heat from the steam and lose it during exhaust.

If the jacket be applied to a single cylinder, it gives little heat, although the effect produced is very great. For the larger part of the heat given up by the walls, and employed in useful work during expansion, is that already imparted by the steam to the metal during admission. In a compound engine, on the other hand, it is the heat given up by the steam in the jacket which increases the work performed during expansion. M. Hirn says: "With such striking differences caused by details of construction apparently almost insignificant, we are led to believe that a given engine, with a single cylinder and without a jacket, probably may, in consequence of some small structural difference, utilize the heat given up to the walls during admission better than some other engine. Far from being impossible, it is in fact quite likely that the proportion between the work of expansion, for instance, and the exhaust cooling may depend partly upon the relation existing between the diameter of a cylinder and the stroke, or the proportion between the total volume of the cylinder to that of the steam during admission."

One more word concerning superheating, which was employed with remarkable economical effect for thirty years by M. Hirn at Logelbach, and which deserves the closer attention of engineers. This is perhaps the most efficacious means of counteracting the injurious effect of the cool walls upon the hotter steam. It is the best way of increasing the work during expansion by diminishing the exhaust cooling and the initial condensation, because the steam thus contains in itself the heat necessary for these different operations. Of course, neither the advantage obtained by employing superheated steam, nor that afforded by the steam jacket, can be exactly represented numerically. Those who have read the foregoing remarks will easily understand that it depends upon the preliminary conditions under which the engine is already working with saturated steam.

The Dinsmore Process.

[Contributed by Mr. Norton H. Humphrys to the London Journal.]

The paper on this subject, which was read by Mr. Isaac Carr at the recent meeting of the Manchester District Institution of Gas Engineers, presents several features that are interesting in a theoretical, as well as in a practical sense. The importance of an increased yield to the extent of 10 per cent., with an increase of 20 per cent. or so in quality, is obvious, especially considered in connection with the comparatively simple arrangement that, according to Mr. Carr, is sufficient to secure such results.

The apparatus described in the paper is certainly a great improvement on that originally proposed, and is the more worthy of attentive consideration as being the outcome of experiments on a working scale. If any valuable illuminants are to be extracted from the tar, by exposure of the same to the influence of heat, this can only be done while the tar is in a state of vapor. And therefore it must be more reasonable to deal with the crude gas fresh from the retort, than to condense the tar out of the gas, and subsequently revaporize it. But Mr. Carr runs full tilt against the established practice in gas engineering. The general rule is to insist on the importance of getting the gas away from the retort as soon as possible. Any appliance that assists to this end—such as the exhauster or the anti-dip valve—is usually said to increase both the yield and the quality of the gas. Claims of this nature have been advanced over and over again, and it is a curious fact that Mr. Carr should obtain similar advantages by going to work in an opposite direction. Instead of hurrying his gas away from the high temperature of the retort, he gives it a prolonged contact therewith. An important feature in connection with the subject is that the Dinsmore process appears to be an anti-dip process—i. e., the gas passes straight away from the duct to the foul main, without meeting any equivalent to the ordinary hydraulic seal. It should further be stated that, according to the opinions general amongst gas engineers, the effect of passing crude gas through a hot retort, is simply a depreciation of quality, attended with a deposition of carbon.

The plain description given in the paper enables one readily to calculate the progress of affairs in the empty retort, or duct, as it is called. The production from six retorts passes through it, and a fairly regular

composition is secured by charging the retorts respectively at regular hourly intervals. So we may say that both the quantity and quality of the gases passing through the duct are practically regular from hour to hour. According to Professor Foster's report, the daily make per bench is 32,500 cubic feet; so that the quantity passed per hour is 1,350 cubic feet, or 22.5 cubic feet per minute. This quantity is, speaking roughly, about equal to 1.33 of the capacity of the duct, so we may say that each particle of the gas is exposed to the heat mentioned—a bright cherry red, cooled down at the outlet to a dull red—for about 45 seconds. The effect of this heating, as usually stated, would be an increase in the proportion of free hydrogen and marsh gas, with a corresponding loss of illuminants. But according to both Mr. Carr's experience and Mr. Foster's report, this does not represent the facts. A sample of pure Dinsmore gas made on November 11, contained, amongst other constituents, 6.76 per cent. of hydrocarbons, 40.34 per cent. of marsh gas, and 43.98 per cent. of hydrogen. A sample of the town gas, made on the same day, contained 4.37 per cent. of hydrocarbons, 33.39 per cent. of marsh gas, and 50.6 per cent. of hydrogen. This town gas consisted of a mixture of one part Dinsmore gas to two of ordinary gas, made by the usual process; and it therefore follows that the "ordinary" gas contained not much more than 3 per cent. of hydrocarbons, about 30 per cent. of marsh gas, and about 54 per cent. of free hydrogen. But the hydrocarbons in the ordinary gas are of a very different character to those in the Dinsmore gas. In the town gas we have a carbon density of about 3.7, and a hydrogen density of 6.3: as compared with 2.9 and 5.8 respectively in the Dinsmore gas. The effect of the lesser carbon density in the hydrocarbons shows itself in a marked manner in the specific gravity of the Dinsmore gas, which ranges from .420 to .440, merely a trifle more than that of the "ordinary" gas. But it must be remembered that the Dinsmore gas is freed from carbonic acid, whilst the town gas contains 2 per cent. of that impurity. Gas of 22-candle power made by the ordinary process is usually found to have a specific gravity of .530 to .550; and no explanation of the comparative lightness of the "Dinsmore" gas is apparent from the analysis. It may be remarked that, according to published analyses, the carbon density in the hydrocarbons rarely exceeds 3; so the illuminants in the Dinsmore gas do not present any special feature in the matter of carbon density, as compared with ordinary gas. The hydrogen density being about twice that of the carbon, indicates a composition corresponding to that of the olefines (C_nH_{2n}); but this result might also be made up by a mixture of paraffines (C_nH_{2n+2}) with acetylene (C_2H_2). The extreme lightness of the gas, which is the more noticeable when we observe that it contains 8 per cent. of carbonic oxide—which is a comparatively high proportion—precludes the presence of almost all hydrocarbons other than ethylene, acetylene, and perhaps ethane. Benzene vapor is nearly three times, and naphthalene more than four times as heavy as air.

It is generally supposed that the heavy hydrocarbons in coal gas are principally made up of bodies of the paraffine and olefine series. The hydrocarbons in coal tar are stated to comprise heavier members of these classes—also benzenes, naphthalenes, acetylenes, and crotonylenes, or pseudo acetylenes—besides small quantities of several other classes. If we examine the results likely to obtain by passing a mixture of these bodies, largely diluted with hydrogen and marsh gas, through the "ducts" as given in chemical text books, we shall find that—

1. The higher members of the paraffine classes may be decomposed into lower members of the same class, and small proportions of other hydrocarbons, together with a proportion of free hydrogen.
2. The olefines may be decomposed into bodies of the acetylene class and free hydrogen. At a full red heat they may be converted into paraffine, with a separation of carbon in the solid state.
3. Benzenes may be converted into acetylenes with separation of free hydrogen and various secondary products.
4. Naphthalenes and acetylenes are not likely to be affected to any practicable extent.

Apart from these reactions, which are all of an analytical or "breaking up" character, there may be some of a synthetical or "building together" character, such as the union of carbon and hydrogen to form acetylene, etc.

It has already been observed that the reactions obtaining in the duct are attended with the formation of hydrocarbons of comparatively low specific gravity—i. e., the lower members of the various hydrocarbon series; and it further appears that they are attended with the deposition of but little solid carbon. It may be suggested whether the temperature of distillation in the Dinsmore bench is not lower than that usually practiced. We are told that the duct, which is situated in the hottest part of the setting, should not exceed 1,800°; and the charges used—2

cwt. in the bottom retort, and 2½ cwt. in the others—are rather light, considering they remain in for six hours. The analysis of the Dinsmore gas is very similar to that which might be expected to obtain from rich gases made by working at moderately low temperatures in the ordinary way, except that under such circumstances the proportion of free hydrogen is usually lower. But there is the circumstance that the yield of gas is increased 10 per cent. or so, which must be borne in mind when making comparisons between the *percentage* of hydrogen and marsh gas present in the Dinsmore, as compared with the ordinary gas. The same bulk of hydrogen—viz., 5,400 cubic feet—that would represent 54 cent. on a make of 10,000 cubic feet of gas per ton, would only represent 49 per cent. on a make of 11,000 feet. This increase of bulk cannot be due to decomposition of heavy hydrocarbons resulting in the formation of marsh gas and hydrogen. The increase of the former is especially marked, as it amounts (after allowing for the increase in bulk as above noticed) to nearly 15 per cent., or more than enough to account for the larger yield secured by this process.

But the analysis and the illuminating value of the gas, show that while the heat of the duct undoubtedly exercises a negative action, so far as illuminating power is concerned, by decomposing hydrocarbons with the result of increasing the bulk of the gas—a thing that cannot be done without some loss of illuminating value, since the resulting products are certainly of lower value, and indeed may have no lighting power whatever—there are also reactions of a positive character, whereby substances that under ordinary circumstances would be deposited with the tar, are converted into others that are retained in the gas, and are possessed of high illuminating value. The positive reactions are more than sufficient to balance the negative ones; and therefore the net result of the whole is an increased percentage of hydrocarbons, and an increase of illuminating power. This advantage is secured at the expense of some 30 per cent. of the tar; and the increased bulk is much greater than that which might be expected to follow the decomposition of the hydrocarbons that under ordinary circumstances would remain in the gas as such. The greater part of it must be credited to substances that usually remain in the tar.

It is to be hoped that the inquiry undertaken by Professor Foster will be further extended to include a comparison of the heavy hydrocarbons existing in the "Dinsmore" gas, with those obtained in the usual way. Until some further information on this head is available, it is not possible to speculate with any safety as to which of the reactions above named are of most importance, or prevail to the greatest extent. But from the fact that Mr. Carr moderates the heat obtaining in the duct by cooling (if one may use the expression) the back part, it appears that the gases are just exposed to the heat for a sufficient time to ensure their being raised nearly to the maximum temperature obtaining in the duct, but are not allowed any prolonged exposure to this temperature. They are, so to speak, toasted but not allowed to scorch. If this point is not observed, we learn that there is some danger of deterioration in the quality of the gas, together with separation of solid carbon. In the course of conversation with Mr. Carr, I learnt that the same result would follow if the stream of gas through the duct was diminished from any cause—such, for instance, as one or more of the retorts not being in use. Under normal working, the separation of solid carbon is inconsiderable; and therefore it appears that Mr. Carr favors the class of reactions that result in the separation of free hydrogen—such, for example, as that concerned in the formation of acetylene.

Not only does the Dinsmore process practically do away with the hydraulic seal, by relegating it to the subordinate position of a safety bye-pass, but it also deals with another vexed question—viz., that of stopped ascension pipes. A plain ascension pipe, we are told, used as the outlet from the duct, would block up solid in a few hours' time; but the use of a water jacket, into which water runs at the ordinary, and escapes at a boiling temperature, prevents this trouble. The water jacket simply acts as a cooler; and the gas escaping from the duct must certainly receive a rapid reduction in temperature. How this should enable the crude gas to carry off tarry matters, that would be deposited with such rapidity in a warmer pipe as to block it up in a few hours, is one of those obscure points that will perhaps be cleared up when we arrive at a clear understanding as to the cause of stopped ascension-pipes. Even with water jackets of insufficient capacity, Mr. Carr found that the deposition of pitchy matter was greatly accelerated, thus affording further support to the supposition that the tarry deposit is prevented by simply cooling the pipe to a proper degree.

The actions obtained in a Dinsmore duct appear to be similar to those that occur in the superheater of a water gas apparatus of the Lowe type. In the one we have a mixture of hydrogen, marsh gas, and carbonic oxide, carrying a small proportion of illuminants, and loaded with

tarry vapors; and in the other a mixture of hydrogen and carbonic oxide, loaded with heavy hydrocarbonaceous vapors given off by the partial vaporizing and partial gasifying of the petroleum that is admitted at the upper part of the cupola. The fact that the Dinsmore duct converts some 30 per cent. of the tar into permanent gas, gives some indication of the value of the superheater as a "fixing" agent, especially when it is remembered that the former is empty, whereas the latter is usually packed with firebrick.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

WE are in receipt of a very pleasant reminder from Mr. Geo. F. MacMun, Superintendent of the Natick (Mass.) Gas Light Company, that his Company is still in the field, and proposes to remain so, as a dispenser of cheap and good gas. That the hold of that corporation on the goodwill of the residents may be still further tightened, we have only to remark that on the first inst. the proprietors authorized their Superintendent to announce that the gross rate for gas is to rule at \$2 per 1,000 cubic feet, prompt payment to secure to the ordinary user a rebate of 10 cents per 1,000, while all those whose monthly consumption amounted to 10,000 cubic feet and over are granted a rebate of 20 cents per M. This means cheap gas for Natick, and also proves that the management of the Company is abreast of the times.

WE understand that Mr. W. L. Cosgrove, of Evanston, Ills., has been appointed Secretary of the Atlanta (Ga.) Gas Light Company, which is now being operated by the United Gas Improvement Company. We wish Mr. Cosgrove every possible success in his new field.

WE are indebted to an occasional correspondent for the following account of something that happened, on December 24, at Des Moines, Iowa: "Manager E. G. Pratt, of the Capital City Lighting Company, was yesterday afternoon made the recipient of a handsome surprise, the employees presenting him with a gold watch with the initials 'E. G. P.' on the exterior of the case, while the inside cover bore the inscription, 'Presented to Mr. E. G. Pratt, Christmas, 1889, by the employees of the Capital City Gas Light Company, and of the Thomson-Houston Electric Light Company.' The presentation took place in the afternoon. Mr. Pratt, accompanied by Mrs. Pratt, reinforced or flanked by a wagon load of turkeys, had gone to the works of the Company on the east side of town, and after the fowl had been distributed the men did not seem in any hurry to move off. The cause of their loitering was about like this. The assignment of the turkeys having been completed, Mr. M. T. Wright, Secretary of the Company, stepped forward and thanked Mr. Pratt on behalf of the men, and then introduced Mr. Keffer, who he (Secretary Wright) was inclined to believe wished to say a few words to the Manager. Mr. Keffer then spoke as follows: 'Mr. Pratt—I have been delegated by the employees of the several light companies under your management, the most of whom surround you at this time, to address a few words to you, from a business and social standpoint, touching somewhat upon the history of the Companies. The Capital City Gas Light Company was organized and commenced business in this city in 1876, and for the first ten years of its existence was under the management of Mr. W. A. Agard, who as a manager made it one of, if not the most popular, corporations in the city. It was a Company with which the business men of the city were pleased to do business, and every patron of the Company was its friend. In due course of time the Company sold out and became a part of the great system of the United Gas Improvement Company, of Philadelphia, and Mr. Agard, having business interests elsewhere, resigned his position. The home Company, in casting about for a suitable successor to Mr. Agard, made what seems to us a wise selection in choosing you. And you came among us to assume the duties of the position about three years ago. Your whole life had thus far been spent near your boyhood home, and from which you had never ventured very far away. It required, it seems to us, a good deal of nerve for a man who has had the honor to have been born and reared so near to the center of the earth—Boston—to determine to come to what to you must have been in your imagination the wild and woolly West. But possessing a good supply of nerve, which has been shown, and we suppose backed up by a fair salary, you made the venture; and you found the West not wild at all, and I do not think you have yet seen any evidences of wool. Be assured, Mr. Pratt, that we are not trying to pull the wool over your eyes on this occasion. Upon taking charge of affairs it became your duty, first, to set the machine in motion according to the plans of the new Company. This we all know required a great deal of hard study and harder work. You were ably

assisted, however, by your former co-laborer, hard worker, and always a gentleman, Mr. W. A. McEwen, our efficient Secretary, to whom we all reluctantly said good-bye only a short time ago. It then became your duty to look out for your charge from a business standpoint, and that you have succeeded admirably in all your undertakings is evident on every hand. When you came to us we had a gas works—a good gas works—and a small arc light plant. To-day, thanks to your efficient management, we have a gas works the peer of any in the Northwest, and an electric plant second to none. Our pipes and lines have been extended in every direction. The reputation and good name of the Company have been kept up to their former high standard, and it is to-day a model institution of its class. We realize that to you must and should be given great credit, too, for the success thus far attained by the Company; and yet is said that 'things don't happen.' When we consider the fact that you commenced this business in an humble position, similar to that now occupied by our friend Mr. Rivers, as a cleaner of lamps, and that step by step you have progressed until coming to your present high place, we are not surprised, for it is only the legitimate outcome of knowing what to do, how to do, and when to do. We come together to-day, Mr. Pratt, from the different departments of this great plant, a great crowd of men, every one of whom earns his bread by the sweat of his brow, and whose dearest action is on the field of labor, your friends, and to give honor to whom honor is due. It has been from time immemorial the custom upon occasions such as this, when employees, recognizing the ability and services of their manager or superintendent, in addition to their congratulations, to leave something of a more enduring character than the words they may speak, and taking advantage of this occasion, on this Christmas eve, they have requested me, as one of their number, to present you with this souvenir of the day, something at once useful and beautiful. We ask you to accept it with our best wishes, and expressing the hope that our relations, which have ever been so pleasant in the past, may continue, and that even greater success may attend your efforts in the future, and that you and your estimable wife—without whom your success might not have been—may have a very merry Christmas and a right happy New Year.' To say that Manager Pratt was surprised is to put it very mildly indeed, and he ought to be extremely thankful that no merciless stenographer was on the platform, with clever symbol and unerring pencil, to transcribe his incoherent speech of thanks, which, however, was none the less agreeable to his hearers, even if it lacked somewhat in rhythm. The occasion was a most enjoyable one, and Manager Pratt will remember it for many a day."

WE regret to announce the death of Mr. A. W. Benson, formerly President of the Brooklyn (N. Y.) Gas Light Company.

THE Decatur (Ills.) Gas Company's electric annex seems to be in high favor with the residents of that city. If we mistake not, the Company is under contract to furnish not less than 1,200 incandescent lights, of 16 candle power each.

THE Smith Fuel and Illuminating Gas Company has been incorporated in Michigan, with a capital stock of \$600,000. The Company proposes to operate under patents granted to Ambrose G. Smith, of Sheboygan, Wis. A part of the scheme is to sell "State rights" for the operation of the Smith type of apparatus; and we would advise those approached under this head to look into this thing pretty closely.

ADVICES from St. Joseph, Mo., are to the effect that Chas. McGuire, of that city, has applied to the Council for an ordinance to operate a fuel gas works. This ordinance differs from the Crosby application (which, as was reported in the JOURNAL, had been laid on the table by the Council, with the understanding that it would remain there for some time) in that McGuire agrees to furnish light, heat and power from his gas to the City Hall, city prison and fire engine houses, without charge. He also agrees that his Company shall have three miles of mains laid by Aug. 1, 1890, that length to be increased to ten miles within 18 months from the date of the franchise, at which time the gas is to be ready for distribution on a large scale. It is also stipulated that the price to be charged for illuminating gas shall not exceed \$1 per 1,000, the rate for a heating gas supply to be 75 cents per 1,000. From our present knowledge of this last application to the Council we believe that it is not made in good faith; further, that St. Joseph can get along very well without McGuire's proposed gas company.

THE Springfield (Mass.) Gas Company has over 500 gas stoves on its services, 40 per cent. of which were placed in 1889. We might also note that the cutting off of the public lamps (the public lighting is now

almost entirely performed by means of electricity), which represented a shrinkage of something like 3½ million cubic feet per annum in the send-out, has not diminished the total output for the year. This speaks well for Mr. Hallett's determination to keep in front, and shows that his confidence in establishing a large increase in the Company's day trade was well founded.

It is more than probable that the Louisville (Ky.) Gas Company will make a trial on a fairly large scale of the Gordon burner for street illumination. The send-out of the Company for the year shows a large increase—in fact, we should not be surprised to hear that the maximum send-out (daily) approached closely to 2½ million cubic feet. Engineer Barret's new holder ought to be a source of great consolation (and safety) to him these dark days.

THE following figures show the quantities of gas sent out from the Philadelphia works on the dates mentioned—the quantities are in millions of cubic feet:

Year.	Dec. 24.	Dec. 25.	Dec. 26.
1880.....	9,115	7,251	6,416
1881.....	9,746	6,746	7,350
*1882.....	7,496	7,766	9,740
1883.....	11,624	8,436	9,723
1884.....	11,268	8,665	10,205
1885.....	12,674	9,070	10,839
1886.....	13,973	10,524	9,474
1887.....	13,415	9,479	11,075
1888.....	14,454	10,784	12,933
1889.....	13,360	10,094	12,470

THE new Company at Duquoin, Ills., is almost ready to supply gas. The public lamps (100 in number) have been placed in position.

MR. LYNN R. ZIMMERMAN, of Rochester, N. Y., has been appointed receiver of the Medina (N. Y.) Gas Light Company, a receivership having become necessary because of the verdict of damages awarded Wm. Allport, who sued to recover for injuries occasioned by an explosion at the works some months since.

THE following notice has been published by the proprietors of the Newton (N. J.) Gas Light Company: "Nearly four years ago the Newton Gas Light Company reduced the price of gas from \$4 to \$3 per 1,000. We take pleasure in announcing a further reduction—the concession to take effect on all gas consumed from Dec. 1: In quantities of less than 5,000 feet per month, \$3 per 1,000; in quantities of 5,000 feet or over per month, \$2.50 per 1,000. From these prices a discount of 10 per cent. will be allowed on all bills paid within 30 days, making the net prices \$2.70 and \$2.25. If the Company meets with sufficient encouragement, it hopes to be able to make a still further reduction in the future." This is the practice that pays.

SOME days ago the proprietors of the Somerville (N. J.) Electric Light Company made a proposition to the authorities for the public lighting that was based on very reasonable terms. The Gas Company, however, also submitted a bid that was finally accepted by the Town Commissioners, and a contract executed under it. The rate agreed on was \$1.50 per lamp (a total of 70 posts to be maintained) per month, the lighting to be kept up every night and all night. No wonder the Town Commissioners acted as they did.

IN the case of H. A. Keyser vs. the Mahanoy City (Pa.) Gas Company, tried at Pottsville in the last week of December, a verdict for \$3,000 was awarded the plaintiff. The latter is a hotel keeper, and the basis of his complaint was that his business had been ruined by the offensive odors emanating from defendant's plant. The case will be appealed.

IN our last issue we published an account of certain action by the Newport (R. I.) Sanitary Protective Association in respect to the proposed supply of a mixture of coal and water gas by the Newport Gas Light Company. It may be remembered that a portion of that action was the appointment of the President of the Association as a committee to interview the President of the Gas Company on the exact nature of the gas that was to be supplied by the Company. The inquiry was made, and the reply thereto of Mr. Henry Bull, President of the Company, is as follows:

*Sunday.

"OFFICE NEWPORT GAS LT. COMPANY, }
"NEWPORT, Dec. 24, 1889. }

"Dear Sir: I have your note asking to be informed what percentage of water gas our Company proposes to use as an ingredient of the illuminating gas of this city; and in reply would say. Our primary object in having a water gas plant is to provide additional security against our city being left in the darkness from any serious accident to our works, or from sickness, death or defection of skilled workmen, whose places could not readily be filled. Not that we are specially liable to such contingencies, for our works are second to none of their size in the country, and are provided with every safeguard known in the manufacture and distribution of gas. The additional advantage of a small water gas plant is that it can be fitted up at once to supplement the gas in our holders, on the first indication that the supply is likely to be short. Our secondary object in having a water gas plant is to determine by our own experiments the feasibility of supplying mixed gases, which it is now generally claimed will produce, at the same cost, better light than either kind alone. We are led to do this from the fact that there are now in the United States 367 water gas plants in use, furnishing that gas either as an entirety, or as an ingredient of coal gas, all of which have sprung into use in 14 years. In this State, Woonsocket has put in one recently, and the city of Providence is now erecting one with a capacity of 800,000 cu. ft. daily. In regard to the relative poisonous influence of the two gases, the opinion now prevails among those best informed on the subject, that there is little or no difference between them in this respect, and that neither is deleterious to the public health except through ignorance or carelessness in their use. From these explanations you will see that I cannot now give you a categorical reply to your questions, but in order to allay all apprehensions which your Society may entertain for the safety of gas consumers, I assure you that under no circumstances will this Company send out any gas whose presence in the atmosphere to the extent of 8 per cent. is rapidly fatal to life through its de oxygenating action on the red blood corpuscles, as well as its specific effect on the central nervous system. I am very truly yours, HENRY BULL, President."

THE "City Gas Company, Rochester, N. Y.," has been incorporated by James A. Chapin and Ed. T. Rice, Jr., of New York City, and Samuel Walters, of Jersey City, N. J. Its term of life is put at 50 years, and it is capitalized in \$500,000. Although the avowed objects of the Company "are to manufacture and sell gas, electricity, and other agents for the production of light, heat and power," it is not at present surmised that the project is intended to compete with the artificial gas company of Rochester. It probably had its inception in the recent howl raised against the natural gas suppliers in upper New York for their increased gas rates, and most likely has to do with the supply of the natural article.

IN future the contracts for public lighting by means of arc lamps in Philadelphia are to be based upon the intensity, etc., of the current furnished, instead of on the present estimate of candle power.

IT is presumed that this determination arose from the fact that recent tests for candle power made on arc lamps furnished under contract to the city of Philadelphia proved the illuminating value to be greatly under that bargained for by the city. For instance, the Thomson-Houston lamps (2,000-candle power nominal) had an average value of 1,160 candles, the Brush record being 936 candles. The United States Company's lamps (1,000-candle power nominal) yielded but 479 candles.

THE Newark (N. J.) Gas Company has declared a quarterly dividend of 2½ per cent.

THE Pottstown (Pa.) Gas and Water Company has declared a stock dividend of 25 per cent. The Company will build a new water plant this year.

ABOUT a fortnight ago Senator Butler again introduced the bill offered by him at the last session of the United States Senate to incorporate the Equitable Gas Light and Fuel Company of the District of Columbia. The incorporators named are Messrs. Chas L. Mitchell, Jacob Bertschman, W. A. De Long, Harry Keene, C. D. Harrison, Frederick W. Jones and E. W. Saportas. Capitalized in \$2,000,000.

THE Newton and Watertown (Mass.) Gas Light Company is engaged in experimenting with an electric system for lighting and extinguishing the public lamps.

THE Dover (N. H.) Gas Light Company, having been appointed local agent for the sale of the Welsbach incandescent gas burner, has fitted

up its offices on Portland street with an extensive assortment of the various sizes of the burner noted.

APPLICATION has been made to the Provincial Legislature by certain promoters for a charter for a company to be known as the Montreal Consumers Gas Company. The capital stock is placed at \$3,000,000, with power to increase the same to \$6,000,000. It is understood that English capitalists are behind the scheme. The charter of the present Montreal Gas Company does not expire until 1895, and under its provisions the Company is obliged to make a considerable concession in gas rates, the same to take effect in May of this year.

A SINGULAR accident occurred in the laboratory room of the Lawrence (Mass.) gas works one day last week. Messrs. H. H. Church, of the gas works, C. W. Stevens of the Wright Manufacturing Company, and G. S. Stevens, of the Atlantic Mills, were examining the various chemical apparatus in the laboratory when a bottle containing ammonia burst, the liquid causing severe burns to two of the party.

It is said that an opposition gas enterprise has been organized for Owego, N. Y., the plant for which is to be located on the site of the old flour mills, in what is known as the Canawanna district. The Company is to be known as the Citizens Gas Company, and its Directors are: Messrs. W. E. Dorwin, W. L. Haskins, C. O. Thompson, E. T. Stone, W. E. Mayor, D. W. Pitcher and Geo. F. Andrews, of Owego, and Geo. F. Lyons and W. G. Phelps, of Binghamton.

THE bids for the lighting of Boston by means of arc lamps have been rejected, and new specifications have been arranged for.

A RECENT issue of the Los Angeles (Cal.) *Tribune* contained the following: "The Los Angeles Lighting Company has purchased the plant of the Lowe Gas Company, and this transfer of property has led to complications likely to be settled in the courts. It is said the new company refuses to recognize the contracts entered into by its predecessor, and claims the right to fix its rates irrespective of any agreement entered into by the Lowe Gas Company. In pursuance of this policy a collector of the Company called on H. J. A. Stuhr, a wholesale liquor dealer on West First street, and presented a bill at the usual rates. This Mr. Stuhr said he did not feel compelled to pay, as by the terms of an unexpired contract with the Lowe Gas Company he has heretofore received a rebate payable in shares of the company. A day or two thereafter a plumber called at Stuhr's warehouse, saying that he had come from the Los Angeles Lighting Company to remove the meter. Stuhr objected to this summary method of settling the dispute and ordered the plumber from the premises. Going at once to the police station the plumber laid the case before the department, and an officer was detailed to protect him from harm. Reinforced by an additional helper from the Company's office the three repaired to Mr. Stuhr's store, No papers nor authority of any kind were shown by the officer, except his star, which Mr. Stuhr said he regarded as scarcely sufficient in the replevin of property or the violation of a contract for lighting his premises. He submitted, however, upon pain of arrest, to the removal of the meter, but will institute suit to determine what right the Company had to act in the manner described."

THE Queen City Electric Light Company, of Dallas, Texas, is engaged on the construction of its central station.

It is reported that the Board of Trustees of Saratoga Springs, N. Y., have granted a franchise for the operation of an opposition gas and electric light plant in that place. The capital stock of the new concern is put at \$100,000, and as the capital of the old Company is \$300,000, the Trustees, by their injudicious action, have placed the gas consumers under obligation to pay interest on an additional 33 per cent. of capital investment. Now is the time for cheering over opposition, but the result is sure to furnish a season of howling about consolidation.

SHORTLY before Christmas the Hartford *Daily Times* notified the residents that "Gift No. 5" on its Christmas tree consisted of a box of wax candles, which were intended for the Gas Company, "to help it out on dark nights." Taking the "funny man" at his word, Mr. Harbison visited the *Times* office on Christmas morning and demanded that "Gift No. 5" be given him. He got the candles.

THE water gas plant for the Hutchinson (Kas.) Gas Light and Fuel Company will soon be in working order.

GAS was turned into the mains of the new gas works at Aberdeen, South Dakota, on the evening of December 20th. Supt. Gray is to be

congratulated on the celerity with which construction work was pushed at this point.

THE rumor is current in Pittsburgh that the Philadelphia (natural gas) Company is shortly to put a new contract schedule in force that will show a large increase over the rates for 1889.

Recent Patent Issues.

The following list of recent patents relating to the gas interests is specially reported by Franklin H. Hough, solicitor of American and foreign patents, 925 F street, N. W., Washington, D. C.

ISSUE OF DECEMBER 3, 1889.

- 416,520. Gas, Apparatus for Manufacturing of. R. R. Turner, Columbus, O.
- 416,609. Gas Apparatus, Oil. A. Henning, Oakland, Cal.
- 416,624. Gas Burner for Incandescent Illumination. A. C. Humphreys, Philadelphia, Pa.
- 416,649. Gas Engine. C. Sintz, Springfield, O.
- 416,216. Gas Governor. F. Ellis, San Francisco, Cal.
- 416,635. Gas Lighting System. A. Lungren, New York, N. Y.

- ISSUE OF DECEMBER 10, 1889.

- 416,776. Apparatus for Mixing Gas and Air. E. B. Denny, Newark, N. J.
- 416,825. Apparatus for Manufacturing Gas. T. J. Close, Philadelphia, Pa.
- 416,986. Gas Burner, Coal Oil. L. J. W. Bairn, Chicago, Ills.
- 417,101. Gas Burner, Safety Attachment. M. Siersdorfer, Louisville, Ky.
- 416,979. Gas Burner, Safety Attachment. R. P. Williams, Boise City, Idaho.
- 416,707. Gas Burner, Self-Lighting. E. S. Allen, New York, N. Y.
- 416,753. Gas Furnace, Regenerative. C. M. Ryder, New York, N. Y.
- 416,722. Gas Governor and Pressure Regulator. N. J. Ryder, Washington, D. C.
- 416,895. Gas Light Safety Catch. J. D. Bowman, Altoona, Pa.
- 417,075. Gas Lighter, Electric. N. Newman, Springfield, Ills.
- 417,198. Gas Lighter, Electric. N. Newman, Springfield, Ills.
- 417,134, 417,135 and 417,136. Gas Pressure Regulators. H. J. Bell, Gloucester City, N. J.

ISSUE OF DECEMBER 17, 1889.

- 417,431. Gas, Apparatus for Manufacturing of. J. Schinneller, Pittsburgh, Pa.
- 417,526. Gas Burner, Incandescent. J. L. Stewart, Philadelphia, Pa.
- 417,471. Gas Engine. W. E. Crist, Brooklyn, N. Y.
- 417,472. Gas Engine Igniter. W. E. Crist, Brooklyn, N. Y.
- 417,624. Gas Engines, Operating. J. C. Beckfield, Allegheny, Pa.
- 417,658. Gas for Heating and Illuminating Purposes, Apparatus for Manufacturing of. B. T. Babbitt, New York, N. Y.

ISSUE OF DECEMBER 24, 1889.

- 418,016. Gas, Apparatus for Manufacturing Illuminating and Heating. J. Hanlon, New York, N. Y.
- 418,018. Gas, Apparatus for Manufacturing of. J. Hanlon, New York, N. Y.
- 418,017. Gas, Apparatus for Manufacturing of Illuminating. J. Hanlon, New York, N. Y.
- 417,719. Gas Burner, Automatic Safety. N. M. Garland, St. Louis, Mo.
- 417,765. Gas Burner, Open. G. E. Wright, Birmingham, England.
- 417,924. Gas Engines, Automatic Ignition in. E. Korting, Hanover, Prussia.

ISSUE OF DECEMBER 31, 1889.

- 418,270. Gas and Electric Light Fixture Combined. D. J. Braun, Chicago, Ills.
- 418,550. Apparatus for Manufacture of Gas. M. C. Burt, Lake View, Ills.
- 418,615. Apparatus for the Manufacture of Gas. J. Hanlon, New York, N. Y.
- 418,647, 418,648, and 418,649. Apparatus for Manufacture of Gas. P. W. McKensie, New York, N. Y.
- 418,551. Apparatus for Manufacture of Gas by Electricity. M. C. Burt, Lake View, Ills.
- 418,417, 418,418, and 418,419. Gas Engine Igniter. L. H. Nash, South Norwalk, Conn.
- 418,314. Gas Retort Furnace, Regenerative. W. Foulis, Glasgow, Scotland.

A. M. CALLENDER & CO.,

PROPRIETORS.

EDITOR—Jos. R. Thomas, C.E.

ASST. EDITOR—T. J. Cunningham.

MANAGER—C. E. Sanderson.

PUBLISHED ON EACH MONDAY OF THE YEAR AT

No. 42 Pine Street, New York.

This is a recognized official organ of LIGHT, HEAT, STEAM, WATER SUPPLY, VENTILATION, SANITARY IMPROVEMENT, AND GENERAL SCIENCE

TERMS:

SUBSCRIPTION—Three Dollars per annum, in advance. Single copies, 10 cents.

AGENTS.

NEW YORK.—AMERICAN NEWS CO., 39 and 41 Chambers Street. PHILADELPHIA.—PRATT & CO., Corner Ninth and Arch Streets. Germany.—B. WESTERMANN & CO., of New York.

MONDAY, JANUARY 6, 1890.

Gas Stocks.

Quotations by Geo. W. Close, Broker and Dealer in Gas Stocks.

16 WALL ST., NEW YORK CITY.

JANUARY 6.

All communications will receive particular attention. The following quotations are based on the par value of \$100 per share.

Table of Gas Stocks with columns for Company Name, Capital, Par, Bid, and Asked prices.

Out of Town Gas Companies.

Table listing Boston United Gas Co. and its various series with prices.

Table of Bay State Gas Co. and other companies with columns for Stock, Income Bonds, and various financial metrics.

Advertisers Index.

Table listing various companies under categories like GAS ENGINEERS, GAS AND WATER PIPES, GAS WORKS APPARATUS AND CONSTRUCTION, etc.

Table listing various industrial processes and equipment under categories like PROCESSES, INCLINED RETORTS, GASHOLDER TANKS, etc.

WANTED,

A Superintendent for Gas and Electric Light Plant,

At Washington, Daviess County, Ind. Call at this Office for particulars.

SITUATION WANTED

As Inspector,

By man of experience, who understands stove work and the various lamps and burners, and all kinds of street work. Address "INSPECTOR," 760-2 Care this Journal.

Position Wanted

As Superintendent or Assistant of a Gas Works, By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address 758-3 "C.," care this Journal.

FOR SALE,

Otto Gas Engine, 15-Horse Power,

With Counter Shafting, Belting, etc. Completely fitted for running electric lights. Used only 10 days; satisfactory reasons for selling. Address 761-2t "C. B.," Post Office Box 5104, Boston, Mass.

WANTED,

A Six-Inch Exhauster and a Six-Inch Governor,

Both in good order; second-hand. State price. 761-1 GAS COMPANY, care this Journal.

FOR SALE,

All the Appliances Necessary for the Passing of 100,000 Cubic Feet of Coal Gas per Day.

Now in operation at Stamford, Conn. Reason of sale, incapacity of present plant. For further information address 759-4 STAMFORD GAS LT. CO., Stamford, Conn.

FOR SALE.

A Complete Water Gas Plant. 60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL Interior California Coal Gas Plants, now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

SECRETARY, 123 Beale Street, 760-1f San Francisco, Cal.

6 PER CENT.

First Mortgage Bonds

ON GAS WORKS

SITUATED IN GROWING WESTERN TOWNS.

Principal and Interest Guaranteed.

INTEREST SEMI-ANNUALLY.

For sale by the undersigned, who will furnish all necessary information regarding them.

JOS. R. THOMAS, 42 Pine St., N. Y. City.

Fuel and Its Applications.

By E. J. MILLS, D.Sc. F.R.S., and F. J. ROWAN, C.E., assisted by others, including Mr. F. P. Dewey, of the Smithsonian Inst., Wash., D. C.

7 PLATES, AND 607 OTHER ILLUSTRATIONS. ROYAL OCTAVO, PAGES XX, 802. HANDSOME CLOTH, \$7.50.

A. M. CALLENDER & CO., 42 Pine St., N. Y.

PATENTS.

FRANKLIN H. HOUGH

Solicitor of American & Foreign Patents.

925 F. ST., WASHINGTON, D. C.

(NEAR U. S. PATENT OFFICE.)

Personal attention given to the preparation and prosecution of applications for Letters Patent. All business before the U. S. Patent Office attended to for moderate fees. **No Agency in the United States possesses superior facilities for obtaining Patents,** or for ascertaining the patentability of inventions. Copies of patents furnished for 25 cents each. Correspondence solicited.

PHILADELPHIA.

STEPHEN A. MORSE, President.
GODFREY REBMANN, Vice-Pres.

NEW YORK.

EDWIN F. MORSE, Secretary.
CARLTON M. WILLIAMS, Treas.

CHICAGO.

STANDARD GAS LAMP CO.,

Main Office, 411 Cherry St. Factory, 1101, 1103, 1105 Frankford Av. PHILADELPHIA, PA.

It is to the interest of Gas Companies and Cities to double the efficiency of the light on streets by using Dyott's Patent "CHAMPION" LAMPS. They save 50 per cent. over others in cost of repairs, are ornamental, and indestructible except by violence.

Our Patent System of Instantaneously Lighting Gas (without electricity), for Railroad Depots is unequalled. Dyott's High Candle Power Burner is a very superior lamp where a concentrated and brilliant light is wanted in Hotels, Stores, Depots, etc.

Special Drawings furnished and Estimates cheerfully given, either from Architects', Engineers', or our Draughtmen's Plans. We manufacture every description of Plain and Ornamental Lamps, Posts, Brackets, Clusters, etc. Correspondence solicited.

Simpkin & Hillyer

RICHMOND, VA.

MANUFACTURERS OF

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

C. & W. WALKER'S PAT. PURIFYING MACHINE.

TAKING ALL THE WORK FROM THE OUTLET OF THE CONDENSER TO THE INLET OF THE PURIFIERS.

Patented in Great Britain and Ireland, Australia, France Germany, Italy, and the United States.

These Four Machines Purify 12 Millions per Day, and only occupy a Ground Space of 60 ft. by 12 ft., and are 23 ft. 6 in. High.

Four of these powerful Machines for the new extensions at the Beckton Gas Works, London, are now working, purifying Twelve Million Cubic Feet of Gas per day, each Machine taking Three Millions per day.

These Machines can be seen at Beckton, where, after being long and abundantly tried, tested, and proved in every variety of working, have been accepted by the Gas Light and Coke Company, of London, as superior to all other apparatus for taking all the work of the purification of gas between the Condensers and the Purifiers.

The Machine is the most important improvement effected in gas works for years past. The purifying power developed is most remarkable. We send an Engineer with a working model to any Gas Company inviting information. It is equally adapted to gas works of any size.

DESCRIPTION.

The gas enters into the washing chamber at the lowermost part, where it is first subjected to a thorough washing in the strong Ammoniacal Liquor. The washing is most effective. The entire surface of the Ammoniacal Liquor is in a bubbling state of ebullition, presenting an

agitated, frothy surface all over. All the Tar left in the gas after surface condensation is here completely extracted, and a large amount of Carbonic Acid.

The gas, thus so far purified, ascends from the washing chamber and passes from one superposed chamber to another in contact with the enormous amount of movable, constantly dipping wetted surfaces, leaving the uppermost chamber entirely purified from Ammonia, meeting the chemical requirements of the Board of Trade.

The Machine is self-cleansing, and can never choke or stop up; and in this important respect it is superior to all Machines heretofore known. The space occupied by the Machine is very small. In most cases it can be placed in the space inside the end of the Purifying House. Its cost is less than any other known apparatus for purifying gas from Tar and Ammonia.

These Machines are at work and in hand for Widnes, Burnley, and Oswaldtwistle, in Lancashire; at Harrogate and Wakefield, in Yorkshire; at Salford, in Cheshire; at Stone, in Staffordshire; also at Cheltenham and Northampton, also at Melbourne, in Australia.

Apply, until American Agency is appointed, to

Office, Room 55, Mason Building, 70 Kilby Street. Boston

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

“The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 24-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers.”

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3 ft. square,	5 ft. deep.
No. 2,	“	125,000	“	4 “	“
No. 3,	“	250,000	“	5 “	“
No. 4,	“	500,000	“	6 “	“
No. 5,	“	750,000	“	7 “	“
No. 6,	“	1,000,000	“	8 “	“
No. 7,	“	1,250,000	“	9 “	“
No. 8,	“	1,500,000	“	10 “	“
No. 9,	“	2,000,000	“	12 “	“
No. 10,	“	3,000,000	“	15 “	“

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

SMITH & SAYRE MFG. CO.,
No. 245 Broadway, - - - New York City.

Brenner Self-Sealing Retort Door.

WILLIAM B. LUNDIE, Superintendent of the 42d Street Station of the Consolidated Gas Company, of New York, writes, under date of Jan. 4, 1889:

"We have 320 Brenner Self-Sealing Lids in use at this Station, built by the Smith & Sayre Mfg. Co. They require very little attention, and are the best of the kind that I have seen, giving entire satisfaction."

GREENOUGH'S
"DIGEST OF GAS LAW."
 Price, \$5.00.

This is a valuable and important work, a copy of which should be in the possession of every gas company in the country, whether large or small. As a book of reference it will be found invaluable. It is the only work of the kind which has ever been published in this country, and is most complete. Handsomely bound. Orders may be sent to

A. M. CALLENDER & CO.,
42 Pine Street, N. Y.

GAS vs. ELECTRIC LIGHT.

We would invite attention to the able and exhaustive argument of General A. Hickenlooper, President of the Cincinnati Gas Light and Coke Company, contained in a handsome pamphlet of 96 pages, entitled "EDISON'S INCANDESCENT ELECTRIC LIGHTS FOR STREET ILLUMINATION. REPORT OF AN ARGUMENT DELIVERED BY A. HICKENLOOPER BEFORE THE COMMITTEE ON LIGHT, MUNICIPAL COUNCIL, CITY OF CINCINNATI, JULY 22, 1886."

This is a subject of special interest to all Gas Light Companies.

Prices.

25 copies.....	\$7.50	100 copies.....	\$22.50
50 copies.....	12.50	250 copies.....	50.00

A sample copy will be sent by mail on receipt of 50 cts. **A. M. CALLENDER, & CO., 42 PINE ST., N. Y. CITY.**

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's
OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,
OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
37 in. high. 20 in. wide.	12 in. high. 17½ in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	36 in.

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
31 in. high. 17 in. wide.	9½ in. high. 14½ in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 16 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loosering which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 3 inches high. Consumption, 6 cubic feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. ½ in. supply pipe should be used where the pressure is 1 in. or over.

[OFFICIAL NOTICE.]

New England Association of Gas Engineers.

SECRETARY'S OFFICE, BIRMINGHAM, CONN., Jan. 10, 1890.

The Twentieth Annual Meeting of the New England Association of Gas Engineers will be held at Young's Hotel, Boston, on Wednesday and Thursday, Feb. 19th and 20th. The meeting will be called to order on Wednesday, at 10 A. M., by the President, Mr. R. B. Taber.

At the present moment it is impossible to give a list of the papers which will be read at the meeting, but it is hoped that the literary part of the programme will equal any of those held in past years.

Persons eligible for membership who desire to join the Association will please communicate with the Secretary, who will forward at once blank form of application.

CHARLES H. NETTLETON, Sec'y.

BRIEFLY TOLD.

GAS STOCKS AS INVESTMENTS.—Following up our remarks of a week ago on the satisfactory increase in the gas business as shown from the records of the last twelvemonth, it is our present purpose to offer something further in confirmation of the fact that gas proprietors and gas makers share equally in the comfortable assurance that not only is their

joint dependence holding its own against all comers, but is again outstripping them, as in the days of about a decade ago. In the course of the past year we have collated from various reliable sources the opening and closing prices of gas shares at 87 different points in the country; and we think the result of the teaching disclosed by the figures is most convincing as to the upward tendency of this class of securities. The figures were obtained from places representative of all grades in respect to varying magnitude. That is, the Consolidated Company of this city, with its \$35,430,000 of capital, shares in the average with a small company in Illinois with a capital of less than \$20,000. The total capital figuring in the average is 62 millions of dollars. Of the 87 places noted a decrease in the value of the shares is found to have occurred in 5 instances—the average shrinkage being represented by 12½ points—while an increase, ranging from 2½ points to 35 points, is the result at the remaining localities about which inquiry was made. Spreading the averages over the entire value of the 62 millions, we find that the net average gain for the year (all these deductions are based on the market changes, on the "high and low" quotations for the year) was 11½ per cent., representing an increase in value for the twelvemonth of the snug sum of \$7,285,000. The average rate of dividend of these companies—excluding the Consolidated Company of this city, but admitting in the average 3 companies that did not pay any dividend—is shown to be 7.75 per cent. The dividend paid by the Consolidated Company for the year was 5 per cent., as against the 4 per cent. return made by it in 1888. The returns received go to show that Massachusetts gas shares are those which increase in value in the greatest relative proportion, and we may be forgiven for hinting that the method of State protection there followed is in no small degree responsible for the confidence manifested by investors. We would like to have it in our power to place before our readers these statistics in unmasked form, but as it was with our inquiries for sendout figures, so also was it with the request for the market valuation of shares—"the facts are so and so, but do not handle them so that our identity may be revealed." In any event, the figures, even though somewhat obscured, are nevertheless of a sort well calculated to dissipate any cloudy idea that gas shares do not continue to find favor with investors who value safety and progress as factors to determine them in the interest-earning disposition of their funds.

AN OLD-NEW FIRM.—It is probably no very great secret by this time that the Smith & Sayre Manufacturing Company has ceased to be, and that gas men are called to welcome its successor in the shape of the Isbell-Porter Company. Of course, the implied change is in reality no change at all, for both Messrs. Porter and Isbell have been the Smith & Sayre Company for years, and it is quite a certainty that they shall continue so for years to come. No change whatever is to be or has been made in the business of the firm, whose headquarters, as before, are to be at 245 Broadway, this city. We might, however, modify our statement in respect to the "no change whatever" clause by adding the qualifier that important changes are to be made on the Newark (N. J.) factories of the firm, which are to be greatly enlarged. This action had to be taken to enable the Company to keep easy pace between the reception and completion of contracts. The Company reports that the business outlook for 1890 is of the brightest sort.

THE METER COMPANY ANNUALS.—We are in receipt of copies of the annuals published by the Messrs. Helme & McIlhenny, of Philadelphia, the American Meter Company, and D. McDonald & Company, of Albany. We thought (and so said) last year that the meter men had about reached perfection in the arrangement and printing of their annuals, but that we were in error is easily discovered by a glance at the editions for this year. The lighting tables are as usual a feature of the books, and the supplementary pages are charts of information at once valuable and prettily arranged. The American Company's designer has brought out something novel in the way of a cover this year. The Helme & McIlhenny volume is notable for the fact that apart from its convenient pocket shape, it contains but $6\frac{1}{2}$ sheets devoted to advertising—this feature is not very prominent in any of the annuals now before us—and the McDonald specimen is notable particularly for the nice discrimination shown in editing the technical matter with which its pages abound. In their entirety the annuals are models of neatness, and there is little doubt that they will be eagerly sought for. Another thing in connection with the current editions that cannot help to attract the attention of the "old-timer" is the great disparity in their appearance when compared with the original volumes of some years ago. Of course, the difference is all in favor of the annual of to-day.

THE Parker-Russell Mining and Manufacturing Company, of St Louis, Mo., has been again awarded the annual contract for repairs and renewals to benchwork in both plants of the Cincinnati Gas Light and Coke Company.

ANNUAL MEETING, LEBANON, PA.—At the annual meeting of the Lebanon (Pa.) Gas Company (two-thirds of the stock being voted on) the following officers were chosen: President, Col. T. T. Worth; Secretary and Treasurer, John W. Mish; Managers, Messrs Anthony Aurentz, C. H. Killinger, Chas. H. Meily, J. W. Mish, Geo. H. Reinohel, Grant Wiedman and Col. T. T. Worth. The regular semi-annual dividend of 4 per cent. was declared, but the Managers failed to order a reduction in the gas rate, which it was presumed had been fully provided for. The average rate obtained for gas in Lebanon is \$2.35 per 1,000 cubic feet, but it is quite likely, however, that a considerable concession will be made in the year. Large plant extensions were completed last year, these including a holder of 30,000 cubic feet capacity, the iron work for which was furnished by Messrs. Deily & Fowler, and the excavation and tank work by Mr. W. C. Whyte, of New York. Both contractors finished their tasks in their usual manner. An interesting thing in connection with the executive management of this Company is afforded in the case of Secretary and Treasurer Mish, who has acted in that capacity since 1856, the year in which the Company was incorporated. Of the 15 persons named in the original papers of incorporation but five are living, and only two of these are at present holders of the stock.

THE Poughkeepsie (N. Y.) Gas Company will this spring put up an auxiliary holder on the site of the Laurel street plant. As an evidence that cheap gas for cooking, heating and power purposes pays (the Poughkeepsie rate for these purposes is \$1 per 1,000) we may note that the Company now has in position 200 cooking and heating stoves, and the average monthly consumption chargeable to this use is rather over than under 250,000 cubic feet.

It seems that the Brush Electric Light Company, of Cincinnati, O., is in the position of the youth who filled his mouth without paying due heed to the capacity of the same. In its eagerness to secure the contract for the public lighting it bid the remarkable rate of \$59.98 per lamp per annum, the schedule calling for all-night lighting and 2,000-candle power. We think the Company is hesitating in the breach, simply because at the figures noted it must lose money on every lamp that it would maintain. It is said that the "Parent Company," which it is presumed in this case is the Thomson-Houston Company, of Boston, objects to completing the contract for the simple reason that there "is no money in it." In any event, the Company is not taking any steps to get ready for the work.

At the annual meeting of the Fresno (Cal.) Gas and Electric Light Company, the following result was reached: President, Lewis Leach; Vice-President, F. G. Berry; Secretary, F. C. White; Superintendent, Daryille Decker; Assistant Superintendent, S. E. Johnson; Directors, Lewis Leach, F. G. Berry, P. P. Dryler, W. W. Phillips and C. M. Berry. Important betterments will be made at Fresno this season.

WE understand that the formation of a Gas Company for Aurora, Neb., is being seriously considered. Aurora is the capital seat of Hamilton county, and is growing rapidly in population and wealth.

THE recent rise in Baltimore Consolidated gas shares is attributed by some to the likelihood that the City Council will pass an ordinance based on the lines of the proposition recently submitted by Mr. Armstrong, whose argument and suggestions will be found in the JOURNAL for December 23, 1889. Perhaps this likelihood may have had some effect in the direction indicated; but the "guessers" should not lose sight of two other factors that would cause a similar result—the greatly increased business of the Company, which now more than ever feels the impulse of good management in all its departments.

THE Supreme Court of the State of Illinois has decided that an accepted franchise constitutes a contract. This finding was made in the case of the Chicago Municipal Gas Light and Fuel Company vs. the Town of Lake, and the salient points of decision are: The revised statutes of Illinois, c. 32, section 5, which authorizes corporations to exercise all powers necessary to carry into effect the objects for which they are formed, does not empower a gas company, incorporated for the purpose of supplying gas to towns, to lay pipes in the streets of a town whose charter gives the town authorities power to control and regulate its streets, without the consent of the town. A town ordinance authorizing a gas company, on condition of its furnishing gas at specified rates, to lay pipes in the streets, is, after it has been accepted by the gas company, a contract and not a revocable license.

WE understand that Mr. Frederic Egner has been appointed Engineer-in-Chief of the Laclede Gas Company, which means that he is to have charge of the works' end of the gas supply of the city of St. Louis. A superintendent is to be named for each station division of the plant. While not in position to say that the appointment has been officially made, nevertheless our information comes from a source so unlikely to be misinformed that we will venture to extend to him our congratulations on his promotion.

Experiments on the Relation of Electric Lamps to Combustible Bodies.

The Paris Society of Electricians have carried out a series of experiments as to the danger of fire from electric lighting. An experiment was made with a bare wire, placed on a small board, and in part with a second board—a wire which should normally conduct a current of about four amperes—and the current was carried up to 40 amperes without the wood commencing to carbonize. For a current much more intense the wood took fire at the part where the wire is uncovered before burning the other part, where the want of air made inflammation slower. It is known that these accidents are avoided in a very efficacious manner in practice by the use of fusible plugs. In order to determine to what extent the lamps themselves were capable of setting fire to strips and combustible bodies placed in their vicinity, the globe of an ordinary arc lamp of the Canse system was enveloped in several thicknesses of green tarlatan; a 32 candle incandescent lamp was enveloped in the same way, the folds of the material being joined under the lamp by an india rubber band; a lamp of 33 candles was covered with a cotton cap of double thickness; another was covered with a calotte of black silk, which was in its turn covered with another of black velvet; two lamps were covered with two layers of gummed wadding, white in one case and black in the other; a lamp of 32 candles was placed in vertical fold formed by an old theatrical decoration; and lastly, a lamp of 300 candles was applied against an old decoration. It was found that neither carbonization nor exaggerated heating took place in 20 minutes in the first, second, fifth or seventh experiment; at the end of a minute and a half the material in the eighth case carbonized at contact with the glass and began to burn without flame; at the end of two minutes, after melting and carbonization of the layers of wadding, the lamps in experiment sixth burst in, setting fire to the envelope; in about six minutes the velvet calotte was carbonized and began to burn slowly; at the end of ten minutes the cotton cap was partly carbonized at the points of contact, but combustion had not been commenced.

The Market for Gas Securities.

THE market for city gas shares was buoyant during the week, and the investment demand was a feature of the purchasing. No doubt the December and January interest and dividends are finding their way into permanent investments. Consolidated sold to-day (Friday, noon) at 95½, and it is worthy of note that this is the highest figure touched since 1887. Other city shares also joined in the upward movement. All classes of Brooklyn stocks are strong and higher. Chicago Trusts are steady at 44¼ to 44¾; and Baltimore Consolidated is up to 49¾ to 50. The Poughkeepsie (N. Y.) Company has increased its capital stock from \$84,000 to \$100,000. The shares of this Company are freely bid for at 120, with no offerings.

The Chemistry of Illuminating Gas.

Article XXXV., in the well written series on this subject, as contributed by Mr. Norton H. Humplrys to the *London Journal*, is as follows:

An important paper on the manufacture of illuminating gas from paraffine oil was read before the Royal Scottish Society of Arts, by Dr. Stevenson Macadam, in 1882. He stated that for several years past his attention had been repeatedly drawn to the subject of the production of gas of a permanent quality from these oils. At the commencement, the experiments were not very satisfactory, owing to the varying quality of the oil; but later on, by working with special kinds of oil which had to some extent undergone purification, and by paying attention to the question of the temperatures at which these oils were subjected to destructive distillation, he obtained reliable results. He had employed the crude oil which first came over in the distillation of shale for the purpose of making permanent gas, and had also taken it as a sort of standard as to the quality of the gas obtained from the other oils. If the crude oil was distilled and the volatile spirit removed from the distillate, green oil was obtained; and this, when rectified by the employment of acids and alkalis, so as to remove the tar bases, and treated for burning oil, intermediate oil, and solid paraffine, yielded a residue known as blue oil. An extremely volatile spirit known as gasoline was extracted from the first distillate of crude oil; but it was so combustible and explosive as to be unsuitable for the preparation of gas. An oil suitable for gas making should be thin enough to run readily into the retort at ordinary temperatures; and regard should be had to the specific gravity, and to the flashing and firing points. As to the method of working, he kept the retort at a cherry red heat, for which purpose some little skill was necessary, just as with a coal gas retort. The oil was supplied to the retort from a suitable reservoir through a long syphon tube, so as to prevent the gas being driven back, and the supply of oil could be easily regulated. Working in this manner no difficulty arose. The retorts kept wonderfully clean, and after working one for a whole day there would only be a little deposit of soot. He obtained the following practical results:

	Crude oil.	Green oil.	Blue oil.
Cubic feet of gas per gallon,	98.7	102.5	127.4
“ “ “ ton.	26,026	25,977	32,492
Candle power of 5 cu. ft.	50.4	53.2	54.3

About 80 per cent. of the quantity of light that would be obtained by burning the oil in lamps of the best construction was represented by these quantities of gas; and the cost of a ton of crude oil was £4 18s. 10d., or something less than 4s. per 1,000 cubic feet of 50-candle gas. The crude oil has the disadvantage of a low flashing point—92° Fahr. The green oil, having had the more volatile constituents extracted, was better. It flashed at 165° Fahr., and fired at 193° Fahr. It could be obtained for 7d. per gallon, or £7 9s. per ton. The blue oil was heavy, but fluid at ordinary temperatures, and, of course, more expensive. Dr. Macadam had also worked with a number of other oils, but had not obtained satisfactory results either in regard to quality or quantity. The heavier oils obtained by the destructive distillation of coal were included in this category. The best result obtained from them was 95 cubic feet of 42 candle gas per gallon, or 25,000 cubic feet per ton. The manufacture of oil gas was much simpler than that of coal gas. No scrubbers or purifiers were needed. The gas was simply passed through the condensers, where a little tar separated, and then it was conveyed to the gas-holders, and was quite permanent.

In a communication to the *Journal*, a year or two later, Mr. Ivison Macadam mentions the important fact that gas made from “crude oil as obtained from shale, or semi-refined varieties, such as the so-called “blue or green oil,” is much contaminated with sulphur and ammonia compounds, and with carbonic anhydride. It may here be remarked that there is considerable divergence on this point. As just noticed, Dr. Stevenson Macadam infers that the oil gas needs no purification. As a matter of fact it is usual to subject oil gas, in practice, to the action of a scrubber and a lime purifier, even when secondary products are used; so we may safely infer that this would be indispensable in the case of crude oil or crude petroleum. If the gas is to be used for buoys, railway trains, etc., the impurities may remain; but he considers it necessary that they should be removed if the gas is to be distributed in the ordinary way. He therefore suggests the employment of purer oils as a means of avoiding the expense of purification. He then describes the apparatus patented by Mr. Paterson, which simply consists of a number of tubes carried through the lid of an ordinary horizontal retort, nearly to the back end. The fluid is fed into these tubes and is vaporized as it passes along them. The vapor in the course of its return journey from the back to the front of the retort, is converted into permanent gas. The conversion is not complete, as a quantity of oil is deposited in the con-

densers, and it is so far charged with soot that it cannot be used again. But the results are very satisfactory; 100 cubic feet of 60-candle gas being readily obtained from ordinary burning oil. In this gas there are about 36 per cent. of olefines condensable by bromine; and the carbonic anhydride does not exceed 1.4 per cent. The proportion of this impurity would, however, depend upon the quality of the oil used. Reckoning the oil at 6d. per gallon, and the manufacturing charges at 1s., the cost of 1,000 cubic feet of oil gas would be 6s. But in comparing this with ordinary coal gas the quality must be considered. Bulk for bulk, the oil gas would be dearer; but when the 60 candle oil gas is compared with 16 or 20-candle coal gas it is much cheaper, light for light.

At a later period this gentleman read a paper before the Glasgow and Scottish Section of the Society of Chemical Industry, comprising a description of practical tests conducted upon several kinds of oil obtained in the Scottish shale industry, and one test of ordinary American petroleum. The results obtained are considerably higher than those already indicated, which may be due to improved apparatus, and also to the use of a burner suited to the consumption of these high quality gases at the photometer. In the course of the discussion which followed the reading of the paper, Dr. Wallace asked if the author had tried ordinary crude oil from blast furnace tar. A trial of this substance made by himself did not afford very promising results. It gave a large proportion of tar in the condenser, about one-third of the whole, and exhibited a tendency to choke up the pipes and to deposit carbon in the retorts. This oil was very cheap, and if it could be conveniently applied, it might well be used in conjunction with common coal as a means of producing gas equal to cannel gas—say, 22 to 26-candle power.

This subject was daily increasing in importance, because the cannel coal fields, particularly those of the better class, were being rapidly worked out, and some gas suppliers had even thought of reducing the quality of their gas, in view of the difficulties that might be experienced in the obtaining of supplies of first-class or even second-class coal. Mr. W. Foulis criticised the Paterson apparatus. He thought the small tubes would be likely to get choked, and that, being fixtures, they would interfere with the removal from the retort of the carbon that would undoubtedly accumulate. He also suggested the use of a jet of steam in conjunction with the oil. A simple apparatus on this principle was used in America in ordinary retorts, and, being attached to the lids, it could be taken away or brought into use, as might be desired, in a few minutes. It consisted of a tube attached to the mouthpiece and extending nearly to the back of the retort. Inside it was an inner tube, into which the oil was blown by a jet of steam. Escaping from this, the vapor and steam passed down the outer tube to the back of the retort, and were converted into permanent gas in coming forward to the ascension pipe. Professor Mills asked how long the retort would run without cleaning, and also as to the quantity of fuel required to maintain the high temperature at which it was worked. Mr. Macadam said he had not obtained satisfactory results, or figures of any practical value, with blast furnace tar; and he did not think the Paterson apparatus would give good results with such oils. The rectified coal oil used in his experiments was obtained from ordinary coke ovens. Though the tubes in the retort might at first sight appear an objection to a practical man, he had worked with them for some months without choking; and the apparatus had been in the hands of ordinary workmen, in no way specially skilled. The tubes were attached to the door of the retort, and could be removed with it; so they could scarcely be regarded as fixtures. It was seldom that cleaning was required, but when necessary it could very easily be done. He had made some experiments with the use of a jet of steam, and would bring forward his results on some future occasion. The gas had been rigorously experimented upon in regard to permanency, and proved to be quite as permanent as the coal gas supplied in Edinburgh. Although the tar contained a large proportion of naphthaline, it must be remembered that the proportion of tar was small; and he could not say if there was much naphthaline in the gas. He could not at the moment give the cost of the gas.

The preceding, together with some other matter relative to the subject of gas making from oil, invoked an editorial article in the *Journal* presenting other phases of the matter which should not be passed unnoticed. While admitting that experiments of this kind are deserving of every encouragement, as it is impossible to learn too much about the gas-making properties of mineral oils, especially as throwing a side light on some of the obscurities of coal gas manufacture and purification, it was submitted that there is a wide chasm to be bridged before the system of oil gas making can be worked in practice on a large scale. Professor Macadam's results were obtained from iron retorts worked at moderate heats; and there seemed to be a general idea that these liquid hydrocarbons needed only a moderate heat to gasify them, and

further, that this heat should be applied by degrees, so as first to convert the oil into vapor, and then to "fix" the vapor as a permanent gas. The experience of gas engineers who had had occasion to carbonize oil in ordinary gas works did not agree with this, as they found that the hottest clay retorts were best for the purpose. The residual deposit of carbon was the *crux* of oil gas making. Professor Macadam admitted that at least three-eighths of the burning oil remained in forms other than gas; and it might be assumed that carbon accounted for a considerable portion of the loss. The carbon deposit troubled the early American carbonizers of oil, and finally convinced them that they were working on the wrong principle. As soon as the oil met the heated surface, the more volatile portion passed off as vapor. The "fixing" of this vapor was attended with some formation of carbon, which was deposited in the retort. The liquid that remained was found to be heavier, richer in carbon, more difficult to gasify, and left a considerable deposit of carbon. So the result was a rapid accumulation of carbon, especially where the liquid entered the retort, but also upon all parts of the heated surface. In the iron retort comparatively little deposit would be formed at first, but as it deposited it would form a coating on the interior surface of the retort, like boiler scale, which would reduce the temperature to which the fluid was exposed. After a time the foul retort would not give more than half as much gas as was obtained at the commencement.

Many attempts had been made to get over this deposit of carbon—such as filling the retort with thin sheet or scrap iron; but the fact remains as one of the gravest evidences against mineral oil gas, that the direct carbonization of oil from gas has been abandoned in the United States after repeated trials. These attempts had discovered that the two principles that the oil must be gasified at the highest possible temperature, and that contact of the fluid with the interior surface of the retort should be avoided as far as possible. This might be accomplished by injecting the charge in a spray sufficiently fine to be gasified by radiant heat before it could touch the sides.

Carburetor for Gas Engines.

U. S. Letters Patent (No. 415,978) were granted on Nov. 26, 1889, to D. S. Reagan, of San Francisco, Cal., for an improved carburetor for gas engines. In describing the same Mr. Regan explains that the details of construction will be readily understood by an examination of the drawings, in which Fig. 1 is a vertical section taken through *aa* of Fig. 3; Fig. 2 is a perspective view of the exterior of the carburetor; Fig. 3 is a horizontal section taken through *dd* of Fig. 1; and Fig. 4 is a view showing the connection of the carburetor with the engine.

The object of the invention is to provide a device for charging atmospheric air with the vapor of a light hydrocarbon liquid, and transmitting this vapor directly to the engine cylinder, within which it is ignited and exploded, so as to propel the piston of the cylinder, said piston acting as a pump during alternate strokes, by which a sufficient quantity of air is drawn into the vacuum produced by the movement of the en-

gine piston to form a single charge for the engine, the carburetor ceasing to act immediately upon the stopping of the engine.

A is the exterior casing of the carburetor, having an extension or chamber *C* in the center of its upper portion. The top of this chamber *C* is covered by a flexible diaphragm *D*, which may be made of any suitable flexible material—as leather or parchment—and which serves by its flexibility to relieve the apparatus from the sudden vacuum which would otherwise be caused by the stroke of the engine piston.

G is a pipe extending from the chamber *C* to the engine cylinder *H*, and through which the carbureted air passes to the engine, being drawn

Fig. 3.

Fig. 4.

in at *E* by the vacuum caused by the forward movement of the piston when the valve is open.

The carburetor proper consists of a vertically arranged spiral partition *B B*, extending from the top of the casing *A* down to a point near the bottom, leaving a small space beneath the lower edges of the convolutions of the spiral, through which the liquid contained in the carburetor may pass freely and be constantly maintained at an even saturation throughout the apparatus. The liquid is introduced into the chamber through a filling nozzle, as shown at *F*, and is maintained at a sufficient depth to fill from one-half to two-thirds of the chamber.

E is a pipe extending into the top of the chamber *A*, and having its lower end very near the bottom of the chamber and beneath the surface of the liquid. This pipe is placed at the outer end of the spiral, and when the engine is in motion air will be drawn into the carburetor through this pipe by the stroke of the engine piston. This air being delivered beneath the surface of the liquid causes a considerable agitation, and by its ebullition through the liquid it becomes charged with the vapor, while its passage over the surface of the agitated liquid, following the channels made by the spiral, will complete its saturation, so that when it has reached the center, where it is delivered upward into the chamber or extension *C*, it is sufficiently saturated for the purposes of the engine. At each stroke of the piston, when the valve is open to allow the cylinder to receive a charge, vapor is drawn into the cylinder from the chamber *C*, and a corresponding amount of air is drawn through the pipe *E* into the carburetor, the chamber *C* being thus supplied with successive charges during the operation of the engine only. It will be seen that by this construction the air is drawn through the apparatus by means of the vacuum produced by the engine piston, and that there is no chance for leakage by forcing the vapor out through any openings in the carburetor. The pipe *E* acts as a seal to prevent any return of the air which has been drawn into the apparatus, and the flexible diaphragm *D* acts as a relief, vibrating easily with each stroke of the piston. The amount of air drawn into the carburetor at one stroke passes into the engine cylinder at the next stroke, and it will be manifest that only so much air is carbureted at each time as will serve for the following stroke of the engine piston, the operation ceasing instantly when the engine stops.

The Foulis Regenerative Furnace.

U. S. Letters Patent (No. 418,314) were granted, on December 31, 1889, to Mr. William Foulis, Glasgow, Scotland, for improvements in "regenerative gas retort furnaces," the protection sought for being supplementary to that obtained by the inventor in England on June 19, 1886, the serial number of the English patents being 8,157. Although the Foulis system has been described in the JOURNAL, we are inclined to the view that the publication of the inventor's specifications in respect to the American patent will not be without interest. Mr. Foulis says :

In regenerative gas retort furnaces, as at present arranged, combustible gas produced by partial combustion of fuel in a gas producer enters the combustion chamber, where it meets and burns with air heated by its

passage through flues arranged side by side with those which carry off the waste products of combustion.

Usually the gas enters the combustion chamber in a horizontal direction and the hot air rises vertically to meet it, so that the main heat of the combustion is directed immediately upon the structure above, causing rapid deterioration of the structure, and producing deposits and incrustations which seriously interfere with the free passage of the gases and render necessary frequent stoppage and repairs.

The object of the present invention is to remedy this evil in such furnaces, which is effected in the following manner: The hot air flues, instead of opening vertically into the combustion chamber, are continued beyond the point where the gas enters it. They are then directed upward to about the level of the combustion chamber and open with widened mouths into the flame chamber, where the air meets the gas and enters into combustion with it. The gas and hot air being thus made to meet

on the same level as they are moving horizontally, the flame, instead of being directed upward, impinging on the structure above, and causing intense local heat, sweeps freely along the flame chamber, delivering its heat uniformly over the furnace without such local intensity as can damage the structure. It is found, moreover, that by thus permitting the flame to take a free course, impinging as little as possible on any solid obstacle, more perfect combustion and complete evolution of heat are secured.

The accompanying drawings are vertical sections showing this invention applied to a regenerative gas retort furnace, these sections being taken on different planes, as follows :

Fig. 1, in its left half, is a section on *AB*, and in its right half on *CD EF*, of Fig. 2, which on its left half is a section on *GHIKLMNO*, and on its right *GHIKPO*, of Fig. 1. Fig. 3 is a section on *QR*, of Fig. 1, and Fig. 4 is a section on *ST*, of Fig. 2.

The gas generated in the producer *a* passes by the flues *b* into the combustion chamber *c*, where it meets with the supply of heated air and burns. As indicated by the arrows, the flame, which is mainly developed in the chamber *c*, and the products of combustion circulate between and around the retorts *d*, and then the products descend along the zigzag channels *e* to the flues *f*, whence they pass to the chimney shaft. The air entering at *g* ascends the zigzag channels *h*, which are arranged between the channels *e*, and separated from them by thin partitions, so that the air in its ascent along the channels *h* becomes heated. The uppermost channel *h* is extended beyond the mouth of the gas flue *b*, and an uptake from its end expands, as shown in Fig. 4, to a wide mouth *k*,

opening into the combustion chamber *c* at or about the same level with the gas flue *b*. Thus the heated air directed across the stream of gas mingles with it, supporting combustion and producing a gentle flow of flame along the chamber *c* (indicated by the arrows *l*), the flame and products thence diffusing themselves among the retorts.

Instead of a single mouth to the gas flue *b* and the air supply *k*, there must obviously be several mouths, so as to subdivide the gas and air into several streams directed either obliquely across or parallel to one another, so as to produce a flame traveling horizontally along the combustion chamber *c*.

I claim :

In a regenerating gas furnace, a combustion chamber, the walls thereof provided with horizontal air passages and horizontal gas passages opening into the said chamber in the same horizontal plane, near the bottom thereof, whereby the resultant flame is caused to travel horizontally near the bottom of the chamber before rising, as and for the purpose described.

The Deterioration of Electrical Conductors.

M. Firmin Larroque has published an account of some of his observations on the deterioration of copper conductors by the long-continued passage of strong currents of electricity through them. His attention seems to have been first called to the question in 1884, when he examined the electrical and mechanical properties of some pieces of electric lighting cables that had been in use for some years. One specimen—a portion of a cable which had conveyed electricity to a lighthouse lantern for a period of twenty years, gave very striking results. It was extremely brittle, and broke in fragments under the hammer, whilst its fractured surface resembled in all particulars that of electrolytic copper. The current through this cable had not been in any way excessive, nor had it been subjected to any heavy mechanical straining. Similar though less marked results were obtained with other cables, which had been in use for shorter spaces of time. The currents in all these cases were direct, but a portion of the secondary circuit of a small Runkorff coil, for many years employed in igniting the gas of a Lenoir gas engine, gave M. Larroque an opportunity of examining the effects produced by an alternating current. This coil had become very brittle, and broke up during the process of unwinding; its electrical resistance, moreover, had increased about 31 per cent. during the years it had been in use. M. Larroque then determined to make some systematic experiments on this subject. He endeavored in the first place to determine whether the long-continued passage of a powerful current of electricity

caused any expansion of the wire, and secondly, whether, and in what degree, it altered the elastic properties of the material. For each experiment nine pieces of copper ribbon 10 mm. broad and .3 mm. thick, were provided, and for the second of the experiments, each specimen was bent into a zigzag of 80 bends. One end of the zigzag was attached to a rigid support, and from the other a weight of 10 grammes was hung. Some of the specimens were hard drawn copper, and the others were made from the annealed metal. Through seven of the nine specimens a current, in some cases alternating, in the others direct, and ranging in different cases from .5 to 2 amperes was passed, whilst the other two specimens, one of which was hard drawn and the other annealed, were kept as standards, so as to eliminate any changes arising from causes unconnected with the passage of an electric current. Should the elasticity of the specimens be altered by the current, the position of the 10-gramme weight would of course vary correspondingly, and means were taken for the accurate estimation of such changes. During the first nine months of the four years over which the experiments have been prolonged, the observations showed a want of uniformity, but since then have been very regular, and the results now published show that the elastic properties of the wires have been very considerably changed. This variation takes place the more rapidly with strong than with weak currents, and with alternating than with direct.

The Kusnezov Gas Washer.

Vassily Kusnezov, of St. Petersburg, Russia, has been granted protection in this country (Letters Patent No. 415,646, Nov. 19, 1889) for a gas washer for application to gases obtained from naphtha or crude petroleum. Referring to the drawings, Fig. 1 represents a vertical section on the line 1 2, Fig. 3; Fig. 2 is a perspective view with the top and two adjoining sides cut off; and Fig. 3 is a sectional plan view on the line 3 4, Fig. 1.

The washer consists of a metallic casing *A*, preferably of rectangular form. This casing is divided by a horizontal partition or plate *B* into two compartments or chambers, in communication with each other only by a vertical pipe or duct *C*. The lower chamber, into which the gas to be purified enters by the openings *D*, is divided by vertical partitions *E*

and *E'*, which cross each other at right angles and form a great number (from 64 to 500) of vertical chambers or ducts, communicating with each other alternately at the bottom of the casing above the level of the water contained therein, and at the top immediately under the partition *B*. By this arrangement the gas must pass in a circuitous course consecutively through all the vertical channels and ducts of the lower chamber, as shown by the arrows in Figs. 2 and 3, until it reaches the last vertical duct *C*, which leads to the upper compartment. The partitions *E'*, beginning at some distance from the plate *B*, do not reach the bottom of the casing (see Figs. 1 and 2), so that the water is at the same level in all the channels or ducts. In passing under the lower edges of the partitions which do not reach down into the water the gas is brought into contact with the water, which retains the particles of naphtha contained in the gas (and which escaped the hydraulic main), and is thereby cooled and purified. After passing through all the channels or ducts of the lower chamber the gas ascends through the tube or duct *C* into the

upper chamber, where it passes over a layer of water, with which this chamber is filled to about one third of its height. In this upper chamber there are arranged a number of metallic partitions *F* parallel to

each other, and alternately open at opposite ends, so as to form a serpentine channel for the extended flow of the gas over the water, by which it is finally purified, and is let off from the apparatus by the opening *G*. An inlet *a* and outlet *a'* for the water are provided for each chamber.

The Incandescent Light Controversy.

The *Scientific American* believes that the controversy now in progress between the promoters of the rival systems of incandescent lighting, though some will think of doubtful expediency, so far as the companies are concerned, admirably serves to acquaint a public now grown timorous, with the detail of operation, and with the nature of precautions which, if employed, would render both systems entirely safe, at least to the user.

With perceptions sharpened by constant investigation, the rival champions have each in turn pointed out the defects of the other's system of lighting—defects which, because of the reticence of the companies, have till now only been surmised by the public.

It is the purpose of this article to examine these as they have been pointed out, inquiring as to the mischief that might come, and describing the steps which the studies of practical electricians show to be necessary for their correction.

The alternating current system, the attack on which led to the present controversy, is used very generally on both sides of the water for incandescent as well as for arc lighting; its chief recommendation being the power it possesses to light extensive districts from a single station. In an arc light circuit the current reaches the lamps directly from the conductors, the voltage varying, according to requirement, from 1,200 to 2,000. In the incandescent system this high voltage is maintained in the street circuit, but by the interposition of converters or transformers, located in or near each building, a secondary current of scarcely more than 50 volts is produced. This is suitable for operating a number of lamps, each equal to a full working five-foot gas burner of 16-candle power. The

transformer is made up of two separately wound and insulated coils, one of thin wire connected to the street mains, and the other of thick wire connected to the wires of the building to be lighted; currents sent through the coil of thin wire induce in the nearby coil of thick wire currents the voltage of which bears the same ratio to that of the primary current as the number of convolutions in the primary bears to the secondary coil of the converter. For example, if the electromotive force of the primary or street current is 500 volts, and the electromotive force of the secondary current is required to be 500 volts, the primary coil will require ten times as many convolutions as the secondary. The promoters of this system say that it is an easy matter to make the insulation between the two already separated coils effective and to prevent the current in the primary wire from penetrating it. On the other hand, their rivals say that no system of incandescence which has a high tension current behind it can be rendered absolutely safe, that breaks or leakages will come, because the mechanisms of man, however ingenious, are never perfect, and human watchfulness and foresight not to be depended upon. They instance the case of the employee of the Manhattan Electric Light Company, who got his death shock while carrying a portable incandescent light in the engine room of the station, a lamp, be it said, supposed to be protected from the main current by a converter. There would seem to have been a break in the insulation of the wire, which his hand must have rubbed against, his face perhaps touching a steam pipe, thus forming a ground. The station men say that only 120 volts were on the circuit, but as this would not destroy life, it is evident that the high pressure alternating current must have reached the wire, and passing through his body, got to the ground through the steam pipe.

This, however, happened within a station, and it is claimed cannot be construed as an argument against the safety of the system any more than the death of a man who should fall against a fly-wheel could be used against steam engines. The alternating current people say, and truthfully, it would seem, that the record does not furnish proof of a single case of death among the thousands who have been using the system where applied to incandescent lamps.

The continuous low tension system is that used in the circuits of Mr. Edison. Here the voltage on the street circuit, varying between 100 and 200, even the higher pressure not in the least dangerous to life, is the same on the house circuit. All underground mains are meshed into one network, and while in the alternating system the wires are designed to supply only about 1,500 to 2,000 lights per pair, and made of such a size that there is scarcely any decrease in the intensity of the lights at the further end, even when the demand for current is excessive, the low tension system at times calls for an enormous electrical energy, the pressure being far greater nearest the station than away from it. At times, when the switch is worked to put out the lights in a certain district an arc of blue flame is formed which must be blown out. This charge, made by a rival company, though true, is misleading, because the arc is harmless, never known to do any harm. The charge is made against the Edison system that it is subject to leakage which at times leads to fire. But it does not and cannot take life, while leakage from the alternating street mains can take life as well as start fires.

As will be seen, both systems have striking advantages, and to all appearance are fairly safe. Disinterested electricians, however, insist that to be rendered incapable of harm, where high tension currents are permitted in the streets, whether overhead or underground, every wire entering a house should be provided with a cut-out of lead or its alloy. It is a simple and inexpensive precaution by which a wire, however dangerously environed it may be, cannot transmit a high tension current beyond a certain point. Copper fuses at about 2,000° F., but lead at 608°, and its alloy at about 375°, and thus a strip of lead joining the house system with the outside current would melt and break off all connection should a vagrant current of high intensity essay to pass.

Coke and Charcoal Compared.

The *American Manufacturer* calls attention to the results of the following experiments, published by Dr. W. Thoerner, in *Stahl und Eisen*, in the matter of the comparison of coke with charcoal. He finds:

1. That charcoal consists of a large number of more or less regularly arranged cells which are joined together longitudinally. The walls of the cells are readily porous to gases, and are very easily oxidizable.

Coke, on the other hand, contains generally separate unconnected cells or groups of cells, the walls of which are composed of a dense and vitreous mass which does not admit of the passage of gas through it, and is exceedingly difficult to oxidize.

2. That the relatively smaller action in blast furnace practice of coke as compared with charcoal would be increased were it possible to cause

the structure and character of coke generally to more closely resemble that of charcoal, either by the formation of a coke more porous though sufficiently strong, or with greater certainty by rendering the coke substance more easily oxidizable.

The following table gives the results of the examination of several specimens:

Variety of Fuel.	Ash per cent.	Specific Gravity.		In 100 Grammes Coke.		Volume of 100 Grams of Coke.
		Apparent.	Real.	Cell Space Cubic Centimeters.	Coke Substance, Cu. Centimeters.	
1. Retort coke, Osnabruck Gas Works.....	3.8	1.825	0.850	61.6	54.8	116.4
2. Retort coke, Osnabruck Gas Works.....	7.5	1.811	0.868	60.6	52.2	115.2
3. Compressed coke, Cologne-Musen Co.....	7.7	1.852	0.974	48.6	54.0	108.6
4. Compressed coke, Cologne-Musen Co.....	6.9	1.786	0.909	40.2	56.0	103.2
5. Ordinary Coppee coke, Cologne-Musen Co.....	7.99	1.880	0.926	54.8	53.2	108.0
6. Carlsgluck and Planetfeld, Dortmund coal field....	7.8	1.825	0.909	55.2	54.8	110.0
7. Maassen, low level.....	7.3	1.852	0.890	54.4	54.8	112.4
8. Westhausen, Bodelschwingh.....	10.6	1.852	0.909	54.8	54.0	108.8
9. Neu-Iserlohn, Langendreer	8.8	1.852	0.874	60.4	54.0	114.4
10. Dannenbaum, Bochum....	8.45	1.894	0.800	59.6	52.8	112.4
11. Germania Works, Grevenbruck.....	7.6	1.909	0.963	58.4	52.4	110.8
12. Heinrichshutte, Au, a. d. Seg.....	7.6	1.887	0.980	49.0	53.0	102.0
13. Meiler coke, Silesia.....	2.9	1.488	1.646	28.4	67.2	95.6
14. Fine charcoal.....	2.9	1.626	0.382	200.4	61.6	262.0
15. Oak charcoal.....	2.45	1.347	0.587	96.2	74.2	170.4
16. Beech charcoal.....	2.10	1.481	0.594	100.8	67.6	168.4
17. Birch charcoal.....	1.65	1.351	0.484	132.5	74.0	200.5
18. Anthracite.....	9.3	1.666	1.572	3.6	60.0	63.6
19. Bituminous coal.....	8.30	1.323	1.300	1.4	75.6	77.0

In comparing these results, Dr. Thoerner observes that amongst the coke samples examined the meiler coke has the least porosity—28.4 cubic centimeters per 100 grammes—and the ordinary retort coke the greatest—61.6 cubic centimeters. The porosity of coke produced in ordinary ovens varied from 54.8 to 59.6 c.c. per 100 grams., a notable exception, however, being the “pressed coke,” Nos. 3 and 4, produced on the Lurmann system, in which the porosity is only about 47 c.c. on the same weight of coke.

The porosity of the charcoal varied between 96.2 cubic centimeters and 200.4 cubic centimeters per 100 grams., and it is curious that pine charcoal, the most porous of the varieties examined, possessed the densest charcoal substance.

Microscopical examination of the form and size of the cells and the strength of the cell walls necessitated the use of thin sections, which were photographed under the microscope by Dr. Thoerner and engraved for his paper. It was observed that the smallest details of the structure of the original wood were preserved in charcoal, the arrangement of the cells being such that the gaseous products of coking could escape easily, and therefore in burning the charcoal oxygen could easily enter. The charcoal substance is not fused by coking, but remains in an easily combustible form, whilst the coke substance is found to be fused into a dense, impenetrable, vitreous mass.

Experiments on the resistance to crushing stress shown by the different varieties of coke were found to give erroneous results when the coke was carefully turned into a cylindrical form. Mr. John Fulton, of Johnstown, in his investigations on the physical properties of coke, relied greatly on the indications of hardness given by resistance to crushing stress, but Dr. Thoerner remarks that the use of cubes, as employed by Mr. Fulton in his experiments, is open to the objection that it is almost impossible to obtain from such a brittle material cubes of exactly the same size, and that he found that cubes produced were never free from slight cracks. It was, however, shown by the experiments with cylindrical test pieces that, as a general rule, the crushing strain of coke was from 0.97 to 1.73 kilograms. per square millimeter of surface, but as the results agreed very badly, a further series of tests was made in which the coke was cut to pieces of about 10 millimeters diameter, surrounded by an iron jacket and put under a piston, by means of which it was subjected to a crushing stress. The volume to which the coke was compressed by successive increasing loads was noted after each load, and

the results showed that the relative strength or compressibility was, as a rule, directly dependent on the porosity, both in the case of charcoal and in that of coke.

In the following, Sir I. Lowthian Bell's line of investigation into the relative resistance of coke and charcoal to carbonic acid, Dr. Thoenner subjected the specimens to a preliminary heating at a white heat in a current of hydrogen, and found a considerable loss in some cases.

The following numbers show the decrease in weight per cent.

No. 2.	Retort coke.....	0.25
No. 3.	Compressed coke.....	1.41
No. 4.	Compressed coke.....	1.15
No. 5.	Coppee coke.....	1.13
No. 6.	Carlsgluck, etc., coke.....	1.55
No. 7.	Maassen coke.....	1.70
No. 8.	Westhausen coke.....	1.70
No. 10.	Dannenbaum coke.....	0.75
No. 13.	Meiler coke.....	29.70
No. 14.	Pine charcoal.....	17.90
No. 15.	Oak charcoal.....	13.20
No. 16.	Beech charcoal.....	11.80
No. 17.	Birch charcoal.....	13.20

The above considerable loss in the case of Meiler coke and others is explained as being due to the escape of hydrocarbons and not to evolution of water.

In examining the action of carbonic acid and of air on the specimens, 1 gram of each sample of coke and 0.5 gram of each variety of charcoal were placed in a platinum tray, and heated in currents of air or carbonic acid for different periods with the following results :

Fuel	Heated in Carbonic Acid (Loss Per Cent.)			Heated in Air for 10 minutes. 4.5 liters air being used. Loss Per Cent
	For 15 Minutes. 500 c. c. CO ₂ used.	For 30 Minutes. 1 Liter CO ₂ used.	For 2½ Hours. 5 Liters CO ₂ used.	
1. Retort coke.....	10.6	27.2	46.8
2. Retort coke.....	11.8	36.6	45.0
3. Compressed coke...	13.8	38.0	52.0
4. Compressed coke...	8.4	27.2	48.9
5. Coppee coke.....	8.7	27.5	50.1
6. Carlsgluck coke....	8.3	20.3	54.4
7. Maassen coke.....	8.9	29.3	54.5
8. Westhausen coke..	9.5	26.2	52.9
9. Neu Iserlohn coke.	12.2	34.0	46.8
10. Dannenbaum coke.	6.8	22.6	57.1
11. Germanialutte coke	8.9	32.0	52.1
12. Heinrichslutte coke	6.9	24.3	52.5
13. Meiler coke.....	45.6	100.0	87.7
14. Pine charcoal.....	61.1	96.3	100.0
15. Oak charcoal.....	48.8	85.0	78.6
16. Beech charcoal....	60.4	95.0	80.3
17. Birch charcoal....	68.0	95.0	100.0
18. Anthracite.....	45.4
19. Bituminous coal....	74.4

Chimney Proportion.

A foreign contemporary calls attention to the fact that the rearing of high chimney shafts in connection with factories, chemical works, etc., constitutes a specialty in building construction, and may fairly be considered as a matter of very considerable economic importance.

We do not propose in the present paper to go at all practically into the details of high chimney construction. Readers desirous of information on this subject may be safely referred to Messrs. Robert M. Bancroft and Francis J. Bancroft's excellent book on the subject, which is an exhaustive and authoritative resume of the matter.

Our present purpose is to call attention to some articles which appeared not long since in a German technical contemporary on the matter, and which considered it with special reference to the question whether decrease in height of factory chimneys might not effect a saving of fuel without impairing general efficiency.

Herr P. Huth records a case in which the erection of a new boiler in a relatively disused building necessitated (after an unsuccessful attempt to use it) the demolition of the old chimney, the dimensions of which were: Height, 65.61 ft., lower diameter, 19.68 in., diameter of interior of chimney, 13.78 in. The entire length of the draught, including the flue, was about 98.42 feet. In the new chimney the entire length of the draught, including the flue, was proposed to be about 95.14 ft., and the diameter at the narrowest square portion, 25.59 in.

Partially for experimental purposes and partially with a view to economy, a trial was made of heating the boiler when the chimney was 39.37 ft. in height. Although the results were affected by the damp masonry, there was a distinct improvement perceptible as compared with the old

chimney. At a height of 45.93 ft. the trials were still more satisfactory, and at 52.49 ft. all requirements were completely fulfilled, the smoke being absolutely white and sometimes scarcely noticeable, without any soot or flying ash. The heating of the boiler was excellent, and the consumption of coal 15 to 20 per cent. less than was the case with the old chimney. The top was then finished in the usual way, without any further improvement or addition to the height.

From these facts Herr Huth deduces the fact that not only the height, but also the diameter of a chimney in proportion to its height, demand attention for economic and administrative reasons. High chimneys are, he considers, as a rule too narrow in proportion to their height, and hence do not draw well, or else waste fuel and cover the neighborhood with soot and flying ash. The effort to remedy these evils by still further increasing the height of chimneys leads to their aggravation.

Herr Huth suggests more detailed researches as likely to elucidate the subject further. In a later number of the same journal, Herr Ramdohr, of Gotha, confirms the assertion that there is a dearth of exact information as to this point. He alludes to the opposite extremes of making chimneys decrease or increase in their internal diameter at the top as compared with the base. He recommends uniform diameter, and thinks that this should be estimated rather fully, in order that the heated gases in the center of a chimney may be, if possible, surrounded by a cooler stratum which protects the brickwork to some extent from the heat.

This uniformity of diameter can be obtained by cutting the bricks or by dividing the chimney into sections and ascertaining that no portion of these had less than the minimum diameter. This diameter can be estimated in proportion to the extent of the grate surface of all the fireplaces which the chimney serves, being about equal to the flue grate surfaces. This varies with different combustibles, brown or mineral coal, wood, etc., from one-eighth to one-fourth of the entire grate surface. The lower a chimney the larger may be its cross section.

The height, even when the boilers are small, should not be less than about 50 ft. For large steam appliances a height of 100 ft. to 120 ft. will usually suffice, providing the cross section be suitable.

When the fireplaces are some distance from the chimney, the height of the latter would be about 160 ft. to 200 ft., the cross section being modified on account of the coating of the smoke gases during their passage.

As to the form of the cross section of such chimneys, it is considered that a circular shape is preferable on account of its resistance to the wind pressure. An octangular form is considered a very suitable alternative, as only one special shape of brick is indispensable; and finally, it is stated, that the top of the chimney should not be called upon to bear any but a very slight projection, the whole being carefully surmounted with iron round the top of the brickwork.

Petroleum Market for 1889.

Messrs. Watson & Gibson, in an article specially prepared for a New York city contemporary, thus review the course of the petroleum market for the year 1889 :

The year 1889 opened with a dull market in petroleum, at something of a decline from the latter days of 1888. The highest price during the first week of this year was 85½ cents. The total net stock on the 31st day of December amounted to 18,595,474 barrels. Early in the month of January a conference took place between the representatives of the Standard Oil interest and the organized producers, resulting in a harmonious agreement between them. By this agreement the Standard extended the time of a "call" of 3,500,000 barrels until July 1st, and the Standard agreed that it would at that date accept any of this reserve oil which might remain unsold at a net profit to the producer of at least five cents per barrel. The Standard were to continue to carry this oil until July 1st, or till any previous date, when it might be called by the producers. This agreement, being a continuation of an option previously existing, did not have any very important effect upon the price of oil. From the first of the year up to the present time there has been a continual and steady reduction of the stock of oil above ground, but this gradually improving change in the situation did not begin to assert itself until the present autumn, and then only in a very moderate and indifferent sort of a way. The prices during the early months of the year ranged between 85 and 92½, falling to 80 cents the latter part of April. On the 24th of June, being just prior to the expiration of the "call" held by the producers, there was an important change in the temper and extent of speculation in the oil market, and the total dealings on that day in the Consolidated Exchange ran up to 4,910,000 barrels. The price on that day advanced from 83¾ cents at the opening to 95, reacting before the close to 89¾. This was not only an important advance, but an utter surprise to speculators and traders. On the 28th of June the Standard purchased from the producers the 3,500,000 barrels of oil which they had been carrying, subject to a "call" by the producers. They paid for it 91½ cents. By this trade the producers made something over \$200,000, and the relations between themselves and the Standard, which began in November, 1887, at the time of the original shut down movement, were terminated.

The price during the early part of July held around in the vicinity of

90 to 92, but on July 20th it rose to 95½ cents, and on July 27th to 102¼, having on the latter day advanced from 95¼ cents. These higher prices naturally resulted in an increase of development work in the field, which gave a larger production during the autumn months than had previously been turned out. The total exports for refined oil for the fiscal year ending June 30th were 496,691,346 barrels, against 452,855,695 the year before. Early in the present autumn oil advanced above \$1.12 and there was a good deal of talk about very high prices for it, but speculation was almost at a standstill and the constantly decreasing stock of oil did not create any enthusiasm among buyers, or any adequate speculative response.

The growth of the Russian oil business and its successful introduction on an enlarged scale in the far East, and the completion of a pipe line across the Suram Pass, which lies between Baku and Batoum, are important features to be considered in estimating the value of American oil.

Secondly, the existence of a large field in Ohio, the visible supply of which equals the visible supply of Pennsylvania oil, selling at about one-sixth the price of the latter, exercised a bearish or at least deterrent influence on would-be buyers. It is not an established fact that Ohio oil can be economically refined, but it is stated to be a fact that its refining is chemically possible, and, as the production is now at the present low price, fully half the production in Pennsylvania, and its possibilities of increase are very great whenever its price shall be advanced, it remains a constant menace to the prices of Pennsylvania oil. The oil dealt in on the exchanges is Pennsylvania oil, and since the new oil coming out of the wells of Pennsylvania commands a premium of about 25 cents, none of the fresh oil goes into the tanks covered by the certificates dealt in on the exchanges.

The oil now in the custody of the pipe line companies, which is a good delivery on the exchanges, is the old Bradford and Alleghany oil, and it is deteriorating by age. We believe that Ohio oil will be utilized for the production of illuminating fluid and the Standard has for some time had a large refinery at Lima. It may be feasible to blend Ohio with the Pennsylvania oil. In view of all the conditions surrounding the business, the utter and complete absence of all speculative desire on the part of the public, and the interest which the Standard must have, as the chief consumer of petroleum for conversion into refined, we cannot see our way to recommend purchases of Pennsylvania oil at current prices, notwithstanding the apparently strong and bullish complexion of statistics. We think that the price of Pennsylvania and Ohio oil must be more closely approximated, and we predict that within the year 1890 the Standard will openly admit what they now deny, that Lima oil can be successfully and economically refined.

Fluctuation in Prices per Barrel (40 gals.) of Petroleum during 1889.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

It is about settled that Cleveland (O.) will appoint an official gas inspector, and that his office shall be equipped with all the modern appliances for testing for purity and candle power. The next step will be to provide for the appointment of an electric light inspector, who shall also be required to report on the average lighting value of the arcs supplied to the city.

THE employees of the Laclede Gas Light Company were made happy on Christmas eve. by the reception each of a good-sized turkey. The donor was President McMillin.

JAMESTOWN, N. Y., intends to install and operate an arc lighting plant on municipal account.

THE competition for supremacy between the Fremont (Ohio) Gas Company and the local electric light company has terminated in the purchase of the former by the latter. The proprietors of the Gas Company are said to have received a good round sum for their property, which was valued at \$75,000. During the contest gas was sold at as low a figure as \$1 per 1,000, while electricity could almost be had for the asking.

THE following are the bids made in response to the second call by the authorities of Boston, for the public lighting by means of arc lamps, the Mayor having rejected the bids submitted under the first call on the ground that the rates were excessive: Suburban Light and Power Company, Roxbury district, 1-year contract, 39.99 cents per arc per night; 3 years, 38.99; 5 years, 37.99; for city proper, South Boston, West Roxbury and Dorchester, 5 years, 39.74 cents; Brookline Gas Company, for Brighton district, 5 years, 40 cents; Walworth Light and Power Company, for city proper, East and South Boston, Charlestown, Roxbury, West Roxbury, Brighton and Dorchester districts, 5 years, at 40 cents. The proposals were based on all and every night lighting, arcs to be of 2,000-candle power. The award of the contract was taken under advisement. It will be noted that the Boston Electric Light Company and the Charlestown Gas Company, both of which submitted bids in the first competition, did not make a tender in the last. The Mayor, however, received letters from each of the named corporations, both conveying the information that because of the restrictions in the specifications (the second set of the latter announced that no bid would be recognized that exceeded 40 cents per arc per night) they could not assume a contract at the maximum rate named and fulfil their obligations with justice to their stockholders.

AN independent authority, writing on the recent ill-advised labor agitation among the English gas stokers, says: "The gas strikes at Manchester and Salford are over. The places vacant by the ill-timed action of the leaders and the foolish complicity of the men have been to a large extent filled. Some of the old hands have returned—sadder, if not wiser, men, but many have left never to return. The rate payers of the city of Manchester and of the borough of Salford undertook to give more wages and to lessen the hours of labor. But they were not prepared to become the mere agents of the Gas Stokers Union, and to insist that none should be employed except union men. Hence they put up with some inconvenience rather than coerce the gas committees of the two corporations. No such demand has ever been made by the older unions, although strikes against non-union hands have sometimes taken place. Such strikes have usually been ineffective; they have entailed great suffering and misery, and at the best they have been won at great cost. If it is right for the men to strike against non-union hands, it is equally right for employers to insist upon employing none but non-union hands. The policy in either case is sure to give rise to a feeling of permanent hostility, and further it violates the spirit of the law which now gives to all men equally the right to combine. Recent experience shows that there is a disposition abroad to rely upon force rather than

*Estimated.

upon moral or legal right; but force only engenders force in labor conflicts."

IN the meantime we might remark that the difficulty between the proprietors of the Lockport (N. Y.) gas works and their employees has been satisfactorily arranged.

SOME time ago Judge Black, of the Missouri State Supreme Court, rendered a decision in respect to a case known as the "grading suit," under which it became necessary to construe certain sections of the charter of Kansas City. In his opinion Judge Black holds that the charter "is the supreme or organic law of the city, and supersedes all previous laws enacted by the general assembly of the State for the regulation of the city's affairs." Under this ruling it is now held by the municipal authorities of Kansas City that the city has the right to say at what rate gas and electric light shall be supplied. Section 12 of Article 14 of the Kansas City charter is: "Provided, That no such person or corporation shall in any event charge more for light for the city or private parties than the prices specified, from time to time, by ordinance of the city, and that the city shall also have power to regulate and fix from time to time the prices such person or company may charge for the renting of meters or apparatus for ascertaining the quantity of material or means consumed for lighting. And provided, further, That the city shall not, in making the original grant, nor in any manner subsequent thereto, ever agree or bind itself to pay any fixed price for lighting streets, avenues, etc., for a longer period than one year."

ARTICLES incorporating the National Gas and Electric Fixture Company were filed at Camden, N. J., on December 30, 1889. The capital stock of the concern is fixed at \$500,000, with 5 per cent. paid in. The incorporators are Messrs. Benjamin Thackara and Clement M. Biddle, of Philadelphia, H. C. Beck, of Brooklyn, N. Y., Jno. C. Cassidy, of East Orange, N. J., and Charles H. Fischer, of Mount Vernon, N. Y.

AT the annual meeting of the Covington (Ky.) Gas Company, no change was made in the executive management. Colonel Amos Shinkle, President of the Company, believes that 1890 is to be a great gas year.

A CORRESPONDENT, writing under date of December 29, 1889, from Kansas City, Mo., says: "Some months ago the question of removing mail boxes from the gas lamps in the city that are no longer in service because of the substitution of arc lights, came up. The posts could be removed to other parts of the city if it were not for the mail boxes attached to them, and it is but a mere matter of generosity on the part of the Gas Company that the posts have been allowed to be so used at all, even when the posts were a part of the public lighting equipment. Secretary Woolcott has informed the post office authorities that the Company would now like to transfer the posts, and has forwarded a list of the ones which it is desirable to remove, to the Postmaster. He will not insist on an immediate transfer, but will grant ample time for the removal of the mail boxes to other locations."

THE authorities of Denver, Col., headed by the Mayor, have been investigating the matter of the economy involved in the operation of municipal electric lighting plants. A portion of their researches is shown in the following replies received from localities where such plants have been in operation for a year or over:

Locality.	No. lights.	Cost of installation.	Annual cost per lamp.
Bay City, Mich.	120	\$30,280	\$39
Madison, Ind.	81	18,500	60
Topeka, Kan.	120	26,500	88
Little Rock, Ark. ...	95	27,000	75
Wichita, Kan.	150	55

At Bay City water power is availed of, steam being the motor in the other instances. The annual maintenance charges do not include anything for wear and tear or interest.

IN completion of our former mention of the explosion last month at the works of the Asheville (N. C.) Gas Company, in which two employees (Louis Guthrie and Wm. Gates) lost their lives, we may say that the testimony taken at the coroner's inquiry showed the accident to have resulted from the placing of a common lantern (with a light burning therein) at a point about 3½ feet from an open manhole in the gasholder crown—the gasholder having been let down for repairs—from which gas was still escaping. The verdict bluntly states that "the victims lost their lives because of the employment of incompetent men at the gas works." And the evidence more than bears out that arraignment.

CANTON, Ohio, pays at the rate of \$108 per annum for each arc light supplied on city account. The lamps are of the 2,000-candle power variety, and are suspended over the street centers. All-night lighting is the rule. Cleveland employs for the lighting of one square mile in the center of the city four towers (one of which is 250 feet in height, the others being 150 feet from the surface), one of which carries eight 4,000-candle power arcs, while the others carry 6 lamps, each of a like illuminating value—4,000 candles. In addition to these 78 arcs (2,000-candle power) are maintained at other points. A lighting table of 3,760 hours per annum is followed. For the mast lights the charge is 10½ cents per lamp per hour; for the others 3.7 cents per hour is the rate. It is said that the mast illumination gives the greater satisfaction.

A CORRESPONDENT writes: "In the last week in December 800 shares of the Fitchburg (Mass.) Gas Light Company's stock was sold at auction. The entire block was purchased by Mr. Geo. F. Fay, who secured the shares at par. This sale was the final act in the purchase by the Gas Company of the Wachusett Electric Light Company, the arrangements for which were made some time ago. The terms of the consolidation called for an increase in the capital stock, and the shares bought in by Mr. Fay will represent that increase.—OBSERVER."

AT a recent meeting of the City Council of East St. Louis, Mo., it was resolved to accept a proposition for the public lighting, submitted by the Citizens Electric Light and Power Company, under which 60 arcs (2,000-candle power) are to be maintained for a period of 3 years, at an annual charge of \$125 per light per annum. This decision is made in face of the fact that some years ago the authorities awarded a 30-year contract for the public lighting to the East St. Louis Gas Light Company, which contract will not expire until 1905. The Company will undoubtedly resort to the courts in the maintenance of its rights, but the contract-breakers are of the opinion that the Company is without redress, basing their belief on a decision of the State Supreme Court to the effect that no corporate body (in this sense meaning the municipal or local legislative authority) can legislate for a term longer than its own existence.

THE proprietors of the Davenport (Iowa) Gas Light Company have kept up with the procession in the year just closed. In the twelvemonth expenditures on plant account have amounted to \$29,000. Of this sum \$20,000 was put into new apparatus, while \$9,000 was apportioned to the street department. In the year 1½ miles of new mains were buried, and the balance of the system (27 miles) was thoroughly inspected and repaired. The Company is now in excellent shape for business, which is progressing most satisfactorily.

THE Pawtucket (R. I.) Common Council has amended its contract for public lighting with the Pawtucket Gas and Electric Light Company so that the 2,000-candle power arcs now supplied on the all-night schedule may be changed to half arcs.

SUPERINTENDENT HAYDEN, of the Fishkill (N. Y.) Gas Company, has taken advantage of the continued mild season to overhaul the main system, which, to say the least, was far from being a model one.

A ST. LOUIS newspaper says that the talk about introducing and attempting to pass another gas bill in lieu of the vetoed Branham-Hardesty imposition is ridiculous, and then adds the following simple truths: "No additional gas works are needed in this city. The old gas trust was a pretty tough thing for the people, but the remedy is not in the direction of new companies. The history of gas legislation shows that every new company eventually increases the cost of gas by compelling the old companies to absorb it and to pay interest on increased capitalization."

THE following is from the Clinton (Mo.) *Democrat*, dated the 2d inst.: "For nearly one year the *Democrat* proprietors have contemplated making an exchange of the 4½-horse power Bookwalter steam engine for a motor power for our newspaper and job presses which required less personal supervision, and at the same time suitable for all demands. A water motor was placed in position last summer, but its capacity was inadequate and again our steam engine performed its daily service. Recently, correspondence was re-opened with the Van Duzen Gas Engine Company, Cincinnati, O., for the purchase of an engine, which resulted in our placing an order by telegraph subject to 15 days trial. When the engine arrived a substantial stone foundation was put in and connection made to the gas meter. The engine has now been tested, and it gives us pleasure to say fills our highest expectations. It is simple in construction, economical in use of gas, develops full power, runs as

steadily as a clock, and has come to stay as a permanent fixture in our press room. Its floor space is 4 x 4 feet, height 6 feet, weight 1,600 lbs. With not more than one-half of its 4-horse power developed, it runs with ease our 33in. by 48in. Campbell press and Dexter folder, paster and cutter and 14½ by 22 Peerless and 9 by 12 Gordon job presses. To Mr. J. T. Marsh, Superintendent of the Clinton Gas, Coal and Coke Company, the *Democrat* is under lasting obligations for his many acts of courtesy, in placing the engine in position and for instructing us in its management. He has been a citizen of Clinton over 6 years, and is always at his post of duty. Our gas engine can be seen in operation every week day, from 4:30 to 5 P.M., and Mondays and Thursdays from 9 to 12 A.M.

ACCORDING to the annual report of the Superintendent of Public Lights (Mr. J. S. Read), there are now maintained at Pawtucket (R. I.) 156 electric, 110 gas and 147 oil lights, an increase of 18 gas lights and 7 oil lights over last year. During the year 2,160 chimneys in the oil lamps were broken, while 1,586 lights of glass were broken in the gas lanterns. The total expenditure was \$24,485, and the rebate on lights for the year was only \$162.64.

THE Walla Walla (Wash.) Gas and Electric Light Company is building a new engine and dynamo house. A new 100-horse power engine has also been ordered.

EVEN the Knights of Labor, of St. Louis, were opposed to the Bramham-Hardesty gas works grab, as shown by the action taken at a meeting of the Executive Committee of the Knights held on December 29. It must have been a decidedly tough grab when they were forced to attest its indigestibility.

THE Fuel Gas Improvement Company of Pittsburg, Pa., has been chartered.

A DÉSPATCH from Eau Claire, Mo., dated December 24th, says that during a violent *thunderstorm* on that date, a flash of lightning caused sad havoc to the wires of the local Brush electric company, and that a similar visitation burned out the McDonough incandescent plant.

IT is rumored that Colonel J. M. Thompson, well-known in St. Louis gas circles, may secure the appointment of United States Assistant Treasurer at St. Louis.

THE offices of the New Bedford (Mass.) Gas Company are now located in the Winslow Building. Another evidence of Mr. Taber's good taste.

SUPT. WHITEMORE, of the Bath (Me.) Gas Company, has completed the alterations at the works rendered necessary by the marked increase in the business of the Company.

THE Suburban Gas Company has been incorporated at Chicago by Messrs. R. Custer, M. Cameron and J. A. Griffin. It is capitalized in \$50,000.

THE annual meeting of the Trenton (N. J.) Gas Light Company will be held to-day.

THE Plattsburgh Light, Heat and Power Company has been incorporated, with a capital of \$100,000. The Trustees are A. L. Inman, Jno. H. Myers, G. M. Cole and S. A. Kellogg, of Plattsburgh, and H. M. Pierson, of Brooklyn.

IT is interesting to note how the increase in the number of gasoline street lighting contractors has gradually reduced the contract rates in various cities. Perhaps the best illustration of this is shown in the bids recently opened by the Council's Committee on Gas, Minneapolis, Minn., for supplying that city during the coming year with 2,000 or more gasoline street lamps. The bids are appended :

Bidder.	Per Post.
W. Forrestal & Co., St. Paul.....	\$17.20
Wheeler Reflector Company	15.60
Wheeler Gasoline	15.84
Jno. Van der Horck.....	16.96
Chester Oil Company.....	16.50
N. Western Globe Gas Light Company....	14.40

The lowest bid is something like \$5.60 per post under the present contract rate, the work being in the hands of the Wheeler Reflector Company.

THE contract between the St. Charles (Mo.) Gas and Coal Company and the authorities for the public lighting of that place expires on the 31st inst. It is probable that an attempt will be made to have the new contract based on a mixed system of gas and electric lighting.

THE Uniontown (Pa.) Electric Light and Power Company has been chartered. Capitalized in \$50,000.

THE Boston *Traveller* says that the gas people have met unsurmountable obstacles in their efforts to get control of the gas plants at Chelsea and Brighton, and as the indications now point, they are hardly likely to be successful in their move for the possession of the Waltham plant. Some of the stockholders have deposited their holdings in accordance with the request of the Directors, and under the agreement the Trustees are authorized to accept not less than \$140 per share. Very many of the stockholders are not, however, satisfied with this figure, and are not inclined to come into the arrangement. This latter decision would seem to be in line with wisdom, for we fail to understand how the Waltham property can be more valuable to outsiders than to those who are so intimately acquainted with its past history, present business and future prospects.

IN the meantime, mention of the Bay State syndicate brings to mind the fact that certain people well-informed in respect to Brooklyn (N. Y.) gas matters, assert that the companies of that city are likely to come under the control of Messrs. Addicks and his associates. Speaking on our own account we are not inclined to share this view, for we presume that such men as Mr. Morgan of the Nassau Company, and General Jourdan of the Fulton Municipal Company, know pretty well when they have a good thing, and know also how to take care of it.

TESTS of the illuminating power of Hartford (Conn.) gas, made by Prof. Mixer, the State Gas Inspector, on Dec. 31, shows an average lighting value of 17.80 candles.

FROM the Springfield (Mass.) *Republican* we take the following summary of the annual report of the Committee on Street Lighting for the past year.

"The Committee on Street Lights reports that the appropriation amounted to \$32,500, and the receipts, \$8 from the sale of globes; the expenditures amounted to \$27,437, leaving a balance unexpended of \$5,071. This does not include \$7,449 paid for electric light poles, which was taken from the money in the treasury not otherwise appropriated. The number of electric lights in use is 294, of gas 54, and of oil 349. There are 44 electric lights already established not as yet in operation—an increase in the number of lights established over last year of 283. The electric lights are furnished by the United Electric Light Company, of this city, under a five-year contract recently signed by this Committee, at a cost of little less than 23 cents a night for each light. The Committee believes the contract to be admirably adapted for practical use, containing no technical terms capable of a double meaning, and owing to many requests they have had from other cities for a copy, they have included this as a part of their report. The report then gives a sketch of the struggle which the Committee had to secure the new contract. After finding at the beginning of the year that the price was exorbitant, and getting permission of the City Council, the Committee served notice, February 22, on the United Electric Light Company to that effect. Then the Committee endeavored to secure an estimate from the local Company. Being unable to obtain reasonable figures an order was introduced in the City Council asking leave to advertise for proposals for lighting the city; but the Aldermen tabled the measure. Almost discouraged the Committee began to agitate the question of municipal lighting, especially from a financial standpoint. The Committee did not favor it as expedient, and except as having a tendency to induce the local Company to accept a reasonable offer. It had the desired effect, for May 22 a contract with the United Electric Light Company was signed, they agreeing to furnish 300 half-arc electric lights for \$83½ a year for each light, a very satisfactory reduction from the former price of \$219. This investigation was carried on at an expense of less than \$20 to the city. Under the contract the city is required to furnish the lamp poles. The Committee endeavored to secure chestnut poles, but had to get of the Massachusetts Construction Company, of Boston, Georgia hard pine poles, which are believed to be equally durable. The work of setting the poles was also done by this Company. The Committee believes the contract to be very fair and reasonable, and recommends that a strict observance should be insisted on by the city. It is also recommended that the lights be tested from time to time, for electric lights, to be a success, must be of the specified candle power. Owing to the irregular streets and the unnecessary number of shade trees on many of them the Committee found it very difficult to derive the best results from lights in many localities. This has been obviated by using mast arms placing lights over the street. The arms used by the city are two patterns, the Brady, the longer in use and giving general satisfaction, and the other, the Russell, a much neater and lighter arm, equally satisfactory. It is recommended that the electric lights be increased so as to dispense as far as possible with the gas and oil lights, especially on the principal streets, where they serve the double purpose of giving light and protection. In June the Committee advertised for proposals for the care of the gas and oil lights, but owing to the greatly increased number of electric lights, no bids were received. T. W. Hamilton has continued the work at the old price, 2 cents a night for gas, and 2½ cents for oil lights, although he is under no contract. The Committee believes that the time has arrived when the city should establish by ordinance a superintendent of street lights, whose duty shall be to carefully inspect all electric lights and report any irregularities to the Committee, also to have supervision of all other lights of the city."

Position Wanted

As Superintendent or Assistant of a Gas Works,
By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address
758-3 "C.," care this Journal.

FOR SALE,

Otto Gas Engine, 15-Horse Power,
With Counter Shafting, Belting, etc. Completely fitted for running electric lights. Used only 10 days; satisfactory reasons for selling. Address
761-2 "C. B.," Post Office Box 5104, Boston, Mass.

FOR SALE,

All the Appliances Necessary for the Passing of 100,000 Cubic Feet of Coal Gas per Day.
Now in operation at Stamford, Conn. Reason of sale, incapacity of present plant. For further information address
759-4 STAMFORD GAS LT. CO., Stamford, Conn.

FOR SALE.

A Complete Water Gas Plant.
60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

760-1f SECRETARY, 123 Beale Street, San Francisco, Cal.

Fuel and Its Applications.

By E. J. MILLS, D.Sc. F.R.S., and F. J. ROWAN, C.E., assisted by others, including Mr. F. P. Dewey, of the Smithsonian Inst., Wash., D. C.

PHILADELPHIA, PA.

No. 29 Champion.

It is to the interest of Gas Companies and Cities to double the efficiency of the light on streets by using Dyott's Patent "CHAMPION" LAMPS. They save 50 per cent. over others in cost of repairs, are ornamental, and indestructible except by violence.
Our Patent System of Instantaneously Lighting Gas (without electricity), for Railroad Depots is unequalled.
Dyott's High Candle Power Burner is a very superior lamp where a concentrated and brilliant light is wanted in Hotels, Stores, Depots, etc.
Special Drawings furnished and Estimates cheerfully given, either from Architects, Engineers, or our Draughtmen's Plans.
We manufacture every description of Plain and Ornamental Lamps, Posts, Brackets, Clusters, etc. Correspondence solicited.

All Flames are Regulated by a Direct Needle Valve.

The JEWEL

IS THE

Only Well-Made Gas Stove on the Market.

Write for our 1890 Catalogue and see for yourself.

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

GUARANTEED ESTIMATES of Cost of Gas Furnished on Application.

GASHOLDER TANK CONSTRUCTION, ETC.

Gas Companies and others about to erect Gasholders will find it profitable to consult W. C. Whyte, who for over 30 years has made a specialty of

Tank Excavation and Mason Work.

Fifty Tanks now in operation show the sort of work done. Address

W. C. WHYTE, No. 15 Cortlandt Street, N. Y. City.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

CONNELLY & CO., No. 111 Broadway, New York City.

E. STEIN, Sec.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

[OFFICIAL NOTICE.]

New England Association of Gas Engineers.

SECRETARY'S OFFICE, BIRMINGHAM, CONN., Jan. 10, 1890.

The Twentieth Annual Meeting of the New England Association of Gas Engineers will be held at Young's Hotel, Boston, on Wednesday and Thursday, Feb. 19th and 20th. The meeting will be called to order on Wednesday, at 10 A.M., by the President, Mr. R. B. Taber.

At the present moment it is impossible to give a list of the papers which will be read at the meeting, but it is hoped that the literary part of the programme will equal any of those held in past years.

Persons eligible for membership who desire to join the Association will please communicate with the Secretary, who will forward at once blank form of application.

CHARLES H. NETTLETON, Sec'y.

BRIEFLY TOLD.

ARC LIGHTING AT BOSTON, MASS.—Our item columns contain an account of the award for public lighting by means of arcs in Boston for the current year, the bulk of which is to be performed by the Suburban Light and Power Company, at its bid of 39.74 cents per night per light for city proper, and 39.99 cents for the Roxbury district. The Boston Electric Light Company refused to tender for the work because the new set of specifications provided that the maximum rate that would be considered should not exceed 40 cents per light per night, the refusal being based on the fact that at the maximum rate the Company would not be serving the interests of its stockholders did it attempt to secure the work. The Charlestown Gas Company, that had been performing the arc lighting for the Charlestown district, also refused to tender, and for similar reasons to those submitted by the other Company; but we understand that the Charlestown proprietors have reconsidered their former determination, and have since agreed to go on with the lighting of the district at the rate of 40 cents per arc per night. This later action we presume may be fairly taken as indicative of the fact that the Gas Company can supply electric currents for lighting more economically than can be done by an independent Company. But be this as it may, we are just now more concerned with the reasons put forward by President Gilbert, of the Boston Electric Light Company, in defending, or rather explaining, his action in the matter of refusing to submit a tender. Having asserted that the officers and directors of the Company proposed to do all in their power to protect the amount of money invested by the stockholders in their business, he stated that he was perfectly willing to leave the settlement of a contract price to the decision of the State Board of Gas and Electric Light Commissioners, or would consent to an inspection of the Company's books by an expert or experts to be named by the Mayor, and abide by the result. Continuing, President Gilbert said: "If Mayor Hart had removed the restriction of a 40-cent limit, the Company could have put in a bid of 50 cents for districts where the housetops are wired, and for the remaining circuits an offer for a lower figure could have been made that would have brought the total average expense below 50 cents a light per night. At present it costs the Company 47 cents per light to illuminate the streets, hence, and simply from a business standpoint, the Company could not make an offer of 40 cents, on the basis more particularly of a yearly contract." From President Gilbert's statement it would seem that arc lighting (that is, where a fair attempt to keep up to the candle power named in the specifications is the rule) is not a great bonanza at rates that are even largely in excess of many now maintained at various points in the country. President Gilbert's statement, in any event, has the merit of being plain, if not blunt.

THE AMENDMENT WAS NOT ACCEPTED BY THE GAS COMPANY.—The following item was printed in our issue for January 13th: "The Pawtucket (R. I.) Common Council has amended its contract for public lighting with the Pawtucket Gas and Electric Light Company so that the 2,000-candle power arcs now supplied on the all-night schedule may be changed to half arcs." Naturally this conveyed the intimation that the ordinance or agreement had been adopted by the Council and accepted by the Company. This, however, was not the result; the amendment

or order was only introduced, and the Gas Company negatived the proposition.

AN APPLICATION FOR AN OPPOSITION CHARTER AT FREEPORT, ILLS.—At a meeting of the City Council of Freeport, held on the 6th inst., Clerk Osborne read a lengthy ordinance, based on a proposition from Nathan Shelton, regulating the acts and prospects of an opposition gas company. The promoters propose to supply an uncarbureted fuel gas, under the Evans process, and to charge the consumers for it at the rate of \$1 per 1,000. Ald. Holland, immediately on the reading of the proposition, after asserting his belief that such a measure should receive careful attention, moved that a committee of three, acting in conjunction with the Mayor, should be appointed to sift the matter thoroughly. This opinion was concurred in by the Council, and the Mayor appointed Messrs. Holland, Brunn and Flachmeir as such committee. The Freeport Gas Light and Coke Company charges from \$1.80 to \$2.25 per 1,000 cubic feet for a good quality of illuminating gas, and its service so far has given good satisfaction to the residents. We imagine, however, that if the Council Committee gives the proposed ordinance a careful scanning, and goes thoroughly into the aims and objects of those who are backing it, the project will not be indorsed by the authorities.

SUIT FOR DAMAGES.—In the suit of Mr. J. S. Brown, of Bishop street, Montreal, who asks for \$800 damages against the Gas Company, alleging that his family's health was injured because of gas that escaped into his residence from a fractured street main, defendant has called the city into the case to guarantee it against the outcome of the suit. This is asked for because the main in question was fractured by the impact from a heavy steam roller used by the city in the operation of macadamizing Bishop street.

PROCESSES AND THEIR DEVELOPMENT IN ENGLAND DURING 1889.—In its retrospect for the last year, the *London Journal* thus makes mention of certain new processes and inventions in the gas industry:

"A fair number of new processes and inventions in connection with gas making have attracted public attention during the past year. There has been a distinct revival of speculation in new or ostensibly novel descriptions of illuminating and fuel gas. To say little of such devices as the Lawrence automatic gas, which is simply gas carbureted with petroleum spirit, or the Lothammer gas, which is carbureted under pressure with the same material, notice must be taken of the remarkable 'boom' in water gas, which was secured by the clever financial operations of the promoters of the British Water Gas Syndicate. The £5 shares of this venture (£3 paid) were at one time forced up to £26; and two concessionary companies were launched before the bubble collapsed. The question of the possibility of utilizing water gas plant as an auxiliary to the coal gas plant in British gas works, previously regarded as impracticable on the score of expense of production, was seriously raised towards the close of the year, when the Directors of the Gas Light and Coke Company sent their Chief Engineer (Mr. G. C. Trewby) to the United States to inquire into this and other matters of which American gas engineers have special knowledge. Several American gas engineers of experience in water gas manufacture came to this country about the same time with a view to demonstrating the practicability of making carbureted water gas here at a cost comparable with that of ordinary coal gas. It was reported that at least two, and perhaps more, of the London Gas Companies contemplated putting these claims to the proof of experiment on a working scale; and a working water gas plant has actually been erected by the Van Steenberg syndicate at Humphreys' Hall, Knightsbridge. Meanwhile pressing labor troubles caused attention to be given in increased measure to devices for reducing the handiwork of coal gas manufacture. Favorable notice was taken of the inclined retort settings of M. Coze, of Rheims, the successful working of which with English caking coal was proved to the satisfaction of a deputation of representative English engineers who visited Rheims for the purpose. M. Coze's success has already attracted a host of imitators, with whom he will probably have to fight for his profits if his system, or anything like it, should be generally adopted.

"The Dinsmore process of improving coal gas by carbonizing the tar has been partially adopted at Widnes, and is being experimented with in some other places. Mr. Valon, at Ramsgate, has developed a process for the production and use of pure oxygen in gas purification, by an ingenious modification of the Brin process for separating oxygen from the atmosphere. The Claus system of continuous gas purification by liquids in closed vessels was adopted at the Belfast gas works and used successfully for 72 days, when there was a complete breakdown of the pumps attached to the apparatus, which proved to be of unsuitable pattern. The capability of the plant, when in proper order, and the reliability of

the system for dealing with a daily make of 1,600,000 cubic feet of gas, were, however, established; and the apparatus is shortly to be started again with new pumps. The interesting problem of dispensing, wholly or in part, with the lofty guide-framing of gasholders, received further elucidation from the continued success of the Rotherhithe experiment, in which a triple-lift holder has framing only to the height of the second lift. The example was followed in designs for enlarging several other holders belonging to the South Metropolitan Company. Mr. W. Gadd, of Manchester, brought out a patented invention for guiding gasholders from the base, which was to be tried on a holder not yet finished, at Northwich. Mr. E. Lloyd Pease, of the firm of Messrs. Ashmore, Benson, Pease & Co., of Stockton, patented a system of rope-guiding for gasholders, which was tried with success on a holder at Haslingden."

The Market for Gas Securities.

During the week the market for city gas shares was strong even to buoyancy, although the actual number of transfers was not exceptionally large. Consolidated sold up to 96½, and then reacted somewhat, but at no time did it go below 95½, the highest point of the previous week. To-day (Friday, Jan. 17) opening sales were made at 95½, and some brokers predict that lower figures will be recorded. We, however, do not share this belief, unless a considerable disturbance in the loan market takes place. Other city shares are also strong.

Brooklyn shares are well up to the mark, with every indication that important developments in respect to consolidation of interests will shortly take place.

The event of the week in New York proposed gas legislation was the introduction by Senator Roesch, on the 16th inst., in the State Senate, of a bill amending the gas companies' act to the extent of empowering gas companies to borrow money to pay debts or extend operations by bonds issued on franchise or property, not to exceed in amount the capital stock, the issue to be made only with the consent of two-thirds of the stockholders.

In out-of-town shares the most notable showing is made by the Consolidated Company, of Baltimore, the bid rate having been advanced thereon to 55, holders offering at ½ point higher. This is an advance of 5 points for the week.

Bay State (Boston) common is inquired for at 23, while Laclede common is offered at 18½. Chicago Trusts are at 46 bid.

It is likely that American capital will be invoked to carry out the provisions of a franchise recently granted by the authorities of Monterey, Mexico, for the operation of a gas works at that point.

Correspondence

[The JOURNAL is not responsible for the opinions expressed by correspondents.]

Dr. Wilkinson Objects to the Figures.

NEW YORK CITY, Jan. 11, 1890.

To the Editor AMERICAN GAS LIGHT JOURNAL:

My attention has been called to the article "A Question and an Answer," in your JOURNAL, December 9th, 1889.

Mr. Smithson does not give you the whole story as to what the new gas company propose to do. In the first place, they have a complete coal gas plant of sufficient capacity to make coke for the balance of the works, which will consist of a process of "wood water gas," so successfully used for several years at the New York Mutual Company's works. We there found that wood of no matter what kind, oak, chestnut, pine (fat or lean), hemlock, bark, etc., would in every case produce the same number of cubic feet per pound; the average for the whole time being 55,000 cubic feet per cord.

The process is patented, and has not been used in works named by you. It is entirely different in working and results from the usual wood-gas making; hence the figures you give do not apply. We all know what Australian shale will do as an enricher, and the figures you quote have been far exceeded by the process we propose.

Again, it is by no means certain that we shall use shale; for I have before me a sample of oil that can be had in any quantities—1,000 barrels per day, if wanted—delivered in San Francisco at a price that will enable the company to deliver gas (of 25-candle power) in holder at about one-half the price named by you.

As a rule, I do not answer such statements; but when I have the figures of actual work I feel it a duty to give them to the profession.

A. W. WILKINSON, M. D.,
Chemist to the Mutual and Equitable Gas Light Companies, N. Y. city.

Another Step in the Granger Process.

Letters patent (No. 418,711) were granted, on January 7, to Arthur O. Granger, of Philadelphia, for an improvement in a gas making process, the apparatus for which was patented by him on January 9, 1885, the serial number of the patent being 152,385. The specification submitted with his latest effort is as follows :

My invention has reference to a process for the manufacture of water gas ; and it consists in first heating up a bed of carbon in a generator, and with the products of combustion therefrom heating up a superheater or fixing chamber by internal combustion, then passing steam into the bed of carbon producing water gas, then passing the water gas, mixed with carbureting fluid, through the superheater, entering at the end where it is least hot, and causing it to pass through the superheater, gradually entering a zone of greater temperature, until it finally escapes to the washer or holder from the end which is hottest, as is fully set forth in the following specification and referred to in the claim.

The object of my invention is to insure the illuminating gas passing into the superheater, at least the hot portion, and leaving the same at its hottest part, by which the thorough decomposition and fixing of the gases result, and at the same time the production of lampblack is entirely overcome. In apparatus in which the hydrocarbon vapors or liquids are caused to enter the superheater at its hottest portion of the hydrocarbon is instantly converted into lampblack and fixed upon the filling or lining of the superheater. By overcoming this production of lampblack I greatly increase the production of illuminating gas, as well as improve the working of the apparatus.

In the drawing is shown a sectional elevation of water gas apparatus in which to carry out my improved process.

H is a superheater, and *G* is a generator, which are connected together in any suitable manner, as by the connecting flue or passageway *E*, which opens from the top of the generator into the bottom of the superheater, or by an auxiliary flue connecting with the upper part of the said superheater. The generator is provided, as usual, with the blast pipe *I* and the steam pipe *J*, preferably entering below the grate bars.

The superheater *H* is provided with a lower combustion chamber *K* and auxiliary flue *C*, connecting the flue *E* with the upper part of the said superheater and above the filling *I*.

A is a water-cooled valve and works on the water-cooled seat *B*, and is adapted to close the entrance to the chamber *K* or the flue *C*, by which the product from the generator may be caused to pass either into the chamber *K* or the flue *C*, as desired, thus causing the said products to pass into the top or bottom of the superheater.

L is the smoke outlet opening from the top of the superheater, and *F* is the gas outlet opening from the chamber *K* and connecting with the usual water seal or washer.

D is the hydrocarbon spraying nozzle, which admits hydrocarbon fluid into the upper part of the superheater, preferably where the water gas, which passes through the flue *C*, enters the superheater. If desired, the fluid hydrocarbon may be admitted anywhere in the flue *C* or in the superheater proper, or it might be admitted in the generator.

In making gas the valve *A* is turned up, so as to close the flue *C* and open the passageway from the generator into the bottom of the superheater or its chamber *K*. The smoke outlet *L* is opened and the blast from pipe *I* is turned on. The coal in the generator is brought to incandescence by the blast from the pipe *I*, and the products are caused to pass into the chamber *K*, and are burned therein, the products therefrom passing up through the filling or internal brickwork of the superheater and escaping by the chimney outlet. The air blast from pipe *I* is then shut off, chimney *L* is closed, and valve *A* turned so as to close the entrance to the chamber *K* from the generator and open the auxiliary flue *C*. Steam is then admitted from pipe *J*, which, in passing up through the generator, is decomposed, forming carbonic oxide and hydrogen, which are conducted up through the flue *C* to the upper end of the superheater, where they are preferably brought in contact with a carbureting fluid from nozzle *D*, and the mixed gases then pass down through the superheater, entering that portion thereof which is least hot and emerging from that part which is hottest, becoming thoroughly incorporated and fixed into an illuminating gas, which then passes off by flue *F* through the usual water seal to the holder, if desired, preferably passing through purifying apparatus before reaching the said holder.

If desired, the auxiliary flue *C* might be separate and distinct from the superheater and built in the form of an external tube, and in place of one valve, *A*, two valves may be used, one controlling the entrance to the bottom of the superheater or chamber *K*, and the other the auxiliary flue thereof ; and it is evident that the smoke outlet might be from pipe *F* and the gas outlet from *L* ; but of course in this case the hydrocarbon nozzle *D* would be located at the bottom of the superheater or in the chamber *K*, the principle involved being identical with that hereinbefore described.

It is immaterial to my invention what the construction of the generator may be or what location may be given to the gas outlet or the steam and blast pipes.

Pressure Gauges and Pressure and Exhaust Registers.

W. Ralph Herring, in his articles on the "Construction of Gas Works," now running in the *English Gas Review*, makes the following remarks on the pieces of apparatus mentioned in the headline:

Pressure Gauges.—Gas as generated from the coal during the process of destructive distillation when subjected to the ordinary pressure existing in the apparatus of gas works, assumes a volume about 380 times greater than the coal from which it is extracted; and this volume is capable of augmentation and diminution by the effect of the variable atmospheric pressure and temperature. For the purpose of appreciating the various pressures to which the gas is subjected in the apparatus on the works, the water gauge is employed, which, in its simplest form, consists of a glass tube of about five-eighths of an inch internal diameter, bent in the form of a letter U. This tube is half filled with water, and a scale divided into inches and tenths of an inch is placed between the two tubes. One of the ends of the tube is covered by a perforated cap, while the other is made to communicate with the apparatus it is intended for. The gas pressure will depress the water in the tube to which it is connected, and raise it in a corresponding degree in the other tube; and the distance between the two levels indicates the pressure, which up to two or three inches is generally described in "tenths," and above this amount the term inches is applied.

The tubes are usually of equal diameter, so that the depression in one is equal to the rise in the other; but when two tubes of unequal diameters are employed, such as when a small tube is placed inside a larger one, the depression and elevation of the liquid is in proportion to their respective areas. At one period, when the baneful effects of heavy pres-

sure were not understood, it was by no means unusual to find a pressure of 30 or even 40 inches in some works, occasioned by small or choked mains and by defective purifiers. In these cases mercurial pressure gauges were used, which are similar to the water gauge, but having tubes of only a quarter of an inch in diameter, and as mercury is about thirteen and a half to fourteen times heavier than water, these gauges were made proportionately shorter. Thus a column of 30 inches of water would be substituted by a mercurial gauge of $2\frac{1}{4}$ inches in length; but, with the advanced knowledge now prevailing, such pressure should never exist; at the present time, therefore, the mercurial gauge is no longer in requisition, and any slight variations in the pressure are not nearly so well indicated by this as with the water gauge.

If tubes of unequal area are employed—say the one of ten times larger sectional area than the other—the water will be depressed nine-tenths in the smaller, and elevated but one-tenth in the large tube, and, by taking advantage of this circumstance, the pressure gauge can be made to indicate with one tube only, which in some cases may be desirable.

In all the various parts of gas works, whether in the retort house or on the apparatus, the simple tube gauge is preferable to all others, as there is no likelihood of its being [disarranged, whereas with other descriptions, if the water is not maintained strictly at the level, or when roughly handled, they are liable to mislead. By means of the gauge we are enabled to know the exact pressure existing in any part of the works, and from this ascertain the existence of any obstruction, either in the connections or in the apparatus, and stoppages in the district mains are, likewise, readily detected by its aid.

It is, for the before-mentioned reasons, important that a pressure-gauge be fixed to the inlet and outlet of each piece of apparatus through which the gas has to pass. In some cases, such as the washers, and more particularly the purifiers, one gauge on the inlet of each is sufficient, as the difference between the one and the other indicates the pressure.

Pressure and Exhaust Registers.—The principle of the action of these instruments is the same as that of the foregoing, with the important difference in make that they record as well as indicate the pressure or exhaust, as the case may be. This is accomplished by means of a float in water to which a vertical spindle is attached, having a lead pencil at the upper end, pressing upon a cylindrical graduated roll of paper upon a drum which is caused to revolve by clockwork once in the twenty-four hours, the paper roll being renewed daily.

The exhaust register should be connected to the mains at a point on the inlet side, and the record shows exactly whether the exhauster has been kept working with regularity.

The pressure register is in communication with the street mains, beyond the governor, and records the various pressures maintained therein during the day and night. The difference between the exhaust and pressure registers is simply one of detail in construction.

King's pressure-gauge works on somewhat the same principle, viz., a float in a suitable vessel of water. A cord is attached to the float, and passes over a small pulley on a spindle running in roller bearings. On one end of the spindle is a fixed pointer, which moves in front of a semi-circular dial, on which are inscribed very fine divisions indicating the pressure according to the rising or falling of water line caused by the pressure of the gas. This gauge indicates much finer variations of pressure, but is not used much, except when in skilled hands, as the loss of water by evaporation requires to be constantly made up, otherwise the indicators would be incorrect. This disadvantage has been quite recently overcome by the introduction of Messrs. Harrison and Sheard's patent mercurial gas pressure-gauge, Messrs. W. and B. Cowan (of Smith Square Works, Westminster, S. W.) being the manufacturers. It is a most convenient and portable appliance, and is constructed on the principle of the "King's" gauge, but with mercury to operate the float instead of water, thus absolutely overcoming the difficulty of loss by evaporation. To the float is attached a small spindle, on the upper end of which is a rack, which actuates a pinion on the pointed spindle. The dial can, when required, be made to indicate vacuum and pressure. The top of the float-chamber is arranged in such a manner that even if the gauge were turned upside down the mercury could not escape, thus allowing the instrument to be carried from place to place without fear of derangement. This is a very valuable instrument, and one that should be in the hands of all gas managers. I see no reason why the principle of substituting mercury for water should not be applied to the gauges on jet photometers, as now, with water, and in hot rooms, the level of the water requires constantly adjusting, and one can scarcely even look at the jet without the question presenting itself to the mind, "Is the water-line right?"

The Alexander and Paterson Process of Making Oil Gas.

Letters Patent (No. 419,098) were granted on the 7th inst., to Messrs. Thomas and Samuel Alexander, of Kirkintilloch, Scotland, and Robert Paterson, of Glasgow, Scotland, for an improved apparatus for making oil gas—the matters had already been protected by English patents—the principal features of which are outlined in the following specification. The inventers say:

Our invention has for its object, by improved, simple, and easily managed apparatus, to make gas of good quality from oil, the same be-

Fig. 1.

Fig. 2.

ing specially designed for use at country houses or in connection with works or other buildings where gas is made on the premises.

In carrying out our invention we employ one or more horizontal retorts of a cylindrical form arranged in a building with a fire grate and flues suitable for heating the retorts with ordinary fuel. The oil to be

converted into gas, and which is by preference purified petroleum or mineral oil, is led into each retort by two or more straight horizontal pipes placed near the inner surface of the retort, by preference at the upper part, and extending from the front end of the retort nearly to the back end, the inner ends of the pipes being open. The oil is partly converted in passing along the horizontal pipes and issuing from their inner ends. The vapor or gas is further acted on by the heat in passing from the back to the front end of the retort, at which latter part the outlet is situated.

Minor improved details, upon which the practical success of the apparatus largely depends, are hereinafter described.

Fig. 3.

In the accompanying drawings, Figs. 1 and 2 are front and side elevations; and Figs. 3 and 4 are vertical sections, as at right angles to each other.

In the apparatus two cylindrical iron retorts 5 are placed in a brick building 6, the back ends of the retorts being formed with studs 7, by which they are supported in the back wall of the building. The front ends of the retorts project through the front wall of the building 6, and each retort is fitted with two end covers 8 9, each upper cover being bolted to the retort in a comparatively permanent manner, while each lower half 9 is held in place by a common bridle and screw 10, so that it can be easily opened for cleaning out the retort. Within the building 6 the retorts 5 rest on a horizontal fireclay slab 11, and the fire-place 12 is made at one side and communicates with an upper oven space 13, in which the retorts are situated. The fire gases pass over the retorts 5 and have free access to their sides, and then pass downward at the side further from the fire-place 12 and enter through ports into a flue 14, extending under one of the retorts. From the front end of the flue 14 the fire gases enter a flue 15 under the other retort and proceed along it to a chimney at the back (but not shown).

Through the top front cover 8 of each retort 5 two pipes 16 are fixed

Fig. 4.

so as to extend along inside the retort near its upper internal surface to within a short distance of the inner end of the retort. These pipes 16 have their inner ends open, and are supported near their inner ends by a ring 17, placed inside of the retort, and which ring divides the retort into oil or gas chambers. The pipes 16 are made quite straight to facili-

tate the cleaning, and each is fitted with a screw-plug 18 at its front end which can be withdrawn to admit a cleaning instrument. The oil is led into each pipe 16 at one side, near its outer end, by a pipe 19, made with a siphon bend and provided with a funnel 20 at its outer end. Each retort pipe 16 is separately supplied with oil, the several funnels 20 being for convenience arranged in a horizontal row beneath separate stop-cocks 21 upon a main supply pipe 22, fitted with a main stop-cock 23, and connected with an oil tank (which is not shown, but which should be placed at a level a little higher than the stop-cocks 21). The total supply of oil can be regulated by the main stop-cock 23, while the portion of the supply allotted to each retort pipe 16 can be separately regulated by the branch stop-cocks 21. The gas formed in the retorts 5 passes off by ascension-pipes 24, connected to their front ends at the tops, into a main 25, and thence by a pipe 26 into a vertical pipe 27, which is provided with two stop-cocks 28 29, one above and the other below the junction of the pipe 26. The upper stop-cock 28, when open, communicates directly with the atmosphere, and the lower one 29 communicates with an ordinary assemblage of pipes 30, known as an air condenser, the set of these pipes 30 being supposed to be seen in edge view in Fig. 1 and to be extending backward. A branch pipe 31 (shown in Fig. 1) is at the back end of the condenser, and is for the attachment of a pipe leading to a gasholder of any convenient kind. The lever handles of the two stop-cocks 28 29 are connected by a rod 33 in such way that the action of opening one closes the other. When freshly starting to make gas the upper stop-cock 28 may be opened to allow the gas or vapor first formed, and which is mixed with air, to escape to the atmosphere instead of mixing with any good gas there may be in the condenser and gasholder. The gasholder drum is counterbalanced by weights made sufficiently heavy to raise it and produce a partial vacuum inside of it for the purpose of drawing the gas from the retorts and through the condenser and piping. This arrangement makes it necessary to provide the two connected stop-cocks 28 29, hereinbefore described, and the closing of the lower one 29 when the upper one 28 is open prevents air from being drawn in by the action of the partial vacuum.

Our improved apparatus, as hereinbefore described, is such as to allow of the action being easily and satisfactorily regulated and controlled, without which good gas cannot be formed economically and the apparatus cannot be kept in good order. With a suitable regular heat in the oven or flue space 13, it is essential for good working that neither more nor less than the proper supply of oil should be maintained. By opening the stop-cock 28 and allowing gas to issue from it its color will afford a means of judging whether the action is going on properly, and the attendant can adjust the supplies of oil or the heat from the furnace accordingly.

The Illinois Coal Industry.

The eighth annual compilation of statistics of the coal industry of Illinois has just been completed by Col. Lord, Secretary of the State Board of Labor Statistics, and is ready for publication. The record for the year ending July 1, 1889, shows the following summaries from the reports of the several mine inspectors as compared with the preceding year:

	1889.	1888.
Number of tons of lump coal mined.....	11,597,963	11,855,188
Aggregate value of product at the mine.....	\$12,496,885	\$13,309,030
Average value per ton at the mines.....	\$1.0775	\$1.123
Number of employees of all kinds.....	30,076	29,410
Number of miners..	23,583	23,648
Number of other employees (including boys)..	6,943	5,762
Number of boys employed underground.....	859	868
Average price paid per ton for hand mining..	\$0.731	\$0.716
Number of men killed	42	55

The total fuel product, including what goes through as well as over the screens, for 1888 was 13,396,362 tons; and for 1889, 13,105,698 tons. There is a shortage of 694,452 tons in the northern half of the State, and an excess of 437,227 tons in the southern half over any previous year. Macoupin is the banner county, raising 1,202,187 tons. The average value of coal at the mines in the State has gradually declined from \$1.51 in 1882 to \$1.07 in 1889. This, however, gives little idea of the wide variation in values in different localities and under differing conditions. The extreme of prices reported is from 50 cents to \$2.25 per ton. Fifty cents per ton on the track is given as the average value of coal at several places in St. Clair county, and in one instance 60,000 tons are reported at this price. This is, however, altogether exceptional, and is the lowest price ever given the inspectors. Above this, prices range in the same vicinity from 62½ cents to \$1 per ton, giving an average for the

fifth district of 87 $\frac{7}{10}$ cents. In the second district, on the other hand, in the northwestern portion of the coal fields, prices range from \$1.25 to \$2.25 per ton at the pit, with an average of \$1.43. These extremes in prices are by no means arbitrary, but doubtless fairly indicate the actual difference in the cost of production; for competition is sufficiently active everywhere to keep prices close down to the cost of the coal.

In view of the mildness of the winter and the depression in trade occasioned by it, and more especially in view of the general suspension of operations in the northern field pending a settlement of the wages question during the last two months of the year, the falling off in the annual output is perhaps less than might have been expected. The number of mines and of men is slightly increased over all former years; the average value of the product has dropped from \$1.12 $\frac{1}{2}$ to \$1.07 $\frac{3}{4}$ per ton; the average number of days of active operations has fallen from 220 to 211; the price of hand-mining for the State at large is found to have slightly increased, and the number of fatal accidents has materially diminished. There has been rather more than the usual number of new mines opened, but a corresponding increase in the number closed, while the number of mining machines reported as in use is less by 37 than the number in use the year before.

The four mines from which have been delivered the greatest tonnage during the year and the only ones which have produced over 200,000 tons are the Chicago, Wilmington and Vermillion Coal Company, No. 1, at Streator, La Salle County; Consolidated Coal Company of St. Louis, No. 6, at Staunton, Macoupin County; Consolidated Coal Company, of St. Louis, No. 1, at Mount Olive, Macoupin County, and Pana Coal and Mining Company, Colliery No. 1, at Pana, Christian County—the total tons produced being 922,484. The average daily wages paid machine men indicate ruling rates of \$2.25 and \$2.50 per day for machine operators, \$1.75 for helpers, \$2 for blasters, \$1.75 for loaders, \$2 for timber men, \$1.50 and \$1.75 for laborers and \$2 for drillers. The average prices paid for mining by hand decreased from 80 cents per ton in 1883 to 73 cents in 1889, though in 1886 the average was as low as 67 $\frac{1}{2}$ cents. These are general averages by districts. The extremes show the lowest to be 31 $\frac{1}{2}$ cents and the highest \$1.50. The price paid for the greater portion of hand-mining is from 50 cents to 95 cents a ton, the latter in the thin web coal of Will and Grundy counties and the former in the high and dry seams of the southern fields.

This year the machine-mined coal is 21 per cent. of the entire product; last year it was 19 per cent. The increase in the output of this character is largely in the fourth district, and the decline in the first and fifth. Several new machines have been produced during the year and several experiments have been made in the use of electricity in the place of compressed air. The mine at Girard, in Macoupin County, has an electric plant on trial which is furnishing motive power to a new device for under-cutting the coal and at the same time furnishing a current for a system of electric light throughout the workings. With the gradual development of the coal resources of the State it is found that the number of operatives drawn there by the demands of this industry increases year by year, regardless of the fluctuations in trade in wages. This receives fresh illustration in the totals reported for this year, which has not been altogether a prosperous one, and yet the number of employees now in the State is reported as 30,076, or 666 more than in any previous year.

After rehearsing the history and results of the great wage controversy in Northern Illinois the report says: "Thus ended a strike which involved more men, more loss of time, more loss of good wages and of product, occasioned more distress, commanded more public sympathy and discussion, more public declarations of the points at issue by both parties, and at the same time was conducted with more patience and moderation on the part of the men in view of their number and distress, than any which has occurred in the history of coal mining in this State."

Methods of Lighting Work on the New Croton Aqueduct.

The *Engineering Record*, in the course of a series of articles on "Builders' and Contractors' Engineering and Plant," alludes in the following manner to the methods of lighting followed by the contractors in charge of the work on the new Croton Aqueduct:

The methods employed for lighting the tunnel of the new Croton Aqueduct during its construction were chosen by the different contractors to suit their own ideas as to system, except on that portion of the work where the orders to use improved methods were complied with.

On the Northern Division, where the work was executed by Brown, Howard & Company, kerosene lamps and gasoline torches were generally used, Each torch being provided with 15 burners, consumed a large amount of oxygen, nearly as much as 15 men would require, and

the smoke from the torches and lamps sometimes became so dense in the headings as to cause a stoppage of the work. When more torches were added to increase the light the increased amount of oxygen consumed and smoke evolved produced an opposite effect, making the lights so dim that the darkness was almost visible; while the lamp-black emitted by these lamps filled the lungs of all exposed to its influence.

The stationary lamps were constructed of tin, with a flat reservoir to hold the burning fluid, from which a small pipe extended down about 2 feet, and then projected horizontally about 10 inches, terminating in the burner. Hat lamps were used by the miners, in which miners' oil was burned with kerosene added to increase the flame. Candles were also occasionally used for hat lights.

These lights were also used by John Brunton & Company at the beginning of the work below Harlem River, but they were generally replaced by electric lights in December, 1886. As the headings on this portion of the work were advanced only a few hundred feet at that time the bad effect of the oil lamps was less noticeable.

Electricity was introduced on the Northern Division in 1886, but the lamps placed in the tunnel were very far apart. In the tunnel leading from shaft 2 the intervals between the lamps varied from 500 to 600 feet. At shaft 11 there were three lamps in 2,000 feet. In November and December, 1886, the official report showed that 7 electric lights were burning in the headings of shaft 2, and the same at shaft 3. At shaft 5, on December 21, 3 lamps were reported to be in use by the bricklayers, and 8 along the tunnel; but this is the only case where so many lamps were used. Two lamps were reported at shaft 6, and 4 at shaft 9. The full number of electric lamps given above was not burning all the time, but only at intervals, particularly in the tunnel. Frequent reports were made of from 5 to 7 gasoline torches being used by the bricklayers in one heading.

On the Southern Division, which was built by O'Brien & Clark, electric lights were the rule, and, consequently, the condition of the atmosphere was very much better. The lights were not frequent enough in the tunnel to permit one to travel about freely without the aid of lamps, but all points where work was in progress were well lighted by electricity. On a portion of the work 4 lamps were burning within 1,000 feet; but in other places they were 500 feet apart. The miners and muckers were provided with the usual hat lamps, but in some of the headings candles were used altogether for hat lights, especially at shafts 16 and 17.

An electric light plant was placed at nearly every shaft. A complete electric lighting plant would have required a steam boiler, an engine, a dynamo, and necessary lamps, but as boilers were provided for operating the compressors and hoisting engines at each shaft, the surplus power was generally sufficient for operating the dynamos. At many of the shafts the dynamos were placed in a room separated from the rest of the plant to guard against accidents.

The best location for the wires in the tunnel was up out of the way near the roof, and secured to the rock or the arch of the completed conduit. On a portion of the work the wires were placed only a few feet above the floor, where they were liable to cause accidents whenever the insulation became imperfect. The lamps were suspended from the center of roof, or at one side, as was most convenient.

The engines used for operating the dynamos were small, usually from 15 to 20 horse power, and the dynamos were adapted for divided arc lamps. To operate a full-sized arc lamp of 2,000-candle power requires about 1-horse power. The lamps used were of 1,200-candle power, which did not require more than $\frac{3}{4}$ of a horse power each. Only one plant supplied more than 15 lights, so that a 15-horse power engine gave ample power except where there was more than one dynamo at a shaft. At Shaft 30 there was a large dynamo with capacity for 30 lamps, which supplied the current for lighting 6 shafts, from Shaft 27 to 32, inclusive. The conditions here were different from those on any other portion of the line, and unusually favorable for lighting several shafts with a single plant, as these shafts were either located in Tenth avenue or adjacent to it, permitting the telegraph poles on the avenue to be used for carrying the wires between the shafts, which were only $\frac{1}{2}$ a mile apart or less.

The dynamos and conductors used on the Aqueduct were in use continuously day and night, and were subjected to pretty rough treatment, the wires being carried in wet shafts and tunnels, in process of construction, and having, with the lamps, to be shifted daily to permit blasting.

Lightning arresters, to protect the dynamos, were placed on the main current wire, outside of the stations, except in the Ball system, where the wet poles were expected to supply all the conduction needed.

The lamps used for arc lighting on the Aqueduct differed slightly from the ordinary lamps for street service, but the change was only that necessary to adapt them for rough usage.

The dynamos and lamps used for supplying light in the Aqueduct

shafts and tunnels were furnished by the following parties: the Bell Electric Light Company, New York City; the Thomson-Houston Electric Company, Boston, Mass.; the Schuyler Electric Company, Middletown, Conn.; the United States Electric Lighting Company, New York City, and the Brush Electric Company, New York City and Cleveland, Ohio.

Power for running the dynamos was supplied by engines of the following makes—viz.: Westinghouse, Payne, Lidgerwood, Greenfield, Sullivan & Ehlers, and the New York Safety Steam Power Company.

Former for Square Pipe.

The Pittsburgh Sheet Metal Tool Company, Limited, of Allegheny, Pa., is introducing to the trade a machine for forming square heater pipe, cans, boxes, etc., a general view of which is shown in the accompanying illustration. The manufacturers state that this is one of the best for the purpose which has ever been offered the trade, and that it will form a perfect angle up to 90° with one motion of the hand. It is designed for executing any description of square work. It is claimed to be speedy, accurate, and economical in operation. The arrangement of the gauges is such as to make it unnecessary to lay off the sheets to be formed, and that when once set long and short sides can be alternately made as readily and speedily as if but one gauge was employed. A

Machine for Forming Square Pipe.

careful inspection of the accompanying illustration will convey a very good idea of the general arrangement of parts, making a detailed description unnecessary in this connection. The machine weighs about 45 pounds, and may be employed on any bench without the necessity of fastening it down. It is said to be in use in a number of large manufacturing establishments in Pittsburgh and other cities, and those who have employed it speak in high terms of its operation.

The Lighting of an Imperial Railway Train.

M. Warchowsky, Engineer and General Inspector of the Russian railways, gives a description of the somewhat extensive electric lighting of the Imperial train which was adopted after preliminary experiments with a part of the train only. The firm of Jablockhoff & Co., of St. Petersburg, constructed and fitted the incandescent lamps, which are of 6 to 8-candle power at 30 volts, the conductors arranged with contacts between the carriages, the accumulators disposed in three groups, the apparatus for charging these accumulators, the voltmeters and ammeters, and also the dynamo. The steam engine for driving the dynamo is a Brotherhood 3-cylinder machine. The boiler, horizontal, with iron fire box and tubes, was made by Messrs. Nobel, St. Petersburg. The dynamo, steam engine, boiler, the battery of 36 accumulators, and the reservoir of water are fitted in the middle compartment of a wagon with four partitions specially constructed for the purpose. The other compartments containing the fittings and oil, the fire pumps, the Graftio apparatus for controlling the speed of the train, and, lastly, a Schwarzkopf apparatus for prevention of explosion of the boiler. The Imperial train consists in all of 15 carriages. The total number of lamps employed is 253, and they are disposed as follows: Electric wagon, 6; workshop wagon, 8; the Minister of Internal Communications, 22; the Czar's servants, 15; kitchen wagon, 13; buffet wagon, 13; dining-room car 26; Czarina's car, 18; Imperial car, 36; Grand Duke, 20; ladies-in-waiting, 21; body guard, 13; luggage, 7. All the incandescent lamps can be turned on or off separately by the aid of two cords, one red, the other black. Another battery of 18 accumulators is placed in the buffet

wagon, enclosed in a wood box; a third battery of the same number of cells is placed in the dining room car. The accumulators are charged by the main current from the dynamo. The engine is capable of working at 15-horse power, but works usually at about 12-horse power. In the carriages the lamps are distributed singly and in groups. The lamps are either obscured or fitted with ground glass shades, and in the Imperial car movable fittings are used.

When the whole of the train was completely fitted, the authorities made two thorough tests. First, the train when standing was lighted for 24 hours; secondly, the train was completely lighted during the journey from St. Petersburg to Moscow (400 miles), at an average speed of 35 miles an hour, at Moscow during a stoppage of 10 hours, and throughout the return journey to St. Petersburg. During the last test the dynamo was stopped for about two hours, and the accumulators completely charged were then used alone. The Imperial train during the journeyings of the Czar in 1888 ran a distance of more than 5,000 miles, and the electric light always worked well. The train was partially wrecked during the catastrophe of October, 1888, but the wagon on which was this rolling electric central station, which followed next to the tender of the second locomotive, was practically uninjured.

Electric Lighting of Ships.

Engineering says the past year has been notable for the large proportion of vessels fitted with the electric light, and also for the progress made in the economical and efficient production of that light. The speed of dynamos has formed one of the most important subjects of study by the electrician, and while in the case of almost all other engines greater speed is the desideratum, here the reduction of the number of revolutions is the aim sought after, for thereby is the life of the machine lengthened. We are now within a short distance of attaining 200 revolutions. The arc lamp, because of the great care it requires—and which is seldom given on shipboard—is being superseded by sunbeam and groups of high candle power lamps, which are adopted specially for cargo working. The relative advantages of single and double wires in ships is a bone of contention amongst electrical engineers; but the tendency is regarded as towards the single wire system, where with due care on the part of the engineer there is no likelihood of the compass being affected. Dynamos for incandescent lighting are of such low pressures as to insure complete safety of life. Danger alone lies in improper qualities of materials and indifferent workmanship. Steamers of all types now adopt the electric light, and this year the number of cargo vessels fitted with an installation has been most marked. It is used for all purposes, and in one particular respect in which the development is most noteworthy; it is the fitting of cargo boats with long cables which may be run from the ship over the wharves to light them up when cargo is being moved. It is too late in the day to speak of the general advantages of the electric light over the paraffine lamp.

The Conversion of Gas Globes into Regenerative Lamps.

[A paper read by Mr. D. R. Gardner, before the Glasgow (Scotland) Philosophical Society.]

The author began by stating that he was led up to the invention he was about to describe by his experience in connection with the consumption of smoke in boiler furnaces. Many years ago, after having been summoned for creating an alleged nuisance by smoke, he investigated the principle of consuming, or rather of preventing smoke; and he found that highly heated air, properly applied in the furnace, was all that was necessary. He afterwards proceeded to bring this principle to bear in the production of a regenerative gas lamp suitable for shops, halls, etc. He studiously avoided the method in which other inventors had carried out the principle of regeneration in gas lamps, and was led to supply the air from the bottom of the shade alone, and to control the draught by means of a damper at the top of the funnel, which, by being screwed up or down, adapted the lamp for burning gas of any quality or at any pressure. In like manner he carried out the same principle in ordinary gas globes or shades.

With the view of explaining the science of increasing light for illuminating gas, the author quoted from an article in "Ure's Dictionary of Manufactures and Mines," to show that the proper burning of illuminating gas depended upon certain physical and chemical conditions, the due observance of which was of great importance in the development of a maximum amount of light. Chief of these was the prevention of the escape of any particles of carbon unconsumed. He also referred

to Dr. Frankland's Argand burner, fitted with a double chimney for the purpose of highly heating the air; the result being that when 3.3 cubic feet of gas were consumed per hour with the single chimney, 13-candle power was yielded by the gas, whereas by employing the double chimney 21.7-candle power was developed. The double chimney was tried by the author before he was aware of its previous use; but he found it to be valueless, as the double glass considerably obstructed the light, and the dirt and moisture carried in by the current of air further obscured it. He then resorted to the ordinary globe, and discovered that by materially diminishing the outlet the flame materially increased in size. His thoughts were at once directed towards the materials and form best suited for a cover to the shade. Asbestos was tried, by moulding or fitting it on the globe; but when a high temperature was maintained the globes would occasionally crack. Latterly, after making various attempts to overcome this and other difficulties, the author hit upon the expedient of using small plates of mica between the asbestos and the glass shade as non-conductors of heat. Although he had subjected the shades to very severe tests, he had not since broken one. The cover might now be considered to be as simple and perfect as it was possible to make it, as it suited all qualities of gas, the different pressures, the vari-

increased luminosity to the carbon contained in the gas, and that it is necessary to retard the flow of gas at the burner. The question came to be: "Had those two points been attained by the application of the asbestos cover?" One experiment, he remarked, would be sufficient to demonstrate this. He caused a cloud of smoke from a piece of brown paper to enter the shade, which showed a quiet condition of the atmosphere around the flame, and consequently a retardation of the flow of gas at the burner, while the temperature of the surrounding air was raised to the point desiderated by Dr. Frankland for the combustion of the light carbureted hydrogen that passes off unconsumed from an ordinary gas flame. Mr. Gardner declared that he had burned a number of lights with the covers on in a small room for a couple of hours, and on returning to the room from the fresh air, he could not perceive the slightest unpleasantness in the atmosphere; whereas if the shades had been without covers the air of the room would have been both disagreeable and unhealthy.

The illuminating power attained by Glasgow gas by the use of the Gardner asbestos cover had been tested by Mr. Terrace, under the direction of Mr. Foulis, and the results were shown in a table exhibited, of which the following is a copy:

Description of Globes (Clear).	Tests with Union Jet Burners at 5-10ths Pressure.		Illuminating Power Corrected to Five Cubic Feet.			Increase per Cent. with Cover.

ous sizes of burners, and could be used with the present shades and gas fittings by merely placing it on the shade and adjusting the regulator. The appliance has been patented in the United Kingdom, and will be in other countries.

The following is a brief description of the cover in the form now arrived at by the inventor: Sheet asbestos, specially prepared for the purpose, is cut into discs varying from 4 up to 7 $\frac{1}{4}$ inches in diameter, and rising $\frac{1}{4}$ inch to each size, so as to suit all the different sizes of shades. In order to hold the cover in its place three asbestos studs are fixed on its lower surface, moving in an eccentric, which allows the cover to be most perfectly fitted. Round the lower edge there are half-a-dozen discs of mica fixed. These act as non-conductors between the glass shade and the cover. In the center of the cover there is punched out an opening 1 $\frac{1}{4}$ inches in diameter, and the disc so removed is fixed by means of a stud to the cover at one side of the opening on which it turns—thus becoming a valve to regulate the size of the aperture according to the quality and quantity of gas used.

Mr. Gardner stated that he had recently called upon Mr. W. Foulis, the General Manager of the Glasgow Corporation Gas Department, to confer with him on the invention. This gentleman at once heartily took up the matter, and volunteered to have it subjected to a thorough scientific testing photometrically by Mr. D. Terrace at the Dawsholm Gas Works. The author then briefly referred to some of the papers on "The Economical Use of Gas," by Mr. Terrace and the late Dr. Wallace, and went on to state that the former gentleman, in showing that the improvement under consideration was not to be had from burners, said that in testing several of the devices intended to improve the ordinary open gas flame, he found no increase in luminosity per cubic foot of gas consumed from that given by the Union-jet burner consuming 5 cubic feet per hour, at 0.5 inch pressure. At this stage Mr. Gardner directed the attention of the members to a table in which were embodied the results of a series of tests made by Mr. Terrace, with the view to ascertain the loss of light with small burners and high pressure; also to a table showing the loss of light resulting from using different kinds of shades. He stated that if the extremes of the two tables were taken together the loss of light was something like 91 per cent.

In summing up, the author said he found from the different authorities that highly heated air produces complete combustion, and gives an

Proceeding, the author stated that the tests were taken horizontally and in the most favorable conditions for the open flame, viz., with a No. 8 burner consuming 5 cubic feet of gas per hour at 0.5-inch pressure. Comparing the covered globe with the open flame, an increase of light was obtained of from 10.36 to 21.56 per cent. Then, comparing the covered with the uncovered shades, a greater difference was arrived at, viz., 17.12 to 41.11 per cent. Blackened covers were tried in order to see if the increased luminosity was due to reflection; but they also showed the same good results. Tests were made at an angle of 45°, which is about the usual position of a light in relation to the person using it, and they gave, with a covered shade and a No. 8 burner, 53.76 per cent. more light than the open flame; whereas on comparing the light from the covered shade with that from the uncovered shade, 72.70 per cent. more light was obtained. With a No. 4 burner the increase of light, by using a covered shade, rose to as much as 120.5 per cent.

In conclusion, Mr. Gardner said that looking at the immense daily waste of gas (amounting, according to the late Dr. Wallace, to £130,000 per annum for Glasgow alone, fifteen years ago), he thought it would be well for the Glasgow Corporation Gas Trust to lead the way in promoting its economical consumption by instituting a Lighting Department that would superintend the burning of the gas, and not allow the consumers to waste so large a percentage of it.

There was very little time allowable for the discussion of the subject raised by Mr. Gardner's paper: but, as Mr. Foulis was present, he was called upon by the Chairman to make a few remarks. This gentleman said he had been much interested in the invention, the results of the testing of which had greatly surprised him. The gas authorities of the city and himself were always ready to encourage every feasible attempt to improve the illuminating effect of the gas supplied to the consumers, and in this spirit he had authorized Mr. Terrace and his assistant (Mr. Duncan) to test Mr. Gardner's invention most thoroughly. The results were seen both in the table exhibited and in the lamps with which Mr. Gardner had been experimenting that evening. He (Mr. Foulis) was not, however, yet prepared to admit that the whole of the effect, if even any appreciable amount of it, was obtained by the increased heat of the air used in the combustion of the gas. He rather thought it was almost wholly due to the quietness of the atmosphere within the shade. Having alluded to the experimental investigations which Mr. John Methven

had lately been conducting in a somewhat similar direction, but with Argand burners and the use of chimneys necessary for them, he remarked that he had been deeply interested in Mr. Gardner's paper and the experiments, and felt that the Society was much indebted to him for having brought the subject before them.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE following plain, common-sense letter is well worth reading :

POUGHKEEPSIE GAS LT. COMPANY,
POUGHKEEPSIE, N. Y., Jan. 13, 1890. }

To the Editor AMERICAN GAS LIGHT JOURNAL :—I wish to thank you in behalf of our Company for the stand you have taken in regard to the general adoption by gas companies of the business of supplying electric currents. We have, I suppose, the very best facilities, from the peculiarities of our present position, for engaging in the production of what has been called the light of the future. We have a gas plant lying idle in the center of the city, with the privilege of paying a good round tax yearly on the same. We are often told by the venders of patented electric light apparatus that we are the only ones who could supply at a profit in Poughkeepsie this light of the future. Estimates have been received by us, and we have also figured on the prices received by the electric company doing business in our city, and the result is that we prefer to pay taxes on idle plant ; for experience has taught us that if we put half the capital and energy into our present business that would have to be employed did we determine to engage in electric lighting, our stockholders would be quite satisfied over the net result. Let me here state what we have been taught by our competitor in the business of supplying light. First, we find that, as a rule, where they succeed in securing a contract to light up a building the gas burners in that building were in bad condition. They make an impression on the mind of the user at once—he had poor gas burners and an inferior light ; the change to new incandescent lamps undoubtedly gives him a more satisfactory illumination. Naturally, his next door neighbor is called in, and the advertisement is secured. In fact, our electricians employ a man whose duty it is to ferret out places in which inferior gas burners are employed. In olden days, I must confess, we never thought of such a thing as looking after the state and condition of gas burners ; we let the consumer study the matter out for himself. But electricity and its advocates have taught us a good lesson, and brought us to the practice of doing that which in justice to our business was essential, provided we desired to give it that standing rightfully its own from inherent merit. We employ a man now to attend to all complaints, who is further instructed with the task of placing new burners where such are needed. The plan gives good satisfaction, for the burners are adjusted free of charge to the customers. We find this to be one of the best investments that we have ever made. The burner (made by the Jackson Burner Company, of your city) that we favor most is not expensive—it is an all steel burner and does not corrode. Of course, the Jackson article is for ordinary consumption in stores and dwellings ; for outdoor lights we use the Gordon lamp. We also use, in direct competition with the incandescent light, the albo-carbon, which, in my opinion, furnishes the cheapest illumination when the apparatus is properly cared for. But, Mr. Editor, permit me to impress on your mind that our field for gas supply is larger than that for illuminating purposes pure and simple ; and it is bound to widen when it can be shown that cooking by gas can be accomplished (at certain fairly remunerative figures) 25 per cent. cheaper than when dependence is placed upon the ordinary coal range. When you can afford to sell gas for such use at \$1 per 1,000 in the summer months, and all the time, why can you not keep your works going all the time at their full capacity? We started last May in the cooking business, and made the start with but little faith in our ultimate success as to the new enterprise ; but one season's struggle has demonstrated to our entire satisfaction that this year will be the twelvemonth of our greatest output, for the demand is greater than we ever expected it would be. We, however, did not secure this result and that trade by simply putting the cooking, heating and power rate at \$1 per 1,000. We had to experiment on the different kinds of stoves that were offered on the market, and when we found the specimen best adapted for our gas we not only placed them ourselves, but instructed the consumer how to use them to the best advantage, and after a half dozen had been placed we found no trouble in securing additional customers. What I would say, in conclusion, to my fellow gas men is this : If you have an opposition electric lighting company in your city all that you need do to hold your position is to put as much energy and capital into your gas business as they do into theirs. If, then, you do not earn double what they

do on the investment, all I have to say is that your gas plant is not up to standard.

Yours,
JOHN TRACY.

A LINE or two from Mr. James Ferrier, Superintendent of the Eufaula (Ala.) Gas, Electric Light and Power Company, says that both divisions of the Company's business are going along smoothly and satisfactorily. We imagine, however, that the last fall season must have been an anxious one with him, and a busy one withal. We incline to this view from the fact that between September 7th and October 29th a new bench of 3's was added to the gas plant, while the same period beheld the placing, complete, of a 50-light arc installation. Within two weeks from the arrival of the machinery the electric lamps were in service.

MR. J. FRED SEAMON, formerly Inspector of the City Gas Works, Wheeling, West Va., has been appointed Superintendent of the works of the Cumberland (Md.) Gas Light Company. The new appointee takes the place of Mr. C. A. Seay, who has acted as Superintendent of the Cumberland Company since 1854.

MR. JNO. CABOT, of this city, has returned from his protracted visit to Europe. He looks hale and hearty, and had a splendid time, but hereafter his P. O. address will be at the old station, 306 to 310 Eleventh avenue, N. Y. City.

MR. ADAM WEBER informs us that he has been awarded the following contracts:

- 24 benches of 6's for 14th st. station Consolidated Gas Light Co.
- 26 " " 42nd st. " " " " "
- 20 " " Equitable Gas Company, N. York City.

These benches are to be fired with the new and improved Weber recuperative furnace.

SOME days ago the Union Depot, Birmingham, Ala., was thrown into confusion because of an incipient conflagration that occurred thus wise: In the dining-room of the depot both gas and electricity are used for lighting, and the electric wires are trailed along the service pipes of the chandeliers. A defective bit of insulation permitted contact of the current wire and the gas pipe, whereupon the latter was burned through, permitting the gas to escape. On the ignition of the gas the wooden ceiling took fire. The flames, however, were extinguished before they had gained any headway.

THE bids recently opened by City Works Commissioner for the public lighting of Brooklyn, N. Y., for the ensuing year, show no change over those submitted in 1889 save in respect to the rate asked by the Brooklyn Gas Light Company. The proposals are as follows :

Bidder.	Rate per Light.
Citizens Electric Light Company.....	\$182.50
Municipal " " "	182.50
Brooklyn Gas Light Company.....	22.00*
Peoples " " "	22.00
Nassau " " "	22.00
Citizens " " "	22.00
Williamsburgh " "	21.75

The electric lighting specifications call for 1,200-candle power arcs (they have been " calling " for that illuminating value for some time back, but it is notorious that their real power does not exceed 400 candles) and 4,000 hours of burning. The gas lamps are equipped with 3-foot burners, and are lighted on an average of 4,000 hours per annum. The bid prices include lighting and extinguishing charges.

THE Brooklyn companies also agreed to supply gas to the public buildings at the uniform rate of \$1.60 per 1,000—which, by-the-way, is the maximum rate that may be charged for gas within the city limits.

WE understand that the Suburban Light and Power Company has been notified by the Mayor that its offer for lighting Boston has been accepted. The terms of the contract for the city proper, South Boston, Dorchester and West Roxbury are 39.74 cents per arc per night, the rate for the Roxbury district to be 39.99 cents. There are about 900 lamps in the allotment, and it is estimated that under the agreement Boston will save something like \$72,000 over the total sum paid out on like account last year. The new Company—it is at present without sufficient plant facilities to carry out the work—has pledged itself to be ready to light

*Last year, \$19.80.

both Roxburys and Dorchester within six weeks, South Boston within 12 weeks and Boston proper within 16 weeks. In the meantime, the Boston Electric Light Company (which performed the lighting for 1887) will keep on the service until the successful bidders are ready to take up the task.

No doubt the Boston authorities are satisfied that the Suburban Light and Power Company is solvent and amply able to perform all its promises; but in view of the very low figures that it has seen fit to accept (and presuming that the requirements as to candle power and service are to be looked after critically by the Superintendent of lamps), we nevertheless are under the impression that many a strain will be made during the life of the contract, on even what is known as the French style of measurement, by the Company. Lamps of the illuminating value required by the specifications cannot be supplied at a profit in Boston at the accepted contract figures.

THE proprietors of the Troy (N. Y.) Gas Company have placed on Second street, between Broadway and Congress street, ten Gordon lamps, with a view to making a determination whether such lamps can be depended upon with certainty for public lighting. The New York samples, it might be added, are answering every requirement.

MR. JNO. MACKEOT, Supt. of the West End Gas Works (Main street, Pittsburgh, Pa.), was the victim of a painful accident some days ago. While overlooking repairs to an oil tank, an explosion occurred that scattered the burning oil over the Superintendent's face and neck.

ABOUT a fortnight ago the City Council of Monterey, Mexico, granted a franchise for the operation of a gas and water works at that point to Messrs. B. F. Larue, G. S. Butcher and Blas D. Guiterrez. The concession is a good one, and the gentlemen named are perfectly solvent. This place is the capital of Nuevo Leon, Mexico, is on the river San Catalina at a point about 175 miles south of Laredo, Tex., and is in the heart of a very fertile valley. Population about 28,000.

THE proprietors of the St. Croix (Me.) Gas Company are inclined to add an incandescent plant to their present arc installation.

SUPT. DOUGLAS, of the Mutual Gas Light Company, Savannah, Ga., is busily engaged in making important extensions to the Company's distributing system. About two miles of 4-inch pipe will be placed, and we have an idea that it will prove to be about as good an investment as the Company ever made.

A CORRESPONDENT informs us that the General Statutes of the State of Ohio contain the following provision: "The Council of any corporation in which gas works may be constructed, may provide by ordinance for the appointment of an inspector of gas, whose duty it shall be to inspect all gas and gas meters, and certify the correctness of all bills against consumers, make photometric tests, and perform such other duties as may be prescribed."

SENATOR BUTLER has offered a resolution in the Senate directing the Committee on the District of Columbia to inquire into the expediency of the purchase by the government, by condemnation or otherwise, of the works of the Washington Gas Light Company, and to inquire what would be a reasonable profit on the capital stock of said Company, and what dividends have been paid in the past 10 years on the stock. The Committee is directed to report their investigations to the Senate. Have we not been treated already to a nauseating plethora of farcical investigations into the gas supply of Washington that originated in the "Upper House?"

THE authorities of Philadelphia are figuring on what the probable cost of introducing the eight hour labor system in the city would amount to. Their investigations so far point to the fact that in the Bureau of Gas the extra amount of cash required per annum would be \$255,360.

THE electric plant of the Rockville (Conn.) Gas Company has been completed. It is said to be quite satisfactory to the proprietors.

THE Chairman of the Finance Committee of Cincinnati Councils has reported an ordinance under which it is proposed to create the position of Electrical Engineer, the appointment to be made by the Mayor, subject to approval by the Council. The term of office is to be for two

years, the salary \$2,500 per annum, and the bond to be \$5,000. Further, that the sum of \$1,000 shall be appropriated annually to the Cincinnati University for the use of scientific apparatus for testing electric apparatus for light and power, and "artificial illumination of every kind."

THE City Council, of Columbus, Ga., having determined that the city was not being properly lighted under the arc contract now in force, has decreed that hereafter, within certain defined limits, there shall be only 600 feet between arcs.

ABOUT a fortnight ago Mayor Davidson, of Baltimore, forwarded to Capt. Hall, President of the Consolidated Gas Company, the following letter: "So much has been said and written in regard to what may be called the Armstrong proposition, and some of its features are so interesting that it is well worth considering. That the supply of gas is in the nature of a natural monopoly, and that the time has arrived when cities must derive some portion of the revenue to meet their necessarily enormous and increasing expenses from such monopolies may be conceded. The question then presents itself as to the certainty and amount of the city's revenue according to the proposition offered. If Mr. Armstrong's figures and estimates could be guaranteed the proposal would be very inviting, but as they are merely conjectured, I would suggest something more definite and certain. For instance, let the Gas Company (1) waive its claim to any exemption of its plant from taxation; (2) to agree to supply the city with gas at, say, \$1 per 1,000; (3) pay the city as a bonus, say, \$10,000 during 1890, and increase the same \$10,000 during each year for 25 years, such bonus to be considered as part of the expenses of the Company in ascertaining the profits to be paid to the city; (4) the city to reserve the right to abrogate the agreement at the expiration of any period of 5 years, upon giving, say, one year's notice to that effect. In this shape the city would derive immediate advantage from the arrangement though small in proportion to the enhancement in value of the Company's stock immediately upon the adoption of the measure, and at the same time the gas consumer will pay no higher rate than he will probably be compelled to pay for some years without such a measure." Mayor Davidson's cool assurance, say, for solidity, is little short of remarkable; and so it also seemed to strike the gentleman who was favored with the communication. On the day following the reception of the letter Capt. Hall sent the following reply: "We are in receipt of your letter. It has been read to the committee, and it is their unanimous opinion that the proposition is so onerous that it is impossible to accede to it under any circumstances."

THE following is the result of the recent election held by the Laclede Gas Light Company, shortly after the purchase by the latter of the old St. Louis Gas Light Company's franchises and property: President, Emerson McMillin; Vice-President and Purchasing Agent, J. D. Thompson; Treasurer and Paymaster, George M. Paschall; Secretary and General Bookkeeper, Alex. Ross; Engineer, Frederic Egner; Supt. Station "A," John B. Taylor; Supt. Station "B," Geo. C. Brown; Supt. Stations "C" and "D," Geo. T. Thompson—and a decidedly efficient staff it seems to us to be. It is the intention of the management to expend about \$500,000 in remodeling the works of the old St. Louis Gas Light Company at Second and Convent streets, and to use them as the main station of the Company, to be known as station A. Station B is the works of the Laclede Company, on Main and Howard streets. Station C is to include the two gasholders at 14th and Gratiot streets, and station D includes the new holder at Evans avenue and Sarah street.

MR. JAMES HOOPER, who had been Superintendent of the Media (Pa.) gas works for a number of years, has been incapacitated for duty because of ill-health.

SOME time ago we noted the incorporation of the Plattsburgh (N. Y.) Light, Heat and Power Company, which was formed for the purpose of consolidating the present gas and electric light interests of the place. The gas interest predominates in the amalgamation. It is probable that the gas plant will be transferred to the electric lighting station.

IT is estimated that an expenditure of \$200,000 will be made this year by the Gas Bureau of Philadelphia in main extensions.

IN 1852 the San Francisco (Cal.) Gas Light Company charged \$15 per thousand cubic feet for gas; now the ruling rate is \$2. During the past year a marked increase took place in the use of gas for purposes other than lighting.

AMONG the matters to be considered at the coming annual election at the stockholders of the Edison Electric Illuminating Company, of this city, will be a proposition to increase the capital stock from \$2,500,000 to \$4,500,000; also, to create a mortgage to secure a series of bonds on the present "and certain future property of the Company." The meeting will be held on the 28th inst.

SOME complaint has been made of late in Philadelphia about the poor quality of the gas that is being supplied to consumers, which is in direct conflict with the daily reports made at the works. These latter determinations go to prove that the quality of the Quaker City gas was never better than now. It is likely, however, that those who complain are consuming gas through undersized services and imperfect burners. Another reason, perhaps, and a good one, too, is that the main system in several districts of the city is all too small for the drafts that are being made upon it.

THE ordinance introduced in the St. Louis House of Delegates by Mr. Stone, under which it is proposed to regulate gas rates in the city, is as follows: "For a period of five years from and after the passage of this ordinance the price of illuminating gas in the city of St. Louis to consumers shall not exceed 90 cents per 1,000 cubic feet on all bills paid within 5 days after the presentation thereof, and 95 cents per 1,000 cubic feet on all bills paid after the expiration of 5 days from presentation, and for said period of years in said city the price of gas sold to consumers to be used for fuel and power purposes shall not exceed 45 cents per 1,000 cubic feet on all bills paid within 5 days after presentation, and 50 cents per 1,000 cubic feet on all bills paid after the expiration of 5 days from presentation." The Stone measure evoked a lively discussion, which terminated in its indorsement by the House. The ordinance now goes to the Council for concurrence. Mr. Stone, in arguing in support of his pet project, admitted that it was very uncertain whether the price of gas could be so fixed, but he thought it would be well to pass the ordinance, and then permit the courts to define it. Mr. Stone could give Dogberry points.

SENATOR HAYS has introduced to the notice of the Kentucky Senate an Act to amend the charter of the Louisville Gas Company, empowering the latter to supply electric currents. The City Council of Louisville recommends the adoption of the Act.

As the result of a recent shipment of Breckenridge cannel, by Messrs. Perkins & Co., of this city, to Rio de Janeiro, that firm has just contracted with the Gas Company at that port for the delivery of 5,000 tons of Breckenridge during the next six months. Messrs. Perkins & Co. have chartered a vessel which will clear from Newport News next month with the first installment (1,600 tons) on account of the contract.

THE annual meeting of the American Society of Civil Engineers was held at the House of the Society on the 15th and 16th inst. The meeting was in every way successful.

JUDGE COLT, in United States Circuit Court, for the Massachusetts district concerned, recently heard argument in the case of the Lynn Gas Light Company vs. Aaron S. Higgins, et al. This was a libel in admiralty brought by the owners of the schooner Calvin P. Harris to recover compensation for damages sustained by that schooner in the channel leading to the dock of the Company, September 1, 1885, as the vessel was making her way to discharge a cargo of coal on the wharf of the Company. The damage to the schooner was caused by grounding on a bar that had formed across and in front of the dock, and which the libellants assert, in respect to its existence and dangerous state, should have been known to the respondents. The latter denied that the vessel was staunch and strong, and not only so, but that it was weak and unfit to carry the cargo on board. They also denied that they maintained the channel; neither did they require the Harris to pass through it. They did not know of the existence of any hard or dangerous bar at the point mentioned, and alleged, if the master of the vessel knew if any sand or earth had worked into the channel, that the respondents had no knowledge of such state of affairs. Further, that the damage was the result of the negligence and lack of skill of the parties in charge of the vessel. The District Court found damages amounting to \$4,750.

THE proprietors of the Galesburg (Ills.) Gas Light and Coke Company have issued the following notice: "As it has been our custom to reduce the price of gas about every three years, we now announce the following changes in the schedule: For gas consumed after April 1st,

1890, the price will be reduced from \$2.50 to \$2 per 1,000 cu. ft., with following discounts when 1,000 cu. ft. or over are consumed on one or each meter per month, providing the bill is paid on or before the 15th of each month:

Discount Rate.	Monthly Consumption.
20 cents per 1,000.....	1,000 to 3,000
40 " "	3,000 " 10,000
50 " "	10,000 and over,

making net rates of \$1.50, \$1.60 and \$1.80 per 1,000, which gives the people of Galesburg gas at a lower price than is customary in cities of this size. We make this price to induce a more general use, not only for light, but for cooking, heating, etc. It is our intention to offer great inducements to housekeepers to use gas stoves as soon as the season arrives."

THE amended fuel gas ordinances offered for consideration by Messrs. A. A. Woods and L. E. Lemaire to the New Orleans City Council have been indefinitely postponed.

AT the annual meeting of the Peoples Gas Light and Coke Company, of Cleveland, O., the following Directors were chosen: George H. Warming-ton, Chas. McNeill, M. A. Hanna, R. P. Rhodes and Belden Seymour, Jr.

THE Bloomfield (N. J.) Town Committee has awarded to the Montclair Gas and Water Company a contract for the public lighting. Under its terms the Company is to maintain a stated number of gas lamps (3-ft. burners), the same to be lighted every night until 1 A.M., at a charge of \$16 per lamp per annum.

MR. J. M. GLICK has been elected Secretary of the Girardville (Pa.) Gas Company.

AT the annual meeting of the stockholders of the White Plains (N. Y.) Gas Light Company, the following officers were elected: President, Samuel Conover; Vice-President, J. T. Chesborough; Treasurer, Samuel R. Pullen; Secretary, E. R. Phelps. The capital stock is to be increased to \$150,000, the increase to be devoted to plant enlargement.

THE Macomb (Ills.) Electric Light and Gas Company has been incorporated by Messrs. Chas. Ketteron, H. W. Cummings and J. N. Rume. Capitalized in \$25,000.

THE Poughkeepsie (N. Y.) Gas Light Company offers to perform the public lighting (on an all-night schedule) at the rate of \$20 per lamp per annum.

THE proprietors of the Herkimer (N. Y.) Gas Company announce a reduction in the sales rate to \$2 per 1,000 cubic feet.

MR. SIMON O. DALRYMPLE, who had been a Director in the Salem (Mass.) Gas Light Company for many years, died on the 12th inst.

Corrosion.

The *Locomotive* says that the purest water often is the most active in corroding and pitting plates, and this makes it probable that the active substance, in some cases at least, is air. It is well known that water is capable of dissolving a considerable amount of air; in fact, it is this dissolved air that enables fish to breathe. It is not so widely known, however, that the oxygen of the air is more soluble than the nitrogen. If a small quantity of water be shaken up in a bottle it dissolves some of the inclosed air, and when this is afterward driven off by boiling and analyzed, it is found to consist of oxygen and nitrogen in the proportion of 1 to 1.87, instead of 1 to 4, as in the natural air. Thus the dissolved air, being more than twice as rich in oxygen as common air is, and being brought into more intimate contact with the metal by means of the water that holds it in solution, exerts a correspondingly more noticeable effect.

It is probable, too, that water plays some other important action in connection with the oxidation of metals, for it has been found by recent experiments that pure oxygen will not combine with things that it has the greatest affinity for, provided it is perfectly dry. Even the metal sodium, which has an intense affinity for oxygen, may be heated in it to a very high temperature without combination, provided sufficient precautions are taken to exclude the slightest trace of moisture. It appears, therefore, that water plays a most important part in the oxidation of metals by air—a part, indeed, that we cannot explain, and that we really know but little about.

SITUATION WANTED

As Inspector in a Gas Works

By a man of many years' experience. Understands stove work, improved lamps, inspection of houses, meter proving, etc.

763-2 Address "CAPABLE," care this Journal.

FOR SALE.

A Complete Water Gas Plant. 60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

FOR SALE,

One 5-ft. Station Meter.

One Hydraulic Main (five sections), wrought iron, 22 by 24, with Bye-Pass on Dip-Pipes.

25 Valves, Stand-Pipes, 7-inch Mouthpieces and Lids, all complete, ready for use, to fit up five benches of 5's.

This apparatus is all in first-class condition.

Price, \$800, f.o.b. cars or boat, Poughkeepsie, N. Y.

Inquiries may be sent to this Office.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

WALTHAM, MASS.

Office, Room 55, Mason Building, 70 Kilby Street, Boston

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3	ft. square,	5	ft. deep.
No. 2,	"	"	"	4	"	"	"
No. 3,	"	"	"	5	"	"	"
No. 4,	"	"	"	6	"	"	"
No. 5,	"	"	"	7	"	"	"
No. 6,	"	"	"	8	"	"	"
No. 7,	"	"	"	9	"	"	"
No. 8,	"	"	"	10	"	"	"
No. 9,	"	"	"	12	"	"	"
No. 10,	"	"	"	15	"	"	"

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

WM. W. GOODWIN, Prest.

E. STEIN, Sec.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5, 10, 15, 20, and 25 Horse Power. All Engines Guaranteed for One Year.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
37 in. high. 20 in. wide.	12 in. high. 17½ in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	36 in.

This Stove has four burners on top, and double oven burner.
Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure.
The top is made in sections, so that a greater variety of cooking utensils may be used.
By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners.
Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
31 in. high. 17 in. wide.	9½ in. high. 14½ in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 18 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loosering which converts it into an ordinary open top stove.

The consumption of this Stove is 33 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 3 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps.
Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure.
½ in. supply pipe should be used where the pressure is 1 in. or over.

[OFFICIAL NOTICE.]

New England Association of Gas Engineers.

SECRETARY'S OFFICE, BIRMINGHAM, CONN., Jan. 10, 1890.

The Twentieth Annual Meeting of the New England Association of Gas Engineers will be held at Young's Hotel, Boston, on Wednesday and Thursday, Feb. 19th and 20th. The meeting will be called to order on Wednesday, at 10 A.M., by the President, Mr. R. B. Taber.

At the present moment it is impossible to give a list of the papers which will be read at the meeting, but it is hoped that the literary part of the programme will equal any of those held in past years.

Persons eligible for membership who desire to join the Association will please communicate with the Secretary, who will forward at once blank form of application. CHARLES H. NETTLETON, Sec'y.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., January 20, 1890.

To Members of the Ohio Gas Light Association:

Gentlemen—The Sixth Annual Meeting of this Association will be held at Toledo, O., on March 19 and 20, 1890.

This announcement is made thus early in order that all members may be reminded of the meeting in ample time to make their arrangements to

be present. Every member is urged not only to attend this meeting, but also to interest himself in inducing others of his acquaintance who are eligible for membership, but who have not as yet joined the Association, to come to the meeting and become members.

It is not intended that as many papers as usual shall be presented at the forthcoming meeting, in order that more time than formerly may be had for the discussion of those that are read, and for such other matters and business as the members may desire to dwell upon.

Although the Secretary has for some time been engaged in the work of soliciting papers for this meeting, he has not yet secured as many as should be had, notwithstanding fewer are desired than heretofore, and he therefore earnestly calls upon all members who can possibly do so to notify him immediately of their willingness to furnish papers.

It has been decided that an interesting and valuable feature of our meeting would be a "Question Box," in which members can place questions, which will be withdrawn and read to the meeting and answered and discussed by the members. Every member is requested to send to the Secretary at once any question or questions which he would like to have thus brought before the meeting.

Future circulars will announce further details concerning the meeting.

Respectfully, IRVIN BUTTERWORTH, Sec'y.

OBITUARY—OLIVER E. CUSHING.

Again are we called on to record the death of a member of the fraternity whose persuasive personality and cheerful manner had always been potent in making for him a warm place in the hearts of his confreres—a place that once gained by him was never made vacant, so strong was his hold on the gentle force of retaining through innate merit and goodness and loveliness a friendship once sealed in the pact of companionship. The shining mark so unerringly aimed at by death in this instance was afforded by Oliver E. Cushing, who since 1860 had been agent and engineer of the Lowell (Mass.) Gas Light Company. Neither was the dread visitor ever a more silent conquerer. About a fortnight ago deceased experienced an attack of the prevailing influenza, but his seeming recovery had been to all appearances rapid—in fact on the day preceding his death he was able to leave his room—but even in the act of congratulating himself on his recovery an attack of heart failure carried him off. However, the end was painless, death claiming him at an early hour of the morning of the 17th inst. In accordance with our custom we herewith publish an account of his life, which can be accepted as substantially correct.

Oliver Edwards Cushing was born at Chelmsford, Mass., in March, 1829, and almost within view of his birthplace was the whole of his useful life spent. Having received an education in the local public schools, graduating with honor from Phelps Academy, in 1845, the tendency of which was to fit him for the profession of an engineer, he, in various positions, proved his worth and merit for business direction, and his success was such that the proprietors of the Lowell Gas Light Company—Chelmsford is but 3½ miles southwest of Lowell—invited him, in 1860, to the post of agent of their Company. To those not intimately familiar with the plan of conducting business corporations in some of the East-

ern States it might be well to explain that an agent is the virtual manager of his company, and in the case of Massachusetts gas companies the agent is usually the engineer also. So it was with the subject of this sketch, and his capacity as an engineer is shown in the fact that while many of his contemporaries were debating a decade and a half ago how to sell gas cheaply, Mr. Cushing was the leader in so selling it. In fact Lowell may justly claim the distinction of being the banner cheap gas city of America, where the rate for some time back has ruled at \$1.10 per 1,000 cubic feet. We instance this merely to show what a progressive man Mr. Cushing was, and that his progressiveness found vent in action. To speak at length on the growth of the Lowell Company is not necessary here in illustration of Mr. Cushing's success in the management of its affairs. Suffice it to say that he was the zealous and capable director of its fortunes. In other local councils his voice was often heard, and many other local enterprises have been benefited by his direction. He was President of the Board of Trustees of the Lowell Cemetery, Vice-President of the Five Cent Savings Bank, and Clerk of the Vestry Board of St. Anne's Parish, of which church he had always been an ardent supporter. The only public office held by him was a chair in the Board of Aldermen (1885). Of his immediate family his widow and three daughters survive.

Turning now to his more extended relations with the fraternity of the country, the records show that he was one of the party of 16 who, at Boston, Mass., on February 2d, 1871, subscribed to the original articles of agreement forming the New England Association of Gas Engineers—this meeting being the sequel of the sad gathering at Worcester, Mass., of December 18, 1870, when the remains of the late Jas. B. Blake, ex-Mayor, and Engineer of the Worcester Gas Light Company, were consigned to earth. At the initial meeting of the Association Mr. Cushing was elected one of its Directors, and although he refused thereafter to occupy higher office in its gift, his voice and presence were ever at its command. He was elected to membership in the American Association at the second annual meeting—Brooklyn, N. Y., October 21, 1874—and his course therein was in accord with his history in the New England body. He became a member of the Society of Gas Lighting in 1876, and, if we mistake not, was a charter member of the Guild of Gas Managers, of which organization he was at one time President. Of all these bodies he was a member at the time of his death, and it need not here be said that his loss will be keenly felt by each.

The funeral services were celebrated at St. Anne's Church, on the 20th inst., the ceremonies being conducted by the Reverend Dr. Chambre, a close friend of the deceased. The attendance was of a most noteworthy character, and could one have banished the knowledge of the sad reason why all were gathered in the sacred edifice, it would seem as if a joint conclave of the Guild of Gas Managers and the New England Association was in session at Lowell.

The moral that is to be drawn from this concise narrative of a busy, useful and even life, is that the gas industry of this country owes its present stability to the quiet though persistent efforts of such pioneers in its history as Oliver E. Cushing and others of his type. In conclusion, we have but to say—and our acquaintance with the deceased covers a period of over a quarter of a century—that a kindlier gentleman nor a more faithful friend than Oliver E. Cushing ever found refuge from the cares of life in the repose of the grave.

OBITUARY—THEOBALD FORSTALL.

Before the first shock occasioned by the news of the sudden death of Mr. Cushing had abated, came a renewal of our sadness in the intimation that Mr. Theobald Forstall, of Chicago, Ills., had gone over to the majority. It is true that we were aware and shared with others in the apprehension so created that Mr. Forstall's tenure of life had been more than uncertain for some months back—but whoever of the living can accept with equanimity at once the bald fact that one's relative, co-laborer or friend lies quiet in death? Mr. Forstall had for months been suffering from a malady that resisted all the skill of his physicians to ward off its insidious attacks, but many months, if not years of useful life seemed to be yet before him. The prevailing scourge that has so deeply set its mark on almost all the peoples of the globe aggravated his disease, to which he fell a victim on the evening of the 19th inst.

Deceased was born in New Orleans, La., in 1836, and traced his lineage back to the earliest French settlers of that section, many of his relatives having taken great part in the religious, civil and warlike events that make up the history of that section of our country when it was yet a French dependence. At an early age deceased was thrown completely on his own resources, and adversity soon developed those latent resources that would have made him successful in any branch of industry,

and which did cause his name to be known, almost as a household word, wherever the art of gas making is practiced. In 1856 we find him located in Stillwater, Minn., where, at the age of 20, he was in control of an important business enterprise, relinquishing the same in 1860 to engage in the shipping business at his birthplace. The outbreak of the civil war all but bankrupted him, and next we find him in the Confederate army, from which he was soon released as invalid. In 1864 he became a bookkeeper in the counting-room of the New Orleans Gas Light Company, where his great knowledge—deceased was always a remarkably close student and a most retentive observer—soon brought him outside the narrow precincts of the counting-room. Shortly, then, he was named General Manager of the Company, and this was followed by his appointment (in addition to his other duties) as the Company's Engineer. In 1874 he was elected to membership in the American Association—2d annual meeting, Brooklyn, N. Y., 1874—and the potency of his personality was soon felt in its affairs. He was an earnest advocate before it of the abolition of Sunday labor in gas works, and his remarks on that subject, while commanding widespread attention to the subject, also directed the notice of his confreres towards himself. Although always something of an invalid, his bodily ills were in no wise reflected in his vigorous mentality. Logical, calm and just, he was not to be diverted by bombast nor influenced by flattery. Perhaps the ablest paper ever read before the American Association was that contributed by him to the third semi-annual meeting (Washington, D. C., May, 1875), on the subject of "The Proper Preparation of Lime for Use in the Purification of Coal Gas." At all events it established completely in this country Mr. Forstall's fame as an engineer. He served the Association as Vice-President in 1881-2, and was its President in 1883. In 1887 he became a member of the Society of Gas Lighting, and joined the Western Association at the Chicago meeting, 1888. There can be no doubt about the fact that to Mr. Forstall's ability and service much of the prestige attained by the American Association is due.

In 1882 three cities—St. Louis, Philadelphia and Chicago—bid for his services in connection with the engineering management of certain gas works. He elected to go to the last named, there to assume the Vice-Presidency and General Management of the Chicago Gas Light and Coke Company, and became President of the latter corporation after the Trust agreement was an accomplished fact—he resigned the Presidency on the occasion of the last annual meeting, Jan. 13th. The wonderful success achieved by him at Chicago is still too fresh in the minds of our readers to require recounting here. Taking hold of the affairs of the Company at a period when everything in connection with it was awry—a worn-out plant, sharp competition that savored of anything but fairness, and a disquieted host of customers—it required a steady hand and stout heart to master the difficulties that presented themselves. He solved the riddle and served his employers in a fashion that will cause his course to be long remembered by those who were dispassionate observers of the contest. But the victory was all too dearly bought. Anxiety and long vigils completed the wreck of a constitution at best never robust, and now the highest penalty has been exacted from him. It admits of no doubt that if ever a man wrecked himself on the deck of action that man was Theobald Forstall. He was in his leisure hours—unhappily, of late, all too few—a delightful companion, whose delicacy and wit were only outshone by his candor and polish. His wife and nine children survive him.

At the annual meeting of the Poughkeepsie (N. Y.) Gas Company Mr. W. H. Young was elected President, vice Mr. E. S. Atwater, resigned. Mr. Atwater has consented to act as legal adviser of the Company, retains his interest in the enterprise, and continues to hold his place as Director. Mr. Atwater accomplished much during his occupancy of the chair.

At the annual meeting of the Consolidated Company of this city the following Trustees were chosen: Gen. Chas. Roome, Thos. K. Lees, Oscar Zollikoffer, Thomas Rutter, Harrison E. Gawtry, Percy R. Pyne, Sam Sloan, Jas. W. Smith, Henry Day, John P. Higgins, H. Clausen, Jr., Wilson G. Hunt and Eugene Higgins.

The Market for Gas Securities.

Consolidated keeps making a net advance during each week, and today (noon, Friday) is at 97½ bid, offered at 98. Apart from its intrinsic worth as an acceptable investment to ordinary investors, these shares have been largely absorbed within the last three weeks by companies (fire and life insurance, etc.) who seek safe and profitable places for a portion of their surplus funds. Other city shares are strong and higher, and the same applies to Brooklyn. Baltimore Consolidated holds its advance, being at 52½-53. Bay State (Boston) common is at 23 to 24, and this stock seems to us at the figure to be worth looking into. Advices from all points are favorable to the shareholder.

[A Paper read before the Society of Gas Lighting.]

Looking Backward.

By MR. J. L. HALLETT, SPRINGFIELD, MASS.

This is a retrospective glance seemingly not unprofitable for us to consider at this time; for, in the light of the past and present condition of the gas lighting business, we may be able to discern and at least partly shape the pathway of the future.

Prior to 1871 there was neither a Society of Gas Lighting nor a kindred Association in this country devoted to the consideration and advancement of matters connected with gas engineering and manufacture. The gas manager stood alone, securely entrenched and fairly independent of outside influences respecting the growth of his business; and he had none of the care and worry of those in ordinary mercantile trade, with one or more competitors in the same block. He was particularly favored in that he controlled a monopoly, "With none to molest or make afraid."

The soliciting of business was unheard of; it must come to him. Every foot of service pipe, meter connections, each burner and every hour of labor taken up in completing the laying on of a gas supply were charged to the consumer, and at a handsome profit, too. Even a tax was levied for the use of that indispensable machine, of equal benefit to both producer and consumer—the meter—which furnishes the only effectual method of determining the quantity of gas sold, and accordingly the size of the gas bill.

Fifteen-candle power gas and a yield of 3.5 cubic feet per pound of coal carbonized was thought creditable, while a shrinkage of 20 per cent. in distribution was of slight concern, not worth digging for; for, at the prices charged, the shareholders were reasonably satisfied with the profits. True, it is thought that the fathers lived up to the light of their day and should not be severely criticised.

Gas Light Associations and weekly issues of papers devoted to the lighting industry have since multiplied, and both have found and imparted knowledge on the subject of gas and electric lighting which could in no other way be obtained. To these sources much credit is due for the brilliant progress made in our business during these later years.

Competition and would-be competitors—cheap oil with improved lamps and burners and electric lighting—have stimulated the gas manager to greater activity. With improved furnaces and settings the yield has nearly doubled, the waste has been reduced to a minimum, and the candle power is 25 per cent. greater, while the price charged is less than the product cost in the earlier days.

The custom of charging for setting meters and meter rental is almost wholly discarded. For the old-style closed globe and iron burner, with its flickering light, opal, etched and ground shades, with large opening and automatic governing burners have been substituted, producing a soft, steady and pleasant light. Formerly 3 candles per foot of gas was the maximum standard attained, but that is now in some States the minimum low limit. No company could exist with that power light against the present competing lights.

The high candle power burners of recent invention, developing 17 candle power per cubic foot of gas, have met the public demand for more light, and are boons to gas companies. What the outcome of this service will be we can only predict. Is it unreasonable to assert that in the near future the inventor will devise a burner—embodying the principles of the Lungren, Wenham, arc, and other high candle lamps, suited to parlor, library, and store fixtures, and in appearance not unlike the incandescent electric lamp, but devoid of shadows—that will develop 85 candle power in place of the common 5-foot burner of 18 to 20?

The efficiency of such a substitute would reduce the cost of lighting to so low a figure that few, if any, incandescent electric lamps would be found in public places, and new impetus would be given the gas lighting business. As 17 candles per foot is now developed in the larger burners, may a commensurate result not be attained in a divided light with a corresponding lessening of cost and heat?

The encircling of the town or city with electric wires, cutting out the hundreds of gas lamps, means a diminution of many million feet, which is a serious loss. Neither is it a pleasant thing to see the names of many of our best customers, of years' standing, dropped from the gas ledger by the inroad of a competing light company, with our only alternative to erect an electric plant or purchase from others a franchise of doubtful profit.

Because of the large increase in population and general business prosperity, the effect of the pushing electric companies has not yet been felt on the output. In fact, an increase is generally reported. These electric companies, in my opinion, would not in any sense be our competi-

tors were the charges for electric light put on a commercial paying basis. This is evident from the large number of electric light companies that, having sunk their entire capital and sold out for a sum equivalent to their debts, have either gone into insolvency or are doing business at a loss. While this is the case, it is equally true that as the electric light becomes no longer a novelty, and it is demonstrated that for the same money more light can be obtained from gas, with more reliable service, former patrons return either wholly or in part to gas lighting. However, it is said that electric lighting companies have come to stay, and that they will demand and secure a share of the lighting business.

The problem, then, for us to consider is how to meet this competition and increase the yearly output. Without borrowing from the future for supposable or hoped-for devices for improving and further diminishing the cost of lighting with gas, how are the fires to be kept burning, and how is our revenue to remain intact, with the resources at our present command?

Fortunately there is a remedy. The gas manager has three strings to his bow—light, heat, and power. The last two have hitherto been secondary forces, and, comparatively, very little attention has been given to their development. Thanks to the meter and other manufacturers, the stoves, ranges, and other appliances for domestic and mechanical purposes, and gas engines for power, have reached a state of perfection that for efficiency and economy can without hesitation be recommended.

We might differ in opinion as to the best method for introducing such apparatus, but all will agree that the greater number of such devices that are put into practical use, either by gift, sale, or rental, the better it is for the receipts of the company.

Our policy in regard to stoves is, whenever possible, to sell them at cost, believing that an article that costs something will be more appreciated and have better care than if the property of others. A few ranges have been loaned at a nominal rental to those that could not afford to purchase.

To show what a limited knowledge the consumer has of these appliances. In a canvas made last summer we found some who did not know what a gas stove was. Many others were prejudiced, and thought the daily use of gas for cooking would be a ruinous expense. To overcome these prejudices, and to demonstrate the efficiency and economy of such a use of gas, 275 stoves were given away. These helped the sale of 248 more. The result was that the skeptical were more than pleased, and their old kerosene stoves were discarded forever. Statements were made by some that, to their surprise, the cost for gas was no greater than it had previously been for oil. The revenue from these gift stoves in one season paid for their cost and yielded a profit to the Company beside.

Without special advertising or any unusual effort to dispose of stoves, excepting in the case given, in four years 1,100 stoves have been placed, which, with those previously sold, make a total of about 1,900 now in use in our city.

The effect these have had on the output is shown in part by the amount of gas distributed from 8 A.M. to 3 P.M. in the months of June, July, August and September:

	June.	July.	August.	September.	
1886....	314,000	298,000	251,000	313,000	= 1,176,000 cu. ft.
1887....	317,000	314,000	431,000	485,000	= 1,547,000 "
1888....	488,000	527,000	540,000	614,000	= 2,169,000 "
1889....	568,000	633,000	604,000	720,000	= 2,525,000 "

This last item multiplied by three, to cover the gas used morning and evening, would give 7,575,000 cubic feet, the approximate amount to the credit of gas stoves in four months being 4,000 feet to each stove. This is 38 per cent. of the whole output for the summer months, and nearly one-tenth of the total output for the entire year.

While the increase in make in the months named in four years was 40 per cent., the increase in the stove consumption was 115 per cent.

In addition to cooking stoves and ranges, 48 heating stoves, of an improved pattern, and very effective for the work required of them, were sold for fall, winter and spring use—a total of 571 stoves in the year.

Looking backward and looking forward, here is a field that legitimately belongs to our craft for their occupation. The people only have to be taught the advantages that may be obtained by them in the use of gas for domestic and mechanical purposes and they will gladly adopt these appliances.

Systematic efforts would bring surprising results.

THE City Council of Poughkeepsie, N. Y., have awarded the contract for public street lighting to the Electric Light Company, at its bid of \$113 per arc per annum, while the Poughkeepsie Gas Company is to light the public buildings, at the rate of \$1.75 per 1,000 cubic feet,

Utilization of Residuals from Coke Manufacture.

Mr. C. M. Percy is contributing a series of articles to the *Colliery Engineer* on the subject of improvements in coke manufacture in Europe, and a most interesting chapter in the series is his comment on the possibility of utilizing the residual products from such manufacture. In referring to the Pernolet system of doing this Mr. Percy says:

Before describing his apparatus in detail Mr. Pernolet proceeded to estimate the reduction in the price of producing coke which would result from the process. The supplementary products, due to the improved arrangements, were a larger yield of coke, and all the tar, the ammoniacal liquors, and the gas which would be obtained from the same coals if distilled in the retorts of a gas manufactory.

The increase in the yield of coke depended partly on the kind of coal, and partly on the way in which the charging was done before the introduction of the improvements. In the great coke works at St. Etienne, where ovens with hemispherically vaulted tops were used, the yield of coke had been advanced from 58.8 to 69.3 per cent., and at another establishment from 54.6 to 69.5 per cent.

In general it might be said that the increase in the yield from the rich and partially rich coals was from 10 to 15 per cent. Consequently, in distilling the same quantity of these coals, there would be a return of coke exceeding on an average one-sixth that which was obtained from the old ovens before their alteration. As to the tar, the amount collected depended on the nature of the coal, and on the care taken both in the distillation of the coal and in the condensation of its volatile products. This proportion had averaged 2.53, 3, 3.25 per cent., and had reached even as high as 5 per cent. where only very bituminous coals were employed. Taking, therefore, the average of these various averages, the amount of tar obtained from the bulk of coal distilled may be taken at 3 per cent.

The proportion of ammoniacal liquors depends not only on the conditions mentioned for the coke and tar, but also on the quantity of moisture contained in the coal.

At one works where unwashed coal was used, for every 100 parts of coal distilled there was not obtained much more than 6 parts of ammoniacal liquor; while at several other works, where the distillation was principally from washed coal, the quantity of liquor collected amounted to 10 or 12 per cent. But in other respects the useful substances contained did not appear to have any relation to the amount of water collected, and the aggregate of resulting ammoniacal substances showed but little variation for the different coals which had been tried.

Provided the condensation was properly attended to, the quantity might be stated at a weight of not less than 10 pounds, and sometimes of as much as 13 pounds of sulphate of ammonia per ton of coal distilled.

The gas obtained had only been computed at the ovens of one establishment, and it was found that by charging the ovens to a height of 2 ft. 4 in., and distilling 6 tons per oven in 72 hours, from 10,000 to 11,500 cubic feet of purified gas were generally obtained from a ton of coal, yielding from 69 to 70 per cent. of coke fit for delivery to the railway companies for locomotive use.

The density of that gas was to that of common air as 40 to 100, and its illuminating power was equal to that obtained from the same coal distilled in retorts, in the ordinary process of gas manufacture; so that the weight of purified gas was about 15 or 16 per cent. of the weight of the coal distilled.

Where coke is manufactured for metallurgical purposes, it is not usual to collect the gas given off, but it is conducted beneath the ovens, to be there consumed in maintaining the necessary temperature for distillation. Provided that the coal is rich or partially rich, this gas will be found sufficient for the purpose (precaution being taken to avoid the risk of explosion); but generally it is desirable to force the heat in order to obtain at once a firmer coke and a tar richer in benzene. This had been obtained without any increased expense, by burning, in addition in the fire-grate, either the small rubbish, which was not good enough to be sold as coke, and which at some places will form from $2\frac{1}{2}$ to 3 per cent. of the coal distilled, or the residue from the washing, which is of usually small value, and may amount to 10 per cent. of the coal distilled.

At one establishment, where the heating of the ovens was entirely performed with gas coke from the retorts, from 22 to 23 per cent. of the weight of coal distilled was burnt; but as the coke contained probably not less than 12 or 15 per cent. of cinder, the consumption stated represented about 20 per cent. of pure coke, that is to say, of carbon. That statement would give an accurate idea of the maximum amount of heat required for ovens then actually in use, which were large and cylindrical

vaulted, 23 ft. 4 in. long, by 6 ft. 8 in. wide, and were provided at both ends with openings the full size of the furnace, closed with cast-iron doors; an arrangement, however, not the most advantageous.

M. Pernolet said that by his improvements in the manufacture of coke, there could be extracted from 1,000 tons of coal 650 to 700 tons of good coke instead of from 500 to 600 tons; 25 to 40 tons of tar; compounds of ammonia, equivalent to at least 5 tons of sulphate of ammonia.

Now, then, as to value of these resulting products. Seven shillings to eight shillings per ton for coke (a very low price indeed; while we write, coke in England is selling at double these prices); twenty to thirty shillings per ton for the tar (that we venture to think will not now obtain;) and £14 to £15 per ton for the sulphate of ammonia (that also is an outside figure;) the total net value of the improvement under the Pernolet system, amounting to £100 per 1,000 tons of coal, or say two shillings per ton.

If it be assumed that at Newcastle, or say, County Durham, and at Wigan, Lancashire, in order to procure one ton of coke, worth say about 8 shillings (certainly a very much under estimate in 1889), it is not at all uncommon to use two tons of rich coal, and this certainly is not uncommon in Lancashire even yet, and that the nature of this coal is such as to permit of the extraction of all the supplementary products. M. Pernolet said it would be seen that the adoption of his ovens would effect a saving of more than four shillings per ton of coke manufactured, and consequently upon a basis of a selling price, eight shillings per ton would reduce the cost of production at least 50 per cent.

But great as even this was, the reduction might be carried still further. If all the gas, or even part of it, were made use of, as there was every facility for doing, particularly in the works which have both coke ovens and gas apparatus, and also in those small gas works where canal coal is generally used, a substantial item of expense might be entirely got rid of by the alteration of some of the ordinary ovens; for the employment of the gas would effect so great an economy as to constitute an advantage equal or even superior to that which could be obtained from the supplementary products estimated at higher prices, because, since on the one hand the gas produced by the improved ovens was capable of supplying all the heat required for the distillation of coal, and on the other hand, the heat can be produced by 20 parts of carbon to 100 parts of coal distilled, it follows that the process of heating would not consume more than 500 pounds of the most ordinary coal to transform into coke a ton of coal yielding in the Pernolet ovens from 10,000 cubic feet to 11,500 cubic feet of gas, at an average expense of one shilling at the highest, or about one penny per thousand cubic feet, or at less than the thirty-sixth part of the lowest price of gas employed in Newcastle, North of England, for the town supply.

[I have very often been struck with the pertinacious manner in which a certain class of inventors will exaggerate the possible benefits of their invention. The gas made and supplied to the principal towns of England not only does not cost three shillings a thousand cubic feet, but can be made and is put into gasholders at less than one shilling a thousand, and neither the Pernolet nor any other system can give us gas at a penny a thousand. We are having just now in England, a craze about water gas, and upon this some excellent criticisms were made at the recent Paris meeting of the Iron and Steel Institute.]

The reduction, says M. Pernolet, in the price of coke effected by the use of his ovens, would generally be at least from four shillings per ton to four shillings and sixpence per ton, and it might amount to eight shillings or nine shillings per ton.

[It really amounts to this, that as compared with the ordinary process of coke manufacture, we should have all the amount of coke we used to make, produced free of cost.]

But it is important to make a more profitable use of the gas than that which it had been applied at the establishments referred to by M. Pernolet; for it was frequently burnt when the most ordinary description of fuel would afford all the heat required, and when the large supply of gas might be increased in value, by reserving it for special purposes, not limited to the lighting of towns, but extended to heating steam boilers or stoves, or the air of blast furnaces, or to evaporating and distilling liquids, puddling cast iron, reducing mineral oxides, and to many other uses of which some had got to be, and no doubt would be, discussed.

[It strikes one upon reading this that hot air for blast furnaces or steam boilers in connection therewith can hardly be included. Blast furnaces as now worked produce sufficient and more than sufficient waste gas to heat all the blast and generate all the steam.]

But sufficiently varied as the best possible purposes which we have named would seem to be, M. Pernolet was not exhausted, and he remarks that it has been proved that one of the elements of illuminating

gas may be transformed into alcohol, and that hitherto that manufacture had only been stopped by the expense of evaporating the dilute sulphuric acid which is present in large quantities. The gas of the Pernolet ovens being able to furnish at once both a supply of alcohol at a low price and a fuel eminently fitted to evaporate it, might perhaps help to introduce the manufacture into the field of commerce.

As regards the use of gas in blast furnaces, for the manufacture of cast iron, an application of it had recently been made in France, by which it was said a purer iron had been obtained, with a saving of 40 per cent. of the fuel usually necessary; and it was also stated that after several weeks' experience twenty Pernolet ovens yielding on an average 20 tons of coke per day, would keep one blast furnace supplied both with coke and gas.

So far, in his remarks, Pernolet had been referring to the employment of the richer, more bituminous kinds of coal, and these were in fact the best adapted for obtaining the products of distillation. But, though the saving would not be so considerable, the Pernolet oven might be profitably used for the poorer coals, and even for the anthracites, provided that some of the richer kinds be used with them. [It is now an unusual occurrence to mix bituminous and anthracite coals for coking. When I visited South Wales last year, I found that the Coppee oven made coke with much success from a mixture. The bituminous coal was too gaseous, and the anthracite coal not gaseous enough, but a proper mixture was found just the thing.]

In such cases the economy would consist chiefly in the smaller quantity of the superior coal required, but of course the products would be proportionally less abundant, in consequence of the small amount of tar, hydrole of ammonia, or gas furnished by the poorer part of the mixture. There would, however, result an important reduction in the price of coke, not only on account of the saving effected in the distillation of the rich coal, but because the poorer kinds, when thus mixed with the richer, instead of being charred alone, would yield three times as much coke as when used singly; in fact, by means of this mixture, it was easy to transform into good coke such coals as were usually considered incapable of being charred, or at least of yielding coke in pieces of an available size.

The collieries of Earl Granville, at Hanley, North Staffordshire, are mentioned as an example where two sorts of coal are used; one flaring, but poor, which had hitherto only been charred in the open air, and in large pieces; and the other partially rich, which was charred in the ordinary ovens—all the poor and comparatively small coal, in pieces less than six inches thick, being rejected. Yet, by mixing it with the partially rich kind found in that neighborhood, and by charring the whole in the Pernolet ovens, the poorer coal might be used with facility, and at least 65 per cent. of good coke would be obtained, instead of the 45 or 50 per cent. produced by the rich coal, when charred by itself in the coke ovens in ordinary use.

In certain cases, also, tar, or dry pitch, might be used with coals which had little or no bitumen, and which were at the same time too brittle to be put into blast furnaces in their crude state. By the admixture of from 8 to 10 per cent. of the above substances, these coals would be supplied with all the bitumen in which they were naturally deficient, and would then become profitable for use in blast furnaces; for if only the small, cheap coal were consumed, the cost of the mixture would not exceed that of ordinary coking coal. Still, the agglomerating matters, being much more expensive than the small coal with which they are combined, it is always important to economize them; and the best way of economizing them is to exclude the air, and thus prevent them from burning, and to collect the products of distillation, and to contribute to their formation during the process.

These recommendations, said M. Pernolet, constitute the leading characteristics of the new system.

The Limiting Pressure upon Foundations.

A writer in the *Mechanical World* notes that very little data is available as to the limiting pressure to which foundations may be subjected. Since the safe load will vary considerably with the nature of the soil, the only satisfactory method of determining this important factor is by direct experiment. In the erection of the weighty and lofty structures on the Champ de Mars, in Paris, in connection with the exhibition, experiments were conducted with this object in view, for the purpose of determining the size of foundations. The method adopted was to level a large surface of ground and place four rectangular blocks of cast iron, 1 foot 8 inches square, so disposed as to form corners of a square, the distance apart being 11 feet 8 inches from center to center. These blocks were bridged by girders of T-iron, and these were then loaded with the

same until a total weight of 143,923 pounds was reached, when a settlement occurred. The pressure on the ground was 7,311 tons per square foot. During the night the settlement increased about $\frac{1}{4}$ of an inch. The load was increased next day to 209,776 pounds, when some of the corner blocks had sunk out of sight, leaving the girders on the surface of the soil. It was found by these experiments that the soil was capable of resisting a load equivalent to 5.43 tons per square foot. When the load reached 7.31 tons, settlement took place, and the ground was incapable of supporting a load of 8.14 tons per square foot.

Origin of the Rock Pressure of Natural Gas in the Trenton Limestone of Ohio and Indiana.

The appended facts are taken from a paper on this subject delivered by Prof. Edward Orton (State Geologist of Ohio) at the New York meeting of the American Geological Society.

Natural gas derived from the Trenton limestone has supplied during the last year, and is now supplying all the fuel and a considerable part of the artificial light that is used by at least 400,000 people in Northwestern Ohio and in Central Indiana. Within the same limits it is the basis of a varied line of manufactories, the annual product of which will make an aggregate of many millions of dollars. More than 40 glass furnaces, not one of them three years old, are now in very successful operation within the territory named, while iron and steel mills, potteries and brickworks, and a long list of factories in which cheap power is a desideratum, have been built up on all sides with wonderful rapidity.

The largest gas production of Trenton limestone that has yet been reached is to be credited to the present year. A well drilled at Stuartsville, six miles north of Findlay, early last summer, produced through the casing, a pipe $5\frac{1}{2}$ inches in diameter, 28,000,000 cubic feet of gas every 24 hours. There are but few wells in any fields that exceed these figures. Most of the wells that have been so reported have been estimated, not measured. An equally astonishing advance had been made in the oil production of this rock, within four counties of Northwestern Ohio. Single wells during the last year have begun their production at a rate of 10,000 barrels a day, and more than 200,000 barrels of total production are already to be credited to single wells of the new field, while a considerable number have passed the 100,000 barrel mark.

The rock pressure of the gas is a vital factor in all this production. To its energy is due the propulsion of the volatile fuel from the wells where it is released through 20, 30, 50 miles of buried pipes to the cities which it supplies with the unspeakable advantages of gaseous fuel. This is the same cause that lifts the oil from the rock in all flowing wells.

By rock pressure is meant the pressure which a gauge shows in a well that is locked in after the drill has reached the gas reservoir. The iron tubing of the well becomes by this means a part of the reservoir, and the same conditions as to pressure are supposed to pertain to it that are found in the porous rock below. The rock pressure of gas varies greatly in different fields, and to a less, but still an important extent, in different portions of the same field. The highest rock pressure recorded in the Trenton limestone is about 650 pounds to the square inch, while there are considerable sections of the gas territory that never reach 300 pounds pressure per square inch. The original pressure in the Findlay field was 450 pounds, varying somewhat in wells of different depths.

In the Wood county field from which the largest amount of gas is now being conveyed to Ohio cities the original pressure ranged from 420 to 480 pounds, the general pressure being counted 460 pounds to the square inch. There were occasional records made of higher pressures still in single wells, but of such cases the number is very small, and the existence of these incredulous pressures was short lived.

In the Indiana field a still greater reduction of rock pressure is noted. The range of the principal Indiana wells is between 250 and 325 pounds to the square inch. The Indiana gas wells, as compared with the Ohio gas wells, are marked by a reduction in total depth as well as in rock pressure, the figures for depth in the productive territory seldom or never passing 1,000 feet.

Sagacious operators are becoming satisfied by their own experience that the root of rock pressure is to be found in the water column that stands connected with the porous rock in which the gas and oil are contained.

When the drill descends into the gas rock proper, dry gas escapes; when into the contiguous and lower-lying terrace, oil accompanied by the gas appears; but at a little lower level salt water is struck, and this rises promptly in the well, sometimes to the point of overflow. Far out from the narrow ridges, or restricted terraces, where gas and oil are found, the salt water reigns undisturbed, and whenever drilled to it, rises in the wells as in those already described.

The rise of the salt water is unmistakably artesian. It depends on hydrostatic pressure, as does the flow of all artesian wells, and its head must be sought, as in other like flows, in the higher portions of the structure that are contiguous. The nearest outcrops of this porous Trenton are found in the shores of Lake Superior, at an altitude of about 100 feet above tide.

It is certainly significant that an abundant flow of salt water is struck in boring in Northern Ohio or in Indiana. No matter at what depth, it rises generally to the level of Lake Superior, or, in other words, about 600 feet above tide. If the mouth of the well is below this level, as in the case in the Wabash Valley, the salt water overflows. The height to which the salt water rises in any portion of the field is one of the elements to be used in measuring the force which can be exerted on the gas and oil that are caught in the traps of the terraces and arches of the porous Trenton limestone.

The rock pressure of the gas differs at various points, because of the difference in depth of the rock below sea level. The rock pressure of Trenton limestone gas is due to a salt water column measured from about 600 feet above tide to the level of the structure which yields the gas.

There is no danger that the great gas reservoirs of to-day will "cave in" or "blow up" after the gas is withdrawn from them. The gas will not leave the porous rock until the salt water obliges it to by driving it out and taking its place. The doctrine lays the axe at the root of all the optimistic theories which blossom out in every district where natural gas is discovered, and especially among the real estate operators of each new field, to the effect that nature will not fail to perpetually maintain or perpetually renew the supplies which we find so delightfully adapted to our comfort and service. So far as we are concerned, it is certain that nature has done about all that she is going to do in this line. In her great laboratory a thousand years are as a single day.

Judging from the present indications, the Trenton limestone gas in Ohio is not likely to be long-lived. It seems entirely probable that the term of its future duration can be expressed within the limits of a number of one digit. In considerable sections of the field the salt water is very aggressive. It requires a steadily increasing pressure on the wells to hold it back.

Mr. Trewby on the Manufacture of Water Gas.

The London *Journal* has interviewed Mr. G. C. Trewby, of London, on his visit to America, with the following result:

The great attention which is now being paid by gas engineers and managers throughout the United Kingdom to the question of the manufacture of water gas, induced us to invite Mr. G. C. Trewby, the Chief Engineer of the Gas Light and Coke Company, to send for publication in these columns a communication giving an account of his recent trip to America, and the results of his investigations, on behalf of his Company, into the various water gas processes which are in operation in that country. Owing to the pressure of business engagements Mr. Trewby could not comply with our request, but courteously suggested that a representative of the *Journal* should wait upon him. The suggestion was carried out a short time since when Mr. Trewby gave a *resume* of the information which he gathered in America. This we now present to our readers practically in Mr. Trewby's own words.

Acting under the instructions of my Company, I recently visited the United States and the borders of Canada, and made myself acquainted with some of the principal carbureted water gas processes in use there. I found in most of the cities that carbureted water gas was more or less manufactured. In New York about two thirds of the supply is water gas, and at Toronto, one-half. At Chicago, on one day in September, when I was there, 7 million out of the 8½ million cubic feet supplied were water gas. At Washington the proportion of water gas varies according to the daily consumption—ranging in the winter time from 35 to 50 per cent. I am not able to give the proportion in all the towns, because I had not time to visit all the companies or works to collect statistics; but it will perhaps be sufficient for me to state that where petroleum spirit or crude oil is bought cheaply the manufacture of water gas is on the increase.

The reasons which have led the different companies to supplement their coal gas supply with water gas have been, in the first place, the cheapness of petroleum; and, secondly, the desire on the part of the public to have a higher illuminating power. In some of the towns companies have been started for the exclusive purpose of manufacturing nothing but carbureted water gas under special patents. In New York there are three distinct Companies who make nothing but this gas, besides the Consolidated Company, who make something like one-half. The illuminating power of the water gas supplied in New York is about

30 candles; and the peculiarity about this high illuminating power is that the gas burns with a clear white flame without any appearance of smoking. It has been found to satisfy the public requirement of a high candle power, and is a successful rival of the electric light wherever introduced. In the case of some few works that I visited where coal gas of about 16-candle power was supplied, the consumption had fallen off year by year during the last few years, and the electric light had made considerable advance. As far as I was able to judge there does not seem to be much consumption of the gas for cooking and heating purposes; but this may be accounted for by the price ranging from 5s. to 8s. per 1,000 cubic feet.

A good deal has been said about the deleterious nature of water gas by reason of the large percentage of carbonic oxide it contains. Plain water gas contains about 40 per cent. of carbonic oxide. But in carbureted water gas the proportion is reduced to about 32 per cent., and by specific processes even below that. The quantity in ordinary coal gas is about 6 per cent. Of course, there is no prejudicial effect produced by burning a gas containing a large percentage of carbonic oxide. The danger is that when an escape takes place fatal effects are likely to be produced much sooner by breathing an atmosphere of this kind than with an atmosphere of coal gas. Notwithstanding this, I was informed that during the seven years water gas has been used in Chicago not a single death could be traced to this cause.* The old Boston Coal Gas Company, who opposed the introduction of water gas some years ago, induced the Legislature of Massachusetts to pass a law limiting to 10 per cent. the maximum amount of carbonic oxide to be allowed in that city; and although this would allow of an admixture of water gas equal to 16 per cent. of the whole bulk, yet it has been found impossible to make anything like this quantity and still get within the limit, because the water gas and coal gas could not be thoroughly mixed together, and the official tester might be able to find some particular point where more than the allowed 10 per cent. of carbonic oxide existed. The present Boston Gas Company hope to have the law abrogated, especially as Massachusetts is the only State in the Union that has passed it; and, as far as I am aware, nothing of the sort exists in Canada. This being the state of the case, I think there is no fear of any legislative action that would interfere with the judicious use of carbureted water gas in this country.

Passing on to a description of the manufacture of water gas, I may shortly state that it is a very old invention; some patents in connection with it being taken out by Kirkham in 1852. The gas is produced in a vessel after the style of an iron cupola—either rectangular or circular—which is filled with anthracite coal or coke. The heat is brought up to the point of incandescence by blowing air into the cupola; and the products of combustion are allowed to pass off into the air. The next operation is the making of the water gas, which is effected by shutting off the air, and blowing superheated steam through the fuel. The steam being composed of hydrogen and oxygen, these two gases are separated. The former passes off in a free condition, and the latter combines with the carbon of the fuel, and forms carbonic oxide. These two gases, together with some carbonic acid and nitrogen, and a small percentage of sulphureted hydrogen, form what is known as crude water gas. The effect of the steaming is, of course, to bring down the temperature of the fuel. Therefore, at the end of ten minutes, this has to be discontinued, and the mass of fuel blown up again with air; and about every two hours or oftener, fresh fuel has to be added.

There are three distinct methods of carbureting the water gas. One is known as the Tessie du Motay process. In this the gas is taken to a small gasholder which acts as a governor; thence it is led into a carbureting vessel supplied with naphtha; and from there it passes up to the fixing retorts, which are ordinary clay gas retorts. The water gas and naphtha go in at one end of a 20-foot retort, and out at the other end as a fixed gas; the contact with the red-hot sides making the fixing permanent. The gas then passes into the hydraulic main, and from thence through the washers, etc., in the ordinary way to the gasholders, I was told that, in the cold weather, the gas does not suffer any greater loss in illuminating power than cannel gas.

The second method of carbureting consists in the use of what is called a superheater, which is a circular or rectangular vessel, surrounded by sheet iron and lined with fire brick, and filled with pigeon holed work. The operation consists in passing the hot producer gas through this vessel; admitting, if necessary, a secondary supply of atmospheric air to effect the complete combustion of producer gas. By this means, the superheater is made red hot; and when the water gas is generated, it is passed through this vessel, and at the same time naphtha or oil is spread on the top of the producer or bottom or top of the superheater—depending upon the course the gas is made to take. This makes an illuminat

* Mr. Trewby must be incorrectly reported in respect to this.—ED. A. G. L. J.

ing gas of a permanent character, but not of such a constant or rich quality as by the first-named method, although the cost is apparently less. One advantage it possesses is that crude petroleum or "gas oil" can be used, which is inadmissible in the Tessie du Motay method.

The third process consists in carbureting the water gas in the cupola, without the use of a subsequent superheater. The operation consists in blowing up the cupola in the ordinary way; then, while the steaming is proceeding to make water gas, naphtha is introduced in several places round the circumference, and about two-thirds of the height of the incandescent fuel. Therefore the naphtha vapor would have to pass through one-third of the heated carbon in contact with water gas; and it is claimed that the same action takes place as with the use of a separate superheating vessel. Great care is exercised to keep the fuel at one regular height.

There is another process which differs very much from the foregoing. It is called the Jerzmanowski; and the object of the process is the reduction of the amount of carbonic oxide made. The operation is as follows: A fire-clay retort is set in an oven. It is filled with limestone, which is heated to redness. Steam and naphtha vapors are introduced into the mouthpiece of the retort, and passed up through the heated limestone, which decompose some portion of the carbonic oxide formed, substituting for it carbonic acid. Another modification of the same plan is by the use of a rectangular producer divided into two parts. The first half is filled with anthracite coal or coke, and the second with limestone. The heat is blown up in the usual way; and the producer gas passes down through the limestone. When gas is being made, naphtha is passed on to the top of the limestone at the rate of $1\frac{1}{2}$ to 2 gallons per minute. The effect of this method of working is to reduce the carbonic oxide from what it would be in the ordinary way—namely, 32 per cent.—to not more than about 20 per cent. This gas, which has an illuminating power of about 5 candles, is conveyed to a governing gas-holder, and brought back to the coal gas system of retorts to be carbureted in the same way as in the Tessie du Motay process first described. The process was originally introduced to meet the objection that has been raised to a large percentage of carbonic oxide, the reduction of which can only be effected by changing it into carbonic acid, which has no heating power, and exists as a diluent of the gas. It is claimed that the illuminating power is not appreciably lessened by leaving it in; a small extra amount of naphtha being sufficient to compensate for the deterioration in the illuminating power.

There is a process called the Meeze, which has been experimentally tried in New York, with very favorable results, for a period of fourteen months, and is now about to be tried by The Gas Light and Coke Company at one of their works. The apparatus consists of a circular retort, 18 inches in diameter, and 20 feet long, through the centre of which a cast iron pipe, about 6 inches in diameter, is led from one end to the other. The oil to be used, and superheated steam, are passed through this pipe to the extreme end of the retort, and find their way back between the pipe and the sides of the retort in contact with conical deflectors; and in this way a certain quantity of steam is taken up in combination with the oil, and made into a very rich gas. The water gas, manufactured in the ordinary way and already stored in a holder, is brought into contact with this gas, either in the retort or in the hydraulic main; the result being that a gas of 27-candle power is said to be produced. This process was brought out for the purpose of dealing with the heavy oils and petroleum, and is thought to be thoroughly suited for the Russian petroleum, which is very heavy, and contains but little naphtha. If anything is to be done in introducing water gas into this country to any large extent, it will probably be by means of the importation of Russian petroleum, which, as far as I can see, is likely to be delivered here at a cheaper rate than American oil, unless it be the Lima oil, which is found in the State of Ohio. This oil, however, contains a large quantity of sulphur. It must be understood that, in the manufacture of water gas, no alteration is required in the existing plant of a gas work. The only addition would be a cupola, and the necessary blowing apparatus for getting the fuel up to a state of incandescence.

I cannot close my account of the various processes I inspected without mentioning the cordial way in which I was received by the different gentlemen connected with the gas industry in America and Canada with whom I came in contact, and to whom I am greatly indebted for the amount of useful information I have collected.

THE new Lowe type of water gas apparatus recently installed on the Pottsville (Pa.) plant by the United Gas Improvement Company was started up about a fortnight ago. No hitch of any kind occurred at the initiation.

Paints and Painting for Iron Work.

Some time ago, in an article on "Paints," the *London Journal* remarked that whether the winds of the season breathe soft or biting, the approach of spring never fails to bring one sign of its presence beside lengthening days, and that is, the painter. Continuing, the commenter says:

It almost appears that the forcing process whereby the period of youth and immaturity has been abbreviated in many modern instances has extended to the years, and that spring is hurried over, not to make more room for summer, but to allow the artificial mist and gloom which exaggerate our winters to work out their full developments. Whether winds breathe soft or biting, however, what becomes of painters in the winter is a problem upon which other varieties of the British workman are wont to exercise a rough-and-ready wit; but it is certain that, whereas town residents learn through correspondence in the newspapers that those traditional harbingers of spring, the swallows and the cuckoo, have been seen and heard in country places, they might retaliate upon country cousins by naming as urban spring visitants the cheerful painter and his associate the whitewasher. Not only do town residences confess the presence of these busy visitors, making life so intensely wretched for anybody else who cannot get out of their way; but also in the grimmest factories painters are manufactured out of "handy men," and set to touch up iron and wood work stained and worn by the long winter's wear. The modern extension of the use of wrought iron and steel in place of the less perishable cast iron, has rendered the regular use of the paint brush imperative in places where it was formerly seldom seen. In gas works particularly, there is now much more wrought iron and steel than could have been found a generation earlier, and the consumption of paint has accordingly largely increased. The manufacture of paints for iron work is a very much more important industry than it used to be; but it is to be feared that in many cases increased excellence of the product has not accompanied the swelling of the trade. Of course it may be said, and with a great deal of truth, that the advance of knowledge in the matter of paint making has in some respects led to many improvements in the character of paints in general, and especially in regard to the preparation of paints for special purposes. Paints can now be bought that will cover and stand and preserve their colors when applied to purposes for which a few years ago painting was regarded as an unavailable means of protection. All the same, there is much truth in the reproach that when the application of chemistry to manufactures facilitated adulteration, it was in the paint, varnish, and oil trades that scientific sophistication found its favorite home.

Consideration of paints and painting is, as we have already said, seasonable just now; but it is also suggested by a paper of Professor V. B. Lewes, F. C. S., etc., read before the Institution of Naval Architects. The corrosion of iron ships is a subject which, regarded in its narrowest aspect, would not appear to specially interest gas engineers. Looking at ships as structures built of iron and steel, however, and only differing from other structures in the same materials by the severity of the corroding influences and strains to which they are exposed, it becomes clear that all who are interested in the preservation of these materials from the destroying influence to which they are naturally liable, must be able to draw valuable instruction from the experience of those who have to deal with these influences when manifested in their extreme rigor. Iron is perishable everywhere and under all ordinary conditions of use; but what will preserve the ironwork of a ship would, as one may reasonably conclude, preserve ironwork anywhere. It is this thought that impels us to devote some attention in these columns to Mr. Lewes's interesting paper.

The author does not set out with any claim to having made or heard of any new or startling discoveries in connection with his subject, but merely desires to keep the matter before the world of technical workers in iron and steel, in order that the ever-present importance of this particular quality of iron structures—perishability—should not be lost sight of. Professor Lewes has already done good service by pointing out in a paper read two years ago that in all processes of rusting, carbonic acid gas and moisture play an important part, the iron uniting with the carbonic acid and oxygen of the water to form ferrous carbonate, then taking up oxygen dissolved in the water, or present in the atmosphere, as the case may be, and decomposing into ferric oxide (rust) and carbonic acid, which being liberated in actual contact with the moist surface of the iron, carries on the process of "rusting." This view of the phenomena is confirmed by a paper read by Professor Crum-Brown before the Iron and Steel Institute in Edinburgh, and is generally accepted as the true explanation of the corrosion taking place on iron or steel surfaces

exposed to moist air or fresh water. The action of salt water on iron has been supposed by some chemists to involve a more complicated reaction; but Professor Lewes is persuaded that this is mythical, and that there is no essential difference between the rusting of iron in salt water and in fresh. Salt water, however, may, and probably does, set up a galvanic action between iron and any foreign substances in contact with it; but with this part of the question we are not particularly concerned. Any place where wet coal or carbon dust is brought in contact with iron, which is specially the case in gas works, is held by Professor Lewes to show speedy corrosion of the metal.

Dismissing metallic coatings of ironwork as unsatisfactory, Professor Lewes enumerates five divisions of non-metallic preservative coatings in common use. These consist of oil paints; pitch, asphalt, tar, or waxes; varnishes consisting of resins and gums dissolved in volatile solvents; varnishes containing substances to give them body; and coatings of cement. Before going into these in detail, he gave some necessary consideration to the condition of the surfaces to which they have to be applied. When an iron structure is scraped down to the bare metal, there is presented a huge surface which varies in temperature much more rapidly than the surrounding air. As it cools, so the iron chills the layer of air in immediate contact with it, and shows, by what is called "sweating," the deposition of surplus water on its surface, over which the protective coating has to be applied. If now a rapidly drying varnish is put on, the evaporation of the volatile solvent causes again a further loss of temperature, which brings another deposition of condensed moisture, this time on the surface of the protective, so that the coating is sandwiched between two layers of moisture, both of them probably acting deleteriously upon the resin or gum of the varnish, whilst the moisture on the iron also prevents adherence of the varnish to the metal. If instead of a quick-drying varnish a paint had been used, the second deposition would not have taken place; but the sweating of the iron would have prevented cohesion, and when dry, any rubbing of the coating would bring it off in strips. The condition of the skin of an iron structure, while the coating intended to protect it is being applied, is one of the prime factors in the observed discrepancies in the behavior of such compositions. Too much stress cannot be laid upon the condition of the surface of the iron at the time of coating; and it is perfectly essential either to have a dry surface or else a composition which is not affected by water. The author remarks that when an old iron structure is broken up, on the backs of the plates may often be seen the numbers painted on them in white lead and linseed oil when the work was put together, and under the paint the iron in a perfect state of preservation, the secret being that the paint was put on while the plates were hot and dry.

Compounds prepared with boiled linseed oil are, however, open to objection, on account of the presence of lead. The drying of boiled linseed oil is due to the fact of its containing a certain quantity of an organic compound of lead; and the drying property is moreover imparted by boiling it with litharge (oxide of lead), so that lead compounds are present even when the oil is not mixed with red or white lead pigment. When boiled oil dries, it does so by absorbing oxygen from the air, and becomes converted into a kind of resin, the acid properties of which also have a bad effect upon iron. Protectives of the class of tar and its derivatives, such as pitch and black varnish, and also asphalt and mineral waxes, are regarded by Professor Lewes as among the best. Certain precautions, however, must be taken in the case of tar and tar products, both of which are liable to contain small quantities of acid and of ammonia salts. If care is taken to eliminate these, and if it could be contrived to always apply this class of protectives hot to warm iron, the question of protection would be practically solved; bituminous and asphaltic substances forming an enamel on the surface of iron which is free from the objections to be raised against all other protectives—that is, of being microscopically porous and therefore pervious to water. Spirit or naphtha varnishes are condemned by Professor Lewes as open to several objections. Varnishes to which a body has been given by some pigment, generally a metallic oxide, are preferable to the last class, "if the solvent used is not too rapid in its evaporation, and if care has been taken to select substances which do not themselves act injuriously upon iron, or upon the gums or resins which are to bind them together, and are also free from any impurities which could do so."

At the present time, as the author truly remarks, the favorite substance for this purpose is the red oxide of iron; but care should be taken to exclude from it free sulphuric acid and soluble sulphates, which are common impurities and extremely injurious. The finest colored oxides are, as a rule, the worst offenders in this respect, as they are made by heating green vitriol (sulphate of iron), and in most cases the whole of the sulphuric acid is not driven off, the heat required being injurious to the color. The acid is often neutralized by washing the oxide with di-

lute soda solution; but very little trouble, as a rule, is taken to wash it free from the resulting sulphate of soda, which is left in the oxide. The best form of oxide of iron to use for paint making is obtained by calcining a good specimen of hematite iron ore at a high temperature. When prepared in this way it contains no sulphates, but a proportion of clay which is harmless if it does not exceed 12 to 18 per cent. Paint makers can easily test their red oxide for soluble sulphates by warming a little of it with pure water, filtering, and adding to the clear solution a few drops of pure hydrochloric acid and a little chloride of barium solution. If a white sediment forms in the solution the sample should be at once rejected.

In the application of a preservative coating to iron, Prof. Lewes directs, first, thorough scraping and scrubbing from all non-adherent old paint and rust. New iron should be pickled with dilute acid to get rid of every trace of mill scale; the acid to be neutralized afterwards by a slightly alkaline wash, and this again to be washed off by clean water. Under these conditions, and given a composition of good adhering properties, but little apprehension need be felt with regard to the ravages of corrosion, the chief remaining risks being from abrasion or other mechanical injury to the composition, coupled with improper constituents in itself. In conclusion, we have only to recognize the great care and knowledge with which Prof. Lewes has prepared his paper, which has been reprinted, and may be profitably consulted in detail by all who are in any way interested in the subjects of ironwork and ironwork paints.

SPECIAL ENGLISH CORRESPONDENCE.

COMMUNICATED BY NORTON H. HUMPHRYS.

SALISBURY, Jan. 10, 1890.

Gardner's Gas Globes.—The Rights of the Sweep.—Recent Strikes.—Dangers of Civilized Life.—Mr. G. C. Trewby on Water Gas.

Mr. D. R. Gardner, of Glasgow, has lately directed attention to a fact which has been pointed out in other ways on two or three occasions previously, but has not hitherto attracted the attention of gas consumers to any important extent. It is nevertheless a matter of great importance to all users of gas who wish to obtain the best possible value for their money. I allude to a principle first illustrated by Michael Faraday, about 50 years ago, by surrounding an ordinary argand gas burner with a cylindrical glass chimney about one inch or so larger in diameter. The air for the supply of the flame was thus caused to enter at the top of the outer chimney, and passing down the annular space between the two glass cylinders, became heated to a considerable degree before reaching the gas burner. The result was a great improvement in the "duty" obtained per cubic foot of gas used, and it was due to two causes. The first was a diminution in the quantity of air passing through the gas burner, and the second the heating of the air previously to reaching the flame. These two causes are both concerned in all endeavors to improve gas burners. In the modern regenerative burner it is usual to claim that a great advantage results from the heating of the air supply by means of some of the waste heat from the products of combustion. But a part of the benefit is undoubtedly due to the fact that the air supply, in following the tortuous course designed for it, is greatly diminished as compared with the supply of air that reaches an ordinary open flame. Just as a large excess of air admitted to a boiler furnace reduces the heating effect obtained from the fuel by taking away a part of the heat, so the large volume of air, rushing up the chimney of an argand burner, or through the openings of an ordinary globe, diminishes the flame temperature, and thereby causes a certain loss of light. Some few years since, Mr. Lewis T. Wright showed that by the simple expedient of a disc, the same diameter as the chimney, supported on the top by a cross bar and adjusting screw, the air supply could be adjusted to suit the quality of the gas consumed. The cap, in effect, is analogous to the damper of an ordinary furnace, and just as careful adjustment of the damper will economize the fuel, so attention to the air supply of the burner will economize the light. The same thing may be illustrated by introducing halfpence, one on the other, under the central opening in a Standard argand burner, and it is quite possible to increase the quality of the gas to the extent of a candle or two by this means.

Mr. Gardner applies this principle to ordinary globes in a very simple manner. He cuts a disc of asbestos sheet rather larger than the top of the globe, and fits on the under side three asbestos studs, each moving on an eccentric axis, for the purpose of accurately fixing the disc in contact with the top of the globe. At first it was found that the heat of the discs would cause the globes to break, but this objection was entirely overcome by the use of strips of mica between the disc and the globe. They act efficiently as a non-conductor. An opening about 1½ inches in

diameter is punched out of the center of the cover, and is covered by means of a circular piece of similar size, hinged on a pivot at one side, so that it can be turned to cover the hole, or to uncover it, to any desired extent. By turning the disc the air supply to the flame can be governed and adjusted so as to give the best result. Mr. Terrace, of the Tradeston gas works, Glasgow, has tried a series of experiments with this device and finds that it has the effect of improving the duty yielded by the gas to the extent of 20 to 30 per cent. Globes fitted with Mr. Gardner's simple arrangement ought, therefore, to find a ready sale.

An Irish newspaper publishes a complaint, presumably from a member of the sooty fraternity, as to the "unfairness" of the local gas companies in fixing gas stoves and so interfering with the business of chimney sweeping. No doubt the sweep has little ground for expecting an increase of business. People are slowly—very slowly—learning that it is better and cheaper to convert all the carbon into carbonic acid, and to secure the benefit of the heat thus evolved, than to deposit it in their flues as soot. The age of smokeless fuel will come, and it is not likely to be kept back by considerations of sympathy for the sweep, much less on account of anything in the way of vested interests in his business. His visits are regarded as a necessary nuisance, and would gladly be dispensed with. But owing to the slowness with which the public move in matters concerning their everyday welfare, he may count on no very great loss of business for many years yet.

The recent strikes of gas workers in Manchester, Salford, and London, offer a very large field for instruction. The experience thus gained leads to several conclusions of a general nature, useful to those who undertake the organization of labor disputes, beside those interesting to gas companies, with which we are specially concerned. It has shown that the business of gas making can be carried on, if need be, by ordinary, able-bodied laborers, under intelligent supervision, and that a matter of a fortnight or so is quite sufficient to make a fairly competent scoop driver or coke drawer of a raw recruit. In agitating for shorter hours of labor, the malcontents themselves have greatly aided this result, for it is only reasonable to suppose that a man unused to furnace work would become inured to exposure to heat with much greater facility on the eight hour, than on the twelve hour shift. The great stronghold of the stoker was not skill so much as strength and endurance. This has been broken into considerably by the reduction of hours of labor, and numerous other privileges so freely accorded by the companies, and I hear that men used to light labors only—clerks out of employ, hawkers and petty tradesmen, and such like—are able to undertake retort house work without discomfort. Another point unmistakably set forth is, that new hands take much more kindly to the scoop as compared with shovel charging. Some of this may be due to the fact that a badly charged retort is great trouble to an experienced rake hand, and of course much more so to a new beginner. But the chief lesson is the fact that in cases where the men have always been treated liberally, and no act of tyranny or oppression can be put forward as a cause for the strikers, the position of the employers is very strong, and that of the laborers is at a corresponding disadvantage. Had it been known that injustice of any kind was exercised toward the men, either at Manchester, Salford, or South London, the vacancies created by the continued withdrawal of the old hands would not have been so quickly filled up. The only chance of conducting a strike with any reasonable hope of success, is when a good case can be made out for public sympathy, or where, on account of special skill or other peculiarities of the work, the place of the strikers cannot be filled up. So far as the gas industry is concerned, it is to be hoped that the recent experience, disastrous as it has proved to many a steady and respectable working man, will not be without its use, as tending to promote a better understanding between employers and the employed. It may lead the latter to see that their masters are not necessarily their enemies, nor labor agitators their friends; whilst the former may reflect that payment of wage is not everything. The places referred to above are rather noted for kindness to the men than otherwise, but there are many employers of labor who need to be reminded that a little sympathy with the monotonous life of the toiler, a little endeavor in the way of brightening his colorless existence, is not thrown away.

The advance of civilization certainly increases our sorrows in one respect, and that is in regard to the various dangers that beset us on our way-through life. The latest public scare is that called the influenza epidemic, which is said to have raged all over Europe. The plain fact is that with the recent cold, damp, and extremely variable weather, coupled, perhaps, with the free living usually indulged in at this season of the year, has rendered ordinary catarrh more prevalent than usual of late. In gas circles a great deal of attention has been directed towards

the dangers of water gas, and also those of electricity. As usually happens in these cases, a great deal of exaggeration has occurred in both directions, and the main points at issue have been obscured or greatly distorted. One or two zealous individuals, roused by accidents that have come within the narrow range of their own personal experiences, have promulgated their views on the poisonous nature of water gas or of electricity, as the case may be, and being very scantily informed as to the principles of chemical and electrical science, have done more harm than good. Others, whose interests happen to be concerned, have hastily flown into print with a view of counteracting the effects of such statements on the mind of the public, and have proved too much. The accident at the Leeds forge, alluded to in my last letter, has been pronounced to be due to water gas. At the last moment the Company withdrew their attempts to account for it in other ways. But this accident is not sufficient to condemn water gas. Undoubtedly it is more poisonous than coal gas, just as a solution of arsenic containing 35 grains of that death-dealing element would be more poisonous than one containing only 7 grains. Yet both solutions might be safely used with the observance of proper precautions, and mixtures containing 20 or 30 per cent. of carbonic oxide might be distributed to the public as safely as ordinary coal gas, provided that the proper means were taken to guard against accident. The same considerations apply to electricity, the distribution of which is attended with special dangers. It is useless to deny the existence of such dangers, on the one hand, or to decry them as utterly unavoidable and without remedy on the other. Once let the principles underlying them be ascertained and clearly defined, and the precautions necessary to prevent them can readily be determined. Whilst deprecating recklessness, we must not run into the avoidance of every possible source of danger.

The current number of the *Journal of Gas Lighting* contains some interesting observations by Mr. G. C. Trewby, Chief Engineer of the Gas Light and Coke Company, on the information gathered during his recent visit to America, for the purpose of investigating the various water gas processes that are in operation in that country. He thinks that if anything is done in the way of introducing water gas into this country to any large extent, it will probably be by means of the importation of Russian petroleum, which is likely to be delivered in England at a cheaper rate than the American product, with the exception, perhaps, of Lima oil. Mr. Trewby acknowledges the cordial manner in which he was received by gentlemen connected with the gas industry, both in America and Canada, with whom he came in contact.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

MR. JAMES C. LORD, who had been in charge of the Washington (Ind.) Gas Light Company's plant since March, 1877, has been appointed Superintendent of the Fort Worth Gas and Electric Light Company, Fort Worth, Texas. Mr. Lord is quite conversant with the electric light business, as the Washington Company was also engaged in the furnishing of electric currents. He is to be congratulated on his promotion to so large a field as Fort Worth certainly is, and his new employers are also to be congratulated on having secured such a competent man. We make no doubt that he will be fully up to the responsibilities of his new post, which will prove to be anything but the berth of a sinecurist.

MR. EDWARD P. GARTLAND, of the St. Louis Gas, Fuel and Power Company, has been named to succeed Mr. Lord at Washington, Ind.

MR. C. T. YERKES has been elected President of the Chicago (Ills.) Gas Light and Coke Company, vice Mr. Theobald Forstall. The First and Second Vice-Presidents chosen are C. R. Cummings and C. G. K. Billings respectively. The changes in the Board of Directors are the replacing of Messrs. Theobald Forstall, C. N. Fay, and W. W. Gibbs by Messrs. E. C. Benedict, Henry Fitzhugh, and F. S. Winston.

THE authorities of Rome, Ga., have determined to sell at auction shortly all the old gas lamps and posts that have been put out of service because of the adoption of electricity for illuminating the streets. Perhaps they would be doing about as well if they stored them for a while.

WE understand that Mr. Andrew C. Daniel, a member of the Board of Directors of the Consolidated Coal Company (St. Louis, Mo.) has purchased a controlling interest in the Danville (Ills.) Gas Light Company.

THE Edison Electric Illuminating Company, of Boston, has announced a reduction (to take effect Feb. 1) in the rate per hour for each 16-candle incandescent lamp. The new schedule calls for 1 cent per hour, as against the ruling one of 1½ cents per hour.

MR. HENRY SKILLMAN has been appointed Secretary of the Lexington (Ky.) Gas Company. By the way, what has become of the gentlemen who some months ago succeeded in inducing the City Council to grant them an ordinance for the operation of a fuel gas plant in this place?

AT the annual meeting of the Spencer (Mass.) Gas Company the following officers were chosen: President, Hon. Luther Hill; Vice-President, Hon. Geo. P. Ladd; Treasurer Richard Sugden; Secretary, Emerson Stone. The matter of raising the gas rate to \$1.50 per 1,000 (it is now \$1.25) was discussed, but the shareholders finally decided—and by unanimous vote—not to make any change. The average candle power of the gas sold by the Company during 1889 is returned at 20.70.

THE Directors of the Jefferson City (La.) Gas Light Company have declared a dividend of 2½ per cent. out of the earnings for the 6 months ended Jan. 1.

H. E. BYRON, Corporation Clerk of Linwood, Ohio, advertises for proposals for the lighting of 75 public lamps, hours of lighting same to be based on a moontable averaging 18 nights per month. Deodorized gasoline (74°) is to be the illuminating agent, and the bidder is to agree to keep the lamps "clean and in good repair." The contract is to run for 3 years, and the competition closes at noon of Friday next.

JUSTICE FURSMAN, of Troy, N. Y., on application of Judge Wilkinson has appointed Messrs. J. Irving Wendell, J. Crawford Green, and Geo. A. Stone, of Troy, appraisers to determine the value of 362 shares of stock in the old Troy Citizens Gas Light Company, held by Cornelius Callahan and others, of this city. Callahan refused to accept the price allotted the other shareholders when the terms for the consolidation of the three independent Troy gas companies were being arranged.

IN Circuit Court, before Judge Bartlett, a novel suit was brought by one John O'Brien, against the Manhattan Elevated Railway Company, plaintiff asking for damages for personal injuries in the sum of \$15,000. In presenting his case, counsel for plaintiff explained that O'Brien, in the performance of his labors for the Company—he was at the time of the accident hauling coal in cans to a platform in the structure owned by defendant, at the corner of Morris and Greenwich street—he had to step upon a single plank. Owing to insufficient light—it was early in the morning in the winter season—he slipped and fell, receiving injuries that resulted in gangrene of the lungs. From the evidence it was shown that the gas service pipe had been rendered temporarily useless because of "the gas being frozen therein." After testimony for plaintiff had been submitted, Mr. Ward, of counsel for defendant, moved to dismiss the case on the following grounds: The contributory negligence of the defendant; his acceptance of the risks attaching to his employment; the absence of proof of negligence on the part of the defendant, and that the accident was not of a nature for which the Company could be held blamable. After hearing counsel, Judge Bartlett said: The only negligence of which there is any proof at all is the failure of the defendant to keep the place properly lighted where the plaintiff was injured. Counsel for the plaintiff, upon the argument of this motion to dismiss the complaint, assert positively—what I am inclined to think the evidence shows, but they assume the position whether the evidence shows it or not—that this place where the accident occurred had always previously been sufficiently well lighted to enable the workmen there to do their work safely. As I have already suggested, the law does impose upon the master the obligation, which he cannot delegate or evade, of providing his servant with a safe and suitable place in which to do his work, or at all events, to use due diligence to make such provision. That obligation is generally, if not always, fulfilled by providing such a place as shall be safe and suitable in the first instance. I think that rule may be stated without any qualification, so far as premises or machinery are concerned, which are not apt to become dangerous simply by the lapse of time or the failure to inspect. So that this Company did their full duty to this employee and the others who were called upon to work in the same place, when they provided, so far as this case is concerned, suitable light at the point where the accident happened. That obligation they have fulfilled always up to the present time. I am unable to see how any negligence can be imputed to them, unless it is held either that they were bound to daily and almost hourly inspection of the gas there, which I think would be unreasonable, or unless some notice had been given to them of the dark condition of that part of the building. It does not appear to have come to anybody's attention that the place was dark until this man—very unfortunately, and we must assume, for the purpose of this motion, without any negligence on his part—suffered this injury. But we cannot shut our eyes to the fact that there are a great many accidents that are inevitable, or at all events for which nobody is to blame. I am inclined to think, on the evidence in this case, that the law does not hold the defendants liable; that they had fulfilled their obligation to keep the place properly lighted always theretofore; that they had no notice that it was dark on this occasion, and I cannot

see in the surrounding circumstances or in the lapse of time anything which ought reasonably to have put them upon such notice. For these reasons the motion to dismiss this complaint must be granted.

THE Citizens Gas Light Company (Newark, N. J.) has elected the following Directors: Messrs. A. A. Smalley, S. H. Condict, W. Clark, John L. Blake, C. A. Lighthipe, H. C. Kelsey, G. A. Halsey, Edmund L. Joy and H. Powles.

ACCORDING to the reports of the Gas Bureau (Phila., Pa.) the receipts for the year 1899 were \$3,658,224.83, and the expenditures, \$2,851,019.51, leaving a cash profit of \$807,205.32. The expenditures, however, included \$292,146.08 spent for extensions, so that the real profit from works operation was \$1,099,351.40. The receipts for the previous year were \$3,870,383.69, and included \$125,000 paid by the Schuylkill River East Side Railroad Company for damages to the Fifteenth Ward works. For the same time the expenditures were \$3,321,962.74. The receipts as compared with those of the preceding year were as follows: For gas, services, etc., at main office (1888), \$2,177,329.52; 1889, \$2,178,704.53. Spring Garden office (1888), \$869,174.72; 1889, \$903,922.02. Germantown office (1888), \$125,458.99; 1889, \$124,413.33. Frankford office (1888), \$62,803.10; 1889, \$61,812.18. Manayunk office (1888), \$46,586.71; 1889, \$46,486.65. For coke, tar, etc.: At Market street works (1888), \$218,544.08; 1889, \$170,322.69. Point Breeze works (1888), \$105,832.89; 1889, \$94,708.04. Manayunk works (1888), \$3,890.13; 1889, \$3,485.03. Richmond works (1888), \$130,603.10; 1889, \$56,501.31. For rents, repairs to mains, damages, etc., \$17,869.05. The falling off in the receipts from the sale of coke, tar, etc., is accounted for by the manufacture of water gas. A comparison of expenditures shows the following:

Account.	Year.	Amount.
For works.....	1888.....	\$128,568.32
" "	1889.....	276,386.39
For mains.....	1888.....	163,576.36
" "	1889.....	140,848.59
For services.....	1888.....	91,059.71
" "	1889.....	96,779.68
For gas.....	1888.....	2,120,011.73
" "	1889.....	1,654,772.85
For repairs.....	1888.....	273,088.87
" "	1889.....	273,689.55
For public lighting...	1888.....	157,809.32
" " "	1889.....	82,304.40
Miscellaneous.....	1888.....	386,848.43
"	1889.....	326,238.05

In addition to the gas sold, about 650,000,000 cubic feet were manufactured for and used by the city without cost, and if this were paid for at the rate of \$1.50 per 1,000 the receipt for the same would bring the total profit of the works up to \$2,074,351.40.

ONE of the local dailies, in commenting on these figures, believes the outcome is very creditable to Gen. Wagner's direction and Chief Park's supervision, and follows the encomium by remarking that "it (the report) demonstrates very clearly that the city would have been foolish to have sold the works a year or two ago at any price, much less at the price originally offered." The same authority also believes that as Gen. Wagner has met with so great a measure of success in carrying on the gas works bureau, a municipal electric lighting plant ought also to be installed and committed to his care.

IN the meantime it seems to us that if the figures submitted prove anything at all they are most potent in the line of showing that Philadelphia gas rates are altogether too high. Gas should be sold in that city certainly at a figure not in excess of \$1.25 per 1,000, with, say, 10 cents per M. off for prompt payment.

THE Brown estate holding (which comprised a majority of the shares) in the Madison (Wis.) Gas Light Company has been purchased by Western capitalists.

AMONG the recommendations submitted by the "Committee of 17," appointed some time ago to report desirable amendments to the city ordinances of Dunkirk, N. Y., is one to the effect that hereafter all gas and water services from street main to cellar wall lines shall be of leaden pipe.

AT the annual meeting of the Hartford City (Conn.) Gas Light Company the following Directors were elected: Messrs. John P. Harbison, F. B. Cooley, J. L. Howard, H. K. Morgan, George Roberts, Hugh Harbison, Atwood Collins, Nathaniel Shipman and Rodney Dennis.

THE Council of Fort Worth (Texas) has decided to accept the report from its sub-committee, which recommended that a municipal electric lighting plant be installed, at a cost not to exceed \$27,000. Arc and incandescent lamps are to be maintained—the Brush type to be employed for the former, the Edison being selected for the latter.

THE owners of the franchise for the establishment of a gas and electric lighting plant at Cicero, Ills., will erect the gas works this spring.

THE proprietors of the Niagara Falls (N. Y.) Gas Company have chosen the following officers: President, S. M. N. Whitney; Secretary and Treasurer, A. W. R. Henning. Directors, S. M. N. Whitney, Amos W. R. Henning, W. F. Evans, W. B. Rice, Benjamin Flagler, Francis R. Delano, E. E. Davis, J. Vedder and S. F. Symonds.

THE Phoenix, Arizona, gas works (built 3 years ago) comprises an oil gas plant of the type manufactured by W. Smith, of Pittsburgh. The daily capacity of the works is about 30,000 cubic feet; the holder capacity is equal to 66 per cent. of the maximum make; the main mileage is 1½, and 12 street lamps are paid for by the authorities. The works cost \$30,000. The officers are: President, N. C. Parsons; Vice-President and Treasurer, J. H. White; Secretary, A. P. Wade; Superintendent, H. Ohnick.

THE Directors of the Peoples Gas Light Company (Cleveland, O.) have named the following executive management: President, Geo. H. Warmington; Secretary and Treasurer, Julius M. Carrington; Supt. and Engineer, Edward Lindsley; Asst. Supt., Daniel Warmington.

THE following are the bids submitted in response to the invitation of the authorities for tenders for the public lighting of Clinton, Iowa:

Bidder.	No. of Nom. 2,000 c. p. Arcs.	Actual Candle Power.	No. Incan. Lights 32 c. p.	No. Incan. Lights 25 c. p.	Price per Light per Annum.
Excelsior Electric Co. (burn all and every night).....	any	1,600	\$90 00
Clinton Gas Lt. & Coke Co. (all night P. G. and M. T.)	45	700	75 00
Clinton Gas Lt. & Coke Co.	200	20 00
Clinton Gas Lt. & Coke Co.	225	18 00
Brush Electric Co. (burn all night P. G. and M. T.)....	50	130 00
Brush Electric Co. (burn all and every night).....	50	142 50
Schuyler Electric Co. (burn all and every night).....	75	150 00
Fort Wayne Electric Co. (burn all and every night)	50	1,700	137 50

Keystone Const. Co.	75	22 00
Keystone Const. Co.	75	20 00

THE following letter holds several good hints:

TONAWANDA, N. Y., Jan. 18, 1890.

To the Editor AMERICAN GAS LIGHT JOURNAL: It is with pleasure and interest that your valuable issues of gas items, appearing from time to time, are perused, the reader extracting therefrom good and valuable information. As yet, however, I have seen nothing to "elevate" and do justice to one of the most important accessories of our business, viz., the much abused and condemned gas meter—innocence and purity are fully stamped on its face. A silent, just and honorable calling it has to perform; and as a just monitor between man and man it should be justly treated and respected. Yet, when placed in a building, some dark, out-of-the-way corner is selected for its location—"out of sight, out of mind," seems to be the custom. Consumers should for their own protection have their meters in convenient and accessible places. By so doing the consumers can easily read their meters and control the flow of gas, thus helping the faithful meter taker in the prosecution of his duties.—METER.

THE proprietors of the Tonawanda (N. Y.) Gas Light Company are now about to enjoy the fruits of their intelligent scheme of reorganization, that was perfected some two years ago, and there can be little doubt that a good round dividend rate will soon be their reward. The rates

for gas, determined on the first of the year, and which are to rule for the present, are:

Monthly Consumption.	Net Rate per 1,000.
4,900 cu. ft. and under....	\$1.50
5,000 " to 15,000 cu. ft.....	1.40
15,000 " and over.....	1.25

Street lamps for public lighting are supplied at the very low rate of \$18 per post, on an all night burning table. These rates are surely of the liberal sort, and cannot fail to tell in the increasing prosperity of the Company.

MR. GEORGE SHEPARD PAGE, of this city, sends the following greeting to the fraternity:

HOTEL METROPOLE, MONTE CARLO, Jan. 7, 1890.

Dear Mr. Editor:—Possibly some of the readers of the JOURNAL, as well as yourself, will be interested to know that Mrs. McMillin, with her two daughters and son, as well as Mrs. Page and the writer, are spending some days in this most delightful winter resort. Mrs. Page and I were in Rome during the Holidays. Mr. McMillin's family are to remain abroad for a year. Miss Stella McMillin will during that time be under the instruction of the famous Madame Lagrange, in Paris, perfecting the training of her already remarkable voice—a pure soprano.

Mrs. Page and I return to London towards the close of January. Notwithstanding a severe attack of influenza experienced in Rome, I am being greatly benefited by the needed rest from most active attention to business for the three past years. * * *

Wishing you all, and my many friends among your patrons, a happy and prosperous New Year, I remain,

Sincerely yours, GEO. SHEPARD PAGE.

THE enterprising proprietors of the Alton (Ills.) Gas and Electric Light Company have made many improvements on their establishment. The office quarters have been renovated and renewed. An automatic governor has been placed, and the new bench of retorts is equal to the work that was expected from it. Supt. Tracy also informs us that an additional dynamo will be placed in the electric annex at an early date in the spring. He will also make a determined effort to popularize the use of gas for cooking and heating, and if his success at Alton will be like that obtained by him at Peru, Ind. (his old post of duty), a marked increase in day output will be the result.

AT the annual election of the Williamsport (Pa.) Gas Company the following result was reached: President, Hon. Joseph M. Gazzam; Secretary, Treasurer and Superintendent, C. A. Byers; Assist. Supt., M. J. Winters; Solicitor, Jas. G. Reading, Jr.; Collector, Jas. Calvert. Directors, the Hons. Jos. Gazzam, R. P. Allen and R. J. C. Walker, and Messrs. H. Mudge, John G. Reading, Jr., B. C. Bowman and John G. Reading.

MENTION of the election at Williamsport brings to mind one result of *la grippe* at that point. About a fortnight ago (the trouble lasted for two days) the people complained of bad gas, and the reason therefor was the sudden prostration, by an attack of influenza, of the working force in the purifying house.

A STILL more remarkable instance of the power of this unwelcome visitor is shown in the fact that the annual meeting of the stockholders in the Newport (R. I.) Gas Light Company (set for the 13th of January) had to be postponed for a fortnight—so many of the stockholders were suffering from the influenza that a quorum could not be gathered together at the appropriate time.

THE following Directors were chosen at the annual meeting of the Brooklyn (N. Y.) Gas Light Company: H. D. Polhemus, H. K. Shelton, A. M. White, Jas. H. Armington, H. H. Rogers, G. H. R. Lyman, A. E. Orr and W. Cary Sanger. We understand that Mr. Sanger has been elected to the Presidency.

THE Mansfield (Mass.) Gas and Electric Light Company has been incorporated by a score of local capitalists. Its President is A. F. Rogerson, and W. C. Winter is its Clerk and Treasurer. It is proposed to commence construction work on the gas plant next March. This place is in Bristol county, Mass., at a point 24 miles south and west of Boston, and 20 miles north, northeast of Providence, R. I. It is quite a manufacturing center—cutlery, straw goods, furnaces, spindles, etc.—and has a population of perhaps 5,500.

THE family of the laborer Guthrie, who was killed in the explosion at the Asheville gas works, have brought suit against the Company for \$25,000 damages.

FOR SALE.
A Complete Water Gas Plant.
60,000 Cu. Ft. Daily Capacity.
 Fully equipped; all the latest improvements; Includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

FOR SALE,
One 5-ft. Station Meter.
One Hydraulic Main (five sections), wrought iron, 22 by 24, with Bye-Pass on Dip-Pipes.
25 Valves, Stand-Pipes, 7-inch Mouthpieces and Lids, all complete, ready for use, to fit up five benches of 5's.
 This apparatus is all in first-class condition.
Price, \$800, f.o.b. cars or boat, Poughkeepsie, N. Y.
 Inquiries may be sent to this Office.

GAS WORKS FOR SALE.
 A CONTROLLING INTEREST IN SEVERAL
Interior California Coal Gas Plants,
 now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

Gordon Street Lamp.

The Lungren Lamp.

A Successful Competitor of the Incandescent Electric Light for Interiors, etc. Is especially applicable for the lighting of Offices, Stores, Factories, Mills, Show Windows, Libraries, and all situations where an increased illumination is desired.

More than 25,000 Lungren Lamps are now in use. Testimonials, references, or any desired information will be cheerfully given.

Lungren Lamp.

THE SIEMENS-LUNGREN CO., N.E. Cor. 21st St. & Washington Av., PHILADELPHIA.

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

JEWEL GAS STOVES

MANUFACTURED BY

GEORGE M. CLARK & COMPANY,

Nos. 157 & 159 Superior Street, - - - Chicago, Ill.

EVERY CONCEIVABLE SIZE AND STYLE,

Ranging in Prices from \$1.50 to \$30.00.

WE USE NO GAS COCKS.

All Flames are Regulated by a Direct Needle Valve.

The JEWEL

IS THE

Only Well-Made Gas Stove on the Market.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15² 20, and 25 Horse Power. All Engines Guaranteed for One Year.

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

Wet Meters, with Lizar's "Invariable Measuring" Drum.

Agencies:

177 Elm Street, Cincinnati.

244 & 246 N. Wells Street, Chicago.

510 North Second Street, St. Louis.

222 Sutter Street, San Francisco.

HELME & McILHENNY,

(Established 1848.)

GAS METER MANUFACTURERS,

Nos. 1339 to 1349 Cherry Street, Philadelphia, Pa.,

WET AND DRY GAS METERS, STATION METERS, EXPERIMENTAL METERS, METER PROVERS,

Center Seals, Pressure Registers, Governors, Indicators, Photometers, and all other kinds of Apparatus for use in Gas Works.

FOULIS' PATENT STATION AND DISTRICT GOVERNORS.

REPAIRING DEPARTMENT.—We employ a special force of skilled workmen repairing meters of all makers.

WM WALLACE GOODWIN, Prest. and Treas.

WM. H. MERRICK, Vice-Prest.

S. L. JONES, Sec.

S. V. MERRICK, Supt.

THE GOODWIN GAS STOVE AND METER CO.,

Successors to W. W. GOODWIN & CO.

1012, 1014 and 1016 Filbert St., Phila., Pa.

142 Chambers St., New York City.

76 Dearborn, St., Chicago, Ills.

WALDO BROTHERS, Agents, 88 Water Streets, Boston, Mass.

MANUFACTURERS OF

DRY AND WET GAS METERS,

Station Meters (square, cylindrical, or in staves), Glazed Meters, King's and Sugg's Experimental Meters, Lamp Post Meters, etc., etc. Meter

Provers (sizes 2, 5, and 10 feet), Pressure Gauges of all kinds, Pressure Registers, Pressure and Vacuum Registers, Pressure Indicators

(sizes 4, 6, and 9 inch), King's Pressure and Vacuum Gauges, Dry and Wet Center Seals, Dry and Wet Governors, Exhauster

Governors, Photometers of all descriptions. Letheby's Sulphur and Ammonia Test Apparatus complete. Also, Testing

and Chemical Apparatus of all kinds, and of the most perfect description, for all purposes relating to Gas.

Manufacturers of the "SUN DIAL" GAS STOVES, for Cooking and Heating.

Goodwin's Improved Lowe's Jet Photometer.

Agents for Bray's Patent Gas Burners and Lanterns.

Special attention to Repairs of Meters and all Apparatus connected with the business. All work guaranteed first-class in every particular. Orders filled promptly.

G. B. EDWARDS, Manager, New York.

S. S. STRATTON, Manager, Chicago.

D. McDONALD & CO.,

GAS METER MANUFACTURERS.

(Established 1854.)

51 Lancaster St., Albany, N. Y.

34 & 36 West Monroe St., Chicago, Ill.

STATION METERS, EXPERIMENTAL METERS, METER PROVERS, PRESSURE & VACUUM REGISTERS, PRESSURE GAUGES, ETC

Also STAR GAS STOVES, RANGES, and HEATING STOVES.

We use only the very best materials, and employ the most skilled labor, and by our long experience (32 years) and personal supervision of every detail, we feel justified in assuring the public that our goods will give perfect satisfaction. Every Meter emanating from our establishment will bear the State Inspector's BADGE, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

NEW ONE-THIRD HORSE POWER "OTTO" GAS ENGINE.

Fitted with
TUBE IGNITER,
and of
THE MOST SIMPLE
CONSTRUCTION.

Will Regulate its
GAS CONSUMPTION
in
PROPORTION TO THE
WORK DONE.

Capable of Driving a No. 18 Enterprise or Star Coffee Mill, One Job Printing Press, Three to Four Fans, Dentists' Machinery, Amateur Tools, Household Pumps, Etc.

Many Valuable and Recent Improvements on all other Sizes,

AMONG WHICH ARE

INTERCHANGEABLE DUPLICATES OF SLIDES, PLATES, and COVERS,
Sent with each Engine Free of Charge. Also,

Power in Most Sizes has been Increased, while Floor Space has been Reduced.

SINGLE CYLINDERS AND TWIN ENGINES; HORIZONTALS AND VERTICALS, COMBINED WITH
WATER PUMPS, SEWAGE PUMPS, AIR COMPRESSORS, DYNAMOS, ETC.

Will Outdo in Economy and Every Other Respect the Rented or Electrical Power.

SIZES, 1-3d to 100 HORSE POWER.

"Otto Gas Engine Works,"

SCHLEICHER, SCHUMM & CO.,

151 Monroe St. (Kent Building), Chicago.

[OFFICIAL NOTICE.]

New England Association of Gas Engineers.

SECRETARY'S OFFICE, BIRMINGHAM, CONN., Jan. 30, 1890.

The Twentieth Annual Meeting of the New England Association of Gas Engineers will be held at Young's Hotel, Boston, on Wednesday and Thursday, Feb. 19th and 20th. The meeting will be called to order by the President, Mr. Robert B. Taber, on the 19th inst., at 10 o'clock A.M. It can now be definitely stated that the following papers will be read sometime during the meeting:

"Vaporization and Feed of Oil to Generator or Retort," by Dr. Robt. Amory, of Brookline, Mass.

"Management of Small Gas and Electric Light Plant," by S. J. Fowler, of Westfield, Mass.

"A Point or Two in Regard to Illuminants During Condensation and Purification," by George F. Goodno, of Dedham, Mass.

"Notes on Revivification of Oxide," by Waldo A. Learned, of Newton, Mass.

"Various Methods of Introducing Gas Stoves," by H. A. Norton, of Boston, Mass.

"A Few of the Advantages of Water Gas over Coal Gas for Small Works," by F. H. Parker, of Burlington, Vt.

"Why I Shall Make Water Gas," by A. B. Slater, of Providence, R. I.

"A Chapter of Don'ts," by W. H. Snow, of Holyoke, Mass.

"Some Notes Taken in a Small Gas Works," by Ralph Woodward, of Waltham, Mass.

"Problems Constantly before the Gas Manager," by E. H. Yorke, of Brockton, Mass.

In addition to the above there are partially promised several other papers. I think all the members who see this notice will agree that, judging by the above list, the coming meeting bids fair to be a greater success than any of the meetings which have been held in previous years. The topics are quite varied, and many of the subjects are among the most important that gas managers have to deal with at the present time.

The officers of the Association believe that no member of the Association, and no one connected with the active business management of any gas company in New England, can afford to be absent from this meeting. Persons eligible for membership and desiring to join the Association will please apply at once to the Secretary, who will forward them blank applications. Although the membership is large, there are still a good many persons connected with the gas business through New England who do not belong to the Association. It is hoped that all such persons will see fit to join at the coming meeting, and make the Association what it ought to be, truly representative of the gas interest in the New England States.

CHARLES H. NETTLETON, Sec'y.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., January 20, 1890.

To Members of the Ohio Gas Light Association:

Gentlemen—The Sixth Annual Meeting of this Association will be held at Toledo, O., on March 19 and 20, 1890.

This announcement is made thus early in order that all members may be reminded of the meeting in ample time to make their arrangements to be present. Every member is urged not only to attend this meeting, but also to interest himself in inducing others of his acquaintance who are eligible for membership, but who have not as yet joined the Association, to come to the meeting and become members.

It is not intended that as many papers as usual shall be presented at the forthcoming meeting, in order that more time than formerly may be had for the discussion of those that are read, and for such other matters and business as the members may desire to dwell upon.

Although the Secretary has for some time been engaged in the work

of soliciting papers for this meeting, he has not yet secured as many as should be had, notwithstanding fewer are desired than heretofore, and he therefore earnestly calls upon all members who can possibly do so to notify him immediately of their willingness to furnish papers.

It has been decided that an interesting and valuable feature of our meeting would be a "Question Box," in which members can place questions, which will be withdrawn and read to the meeting and answered and discussed by the members. Every member is requested to send to the Secretary at once any question or questions which he would like to have thus brought before the meeting.

Future circulars will announce further details concerning the meeting.

Respectfully, IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

MR. HALLETT'S SUCCESS AT SPRINGFIELD, MASS.—Our last issue for January contained a paper, read by Mr. J. L. Hallett, of the Springfield (Mass.) Gas Light Company, entitled "Looking Backward," that must have been read with interest by the fraternity, but which also must have afforded them surprise in the nature of the facts recorded. Perhaps no clearer illustration of what may be accomplished in the line of increasing day consumption, by means of well directed and intelligent effort, has yet been put forward in this country than is afforded by the practice of Mr. Hallett at Springfield during the last four years. The figures as given are so concisely arranged, and carry their own story so plainly, that any comment of an extended nature here respecting them would of necessity savor much of reiteration. Yet we cannot help remarking that if the Springfield Company's output of gas for day purposes in the four months named—June, July, August and September—amounts to 10 per cent. of the total output for the year, its manager ought to come in for most hearty congratulation. Adding to this the knowledge that the aforesaid consumption amounts to an increase of 38 per cent. on the total sendout for the particular third of the year to which the tabulation refers, it looks to us that the solution of the fuel gas problem in the East—especially when one remembers in this connection what has been accomplished at Worcester and Lowell, Mass., at Providence, R. I., at New Haven, Birmingham and Hartford, Conn., and at Nashua, N. H.—in so far as the same refers to the domestic phase of the question, is as good as solved. One other striking outcome of the Springfield figures is the large quantity of gas—4,000 cubic feet per month—that is consumed per fixture per month. It is more than likely that many large ranges are in service, which also goes to show that the wealthier class of residents have taken kindly to fuel gas. The story of Springfield's success, so concisely and plainly told by Mr. Hallett, ought to be proof positive to the few remaining "doubters" of the poverty of their belief that there is no great profit in or field for the distribution of gas for fuel purposes by the existing gas companies of the day.

MR. HALLETT'S RESIGNATION FROM THE SPRINGFIELD COMPANY.—Elsewhere in this issue will be found a communication from "Observer," giving a synopsis of the doings at the annual meeting of the Springfield Gas Company. To our intense surprise and great regret we find that the leading feature of the session was the voluntary retirement of Mr. Hallett from all connection with the executive management of the Company. While it is not in any sense an agreeable task to refer to personal differences respecting the management of any business affair, we nevertheless, from an intimate acquaintance with Mr. Hallett, whose calmness of habit precludes the idea that he acted in this case with haste or without sufficient cause for his determination to sever a business relation that covered a period of 25 years, must hold him to have been the injured and aggrieved party. Place without honor and authority is valueless; and Mr. Hallett is not of the caliber of those who can content themselves in a persistent attempt to pose as placid "occupiers of emptiness."

OBITUARY NOTE—WILLIAM PARRISH, SENECA FALLS, N. Y.—Again are we called upon to chronicle the death of a member of the fraternity in the person of Mr. William Parrish, Treasurer and Manager of the Seneca Falls and Waterloo (N. Y.) Gas Light Company. Deceased, who succumbed, on the morning of January 24th, to an attack of pneumonia, was born at Canandaigua, N. Y., on April 23d, 1828, and was educated at the Canandaigua Academy. Having graduated, he visited the West, and on his return therefrom engaged in business at Buffalo, N. Y. In 1868 he succeeded his brother Stephen in the general charge of the Seneca Falls and Waterloo Company, remaining in this position until death severed the connection. Deceased was elected to membership in the American Gas Light Association in October, 1881, and was a fre-

quent attendant at its sessions. He served his Company faithfully and efficiently. His only public office was that embraced in a three years' term as Superintendent of the County Poor, the responsibilities attaching to which were borne in most worthy manner. A local authority, in a sketch of the life of deceased, says: "In his demise our village loses a citizen whose place cannot be easily filled. His many acts of kindness, his genial presence, and his sterling manhood, will long keep his memory green. He was one of the kindest of parents, a loving husband, an obliging neighbor and an accommodating friend, whose death is deeply regretted by the entire community. To the family in their affliction sympathy and condolence will go forth as sincerely from the hearts of strangers as from those of friends."

MANDAMUS PROCEEDINGS, SUPREME COURT, PHILADELPHIA, DECIDED AGAINST THE TRUSTEES OF THE ROMAN CATHOLIC HIGH SCHOOL.—Our readers have from time to time been informed of the various stages of the legal procedure in the case of the Trustees of the Roman Catholic High School, of Philadelphia vs. the Department of Public Works, and in concluding this history we can now say that the Supreme Court has sustained the ruling of the Court of Common Pleas, which was adverse to the Trustees. A summary of the case is that complainants asked for a mandamus requiring the Department of Public Works to make the necessary connections for the introduction of gas into the new Catholic High School, at Broad and Vine streets. The connection and service were refused on the ground that tenants of houses which had been on the site were indebted to the city for gas which they had consumed. The mandamus was asked for on the ground that the Trustees were in no manner indebted to the city for gas, and that no lien existed against land for gas used on premises over it. The lower Court refused on the ground that the ordinance reserving to the Trustees of the gas works the right to refuse to introduce gas into premises until all arrears due on said premises shall have been paid was one which it was within the power of the city to make and enforce. The Supreme Court indorsed this opinion.

FLEMMING BENCHES AT PHILADELPHIA.—The Philadelphia gas works authorities have decided to put in 24 benches of sixes, to be fired under the Flemming plan, at the Point Breeze station. Messrs. Gautier & Co., Jersey City, are to furnish the fireclay materials, the castings to be supplied by Jas. R. Floyd & Sons, of this city. This is good testimony to the value of the Flemming furnace, as the last contract is a sequel to the one awarded a year ago, under which the construction of 24 benches of this type was authorized.

MESSRS. CONNELLY & CO. REPORT GOOD BUSINESS.—Writing under date of January 29th, the Messrs. Connelly & Co., Limited, of this city, say: "Iron sponge is not only holding its own but its use is gradually extending all over the country, and the business increases each year. Our shipments during the present month exceed those of any month in the past, being almost 40,000 bushels, or 45 carloads—almost two carloads for every working day. In automatic governors we have done an unexpectedly large business during the present winter; for gas companies as a rule do not break connections and place machinery of this character during the winter. Notwithstanding this practice we have shipped 12 governors since the first of December; and from the numerous inquiries from all parts of the country we anticipate a regular boom in the enlargement of gas plants next season."

ANNUAL ELECTION, HOUSTON, TEX.—The annual meeting of the Houston (Tex.) Gas Light Company resulted in the following choice of officers: President, T. W. House; Vice-President, T. H. Scanlan; Secretary and Treasurer, G. R. Vaughn; Directors, Messrs. B. A. Shepard, T. H. Scanlan, Jno. T. Brady, Henry S. Fox and T. W. House.

THE works of the Freeport (Pa.) Gas Company were closed on 1st inst. The reason for this is stated to be the competition of natural gas.

ANNUAL MEETING, ILION AND MOHAWK, N. Y.—At the annual meeting of the Ilion and Mohawk Gas Light Company it was determined to construct a gasholder of 50,000 cu. ft. capacity. The officers chosen were: President, Hon. Thomas Ringwood; Vice-President, John Hoefler; Treasurer, C. W. Carpenter; Secretary, John V. Schmidt; Manager, John A. Giblin; Directors, Thos. Ringwood, John Hoefler, John V. Schmidt, C. W. Carpenter, A. N. Russell, F. C. Shepard, M. J. Richardson, Edmund Roche and H. D. Alexander.

THE offices of the Elizabeth (N. J.) Gas and Water Companies have been consolidated. Mr. Thomas P. Smith, for many years Collector for the Gas Company, has been appointed Secretary and Treasurer.

Flannery's Patent Gas and Liquid Holder.

On Jan. 21 U. S. Letters Patent (No. 419,845) were granted to Joseph Flannery, of this city, for improvements in gas and liquid holders. In his specification the inventor says :

The object of this improvement is to provide a simple and ready means for storing liquid, and particularly oil to be used in the manufacture of gas ; to effect a saving of the gaseous vapors arising from the evaporation of the stored oil and prevent the escape of such vapor in the surrounding atmosphere ; to provide means for forcing the liquid stored in the tank, therefore to guard against danger from explosion of the oil, and to effect a saving of ground space over what has heretofore been possible as such storage tanks have been erected. To accomplish these results I place a tank for containing the liquid directly within the the gasholder, whereby the tank will be always surrounded by water, by which the gasholder is sealed, and will therefore be always kept cool, and at the same time so inclosed as to be protected against danger from sparks or other causes which might tend to induce an explosion. I further provide the tank with a vent by which the gaseous vapors arising from the evaporation of oil within the tank may pass directly into the gasholder, thereby not only enriching the gas in the holder and preventing waste, but also providing against the escape of such gaseous vapors into the surrounding atmosphere, as is the common practice, by which the atmosphere is contaminated and the health of a neighborhood

vided with cocks s^1 . D designates a liquid tank, which tank has, as shown, a closed bottom and top, and is secured at its lower side to the bottom of the well C . d d^1 are respectively filling and emptying pipes, by which liquid is delivered to and from the tank D . They are provided with cocks s^2 s^3 . e designates a vent in the upper portion of the tank, by which means open communication is afforded between the tank and the gasholder.

In Fig. 4 I have shown that a float f may be employed, which float is mounted upon a spindle f^1 , extending upwardly through the vent e , and upon which is secured a valve f^2 , adapted to seat upon a valve-seat f^3 ,

formed upon the inner end of the vent e when the liquid in the tank shall have risen to a sufficient height. This will prevent any overflow of oil into the water space between the tank and the sides of the well when oil is contained in the tank.

In Fig. 1 I have shown the well as made of metal—such as plate iron—and in Fig. 2 I have shown the same as constructed of masonry. In the latter case the bottom of the well is formed of cement or similar material, and the tank D rests thereon.

endangered. As the tank is in open communication with the gasholder, in which a heavy pressure is maintained, the weight of the holder and the pressure therein will operate to force oil out of the tank through its delivery pipe, and raise it to a considerable elevation when it is desired to withdraw the oil, the effect being that of a force pump. The arrangement of the tank within the holder will not curtail the gas space of the gasholder, for the reason that the space occupied by the tank is ordinarily filled with water. By placing the tank within the gasholder it will be seen also that a considerable saving is effected in the ground space over what could be effected if the tank and the gasholder occupied different and separate positions.

Gaseous vapors arising from oil stored in the tank will pass out through the vent e , and will become mixed with the gas in the gasholder, thereby enriching such gas and preventing the waste of said gaseous vapors, besides wholly confining them so that they cannot escape into the surrounding atmosphere.

In the accompanying drawings Fig. 1 is an elevation, partly in section, of a gasholder and tank embodying the improvements. Fig. 2 is a similar view, but partly broken away to save space, and illustrating a slightly modified construction. Fig. 3 is a plan or top view of the improvement shown in Fig. 1. Fig. 4 is a vertical section of the tank, and shows a slight modification. Similar letters of reference designate corresponding parts in all the figures.

When it is desired to withdraw oil from the tank, the cock s^3 in the filling pipe d is closed and the cock s^2 in the emptying pipe d^1 is opened. The weight of the gasholder and the pressure therein will then operate to force oil out through the emptying pipe and raise it to a level considerably above the level of the oil in the tank. This is advantageous where the tank and holder are situated at a level below that at which it is desired to use the oil.

A designates the gasholder, which may be of the usual or any desired construction, adapted to be moved upwardly and downwardly in the frame B . C designates the well in which the lower portion of the gasholder is received and in which the water is contained. a a^1 designate gas inlet and outlet pipes, respectively, which may be of the ordinary construction and open directly into the gasholder. They are pro-

Of course, instead of using separate pipes for filling and emptying the tank, both operations might be performed through a single pipe.

Steel Pressure Blower.

The accompanying engraving shows a Buffalo steel pressure blower mounted on an adjustable bed and provided with countershaft. It is designed and constructed with special reference to high pressure duty, such as supplying blast for cupola furnaces, forge fires and sand-blast machines; also for forcing air long distances. By means of a tightening screw the blower may be moved upon the bed while running at full speed, taking up any slack, giving both belts a uniform tension which is regulated at the will of the operator, and is an important point in preventing the inconvenience and loss incurred by a stoppage during heat when blowers are used for cupola purposes. A decided saving by use of the bed is gained in the wear and tear of belts, for a simple turn or two of the nut on the end of the adjusting screw and retightening of the holding-down bolts takes but a moment or two and accomplishes the same end as the relacing of the belts, which usually is put off until the belt will run no longer on account of so much slack. Special attention should be directed to pressure blower belts on account of the high rate of speed at which they must necessarily run, and absolutely perfect alignment of the countershaft with the blower is essential in order to secure smooth running, even tracking, and to avoid undue wear of belts by slipping.

A telescopic mouthpiece is employed in order that the blast piping may not be disarranged in moving the blower on the bed, while suffi-

be eclipsed to the extent of three or fourfold. But so long as the parliamentary standard remains what it is gas engineers will have to make gas that will fit in with the standard, irrespective of its suitability for general purposes to the consumer. Judging from published analyses, a gas that will satisfactorily pass the 16-candle parliamentary standard may vary in composition within the following limits: Illuminants, from 3 to 5 per cent.; hydrogen, from 43 to 53 per cent.; marsh gas, from 35 to 45 per cent.; carbonic oxide, from 3 to 8 per cent.; impurities, such as nitrogen, oxygen, air and carbonic acid, from 2 to 10 per cent. by volume.

There is no reason for supposing that the constituents of coal gas are present in other form than that of a plain mechanical mixture; and it therefore follows that the specific gravity is merely a sum of the specific gravity of the various constituents. The apparent simplicity of this method of arriving at its specific gravity is, however, greatly mitigated by the fact that obtaining an accurate analysis of coal gas is a very difficult thing. Even in the hands of the cleverest chemists it is scarcely possible to entirely exclude calculation. Very few published results are free from the objection that indirect methods of estimation have been resorted to in the case of one or two constituents at least. On the other hand, the accurate determination of the specific gravity by direct weighing is a delicate operation, calling for the best available skill. Not only must there be accurate weighing of the gas, but also accurate reading of the barometer and thermometer, to say nothing of some rather intricate

cient length is afforded to the countershaft so that tight and loose pulleys can be used for main driving belt; a self-oiling device fitted to the countershaft enables it to run at high speeds for long periods of time without heating or cutting. A prominent feature of these blowers is the solid case, the peripheral portion of the shell being cast in one solid piece, dispensing entirely with the objectionable "putty joint." Thus, being practically one piece, under the hardest service the bearing must always be in perfect alignment, vertically and laterally, with the rest of the machine. The journals are long and heavy, in the standard ratio of length to diameter of 6 to 1—, with cap bearings secured by bolts screwed in the lower half of bearing held in place by lock nuts.

The Specific Gravity and Illuminating Power of Coal Gas.

[Communicated by NORTON H. HUMPHREYS to the *London Journal*.]

Some little confusion seems to have arisen lately as to the value of the specific gravity test as a means of determining, or rather approximately indicating, the value of an illuminating gas; and it may therefore be interesting to examine some of the principal factors concerned. It should first be specified that the term "illuminating value" is very indefinite. It simply indicates the value of the gas as ascertained by one particular plan—the consumption at the rate of 5 cubic feet per hour in an Argand burner—which may or may not be favorable to the gas under examination. Further, the absurdity of regarding the results thus indicated as anything like an absolute quality of the gas is illustrated by the fact that by means of regenerator and other improved burners they can

arithmetic afterwards. It is not too much to assert that some of the published data on this subject are based upon experiments in which the whole of the above precautions were not rigidly observed. Sometimes, for practical purposes only, a rapid approximate test, such as the diffusion test, is used. In other cases the results quoted are gathered from foreign sources, originated in countries where different standards of temperature and pressure to those used in England prevail. But even after allowing for all these possible sources of error, there still remains a wide divergency to be accounted for.

Owing to the variations in weight, due to changes of temperature and pressure, to which it is continually subjected, it is not usual to give the actual weight of the sample of gas experimented upon. The result ultimately obtained represents the weight of the dried gas under standard conditions of temperature and pressure. And even this is not stated in direct terms, but as a fraction of the weight of an equal bulk of air under similar conditions. The weight of a cubic foot of dry air, at 60° F. and 30 inches of mercury, is about 537 grains; and, therefore, if the specific gravity of a gas is stated as 0.5, the actual weight is $537 \times 0.5 = 268.5$ grains per cubic foot. If this quantity of air has been standing over water it will have taken up about 1.7 per cent. of water vapor, and will weigh rather lighter—about 532.5 grains. But a cubic foot of gas, saturated with moisture, would be rendered rather heavier. The vapor of water at 60° F. is lighter than air, but not so light as coal gas. The reason for taking the weight of the dry gas is that the water vapor varies according to temperature and pressure.

If the several constituents present in coal gas were about equal in the

matter of specific gravity, a moderate variation in constitution would not have much effect as regards the weight. But, as a matter of fact, they vary over a wide range, as shown by the following table, which gives the principal constituents of coal gas, their specific gravity, weight of a cubic foot in grains, and ratio to an assumed specific gravity of 0.45, or 242 grains, which may be taken to represent that of 16-candle gas :

	Specific Gravity.	Weight in Grains.	Ratio.
Hydrogen.....	.069	37	0.15
Marsh gas.....	.553	300	1.20
Acetylene.....	.898	482	1.99
Carbonic oxide.....	.967	519	2.14
Olefiant gas.....	.968	520	2.15
Nitrogen.....	.971	521	2.15
Air.....	1.000	537	2.22
Oxygen.....	1.106	594	2.45
Carbonic acid.....	1.520	821	3.39
Benzene.....	2.695	1,445	5.97
Naphthaline.....	4.423	2,372	9.58

The highest constituent present is hydrogen, which is less than one-sixth the weight of the gas. It is rather singular that this is the only constituent that is lighter than the mean—all the rest being heavier; and with the exception of marsh gas nearly twice as heavy, and upwards. Several of the constituents are near the twofold limit; then there is carbonic acid; and lastly, the heavy vapors of benzene and naphthaline.

Assuming that the gas of 0.45 specific gravity contained the lower limit of hydrogen (43 per cent.) the effect of adding another 10 per cent. would be as follows :

$$\frac{(.45 \times 10) + .069}{10 + 1} = .415$$

making it lighter to the extent of nearly 8 per cent. Or the effect of taking away 10 per cent. would be :

$$\frac{(.45 \times 10) - .069}{10 - 1} = .492$$

an increase of nearly 10 per cent.

The addition of 10 per cent. of marsh gas would raise the specific gravity :

$$\frac{(.45 \times 10) + .553}{10 + 1} = .460$$

and taking away a similar quantity would lower it :

$$\frac{(.45 \times 10) - .553}{10 - 1} = .439$$

In a similar manner the effect of variation in the proportion of carbonic oxide can be arrived at. The addition of 5 per cent. of this gas would raise the specific gravity thus :

$$\frac{(.45 \times 100) + (.967 \times 5)}{100 + 5} = .474.$$

Or the deduction of a similar quantity would lower it :

$$\frac{(.45 \times 100) - (.967 \times 5)}{100 - 5} = .423.$$

From these calculations it is plain that variations in the proportion of hydrogen and carbonic oxide, which need not necessarily exert any marked influence on the photometrical value of the gas, may alter the weight and specific gravity to the extent of 10 per cent. or more in either direction.

Although the illuminants are present in small proportion there is reason to believe that they are certainly not less than four, and perhaps as much as five times as heavy as the mean. But in their case there is a compensating cause. If they are small in quantity, they must be heavier, and therefore richer in quality. It was this consideration that led Mr. Lewis Thompson to suppose that in gases of equal illuminating value the *weight* of the illuminants, which is a very different thing from the percentage by volume, would also be practically equal. Scientists and others who talk about coal gas being only charged with a trifling proportion of illuminants, have probably overlooked the fact that it consists of heavy hydrocarbons to the extent of 20 to 25 per cent. by weight. The 10 cubic feet of the gas above referred to would weigh 2,420 grains; and if it contained 5 per cent. of hydrocarbons, of which the average specific gravity was 2, the weight would be 537 grains, or more than 22 per cent.

But the chief cause of variation in specific gravity is the presence of impurities, such as nitrogen, oxygen, air, or carbonic acid. Not only do these range from 2.2 to 3.4 times the weight of the mean, but there is the important fact that an additional weight of illuminants must be present in order to make up for the depreciating effect of the impurities on the illuminating power. The removal of such impurities would cause

an important increase in the photometrical value; and therefore a 16-candle gas containing appreciable quantities of them is, to all intents and purposes, an adulterated 17, 18, or 19-candle gas, according to the proportion present. The removal of the impurities would also be attended by a reduction in the specific gravity and at the same time improve the illuminating value of the gas.

The most common impurities of this class are nitrogen and carbonic acid. The former is very slightly heavier than carbonic oxide; so we may apply the calculation for that substance to it, and say that variations to the extent of 5 per cent., either way, in the proportion of nitrogen present, would cause the specific gravity to range from 0.423 to 0.474. The effect of carbonic acid is very similar; for although it is present in smaller quantities, its specific gravity is high. In towns where the sulphur clauses prevail this impurity must of necessity be removed from the gas. In other places, for reasons which need not here be entered upon, there is as much as 2 per cent. of carbonic acid in the gas. Applying the above form of calculation, we shall find that 2 per cent. of carbonic acid added to the gas increases the specific gravity to 0.480; or a similar quantity deducted from the gas will reduce the specific gravity to 0.424.

It appears that within the variations in constitution that are found to occur in the ordinary way of manufacturing gas from coal, the only constituent that is not likely to exercise an important influence on the specific gravity is marsh gas. This will probably not affect it to the extent of more than 2 per cent from the mean in either direction; whereas the others range from 5 to more than 10 per cent. With the exception of the illuminants there is no reason to suspect the existence of any compensating influence—*i.e.*, that the presence of a large proportion of any one constituent must necessarily result in the presence to a correspondingly small proportion of any other one; though, of course, if one is high, the others as a whole must be correspondingly less. In order to confine the specific gravity within reasonable limits of accuracy as an indicator of photometrical value it is necessary that the proportion of hydrogen and carbonic oxide present should not vary beyond narrow limits; and also that nitrogen, oxygen and carbonic acid should be conspicuous by their absence. If so much difference exists between samples of illuminating gas made on the same system, by the destructive distillation of coal, a much greater difference may be expected to obtain between the specific gravity and photometrical value of other kinds, such as oil gas, wood gas, or carbureted water gas.

The Operation of Felling an Electric Light Pole.

An observant New Yorker, in recounting some of the sights that attract crowds of the curious in this city, says that for several months past New York city has been endeavoring, through its authorities, to do away with all electric conductors stretched upon poles, and to compel the placing of them in so-called subways in the streets. The city, in carrying out this work, has frequently been called upon to take down a pole so located that the placing of it in a horizontal position called for nice judgment and well adapted rope connections. How these poles are taken down when they must be felled in exactly the right position, or in other words, when the top of the pole must not vary 4 feet from the line it stood in, are questions which of course interest every one. The method of taking down a pole, therefore, which stood between the elevated structure in Church street, and from which structure the house line of the building was not more than 7 feet away, presents points of general interest. After this pole had been relieved of its cross bars and all wires connected with it, it was stayed at the bottom with four ropes placed at right angles to each other and attached just above the cut. These ropes were intended to prevent any movement or jump of the butt of the pole. It was then provided with three ropes about midway between the top and the bottom, one of which was so arranged as to guide the descent of the pole, the other to prevent the pole falling in the opposite direction, and the third to insure the pole falling in a line with the elevated road.

The cutting of the pole at the base, evidently done by a backwoodsman, since he handled his axe with a degree of precision not found in the city, was begun on that side toward which it was desired to fell the pole. After he had cut beyond the center of the pole he began work on the opposite side. As he approached the dividing line between his cuts all ropes were tightened. Thus the butt of the pole by its four ropes was prevented from any jumping, and also the top of the pole was prevented from striking the building, where it might have done some damage, by the rope connected with the elevated railroad, and it was also prevented from falling too fast in either direction by ropes which extended parallel with the elevated structure. After he had cut about half way through this side of the butt of the pole, the rope was hauled on that side to

which it was desired the pole should lean, and as the pole gave way to this pressure the rope upon the opposite side was played out, while that toward the elevated structure was so guided that the pole just missed the cross ties; and in this way was lowered to the street without any hitch whatever, and without deviating 12 inches from the line it should have followed. The system of taking down poles, as developed here in New York, shows that by the simplest means any pole can be felled and carried down within the closest limits; in other words, as was the case with the pole above mentioned, it can be taken down by an elevated structure projecting over the sidewalk and between the buildings on the line of the sidewalk, and yet can be done easily and gently and without in any way interfering, beyond a few minutes, with travel on the elevated road or on the sidewalk.

The Dangers of Electric Lighting.

BY S. Z. DE FERRANTI AND FRANCIS INCE.

[These authors have prepared the following review (for *Engineering*) of the dangers of electric lighting. The concluding portion will be given in our issue for February 10th]:

The time has now arrived when it is absolutely necessary for the public generally to clearly understand one or two matters connected with electrical science, and we propose to explain to the uninitiated certain electrical terms, and, having explained them, to show what are the "dangers of electric lighting," whether a high tension or a low tension system is used.

In the first place it is of primary importance to understand that, when dealing with an electric current, two things require immediate attention; first of all, the "tension" or "pressure" of the current; and secondly, the "quantity," and to understand fully the meaning of the terms pressure and quantity, take water by way of illustration. With water no one has any difficulty in understanding that, with a pipe of a given size, and with water flowing through it from a cistern placed 20 feet above it, a certain quantity of water would flow through the pipe in a minute; but if the cistern were then placed 40 feet above the pipe, a considerably larger quantity of water would flow through the same pipe in a minute, this result being brought about by the extra pressure due to the water falling through 40 feet in lieu of 20 feet. Tension or pressure of an electric current, technically called "volts," may be taken as similar to water pressure. Now, with regard to quantity, here again a pipe of a certain size will, at a given pressure, allow a certain quantity of water to flow through it in a given time, and if the water pressure be doubled, about twice the quantity of water will flow through it in the minute. So again with the electric current, if a conductor, or bar, or tube of copper of a given size be taken, the quantity of current which will pass along it varies with the pressure; that is to say, that if the current is sent into the conductor with a pressure we will call one, a given quantity of current passes along the conductor in a minute, and if we have a pressure of twice one, or two, twice the quantity of current will pass along the conductor in the minute. Quantity is technically called "amperes."

We will now pass to another matter; we must consider what work—or useful energy—can be got out of a current. This is arrived at by multiplying the pressure and the quantity together, and the result is called "watts," and watts, therefore, represent the actual work—or energy—any given current will give. Now let us explain clearly what this means. A horse power is a power capable of raising a weight of 33,000 pounds 1 foot high in a minute, and to perform this work 746 watts are required, that is to say, the pressure of an electric current multiplied by the quantity must give the answer 746 to make the electric power equal one-horse power; thus a current with a pressure 1 (1 volt) and with a quantity 746 (746 amperes) will equal one-horse power, or a current with a pressure 2 (2 volts) and with a quantity 373 (373 amperes) will also give one-horse power, as $2 \times 373 = 746$; or again, if we have a pressure of 746 (746 volts), and a quantity of 1 (1 ampere), the two multiplied together still give 746, and thus we should still have a power equal to one horse.

Now, it will be remembered that when dealing with water passing through a pipe, the quantity passed in a minute was about doubled if the pressure was doubled; therefore if you wish the pipe only to deliver a certain quantity of water in a minute or to do a certain work, the size will be reduced, if your pressure is increased. So with electricity, if you increase your pressure you decrease the size of your conductor, as the quantity of electricity always passing will be less, to do certain work.

To make ourselves clear, let us give an illustration: The pressure at high electricity is used ordinarily for lighting incandescent lamps is

100 (100 volts), and the quantity of current a 10-candle power lamp consumes is .35 (about $\frac{3}{10}$ of an ampere); therefore to light 5,000 of such lamps a current is required at the constant pressure of 100 (100 volts) and the quantity that would be required is $5,000 \times .35$, or 1,750 amperes, the energy consumed in watts being equal to the pressure (100 volts) multiplied by the quantity of 1,750 amperes, the result is 175,000 watts.

Thus to light 5,000 lamps, the current being sent out from the central station at a pressure of 100 volts, a conductor would have to be provided which would carry in quantity 1,750 amperes; thus the pressure $100 \times$ by the quantity 1,750 gives 175,000 watts, the power required to do the work. Now, if the current were being sent out from the central station at a pressure of 10,000 volts, a conductor would have to be provided which would carry in quantity 17.5 amperes only; thus again the pressure $10,000 \times$ by the quantity 17.5 would again give 175,000 watts, the power required to do the work, and the size of the conductors required therefor in the two cases to do the same work would be in the proportion of 1,750 to 17.5, that is to say, that with a pressure of 10,000 volts the size of the copper conductor would be about one hundredth of the size required if dealing with 100-volt current only.

It is now only necessary for us to point out one other scientific fact, and we shall then be in a position to clearly consider "the dangers of electric lighting;" that fact is that for heating purposes the quantity of the current only has to be considered, and not the voltage or pressure, as it is the passing of too great a quantity through a conductor that causes it to heat, and ultimately to melt, irrespective of the voltage or pressure, which has nothing whatever to do with heating. A pipe, if too much water for its strength was being forced through it, would burst; the electrical conductor with too much quantity through it heats and ultimately melts. Thus, if a conductor is put under ground of a size sufficient to carry current for 5,000 lamps only, and we turn on 10,000 lamps, the conductor will heat, and if we go on turning on more and more lamps, the conductor will ultimately melt at the weakest point. When the continuity of the conductor will be broken, no more current will be passed, the lights go out, and no further danger exists. Now, besides giving a conductor too much work by putting on too many lights, there is a second way in which an underground conductor may be made to do too much work, and so to heat or melt—that is to say, if the conductor is so constructed that it can, and is so placed in the ground that it may, and it does, come into contact with another conductor, such as a telephone or telegraph wire, a gas or water pipe, the current will leak into and through such other conductor, and will find a short way back to the central station from whence it came in preference to going through the lamps or doing other work, the resistance in going back through the earth by the short cut being less than the resistance of the work to be done; just in the same way if a pipe bursts, the water will spout out at the burst point in every direction, as the resistance is less at that point to the water than the resistance in the further length of pipe, if the water were to proceed to do its work; again, as before pointed out, the pipe bursts under the pressure, but the main at the point of contact with another main or wire, where the rush of the current takes place, heats, and finally melts, setting fire to or melting anything in its neighborhood. Here is the danger of fire. Now let us see how this danger is got over in this country. As before pointed out, if too many lights are put on any main, or conductor, the main heats and finally melts at the weakest point; and in the second case, where the conductor comes across another conductor, as above pointed out, there is an enormous rush of current through the conductor, it heats and ultimately melts at the point of contact. Now, how is this danger to be entirely got rid of? The question is in fact answered by the above statement, which must be clear to any one, that when too many lights are turned on the conductor heats and melts at the weakest point.

What have we to do, then? We place at our central station, close to the dynamo which generates the current, the weakest point in every main or conductor that leaves the station; this weakest point is a short bridge of copper so slight and of a so carefully calculated capacity that if a conductor is of such a size that it should be used for lighting 5,000 lights only, if 6,000 lights are turned on the rush of current is too great for the bridge, and it melts or fuses (hence the bridge is technically called a fuse), and that main or conductor is cut out long before any part of it even becomes warm. But you say, What occurs if it is not too many lights that are turned on, but is a contact, as suggested, with another conductor or a gas pipe? Consider for a moment what happens at the point of contact; there is a too great rush of current to that point, and the result therefore is the same as turning on too many lights; if there is too great a rush of current from any cause it must all pass over the bridge into the conductor, and the bridge cares not for the reason that causes the great flow, but the great flow instantly causes the bridge

to fuse, and with a conductor so arranged accident by fire is an impossibility. Mr. Edison has said, in a recent article by his pen on the same subject as that on which we are writing, that "near the corner of William and Wall streets, New York, the underground conductors of the Edison Illuminating Company became crossed (by which he means they came in contact), and the current which was passing through them at a pressure of 110 volts melted not only the wires but several feet of iron tubing in which they were incased, and reduced the paving stones within a radius of 3 feet or 4 feet to a molten mass." Now no man knows better than Mr. Edison that the tension of the current in the mains to which he refers had nothing whatever to do with the heating effect of the current; it was the quantity, and the quantity alone, that caused the heat. Now, if his main were lighting 5,000 lamps of 10-candle power at 110 volts, the quantity of his current would have been, roughly, about 1,700 amperes, and by the contact, this quantity would have been enormously increased, whereas if he had been using a 10,000 volt current his quantity, as we have seen, would have been only 17 amperes about, and the heating power of his current would have been 100 times less; but where was Mr. Edison's bridge or fuse at his central station?

It is clear that he could have had none, or it would have melted before any damage could by any possibility have been done; and his statement proves, as the reader will see, not that a higher tension would have been more dangerous (it would have been safer), but that the work at the station to which he refers must have been done on most incorrect and inefficient principles. Mr. Edison may argue that with increased pressure it is possible to force a greater quantity through a main, and that therefore a 10,000 volt pressure is more unsafe than a 100 volt pressure; but this is not the fact—as the conductor to be melted is in size only one hundredth of the size of his main it will heat and melt sooner, and there is not the same quantity of molten mass to deal with; but the real answer is, that the bridge or fuse at the station, if used, is, with either low or high pressure, the real safety, as it will never allow so large a quantity of current to pass over it as is necessary to cause the conductor to heat, no matter whether the pressure be 100 or 10,000 volts. Take again the calorific effect of the low tension system. We have seen that to do the same work, the low tension system requires 1,750 amperes against 17.5 on the high pressure, and thus if an accident does happen on the low tension system, the immediate calorific effect of 1,750 amperes is called into play. Now, if on the high tension system such an effect could be reached, our engines would be called on to do an absolute impossibility, as they would be required to give 100 times their nominal power before the quantity and equal heating effect of 1,750 amperes could be reached.

Then comes the further question, How did Mr. Edison's mains become crossed, or rather in contact, with another conductor crossing his mains at right angles apparently at a street crossing? This must have arisen through the negligent way in which the Edison mains were placed underground without sufficient protection. It is idle to suggest that this is a danger that cannot be guarded against. It is easy enough to protect one conductor underground from coming in contact by any possibility with another crossing it, and we should be wasting the reader's time if we were to attempt to describe the thousand and one ways in which this may be done, for many will suggest themselves to every reader. But the further question arises, Is it not possible to construct your mains or underground conductors in such a manner that the passing of another main or conductor at an angle above and in contact with it will produce no harmful result whatever? The answer is Yes, distinctly yes.

(To be continued.)

The Demand for More Light.

The *Gas World*, in commenting on the demands for more light, says that in mentioning Bristol as a town where talk about "bad" gas has been somewhat prevalent during recent months we do so only to direct attention to the growing desire of the general public for more light. A decade ago a light that would make darkness visible was considered good enough; and any company seeking parliamentary powers was seldom asked to bind itself to the supply of gas of more than 13 or, at most, 15-candle power. The Bristol United Gas Light Company, working under Acts obtained many years ago, is legally bound to supply gas of only 13½-candle power, and very few English companies are called upon to supply 16 candles. That is the full pound of flesh the public can demand, but, as a matter of fact, very little gas is supplied in this country under 16 candles. The Bristol Company, while it may with impunity supply 13½-candle gas, actually supplies 16-candle gas; and as in Bristol so in nearly every other town and village throughout

England. Yet, notwithstanding this generous interpretation of the bond by the gas companies, the continuous cry of the public, or rather of the public's representatives in council assembled, is "give us more light." To have a "dim religious light" in the streets is not sufficient for the present generation; the light of to-day must be brilliant and all pervading. If we were asked to state what has brought about this change in the public taste, we would say, naming the causes in order of merit, (1) the desire to improve upon the achievements of the past; (2) the example of private enterprise; (3) the impression left upon the public mind by a passing acquaintance with an arc lamp. In an age which we are proud to call an age of progress the desire to improve the public lighting of our streets is a perfectly natural one; a comparison between the general lighting of the streets and that of the outside of an enterprising tradesman's shop (a comparison which most of us involuntarily make every day of our lives) shows that such improvement is, not only possible, but ridiculously easy of accomplishment; and the electricians are continually pushing their arc lamps under our noses, as much as to say: "If the gas companies won't satisfy your desires, we will."

But here the trouble arises. The public wants more light, and because it does not get it, says the gas is "bad." As we have already said, the gas is better in quality than the requirements of the Legislature demand; so to be honest the public must either give up the cry of "bad" gas or set about mending the legislation under which it is permitted to be "bad." There is no medium course so far as the quality of the gas is concerned. But before hastily amending the legislation we would recommend those who are dissatisfied with 16-candle power to see how "bad" even 30 candle gas can be made to appear. We were recently passing through the Fair City of Perth after the sun had set upon its fairness, and although gas of nearly 30-candle power was being burned in the street lamps, the streets would have had anything but a pleasing appearance had it not been for the light streaming forth from the shop windows. What the city is like after the shops are closed we did not wait to see. When this is the condition of affairs where the gas is 30-candle power it must become apparent to the most enthusiastic anti-gas municipal ruler that deficient street lighting cannot be wholly attributable to the low illuminating power of the gas. He may even begin to suspect that the fault lies with his own method of using the gas supplied to him. If he does so there is hope, for he is now on the right path toward improvement.

You cannot light a palace with a candle; neither can you light 30 yards of street by the combustion of 2½ cubic feet of gas per hour through an antiquated burner. The man who attempted the former would be called something not very polite. The latter is equally impracticable, but when the inevitable failure ensues the gas is "bad!" All this cry about "bad" gas is simply beating the air. The public wants more light—there cannot be a doubt about that—but for its new requirements the public must pay—either by paying the extra cost of a higher illuminating power or by consuming more of the present quality gas by means of improved apparatus. Gas companies are paid for providing a certain quantity of light; they cannot be called upon to supply double, or any other multiple of that quantity for the same money. Municipal rulers must therefore face the inevitable by providing the extra money required to pay for the extra light demanded by their constituents. This extra light can, as we have indicated, be obtained in two ways—by increasing the illuminating power of the gas and adhering to the present consumption per lamp, or by increasing the consumption and adhering to the present illuminating power. To our mind the latter course is the proper one to pursue. By increasing the illuminating power you cannot afford that distribution so essential to street lighting, and you also compel the private consumers to pay an extra penny or twopence per 1,000 cubic feet (as the case may be) for an extra illuminating power which many of them do not desire. By adhering to the present quality and increasing the consumption you can distribute the light more evenly, and obtain a higher yield of light per cubic foot of gas consumed by taking advantage of the well known law that within limits the greater consumption in an individual lamp the greater the yield of light per cubic foot of gas. Indeed, under this law you obtain light for which the gas company does not get a farthing.

The subject is one which demands the most careful consideration by those charged with the lighting of our streets. We do not now put the case as one of gas *versus* the electric light; we are simply dealing with the growing demand for "more light." To satisfy that demand will cost money—whether the result be obtained by a more generous and scientific use of gas or by the introduction of the electric light. That gas can satisfy the demand is abundantly proved by what has been done in different corners of London, in Brighton, and in every town where a gas

installation has been fitted up under the eyes of competent supervisors. That the electric light can satisfy it has yet to be proved. In Barnet and in Leamington the incandescent electric lamps have been woeful failures (both financially and practically); and any one who has had experience of the arc lamp must admit that its distributive and diffusive powers are not of a very high order.

Pile Protection.

Mr. J. A. Pritchard not long since read before the Ohio Society of Surveyors and Civil Engineers a very interesting paper on the subject of "Pile Protection." An extract of this paper is appended:

It has been a study with landowners along the streams (I would add here by way of parenthesis that I refer to those who believe in taking care of land, and not those who allow things to go to rack) to devise some effective and cheap method of protecting banks and levees. Some have tried to do this by building cribs of round timber and filling with brush and boulders. These caused the wash to be more instead of less, and were considered failures. Others have built brush dams, excavated new channels and changed the course of the stream. While one attempt at this was successful others failed, and the expense of making a new channel was considerable. In the fall of 1887, there was commenced a system of pile protection, of which there was put in at that time 742 feet in all, which consisted of three wings, and 546 feet, which was in one continuous curve of about 475 feet radius, the piles of which were driven close up to the bank and sheeted on the water side with 2-inch oak sheeting. But it is the wings that I wish to speak of, as to place a continuous sheet along the water front of a large farm that is liable to wash would be rather expensive. The wings are constructed in the following manner: No. 1 is located where the creek makes a curve of 800 feet radius, and consists of thirteen piles seven feet from center to center, seven of which were driven close up to the bank. The remaining six were placed across the stream at an angle of 45°. Brush was then laid across the line of piling well out into the stream. The bottom plank of the sheeting was then forced down on the brush and made fast by 6-inch wire spikes. The sheeting was placed behind the piles on the bank part, and is held in place by a back filling of brush and gravel. On the part which extends into the stream, the sheeting is placed on the front or upper side, and is secured to the piles by 6-inch wire spikes. The top piece of sheeting is made double, and in such a manner as to break joints, and is bolted with $\frac{1}{2}$ -inch bolts, two to a pile. The extreme 35 feet which extends into the stream is double sheeted, and in such a manner as to break joints between the piles, and is bolted at the joints to a 4-inch by 6-inch stay, placed behind the sheeting, with $\frac{1}{2}$ -inch bolts. The piles were driven by horse power with an 800-pound hammer. The leads were placed on a common farm wagon, and were about 16 feet full length. The length of this wing is 84 feet. An estimate of the cost would be:

Thirteen piles, fourteen feet long, at \$1.50..	\$19.50
Driving same, at \$1.50.....	19.50
Boarding three men and team..	5.00
Sheeting, 1,320 feet, at B. M. \$68 per 1,000..	24.90
Placing sheeting and back filling.....	10.00
Bolts and spikes	3.00
Total.....	\$81.90

I would here say that the cost of the whole 742 feet was between seven and eight hundred dollars, or about one dollar per foot. The effects of this wing has been to protect the bank for about 400 feet, at which point the wash originally began, on the opposite side, but since the wing has been placed has begun further up the stream. It also had the effect of deepening the channel, which before was about 2 $\frac{1}{2}$ feet and now is 4 $\frac{1}{2}$ feet deep. Wings Nos. 2 and 3 are built in the same manner, but with a more favorable location and 28 feet less in bank part. No. 3 failed, the stream end having washed out when the ice broke up in the spring of '88. The depth of water where it stood is now about 11 feet. Wing No. 3 is 190 feet below No. 2, and the current does not strike the bank between them, although they are on a curve with a radius of 475 feet. One hundred and sixty feet from wing No. 3 the continuous sheeting begins. My opinion is that the better practice would be to cross the current at an angle not to exceed 20°, and continue the wings 20 to 30 feet further, according to circumstances, and the piles should be longer than those used in this case, and be driven lower, so that when the ice breaks up, that with a moderately high water it could flow over the top of the wing. And there should be two piles driven from 8 to 10 feet back of the wings, and two heavy round timber braces placed at the end pile and the third from the end to insure stability, as the weight sustained during an ice gorge is tremendous. I am not aware that any engineer was called on to

plan or locate the work that has been done, but I think that by being properly located, that a wing, not to exceed a cost of eighty dollars, can be made to protect a bank from 200 to 500 feet, according to the curvature of stream where located.

Fifth Annual Report of the Massachusetts Board of Gas and Electric Light Commissioners.

The Fifth Annual Report of the Board of Gas and Electric Light Commissioners has been presented. In the State there are 75 gas companies, 26 of which have the right to supply both gas and electricity, and 100 electric light and power companies. So far the policy of the Legislature, as shown in the various acts for the regulation and control of gas and electric companies, has been fully justified. The work of the Board in executing these laws has been done with a constant regard for the welfare of the communities in which it was called upon to act. It has had, following the policy indicated by the Legislature, great confidence in the wisdom of allowing one company to do all the lighting in smaller cities and towns. When consumers have been shown the powers of the Board to regulate the price and quality of light a general approval of the enactments and of its action has been manifested. The companies are as a whole very ready to correct any fault to which their attention is called by the Board. In executing recent statutes the Board has reluctantly been compelled to refuse new companies the privilege of going into business, but these adverse decisions were felt to be most beneficial to the permanent interests of the city or town. Seven gas companies have been authorized to engage in electric lighting business, and there have been six cases before the Board on appeal from the decisions of the Mayor and Aldermen and Selectmen of as many cities and towns. The various decisions are given at length.

In the past year the property of the Cottage City Gas Company has passed to a new company, but the business has been so interrupted that no report of value could be made. The Citizens Steam and Gas Light Company, of Lynn, gave up making gas early in the year, and its works were destroyed in the late fire. The New Bedford Company has been authorized to supply gas to Fairhaven.

The Board since its last report has continued its investigations on the subject of water gas. It is understood that the parties in interest do not desire to offer further evidence in the cases pending at the close of the year. The Board believes that some modification of the present law is desirable, and that a report of the work of the Commissioners in this branch of their duties ought to be made to the Legislature at the present time. Accordingly a very long and interesting chapter is devoted to water gas. The Board, by personal inspection and correspondence, has heard from more than a hundred companies. So many different items and circumstances enter into the manufacture of gas that it is not easy to exactly determine the relative cost of water and coal gas; but from a wide survey the Board estimates the cost of coal gas in the holder at from 50 to 57 cents per 1,000, and of water gas at from 46 to 55 cents. Various improvements in the manufacture of water gas are noted, and the advantage afforded by its apparatus in the production of gas of the high illuminating power now demanded is alluded to. The larger companies recognize these advantages, and nearly one-third of all the companies in the country now manufacture some water gas. Various benefits resulting from the manufacture of both kinds of gas in the same works are specified.

The question of the comparative safety of water and coal gas is pronounced a very perplexing one to solve satisfactorily. One or more members of the Board have examined personally the premises where deaths have occurred from asphyxiation by inhaling gas. A few of these deaths were caused by coal gas, others probably by a mixed gas, but the larger number were due to water gas. Results of the investigation are given in detail. As near as can be estimated from reports received from various sources there were 107 deaths in the United States, in 1889, from inhaling illuminating gas. There is conclusive evidence that 30 of these persons committed suicide, and there were several others where the circumstances pointed to the same fact. But this leaves 77 deaths caused by the accidental inhaling, 25 happening in places where only water gas is manufactured; 46 occurred in places where mixed gas is made; and 6 in towns using coal gas only. Forty-six of the deaths occurred in hotels, mostly of the cheaper class, lodging and boarding houses, where the rooms were small and poorly ventilated. In 18 of the accidents the gas was blown out by ignorant persons; 8 deaths were caused by gas stoves; 1 by a leaky pipe, and 3 by defective keys where the gas is turned on to the burner. Various statistics bearing on these deaths are given, and the inferences drawn are that about 30 per cent. of the deaths from illuminating gas are

suicides, 20 per cent. are persons more or less intoxicated at the time of the accidents, and a considerable number are persons unacquainted with the use of gas. A comparatively small number of cases are purely accidents that could not have been avoided.

The Board's interpretation of chapter 428 of the acts of 1888, is that it is not permitted to issue a revocable license or one subject to modification, or qualify in any way the certificate they issue "that in their opinion the gas can be used with safety" for illuminating purposes. The danger which appertains to the careless use of any gas is an obstacle in the minds of the Commissioners against granting a license in the form required by the law. The question of the comparative safety of the various kinds of gas and the considerations bearing upon their use are discussed, and suggestions advanced as to the means for securing greater safety. The Board is firmly of the opinion that the certificate as to safety ought to be omitted from the license, and that it should be empowered to place such conditions in the license as will tend to guard the community against accidents. A draft of a bill embodying these ideas is submitted.

The usual elaborate tables are included in the report. These are prepared by the efficient clerk, Mr. Walter S. Allen, and involve a great amount of labor. The average price for coal gas to consumers of 24 companies making more than 30,000,000 feet each is \$1.4495 a thousand. The average for the rest is \$1.987, an average for all of \$1.4935 a thousand. In 1886 the average price was \$1.72, in 1887 it was \$1.66, and in 1888 it was \$1.56, showing a gradual reduction each year. The number of meters in use June 30 was 100,714, representing a capacity of 742,781 lights, an increase of 5699 meters, or 41,930 lights.

The number of public gas lamps continues to diminish in about the same ratio as last year, electric lights taking their places. The coal gas companies lost 999 lights.

The total income of all the companies was \$4,869,342.11. The expenses were \$3,314,337.98, leaving the net income \$1,555,004.13.

The year was an active one for those engaged in the electric lighting business. There were 44 new electric light and power companies, and 4 new companies for the manufacture of gas and electric light incorporated. The Board says there is a demand for a simple and economical means of testing the candle power and quantity of electricity supplied to consumers.

The demand for both gas and electric light is constantly growing, and the advance in electric lighting has been especially noteworthy. The following table shows the number of electric lights of various candle power in use in the State in 1888 and 1889:

	1888.	1889.
16-candle power.....	52,075	80,075
20 " "	1,200	2,800
15 " "	880	880
2,000 " "	5,846	6,978
1,200 " "	2,757	4,206
1,600 " "	110	130
1,500 " "		35
1,800 " "		40
800 " "		140.

Annual Meeting of the Springfield (Mass.) Gas Company.

"Observer" forwards the following regarding the annual meeting of the Springfield (Mass.) Gas Company:

The annual meeting of the Springfield Gas Company was held on the 27th of January, and resulted in some radical changes in the management, the most important of these being the resignation of Mr. J. L. Hallett from all active participation in the direction of the Company's affairs. To say that this will be regretted by the Eastern fraternity is to put it mildly; and, speaking for myself solely in giving utterance to the opinion, I have every reason for believing that a certain clique in the ownership are responsible for having made it so unpleasant for Mr. Hallett that in justice to himself he could no longer retain the place and preserve his self-respect. When the situation is fit for final review I will forward a statement of the case for the judgment of your readers.

To come back to the proceedings, Messrs. J. L. Hallett and W. H. Wesson retired from the Board of Directors, and were succeeded by Edward S. Brewer and James Kirkham. The plan announced some time ago to separate the offices of Treasurer and Superintendent was carried out, and Ira B. Allen was chosen Treasurer, receiving a large majority of the 3,484 shares of stock represented. Joseph L. Hallett, who has held for two years the offices of Treasurer and Superintendent, had sent in his resignation of the latter office to the Board of Directors a week ago. The Directors tabled the resignation, and Mr. Hallett ap-

pealed yesterday to the stockholders. As they took no action to define the duties of Treasurer and Superintendent, Mr. Hallett will persist in his resignation as Superintendent. E. S. Brewer was chosen clerk of the corporation to succeed Ira B. Allen.

As stated in Mr. Hallett's report given below, the trouble in the management of the Springfield Company has been partially due to a misunderstanding between Mr. Hallett and the bookkeeper, Ira B. Allen, who has for some time been ambitious to become Treasurer. After a dispute about the conduct of each regarding the Treasurership, Mr. Hallett discharged Mr. Allen. The Directors questioned Mr. Hallett's right to take such action, and Mr. Allen was taken back at their request. This resulted in Mr. Hallett's resignation as Superintendent and Manager. Mr. Hallett has been with the Company since his return from the war 25 years ago, and has been its Manager for eight years. Below is the report he submitted as Treasurer, Manager and Superintendent of the Company:

The manufacturer feels a sense of pride when, as the time comes around for the semi-annual and annual accounting, the balances are all found on the right side. This is especially true when the business is threatened with loss from competition. There was a time when the gas lighting industry was practically a monopoly and the gas manager independent of criticism. There was no thought of seeking trade; it must come to him, and every foot of service pipe and item of labor was charged to the consumer at a large profit. Nor is it long since a tax was levied on the consumer for the use of that indispensable machine, the meter, of equal benefit to both producer and consumer in determining the amount of the gas bill. Then 3½ cubic feet of 15 candle power gas to the pound of coal was thought creditable, and a shrinkage of 20 per cent. in the annual output was of such little consequence it was not considered worth digging for; 18,000 feet to a bench of retorts was an excellent result. The gas business of 1890 is wholly unlike that of former years. Competition and would-be competitors, cheap oil with improved burners, have stimulated the gas manager to greater activity. The yield of gas from the coal has nearly doubled. Candle power is 25 per cent. better, and the unaccounted-for gas reduced to a minimum, while the price now charged the consumer is less than the product then cost. Instead of 18,000 feet to the bench 50,000 is now obtained. Improvements in the method of making and using gas have placed the gas business on a better footing. In lieu of the old-style closed globe and iron burner with its flickering light, opal, etched and ground shades, with large opening and automatic governing burners, have been substituted, producing a soft and pleasant light. The Lungren and arc high power burners (the latter made in this city) have met the demand for more light, have displaced the electric light in some cities and to a limited extent here.

The encircling of the city with electric wires, cutting out hundreds of gas lamps, means a diminution of millions of feet in the annual output. Nor is it a pleasant thing to see the names of some of our best consumers of years standing dropped from the gas ledger by the inroad of a competing light company, with the only alternative to erect an electric plant or purchase from others a franchise of doubtful profit. Considering the large growth in population and general business prosperity, the effect of competition has not yet been felt. In fact, the records show an increase of over 3,000,000 feet over the previous year. Nor would there be any loss in the annual sales, in my opinion, were the charges for electric lighting put on a paying commercial footing. This is evident from the number of electric companies throughout the country that have sunk their entire capital and sold out for a sum equivalent to their debts, have gone into insolvency, or are doing business at a loss. While we are losing some customers as the electric light system is extended, it is equally true that as the electric light becomes no longer a novelty, and as it is demonstrated that for the same money more light is obtained from gas, with more reliable service, our former patrons return to gas lighting.

During the year special efforts were made to increase the summer consumption by the use of gas stoves. This is a department of the business that admits of large development. Stoves and ranges for domestic and mechanical purposes, and gas engines for power, have reached a state of perfection that, for efficiency and economy, can without hesitation be recommended. Our policy in regard to stoves is, where possible, to sell them at cost rather than to rent, believing that an article that costs something would be more appreciated and have better care than if the property of others. To show what limited knowledge the public has of these appliances, in a canvass made last summer we found those who did not know what a gas stove was. Others were prejudiced, and thought the daily use of gas for cooking would be a ruinous expense. To overcome these objections 275 stoves were given away, and these helped the sale of

as many more. The result was, the skeptical were more than pleased, the old kerosene stoves discarded forever, and statements made by some that, to their surprise, the cost of gas was no greater than it had previously been for oil. The revenue from these gift stoves in one season paid their cost and a profit beside. Seventeen ranges, 48 heating stoves and 506 cook stoves were sent out during the year, making about 1,900 now in use. Thirty-eight per cent. of the output for the months of June, July, August and September, and 10 per cent., or 8,000,000 feet of the whole amount of gas made in the year, can be credited to gas stove account. The people have only to learn the advantages of cooking and heating by gas, and they will readily adopt it in preference to all other fuel. The State Gas Inspector reports that the illuminating power and purity of the gas is better than in any previous year.

The report for the year shows that 7,015 tons of coal have been used, an increase of 230 tons over 1888, while 46,290 gallons of crude oil have been consumed, an increase of 4,678 gallons over the previous year. There were 82,582,000 cubic feet of gas made, an increase of 3,363,000, while there were 758 meters set. There have been 13,043 feet of gas mains laid, against 10,935 the preceding year, while 159 houses have been connected with gas, 19 with steam, and 571 gas stoves and ranges have been disposed of. The city has disused 483 public lamps. The average candle power of the gas has increased to 18.58, from 18.24 in 1888, while the sulphur has been reduced from 9.88 to 9.72, and ammonia from 2.41 to 2.10.

Mr. Hallett continues as follows: I am pleased to report that the make of gas for January, 1890, will approximate the send out of January, 1889, notwithstanding the loss of the public lamps. The earnings have now reached such proportions, I believe the time has arrived when a substantial reduction of not less than 25 cents per 1,000 feet in the price of gas should be made. This is due the consumer, as the use of gas for lighting, fuel and mechanical purposes has become a public necessity. This reduction would still provide for all fixed charges, including 8 per cent. dividends amounting to \$40,000 and leave a handsome margin for the extension of the plant. In 10 years the amount of gas made has doubled. The output was 41,071,000 in 1879, while in 1889 it was 82,582,000 cubic feet. The net profits for 1889 were \$60,224. The earnings in 10 years were \$629,676, including \$32,000 earnings on the steam plant, from which were distributed \$525,500 in dividends. While generous to ourselves the public is entitled to a share of the profits in a reduction in the price of this commodity, and it is wise for you to keep in mind that the rights of the consumers are fully protected as to the matter of the price and quality of the gas, and that if a reduction is not considered, advantage of the provisions of statute authorizing application to the Gas Commissioners for a reduction in prices may be made.

In presenting this report and laying down my charge as Treasurer, not being a candidate for re-election, I wish to submit to you, stockholders, a question, the definite settlement of which will facilitate the work of whoever we may elect as Treasurer. Has the Treasurer the privilege of appointing his own clerks and bookkeeper, the privilege to appoint carrying with it the right of removal? This question has already been raised in your Board of Directors and with what seemed to me a singular unanimity of opinion, they agree that the Treasurer has no such privilege or right. A brief statement of a few facts may serve to set forth the question clearly. On January 10, for what seemed to me imperative reasons, I discharged Ira B. Allen, who had been for many years in our service. The Directors claimed that in such discharge I had exceeded my authority and they requested that he be reinstated. I presented to them a written account of Mr. Allen's conduct, and set forth what I considered the privilege of the Treasurer to choose his own subordinates. Their opinion, however, remained unshaken. In the course of a few days Mr. Allen, in company with one of the Directors, called on me and offered full apology for his conduct, and out of consideration for him, as a personal matter, I received him back in his old place. I took him back not because I thought that in his discharge I had exceeded any authority vested in me as Treasurer, nor because in his discharge I had acted unjustly, for his apology showed the propriety and rightfulness of my action, but I reinstated him because he had been a faithful servant of the Company for many years, and after this unfortunate experience I thought that neither I nor the Company would have any reason to complain of his future.

The really important question (for Mr. Allen happens only to be the cause that brings it to the surface), as to whether the Treasurer has the right to appoint his own clerks, is left wholly undetermined. I quote from my statement to the Directors:

During 25 years, to my certain knowledge, the Directors, as a Board, have never been solicited or counseled in regard to the appointment of any employe of the Company; with the exception of a Superintendent,

and in the case of Elis A. Hallett. To this the records attest. The only by-law bearing on appointments is article 5 which reads, "A President shall be chosen by the Directors who shall preside," etc., "all other officers or agents shall be appointed by the Directors, who shall prescribe their duties and fix their compensation," also, "the Directors shall elect a clerk who shall keep a record of the Board." The word "agents" as here used does not apply to mere clerks and employes; otherwise all laborers at the works could only be employed and discharged by the Directors. The fact that the Treasurer is responsible for all of the moneys received, keeps the accounts and is the party in charge of the finances of the Company, is required to give bonds for the faithful performance of the duties of his office, carries with it, by implication, the right to choose the bookkeepers and clerks who are to handle the money for which he and his bondsmen are liable, and make entries on the books for the accuracy of which he is responsible.

For the best interests of the Company and for the convenience of the Treasurer who may be elected and for our common interests as stockholders this question ought to be decided.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

In our issue for the 13th ult. it was stated that the trouble between the Lockport (N. Y.) Gas Light Company and its employees had been satisfactorily arranged. There are more Lockports than the one in this country, and unfortunately imperfect proof reading caused our item to be credited to the wrong place. As it would not do any particular good now to name the Lockport where the labor trouble did crop out, we will not so identify it. We can, however, in justice to the Lockport (N. Y.) Company, say that its principal employees are the same who have figured on its pay rolls for terms ranging from 15 to 30 years. Oh, no; it was not Lockport, N. Y.

In a letter recently received from an esteemed correspondent, the following tribute to the late Theobald Forstall is paid: "Mr. Forstall was a self-made man; he was fearless and honest. In all the years I have known him I never knew him to do anything to be ashamed of. Not a time server, he knew his duty and performed it. He made many friends and very few foes. Though others might differ with him, yet they recognized his simple sincerity, and were bound to admire him for it. A busy man, yet he always had time to extend to others the courtesies of a gentleman. He imparted information to others very freely, and the student and uninitiated in gas works were never turned away unanswered when seeking information. I feel that a great man has fallen; quiet and unostentatious, he wielded an influence such as few men have. He was prompt, thorough and painstaking—a man of clear foresight and prompt judgment. He was a thorough believer in low prices for gas—\$1 was his mark. He had been ailing for some time, and his trip to Europe last summer did not benefit him. On his return he grew rapidly worse, and we all said that death had marked him for his own. He did not like to have any reference made in his presence to his health. He declined to go south or elsewhere for his physical benefit, preferring to be with his family, to whom he was much attached. He was a kind husband and father, and a true friend. We all miss him greatly. I think the worry and cares of business had something to do with his early breaking down. It gives me great satisfaction to say that his son Alfred, who is in charge of the works of the Chicago Gas Light and Coke Company, is a most estimable young man, well qualified to keep the name of Forstall before the fraternity. I attended the funeral services, which were very simple; the ceremonies were carried out in accordance with the wishes of deceased. He desired that no one mourn for him.—J. S."

SOMETHING over a fortnight ago an explosion occurred in the purifying room of the Ottawa (Ont.) gas works, that caused damage to the amount of \$500.

A MEETING of representative citizens of the borough of Downingtown, Pa., was held a few days ago, the purpose for which the gathering was called being to agitate the availability and good policy of purchasing from the present owners the coal gas and water supply plants, the same to be thereafter operated on borough account. The sentiment of the gathering was strongly inclined to the affirmative of the proposition, and a committee of 5 (Messrs. Jos. H. Johnson, John McGraw, H. B. Sides, S. A. Bicking and D. M. Cox) was appointed to interview Mr. Frank Buck, President of the Company, as to what the proprietors would consider a fair price for the property. The President, who spoke for perhaps 85 per cent. of the stock, replied that the entire capital of the Company (meaning both gas and water divisions of the enterprise)

could be purchased for \$75,000, and that that offer would remain open for 30 days. The citizens, on receiving the report of the committee, enlarged the latter to 15 members, with instructions to have the law examined, to determine whether or not it was in the province of the borough to raise money for such a purpose. The water works franchise of the Company is a valuable one, and the gas works portion of the enterprise would no doubt have been fairly profitable had even ordinary routine business management been devoted to its development.

At the annual meeting of the Peoples Gas Light Company (Manchester, N. H.) the following officers were elected: President, John B. Varick; Vice President, Frank Dowst; Treasurer, W. L. Elkins, Jr.; Supt., Walter G. Africa; Directors, W. L. Elkins, Jas. F. Briggs, John B. Varick, Frank Dowst, Alonzo Elliott, Jas. A. Weston and W. L. Elkins, Jr.

THE Aurora (Ills.) Gas Company has been greatly enlarged and improved the past season. Over 7 miles of mains were put down, and plans for an extension similar to that of 1889 are being prepared for 1890. Mr. Copley says that the Company proposes to keep its pipe lines ahead of the times instead of behind them. This probably means that the mains are to be extended to what is known as the Downer Place Addition. The moneys expended on betterments in 1889 must certainly foot up \$40,000.

THE Newport (R. I.) Gas Light Company will soon be in readiness to start up its auxiliary water gas plant. And this reminds us that if the annual meeting of the shareholders had to be postponed because of *la grippe*, the latter demon seems to have been unable to "hold down" the engineering and executive management. In any event, the reports of work accomplished for the last six months of 1889 show that over 4 per cent. had been earned on the capital stock, which rate of dividend was declared when the annual meeting was finally brought off.

THE Westinghouse Machine Company, of Pittsburgh, has received an order through its agency at Copenhagen, Denmark, for one of its famous automatic compound engines. The size selected is 14 and 24 by 14, and it will be set up at Kopparberg's Bergslaget, at Falur, near Stockholm, Sweden. Large numbers of these engines are now being shipped to foreign countries.

At the annual meeting of the Belfast (Me.) Gas Company the following officers were elected: President, W. B. Swan; Clerk and Treasurer, John H. Quimby; Supt., A. K. Pierce; Directors, W. B. Swan, N. F. Houston, A. A. Howes, Chas. R. Hazeltine and John H. Quimby.

THE Fremont (O.) Electric Light and Power Company and the Fremont Gas, Steam and Plumbing Company have been consolidated. Mr. W. H. Ford has been chosen Secretary of the consolidated enterprise. Important plant improvements—both on the gas and electric light divisions—will be carried out forthwith. Mr. Fred. Fabing, former Superintendent of the gas works, will carry on the plumbing business in Fremont. We wish him the best of good fortune in this venture.

At the annual meeting of the East Boston (Mass.) Gas Company the following Directors were chosen: Stephen H. Whidden, Thomas J. Whidden, William R. Sturtevant, John Thompson and Geo. L. Thorn-dike. The resignation of the Company's former Treasurer, Mr. Frederick Pease, was received and accepted.

THE Altoona (Pa.) Gas Company has made a demand on the authorities for damages in the sum of \$177.80, for injuries occasioned the gas mains because of the falling in of the walls of the sewer drain now being laid through Ninth street, between Eighth and Eleventh avenues.

WE are in receipt of a couple of blotter calendars from the Kerr Murray Company, which we presume is the first issue of a series that shall be continued for the year. The calendar is for the current 30 days. It is a good idea.

WE are also in receipt of a very handsome annual calendar, published at the instance of Nathaniel Tufts, of Boston, Mass. It is a beautiful specimen of the engraver's art and the printer's skill. The etching on supporting sheet shows a typical mid-winter scene in New England—that is, it would be typical of the scene that should exist now, but which does not. The etching, however, has yet two chances of becoming emblematic of the winter season—the current month and December next.

THE Philadelphia *Inquirer*, of January 24th, said: "Financial circles found a choice morsel of gossip yesterday in the rumor that there had been consummated the sale of a controlling interest in the United

Gas Improvement Company to a syndicate of English capitalists. To understand what such a sale means to the money market, it is necessary to know that the capital stock of the Company is \$5,000,000, and that its gas plant possessions throughout the United States are almost of inestimable value. Practically it is a trust that seeks control of the gas interests of the country. The plants of city after city have been purchased, and many important patents in the gas manufacturing industry are owned by it. Based upon the knowledge that negotiations were pending for the purchase outright, or of a controlling interest in the Company, unknown investors have been buying all the stock of the Company coming out on the market. Within the past few days there has been a large increase in the market quotations of the stock. Its par value is \$50, and yesterday 100 shares were eagerly bought in at 80, and 14 shares at 81 just as readily found a purchaser. This is against its closing price of 72½ in the early part of the month. The terms of the rumored syndicate purchase are shrouded in mystery; in fact, every effort is being made by those in interest to keep the matter strictly secret, but the shrewdest financiers give greatest credence to the most conservative statement of the hour, which is that \$100 per share was offered for a controlling interest in the stock. A prominent officer and large stockholder of the Company, who asked that he be quoted anonymously, said last night: "I will not deny that there have been negotiations with a number of English gentlemen who propose forming a syndicate and putting their capital in our Company, but nothing definite has been arrived at yet. I am not at liberty either to state the names of those who will compose the syndicate or of the terms of the negotiations. Everything in life is so uncertain that it is hard to say when any proposition will be consummated. I can say, though, that none of the negotiations so far considered contemplate a change in the methods of the Company or of officers. The way I account for the sudden rise in the stock is that its intrinsic value has met greater appreciation in the eyes of financiers. Not at any time during the past year, though I am a large holder, would I have accepted \$100 per share for my stock. For a long time we have been looking for capital. We could use it advantageously; but I think the terms for a controlling interest would have to be more seductive than any sensible financier would offer. There is no desire to sell such an interest; we consider the works too valuable for that. I do not think the recent increase in stock at all artificial."

WE gather, from an independent source, and one quite likely to know something of what is going on in the above respect, that the Company has been successful in securing a long loan (at low interest rates) of considerable magnitude, the money to be used in increasing the number of leaseholds, or actual purchase of plants, to be operated by the Company.

MR. ROBERT F. MULLINS, lessee of the Fishkill and Matteawan (N. Y.) Gas Company, is endeavoring to secure a contract for the public lighting by gas of these villages. As an inducement he offers to supply gas to the lamps at a concession of 25 cents per thousand cubic feet from that now charged as the lowest net rate to ordinary consumers.

MR. MULLINS' proposition recalls to mind the fact that Superintendent W. H. Hayden has made many changes at Fishkill in the plant conditions respecting the gas supply. Hayden does not believe in manufacturing gas simply for the purpose of permitting an abnormally large percentage of the product to wander at its ill smelling will through the soil that covers the mains.(?)

At the annual meeting of the Charlestown (Mass.) Gas Company the officers chosen were: President, J. F. Hunnewell; Clerk and Treasurer, G. B. Neal; Directors, J. F. Hunnewell, W. W. Wheildon, P. J. Stone, J. A. Sawtell, L. B. Hathan, C. F. F. Byam and C. R. Lawrence.

WE understand that an explosion that occurred on the works of the Sioux City (Ia.) Gas Light Company, on the night of Jan. 21, destroyed apparatus valued at \$10,000.

THE electric light plant at Cleburne (Texas) has passed out of the receivers' hands, the property and franchises having been purchased by Max Elser, of Fort Worth and W. H. Gaston, of Dallas.

At the annual meeting of the Warsaw (N. Y.) Gas Company the officers chosen were: President, S. D. Lewis; Vice-President, Augustus Frank; Secretary, J. B. Gates; Treasurer, B. F. Fargo; Directors, T. G. Hulett and L. W. Pettibone, of Niagara Falls, and S. D. Lewis, Augustus Frank, L. W. Thayer, Wm. Bristol, E. E. Forman, L. H. Humphrey and J. B. Gates, of Warsaw.

THE following leaves from the history of the Providence (R. I.) Gas Company will be read with interest :

Year.	Annual Output, Cu. Ft.	Year.	Annual Output, Cu. Ft.
*1849.....	6,178,000	1860.....	58,143,000
1865.....	75,626,000	1870.....	132,310,000
1875.....	258,039,000	1880.....	280,833,400
1881.....	305,780,600	1882.....	310,026,500
1883.....	329,622,000	1884.....	344,773,000
1885.....	354,000,000	1886.....	361,149,000
1887.....	383,096,000	1888.....	429,720,000
1889.....	450,000,000		

The Company has a main mileage of 161, and 12,700 meters are in position. The unaccounted-for gas is returned for '89 at 8.7 per cent. The Company is notable in Providence financial history from the great number of shareholders, a statement of which is here given to prove the faith of the residents in the stability of the enterprise: There are in all 938 shareholders, among which the 50,000 shares are distributed. Of these 323 are men, holding 19,236 shares, 453 are women, holding 17,283 shares, 73 are trustees, holding 690 shares, 13 are guardians, holding 215 shares for their wards, and 41 are administrators and executors, holding 220 shares. Besides these 30 institutions have 4,124 shares. Three stockholders have 1,000 shares or over, 9 have from 500 to 1,000 shares, 123 have from 100 to 500 shares, 110 have from 50 to 100 shares, and 693 have less than 50 shares. There are 46,188 shares held by 833 shareholders in Rhode Island, and 3,812 shares are held by persons outside of the State. These latter can be traced to Massachusetts, New York, Connecticut, Maine, New Jersey, Vermont, California, Illinois, Ohio, New Hampshire, Pennsylvania and Virginia.

MR. A. B. RICHARDSON, of the Dover (Del.) Gas Company, writing under date of Jan. 22, on the subject of the Toraya process of gas making which is soon to be tried on a fairly large working scale at one of the branches of the Philadelphia municipal gas works, says: "The new Toraya process of making gas appears to be very similar to a process used here in Dover in 1862. The gas works in this town were built just before the war to manufacture gas from rosin, and during the war rosin went up to \$60 per barrel. Then the following process was resorted to: Yellow pine wood was cut up into small blocks and soaked in oil until the wood was completely saturated. The blocks were then put into a charger, and the charger put into the retorts (of which there were six) and kept until all the gas was taken from the wood, which left the blocks transformed into very nice charcoal. The gas was then passed from the retorts to a scrubber filled with shavings, thence to a purifier filled with lime, thence to gasholder and street mains. As to the quality of the gas. If the blocks had taken up just the right quantity of oil the gas would be good; if not enough oil had been absorbed it would be poor; if too much oil it would smoke. In fact the ceilings in all the houses that burned the gas were well smoked, and, furthermore, the oil condensed in the pipes and fixtures, so that when the key was opened to light the gas the oil would come out in a spray before the gas would ignite. If the key was opened to light a burner that had not been used for 10 days, the gas would be so poor that it would not light until the freshly-made gas came to the burner. The consumers finally became so disgusted that they quit using the gas, consequently the works were shut down for a year. Then the firm of Richardson & Robbins bought the works and eventually fitted them up for making coal gas. The meters were worthless, the pyroigneous acid having destroyed all the diaphragms. Perhaps the Toraya Gas Company has overcome the difficulties."

AT the annual meeting of the Davenport (Ia.) Gas Company the following result was reached: President, J. J. Richardson; Secretary and Treasurer, Ross Woodmansee; Directors, G. H. Pendleton, O. T. Gaylord, R. Woodmansee, W. C. Putnam and J. J. Richardson.

MR. J. H. FARISH, Secretary and Treasurer of the St. Joseph (Mo.) Gas and Manufacturing Company writes: "It might interest the gas fraternity to know that our fuel gas schemers are not all dead. A few days ago Mr. W. S. Crosby, of Chicago, the chief promoter of the enterprise, despairing of the resurrection of his first bill, prepared another—a twin brother of its predecessor, except that it called for a deposit of \$15,000, to be made by him, and to be held by the City Comptroller, until the sum of \$50,000 should have been expended by him, the said Crosby, in the erection of a fuel gas plant, when the deposit should be returned to him. At the same meeting of the City Council another water gas bill was introduced by one Charles McGuire, an obscure resi-

dent of this city, and undoubtedly a 'man of straw.' In his bill, Mr. McGuire, as a bait to our Councilmen, proposes to furnish what *light* and *heat* the city may wish in all of its public buildings, for *nothing*. It seems hard for a legitimate enterprise to live when so many people are willing to do business for nothing. However, both ordinances have been referred to a special committee of five, by whom the matter will soon be investigated."

THE authorities of St. Joseph would seem to be easily gulled were they to swallow the bait offered by either Crosby or McGuire; for certainly neither proposition contains anything likely to be of material benefit to the city. Should Crosby be successful he gets his \$15,000 back. Quite likely he would expect to receive interest on it—and as for McGuire—well! when his employers had been successful in blackmailing the present St. Joseph Company, the latter could of course elect to work under its old charter. In the event of the McGuire coterie being obliged to buy out the old company, they would undoubtedly elect to work under the old company charter, wherefore the city would not be a gainer in either event. The rulers of St. Joseph might better encourage and protect the old company, whose course towards the public has always been of the liberal order.

IN proof of this latter claim we beg to submit the following evidence, which comes to us in the shape of an official announcement from Secretary Farish. The concession took effect on the first inst., and its terms, as explained by Mr. Farish are: "Conforming to our usual custom of reducing the price of gas from time to time as our increasing consumption would justify, we have reduced the price of gas to \$1.50 per 1,000 cubic feet to all customers using from 1,000 to 100,000 cubic feet monthly. Quantities in excess of this are to be supplied at \$1.37½, and gas used for fuel or power purposes is to be sold at \$1.25."

WE think our readers will agree with us that these are cheap rates. Further, the article of gas that the St. Joseph Company distributes—when used for fuel purposes—at the rate of \$1.25 per 1,000 will be found at least twice as effective as the article which Crosby *proposes* to distribute at a slightly lower rate. We would also like to add in conclusion, that the Company's ability to supply gas at these rates is a striking testimonial to the ability of its engineer—Mr. K. M. Mitchell.

A LINE from Mr. John Lorenz, Supt. of the Johnstown and Gloversville (N. Y.) Gas Company, informs us that oil of a good quality has been struck in a well that was being drilled for gas about one mile south of Johnstown. Naturally, great excitement prevails in the district over the discovery; but as yet nothing definite has been learned as to the yield, work on the well-hole having been temporarily suspended.

MR. H. A. NORTON, No. 4 Central street, Boston, Mass., succeeds Messrs. Sprague & Sons as agents for the fireclay goods from the works of James Gardner, Jr., Lockport Station, Pa. The Messrs. Sprague resigned the agency because of the pressure of other business. We congratulate Mr. Gardner on his good fortune in securing so capable a successor to the Messrs. Sprague—who are, as they ought to be, in high favor with the Eastern fraternity—since Mr. Norton is the worthy son of his father—Nashua's Honorable gas man.

AT the annual meeting of the Wallingford (Conn.) Gas Company the following officers were elected: President and Treasurer, Col. W. G. Leavenworth; Secretary, Judge L. M. Hubbard; Directors, L. M. Hubbard, W. S. Leavenworth, G. W. Hull, B. A. Treat and Mrs. W. C. McClellan.

AT the annual meeting of the Van Wert (Ohio) Gas Light Company the following officers were elected: President, A. C. Glenn; Vice-President, D. Shepard; Secretary and Superintendent, J. M. Tryon; Treasurer, G. C. Glenn. It was decided to increase the capital stock to \$37,500 from \$25,000. The business of the Company is increasing steadily, and the outlook for the year is of the most encouraging sort.

THE meter manufacturing firm of Bell & Jones will erect the new 14 ft. by 14 ft. station meter for the Philadelphia municipal gas works station at Point Breeze. The contract was awarded on Jan. 28th.

"SOME of the residents of Chelsea, Mass., are preparing a petition for the consideration of the State Board of Gas and Electric Light Commissioners in which it is sought to secure a cheaper gas rate for the city. There is evidently some malice behind this movement that can probably be traced to those not widely separated from others connected with the project for establishing a fuel gas plant in Chelsea.—HADDAM."

At the annual meeting of the Newport (R. I.) Gas Light Company, Mr. Henry Bull was re-elected President, Mr. Thomas A. Lawton was chosen Treasurer, and Mr. Andrew K. Quinn was named as Secretary. The Directors are Messrs. Henry Bull, Jas. C. Swan, Thos. A. Lawton, Philip Rider, Robt. S. Case, W. H. Fludder and A. K. Quinn. The latter takes the place of the late Mr. John A. C. Stacy.

The Cambridge (Mass.) Gas Light Company has reduced its net selling rate to \$1.60 per 1,000 cubic feet.

NEW YORK and Rochester capitalists hold an option to purchase the Batavia (N. Y.) gas works, the option to last until February 20th. It is likely that a sale will result.

ACCORDING to the minutes of a recent session of the Committee on Lamps of the Boston Board of Aldermen, several residents on Commonwealth avenue have petitioned for the restoration of gas lamps on that avenue. Messrs. C. P. Curtis, C. Woodburn and E. I. Brown appeared before the Committee and asserted that the electric lights were of but little use, particularly in the summer time, as the shade trees in the park prevented the light from extending to the sidewalks. They *wanted the gas lights restored*, but did not want the electric lights to be removed. The petition was taken under advisement.

At the annual meeting of the Manchester (N. H.) Gas Light Company the following officers were chosen: President, Hon. Moody Currier; Clerk, Lucien B. Clough; Treasurer, Walter M. Parker; Directors, Hons. Moody Currier, Nathan Parker, Daniel Clark, G. Byron Chandler and Mr. Chas. Warren.

PETER J. KLINGES has brought suit in the Philadelphia Court of Common Pleas (No. 3) on behalf of Henry Sauer, who asks for \$5,000 damages for injuries occasioned by an explosion of gas on December 28, 1889. Complainant had for five years been a tenant of the premises 2313 East Thompson street, where he carried on the business of a baker. He claims that owing to the wearing out, by oxidation, of the service pipes from the gas main, gas escaped and accumulated in the vault under the house in such volume that an explosion occurred. Sauer was severely burned, and he further asserts that his business was ruined because his house was so badly damaged that he was compelled to remove.

PATRICK HOYT, a well-known character in the employ of the Citizens Gas Light Company, of Newark, N. J., died about a fortnight ago. He was known among his fellows as "the gas house poet."

THE annual meeting of the stockholders of the Brookline (Mass.) Gas Light Company was held at the office of the Company in Brookline, on Wednesday, January 22, President Robert Amory in the chair. The report of the Clerk and Treasurer, Francis W. Lawrence, was a very satisfactory one. President Amory, in presenting the Directors' report, stated that the loss by leakage had been reduced to 10.95 per cent., although the number of consumers per mile of main has not correspondingly increased. The taxes are a little more than the salaries of the Company's executive officers. The profits of the Company from electric street lights were barely 4 per cent. last year on the cost of installation. There is every reason to believe that the cost of a municipal plant to the taxpayers would be very much larger than it is to a private corporation of a Gas and Electric Light Company combined under one management, and with this understanding of the case, the Directors had agreed to furnish electric lights for Brighton at 40 cents per night for 5 years. This will yield small profit, but will obviate the necessity of enlarging the Company's gas plant, the demands upon which are now almost up to the limit. President Amory reported the sale of the stock of the Suburban Light and Power Company to a Roxbury syndicate. The following named Directors were chosen by a vote of 3,354 shares each, the entire number thrown: Robert Amory, Wm. H. Hill, Francis W. Lawrence (Clerk and Treasurer), F. H. Odiorne, McPherson Lemoyne. Organization was effected with the unanimous choice of Mr. Amory as President.

Recent Patent Issues.

The following list of recent patents relating to the gas interests is specially reported by Franklin H. Hough, solicitor of American and foreign patents, 925 F street, N. W., Washington, D. C.

ISSUE OF JANUARY 7, 1890.

- 419,098. Gas, Apparatus for Making Oil. T. and S. Alexander and R. Patterson, Kirkintilloch, Scotland.
418,807. Gas Blow Pipe. D. M. Monroe, Baltimore, Md.
418,846. Gas Burner for Stoves. J. H. Keyser, New York, N. Y.
418,821. Gas Engine. J. D. Smith, Philadelphia, Pa.
418,711. Gas, Manufacture of. W. Rogers, Pittsburg, Pa.

ISSUE OF JANUARY 14, 1890.

- 419,183. Gas Burner. G. K. Cooke, Jamaica, N. Y.
419,444. Gas Fuel Burner. C. L. Holden, Indianapolis, Ind.
419,350. Gas Washing Apparatus. M. A. Piedra, Schriever, La.

ISSUE OF JANUARY 21, 1890.

- 419,845. Gas and Liquid Holder. J. Flannery, New York, N. Y.
419,651. Gas Burner. W. F. Folmer, New York, N. Y.
419,652. Gas Burner. W. F. Folmer, New York, N. Y.
419,784. Gas Burner. W. S. Mead, New York, N. Y.
419,806. Gas Engine. C. W. Weiss, Brooklyn, N. Y.

ISSUE OF JANUARY 28, 1890.

- 420,193. Gas and Liquid Holder. J. Flannery, New York, N. Y.
420,169. Gas Engines, Gas Regulator and Equalizer for. W. C. Rossney, Cambridge, Mass.
420,241. Gas Motor or Engine. P. J. McMahon.
420,412. Gas Regulator. J. H. Lehman, Philadelphia, Pa.

Correspondence

[The JOURNAL is not responsible for the opinions expressed by correspondents.]

The Lighting Situation at Fort Scott, Kas.

FORT SCOTT CITY GAS COMPANY,
FORT SCOTT, Kas., January 27th, 1890. }

To the Editor AMERICAN GAS LIGHT JOURNAL:

A word about the present condition of the lighting interests in Fort Scott, Kas.

Having seen nothing in the JOURNAL in regard to the present *raid* upon the lighting industries of the city, I think it may interest the JOURNAL readers, and the gas fraternity generally, to learn what is going on in this portion of Kansas. The total failure to develop and distribute natural gas at this place three years ago left the parties badly stranded, and several later attempts to form combinations by which the old natural gas pipe lines were to be made use of for an opposition illuminating company all resulted in failure, until last summer, when, in the throes and agony of despair, the parties visited New York and picked up one W. H. Frost, at the time in the employ of the "Consolidated Gas Company," and induced him to put his money, or that of others, into a scheme with the idea of wiping out, at one fell stroke, all of the legitimately invested gas and electric light interests in this city.

A reorganization of the old Company was effected by electing Mr. Frost President and General Manager, and Messrs. Geo. G. Porter and C. W. Isbell, of the Smith & Sayre Mfg. Company, New York, named in the Directory, together with others here, who had been hurt in the failure of the natural gas scheme.

Work was commenced on an expensive "coal gas plant," and *flaming advertisements* inserted in the daily papers that gas would be furnished for both *heating* and *lighting* purposes at 50 cents per 1,000 cubic feet, and that it would be as cheap as coal *for fuel*.

Gas was to be furnished by the 1st of January, 1890, and the city was thoroughly canvassed for consumers. Service pipes and meter connections were to be put in free of charge, and people were led to believe that they were to have this gas for fuel as cheap or cheaper than coal. Their building is still incomplete, but work is progressing on it, and I presume that in a few months they will be ready for business.

It is possible that Eastern capital may find it very profitable to invest in opposition gas companies in Kansas for the purpose of selling gas at 50 cents per 1,000 cubic feet, but the average gas manager will be pleased to learn by what method it can be accomplished. If it has ever been demonstrated in the East that such a thing can be done, why does not New York keep her *educated experts* at home, building gas works and selling cheap gas? This question we would be pleased to see answered.

The Fort Scott City Gas Company, that has supplied the town with gas for over 20 years, extending its works from time to time to meet the wants of the people, laid out in 1887 and 1888 \$30,000 for improvements and extensions, and owns as complete a manufacturing and distributing system as can be found in any city of the size of Fort Scott, either East or West. To sum up, it has a capacity of over 200,000 feet per day, and nearly 15 miles of substantial cast iron mains, the price for gas ranging from \$1.25 to \$2 per 1,000.

The electric light plant established over 4 years ago with a capital invested said to be nearly \$100,000, is furnishing incandescence lights at from 25 to 75 cents each per month, against which the old Gas Company has thus far held its own.

The fact of two Gas Companies and one arc and incandescence electric light plant engaged in a triangular fight, in a city of the size of Fort Scott, does not look promising for large dividends in the near future. The old Companies, backed by home capital, will maintain their position at all hazard, and somebody will suffer.

L. K. SCOFIELD, President Ft. Scott City Gas Co.

The Market for Gas Securities.

Consolidated sold up to 97 $\frac{1}{2}$ during the week, but rather free offerings towards the close drove the sale back to 96 $\frac{1}{2}$, at which figure opening sales were made to-day (Friday, January 31). On Wednesday Muller sold at auction 33 shares Consolidated at 97 $\frac{3}{8}$. Equitable is steady at 119 to 122, and Mutual is at 107 $\frac{1}{2}$ bid. Brooklyn shares are inclined to higher prices, old Brooklyn being quoted at 108 to 110, while there is every likelihood that it will soon score a still further advance. Metropolitan is at 93 to 96, and Peoples is bid for at 77. In out of town shares we note that Cincinnati gas is at 201 $\frac{1}{2}$ bid. Baltimore Consolidated lost some of the recent advance, having sold during the week at 52 $\frac{3}{4}$. There is no good reason, however, for the slump. A block of 841 shares Jersey City gas was disposed of at auction this week, at 186. It seems to us the stock is cheap at that figure.

Rumor is very busy with the intentions of those in control of the United Gas Improvement Company, shares in which are advancing rapidly. The Company proposes, as we understand it, to largely increase its operations, and in furtherance of this proposition we believe it has been determined to increase the capital stock from five to ten millions of dollars.

Bay State gas is at 23 to 25, and Laclede Common is offered at 17. Chicago Trust shares are quoted at 47 $\frac{3}{8}$ bid. The reports submitted by 21 Eastern Companies at the annual meetings of the shareholders show net average earnings on the capital stocks represented of 9.4 per cent.

Gas Stocks.

POSITION WANTED.

A Mechanical Engineer,

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal,
 765-1f or Box 972, West Bay City, Mich

Position Desired

By a man of practical experience in TESTING, SETTING, and REPAIRING METERS, STOVE WORK, COMPLAINTS, LAYING OF MAINS, SERVICES, ETC. Could manage a works of 20 millions. References A1.

766-2 "J. J. D.," care this Journal.

Position Wanted

As Superintendent or Assistant of a Gas Works,

By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address

765-5 "M.," care this Journal.

Position Wanted

As Superintendent or Assistant,

Or Inspector of Meters, and all outside and inside work. Has had many years' experience; ten years in last employ. Best of references. Address

764-1 "W. A.," care this Journal.

FOR SALE.

**A Complete Water Gas Plant.
 60,000 Cu. Ft. Daily Capacity.**

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

FOR SALE,

One 5-ft. Station Meter.
 One Hydranlic Main (five sections), wrought iron, 22 by 24, with Bye-Pass on Dip-Pipes.

25 Valves, Stand-Pipes, 7-inch Mouthpieces and Lids, all complete, ready for use, to fit up five benches of 5's.

This apparatus is all in first-class condition.
 Price, \$800, f.o.b. cars or boat, Poughkeepsie, N. Y.

Inquiries may be sent to this Office.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL
Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

C. & W. WALKER'S PAT. PURIFYING MACHINE.

TAKING ALL THE WORK FROM THE OUTLET OF THE CONDENSER TO THE INLET OF THE PURIFIERS.

Patented in Great Britain and Ireland, Australia, France Germany, Italy, and the United States.

These Four Machines Purify 12 Millions per Day, and only occupy a Ground Space of 60 ft. by 12 ft., and are 23 ft. 6 in. High.

Four of these powerful Machines for the new extensions at the Beckton Gas Works, London, are now working, purifying Twelve Million Cubic Feet of Gas per day, each Machine taking Three Millions per day.

These Machines can be seen at Beckton, where, after being long and abundantly tried, tested, and proved in every variety of working, have been accepted by the Gas Light and Coke Company, of London, as superior to all other apparatus for taking all the work of the purification of gas between the Condensers and the Purifiers.

The Machine is the most important improvement effected in gas works for years past. The purifying power developed is most remarkable. We send an Engineer with a working model to any Gas Company inviting information. It is equally adapted to gas works of any size.

DESCRIPTION.

The gas enters into the washing chamber at the lowermost part, where it is first subjected to a thorough washing in the strong Ammoniacal Liquor. The washing is most effective. The entire surface of the Ammoniacal Liquor is in a bubbling state of ebullition, presenting an

agitated, frothy surface all over. All the Tar left in the gas after surface condensation is here completely extracted, and a large amount of Carbonic Acid.

The gas, thus so far purified, ascends from the washing chamber and passes from one superposed chamber to another in contact with the enormous amount of movable, constantly dipping wetted surfaces, leaving the uppermost chamber entirely purified from Ammonia, meeting the chemical requirements of the Board of Trade.

The Machine is self-cleansing, and can never choke or stop up; and in this important respect it is superior to all Machines heretofore known. The space occupied by the Machine is very small. In most cases it can be placed in the space inside the end of the Purifying House. Its cost is less than any other known apparatus for purifying gas from Tar and Ammonia.

These Machines are at work and in hand for Widnes, Burnley, and Oswaldtwistle, in Lancashire; at Harrogate and Wakefield, in Yorkshire; at Stalybridge, in Cheshire; at Stone, in Staffordshire; also at Cheltenham and Northampton, also at Melbourne, in Australia.

Apply, until American Agency is appointed, to

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3 ft. square,	5 ft. deep.
No. 2,	" "	125,000	" " "	4 " " "	" "
No. 3,	" "	250,000	" " "	5 " " "	" "
No. 4,	" "	500,000	" " "	6 " " "	" "
No. 5,	" "	750,000	" " "	7 " " "	" "
No. 6,	" "	1,000,000	" " "	8 " " "	" "
No. 7,	" "	1,250,000	" " "	9 " " "	" "
No. 8,	" "	1,500,000	" " "	10 " " "	" "
No. 9,	" "	2,000,000	" " "	12 " " "	" "
No. 10,	" "	3,000,000	" " "	15 " " "	" "

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

PROPRIETORS OF THE

OAKHILL GAS RETORT & FIRE BRICK W'KS

Our immense establishment is now employed almost entirely in
the manufacture of materials for

GAS COMPANIES.

We have studied and perfected three important points. Our re-
torts are made to stand changes of temperature, the strongest
heats of the furnace, and the abrasion of feeding and emptying.

We furnish and build Half-Depth or Full
REGENERATOR FURNACES
of different kinds and most approved styles.

Correspondence solicited.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
37 in. high. 20 in. wide.	12 in. high. 17 1/2 in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	36 in.

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
31 in. high. 17 in. wide.	9 1/2 in. high. 14 1/2 in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 16 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6 1/2 inches diameter, 4 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. 1/2 in. supply pipe should be used where the pressure is 1 in. or over.

[OFFICIAL NOTICE.]

New England Association of Gas Engineers.

SECRETARY'S OFFICE, BIRMINGHAM, CONN., Jan. 30, 1890.

The Twentieth Annual Meeting of the New England Association of Gas Engineers will be held at Young's Hotel, Boston, on Wednesday and Thursday, Feb. 19th and 20th. The meeting will be called to order by the President, Mr. Robert B. Taber, on the 19th inst., at 10 o'clock A.M. It can now be definitely stated that the following papers will be read sometime during the meeting:

- "Vaporization and Feed of Oil to Generator or Retort," by Dr. Robt. Amory, of Brookline, Mass.
- "Management of Small Gas and Electric Light Plant," by S. J. Fowler, of Westfield, Mass.
- "A Point or Two in Regard to Illuminants During Condensation and Purification," by George F. Goodno, of Dedham, Mass.
- "Notes on Revivification of Oxide," by Waldo A. Learned, of Newton, Mass.
- "Various Methods of Introducing Gas Stoves," by H. A. Norton, of Boston, Mass.

"A Few of the Advantages of Water Gas over Coal Gas for Small Works," by F. H. Parker, of Burlington, Vt.

"The Difference between Eastern and Western Methods in the Management of Gas Works," by E. G. Pratt, of Des Moines, Iowa.

"Why I Shall Make Water Gas," by A. B. Slater, of Providence, R. I.

"A Chapter of Don'ts," by W. H. Snow, of Holyoke, Mass.

"Some Notes Taken in a Small Gas Works," by Ralph Woodward, of Waltham, Mass.

"Problems Constantly before the Gas Manager," by E. H. Yorke, of Brockton, Mass.

In addition to the above there are partially promised several other papers. I think all the members who see this notice will agree that, judging by the above list, the coming meeting bids fair to be a greater success than any of the meetings which have been held in previous years. The topics are quite varied, and many of the subjects are among the most important that gas managers have to deal with at the present time.

The officers of the Association believe that no member of the Association, and no one connected with the active business management of any gas company in New England, can afford to be absent from this meeting. Persons eligible for membership and desiring to join the Association will please apply at once to the Secretary, who will forward them blank applications. Although the membership is large, there are still a good many persons connected with the gas business through New England who do not belong to the Association. It is hoped that all such persons will see fit to join at the coming meeting, and make the Association what it ought to be, truly representative of the gas interest in the New England States.

Invitations have been received to visit the Commercial Point and Bay State gas works in Boston, also the Loomis Fuel Gas plant at Waltham, which will add materially to the pleasure of the coming meeting.

CHARLES H. NETTLETON, Sec'y.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., January 20, 1890.

To Members of the Ohio Gas Light Association:

Gentlemen—The Sixth Annual Meeting of this Association will be held at Toledo, O., on March 19 and 20, 1890.

This announcement is made thus early in order that all members may be reminded of the meeting in ample time to make their arrangements to be present. Every member is urged not only to attend this meeting, but also to interest himself in inducing others of his acquaintance who are eligible for membership, but who have not as yet joined the Association, to come to the meeting and become members.

It is not intended that as many papers as usual shall be presented at the forthcoming meeting, in order that more time than formerly may be had for the discussion of those that are read, and for such other matters and business as the members may desire to dwell upon.

Although the Secretary has for some time been engaged in the work

of soliciting papers for this meeting, he has not yet secured as many as should be had, notwithstanding fewer are desired than heretofore, and he therefore earnestly calls upon all members who can possibly do so to notify him immediately of their willingness to furnish papers.

It has been decided that an interesting and valuable feature of our meeting would be a "Question Box," in which members can place questions, which will be withdrawn and read to the meeting and answered and discussed by the members. Every member is requested to send to the Secretary at once any question or questions which he would like to have thus brought before the meeting.

Future circulars will announce further details concerning the meeting.

Respectfully, IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

THE NEW ENGLAND'S TWENTIETH ANNUAL.—In less than a fortnight the members of the New England Association shall have completed their twentieth annual reunion, and he might securely look for pardon who would exclaim that it did not seem as if 20 years had winged their flight from us into the silence of the past since the formation of the Association. Time, however, with even tread and careless of opinion, goes on untiringly. Take it all-in-all, the Association has much to congratulate itself in that time has dealt sparingly with its membership. Of course, it is said, and wisely, that exceptions serve to best prove a rule, and the assertion that time has dealt sparingly with the "Mother Association" can be proved by the record, even though the last exception is furnished in the death last month of Oliver Edwards Cushing, who served on the Board of Directors chosen at the first meeting in Boston, on Feb. 2, 1871. Changes there have been, and many, of course—Greenough, Sr., Hill, of Concord, Armington and Cabot relieved of active service; Cushing and Dwight dead—in fact of the first executives chosen those who still remain in harness are Neal, York and Moore, of Salem. Sturdy and strong and staunch as were the habits and morals of those who founded it, so has the Association progressed with the increase in its years of life and usefulness; and if we may judge from the matter which its Secretary, Mr. Nettleton, has been placing before our readers in the shape of current official notices it is bound to even make better history for itself than that in record of the past. A glance over the paper list will likely cause every member to make successful effort to be present when President Taber sounds the call to order, in order that its promise may be fully availed of. Many of the papers are to be by contributors who have not yet figured on the paper lists, and this of itself is convincing proof of the solidity of the Association. When each is willing to do his duty, the advancement of the common good is assured. In looking over the schedule one cannot but be impressed with the variety of subjects named, and the exceeding value to the fraternity that will arise from their presentation. Two papers in particular we look forward to with great interest, and while it may be as rash to attempt to justify a paper by its title as we are told it is to judge a book by its cover, we nevertheless hold that the contributions to be made by Mr. Goodno, of Dedham, and Mr. Pratt, of Des Moines, have been artfully named, that is, in respect to the facility of their titles for giving rise to anticipation. Aside from the regular list so far collated, it will be noted that Secretary Nettleton has the partial promise of other papers, but even should these fail to materialize the catalogue is sufficiently lengthy to insure plenty of thought food. We would urge upon those qualified to become members of the Association the advantage of so doing; and it goes without saying that the expense connected with the membership is sure to be more than one hundred times counterbalanced in the return that will be received.

DEATH OF DR. LULL, PRESIDENT OF THE DUBUQUE (IOWA) KEY CITY GAS COMPANY.—The fraternity, more particularly those engaged in the West, will join with us in regret over the death of Dr. John H. Lull (President of the Key City Gas Company), which sad event occurred on the morning of Wednesday, January 22d. Deceased had been complaining for some days, but did not attach any great importance to his symptoms. The latter, however, eventuated in an attack of pneumonia, which terminated fatally and with shocking suddenness. John H. Lull was born at Hartland, Vt., in June, 1828, and graduated from the Vermont Medical College, in the spring of 1850, as a duly qualified physician. Having looked the home field over carefully, he determined that preferment would come more quickly in a somewhat more extended field, and accordingly visited the West. In the fall of 1853 he settled in Dubuque, Iowa, in which city was spent the remainder of his busy life. No more devoted or capable citizen was sheltered by that city, and to its material advancement he gave freely of time, counsel and money. Pre-

ferring the greater latitude offered by commerce, deceased did not practice his profession in Dubuque, but turned his attention to business and its responsibilities. To name any of the important local enterprises started within the last 30 years is almost to mention an instance of Dr. Lull's connection with the material interests of Dubuque. Banks, manufacturing companies, public works—all claimed a share of his patronage and counsel. He was President of the Key City Gas Company for many years, and was a firm believer in the stability of gas lighting—a belief that largely added to his store of wealth. Respecting the personal character of the deceased, we are favored with the following from a correspondent:

"He was a man of remarkable breadth of mind and keen penetration. His executive ability was unusual, and it is a simple statement of fact to say that but for his foresight, optimism and energy many of the enterprises of which Dubuque boasts to-day, and which have greatly increased its population and enhanced its wealth, would not have materialized. He amassed means by prudence, and he so employed them as to make them a source of maintenance and blessing to others as well as to himself. No man could have devoted riches to a better use, and no man ever acquired them more justly. Dr. Lull was a diligent reader and profound thinker. His general knowledge was copious, and on certain historical, political and scientific subjects his knowledge of detail was astonishing. Endowed with strong reasoning powers, he drew sound conclusions, and conversation was with him a delight. It was impossible to exchange thoughts with him without being entertained and edified by his discourse. He had a catholic mind. It was expansive and well balanced, and a stranger to bigotry and prejudice; and like his mind, his heart was generous. No religious denomination ever appealed to him in behalf of charity in vain, and the deserving mendicant never left him empty-handed. He took pleasure in placing meritorious persons in the way of business success. His life was useful and honorable, and the loss of it is a loss to the community. To his family his demise is an almost insupportable affliction, but such poor consolation as heart-felt public sympathy can give them is theirs."

CHEAPER GAS FOR PEORIA, ILLS.—Almost every Western gas man is acquainted with Mr. Peter Coffey, Superintendent of the Peoria (Ills.) Gas Light and Coke Company, whose genial personality makes him welcome at all times. The Peoria man, however, is more than genial, in that he stands for what is "known out that way" as a "hustler." For many years he has been in charge of the manufacturing and distributing plants of the Peoria Company, and his command thereof has not been in vain. When to Coffey's ability and tact is coupled the fact that the executive management of the Company is of the progressive sort, one would naturally expect to hear that cheap gas is the rule at Peoria, nor would that presumption be wrongly held. Liberal as the former rates have been, the Superintendent has convinced his Directors that another cut could be made without prejudice in their business. In any event, an announcement has just been made that from and after the 1st prox. the following net rates are to prevail:

Monthly Consumption.	Net per M.
Less than 30,000 cubic feet.....	\$1.35
30,000 cubic feet and over.....	1.20
Gas for stove and power purposes.....	1.00

The only condition for obtaining a gas supply on the basis noted is that bills shall be paid on or before the 10th of the month. The figures speak most eloquently for Supt. Coffey's capability and his Company's tact, and while we are always on the lookout for opportunities of this kind as evidence of the advance that is being made in gas manufacture, we must admit that we were hardly prepared to announce that the next city to enjoy the dollar gas rate would be Peoria. Facts accomplished are those that lead to greater things, and it is in records of this nature that not only the stability but the continued triumph of the gas maker's craft can be proclaimed.

THE opposition to the reappointment of Mr. Rowell as a member of the Massachusetts Board of Gas and Electric Light Commissioners—his term of office expires within a few months—seems to be confined to a clique whose "practical politics" have hitherto been looked on with little favor by those who consider fitness for public service as the best recommendation that an aspirant for public office can present in support of his claim for recognition. While fully believing that Mr. Rowell's chances for reappointment are of the strongest sort, we nevertheless consider it our duty to say that it would be poor reward for faithfulness and fidelity did he fail of reappointment. His course in the Board, in common with that of his colleagues, has been of a nature well qualified to evoke admiration for its candor, impartiality and value.

MR. H. BOSTWICK has filed papers in the District Court (Hastings, Neb.) in which he prays for the appointment of a receiver for the Hastings Gas Light Company; also that the charter of the Company be revoked.

SOME days ago one of the Dominion Gas Inspectors paid a visit to the works of the Windsor (Ont.) Gas Company for the purpose of testing the purity of the gas supplied. He found an excess of sulphureted hydrogen, and complained of the same to Judge Bartlett, who summoned Manager Nash, of the Company, for an explanation. The latter having admitted that the Inspector was in the right, was fined \$12.85 under the statute.

Note on Rankine's Treatment of Chimney Draft.

By PROF. J. BURKITT WEBB.

Prof. Webb, in the last issue of the *Stevens Indicator*, having explained that his attention had been called to a criticism of Rankine and other noted authors, in a paper before the American Society of Mechanical Engineers, by Mr. Gale, in the discussion of which it was stated that a correct solution of the problem, if not two, is contained in "La Chaleur," by Peclet, remarks that on examination it appears that the paper is based upon an incorrect hypothesis, and that the only solution in "La Chaleur," which is claimed therein to be correct, gives the same result as does Rankine.

A brief comparison of the solutions will illustrate a point or two in mechanics and show Rankine's deep mechanical insight.

In Peclet's solution the pressure operating to produce the draft is found by subtracting the weight of a column of hot air, the height of the chimney, from that of an equal column of cold air.

The height of a column of air, which will give the pressure, is then calculated and the velocity reckoned as due to this height, in the same manner as the velocity of water issuing from a vessel is deduced from its height therein.

But Peclet hesitated between representing that pressure by a column of cold air and supposing it to produce the velocity with which the (cold) air enters the chimney, and representing it by a column of hot air, producing the velocity of the (hot) air issuing from the top of the same.

Mr. Hudelo, editing the last edition of Peclet, says that the mechanical theory of heat furnishes the means of deciding between the two formulas, and his analysis leads him to the choice of the column of hot air; the principles of thermodynamics, however, are not needed to show which formula should be used, the principles of mechanics known to Peclet being sufficient.

If the velocity be calculated by means of the column of cold air the total pressure available to produce the draft will be appropriated to the production of the velocity of the entering (cold) air, and nothing will remain to cause the increase of velocity which must accompany the increase of volume, when the air is heated by the fire.

Evidently the pressure at disposal should be supposed to be occupied in causing the final velocity of the (hot) air issuing from the top of the chimney, unless the fire can be supposed responsible for the increase of velocity as well as the increase of volume.

Now, it is a principle of mechanics that the internal forces in a free body or system of bodies cannot affect the motion of the center of gravity of the same, and, therefore, when an elementary mass of air is heated by its internal expansive forces, acting equally in all directions, can have no effect upon the velocity of the mass, which is controlled entirely by external forces.

While it is true that the fire is responsible for the increase of velocity, and, indeed, for the whole velocity, it causes it in an indirect manner; in fact, the fire simply keeps the clock wound up, so to speak, leaving it to run down under the control of gravity alone.

In refreshing contrast to the analysis in the last edition of Peclet, with its thermodynamic mistiness and approximations, is the clear and simple treatment in Rankine's "Steam Engine," some pages before thermodynamics is reached. While Peclet is referred to, the analysis is given in Rankine's own way. The question of head is disposed of in the following words:

"The formula* enables the velocity u to be computed when the head h is given;

"The head h is expressed in feet in height of a column of the hot gas in the chimney.

"The head may be produced in three ways:

- I. By the draft of a chimney.
- II. By a blast pipe.
- III. By a fan or other blowing machine.

"I. The head produced by the draft of a chimney is equivalent to the excess of the weight of a vertical column of cool air outside the chimney, and of the same height, above that of a vertical column, of equal base, of the hot gas within the chimney; and, when expressed in feet of hot gas, it is found by computing the weight of a column of the cool external air as high as the top of the chimney is above the grate and one foot square in the base, dividing by the weight of a cubic foot of the

$$* h = \frac{u^2}{2g} \left(1 + G + \frac{fl}{m} \right)$$

NOTE.—A review of the Hudelo-Peclet treatment may be expected at the next meeting of the American Society of Mechanical Engineers.

hot gas, for the height of an equivalent column of hot gas, and subtracting the former height from the latter."

Fig. 1 illustrates Rankine's conception. CD is the chimney whose draft is to be found. DE is a supposed extension of such height that the column of hot gas EC exerts the same pressure per square foot as the column of cold air AB .

If the outlet at F is closed the column of hot gas balances statically that of cold air, but if F is open the hot gas flows out under the head ED ; and if air is supplied at A the flow will be from A to F .

Fig. 1.

As the atmospheric pressure is the same at A and F it can be omitted entirely from the problem.

Peclet starts with the supposition of a fire outside to warm the air passing from B to C , so that the chimney contains air alone; Rankine supposes hot gas in the chimney, but his analysis applies equally to hot air.

A model could be made to illustrate this action in a tube of the same form, $ABCD E$. Let water be supplied at A , and let a jet of air be blown in at right angles to the current between B and C with sufficient force to mix thoroughly with the water. In AB there will now be solid water, and in CE a lighter mixture of water and air, which will rise to a height DE above the water level at A , when the mixture is properly proportioned, so that the issuing velocity at F will be that due to the head DE .

Thermodynamics may, however, be legitimately brought into the problem, for it must be evident that the density of the hot gas will not be the same at all parts of the chimney, and to get at the weight of the column some average density must be assumed, or the law of its variation must be obtained upon thermodynamic principles. The former method is, however, sufficiently accurate for all purposes.

Rankine knew that thermodynamics was not needed in the problem, and he appreciated fully the importance, in every problem, of seeing clearly the exact bearing of the different principles of mechanics upon the subject, and of making use of such as lead to the simplest and most reliable conclusions.

I am accustomed to use the following illustration of the independence of internal and external motions with my class in mechanics: Suppose a car (Fig. 2) to have mounted upon it a flywheel, on the shaft of which

Fig. 2.

a rope is coiled. The rope is pulled in a direction parallel to the truck with a constant force of 100 pounds. What difference will it make in the motion along the track whether the flywheel is free to turn or whether it is blocked so that it cannot turn?

The principle of momentum solves the problem at once, for we have only to consider that the car and flywheel together constitute a body free to move horizontally, and that, so far as motion along the track is concerned, it is a matter of indifference whether there are also internal motions or not. The 100 pounds will produce a linear momentum of

100 each second (neglecting friction), whether the flywheel is free to turn or not; so that the motion of the car will be the same as though the rope were fast to the car itself.

If, on the other hand, the problem be to find out how much work the force does in each case, account must be taken of the fact that when the flywheel is blocked the 100 pounds moves over the same space as the car, while with the flywheel free it will move over an additional space, due to the rope unwinding from the axle. The simple principle of momentum used above is now no longer sufficient, and the angular momentum of the flywheel must be found, and the work done in rotating the wheel added to that done in moving the car and wheel along the track.

Lighting Cars.

The *Railroad Journal* says that the horrible accident which occurred on the Cincinnati, Hamilton & Dayton Railroad on January 17, reiterates with terrible emphasis the necessity for taking every precaution to prevent the repetition of such calamities. In this case, as in other instances of a similar kind, passengers were fastened in the wreck and burned to death in the presence of the onlookers, who could give no aid, and were helpless to prevent the awful agony which was greater than that of a martyr burned at the stake.

Heating by steam is making progress, but not as rapidly as circumstances demand, as is shown by this and other accidents; but the influence of State legislation and the Railroad Commissioners is now exerted in favor of its general introduction; although it will probably require the sacrifice of more lives, the stimulus of public indignation, and the strong hand of the law to overcome the lethargy of railroad directors and managers.

The subject of lighting cars has received less attention than heating, because the danger is less apparent. That carrying several gallons of very combustible oil, which is distributed in a car where, in case of an accident, it will be most effectually scattered, is a source of great danger, is very obvious. Besides this, if cars are ineffectually lighted, it imposes upon passengers from three to six dismal hours in which reading is impossible, and they are driven to reflect on their misfortunes and shortcomings, which leads to a low state of dejection and melancholy.

Railroad companies have not the excuse any longer that there is no satisfactory system of lighting cars excepting oil lamps. It is not our purpose to sit in judgment on the relative merits of the various systems now in use; but it can be said confidently that if there is none better, the Pintsch system is giving satisfactory results. It has been mentioned in these pages before, that an unwillingness to profit by the experience of others appears to be a national defect in the American character. Precedents are, however, useful guides. In the matter under consideration we have the fact before us that the Pintsch system of lighting cars is used extensively in England, Germany, France, Holland, Italy, Austria, Russia, Sweden, Denmark, Switzerland, Egypt, Brazil, and also in this country, on nearly, or quite, 30,000 cars. The use is not recent either, but has extended over a sufficiently long period to fully test the efficiency of the system. The rate of increase also shows that its use has been sufficiently satisfactory to lead to a rapid extension, as from 1883 to 1886 about 23,000 cars were equipped with it. In this country it is used on the New York, Lake Erie & Western Railroad and ferry boats; the West Shore Road and boats; New York, Providence & Boston; Chicago & Atlantic; New York Central & Hudson River; Boston & Albany; Old Colony; New York & New England; Louisville, New Albany & Chicago; Cincinnati, Hamilton & Dayton roads; Pullman's Palace Car Company; Wagner Palace Car Company; Providence & Stonington Steamship Company's boats; Hoboken Land & Improvement Company's boats; and the New Jersey Central and the Cleveland, Cincinnati, Chicago & St. Louis Railroads are erecting works for future use. In all over 1,000 cars in this country are lighted by this system.

The following description will give a general idea of its essential features:

Process of Manufacture.—The material used for the manufacture of Pintsch gas is crude or refined petroleum, or the residual products of coal oil distillation. Crude petroleum is the cheapest material, and the one generally employed. The oil is passed through suitably arranged iron retorts kept at a high temperature by a coal fire below them. The furnace is of such design that the retorts are evenly heated from end to end, and are kept at such a temperature as to thoroughly convert into gas the oil, which is fed into them through specially arranged pipes and graduating cocks. The product is a rich and permanent gas, and of the highest illuminating power known in the art. From the retorts it

passes through water seals, and is led by a pipe to the condenser, where it is cooled. In this it deposits the vapor of water, tar, etc., mechanically carried over with the gas. From the condenser it passes through a washer, which further purifies it, and then through lime purifiers, which effect the removal of all traces of impurities which may still remain. It is then measured and passes to the gasholders, from which it is drawn by the compressor and stored under any desired degree of compression in the tanks, from which pipes lead wherever it is convenient to convey it for use. The process is a simple one, very direct and economical. A plant capable of making all the gas required for 500 cars is contained in a building 26 ft. 4 in. by 38 ft. 6 in., one story in height. The storage tanks may be placed where it is most convenient, and are larger or smaller in proportion to the requirements of the service.

Distribution to Cars.—From the storage tanks pipes are laid to such points in the yards as are most convenient for charging the reservoirs of the cars. These pipes are provided with suitable valves, and by means of special hose, with quick-acting couplings, the gas is transferred to the tanks under the cars. These tanks are filled to a pressure of 150 pounds. A very much higher compression can be obtained if desired, but experience has shown that it is not good practice to compress the gas more than is needed. The tanks are filled very quickly, and no time is lost on this account, even when the filling is done at an intermediate station. A stop long enough to supply the engine with water or coal, or to change locomotives, is sufficient for filling the tanks.

Pressure Regulation.—At the pressures at which the gas is charged into the tanks, its combustion in lamps is impossible without perfect regulation. This pressure, it should be remembered, constantly though very slowly diminishes as the gas is burned, and the conditions of satisfactory lighting demand that while any gas remains in the tank in excess of atmospheric pressure it shall give as good a light as when the tank is charged to its full capacity. The regulator is placed under the car, and without attention and under all conditions of service maintains a constant pressure of gas on the pipes leading to the lamps, whether one or all are burning, or none are in use. It is entirely automatic, and when adjusted and put in position needs no further attention, and the cover of the iron box containing it need never be removed.

The Lamps.—The lamps manufactured for railroad service are of great variety, and are adapted to every kind of coach. Those for passenger cars are all made upon one principle. They are suspended from the ceiling, and one of the suspending arms furnishes the gas-way. Two or four burners are used, as desired. These are inclosed in glass globes, which perfectly shield them from disturbing air currents, and place them wholly beyond curious or malicious interference. Above the flames is a white porcelain reflector, which greatly aids in the distribution of the light rays, and very much increases the brilliancy of the illumination. These lamps are shadowless, and, as travelers by the lines on which they are employed have observed, four lamps in a passenger coach of full size, give an illumination which permits the passenger to read easily and comfortably.

After the works and the machinery are erected it is said that this system is cheaper than lighting by oil; it is certainly much cleaner and safer, and, as remarked in the early part of this article, we are not prepared to sit in judgment on all the methods of lighting now before the public, but it may be said confidently that if no better system can be found than the Pintsch, railroad companies should adopt it in preference to oil, if for no other reason, to prevent such dreadful accidents as the one already referred to and others equally horrible.

Mr. Jno. West on Gas and Electricity.

At the annual meeting of the Manchester Association of Engineers, the President (Mr. Jno. West, M. I. C. E.) delivered a very comprehensive address, a large portion of which dealt with the subject of gas and electricity. An abstract of his remarks in this respect is appended:

Having referred to the gradual advance made in electric lighting from the time of the display at the Paris Exhibition of 1878, and subsequently in conjunction with gas, at the Crystal Palace, in 1882-3, the President noticed the first legislation in regard to the new system of illumination—the passing of the Electric Lighting Act of 1882—and the important amendment lately made therein by the extension of the time which must elapse before undertakings can be acquired by local authorities, and the modification of the terms under which the transfer is to be made. These alterations, he pointed out, had encouraged electric lighting, and companies had sprung up in London and the provinces to lay down plant for supplying the light. In some cases, where the gas works belong to the municipalities, they themselves had obtained powers

to supply the electric light as well as gas. Ten companies had been formed for lighting London, with a united capital of more than £3,000,000 sterling. The systems under which electricity is supplied by these companies—viz., the direct continuous current and storage, and the alternating transformer systems—were next described; and credit was given to electrical and mechanical engineers for having produced some very superior steam and gas engines and dynamos, and generally improving the plant, so as to ensure steadiness of light. The charges, Mr. West stated, were 7d. to 8d. per Board of Trade unit of 1,000 watts; and he added that some companies would not furnish a supply to a consumer under a minimum charge of £14 per annum.

While admitting that electricians had made some progress in perfecting machinery for securing a better and more regular supply of electricity, the President said it must not be forgotten that improved lighting by gas had also made very rapid strides. He mentioned that 13 years previously he read a paper before a Philosophical Society upon the "Economic Consumption of Gas;" and another during the year 1882, at the Smoke Abatement Exhibition in Manchester, where he displayed a number of defective burners that had been used by the consumers, and compared them with the more recent and improved burners then obtainable, when it was found that a great many consumers were not getting out of the gas anything like the illumination it would afford even with a good ordinary burner. Since that period, two new systems of burners had been perfected—those of the regenerative type, with which were associated the names of Siemens, Sugg, Wenham, Fourness, and others, and the incandescent burners of Welsbach, Clamond, and others. The burners, particularly those of the regenerative kind, had come into general use, and from them a better light could be obtained with from one-half to one-third the quantity of gas. In support of this statement, the results of tests of the various kinds of burners referred to—made by Mr. A. Smith, of Aberdeen, and Messrs. W. Foster and C. J. Lambert—were given.

The President next proceeded to compare the relative cost of gas and electricity, with equal light from each. He pointed out that eminent electricians state that a 16-candle power incandescent lamp is calculated to last about 1,000 hours, during which time it would absorb 60 Board of Trade units of electricity. The cost of this at 8d. per unit, would be 40s., to which must be added 3s. 9d., the cost of the lamp—making a total of 43s. 9d. per 60 units, or 16,000 candles. To make the comparison clear, he gave the cost of gas in London, Manchester and Aberdeen to produce the same amount of light, both with ordinary and regenerator burners. The results are shown in the following table:

	Quality of Gas.	Consumption to Produce 16-Candle Power per Hour.	Consumption Required for 1,000 Hours.	Price per 1,000 Cubic Feet.	Cost per 1,000 Hours.	No. of Times Gas is Cheaper than Elect'y.
<i>Ordinary Burners.</i>						
London.....	16	5.00	5,000	2 6	12 6	3.5
Manchester.....	20	4.00	4,000	2 6	10 0	4.4
Aberdeen.....	28	2.88	2,880	3 6	10 1	4.3
<i>Regenerative Burners.</i>						
London.....	16	2.50	2,500	2 6	6 3	7.0
Manchester.....	20	2.00	2,000	2 6	5 0	8.7
Aberdeen.....	28	1.44	1,440	3 6	5 0½	8.7

In reference to the preceding table, the President remarked that possibly he might be charged with having compared the electric light with both the best ordinary and regenerator burners. To this he could only reply that these burners were within the reach of all consumers, and that it would be to their great advantage to adopt them. He pointed out that he had compared the gas with an electric lamp assumed to give the same light throughout the 1,000 hours; but this was not the case, as it was found that after they had been used for a time the carbon filament became volatilized and deposited on the glass, consequently the size of the filaments was diminished and the surface of illumination reduced—the carbon on the glass further reducing the light. These facts had been confirmed by the experiments of Mr. Preece, Chief Electrician to the Post Office, who stated that ordinary commercial lamps consuming 3.54 watts per candle power when new, required 6.1 watts per candle power after burning 900 hours—the mean absorption being 5.25 watts per lamp. Stated the other way, it appeared that the candle power of the lamps after burning 900 hours was only 58.5 per cent. of the initial duty; and the mean value of a lamp during its life was only 67 per cent. of that which it possessed when new. Assuming an average use of four hours per day for a lamp, this meant not only that all incandescent lamps must be renewed before 225 days (when their luminosity was

little more than half what it was when new), but, taking all the lamps in an establishment together, three should be provided to do the work of two if the intended average lighting effect was to be maintained. The President said he was prepared to admit that the introduction of the electric light would be advantageous compared with gas consumed in ordinary burners, when a room was low-pitched, without any means of ventilation, and where a number of people were assembled assisting in the vitiation of the air. At the same time he was bound to say that by the adoption of regenerative gas burners not only would the maximum illuminating power per cubic foot of gas be obtained, but the products of combustion would be carried away without being permitted to enter the room, and the warm vitiated air would be removed as it rose to the ceiling. It appeared to him that some people preferred the electric light for reasons outside its advantages as a lighting agent—one because of its value as an advertisement, another because it was fashionable, and so on. But let the cause be what it might, he saw no reason why they should not have the electric light if they had a fancy for it, and were willing to bear the additional expense attending its adoption.

Mr. West then proceeded to give his views as to the cheapest and best way of producing and delivering electricity to the consumer under varying circumstances. He said he had been informed that in one town a complete electric lighting plant, driven by steam power, for the supply from a central station of 3,000 incandescent lamps of 16-candle power, with cables laid along the streets, would cost about £20,000. Mr. J. Ferguson Bell, of Stafford, had stated that in his town it would cost £14,500 for a like installation without reckoning the cost of land. Then there was the plan of supplying oneself (provided the number of lights was sufficiently larger) by means of a complete plant, driven by a gas or a steam engine, on the consumer's own premises. He had been supplied with the cost of a complete electric installation, including fittings for 320 incandescent lamps of 16-candle power each, which had been working for about two years at one of the banks in London. The plant was driven by gas engines, and the building being very dark, the lamps had to work for about 1,800 hours per annum. The following were the figures supplied to him:

Outlay on Plant.

Two 9-horse power "Otto" gas engines and fixing	£650	0	0
Two dynamos.....	300	0	0
Two sets of accumulators.....	1,250	0	0
Fitting up the bank throughout with wire, lamps and all accessories, including architect's charges	800	0	0
	£3,000	0	0

Working Expenses.

Gas used, 2,000,000 cubic feet, at 2s. 6d. per 1,000 ft.	£222	0	0
Proportion of wages of attendant who does other work.....	75	0	0
Oil, waste and water.....	25	0	0
Repairs to engines and dynamos, and depreciation at 10 per cent.....	95	0	0
Repairs to accumulators, and depreciation at 15 per cent.....	187	10	0
Cost of renewals of incandescent lamps (each burning 1,000 hours, at 3s. 9d. each).....	108	0	0
	£712	10	0
Interest on capital, at 10 per cent.....	300	0	0
	£1,012	10	0

Current of electricity supplied, about 35,500 Board of Trade units.

Analyzing the foregoing figures, the President pointed out that the cost per Board of Trade unit for generating electricity, including wear and tear and interest on capital, was 5.58d.; interest on fittings, 0.56d.; renewal of lamps, 0.7d.—total, 6.84d. If the bank had obtained electricity from a company supplying from a central station at 8d. per unit, the total cost to them would have been as follows: Electricity, 8d.; interest on fittings, 0.56d.; renewal of lamps, 0.7d.—total, 9.26d. So that by generating electricity on their own premises they saved 2.42d per unit, or £357 19s. 2d. per annum. In this case, as shown by the accounts, accumulators were employed, so that the electricity could be generated during the daytime with smaller gas engines than would otherwise be required; but the loss of efficiency by the use of accumulators was about 20 per cent., and was a great drawback. He thought it would be found in practice that the most economical and satisfactory way of producing and supplying electricity to the consumers would be by gas engines on their own premises, or by a system of very small central stations, where a few houses or shops in close proximity could be worked by the direct system of distribution. By this plan it would be

possible to avoid expensive outlay on buildings, and at the same time to advantageously use the existing gas mains, as well as dispense with the cost and maintenance of an electric meter on the premises. The cost of generating plant for 400 16-candle power incandescent lamps, burning 1,800 hours per annum, on this plan of electric lighting by the use of gas engines and dynamos on the consumers' premises (already fitted up with wires and lamps) would be as follows:

Outlay on Plant.

One 20-horse power gas engine, fixed complete.....	£500	0	0
Dynamo	260	0	0
Slides, disc-wheel bearing and fixing, switches and cables in house.....	140	0	0
Total.....	£900	0	0

Working Expenses.

Gas used, 2,160,000 cu. ft., at 2s. 6d. per 1,000 ft....	£270	0	0
Proportion of wages of attendant.....	75	0	0
Oil, waste, and water.....	35	0	0
Repairs to engine and dynamos, with depreciation at 10 per cent.....	90	0	0
Proportion of rent, etc.....	100	0	0
	£570	0	0
Interest on capital, at 10 per cent.....	90	0	0
	£660	0	0

Current of electricity supplied, about 43,200 Board of Trade units.
Cost per unit of electricity, 3.66d.

In the case of an installation of direct generating plant for electric lighting by the use of gas engines and dynamos on the consumer's premises (already fitted up with wires and lamps), to supply fifty 16-candle power incandescent lamps, burning for 1,800 hours per annum, the cost would be as follows:

Outlay on Plant.

One 4-horse power gas engine, with dynamo, etc....	£275	0	0
--	------	---	---

Working Expenses.

Gas used, 270,000 cu. ft., at 2s. 6d. per 1,000 ft.	£33	15	0
Proportion of wages of attendant.....	18	4	0
Oil, waste, and water.....	8	0	0
Repairs	6	0	0
Depreciation	13	10	0
Rent.....	4	0	0
	£83	9	0
Interest on capital, at 10 per cent.....	27	10	0
	£110	19	0

Current of electricity supplied, about 5,400 Board of Trade units.
Cost per unit of electricity, 4.93d.

By this plan electricity could be supplied, as shown by these examples, at prices varying from 3.66d. to 4.92d. per Board of Trade unit, according to the size of the installation, inclusive of working expenses, repairs, depreciation, and interest on capital. The usual charge by the London electrical companies, whose supply is generated for extensive districts in large stations driven by steam power, is 8d. per unit; showing a saving of 4.34d. and 3.07d. per unit respectively in favor of the gas engine scheme. To explain how the charge for working by gas was obtained, the President stated that he first took the quantity of gas required per indicated horse power per hour at 20 cubic feet. With this quantity of gas a maximum of eight lamps of 16-candle power each could be maintained per hour; and by allowing a little extra for irregularities, and taking 50 cubic feet of gas to produce one Board of Trade unit, the gas would cost 1½d., to which must be added the other figures in the table of working expenses.

Mr. West explained that the reason electricity could be distributed to consumers by gas engines cheaper than from a large central station was because the very expensive cables for distributing the electricity (which in most cases take one-third of the capital employed) could be dispensed with, as also the further expenses for renewal after the cables had been in use for a time. It was stated that Mr. Edison's cables in Berlin only last three years. These cables cost £90,000 for 36,000 lamps of 16-candle power and 144 arc lamps. From these facts it was quite clear that the interest on the first cost and maintenance and renewal of distributing plant alone would be more than the cost of gas delivered on the con-

sumer's premises from the existing mains. He expressed the opinion that the Corporation of Manchester were quite right in taking steps to obtain a Provisional order from the Board of Trade for supplying the electric light, for which they could put up plant themselves, or employ other parties to supply them. They had excellent distributing plant for the purpose in the existing gas mains, which, by the aid of gas engines, would supply a power available at any time, requiring no constant attention, and causing no nuisance from smoke. These engines were already extensively used; Messrs. Crossley Bros. having sold 550 for the purpose. Where the outlay on plant was an impediment, he advised corporations and gas companies to throw more enterprise into their undertakings, and provide and let out on hire gas engines and dynamos in the same manner as they now let out cookers and gas stoves. In some cases it might even be advisable to sell the gas at a cheaper rate for electric lighting and heating purposes.

The President said he had not referred much to the use of arc or incandescent electric lamps for public lighting, because it had been proved over and over again that these lights could not possibly compare with improved gas burners and lanterns, either for cost or efficiency in lighting power. In many cases where arc lights of high power were employed on outdoor work they had been superseded by the Lucigen and Wells portable lights. Before leaving this subject, he said it must not be forgotten that in nearly all cases both gas and electric light are obtained from the energy contained in coal, and that gas companies and corporations who own gas works could produce as much light direct from the gas made from a ton of coal (if properly applied) as could be derived from a ton of coal by any other means, besides having the resulting coke, tar, and ammoniacal liquor to dispose of. Therefore, as far as he could judge, gas must remain by far the more economical of the two methods of lighting.

Mr. West concluded his address with an appropriate reference to water gas. He remarked that the subject of water gas had been brought very prominently before the public during the last year or two, more perhaps for the purpose of floating speculative companies than because of any real novelty in it; for at least 30 years had elapsed since it was new to English gas engineers. Many had been the trials of variations of the same principle, owing to the extreme simplicity of the apparatus and the large amount of work that could be done on a small area; but the question of ultimate economy had often prevented the success of schemes which were otherwise satisfactory. He explained that he was referring more particularly to the use of water gas for general lighting purposes, as there were many examples in England of its admirable qualities as a heating agent. Having described the method of generating the gas, he pointed out that there is a great difference between the circumstances of the production of water gas as a lighting agent in America and England, inasmuch as in America the petroleum oil used to invest the gas with lighting properties is easily obtained at a very low price, and the price of coal gas is much higher than it is in this country. A greater margin thus exists between the two kinds of gas. As a heating agent water gas was, he said, very valuable where a high flame temperature was desirable; as the theoretical temperature was about 5,000° F., while that of coal gas was about 2,500° F. He went on to show that mistaken notions are frequently held by persons not specially interested in the question, though of thoroughly scientific education, as regards the heating value of ordinary coal gas compared with the so-called "heating gas." He said the fact was that, roughly speaking, the better the lighting qualities of a gas the greater its heating value; and a far larger number of heat units were contained in a pound of ordinary coal gas than in the same weight of the best "heating gas" (taking the term "heating gas" to be simply a name to distinguish it from a gas which had not only greater heating value but lighting value as well) yet produced. As a lighting agent water gas had to be carbureted, or employed with some material capable of being raised to incandescence, such as magnesia, in the form of a comb, which, however, required a frequent renewal. English engineers who had visited America to inspect the water gas processes in use were of opinion that it might be an advantage to adopt the same system to a certain extent in England if petroleum could be bought at a sufficiently low price to make the gas a commercial success: but he thought this was very questionable.

ACCORDING to the annual report of the Manufacturers Natural Gas Company, of Pittsburgh, the gross receipts for the year are returned at \$235,149.38, and the expenses for same period were \$151,839.97. The net receipts were \$83,309.41. During the year the Company claims to have expended \$58,128.27 in "permanent improvements," a portion of which was devoted to the burying of 36 miles of 12-inch pipe. The main mileage of the Company is returned at 136.

[Concluded from page 139.]

The Dangers of Electric Lighting.

BY S. Z. DE FERRANTI AND FRANCIS INCE.

In order to use the electrical current two mains or conductors are required, an out main from the central station, and a home main (and one intermediate or third main is also required where the three-wire system is used), and each lamp that has to be lighted has one end of the filament joined to the one main (say, the out main), and the other end to the other main (say, the home main), the passage of the current from the one main to the other through the carbon filament causing the filament to incandesce and to give light. Now, if the mains from the central station are constructed with one tube of copper within another, and with insulation between, as shown in the figure, the central ring, marked *A*, being the out main, say, and the outer ring *B*, being the return or home main, the shaded part between the two being the insulation, the only leakage of current that can ever take place is, say, from *A* to *B*, if there is any defect in *C*, and the current returns to the station through the leak by *B*, without passing through a lamp or doing any work, and

if the leak is so serious between *A* and *B* that it causes a larger quantity to go back to the station than the bridge there will stand, the bridge melts before any damage is done to *A* or *B*; and if another main or wire actually comes in contact with *B* the current will not leave *B* and find the way back by the earth (as it would do if two separate out and home conductors were used), but it is controlled by *A*, and any leakages can only be to *A*. Hence, with a conductor constructed, as above shown, with a current passing through it of 10,000 volts, any one may hold *B* in their hands and they will receive no shock and no current will pass into them. This has been practically demonstrated by a test on the underground railway, where one of the writers held, as many others did, *B* in their hands, while a current of great pressure was passing through it, a pressure that would have meant instant death if it had been possible for the current to leak from *B* and pass through the body to earth. Thus we have the double safety, the bridge and nature of the conductor used, this safety being not only, as the reader will observe, a safety against fire, but it is an absolute safety to human life. And thus a man may work in close proximity to a conductor constructed as suggested, in fact, he may sit on it while he is working, and he will be out of all danger, and he is no longer, as Mr. Edison suggests, in fear of a "death-dealing current," for the current, whatever its pressure, whatever its quantity, is so controlled as to be absolutely harmless. Thus, to sum up the meaning of the above concentric mains, we may say that, whatever fault may occur, the whole effect is produced and contained in the main itself, and it is impossible that there can be, and there is in fact no danger and no damage done outside. We have thus a perfect protection for life and property from all forms of current.

Again, Mr. Edison says there is "no known insulation which will confine these high tension currents for more than a limited period;" and again he says, "the influence of the air or of gas or other agents renders it (the insulation) finally very susceptible of being pierced by a spark of static electricity." Mr. Edison would have been more accurate if he had said that there was no insulation known to him which would confine these high tension currents for more than a limited period; and, again, how can the air, gas or other agent get at the insulation if it be confined between two tubes in the way suggested and they are properly joined the one tube to the next? Again, if the mains be constructed according to the figure, and a spark of static electricity did pierce the insulation, what would be the effect? There would be no danger, no external damage; too great a quantity of current would flow over the bridge, and the bridge would give way, and, as before explained, no detrimental effects would be produced. But there is an insulating substance known which was manufactured before the commencement of the Christian era of which specimens that have been exposed to the air for centuries still exist in perfect preservation. How will such an insulator stand when hermetically sealed between two tubes? Then, again, Mr. Edison says, "the risk, too, is greatly increased by the fact that consumers who are

supplied with current from a low tension system are accustomed to handle their electrical appliances freely, knowing them to be harmless; I say nothing of the injustice to vendors of harmless supplies of electricity." Here, again, Mr. Edison knows, and no one better, that even if the current is sent out from the central station at a tension of 10,000 volts, the tension is lowered at distributing stations by a suitable device, and that current the consumer has to handle is only at a pressure of 100 volts, and the pressure is so lowered and controlled that by no possibility whatever can the higher pressure get into any house. What, therefore, is the difference in the danger to the consumer whether the current has an initial pressure of 100 volts or 10,000?

Mr. Edison speaks of the alternating current as being more dangerous to life, and no doubt it is, if a high pressure were used in the customers' houses; the writers were, however, both present when Colonel Armstrong, as the representative of the Board of Trade, called upon them for the purpose of trying the effect of shocks from an alternating current at varying pressures, and in our presence he first of all took a shock from an alternating current machine at 50 volts; he then had the pressure increased to 100 volts, and then to 150 volts, and then to a pressure of 200 volts, at which pressure he said he was satisfied, and he could bear the 200-volt shock with perfect ease, being a pressure of twice that used in consumers' houses; in fact, in the Board-room of the London Electric Supply Corporation there are two openly exposed terminals, and the Directors constantly take hold of these, the effect of the 100-volt alternating shock being hardly perceptible, and being rather pleasant than otherwise. Further, we have had several accidents where men in the station have received a shock direct from the machine with a 2,400-volt alternating current, but not in one instance has death resulted. Mr. Edison speaks of the danger to life of alternating currents at low pressure, but it must be borne in mind that the specimens experimented on at Mr. Edison's laboratory were pickled and prepared so as to make the effects of the current as deadly as possible, and were therefore placed in an unnatural condition.

This article shows that the saving of copper in the mains or conductors is enormous as the tension increases, and what this means may be made more clearly apparent by a statement of the fact that if the pressure from the station was 100 volts only, the stations to light London could not be placed at a greater distance than a mile apart, each station lighting a half-mile radius, as otherwise the copper mains would have to be of such an enormous size to carry the quantity of current that would be required at this low pressure, that the cost of mains alone would render the price at which the current could be supplied so high as to make lighting by electricity impossible.

Again, it is much more costly to build a large number of small stations than one large station, and every small station requires its staff, its engine drivers, etc. In a large station one man can drive a 10,000-horse power engine which will light 200,000 10 candle power lights, whereas with small stations and small engines, say of 250-horse power each, which would light 5,000 10 candle power lamps, each engine must have its attendant; and the question is not, as Mr. Edison would suggest, a mere question as to saving a few pounds "in investment in real estate and copper;" it is a question of saving so much as to make the difference between success and failure, where it is necessary to compete with gas at a low price. But this is not all; in large cities it is impossible to buy land at every mile, and to put up a central station for the manufacture of electricity, for the station is a nuisance, and one is perpetually harrassed with litigation; application after application is made for injunctions; the taking of coal in the large quantities required is a nuisance; the smoke is a nuisance, and only high-priced steam coal can be used, and that, too, saddled with the heavy expense of cart carriage; the vibration and noise from the engines is a nuisance, and stations in the residential parts of any city will be stopped one after the other by injunction.

Again, at these small stations spread over a city, to get water is a difficulty, and in consequence power can only be obtained at a very high rate of coal consumption; whereas, with a suitable site at a distance, the quantity of coal used can be reduced enormously, making a saving which will alone go far towards a dividend on the capital expended.

These are all circumstances that require most serious consideration, and Mr. Edison's argument on these points is in fact a mere argument in favor of a monopoly for his low tension system, a system which can exist and be carried on profitably in America, where the price of gas is enormous; a system which would render electric lighting impossible in London with gas at 2s. 5d. per 1,000 cubic feet, and a system which makes the people of America pay a price for their lighting unnecessary to give a good return on capital invested on a better and a less costly system.

Mr. Edison points out that a larger number of fatal accidents have occurred through electricity in New York than in any other city in the world, and gives the reason that New York has a greater number of wires overhead than any other city in the world. No doubt this is the reason, coupled with the fact that probably in no other city in the world are the overhead wires arranged more negligently and with more disregard for the care of human life. There can be no doubt but that overhead wires, whatever the care may be that is taken with them, are, and always must be, a danger; but with conductors placed underground, and with due care, and properly constructed, there can be no danger whatever. Mr. Edison has pointed out that in this country the safety of the people is placed in the hands of the Board of Trade, a body we have found most obliging and most reasonable in their requirements, while insisting with the utmost severity that no system shall be adopted which does not give absolute safety to human life, and who, after seeing our work, have been perfectly satisfied to advise the government to pass our Act, which enables us to deal with a 10,000-volt current.

Mr. Edison does not deal with the transmission of power from those sources which nature gives us for nothing at certain centers; we refer to water power, and from which, by the aid of high pressure electricity, and high pressure electricity alone, can the force be transmitted to a distance and utilized for the purposes of man; according to Mr. Edison these forces are to run on unutilized forever as they have done for ages past. His argument that because a nitro glycerine factory is dangerous on the surface of the earth we should not think of putting it underground, is not applicable to the subject of electricity or to the putting of electric mains underground, though we cannot say that the idea of the nitro glycerine factory underground is so absurd as Mr. Edison appears to think; for it will be within the memory of many of our readers that about fifteen years ago a barge laden with gunpowder, on the Regent's Canal, exploded at the bottom of the Avenue road, where the canal is in a deep cutting, and the opinion of one of our great experts was that this fact saved London, serious as the damage was in the immediate neighborhood. It is clear beyond a doubt that if mains are properly placed underground there can be no danger, and no accident can take place.

We think we have said enough to show that the dangers of electric lighting are no more in the high tension system than the low, provided both systems are carried out with equal care and all proper safety devices are used in the one case and in the other; without these devices and without this care neither system is safe, and it is clear beyond a doubt that the low pressure system is not safe as at present carried out in New York, and it never will be until the State steps in and the use of electricity is regulated there by well-devised rules and under the supervision of competent officers; but Mr. Edison is as far behind the time when he suggests that no station shall send out a current at a pressure exceeding 100 volts as the alarmists were when railways were first introduced, and it was considered that no train could in safety ever run at a rate exceeding twenty miles an hour.

No doubt if a train ran at only ten miles an hour an accident would not have such serious results as with a train running at fifty miles, but is this an argument why trains should not run at fifty miles per hour? We have to consider the percentage of risk, and this we find has not been materially increased by the increase of speed. So it is with electric pressure. As the pressure increases, extra precautions have to be taken with regard to safety, and we believe with Sir William Thomson, who stands as an authority in the world of science as high as Mr. Edison, that it is not a question whether a pressure of 10,000 volts (the highest pressure yet utilized) is to be used or not. The pressure may be anything so long as proportionate precautions are used, and we think it may be that in a few years' time people will think as little of 10,000 volts as we do now of 1,000, and will laugh at the present alarmist idea that in a pressure of 100 volts the limit of safety has been reached.

Mr. Edison says in his article: "The public would scarcely be interested in the details leading up to the conclusions to which I have come, for the reason that it would involve a mass of matter such as they have been attempting to digest during several months past." We have not adopted Mr. Edison's dogmatic method of dealing with the subject, and do not know to what mass of matter he refers. We have avoided attempts to give results the weight of our opinions without giving reasons; we have explained as clearly as we are able our views, giving such reasons as would enable the general public to follow our arguments without, we hope, too much trenching on the land of technical science, and we trust our readers will see that there are other arguments besides those of Mr. Edison, and that there are reasons why the dangers of electric lighting under a high pressure system are no greater, if they are so great, as those of a low pressure system, for which Mr. Edison clearly claims (while he disclaims) a monopoly.

Mr. Edison very properly gives great weight to facts. Let him then consider that in New York the deaths through electric shocks have been very frequent, with a tension, we believe, never exceeding 2,000 volts, and rarely exceeding 1,000; while in London, where for years we have been using a tension of 2,400 volts, with miles of both overhead and underground conductors, we have never had a single accident with our mains or a single death. Why this difference between London and New York? The reply is, that here our work is done properly, there it is not. Our work is put up to last, theirs in New York to serve the purpose of the moment.

If the reader has followed us so far and will allow us in closing this article to be prophetic, we will say that in the future our railways will be worked, our lighting will be done, our power will be transmitted to a great distance; all this will be done entirely by the aid of high pressure electricity; it is high pressure in electricity like high pressure in steam, which is going to carry—which is carrying—everything before it, and this high pressure will be used, and will be doing the work of the world, when the low pressure system Mr. Edison now so strongly advocates has passed away and been forgotten.

Three Types of Electric Meters.

La Nature recently published an article descriptive of three types of electric meters that were first publicly displayed at the Paris Exhibition. In the illustrations Fig. 1 stands for a general design of Blondlot's watt-hour instrument. M. Clerc's watt-hour device is outlined in Fig. 2, while the meter of MM. Paccard-Borel is pictured in Fig. 3. The watt-hour devices are for continuous service current, while the last-named apparatus is for alternating work. Blondlot's meter is constructed with two essentially distinct parts—the measuring apparatus and the integrating apparatus. The former of these is an electro-dynamometer whose fixed bobbin with vertical axis is wound with coarse wire and is traversed by the total current furnished to the consumer. The fine wire bobbin placed within the coarse wire one is mounted in derivation between the distribution terminals of each subscriber. The couple exerted upon the movable bobbin by the fixed one is thus proportional to the product, eI , of the intensity, I , of the principal current by the difference of potential, e , at the terminals of distribution. A counterpoise arranged upon an arm mounted upon the axis of the movable bobbin balances the electro-dynamic couple and causes a deflection of this bob-

Fig. 1.

bin by an angle proportional to the product, eI . The clockwork movement, an ordinary timepiece, periodically closes (once every 5 minutes in the case considered) the circuit of a special derivation constituted by two solenoids. The effect of the first of these solenoids is to bring back the fine wire bobbin to zero, and that of the second, which is arranged horizontally, is to render momentarily interdependent the axis of an evolution counter which, in every operation, revolves by an angle equal to that made by the movable bobbin before being brought back to zero. The rotations thus given periodically to the revolution counter are totalized, and may be read upon a horizontal dial actuated by an endless screw mounted upon the first axis of the revolution counter.

The movable bobbin, in passing over a vertical dial placed beneath the clock, makes known the power furnished every instant by the apparatus controlled by the counter. The intervals of time that separate two

different gatherings may be read upon the dial of the clock, and the integrations made by the apparatus may be known from the horizontal dial, so that the consumer has under his eyes at every instant all the elements of verification that are necessary to him.

Clerc's meter, shown in Fig. 2, is in principle analogous to Blondlot's, but differs from it in the mode of periodical integration. The clock is kept in motion by a derivation from the line. It carries along, at a uniform angular speed, a crank fixed upon the principal axis. When the power expended is nil, the needle fixed upon the axis of the movable bobbin is in the position represented in the cut.

If a current passes into the two bobbins, the needle is deflected toward the right by an angle that counterpoises, properly arranged upon the

Fig. 2.

axis, permit of rendering sensibly proportional to the product $e I$. The crank carries the needle back to zero once per revolution.

These rotations are transmitted to the revolution counter, and totalized by means of a mechanical arrangement that may be seen in front in the figure. This arrangement consists essentially of a small finger suspended from a lever fixed to the axis of the movable bobbin. When the lever moves from right to left, it carries along the large wheel mounted upon the axis of the totalizer. In moving from left to right, the finger slides over the felly of the wheel, and the rotation effected in the preceding movement continues as in the Blondlot apparatus. The needle indicates the power in watts, and the counter the total of the watt hours furnished to the consumer.

The Paccaud-Borel meter is designed for the measurement of alternating currents. It belongs to the class of motor counters, and is based upon the special properties of the magnetic field produced by alternating currents of great frequency. Suppose there are two bobbins whose axes

Fig. 3.

are arranged rectilinearly, having an unequal number of spirals, and mounted in derivation, one with respect to the other, so that the total current traverses them at the same time and divides itself unequally at every instant in each of them in consequence of irregularity of the coefficients of self-induction. Each of these bobbins will tend to produce a magnetic field whose intensity will depend at every instant upon the intensity of the current traversing it. The resulting field will be rotary in a direction determined by the attachment of the terminals between themselves. A thin iron disc placed in the rotary field will tend to turn in the direction of rotation of the field, and so much the more quickly in proportion as the field or the current producing it is more intense. Upon arranging vanes, forming a regulator upon the same axis with the disc, and upon properly proportioning the different parts of the apparatus, it is possible, as may be seen, to form a sort of electric motor, which,

between certain limits, will revolve with an angular speed sensibly proportional to the efficacious intensity of the total current.

It is with a view to obtaining such necessary proportions as perfectly as possible that the practical apparatus does not entirely resemble the theoretical one that we have just described.

In the model represented in Fig. 3 one of the magnetic fields is produced by an electro-magnet; on the other hand, the vanes of the brake are movable, and they rise in order to preserve the proportionality at great distances in reducing the value of the resistant couple due to the air. The number of revolutions registered upon a counter is proportional to the quantity of efficient electricity furnished to the circuit.

The Financial Aspect of Natural Gas.

By CHARLES HARRISON.

Although the natural gas industry is in its infancy, being but seven years of age in Pittsburgh, the pioneer city, it has had an important effect on commercial enterprise and economic conditions. Throughout the whole area of natural gas production, from Western Pennsylvania to the fields of Indiana, manufacturing has been stimulated, and the production of manufactured commodities and the consumption of raw materials, vastly increased, the effect of which is not limited to the gas producing territory, but is diffused throughout America. The commercial phases of the industry, the advantages arising from the use of such fuel to manufacturers, the comfort and convenience added to the homes of the people, the advancement in material wealth, additional employment to labor, and various other attributes of a substantial nature, have been widely discussed and generally understood. But the purely financial considerations attending this new industry and enterprise have as yet taken form so little removed from the speculative and experimental as to make definite conclusions nearly impossible. Financiers have nevertheless had considerable experience with the stocks of corporations engaged in the industry. Bonds issued in furtherance of such enterprises are occasionally offered, and order is so gradually emerging from chaos that indications of permanent truth and reliable principles are making their appearance.

The first feature presenting itself to financial consideration is that the industry has from its inception been in the hands of companies or incorporations. Individuals have leased territory and produced gas, and they will probably continue to do so; but in all States wherein natural gas has been utilized as fuel, the distribution has been made to consumers by incorporations. One leading reason why this must continue to be the case is that the places of production are at considerable distance from the places of consumption, the intervening territory being occupied and owned by many persons. In order to obtain rights of way for the pipes through which gas can be conveyed, the power of eminent domain is frequently essential, and this is conferred on corporations exclusively. There is no probability that natural gas can ever be successfully handled by private individuals. A large number of corporations have accordingly been organized to conduct the business. Their stocks have been on the public markets, and their values have become, to some extent, known through the quotations obtained from trading in them. The market has varied widely, the same stocks fluctuating between 135 per cent. of their par value and 32 per cent., often without material difference in their dividend earning capacity, the regularity of dividend payment, or any other known reason than speculative causes. At present, to find a natural gas stock on the market worth par is a decided exception, notwithstanding the fact that several have been paying dividends of from 9 to 12 per cent. per annum regularly for a term of years, and are still in a position to continue them.

All natural gas stocks are speculative and subjected to so many influences against which no human foresight can afford protection, that however valuable they may be as immediate profit payers, they have never risen to the dignity of legitimate investments, and there is no prospect that they ever will. They cannot, for many years at least, from the fact that the sources of supply are beneath the earth, where the human eye can never penetrate, and, unlike many other mining operations, the extent of the "vein" or "lode" cannot be even surmised, much less surveyed. That the wells from which the supply is obtained are really exhaustible, howsoever great may have been their output or uniform their pressure for years, has become a demonstrated fact. No inexhaustible natural gas well has yet been discovered, or one which has not suffered a diminution of pressure, though this fact was denied only a few months ago. Increasing demand upon productiveness has led to more rapid exhaustion, and the rate at which companies have been compelled to seek new territory has been accelerated.

All the great companies, a few years ago, were supposed to be in

possession of territory practically inexhaustible, but there is scarcely a great company in existence, after five years of experience, that is not seeking new territory on account of diminishing supply from those fields which promised to be permanent. That several of the companies have been successful in finding new and prolific territory, is matter for congratulation to the stockholders; but such extensions involve expenditure not contemplated in the earlier days of the enterprise. It is evident that the wells cannot be brought to the pipe; the pipes must therefore be extended to the wells. Every new well drilled, and every foot of pipe laid to make its production available (if, indeed, there be any production), causes an additional outlay of capital which would not have been the case had the wells been originally inexhaustible, as contended. New territory adds still more to the disbursements of the corporation, whether it be obtained in fee or on royalties; and the extension of the pipe system is generally much greater to new territory than from line to well in territory already in possession. It therefore becomes a matter of interest in some cases as to whether these extensions of the pipe lines of companies to new wells in the old or in new territory, and the new wells themselves, which have been found to be imperatively necessary to the successful operation of the plant, should be charged to the stock or the expenses account. It is in dispute and undecided; but in case of leased lines, it makes a vast difference where a division of profits is made the basis of rental. Natural gas may be inexhaustible in the aggregate; and the supply may be all that is claimed for it by the most sanguine of those engaged in the industry. But the extensions of lines and additional expense on account of the exhaustion of wells in all known fields, is a truth too well established to be successfully refuted. How far this may have to be continued, with what rapidity it may be required to supply the demand in the future, cannot be known. This very element of uncertainty will always keep the financial aspects of the industry purely speculative, and render it impossible to attain such a settled condition as to make a legitimate investment, or the stocks of the companies such securities as a court would order trust funds to be invested in, whatever present profits or prospective gains of particular companies may be.

From an economic point of view, it is evident that the cost of production of natural gas must increase as long as wells are exhaustible. Territory becomes scarcer and more uncertain, and the plant of companies larger and more expensive to maintain and operate. At the same time the price to the consumer cannot be arbitrarily advanced to meet this increased cost of production, because there has been no exhaustion of coal fields nor of means of transportation. As much solid fuel of all kinds is within as ready reach of consumers as was the case before natural gas was introduced as fuel; besides which new competitors have appeared in the market. The prolific oil fields of Ohio, particularly, have been utilized for fuel purposes, since natural gas was introduced, and they make a highly successful competitor where conditions are favorable to its supply and gas has to be piped a long distance. Beside oil as fuel, manufactured fuel gases are being devised, and have already supplanted coal in some localities. They are claimed to present nearly as desirable economic features as natural gas itself. Competition must prevent any great advance in the price of natural gas. With constantly and inevitably increasing cost of production, and no opportunity for a corresponding cost to the consumer, what is to prevent ultimate bankruptcy of every natural gas company? Clearly, nothing but the economies rendered possible by experience in distribution, or increasing its effectiveness in use. By the knowledge which comes from experience alone can they be saved. The number of gas companies already rendered insolvent, sold out by the sheriff, or absorbed by other more prosperous companies, is a practical suggestion that it takes something more than gas producing territory, a pipe line, and customers to make a successful natural gas plant. Not a company went into operation without all these, but the number of financial wrecks is very large for the length of time the industry has been in progress, and the supposed profit there is in the business. The great problem is whether the advantages of skill and information derived from long experience in the production and distribution of natural gas will be able to keep pace with the continued cost of production. Whether it be possible or not, the conclusion is unavoidable, that the longer the natural gas industry is continued, the more hazardous it becomes for inexperienced persons to embark in it.

The petroleum industry was long recognized as being the most uncertain and speculative of mining operations; but natural gas is even more speculative than petroleum. All the uncertainty in the production of oil is present in the production of natural gas; but in oil the uncertainty ends. Petroleum has a market throughout the world. Gas has no market except at the end of the pipe. Petroleum having been procured,

a variety of ways of transportation are possible. If in barrels it becomes too expensive, the tank car is available; if the tank car costs too much, the pipe line can be laid down; or the reverse order may be resorted to in extremity. But in handling natural gas but one means of transportation is possible. In natural gas the place of consumption is fixed. No further can it go to get a better price. It has all the disadvantages and uncertainties of oil; while in points of conveyance and market it has none of the advantages. In 30 years petroleum has never ceased to be a speculative commodity; the stocks of the companies engaged in the enterprise equally so. Natural gas companies must be even more of a speculative nature for a longer period, if they continue for that length of time.

Besides their stocks, the bonds of corporations engaged in the natural gas business have a degree of financial interest. The amounts thus far issued have been small, and all issues have been under such conditions as to present little from which satisfactory estimates can be formed of the value of such securities. So far as is known, there has been no uniformity in the issues of bonds by various corporations; and the conditions under which they have been made were so entirely dissimilar each to the other, that only general principles can be relied on in approximating the value of any particular class. The value of a bond depends principally, first, on its validity; secondly, on the credit of the corporation issuing it; thirdly, on the market value of the collateral security or tangible property pledged for its redemption; fourthly, on the rate of interest it bears, and the length of time it has to run. Natural gas companies organized and doing business in Western Pennsylvania have issued bonds, but they have been placed through private agencies on private terms, so that very little is publicly known of the value that has been placed upon them. It may be said, however, that the validity has never been questioned seriously; the companies issuing them having been regularly dividend paying institutions as a rule, and hence of good credit. Each company has mortgaged a plant costing far more than the face value of the bonds to secure the payment; and so long as there is a supply of gas, the collateral security is probably unquestionable. But from the exhaustibility of the wells from which the supplies are obtained, the comparative worthlessness of a pipe line having nothing to fill it with, and the constantly increasing expenditures of established companies more particularly pointed out above, the general rule, that the longer a bond has to run the more valuable it is, does not necessarily apply to natural gas securities. Besides these considerations, the risks of the business are so great, and its speculative character so pronounced, that a high rate of interest becomes essential to indemnify against the contingencies of the investment. The securities issued by a corporation partake, to some extent, at least of the speculative character of the business in which it is engaged. The business risks and expenses of a municipality are at least as great as those of a business corporation, and are liable to be much more so. Natural gas trustees are generally gentlemen of success in their vocation, but without practical knowledge of the details of production or distribution of natural gas. Practical affairs inevitably become more risky under inexperienced management than under the direction of experienced men. Bonds issued by a municipality under such management, and having nothing but public credit behind them, cannot be so desirable as those issued by business corporations, whose affairs are conducted by persons of experience in every department, and which give collateral security on their tangible plants as well as the security of experience and actually invested capital.

Improvements on Coze's System.

The *London Journal* points out that an improvement in inclined gas retorts, after the pattern with which his name is now identified, has been patented by M. Andre Coze, of Rheims. This patent covers the form of the retorts, the method of connecting them to the charging mouthpieces, and the construction of the charging truck or wagon. The retorts are for the whole of their working portion of the peculiarly flattened A-shape which M. Coze holds to be desirable for the proper distribution of the charge; but both ends where they pass through the brickwork of the setting are of contracted area. It is claimed that by this means the disengagement of the gases is greatly facilitated, while the coal is distributed in a regular manner throughout the retort, and choking of the upper end prevented. The charging mouthpieces are made with sockets to fit on the ends of the retorts; and the bends by which the inclined axis of the retort is changed into the vertical are made with duck-feet in order to take their weight off the retorts. The alteration of the charging truck consists in making it carry as many tilting hoppers, provided with automatic closing gates at their lower ends, as may be required for use at one time. Thus, supposing a setting of three retorts to be in use—or,

which amounts to the same thing, three retorts out of a large setting require to be charged at the same time—a truck would be made to take the three tipping shoots, and this would save time. The shoots are provided with means for checking the too rapid fall of coal, or of large lumps, which might otherwise choke the opening into the retort below. It is regarded as an essential feature of this combination that the retort, the charging mouthpiece and the tilting hopper should together at the time of charging constitute a continuous passage for the distribution of the coal in the retort.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE Asbury Park (N. J.) Gas and Electric Light Companies have an understanding whereunder each refuses to supply light to parties that are in arrears on the books of either Company. There is sound sense in a combination of that character.

AT a special town meeting (Wakefield, Mass.) it was voted not to grant the Citizens Gas Light Company the privilege of erecting poles and stringing wires over the streets for the purpose of furnishing electric currents for light and power.

THE Western Gas and Fuel Company has been incorporated at East St. Louis by Messrs. Henry O'Hara, Jos. W. Shepard and Henry D. Sexton. It is capitalized in \$500,000, and its objects are the manufacture and sale of gas for illuminating and fuel purposes.

THE Peoples Gas and Electric Company, to operate in the villages of Palmyra and Riverton, N. J., has been incorporated by Messrs. Charles H. Edgerton, W. H. Miller and Israel Roberts. It is capitalized in \$50,000. The Company will construct and operate a gas and electric light plant. These are adjoining villages in Cinnaminson township, Burlington county, N. J., and are about 8 miles northeast of Camden. The joint population must be close to 5,800 souls, and both places are growing rapidly. There can be little doubt that a venture of the sort proposed will insure a fair rate of profit from the start.

MR. JOHN LILLIE, President of the newly incorporated Port Townsend (Washington) Gas and Fuel Company, writes us that the projectors are preparing to build their works, and expect to have the same in operation on or before next October. Port Townsend is the capital of Jefferson County, is on Puget Sound near the Strait of San Juan de Fuca, at a point about 44 miles northwest of Seattle. It has an excellent harbor, and is being developed rapidly. To show how its natural facilities for commerce have attracted the attention of those constantly on the lookout for such situations, we may note that ten years ago its population was returned at 593, whereas to-day it shelters no less than 6,500. Further, Mr. Lillie estimates that by the close of the year it will give residence to 10,000 people.

AT the annual meeting of the Grand Rapids (Mich.) Gas Company the following Directors were elected: Messrs. Thomas D. Gilbert, Noyes L. Avery, H. D. Walbridge, Wm. D. Gilbert, Chas. F. Rood and Philo C. Fuller. The Directors made quite a radical change in the personnel of the officers of the Company. Hon. Thos. D. Gilbert has been Secretary and Managing Director of the Company for many years—from its organization almost. He has in that time made the Company one of the best in the country, and while it has been profitable to its owners, it has also been considerate to its patrons, who have had the benefit of good gas at extremely low rates. In consideration of his years of activity the Directors determined to put the clerical labor on someone else, as their choice of officers will show. In organizing they made the following appointments: President, Hon. Thos. D. Gilbert; Vice-President, Noyes L. Avery; Secretary and Treasurer, H. D. Walbridge. In their annual report the Directors say they are "gratified to be able to report a very satisfactory condition of the property of the Company, and nearly the usual annual increase in all departments of its business." Commenting on the use of electricity, the report says: "The increase in the output of gas has been somewhat affected by the experiments now being tried by several of our large customers in the use of electricity. We have no fears for the future in our competition with electricity, unless very great economies can be introduced in its generation and distribution. As an offset to any future developments in that direction we are constantly doing something in the way of improving methods and economies in management, while our residual products are constantly increasing in value. It is well known that the price at which gas can be sold at a profit depends largely on the quantity that can be disposed of after the means for its production are established. The people of Grand Rapids

have always been liberal patrons of the Gas Company, and we have endeavored to meet them more than half way by always keeping our prices at the lowest point consistent with reasonable dividends on our investment. We can point with pride to the fact that while the average price at which gas is sold in the United States is about \$1.85 per 1,000 feet, in this city it is \$1.14, while some of our largest customers have it as low as 90 cents. The wisdom of our Common Council in never having given serious encouragement to an opposition gas company is clearly shown by the fact that among the 20 cities in the Union where opposition companies have been given franchises there is no competition, and in not one of them is gas sold as cheaply as in this city. The low price at which gas is sold here has encouraged its use, for cooking and heating, and the sale of stoves is rapidly increasing. The Common Council has also come to the conclusion that gas is the best and most economical means of lighting the streets, and when they give us permission to light the lamps 'all dark hours,' instead of by moonlight schedule, every one will be satisfied."

WE congratulate the management of the Grand Rapids Company on the success that has attended their efforts, the greater part of which, however, we make bold to assert, is fairly chargeable to the unremitting attention and liberal policy that have always been marked features under the administration of President Gilbert.

MR. KEPLINGER has introduced into the Lower House of the Maryland Legislature a measure which affects the Baltimore Consolidated Gas Company. Briefly stated, the leading features of the Keplinger scheme are appended: Sec. I. declares that the price of gas in Baltimore shall not exceed the sum of \$1.25 per 1,000 cubic feet. If at that price the clear yearly profit of the Consolidated Gas Company, and in this Act called "the Company," shall exceed 6 per cent. per annum on the capital stock, to be paid as a dividend to the holders of said stock, the excess beyond that sum to the extent of 1 per cent. per annum upon said capital stock shall from time to time be invested in dividend-paying securities, including the bonds of several companies, of which "the Company" is a consolidation, and the dividends and interest arising from such securities, in order that the same may accumulate at compound interest until the sum so accumulated shall equal in amount the bonded indebtedness of "the Company," when, or as soon thereafter as it shall become due, said bonded indebtedness shall be paid, and that all excess of clear yearly profits of "the Company," beyond a sum sufficient to pay a dividend of 6 per cent. per annum to the stockholders as aforesaid, and 1 per cent. per annum with which to pay the bonded indebtedness as aforesaid, shall become the property of the city of Baltimore, and to be paid into the treasury of the city. Section II. provides that the books of "the Company" shall be open to the Commissioners of Finance of Baltimore, who shall report to the Mayor of said city annually what amount of the clear yearly profits of "the Company" the said city shall be entitled to under the first section of the Act, and "the Company" and its officers shall offer all reasonable facilities for such inquiry, and refusing to do so shall forfeit its charter. Section III. provides, in consideration of the performance by "the Company," it shall have the exclusive right to make, distribute and sell illuminating and heating gas in Baltimore, for the period of 25 years from the passage of this Act. Section IV. provides that the ordinary remedies at law and equity shall apply to all questions arising under the Act. Section V. provides that the Act shall become effective on June 1st, 1890.

WE also understand that another measure will be introduced at this session of the Legislature, the gist of which is that the Consolidated Company shall pay to the city the sum of \$10,000 per annum in return for an exclusive franchise to furnish gas at the rate of \$1.25 per 1,000, for a period of 25 years.

MR. FRANK W. PENWELL, one of the purchasers of a recently-acquired controlling interest in the Danville (Ills.) Gas Company, also acts as President of the local Merchants Electric Light and Power Company.

ON January 28th Mr. E. C. Jones received his appointment as Assistant Engineer of the Boston Gas Light Company. This is in addition to the position as Superintendent of the North End Station. His office will be at the North End plant.

PETITIONS are being circulated in Massachusetts for signature, the intention of the movers therein being to ask the Legislature to pass a general law under which cities, towns and villages may operate lighting plants on municipal account.

JOHN H. ELLIOT has been elected President of the Keene (N. H.) Gas Light Company, Mr. Geo. M. Rossman continuing to act as Treasurer and Superintendent.

SOME time ago August Evering, of Vincennes, Ind., determined to satisfy an incredulous local public that coal existed in paying quantities underneath the soil of Vincennes. Undismayed by their adverse prophecies Evering's shaft eventually reached the coveted material, and the prophets changed their tune from ridicule to adulation. Having raised about 5,000 pounds of the coal to the surface, it was decided that the product should be sold publicly at auction on a given day; and when the hour was at hand almost all Vincennes was within sound of the auctioneer's voice. The first bid was \$20, which was followed by many others, or until the sum of \$100 was announced, at which figure the black diamonds were knocked down to Mr. George G. Ramsdell, who remarked that "although the material came high," he had "to have it."

Two days afterward the successful bidder succumbed to the advances of *la grippe*, from which we hope he will speedily emancipate himself.

GOSSIP in Belleville, Ills., is to the effect that negotiations were on foot which had for their object the consolidation of the Belleville Gas Light Company with the Brosius Electric Light Company, which now has the contract for the public lighting. Mr. Abend, who is largely interested in the Gas Company, was interviewed on the subject, and admitted the proposition had some advocates, but that he was opposed to it. He further said: "The Belleville Gas Company can furnish artificial lighting at a rate below that which could be made by any other company. I am in favor of reducing the rate for gas to \$1.50 per 1,000 from the first of April, and if the Council will afford the opportunity, I am in favor of submitting an offer of \$15 per post per annum for gas lighting, and to supply arc lamps west of Illinois street for \$75 per annum each."

WE do not see how the Council can very well overlook Mr. Abend's proposition, since the city is now paying the Brosius Electric Light Company \$120 per annum, each, for the arcs in service. The contract, however, under which this work is being performed—it is a three-year agreement—expires by limitation on April 30th. Perhaps it is from this circumstance that the Brosius Company's owners favor consolidation with the Gas Company; and likely it also is that Mr. Abend's opposition to the amalgamation is based on the fact that the Belleville Gas Company, having struggled with the competition of the past three years, ought not now to be used as an instrument for propping the waning fortunes of the local electricians.

THE plant of the Chillicothe (Mo.) Gas, Electric Light and Water Company has been sold by Receiver W. E. Gunby, for \$50,000, to Mr. Alexander G. Black, of New York. The latter will, in conjunction with his associates, make many improvements on the property.

THE proprietors of the Talladega (Fla.) Gas and Water Company have voted to bond the plant, the proceeds to be applied to extensions and betterments.

MR. HENRY W. BOND, attorney for the Laclede Gas Light Company, has requested Mayor Noonan for the necessary time wherein to prepare and file a written opinion on the bill recently passed by the Municipal Assembly reducing the price of gas from \$1.25 to 90 cents per 1,000. Mr. Bond contends that the city has no right to regulate the price of gas, since the Laclede Company has filed with the city its acceptance of the conditions imposed by the St. Louis Gas Company's amended or substitute charter.

TOWARD the close of January a hearing was given at the Chelsea (Mass.) City Hall, by the Board of Gas and Electric Light Commissioners, on the petition of J. B. Everdean and others, that the Chelsea Gas Company be obliged to supply incandescent electric lights on the basis of a meter system. Mayor Champlin opened for the petitioners in the statement that it cost the objector something to stand in antagonism to the Chelsea Gas Company, as it always had a monopoly of the gas business in the city. This rather poorly defined sentiment was followed by another equally absurd remark that as the Chelsea Gas Company was controlled or owned by non-residents no care was had by it in respect to the interests of the community, who had to pay unreasonable rates for light. After other partisans of the Mayor had echoed the sentiments of their leader, the Gas Company's representative replied that it was ready and anxious to introduce the meter system as soon as it was demonstrated that a reliable electric current meter had been put upon the market. The Commissioners reserved their decision.

IN view of the cogency of the Chelsea Company's implied objection to the meters now in the market we fail to see how Mayor Champlin and his "echoers" are to be appeased; for finally the Board cannot be expected to solve a problem off-hand that has caused and will cause many a sleepless night to the inventive division of the electrical fraternity.

THE American Gas Engine Company has been chartered at Chicago, by Messrs. Chas. Fellows, C. W. Annable and H. C. Johnson. Capital, \$200,000.

WRITING under date of Jan. 30, a correspondent says: "At the annual election of the Washington (O.) Gas Co. the following officers were elected: Pres., Morris Sharp; Sec. and Treas., Jerome Penn. Supt. Penns' annual reports show an increase over the half year, despite the competition of electric light, which displaced nearly half of the public lamps, and also took away quite a number of private consumers. The following are some of the percentages of increase: Gas used by private consumers, 18 per cent.; meters in service, 20 per cent.; gas stoves sold, 110 per cent.; gas engines in use, 100 per cent.; the company has leased a large room (18 ft. by 80 ft.) which will be used for an office and a workshop, from and after the first inst. The company expects to keep on hand a good supply of gas stoves and fixtures, and intends to make every possible effort to increase the use of gas for cooking and heating. The company's new dynamo was started last night. This gives it a capacity for 100 arcs, 51 of the latter being now in duty on the streets, and 25 are employed commercially. The company has a contract with the authorities for additional public lights, which will be placed this summer. The new bench of 5's put in last season worked satisfactorily, and another bench will be installed this summer.—J. P."

SECRETARY PENN has met with great success at Washington Court House, and his figures are vouchers that bear most eloquent testimony to the fact.

THE following Directors have been chosen by the proprietors of the Centralia (Ills.) Gas Company: Messrs. S. M. Warner, E. S. Condit, F. Kohl, G. L. Pittinger, Seymour Andrews and F. M. Tomkins.

By the breaking of an oil gauge on the apparatus in the generating room of the Macon (Ga.) Gas Company, an explosion occurred that threatened disastrous consequences. The coolness and bravery of Supt. Wilcox alone prevented a tremendous explosion.

THE authorities of Lincoln, Nebraska, have again appointed a "City Gas Inspector." This time his name is E. J. Flaherty.

AT the annual meeting of the Pulaski Gas Light Company of Little Rock, Ark., the following officers were chosen: President, Maj. John D. Adams; Treasurer, Charles F. Penzel; Secretary, Dean Adams. The officers and Messrs. John G. Fletcher and J. H. McCarthy are the Directors.

THE Trustees of the Consolidated Gas and Electric Light Company, of Westchester County, New York, are Chas. B. Ludwig, H. S. James, A. B. Gilbeck, H. M. Henderson and Leonard G. Levy.

THE City Council of Fort Worth, Tex., has completed the plan under which the city is committed to the operation of a municipal electric lighting plant. The Edison United Company is to make the installation, and the contract calls for a plant equal to the maintenance of 308 incandescent lamps (from 25 to 32 candle power each) and 42 arcs, candle power of latter to be 2,000 nominal. The Edison Company is to receive \$27,000, and the authorities estimate that "other expenses" will bring the total cost of the installation up to \$40,000.

JUDGE PHELPS, of the Burlington, Iowa, District Court, has refused to grant an injunction prayed for by the Burlington Electric Light and Power Company in restraint of the Burlington Gas Light Company. Plaintiff contended that as the Gas Company was operating an electric light supply, without authority of a franchise for such operation, it should be ordered to cease such supply, and that the city should at once remove the Company's poles from the streets. In denying the injunction, Judge Phelps said that the Gas Company could operate its electric plant without special franchise, as long as the "fact of its operation advanced the public good."

THE plant of the Batavia (N. Y.) Gas Light Company has been sold to certain parties, who were represented in the preliminary negotiations by Mr. W. C. Jacobs. It is probable that Rochester (N. Y.) capitalists

are those now in control, and we think they have secured a good property.

AT the annual meeting of the Hoosick Falls (N. Y.) Gas Light Company the following officers were elected: President, Walter P. Warren; Vice-President and Secretary, C. A. Cheney; Treasurer, Willard P. Parsons; Directors, Walter A. Wood, Walter P. Warren, C. E. Dudley Tibbets, C. W. Tillinghast and C. A. Cheney.

A. R. TAYLOR, on behalf of Daniel Donoghue, of St. Louis, has brought suit, in the sum of \$5,000, against the 1889 Board of Trustees of the St. Louis Gas Company. Complainant (who was an employee of the Company), on September 11, 1889, was injured by the caving in of the walls of a pipe trench, and this suit is to recover damages for injuries to person.

AT the annual meeting of the Youngstown (O.) Gas Company the following officers were chosen: President, George Tod; Secretary and Treasurer, P. T. Caldwell; Superintendent, Moses Coombs, Jr.; Directors, George Tod, C. H. Andrews, John C. Wick, W. J. Hitchcock and A. B. Cornell.

THE Mahoning Electric Light Company's proprietors also effected an organization identical with that of the Youngstown Gas Company.

AT the annual meeting of the San Francisco (Cal.) Gas Light Company Messrs. J. B. Crockett, Adam Grant, Levi Strauss, P. J. Donohue, D. J. Murphy, Ch. de Guigne and Geo. W. Prescott, were chosen Directors. In his annual report President Crockett reported that a greater quantity of water gas had been manufactured at the works in the last twelvemonth than in any previous year, though the manufacture of same was suspended during June, July and August, on account of a scarcity of oil supplies. The sales of gas were $37\frac{1}{2}$ millions cubic feet greater than in 1888. The number of street lamps lighted was 5,355, an increase of 175. There had been a net gain of 1,653 consumers. Much attention had been given to main renewals and extensions. Secretary Barrett's report showed net assets amounting to \$7,070,599. The cash in the treasury applicable to dividends is \$370,020, which would seem to show that shares in the Company are a bargain at present quotations. During the year 12 monthly dividends of 30 cents each per share were paid, the disbursements on this account amounting to \$360,000.

THE proprietors of the new Gas Company at Duquoin, Ills., have determined to sell gas at the following figures: For lighting, \$1.50 per 1,000; for cooking and heating, \$1.25 per 1,000.

AT the annual meeting of the Bristol (R. I.) Gas Light Company the following result was reached: President, Hon. R. S. Franklin; Sec., Treas. and Supt., J. Howard Manchester; Directors, Hon. R. S. Franklin, J. C. Swan, Col. Augustus P. Sherman, A. C. Church and J. H. Manchester.

ARGUMENT is now on in the Supreme Court of Pennsylvania, on the appeal of the Penn Gas Coal Company from a Common Pleas (Westmoreland county) decree refusing to grant a preliminary injunction against the Versailles Fuel Gas Company. The Penn Company is the owner of six tracts of land in Westmoreland county, with the right to remove all the underlying coal without liability for damage, and over the surface of this land the defendant proposes to lay its pipe lines, which will necessitate the leaving in place of about 50 acres of coal, of a value of at least \$30,000. It is also alleged that the pipe is being laid in a way dangerous to life and property. Decision is expected in a few days.

THE net gas rate at Cambridge, Mass., is to rule at \$1.60 per 1,000 from April 1st. This is a reduction of 15 cents.

THE Wallingford (Conn.) Gas Company is experimenting with a high power gas burner for street lighting purposes.

AT the annual meeting of the Malden and Melrose (Mass.) Gas Light Company the officers' reports were of the most encouraging nature. The increase in sendout over that for 1888 was much beyond the hopes of the shareholders. A quarterly dividend of 2 per cent. was declared, and the following officers were elected: President, Joshua T. Foster; Treasurer, Geo. D. Bill; Directors, J. T. Foster, Geo. D. Bill, A. M. Copp, D. V. Cox, J. H. Converse, L. P. True, E. S. Converse, D. W. Gooch, L. B. Hildreth and D. Russell.

MR. PETER ENGLISH, in connection with G. D. Lewis, visited Galesburg, Ills., with a view to "working up a healthy sentiment" for the establishment at the latter place of an opposition gas plant of the English process type. They believe that it will require \$100,000 of nominal capital to start the Galesburg venture, of which 50 per cent. is to be paid up, and they would like residents of Galesburg to take half of the sum required. They "point with pride" to the success of the English plant at Aurora, Ills., where a 24-candle gas is said to be sold at \$1.25 per 1,000. In reality, Aurora is far from satisfied with the English system of gas making and supply, and the complaints about poor service are frequent and loud. In the meantime Galesburg capitalists might do well to look over these facts prior to putting down their names in Mr. Lewis' subscription book. The city has a population of about 12,000, who are now consuming about 8 millions cubic feet of gas per annum, the rates for same being \$1.50, \$1.60 and \$1.80 per 1,000. At these rates the Company manages to earn a dividend. Start another Company, capitalized in \$100,000, then divide the profits arising out of the maximum sales noted, and where will shareholders in either concern receive a return? If Galesburg's capitalists are wise they will not only refuse to invest in this scheme, but will join together in keeping a franchise for an opposition company from all comers. Another company would put an end to Galesburg's opportunity in the future for cheap gas.

Influence of Temperature on Electric Tests.

The *Engineering Record* asserts that the question of temperature bears an important part in all tests of wire employed for electric transmission, since the resistance, both of metals and insulating materials, varies with the temperature.

Thus, we find it stated that the resistance of iron wire increases about 0.35 per cent. for each additional degree Fahrenheit, while the resistance of copper wire increases about 0.21 per cent. for each additional degree Fahrenheit. According to the Washburn & Moen Manufacturing Company, Dr. Mattheisen's report of the British Association Committee on Standards of Electrical Resistance states that hard iron varies between zero and 100° Centigrade (32° and 212° Fahrenheit) as much as 39.2 per cent., while German silver varies only 4.4 per cent. An alloy of silver with 31.4 per cent. of platinum varies only 3.1 per cent. For the best resistance coils some metal or alloy is used that is affected as little as possible by variations of heat.

It is necessary, for the sake of comparison, to fix a standard of temperature to which all tests shall be reduced. Cully gives this standard at 75°, a temperature high enough to exaggerate faults in insulation, yet not so high as to injure the material. Sprague says 60° F. is the most convenient for the adjustment of resistances. In this latitude, where for months a temperature so low as 60° is not reached, from 70° to 72° is found to be a more convenient scale, and it has been adopted by the Standards Department at Washington.

Luminous Paint.

Until recently the commercial manufacture of luminous paint has been confined to England, where a single factory turned out a small supply at a price of about \$3 a pound. This enormous cost seems to have prevented the use of the paint except as a curiosity. During the past year, however, a firm in Austria has found means to produce it and place it on the market at 50 cents a pound, or about one-sixth of the English price. Even at 50 cents a pound, a substance composed of roasted oyster shells and sulphur might be manufactured at a good profit, but at that price it is likely to come into extensive use. Wherever it can absorb light during the day it will give it forth at night, and it is said that a railway car in England, which has had its ceiling painted with it, was so brilliantly illuminated that one could see to read a newspaper in it during the darkest night, without other light. With all due allowance for the enthusiasm of early experimenters, there is no doubt that cars with ceilings so painted would be pleasant to ride in whether one could really see to read in them at night or not; and for making keyholes, stairways and sign-boards luminous, the paint would be invaluable. Its application to stairways is a particularly obvious one, and the Austrian manufacturers furnish a kind of wall paper on which the paint can be used to better advantage than on the bare plastering. The paper, which is of a leathery texture, is first treated with lime water, and then primed with a composition, furnished by the same firm. After this is dry, two thin coats of the luminous paint are applied, and the whole may then be varnished.

The Market for Gas Securities.

The market for city gas shares, in common with other stocks that suffered from the persistent hammering of those interested on the "short" side of the speculative turn, was inclined to dullness, although prices suffered very little. The truth is, that the quantity of Consolidated stock available for some time back for speculative purposes has been greatly curtailed in the last six months. The shares have found their resting place in the "strong boxes" of investors; hence, on a weak general market the effect is not exerted on quotations, but is shown in a cessation of stock offerings. On one day of the week only 5 shares were sold on Exchange. The bid figure to-day (Friday) is 96½, as against 96½ a week ago. Brooklyn shares are strong, notably Nassau, which is at 115 bid, with no offerings. Baltimore Consolidated is again at the advanced price of a fortnight ago, 54½-55. Chicago Trusts are strong at 47¼ bid. Bay State common is in demand at from 23-24½. We omitted to note in its proper place that Standard, of New York city, is again being inquired after. The common is quoted at 42-46, while the preferred rate may be returned at 83-86. Laclede common is weaker at 16½-17¼.

In connection with the Baltimore gas supply, well informed people think that an arrangement will be perfected by the Maryland Legislature under which the Consolidated Company will, in consideration of certain concessions to the city, be granted an exclusive right for a term of years.

Gas Stocks.

Quotations by Geo. W. Close, Broker and Dealer in Gas Stocks,

**POSITION WANTED.
 A Mechanical Engineer,**

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked. Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal,
 765-1f or Box 972, West Bay City, Mich

Position Desired

By a man of practical experience in TESTING, SETTING, and REPAIRING METERS, STOVE WORK, COMPLAINTS, LAYING OF MAINS, SERVICES, ETC. Could manage a works of 20 millions. References A1.

766-2 "J. J. D.," care this Journal.

Position Wanted

As Superintendent or Assistant of a Gas Works, By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address

765-5 "M.," care this Journal.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

SECRETARY, 123 Beale Street,

760-3 mos. San Francisco, Cal.

FOR SALE.

**A Complete Water Gas Plant.
 60,000 Cu. Ft. Daily Capacity.**

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

FRIEDRICH LUX,

Ludwigshafen am Rhein and London.

**Lux Mass
 GAS GOVERNORS,
 Gas Balance.**

FOR SALE,

One 5-ft. Station Meter.

One Hydraulic Main (five sections), wrought iron, 22 by 24, with Bye-Pass on Dip-Pipes.

25 Valves, Stand-Pipes, 7-inch Mouthpieces and Lids, all complete, ready for use, to fit up five benches of 5's.

This apparatus is all in first-class condition.

Price, \$800, f.o.b. cars or boat, Poughkeepsie, N. Y.

Inquiries may be sent to this Office.

Fuel and Its Applications.

By E. J. MILLS, D.Sc. F.R.S., and F. J. ROWAN, C.E., assisted by others, including Mr. F. P. Dewey, of the Smithsonian Inst., Wash., D. C.

7 PLATES, AND 607 OTHER ILLUSTRATIONS. ROYAL OCTAVO, PAGES XX, 802. HANDSOME CLOTH, \$7.50.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owners of the RECENT Mackenzie Patents,

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day.

The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn, Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES or other RETORTS, NOR THEIR EQUIVALENTS, are used.

Neither COAL, COKE, nor any other, HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD.

The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM.

The Gas requires NO PURIFICATION whatever.

The FUEL GAS COSTS VERY MUCH LESS than PURE UNCARBURETED WATER GAS, and contains DOUBLE THE HEAT UNITS.

The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE, and consists of a Single Body with a capacity of ONE THOUSAND to ONE HUNDRED THOUSAND cubic feet per hour.

Works may be constructed to run by the CONTINUOUS or ALTERNATING method. If run continuously, the limited amount of Nitrogen present is neutralized by Carbon.

The Gas can be made of a HIGH GRADE for illuminating purposes, of a MEDIUM QUALITY for distribution for domestic purposes, and of a LOW GRADE for manufacturing uses.

Wherever Liquid Hydrocarbons can be had the MACKENZIE PROCESS WILL COMPETE IN PRICE AND SUPPLY ALL THE ADVANTAGES incidental to the use of NATURAL GAS.

This Company desires contracts for the construction of Plants, parts of Plants, Apparatus, Buildings, Holders, and Street Mains, for either of the above purposes, and will Lease or Purchase Works upon satisfactory terms.

Information will be promptly given regarding material required for production of Gas, actual cost of product, cost of works, etc.

STANDARD GAS LAMP CO.,

Main Office, 411 Cherry St. Factory, 1101, 1103, 1105 Frankford Av.

PHILADELPHIA, PA.

It is to the interest of Gas Companies and Cities to double the efficiency of the light on streets by using Dyott's Patent "CHAMPION" LAMPS. They save 50 per cent. over others in cost of repairs, are ornamental, and indestructible except by violence.

Our Patent System of Instantaneously Lighting Gas (without electricity), for Railroad Depots is unequalled.

Dyott's High Candle Power Burner is a very superior lamp where a concentrated and brilliant light is wanted in Hotels, Stores, Depots, etc.

Special Drawings furnished and Estimates cheerfully given, either from Architects, Engineers, or our Draughtmen's Plans.

We manufacture every description of Plain and Ornamental Lamps, Posts, Brackets, Clusters, etc. Correspondence solicited.

The Gordon Portico Lamp.

A successful Competitor of the Arc Electric Light for lighting Store Fronts, Show Windows, Depots, Railway Sheds, etc., etc.

Gordon Portico Lamp.

The Gordon Street Lamp.

A Successful Competitor of the Arc Electric Light for lighting Streets, etc., etc.

Gordon Street Lamp.

The Lungren Lamp.

A Successful Competitor of the Incandescent Electric Light for Interiors, etc. Is especially applicable for the lighting of Offices, Stores, Factories, Mills, Show Windows, Libraries, and all situations where an increased illumination is desired.

More than 25,000 Lungren Lamps are now in use. Testimonials, references, or any desired information will be cheerfully given.

Lungren Lamp.

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

JEWEL GAS STOVES

MANUFACTURED BY

GEORGE M. CLARK & COMPANY,

GUARANTEED ESTIMATES of Cost of Gas Furnished on Application.

GASHOLDER TANK CONSTRUCTION, ETC.

Gas Companies and others about to erect Gasholders will find it profitable to consult
 W. C. Whyte, who for over 30 years has made a specialty of

Tank Excavation and Mason Work.

Fifty Tanks now in operation show the sort of work done. Address

W. C. WHYTE, - No. 15 Cortlandt Street, N. Y. City.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE."

Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used *in every State in the Union*, and purifying daily over *thirty-five million cubic feet*. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR.

Has been on the market but *three years*, and in that time has been introduced *more generally* than any invention ever designed for use in gas works. Over *two hundred* of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is *complete* without one of these machines.

STEAM JET EXHAUSTER.

Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for *mixing air* with oil gas. *No works* too small to use them profitably.

Prices given on all our specialties *delivered at any point in the United States*. Correspondence solicited.

E. STEIN, Sec.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

No. 32 Pine Street, - - - New York City.

ENGINEER AND CONTRACTOR FOR THE

Erection and Extension of Gas, Water, and Electric Light Works.

SOLE REPRESENTATIVE OF THE

McILHENNY REGENERATOR FURNACE PATENTS

And the Martin Water Gas Process.

Edison Incandescent and American Arc Electric Light Plants Installed.

Correspondence with Gas Companies contemplating extending or improving their Plants respectfully invited. Plans and Estimates Furnished.

GAS COALS.

CANNEL COALS.

GAS ENRICHERS.

JAMES D. PERKINS. **PERKINS & CO.,** F. SEAVERNES.
228 & 229 Produce Exchange, New York.

Cable Address, "PERKINS, NEW YORK."

Post Office Box 3695, New York.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to

Agency for U. S., Room 93, Nos. 2 & 4 Stone St., N.Y. City.

The Standard Oil Company,

REFINERS OF

NAPHTHA AND GASOLINES.

ALSO MANUFACTURERS OF

A Special Grade of Naptha for Gas Companies

FOR ENRICHING COAL GAS.

Correspondence solicited.

No. 43 Euclid Avenue, Cleveland, Ohio.

To Gas Companies.

[OFFICIAL NOTICE.]

New England Association of Gas Engineers.

SECRETARY'S OFFICE, BIRMINGHAM, CONN., Jan. 30, 1890.

The Twentieth Annual Meeting of the New England Association of Gas Engineers will be held at Young's Hotel, Boston, on Wednesday and Thursday, Feb. 19th and 20th. The meeting will be called to order by the President, Mr. Robert B. Taber, on the 19th inst., at 10 o'clock A.M. It can now be definitely stated that the following papers will be read sometime during the meeting:

"Vaporization and Feed of Oil to Generator or Retort," by W. R. Addicks, of Boston, Mass.

"Municipal Control of Gas and Electric Light Companies," by Dr. Robt. Amory, of Brookline, Mass.

"Management of Small Gas and Electric Light Plant," by S. J. Fowler, of Westfield, Mass.

"Some Experiments in the Photometer Room," by N. W. Gifford, of New Bedford, Mass.

"A Point or Two in Regard to Illuminants During Condensation and Purification," by George F. Goodno, of Dedham, Mass.

"Notes on Revivification of Oxide," by Waldo A. Learned, of Newton, Mass.

"Various Methods of Introducing Gas Stoves," by H. A. Norton, of Boston, Mass.

"A Few of the Advantages of Water Gas over Coal Gas for Small Works," by F. H. Parker, of Burlington, Vt.

"The Difference between Eastern and Western Methods in the Management of Gas Works," by E. G. Pratt, of Des Moines, Iowa.

"Why I Shall Make Water Gas," by A. B. Slater, of Providence, R. I.

"A Chapter of Don'ts," by W. H. Snow, of Holyoke, Mass.

"Some Notes Taken in a Small Gas Works," by Ralph Woodward, of Waltham, Mass.

"Problems Constantly before the Gas Manager," by E. H. Yorke, of Brockton, Mass.

In addition to the above there are partially promised several other papers. I think all the members who see this notice will agree that, judging by the above list, the coming meeting bids fair to be a greater success than any of the meetings which have been held in previous years. The topics are quite varied, and many of the subjects are among the most important that gas managers have to deal with at the present time.

The officers of the Association believe that no member of the Association, and no one connected with the active business management of any gas company in New England, can afford to be absent from this meeting. Persons eligible for membership and desiring to join the Association will please apply at once to the Secretary, who will forward them blank applications. Although the membership is large, there are still a good many persons connected with the gas business through New England who do not belong to the Association. It is hoped that all such persons will see fit to join at the coming meeting, and make the Association what it ought to be, truly representative of the gas interest in the New England States.

Invitations have been received to visit the Commercial Point and Bay State gas works in Boston, also the Loomis Fuel Gas plant at Waltham, which will add materially to the pleasure of the coming meeting.

CHARLES H. NETTLETON, Secretary.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., January 20, 1890.*To Members of the Ohio Gas Light Association:*

Gentlemen—The Sixth Annual Meeting of this Association will be held at Toledo, O., on March 19 and 20, 1890.

This announcement is made thus early in order that all members may be reminded of the meeting in ample time to make their arrangements to be present. Every member is urged not only to attend this meeting, but also to interest himself in inducing others of his acquaintance who are eligible for membership, but who have not as yet joined the Association, to come to the meeting and become members.

It is not intended that as many papers as usual shall be presented at the forthcoming meeting, in order that more time than formerly may be had for the discussion of those that are read, and for such other matters and business as the members may desire to dwell upon.

Although the Secretary has for some time been engaged in the work of soliciting papers for this meeting, he has not yet secured as many as should be had, notwithstanding fewer are desired than heretofore, and he therefore earnestly calls upon all members who can possibly do so to notify him immediately of their willingness to furnish papers.

It has been decided that an interesting and valuable feature of our meeting would be a "Question Box," in which members can place questions, which will be withdrawn and read to the meeting and answered and discussed by the members. Every member is requested to send to the Secretary at once any question or questions which he would like to have thus brought before the meeting.

Future circulars will announce further details concerning the meeting.

Respectfully, IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

ATTEMPTING TO SETTLE THE BALTIMORE (MD.) GAS QUESTION—Readers of the JOURNAL have from time to time been advised of the approach toward a settlement of the matter of regulating gas rates in Baltimore, which settlement is noteworthy from the fact that its plan is based on protection to the Gas Company. The Armstrong measure was somewhat crude and its conditions were such as to antagonize the Gas Company, hence there is slight reason for believing that it will ever become law. As hinted in our last another bill (to which we believe the proprietors of the Consolidated Gas Company are not altogether averse) has been presented to the Legislature, the substance of which is shown in the following lines from a correspondent at Baltimore:

"A gas bill, which it is intended shall be reported from the Committee on Corporations as a substitute for the Armstrong bill, has been handed in. The bill provides that the Consolidated Gas Company shall have the exclusive privilege of manufacturing and furnishing gas for 25 years in the city of Baltimore, at \$1.25 per 1,000 cubic feet. In consideration of this privilege the Company is to pay into the city treasury the sum of \$10,000 per year. If the Company shall declare a dividend amounting to 3 per cent. a year, then they shall, in addition to the \$10,000, pay to the city 3 per cent. upon the 3 per cent. dividend. That is, if a 3 per cent. dividend is declared upon the present \$11,000,000 of stock, or \$330,000, the city is to get 3 per cent. upon that sum, or \$9,900, making, with the \$10,000, a total payment to the city of \$19,900 per annum. That is the full amount which the bill proposes to give the city, for there is no provision to increase the payment in the event of the Company earning, say, a 6 per cent. dividend. Mr. Colton, in committee, has amended the bill to provide that if at any time the average charges for gas in the cities of Brooklyn, New York, Boston, Jersey City, Philadelphia and Washington shall be less than the price charged in Baltimore, then the Consolidated Company shall sell gas at less than \$1.25. Another amendment provides that if at the end of ten years no dividend is declared by the Consolidated Gas Company, then the exclusive feature of the bill shall lapse. It is quite likely that this bill will be endorsed by the Legislature."

PERSONAL.—Mr. H. C. Leonard, of the Portland (Oregon) Gas Light Company, sailed from this port for Europe, per steamship Trave, on the 8th inst. He goes abroad for a pleasure trip.

MR. SAMUEL J. FOWLER has been appointed to the Superintendency of the Springfield (Mass.) Gas Light Company, vice Mr. J. L. Hallett, resigned. Mr. Fowler has for some time back been Superintendent of the Westfield (Mass.) Company.

RECOMMENDING A CHANGE IN THE MASSACHUSETTS CARBONIC OXIDE REGULATIONS.—The Board of Gas and Electric Light Commissioners (Mass.) have submitted to the Legislature the following draft of a bill proposing to alter the current restrictions in the matter of the percentage of carbonic oxide that may be retained in illuminating gas as distributed in that State—the Commissioners "strongly recommend" the passage of the measure:

"Section I.—The Board of Gas and Electric Light Commissioners may, on such terms as it deems prudent, license any gas company now or hereafter authorized to make gas for illuminating purposes to make and sell water gas for such purposes containing any percentage of carbonic oxide that said Board may determine; and may at any time, after notice to a company so licensed, alter or revoke the license.

"Section II.—The percentage of carbonic oxide allowed, and the terms and conditions imposed by said Board, shall be stated in the license, a copy of which the Company shall cause to be delivered to each of its customers; and if the Company holding the license does not exceed the limit of carbonic oxide so fixed, nor violate any of the terms and conditions contained in the license, it shall be exempt from any penalty or prohibition provided in section 14 of chapter 61 of the Public Statutes relating to carbonic oxide.

"Section III.—Chapter 428 of the Acts of the year 1888 is hereby repealed.

"Section IV.—This Act shall take effect upon its passage."

EXPLOSION AT THE ST. PAUL (MINN.) GAS WORKS.—The following letter explains itself:

THE ST. PAUL GAS LIGHT COMPANY, }
St. Paul, Minn., Feb. 10, 1890. }

To the Editor AMERICAN GAS LIGHT JOURNAL:

An explosion of gas occurred at 5.50 P.M., Saturday, the 8th inst., in our condenser room, damaging the building to the extent of some \$5,000, killing one man and injuring three others. This room is at the end of our retort house, separated by a heavy brick wall, and contains an exhauster, condenser and scrubber. The building and machinery were new, and the structure was well ventilated. The force of the explosion laid low the four walls, completely wrecking this portion of the building; but fortunately the machinery, as well as the benches in the adjoining room, suffered no damage; hence we will be able to repair the building and have the plant in operation in about 8 days. As yet we are unable to give any cause for the accident. Mr. A. D. Cressler and the writer were in this building 40 minutes previous to the explosion, and found everything in perfect working order—Mr. C. declaring our arrangement and machinery the very best. The night foreman was in this room two or three minutes prior to the accident, and declares that the machinery was working all right, with no indication of leakage. As soon as possible we cleared away the debris, in order to get the condition of seals and Huntoon governor, which we found full of water and perfectly sealed, making out the explosion to be still a greater mystery. The portion of our works containing the water gas apparatus was in no way impaired—being entirely separated from the coal gas plant—hence we were able to maintain the regular supply of the city without interruption. Daniel Desmond, the man who lost his life, was an old-time gas man, and well known to many of the gas fraternity. He came to St. Paul with Mr. Kennedy some 30 years ago, and has been in the employ of this Company during the entire period. He assisted Mr. Kennedy in the construction of this plant, and was for many years Superintendent; of late he has had charge of the street department. He was a faithful and conscientious man, and most worthy of the esteem and confidence in which he was held by this Company and all with whom he came in contact. The injured men were employed as stokers in the retort house. Should we discover the source of the accident while overhauling the machinery, etc., shall take pleasure in rendering the JOURNAL a full account of it.

Very respectfully, B. F. ELLISON, Genl. Supt.

The Market for Gas Securities.

Consolidated is at 96½, or within a quarter of a point of the price reported in our last. There is nothing of interest to note in connection with the shares, which are being withdrawn from the market every day. Brooklyn shares are steady to strong. We note the following sales at auction: 4,000 Williamsburgh 1st mortgage 6's at 111½; 223 shares Williamsburgh gas, at 121½; 50 shares Brooklyn gas, at 111½; 25 shares Nassau gas, at 120½; 100 shares Consolidated gas, at 96½; 50 shares Flushing (L. I.) gas, at 161; 500 shares Peoples gas (Brooklyn), at 80. Chicago Trusts are weaker, influenced no doubt by the attempt on the part of the authorities to reduce the gas rate to \$1 per 1,000. Laclede common is weak, at 16-18, while Bay State common is inquired for at 24-25. We note a sale of 6 shares of Petersburg (Va.) gas, at 144. The Citizens Gas Light Company (Brooklyn) has named the following Directors: S. E. Howard, John P. Rolfe, E. J. Dennison, J. W. Gordon, John Byrne, S. A. Lathrop and F. S. Smith.

M. Sainte-Claire Deville's Study of Coal Gas.*

Writing in respect to certain conclusions arrived at by him in his connection with the Paris (France) gas works, M. Deville says :

I have found that if gas taken at the exit of the meter at the commencement of the charge, *i. e.*, rich, but not tarry gas, be superheated, it requires a very intense heat applied to a slow stream of gas to produce any perceptible difference between the heated and unheated gas. The difference thus produced consists in the loss of about 12 per cent. of its benzine, and 35 cent. of its other hydrocarbons, absorbable by bromine, accompanied by the deposition of carbon in the porcelain tube, and production of naphthaline and anthracene.

If, instead of superheating the gas after purification from tar, it be heated together with the volatile products formed during the distillation, the results are the same as regards the benzine and rich hydrocarbons, so that all that can be concluded is that benzine resists a high temperature better than other hydrocarbons. This question, as to the relative amounts of benzine formed during the successive periods of the distillation, which is of theoretical interest, requires further investigation.

However this may be, we know sufficient to be able to affirm that, among all the hydrocarbons which contribute to the illuminating power, benzine is the only one which exists in considerable amount throughout the whole of the distillation.

Experiments carried out on the laboratory scale show that, speaking generally, a high temperature favors its production.

It remains to be learned whether the proportion of benzine depends on the temperature of the coal at the precise moment of decomposition, or on the temperature to which the volatile products are submitted after their formation, during their passage along the red hot walls of the retort.

Recapitulation and Conclusions.—The two chief subjects treated in this article are :

(a) The classification of gas coals according to their elementary composition.

(b) A study of the amount of benzine contained in the gas, and on the part played by this hydrocarbon in affecting the illuminating power of the gas.

I. At the experimental works of the Paris Company, during the last twelve years, 1,012 coal tests have been carried out, 36,000 kilos being employed for each test.

Of these 1,012 tests, 898 have been made with coal from 23 sources, that from each source having been tested on the average 39 times.

The average results of this large number of experiments are therefore free from variations due to accidental deviations from the normal character of the coal, and consequently clearly show the influence of the composition of the coal upon the various properties of the gas, which are of interest to the gas manufacturer.

The basis selected for this classification is the amount of oxygen contained in the coal, which is considered to represent the combined water, and thus to be the best indication of the geological age of the coal and of its degree of carbonization.

By dividing the coals tested into five classes of types, containing increasing amounts of oxygen, from 5.5—12 per cent., and by calculating the average results from each type, the following conclusions have been arrived at :

As the coal becomes richer in oxygen, the gas produced by its distillation becomes gradually richer in heavy constituents—carbonic acid, carbonic oxide, marsh gas, and illuminating hydrocarbons, and poorer in pure hydrogen.

Its density and illuminating power both increase. It is also to be observed that the proportion of volatile matter, determined by calcination in a crucible, also increases, even when the amount of combined water is deducted.

The volume of coke remaining in the retorts becomes larger as the percentage of oxygen diminishes. The products of condensation (tar and ammoniacal liquors) increase with the amount of oxygen.

Considering the five types of coal, it is found that type III. comprises the best gas coals, those namely which give a rich gas and yet leave a fair quantity of coke of good quality. Types I. or II. give inferior gas, but much coke.

The remaining classes—IV. and V.—give a rich gas, but their coke is small in quantity and of poor quality.

II. The benzine contained in gas may be estimated by simply weighing the products condensed at -22° , and adding to the weight thus found per cubic meter (moist at 15°) a constant equal to 23.5 grms.

I have shown :

(1.) That air artificially charged with a known weight of pure benzine deposits the whole of this at -70° , and that the amount which condenses between -22° and -70° , is exactly equal to 23.5 grms. per cubic meter (dry at 0° 1,760 min.); this number agrees with that calculated from Regnault's numbers for the vapor pressure of benzine.

(2) That gas treated in the same manner deposits, whatever be its composition, 247 grms. of liquid between the same temperatures, from every cubic meter measured dry at 0° 1,760 min., which corresponds to 23.5 grms. per cubic meter, moist at 15° .

(3) That the liquid thus deposited consists of almost exactly 23.5 grms. of pure benzine, mixed with a little toluene, xylene, etc.

Applying this method of determination under very varied circumstances, I have arrived at the following conclusions :

(a) The average gas of the city of Paris contains 39 — 40 grms. of benzine per cubic meter, composed of :

Pure benzine.....	77
Other hydrocarbons of the aromatic series....	23
	100

From 7 — 8 per cent. of the weight, and from 1 — 1.1 per cent. of the volume of the gas is therefore made up of benzine vapor.

Independently of benzine, the gas contains 4 — 4.5 per cent. by volume of hydrocarbons incombustible at 70° .

The illuminating power of the gas is found to be :

Due to benzine.....	65
Due to other hydrocarbons.....	35
	100

(b) The various qualities of gas may be classed in two symmetrical groups with—

I. Rich, or comparatively rich, gases.

- A. Produced from oxygenated coals.
- B. Obtained by distillation, at a low temperature.
- C. Evolved during the first stages of distillation.

II. Poor, or comparatively poor, gases.

- A. Produced from coal poor in oxygen.
- B. Obtained by distillation at high temperatures.
- C. Evolved during the last stages of distillation.

(1) The weight of benzine contained in a cubic meter of gas is almost the same in all six varieties.

(2) The benzine obtained from gases of the second group is a little richer in pure benzine, and, consequently, a little poorer in toluene and cumene, etc., than from those of the first group. The difference is small but clearly marked.

(3) Rich gases of the first group at the moment of leaving the retort are at a lower temperature than those of the second group, or, to speak more accurately, the temperature of the coal at the exact moment of decomposition is higher for gases of the second group than for similar ones of the first.

We see, therefore, that rise of temperature appears to have the effect of progressively destroying the hydrocarbons of the olefine and acetylenic series, and also those of the aromatic series, with the exception of benzine; of producing, or, at least, of not destroying benzine; of producing pure hydrogen; and finally, of forming naphthaline, anthracene and graphite.

These results may, therefore, be considered as an industrial confirmation of Berthelot's theories on the subject.

(c) As regards illuminating power, benzine plays a secondary part in very rich gases, an important part in gases of average richness, and is almost the sole source of the light given by very poor gases. If the whole quantity of benzine present in a gas be removed by refrigeration to 70° , and the loss of illuminating power thus occasioned divided by the weight condensed (which is almost constant for all gases), it is found that the quotient, which expresses the candle power of one gramme of benzine burnt in 100 liters of gas, is much higher for poor than for rich gases.

The limits actually observed are 0.040 candles and 0.250 candles.

This proves that if gas, itself devoid of illuminating power, be progressively enriched with a hydrocarbon, that the illuminating power of the mixture increases much less rapidly than its richness in illuminating material.

It is necessary to remark that these facts have only been proved by applying to all gases, rich or poor, the photometric method founded on the use of the Bengel burner.

It would be interesting to study the variation of illuminating power when each gas was burned at a burner suited to its composition, as the Bengel burner is adapted to the average Paris gas.

* See JOURNAL, Nov. 4, 1889, p. 633.

A Test of an Otto Gas Engine.

By EDGAR KIDWELL and EDWIN R. KELLER.

[An abstract of a test made by the authors for a graduating thesis in the Department of Mechanical Engineering, University of Pennsylvania. The article originally appeared in the *Journal of the Franklin Institute*.]

Methods.—The engine experimented on was a 7-horse power (nominal) Otto type engine. The volume of the cylinder and clearance space was determined by filling with water and found to be 0.439 cubic feet for the total volume, and 0.1796 cubic feet for the clearance space, leaving 0.2594 cubic feet for the volume swept through by the piston each stroke.

The gas used during the test was passed through a large meter, and thence through rubber bags to the cylinder, a portion passing through a second meter, being taken from the same supply for the jet.

The pressure of the gas used was taken by a manometer attached to the supply pipe, and the absolute pressure of the gas was found by adding to this reading that of the standard signal service barometer. The temperature of the gas was taken as that of the room, the meter, bags and pipes being practically entirely within the room. Samples of the gas were taken for analysis. The amount of cooling water used was weighed by allowing it to discharge in a vessel for periods of ten minutes during the test, the water running at practically the same quantity per minute throughout the entire test. The temperature of the water before and after leaving the cylinder jacket was taken by thermometers placed as shown in Fig. 1, which also shows the position of a Brown's

pyrometer placed in the exhaust pipe of the engine. The length of pipe between the cylinder and pyrometer was carefully covered with asbestos board, preventing radiation to a great extent.

The power developed in the cylinder during each explosion was determined from a mean indicator card constructed as described below, the power given off by the engine being absorbed by a friction brake on the fly-wheel.

The speed was taken every five minutes by a revolution counter and stop-watch.

It was found necessary to limit the duration of the tests to one hour at a time, because of the heating of the fly-wheel. The engine was started and allowed to run an hour; the brake was then put on, and after the engine had settled down to steady condition the test began. It was continued for an hour, the brake was removed, and the engine kept running until the wheel cooled down, when the brake was replaced and another set of observations made. The total duration of the tests, that is, the actual time during which the observations were made, was three hours, ten minutes.

Apparatus.—The thermometers used were made by Henry J. Green, of New York, and read to degrees Fahrenheit. The pyrometer used was made by Edward Brown, of Philadelphia, and was graduated at intervals of 10° to 1,200° F. The revolution counter used was of the endless screw and wheel type, reading to single revolution. The stop watch read to one-fifth second. The meters used were a large one, made by the Goodwin Meter Company, for gas engine tests, and an ordinary 7-light meter made by the same Company. The scales for weighing the water read to 1/100-pound.

The apparatus used for analyzing the gas was an Elliott apparatus, similar to that used at the International Electrical Exhibition, in 1884.

A Crosby indicator, with a 100-pound spring, was used throughout the test.

The bulbs of the thermometers used for measuring the temperature of the jacket water were inserted in thin metal cups screwed into the pipe connections, as shown in Fig. 1, the lower one being kept full of water, and the upper one of oil.

The following are some of the results of the test :

Date, Jan. 19, 1889.	
Time of test.....	3 hrs. 10 m.
Temperature gas.....	62°.2
Temperature of exhaust.....	774°.28
Temperature of entering water.....	50°.43
Temperature of exit water.....	89°.19
Manometer, inches water.....	3.06
Barometer (reduced to pounds).....	14.85
Total gas used, cubic feet.....	344.4
Gas for ignition.....	9.625
Average revolutions per minute.....	161.6
Explosions missed per minute.....	6.83

Computation.—As the test was rather for determining the distribution of the head developed by burning the gas, or for getting data for determining its efficiency as a heat engine rather than as a machine, and as the observing force was limited, the brake horse power was not taken.

The indicator cards were worked up in the following way. Fig. 2 is

Indicator Diagram of Otto Gas Engine. Mean of 42 Cards. Scale, 25 lbs = 1" 3/16 in. ft = 1' Speed, 161.6 Revolutions per minute. Area card = 22 sq. in. Mean effective pressure = 59 lbs.

a mean card obtained as follows: On each of the 42 cards taken 28 lines were drawn at right angles to the atmospheric line as shown, and the pressure of the bottom and top of each card was read and tabulated. From the mean of these tabulated values the card shown in the figure was drawn. From this card the horse power was calculated as follows:

- Mean pressure for card = 59 pounds.
- Mean pressure per foot = 59 × 144 pounds.
- Value of stroke in feet = .2594.
- Work per explosion = 59 × 154 × .2594 ft. pounds.

$$\text{Explosion per minute} = \frac{161.6}{2} - 6.83 = 73.97.$$

$$\text{Horse power} = \frac{73.97 \times 59 \times 144 \times .2594}{33,000} = 4.939.$$

It will be noticed that the exhaust and admission parts of the diagram are omitted, as they practically coincided with the atmospheric line.

In addition to finding the work done, the mean card was used to determine the general equation of the expansion, compression, and explosion part of the diagram.

In determining these curves the part between ordinates (8) and (28) was taken for the compression curve in the calculation; the explosion curve was taken to embrace all the upper curve between (23) and (28); and the expansion curve was taken to cover all the upper curves between (5) and (18).

The expansion and compression curves were assumed to vary according to a law $p v^n = c$, in which p is the pressure in pounds per square inch and v = the volume in cubic feet of the mixture, while c and n are constants. By taking the values of p and v , as given on the mean indicator card by the method of Least Squares, the most probable values of n and c were determined.

The equation to the curve of expansion was found to be

$$p v^{1.4385} = 15.901,$$

and for the compression curve was found to be—

$$p v^{1.5313} = 3.7557.$$

The explosion curve was found to be practically a parabola, whose equation is—

$$y = -1.788 x + 32.833 \pm \sqrt{89.423 x - 1588.61}, \text{ in which}$$

$$y = \frac{p}{10}, x = 100 v.$$

The broken lines on Fig. 2 show the curves corresponding to the equation, and the following table gives the errors by calculation:

Expansion Curve.

v	p from Equation.	p from Card.	v	p from Equation.	p from Card.

.19139	97.10	97.01	.20908	121.91	122.49

Heat.

From the mean indicator card it was found that the mean pressure was 59 pounds per square inch, and the work performed per explosion was 59 × 144 × .2594 (volume passed through by the piston) = 2203.8 foot pounds. This is equivalent to—

$$\frac{2203.8}{772} = 2.854$$

heat units transformed into work at each explosion.

From the amount and temperature of the jacket water it was found that 461.92 heat units were carried away per minute by the cooling water. Or, as there were 73.97 explosions per minute—

$$\frac{461.92}{73.97} = 6.24$$

heat units removed per explosion by the cooling water.

The following gives the results of the tests of the gas used as determined by the Elliott apparatus:

	By Volume. Per Cent.	By Weight. Per Cent.
CO ₂50	1.923
C ₂ H ₄	4.32	10.520
O.....	1.00	2.797

H ₂ O.....00139464
N added.....00710110
N.....00016190
01005594

The heat carried off in the products of combustion is—

	Heat Units.	Per Cent.
In H ₂ O (steam).....	1.9291	
CO ₂2149	
N.....	.2438	
Heat carried off in exhaust.....	3.4049 = $\frac{3.40}{12.44}$	= 27.93
Heat converted into work.....	2.85	= 22.91
Heat taken by jacket water.....	6.24	= 50.16
Total heat accounted for ..	12.49	100.4
Total heat received.....	12.44	

These calculations are made on the supposition that the amount of air supplied to the cylinder is just enough to cause complete combustion, and are given for what they are worth. That they are, at least to a certain extent, justifiable can be seen by the following:

.00079346 pounds of gas occupying $\frac{334.78 \text{ (cubic feet, total)}}{14054 \text{ (no. explosion)}}$ cubic feet, at 62.2° F. and a pressure of 14.96 pounds per square inch, requires .00923373 pounds of air to completely burn it.

It is fair to suppose that just before the mixture of gas and air is compressed it has the temperature of the cylinder, which must be about that of the jacket water, or 89.19° F. The gas occupies a volume of

$$\frac{334.78}{14054} \times \frac{548.59}{521.6} \times \frac{14.96}{14.85} = .02523 \text{ cubic feet.}$$

.00923373 pounds of air at 14.85 pounds per square inch and a temperature of 89.19 occupies .22985 cubic feet. The total volume occupied by the gas and air is therefore .25508 cubic feet. The clearance volume was filled with the products of combustion at this same pressure and temperature before the mixture of gas and air was drawn in. The incoming gas and air should therefore fill a volume equal to the stroke displacement, or .2594 cubic feet, and we have therefore a volume of air = .2594 — .25508 = .00432 cubic feet of air drawn in, but not used, a quantity that we can omit in our calculations.

Water Gas for British Gas Works.

By C. J. R. HUMPHREYS.

[Communicated by the author to the *London Journal*.]

I have been very much interested in the article which appeared in the *Journal* for Nov. 19, last year (p. 962), entitled, "Is Water Gas Possible for British Gas Works?" wherein you—very justly, I think—make the point that at this time it is not wise to declare that water gas is inadmissible to British gas works. The article interests me particularly, as I have been using water gas in connection with coal gas at my own works; and on this general question I should like to speak at length. I will, however, reserve what I have to say on the point for another time; and will consider in the present communication that portion of your article in which you deal with inclined retorts in connection with the manufacture of water gas. This is a very interesting phase of the question, because, admittedly, where water gas is to be used as an auxiliary in connection with the manufacture of coal gas, the coke resulting from the manufacture of gas by the regular process is the fuel which should be used in the production of water gas—firstly, because the fuel is right at hand; and, secondly, because it disposes at once of a portion of a residual product which at times is nearly a drug on our hands. Obviously, then, the scheme is to convey the coke from the retorts to the cupolas with the least possible amount of labor; and if the heat which the coke possesses when it leaves the retorts can be retained till it is deposited in the cupolas, there is a very decided gain. I believe that in some gas works in this country—notably the Kansas City (Mo.) works—the coal is conveyed from the retorts (which are horizontal, fired by generator furnaces) to the cupolas in buggies; but clearly more labor is involved in the scheme than would be required if inclined retorts were used, and so disposed that the coke from them would drop readily into the cupolas—or generators, as perhaps they are more commonly called. In fact, it was when the manufacture of fuel gas came under consideration, and the imperative necessity of reducing the labor per 1,000 cubic feet of gas manufactured to the lowest point was apparent, that the advantages of inclined retorts presented themselves. From these investigations there grew the fuel-gas process of Messrs. A. C. Humphreys and Walton Clark, which combines the inclined retorts for the manufacture of coal gas and the generators for the production of water gas.

In the article to which I have already referred, the statement is made that the combination of the inclined retort and the water-gas generator is made use of in more than one fuel-gas process; but, as far as my knowledge goes, it is only used in the Humphreys-Clark process. As I have had an opportunity of making a cursory examination of the experimental plant which has been put up at Jersey City, N. J., to show the working of the process, a short description of the scene may not be without interest; reserving for a future occasion a more extended description of the plant, with an account of the results obtained. Concisely stated, the works consist of two benches of inclined retorts, and a generator in front of each setting adjacent to the lower end of the retorts; and the dampers and valves are so arranged that the "blow" gases from the generators can be passed round the retorts of either or both of the settings, or they can go direct to the stack, or any portion of the waste gases can be lead to the settings, and only the balance allowed to escape through the chimney. In working the plant, the coal (ordinary bituminous gas coal) is conveyed to the upper end of the retorts on an overhead track in buggies with openings in the bottom through which the coal is dumped on to a shoot, which guides the coal into the mouth of the retort. The arrangement of the shoot is somewhat peculiar, and of such a nature that the angle it makes with the mouth of the retort can be quickly changed. By experiment, it has been determined what is the proper angle to employ for different kinds of coal; consequently it is found easy in practice to discharge the coal from the buggies into the retort so that the coal will be spread evenly over the length of the latter, without any danger of running through the retort into the channels connecting the generators and the retorts. The coal is baked in the retorts in the usual time—viz., four hours—during part of which the water gas from the generators is allowed to flow through the retorts; the hydrogen absorbing most of the lighter hydrocarbons which in ordinary distillation pass off as tar. From the retorts the combined gas passes through a hydraulic main, and is drawn by an exhaustor through condensers, scrubbers, etc. At the end of the period of distillation the red hot coke is pushed from the retorts into the generator. During this process it is not found necessary to remove the lid, as, by a peculiar plunger device, the coke is readily pushed from the retort. By this means the retort is, in a few seconds emptied of the coke resulting from the carbonization of 250 lbs. of coal. The retorts are

heated by the waste heat of the gases which pass off from the generators during the time of "blowing up;" and the interiors of the retorts are heated by the passage through them of the hot water gas made during the run.

It will thus be seen that the process embodies many economies—the utilization of a portion of the waste or "blow" gases from the generators; the absorption of a portion of the heat of the water gas (which those who have made water gas know to be an item of importance); and the conservation of the heat which the coke possesses as it passes from the retort. Add to this the almost infinitesimal amount of labor involved—the term is not too strong when we remember that all the labor required besides working the valves is the filling of the coal buggies and conveying them to the elevator—and the licking up of the tarry vapor by the water gas in the retorts (for it is found that very little tar is collected in the drips), and we have the promise of a very cheap gas. The resulting gas is, of course, a mixture of coal and water gas of but very low illuminating power, but exceeding in heating effect many of the so-called fuel gases. Add to this scheme an oil carbureter and superheater, and by the use of 2 gallons of Lima crude oil per 1,000 feet, a good illuminating gas could be produced. We thus see the vast possibilities of such a plan—not in the fuel gas field alone, but also, and perhaps to a far greater extent, in that of illuminating gas, unless the future development of the plan brings to light some unforeseen and untoward obstacle.

I hope to be able, in the near future, to take up this matter again, and describe the plant more in detail, and give more information in regard to the nature of the gas produced.

Device for Charging Gas Retort Furnaces with Hot Residual Coke.

Mr. G. R. Hislop, of Paisley, Scotland, has been granted English letters patent (No. 3,391, Feb. 26, 1889) for an invention the object of which is to provide means for directly charging gas producers and gas or shale oil retort furnaces with hot residual coke from the retorts heated by such furnaces, in lieu of transferring the hot coke into buggies and charging the furnaces therefrom.

To that end there is formed a mouthpiece upon a crown plate which is bolted on the top of the projecting brick breastwork of the retort oven and over the ordinary cleaning and charging doors; and therefrom there is formed a shoot extending downwards and rearwards through the upper front wall of the furnace at such an inclination as to discharge the fuel at or near the middle of the furnace. This mouthpiece is furnished with a self-sealing door operated by levers; and it has hinged or jointed to it a hopper which may be raised and held by a

catch close up against the front of the retorts, or lowered and retained (by the same or a separate catch) in such a position that it forms an inclined plane over which and through the mouthpiece the hot residual coke drawn from the retorts is discharged directly into the producer or furnace.

Fig. 1 is a front elevation, and Fig. 2 a side elevation, showing the hopper and part of the front of the retort oven. Fig. 3 is a detailed view of the door covering the shoot leading from the hopper.

The crown of the producer is terminated preferably in an arch of brickwork A; and through the top a port or shoot B is formed for the

passage of the coke into the producer. The upper or arched portion is bound together by metal jacket plates *C*, securely bolted to the front plate *D* of the producer and the front of the oven *E* respectively. The front plate is furnished with an upper door *F* to facilitate the cleaning of, and a lower one (not shown) for withdrawing the ashes from, the producer. On the top of the jacket plates and over the opening *B* for the passage of the coke, a cast iron crown plate *G*, with doorway *H*, is fixed at a suitable inclination from the face of the oven. The doorway *H* is furnished with ears and stop snugs, and is planed on its face and fitted with a corresponding door or disc *I* hinged on a pin passing through the one ear and held by a jamming lever *J* on the other. The disc *I* at the back passes under pocket plates fixed on snugs to define the travel and fix the position of the disc. On top of the pins passing through the ears and hinging the disc and jamming lever, adjustable journaled *K* are formed to receive and carry the axis pin of the charging hopper *L*. The latter is preferably ovular in form and expanded at the mouth to the width of the retort or retorts above. The hopper is preferably placed immediately under the central retorts of the oven; and by casting the hinged oscillating disc *I* sufficiently thick on its lower edge to reduce the angle of inclination, it, when shut, holds the outer edge of the hopper within the line of the retort mouthpieces, and simultaneously with allowing the disc *I* to fall out of position, by reversing the jamming lever *J*, the hopper *L* also falls to the necessary angle to receive the contents of the retorts above it, which are shot into the producer at such an angle as to deposit them in the center of the furnace.

The Walker Gas Washer.

United States letters patent (in supplement of English letters patent, No. 14,925, granted October 17, 1888) No. 420,751 were granted, on the 4th inst., to Mr. William T. Walker, Highgate, England, for certain improvements in apparatus to be used in the purification of coal gas. In his specification, Mr. Walker says:

This invention has reference to apparatus for purifying coal gas—such, for example, as the apparatus described in the specification of letters patent No. 245,527, of August 9, 1881—in which apparatus surfaces are alternately submerged in liquid and raised by a vertical reciprocal dipping movement, so that they when raised present a freshly wetted surface to the gas to be purified, which passes in contact therewith.

Apparatus of this description is very liable to become clogged and inoperative by the accumulation of dense matters; and it is the object of this invention to overcome that objection, to reduce the first cost of the apparatus, and to simplify it and generally render it better adapted for use, as hereinafter described.

iron, to contain the wetted surfaces, the said frames being open at the bottom and at the sides. They are operated by a reciprocating vertical dipping movement, and the said boxes are at each downward movement entirely submerged, so that the liquid scours and washes the said surfaces, and any thick or dense matter is carried freely off and discharged clear of them. The surfaces contained in the said boxes may be made of any suitable material; but Mr. Walker prefers for the purpose either

plain iron plates or thin boards of wood, *b*, which may be connected together in groups by bolts, *b*², passing through all the plates or boards. Distance pieces are placed between the plates or boards to keep the proper spaces between them. They are supported at their ends upon the angle bars *b*⁴. The said plates or boards *b* are set vertically and a free-way is left between them to allow the dense or thick matter to be washed freely from them. The said spaces are entirely free and open at the bottom and at the sides, as shown clearly at Fig. 5, and there is also a space between the tops of the said plates or boards and the top of the box *B*, as at *b*³ in Fig. 3, to allow of the free passage of the washing liquid. Thus arranged the apparatus is adapted for purifying the gas as it passes from the condensers to the purifiers, and it may be used either in place of or in combination with the ordinary apparatus for purifying gas by oxide of iron or lime. He effects this by isolating the interiors of the superposed tanks *A* from each other by a gas tight seal, consisting of an inverted bell *C*, which is secured to the casting *B*, and that in turn is secured to the operating shaft *D*. The said bell *C* dips into a vessel *E*, secured to the tank and containing liquid, so that the joint is maintained by the liquid as the shaft *D* reciprocates vertically. The gas inlet passage to each tank is, at *F*, external to the said seal and between the opposite sets of wetted surfaces *b b*, and receives the gas to be purified, preferably, from a flat connecting passage *G* beneath each tank *A*, and with a mouth at each side of the machine—one for the attachment of the branch from the inlet main and the other at *g*⁵ for facilitating cleaning. The machine, thus having each of its superposed tanks *A* isolated one from the other, and so constructed as to bring its inlets and outlets to its exterior, can be arranged with a system of connecting pipes and valves, enabling the gas which is to be purified to be brought into communication with any chemical agent, in either or any of the tanks, in any order desired. Thus the gas, after having its tar extracted in the lowermost portion of the machine, may be conducted from No. 1 tank through all the tanks above to No. 6 tank, or either of the tanks may be by-passed; or the gas may be conducted so as to work right round in a circuit. For example, it may be conducted first to tanks Nos. 5 and 6, and thence to tanks Nos. 1, 2, 3 and 4. These connections and valves, as shown in Figs. 1 and 2, are as follows:

Figures 1 and 2 are elevations at right angles to each other (the lower parts being in section) of an apparatus arranged according to the new method. Fig. 3 is an enlarged section of a part of the same. Fig. 4 is a horizontal section on the line 1 2, Fig. 3. Fig. 5 is a vertical section on the line 3 4, Fig. 4.

According to the plan frames *B* are constructed preferably of cast

X is the general inlet main, having a branch *x* and a valve *x*² to each tank leading into the passage *G*. *Y* is the general outlet main, having a branch *y* and valve *y*² to each tank. *W* is a main for working or by-passing any of the tanks, the said main having inlet branches and valves *w*, outlet branches and valves *v*, and by-pass valves *u* to each

tank. *T* is the return main for conveying the gas from No. 6 tank at the top to No. 1 at the bottom, and *t* is its valve. *S* is a pipe for conveying the gas from No. 5 tank to No. 2, and *s* are its valves. *R* is a pipe for conveying the gas from No. 1 tank to No. 5 tank, and *r* is its valve. *Q* is the general by-pass main for by-passing the whole of the tanks, and *q* is its valve. *P* are the liquor overflow pipes for conveying the purifying liquids from one chamber to another, and *p* are their valves. The gas inlet is shown by the arrows in the lower part of Fig. 1; *N* is the tar well; *M* is the apparatus for reciprocating the boxes *B*.

Device for Testing the Gradients of Pipes.

Mr. J. Leslie Anderson, of Newcastle-on-Tyne, England, recommends the use of the simple instrument herewith illustrated as a ready means for testing the gradients of pipes. The inventor has used it with unvarying satisfaction for a term of years.

By simply laying it on its side over a detail of the required gradient the instrument can be at once adjusted, there being no need to mark a scale of gradients on the slide, although that could be done if desired.

The Vagaries of the Electricians.

The *Gas World*, in commenting on certain proposed electric installations in England, remarks:

The vagaries of the electric light are so pronounced that the exhibition of the same undesirable qualities by its professors does not strike the observer as a thing surprising. We are accustomed to hear so many contradictory opinions expressed by the electricians that one more or less does not affect the general result—they are all taken by sensible people *cum grano salis*. We would not for a moment suggest that the many eminent men who have associated themselves with electric science wilfully endeavor to mislead the public; rather would we say that it is a case of the blind leading the blind. In this country we have a body of consulting electrical engineers whose names are honored and respected throughout the length and breadth of the land—they are recognized as men who have attained the highest scientific distinction—but so far as the commercial side of their particular science is concerned they are but as babes. The operations of the practical workers in the realms of electricity have up to now been upon so limited a scale, comparatively speaking, that consulting engineers have not yet had placed at their disposal the data necessary to a uniformity of opinion. They can ascertain the price of a dynamo, the price of a lamp, and the price of a yard of copper wire; but there is very little to guide them to a proper estimate of what these three are capable of when coupled up, or how long they will last. The multiplication of "systems" is another complicating element. The consulting engineer may have some reliable data concerning a continuous-current low-pressure installation; but then his note-book fails him when he wants to compare this with any other kind of installation. The truth is the consulting engineers are groping in the dark, and they have not the courage to confess it. Data is what they require, and, judging from the slow progress the Deptford scheme is making, practical workers are not in a hurry to supply their wants.

We have before us a recent example of what we have indicated above. For an electric light works to supply 10,000 sixteen-candle power lamps in St. Pancras, Prof. H. Robinson, M.Inst.C.E., estimates the cost at £49,731; for an installation of the same size in Brighton, Mr. Shool-

bred's estimate is £30,000—practically a difference of £20,000. The systems are different and the localities are different; but each engineer thinks his system the best, and the difference of locality cannot amount to much, seeing that neither estimate includes the cost of a site. Of Mr. Shoolbred's report to the Brighton Council we have little to say, beyond congratulating that gentleman on the bold manner in which he solves the problem which has been puzzling the heads of scientists ever since electricity became known. He says: "It may here be mentioned that the words 'current' and the 'flow' thereof, still popularly used in speaking of electrical matters, are not intended to mean any actual translation of matter. Those words imply more precisely that the molecules forming the conducting wires are thrown, by the exciting magnetism of the dynamo, into a temporary and unstable condition of disturbance, and that this artificial condition is communicated from one molecule to its neighbor, and so throughout the length of the conductor." We cannot say that Mr. Shoolbred's definition is incorrect; we can only remind him that it is not yet generally recognized.

Professor Robinson's report to the St. Pancras Vestry, an abstract of which appeared in our last issue (pp. 100, 101), calls for more detailed notice, inasmuch as, if hurriedly read, it may lead to erroneous conclusions. Professor Robinson deals with both big and little figures. The big ones are comparatively plain, but the little ones must be studied to be understood. Briefly stated, the scheme which he has recommended to the St. Pancras Vestry, and which the Vestry has adopted, is this: A central station to produce current for 10,000 16-candle incandescent lamps; neighborhood of central station to be supplied direct at low pressure; outlying districts to be supplied from five transformer stations worked from the central station by continuous high-pressure current; transformer stations to be also storage stations (with about two hours supply in store!). The cost of erecting the central station and the transformer stations (with the necessary generating plant and storage batteries, and six miles of mains capable of supplying 25,000 lamps) he estimates at £49,731. This does not include the cost of a site for the central station, the Vestry, we believe, having vacant land whereon it can be erected. These works he estimates equal to produce 600,000 watts—530,000 to the incandescent lamps, 20,000 to 40 arc lamps to be used for street lighting, and 100,000 watts of leakage—introducing a point upon which data is much required.

The annual cost of running the installation next engages Professor Robinson's attention. The current supplied to the arc lamps in the streets he charges at 3½d. per unit, and the total cost per lamp per annum (including lamplighter, which is evidently a misnomer) he places at £38 11s. 4d.—£1,542 13s. 4d. for the forty lamps. The two hundred gas lamps which the forty arcs will displace cost only £560 per annum, but then Professor Robinson triumphantly exclaims that the increased cost will result in an increase of 1,300 per cent. in light. If those who put forward this statement could only realize what it means they would abstain from their folly. But at present we are concerned with Professor Robinson's figures, not his fancies. As we have seen, he puts the cost of supplying an arc lamp at £38 11s. 4d. per annum, but to this we have to add the cost of the lamps themselves. "The prime cost of the forty arc lights, if erected in the cheapest possible manner, would be," says the Professor, "£1,000." No provision for renewals, for interest, or for redemption of capital appears to be made. Five per cent. would be a very low estimate to cover the omissions. Add five per cent. to £38 11s. 4d., and we get £40 9s. 10d. as the annual cost of an arc lamp—£1,620 for 40 arc lamps, against £560 for 200 gas lamps! If this is the best St. Pancras can do so much the worse for St. Pancras. In most towns in the United States, were gas is so dear, the electric light companies would be ashamed to charge such a price as this.

It is where Professor Robinson deals with the cost of producing the electric current that his report becomes most misleading. For 10,000 lamps he estimates an annual consumption of 800,000 units, and the cost of producing this he puts at 2.80d. per unit. To this, however, he adds 0.75d. for sinking fund (does this include interest?)—making the cost 3.55d. per unit. But if this be correct, it is astonishing that we have not heard of any dividend being declared by those companies who are charging 8d. per unit. To talk about 3½d. per unit when 7d. or 8d. is the usual price may be an alluring bait to the St. Pancras householder at the first glance, but let us see how matters would stand with him were he to get the electric light at Professor Robinson's cost price. For 1,000 hours electric light: 60 units at 3½d. = 17s. 6d. + 3s. 9d. for a lamp = 21s. 3d. For 1,000 hours gas lighting: 5,000 cubic feet of gas at 2s. 6d. per 1,000 = 12s. 6d. + 1d. for burner, 12s. 7d. That is to say, taking Professor Robinson's figures at their best and the figures for gas at their worst, the price of electric lighting would exceed that of gas lighting by close upon 70 per cent. In Brighton, where the Corporation proposes to charge 6d.

per unit, the difference in cost between electric lighting and gas lighting will be about the same. It is to be hoped that the householders of St. Pancras and of Brighton will be made aware of these simple facts before it is too late.

Technical Education.

Engineering, in discussing this subject editorially, remarks that the subject of technical education, like the poor, we have always with us, and for this reason it is apt to be continually shelved till a convenient season, in the press of subjects of more immediate but not greater interest. We are reminded of our duties in this matter by the receipt of several recent publications, which suggest points decidedly deserving of consideration. One of the most important of these particulars is a compilation issued by the National Association for the Promotion of Technical and Secondary Education, entitled "Technical Education in England and Wales." This work is intended to give a brief account of the main objects and working of the chief organizations and institutions which at present exist in England and Wales for promoting and diffusing technical and scientific instruction. A triple classification is attempted, the compilers dividing the matter according to organizations, to grades, and to localities. This has raised an initial difficulty which might well have been avoided; but in spite of it the work is one which may be cordially recommended to all interested in the subject; a term which will naturally include every intelligent employer of labor, and indeed every patriotic individual throughout the kingdom. In saying this we do not wish to support that wholesale demand for technical education, the "vague cry," as Lord Armstrong calls it, which some sciolists appear to think is the panacea for all industrial ills. In fact, much harm has been done by what is termed technical education, wrongly so called if we are to give the term education its true dignity of the acquirement of useful knowledge. In our own profession more especially this danger exists, that we may become too professorial. It is a rock the French educationalists have split upon, and even the practical Germans with their vast system of State-supported education, have failed to avoid it altogether.

Professor Coleman Sellers, of the Stevens Institute of Technology, has recently given in a letter to the *United States Railroad Gazette*, a few instances worth quoting. He mentions some mathematical professors who were fond of discussing equations at once capable of application to the motions of the planets, and of the connecting rod of a steam engine; but they had only developed their knowledge in the former direction, and the transformations needed to reduce it to shape were by no means easy. Even when practical problems are approached by the mathematicians, it is considered, Professor Sellers remarks, rather undignified to make them too practical, and broad generalizations are preferred to direct every-day examples.

Professor Sellers illustrates this by an incident within his own knowledge. Some years ago it was determined by the authorities to make the *Journal of the Franklin Institute* of a less severely scientific but more useful character. A new editor was appointed, and among articles awaiting publication were found some of a highly mathematical character from the pen of a certain learned professor. These were returned to the writer with an intimation that they were hardly of sufficient interest to mechanics at large to be appropriate to the new character of the journal, and asking him to contribute something of a more popular character. The professor took the matter in good part; he said that he had himself been surprised that the journal was willing to publish articles of so purely a theoretical character as he had been writing, but as long as they were willing, he, as a mathematician, was well pleased to work in that line. In place of the mathematical dissertation, he inclosed a valuable practical discussion on the action of jam nuts.

This professor was evidently a man of good nature and good sense, which only emphasizes the moral of the tale; but we will quote Professor Sellers' own words: "The incident well illustrates the tendency on the part of the educated professional instructor to direct his energies along the line of the general and unpractical rather than that of the concrete and useful. And it naturally followed that young men taught under this system, if they came into the workshop, would be distinguished more by ignorance of the concrete methods there called for than by their knowledge, however profound, of the generalities which were not required and which they did not know how to reduce to some useful shape."

This is the danger into which an ill-considered scheme of technical education is likely to lead. There is something about the educational profession that has a narrowing tendency, and it is only the most healthy and practical characters can withstand this. Schoolmasters and profes-

sors are always apt to forget that education is a means to an end; and it may be said in passing that the present system on which State education is conducted is calculated to intensify this evil. Fortunately for us at present the chief engineering professors at our technical colleges have not been professors all their lives, but have acquired their scientific knowledge in the course of practical work. Unhappily there are signs that this wholesome state of affairs is not likely to continue, and young men—sometimes very young men—fresh from college, are being appointed to professorial chairs. It is not possible for a teacher to know what scientific attainments will be of the greatest value to the future practical or producing engineer unless the teacher has been himself engaged in practical work. In writing on this subject over 20 years ago, when technical education was seldom heard of, we took occasion to point out the danger of over-refinement of theory. If it were necessary then, how much more so is it now when the professor is so widely abroad.

It may be said that it is the professor's duty to teach only the scientific principles upon which the practical work of the engineer should be founded, leaving the application of these principles to the time when the student shall be launched on his career in life. As a general proposition this is not to be gainsaid. The most perfect academical training cannot take the place of practical work. For educational purposes we had better be without our colleges than our workshops, and that is the reason British engineers still rank before all others, and that in spite of the admirable State-supported systems of technical education of Germany, France and Switzerland. But whilst we acknowledge this limitation to the professor's duties, we must not forget that men, especially young men of the students' age, are not machines, and want some living interest to give them zest for their work. There are few so mentally constituted as to delight in mathematics for their own sake (even the great Bidder invoked the aid of peas), and even these few are little likely to become successful engineers. The purely professional training can hardly fail to relapse into that barbarous system of doing lessons for lesson's sake under which nine out of ten middle-aged persons were brought up.

It is to such reasons that the success of the few private technical schools which we possess in connection with works, such as Armstrong's, the London and North-Western, at Crewe, and Mather and Platt's may be attributed. The latter has been especially successful and is worked on an eminently practical basis. In his evidence before the Royal Commission on Technical Education, Mr. Mather described the system upon which it is carried on. The drawings made are of work actually in progress in the shops. One day the teacher, who is employed in the works himself, gives the necessary calculations, and the next the pupil sees the work carried out practically and commercially in the shops. Mr. Mather told the Commissioners that his firm had derived incalculable advantage from the school. "We desire," he said, "to send out yearly one or two thoroughly competent men who shall not be simply mechanics in the ordinary sense of the word, but shall be able to turn their attention to anything coming under their notice, whether they have done the same thing before or not. We had the greatest difficulty in finding such men until we began to take them from the school; and since the school has been established we have been able to send boys of 20 and 21 to long distances from England, and place in their hands work with which they have not had much to do before."

We have dwelt at length on what appears to us to be the great danger to which technical education is subject. Great Britain has everything to expect from technical education; without it our still unrivalled factories and workshops will not keep us in front of the world's industry. Prof. Coleman Sellers tells another tale, not this time of a professor. The owner of a large machine shop once applied to him for a spur-wheel. He had marked the diameter on a wooden rod. On being asked whether the mark indicated outside diameter or pitch line, he replied: "Pitch line! What the h— is pitch line? I want a wheel as big as this stick with eighty teeth in it." Now, it will be evident that such men as this, however well equipped for primitive times and rural districts, are not calculated to uphold national engineering industry; but we would rather depend on such a one than on the product of the professors referred to, who could not accommodate the mathematics of the solar system to the movement of crank and connecting rod.

MR. REED, of the Wyoming Legislature, has moved for the adoption of a bill providing for the granting of franchises to gas companies by local authorities; said grants, however, not to become operative until they shall have been indorsed by the voters of the cities affected by said grants.

The Possible Average Depth at Which Coal is Now Being Worked in the British Isles.

In a paper read by Mr. Jas. Dickinson, Inspector of Mines, at a meeting of the Manchester Geological Society, the author gives the following opinions respecting this subject

In connection with the question of the progress of the exhaustion of our coal fields there is a point of much interest which could only be successfully dealt with by the co-operation of mining engineers well acquainted with the different districts. I refer to the depth at which coal is being extracted, and the rate at which that average is increasing during successive intervals of (say) 20 or 25 years. With the information now in my possession I cannot pretend to offer more than a very general answer to the question of the average depth, and it is tolerably certain that even between our largest and most important coal fields there may be considerable difference in the average depth of coal produced in each. The question is not to be solved by taking the depths of the deepest and shallowest pits, and taking the mean proportional between them, for we must recollect that the rate of output from shallow pits will generally be very much slower than that from deep pits, as owing to the great primary cost of the latter they can only be made to yield a profit after a large quantity of coal has been raised and disposed of; while, on the other hand, a comparatively small output will suffice to keep a shallow colliery alive. On the above accounts an estimate could be more nearly arrived at by supposing the average depth to be somewhat greater than that between the shallowest and the deepest pits. If we suppose that at the time of the introduction of the steam engine into coal mining in 1820-25, the average depth did not exceed one hundred yards, owing to the necessity of employing horse power for winding and pumping, and if we were to assume the average depth at the present day to be 350-400 yards (probably a near approximation) we should be able to determine the rate of increase of average depth during the last 65 or 70 years. Supposing the rate to have been uniform (which it unquestionably was not) the increase of the average depth would have been at the rate of $4\frac{1}{2}$ yards per annum, or 90 yards in 20 years. But the rate of increase ought to be represented not by a straight line but by a curve corresponding in some degree to that which represents the progressive rate of coal-production from the beginning of the century to the present time. The fact that more than one seam of coal is worked in a coal district somewhat complicates the problem here presented, and for the sake of simplicity it might be stated as "the depth from which the maximum quantity of coal is raised." Now this could be determined if we had before us the depths of all the coal pits or their workings and the output from each particular seam; but this could not be obtained without investigation into details which, proprietors might not wish to have revealed, and which we should have no right to demand. There could be no objection, however, as it seems to me to the disclosure of the depths of all the pits in a coal district and the name of the seam worked; in fact, these details are generally fully known, and if we take these details as a sufficiently close approximation, and make a correction for the cause indicated above, we may come to a tolerably close approximation as regards the average depth. Such details regarding the coal fields of Yorkshire, Derbyshire, and Notts, have been furnished to me by my friend, Mr. J. T. Boot, mining engineer, of Mansfield, and from a comparison of the depths I have obtained the following results, which may not be without interest:

Depth of Collieries in the Counties of York, Derby and Notts.

Yards.	Collieries.	Yards.	Collieries.
Between 0 and 50.....	* 8	Between 300 and 350.....	8
Between 50 and 100.....	*14	Between 350 and 400.....	2
Between 100 and 150.....	*31	Between 400 and 450.....	2
Between 150 and 200.....	21	Between 450 and 500.....	5
Between 200 and 250.....	14	Between 500 and 550.....	4
Between 250 and 300.....	10	Between 650 and 700.....	1

* Some of these are not at work.

Mr. Boot states that in any estimate as to the average depth of mining the shallow pits ought not to be taken into account, some of them not being even at work. If, then, we disregard pits over 100 yards and assume that the output of the deeper pits (say those under 250 yards) is about double that of the shallower (say under 250 yards), we still find that the depth of maximum output will be at a depth of about 250 yards, there being 66 collieries above that line and 32 below, I think 250 yards is in all probability a close approximation for this great coal field, considering that owing to a general low dip of the bed and the occurrence of local flexures (forming synclinal and anticlinal curves) the seams remain at comparatively shallow depths over large areas. As regards the Lancashire and Cheshire coal field, including that of Burnley, I feel satisfied from my own knowledge that the case is different, and that a

depth of 250 yards would by no means represent the average for coal production. Perhaps some member of the society would endeavor to work the question out for this district on the principle I have adopted above for the Yorkshire and Derbyshire district, or upon some more reliable data. On the whole, I am of opinion that a depth of 350 to 400 yards would represent more nearly that here under discussion. As regards other coal fields, those of Newcastle, Central Scotland, Staffordshire and South Wales are the most important; and as far as my information extends I am led to believe that a similar depth (that of 250 yards) represents that from which the maximum quantity of coal is now being raised. In conclusion, I would venture to urge on H. M.'s Inspector of Mines, and especially on Mr. Dickinson, the importance of taking up this problem with reference to each of the coal fields under their charge, as by such determinations we shall arrive at a truer knowledge of the exhaustion of our coal fields than by any other method.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

MR. ADAM WALLACE, Secretary of the La Fayette (Ind.) Gas Light Company, writing under date of the 5th inst., says: "The following may be of interest to you and the gas fraternity. On Monday, Feb. 3d, the stockholders of this Company held their annual meeting and elected the following to serve as Directors: Cyrus Bell, A. Wilson, Wm. Wallace, R. R. Hitt, J. O. Morgan, R. W. Sample and C. H. Peirce; Mr. R. W. Sample succeeding the late Mr. Moses Fowler, who had been President of the Company. Mr. C. H. Peirce took the place held by his father, from January, 1857, until the death of the latter in January last. The Board then elected Wm. Wallace President, and A. Wilson, Treasurer, reappointing myself to the Secretaryship. Mr. Wm. Wallace has held the position of Superintendent for the last 23 years, which position he still retains in connection with the Presidency. The Company contemplates adding a water gas apparatus to be run as an auxiliary to the coal gas plant. While we do no city lighting our sales of gas show a large increase for the year 1889, with excellent prospects for 1890."

At a meeting of the Directors of the Troy (N. Y.) Gas Light Company, held about a fortnight ago, the feasibility of disposing of the Company's property, corner of Hill and Liberty streets and on North Fourth street, was discussed. It was decided to locate the new works of the Company on the site of the Hannibal Green spring factory at the foot of Smith avenue. Secretary Davenport, in confirming this report of the action of the Directors, said: "It is the intention of the Company to dispose of all the property which cannot be profitably employed. We intend to consolidate our gas making plant, in so far as it is possible, under one roof. The holder on Jefferson street will be retained, and it is likely that the holders at Liberty and Hill streets will also not be disposed of. All the other buildings and land at the latter place will be parted with, and so will the uptown works at North Fourth street. Many advantages will accrue to the Company under the new scheme. We will have our own dock for the reception of coal, which heretofore we have been compelled to cart at a great expense. We can also take our water direct from the river, which will be a decided advantage over the driven well system." From this it will be seen that Supt. Henry C. Shields has a busy season before him.

EARLY this month President Odiorne, of the Gloucester (Mass.) Gas Light Company, appeared before the local committee on Mercantile Affairs to oppose the petition of Geo. Moore and others, who propose to incorporate the Union Electric Light and Power Company. He urged that the field for the supply of artificial light was so restricted that two companies could not possibly survive with profit to the shareholders. He would not, however, oppose the furnishing of electricity by the petitioners for power purposes. The Committee reserved its decision, but in all probability the matter will eventually come before the Board of Gas and Electric Light Commissioners.

THE ordinance to grant the Toraya Gas Company the use of the Manayunk station of the Philadelphia City gas works for a protracted trial of its system of wood gas manufacture has been voted on adversely by the Philadelphia Select Council. The vote was 26 against to 1 in favor.

IT is reported that Messrs. Lord & McCabe have brought suit against the New Orleans Gas Light Company, alleging that defendant has infringed certain patent rights vested in plaintiff. In its answer defendant pleads that it had constructed, used and operated an apparatus for

manufacturing illuminating gas from petroleum long prior to the issuance of the letters patent to plaintiffs herein to wit (since April, 1873), and which apparatus it uses and was using at the time of the institution of this suit. That the essential idea and feature of the said apparatus as used by the defendant consists of a system of double retorts, or a retort within a retort, used for the purpose of vaporizing petroleum, and this combination of retorts was no novelty at the time of the issuance of the letters patent referred to in plaintiff's petition, but were well known to science and in practical use in the manufacture of gas throughout this country and Europe—notably by the Springfield (Mass.) Gas Company, the Boston (Mass.) Gas Company, the Metropolitan (N. Y.) Gas Company, the Laclede (St. Louis) Gas Company, the Cleveland (Ohio) Gas Company, and by many others. Again, defendant specially denies that it has in any way infringed upon the patent rights asserted by plaintiffs, or that it has in any manner used the ideas or combination claimed as essential novelties in said patent. The case is before Judge Edward C. Billings, in the United States Circuit Court for the district.

IN completion of our former mention that one H. Bostwick had prayed for the appointment of a receiver for the Hastings (Neb.) Gas Light Company, we might add that the impelling cause for this action is to be found in the fact that Bostwick claims the sum of \$3,000 "for services rendered in soliciting patronage for the Gas Light Company, and for other services done and performed for the Company since January 1st, 1886." The peculiar interest attaching to Mr. Bostwick's "modest claim"—it really amounts to asking \$1,500 per annum for two years' services—will be readily appreciated from the following analysis that comes to us from a Hastings correspondent: "When this case is properly indexed it ought to read 'Harrison Bostwick vs. Harrison Bostwick,' instead of 'Harrison Bostwick vs. The Hastings Gas Light Company,' for he virtually sues himself. When Mr. Bostwick (some 4 years ago) was seen going from house to house soliciting patronage for the Gas Company, the people presumed that he was so engaged because of his desire (so loudly and frequently proclaimed) to forward the interests of an enterprise that promised to be of great local value; and Mr. Bostwick was given great praise for his public spirit. Now, however, he claims that the Gas Company, estimating at its true value his ability to wield important political and personal influence, employed him to obtain patronage and secure consumers for it, and alleges that because he is now performing like service for a rival Company, his old employers refuse to pay for what he did for them. The old Company replies that it never employed him, hence it owes him nothing. The trial of this case and its results are of vital interest to many people in this city. Should the issue go to the Supreme Court, there to be decided that the man who has given encouragement to home enterprises is entitled to recover the sum of \$1,500 per annum for his services, there will be no end to the litigation that would surely follow. If that rule would hold good, I make bold to say that our local paper, for instance, could collect a sum sufficient to pay for the construction of a building that would put in the shade the famed Equitable Building of New York city. Again, if Mr. Bostwick recovers the amount for which he sues, it will not be safe for any party to make an investment here until the assurance is given that no 'influential' and 'patriotic' citizen has signed an agreement that he will either solicit patronage for or give encouragement to the proposed enterprise."

THE Pennsylvania Gas Company (natural gas) has issued a notice to the effect that no new patrons can be served from the Jamestown (N. Y.) lines, as the capacity of the same is unequal to any further drain.

THE Columbia (Pa.) Gas Company has chosen the following officers: President, James A. Myers; Secretary and Treasurer, J. C. Clarke; Superintendent, Wm. B. Faesig.

THE Philadelphia Councils Committee on Gas Works, at a meeting held early this month, have authorized Director Wagner to place 1,000 gas and 1,000 gasoline lamps in the county precincts during the year.

CERTAIN speculators who are attempting to secure a franchise for the operation of a fuel gas plant in St. Louis, propose to work under the Brazelle process. In support of their scheme they alleged that this process was in successful operation at the works of the Paris (Ills.) Gas Light and Coke Company. The President of that Company, when interviewed on the measure of success that had been gained in its operation of the Brazelle system, said: "The Brazelle process was in-

stalled at the works, having been operated experimentally for eight months, and then the gas was supplied to the city for about three months longer. The system is not even a partial success. The history of our connection with the Brazelle process is as follows: A small experimental apparatus had been erected, and the results from it appeared so promising that we determined to discontinue the manufacture of illuminating coal gas and distribute this fuel gas instead, relying upon an incandescent burner to give it luminosity. We were speedily obliged to give the plan up, as it was too expensive and uncertain. Then we attempted to carburet the gas by the addition of oil in the generator, but the attempt was a failure, for the added oil was partly burned out in passing with the gas down through the fuel, and partly deposited by the other extreme of temperature in the fire brick chamber which followed. After 'blowing up,' when the operation of gas making was going on, an explosion would frequently occur, of sufficient force to throw open the lids of the generators, or to loosen the fire brick linings in the same. A very stubborn clinker was formed by the down-draft; the coal used in the process was the same as that which gave us 8,000 cubic feet of good illuminating gas, when carbonized in retorts under the old process; but though Mr. Brazelle claimed to be able to obtain 60,000 feet per ton, he never did make over 11,000 feet, and often not more than 9,000 feet, and this a gas of no illuminating power whatever, and of far less heating value than the coal gas formerly made. Of course, with his process, we saved no tar nor coke, and the gas was consequently far more expensive than coal gas. Dr. Brazelle's method of estimating the yield per unit of coal was also rather peculiar. He first weighed the coal, then after the material had been burned, weighed the remaining ash, and charged the *difference* in weights as the amount of coal used. Even by this figuring he was unable to *make* over 11,000 cubic feet per ton. As a result of this change the only people in Paris who seemed satisfied with the Brazelle gas were the dentists, who found it to answer nicely in fusing their gold. For steam raising and the more extended uses of fuel it would not do at all. The consequence was that when, in January, 1890, the process was finally rejected, the Gas Company had to begin all over again, at a disadvantage much greater than that attending the operation of a new company; for not only had our former customers turned to the use of oil or electricity, but popular sentiment was very strong against us for the loss of the hitherto reliable heating and illuminating agent. After the rejection of this process we returned to making coal gas until a water gas plant of the Pratt & Ryan type was installed, and as this latter has been giving good satisfaction ever since, operated by the same workmen who attended the Brazelle apparatus, no claim of incompetent handling can be alleged in respect to the system that failed so much of Brazelle's 'success' at Paris, etc."

ONE of the substantial institutions of Clinton, Iowa, is to be found in the works and business of the Clinton Gas Light Company, which was incorporated 21 years ago, and which has since been in control of local capitalists. It is capitalized in \$65,000. About 300 consumers are on its rolls, the main mileage is 10; there are 75 public lamps, and the output last year was 6,119,000 cubic feet. Mr. Oliver Messer is Superintendent. The Company's business increases constantly, and it enjoys the confidence of the public.

AT the annual election of the Peoples (Jersey City, N. J.) Gas Light Company, the following Directors were chosen: F. Morris Perot, Thos. M. Williams, Thos. M. Gopsill, M. A. Cowisen, M. T. Newbold, Frank Stevens, Wm. Muirhead, Jas. L. Ogden and Geo. W. Conklin. The Directors subsequently indorsed the following executive management: President, F. Morris Perot; Vice-President, Thos. M. Gopsill; Secretary and Treasurer, E. N. Case.

AT the annual meeting of the Stockholders of the Easton (Pa.) Gas and Electric Light Company, the following Directors were chosen: General R. Thomas, M. M. Dawson, R. B. Dison, W. H. Thompson, T. Tunis, W. E. Shanahan, Col. O. Tilgiman, Jas. H. Covington, C. T. Wrightson and Jas. H. McNeal.

THE gas supply of Dalton (Ga.) is giving great satisfaction to the residents.

THE Directors of the San Francisco Gas Company have re-elected the following officers: President and Engineer, J. B. Crockett; Vice-President, Adam Grant; Secretary and Treasurer, W. G. Barrett.

THE Galesburg (Ills.) Gas Light and Coke Company's proprietors having decided to change their method of manufacture from coal to water

gas, have contracted with the National Gas Light and Fuel Company for a Springer apparatus having a capacity of 120,000 cubic feet per diem.

THE following figures and facts are taken from advance sheets of the annual report of Mr. Charles W. Hinman, Massachusetts State Inspector of Gas and Meters. During the past year 13,592 gas meters were inspected, of which number 13,412 were either new or recently-repaired instruments, 180 meters which had been in use some time, and which were suspected to be incorrect either by the consumer or the companies, were brought in for re inspection; of these 42 were found to be too fast, the average error being 5.65 per cent.; 121 were found to be within the legal limits—2 per cent.—16 were found to be too slow, with average error of 15.41 per cent.; and one meter did not register at all. The average error of meters that registered was 0.05 per cent. too slow. All the consumers' meters at present in use in the State are dry, and there is a gradual increase from year to year in the proportion of correct meters to the whole number complained of. The gas made by the various companies in the State has been inspected in the usual manner. Numerous analyses has shown that coal gas, as manufactured in Massachusetts, never contains as much as the legal limit of 10 per cent. of carbonic oxide. Comparing the results with those of last year, there is on the average found to be a slight falling off in the candle power of the gas of the larger companies. This decrease amounts to 0.11 of a candle power. The gas of two of the companies shows a decrease of about 1 candle each; but the lowest average among the larger companies is 2 candles above the legal standard of 15 candles. None of the other changes in the gas of these companies exceed about one-half of candle. The fluctuations in these candle powers have been more pronounced than last year; but the largest fluctuations have been at those places where a mixture of petroleum gas and water gas is used as an auxiliary to coal gas. It is desirable to keep the gas uniformly at one standard, as each grade of gas requires a different burner, or a new adjustment to produce the best result. The gas of the smaller companies has almost exactly the same average candle power as for the previous year, but there are a few considerable variations from the results of the previous years.

THE following terse letter explains itself:

“PORT HOPE (ONT.) GAS COMPANY, Feb. 10, 1890.

“To the Editor AMERICAN GAS LIGHT JOURNAL:—If a gas manager who has had experience in operating an electric light plant of, say, 50 arcs, and another who has about the same service in incandescent lamps, would, through your columns, give to their brother managers the benefit of that experience as to cost of installation, operating expenses and receipts, they would do a good service to their brethren now beset by electric light plant sellers whose statements are to be accepted with a grain of salt.

J. SMART, President.”

THE following officers have been chosen to manage the affairs of the New Britain (Conn.) Gas Light Company: President, G. M. Landers; Secretary and Treasurer, A. P. Collins; Superintendent, E. C. Learned; Directors, Geo. M. Landers, Wm. Bingham, L. F. Judd, Jas. H. Eddy and A. J. Sloper.

AT the annual meeting of the Independence (Mo.) Gas and Coke Company the following Directors were chosen: C. C. Chiles, L. P. Williamson, W. H. Waggoner, D. Bullard, W. M. McCoy, H. C. St. Clair, J. P. Alexander, R. D. Wirt and J. McCoy.

MR. J. E. MAYO, recently in charge of the Saratoga (N. Y.) Gas and Electric Light plants, has taken service with the Rockford (Ills.) Company.

THE property and franchise of the Corsicana (Tex.) Gas Light Company were disposed of at auction sale on the 4th inst. Messrs. Simkins & Niblett, local attorneys, representing a majority of the bonds, purchased the property. The Company will be reorganized. Our information is to the effect that this sale—the property had been in the hands of a receiver since last August—was brought about on account of legal complications involving the title to the property. We understand that the Company's business has been sufficient to yield a fair profit.

THE bill reducing the price of gas in St. Louis to 90 cents per 1,000 cu. ft. has passed both branches of the municipal legislature, and the posted division claim that Mayor Noonan will sign the ordinance. In the

meantime, however, it is of record that the Mayor believes the adoption by the Laclede Company of the old St. Louis Company's amended or substitute charter will prevent the city from carrying out the proposed attempt to regulate gas rates, at least for a term of years. It looks as though the matter will have to go through a very wearisome tangle of law ere the question is finally decided.

THE authorities of Cleveland, O., have been investigating the matter of public electric lighting, and a portion of the investigation consisted of the obtaining of figures from the authorities of other cities as to the rates paid for lighting the lamps in those cities. A compilation of the answers so far received is appended: New Orleans has 934 arc lights of 2,000-candle power, burning every night and all night. Of this number 634, in the city proper, cost \$125 a year; 262 suburban, \$146; 38 across the Mississippi, \$205. The city operates under a 5-year contract. For every lamp not lighted a pro rata reduction, with 10 per cent. added, is made from the monthly bills. The police report lamps not lighted. The entire city is lighted by electricity. Gas lamps per post before electricity was adopted were \$16. Cost of gas for city buildings is 1 cent per burner per hour. Fort Wayne, Ind., runs its lights on the Philadelphia or moon schedule, or all night, if the chief of police or chairman of the fire committee orders it. The lights are 2,000-candle power, and cost \$135 a year, with a reduction of 5½ cents an hour per light for any lights reported out by the police. Memphis burns 100 arc lights of 2,000-candle power, all night and every night, for \$187.50 a year. It pays \$20 a year for gas lamps, the same as Kansas City. Denver uses 1,100 20-candle power incandescent street lamps, which cost \$26 a year. For 2,000-candle power arc lights, all night and every night, it pays \$240 a year. For lamps burned on the moonlight schedule the cost is \$150 a year. No gas or gasoline lamps are used. At St. Paul only 54 arc lights are used. They burn until midnight at 35 cents a night. It pays \$2.46 a month for gas lamps, and has been paying \$25 a year for gasoline, but recent bids sent the gasoline prices down to \$16.80 a year. Omaha has just entered into a contract with the Thomson-Houston Company for lighting the city with 100 arc lights for 5 years at \$175 a year. The lamps are 2,000-candle power, to burn all night, and the electric light company to make all repairs. It has also made a 5-year contract for gas lamps to burn 5 feet of gas an hour, producing a 16 candle power light for \$25 a year. Gasoline lamps are \$19 a year. The Brush system is in use in Detroit, which city contains about the same area as Kansas City. It makes contracts for only a year at a time for lights, and has about six hundred 2,000-candle power lights, which cost \$140 a year to burn every night and all night. Buffalo has 1,223 arc lights, which cost 42½ cents per night for all night and every night. This is \$155.61½ a year. There are three systems used by the city, and the lights are lighted and extinguished by a printed schedule for each month. The city has 4,390 gas lamps burning 4 feet an hour, which cost \$17 each a year. The city of Milwaukee uses 270 arc lights of 2,000 candle power, burning each night and every night, for which it pays \$150 a year for each. Gas lamps cost \$24.70 a year, and gasoline, \$20. Quincy, Ills., goes by the moon schedule. It has one hundred and eighty-one 2,000-candle power arc lights burning when the moon does not shine, which cost \$100 a year each. It uses no gas or gasoline. St. Joseph has just completed an electric light plant and starts out with 210 arc lights, to cost \$6 a month, or \$70 a year—\$3 a year cheaper than St. Louis. The lamps are 2,000-candle power and burn all night and every night. Gas lamps cost \$15 a year, and gasoline, \$17. Pittsburg uses 300 arc lamps of 2,000-candle power, burning all night and every night, and pays \$105 a year. It also has 1,000 twenty-five-candle power incandescent street lights, which cost \$16 a year each. Gas lamps cost the same. In Kansas City, Kas., 96 arc lights of 2,000-candle power are furnished all night and every night at \$144 a year. The St. Louis contract is for 1,600 arc lights of 2,000-candle power, to burn all night and every night, at \$78 per year; 800 incandescent lights, of 30 candle power, at \$17.50 a year, and 800 of the same at \$20 a year.

MR. ROBERT J. DOBSON, who has been for the last 20 years connected with the Seneca Falls (N. Y.) Gas Light Company, under the late Wm. Parrish, has been appointed Superintendent and General Manager of the Company.

CURRENT rumor has it that the New Bedford (Mass.) Gas and Electric Light Company has absorbed the local Edison Electric Illuminating Company. It is understood that the basis of consolidation is 10 shares of the latter stock for 8½ shares of the former. This places the light supply of New Bedford entirely in the control of Mr. Taber's Company.

THE Louisville (Ky.) Gas Company is figuring in the local Law and Equity Court as defendant in a suit for damages (assessed at \$20,000) brought by a former employee—Peter M. Gillem. Plaintiff was employed as an ordinary laborer, and, on June 26, 1889, while moving a wheelbarrow loaded with brick, was injured through the toppling of a set scaffold. Gillem charges faulty construction.

THE Proviso (Ills.) Light and Water Company has been incorporated by Messrs. H. E. Broughton, Henry Struble and G. L. Thacher. It is capitalized in \$15,000. This place is a post township of Cook county, Ills., and is about 11 miles west of Chicago. Population about 6,500.

THE Gas Committee of the Kansas City (Mo.) lower branch of the local government recently held a session, at which certain matters affecting the Gas Company were discussed. Col. M. J. Payne, President of the Kansas City Company, spoke against the passage of the pending ordinance granting to an opposition gas company the right to lay pipes for the supplying of natural and manufactured gas for fuel purposes. Colonel Payne convinced the committee that his Company had been granted by the State Legislature an exclusive franchise for supplying the city and its inhabitants with gas of whatever sort. He also stated that the Company had expended nearly \$140,000 in constructing works for the purpose of supplying the city with fuel gas. "We have built a reservoir in the East bottoms," said Mr. Payne, "that will hold 1,000,000 cubic feet of gas. We have laid a 24-inch main from the city proper to it, which main is double the capacity of that which is now supplying the city with illuminating gas. We propose to base the cost of this fuel gas upon the price of a ton of coal, say at \$4 per ton." It was shown that Colonel Payne's Company had an exclusive franchise, and the committee therefore returned an adverse report upon the ordinance granting to George Sheidley and others the right to lay mains for supplying the city with natural and manufactured gas.

FOR its alkaline and vivid "cheekiness" the following action, taken last week by "District Assembly 41, Knights of Labor," of Baltimore, Md., will be appreciated. The "Knights," in debate on the bill now before the Maryland Legislature, under which it is proposed to regulate the gas supply of Baltimore, resolved, that while they considered it to the best interest of the community that the city should own its own gas plant, yet they recognized the great danger of placing any greater power in the hands of the municipal government until there has been secured the Australian system of voting and other necessary measures for the proper administration of public affairs. The resolutions stated that it is useless to ask for more than they could reasonably expect to secure. They claimed that as it appeared the Gas Company could make gas at 60 cents per 1,000 and pay interest on \$6,000,000 in bonds, therefore the Legislature ought to be called on to reduce the cost of gas 50 cents per 1,000 feet.

THE Dayton (Ky.) City Council is considering an ordinance under which it is proposed to grant to the Bellevue Gas and Light Company an exclusive charter, to last for 25 years.

On the Most Economical Engine for Small Power.

Professor J. E. Denton, in the last issue of the *Stevens' Indicator*, writing on the above-named subject, says:

A certain machine shop possesses two steam engines, one a plain slide-valve throttling 5½-inch bore by 7-inch stroke, the other an automatic cut-off, 7-inch bore by 14-inch stroke, both non-condensing. The shop required 7-horse power to run it, exclusive of the power to overcome the friction of the engine. The question arose whether it was cheaper to run the shop at 70 pounds boiler pressure with the plain slide-valve engine cutting off at three quarters, or with the 7-inch by 14-inch engine cutting off at one-fifth under the automatic action of its governor, or whether fuel would be saved by operating the engines on the compound principle, using the small engine as the high pressure cylinder and exhausting from it into the larger engine through a receiver, the system still being non-condensing. Both engines were carefully overhauled and made perfectly tight at their valve seats and pistons.

Each engine was then tested to determine the power absorbed to run itself, with the result that the small engine absorbed ¼-horse power, and the large engine 2½ horse power. The small engine was then made to perform 7¾ indicated horse power at 70 pounds boiler pressure and 146 revolutions per minute, the exhaust escaping into the atmosphere

at a back pressure of 17 pounds. The steam consumption per hour per horse power was 45 pounds.

The large automatic engine was then made to perform about the same indicated horse power at the same steam pressure and revolutions, the cut-off being about one-fifth. The steam consumption per hour per horse power was 35 pounds.

The same work was then performed by operating the engine on the compound system at the same boiler pressure and same cut-off in the small engine, and with 26 pounds receiver pressure and about one-half cut off in the larger engine, the exhaust passing into the atmosphere from the larger cylinder. The ratio of the cylinders made the ratio of expansion 4½, including clearances, or practically the same as the real ratio of expansion when the large engine was used alone, the clearance of the latter being 5 per cent. The steam consumption per hour per horse power was 33 pounds.

It follows from these results, that to obtain the 7 net horse power required to operate the shop, the indicated horse power for the three methods would be as follows:

System.	Friction.	Net Work.	Total or Indicated H.P.
Small engine	0.6	7	7.6
Large engine.....	2.5	7	9.5
Compound engine	3.1	7	10.1

The expense measured in steam consumed per hour will therefore be as follows:

Small engine.....	7.6 × 45 = 342 pounds.
Large engine.....	9.5 × 35 = 333 pounds.
Compound engine.....	10.1 × 33 = 333 pounds.

It is evident that so far as the coal consumed is concerned, the three methods are practically equal. The best method will therefore be the one which gives the least wear and tear, or the least trouble to apply, the first cost being too small in both cases to make interest a sensible factor.

This makes the most economical method that which derives the required power with the large engine alone, as the load upon it is only about half its working capacity, and, consequently, the wear and tear is very light; and, as a matter of fact, the engine has done the work for years with far less attendance and repairs than would be required if the small engine was made to perform the required work.

It is worthy of note that the greater proportional power required to overcome the friction of the automatic engine is due to the fact that its main shaft and flywheel, which cause the greater part of the friction, weigh much more in proportion to the total mean pressure on its piston than is the case with the small engine.

Electric Light at the British Museum.

In the galleries on the ground floor there are 69 arc lamps of various powers, while on the upper floors there are 57 arc and 627 glow lamps. In addition to these there are 5 large arc lamps in the reading room, 6 in the courtyard, and upwards of 200 glow lamps in the offices and passages. The total current required to work the whole of the lamps is nearly 1,200 amperes, with an E.M.F. of 115 volts at the lamp terminals; and this output is produced by the expenditure of nearly 200-brake horse power. The current is generated by four Siemens dynamo machines, each capable of giving an output of 450 amperes and 130 volts, which are connected to a general switchboard in the engine room by means of which they can be put to work in parallel to any or all of the circuits.

The switchboard is fitted with instruments indicating the current given off by each dynamo, and four circuits are led from it round the Museum—two for the upper and two for the lower floor. The main wires are laid outside of the building.

In order to insure safety, and to guard as far as possible against failure of light, the motive power is in duplicate. The four dynamos are driven in pairs, each pair by a separate engine with a separate counter-shaft. Each engine has a separate steam pipe in direct communication with the boilers, and there is an ample reserve of boiler power.

The power of the engines and dynamos is so adjusted that each of the two sets is capable of working the whole of the lamps in those galleries proposed to be lighted on any one evening; the other set standing by ready to work. Further, in order to work, if required, at half-power, or in order to provide half-light for the whole of the galleries—which light should suffice for an emergency, such as sudden fog or accident—the lamps are connected in pairs alternately, so that half of the number being cut off, the light of the other half still remains evenly distributed.

POSITION WANTED

As Manager of a Gas Works

Making from 5 to 10 million cubic feet per annum. Six years' experience. Address "J. M. M.," 767-4 Care this Journal.

POSITION WANTED.

A Mechanical Engineer,

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked. Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal, 765-1f or Box 972, West Bay City, Mich

Position Wanted

As Superintendent or Assistant of a Gas Works,

By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address 765-5 "M.," care this Journal.

FOR SALE.

A Complete Water Gas Plant. 60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

FOR SALE.

We offer the following gas apparatus for sale, delivered f.o.h. cars Fort Worth, Texas:

Two Benches of 3's, with cast iron Hydraulic Main, Dip and Ascension Pipes, and Mouthpieces (14 by 23 in.).
One Bench of 6's, with cast iron Hydraulic Main, Dip and Ascension Pipes, and Mouthpieces (12 by 20 in.).
Two Benches of 3's, with cast iron Hydraulic Main, Dip and Ascension Pipes, and Mouthpieces (14 by 24 in.).
Four Purifiers, 6 ft by 6 ft., with 6-in. Connections and Center Seal. **Steam Jet Exhauster. One Set Pipe Condensers** (6-in.). **One Upright Scrubber**, 11 ft. high by 36 in. diam., with Bye-Pass. **One Station Meter**, daily capacity 100,000 cu. ft. **One Upright Boiler**, 20 horse power.

All of above apparatus in first-class condition and are so guaranteed. For further particulars address

FORT WORTH LT. AND POWER CO.,

767-4

Fort Worth, Texas.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

SECRETARY, 123 Beale Street,

760-3 mos.

San Francisco, Cal.

FOR SALE,

One 5-ft. Station Meter.

One Hydraulic Main (five sections), wrought iron, 22 by 24, with Bye-Pass on Dip-Pipes.

25 Valves, Stand-Pipes, 7-inch Mouthpieces and Lids, all complete, ready for use, to fit up five benches of 5's.

This apparatus is all in first-class condition.

Price, \$800, f.o.h. cars or boat, Poughkeepsie, N. Y.

Inquiries may be sent to this Office.

THE NEW HANDY BINDER.

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filed in the Handy Binder, becomes a volume of great value, always convenient for instant reference. Handy Binder, Postage paid, \$1.00.

A. M. CALLENDER & CO., 42 Pine St., N. Y.

GREENOUGH'S

"DIGEST OF GAS LAW."

Price, \$5.00.

This is a valuable and important work, a copy of which should be in the possession of every gas company in the country, whether large or small. As a book of reference it will be found invaluable. It is the only work of the kind which has ever been published in this country, and is most complete. Handsomely bound. Orders may be sent to

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owners of the RECENT Mackenzie Patents,

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day.

The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn, Crude, and Fuel Oils, Naphtha, etc.

Neither PERISHABLE PIPES or other RETORTS, NOR THEIR EQUIVALENTS, are used.

Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD.

The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM.

The Gas requires NO PURIFICATION whatever.

The FUEL GAS COSTS VERY MUCH LESS than PURE UNCARBURETED WATER GAS, and contains DOUBLE THE HEAT UNITS.

The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE, and consists of a Single Body with a capacity of ONE THOUSAND to ONE HUNDRED THOUSAND cubic feet per hour.

Works may be constructed to run by the CONTINUOUS or ALTERNATING method. If run continuously, the limited amount of Nitrogen present is neutralized by Carbon.

The Gas can be made of a HIGH GRADE for illuminating purposes, of a MEDIUM QUALITY for distribution for domestic purposes, and of a LOW GRADE for manufacturing uses.

Wherever Liquid Hydrocarbons can be had the MACKENZIE PROCESS WILL COMPETE IN PRICE AND SUPPLY ALL THE ADVANTAGES incidental to the use of NATURAL GAS.

This Company desires contracts for the construction of Plants, parts of Plants, Apparatus, Buildings, Holders, and Street Mains, for either of the above purposes, and will Lease or Purchase Works upon satisfactory terms.

Information will be promptly given regarding material required for production of Gas, actual cost of product, cost of works, etc.

PHILADELPHIA, PA.

It is to the interest of Gas Companies and Cities to double the efficiency of the light on streets by using Dyott's Patent "CHAMPION" LAMPS. They save 50 per cent. over others in cost of repairs, are ornamental, and indestructible except by violence.

Our Patent System of Instantaneously Lighting Gas (without electricity), for Railroad Depots is unequalled.

Dyott's High Candle Power Burner is a very superior lamp where a concentrated and brilliant light is wanted in Hotels, Stores, Depots, etc.

Special Drawings furnished and Estimates cheerfully given, either from Architects', Engineers', or our Draughtmen's Plans.

We manufacture every description of Plain and Ornamental Lamps, Posts, Brackets, Clusters, etc. Correspondence solicited.

The Gordon Portico Lamp.

A successful Competitor of the Arc Electric Light for lighting Store Fronts, Show Windows, Depots, Railway Sheds, etc., etc.

Gordon Portico Lamp.

The Gordon Street Lamp.

A Successful Competitor of the Arc Electric Light for lighting Streets, etc., etc.

Gordon Street Lamp.

The Lungren Lamp.

A Successful Competitor of the Incandescent Electric Light for Interiors, etc. Is especially applicable for the lighting of Offices, Stores, Factories, Mills, Show Windows, Libraries, and all situations where an increased illumination is desired.

More than 25,000 Lungren Lamps are now in use. Testimonials, references, or any desired information will be cheerfully given.

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No.	Capacity (cu. ft.)	Dimensions (ft.)
No. 1,	50,000 to 100,000	3 ft. square, 5 ft. deep.
No. 2,	" " 125,000	4 " " " "
No. 3,	" " 250,000	5 " " " "
No. 4,	" " 500,000	6 " " " "
No. 5,	" " 750,000	7 " " " "
No. 6,	" " 1,000,000	8 " " " "
No. 7,	" " 1,250,000	9 " " " "
No. 8,	" " 1,500,000	10 " " " "
No. 9,	" " 2,000,000	12 " " " "
No. 10,	" " 3,000,000	15 " " " "

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

WM. W. GOODWIN, Prest.

E. STEIN, Sec.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

PROPRIETORS OF THE

OAKHILL GAS RETORT & FIRE BRICK W'KS

Our immense establishment is now employed almost entirely in the manufacture of materials for

GAS COMPANIES.

We have studied and perfected three important points. Our retorts are made to stand changes of temperature, the strongest heats of the furnace, and the abrasion of feeding and emptying.

We furnish and build Half-Depth or Full REGENERATOR FURNACES of different kinds and most approved styles.

Correspondence solicited.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

"SUN DIAL" GAS STOVES,

The Most Economical, Efficient, and Durable Gas Stove Made.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
37 in. high. 20 in. wide.	12 in. high. 17½ in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	36 in.

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
31 in. high. 17 in. wide.	9½ in. high. 14½ in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 16 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 3 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. ¼ in. supply pipe should be used where the pressure is 1 in. or over.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., January 20, 1890. }

To Members of the Ohio Gas Light Association:

Gentlemen—The Sixth Annual Meeting of this Association will be held at Toledo, O., on March 19 and 20, 1890.

This announcement is made thus early in order that all members may be reminded of the meeting in ample time to make their arrangements to be present. Every member is urged not only to attend this meeting, but also to interest himself in inducing others of his acquaintance who are eligible for membership, but who have not as yet joined the Association, to come to the meeting and become members.

It is not intended that as many papers as usual shall be presented at the forthcoming meeting, in order that more time than formerly may be had for the discussion of those that are read, and for such other matters and business as the members may desire to dwell upon.

Although the Secretary has for some time been engaged in the work of soliciting papers for this meeting, he has not yet secured as many as should be had, notwithstanding fewer are desired than heretofore, and he therefore earnestly calls upon all members who can possibly do so to notify him immediately of their willingness to furnish papers.

It has been decided that an interesting and valuable feature of our meeting would be a "Question Box," in which members can place questions, which will be withdrawn and read to the meeting and answered and discussed by the members. Every member is requested to send to the Secretary at once any question or questions which he would like to have thus brought before the meeting.

Future circulars will announce further details concerning the meeting.

Respectfully, IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

TIDINGS FROM THE NEW ENGLAND MEETING.—"Boston, Mass., Feb. 19, 1890.—Those who were in Boston on the evening of last Tuesday, were inclined to be alarmed over the unusual atmospheric conditions that prevailed—conditions that were abnormal even in connection with or contrasted to those that have ruled in this oddest of Eastern winters. Hail, snow, lightning and thunder, are not often felt, seen or heard, at one and the same moment; but that melange was served up in Boston at 10 P.M. of the 18th inst. But those within the walls of Young's—and many a gas man had already visited the clerk and confided his grip to 'front,' ere the lightning flashed and the thunder crashed—cared nought for the weather. And why should they? Turning that question over to the custody of any who feels that he can answer it, I may say a decidedly loud whisper was in the corridor that Secretary Nettleton would be an absentee. This was a bit of a damper; for he has become such part and parcel of the Association in general, and the Secretary's desk in particular, that his good offices have assumed the nature of a staff. Sure enough, next morning, when in precise and trained tones Chairman Taber opened the way for business, the man from Bir-

mingham was absent. The Moses selected to show the route in respect to the Secretary's duties was no less a party than Mr. Humphreys, of Lawrence, wherefore I am led to remark that Nettleton was worthily represented. Mr. Nettleton had hoped to be back in time from a visit to the far West, as he had been hastily summoned to Grand Island, Nebraska, but it was not to be. Hastily noting that the melange of Tuesday evening was followed by clear, cool weather to-day, it is with great satisfaction I note the presence of a goodly assemblage of delegates. As is usual with the New England Association, no time was wasted in formalities, but steadily guided by the rhythmic rulings of President Taber, the order was proceeded with. One other notable thing in connection with the attendance was the presence of Honorary Members Vanderpool, Benson and Thomas, whose attendance made all the more noticeable or pronounced the absence of many whom the Association was wont to greet with favor. To report the regular business, however, is perhaps more what you and your readers desire than what has so far been written here; and with that as a guide, I can have nothing but praise for President Taber's address, although I am not entirely at one with him over some of his conclusions in respect to electric lighting. Scholarly and precise as is the usual manner of diction employed by Mr. Taber, I must say that a more beautifully rendered tribute to the memory of a dead companion or associate I have never listened to than that poured forth by President Taber over the late Mr. Cushing, of Lowell. Beauty of wording marked the tribute; depth of sentiment perfumed it, and truthfulness leavened it. Having for years been a close personal friend of deceased, I may be pardoned for this extended reference to Mr. Taber's expression of thought respecting that friend. And I know that as I feel about this sad event, so do the others of the New England Association who were privileged to call Cushing their friend. As a whole, Mr. Taber's address was of the quality that might be expected from him. He does not beg questions, but answers them. The paper list carried out its promise fully, and I must say also that Pratt's contribution completely verified the promise raised by its title. If all handsome bindings but inclosed similar 'meat,' you could always be safe in 'judging a book by its cover.' Not having at this hour heard Mr. Goodno's paper read, I am in the dark as to whether a like verdict shall apply to it; but it is quite safe to say that it shall, for Goodno is thought pretty well of 'out this way.' Of course I could not take such liberty, unsheltered from the cloak of a name that shelters one in an expression of opinion; and I assure you that many of the Eastern fraternity would like to know who 'Observer' really is. It was expected that Dr. Amory would handle his subject well; and the Doctor justified the expectation to the letter. There can be no doubt that his remarks anent the "Municipal Control of Gas and Electric Light Companies" will have close attention from your readers. Slater—another man who never begs the question, since he always answers it—told in his usual clear style about "Why I shall Make Water Gas." New Bedford seems to be especially favored in that the 'second string to its bow' at this meeting—Mr. N. W. Gifford—was in high unison with his fellow. His "Some Experiments in the Photometer Room" will likely be repeated by others when they understand how the New Bedford ones were conducted. I did not intend to make such extended reference to the papers, but their merit and importance are the excuse that I offer. Before closing this portion of my subject I should be decidedly amiss were I not to make mention of President Taber's manly utterances in respect to the value and worth of the Massachusetts Board of Gas and Electric Light Commissioners. He is all the more to be commended for this, since, if I greatly mistake not, he was not originally a supporter of the movement that resulted in the creation of the Board. However, it is New Bedford policy, as a rule, to wait until a thing has been tested ere New Bedford gives an opinion—a safe rule, too, it may be set down to be. The officers chosen to serve for the current year are:

President—Chas. F. Prichard, Lynn, Mass.

Vice-Presidents—Horace A. Allyn, Cambridge, Mass., and Wm. A. Wood, Boston, Mass.

Secretary and Treasurer—Chas. H. Nettleton, Birmingham, Conn.

Directors—Edward C. Jones, Henry B. Leach, Z. M. Jenks, Wm. Badger and E. C. Learned.

While the applications for membership this year were on the small side, it is nevertheless a fact that the available ones outside the rolls of the Association are not in very great numbers.

To-night we hold carnival in the banquet hall. That pleasure awaits us cannot be successfully denied. To-morrow it is likely that the members will inspect the plants of the Bay State Company, an invitation to that effect, extended by Mr. J. Edward Addicks, having been accepted by the Association. It does not seem necessary that I should

say the meeting is a success, but I, nevertheless, must say that such is the case.—OBSERVER."

"*Thursday*, Feb. 19.—The banquet proved a most enjoyable affair, and the business proceedings of to-day, which were carried out with dispatch, were more than ordinarily interesting to gas men. The proposed visit to the works of the Bay State Gas Company, however, had to be abandoned, a heavy snow fall, that set in early this morning, putting comfortable moving about in carriages out of the question. It is likely that some of the members will visit Waltham to-morrow, there to inspect the fuel gas plant in operation at the great watch factory. I have but time to add that the meeting marking the end of the Association's second decade was both brilliant and valuable.—OBSERVER."

ANNUAL MEETING, CLINTON, MASS.—At the annual meeting of the Clinton Gas Light Company, held on the 18th inst., the following officers were elected: President, Eli Forbes; Treasurer, Clerk and General Manager, Henry N. Bigelow. Directors, Eli Forbes, Henry N. Bigelow, Herbert Parker, John R. Foster and John E. Thayer; Superintendent, W. H. Spaulding. A reduction in gas rates (amounting to about 5 per cent. on the present schedule) was ordered. This places the prices at the following: Gross to ordinary users, \$2.50 per 1,000; net, \$2.25; other consumers, \$2 per 1,000. Extensive betterments have been made to the Company's electric plant within the last three months.

PERSONAL.—We regret to have to announce the death, at her home in Albany, N. Y., on the morning of Sunday, 16th inst., of Emeline Griffin, wife of Noel E. Sisson.

ANNUAL REPORT, SUPT. OF PUBLIC LAMPS BOSTON, MASS.—We are indebted to Supt. Geo. H. Allen, for a copy of his report respecting the operations of the Boston Public Lighting Department during 1889. From the figures presented we find that there are 9,958 public gas lamps in use, to which must be added 798 high power arcs, 300 oil lamps, and 48 naphtha lamps. The Lamp Department employs 161 men, of which 151 are allotted to the lamplighting corps. The cost for the lighting is appended:

Electric lamps.....	\$180,895.96
Gas lamps.....	229,061.54
Oil lamps.....	6,201.91
Naphtha lamps.....	1,411.90

The cost of lighting, extinguishing and repairs is returned at \$127,256.15, and the total expenditure on department account for the year is reported to have been \$593,798.23. The gas lamp contracts run until July 2, 1894, and the burning table calls for a lighting service covering 3,828 hours per annum. The burners used are fitted with an automatic regulator, and consume gas at the rate of 4 cubic feet per hour. It is also shown that the city now maintains "80 large gas lanterns," consuming from 15 to 30 cubic feet of gas per hour; but these do not seem to grow in favor, for, quoting from the language of the report, that as "the first cost of these lanterns is about \$40, and as the expense of maintenance is very large, it would be of advantage to substitute the electric light for them at an early day, provided it can be accomplished without materially increasing the expenses of the department." The total quantity of gas consumed in the lamps was 158,946,216 cubic feet, which was supplied by eight different companies, and the average cost of the supply for the entire district is \$1.453 per 1,000 cubic feet. The Boston Company proper charges \$1 per 1,000.

SOME of the storekeepers of Brooklyn (notably Baldwin, the clothier, and Wilson's restaurant proprietors) have already abandoned the use of incandescent electric lamps supplied with current from the Brooklyn Edison central station. The service was found by them to be fully twice as expensive as gas; hence the change. The ruling gas rate in Brooklyn is \$1.60 per 1,000 cubic feet.

The Market for Gas Securities.

The city market for gas shares shows no change, unless it may be said to have shared, in common with the market for railroad securities, in the weakness of the demand from investors, whose dividends have evidently been placed. Consolidated is at 96 bid, which shows that even a weak general market has no power to affect it greatly. Mutual is up to 109, and it would not surprise us to see it go higher. Brooklyn shares are steady to strong. Baltimore Consolidated is weak, probably on realizing sales; and Chicago Trusts are lower. Laclède common is offered at 15. Eastern shares are all in the line of higher figures, and this observation applies with great force to the Massachusetts companies. Can it be that the State Gas Commission is partly responsible for the feeling of security that prevails among shareholders there?

The Northwich Gasholder on Messrs. Gadd and Mason's Principle.

By THOMAS NEWBIGGING, C.E., in the *London Journal*.

Since the reading of my paper before the Manchester District Institution of Gas Engineers, at the meeting held at Doncaster about 18 months ago, at which the invention of Mr. Gadd was first prominently introduced and described, down to the present time, I have resisted the temptation to speak or write at length on the subject, believing that the best

of the outer or lower lift is 60 feet; and of the inner or upper lift, 58 feet. The average diameter is therefore 59 feet. The height to which it rises when fully inflated is about 38 feet; the total height of 40 feet being reduced by the cup and grip and the bottom seal.

The top curb of the inner lift consists of two angle-iron rings 4 in. by 3½ in. by ½ in., and 5 in. by 3½ in. by ½ in. The roof framing is of the usual kind, consisting of a series of main rafters, 3 in. by 4 in. by ½ in., trussed on the bowstring principle, secured to the curb at the outer end, and at the other end to the center or crown plates at the head of the king post.

Section through Cup and Grip.

illustration of the value of the invention which is so great an innovation on all that has previously been suggested or attempted in this direction, would be its presentation in the shape of a practical working example.

Now that the new principle of guiding has become an accomplished fact in the holder that has just been completed and put to work at Northwich, it is neither necessary nor desirable that I should longer refrain from a detailed reference to the merits of the new system. The best form this can take at present is obviously that of giving a full description, with illustrations of the holder.

The vessel is telescopic, in two lifts, each 20 feet deep. The diameter

The secondary rafters are of flat iron, 3½ in. by ½ in. The main tie rods are 1½ in. diameter. There are 16 vertical stays, each of 3 in. by 3 in. by ½ in. angle irons, with a piece of ½ in. plate riveted between in the inner lift. The hydraulic cup and grip are of the usual construction, 18 in. deep by 8 in. wide. The vertical stays of the outer lift are also 16 in number, one-half of them being made rather stronger than the other, and are ranged on the outside of the vessel, so as to admit of the guide rails being placed inside. The bottom curb is of channel iron, 8 in. by 3 in. by ½ in., and projects from the holder towards the tank. This curb, for single-lift holders, would answer equally well if placed inside; and even in telescoped vessels its adaptation in this way is possible. The

roof sheets are 10, 12 and 14 B. W.G. The holder is surmounted by a handrailing 2 feet in height.

I have been thus precise in describing the holder in order to show that the details throughout are substantially those of other holders guided in the ordinary way; the only difference being that the trussing is heavier than is usually adopted. I am now perfectly satisfied, however, that any additional strength or weight in this particular was quite unnecessary; and from the experience I have gained should have no hesitation in designing and constructing a holder to be guided under the changed conditions of materials as light as, or even lighter than, those of one guided on the old principle.

And now as to the guiding arrangements, which form the new departure. They are of the simplest character (which indeed is their chief merit), and require but little description. They consist for the outer lift of eight steel rails of H section, 4 in. by 3 in. by $\frac{1}{2}$ in., placed against the tank wall at an angle of 45° , and attached to the coping of the tank, and at four other equidistant points in their length by jagged bolts let into stones built into the brickwork. The rails for guiding the inner lift are the same in number, and nearly the same in section—3 in. by 3 in. by $\frac{1}{2}$ in.—the web being shorter, placed at the same angle, riveted at distances of 12 inches apart to the side sheets, to the vertical stays at the point of intersection, and secured top and bottom by means of lugs to the grip and curb respectively. The guide-rollers, one on each side of each rail, are of steel, and are 10 inches in diameter, revolving on 2-in. wrought iron axles, attached to cast iron carriages bolted to the bottom curb on the outer lift, and to the cup of the inner lift. The rollers on the latter work within the channel against the web; and the former, which are grooved, clip the outer table of the rails. These several details are shown in the accompanying illustrations, and will be readily understood. In the next holder of the kind a few modifications—chiefly in the method of fixing the guide-rails and carriages—will be introduced. It will thus be evident that in rising and descending the vessel has a helical or screw-like movement, and turns, in the course of its ascent to its full height, a distance of one-fifth of its circumference. The full pressure given by the holder is 7 inches; and by the bottom lift, $4\frac{1}{2}$ inches. There is scarcely any perceptible difference in the indicated pressure during the ascent and descent.

The actual saving in weight of the total structure, as compared to what would have obtained had the holder been guided by upper framing composed of eight wrought iron standards having cast iron base plates, and braced with lattice girders, and the necessary wind ties, is 36 tons. The slightly increased weight in the bottom curb and spiral rails in the lower lift, does not exceed 2 tons, which will be a deduction from the above. What the cost of the additional material for the upper guide framing, finished and erected, would have been can therefore be easily reckoned. It amounts to at least £600; and this sum may be taken as representing the saving, at current prices, which is effected in the practical application of Mr. Gadd's invention to the comparatively small structure under consideration. It is to be remembered, also, that the tank being built without the usual brick piers and heavy base stones for standards or columns, necessarily costs less than one having these additions.

The contractors for the holder (Messrs. Clayton, Son & Co., Limited, of Leeds) experienced but little difficulty in bending the rails to the peculiar curvature (resembling that of a winding stair rail) which they had to assume, or in the attachment of them to the sides of the tank and holder. Certainly, if any slight difficulty did present itself in regard to these it will disappear in carrying out future work of the kind.

I have elsewhere remarked that in applying the principle to a two-lift holder of only 60 feet diameter, each lift being 20 feet high, or, together, two-thirds of the diameter, the test to which the invention has been put is a tolerably severe one. The conditions of stability in a holder of, say, 200 feet in diameter in three lifts of 40 feet each, are palpably superior by a difference of 10 per cent. to those which obtain in the present structure. In other words, if the two lifts in the Northwich holder were reduced from 20 feet to 18 feet in height each, the comparison would be equal—though, of course, it may be argued that the wind pressure at the higher altitude is usually stronger.

The Northwich holder, whilst inflated with gas to a height of 30 feet, has already been tested under stress of a series of strong gales which have occurred, and it has not shown any movement worth recording. Of the stability of the structure under any wind strain to which it is liable to be subjected, I have no doubt whatever; and I am convinced that the more closely the principle of its action is investigated and studied the more evident it will appear that, as compared with the old method of gasholder guiding, the new system, for efficiency, economy and beauty, takes a vast stride forward.

Claus' Method of Producing Water Gas, and Obtaining Hydrogen, Carbonic Oxide or Carbonic Acid, and Certain Bye Products.

According to the London *Journal*, English Letters Patent (No. 50, Jan. 1, 1889,) have been granted to C. F. Claus, of Suffolk House, London, for a method of securing the results outlined in the above heading. Our authority states that the somewhat lengthy specification of this invention is not accompanied by drawings of the plant proposed to be employed in carrying it out. The patentee explains that the gaseous mixture (consisting principally of carbonic acid, carbonic oxide, and hydrogen) commonly called "water gas," and which is now produced extensively by various methods, forms the basis from which he obtains, by the processes now to be described, hydrogen, carbonic acid, and carbonic oxide, each separately, and in a more or less pure condition. The water gas for his purposes can, of course, be manufactured in some other manner; but he prefers to produce it by the means claimed in the present invention.

He passes an uniform and continuous stream of highly superheated steam through a deep layer of fuel—preferably smokeless fuel, such as coke or anthracite—whereby the water or steam is decomposed, and forms, according to the depth of the layer of fuel or the temperature of the incoming superheated steam, either mainly carbonic acid and hydrogen, or principally carbonic oxide and hydrogen, or mixtures of carbonic acid, carbonic oxide, and hydrogen. In the ordinary mode of producing water gas, it is the practice to fan ignited fuel by means of blasts of air into a state of high incandescence; and steam is then passed through the hot fuel so long as the temperature remains sufficiently high to decompose it into hydrogen, carbonic acid, and carbonic oxide. After the fuel has become too much cooled down to have this effect, the steam is shut off, and the air blast is again admitted until the desired heat is once more obtained, when steam is re-admitted, and so on alternately. In the present process, however, the current of steam is superheated to such an extent that, in passing through the fuel, it will cause the ignition thereof, and will maintain it at a temperature sufficiently high to ensure the decomposition of the steam into a gaseous mixture consisting of the gases already mentioned; no air blast being used for promoting the combustion of the fuel, and there being no necessity for previous ignition of the fuel. A furnace similar to a blast furnace or lime kiln is used as the receptacle for the fuel, built of thick brickwork, and covered outside by gas-tight ironwork, as are the conduits and gas connections. The fuel, as it becomes consumed by the superheated steam, is replenished from the top through an opening, and the ashes are withdrawn from an opening (capable of being closed by a door) in the bottom of the fuel receptacle.

For superheating the steam, apparatus somewhat similar to a Whitwell regenerative and alternately working blast heating stove is used in such a manner that, whilst the steam is passing through one part of it, the other portion is being heated to the requisite temperature; and, when the one part has become cooled down to a temperature no longer high enough for properly decomposing the steam, the current is turned into the other part that has been heated up in the meantime. The direction of the current of the heating gases being changed in a corresponding manner, this current is turned into the part of the stove which has been cooled down by the steam passing through it, and so on continually. The result is that one part of the stove is always at a sufficient temperature to ensure the decomposition of the steam.

As soon as one or more of the chambers are cooled down, they are shunted out from the course of the steam, and connected with the circuit of the chambers which are being heated by the generator gases. When heated to the required temperature, they are again connected with the steam circuit; and a corresponding number of cooled chambers are simultaneously connected with the circuit of the heating gas, and so on continually. The gases and the steam to be heated travel in the same direction through the chambers; and in this manner, a number of chambers are continually heated, while an equal number are having their stored up heat abstracted by the steam passing through them.

After the heating of the chambers, they are full of the products of combustion of the producer gas. To prevent the water gas being contaminated by this, a blast of steam is sent through the chambers, to drive out the products of combustion before the re-admission of steam to be superheated. This may be done by the steam blast entering direct; but it is preferred to do so by first passing the steam through the ordinary generator, and then through the chambers—the air supply to the ordinary generator being stopped for the time, and whilst the steam jet passing through is being used for the purpose named. The patentee's object is to obtain the whole of the water gas produced for use for the purposes for which it is manufactured, and not to use any of the gas for

heating the chambers or regenerators. He therefore effects the heating of the Whitwell stoves employed for the purpose by means of less valuable ordinary producer gas, obtained in the well-known manner from any kind of fuel, either with or without the aid of steam, and does not use any part of the water gas produced for heating any of the apparatus connected with its manufacture. He thus claims to obtain nearly double the quantity of the more valuable water gas than is usual in the ordinary mode of working.

The gases which are produced by the action of the superheated steam upon the fuel are either: (1) Principally carbonic acid and hydrogen; or (2) principally carbonic oxide and hydrogen; or (3) a mixture of carbonic acid, and carbonic oxide, and hydrogen. These are all accompanied by the ammonia which is simultaneously formed by the action of the superheated steam upon the nitrogenous matter contained in the fuel wherewith the water gas is produced. By using steam alone and dispensing with an air blast acting upon the fuel, and by passing the steam in a continuous current through the fuel, the whole of the fuel is consumed by the steam alone, and practically the whole of the nitrogen in it is converted into ammonia available for recovery by a process described later on, instead of only part of it, as in previous processes.

To separate the carbonic acid from the hydrogen, or from mixtures of carbonic acid, carbonic oxide, and hydrogen, and to recover at the same time the ammonia above referred to, the patentee first reduces the temperature of the mixed gases. This is carried out by employing the heat inherent in the gases after they leave the generator, in two separate operations—viz., in the heating of the ammoniacal scrubber liquor, and in distilling it after it has been heated by means of this heat. The gases become cooled by these operations; and after they are thus cooled, they are passed through a series of scrubbers wherein they are brought in contact with free ammonia either in a gaseous or liquid state, whereby the carbonic acid becomes absorbed, whilst a solution of carbonate or sesqui-carbonate of ammonia is formed. The residual hydrogen or carbonic oxide and hydrogen gas is conveyed into a gasholder; and the solution of carbonate of ammonia formed in the scrubbers is heated by the hot gases. The greater part of the carbonic acid is thereby driven out and collected in a holder for use; and the free ammonia left behind in the liquid is distilled off by means of the hot gases, and is returned to the scrubbers to there take up more carbonic acid from a fresh quantity of gases—a certain stock of ammonia being kept for that purpose in constant circulation throughout all the apparatus, as in the now well-known Claus arrangement for gas purification.

After giving a very elaborate description of the process, of which the above is a mere outline, the patentee proceeds to describe how he proposes to separate the carbonic oxide and hydrogen and to obtain them separately. He says: When water gas is produced which contains carbonic acid, or when it has intentionally been produced with a large percentage of it, which has been removed by the process already described, and the ammonia, which may have been associated with it in one way or another, has been removed and recovered from it, the two residual gases, carbonic oxide and hydrogen, have by that operation been cooled down. They are then heated up again to a temperature somewhat above that at which hydrogen will reduce oxide of iron—say, to about 400° to 500°—but below that at which carbonic oxide will do so. This heating of the gaseous mixture may either be accomplished by means of a heating stove, such as that described for the superheating of the steam, or (as the temperature required is a comparatively low one) in stoves such as those used in connection with blast furnaces, consisting of a number of inverted U-shaped pipes. When the gaseous mixture has been heated up to the temperature above mentioned, it is passed into one of a set of six, eight, or more chambers filled with porous (yet firm) pieces of oxide of iron, and which are worked in rotation. After passing through the first kiln, the mixture flows into the second, and so on through the whole series. The hydrogen is by this operation separated from the carbonic oxide, by forming water with the oxygen of the oxide of iron and spongy metallic iron. The water formed is condensed; and the carbonic oxide is conveyed to a holder for use. The oxide of iron kilns are closed ones—connected, however, by means of iron tubes thickly lined by bad conductors of heat. They communicate with one another by pipes so arranged that any one or more of the kilns may be shunted out of connection with the others by means of valves. They are further so arranged that the gaseous mixture may be turned into any one of them, and, by similar means, the exit gases may be taken out of any one of them. The heated gaseous mixture enters one kiln of the series; and the part of the mixture which passes through the kiln enters the next kiln, and so on—the gas from the last kiln passing into a holder. As soon as the oxide of iron in the kiln into

which the gaseous mixture first entered has become converted into metallic iron, the gaseous mixture is turned off from this kiln, and into the next kiln, which thus becomes the first in the series; and so on continually. The effect of this is that each kiln in its turn becomes first, intermediate, or last in the series. The kiln which contains the oxide of iron converted into metallic iron sponge, when shunted out from connection with the other kilns, is then connected with the hydrogen holder, and steam (superheated as described) is passed into it; and the hydrogen thus formed is conveyed into the holder. The superheated steam is, however, with more advantage passed successively through several of the kilns containing the metallic sponge; entering the one connected with the heated gases first, and leaving that connected last with the heated gases. When the metallic iron sponge contained in the kilns has, by the action of the superheated steam, been converted into oxide of iron, the first of the kilns is disconnected from the hydrogen holder, and again connected with the set of oxide of iron kilns, through which the gaseous mixture is passing; and this kiln then becomes the last in the series—a *modus operandi* the advantages of which will be understood without further description.

The Massachusetts Board of Gas and Electric Light Commissioners on the Subject of Water Gas.

[From advance sheets of the Fifth Annual Report from the Board, and reprinted with the consent of the Commissioners.]

The Board since its last report has continued its investigations on the subject of water gas. It is understood that the parties in interest do not desire to offer further evidence in the cases pending at the close of the year. The Board believes that some modification of the present law is desirable, and that a report of the work of the Commissioners in this branch of their duties ought to be made to the Legislature at the present time.

In the course of its inquiries the Board has endeavored to ascertain what commercial advantages, if any, might accrue to the companies from an extension of the present statutory limit of carbonic oxide, believing that in any such advantages the consumers would ultimately share, and that the companies ought to be permitted to avail themselves of them, if they could do so without prejudice to the public interest. For this purpose information has been obtained by personal inspection and correspondence from more than a hundred companies. The Board desires to gratefully recognize the uniform courtesy which has been freely extended it by the engineers in charge of water gas works in other States, and to acknowledge its obligations for the information so freely furnished.

It is clear that the cost of gas, whether coal or water, is not an inflexible figure, the same for all times and places; an advance of 50 cents per ton in coal or of one cent per gallon in oil, making an increase of 10 per cent. in the cost of coal and water gas respectively. In certain large works where both kinds of gas have been made, the advantage in cost of production has been sometimes with one, sometimes with the other kind of gas. There are more exclusively water gas works in the anthracite coal region in Pennsylvania, and within easy reach of it, than in any other portion of the country of the same area; because there the price of anthracite coal has been low, and that of gas coal relatively very high. The particular location of a gas works and its arrangement, the quality of the materials and kind of apparatus used, and the kind of labor and superintendence available, may make even larger variations in the cost of either gas.

The expenses of distribution, management, taxes, etc., are not likely to vary greatly, whether coal or water gas is the product; so that the fact of value in estimating the cost of the two gases is the cost to manufacture or cost in the holder, as distinguished from cost at the meter.

The principal items of cost in the holder are for materials, coal and oil, labor and repairs. From the cost of materials in coal gas is to be deducted the very considerable receipts from the sale of coke, tar and ammoniacal liquor. Under the best conditions in this State these receipts have reached 50 per cent. of the cost of coal, and in some companies more favorably situated they have reached a much higher percentage.

A ton of good gas coal will yield approximately 10,000 to 11,000 feet of gas. In order to secure the candle power usually supplied in this State there must be added about 10 per cent. of cannel, or something more than 5 gallons of oil, equivalent to more than one-half gallon per 1,000 feet.

In the production of illuminating water gas there is commonly used more than 50 pounds of hard anthracite coal, and from 5 to 6½ gallons of oil for every thousand feet of gas, although in the very best works

and under very favorable conditions these quantities may be slightly reduced. These two items nearly make up the cost of water gas in the holder.

In coal gas the cost of labor is a most important element. It often nearly equals one-half the gross cost of materials, and in many companies does not vary much from the net cost of coal. In water gas the cost of labor is small.

It has been very difficult for the Board to obtain definite and reliable information as to the cost of repairs in water gas works. It is not a very considerable item in coal gas, and is probably about one-half as much in water gas.

The following figures show the range of cost in certain companies, each item being calculated independently of the other, and, it is believed, fairly indicate the difference of cost in the holder of the two gases :

MATERIALS.	
<i>Coal Gas.</i>	
Gas coal.....	40 to 43 cents.
Oil or cannel.....	3 to 7 cents.
Residuals.....	13 to 23 cents.
Net, for materials.....	20 to 30 cents.
Labor.....	14 to 20 cents.
Repairs.....	5 to 8 cents.
Total.....	50 to 57 cents.
<i>Water Gas.</i>	
Coal.....	11 to 15 cents.
Crude oil.....	13 to 18 cents.
Naphtha.....	24 to 33 cents.
Materials.....	26 to 33 cents.* 38 to 45 cents.†
Labor.....	5 to 11 cents.
Repairs.....	2 to 3 cents.
Total.....	46 to 55 cents.

The figures relating to coal gas are taken from the returns of certain companies in this State, as made to the Board. The figures relating to water gas are estimates based upon information procured without the State, and intended to show what the same companies might do at current rates for materials, if they were making this instead of coal gas. It may be noted that the companies now making water gas in this State have not yet been able to equal the figures given. The relations shown above may be greatly changed at any time. The figures given for naphtha and crude oil are suggestive. A few years ago, when the number of water gas works was small, the price of naphtha was about the same as that of crude oil to-day. As the demand for naphtha for gas making purposes increased, the price advanced to a point which nearly neutralized the advantages of its use. Recently a crude oil, from the Ohio fields, difficult to refine, has come upon the market at a low price, and an apparatus specially adapted for it has again reduced the cost of water gas to the low point reached when naphtha was first introduced. There are now signs of an advance in its price.

There have been great improvements in water gas apparatus, and there is much activity in this direction now. It is now claimed that cheap bituminous coal and slack can be made to do the work of expensive anthracite; and, if the expectations of the inventors of this new process are realized, the cost of producing water gas may be greatly lessened.

In companies whose output is below a certain limit, the peculiar condition under which they make gas causes the cost to vary greatly from the figures given above. In these the cost per 1,000 feet for both coal and labor rises rapidly where coal gas is made. There is little or nothing obtainable from residuals, as all or nearly all the coke is used to carbonize the coal, and the production of gas per man is much reduced, since of necessity the gas maker must be idle much of the time. In a properly constructed water gas works of very small output, while the cost of coal may be easily doubled by the necessity for frequently cooling and reheating the apparatus, the cost of labor is not materially different from the same item in large works. In a single day one man may make and store water gas sufficient for several days' consumption, during which the works need no attention, and the gas maker can devote himself to the numerous other details of the business. Instances have been observed by the Board, in other States, where small works have been carried on in this manner with apparently good results. For reasons not easy to enumerate, the attempts by small companies in this State to pursue a similar course have not heretofore been entirely successful.

Although in the larger works, except in favored localities, the commer-

cial advantages of manufacturing exclusively coal or water gas may not be considerable, with the methods and apparatus now most in use, the advantage to company and consumer in the combination of the two gases is now generally recognized by the larger companies, and nearly one-third of all the companies in the country manufacture some water gas. The development of electric light, combined with other causes, has greatly increased the public demand for light; a gas of 15 or 16 candles is no longer acceptable, and from 18 to 20-candle gas is as low as companies in the larger towns and cities think it wise to distribute. Gas of this quality cannot be produced with ordinary coal alone, but requires the addition of cannel coal or of oil; which latter, from its low cost and the facilities for handling, has been most generally adopted. For this use of oil the ordinary appliances of a coal gas works are but poorly adapted. When oil is used in them, it has shown a decided tendency to pass with the coal gas as a vapor, much of which is subsequently deposited in the mains or fixtures in a liquid form, or, by causing a hard substance to form at the tip, obstructs the flow of gas, and causes the forked and irregular flame so common where such gas is used; and the gas often manifests an uncontrollable tendency to smoke. To a high candle power secured in this way is often due the blackened spots in the ceilings of dwelling houses where such gas is used.

A water gas apparatus affords the means for avoiding these difficulties. In this the heats best adapted to breaking up the oily particles into a fixed gas may readily be attained, and gas of a very high candle-power be made. When coal gas is made at the same works, and the two are mixed in the proper proportions and best manner, the unfortunate results mentioned as due to oil should not occur. The gas is composed of the same constituents, but in different proportions, and reaches the burner with that combination of heating and illuminating elements calculated to produce a clear, white flame, free from smoke.

Numerous other reasons suggested by local conditions have induced companies to add to coal gas works apparatus for making water gas. It enables a company to easily meet a sudden demand for an unusual amount of gas. It can be made ready for gas making at an hour's notice, then allowed to cool when the demand is over, and this course repeated indefinitely without injury, while coal gas benches once treated in this manner would probably need rebuilding. An unexpected dark day may thus be readily provided for, and the considerable changes in consumption where street lights are burned by moon schedule, but are unexpectedly called for on stormy nights. In some places the increased consumption has made necessary some increase in the capacity of the works, which has been secured with less expense for extension by the introduction of water gas apparatus, with a consequent saving in capital account. A brief period of extraordinary consumption in midwinter is sometimes provided for in this way. In many works where both kinds of gas are made, coke produced at the works is substituted for anthracite coal, furnishing a profitable use for surplus coke, and preventing a reduction of its price.

These are some of the indirect advantages resulting from a manufacture of both kinds of gas in the same works. They are quite independent of whether one gas made alone costs a little more or less than the other. To secure them requires the distribution of a gas containing somewhat more than 10 per cent. of carbonic oxide.

The question of the comparative safety of water and coal gas is a very perplexing and difficult one to solve satisfactorily. One or more members of the Board have personally examined the premises where a large number of deaths have occurred from asphyxiation by inhaling illuminating gas in Brooklyn, New York city, Baltimore and other cities. A few of these deaths were caused by coal gas, others probably by a mixed gas; but the larger number were due to water gas. Some valuable suggestions have been obtained from these inquiries, although great difficulty was experienced in securing exact or definite information. It was impossible, for instance, in most cases to ascertain the length of time the gas was discharged into the room; and in many cases the size of the burner, and whether partially or wholly open, were only matters of conjecture. Most of the accidents investigated occurred at the cheaper boarding and lodging houses. It was found in one city—and the same facts also applied to the others in a less degree—that a very low price for gas, great activity on the part of competing companies in canvassing for customers, and the very favorable terms that were made for piping buildings and furnishing fixtures, had led to the introduction of gas into the very cheapest lodging and boarding houses that are frequented by the dissolute and ignorant classes. In several instances it was evident that the inhaling of gas alone would not have produced death, but caused it by aggravating diseases existing at the time of the accident. Some of the rooms contained less than 500 cubic feet of space, and the average space of all the rooms was about 1,100 cubic feet. The largest

* Crude oil. † Naphtha.

amount of gas was 75 cubic feet, as nearly as could be ascertained, in a room containing 748 cubic feet of space; but there was an open transom at the time of the accident, and the person lived 12 hours after being discovered. The smallest amount of gas was 18 cubic feet, in a room containing 806 cubic feet of space; and the person was dead when found. The average amount of gas in the rooms was about 38 cubic feet. But, as before intimated, the information in regard to the amount of gas in the rooms where deaths occurred is unsatisfactory. In three instances, where a man and a woman occupied rooms together, the men died and the women recovered.

In addition to these investigations the Board has obtained, from newspapers and other sources, information in regard to the deaths of 107 persons in this country from inhaling illuminating gas during the year 1889. This is probably not the whole number of deaths from this cause, but perhaps complete enough to give some facts of interest in considering the question of danger from illuminating gas. There is conclusive evidence that 30 of these persons committed suicide, and there were circumstances attending the deaths of several others that indicated more or less strongly the same cause. But, deducting from the whole number only those suicides about which there can be no doubt, there were 77 deaths caused by accidentally inhaling illuminating gas. These occurred in the following towns and cities, viz.: Yonkers, N. Y., 1; Baltimore, Md., 7; Oakland, Cal., 3; Jersey City, 2; New Brunswick, N. J., 1; Amesbury, Mass., 1; Paterson, N. J., 6; Huntington, Pa., 1; and Bethlehem, Pa., 3. In these places only water gas is believed to be manufactured. In New York city there were 24 deaths; Philadelphia, 2; San Francisco, 7; Chicago, 5; Brooklyn, 3; Washington, D. C., 2; Minneapolis, 1; Charlestown, Mass., 1. In these towns and cities a mixed coal and water gas is made, or there are coal and water gas plants in operation. There was 1 death in Cincinnati; 2 in Milwaukee; 1 in Lincoln, Neb.; 1 in Belleville, Ill.; and 1 in Portland, Me. These have only coal gas plants. The following are the number of deaths for each month, viz.: January, 9; February, 5; March, 6; April, 3; May, 5; June, 7; July, 1; August, 1; September, 5; October, 10; November, 11; December, 12.

Forty-six of the deaths occurred in hotels—generally of the cheaper class—lodging and boarding houses, where the rooms were usually small and poorly ventilated. In 18 of the accidents the gas was blown out by ignorant persons, and in 46 instances it was found turned on without any satisfactory evidence as to the cause. In 8 instances death was caused by gas stoves, in 1 by a leaking pipe, and in 3 by defective keys where the gas is turned on at the burner. Twenty-five of the persons killed were females, and 52 were males. Of the males, 17 were business men, 4 farmers, 2 professional men, 6 laborers, 2 sailors, 2 mechanics, 1 janitor, 1 railroad man, 1 teamster, 1 bartender, 1 waiter, 1 student, and 7 unclassified. Ten of the females were servants. In 20 cases the persons were more or less intoxicated at the time of their deaths.

It will be seen that 26 of the deaths occurred in places where only water gas was manufactured, 6 in those having only coal gas plants, and 46 in towns and cities where is furnished a mixed water and coal gas, or where there are plants of each gas. The largest number of deaths was 24, in New York city. In New England, where 14 cities and towns are furnished with water gas and 6 with a mixed water and coal gas, there were 3 deaths. One of these resulted from inhaling water gas, 1 from coal gas, and the third one was caused by a mixed water and coal gas.

Some of the inferences to be drawn from the above facts are that about 30 per cent. of the deaths from illuminating gas are suicides; that about 20 per cent. are persons more or less intoxicated at the time of the accidents, and a considerable number are persons unacquainted with the use of gas. A comparatively small number of cases are purely accidents that could not have been avoided.

From the fullest consideration which the Commissioners have been able to give to the Act, chapter 428, Acts of 1888, they believe that the correct interpretation of the statute does not permit them to issue a revocable license or one subject to modification, to impose any terms or conditions in the exercise of it, or to qualify in any manner the certificate which the license must contain, "that in their opinion the gas can be used with safety" for illuminating purposes. The degree of danger in the use of coal gas, water gas, or a mixture of the two, depends largely on the amount of carbonic oxide it contains. It is probably true that the Legislature of 1880 fixed the limit of carbonic oxide at 10 per cent. because that limit was not exceeded in the manufacture of coal gas, and not because it was safe. Many reliable gas engineers now believe, and have expressed the opinion to the members of the Board, that commercial necessities exist at the present time for permitting a larger

percentage. The danger which appertains to the careless use of all the gases named is an obstacle, in the minds of the Commissioners, against granting a license in the form contemplated by the statute. Coal gas is used for illuminating purposes, not by reason of its elements of safety, but because of its ease of distribution, convenience, neatness, economy, and the excellence of its light. Its dangers are widely known. Water gas or a mixed gas is somewhat more dangerous; but should its use be wholly prohibited, if the present state of the art shows that in some communities a better and cheaper light can thereby be supplied, and the increased risk can by care be overcome?

In many cities and towns a mixed gas is served, containing from 10 to 20 per cent. of carbonic oxide; in others, water gas having from 25 to 30 per cent. of the same constituent. In these places, as a rule, the question of safety or danger does not enter into the calculation; the managers of the gas companies there simply consider the economy and quality of the light, and the same is true of the consumers. As the accidents are chiefly caused by ignorance or carelessness, the general public feels no alarm, as people do not ordinarily charge themselves with being either careless or ignorant. But all intelligent persons agree that too much caution cannot be exercised. When used by watchful, careful consumers, almost any gas can be called safe; but in the hands of the careless or ignorant, the same gas will be dangerous. The more poisonous gas can perhaps be made practically safe by keeping the gas pipes and fixtures tight, by the use of smaller burners, or by providing ample means of ventilation if the gas by any means should escape.

If a thing in itself be dangerous, the knowledge of its character and a warning in its use are likely to prevent harm. How can a certificate of safety be attached, without misleading the very ones whom it is desired to make more careful? Although a mixed gas or water gas is somewhat more rapid in its poisonous effects, if inhaled, than common coal gas, is it not quite probable that a little more care on the part of those who distribute and use the gas may fully offset the increased element of danger it contains? The mere knowledge that it is more harmful would naturally lead people to be more careful. Some of the accidents are caused by defective fixtures or burners; these could be inspected and kept in repair. A company might be required to examine them periodically. If the proportion of carbonic oxide be extended, especially to the degree found in water gas, the size and number of burners in sleeping apartments might be limited, and means of ventilation insisted upon. The attention which has of late been called to deaths by the inhalation of gas has led inventors, with more or less success, towards the discovery of some automatic device for closing the pipe or burner, in case the light is blown out or by some accident the gas is turned on. Something of the kind might be desirable, especially in lodging rooms. These suggestions are made simply by way of illustration. Other and more effective provisions might be adopted. The Board is firmly of the opinion that the certificate as to safety ought to be omitted from the license. Such a certificate, it is confidently believed, will in no way serve to protect consumers. The Board respectfully suggests that it should have power to place such conditions in the license as in its judgment will tend to guard the community against accidents. The license should also be made revocable, or be subject to modification, as the most practical means of enforcing its provisions and speedily preventing any further danger which might be likely to arise.

For these reasons a change of the statute is urged upon the attention of the Legislature. The draft of a bill* embodying the views of the Commissioners, is submitted, and the passage of some such act is respectfully and strongly recommended.

At the stockholders' meeting of the Waltham (Mass.) Gas Light Company the following result was reached: Clerk and Treasurer, Geo. A. Stearns; Directors, Lowell Clark, John R. Farnum, Arthur T. Lyman, A. M. Goodale, Geo. A. Stearns, Wm. Roberts, and Augustus Flagg. The last two named take the places of M. H. Young and C. E. Getchell, resigned. The annual report of the Treasurer shows that the balance on hand, Jan. 1, 1889, was \$41,639.25, and the income for the year \$27,631.59, making a total of \$69,270.84. Out of this dividends to the amount of \$8,400 were paid, interest took \$1,022, insurance, \$388, and construction \$4,142, leaving a surplus on Jan. 1, 1890, of \$55,308.84. The income in 1888 was \$28,419.26, or \$787.67 more than in 1889. The Company now has 42 arc electric lights in use for the city, and 50 for commercial purposes, besides 61 incandescent 65-candle power lamps, and 565 of 40-candle power.

* For a copy of bill, see JOURNAL, ante, p. 206.

[OFFICIAL REPORT.—REVISED BY THE SECRETARY.]

TWENTIETH ANNUAL MEETING, NEW ENGLAND ASSOCIATION OF GAS ENGINEERS.

HELD AT YOUNG'S HOTEL, BOSTON, MASS., FEB. 19 and 20, 1890.

FIRST DAY—FEB. 19—MORNING SESSION.

The Twentieth Annual Meeting of the New England Association of Gas Engineers was held at Young's Hotel, Boston, Feb. 19 and 20, 1890, the President, Robert B. Taber, of New Bedford, Mass., in the chair.

The first session was called to order Wednesday, Feb. 19, at 10 A.M. The President announced that the Secretary, Mr. C. H. Nettleton, was necessarily absent, and, on motion of Mr. Stiness, Mr. C. J. Russell Humphreys was appointed Secretary *pro tem*.

COMMITTEE ON INVITATIONS.

The President—I will appoint Mr. Slater and Mr. Norton to serve as a committee to invite gentlemen who have done us the honor of being present, and who may be eligible to be with us, to join us; and also to invite anyone whom they may know to be in the city, and whose attendance might interest or benefit the Association, to meet with us.

Mr. Slater—I presume that "eligible to meet with us" means any gas man?

The President—I purposely put it in that way. Your own sense of their eligibility will determine whom you shall invite to join with us in our deliberations.

DISPOSING OF THE MINUTES.

The President—The first business in order will be the reading of the minutes of the last meeting.

Mr. Harbison—I move, as the minutes have been printed in the AMERICAN GAS LIGHT JOURNAL, that they stand approved as printed.

Mr. Stiness—I second that motion.

The motion was passed.

APPLICATIONS FOR AND ELECTION TO MEMBERSHIP.

The President—The next regular business will be the consideration of applications for membership. The Secretary has a list of those whose names have been scrutinized by the Board of Directors and approved by them.

The Secretary read the following list of applicants for membership, as approved by the Board of Directors:

Active Members.

A. C. Anthony, Providence, R. I.	E. J. Nutter, Milford, Mass.
Henry Boardman, Bangor, Me.	J. J. Nutter, Milford, Mass.
Andrew J. Horton, Brattleboro, Vt.	G. M. Rossman, Keene, N. H.
F. H. Lane, Wallingford, Conn.	L. A. Saville, Lexington, Mass.
H. M. Lane, Leominster, Mass.	Wm. H. Spaulding, Clinton, Mass.
F. W. Norton, Nashua, N. H.	

Associate Members.

Frank H. Brown, Waltham, Mass.	Wm. E. McKay, Boston, Mass.
Geo. C. Hicks, Boston, Mass.	Chas. E. Willard, Boston, Mass.
William Homes, Boston, Mass.	E. H. Woodward, Concord, N. H.

On motion of Mr. Harbison, Mr. Stiness was directed to cast the ballot of the Association for the election of the applicants named; and they were declared to be duly elected to membership. The new members were then introduced to the Association.

RESIGNATION OF MR. JAS. PORTER.

The Secretary having read a letter from Mr. James Porter, resigning membership in the Association, the President remarked that the Directors acted upon it last night, and approved it; but he thought it proper that it should be brought before the whole body.

LETTERS OF REGRET.

The President—We have several letters received from members of our own body, and from others who have been invited to attend this meeting, regretting their inability to attend. The Secretary will read the names, but I think we will not delay business by reading the letters.

The Secretary stated that letters of regret had been received from—

H. C. Adams,	T. J. Hayward,
Walton Clark,	Prof. E. G. Love,
C. A. Coffin,	John McIlhenny,
W. H. Denniston,	George S. Page,
Frederic Egner,	Geo. G. Ramsdell,
D. D. Flemming,	W. Cary Sanger,
G. A. Hyde, Jr.,	Robt. Young.

Mr. Stiness—I would like to ask if, in the reading of papers, we are to follow the printed programme. I suppose there are some members here

who feel more interest in some of the papers than they do in others; and as our country members do not get to Boston every day, I have no doubt they would be glad to know when certain papers are to be read, in order that they may be present to hear them.

The President—The announcement merely states that "during the meeting the following papers will be read." It was understood that Mr. Nettleton would give us some idea how he had arranged this matter; and in his absence the Directors at their meeting last evening thought they would select such times for reading the papers as the writers of the papers might prefer. For that reason I cannot now state the order in which the papers will be read; but if anyone having a desire to hear a certain paper will express it, and the writer can be found, the paper may be read at any time. There are certain of the papers which would naturally group themselves, and which should properly be read together, but no definite arrangement of that kind has been made. The Secretary will listen to suggestions from any member as to the order of reading, and I have no doubt the meeting will be glad to follow any desired order. The reading of Mr. Addick's paper has been deferred until to-morrow, as he is not prepared to read it to-day.

ROLL CALL.

Upon the call of the roll the following members answered to their names as being present:

Honorary Members.

Jos. R. Thomas, New York City. Col. Fred. S. Benson, Brooklyn, N. Y.
Eugene Vanderpool, Newark, N. J.

Active Members.

Addicks, W. R., Boston, Mass.	Learned, Waldo A., Newton, Mass.
Africa, W. G., Manchester, N. H.	Long, Robt. J., Salem, Mass.
Allyn, H. A., E. Cambridge, Mass.	Macmun, Geo. F., Natick, Mass.
Amory, Dr. R., Brookline, Mass.	Manchester, Geo. L., Easthampton, Mass.
Anderson, Wm., Marlboro, Mass.	Manchester, J. Howard, Bristol, R. I.
Andrew, John, Chelsea, Mass.	Moore, David, Salem, Mass.
Atwood, H. A., Plymouth, Mass.	Neal, G. B., Charlestown, Mass.
Badger, Wm., Concord, N. H.	Norton, H. A., Boston, Mass.
Bill, Geo. D., Malden, Mass.	Parker, Albert H., Bangor, Me.
Blood, F. C., Ware, Mass.	Prichard, Chas. F., Lynn, Mass.
Boynton, D., Chicopee, Mass.	Quinn, Andrew K., Newport, R. I.
Burnham, J. H., E. Boston, Mass.	Richardson, F. S., N. Adams, Mass.
Cabot, J., New York City.	Sherman, F. C., New Haven, Conn.
Coffin, J. A., Gloucester, Mass.	Slater, A. B., Providence, R. I.
Coggshall, H. F., Fitchburg, Mass.	Slater, A. B., Jr., Providence, R. I.
Cooper, A. F., Exeter, N. H.	Snow, Wm. H., Holyoke, Mass.
Copp, A. M., Boston, Mass.	Spaulding, C. F., Waltham, Mass.
Coyle, P., Charlestown, Mass.	Spaulding, C. S., Brookline, Mass.
Davis, F. R., Athol, Mass.	Spear, J. Z. A., Dorchester, Mass.
Fowler, S. J., Westfield, Mass.	Stedman, W. A., Rochester, N. Y.
Gerould, C. L., Brooklyn, N. Y.	Stiness, S. G., Pawtucket, R. I.
Gillmor, O., Norwich, Conn.	Taber, R. B., New Bedford, Mass.
Goodno, G. F., Dedham, Mass.	Tarbell, A. Willis, Waltham, Mass.
Greenough, M. S., Boston, Mass.	Tarbell, Wm., Waltham, Mass.
Harbison, J. P., Hartford, Conn.	Tilton, D. D., Newburyport, Mass.
Hassett, E. J., Beverly, Mass.	Todd, J. R., Middletown, N. Y.
Humphreys, C. J. R., Lawrence, Mass.	Wells, Levi W., Boston, Mass.
Jenks, Z. M., Woonsocket, R. I.	Wetherbee, G. E., Worcester, Mass.
Jewitt, M., Clinton, Mass.	Wood, Gideon, New Bedford, Mass.
Jones, E. C., Boston, Mass.	Wood, W. A., Dorchester, Mass.
Kelly, H. H., Greenfield, Mass.	Woodward, R., Waltham, Mass.
Lamson, C. D., Worcester, Mass.	Yorke, E. H., Brockton, Mass.
Leach, H. B., Taunton, Mass.	
Learned, E. C., N. Britain, Conn.	

Associate Members.

Coburn, Cyrus M., Chelsea, Mass.	Smith, Robt. R., N. Hartford, Conn.
Davis, Fred. J., Waltham, Mass.	Tufts, Nathaniel, Boston, Mass.
Gifford, N. W., N. Bedford, Mass.	Tobey, F. Jr., New Bedford, Mass.
Holmes, R. E., W. Winsted, Conn.	Waldo, Chas. S., Boston, Mass.

The Committee on Invitations announced that the following non-members would attend the sessions at the invitation of the Association:

Barker, F. E.	Daley, D. R.	Graeff, Jr., G. W.	Rowland, C. L.
Bush, J. S.	Dickey, C. H.	Howard, Gov. J. L.	Shelton, F. H.
Blodget, C. W.	Fowler, Jno.	Kreischer, G. F.	Sprague, F. R.
Corbett, C. H.	Fry, C. C.	Loomis, B.	Stanley, I. N.
Coggeshall, C. H.	Floyd, F. W.	McDonald, W.	Wood, A. C.
Coffin, A. B.	Goodwin, W. W.	Mooney, Wm.	White, Wm. H.
Down, W. H.	Gardner, Jr., J.	McGeorge, D. H.	Weber, O. B.

(To be continued.)

The Proposed Hatteras Light.

The proverbial dangers of Cape Hatteras, says the *Engineering Record*, are due not only to its exposed position on a much-traveled line of coastwise trade, but to the fact that very dangerous shoals extend from it several miles seaward, on which vessels might strike in bad weather before seeing the light on the Cape itself. Several whistling buoys placed on the shoal had been carried away, owing, as is supposed, to the links of their mooring chains having chafed through by incessant motion in the grinding sand, and with increasing commerce the loss and danger became so great that in January, 1883, many underwriters, merchants, owners and sea captains petitioned Congress for a lightship to be stationed at that point, which, in view of the fate of the buoys, the Light House Board did not consider wise, as if the lightship should get adrift on a lee shore her loss with all on board would be inevitable.

A lighted beacon, consisting of a skeleton iron tower, 40 or 50 feet high, with a reservoir for compressed gas, had already been suggested, and Major O. E. Babcock, U.S.A., Engineer of the Fifth Light-house District, was ordered to examine and report as to the feasibility of such a scheme. He, in July, 1883, reported the project feasible, though likely to be dangerous and expensive in execution; as, however, the preliminary work would be as expensive for a beacon as for a light-house, he advised the construction of the latter on an iron pier, built after the manner of those at Long Branch and Coney Island, the light-house itself to be of the same character and 80 to 100 feet high.

Nothing more seems to have been done for nearly two years, when, in June, 1885, plans and estimates for the proposed structure were obtained from SooySmith & Co., engineers and contractors, of New York city. They advised the use of an octagonal wooden caisson for the foundation, and estimated the cost of the entire structure at \$500,000. In January, 1888, Congress appropriated that sum for the construction of the light house with the important provision "that such contractors for doing this work may be selected by the Light-house Board, as may, in the judgment of the Board, be best fitted by reason of skill, experience, possession of plant and control of means to do the work." Bids have accordingly been invited for the complete construction, equipment and temporary maintenance of the proposed light-house, and will be received up to July 1, 1890.

The following extracts are taken from the specifications:

The locality is one of the most exposed on the coast. The site has about 24 feet of water over it at low tide; the rise and fall of the tides at the site is about $1\frac{1}{2}$ feet; the current velocity has been estimated at 4 knots per hour after heavy gales, and the surface of the shoal at and in the vicinity of the site is composed of fine gray sand with broken shells.

The tower is to be an inclosed structure, 150 feet high from low water mark to the focal plane of the lantern.

The foundation of the tower must be solid and massive to withstand the impact of the waves. Its base must be sunk to a stratum underlying the surface of the shoal which offers sufficient resistance to the weight of the structure; and should this stratum consist of material which can be scoured or displaced by the sea, it must be deep enough below the latter to be out of all possible reach of the destructive action of the water.

The site all around the structure is to be protected by a riprap packing, composed of granite blocks, weighing not less than 2 tons apiece. The slope line of the packing must intersect the foundation at low water mark and the original surface of the site at a distance of 40 feet from the structure.

The first floor of the structure is to be at least 30 feet above high water mark. The choice of the various kinds of material to be used in the construction of the tower is to be left to the designer and the contractor.

The probable construction will be that of an immense wooden caisson with a tapering iron tube projecting upwards from its center. This will be built at some convenient port and towed out to its site, being lifted on the way over a bar where there is but 8 feet of water at high tide. When the site is reached it will be rapidly sunk until the cutting edges enter the sand, when the water will be forced out by compressed air and the bottom excavated from within until the desired depth is reached, when the entire caisson and the tube up to 30 feet above high water will be filled solid full of concrete. Above this will rise an iron or steel tower having 10 stories, including the watch room and lantern.

The contractor must fix the time at which he will have the work completed, and must commence work within one month after the contract has been awarded. When the light-house is finished he must completely equip it and keep it in satisfactory operation for one year before any of the work is to be paid for.

The Hatteras Light, when completed, will be one of the most important and difficult pieces of light-house work ever executed, the only

structures comparable to it being the Rothersand Light-house on the coast of Holland and that on Fourteen Foot Bank in Delaware Bay.

Preventing the Incrustation of Boilers.

Walter Chambers, in an article on this subject, says that although much has already been written upon the management and care of steam boilers, and many expedients proposed for removal of incrustation, more might advantageously be said about the benefits to be gained by a wider recognition of those means for promoting economy by preventing incrustation and its attendant waste of fuel. It is estimated that 1-16 inch of scale causes a loss of 13 per cent. of fuel; $\frac{1}{4}$ inch, 38 per cent., and $\frac{1}{2}$ inch as much as 60 per cent., besides predisposing the boiler to explosion as well as incurring the loss of time and labor for its removal.

Many of the misnamed and anti-incrustators contribute to the evil, as they contain organic matter, and help rather than hinder incrustation, while those that are effective in water containing carbonates of lime frequently liberate pyroligneous acid that adversely affects the iron; then the alkaloids, when used in excess, conduce to foaming, and, in conjunction with the oil from the engines, they saponify or form soap.

The presence of damp air is prejudicial to the interior of a boiler, as the process of oxidation or corrosion is thereby accelerated; when we reflect that the feed pump is commonly made about twice the capacity required for the feed water, it is obvious that a considerable amount of air, and consequent deterioration of the boiler, is thus accounted for. A remedy is easily found in a self-adjusting pump, the duty of which could be controlled by means of a float, so that it would deliver the requisite amount of solid feed water without air. A thorough system of economy and efficiency would comprise a surface condenser for returning the pure water obtained from condensation of the exhaust steam from the engine, together with a small evaporator heated by the waste chimney gases, for making up any loss of pure water due to leakage of steam. These are simple and now well recognized contrivances, and a comparatively small outlay in this direction would prevent the many evils due to incrustation and should lessen the premium of insurance and effect a saving in expenditure.

Boilers are subject to the chance of damage when safety valves or pressure gauges are out of order. Not a day should pass without ascertaining that the former are in operation, while the index of the gauge should, if correct, stand at zero when the steam is off, and also show the same pressure as the safety when it blows off, so its accuracy is readily ascertained.

The level of water in the boiler should be verified at regular intervals by means of the gauge cocks fitted for that purpose, quite independently of the gauge glass; all these require frequent blowing to ensure safety, since we learn that the majority of serious explosions are due to shortness of water. The benefits of using hot feed water have already been referred to, and in no case should cold water be pumped into a hot boiler, as local contractions, leaky seams and joints, and even ruptures may be occasioned, while for similar reasons cold air currents should also, as far as possible, be excluded from the furnaces and flues.

Boilers also suffer, to a considerable extent, from the lubricants from the engine that find their way in with the feed water. Many of them are deleterious to a degree, and have doubtless contributed to many adverse occurrences. Perhaps there is no detail deserving of more attention than that of selecting suitable lubricants. Their influence upon the economy of the boiler will be more apparent when referring to efficient lubrication in its relation to the durability of machinery.

The Connellsville Coke Trade.

A local authority writes that the coke trade of the Connellsville region for 1889 beats the record from 15 to 20 per cent., and is altogether immense. But, big as it was, the record for 1890 will, unless all signs fail, not only equal, but surpass it. With such a comforting assurance for the future, we may contemplate the past with some degree of complaisance. During the year just ended the Connellsville coke operators marketed 326,220 cars of coke, aggregating 5,825,000 tons. A large portion of this immense output, the greatest output in the history of the greatest coal region in the world, was sold at prices near the dollar mark, yet the average price of the total output was about \$1.40 per ton, at which rate the spot value of the yearly output would be about \$8,150,000. The output for 1888 was in round numbers 5,000,000 tons, of the average value of \$1.20, making a total value of \$6,000,000. These figures show a decided increase in trade during the past year, in spite of the very dull manner in which it opened. The beginning of 1889, it will be remembered, ushered in a declining coke trade, which continued into Februa-

ry, when production and shipments were 25 per cent. below January figures. Production was therefore restricted both by allowing ovens to grow cold and by ordering lay-off days. The demand increased somewhat in June, but the Johnstown disaster retarded eastern shipments considerably. The July output rose to the January average, but the August strike cut it down again to the February figures. Since then it has been hovering between 500,000 and 600,000 tons per month.

The following is a statement of the estimated tonnage for 1889, condensed from the weekly reports collected by the *Courier*:

January.....	524,447
February....	417,280
March.....	433,090
April.....	418,534
May.....	454,250
June.....	421,178
July.....	497,115
August.....	415,254
September.....	513,190
October.....	600,624
November.....	537,645
December.....	593,219
Total.....	5,825,826

The shipments for 1889 show a grand total of 326,220 cars, an average of 1,046 cars per day for every working day in the year. Following is a comparative statement from the *Courier* files, showing the shipments during 1888 and 1889, with the daily averages appended:

1888.	Pitts.	West.	East.	Total.	Av.
January.....	4,125	13,600	2,500	20,225	778
February....	3,500	10,500	4,500	18,500	740
March.....	2,625	12,000	4,000	18,625	680
April.....	2,000	12,600	5,600	20,200	808
May.....	4,300	13,800	6,700	24,800	919
June.....	4,900	9,460	4,800	19,160	766
July.....	4,000	10,700	5,860	20,560	790
August.....	5,350	12,450	6,650	24,450	905
September...	5,270	13,916	6,140	25,326	1,013
October.....	5,900	17,900	5,925	29,725	1,100
November...	6,325	17,685	6,060	30,070	1,156
December....	6,800	17,900	6,100	30,800	1,174
Totals....	55,095	162,511	64,835	282,441	905
1889.	Pitts.	West.	East.	Total.	Av.

Totals...	72,778	187,021	66,421	326,220	1,046

The prices for coke for 1889, like those of 1888, ran the gamut from \$1 or less to \$1.75 or more. The operators started out in 1888 by dropping the figure from \$2, to which coke had gotten during the latter part of 1887. Within three months it was down to the dollar mark. The two concluding months of the year saw a big demand and a modest advance in price to \$1.25. This figure held good for the first three months of 1889, in spite of a declining demand, but April 1 saw a slumpy market, and in a few short weeks dollar coke again ruled. During the midsummer it was hard to get 90 cents for it. In August the workmen took the bull by the horns by demanding an advance in wages equivalent to 12 per cent. They enforced it by a successful strike and prices perforce went up from \$1.35 to \$1.50. A booming trade set in and sustained this rather radical advance. November and December coke sold for \$1.75, with special orders as high as \$1.90 to \$2. A determined move was made to put the price to \$2 with the beginning of the present year, but more conservative counsels prevailed.

The following table gives the prices of coke for the last six years, on board the cars at ovens, per ton of 2,000 pounds:

Month.	1884.	1885.	1886.	1887.	1888.	1889.
January..	\$1.00	\$1.10	\$1.20	\$1.50	\$1.75	\$1.25
February.	1.00	1.10	1.35	2.00	1.75	1.25
March....	1.00	1.10	1.35	2.00	1.50	1.25
April.....	1.10	1.20	1.35	2.00	1.00	1.15
May.....	1.10	1.20	1.50	2.00	1.00	1.10
June.....	1.10	1.20	1.50	2.00	1.00	1.10
July.....	1.00	1.20	1.50	2.00	1.00	1.00
August...	1.10	1.20	1.50	2.00	1.00	1.00
September	1.10	1.20	1.50	2.00	1.00	1.35
October...	1.10	1.20	1.50	2.00	1.00	1.50
November	1.10	1.20	1.50	2.00	1.25	1.75
December.	1.10	1.20	1.50	2.00	1.25	1.75

Among the notable features of the coke trade of 1889, aside from those already touched upon, two stand out in bold relief, namely, the ear famine that was and the coke king that is. As soon as the fall trade began to boom and the operators knew once more what it was to have orders to their full capacity, the railroads betrayed an inability to handle all the traffic. Both cars and motive power seemed inadequate. Some of the larger operators, despairing of a remedy, bought large numbers of individual ears. These, together with the cars furnished by the railroads, last month, for the first time, were able to meet the demands made upon them.

During the year the H. C. Friek Coke Company succeeded in purchasing controlling interests in a number of ovens, buying several of their largest competitors outright. Their holdings now cover about two-thirds of the region. They made their principal purchases during the summer, when trade was dull, with prices nearer 90 cents than \$1. The year has also been marked by considerable activity in the oven building line. As a consequence the total number of completed ovens in the region has increased from 13,975 to 14,458.

Profit in Gas Making.

The half-yearly report of the Directors of the London Gas Light and Coke Company, for the six months ended December 31, 1889, seems to us to show that there is good profit in selling gas cheaply. We make the following extracts from the report:

The accounts for the half-year ending the 31st of December last show that, after providing for interest and preference dividends, a balance of £574,785 remains, out of which the Directors recommend the statutory dividend on the ordinary stock of the Company at the rate of 13 $\frac{1}{4}$ per cent. per annum.

The half year just passed has been remarkable for a substantial increase in the quantity of gas sold, which amounts to nearly 5 $\frac{1}{2}$ per cent. over the quantity sold in the corresponding period of 1888. This result is mainly due to the rapidly extending use of appliances for cooking and heating by gas, and, in a lesser degree, to the improvement in the lighting business brought about by natural expansion and by the undoubtedly prosperous condition of general business. The great number of cooking and heating stoves sold and fixed by the Company during the past six months, leaves no doubt in the minds of the Directors that the use of gas for fuel is being very largely developed.

In order to meet the requirements of the public for a more extensive supply of gas, it will be necessary to increase the manufacturing plant at some of the Company's stations, and also to add to the storage and distributing plant by the erection of additional gasholders. For these purposes an issue of new capital will shortly be necessary, of which due notice will be given to the proprietors.

The favorable condition of the trade of the country, while exercising a beneficial effect upon the Company's business, has, on the other hand, greatly augmented the price of materials used in construction and of coal for carbonizing. The rise in the price of iron, fire goods, and stores generally is very considerable; and this increased cost of material, coupled with the very large addition which has been made to the expenditure of the Company in wages (amounting to about £150,000 per annum), will cause a heavy addition to the charges on revenue, and tend to retard the further decrease in the price of gas. The extent to which the balance of profit may be adversely affected will, in a great measure, be governed by the increase which may be looked for in the sale of gas, together with improved prices of coke and other residuals.

With regard to the supply of coal, the contracts, at favorable prices, under which the Company is working have yet about six months to run. Proposals for the extension of some of them for further periods, with a re-arrangement of price, are under the consideration of the Directors.

The Company has, so far, been free from the labor troubles and

complications which have lately occupied so large a portion of public attention, and which resulted in the crisis in Manchester and South London. The new arrangements of eight-hour shifts, and other modification of working hours and rates of pay, which were agreed upon in the spring with the Company's workmen, have, in spite of such minor difficulties as are incident to novel conditions of manufacture, worked fairly well. The Company has strictly adhered to its engagement with the men, who, on their side, have, on the whole, responded in the same spirit. The Company has abstained from in any way interfering with the organizations of its men, and has endeavored to meet any differences which have arisen in an equitable and conciliatory spirit. The Directors placed no credence in the rumors which became current that their men would throw up their employment for the purpose of bringing pressure to bear in a dispute in which this Company was not immediately concerned; but they did not neglect precautions to meet such a state of affairs had it unfortunately come about.

During the autumn, the Company's Engineer-in-Chief visited the United States of America, with the view of investigating the methods of gas manufacture in the large cities there, more particularly in reference to the various systems of lighting by water gas. The result of his examination led him to the conclusion (in which the Directors concur) that, while enriched water gas for lighting and heating is not likely, in this country, to replace coal gas, it may be found useful to provide for the manufacture of water gas, to be used in addition to, and in conjunction with coal gas on occasions when a large quantity of gas is required to meet a sudden demand. The Directors have inaugurated some experiments for testing, in a practical manner, the feasibility of thus supplementing their manufacturing plant, as well as of other suggested methods of improving the carbonizing of coal and the dealing with residuals.

The judgment of the House of Lords, given on the 9th of August last, in the Nine Elms case, between the Gaslight and Coke Company and the South Metropolitan Gas Company, was in favor of this Company—reversing the two previous adverse judgments in the Courts below. The decision, carrying costs, was unanimous, and protected this Company on all points. A perpetual injunction was granted against the supply of gas by the defendant Company for consumption outside the limits of its own district, and damages, the amount of which is now being ascertained, were awarded to this Company. The Directors attach great importance to this judgment of the final Court, as it confirms the inviolability of the Company's district, as settled by the Act of 1860.

The question of simplifying and improving the method of the official testing of gas for illuminating power and purity has made further progress; and the Directors hope that the public authorities and the Company may be able to agree upon a basis for the legislation necessary for its settlement.

Nothing has occurred since the issue of the last report to alter the opinion of the Directors that the progress of electric lighting will not produce any injurious effect upon the business of the Company.

After a half year full of interest, and not free from anxiety, the Directors look forward with confidence to the continued prosperity of the Company, which, however, can only be secured and shared in by proprietors and employes through the cordial co-operation of all connected with the Company in making its working economical and successful in all its branches.

Tinting Incandescent Lamp Bulbs.

Mr. Arthur S. Huey, of Minneapolis, proposes the following method of treating incandescent lamp bulbs: Prepare the glass by thoroughly washing in soap and water and drying. Then dip in bath (made by beating up the whites of two eggs in one and a half pounds or pints of water, and filtering) and hang up to dry. Dissolve the aniline color in photographer's common collodion. Red or blue aniline will form clear solutions, while the green solution will require filtering. Yellow aniline forms a handsome color, but the surface of the glass presents a frosted appearance after the application. Violet and purple colors may be obtained by combining red and blue in different quantities. When the solution is ready, dip the prepared glass bulbs therein, hang up to dry, and finally pass a current through the bulb for half an hour, that the heat thus generated may harden the coating of the collodion, or place in a current of air. The preparation can easily be removed with alcohol or sulphuric ether, but is not affected by water. Experience has shown that the best results are obtained by not using too much aniline. Make the color light rather than deep, and apply two or three coats.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

SOME time ago we noted that the authorities of Downingtown, Pa., had appointed a committee to negotiate with the owners of the local gas plant, the same to be operated thereafter on municipal account, and that the owners were not averse to parting with their property. While the closing details were being arranged, some of the residents rather unaccountably raised objection, the result of which was that the proprietors of the Gas Company withdrew their offer to sell.

THE town of Centralia, Wash., is to light its streets by electricity, the authorities having granted a franchise to a Company, the proprietors of which are to have an exclusive right for 25 years to distribute electric currents in Centralia. The public lighting contract calls for the maintenance of 10 arcs (2,000-candle power), to be paid for at the rate of \$12 each per month, on a midnight table, the rate to be increased to \$15 per month in case it is determined to run the light until 3 A.M. The rates to ordinary users (on the basis of a 16-candle power incandescent lamp) have been adjusted to the following: To run until 9.30 P.M., \$1.25 per lamp per month; until midnight, \$1.50; all night, \$2.00.

THE reduced gas rates for Steubenville, O., are to take effect on April 1st. Even at the risk of duplicating the information, we give the new schedule:

Monthly Consumption.	Net Rate per 1,000.
Under 5,000 cu. ft.	\$1.50
Over 5,000 cu. ft., but under 10,000	1.35
Over 10,000 cu. ft.	1.20

This is reasonable enough, and speaks well for the Company's liberality.

FROM a Philadelphia source we learn that complaint is loud in some sections of the city about the defective condition of many of the gas services. Chief Engineer Park explains this by saying that the defective pipes pass through soils that are very destructive to iron.

SOME time ago we noted that the Boston Electric Company had instituted suit for patent infringement against Charles W. Holtzer and the Holtzer-Cabot Electric Company. The defendants are charged with infringing letters patent No. 250,590, granted July 27, 1880, to Jacob R. Tirrell, and letters patent No. 281,345, issued July 17, 1883, to Chas. H. Crockett, both relating to improvements in electric gas lighting apparatus. The important feature in the Tirrell invention is turning the gas cock by a single electric impulse. Though the complainants' experts differ as to this, yet upon the affidavits the court holds that the defendant's contention is correct. The issue is then narrowed down to this, whether the court should enjoin the defendants against the use of a burner so constructed that the gas cock is opened by a series of electric impulses, when the claim of the Tirrell patent makes the turning of the gas cocks by a single impulse, one of the most important elements on a motion for an injunction, *pendente lite*, where the mind of the court must be satisfied on the subject of infringement, an injunction should not be granted under these circumstances. As to the Crockett patent, the court was inclined to the opinion that it must be limited to the form of the devices therein described, or what is clearly equivalent. The device for opening the gas cock, and especially the ratchet and pawl, which are found in the defendant's burner, should not be considered the equivalent of the projections at the end of the valve and the opening devices described by Crockett. The defendants' burner, therefore, does not infringe, or at least there is so much doubt of it that no injunction should issue.

AS was predicted in the JOURNAL about a fortnight ago, the plant and franchises of the Batavia (N. Y.) Gas Light Company have gone into new hands. The purchaser, however, was the local Consumers Electric Light and Power Company, whose proprietors will now consolidate the hitherto conflicting interests. The officials of the Consolidated Company have been named as follows: President, S. D. Purdy; Secretary and Treasurer, Chas. H. Caldwell. The capital stock in the enterprise is about \$100,000, and a considerable sum will be expended in betterments to the gas plant.

THE Committee on Manufactures, Massachusetts Legislature, has voted unanimously against the proposition that gas companies in that State should be prohibited from declaring dividends in excess of 10 per cent. per annum.

AT the annual meeting of the Natick (Mass.) Gas Company the following officers were elected: President, Riley Pebbles; Secretary and Treasurer, Edward Clark; Directors, Riley Pebbles, Edward Clark, Harrison Harwood, John O. Wilson and L. Winch.

ON the 6th inst. the Superintendent of the Napa (Cal.) Electric Light Company was ordered to close down the works until further notice. This abrupt decision discomfited the users of incandescent lamps, and the consumers were not greatly mollified when told that the plant was shut down "because it needed repairs." In all probability the supply of electric light currents is not a profitable business at Napa.

AT the annual meeting of the Portsmouth (N. H.) Gas Light Company the following choice of officers was made: President, John Sise; Clerk and Treasurer, Frank J. Philbrick; Directors, John Sise, Marcellus Eldredge, W. W. Cotton, Edward S. Fay and H. W. W. Jackson.

SUPT. TRACY, of the Poughkeepsie (N. Y.) Gas Company, says that the use of gas for fuel purposes in that city is spreading with amazing rapidity.

AN important change (see advertisement of Company, page 267) has occurred in the management of the Westinghouse Machine Company's St. Louis District Agency.

PROF. RICHARD T. ELY, of the Johns Hopkins University, of Baltimore, Md., has again turned his attention to gas matters, having delivered (Feb. 13) the second of his two lectures on "Taxation." He spoke before a large audience in the Peabody Institute, and a summary of his speech is appended:

The results of our inquiry into taxation thus far have given us results which may be formulated under these five heads.

1. Taxes have brought us representative government, and they tend to grow with the growth of free institutions.
2. Taxes are not payments for services rendered by governments but a taking by the nation of that to which it is entitled.
3. The amount to which the nation (State or city) is entitled can only be determined by the conscience and intelligence of the community.
4. Taxation is being used, and will be used to greater extent hereafter, as an agency for social reform.
5. Other sources of income than taxation must be found in governmental pursuits.

Our situation is briefly thus: The expenditures of government have increased with enormous rapidity in recent times, and there is every reason to anticipate that they will continue to increase in the future. The man who has looked only a little way into this subject is tempted to say: If we reform government by means of good civil service and by other devices, we can introduce retrenchment into practical administration. Unfortunately for this theory—for it is pure theory—governmental expenses have increased most rapidly where administration is purest. An inevitable effect of better government in Baltimore or Maryland would be to increase, not decrease, public expenditures. On the other hand, the difficulties in the assessment and collection of taxes increase rapidly after a certain point is reached. In a city like Baltimore we need twice as much to spend to give us what as a city we need; yet it is evident that our tax rate is already too high. We must, then, if we would keep pace with the world's progress, turn to industrial pursuits for a portion of our public revenues.

Those industrial pursuits which are best adapted to furnish us with revenues are called natural monopolies; and by this we mean that their own inherent properties make them monopolies. There are several important industries which are of this character, but the gas business illustrates them all—perhaps better than any other—because the general principles are in this business so clearly seen. There are those who would have us still believe that competition in the gas business is possible; but surely they are the wildest kind of theorists. What is a theory worth that has not facts back of it? Now, all that I ask is for those who believe that competition in the gas business is a possibility to adduce a single instance of permanent successful competition. Let them dispense with vague generalities and give us facts. Competition has been tried thousands of times, and I defy them to produce the single instance of successful competition. I restrict them to no country and to no clime. They may travel north or south, east or west; they may search Europe, Asia, America; but they will look in vain for successful competition in the gas business. Let us be content with the unvarying testimony of hard facts. Now, there are two ways in which revenue may be derived from natural monopolies. Private parties may pay for the monopolies, or government itself may undertake to operate them. The first method is better than the pursuit of such a Utopia as competition. If people are not willing to consent to public administration, then let private parties pay for monopolistic privileges their full value. These should, however, always be granted for a limited period only,

and the right of purchase without payment for franchise reserved. No perpetual franchises should ever be granted. No one is wise enough to say what may be desirable in the future, and the reserved right of purchase of plants of monopolies makes it possible for the nation, state, or city, to adjust itself to existing conditions. Direct administration by government is, however, preferable. In this case profits accrue to the public, and politics are purified. The following table compares the cost per night of electric lighting in five cities under private management and under municipal ownership of electric lighting plant:

	Private.	City.
Bay City, Mich.....	27.5 cts.	16.0 cts.
Painesville, Ohio.....	19.7 "	10.6 "
Huntingdon, Ind.....	39.0 "	13.7 "
Lewiston, Me.....	50.0 "	14.0 "
Aurora, Ill.....	89.5 "	15.0 "
Average per night.....	45.1 cts.	13.9 cts.

AT the last regular monthly meeting of the Directors of the Port Hope (Canada) Gas Company Mayor Burnham resigned his dual seat, as he now is, by virtue of his Mayoralty position, a Director as representative of the stock in the Company owned by the town. Mr. James Craick was selected by the Directors to fill the vacancy thus created.

THE Board of Aldermen, Hartford, Conn., have decided to equip a testing room for the gas inspector.

THE works of the Freeport (Pa) Gas Company will be closed down on or about April 1. The plant is worn out, and the prospects do not justify any expenditure on renewal account.

THE plant of the Fayetteville (N. C.) Gas Company has been materially added to. The rosin process of gas making has also been abandoned there, and a local coal is carbonized, which is obtained from Egypt, a village in Yancey county.

AT the annual meeting of the Jefferson City (Mo.) Gas and Electric Light Company it was resolved to keep the street lights burning all night during the time of the State re-union of the G. A. R. The Company also offered to furnish gas to the encampment without making any charge therefor. The officers chosen were: President, W. W. Wagner; Vice-President, Louis Schmidt; Secretary, Treasurer, and Superintendent, Charles E. Hess; Directors, W. W. Wagner, H. C. Geisberg, Louis Schmidt, C. E. Hess, and J. C. Fisher.

THE rates charged by the Rockville (Conn.) Gas and Electric Light Company for each 1,200-candle power commercial arc light are: One lamp, from dusk until 10 o'clock, on 4 nights of each week, 24 cents per night; two lamps, 22 cents; three lamps, 20 cents. From dusk until 6 o'clock, Tuesday and Thursday evenings, and later than 10 o'clock P.M., at the rate of 5 cents per hour.

A REPORTER of the St. Louis *Republic* (dated the 11th inst.) is responsible for the following: "St. Louis is destined to be the first city in the country to try fuel gas on a commercial scale. The experiment—for such it will be, though believed to be perfectly certain to succeed—will be made in a few months. Of the details, President McMillin, of the Laclede Gas Company, said yesterday: "Yes, we propose to put fuel gas on the market in a short time, say somewhere about the 1st of June or July. We are fortunately situated for the experiment. We have the water gas plant, which, as it is merely a duplication of the Laclede plant, so far as it goes, is superfluous for the making of illuminating gas, but can be utilized without any important changes for the making of fuel gas and its distribution over the territory covered by the water gas mains. Thus we can save possibly \$1,000,000 in the erection of a plant and the laying of pipes. Everything is ready to our hand. It will not take long to find out whether or not we can afford to keep up the making of the gas. Scientifically and mechanically the making of fuel gas is all right. We are certain of our standing; but as to its commercial success we do not yet know. Of course, it is only a question of time—gas is bound to be the fuel of the future; but whether people are now ready to take it in sufficient quantities to warrant us in making it is another thing. We shall sell it at 40 cents a thousand feet. It will cost us, say, 20 cents. That is a profit of 100 per cent. But it is only a profit of 20 cents a thousand feet, after all, and it will take a great many sales at that figure to pay profit on the \$1,000,000 or so invested. We shall need a great many consumers, and as it will be a new thing, we cannot be sure that people will take hold of it with sufficient promptness to make it an immediate success. But if we get enough consumers to

warrant it, we shall extend the pipes over the entire city. That will involve an expenditure of a good many million dollars; so, you see, we shall want to adopt Davy Crockett's motto and be sure we are right before we go ahead."

"How many consumers can you get along the line of the water gas pipes?"

"With our customers and those of the water gas company there are probably from 6,500 to 7,000 consumers along the lines of those pipes. If we got one-half of those we should feel encouraged to go ahead. We should canvass for customers, beginning on the outside of that territory, and as fast as we got enough to justify it, would extend the pipes. In that territory are many houses and offices heated by steam, and those we should not expect to get. But in the residence portion of the city we should be able to get many customers. Of course, many people will be only too glad to get fuel gas. But we expect to introduce it slowly. There are from 80,000 to 100,000 houses in St. Louis, yet there are only about 20,000 consumers of illuminating gas in the place, which will probably be a surprise to most people."

"How will the consumption of fuel gas compare with that of illuminating gas as to volume?"

"It will be larger, say from one-third to one-half more will be required in a stove, for instance, because it will not be as rich gas; that is, it will require more of it to give the same heat. That would bring up the price, say, to 60 cents per 1,000 feet, less than half what is now paid, so that consumers could afford to use it lavishly, if necessary."

"Will you use the same quality of coal in making fuel gas that is used in making illuminating quality?"

"No; we shall use, we expect, an Illinois coal that will be entirely used up, not even tar remaining as a residuum."

"You have faith in the fuel gas idea?"

"The greatest faith possible. As I said, there remains now only the question of getting enough customers to make the manufacture profitable—and that will come sooner or later. I am glad that St. Louis is to be the first place to try it on. There is one town—Jackson, Mich.—where they use fuel gas, but that is too small to determine the question of practicability one way or the other. The first experiment of a sufficient commercial scale will be made right here in St. Louis."

THE annual meeting of the stockholders of the New York and Cleveland Gas Coal Company was held in Pittsburgh, about a fortnight ago, when the following Directors were elected: W. P. De Armit, Henry Phipps, Jr., W. H. Berger, Frank Semple, John Walker, J. E. Umbstaetter, J. B. Hamilton, J. T. Colvin, and J. J. Donnell. The officers elected were W. P. DeArmit, President; Frank Semple, Treasurer; and C. L. Dixon, Secretary. In speaking of the years' business, Mr. De Armit said: "The last year has been so unsatisfactory and unprofitable that we are ashamed to have the figures published. The only cause for congratulation is in the fact that we are no worse off than our neighbors, in fact in better shape than some, and the only remedy I know of is to trust to the future to give us better prices for our product and a greater demand for coal." Another stockholder said: "The past year's business was much below that of the year before and we were far from satisfied with the past, and have little to encourage us in the future. As long as natural gas continues to be in such general use and the prices of it continue as they are, there is nothing in the coal business. We have not decided what will be done, but our Board of Directors will no doubt decide on what is best."

HENRY F. MARTIN, chemist to the Board of Health, recently entered complaint in the Court of Special Sessions against Mr. Jas. W. Smith, President, and Frederick Crowell, Superintendent, of the Consolidated Gas Company of this city. Defendants were charged with violating a section of the Sanitary Code, in that they permitted a nuisance to exist. From the station at Forty-fourth street and Eleventh avenue a number of pipes run into the bed of the North River, the pipes acting as carriers of refuse from the works to the river. It was claimed that the stench arising from the matter so deposited endangered the health of people obliged to reside within the affected district, hence Martin's complaint. No defence was interposed, and the Company was fined \$250.

BUFFALO, N. Y., pays its Gas Inspector, who is appointed for one year by the City Engineer, at a salary of \$1,000, and the passages in the city ordinances defining his duties are as follows:

Section 5—He shall have supervision over the public lamps and of lighting, cleaning, repairing and extinguishing the same; he shall see that they are kept clean and in good order, and at all times provided with good and sufficient burners of the capacity mentioned in the con-

tract between the city of Buffalo and the gas companies from which it purchases gas, and that such burners are kept free and clean, and pass the amount of gas called for in said contracts; and for that purpose he shall, as often as once every month, make a test of each and every one of such burners with some standard purchased by said city and report the result of such test to the Common Council. He shall daily make a photometrical test of the illuminating power of the gas and make weekly reports thereof to the Common Council.

Section 6—He shall have power and it shall be his duty, to enter every public building owned by the city, to test the meters therein and regulate and control the use of gas in each of said buildings. He shall at the end of each month, examine the meters in each of the public buildings owned by the city, make a record of the number of feet of gas consumed in each of said buildings, and report the same to the Common Council. He shall compare the same with the bills for gas furnished by the different gas companies and no such bill shall be paid until the same shall be certified by the gas inspector.

Section 7.—He shall see that the lamps are kept lit during the whole number of hours specified in the contracts between the city and the gas companies. He shall at the end of each month report to the Comptroller the number of lamps not lit during the current month and the number of hours they were not lit. It shall be the duty of the Comptroller to estimate the amount thereof, and deduct such amount from the estimate of gas furnished the city under its contract.

Surely, if Buffalo's Gas Inspector faithfully carries out these instructions, he may be said to earn his salary.

IN our reference to electric lighting rates at Rockville, Conn., it might also have been said that the contract between the Company and the authorities calls for the maintenance of 74 arcs (1,200 candle power) to be lighted on 300 nights in the year, and to be paid for at the rate of \$75 per lamp per annum.

THERE is talk of a gas works for Rapid City, South Dakota.

THE bill regulating the purity of Rhode Island gas, now before the General Assembly of that State, provides that no gas company shall supply in any city or town of the State gas which contains more than 20 grains of sulphur or 10 grains of ammonia per 100 cubic feet of gas, or more than 10 per cent. of carbonic oxide, or any sulphureted hydrogen.

THE annual meeting of the Salem (Mass.) Gas Light Company was notable for its surprises, foremost among which was the refusal of Mr. Wm. H. Jelly, who had been President of the Company for the past 17 years, to accept a re-election. Then an entirely new Board of Directors was chosen in the persons of John W. Leighton, of Boston, John R. Langmaid, H. A. Hale and Edwin Dodge, of Salem, and Geo. F. Sawyer, of Peabody. Mr. David Moore was re-elected Treasurer, and B. W. Sherman was named to succeed himself as Clerk. It is understood that the new management will advocate the operation of an electric lighting plant by the Gas Company, and the change in the Directorate was probably occasioned by a difference of opinion among the shareholders respecting the good policy of such a move. The sendout last year was 44 millions cubic feet, and a good round sum was expended in plant betterment during the twelvemonth.

MONTAGUE HAWK has been appointed meter inspector for the Easton (Pa.) Gas Company, vice Louis Pittenger, resigned.

THE proprietors of the incandescent electric supply of Martinsburg, W. Va., are endeavoring to secure customers on the following basis—the Edison system is used and the lighting value of the lamps is put at 12 candles: For the first light, 75 cents per month; 2d light, 65 cents; 3d light, 50 cents; 4th light, 40 cents; 5th light, 35 cents; 6th and all additional lights, 20 cents. They also offer shopkeepers on the main street, 10 lights for a payment of \$3.80 per month, said lights to be burned according to the user's convenience. That Company ought to be in the sheriff's charge before it is much older.

THE Lawrence (Mass.) Gas Company has chosen the following Board of Directors: Geo. L. Davis, Geo. D. Cabot, Chas. A. De Courcey, Chas. M. Seaver, N. H. Emmons, Benjamin Brewster and J. Lewis Stackpole.

THE City Clerk of San Jose, Cal., has been directed to advertise for plans, specifications and bids for lighting the streets of that city with electric lights for a term of 5 years, or less, as the Mayor and Common Council may determine. The successful bidder shall have its machinery and plant erected and in working order at least one month prior to the 30th of September next, the time at which the present contract for lighting the streets expires. The bond required is \$5,000.

Gas Stocks.

Quotations by Geo. W. Close, Broker and Dealer in Gas Stocks.

WANTED,

A young man to act as

Meter Taker and to Make Himself Useful

in a small Gas Works. Must understand gasfitting and be strictly temperate. Address, with references, 768-2 "G.," care this Journal.

POSITION WANTED

As Manager of a Gas Works

Making from 5 to 10 million cubic feet per annum. Six years' experience. Address "J. M. M.," 767-4 Care this Journal.

POSITION WANTED.

A Mechanical Engineer,

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked. Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal, 765-1f or Box 972, West Bay City, Mich

Position Wanted

As Superintendent or Assistant of a Gas Works,

By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address 765-5 "M.," care this Journal.

FOR SALE.

We offer the following gas apparatus for sale, delivered f.o.b. cars Fort Worth, Texas:

Two Benches of 3's, with cast iron Hydraulic Main, Dip and Ascension Pipes, and Mouthpieces (14 by 23 in.).

One Bench of 6's, with cast iron Hydraulic Main, Dip and Ascension Pipes, and Mouthpieces (12 by 20 in.).

Two Benches of 3's, with cast iron Hydraulic Main, Dip and Ascension Pipes, and Mouthpieces (14 by 24 in.).

Four Purifiers, 6 ft. by 6 ft., with 6-in. Connections and Center Seal. **Steam Jet Exhauster** **One Set Pipe Condensers** 6-in.) **One Upright Scrubber,** 11 ft. high by 36 in. diam., with Bye-Pass **One Station Meter,** daily capacity 100,000 cu. ft. **One Upright Boiler,** 20 horse power.

All of above apparatus in first-class condition and are so guaranteed. For further particulars address

FORT WORTH LT. AND POWER CO.,

P. W. MACKENZIE, CHIEF ENGR. & SUPT.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owners of the RECENT Mackenzie Patents,

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day.

The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn, Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES or other RETORTS, NOR THEIR EQUIVALENTS, are used.

Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD.

The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM.

The Gas requires NO PURIFICATION whatever.

The FUEL GAS COSTS VERY MUCH LESS than PURE UNCARBURETED WATER GAS, and contains DOUBLE THE HEAT UNITS.

The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE, and consists of a Single Body with a capacity of ONE THOUSAND to ONE HUNDRED THOUSAND cubic feet per hour.

Works may be constructed to run by the CONTINUOUS or ALTERNATING method. If run continuously, the limited amount of Nitrogen present is neutralized by Carbon.

The Gas can be made of a HIGH GRADE for illuminating purposes, of a MEDIUM QUALITY for distribution for domestic purposes, and of a LOW GRADE for manufacturing uses.

Wherever Liquid Hydrocarbons can be had the MACKENZIE PROCESS WILL COMPETE IN PRICE AND SUPPLY ALL THE ADVANTAGES incidental to the use of NATURAL GAS.

This Company desires contracts for the construction of Plants, parts of Plants, Apparatus, Buildings, Holders, and Street Mains, for either of the above purposes, and will Lease or Purchase Works upon satisfactory terms.

Information will be promptly given regarding material required for production of Gas, actual cost of product, cost of works, etc.

GAS vs. ELECTRIC LIGHT.

We would invite attention to the able and exhaustive argument of General A. Hickenlooper, President of the Cincinnati Gas Light and Coke Company, contained in a handsome pamphlet of 96 pages, entitled

"EDISON'S INCANDESCENT ELECTRIC LIGHTS FOR STREET ILLUMINATION. REPORT OF AN ARGUMENT DELIVERED BY A. HICKENLOOPER BEFORE THE COMMITTEE ON LIGHT, MUNICIPAL COUNCIL, CITY OF CINCINNATI, JULY 22, 1886."

This is a subject of special interest to all Gas Light Companies.

STANDARD GAS LAMP CO.,

Main Office, 411 Cherry St. Factory, 1101, 1103, 1105 Frankford Av.
PHILADELPHIA, PA.

It is to the interest of Gas Companies and Cities to double the efficiency of the light on streets by using Dyott's Patent "CHAMPION" LAMPS. They save 50 per cent. over others in cost of repairs, are ornamental, and indestructible except by violence.

Our Patent System of Instantaneously Lighting Gas (without electricity), for Railroad Depots is unequalled.

Dyott's High Candle Power Burner is a very superior lamp where a concentrated and brilliant light is wanted in Hotels, Stores, Depots, etc.

Special Drawings furnished and Estimates cheerfully given, either from Architects, Engineers, or our Draughtmen's Plans.

We manufacture every description of Plain and Ornamental Lamps, Posts, Brackets, Clusters, etc. Correspondence solicited.

The Gordon Portico Lamp.

A successful Competitor of the Arc Electric Light for lighting Store Fronts, Show Windows, Depots, Railway Sheds, etc., etc.

Gordon Portico Lamp.

The Gordon Street Lamp.

A Successful Competitor of the Arc Electric Light for lighting Streets, etc., etc.

Gordon Street Lamp.

The Lungren Lamp.

A Successful Competitor of the Incandescent Electric Light for Interiors, etc. Is especially applicable for the lighting of Offices, Stores, Factories, Mills, Show Windows, Libraries, and all situations where an increased illumination is desired.

More than 25,000 Lungren Lamps are now in use. Testimonials, references, or any desired information will be cheerfully given.

Lungren Lamp.

THE SIEMENS-LUNGREN CO., N.E. Cor. 21st St. & Washington Av., PHILADELPHIA.

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

JEWEL GAS STOVES

GASHOLDER TANK CONSTRUCTION, ETC.

Gas Companies and others about to erect Gasholders will find it profitable to consult
 W. C. Whyte, who for over 30 years has made a specialty of

Tank Excavation and Mason Work.

Fifty Tanks now in operation show the sort of work done. Address

W. C. WHYTE, - No. 15 Cortlandt Street, N. Y. City.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

Post Office Box 3895, New York.

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to

Every Meter emanating from our establishment will bear the State Inspector's badge, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

GAS INTO POWER,

BY THE

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

Gas Power the Leading Power of To-Day,
AND SOLVE AT ONCE THE QUESTION OF FUEL GAS.

[OFFICIAL NOTICE.]

Southwestern Gas Association.

OFFICE OF SECRETARY, GALVESTON, TEXAS, Feb. 24, 1890.

The annual meeting of the Southwestern Gas Association will be held in Dallas, Texas, March 12 and 13, 1890. The arrangements for the meeting are now being perfected. Headquarters will be at the Windsor Hotel.

C. P. RUSSELL, Sec'y.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., February 22, 1890.)

To Members of the Ohio Gas Light Association:

Gentlemen—As previously announced, the Sixth Annual Meeting of this Association will be held at Toledo, O., beginning at 10 A.M., March 19, 1890, and continuing two days. Boody House will be the headquarters of the meeting, the various sessions of which will be held in a very suitable room in the same hotel. Members and others desiring to attend are advised to write well in advance for rooms.

The following papers have been promised for the meeting:

1. "Theory and Practice in Gas Management," J. M. Bate, Supt. Gas and Coke Company, Canton, O.
2. "Municipal Control of Lighting," H. Wilkiemeyer, Supt. Gas Light and Coke Company, Portsmouth, O.
3. "Combination of Gas and Electric Lighting in a Small Town," George W. Bowers, Sec. Gas and Electric Light Company, Hillsboro, Ohio.
4. "Our New Coal Gas Works," G. A. Hyde, Engineer Gas Light and Coke Company, Cleveland, O.
5. "Advantages of a Combined Coal and Water Gas Plant," Geo. Light, Asst. Supt. Gas Light and Coke Company, Dayton, O.
6. "Another Year with Fuel Gas," Chas. H. Evans, Manager National Gas Company, Jackson, Mich.
7. "Ohio Street Lighting Statistics," W. C. Hedges, Secretary Gas Light Company, Mansfield, O.
8. "Graduated versus Uniform Rates," Chas. R. Faben, Jr., Supt. Gas Light and Coke Company, Toledo, O.

The following questions have been proposed for the "Question Box:"

1. At what point in the works is the best place for the exhauster?
2. In a lighting territory covered by illuminating gas and the incandescent electric light, which seems to be in the ascendancy?
3. Does a fine gas of 23 to 25-candle power help check the invasion of the incandescent electric light?
4. Should we not confine the work of our Association to the important interest it was established to promote, viz.: gas lighting and the manufacture of coal gas?
5. What system of electric lighting is best for adoption by gas companies?
6. Are cast iron pipes better and cheaper than wrought pipes for gas mains of 2 to 4 inches in diameter?
7. Does it pay to coat gas mains with coal tar?
8. What is the average life of a meter in constant use, with ordinary good care?
9. Is not illuminating gas of good candle power, sold at a reduced price for fuel, the true solution of the fuel gas problem?
10. Which is the correct method of tapping mains, on top or at the side?
11. Is the Welsbach burner with natural gas a success, and what proportion of the lighting does it do in towns having both natural and artificial gas?

Other interesting questions have been proposed, which will be presented at the meeting, and members are requested to come prepared to participate in the discussion of the above papers and questions.

Provision has been made for an exhibit, in connection with the meeting, of all kinds of gas appliances and apparatus, a large room on the ground floor, a few doors from the hotel, having been secured for this purpose. No charge for floor space will be made to exhibitors, and those desiring to avail themselves of this excellent opportunity of displaying their specialties will consign their goods and address their communications to Mr. Chas. R. Faben, Jr., Supt. Gas Light and Coke Company, Toledo, O., who has the matter in hand, and who will arrange the exhibit to the best advantage of all concerned.

In addition to this exhibit there will be other objects of much interest to our members and visitors, and the meeting promises to be in every way successful. It is hoped that every member will show his appreciation of what has been done, by being present; and gas companies not heretofore represented at our annual gatherings will be profited by sending a representative to this meeting.

A cordial invitation is constantly extended to all who may desire to become members of the Association, to do so, and the Secretary would be pleased to hear from any such persons.

IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

THE TOLEDO MEETING.—With the echoes of the New England meeting, and all its lessons of progress and union, still fresh in the senses of the fraternity, our thoughts and hopes are directed toward the annual gathering of the Ohio Association, soon to be held in Toledo, under the guidance of Mr. Lindsley, of Cleveland. The current number of the JOURNAL contains Secretary Butterworth's official outlining of what the members are to have placed before them. In the first place, the local committee have been eminently successful in their matter of a choice of a hotel—the Boody House—which is also to be availed of as a place for meeting. This assures goodly and regular attendance at the sessions, at least in so far as these things depend on any preparations in advance. Passing, but not lightly, from the Secretary's hint about the wisdom of writing well in advance for rooms, we are confronted with the paper list, which amply proves that the sixth annual meeting will not suffer from lack of presentation of topics at once timely and interesting. In connection with the list, we note that some of the papers ought to prove more than ordinarily attractive, since apart from the intrinsic merit of their matters, some of these cannot fail subsequently to be placed in direct comparison with those read on kindred subjects at the New England meeting. The "Question Box" initiation at the Ohio meetings will be most auspiciously inaugurated, since no less than 11 queries have already been committed to its custody. Some of them, too, are on the decidedly complex order, which, of course, will cause their unravelling to be all the more eagerly looked forward to. We would place especial stress upon the Secretary's invitation to the manufacturers of all sorts of gas appliances to send on lines of their goods for display at the proposed exhibition of such, in connection with the convention. The only expense they will be at will be in the forwarding of their exhibits, and the most conservative of the manufacturers must of necessity concede that the advertisement gained will more than repay them for any expenditure so incurred. Even with the hurriedly arranged exhibition at Mansfield, last year, a very creditable display was made, and the exhibitors have no reason to regret that they took part in the affair. A master hand—that of Mr. Chas. R. Faben, Jr.—is in charge of the Toledo exhibition, and it is due to him and the Association that their efforts be encouraged by a good display. That is the recompense which will best humor them. The outlook for a successful gathering is most promising.

IN BAD FAITH.—We are informed that the City Attorney, of Thomasville, Ga., at the request of the City Council, has delivered an opinion respecting the right of that community to grant exclusive privileges to a corporation for a term of years. He declares that a contract between any Georgia city and any corporate company under which exclusive privileges are granted the latter is not binding upon the city unless the city's charter specifically confers such powers. The construction of the law arose from a contest between the city of Thomasville and the proprietors of the Gas Company as to whether the exclusive portion of the Company's charter—to run for 25 years—was valid. When certain capitalists invested their money in a gas works for Thomasville the authorities promised them protection. Now that the money is invested, Thomasville turns them adrift. It is only the same old story—bad faith.

OFFICIAL REPORT.—REVISED BY THE SECRETARY.—CONTINUED FROM PAGE 248.]

TWENTIETH ANNUAL MEETING, NEW ENGLAND ASSOCIATION OF GAS ENGINEERS.

HELD AT YOUNG'S HOTEL, BOSTON, MASS., FEB. 19 and 20, 1890.

FIRST DAY—FEB. 19—MORNING SESSION.

PRESIDENT'S ADDRESS.

President Taber then delivered the following address:

Gentlemen of the New England Association of Gas Engineers:—We meet again to-day as fellow soldiers may, conscious of a forgetfulness born of the very intensity of our absorption in our profession—almost as if the new rays of the incoming morning had greeted us un-awares, so busy have we been in the attempt to meet the increased demand, both mental and physical, developed in the past year.

As a manifest of that activity I have counted the number of papers offered, their wide scope and practical bearing; in fact, the number here present is in itself an earnest that we have need of one another's goodwill and co-operation in the endeavor to do faithfully our "little daily work." For myself I have no word of apology. I did not deserve the honor at your hands; I shall do my best not to disgrace it.

But even now as we gather I listen in vain for the answer in the roll call to the name of one who always answered, and hear only in my memory the funereal tolling of that bell in the quiet graveyard, constantly reiterating in hushed tone the sense of loss we all felt in the death of our friend and associate, Oliver E. Cushing.

"Oh, thicker, deeper, darker growing,

The solemn vista of the tomb

Shall know henceforth another shadow

And give another cypress room—"

Who of us is ever prepared for the death of his friend? I could but think, as on that January day we stood beside the grave decked with evergreen under the drooping sky, the swiftly rushing waters mocked the preacher's words—for were they not rapidly passing away, too—dust to dust—pain and sorrow and loss.

We are not met to-day for sentiment, yet who does not feel that sense of loneliness which closed in as we drove through the ivy-covered gateway and left our friend forever. I want to bear witness to the warm-heartedness, the cordial sympathy, the honest manliness of our associate. You will, I have no doubt, take later action in regard to his memory; but I wish right here to say that I took the liberty in your name to wire at the time my sense of the loss this Association feels as Engineers and men in his sudden death.

In common with the members of the National Association, we shall join in a similar tribute of respect to Mr. Forstall, of Chicago; but our loss in Mr. Cushing is peculiarly ours. No one among us will be more missed than he.

But, gentlemen, as I look over the interests of the gas companies to-day, I wish to premise my observations on a legal decision of Judge Story, who, in a certain case, defined the office and functions of a gas company as a public corporation, not in the sense of a municipal institution, but a quasi-public corporation, devised simply for the purpose of gain. Fortified, therefore, by such a weight of legal acumen, and removed from any stigma (since this is a judicial remark, not a forensic appeal), I presume we must all concur that as the official servants of these gain-seeking corporations we also have this aim in view, in gathering here year after year, viz., such comparison of ideas, plans and investigations as shall bring increased revenue to the corporations with which we are connected, increased light at lower rates to the public, and shall subserve their and our highest business interests. And I dwell somewhat strongly on this basic theory, so-to-speak, of our duties as an Association, since I am afraid that the ancient definition of our special duty as gas engineers may require a creed-changing committee to make it conform to the modified status of the business of furnishing such substitute for daylight as shall be pronounced by our customers every way satisfactory in convenience, everyday adaptability, and, above all, cheap.

I can fancy a club of gas engineers formed for the scientific part of the illuminating gas problem—the chemical section, so-to-speak, of our business. Such an one might spend the hour turning and overturning the theory of the illuminants, measuring their strength and the differentials of various gaseous compounds, perhaps even building up by synthetic processes a gas, innocuous, more luminous, with or without heating qualities, and capable of easy distribution—I sincerely hope also far less wasteful in destructive distillation. To such a body skilled mechanical

engineers might be added, who would construct the formula required for the best erections of plants and laying of mains, the best methods of furnace erection in regenerative benches, or plans of retort house or holder frames. Such a gathering might strictly be called an Association of Gas Engineers, the single aim being adhered to with more or less directness of purpose, of consulting together as to method of manufacture—the applied chemistry and engineering of our special hobby.

On the contrary, to-day I think the twentieth meeting of our Association convenes feeling more or less indistinctly the pressure of an impulse which warns us that the day must not be spent in scientific problems, or theoretical speculations on the manufacture of illuminating gas, important as we have always considered it. I do not allude, perhaps, to any anxiety arising from any existing competition of coal gas with electricity or water gas, as that indefinable sense of a public demand for something which necessitates greater care and thought as regards our relation to that demand. In fact, we to-day lay ourselves open to the criticism that we are no scientists at all, through the necessity of meeting the requirements of such a demand as I have mentioned, which, since the advent of electricity, has grown acquainted with its wants and recognizes any dilatoriness in the good will or ability of a gas company to meet it.

I am glad of the position taken by the Gas Commission, which has resulted in doing away with much of the mystery attending the cost of gas from the public mind, which exaggerated the unknown quantities, both depressing the cost and swelling the profit. This removed, the public has learned to expect better results; and I therefore feel an absolute indifference to any party criticism, whether your discussions shall relate to any topic relative to artificial light and heat, since for the purpose of gain we are gathered not as illuminating gas engineers, not as fuel gas engineers, not as electric engineers—because each of us is or should be all these, and because, by reason of this public demand, we are not so much interested specially in the method and economy of their manufacture as directly in the method and economy of their sale. Perhaps, also, it might be broadly stated that both parties—the manufacturer and the consumer—have found it their interest to investigate the need and requirements of each special light installation, and thus it comes to pass that of the 126 gas companies doing business in New England probably 25 make and sell water gas and 36 electricity, while nearly all are engaged in the sale and rental of gas stoves and, in a less degree, fittings and chandeliers.

To me it seems as if some recognition should be taken of this change of direction (which, after all, may be only temporary), that we may have some idea of what is involved. Is it necessary and profitable, or necessary and unprofitable? Could there not be a medium path pursued without this equipment of the stove manufacturer and the fixture manufacturer, and, more broadly still, the arc and incandescent light? Whence arises this necessity? I answer, What was the necessity for regenerative burners, Lungren and Wenham, which were only partial efforts to perfect local illumination? The incandescent burner, water gas (itself a gas of 20 and odd candles), arc lamps, incandescent electric lamps—what are these but the answer to a call for something, more or less indistinct in the call, and more or less indistinct in application to the needs of a public which required something for usefulness or luxury which it did not possess?

"Blind mouths," we call them. Aye, but not to remain so; and because municipal opposition answers every attempt at anything over competitive prices, the franchise so valuable to any illuminating company of the good will of the community must be gained by reasonable rates and efficient service. Under this pressure many of the petty items of management—meter rents, cost of service and connection, interest on mains, small repairs, burners and tips—these minor sources of aggravations, must be more or less done away with. Skilled workmen must be employed to advise and assist in installation of stoves and gas fixtures and systems of piping. It is noticeable that in France the Paris Gas Company is even desirous of illustrating the advantages of gas as a source of ventilation, a point which I hope our architects also will take up. And like the shopkeeper we must subdivide our wares, because the public will have it so, and vend and sell as best we may—regenerative burners from our illuminating gas department, heating stoves and ranges from our fuel gas department, and electroliers and lamps from our electric department; and, therefore, many of us have come here to-day with this conviction, perhaps better felt than defined, that, to maintain a footing in our communities, care must be taken to make what the people want, as they want it, and learn how to skilfully sell it.

I have added advisedly the words "electric department" to the requirements of a gas company, although I am well aware all do not so consider it. All are agreed on the gas and stove departments, but the

competition of arc and incandescent lamps, irrespective of the corporate ownership behind them, is developing their use in places hitherto supposed impregnable. I shall perhaps be able to allude to this later; it is enough just now for my purpose to emphasize the business habits of the purveyors of electricity, their methods, often very faulty, but always telling in the matter of contracts and choice of customers. Some of their habits, which remind me of those old days when we heard the word pirate uttered savagely enough in these rooms, are not to be considered, perhaps, models; but surely among the new duties which 1889 gave to 1890, I place most prominently the necessity of care and skill in meeting the particular need of each of our consumers.

Connected with this subject, and necessitated by the same clamor of popular pressure, I would call your attention to the necessity of the Association as a body maintaining greater unity if possible in its attitude toward competition and general municipal legislation. There is nothing which has given the representatives of gas companies more respect and power than such an Association of intelligent men who could without any jealousy of interest freely compare notes and expressions and maintain a solid front against opposition. I recognize also the delicacy of any attitude which might be misunderstood to mean any combination against the actions of a legislative body from whom we have derived our charters; but I think this Association has a duty to itself in watching the course of private legislation and furnishing reliable information about matters connected with the gas interests.

The Massachusetts Legislature has bills before it now to repeal the 10 per cent. carbonic oxide law and the establishment of the office of gas commissioners, bills regarding the municipal purchase of works, gas and electric, the overhead wire system—a perfect Pandora's box filled for the nonce with panaceas and blessings. I know I voice the mind of this Association when I say that in the matter of the gas commissioners the repeal of the bill creating their office would be an injury to the best interests alike of the consumers and the gas companies. And I think some expression of this kind is due them from us; for if we have not wholly sympathized with them in all their decisions, no one certainly has ever failed to recognize the justice, legal fairness and courtesy with which these decisions were accompanied; and I would recommend that a suitable committee be appointed by this body, to have the care of this subject of municipal legislation in the different States represented here, and render such aid as may be required, drawing upon our Treasurer, not to exceed a given limit, for the necessary expense.

And now, as I survey the actual work done in 1889, what is the result of the review? The forthcoming report of the gas commissioners will tell of a prosperous year, of good dividends and fair prices. Mr. Hinman reports fair averages of candle power. No one, so far as I know, has reached the dollar limit; no one makes fuel gas; no new improvements of any importance in manufacture have been introduced, except in the substitution of Lima oil for cannel, and home-made iron sponge for lime. As I have before said, the attention of the gas engineer has not been called this way. I had hoped some results might have been reached from the system of inclined retorts, and yet more from the combined firings of Mr. Clark, which I must confess interested me greatly as a move in the right direction. When it is considered that 28 per cent. of the cost of the gas in the holder in America is represented by less than 10 per cent. abroad, it certainly is necessary not to cut down the daily price of labor, but to increase its efficiency by competent apparatus.

Of course, the two great movements of the year have been in the departments of water gas and electricity. Experience has finally solved the question of fuel gas to a question of appliances, and has confined it to my mind somewhat strangely to the development of gas ranges, the number of which has argued barometrically as it were to the activity or heaviness of the atmosphere of the gas company's office. I much regret that the exhibition which it was hoped might be made of heaters and ranges, and which was entered into so heartily by the leading manufacturers, had to be given up for this year at least. It would, I think, have been of interest to watch the development of the heater; for instance, from the plain reflecting stove through what might be called the regenerative plan of the Fuel Gas and Engineering Company to the steam heaters of the Backus type, and the furnace of Mr. Hawley. Here again the idea of locality and appropriateness of use suggests opportunity for each type, and I think the public demand a proper one for a good fuel at a reasonable rate. We need not be frightened at Mr. Young's figures. There will be plenty of time for the extension of our works before fuel gas is a success on such an extended scale as to require millions of capital; but I am heartily glad if the Michigan plan has earned its dividend, that it has dared to try the experiment at 30 cents per 1,000.

In water gas, however, much capital has been invested, mainly as

an auxiliary to coal gas plants, to obtain higher candle power and for prudential reasons. Many things have drawn attention to this subject, such as the visit of eminent gas engineers from England, the great strikes in the works at London, Birmingham and elsewhere, the cheapness of Lima crude oil, and the necessity of increased holder capacity. We have two papers on this subject, and I forbear to take your time.

I have already alluded to my own attitude regarding the electric department. My experience has been such that I could draw no other conclusion. Let me state the facts. For the two years 1886-87, the Gas Company in New Bedford was in opposition to two electric companies, one arc, the other incandescent, and barely held its own. Gas stoves, Lungren lamps a perfect sales department of fittings and fixtures, were no obstacles, and lower prices only resulted in decreased revenue. By the purchase of one plant and the development of a Westinghouse apparatus, the Company in 22 months added 4,500 incandescent lights and 400 arc lights, equal perhaps to 100 per cent. of the revenue and 150 per cent. of the total gas sale, if converted into gas figures. Could this have been done any other way? And yet more; for by the purchase of the Edison plant, now about consummated, a community of 37,000 has found a place for nearly 13,000 incandescents, 550 arcs, with gas sales of 42 millions. And I instance these figures not to boast how mushroom-like this demand has been as to call attention to the demand itself—its quality, its certainty, and the necessity of meeting it. Such questions as, "Could not this all have been done by gas," and "Would not the same capital have paid better?" resolve themselves into the habit of the public, their cultivation and needs. This abnormal demand for incandescent light argues two ways—either poor gas and poor methods of distributing it, poor general management, from the imputation of which we are relieved since we could sell electricity, or it argues a popular demand which will take nothing else. And, therefore, I think an electric department is justified, sometimes at least, and the whole argument resolves itself into some such ledger entry as this:

Dr. The most successful development of gas likely to be compromised by the attention paid to electricity; the excessive cost of capitalization, contract system, uncertain report and depreciation account; the novelty and possible short life of patents and consequent cheapness of inventions and capitalized plant; the unreliability of storage batteries; the danger to life and capital. While to its credit must be placed whatever intrinsic merits electricity may possess as a dividend winner, its own necessity, and the benefits of its control.

The year 1889 has diminished to some extent the debtor side, in furnishing some more reliable data on which to base the capitalization, the repair and depreciation, and danger accounts. Capitalization has averaged \$250 to each horse power, with the best of engines and dynamos; repairs and depreciation are placed within 5 per cent. of the investment; meters and contracts are not so much guess work as formerly, and the cost of electricity has proved not so widely variable in different conditions, or in fact so far different from the cost of gas as many have supposed. But I firmly believe that an opposition controlled by your self is a safe one, and there can be no incandescent lamp installed, except in a few isolated cases, which is not a menace or a substitute, actual or possible, of a gas jet; and the development of either high tension or continuous incandescent systems means the gradual extinction, not of the gas company, but of its immediate profits on any line of main in spite of the tendency and advantage of increased demand for light wherever the gas burner remains. In the race for future development I think both systems are equally matched. What regenerator benches will do, compound condensing engines will do, and though I do not expect we shall ever make gas by electricity at the rate of 17 cents per 1,000, this is as good an instance as any of the million possibilities which the gas engineer expects when he adds the electric department to his already overloaded brain. Mr. Fowler will call your attention more closely than I do to the necessities and economics of the subject. For myself, I have looked upon it somewhat as an insurance of the gas interest, until the *bona fide* legitimate business and popular demand convinced me of its intrinsic merits. I have been amused that the petroleum industry got hit by it as well as the gas. I shall certainly expect that neither prejudice nor unreasoning opposition will hinder a free discussion of the subject.

And now, gentlemen, I ask your attention to the papers which are to be presented by those whose names will give weight to their words. I would ask of each of you to take such advantage of the privileges of the Association that, recognizing some superiority in another's methods or work, you may feel free to ask and the right to expect an answer.

We shall all recognize, I have no doubt, the shadow under which we have met. We all know that each year to us also the horizon of our

purpose opens wider over the untracked seas. I repeat it is our duty to make ourselves acquainted with every revelation of light which can benefit mankind and by any system of municipal distribution. But as I look out over the blue waves so entrancing in the bright sunlight, I know also the possibilities of disaster and defeat and the necessity of conservative management and expense. On the one hand, lie the restriction of sales to new districts, new purposes; on the other the interminable vexations of patents, and the character of the business itself. In front of us our legitimate object this "gain," bringing with it the indorsement and good will of the community. As Matthew Arnold said of History, "The treasures indeed are ample, and we may reasonably fear whether we shall have strength and skill to own them."

COMMITTEE ON PRESIDENT'S ADDRESS.

Mr. Stiness—There is at least one subject in that address which should be referred to a committee for consideration; hence I move that the President's address be referred to a committee to be named by the Secretary, with instructions to report at this meeting. I ask that I may be omitted from the committee.

The motion prevailed, and the Secretary named as the committee Messrs. F. S. Richardson, C. D. Lamson, and H. B. Leach.

TREASURER'S REPORT.

The following report from the Treasurer was read, and, on motion of Mr. Stiness, it was received and placed on file:

Charles H. Nettleton, Treasurer, in account with the New England Association of Gas Engineers.

<i>Receipts.</i>	
1889. Balance.....	\$92 77
Received dues, 1888.....	\$9 00
" " 1889.....	99 00

Permanent fund deposited in the Derby Savings Bank.....	\$600 00

AMENDMENT TO CONSTITUTION.

The President—You will remember that in the call for this meeting an amendment to the Constitution was referred to as having been accepted and approved by the Directors, and recommended by them to this meeting for adoption. The amendment is to Article IV., which now reads:

4. Any New England Gas Engineer may become an active member upon application to the Secretary, accompanied by the endorsement of two active members of the Association, and the membership fee of five dollars, the approval of the Board of Directors, and an election by three-quarters of the votes at any regular meeting of the Association, and by signing an agreement to pay such assessments as may be levied by the Board of Directors. Any Gas Engineer residing out of the New England States may be elected an honorary member by the same vote as is required for the regular election of members of the Association. Any person residing in New England, and connected with industries pertaining to the gas business, may become an associate member upon conditions prescribed for active members. None but active members shall vote or be eligible to office.

It is now proposed to omit the words "residing out of the New England States," in the seventh line. What action will the Association take upon the amendment?

On motion of Mr. Harbison, the amendment was adopted.

COMMITTEE ON NOMINATION OF OFFICERS.

The President—The next business in order is the appointment of a committee to nominate officers for the ensuing year. I wish to say right here that I deem Mr. Norton's action last year sufficiently valid to become the unwritten constitution of this body. He declined a re-election, and I think we had best adopt that plan in all our future work—unless we happen to get an extremely good President, and then we may re-elect him. As I look upon the matter, there are so many of you who are so much better than anybody else to become President of the Association that I think a change each year is the better plan. Therefore, I would like the nominating committee to consider that the President is not eligible to re-election, and I would like that to be the unwritten constitution of our body. Therefore, if it is your pleasure, the Secretary will take the names of a nominating committee, or the President will appoint one, if you so desire.

Mr. Stiness moved that the President appoint a nominating committee. The motion prevailed, and the President appointed as such committee; F. C. Sherman, A. K. Quinn and W. A. Learned.

MEMORIAL COMMITTEE.

Mr. Stiness—I move a committee be appointed to prepare a suitable minute to be spread upon our records with reference to the death of our brother, Oliver Edwards Cushing, and, as we have not the data at hand which would enable them to make a report at this meeting, that they be given authority to report in writing hereafter. I listened, Mr. President, with much interest to your remarks with regard to the death of Mr. Cushing; and, standing as we do to-day with the flowers hardly withered upon his grave, it is eminently fitting we should pause for one moment in the whirl of business to lay upon his fresh grave those flowers of memory, fragrant as they are to-day; and that we should recall him as one whom we have known for so many years as kind and gentle and a perfect man. I was pleased last night as I stood within these walls, and as many men came and gazed upon the counterfeit presentment of Oliver Edwards Cushing, to listen to the kindly feelings that they all expressed; and it brought back to my mind those words, perhaps familiar to you all, "It is pleasant to live in the memory of those we love, for that is not to die." This world is brighter and fairer because Oliver Edwards Cushing lived. I hope that the committee will be given authority, if not able to report to-day, to report in print, and that a copy of their report, suitably inscribed by our Secretary, be sent to the family.

The President—You have heard the remarks of Mr. Stiness, and I know that his motion has your approval, and that we do not need to take a vote upon the subject. I will appoint on that Committee Messrs. Stiness, Slater and Prichard.

READING THE INVITATIONS.

The Secretary read the following invitations to this meeting of the Association:

WALTHAM, MASS., Feb. 5, 1890.

MR. C. H. NETTLETON, Secretary:

Dear Sir—I wish to extend an invitation to the Association to visit the Loomis fuel gas plant in operation here at the works of the American Waltham Watch Company, at the time of the annual meeting this month. * * * * *

Yours very truly,
(Signed) WILLIAM TARBELL.

BOSTON, MASS., Feb. 17, 1890.

ROBERT B. TABER, ESQ., President N. E. A. of G. E.:

Dear Sir—The Boston Electric Club would be pleased to have the New England Association of Gas Engineers accept the privileges of the Club during the session of the Twentieth Annual Meeting of the Association, and extends a cordial invitation to members to visit the Club rooms, where they will be heartily welcomed. Very truly yours,

(Signed) HENRY B. CRAM, Prest.

Mr. W. A. Wood—I wish to say that the President of the Boston Gas Company, Mr. J. Edward Addicks, has extended a formal invitation to the Association to visit both the Bay State and the Commercial Point stations of the Company. It is proposed that at the close of the meeting on Thursday morning, which it is suggested shall not be later than 12 o'clock, the members shall take carriages and go from here to the Bay State works, where lunch will be provided, and that they afterwards visit the Commercial Point station. It will be necessary for some arrangements to be made, and we would, therefore, like to know how many will probably go. The idea is to get back in time to enable members who wish to do so to take the afternoon trains out of town.

The President—The three invitations are before us. What action will you take with respect to them?

Mr. Stiness—I move that the invitation of the Boston Electric Club be accepted. Being myself a member of that Club, I can assure the gentlemen present they will there receive a most cordial greeting from the electrical fraternity of New England. They have a very fine club room, and it is fitting that very close and fraternal feeling should exist between the two advocates of artificial illumination. I also move that the invitation from Waltham be accepted, with thanks. I suppose it would be almost impossible for all of us to visit Waltham, as the programme says that we are to visit the Bay State gas works. I move that that invitation be also accepted, and I feel that all who can visit the works will be well repaid for doing so.

Mr. Greenough—In regard to the visit to the Boston gas works, arrangements are practically as stated by Mr. Wood, that is, we should get away from here to-morrow by 12 o'clock, as we ought to get down to the Bay State works before 1 o'clock. We can get lunch there, visit the works, leave there at half past 2, get to the Commercial Point works at 3 o'clock, get away from there by 4 o'clock; and those who wish will be able to leave town by half past 4. I think any one can be sure of getting out of town by the 5 o'clock trains to-morrow afternoon.

The President—With regard to the invitation from the Electric Club, Mr. Stiness has moved that it be accepted, with thanks. [Adopted.]

The President—I confess the invitation to Waltham gave me great pleasure, but as we have already announced that we are going to visit the Boston works, it was thought best by the Directors that those who would like to go there and remain over on Friday, could visit Waltham. I am sure all who do go will be most heartily welcome. Mr. Stiness' motion is that the invitation be accepted with thanks; and while we cannot as an Association visit Waltham, that as many of our members as feel inclined to make the visit will do so, and that we acquaint Mr. Tarbell with the fact of our acceptance. [Adopted.]

The President—In the matter of the Boston Company's invitation, I certainly feel that we owe them many thanks for their kindness in the matter. It is desirable that as many as possible of the members shall accept the invitation, and that they be notified how many are likely to visit the works. I believe that all the business which we can attend to this morning is now completed, and we will listen to the reading of the papers. I will begin by asking Dr. Amory, of Brookline, Mass., to read his paper on the

MUNICIPAL CONTROL OF GAS AND ELECTRIC LIGHTING.

At the time I was invited by your Directors to write a paper on "The Municipal Control of Gas and Electric Lighting," we had just been through an experience in Boston which so illustrated the subject proposed, that my attention was very naturally attracted by certain phases of the question which have prompted the spirit of this address. I need not say that public discussion of the municipal control of gas manufacture is no new feature, and that many arguments for and against this control have been worn threadbare.

A few years ago I happened to be in the chemical laboratory, at Dresden, of a Professor of the Saxon University, when he was showing me the experimental results of some of his professional researches. It was in the twilight of evening, and being somewhat dark he lighted the gas jet. The illumination was so dim that he apologized for the poor light, and remarked that the city gas works were under the management of the municipal government, and, in consequence, the gas was of a very low candle power, besides being quite impure. I asked him if it was not cheap in price, and though I have forgotten what was the price he named, I remember being astonished at the high rate. I was then living at the best hotel in the city, and was obliged to dress and undress in my room after sundown by the light of an ordinary candle, because gas light was too costly for my landlord or his ordinary guests. I noticed also that the few apartments I visited in that city were lighted, except in the dining rooms and halls, by lamps or candles, in spite of the fact that Dresden is the capitol and court city of the kingdom of Saxony.

I had the same experience at Munich, and not at the time having any intention of managing a gas company, or its works, the affair passed out of my mind as one of the curiosities of German barbarity or poverty; nor did I, as I now regret, investigate further into the matter.

In our own country, the well known financial history of the Philadelphia gas works, managed by trustees appointed by the municipal government, is a curiosity of modern times.

This winter on the expiration of a three year's contract for lighting the streets of Boston by electric lights, the electric lighting companies, as my friend Mr. Neal, of the Charlestown Gas Company will bear me out, were confronted, at a conference with the Mayor of Boston, by the statement that if we would not agree to furnish light at 40 cents a night

for each street light, he would feel obliged to urge upon the city government the necessity of owning its own plant, so that the city might light its own streets.

Up to the present period, gas and electric lighting companies have been guarding only against the competition of their rivals, or the formation of new companies in their locality. They have even gone so far as to urge the parental arm of the State government to ensure to existing companies a monopoly of gas and electric light distribution. In our own State we are supposed to be protected by a Gas Commission, whose judicial and executive authority seeks to limit the sale of gas to companies already in existence, and the Commissioners apparently aim to settle differences between manufacturer and consumer upon an equitable basis of arbitration, rather than to discipline them by allowing the usual commercial custom of competition from companies additionally licensed to do business in the same territory.

That Board in its official reports, points to the fact that competition between rival companies invariably results in consolidation under larger capital investment, and so requires unnecessarily large dividends, which the communities should not be called upon to pay.

At the present time competition of private capital against private capital, previously invested, is not naturally a great cause for anxiety, because history shows that it will generally result in mutual compromise with fair dividends upon all moneys invested; if not by compromise, then by consolidation on a basis of larger capital, thus insuring the payment of omitted dividends which had been suspended during the sharp crisis of competition in previous years.

The *present* outcry is to save this payment of profit to private capital invested in gas undertakings by means of the municipal ownership and management of new plants built upon more modern processes of gas manufacture; and hence, supposed economy in cost of manufacture.

My purpose is to show the fallacy of this popular outcry, for I doubt if we appreciate how strong this demand is growing; and yet we know that the result of acquiescence and submission to this sensational effort will be as in private competition a duplication of invested capital to supply consumers within the same geographical limits. We all must recognize the fact that the same axiom prevails in our business as in other mercantile undertakings. The man or company that can make the largest sales of daily commodities can afford to do this at a smaller margin of profit than his competitor who makes small sales at larger profit. Long bills of sales and small profits will result in turning over invested capital more frequently every year; for instance, one cent made out of a dollar used ten times a year makes 10 per cent. profit during the year. We see an exemplification of this in the larger dry goods and grocery stores in our more populous towns. These do so much more business on capital invested that the small shops disappear very rapidly, and the large shops grow annually larger. Apply this principle to a city which lights its own streets from municipal gas works and consequently makes small sales at less profit. The same main which carries the gas of the private corporation to the shops and houses of its people could just as well supply gas to the street lights, and the private corporation can afford to do this at less cost on account of the larger amount of gas manufactured.

If a municipal government lights its own streets there is no inducement to its managers to increase the annual product of gas; and, therefore, having but a limited amount of gas to make, the expense for the long lines of mains will naturally increase the cost of manufacture. If the town of Brookline should lay independent gas mains for its own street lighting the cost would not be far from \$75,000, or an annual interest account at 8 per cent. of \$6,000; now, as this town used, in 1886, before electric lighting was introduced, 12 million feet of gas, this interest charge for mains would add 50 cents per 1,000 feet to the cost of gas, which otherwise could not be manufactured at so low a cost as compared with companies making a large product.

The North Attleboro Gas Company made for that year about 12 million feet of gas, distributed through less than 9 miles, and was obliged to charge \$2.63 per 1,000. The profit paid in dividend by that Company for that year was only \$800 over the interest which we have assumed as a proper charge for the town of Brookline to pay annually for its mains if used only for street lighting. It seems almost unnecessary to call your attention to the fact that if a town made its own gas every abutter would think he had the right to demand a street light in front of his own door.

During the year 1888 the Brookline Gas Company sold one-quarter of its gas for public street lights. The mileage of mains in Brookline gas territory was, for that year, 52; Boston, 129; Dorchester, 49; and Jamaica Plain, 26. Parallel pipes for these districts would double the capital required, and the cost of these mains in Brookline now amounts

to nearly one-third of its capital used for the manufacture of gas; and in Jamaica Plain to even a larger proportion.

It is quite true that in Boston the percentage which the sales of gas used for street lighting bear to its total sales is a comparatively small portion of its revenue; but there is the stronger reason for the non-investment in a duplication of its pipe mains. The interest on cost of these mains is a very light burden for the Boston Gas Company, as it bears an annual charge of 5 per cent. against 95 per cent. In the more sparsely settled suburbs of that city the receipts for public lighting help to reduce the cost of gas to the house owner.

In order to reduce the cost of distribution the management of a gas company should be zealous in promoting sales of gas in its local territory; therefore, sales should be made to municipal governments for street lighting at such a low price, within the bounds of reason, that a liberal distribution of street lamps should be provided by that government. This will help to pay an interest upon the money required to lay mains through the streets, and as no meters are needed to register the amount of gas consumed, the price of gas for public street service can be for a less sum per thousand than that sold to private consumers.

Allow me just here to protest against the public outcry that private corporations occupy the streets without paying for their use. Common law requires that a personal tax shall be levied upon gas mains laid in the streets of a town or city. The Brookline Gas Company has to pay on her mains, within the limits of Boston, an annual rate upon a valuation of \$35,000, amounting in the present year to a tax of nearly \$26 per mile of main. It is an indirect assessment upon the licensee to use these streets.

It is not necessary to discuss the question of a town entering upon a commercial plan of selling gas to private consumers. The objections to this are as obvious as those against keeping public grocery stores, candy or peanut shops, and meat markets. Nor would it be fair to tax the poor man who now does not use gas in order to supply the rich man who will use gas, no matter what it may cost.

Another serious objection to a town lighting its streets by taxation for the expenses of running a gas plant, naturally occurs in a liability to suits from private individuals meeting with supposed accidents, owing to a negligent illumination of its highways, as well as from other supposed liabilities. Towns do not fare well in suits for damages brought by private individuals; they suffer in costs for actions of tort more severely than private corporations.

We all know, as gas managers, how dangerous are the temptations to spend money in improving our gas plants and electric light installations by listening to the importunities of those who have patent processes for the manufacture of gas or improved electric apparatus, at a cost of merely nothing.

We are all familiar with the common saying that the sale of residual products produces such fabulous prices that the sum received will pay the whole cost of coal, and perhaps a portion of the labor in making gas. Municipalities can borrow large sums of money by special legislation "outside the debt limit," and, consequently, having good credit, can spend money *ad libitum*, especially if managed by men who receive salaries rather than a dividend of profits upon their investment. Directors are mighty wary of increasing the company's debt, which will injure the borrowing credit or cause the stockholders to vote them out of office.

We see this remark exemplified by the large debts in our New England cities and towns for the improvement of their streets, schools, parks, sewers, and water supplies; and this danger has required the intervention of legislative action to limit the borrowing capacity of towns, based upon their assessed valuations. If now we add to the temptations of spending money the authority and power for towns to install gas and electric plants, the taxpayer's burdens will be unduly increased.

I have merely run over some of the arguments against a town establishing its own gas plant. Why, it may be asked, should not a town install an electric plant with which to light its streets, provided the people prefer this method of illumination to that of gas? My answer can be derived from the details of the Gas Commissioners' report for the year 1888.

About \$5,000,000 of capital, bonds and liabilities, are invested in our State electric light companies. Their profits in 1888 from commercial and public lights together have realized about \$220,000, or less than 4 per cent.; but in most instances the liabilities from unpaid bills are carried into the profit and loss account, and amount to nearly \$108,000. If we deduct this from last year's income the profits are reduced to about \$112,000 on an investment of nearly \$5,000,000, or about 2 per cent., and if we exclude the two companies in Boston, this will leave the profit of that year's business for all the other companies in Massachusetts a sum

of \$27,000 on an investment of more than \$3,000,000, or less than 1 per cent. on investment.

Will any town with that showing care to go into the business of electric lighting for its own streets rather than hire the light from established companies? Is the business outlook promising? Are not the electric light companies undergoing the same discipline that our gas companies suffered from 30 years ago, when annual dividends to stockholders of gas companies were very small, and sometimes nothing.

There is one feature of the present day in reference to the subject before us that is only now beginning to form an important argument against municipal control of street lighting. I would have some hesitation in mentioning the argument before any but the audience now before me.

It is an open secret that to-day the profits from electric lighting are too small to induce any success in competition between companies exclusively engaged in this form of lighting; therefore, no municipality could reasonably expect to do a large amount of street electric lighting without combining with it gas lighting. You will see by the following extracts from the Directors' annual report to our Brookline Gas Light Company stockholders how, by a judicious combination of the two industries, a saving economy may be practiced:

"The sales of gas have increased so rapidly each year, that we shall soon outgrow our apparatus for gas manufacture and storage; in fact, this past season we have been obliged to use some of our reserve gas retort benches, on account of the large demand upon our resources. The full capacity of our retort house will yield us only 286,000 feet of gas a day, and during the long days at Christmastide we were obliged to manufacture a daily output of nearly 260,000 feet.

"We have only 8 benches. If we were lighting the same number of street lights as have been displaced by electric lights, we should be obliged to make 25,000 feet more per day for the long winter nights. If we should add to this daily requirement the gas needed for the private residences and public buildings now lighted by electricity, we should be obliged to increase our daily manufacture to 40,000 feet more than we are now making during the season when the nights are long. In other words, without our facilities of to-day for furnishing electric lights in addition to our gas sales, we should have been obliged to enlarge our retort house capacity by one-sixth. This would have required a new retort house to have been built more than 18 months ago, probably also an increase of our purifying capacity."

I ought here frankly to state that in gas companies which do also an electric lighting business, the general expenses, such as administration, rent, or interest on real estate, dividend of profits, general superintendence, taxes and other miscellaneous expenses are divided between the two investments concerned in gas and electric lighting.

Now what chance of competition can there be between a municipal gas and electric plant which furnishes only public lighting, and a private corporation which does or can furnish both public and private lighting by gas or electricity? Add to this the risks of suits for damages against infringements of patent devices used in electrical apparatus, and what city or town will care to assume this additional liability upon its taxpayers?

Municipal Electric Lighting.—What it cost Bangor to establish and maintain a plant.

Mayor Hart, on Jan. 20, received the following from the Mayor of Bangor:

"MAYOR'S OFFICE, BANGOR, ME., Jan. 18, 1890.

"Hon. Thomas N. Hart, Mayor of Boston—Dear Sir:—In reply to your request of Jan 8, will say: Our electric light plant, owned and operated by the city, is a success in every particular, and far exceeds the expectations of even the most sanguine. It consists of 165-light dynamo capacity, with 140 lights actually placed in the streets, all but seven being placed on mast arms; three circuits; total miles of wire, 36, run on poles; 2,000-candle power lamps; good quality of wire, well insulated. We have tried to have everything of good quality and work well done, and think we succeeded fairly well; and our total cost, including steam engine and boiler to be used in cases of emergency, has been about \$33,000. (Original estimate, \$27,000.)

"Our cost of operation, running all night every night, and making a liberal allowance for wear and tear, will not be far from \$6,500 per year, or 13 cents per night per light (or \$47.45 per light per year). This low cost is, of course, due to the fact that our plant is operated by water power owned by the city. We have steam auxiliary, however, and if operated by steam entirely our cost would not exceed 25 cents per night, and probably not be much over 20 cents. I believe any city situated as favorably for fuel as Boston can operate its own plant by steam for not exceeding 25 cents per night for 2,000-candle power arc lights, including

all expenses for wear and tear; and prices heretofore charged by private companies for this service are outrageous.

"I know the arguments that are put forth in their interest and the means taken to influence and frighten the average citizen, and particularly the members of the city government, for I have just been through it all. If you are inclined to investigate this subject to any great extent, I would suggest a pamphlet, *Municipal Lighting*, by Fred. H. Whipple, Mich., as likely to be of great help, and shall be pleased to give you such details of construction and operation of our plant as you may desire.

"Should have replied to your request earlier, but have been confined to the house by sickness for some time, and this is the first work I have done. Yours very respectfully, C. F. BRAGG, Mayor."

I must say that I am somewhat surprised at the contents of this letter, for the figures do not correspond with the experience we have had in Brookline, nor with those published by other companies in Massachusetts. Even suppose the city of Bangor has a water power which costs nothing, we cannot believe that its city government can buy good electric apparatus, or line wire, or poles or labor at any price less than some of the rest of us.

Let us analyze Mayor Bragg's figures by comparison with the usual commercial prices. I have seen some of the poles in Bangor, which are usually only 20 feet above ground; they would cost delivered about \$3 each. Thirty-six miles of poles would require:

Cost of 1,080 poles, at \$3, or.....	\$3,240
Cost of setting 1,080 poles, at \$2, or.....	2,160
Mast arms (133 in number) cost, at \$18.50 each.....	2,460
Double circuit of water proof wire, and labor of stringing, including cross arms, etc., per mile, at \$150....	10,800
Average cost of 150 electric lamp capacity, at \$75.....	11,250
Hoods and hanger boards, at \$6 each.....	798
Cost of station (including building, switch-boards, wiring, etc.).....	3,292*
	<hr/>
	\$33,000

Does this sum of \$33,000 really include the whole cost? I do not think so.

Estimate cost of maintenance for all-night service, 150 arc lamps, 36 miles circuit:

Three trimmers, at \$912 per year.....	\$2,736
Carbons, at \$3.50 per night.....	1,277
Dynamo man, at \$3 per night.....	1,095
Lines, repairing.....	912
(No charge for oil and waste, and no charge for water power.)	
Charge for depreciation of plant, including repairs, 20 per cent.....	6,600
Interest on capital, at 6 per cent.....	1,980
	<hr/>
	\$14,600

Cost of steam plant—

Steam plant, 200 horse power, at \$25 per H.P..	\$5,000
Steam pipe.....	500
Heaters and smoke flue.....	1,000
	<hr/>
	\$6,500

Maintenance of steam plant—

Depreciation, 15 per cent. on \$6,500.....	\$975
Interest, 6 per cent.....	390
Fuel.....	5,000
Oil and waste.....	600
Engineer and stoker.....	1,300
	<hr/>
	8,265
	<hr/>
	\$22,865

I have not counted in the miscellaneous expenses, which may be judged from our own experience to be of no inconsiderable account in the bill for maintenance; as for instance—

Globes.....	\$157 16
Repairs of lamps.....	125 76
Repairs of electric plant.....	440 00
Repairs of lines.....	1,625 00
Superintendence.....	500 00
Globes.....	102 12
Repairs of electric plant.....	2,593 37
Oil and waste.....	200 00
	<hr/>
Average expense for two years.....	\$5,743 41

* No estimate in detail could be made of this cost without inspection of the station, nor any allowance for auxiliary steam power referred to in letter.

The Mayor of Bangor may be a better manager than I am, but I do not see why our electric light companies in Massachusetts cannot produce a better result in their financial showing; for it does not seem to me that a plant of 150 arc lamps can be run at 13 cents a night without steam power, nor at 25 cents a night with the costs of the latter maintenance.

In Brookline we have about 36 miles of street arc lighting, and 129 lamps, and the expense costs us about 42½ cents. If we had 200 arc lights I estimate the actual cost for street lights about 33 cents per night. By the use of the Westinghouse alternating arc lamp system we are promised an annual saving in cost of maintenance for each lamp of \$20, or 5½ cents per night, or a net cost of 37 cents per lamp per night; or for a 200-lamp outfit a further reduction of 7 cents per night.

In conclusion, I wish from these preceding views to sympathize this deduction. There seems to be in the minds of the public an opinion that illuminating companies are pirates that prey upon the purses of the community, endeavoring to take every advantage of a supposed monopoly to make an exorbitant rate of profit. Hence Gas Commissions and City Councils are invoked to interpose the right of eminent domain to compel gas and electric lighting companies to sell their products at an unremunerative price. We see this cloud, no bigger than a man's hand now, in many cities and towns in New England. It is especially a dominant impulse in the mind of Mayor Bragg, as shown by his letter.

I again repeat that we as gas managers must down this monster of public opinion by concessions, and must try our luck at economy of management to increase our prospects of small earnings. We must do this by offers to light public streets and buildings at the lowest possible cost, or else suffer the consequences. The lamentable exhibition in Boston of a disposition to crowd down the throats of the civic authorities a reasonably large price for street lights and for public buildings has resulted in a cat and dog fight which would be ridiculous if it were not dangerous to our existence. The older gas companies have profited by a long experience in meeting this issue. I sincerely hope that our younger brethren in the electric light business will copy our policy, and thus put an end to the popular demand for municipal gas and electric lighting.

Dunkirk, N. Y., 55-arc light plant.—Investment price, \$13,338.71. Salaries of superintendent, engineers and firemen paid by Water Department.

One month's maintenance—

Superintendent's share of salary.....	\$75 00
Engineer's salary.....	90 00
Firemen.....	60 00
Interest on plant, 1 per cent.....	134 00
Rent of station and land per month.....	100 00
Depreciation of plant, 1 per cent....	134 00
Real cost of maintenance.....	\$633 00
Cost of maintenance as reported.....	225 28
	\$858 28

Average number of lights run during month, 55 arc lights. Total amount of coal consumed, 137,777 lbs., at \$1.65 per ton, \$113.55; number of carbons used, 3,412, at \$11 per 1,000, \$38.28.

6 gallons cylinder oil used, at 90 cents.....	\$5 40
5 gallons lubricating oil, at 35 cents.....	1 75
6 globes used, at \$1.....	6 00

Discussion.

The President—The subject of Dr. Amory's paper is now before the meeting for consideration. We would like to have a very free discussion by the Association with regard to the matter. I presume the subject is of most interest to us who live in Massachusetts, and I will ask Mr. Greenough to give us his opinion upon the subject, as relating to Boston or his own personal ideas of the same.

Mr. Greenough—The question of municipallighting is a pretty wide one, and can hardly be touched on to the extent that I would like, in the few remarks that I shall have time to make here at the moment. I

think that Dr. Amory's paper is an admirable one, but I think he touches perhaps too lightly upon the probabilities of cities and towns going into the business for the purpose of supplying private lighting. I have no idea for a moment that the city of Boston, for example, will ever touch the gas business in Boston, unless they propose not only to buy the street lights, but also to supply the private lighting, and thus have a hack at the profits which gas companies are supposed to be making. I think that the Gas Commissioners have proved a most valuable auxiliary to the gas companies. The idea which the public has had for many years of gas companies has been erroneous. There was a time 30 years ago (so my father has told me), when he was sent for by the Mayor of Boston and asked as to the profits of the gas business, and the Mayor gravely told him that he understood that they were sufficient, not only to pay the expenses and the interest on the cost of the plant, but were also sufficient to pay the whole expenses of the city of Boston. The treasurer of the Gas Company had no difficulty in showing the Mayor that the entire gross receipts of the Gas Company would not pay a tenth part of the expenses of the city of Boston at that time; and the Mayor found out that he was in error. When cities do go into the gas business, they will do so for the purpose of making money, and not alone for the purpose of supplying a good light to the public. What Dr. Amory has hinted at in his suggestion as to the mismanagement of the works in Philadelphia, and of the works in Dresden, requires more than a hint to be adequately expressed. I do not wish to be understood as saying that all municipal gas works are mismanaged. I have in my mind one or two municipal gas works in different parts of Europe, where I think the management is admirable; and the gentlemen in charge are honorable men and men of marked ability. But those instances are so much the exception, that the rule is anything but favorable to municipal control. We are continually being confronted, by the agitators of a species of socialism, with statements as to the number of municipal gas works which are being run in different parts of England, Scotland and Germany; but there are very few of them which, on a more extended examination of their figures and accounts, would not tend to discredit these statements, and to cast discredit upon the advantages which are claimed by the socialists. Moreover, there is a very great feeling, on the part of advocates of cheap gas, that the ordinary consumers do not get the benefit of the reductions in the cost of gas manufacture; but that the gas works are run more particularly for the benefit of non-residents tax payers, or fully as much so as they are run for the benefit of the consumers of gas. And, although you have pointed out to you with pride, when you go to Manchester, England, the magnificent City Hall which has been erected out of the profits of the gas works, yet, there is another side to that question; and the gas consumer has been forced in Manchester to see the price of gas put up much higher than has been done for the gas of similar grade supplied by private corporations elsewhere. These facts are undeniable. Looking upon the present situation in this country and upon the situation abroad, where there has been such a demand for relaxation to the laborer in respect to the hours of working, and where we see one gas company after another compelled to yield to the demand for only eight hours of work, thus being placed almost under the dominion of the labor unions, we are led to inquire what we will come to in this country, where universal suffrage is in vogue, and where it is impossible to avoid the conclusion that if the city works were run generally by the city managements, there would be a very large increase in the number of men employed, and a corresponding decrease in the number of hours which they work; and the result might be that the cost of gas would be so increased as to put gas in a very disadvantageous position when brought in competition with electricity. At best, gas has to struggle for its existence. The time has gone by, as I remarked some years ago, when we could fix our own price and collect our money; and the time has come when we have got to sell our gas at a price which will enable us to compete successfully with electricity and petroleum. If the city were running gas works can it be considered possible that the gas would be manufactured as cheaply in any city of this country as it is now being done by private enterprise? There is another thing which I have not seen suggested, and yet which is undeniably true, and that is the putting of gas work, under municipal control would practically mean the stifling of inventions. Necessity is the mother of invention. Gas companies have to make gas cheaper, and they therefore call upon their engineers to devise the methods of doing it. The brains of the gas engineers of the world are continually at work trying to see how they can make gas cheaper. As I have said before, engineers in charge of municipal gas works in different parts of the world have done credit to themselves and their profession, and I think at once of Foulis, Hunt, Valon, Woodall and others; but the number of those from whom useful inventions

have come among the gas profession could be counted on the fingers of both hands. Practically all the steps forward that have been made in our business in the last ten years have been the results of private enterprise. Of course, in this country nearly all the gas business is in the control of private corporations; but the public corporations with which we are familiar are certainly the last to which we would turn for any assistance in that direction. In England and in Germany, especially in England and in Scotland, the best brains of our profession are in the employ, not of the municipal companies, but of the private corporations; because private corporations are willing, as a rule, to pay prices which city governments will not pay. I do not forget Mr. Foulis, of Glasgow, and Mr. Hunt, of Birmingham. I should consider that if the business of gas management went as a whole into the hands of municipal ownership it would be a decided step backward for the profession. The English gas companies which are under the control of private corporations, sell better and cheaper gas as a rule right through the country than the municipal corporations charge for the use of their commodity. I do not think it possible to do this subject justice in a five minutes' talk; and yet, Mr. President, I did not want to decline to respond to your call without saying a few of the things on the subject that come to my mind.

The President—As it is a matter which concerns Connecticut as well as Massachusetts, perhaps Mr. Harbison may have something to say upon the subject.

Mr. Harbison—I have not given this subject much thought. I was quite surprised at a remark made by Dr. Amory in his paper, to the effect that there was a very large public demand for municipal corporations owning lighting stations for the purpose of supplying public lighting. I had not heard that suggestion made in Connecticut. If he has reference to Massachusetts as the New England in which it is becoming general, that may be the fact—I am not so well posted as to Massachusetts; but I do not think that it applies to that large and prominent part of New England which is comprised within the border lines of the State of Connecticut. For myself, I have no faith in the municipal management of lighting stations. Municipalities may be very competent to take care of the street department, and can perhaps manage the water department, but I am not of the opinion that municipal corporations are eminently qualified for giving their fellow citizens light of almost any kind.

Dr. Amory—I would call attention to the fact that there are some cases of the municipal ownership of electric light plants in Maine—as at Lewiston, Bangor, and in some other cities—and if there is any gentleman here from that State, he might give us some information as to how the plan works there.

Mr. Harbison—I want to say a word further as to Dr. Amory's suggestion. His statement may apply to the electric light business, for of course almost any sort of people can go into the electric lighting business; but it requires men of intelligence and of training to properly manage a gas plant.

The President—Is there any one present from Maine or from Massachusetts who has felt the approach of a desire on the part of the public to control his own gas works?

Dr. Amory—I would like the privilege of giving some facts as to Chicago—

Mr. Stiness—And also as to Dunkirk.

Dr. Amory—I had hoped to have a letter to show to the Association to-day which gave the facts as to Dunkirk, and possibly I may get it by to-morrow. I have had no time to go there. I simply want to give from personal observation of two of the stations in Chicago a very low estimate of the cost of the investment. On a lot of land owned by the city of Chicago, on the corner of Chicago avenue and Seventh street, the city built a very substantial and useful building. The lot of land, as nearly as I could get at it from seeing it and from asking questions about it, is 70 feet wide by 100 feet deep; in other words, three city lots. I assume the value of that land to be \$6,000, which I presume is a very low price, but I do not know anything about the value of lots in that part of the city. The building and the chimney stack (which was a pretty substantial affair, and must have cost \$5,000 or \$6,000 to build) I valued at \$45,000. I think that is a very low valuation, and perhaps only 50 per cent. of what it ought to be. The three boilers with automatic stokers are very well set, and are in good order. The Westinghouse, Church, Kerr & Co., new boilers, are put at \$5,000. There are four 125-horse power engines, which I put at \$2,000 apiece, or \$8,000. Thirty miles of underground wire at \$8,000 per mile, or \$240,000. The conduit, which has six ducts, I was informed cost \$17.50 per linear foot. The cable cost 12 cents, and the hauling of that cable cost 4 cents; giving \$1.64 as the cost per linear foot for each duct. That would make \$8,000

per mile, and for 30 miles the investment would stand at \$240,000. Then, 250 dynamos and lamps, at \$60, would cost \$18,000. Steam fittings and miscellaneous investments, \$27,000. So that the whole plant of 250 lights might have cost \$350,000, according to my estimate; and I should think that you might safely add 25 or 50 per cent. to that. I have assumed the annual depreciation to be 10 per cent.; that would be \$35,000 per year, or for each of the 250 lamps \$150 per year. Each circuit is 3 miles long, and there are 10 circuits in all. There are 250 lamp posts, costing \$20 each; and 10 per cent. depreciation of the lamp posts would add \$500 more to the expense. Now, if the pay roll be assumed, from the experience at other stations, to be \$12,000 a year, the carbons \$3,600, the fuel \$10,000, the oil, waste, water, etc., \$4,400, it would make the expense of maintaining that station \$30,000, or \$120 per lamp per year. This added to the \$152 would make \$272 per year for each lamp. If we double the capacity of that station (and the station is large enough for 500 or 1,000 lamps), we should of course have to reduce for each lamp maintenance a sufficient proportion. The depreciation of course would not be so large, and the additional expenses would not be proportionally so much. The average expense for 300 lamps is assumed to be about \$160 per lamp per year, which is not 19½ cents per lamp. That station is not in operation. There is a station in operation where they have a very small space, and every spot of that space is occupied by something or other. They took an old fire engine house and adapted it to their purpose. Their investment, as I make it, is as follows: They have a Wright slow-speed engine, 275 horse power; shafting and friction without load, 57 horse power; so that they only get less than 220 horse power out of the machine. I estimated the cost of that engine and machinery. I put the land, building, machinery, boilers, dynamos, and lamps, and 50 miles of underground conduit, at the same price as before, making the total cost of the investment \$510,000. The labor, as given to me by their chief engineer, and by one or two other men in the station, was as follows: Chief engineer, \$1,200; assistant engineer, \$1,080; four stokers, \$2,880; six trimmers, \$3,240; line tester, \$720; three linemen, \$2,520; add to this for carbons, \$3,800; fuel, \$12,000; depreciation, \$51,000; making the total expense for that station per year \$78,640. That was for from 278 to 302 arc lamps, which was all that they furnished from that station. So that if my estimate is correct, the cost might be 75 cents per lamp per night. At Pittsburgh I went over the East End Electric Light Station, and although I have not transposed all my figures, I have them here in a notebook, and they may be interesting to those who wish the facts. The East End Electric Light Station has been established for three years. Until a year ago they had only 3,000 incandescent lights, and a very few commercial arc lights. This last year they are maintaining 400 arc lights and the 3,000 incandescent lamps have increased in one year to 14,000: and they compete with kerosene oil to a very limited extent, and with natural gas at 10 cents per 1,000, and with manufactured gas at \$1 per 1,000. So that Mr. Harbison need not feel quite so sure that gas is the only thing that is going to furnish light.

Mr. Harbison—He is not. The sun gives considerable light down our way.

Dr. Amory—We have got to use the sun, too. Their coal slag in Pittsburgh costs 4½ cents per bushel. For natural gas they pay 3 mills per horse power per hour. That Company never paid a dividend. They have invested \$300,000 in stock and \$150,000 in bonds, which is the extent of their power to contract debt. They still have orders for 100 arc lights which they cannot fill, and for 1,000 incandescent lights which they cannot fill. They have 270 miles of wire, and no underground circuit. They do their own wiring. They have this force: One engineer, who is a machinist and does the repairing, to whom they pay \$100 per month; three engineers, one of whom they pay \$3 per day, and the others \$2.50; two stokers, at \$1.75; two oil boys, who handle the distribution of the natural gas under the boilers, 75 cents per day. They have an 1,800-horse power engine capacity (a Westinghouse engine), and 1,360 boiler capacity at 80 pounds pressure. They have 15 linemen at \$2.75 per day; 7 ground men at \$1.75 per day; 1 foreman, at \$75 per month. They run an incandescent light circuit eight miles from their station.

Mr. Lamson—Are they making any money?

Dr. Amory—You will remember that the first year they only had 3,000 incandescent lights. They cannot possibly have made money except during the last year.

Mr. Lamson—When they are doing all they can hope to do, will they be able to make any money, or are they doing it for the fun of the thing?

Dr. Amory—They are doing as gas companies have often done—they are organizing their concern into a paying basis. I think their financial arrangements are well managed. They have bought real estate;

they have put up 270 miles of circuit; and, of course, they are under-capitalized.

Mr. Lamson—On such figures as you have given they cannot do business and make a profit.

Mr. Stedman—Allow me to suggest to Mr. Lamson that the primary object is not to make a profit on the sale of the light, but by that demonstration to sell a good deal more electrical apparatus.

Mr. Lamson—I want to know where the fun comes in.

Dr. Amory—I want to correct Colonel Stedman on that point. This Company is not to my knowledge owned by the Westinghouse people.

Mr. Stedman—They use Westinghouse machinery.

Dr. Amory—But I do not think it is under the Westinghouse people. I judge from what I heard the Westinghouse people are not in control of the stock. I will add that they charge six-tenths of one cent per hour for each 16 candle light, which is measured by meter; and they charge 25 cents per month for the use of that meter. I am only giving you the facts. Of course, I know nothing about their affairs. I want you to realize that a year ago they would only sell 3,000 incandescent lamps, and, of course, they could make no money. The past year they have sold 14,000 incandescent lamps and 400 arc lamps; for each of the latter they have received \$100 per year. They use natural gas for fuel, which costs 3 mills per horse power per hour, as against 8 or 9 mills here. I cannot give you any further information than that. It is only three years since they first began to do business. I can give you an estimate of their valuation: 3,450 poles, 50 to 60 feet in height, at \$10 per pole, will be \$34,500; 270 miles of wire, at \$160 per mile, would be about the same; 400 arc lamps and dynamos, at \$60 per lamp, would be \$24,000; one 1,800-horse power engine, reckoned at \$15 per horse power, would be \$27,000; their boiler, 1,400-horse power, at \$10, would be \$14,000; their land and buildings, etc., \$125,000. They have a whole block. They own this land. Their contingencies would make their total investment cost, as I valued it, \$300,000. They have an alternating plant of 15,000 lights, which, at \$8 or \$9 a lamp capacity, would make \$420,000, and their whole investment would, therefore, be about \$450,000. I do not see but that that comes out pretty fairly. I presume that next year they will make some money. I do not see why they should not.

The President—The discussion has drifted somewhat away from the original subject. While we recognize the necessity of becoming acquainted with these details, I think we had better pass over this discussion, as we have so many other papers before us for consideration.

Mr. Harbison—I think the Association is under obligations to Dr. Amory (I am sure I am) for the time that he has taken to gather these statistics and to prepare this paper, which is interesting, to say the least. I move the thanks of the Association be tendered him for his kindness in the matter. [Adopted.]

(To be continued.)

SPECIAL ENGLISH CORRESPONDENCE.

COMMUNICATED BY NORTON H. HUMPHRYS.

SALISBURY, Feb. 10, 1890.

The Gas Stokers Strike in South London—The Gas Light and Coke Company Gas Testing in London—Gadd and Mason's Gasholder Construction.

The strike of stokers in South London has been brought to a close, and in a manner that is simply farcical. The various labor Unions, concerned have come to an agreement (?) with the Directors of the South Metropolitan Gas Company on two conditions. These are that the Company shall revert to the eight hour system as in operation before the strike, and that preference shall be given to former workmen in the case of any vacancies arising. This is the sum and substance of all that is gained by the recent strike. This is the total benefit that the "Union" is able to secure for its members. Yet the officers of the various Unions undertake, upon the acceptance of them, to declare the strike at an end. The farcical nature of the whole thing will be evident, when we remember that neither of these conditions touches upon the points in dispute. The company had previously adopted the eight hour shift and got it fairly into working order. Throughout the dispute there has not been the slightest hint of any fears on the part of the men, as to its rejection. So far from making things hot for their old workmen, the Company were doing their best to satisfy them, and would not, but for the action of the men themselves, take a single new hand, to the detriment of an old one against whom no fault could be laid. The only advantage, then, that the Union has secured for the men, is the stipulation that they shall have the preference when any vacancies arise, a stipulation which is of very little value at this time of

the year. Mr. Livesey has already explained that he has worked the two-shift system during the emergency, but is willing to return to the three shifts as soon as he can get into regular working. But then there are the new men. It was of course necessary to offer every inducement in the shape of promise of regular employment, in order to secure a sufficient number of new men when the old ones left. And these new men have now the first claim, so that the Directors could not honorably turn them off in order to take on old hands. The conclusion, therefore, appears unavoidable, that at the best there are not likely to be vacancies for more than one-third of the strikers, and that even this cannot occur until next winter. And then, that many will only be able to secure temporary work as "winter hands." It also appears that the official agreement (?) has been forestalled by a private understanding between Mr. Livesey and several of the men who have sent in their names as willing to return. Mr. Livesey states that a list of these has been kept, and that all vacancies that arise are supplied from it. This is the end of the great strike. The Stokers' Union, in order to preserve itself a habitation and a name, is obliged to go through the form and agreement that secures nothing for its members. It not only leaves them in the same position as they were before, but lamenting the loss of good situations, thrown up at the bidding of the Union, and lost without the receiving of a single benefit in return.

It only seems a few days ago that the officers of the "Union" were talking, not only of stopping the gas supply in London, but also the coal, to say nothing of other inconveniences that were to be inflicted on the British public, as a means to the securing of their ends. Indeed, one almost fancied that the old inquisition was to come again in another form, and that the public were to be worried and tortured to an unlimited extent, in order to force them to obey the behests of the Union, or to use their influence in furthering its desires. All these bubbles are now pricked and have vanished. Many people will bring forward theories to account for the collapse of the Union, and I would venture to suggest one. That is, because they have done so much unnecessary business on Sundays. No one knows better than gas engineers that certain work must of necessity be done on that day; but when we find a society—let its objects be what it may—making a practice of utilizing Sabbath after Sabbath as regular field days, to the utter disturbance of all associations usually connected with that day of the week, we may safely prophesy that the objects of that society are not likely to prosper. It is a remarkable thing that those gas undertakings which have been foremost in diminishing Sunday labor as far as practicable, are without exception amongst the most prosperous in the country. For a striking example one need not go further than the one just under discussion—the South Metropolitan Gas Company.

At this early period of the year only a few gas undertakings have completed the preparation of their accounts for the last half of 1889. Amongst the first to appear, as usual, are those of the Gas Light and Coke Company; and the information which the Directors bring forward is of a satisfactory character, notwithstanding various little troubles. They are again able to pay full dividends, and have experienced a large increase—more than 5 per cent. as compared with last year—in the sale of gas. This is chiefly ascribed to the extended use of gas stoves for heating and cooking. During the half year they have sold 2,600, and let on hire nearly 5,600 stoves, in addition to those previously disposed of, showing a large and rapid development in the use of gas as fuel. The recent reductions in the price of gas, together with the increased price of coal, are no doubt concerned in this to some extent. With coal at present prices, a high quality heating gas at 60 cents per 1,000 cu. ft. is a comparatively cheap fuel. A considerable extension in the manufacturing, storing and distributing plant will shortly be necessary. The Directors have to contend with increased prices of coal, iron, fireclay and all kinds of materials and stores, besides a very substantial addition of about \$750,000 per annum to the wages account. It is a somewhat disappointing commentary on this liberal treatment of their workmen, that the yield of gas per ton of coal has scarcely been so good. In noticing the result of Mr. Trewby's recent visit to the United States, the Directors say that although enriched water gas is not likely to replace coal gas in England, it may be found useful to provide for the manufacture of water gas, to be used in addition to and in conjunction with coal gas on occasions when a large quantity of gas is required to meet a sudden demand. They are about to conduct experiments on the practical scale in this direction, and also in regard to processes for improved carbonization and dealing with residuals. The Dinsmore process and the inclined retort are probably in view here.

I have on several occasions commented on the work of examining the gas supply in London, as carried on under the superintendence of the Gas Referees. Although the operations in this department are of an

extensive character, costing several thousands per annum, it is surprising how seldom they are referred to in public. If a speaker at a meeting wants to refer to the quality of the gas supply, he usually indicates it by adjectives of his own choosing, just as he might do if it was never officially tested at all. In the public press also, it scarcely ever happens that the quality of the gas is indicated by a reference to the weekly returns of the Superintendent Examiner. The whole is, therefore, only a costly way of playing watch dog upon the gas companies. The Referees also, do not appear fortunate in their relations with the suppliers, or with their own staff. They have offended the former by introducing alteration in the apparatus, which are said to have the effect of considerably deteriorating the apparent value of the gas, and at the same time to be beyond the limits contemplated by the Parliamentary regulations. The amended instructions to the Examiners have had a somewhat similar effect, in that these gentlemen are called upon to devote a much larger space of their lives and attention to their duties, while at the same time nothing has been said about an increased salary. Having really doubled the work, the Referees should have recommended a proportionate increase of remuneration in the proper quarter. The result is that the staff has combined together and forwarded a spirited memorial to the County Council, asking for the adoption of a standard more accurate than the sperm candle at present used, and also for an adequate increase of salary. The fact that, according to the showing of their own superintendent, the results recorded by the Examiners are not of a reliable character, on account of the deficiencies of the sperm candle, in no way detracts from the labor of obtaining those results, and these gentlemen are quite in order in asking for a proper recognition of their skill, patience, and time, that are indispensable to the efficient carrying out of the very elaborate instructions issued by the Gas Referees.

A gasholder without columns, girders, or other external guide framing, has lately been erected at Northwich. It is provided with Gadd and Masous spiral guides, to which I have referred on a previous occasion. The diameter is 60 ft., and there are two lifts each 20 ft. high. At equal distances round the inside of the tank are fixed the guide rails, eight in number, placed against the tank wall at an angle of 45°. A similar series of guides are fixed on the interior of the outer lift for the guiding of the inner lift. The pulleys are made of steel and are 10 in. diameter, working on 2 in. iron axles. The inner pulleys are faced solid, and run in the trough of the guide, which is H shape in section. But those on the outside are grooved, so as to take the outer edge of the guide.

These particulars are taken from a description of the holder furnished to the *Journal of Gas Lighting* by Mr. Thos. Newbigging, C.E. It is estimated that the actual saving in weight of metal used is 34 tons, and this could be increased in future structures of the same kind, seeing that the present holder is somewhat in the way of a new departure, and has, therefore, been made stronger in several parts of the framework than the experience which it has been the means of affording shows to be necessary. The saving in cost of ironwork is put at about \$3,000. The tank is also cheaper, as there is no excavating for piers, no brickwork for same, and no base stones for the columns. The pressure given by the holder when full is 7 inches, of which 4½ inches is furnished by the bottom lift. The holder has been observed whilst under the influence of the strong gales that have recently occurred, and whilst nearly full of gas. It has not shown any movement worth recording. The Northwich holder may, therefore, be taken as a practical demonstration of the truth of the principles first enunciated by Mr. Wm. Gadd. It has been shown to a party of about 100 gas engineers from different parts of the country, who found it fully inflated on their arrival at the works. After thoroughly inspecting it while in this condition and receiving any desired information from Mr. Newbigging and Mr. Gadd, who were present, connection was opened with another holder, and it was allowed to empty itself in the presence of the company. The action of the apparatus was pronounced to be satisfactory in every way.

At a meeting of the Malden (Mass.) Board of Aldermen one of the things considered was the annual appropriation bill. When it was reached Alderman Russell moved that the sum of \$18,000 be substituted for \$16,500 on account of street lights, giving as his reason therefor that in case such action were not taken the city could not add to the electric lighting service, and thought that the price charged (\$90 per annum for each arc burned 300 nights per year) was not excessive. Ald. Devir objected on the ground that Chelsea paid but \$80 per annum for arcs burned every night in the year. The Russell amendment was then rejected.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE ordinance introduced in City Councils of St. Louis, which subsequently received the indorsement of both branches of the government, limiting the price which gas companies might charge for gas to 90 cents per 1,000 foot, has been vetoed by Mayor Noonan. The message announcing this action is reasonable, and so unlike the fulminations of the ordinary city authority when dealing with gas supply, that we reproduce it in full. "I herewith return Council bill No. 44 without my approval. This measure was introduced into the Council on May 10, 1889. It passed that body on July 26, 1889, establishing the price of gas, on and after February 1, 1890, at \$1.18½ per 1,000 cubic feet. At this time the price of gas was, in this city, except in a small territory, \$1.50 per 1,000 cubic feet. In the House of Delegates the bill was considered and so amended, as to establish for 5 years the price of illuminating gas at 90 cents per 1,000 cubic feet, and fuel gas at 50 cents per 1,000. In this shape it passed the House of Delegates, on January 7, 1890. The Council concurred in the amendments and adopted the amended bill on February 7, 1890. In the meantime, on January 1, 1890, the gas company reduced the price of gas to \$1.18½ per 1,000 cubic feet, the price originally placed by the Council, at which price it is now sold to consumers. The power to regulate the price of gas, conferred on the city by its charter, is to be exercised in a reasonable manner; and an ordinance on the subject that is deemed unreasonable by the courts will be held to be invalid and of no force or effect. Taking the price at which the article is sold in the principal cities of this country, which in no case is lower than \$1.25 per 1,000, I do not think St. Louis is justified in demanding coal gas for illuminating purposes at 90 cents per 1,000 cubic feet. The policy of the local government should be to encourage business pursuits and enterprises by not interfering with or hampering them, save in cases where the necessity of municipal action for the protection of the community is obvious. By abstaining from exercising the power to regulate, except in the cases above indicated, a stability and tone are given to investments of capital in this city, and the prosperity and welfare of the community are correspondingly enhanced and augmented. I have during my administration endeavored to act on the above policy, believing it to be fraught with world-wide benefits to St. Louis, and, in the view I take of the matter before me, I cannot give my approval to Council bill No. 44.—EDWARD A. NOONAN, Mayor."

THE Laclède Gas Company have determined to build eight benches of 7's, on the Coze inclined plan. It is hoped to have the settings in operation next May, during the time of the Western Association meeting; and as the first foundation stone is still unplaced, it will be readily seen that Engineer Egner and his assistants will have to keep the contractors moving all the time, if the Western Association is to witness the trial run. It also strikes us that the proprietors of the Laclède Company are to be congratulated on their pluck in determining to make such an extensive trial of a system that still requires time to demonstrate thoroughly its merits.

THE Citizen's Gas Light Company, N. Y., will, at a meeting set for the 12th inst., act upon a proposition to increase the capital stock of the Company from 60,000 shares to 75,000 shares, or an increase in money value at par (\$20) of \$300,000. We understand that the Company will, at the termination of its current contract with the Fulton-Municipal Company, manufacture its own gas on the old works site in South Brooklyn, under the Meeze patents and systems.

THE Directors of the San Jose (Cal.) Light and Power Company have adopted resolutions looking to plant betterment, that will involve an expenditure of \$75,000. The holder contract (vessel to have a capacity of 150,000 cubic feet) has been awarded to the Stacy Manufacturing Company. This looks as if gas were holding its own on the Pacific coast district.

THE proprietors of the Corning (N. Y.) Gas Light Company have decided to engage in the supply of electric currents. The Thomson-Houston system has been chosen, and the installation is to be in working order by May 1.

WE understand that the gas and electric light plants at Evansville, Ind., have been purchased by the U. G. I. Company, which will operate the same hereafter.

MR. RICHMOND E. SLADE, of the White Plains (N. Y.) Gas Company, is a bachelor no longer, having been united in marriage, on the evening of

Feb. 12, to Miss Jennie A. Wiggins, daughter of the late H. S. Wiggins, of Yonkers. May their lot be a happy one.

ONE result of the recent astounding bank developments in this city will be in all probability the postponement of the completion of construction work on the plant of the Empire Gas and Electric Light Company, of Huntington, L. I. President Claassen, whose management of the Sixth National Bank brought him plenty of notoriety at least, was at the head of the Huntington enterprise.

MR. D. W. CRAFTS, of Northampton, Mass., was one of the "regulars" who failed to answer his name during roll-call at the New England meeting. Perhaps his non-appearance may be explained in the statement that an explosion occurred at the Northampton works on the night of Feb. 16. The damage to property, however, was slight, and no one was injured.

S. A. BAXTER, whose connection with the National Oil Company, of Lima, Ohio, is well known in the West, has instituted suit against the St. Paul (Minn.) Gas Company for \$54,168 in the United States Circuit Court, alleging breach of contract as the basis for the action.

SENATOR POYNTZ, we understand, has secured the adoption by the Kentucky Legislature of the following resolutions, which savor very strongly of a "strike" at the proprietors of the Louisville Gas Company:

"Whereas, Through the public prints, and in general comment, statements have been made to the effect that the Louisville Gas Company, a corporation chartered by the General Assembly of Kentucky, is openly, seriously, and flagrantly violating many provisions of its charter; and

"Whereas, The said Louisville Gas Company has by such violations forfeited its charter; and

"Whereas, It has been commonly rumored that the Louisville Gas Company has not kept faith with the city of Louisville in the quality of light furnished, nor with its patrons in the price charged for fuel and other gas; and

"Whereas, It is a matter of public notoriety that the said Gas Company has attempted to interfere with the election of local and State officers by the illegal use of money; therefore be it

"Resolved by the General Assembly that a committee of five from the Senate and five from the House be appointed to investigate the affairs of the Louisville Gas Company; to summon witnesses and swear the same; to examine its books, and to be invested with full power to carry out the spirit of these resolutions, and report the result of such investigation to this body."

It is possible that these resolutions were brought about by the malice of the Louisville Electric Light Company, whose proprietors are anxious that the Legislature should refuse to grant the electric light charter which the Gas Company has been endeavoring to secure. It might be well to add that the authorities of Louisville favor the legislation asked for in this respect by the Gas Company.

WE regret to announce the death of Mr. Joseph Alphonse Pagaud, who has acted as Secretary of the Jefferson City (La.) Gas Company since a controlling interest in that enterprise had been secured by the firm of Jackson & Kilpatrick. Mr. Pagaud's death occurred on the morning of Saturday, Feb. 15.

THE Provincial Legislature has refused to indorse the application for an opposition gas charter for Montreal, Canada.

A CORRESPONDENT sends the following: "H. H. Button, one of Milwaukee's oldest and most highly respected citizens, died at his home in Milwaukee on the morning of February 14th. He came to Milwaukee when a youth, and for many years has been a prominent figure in its business and social circles. He was President of the Milwaukee Gas Light Company, and was senior member of the wholesale drug house of Green & Button. He was very well liked.—T. R."

THE proprietors of the Tallahassee (Fla.) Gas and Electric Light Company are greatly elated over the business outlook.

A VERY peculiar suit is that which has been brought before Judge Hawes, Chicago, by one John Larson, who sues the Chicago Gas Light and Coke Company for \$5,000, because of injuries received by him in a gas explosion at No. 730 Sedgwick street, May 2, 1888. He claims that the Gas Company neglected to turn the gas off, though the premises had

just been vacated by a tenant who had taken away the gas fixtures. The Company's defense was that the explosion was caused by Larson's carelessness in lighting a match.

MR. JACOB NICHOLS, who was largely interested in the fortunes of the Lowell (Mass.) Gas Company, is dead. His demise occurred on the morning of February 16th, was in his 75th year, and was prominently identified with many important local interests.

"THE city of Oshkosh (Wis.) was served with a notice about a fortnight ago by the Oshkosh Gas Company, through its attorneys, Finck & Barber, which in effect is that the Gas Company has wearied of waiting for an answer to the complaint served upon the city some months since, and it will now proceed to take the depositions of scientists or authorities upon the subject of electric lighting in Chicago, Milwaukee and other cities as to the relative merits of the lights furnished by the Gas Company and the Oshkosh Electric Light and Power Company. Suit was commenced by the Gas Company about three months ago against the city and Aldermen of the second ward to show cause why the contract for lighting that ward was not awarded to plaintiff—the lowest bidder; and to compel the defendant to award such contract. The Company claims that by reason of a franchise granted to the Company, of which the Oshkosh Gas Company is the legal successor, it is alone entitled to light the streets of the city. The authorities have simply slighted all the former notices served on them, evidently believing that the Gas Company did not intend to push matters. Now, however, they perceive their mistake. The second ward Aldermen justify their action in letting the contract for lighting in that ward to the Oshkosh Electric Light and Power Company on the ground that the light furnished by the latter Company is far superior to that supplied by the Gas Company. The latter employs the Thomson-Houston system, while the contractors are working under the Brush plan. In my opinion the Gas Company has a good case, and will eventually prove it in the courts to the confusion of the local authorities.—R. E."

IT is more than probable that a gas plant will be erected at Darien, Ga., this spring. This place is the capital of McIntosh county, Ga., and is on the Altamaha river, at a point about 62 miles southwest of Savannah.

THE proprietors of the Electro-Carbon Motive Company, of Chicago—perhaps the concern would be more readily identified under the name of the Baker Gas Engine Company—have decided to put in their manufacturing plant at Aurora, Ills. The Company manufactures gas and gasoline engines and all sorts of electric motors.

"THAT's derved fine," said Farmer Squedunk, as he gazed up at the sign, "Teeth extracted without pain—gas administered." "That's very pooty. I've got the blamedest, ornierest toothache ever was; I read papers, I do, and I know that derved gas trick. Put you to bed and turn on the gas. Next day there is an inquest and a verdict, 'Another fool countryman gone.'"

ARTICLES incorporating the Berkeley Development Company have been filed by Messrs. Geo. W. Kline, Louis Gottshall, W. E. Sell, A. Gunn, and J. L. Scotchler. It is capitalized in \$500,000, and one of its objects is "to operate, lease, etc., all systems, plans or plants in producing light and heat by gas, electricity, etc." Berkeley is a post village of Alameda county, Cal., near the Bay of San Francisco, and is about midway of the latter city and Oakland. It ought to be a good place wherein to operate a gas company.

THE Cicero Gas Company—managed by Messrs. Geo. H. Parks, Henry Frink, C. E. Crafts, J. J. Walsler, F. L. Ball, H. J. Ullman, S. A. Rothermel and Dr. W. C. Gray—asks for a charter to supply gas for light and fuel in the town of Austin, Ills. The proprietors say they will employ the process in use at Jackson, Mich., and the selling rates are to be \$1.50 per 1,000 for illuminating, and 50 cents per 1,000 for heating gas.

THE Lowe type of plant recently installed at Hutchinson, Kas., under the supervision of Mr. Mudie, has answered the tests applied to it satisfactorily.

AT the annual meeting of the Petersburg, Va., Gas Light Company, the following officers were chosen: President, John G. Dunn; Superintendent and Secretary, W. H. Baxter; Treasurer, W. F. Spottiswode; Directors, Alexander Donnan, Dr. H. G. Leigh, John McGill, Nelson

T. Patterson and David Dunlap. The annual reports were indicative of the Company's prosperity.

AT the annual meeting of the Augusta (Ga.) Gas Light Company the President—the Hon. Geo. T. Barnes—was unavoidably absent because his duties as a Congressman required his presence in Washington. His report for the year, however, was read, and it gave general satisfaction. At the election for officers the following result was reached: President, Hon. Geo. T. Barnes; Secretary, H. B. Adams; Directors, G. T. Barnes, P. Walsh, T. G. Barrett, E. R. Schneider and P. H. Langdon. The stockholders authorized the Directors to subscribe \$200 to the exposition, provided the requisite \$60,000 was raised.

THE Senate Committee on General Laws of the State of Virginia has consented to important amendments to the charter of what is known as the Southside Land and Improvement Company. Under the amendments the Company is empowered to construct and operate gas works at Manchester (opposite Richmond) Va., and we understand that that provision will be taken advantage of at an early date.

THE Atlantic City (N. J.) Gas and Water Company has announced a reduction in gas rates to \$1.50 per 1,000 cubic feet.

IN connection with the buncombe resolutions and action authorizing the investigation of the affairs of the Louisville (Ky.) Gas Company by a special committee of the State Legislature, it will be remembered that one of the assigned reasons for the appointment of the committee is the reported bad quality of the gas that is distributed. Louisville has an official gas inspector—Col. Phil. Bate—who has made careful tests of the gas at least once a week since his appointment to office; and his figures invariably show that the quality of the gas is considerably in excess of the legal requirements as to candle power and purity.

IN their estimate of the probable receipts and expenses in the operation of the city gas works at Wheeling, West Va., the Board of Gas Trustees and the Council Committee on Light state that the former are likely to be \$98,000, while the latter are put at \$114,806. As the cash balance from 1889 was \$16,972.28, this would leave a surplus at end of year of \$166.28. In the estimate, however, liberal provision is made for "improvements," the sum of \$16,101 on this account being made up as follows: Resetting 12 benches of 6's, \$4,000; 4 new benches of 6's, \$8,000; general repairs, \$650; repairs to No. 3 holder, \$300; 1 street main governor, \$600; 2 sets lime trays, \$351; 1 exhaustor, engine, etc., \$2,200.

THE Syracuse (N. Y.) *Courier*, of Feb. 21, contains the following: "The Common Council met at 4 o'clock yesterday afternoon, with Mayor Kirk in the chair. The first thing done was to pass a resolution granting a franchise to the Onondaga Gas Light Company. The resolution was introduced by Ald. Matty. After it was read a motion was made that the resolution be adopted. Ald. Klock amended that the resolution be tabled. The amendment was put to vote and lost, and then the adoption of the resolution was voted on and carried. Aids. Small, Matty, Candee, McAuliffe, Segler and Scanlon voted in favor of it, Aids. Klock and Finnegan voted against it. Ald. Wilken was excused from voting, and Ald. McLennan was absent. The franchise allows the Company to lay pipes through the streets within the limits of the city of Syracuse for illuminating and heating gas. No street or pavement can be torn up without 10 days' notice, and no street paved with asphalt can be torn up by the Company without a permit from the Common Council. While laying its pipes the Company shall make a weekly report of streets and pavements torn up and work done. The Company shall furnish 20-candle power light at a rate of \$1.25 per 1,000 cubic feet to the city, and at a rate not to exceed \$1.40 per 1,000 cubic feet to the inhabitants. Before the streets are torn up a bond of \$35,000 shall be deposited with the City Clerk to protect the city against loss from any action of the Company. The Company must not dispose of or sell its plant except to the city, and must not combine with any other company or persons for the purpose of controlling the price of gas, or of gaining power thereby. Pipes are to be laid through any street whenever the Common Council shall direct." In plain language this is an outrage on the vested rights of the old Syracuse Company, whose proprietors have carried on their business with rare fidelity to the best interests of the local gas consumers. We understand that Mayor Kirk has signed the ordinance, and it is not at all unlikely that the passage of the ordinance may hereafter become the subject of legal inquiry.

[SINCE the above was put in type, we hastened to place ourselves in communication with a gentleman (a resident of Syracuse), whose know-

ledge of the facts and factors connected with this brazen deal, being voluminous and accurate, would enable us to give ourselves the precise standing of the position. Thanks to his promptness and courtesy, we can say (and very much to our satisfaction) that the schemers seem to have overreached themselves completely. To employ our correspondents words: "SYRACUSE, N. Y., Feb. 25th: Our charter election occurred on Tuesday last (18th inst.), when the then Mayor and some of the 'combine' Aldermen were defeated. At a meeting of the old Council—held on Thursday last, they, in a clandestine manner and with closed doors—no one was notified of the meeting, except those who had been *induced* to vote—passed resolutions granting a franchise to the new company. This action brought out an universal protest from our citizens; and everybody condemned the proceedings. The Mayor, who up to this time had been opposed to granting a franchise to the new company, was deceived and cajoled into allowing it to go through, found himself in a hole, from which he tried to raise himself, but failed, as the 'combine' of his Council had gone beyond his control. The newly-elected Mayor and Council were inducted into office last evening, and promptly rescinded the resolutions and annulled the franchises granted on Thursday; the vote was 7 to 3—one member was excused from voting. There are now 7 good, square, honest men in the Council of 11. Hence the old Syracuse Company is still in possession of its own. I cannot tell what may be the outcome, but I do not think the opposition will attempt any legal proceedings, for their local agents have not only 'given them away,' but the old company must have strong points against them, which could no doubt be made with telling force." One other point we would like to make in connection with the passage by the former Council of the opposition ordinance, and that is, the cowardice of the schemers, who met to clinch the "agreement" during Mr. A. C. Woods absence from Syracuse, or when he was attending the meeting of the New England Association. However, all's well that ends well.]

ELSEWHERE we note a damage suit against the Chicago Gas Light and Coke Company, brought by one Larson for injuries received in a gas explosion. The jury awarded complainant \$1,500. The case will be appealed.

AT a recent meeting of the Dallas (Texas) City Council an ordinance which sought to name maximum rates for gas and electric lighting was considered. Mr. Kivlen moved to file the bill—this, we understand, is equivalent to the defeat of any measure so disposed of—which, after some opposition, was adopted. Mr. Loeb, in opposing the ordinance, made the following inquiry: "What would my colleague from the Fourth Ward say if I should offer an ordinance compelling him to sell his beer at 2½ cents per glass; or \$1.50 per keg?" The member from the Fourth mumbled something about private interests and public corporations, and retired to ruminate.

IN an explosion in the purifying house of the Owen Sound (Canada) Gas Company, which occurred on the afternoon of February 22, an employee named Nelson was killed, and the works were damaged in \$500.

THE Pueblo (Cal.) Gas and Electric Light Company is increasing the capacity of its arc lighting plant.

THE Highways Commissioners (Flatbush, L. I.) have refused to renew the contract for public lighting with the local Gas Company, on the ground that the rate submitted—\$28 per lamp per annum, which is identical with that of last year—is too high. In the meantime the Company will carry on the lighting, until such time as the matter is adjusted, on the basis of the old rate.

THE plant of the Mauch Chunk (Pa.) Gas Company was damaged by an explosion on the afternoon of February 21st.

ARTICLES incorporating the Aspen (Col.) Economic Gas Company have been filed by Messrs. W. C. Pettibone, Geo. W. Hill, A. H. Pettibone, Henry Webber and J. M. McMichael. It is capitalized in \$25,000.

MESSRS. STEVENSON, Kingman, Walsh and others have applied to the St. Louis House Committee of Public Improvements for favorable recognition of a project to supply illuminating and fuel gas in that city. They agree to charge not in excess of 45 cents per 1,000 for heating and 75 cents per 1,000 for illuminating gas, to give the city 10 per cent. of the net receipts, and to file a bond in \$100,000 that their pledges shall be carried out.

The Market for Gas Securities.

Consolidated gas shares were inclined to the weak side in the interim of our last report, although values were not materially affected. It is undeniable, however, that there was a marked absence of any elasticity in the trading, which was about all effected at a concession from the rates of a fortnight ago. To-day (Friday) the quotations at noon were 95½ to 96. Other city shares, notably Mutual and Standard preferred, were disposed seemingly to go somewhat above prior prices, and this tendency was very marked in respect to Standard preferred, which was bid for freely at 87, while holders insisted on at least 89. The common stock was also in demand, many a nibble at 43 to 46 being recorded. While the preferred may offer a fair chance to investors, we should be chary at advising a purchase of the common. Brooklyn shares are strong, and the thing of moment in that city is the proposed increase in Citizens Company capital, the figures anent which are to be found in our current item columns. It would seem as if the Company had determined to rehabilitate and work its plant, (which as to the district to be supplied is most advantageously situated) on its own account, instead of being willing to figure as a peddler. We congratulate Engineer Byrne on this determination. He has talent, and will now have a chance to make money for his Company.

Chicago Trusts are about as before, and it is generally agreed on that the usual dividend will be declared this afternoon. Laclede common is weaker, at 14½ to 15½, and Baltimore Consolidated has again moved up to the figures of a fortnight ago. The bonds offered by the syndicate now in control of the San Diego (Cal.) works seem to have found favor with investors, the issue having been about all absorbed on the proprietor's terms.

Gas Stocks.

P. W. MACKENZIE, CHIEF ENGR. & SUPT.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owners of the RECENT Mackenzie Patents,
For the United States, England, Russia, France, Germany, Austria, and Canada,
No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day.

The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn, Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES or other RETORTS, NOR THEIR EQUIVALENTS, are used.

Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD.

The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM.

The Gas requires NO PURIFICATION whatever.

The FUEL GAS COSTS VERY MUCH LESS than PURE UNCARBURETED WATER GAS, and contains DOUBLE THE HEAT UNITS.

The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE, and consists of a Single Body with a capacity of ONE THOUSAND to ONE HUNDRED THOUSAND cubic feet per hour.

Works may be constructed to run by the CONTINUOUS or ALTERNATING method. If run continuously, the limited amount of Nitrogen present is neutralized by Carbon.

The Gas can be made of a HIGH GRADE for illuminating purposes, of a MEDIUM QUALITY for distribution for domestic purposes, and of a LOW GRADE for manufacturing uses.

Wherever Liquid Hydrocarbons can be had the MACKENZIE PROCESS WILL COMPETE IN PRICE AND SUPPLY ALL THE ADVANTAGES incidental to the use of NATURAL GAS.

This Company desires contracts for the construction of Plants, parts of Plants, Apparatus, Buildings, Holders, and Street Mains, for either of the above purposes, and will Lease or Purchase Works upon satisfactory terms.

Information will be promptly given regarding material required for production of Gas, actual cost of product, cost of works, etc.

THE NEW HANDY BINDER.

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filed in the Handy Binder, becomes a volume of great value, always convenient for instant reference. Handy Binder, Postage paid, \$1.00.

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per	24 hrs.,	3 ft. square,	5 ft. deep.			
No. 2,	"	"	125,000	"	"	"	4	"	"
No. 3,	"	"	250,000	"	"	"	5	"	"
No. 4,	"	"	500,000	"	"	"	6	"	"
No. 5,	"	"	750,000	"	"	"	7	"	"
No. 6,	"	"	1,000,000	"	"	"	8	"	"
No. 7,	"	"	1,250,000	"	"	"	9	"	"
No. 8,	"	"	1,500,000	"	"	"	10	"	"
No. 9,	"	"	2,000,000	"	"	"	12	"	"
No. 10,	"	"	3,000,000	"	"	"	15	"	"

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

PROPRIETORS OF THE
OAKHILL GAS RETORT & FIRE BRICK W'KS

Our immense establishment is now employed almost entirely in
the manufacture of materials for

GAS COMPANIES.

We have studied and perfected three important points. Our re-
torts are made to stand changes of temperature, the strongest
heats of the furnace, and the abrasion of feeding and emptying.

We furnish and build Half-Depth or Full
REGENERATOR FURNACES
of different kinds and most approved styles.

Correspondence solicited.

THOS. SMITH, Prest. AUGUST LAMBLA, Vice-Prest. & Supt.

Post Office Box 3695, New York.

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
37 in. high.	12 in. high.	12 in. high.	24 in. long.	36 in.
20 in. wide.	17 1/2 in. wide.	18 in. wide.	21 in. wide.	
	12 in. deep.	13 in. deep.		

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6 1/2 inches diameter, 8 inches high. Consumption, 6 feet per hour at 1 in. pressure.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
31 in. high.	9 1/2 in. high.	10 in. high.	21 in. long.	32 in.
17 in. wide.	14 1/2 in. wide.	15 in. wide.	16 in. wide.	
	12 in. deep.	13 in. deep.		

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. 1/2 in. supply pipe should be used where the pressure is 1 in. or over.

[OFFICIAL NOTICE.]

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., February 22, 1890.

To Members of the Ohio Gas Light Association:

Gentlemen—As previously announced, the Sixth Annual Meeting of this Association will be held at Toledo, O., beginning at 10 A.M., March 19, 1890, and continuing two days. Boody House will be the headquarters of the meeting, the various sessions of which will be held in a very suitable room in the same hotel. Members and others desiring to attend are advised to write well in advance for rooms.

The following papers have been promised for the meeting:

1. "Theory and Practice in Gas Management," J. M. Bate, Supt. Gas and Coke Company, Canton, O.
2. "Municipal Control of Lighting," H. Wilkiemeyer, Supt. Gas Light and Coke Company, Portsmouth, O.
3. "Combination of Gas and Electric Lighting in a Small Town," George W. Bowers, Sec. Gas and Electric Light Company, Hillsboro, Ohio.
4. "Our New Coal Gas Works," G. A. Hyde, Engineer Gas Light and Coke Company, Cleveland, O.
5. "Advantages of a Combined Coal and Water Gas Plant," Geo. Light, Asst. Supt. Gas Light and Coke Company, Dayton, O.
6. "Another Year with Fuel Gas," Chas. H. Evans, Manager National Gas Company, Jackson, Mich.
7. "Ohio Street Lighting Statistics," W. C. Hedges, Secretary Gas Light Company, Mansfield, O.
8. "Graduated versus Uniform Rates," Chas. R. Faben, Jr., Supt. Gas Light and Coke Company, Toledo, O.

The following questions have been proposed for the "Question Box:":

1. At what point in the works is the best place for the exhauster?
2. In a lighting territory covered by illuminating gas and the incandescent electric light, which seems to be in the ascendancy?
3. Does a fine gas of 23 to 25-candle power help check the invasion of the incandescent electric light?
4. Should we not confine the work of our Association to the important interest it was established to promote, viz.: gas lighting and the manufacture of coal gas?
5. What system of electric lighting is best for adoption by gas companies?
6. Are cast iron pipes better and cheaper than wrought pipes for gas mains of 2 to 4 inches in diameter?
7. Does it pay to coat gas mains with coal tar?
8. What is the average life of a meter in constant use, with ordinary good care?
9. Is not illuminating gas of good candle power, sold at a reduced price for fuel, the true solution of the fuel gas problem?
10. Which is the correct method of tapping mains, on top or at the side?
11. Is the Welsbach burner with natural gas a success, and what proportion of the lighting does it do in towns having both natural and artificial gas?

[OFFICIAL NOTICE.]

Southwestern Gas Association.

OFFICE OF SECRETARY, GALVESTON, TEXAS, Feb. 24, 1890.

The annual meeting of the Southwestern Gas Association will be held in Dallas, Texas, March 12 and 13, 1890. The arrangements for the meeting are now being perfected. Headquarters will be at the Windsor Hotel.
C. P. RUSSELL, Sec'y.

Other interesting questions have been proposed, which will be presented at the meeting, and members are requested to come prepared to participate in the discussion of the above papers and questions.

Provision has been made for an exhibit, in connection with the meeting, of all kinds of gas appliances and apparatus, a large room on the ground floor, a few doors from the hotel, having been secured for this purpose. No charge for floor space will be made to exhibitors, and those desiring to avail themselves of this excellent opportunity of displaying their specialties will consign their goods and address their communications to Mr. Chas. R. Faben, Jr., Supt. Gas Light and Coke Company, Toledo, O., who has the matter in hand, and who will arrange the exhibit to the best advantage of all concerned.

In addition to this exhibit there will be other objects of much interest to our members and visitors, and the meeting promises to be in every way successful. It is hoped that every member will show his appreciation of what has been done, by being present; and gas companies not heretofore represented at our annual gatherings will be profited by sending a representative to this meeting.

A cordial invitation is constantly extended to all who may desire to become members of the Association, to do so, and the Secretary would be pleased to hear from any such persons.

IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

THE MEETING AT DALLAS, TEX.—Before the current issue of the JOURNAL will have been in the hands of a large number of its readers the members of the Southwestern Association will be in session at Dallas, Texas, the convention days for the same having been fixed at the 12th and 13th insts. There is no blinking the fact that the gathering might have been more extensively advertised, with the certain result that the attendance would have been thereby benefited. Admitting the paucity of notification, however, it is gratifying to be able to say that it was not from neglect of the Secretary, nor from any inclination on his part to lukewarmness in respect to advancing the Association. Secretary Russell, just at the time when his best efforts would be put forth in preparing for the meeting, made a change in his business relations that caused him to leave Houston in order that he might re-attach himself to the Galveston Company. The disorganization consequent upon this action is the good cause for his seeming dilatoriness in respect to advertising the Dallas gathering. In the meantime, both President Enfield and Secretary Russell have not been idle in correcting the earlier omission, and so well have their efforts been responded to that, from our current advice, we confidently look forward to a good and valuable meeting. The gas makers of the great Southwest are very differently situated from their brethren of the East, West and South; and more especially does this remark apply to Texas, where the companies are, in common with other manufacturing interests, largely at the mercies of the railroads. The time will come, however, when engineering skill, backed by ample capital, will emancipate Texas from the iron (or steel) clutch of the railroad magnates, who, with rare blindness, seem bent on withering the resources that it should be their closest aim to foster. No matter whether it be a Willetts, of San Antonio, with his cherished plan of "a corral in the sea," or some one else, a Moses is sure to show the people of the Lone Star State the high road to competition in commerce. This oddity of position ought to cement the gas men of that section in more than ordinarily close counsel. We hope that the meeting will be a successful one, and shall look forward to a report of the proceedings with eager anticipation.

THE LATEST GUN FROM TOLEDO.—During the week we have received a circular from Secretary Butterworth—certainly no one can accuse that gentleman of a lack of attention to his duties as Secretary of the Ohio Association—which is in the nature of a "personal talk" between the members and himself. As a circular, then, we are unable to print it, because of the fatal words "not for publication." As it contains some matters that are worthy of especial mention here, why, we will make due note of these, and feel that in doing so the injunction "not for publication" will not have been infringed. In the first place, the Secretary notes that the Boody House, which has been selected as headquarters and place for meeting, is in all respects a first-class hotel, and that its ordinary rates are from \$3 to \$5 per day, according to the location of the rooms. The Committee of Arrangements, however—no doubt Charlie Faben could tell something about this—seem to have convinced the Boody House proprietor that gas men are such desirable fellows to have about a hotel, that he could see his way clear to making a concession. In any event, a uniform rate of \$3 per day has been arranged for the members and their guests. There is possible trouble in the suspicion that the Boody House may not be large enough to comfortably receive all those who will seek its shelter. Should there be an "overflow" that

contingent can undoubtedly count on good quarters at the Madison House, which is close to the Boody. The Secretary gives it as his belief "that the meeting will be very very interesting and profitable," and in that belief we heartily share. He also asserts that the exhibit of gas appliances and apparatus promises to be very large and interesting. The outing part of the meeting will include a visit to the factory and show-rooms of the Central Chandelier Company. Indeed, there is every indication that the Ohio's Sixth Annual will not be in any respect inferior to the rousing gatherings of its first half decade.

THE SLATER AND PARKER PAPERS.—In our current installment of the proceedings of the New England meeting are many interesting papers and much lively discussion that are sure to be closely read and remembered. In selecting at this time the papers noted in the heading we do so from the fact that one or two points in each seem to call for especial emphasis. Mr. Slater is nothing if not frank, and in his frankness is never illogical. His reference to the "feeling of hostility and even bitterness engendered by the early introduction of water gas" paves the way for a later expression in his paper that is worth reproducing here. This is: "I will say, however, in passing, that in my judgment the feelings to which I referred, of opposition to water gas, etc., etc., were not engendered so much by the gas, or its composition, *per se*, as by the aggressiveness displayed by its early patentees and advocates in forcing its introduction by questionable methods, even before it had reached its present perfected state." And the "bitterness" that was thus engendered had reason for its existence. Questionable, indeed, were the methods employed; and those methods are as much in disfavor to-day amongst men of probity as they were in the early eighties. No; the objection was not so much against the process of manufacture as against the "processes" of the financiers who were interested in its development. Mr. Slater, however, puts the matter so concisely and truthfully that we might take leave of that portion of the subject at this point. We do not concede the soundness of his conclusions about the carbonic oxide content in water gas, which will surely be availed of before long by the incandescence electric lighting promoters, who have armed themselves with some striking figures as to its potency. In fact we think the least said about carbonic oxide the better it will be for the gas maker. In the Parker paper we consider his experiences in the manufacture of coal and water gas, have been, to say the least, one-sided, with the leaning all in favor of water gas. In fact, if the figures of this year's report of the Massachusetts Board of Gas and Electric Light Commissioners are to be accepted as fair, we fail to see wherein the new method is in any essential respect an improvement over the old, save in the instance of the greater ease with which a water gas plant can be operated. If facility of operation is the desideratum then the new plan has it. But we nevertheless incline to the view that greater advances are in store for the coal gas process than for its co-adjutor. The long and short of it, however, is that both will likely work in harmony and to their mutual benefit.

ELECTRIC LIGHT INSTALLATIONS, ETC.—We are in receipt, from the D. Van Nostrand Company, of this city, of a copy of Sir David Salomon's (Bart., A.I.C.E., etc.) "Practical Handbook of Electric Light Installations, and the Management of Accumulators." The book, which is now in its fifth edition, has met with great favor; and this seems to have been fairly earned. Sir David treats his subjects in a manner well calculated to gain the confidence of the reader, and we have no hesitation in recommending the book. It is well printed and profusely illustrated. The Van Nostrand Company are the agents in America for the work, the retail price of which is \$1.50.

Facts and Figures Connected With the Installation and Operation of an Electric Light Plant.

By Mr. JOHN J. POWER, Supt. Natchez (Miss.) Gas Co.

Your issue of February 17th, contains a letter from Mr. J. Smart, President Port Hope (Ont.) Gas Company, appealing to gas managers who have had experience as to cost of installing and operating an electric light plant.

Having built and managed the Natchez Gas Company's electric light station here (though somewhat larger than the one named by Mr. Smart), my experience in that branch of our works may be of some benefit to him, or to some other members of the gas fraternity.

In this connection I would say, that through the columns of your JOURNAL I have been able to gather a varied store of new ideas and information, that many times assisted me in overcoming the difficulties that lie in the gas manager's path; and in this, my first communication, I return my thanks to the JOURNAL and its many able contributors.

and though my crude letter may be wanting in full details, if it is of any assistance it will have accomplished my object in writing it.

The Natchez Gas Light Company, nearly 2 years ago, decided to put in an electric light plant, principally for lighting the streets of our city, which were at that time lit by 110 gas and about 70 coal oil lamps; and after having the same experience as Mr. "S." with the agents of electric lighting companies, they finally chose the Thomson-Houston system, and contracted with that company for a complete outfit of 100 2,000-candle power arc light capacity, the gas company reserving the right to choose the kind of steam boiler and engine to be put in. All the work was done under my supervision. The plant consisted of 1 Hazelton boiler, 125-horse power, and a Beck engine, 100-horse power, with a Stillwell exhaust steam heater and purifier, 3 dynamos—2 of 35-light and one of 30 light capacity—all the lamps and attachments and cost of building to be in the contract, together with 21½ miles of wire. The plant, complete, cost the company \$25,000.

The building, part frame and part brick, is all covered with corrugated iron, 40 by 60 feet; the boiler and pump room is 19 by 40 feet; the space occupied by boiler is 10 feet in diameter. A brick wall divides the boiler from the engine and dynamo room, which occupies the remainder of the building, 40 by 40 feet. Great care was exercised in having good ventilation, which is absolutely necessary for the safety of the dynamos. In putting in foundations for engine and dynamos, I was very careful to have good work performed. The engine foundation is 6 feet deep, on good solid earth, 1 foot of cement and 5 feet of brickwork, laid in cement mortar, every brick shoved and joints struck. The mortar was composed of 1 part cement to 2 of sand. The sides of foundation have a pitch of 3 inches to the foot. The foundations for dynamos were similarly constructed; but only 3 feet deep. To-day those foundations are solid as can be. I have balanced a silver coin on edge on cylinder head of engine when running at a speed of 265 revolutions. We have the Scheiren perforator dynamo belts; and, after a year's hard wear, there is not a flaw or crack to be seen in them.

Our repairs on plant have been very slight, and embrace a new wrist pin in engine, nothing on dynamos; and, except for making some changes on extension shaft of engine, which were necessitated by having to put in another engine to run on incandescent dynamo, might be said to be nil.

Our boiler has proved a great success, making a great saving in fuel; for, from several tests which I have made, both with water evaporation and from card from engine, with Pittsburgh nut and slack (very little nut) we have obtained a horse power for 3.8 lbs. coal consumed. It is easily handled, a very rapid steamer, and, from my knowledge of others of the same make, very durable.

We are now running up to full capacity—84 arcs and 51 incandescents (series) 65-candle power. The city has given us a 5 years' contract, which we obtained after a bitter fight with a rival company, at \$85 per year for 2,000-candle power lights, all night and every night. We have 79 on the streets; also, 17 65-candle power incandescents, at 1½ cents per hour each. The balance of our lights are taken in stores.

Our operating expenses for an average month are as follows:

Engineer	\$80 00
Fireman	50 00
Trimmer (who furnishes his own horse and wagon)	75 00
Lineman (5 days repair line, new lamp ropes, etc.)	10 00
Coal, Pittsburgh slack, at \$3 per ton	175 00
Carbons	70 00
Repairs, new brushes, commutator segments, new globes, etc.	18 50
Oil, \$16, waste, \$3.50	19 50
Total	\$498 00

To this must be added wear on plant, interest on investment, and insurance. So far everything works smoothly, and every visitor to the city claims that we have the best and steadiest lights that they have met with anywhere. The only credit in this connection which I can claim, is that I take especial care to keep everything around the machinery, especially the dynamos, clean and in good trim.

In conclusion, I would say to the intending purchaser of an electric plant, get the best of everything. First, a good system; second, a good steam plant, that will save cost of fuel, which is the heaviest expense in operating; third, suitable buildings, strong, well ventilated and dry; fourth, good men to operate your machinery—it is poor policy to try to get a cheap man, because he is cheap, to run valuable machinery; and last but not least, get the best wire and have it well and securely put up. If of poor quality and poorly put up, it will always be a source of expense, dangerous, and a continued worry to all connected with the plant.

Sulphate of Ammonia as a Manure.

We learn, from the *Journal fuer Gasbeleuchtung*, that the German Gas Association has had presented to it a report of its Committee on the above subject, which was read by Professor Bunte, of Carlsruhe. The funds for the investigation were subscribed by various German gas works, and the work was carried out by the German Agricultural Association, through Professor Marker, of Halle, and Professor Wagner, of Darmstadt. Professor Marker's work was fieldwork, in 40 places all over Germany. In each place a field, as uniform as possible, was divided into two sections, and each of these again into five divisions, each of which had an area of about 3,000 square yards. These plots were used for the study of two questions: one bearing upon the comparative inefficiency of ammonia-sulphate manures in soils containing little or no lime; that is, what is the action of carbonate of lime on the manuring activity of sulphate of ammonia? The result is that lime or marl greatly increases the efficiency of sulphate as a manure.

The year 1888 was very unfavorable for experiments; a late spring, an extraordinarily dry summer, and a heavy rainfall in autumn, which swelled up the crops and predisposed them, especially potatoes, to disease. Still, over all, the comparative statements are worth relating.

Fine powdered lime, 1.6 cwt. per acre, was lightly ploughed in. The variations were: (1) No sulphate, no lime; (2) no sulphate, but lime as above; (3) weak sulphate, no lime; (4) weak sulphate, with lime; (5) strong sulphate, with lime. The "weak" sulphate means, for barley, 80 lbs. sulphate, for beet, oats, potatoes, etc., 120 lbs. per acre; "strong" means 120 lbs. for barley and 200 lbs. for the rest. A phosphate manuring, and in light soil, one with 3.2 cwt. of kainite per acre, ran side by side with the sulphate manuring.

The increases with sulphate were, in pounds per acre:

Oats	546.2 lbs. grain, and 946.7 lbs. straw and chaff.
Barley	203.7 " " " 58.0 " " "
Winter wheat. 158 " " " 234.0 " " "	
Beet-root	197.3 " roots.
Turnips	491.2 " "
Potatoes	646.8 " tubers.

With strong sulphate manuring the increase was still greater.

As to combination of manures, the increases were:

	Lime alone.	Ammonia alone.	Lime and Ammonia.
Barley (grain)	95.7	203.7	535.4
Oats "	147.7	546.2	947.4
Wheat "	59.6	158.0	211.4
Potatoes (tubers)	868.4	646.8	1369.2
Beet (roots)	— 229.6	+ 1964.2	+ 2401.2
Turnips (roots)	+ 640.8	+ 4823.8	+ 4129.6

The second question was the comparison of ammonia sulphate with Chili saltpeter. The variations were the following:

	Barley.	Oats, Beets, and Potatoes.
1. No nitrogen manure	—	—
2. Weaker Chili, pounds per acre ..	110	176
3. " sulphate, " " ..	88	141
4. Mixed (2 and 3) half each	—	—
5. Stronger Chili, pounds per acre ..	176	440
6. " sulphate, " " ..	141	212

The following are the results:

I. Weaker Chili manuring produces much smaller increases than stronger. Barley grain, 207 and 366; barley straw and chaff, 188 and 459; oat grain, 559 and 763; oat straw and chaff, 956 and 1,403; potatoes, 2,401 and 4,912; beet root, 7,200 and 11,645 pounds per acre of increase respectively.

II. Weaker ammonia manuring has, with all the crops, as much effect as an equal quantity of nitrogen applied in the form of Chili.

III. No. 4 produced, with all the crops, the same effect as either No. 2 or No. 3.

IV. With cereals the results under heavy manuring (5 and 6) was the same whether with Chili or with sulphate. With roots the nitrate had the advantage; it brought out 1,312 pounds potatoes and 1,780 pounds beet to the acre in excess of what the strong ammonia did.

Professor Wagner's researches were conducted with plants in plots, which were moved on a barrow between the open air and a greenhouse. His results confirm those of Professor Marker, especially as regards the beneficial effect of lime in conjunction with sulphate. He concludes that, practically, equal weights of Chili saltpetre and of sulphate of ammonia produce the same effects, and that the advantage which Chili sometimes appears to have over an equal weight of sulphate is due to the absence of lime in the soil, and to the action of the soda on the plants.

OFFICIAL REPORT.—REVISED BY THE SECRETARY.—CONTINUED FROM
PAGE 286.]

TWENTIETH ANNUAL MEETING, NEW ENGLAND ASSOCIATION OF GAS ENGINEERS.

HELD AT YOUNG'S HOTEL, BOSTON, MASS., FEB. 19 and 20, 1890.

FIRST DAY—FEB. 19—MORNING SESSION.

Mr. Waldo A. Learned (Newton, Mass.) then read the following paper on—

REVIVIFICATION OF OXIDE OF IRON.

Numerous attempts have been made to revivify oxide of iron *in situ*. Air is introduced in the gas, which not only reduces the candle power, but causes heat and back pressure in the boxes. The loss of candle power may be very small in a gas heavily charged with hydrocarbons—the gas being made by a low heat; but in many works when the heats are high there would be an appreciable loss of candle power.

My experience with air was in July, 1887, when our purifiers ran six weeks without change, purifying 19,600 feet per bushel of oxide. The candle power was reduced and the deficiency made up with an enricher. The heat in the boxes induced me to increase the pressure on the retorts, when a change of purifiers was the result.

Oxygen is used in place of air with good results, provided your purifiers are large, the oxide of good quality and the coal carbonized very free from sulphur, or means taken to remove a large portion of the sulphureted hydrogen before it gets to the purifiers.

Another method has been to force air up through the material, the cover being removed or a special outlet provided. The heat of the steam, with the heat due to the chemical change, produces a high temperature, which causes fire and bursting of the boxes by expansion.

I wish to speak more particularly of the method we have adopted, and used for 28 months, of revivification in the boxes by drawing (not forcing) air through the material by the aid of a steam-jet exhauster. The exhauster is made of a 3-inch to 2 inch cast iron reducer, with $\frac{1}{2}$ -inch steam injection pipe, tapered at the end. Connection is made with the inlet of the purifiers by 3-inch pipe. The outlet pipe of exhauster extends through the roof of building.

The purifiers (12 × 16) are in series, with a dry center seal. The material used is Irish bog ore, a natural oxide of iron, purifying 3,500 feet per bushel; also, a prepared oxide, commonly known as sponge, purifying 4,500 feet per bushel. This sponge, which is made at our works, consists of 15 lbs. iron filings, 10 lbs. sal ammoniac and 1 lb. copperas to a bushel of coarse sawdust. The shavings are wetted with a solution of silicate of soda and water to make them less combustible.

It is a well known fact that when the oxide takes up sulphureted hydrogen from the gas, there is a liberation of a quantity of water which the shavings probably absorb. When revivification takes place about one half the quantity of water is taken up. The moisture must come from the air or the shavings, and a number of reactions may wash off the solution. However, for practical working with new material, there is a decided advantage by its use. It is not essential to use copperas, which is sulphate of iron, and it acts simultaneously on ammonia and sulphureted hydrogen. My method of working is such that it leads me to use it in the mixture.

Coke breeze is used on the bottom layer of purifiers, then 18 inches of oxide of iron and 3 inches of lime on top layer. The object of the lime is to take out carbonic acid. I cannot agree with some of my friends that it is cheaper to enrich the gas than it is to use lime to make up the loss of candle power due to the presence of carbonic acid in the gas. When the material in the box is foul, the cover is taken off, the lime removed, the steam jet exhauster started on two tenths vacuum, which varies with the density of your material, and in from four to six hours it is thoroughly revivified.

The oxide is then turned over in the box to maintain its porosity, as after each revivification the material becomes more dense and the trouble would be back pressure. With the sponge this operation would not be necessary on account of the lightness of the material.

Heat is the greatest impediment in the way of successful revivification. Our first attempts were made with fear and caution. Steam was then used to aid revivification by its moisture, and to reduce the temperature in the material. The steam heat and the heat due to revivification caused too high temperature for successful working. This led to the introduction of water forced over the bottom of the purifying boxes—the object being to reduce the temperature, which was successfully accomplished.

The highest temperature recorded in the foul material in the state of revivification was 225° Fahr. It should not be above boiling point, as

sulphur melts at 235°, when the porosity of the mass would be affected. We have no definite knowledge of the chemical changes that take place in the purifiers, which vary with the quality of coal and conditions of the gas; but we do know that with iron purification, the sulphur compounds are more erratic in their behavior than with lime purification. A box will show sulphureted hydrogen one day, clean the next, followed by foul indication on the third day. It has been stated that this sudden change is due to bisulphide of carbon—it has no chemical combination with oxide of iron as it has with lime, but seems to be mechanically bound on free sulphur. A sudden change of temperature and pressure will throw this impurity off in the gas.

With lime purification we have noticed this rise of sulphur, when our custom of changing purifiers was to allow the third box to do some of the work after the second showed sulphureted hydrogen, the object being to allow the second box to act on bisulphide of carbon the contents being foul. It was only until then in proper condition to act upon this impurity—the first box removing carbonic acid, the second bisulphide of carbon, and the third sulphureted hydrogen; but when the second box receives an access of sulphureted hydrogen, or when carbonic acid comes over from the first box, the conditions change and contents of the second box become useless.

Discussion.

The President—You have heard a very interesting paper. I think Mr. Neal, of Charlestown, has adopted a similar plan; we would be glad to hear from him.

Mr. Neal—I attempted it, then for a time ceased the attempt, only to attempt it again. The first attempt was made with Mr. Shiras, who came to see me about it. He recommended revivifying by injecting steam. I did it splendidly, setting fire to the trays, burning them all up, and making a most intolerable smell, which was a nuisance all round. I think we ran very great risk. That plan was abandoned, and I did not again venture to revivify with lime in the purifiers for a long time. I have used oxide of iron, or iron sponge which I procured from the Connelly's with moderate success. Of late years and for some time past my Superintendent has manufactured the oxide of iron, using pretty much the same materials and the same mixtures used by Mr. Learned. Sometimes I have purified 18,000 feet to the bushel, and sometimes 2,000. It varies very markedly. The sulphur content varies sometimes, from 6 or 8 to 16 or 17 grains. We are using Westmoreland coal. We have for some time past used a steam-jet exhauster similar to that described by Mr. Learned. We remove the cover and let on the steam, and that draws the air through the mixture. For a while, even with the use of air in that way, the boxes became very much heated. I abandoned the use of steam, or at least of air, and then I commenced again. The trouble is when the oxide of iron is first made it is very "sharp," and heats very readily. Then, after awhile, finding that the heat was so great, we would revivify for awhile by drawing through the air to take out nearly all the sulphur, revivifying it very nearly. Our practice is now, after about 4 hours, to take the mixture entirely out of the boxes and place it on the floor of the adjoining shed prepared for that purpose, where it is turned and wetted thoroughly, and then put it back. I asked my Superintendent if that was not unnecessary work. He said it cakes on the bottom of the trays so that it makes a back pressure; therefore it is removed and then placed right back. We find that if we leave it in the boxes to revivify it will heat very badly. I must say that our purifiers, for our manufacture, are rather small, and require to be changed quite often—perhaps the purifiers do not do the work that they ought to do, because we manufacture water gas. I would say, by-the-way, that the coal gas and the water gas are mixed just before the gases reach the purifiers, where they come in with a tremendous rush, and I have found it necessary to prevent the blowing out of the seals of the purifiers, which were rather low, to use a jet exhauster to draw the gas through after passing the meter. This jet exhauster stands between the meter and the gas holder, and it works admirably. We can set it so that the pressure on the purifiers will be almost nothing, or at 2 or 3 inches. By that means I can make water gas, with light seals and small purifiers, to a very great advantage. In speaking of our process of purification, I will say I use a layer of sawdust on the bottom tray, and then place over it cloth or bagging to keep the oxide from mixing with the sawdust. Of course, the sawdust will last for quite a long time. I do not use the shavings which Mr. Learned speaks of.

Mr. Learned—I use breeze instead of shavings.

Mr. Neal—I use as coarse sawdust as I can get, from pine wood, not from hard wood. I am very well satisfied with my present method, but would like it better were it not that we have to change the mixture on the trays.

Mr. Jones—I would like to ask Mr. Neal how any saving is effected.

seeing he continues to remove the oxide from the boxes, and spends money in the removing and handling of the material.

Mr. Neal—I can save something, because the boxes are so small that our purifiers are changed very often. If we remove the mixture we have to turn it over and over, and it does not revivify near so fast—not fast enough for practical use.

Mr. Stedman—You spoke of the oxide heating after it has been returned to the box. Do you mean before the cover has been put on?

Mr. Neal—It would heat after we put it back. It heats after revivifying, if we leave it in the boxes.

Mr. Stedman—I became interested some months ago in brother Neal's success, and got his formula and commenced trying some experiments myself. My object was to get as much iron in the purifier as possible with a given bulk of sawdust. We found that we could use 3,000 pounds of iron with 100 bushels of sawdust, but beyond that point it had a tendency to cake up too much, even when it was first oxidized. We tried various systems of revivification, with the usual result of getting afire now and then; but we watched it pretty closely, and it did not burn out anything more than a small hole each time through the trays. It occurred to me that if we could send air enough through the oxide in a given time we could control the matter of temperature to a great degree. At one of the abandoned gas works we had a large blower and a little engine, which we transferred to our other works and are now using it experimentally. We found that we could always control the matter of temperature, when there was a disposition for the oxide to get too hot, by sending an extra current of air through. The ignition does not follow as it would when you start a fire in the woodpile, and where, when you give it more air, you encourage the flame; for, of course, the result of the heat from oxidation is quite gradual, and, if it can be carried off at any time by means of a good, fierce blast of air, the temperature can always be kept low. We find it rather desirable to encourage high temperatures to facilitate oxidation. In sending through a large blast of air, we found that the oxide was unduly dried, and required moistening again to make it immediately effective when the gas was turned on. We, therefore, adopted the plan of turning the exhaust right into the inlet pipe of the purifier. We have a wet center seal, and by cutting a hole in the top, over the dead part of the seal, and connecting the exhaust there, we have the connection made at the right place every time. When the purifier cover is lifted, we put the blower on for a few moments with a very rapid blast of air, and blow the gas out which is in the purifier, and then run a slower blast, watching it pretty closely at first, until we have ascertained that the temperature is not going up, and still that we have not got an excess of air in there to keep the temperature down too low. With that method of working we have been quite successful. The oxide does not cake; we do not have to turn it over; and we should not have to take it out of the boxes at all were it not for the fact that our scrubbing facilities are too small for the additional work which has been thrown upon them by the consolidation of all the work there in one place; and consequently considerable tar gets into the purifier. We arrest that by a pretty thick layer of breeze on the lower tier, and we find that the breeze gets saturated in about every third or fourth time coming around to that box. We then take out the oxide, renew the breeze, put the oxide back again, and it is already to work again.

Mr. Neal—I might say with regard to the ammonia, that perhaps our method of revivifying, or rather of purification by the use of the oxide, answers the purpose of a washer or scrubber. Our washer is not as effective as it ought to be, and the gas comes in containing say 100 grains of ammonia to 1,000 feet; but when it comes out, by the State Inspector's test, it never is over one per cent. Of course it is working the purifiers very hard, and I would like to put more work on the scrubbers.

Mr. W. A. Wood—I did not quite understand Mr. Stedman's operation. Does he force the air up through the sponge into the inlet pipe?

Mr. Stedman—Yes.

Mr. W. A. Wood—You might draw back on the inlet pipe and pull it through. By exhausting from above downward, the heat of course starting at the bottom, the lower trays can be taken away more easily.

Mr. Stedman—I supposed that the heat was where the air would come in contact with it first.

Mr. W. A. Wood—It seems to work the other way. If you heat at the bottom, and take that heated layer away before it has time to fire the sponge, there is no danger of fire. I have run in that way for three months without taking the material out of the boxes. We did have some fires when we first attempted it, but we manage it now so that two men practically do all the work in our purifiers; and we were obliged to change the boxes nearly every day. It is a very great labor saving to us.

Mr. Allyn—About how long does Mr. Wood carry on this operation?

Mr. W. A. Wood—From four to six hours. I will say that I do not think the revivification is as thorough as when the sponge is taken out and turned over.

Mr. Allyn—Do you detect more back pressure?

Mr. W. A. Wood—The sponge does cake with us after we have revivified four or five times. Our method then, is to take out the oxide at the bottom of the box and throw it up on top, and put the loose material which has not caked down on the trays again. By turning it right in the box itself we get rid of the trouble from that pressure in a short time. I like that method by reason of the fact, if you are obliged to change the purifiers, on account of back pressure, you can get a fresh one in a very short time.

Mr. Allyn—I think Colonel Stedman is right in his supposition, that if the gentleman would allow more air to enter the purifier there would be less danger of generating heat. When I was at the Brookline works, complaint was made on account of the odor which escaped when the lime purifiers were being emptied, so to overcome the nuisance, I put on an apparatus similar to what Mr. Learned is using, and on the first experiment we merely removed the substance through the corner of the purifiers. In 15 minutes it generated so much heat that it was impossible to put a hand on the purifier. After that, we raised the cover enough to just unseal the edge of it, and then had no more difficulty—the purifier never heated at all.

Mr. C. S. Spaulding—We use that same apparatus to-day for revivifying our sponge. We use it as has been mentioned, drawing the air down through and taking the cover of the pan entirely off. We are troubled with heat, and have had fires, but not to amount to much. We leave it in the pans three or four times before taking it out. Every third or fourth time we take it out and put other sponge in, and let that stand out in the yard for revivifying. We find it a great success and a great labor saver.

Mr. Jones—I would like to ask Mr. Learned how much it costs for steam to revivify one box with the arrangement that he has at present?

Mr. Learned—I cannot tell. We have about 60 pounds of steam—a half-inch valve—and we open it about a turn and a half.

Mr. Prichard—I find that about 40 cents of steam replaces about \$2 worth of labor.

On motion of Mr. Jones, a vote of thanks was tendered to Mr. Learned.

Mr. N. W. Gifford, of New Bedford, Mass., here read his paper, entitled:

SOME EXPERIMENTS IN THE PHOTOMETER ROOM.

In the introduction to a work on chemistry published in the year 1758, the author remarked something like this: "There are four elements, viz.: Earth, air, fire, and water. There may be other elements, but as we cannot possibly perceive them by our senses, it is idle to vex our minds with vain conjectures concerning them, and experiments usually lead to disappointment." Had this man lived in our day and been acquainted with the science of photometry, he might have still held the same opinion of experimental research.

I suppose most gas men have known of cases where the photometer falls into bad repute by giving the candle power much lower than the Superintendent believes it to be. I have noticed that this does not often happen when the gas is unquestionably of good quality, but when one fears his gas may be perhaps a candle below the usual standard. Then sometimes the boy reports the candle power down to 15 or even 14. His report is not received with favor, and he is sent back to take the candle power again. He looks at the water line in the meter, finds the candle balance accurate, flames at proper distances from center, etc., but still the pointer refuses to move up the scale. So, what wonder if he consigns the whole science of photometry to the realms of darkness? But says one, "There must be some cause for this remarkable drop," and some of the experiments, which I am about to call your attention to, may suggest some of the causes that may help to bring about this low candle power.

The photometer on which this work was done is of the open type, 100-inch bar, in a room from which the daylight can be shut out. Walls, floor, and ceiling painted a dead black. Size 7 feet by 15 feet, and contains about 900 cubic feet of air space. It is so arranged that gas or candles can be used on either or both ends. The standard of comparison used was a Methven slit. The burner was so arranged that the air supply to the light measured could be taken from a small holder at any rate desired, or could be left open as in the ordinary way. The following averages of several observations will show some of the effects of variations in the air supply, viz.:

Air supply open.....	gave	17.13	candles.
" " 51 cubic feet per hour,	"	15.22	"
" " 46 " " " "	"	15.97	"
" " 42 " " " "	"	17.10	"
" " 35.3 " " " "	"	17.82	"

Thus we see the normal amount of air used in burning 5 feet of gas was 42 cubic feet. When more air was forced through the burner, the light was reduced, and when the air supply was checked the candle power increased, until with less than 35 cubic feet per hour the flame began to smoke. An analysis of the gas showed that 28.19 cubic feet of air was required for the combustion of 5 feet of the gas. So that in the normal condition of things 13.81 cubic feet of surplus air passed through the burner, and, when checked to give the greatest amount of light, there was a surplus of 7.11 cubic feet of air.

So it appears that more air than a certain surplus passing through the burner tends to reduce the light. This reduction is probably largely due to the cooling effect of the aqueous vapor in the air, for when the air supply was passed through a desiccator, the loss suffered was not so great. For instance, the burner supplied with 38.1 cubic feet of dried air per hour gave a light of 18.34 candles, while with the same amount of undried air the candle power dropped to 17.38 candles, a loss of over 5 per cent.

As the volume of air passing through the burner depends on the size of the opening, height of chimney, and amount of heat inside the chimney, it can readily be seen that as the flame decreases, either on account of smaller quantity or a poorer quality of gas, the volume of air coming to it will not decrease in the same ratio. A 16.75 candle gas used 44.2 cubic feet of air per hour, and a 15.62 candle gas used 42.2 cubic feet, but the surplus above what was required for theoretical combustion, as shown by analysis, was almost the same in both cases, a difference of less than one-tenth of a cubic foot. So the weaker flame had as much unnecessary cooling to contend against as the stronger.

Now this disadvantage under which the poorer gas is burned can be overcome to a certain extent by altering the chimney, or by increasing the quantity of the gas to make up for the deficiency in quality. As an example of the first method, I give the following tests with chimneys of lengths ranging from 6 inches to 7½ inches, but of uniform diameter:

With a 6 inch chimney the light was	17.64	candles.
" 6½ " " " "	17.34	"
" 6¾ " " " "	17.17	"
" 7 " " " "	16.82	"
" 7 " " " "	16.40	"
" 7½ " " " "	16.37	"

Here we find a decrease of light from the flame as the length of the chimney is increased, amounting in all to a variation of 7.7 per cent. from the result with the ordinary 7-inch chimney.

To show the effect of increasing the gas consumption, I give the averages of a number of tests in which the rate of burning varied from 10 per cent. below to 10 per cent. above the normal rate.

Gas burning 4-5 feet indicated c. p.	12.19.	Corrected	13.4.
" " 4.75 " " "	14.72.	"	15.85.
" " 5 " " "	15.82.		
" " 5.25 " " "	16.88.	"	16.03.
" " 5.5 " " "	18.29.	"	16.46.

In the last instance, increasing the gas consumption to bring the readings up to 18.29 candles gave a value of 16.46 candles to the gas after being corrected for the increased volume, which amounts to a gain of 64 candles, or 4 per cent. over the candle power found when only 5 feet per hour was burned. In consideration of these facts, would it not be simple justice to the gas, on these occasions of reported low candle power, to increase the rate of burning until the readings are brought up to about the usual figure, and then calculate the result back to a basis of 5 cubic feet per hour?

In connection with this subject of air supply, I have some figures which emphasize the necessity of thorough ventilation for the photometer room. I placed a Sugg burner at each end of the bar and took a series of readings, which showed the light from each to be alike. The room was closed for 2½ hours, when on supplying one of the burners with air from the prover, it was found to give 10.9 per cent. more light than the one taking its air from the room. Again, a burner supplied with 34 feet of air per hour gave a light of 17.77 candles, and on being supplied with the same amount of air having 5 per cent. of oxygen added to it, gave a light of 21.52 candles, or an increase of over 20 per cent.

Discussion.

The President—Have you any questions to ask with regard to those experiments? It is a simple type of experiment which may help some of us out of some of the difficulties which we have all experienced in the photometer room. Has anyone had similar experiences to state, or any questions to ask?

Mr. Humphreys—I would like to ask Mr. Gifford how, in his first set of experiments, he supplied the air to the burner?

Mr. Gifford—I will say that to an ordinary Sugg burner I made a connection through a paper tube large enough to slip up above, so as to go outside of the burner; and while it was not a neat mechanical job, I made it air tight by adhesive double tape. The bottom of the paper tube I connected with iron piping to the meter-prover.

Mr. Harbison—I think Mr. Goodwin, of Philadelphia, can give as much information on that subject as all the rest of the fraternity.

The President—We would be glad to hear from Mr. Goodwin at any time.

Mr. Goodwin—I can simply say that several years ago, from very similar tests, I can verify the statement made by Mr. Gifford. I practically did the same thing in my photometer room, and with practically the same results.

The President—Do I understand it is your opinion that we are to gauge our chimneys in order to limit the air supplied to the burner? Would it be advantageous to have the gas interest determine the size of chimney which should be used with a certain burner?

Mr. Goodwin—The size of chimney which you use makes all the difference in the world as to the illuminating power which you get from a given quantity of gas through a given burner. If the chimney is six, seven, or eight inches long, the difference in height will make all the difference in the world.

The President—Then each burner requires a certain chimney?

Mr. Goodwin—I mean to say that by varying the chimney on a five-foot burner, you get very different results as to the illuminating power, just as Mr. Gifford has stated. I suppose I have made 20 photometers in the past year, and have had ample opportunity for arriving at correct results. Several years ago I made some tests in the same direction, and I can verify Mr. Gifford's statement.

Mr. Coggs—Then you would say that, using 17-candle gas, you would require a 6 inch chimney rather than a 7, according to his results?

Mr. Goodwin—I would not like to say that that would be the size of chimney, but I do say that the chimney has all to do with it as to the illuminating power.

The President—I think these experiments are in the right direction, and will go further as we find the necessity existing because of competition with the electric light.

On motion of Mr. Jones, a vote of thanks was tendered to Mr. Gifford. A recess was then taken until 2:30 P. M.

FIRST DAY—AFTERNOON SESSION.

The afternoon session was opened with the paper, by E. G. Pratt, of Des Moines, Iowa, entitled:

DIFFERENCE IN THE EASTERN AND WESTERN METHODS OF MANAGEMENT OF GAS WORKS.

[In the absence of the author, the paper was read by the Secretary.]

I appreciate the honor of having been called upon to contribute something to the success of this meeting, and while I have regretted many times that I so readily gave my consent to write upon the subject suggested, and had, owing to the pressure of business, almost made up my mind that I would ask to be excused—in fact, was in the act of writing for that purpose—when, in looking through the AMERICAN GAS LIGHT JOURNAL, I noticed that the editor, in commenting upon what might be expected at the coming meeting of this Association, for some reason or other, I know not why, laid considerable stress upon what might be expected from the papers to be furnished by the gentleman from Dedham, and myself. He, however, very adroitly warned the members that the quality of the reading might be only in the title, or cover, which I am very sure will be the case with what I shall have to say; hence I hope that neither he nor any of the members has anticipated too much, for with the very short time now at my disposal I shall not attempt to approach the dignity of a paper, but rather let this pass as a letter to the Association. I did think, when the subject was first mentioned, that it would be an easy matter to write up something interesting—and there was certainly an opportunity of saying a good deal; but, upon a serious second thought, and when I got right down to business, I found there was not so much in it after all—at least unless the one who attempts to speak has confidence that he is perfectly familiar with the affairs and conditions of things as they exist in the East compared with that of the West. It would be generalizing too much for me to make a statement that what has been my experience or observation in the East, while in charge there of the affairs of a small gas works, would apply to that of another in charge of a larger works; or to submit what has since been my experience and observation while living in the West, in charge of the

affairs of a larger concern, was applicable to those of the same size or larger, and I am fearful, too, that I might say something that would invite criticism, or that some member would take exception too. I trust, however, that in giving expression to my observations there will be nothing said to reflect upon either locality; for, certainly, that is not my intention.

It is a pleasant thing, and I am sure New England gas men appreciate it, to be so situated where, because communication is easy, that they do not have to depend entirely upon these annual gatherings for an exchange of greeting and ideas (for probably not a week passes but that you can count upon meeting some gas man eager for information, or willing to impart it, upon some particular point), while we in the West (and I speak as if I had always lived here), are more or less dependent upon the technical papers for what is going on; or, in an emergency, have to rely entirely upon ourselves, or those at our command. This same sentiment I think will bear me out in what I have to say. Take it in the matter of supplies. You of New England can, on twelve hours' notice, get anything you are in need of, not excepting even coal and pipe; and the cost of getting it is immaterial as compared with what, under similar circumstances, it would be here in the West. It is necessary, therefore, for us of the West, to so anticipate all our needs that we can buy in such quantities and at such times that the expense of getting them will be the least, and that they will be on hand at the time when needed most. While it is true that the handling of freight has been greatly improved, still, at its best, it is very slow and often times very unsatisfactory, particularly for such goods as we may be looking for from a distance. If we resort to express, as frequently we are obliged to, the expense thereof adds very largely to the cost of the article. I mention this important factor of transportation to show that the gas man of the West is obliged to take more thought of the morrow than his brother of the East; and hence is cultivating that essential known as "long-headedness," which, by-the-way, is very important in this part of the country, and concerning which I may have more to say later on.

In the matter of labor, I believe it to be true that we pay more here than in the East—not that the cost of living is more, or that the demand for labor is greater, for I do not think there is much difference; but there seems to be an independence innate with the locality that demands more. And, too, the Western laborer is more liberal in his expenditures than his fellow laborer of the East. He takes more recreation, and has more enjoyment of this world's goods. It is also a fact that the average Westerner is wasteful, which habit, I am sorry to say, is sometimes prevalent about a gas works, and it very often disturbs the peace of mind of one brought up in thrifty New England. Then, again, not so much attention has been given to the general condition and appearance of things about the works; for what reason I know not, except it be that false idea of economy that it were better to run a thing for all it was worth and make the repairs only when those became actually necessary, or when the profits would admit. For such a condition of things I believe the management to be directly responsible, and that by proper discipline it could be obviated. The New England gas manager, as a general thing, takes pride in keeping his works in such condition that they will pass inspection at any or all times; and I believe he does this at no greater expense in the end.

I have referred briefly to some of the inconveniences under which the Western manager labors, whereby his operating expenses are in excess of yours in the East; and were it not for the fact that these were to a great degree offset, we would not be able to sell gas as cheaply here as at present is the case. In looking through the directory and noting the price of gas at seven of the largest cities in the New England and Middle States I find that the average gross cost is \$1.44 per 1,000 cubic feet, while in seven of the largest of the Western cities the average gross charge is \$1.46 per 1,000. Just how to explain this I do not know. If all the companies considered were making coal gas, I should say it was because of the value of residuals in the West, as the price we get for them is in excess of what they bring you in the East. We have a market for all our coke and tar, and while the price of the former depends upon the price of hard coal, the demand for the latter is such that we have no difficulty in disposing of our entire output at good prices.

As is well known, however, many of the larger works in both sections of the country have equipped themselves, or are about doing so, with a water gas plant, either because they believe they can make water gas more cheaply, or because no gas works is now considered complete without them, all of which no doubt lessens the supply of these residuals, and so increases the value of what is left, because the demand, at least, remains the same.

There is an advantage, too, that many of us favorably located in the

West have, in being able to use the cheap coals mined throughout this section of the country, which, if not suitable for gas yielding, are certainly very helpful and economical for fuel purposes; and, on account of their cheapness, many of us are enabled to sell our entire output of coke by using these cheap coals under our boilers and in our furnaces that have been specially adapted for the purpose. At some of the Western works they are able to use a large percentage of these native coals for gas making; and mixed with Youghiogeny, Penn, or Westmoreland, get very satisfactory results, both as to yields and candle power.

In the matter of main laying, we have an advantage, inasmuch as the expense of laying pipe here is, on account of the condition of the soil, not so great, even though in some instances we lay our pipes deeper. It may be said, however, that we lay more of it, and that the immediate consumption is not so great to the mile as in the East. This may be explained from the fact that Western towns and cities grow more rapidly, and that to keep up with the prospective growth we are obliged to keep in advance of city improvements, such as sewerage, paving, etc., that all come at once. We frequently lay pipe in a street or locality that to an Eastern man would seem like madness; or as it did to me until I had become somewhat accustomed to the growth of these Western cities. Then, again, much of our pipe was laid originally with little attention as to width of streets, grades, etc., and later on, when these city improvements materialize, we are annoyed with the expense and difficulties incident to straightening, lowering or raising our mains. Many of us, too, are troubled with excessive leakage, which cannot be improved upon until we have instituted a thorough and systematic means of stopping it. The prime cause of all this is probably owing to the fact of the pipe having been originally laid by some contractor who did not consider it important that the joints be made tight, so long as the required weight of lead and yarn was used. These thoughts suggest a whole chapter of difficulties; but of which I will not speak, least I say too much that would be of little importance or interest to you.

In regard to the consumer, I may say he is just as fond of finding fault here as elsewhere, and cannot understand why his bill should be larger in December than it was in July, or that the price should be any in excess of what it is in cities or towns selling more, or that are more favorably located. Naturally he takes gas to be gas, whether here or in the coal fields of Pennsylvania; that is, he assumes it to be his honest belief. He is alive to all new processes, and whenever he reads that some man or woman has invented a process by which gas can be made for 5 cents per 1,000 cubic feet, he is anxious to know why the local company does not adopt such process and give the public the benefit of it. If a deaf ear is turned to his suggestions, then he is in for organizing a company that will adopt the "new ideas," and very frequently finds plenty who interest themselves with him, until after investigation he or they find that it is a myth. Nothing daunted, however, he is always ready for any new process that may present itself, never for a moment stopping to think that we in the business are alert to any new thing; and, if it can be shown to be an improvement over or in addition to what we have, are ready to adopt it and to give our consumers the benefit of it.

It seems to me there are more schemers, or those who live by their wits, in this western country than east; and as franchises are easily acquired, one must keep on the alert all the time, and even sleep "with one eye open," to protect those interests that have been placed in his keeping. The people, however, in communities where this thing has been practiced, noting the repeated failures of these schemes and schemers, are beginning to understand the real status of the case and decide that the local company is not made up of such short-sighted and close-fisted set of fellows as they were at first made to believe.

It is discouraging sometimes to think that the propositions of these people even find audience, when it is considered how attentively we look after the interests of our consumer; but it is to be presumed that human nature is alike in this thing as in many others, and the willingness on our part is usually taken advantage of.

People of the West are fully alive to any new method of lighting, and will be satisfied with nothing but the best. The electric light is cutting quite as important a figure here as elsewhere, and in the smaller towns has materially affected and seriously injured the business of the local gas companies, unless they were far-sighted enough to equip themselves with an electric plant to meet the exigencies, and thus keep out the opposition that is sure to establish itself. While in most of the larger cities the sales of gas continue to increase, still many of these have or are contemplating the necessary plant to supply either kind of light, for they do not believe they can afford to turn away a customer that would patronize them because they did not have the kind of light he had made up his mind would best suit his purposes.

The combination of these two interests greatly increases the responsibility of the manager, and he finds that he must not only keep himself posted in all that pertains to gas, but electricity as well.

In conclusion, I desire to express my gratitude to the Directors of this Association in remembering me and in requesting that I contribute a paper. If in what I have said there may be any good or interest derived, then I shall have been amply repaid.

The paper was not discussed, and, on motion of Mr. Slater, the thanks of the Association were voted to Mr. Pratt.

Mr. A. B. Slater, of Providence, R. I., then read his paper, entitled

WHY I SHALL MAKE WATER GAS.

About the 10th of January I received from our gentlemanly Secretary a note, in language so dignified, so courteously entreating, so earnest, and at the same time so pathetic, that I was left no alternative, no option, but at once I felt impelled to accede to his request and prepare a paper for this meeting which, if it contains nothing new or instructive, may at least serve to amuse you for a few moments. He did not assume the responsibility of selecting the subject, but placed it upon "some one of the Directors," who had suggested as a subject for me to write upon, "Why you went into water gas."

Of course I have no knowledge, or even the least intimation, who this Director is; but, whoever he is, he must be a man of courage, and I ought to be a man of still greater courage to come before this old orthodox New England Association of Gas Engineers with a subject about which so much has been written and said, and which has occasioned so much, may I say bitter, controversy between its promoters and the older gas engineers and managers as this same subject, water gas. To attempt to go over this long controverted ground, and direct your attention to the feelings of hostility and even bitterness engendered by the early introduction of water gas, and the persistent energy displayed by its promoters in experimenting and perfecting apparatus which would overcome the difficulties and troubles encountered for many years upon its first attempted introduction upon a practical scale, would be to write a volume. To the older members of the Association this is all quite familiar, and the younger members can spend their time more profitably in studying the conditions of things as they exist to-day.

I will say, however, in passing, that in my judgment the feelings to which I referred, of opposition to water gas, etc., etc., were not engendered so much by the gas, or its composition *per se*, as by the aggressiveness displayed by its early patentees and advocates in forcing its introduction by questionable methods, even before it had reached its present perfected state, which is almost wholly due to improved apparatus for its manufacture. The objection to carbonic oxide by and of itself is just as forcible in principle and theory to day as at its first introduction. By itself it is just as virulent a poison now as then; but then no gas company does or purposes to send out to consumers carbonic oxide alone, and I am not aware that carbonic oxide has ever been recommended for breathing purposes; but as one of the component parts of the finished gas it really is of advantage, as it produces a high flame temperature, and consequently more perfect combustion than straight coal gas does; and when we come to look at it and carefully consider the facts as they now exist, the question of carbonic oxide practically drops out of sight.

You say at once, "Why?" My answer is, simply from the fact that with the exception, I think, of but two States of this great country, the State and municipal authorities without opposition permit water gas to be made and distributed to consumers.

When we know that by far the larger portion of the gas made and distributed in most of the larger cities of this country is water gas, and with practically no objection on the part of the public, the question is at once reduced to the simple matter of dollars and cents; and the sooner we recognize this fact the sooner we will place ourselves in a condition to take whatever advantage there may be in location, prices of material and labor, cost of construction, or any other conditions which can be secured by its adoption.

The question of quantity and quality of light given by water gas is no longer a mooted one. Again, if compared with the dangerous electric current, which you can neither see nor smell, the question of carbonic oxide, when considered in connection with illuminating gas, is really eliminated. But if applied to the distribution of so-called fuel gas, containing 45 per cent. of carbonic oxide and almost odorless, the old objection is at once revived in all its earnestness. With all the attending dangers, people will take electric light, natural gas, and what is least dangerous of all—and then mostly through gross carelessness—water gas.

The question of the disposal of the residuals (especially coke and tar)

of a large coal gas works is one which occupies a prominent place in the consideration of the policy of adopting water gas, either wholly or in part, as on the net receipts for residuals the net cost of coal gas very largely depends. When a company is so situated as to be able, profitably, to make water gas instead of coal gas, it relieves the manager or superintendent from the labor, care, annoyance, and trouble of the disposal of residuals, which matter is quite a burden in a large coal gas works. The question of the cost per thousand feet to manufacture coal gas or water gas depends almost wholly on the relative prices of gas coal, enriching materials—such as cannel coal, crude oil, naphtha, etc.; cost of material used in generators, prices at which residuals can be readily disposed of, prices paid for labor, etc., etc.

As applied to the company which I have the honor to represent, I recommended the adoption of water gas as an auxiliary to our coal gas plant, for several reasons, among which are: First, based upon present prices, a material saving in the first cost of the gas; second, by combining the two systems, we can make a small saving in the cost of our coal gas, because we can run our coal gas plant more economically; that is to say, we can keep fired and use continuously, without missing charges, such number of benches and keep employed such number of men as we can keep at work to the best advantage, and make up any excessive variations in the demand for gas, with the water gas plant; third, we shall make less coke to be disposed of, and at the same time be our own customer for a considerable portion of what we do make, thus effecting a saving on that residual; fourth, we shall make less tar, which we have not been able to dispose of at remunerative prices; but the lessened quantity will net us about as much in the future as we have heretofore received for the whole. The large quantity of water gas now made in our large cities has very materially diminished the quantity of tar heretofore made, so that the price of this residual is already being considerably advanced. Fifth, the question of labor is an important one which enters into the consideration of this question. A good water gas plant can be operated successfully with one-quarter to one-third the labor that is necessary in a coal gas works. This reduces the risk and annoyance consequent upon strikes or trouble with the men employed; and, finally, we intend to keep our coal gas plants up to the times as far as practicable, and with the addition of a respectable sized water gas works of the latest design and construction we are in a position to secure all the advantages of both systems, either alone or together, according as the price of material and other items of cost may seem to make it advantageous to do so.

The President—I think that before proceeding with the discussion of this paper we will listen to the paper on a kindred subject, by Mr. F. H. Parker, of Burlington, Vt., and then the two papers may be discussed together. In the absence of Mr. Parker, the paper was read by Mr. W. A. Wood. The paper bore the heading—

A FEW OF THE ADVANTAGES OF WATER GAS OVER COAL GAS FOR SMALL WORKS.

The works of the Gas Light Company at Burlington, Vt., were built in 1853, and were run as coal gas works until 1880. At the time the writer took charge (Jan. 1, 1877) the retort house contained four benches of 5's and one bench of 3's, that had been erected with new arches, hydraulic main, exhauster, condenser, etc., in 1874, and were probably at that time as complete works of their size as could be found in New England. Westmoreland coal was used, costing, delivered at the works, \$5.70 per gross ton. The best average yield obtained had been 4.77 feet per pound, and gas was sold at a net price of \$4 to \$4.28 per 1,000.

It is, perhaps, superfluous to remark that the consumers were not satisfied with the price of gas, and as the stockholders were unwilling that dividends should be cut down, a change of some kind was demanded. Quite a supply of tar had accumulated, and it was used as fuel under the retorts. The average yield of gas increased to 4.86 per pound. Some more coke was sold, and the net price of gas was reduced to \$3 and \$3.60 per 1,000, in the hope that the consumption might be increased. The effect was quite the reverse; for this reduction apparently served to remind consumers that they had been paying a high price for gas, and stimulated them to economize in its use, and the annual sendout decreased. As there seemed to be no further economies available towards cheapening coal gas, the Lowe process was adopted, is still in use, and the price of gas has been gradually reduced, the present net price being \$1.60 to \$2.25 per 1,000, and the amount of gas sent out last year was 10,000,000 cubic feet.

Having had rather an intimate experience with coal gas for 3 years and with water gas for 10 years, the following comparisons suggest themselves.

Among the disadvantages connected with the manufacture of coal gas

I recall to memory the very interesting experience with naphthaline; the abundance of limpid tar and tar that was not limpid, the piles of coke for which there was no sale when you wanted to get rid of it, and for which there was such a remarkable demand when you had none to spare; the interesting spectacle of stopped stand-pipes and of retorts with holes in their sides or too much carbon in their interiors, that collapsed just before you were ready to let them down, and had to be replaced at large expense; the services that always froze just as you were starting for supper; the drips that filled just when you could spare no one to pump them; the fires under the retorts that required careful attention night and day; the retort house and its inmates, never clean—the very thought of a strike, or a stoker drunk, sending chills all over you; and, in fact, a life of continuous anxiety and worry. But enough—many of you have been there, and are there now, but are doubtless praying for a brighter hereafter.

I allude, of course, to the experience of the superintendent of small works—one who, as friend Chase says, has the opportunity to become familiar with everything, from a Stillson wrench to a stock ledger; who, from the earnings, is expected to keep the plant in good repair, make all ordinary extensions and pay regular dividends, and yet sell gas at a price but slightly more than is obtained in the larger cities.

Those of you who do not recognize anything familiar in these reminiscences, and who have not been so fortunate as to be connected with a small works where the cold of winter equals that of northern New England, where you may expect 6 feet of frost every winter, little realize the joys you have missed.

On the other hand, with water gas naphthaline is unknown; you make comparatively little tar; coke does not appear upon the premises; you have but one stand-pipe to stop up, and that you clean occasionally when it suits your convenience; retorts and their lids do not trouble you; hydraulic mains full of pitch exist only in memory; services seldom freeze; but very few drips require any attention; you require less help; you make gas at whatever time of the day or night it suits your convenience, due regard being paid to holder capacity; you can thus avoid making gas in the heat of the day in summer, or make once in two or three days as necessary, and have your help in the meantime for other work; you do not require a large stock of materials on hand; your repairs are insignificant and unfrequent, and an occasional coat of paint or whitewash keeps your generator room bright and clean; and upon one occasion a certain individual was seen running our apparatus while attired in a dress suit—yet that is not, strictly speaking, our regulation costume.

The very marked odor of carbureted water gas makes the detection of leaks easy. We have thus been able to stop some that with coal gas were for years unsuspected, and, therefore, to steadily reduce our leakage.

The numerous barrels of brine that were required to be pumped into the mains to keep them clear in winter, when coal gas was made, are no longer a familiar sight upon our streets; and yet I freely admit that whether coal gas or water gas is made, if all trouble from frost closing or breaking mains or services is to be avoided, it can only be obtained by protecting them or by placing them below frost.

We are enabled now to use experienced men from the works to put in services, lay mains and repair leaks, while, when making coal gas, they were so closely confined that we had to rely upon whoever could be secured, as we did not have sufficient work of the kind to warrant keeping any one regularly employed for that purpose.

The rapidity with which water gas is made enables us to send out double our holder capacity each day, if necessary. One man has frequently made, with a generator 5 by 10, outside, 70,000 cubic feet per day, and averaged last season 41,000 cubic feet per day for nine weeks, preferring to do the work alone, as he expressed it, rather than be bothered with green help.

In making these comparisons I don't wish to be understood as claiming any superior results obtained over others working similar processes. On the contrary, I should be much surprised if others, using more modern apparatus, or working under more favorable conditions, do not excel us. We labor under the disadvantage of having a small consumption, considering the extent of our mains, and a small average consumption per meter, as we have comparatively few manufactories.

Neither do I wish to be understood as conveying the impression that water gas works run themselves, or that the position of manager of even a small works is a sinecure. With us life is not always monotonous. Our dear public, like yours, is always demanding more for its money, and the days are very rare when opportunities are not presented to us of combining an abundant amount of practice with our theory.

Discussion.

The President—You have heard two papers, one written by the manager of a works producing 460 million cubic feet, and the other written by the manager of works producing 10 million feet, between which limits, with a single exception, I have no doubt that most of us come. I would like to have a good discussion of the subject. Mr. Prichard was an early advocate of water gas, and had one of the earliest plants. We would like to hear from him.

Mr. Prichard—We have used a water gas plant with considerable advantage, at times when we were working the retort house to its full capacity, and used that to make up the irregularities of consumption. For that purpose it has served us very well. But, in the matter of cheapness, at present prices it is a question which of the two it is better to use.

The President—Mr. Humphreys has been busy for a year putting in a water gas plant, and perhaps he can tell why he did it.

Mr. Humphreys—I put in a water gas plant because I am supplying gas in a mill city where our consumption is very variable. In very dark weather our consumption will increase 100,000 feet per day over a bright day; and to meet that varying demand with coal gas works is very difficult. It is necessary either to keep a number of extra retorts under fire, or to make up all deficiencies on bright days; and while the latter course will work well enough if you have but a couple of dark days in a week, it will not work if there are five or six of them following each other. Since I have been in Lawrence, before the water gas plant was put in, I have stood by the holders many a day when it seemed as if I grew ten years older in the almost impossible effort to keep the holders up. Then, again, I regard the water gas plant as a cheap means of increasing the candle power of gas. Our idea is to make a water gas of about 28 or 30 candles, and to use that for enriching without the aid of any cannel coal. We have done this, using part coal in our generators, and we are now reaching the point where we hope to do it by using coke alone. That is the point we are aiming for—to use our coke from the coal gas works in the water gas plant. With regard to the question of price, which Mr. Prichard refers to, I would like to ask him whether he uses crude oil. In our works that we have we use Lima crude oil; and with that oil I have no doubt that we can make a gas at a lower figure than we can by the coal gas process. I am inclined to think that Mr. Prichard has not used Lima crude oil.

Mr. Prichard—That is just exactly the point. I have one of the old style of Granger works, with shallow generator and single superheater, and it is impossible to use Lima oil without sending the vapors of the oil all over the town. It has caused considerable talk, and so we only use it (the Lima oil) when it is absolutely necessary. If we use naphtha we get along much better. The comparative prices of the two with us, where we have to team the oil to the works, is about 6 cents for naphtha as against 3 cents for oil. You can readily see that what would be economy at 3 cents for oil might carry the balance the other way at 6 cents.

Mr. Harbison—I would like to ask those gentlemen who have had experience in the use of water gas as an auxiliary to a coal gas plant, what change they are obliged to make in their coal gas plant, if any, in order to use water gas in connection with it, and whether they have to have an additional holder; and, if so, how they manage it. I would like them to answer these questions, so that the rest of us who may be considering the question of putting in a water gas plant as an auxiliary may understand what we have to introduce more than we now have.

Mr. Slater—As far as we are concerned, I may say we have made no changes, with the exception of making the connection direct from the generator to one of our holders, which is about 280,000 feet capacity. We go directly from the generator to that holder, and draw the gas from that by an exhauster, and send it through the purifiers of the coal gas works, the same as the other gas. There are no other changes.

Mr. Harbison—I would like to ask Mr. Slater if he knows what proportion of each gas produces the best illuminant?

Mr. Slater—We have not reached that point yet.

Mr. Anderson—I would like to ask the question, with relation to water gas, if there is anything very noticeable in relation to condensation taking place in the meters; and if the meters have to be re-diaphragmed any oftener because of burning water gas.

Mr. Prichard—We do not notice any difference, but I should suspect that if we kept on sending vapors of oil about the town we would have trouble from it.

Mr. Anderson—The reason I ask that question is this: In a room yesterday where meters are repaired I saw a number of meters in which there was considerable condensation. I made some inquiries, and found out that they had been used on water gas; and I was told that such meters had to be re-diaphragmed very often. There was one 250-light

meter there out of which was taken at least 5 gallons of a sort of resinous tar. I have a piece of one of the diaphragms, which is very brittle. The life of the leather is all gone, and for the purpose of examination I will leave it on the table.

Mr. F. H. Lane—I have been using water gas for several years, and I would like to get some facts, from those who have had experience in the matter, as regards condensation.

Mr. Shelton—I am in a particularly good position to know about the effect of water gas on meter condensation, from my connection with the United Gas Improvement Company, of Philadelphia. We have watched that point very closely, because it has been one of the points urged against water gas—that the life of the meter was shortened, that there was more condensation, and points of that nature. The whole thing in a nutshell is this. There is water gas and water gas. If water gas is properly made and thoroughly fixed you will have no trouble from that source. I grant that on some of the older forms of apparatus (one such is within a hundred miles of this city) you can take out a meter, disconnect it, turn it upside down, and get probably half a pint of the matter of which Mr. Anderson speaks. But I will make the prophecy that that apparatus was built ten years ago, has an extremely small superheater capacity, and is not in good shape to take care of the naphtha used, to say nothing of crude oil. The experience of our Company in the different works we operate is that we have to keep close watch on this point. We have compared the records of the drips on the streets, and also the meter reports, since water gas has been made with the back records when coal gas was made, and those statistics show that the effect upon the meters and upon condensation can be taken, to all practical intents and purposes, as just about the same, provided the gas is properly fixed and made with modern apparatus of fair efficiency. I do not mean the apparatus for making water gas of twelve years ago.

Mr. Jones—Mr. Slater in his paper remarked that there were but two States in the United States where prohibitory statutes relating to water gas are in force. May I ask to what State, other than Massachusetts, he referred?

Mr. Slater—I did not refer to them as prohibitory, but simply as States having a carbonic oxide law. I referred to Massachusetts and New Jersey.

Mr. Jones—In the State of New Jersey the law relating to carbonic oxide limits it to 2 per cent., which practically precludes the manufacture of any kind of gas.

Mr. Slater—That refers to new companies.

Mr. Jones—If that law were enforced to the letter it would preclude the use of cooking stoves in living apartments. I understand, with Mr. Slater, that that law refers to new companies organized since the passage of the law, ten years ago.

Mr. Humphreys—I want to say a word in answer to Mr. Harbison. He asked what changes were to be made at works when putting in a water gas plant. We happened to have a couple of small holders, of 20,000 feet capacity each, and we have used those as "relief" holders—making our gas into those holders, and then exhausting it back and putting it through the regular condensers and purifiers.

Mr. Cogshall—I would like to ask Mr. Humphreys what percentage of his whole product is water gas.

Mr. Humphreys—We are using about 12 per cent. of water gas now.

Mr. Harbison—Is Mr. Slater using naphtha or oil; and how many gallons per thousand feet of water gas made?

Mr. Slater—I use Lima oil, but I cannot state any definite quantity as yet. We are not running the water gas plant to its fullest capacity, but simply running it occasionally; and are using from 3½ to 4½ gallons.

Mr. Harbison—How does that agree with Mr. Humphreys' use of oil?

Mr. Humphreys—We are using about 5 gallons.

Mr. Stiness—I am glad to learn that the world moves. If a few years ago a man who occupies the position of my good friend Slater had spoken within the presence of this New England Association and told us why he made water gas, the very arch fiend of Sheol would have been considered pure and white in comparison. But I am very glad that he has given us such a very concise paper. It is in his usual strain, leaving no chance for argument. He argues the points himself. There are no criticisms to be made upon it. I move that a vote of thanks be tendered to Messrs. Slater and Parker for their papers.

Mr. W. H. White—May I be permitted, although a guest, to second that motion, and to say that I antedate brother Stiness; for I remember that (whether through the courtesy of the members of this Association, or through their fear of a double-edged tongue) I was the only man, for some years, who was permitted to speak of water gas in the New England Association without being immediately clubbed by the chair. It fills me with a great deal of pleasure to know that the road in which we

trod many years ago, then unmarked by the single footprint of a regular gas engineer, is now crowded, and that you are pushing one another over the edges of that road in your efforts to accomplish the good which I then foresaw. I most heartily second this motion, and most heartily welcome to the ranks in which I then stood, a lonely apostle, brother Slater.

The President—We are glad to welcome brother White, although he speaks of being a guest, as a participant in our discussions. I wish that every guest here would manifest the same interest that he has. I trust that all will join in the discussions without being individually asked to do so. We bid you all a welcome here in good earnest.

The thanks of the Association were then voted to Messrs. Slater and Parker for their papers.

Mr. H. A. Norton, of Boston, Mass., then read his paper on

VARIOUS METHODS OF INTRODUCING GAS STOVES.

Mr. President and Gentlemen of the Association: It was with reluctance that I accepted your Secretary's request to prepare a paper on a subject so near to me, knowing that you come to the convention to listen to gas engineers. Therefore, I have prepared this paper from material given me by members too modest to proclaim their own success in this direction. It is worthy of note that nearly every apparatus used in connection with the gas business has been remodeled or changed to suit the surroundings in which it has been placed, and to the gas engineer the credit of successful results must be given.

So it is and must be with the introduction of gas cooking stoves. No one rule can be given to bring about the desired result. The engineer should study his plans for introducing gas stoves as he would his plan of mains for distributing gas. The liberal policy pursued by most companies to-day makes the way towards acquainting their consumers with the merits of gas stoves easier. Where stoves are leased or sold below cost, the outlay of money used for that purpose should not be looked upon as too great for the return received that year, but as a permanent investment yearly bringing in a large interest.

They are consumers for life, and in a time and season when most appreciated. The different methods of introduction I shall speak of have accomplished their end to the satisfaction of those presenting them; and while there may be still better ways, let the introduction be not formal, but one that will surmount the barrier between gas companies and consumer, and make the latter feel that he was prejudiced in his supposition.

I speak, first, of leasing stoves; for that method is more popular with the majority. To lease any needed article on approval meets with favor; for the idea of a trial, at a fair investment on the principal, entices the most wary. Once let them take a gas stove as an experiment, then you have completed your task and have a willing captive. Of course, the desired result is to sell the stove, and this is, I think, the most successful method.

The companies leasing stoves charge, and readily receive about 25 per cent. on the price of the stove, all rentals being due the first of each May, thus making the matter of collections easy; and nearly all companies allow at least one year's rent to go towards the final payment when the sale is made.

The companies who sell their stoves outright allow the consumer a fair trial; and while it is a distinction without a difference I am sure, from my own experience, better results can be obtained from leasing. In either case, whether leased and effectually sold, or sold outright, the gas companies should sell at what seems at first thought a loss.

Take, for instance, the supposition, and it is a reality, of putting out 1,000 stoves a year. They would cost from \$16,000 to \$20,000, depending upon the size of the stove. This includes setting up, rent of stoves, salesman or clerk, and advertising.

Take as a basis for a few figures the cost at \$18,000. They will average to consume yearly 10,000 cubic feet of gas, making ten millions cubic feet per annum. Placing the profit at 50 cents per 1,000 cubic feet, which I think is low enough, the profit on gas consumed by 1,000 stoves would be \$5,000 each year.

Were you to lease the stoves at 25 per cent., your income from that source would be \$4,500, making \$9,500 yearly income, 52.7 per cent. interest on your investment.

Were you to sell the stoves at a loss of \$5 each, your income from gas sales would just offset that loss the first year, and bring your investment to \$13,000, upon which you would yearly derive 38.46 per cent. interest. These figures are given for your perusal, and especially for the smaller companies who feel the more heavily the loss made by electric lighting.

They can figure a smaller number of stoves pro rata, and are in some

respects better situated for the introduction of gas stoves. Of the practical results I have nothing to say, as every gas engineer knows them, and a fair trial by their consumers is conclusive. The methods of advertising are various, and must at first be pushed, for you have goods for sale and you must be more than a "Barkis" to your consumers.

Some companies have canvassed each house consumer with good results. Many have used the cooking schools to advantage, had the teachers lecture to their consumers, giving a practical demonstration of the results, and every company should have a salesman or clerk thoroughly conversant with their uses.

The inducement offered by some companies, by reducing the price of gas for manufacturing and cooking purposes, is commendable when circumstances prevent the reduction being made to all; and it takes but a survey of the gas stove field to see that low-priced gas is a prime factor.

In the discussion let me refer those whose efforts ten or even five years ago were unsuccessful, and who lament that theirs is not a gas stove community, to their more successful brother engineers, and urge them to make another effort, aided by others' experience, with a reduction in the price of both gas and stoves.

Discussion.

The President—In the discussion of that paper we shall be glad to hear from all those who have put out gas stoves largely within the past year. I think that Mr. Slater has rather carried off the palm for his method of introducing stoves, or rather by his ability in doing so. I will ask him to give the results of his experience in the introduction of gas stoves in the past few years.

Mr. Slater—We commenced the gas stove business three years ago next June. Our idea was to place the stoves, either by sale or by lease, or in any way that we could induce a consumer to take them; and for the reason that those who have sold gas stoves in Providence heretofore made it a special business, and expected to make something out of it, and did not meet with any great success, we determined to sell them at about the cost price. When we started in our point was to sell the stoves at what they cost us, or lease them at a moderate rental, and so place them within the means of the consumers, and thus induce them to try the stoves, knowing very well that when they once got a stove and used it they would not again be without it. The result was that during the first year we put out some 500 or 600 stoves; and during the last year and a half we have added still more to that number. I think that the most we put out in any one month was 310, in the month of June last. We now have more than 2,600 gas stoves in use; and I should say that the 2,600 stoves would not consume less than twenty million feet per year.

Mr. Allyn—Do you make a special rate for gas used in cooking stoves?

Mr. Slater—The same price as for other purposes.

Mr. Harbison—Can you state about what proportion of stoves are leased and sold?

Mr. Slater—Somewhere from two-thirds to three-fourths on the number of stoves in use are on lease. We find that many who take stoves on lease will afterwards purchase them. After having paid rent for one or two years, if they see fit to pay the balance of the cost of the stove, and own it, we allow them to do so.

Mr. Harbison—Do you find any difficulty in re-leasing a stove that has been once used to another family?

Mr. Slater—None at all. We take it to the shop and clean it up. If the customer wants to buy a stove we let him have a new one; if he wants to rent one we let him have one of those that had been used.

Mr. Harbison—What is your price for gas?

Mr. Slater—At present, \$1.40.

Mr. Harbison—Have you a special department for the stove business? Have you canvassers?

Mr. Slater—We have no canvassers. We have a store on the main street, and make a special department of the stove business.

The President—I find that gas stoves have been introduced successfully in most of the larger towns and cities. Have any of our friends tried them in the smaller towns? Does it pay to introduce them in the smaller towns? I think that Mr. Todd can tell us about that.

Mr. Todd—The plan which I have adopted is that of having a free lunch. My reason for adopting that plan was because I found, when I went to Middletown, N. Y., that the gas cooking stove was very little known. I hired an empty store on the principal street,

and put into it all the different kinds of cooking and heating stoves that in my judgment were the best. I set them all around the place, made the store as attractive as possible, and hired a lady to cook. I had a table spread, and all who came in were welcomed to help themselves. The free lunch and exhibition continued for four days. The first exhibition was two years ago. We found that a good many who came in to see the stoves would ask, will it do this, or will it do that; and we found that the best way of convincing them of its capabilities was to show them by an actual test just what it would do. Last year I did the same thing, and intend to have another exhibition in the month of May. As I have said, when I went there, the gas stove was unknown; but in two years I have put out over 80 stoves; and next year I expect to put out nearly as many more. When people inquire about them, I show them the stoves, and what they will do, and tell them that I will set one up free of cost, and that if, after a fair trial, they do not like it, I will take it out. I give each one a stove on trial for one month. If they do not like it, I take it out, and charge nothing for setting up or taking out, but as a matter of fact I have had to take back but one stove yet. We dispose of the stoves to consumers by selling them at cost, or renting them. The rental is twenty per cent. rent on the net cost, and if the stove is afterward sold to the party who has rented it, the amount paid as rent is allowed on purchase price.

Mr. Slater—We hire a store and pay \$1,800 rent per year for it, and have a good man to run the store, and we sell the stoves at cost and set them free of expense; so that you see what a profitable business we are making out of them, as far as that goes.

Mr. Harbison—Do you add the store rental, the salary of the man and the cost of making connections to the cost of the stove?

Mr. Slater—That has nothing to do with the rental at all. Our object is to get the consumer to the use stoves and burn gas.

The President—I would like to ask Mr. Goodwin whether in his experience in the gas stove business he has found any difficulty in introducing gas stoves in small places, as compared with larger towns.

Mr. Goodwin here stated his experience in the introduction of gas stoves; but at his request his remarks were not reported.

The President—I think Mr. Harbison has also had some experience in putting out gas stoves, and we would like to hear from him.

Mr. Harbison—The gas stove business has been an important factor with the Hartford Gas Company for a number of years. We have had a satisfactory degree of success thus far, considering the efforts that we have put forth. Our efforts have consisted wholly in having the stoves of different makers on hand, posting ourselves somewhat with regard to their capabilities for doing the work claimed for them, and by personal solicitation and representation of their merits to the people of Hartford in inducing them to buy the stoves. We have no faith in the system of giving away stoves. As is well known to most of the gentlemen present, we sell gas at the low rate of \$1.40 per thousand feet to the general public, and just now at even a lower rate than that to large consumers who use it for mechanical purposes—the rate depending upon the quantity they use—so that in some cases we are selling gas as low as \$1.25 per thousand feet. We have more than one stove in use for every four meters in the city of Hartford. Our output of gas between seven o'clock in the morning and five o'clock in the afternoon (which we call the day consumption) has been during the past year more than twenty per cent. of our entire output. We attribute the larger proportion of that to the use of gas in cooking stoves. We never have had a stove that has failed to do all that we represented it would do, when we sold it. We sell a stove with the proviso that if it does not do as we represent it will, we shall take it back and refund the money paid. We sell stoves at what it costs to deliver them at our works in Hartford. We charge the cost of making the connections. We have only one step more to take to become a strictly benevolent institution; but we do not take that step by giving away anything. Our customers are well satisfied with the stoves. We have no extra expense in connection with carrying on the business, because the labors of the men who set the stoves are paid for by the parties who buy them; and the stoves are sold in the office by clerks who are employed to do the clerical work of the office. Two or three of the clerks are well posted with regard to the merits of the stoves, and if one is not ready to attend to a customer, another one can. The only serious difficulty we have is with the cost of the stoves; and that objection is gradually being overcome by manufacturers making from time to time a small concession in price. As they increase their business, they come down a little on the price, which is very gratifying to us and pleasing to those who want to buy stoves. We are sure that continued reduction in price will increase the sales of stoves, so that the profits of manufacturers may be in-

creased by means of the largely increased business which will naturally come from the reduction of prices in stoves, just as a gas company increases its net income or profit by the largely increased business which results from a reduced selling price. The same principle applies in the manufacture of stoves as in the manufacture of gas. A large increase of business increases the net income, because the general expenses are not increased in proportion; and large sales at small profits increase the bank account. We make no profit on the stoves, but we do on the gas which is burned in them. We now have about 1,700 stoves in use in Hartford. During the past year we have seriously considered the question of putting at work a canvasser for the sale of stoves—every house in the gas district shall have a stove. We have more than 75 miles of mains in our city, and we think that by thorough canvassing, we can increase the sale of gas by a more general introduction of gas stoves, and that the increased sale of gas will compensate us for the additional expense. But we have not yet found the right party to go to work at the canvassing. It requires a party of some brains and intelligence, and of some little persuasive ability in talking, to act as a canvasser; and good canvassing agents are very hard to find. When we do find the right man, we have a job for him by way of experiment, if nothing more; and if he makes a success of it we will make the position permanent. I think it will pay every gas manager to give attention to the stove business; and he is very much better qualified to do so than any outsider who has no interest in the business except the profit which he can make by the sale of stoves. The business of the gas manager is to make and sell gas; and he ought to devote a certain proportion of his time, ability and intelligence to making that selling feature of the business prominent. It pays as well as any part of the business.

Mr. Woodward—Our experience has been very much like that of Mr. Harbison in the matter of leasing stoves. We found when we used to lease stoves (a practice which we have discontinued) that when our stoves came back again, we could not sell them at anything like their cost. On that account we discontinued the practice of leasing stoves, and now only sell them. We have been quite successful, and have about 250 stoves in use. Last year we gave away 50 small stoves; but I think there is some question whether that is a good policy, because it stops people from getting a larger stove which can do a great deal more work. I would like to know whether any others have had experience in the matter of giving away stoves; and, if so, how it compares with mine?

Mr. Neal—There is one objection to the use of gas stoves in place of ranges in the kitchen. Perhaps that difficulty has been obviated, but I do not know that it has. I refer to the difficulty of furnishing hot water for washing purposes. For instance, in my house in the summer time we use one of these stoves or ranges, but on Mondays there must always be a fire made in the coal range, because there is no other way of heating sufficient water for general washing purposes; nor have we any means by which we can heat water for use in the bathroom. That fact has been urged as an objection to the use of gas stoves in place of ranges—that when it is necessary to have hot water for general purposes, the fire must be made in the range. I would like to ask Mr. Norton if, in the sale of his stoves, he has any arrangement by which water can be economically heated by gas for the purposes I have mentioned.

Mr. Norton—None of the stoves have a regular hot water back. The stoves are used largely in summer time, when very little hot water is needed; but for Monday's washing, the people generally do as Mr. Neal states—light their coal stoves once a week.

Mr. Harbison—The difficulty stated by Mr. Neal is very easily overcome. Almost all gas stove manufacturers make a hot water generator which will do the work of heating water as thoroughly as the stove will do the cooking. There is no difficulty whatever about it. One of our citizens wanted to overcome that very difficulty, and we told him that the hot water generator would fill the bill. We guaranteed what it could do—having the maker of the generator to back our guarantee, he having told us personally what he claimed for his hot water generator, and stated that he would back it to do as he said, or respond for any loss or damage. Knowing that he was a responsible man we had no hesitation in repeating his statement. That generator we furnished and it was not to be paid for until it had fulfilled the conditions under which it was sold. The purchaser subsequently expressed himself in the most thorough manner as satisfied with the performance of the generator and promptly called for and paid his bill. That was the first generator which we sold. We have had no hesitancy since that time in recommending them, and in promising that they will give as good satisfaction as the cooking stove or range gives. You can have hot water for washing on Monday or on any other day of the week; or for bath purposes, or for any other use for which you want hot water.

(Further remarks were here made by Mr. Goodwin, which are omitted at his request.)

On motion of Mr. Harbison the thanks of the Association were voted to Mr. Norton.

The President—We will turn now from the discussion of hot water to another problem which may get us into hot water. The question of how to run a gas works and an electric light plant together.

Mr. S. J. Fowler, of Westfield, Mass., here read his paper on the
MANAGEMENT OF A SMALL GAS AND ELECTRIC LIGHT PLANT.

The problem of how to run the electric department of a gas company so as not to lose money and so that the department shall pay

dividends or interest on the money invested, is, I find, intricate and consequently interesting, and I hope so large a proportion of this audience is interested in the problem that my solution of the matter may not be unwelcome to you.

In its gas business our company has always pursued the policy of never making any private contracts. Our terms are public, and every customer can know what rate any other customer pays for gas. The same policy we try to carry out in our electric business. We do not believe in making one party carry the burden of capital charges and taking another customer at simply manufacturing cost. We are located in a town the closely settled portion of which contains probably about 7,000 inhabitants. We have a six-inch gas plant, with two benches, one of threes and one of sixes. There is nothing meriting especial mention about our gas works, except that, with the pressure of 100 lbs. on the town water mains, we use a water-jet exhauster, and have done so for the past ten years to our perfect satisfaction. Our make of gas for the last year was very close to 7,000,000 feet. Our price is \$2.50, with 5 per cent. off for prompt payment and an extra 5 per cent. off to consumers using more than 50,000 feet during the calendar year. We furnish about 300,000 feet for a gas engine at \$2.00 per 1,000. The State report of 1889 makes the average price of our gas to be \$2.34.

We bought out the local electric light company in the autumn of 1887, but, finding the plant as sold to us, entirely inadequate to our needs, we abandoned it, with the exception of its electric apparatus and built a brick station, 96 feet by 36 feet, one story high, with a high basement under the engine and dynamo room. Our boiler room is 36 feet by 32 feet, and contains two 54-inch return tubular boilers, of 70 horse power each, built to run at 125 lbs. pressure. The brick stack is 80 feet high and 4 feet square internally.

In our engine and dynamo room, which is 64 feet by 36 feet, are one 70 horse-power McIntosh & Seymour compound condensing engine, connected to two 30-light 9 ampère Schuyler, arc machines for street lighting, and one 100 horse-power engine of the same make and style, connected to one 45-light 7-ampère Schuyler dynamo for commercial lighting, and to one 500-light Thomson-Houston alternating incandescent dynamo. The remainder of the space in the engine and dynamo room is utilized as storehouse, workroom, etc.

In the basement is the condenser, which is supplied with water from the river, about 275 feet distant.

We had run our original electric plant long enough to be assured that there is no bonanza in the electric lighting business at the prices charged by our predecessors, and which seemed to us as high as our customers could afford to pay. We had, therefore, to look to increased business and a proportional diminution of expenses for our profits.

Our prices for electric lights are as follows:

For our street lights we get \$82.18 per year, or 22½ cents per night, for a 9 ampère lamp, running every night from 20 minutes after sundown until one A. M.

According to the report of the Gas and Electric Light Commissioners of last year this was the cheapest service given by any company in the State, and I have no hesitation in saying that the price is less than it should be to meet the proper charges for interest, repairs and manufacturing expenses.

For our commercial arc lamps we get \$100 per year, less a discount of 5 per cent. for each regular night in the week when the lamps are not used after six o'clock.

As a Gas Company, and in the lighting business to stay, we did not believe in a uniform rate per lamp, regardless of the number of hours burned. We therefore made a schedule, from which I select the following:

No. 1.—\$7.80 per year, 1 night in the week, until 9, 1 until 10, 4 until 6.	
“ 2.—\$12.00 “ “ 5 “ “ “ “ 9, 1 “ 11.	
“ 3.—\$13.80 “ “ “ “ “ “ “ “ 6 “ 11.	
“ 4.—\$15.00 “ “ every night until 11.	

The first rate is equivalent to 1½ cents per hour. The second to one cent per hour. The third to ¾ of a cent per hour, and the last to a little over ½ of a cent per hour; so that it is very plain that our charges are much lower per hour for long hours than for short ones.

Our lamps average us nearly 95 cents per month.

We have now wired:

On our street dynamos the equivalent of 63 arcs.

On our commercial arc dynamo the equivalent of 26 arcs.

On our incandescent machinery the equivalent of 330 16-candle power lamps.

Our commercial dynamos are run from early dusk until eleven o'clock every night, except Saturdays, when we run until half-past twelve. I am sometimes asked why we do not run later every night. My answer is that we cannot afford it. We should not have more than 15 or 20 lamps on the line after eleven, and any additional revenue we might derive from them would not pay for the oil used on the engine. The same is true of day service. Undoubtedly this policy of stopping rather than running longer at a loss has cost us some business and decreased our revenue somewhat, but it has lowered our expenses.

Except the first year that the electric light was introduced our increase in gas consumption has been about 8 per cent. per year, and we do not feel that electricity has damaged our gas business in the least.

During the last 18 months we have added about 60 per cent. to the output of power from our electric station.

The increase in our gas business has thus not been at the expense of our electric business, nor has the increase in our electric business been at the expense of gas. The two run along side by side, and, except in a few cases, do not compete; but the growth of both branches is made in new business and also by driving out kerosene oil.

For street lighting it is now generally admitted that arc lamps supply the popular demand for light better than anything else. We have on our streets 49 arc lamps and 6 Sims 25-candle power incandescent lamps, and our streets are illuminated to the general satisfaction of the citizens.

We have no public gas lamps, except 15 on the main thoroughfare of the town, which burn from 1 A. M., when the electricity is turned off, until morning.

For inside lighting arc lamps are in use in certain places, but in our small towns, where there is not a great extent of mercantile business, the cost—the necessary cost—is practically prohibitory to many of the business men, and, therefore, the arc lamp cannot be generally adopted, even if it were in all cases advisable.

The incandescent lamp and gas are our other means of supplying our customers, and it is of the relation of these two commodities that I wish particularly to speak.

Gas pipes are put into almost every building and customers supply their own fixtures, so that in connection with the use of gas the company is put to no expense beyond the running of the service and the setting of the meter.

For electric lighting our company does all exposed wiring, etc., free of charge, the only cost to the consumer being the lamps, which we sell at cost price. We believe it is a good thing for us to own the electric material in town, wherever it may be, as we thus have the right to take it away or change the wiring as we may desire without any great protest. I may add, however, that we chose to do free wiring when we put in our incandescent plant, as we then took out a great many series incandescent lamps which were perfectly satisfactory to our customers but which were, from a financial point, far from satisfactory to us.

Our experience shows the relation between the cost of furnishing electricity and of furnishing gas, to be this. The steam and labor required at the station to produce the electric current are cheaper than the coal and labor required to put an equivalent amount of gas into the holder, but in general the other expenses of manufacture and the cost of distribution, including all outside repairs under this head, are much greater in the case of electricity than in that of gas; and the expense of distributing electricity increases not according to the light supplied, but according to the possibility of supplying it to the various customers. It costs us about \$14 direct, immediate outlay for each and every lamp that we put in. If a converter is fully loaded, somewhat less; but if it is but partially loaded, somewhat more. Our average is \$14 exclusive of the lamp. If the wiring on private premises were not done at our expense, but at the expense of the customer, of course, the cost would be less to us, but would certainly not be less than \$10 per individual lamp even in that case, and this does not include any allowance for the proportionate capital in the station and steam plant. To surely meet all charges for interest, depreciation and repairs, we assume that at least \$2 per year must be allowed, therefore, it is our belief that if we cannot get enough in excess of \$2 out of a lamp to more than meet our manufacturing expenses, it is not to our advantage to have that lamp on our line. We have, therefore, not endeavored to do any private house lighting by our electric department, simply because we do not see how that department could possibly make any money by it. Its income might be increased, but it would be at the expense of the capital account, which is already more than as large as we care to have it.

When a light is to be but little used we believe gas is preferable, both to the company and to the consumer, being more reliable as regards supply, and less liable to accident as regards the fixture. We have, therefore, practically drawn the line at fifty cents per month, and do not care to put in any lamps which would net us less than that. This charge is so high that we have very few lamps on our lines which are not in use at least part of every week day, and we feel that we are utilizing our outlay for lines and electric machinery to the fullest extent, while at the same time a certain class of consumer is relegated to the use of gas.

But our price for gas is such that our saloons and other places which are open late in the evening, generally found it too costly for them, and before the introduction of electricity were using kerosene. Now kerosene has been displaced and we are furnishing electric light at a profit to us, but at a cost to the consumer considerably below that which would be incurred if gas were used.

We actually make a discount to our consumers for the electric light used during that portion of the evening when the demand would otherwise be small. We are obliged to furnish the largest quantity of electricity at a certain time and almost all the expense of the incandescent plant would be incurred if the current were to be developed only during the short time referred to, therefore, at other hours we can afford to charge our customers less per lamp hour. This is a carrying out of the principle so familiar in the gas business of charging less for gas for day consumption. We charge less for electric light used during the time when the mains are not fully utilized, and in this way we are enabled to compete with kerosene.

We have no metered lights, nor under our present system of running do we care for any. Being in a small place, we are able

to watch our customers fairly well and to know whether they are keeping to their contracts, and we are now under no obligation to have any lamps on our lines which do not bring in a regular income, whereas, if we used meters, we should almost be forced to put in lamps as our customers should wish, and the consequent charging per ampere hour would make electricity the direct competitor of gas, which we do not wish, and which we do not believe to be to the best interests of our customers or to the advantage of the company. For it is our opinion that we cannot have a lamp on our line which does not produce an income of at least \$6 per year without its causing us a certain loss.

This we reckon about as follows: Fixed charges against each lamp amount in our case to about \$2, which have to be more than covered before we can begin to earn a profit. If our profit in furnishing light amounts to 40 per cent., then our fixed charges would be met as soon as a lamp produced an income of \$5; but we demand a further income of \$1 to justify our risk in taking the lamp on to our line. These fixed charges we are forced to cover during the hours of heaviest lighting, and a study of our schedule will show that we succeed; but once they are covered we are able and willing to furnish light for longer hours at a very low price; for our business is conducted upon the principle and belief that electricity should be used for steady, continuous lighting, and gas in those places where artificial light is required but a portion of the time; for though we can furnish a given amount of light more cheaply by means of the incandescent lamp than by the use of gas, we require TIME in which to do it. Gas can be burned in such quantity and at such a time as our customers choose.

The length of time during which the electric light is to be used determines the economy of its supply and of its use.

Discussion.

The President—We have before us the question of how to successfully manage a combined gas and electric light plant, and many of us are interested in that subject. Perhaps Mr. Stiness will give us his opinion as to the position taken by Mr. Fowler.

Mr. Stiness—I feel a little hesitancy, at this late day, in speaking of electricity, after the greeting which the electric light men got this morning from the representative of that part of New England called Hartford, in the statement that it took a very bright man indeed to run gas works, but that any man could run an electric light plant. Having been engaged in that for so long a time, I have arrived at the conclusion that I do not know anything at all about electricity, and, therefore, perhaps the statement applies to myself. But the paper which Mr. Fowler has read follows in such close lines with my own experience, that if I were to write a paper on the same subject it would be almost identical with his. With our electric light plants (two electric light stations, equal to nearly 500 arc lights) and with a gas plant of about 70 millions output, we have followed on almost the identical lines which he has marked out. To one point of Mr. Fowler's I wish to refer. If I remember correctly, he said that he makes no special contracts. We have followed in that line ourselves. We have a price list which is put out to all. For us one man's money is as good as that of another. We have, as he has perhaps, different grades; but we furnish, and are compelled to furnish, a 20-candle lamp instead of a sixteen. It has been said by some one to-day that this should be called a "Light Association;" but I wish to say to those who suggest that, that the world moves. We are to-day receiving as members coal gas men, water gas men, and electric light men; but the future of the gas business is, in my judgment, as well assured as the future of the world—exactly. But the people must recollect, and these gentlemen who are concerned in or interested in the business must remember, that it makes no difference what we do; we have got to furnish what the public calls for, and if the public demands the electric light, that demand must be met. As I said one year ago, I looked forward with anticipations of hope that the future of artificial illumination will be far advanced at the end of the next decade of years from what it is to-day. By one speaker this morning it was said that there is a great deal of push in these electric light men. That is exactly what I admire in those gentlemen who have control of the electric lighting interest, not only in New England, but all over this country—they are men of push, they are men of energy; and, above all, there are men of scientific attainments standing behind them who rank with any men that the world can produce. I listened on Monday evening to a paper read by one of our Massachusetts Civil Service Commission, I think Mr. Lord. The electric lighting interests of Boston are taking gentlemen of that character, and are educating the public up to the benefits of electric lighting; and such a course will prove to be of great benefit to them. I will not go on any further in the elucidation of electric lighting; but it is a large field. You have to meet in active competition, unless you take it into your own household. I believe, as Mr. Fowler says, that the alternating system is not antagonistic to the gas company, but that they work together. For an intermittent service gas is decidedly the cheapest; but for a continuous service in the manner in which he speaks of, there are certain hours of the day when we can afford to give them that light at a much less rate, provided it will utilize the line. You know, Mr. President, and I know, that upon the first day of the week we are put to our trumps to find a place in which we may use the current which we must furnish to a few lights which we have on our circuit; and therefore we can go out and take in a seven day service on some lights, at a low rate, and yet make money. The

electric light business is a good paying business when properly managed. That is all that I have to say, except to add, after an experience in the consolidation and combination of gas and electric lighting, that it has not been done at the expense of the gas business. The latter pays us a fair remuneration, although not equal to the old substantial gas business.

The President—Mr. Coggshall has had a good deal of experience this last year in the electric light business, and probably he can give us his reasons for going into it.

Mr. Coggshall—My experience has been so limited that I am hardly prepared to give you facts such as I would like to give a body of men like this; but a year from now, if I live, I will tell you what has been the result of uniting the Fitchburg Gas and Electric Light Companies. The reason we went into it was that the old electric light company, having outgrown its plant, had to lay out a very large sum of money, and a combination of interests at that time seemed very desirable, and this was brought about one year ago. We have erected a new station, and have hardly got into it as yet. We have been running about one month. From our experience in that month we conclude that we are doing a very satisfactory business.

Mr. Holmes—I think that I am connected with the management of the smallest gas works (Winsted, Conn.) in New England, and perhaps the smallest electric light company. Our output of gas is less than two million feet per annum. We were making coal gas, and charging \$3.50 per thousand. We are now making water gas and charging \$2.50 per thousand, with a discount which gives it to the largest consumers at \$2 per thousand. We are running 40 arc street lights, the equivalent of about 30 commercial lights, not arc lights, but large incandescent lights, two in place of one arc, and also about 500 incandescent lights, of which number something over 100 are in factories. We were organized in 1860 to make oil gas, but got a renewed charter in 1872 or 1873 to make coal gas, and a couple of years ago got an additional charter allowing us to distribute electricity. We have earned in years past as much as 3½ per cent. net in making coal gas; but since we have made water gas and electricity we have earned a good deal more than that. It has been hard work to increase the gas consumption. We have no gas stoves except two or three small stoves in saloons, but we are going to try that on this summer. We run our electric lights by water power. That is probably where we make a great gain, as we have a phenomenal water-power for the electric light business, although it is situated four miles from the centre of the town. We have a water power with a fall of 53 feet which runs a 21 inch wheel 390 revolutions per minute, and can get 260 horse power from it, but are now using only about 100 horse power. We charge 75 cents per month for 16 candle power incandescent lights, giving a discount of five per cent. We get \$85 per year for our street lights, and are soon to reduce this price to \$80, and take on 10 more lights. We get about the same price for our commercial arc lights. We are pushing the business a little, are making some money, and are tolerably happy.

Mr. Harbison—I think those who have been for a term of years engaged in the business of manufacturing and selling coal gas are being left in the background and forgotten.

The President—Let me remind the gentleman that the question before us is the management of small gas and electric light plants.

Mr. Harbison—The paper of Mr. Fowler has a statement with regard to the comparative cost of electric and gas lighting; and, if I remember correctly, he said that the electric light, for certain uses, or for certain hours of the day, was cheaper than gas. But bear in mind that his gas is \$2.50 per thousand, and not \$1.40. If he were making his comparison on the basis of \$1.40 or \$1.50 per thousand for gas, his conclusions might have been different. There is one further matter that I want to call special attention to. When my friend from Vermont read his paper this morning he stated, in speaking of the advantages of water gas over coal gas, that 14 years ago he was charging \$3.50 for coal gas, but that ten years ago he put in a water gas plant, and reduced the price to \$2.50. But let him bear in mind that a great many of us were furnishing coal gas 14 years ago and were charging \$3.50 per thousand for it, just as he was, and that without putting in water gas plants we have been able to reduce the cost of coal gas to less than half the price we then charged. In fact, he would probably have been able by this time to sell coal gas for the same price he now sells water gas, if he had stuck to the coal gas business. While we may well consider the advisability of putting in a water gas plant as an auxiliary to a coal gas works, we should at the same time remember that in the last 14 years coal gas has made some considerable advance. We have not been at a standstill. I think that those engaged in the manufacture and distribution of coal gas can show as good results to-day as any water gas company in this country have been able to show. On motion of Mr. Harbison, a vote of thanks was passed to Mr. Fowler.

(A further discussion here followed with reference to the change of name of the Association, at the conclusion of which Mr. Lamson withdrew his motion. By direction of the President the motion and discussion are omitted.)

REPORT OF COMMITTEE ON NOMINATION OF OFFICERS.

Mr. Sherman, from the committee on the nominations of officers, presented the following report:

President—Charles F. Prichard, Lynn, Mass.

Vice-Presidents—Horace A. Allyn, Cambridge, Mass., and Wm. A. Wood, Boston, Mass.

Secretary and Treasurer—Chas. H. Nettleton, Birmingham, Conn.
Directors—Edward C. Jones, Henry B. Leach, Z. M. Jenks, Wm. Badger, and E. C. Learned.

On motion of Mr. Harbison, Mr. Sherman was instructed to cast the ballot of the Association for the election of the nominees of the committee.

The President—I declare that these nominees have been duly elected as officers of the Association for next year. Mr. Prichard will please come forward. (To the President-elect) These gentlemen, Mr. Prichard, have imposed upon you the highest honor which can be bestowed by this Association. It is an honor to be proud of, and in my judgment worthily bestowed; gentlemen, I introduce to you your President for the coming year.

Mr. Prichard—(President-elect)—Gentlemen, I can only say that I thank you most heartily for the honor you have done me, and I hope during the coming year that I shall be able to serve you to your satisfaction. But the President can do nothing without the hearty support and co-operation of the members. Let us unitedly endeavor to maintain and advance the interests of our Association.

THE WORLD'S FAIR COMMITTEE.

Mr. Harbison—At the last annual meeting of the American Association, held in Baltimore, in October last, the subject of a possible and probable World's Fair, to be held in 1892, was discussed, and a resolution was passed authorizing the council of the American Association to appoint a committee to represent that Association, to act in connection with committees appointed by kindred Associations, with special regard to an exhibit in connection with the gas industry to be made at that fair. It would be quite proper in my opinion, for this Association to take some action tending in the same direction. I therefore move that a committee of three be appointed by the chair to consider this question, and to report to the Association to-morrow the names of a committee to be appointed to represent this Association, and to act in connection with the committees of other Associations in respect to the World's Fair, whether it be held in 1892 or 1893.

The motion was agreed to, and the President appointed as such committee: Messrs. J. P. Harbison, H. A. Allyn and C. F. Spaulding.

BADGES.

Mr. Stiness—I notice that our friend Harbison wears a decoration. The American Association of Gas Engineers have adopted a distinctive badge, and the Guild of Gas Managers have also a badge, but there is no distinctive badge for the New England Association. It has been suggested that a committee be appointed to prepare a suitable badge to be worn by the members of the New England Association at its yearly meetings, so that a member can recognize a brother almost as well in the dark as in the light. It is a very convenient form of recognition. I met gentlemen in the hotel to-day whom I have seen here and have heard speak, but had no idea that they were in the gas business. I make the motion that a committee be appointed to prepare a permanent badge for the New England Association.

Mr. Harbison—I would like to second that motion, and to add to it that the committee be authorized to procure a suitable badge for members of the Association at the expense of the Association, and to see to it that each member has a badge before the next annual meeting.

Mr. Stiness—There is another question which enters in and which perhaps the committee can be prepared to report about to-morrow, and that is the matter of the cost of the badges. The badges of the American Association cost \$4 each, and I think a badge for this Association could perhaps be procured for a lesser sum—a different badge, say, for about \$3.

The President—I understand the motion to go so far as to direct the appointment of a committee to select a badge and report here to-morrow. This motion was amended by Mr. Harbison, that the cost of the badges should be paid for out of the funds of the Association. After some discussion the amendment was withdrawn and the motion prevailed. The chair appointed as Committee on Badges: Messrs. S. G. Stiness, C. F. Prichard and J. A. Coffin.

PRINTING THE PAPERS.

Mr. Lamson—I move that next year the papers which are to be read before the Association be printed and distributed among the members at the meeting.

The President—You have heard the motion of Mr. Lamson, that another year (as has been done in two instances this year) all our papers be printed before their presentation to the Association. (Adopted.)

NEWS FROM THE ABSENT SECRETARY.

The President—I have a telegram here from our Secretary which I should have noticed sooner, but was unable to do so:

"From Grand Island Depot, Nebraska. To Robert B. Taber, President of New England Association of Gas Engineers, Young's Hotel, Boston. Expected to be in Boston Tuesday, but was unavoidably detained. Best wishes for a successful meeting."

"CHARLES H. NETTLETON."

The Association then adjourned to Thursday, February 20, 1890, at 9:30 A. M.

(To be Continued.)

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE following, from a correspondent, under date of Feb. 28, at Boston, is, to say the least, interesting:

To the Editor AMERICAN GAS LIGHT JOURNAL:—Here is a chance for you to invest, as per the following advertisement: "Dedham Electric Company, organized under Massachusetts laws. Full paid capital stock, \$50,000. No bonded indebtedness. Subscription list for the stock, at \$100 per share, now open. Investigation will show that this stock will net the investor, from January 1st, 1890, at least 6 per cent. per annum, free of taxes. Orders for indoor lighting solicited. For further particulars and subscription list apply to JOHN R. BULLARD, President." The Company started up January 18, 1890, but is already, you see, prepared to divide 6 per cent. among its stockholders, who have not yet taken up the stock. You may ask why it is necessary to *advertise* the stock; but that's because you don't know how many 6 per cent. stocks are to be had in New England. You know the Atchison Company paid 7 per cent. while the last 10 millions of their stock was being issued! Six per cent. isn't anything where such investments abound. Yours, truly, *

It was remarked at the New England meeting last month that the electric lighting men were "pushing" individuals, and we fail to remember that that remark was controverted. And it goes without saying that the financial management of the Dedham Electric Company, as per their advertisement, are high in the class of "pushers." It requires a good deal of "push" nowadays to convince investors that any per cent. can be earned on the business of supplying electric lighting currents in small towns, and particularly so would this apply to a town of the size of Dedham, where a well-managed Gas Company already exists, also bearing in mind the fact that the projectors of the electrical enterprise feel that \$50,000 will be required to start the project on a commercial basis. Either Dedham wants electric lighting at new hands very badly, or else Mr. Bullard and his confreres are gasconading. Another thing that appeals to us in this connecting is, if Bullard & Co. have such a bonanza, why do they not interview the proprietors of the Dedham and Hyde Park Gas Company with the object of winning the latter over. The Dedham gas men know a good thing when they see it; but they, on the other hand, are also conversant with the practice of separating fancy from fact. That is, perhaps, why they have been so successful.

In our last issue brief mention (necessarily brief because of inability to obtain quickly the details of his life) was made of the death of Dr. H. H. Button, for many years President of the Milwaukee (Wis.) Gas Light Company. To the courtesy of a correspondent (whom we herewith thank for his kindness) we are enabled to give the following particulars respecting the career and work of Dr. Button: "Dr. Button died on Friday morning, Feb. 14th, from congestion of the brain. He was nearly 72 years of age, and had been very much affected by the death of his son-in-law, some three weeks since, who was a man in the very prime of life, full of vigor, possessed of unusual business ability, and who was warmly beloved by the Doctor. This relative had been ill only three days when death carried him off, and the shock to Dr. Button was most severe. Respecting the Doctor's connection with the Milwaukee Gas Light Company, I may say that he purchased his first stock in it in June, 1865, and was elected a Director the following month. After the death of Asael Finch (in March, 1883) the Doctor was elected President and continued to serve until death intervened. He was an excellent President, and took great interest in picking up the different points in gas manufacture, and educating himself in the new ideas advanced from time to time. Although very conservative in his ideas and ways, he was nevertheless anxious to keep up with the times, and to adopt all new methods that tended to cheapen the cost of gas, or to better its quality. He could not be excelled as a financier, and his personal integrity could not be questioned. He was in the very highest sense that the words imply, honest, kind and just. He was the leading advocate of the policy of reducing the price of gas in Milwaukee, and did much for the consumer in being so thoroughly persistent in his efforts in this direction. While it benefited the consumer at the same time, as you well know, it has been the means of putting this Company in the sound financial condition that it is. He will be greatly missed by his friends, and all those who had business connection with him. Mr. John L. Mitchell, now Vice-President, will doubtless succeed him. He is one of our largest capitalists, and will, I believe, be a splendid man in the place. His father (now dead) was Alex. Mitchell, for so many years President of the Chicago, Milwaukee and St. Paul Railroad. Yours, etc., E. G. C."

IT is reported that the proprietors of six large iron smelting or working furnaces in the vicinity of Pittsburg, Pa., are figuring on the possibility of substituting an artificial gas for the natural article. Among the six is mentioned the name of the Pennsylvania Tube Works Company.

A FEW days ago, Captain Supplee, in the second branch of the local government of Baltimore, Md., offered the following resolutions, which were referred to the Legislative Committee:

"Resolved by the Mayor and City Council of Baltimore, That the Legislative Committee be and is hereby instructed to present to the General Assembly of Maryland the following amendments to the measure now pending for the regulation of the contract for gas supply of Baltimore:

"*First.*—The Consolidated Gas Company shall have the exclusive right to manufacture and supply illuminating and fuel gas for 10 years in the city of Baltimore.

"*Second.*—The price charged the city for illuminating gas shall not exceed \$1.10 per 1,000 feet; the price charged private consumers shall not exceed \$1.25 per 1,000 feet.

"*Third.*—Whenever the dividends declared by the Company, after setting aside 1 per cent. as a sinking fund to extinguish its bonded debt, shall exceed 5 per cent. annually, the price of gas shall be reduced 5 cents per 1,000 to both the city and private consumers for each one-half per cent. dividend declared above 5 per cent.; that is to say, whenever the dividend declared shall be 5½ per cent. the price of gas shall be \$1.05 and \$1.20, respectively; when 6 per cent. shall be declared, the price charged shall be \$1 and \$1.15, respectively, etc."

AMONG the notable examples of bold engineering developed in the construction of the great sugar refinery of Claus Spreckels, at Philadelphia, Pa., one of the most unique is the hanging or aerial steam engine foundations. The engines used in this huge establishment are distributed practically all over the buildings, a large proportion of them being on the upper floors. Some of these engines are bolted to iron beams or girders on the second and third stories of the buildings, and are therefore innocent of all foundation. Some of these engines ran noiselessly and satisfactorily, while others produced more or less rattle and vibration. To correct the latter, the engineers simply suspended foundations from the bottoms of the engines, so that, in looking at them from the lower floors, they were literally hanging in the air. From this it would seem that the foundation to an engine does service merely from its weight alone. Hence it makes small difference whether the support be firmly imbedded in mother earth or in the air.

R. S. BLODGET, Chief of Police, Saratoga, N. Y., has adopted the following method of putting an end to stray dogs: A large box, with glass top and sides—the top being removable—is fitted with an ordinary ½-inch service pipe, leading from the riser that serves gas in the station. The doomed animals are placed in the box, the gas is turned on, and the end is accomplished. The first victim was a dog weighing 45 lbs.; the quantity of gas admitted was 8 cubic feet, and at the end of an exposure of a period of 2 minutes and 12 seconds the brute succumbed.

PRESIDENT McMILLIN, of the Laclede Gas Company, is responsible for the following: Some time ago (the month was December) a company announced its readiness to supply natural gas in Columbus, O. The proprietors had rented a large room for an office. Over a desk in a dark corner they placed a 2-burner fixture to use the ordinary manufactured article of gas, being more convenient for illuminating purposes than their own product. Around the room they placed various sample stoves, grates, etc., for burning natural gas to show the citizens how the thing worked. These were connected by various service pipes with their own main in the street, and were kept going all day. When New Year's came they had a big bill from the Columbus Gas Company. It was paid under protest. When February came around the size of that gas bill was something marvellous. It was such a veritable behemoth of a bill that the recipients got up and howled with all their might, ending with a peremptory demand that the offending meter be taken out in-stanter, or before it plunged them into hopeless bankruptcy. A mild-mannered gas employee came around promptly February 2d and read the meter preparatory to taking it away for good. It had been read Jan. 30, and in the three intervening days had recorded 3,000 cubic feet with only two burners going and its hands tied behind its back. The mild-mannered man was astounded. He hurried the meter away and tested it, feeling sure that something was radically wrong. But the meter refused to yield up its integrity. It came out of the test a meter to be proud of. It was all right. Then the mild-mannered man sat down be-

fore it and for a long time wrapped himself in thought as with a blanket. Finally a horrible thought struck him. He put on his hat and started for the office of the natural gas company. Half way there he met the chief clerk—the man who but an hour before had been the chief swearer in the matter—now meek as a lamb, coming to insist that the meter should be replaced at once, and only too anxious to “pay that outrageous gas bill.” He tried hard to keep from explaining, but the mild-mannered man was suspicious and persistent, and it had to come out at last. In tapping the pipes for the various sample stoves and grates a mistake had been made in one connection, and the pipe of the illuminating gas company had been tapped. For six weeks the natural gas people had been using about 25 feet an hour of manufactured gas, and selling natural gas by samples of the artificial article. Of course, the meter went merrily round and the bill went up. The natural gas people wanted the matter kept quiet, but this is so far from home that it won't count.

AT a meeting of the Directors of the Jacksonville (Ills.) Gas Light and Coke Company Mr. M. P. Ayres was elected President, and F. M. Doan was chosen Secretary and Superintendent.

AT a recent meeting of the Committee of Manufactures (Massachusetts Legislature) the matter under consideration was the taking of testimony in respect to the petition of the Amesbury and Salisbury Gas Company for the repeal of the State law (chap. 428, Acts of 1888) limiting the carbonic oxide content in illuminating gas to 10 per cent. One of the testifiers was Mr. C. W. Hinman, State Gas Inspector, who in his remarks went into the subject of water gas in a general way, and detailed the circumstances of the passing of the legislation of some years since in regard to water gas. He said he was largely responsible, perhaps, for the institution of the carbonic oxide limitation. His views, however, had been to a certain extent modified by subsequent experience, and if he had the same work to do over again he should do differently. He had known nothing of the commercial question involved in the oxide clause. Then he regarded it as a matter of little importance, and even the companies themselves made little objection to it. In rich water gas he testified there was no necessity for any oxide limitation, and that in 20-candle water gas 15 per cent. of carbonic oxide was not dangerous.

MESSRS. COFFIN & STANTON, of this city, as representatives of certain capitalists, have purchased for cash the property and franchises of the Crawfordsville (Ind.) Gas and Electric Light Company. We understand that Mr. P. C. Somerville will remain, for the present at least, Manager of the Company. He ought to be induced to remain there permanently.

A CONTROLLING interest in the Media (Pa.) Gas Company has been purchased by Mr. Francis M. Brooke. The cause which impelled him to become the heaviest shareholder in the concern is a queer one. Not long since he purchased at foreclosure sale a plot of ground close to the works, and subsequently acquired another piece in close proximity. The Gas Company's holder stands between the plots, and as Mr. Brooke is desirous of improving the property, he determined to secure control of the gas works, and thus be in position to order the relocation of the offending gasholder.

THE Mattoon (Ills.) Electric Light Company has turned on its current, and begins business with 36 arc lights in circuit.

THE Munn interest in the Freeport (Ills.) Gas Company has been purchased by Mr. L. F. Farwell, which gives to the latter complete control of gas and electric lighting supply of the town.

THE proprietors of the Atlantic City (N. J.) Gas and Water Company have arranged to put in a 16-inch main, from the works, down Michigan avenue to Atlantic, and a 12-inch from Atlantic to Pacific avenues.

THE proprietors of the Greenville (O.) Gas Company have agreed, until further notice, to sell gas at uniform rate of \$1 per 1,000 cu. ft.

ON February 22d, the buildings in which were housed the electric lighting apparatus of the Freeport (Ills.) Gas Light and Coke Company, were destroyed by fire. The loss is returned at \$25,000, and the insurance carried was only \$3,000. The disparity between the amounts mentioned is accounted for on the ground that the insurance rates on risks of this class are very high; further, that insurance companies are by no means anxious to assume such risks. In the Freeport instance the boiler house was a frame structure, and it was in that building that the fire originated. This unfortunate occurrence caused much annoyance to the residents, as the Company has the contract for carrying on the

public lighting, which is on the arc plan, but as Superintendent Runner was authorized by Mr. Farwell to rent power for the operation of an emergency dynamo, the interruption to the street lighting was of but short duration. The station will be rebuilt at once, with brick power buildings, however.

A GAS COMPANY for Vinton and Roanoke, Va., has been organized, and its bill for incorporation has been passed by the Legislature.

IT is now a certainty that the property and franchises of the Indianapolis Gas Light and Coke Company, the Indianapolis Citizens Gas Light Company, and the Indianapolis Natural Gas Company, have passed under the control of the Equitable syndicate of this city. The following circular will prove of interest in this connection:

“OFFICE OF THE EQUITABLE GAS LT. CO., OF NEW YORK, }
340 THIRD AVE., NEW YORK, Feb. 21, 1890. {

“I beg to call your attention to the fact that a syndicate, composed of some of the largest stockholders in this Company, has just completed the purchase of the gas business (lighting and fuel) of Indianapolis, consisting of various natural gas and fuel, illuminating gas, and electric light companies now in existence there, and has organized thereon the Indianapolis Gas Company, and now offers at private subscription a certain portion of the bonds of the new company. These bonds are 30-year gold 6 per cent. bonds, coupons payable April and October, and are offered at par with a bonus of 25 per cent. of stock. This stock will have an immediate and large dividend paying capacity, as the business is already established and is increasing rapidly and steadily. Payments on subscriptions will be through the Central Trust Company, of New York, by installments of 25 per cent., commencing March 15 and ending June 2. In case you want to participate in this enterprise, which will be one of the most successful in its line ever carried on in this country, please let us know at once; and, if you wish further particulars as to the present earnings of the business and its prospects in the future, I shall be glad to furnish them to you if you will call at this office. Very respectfully yours, — — —.”

WHILE no doubt the amalgamated lighting interests of Indianapolis will constitute a much more imposing enterprise than did the Indianapolis Gas Light and Coke Company, when taken singly—although we have an idea that that arm of the new confederacy is the member that shall convey the greatest force to the confederacy—we are nevertheless sorry that its destiny is to be destroyed—if not destroyed, at least cloaked. The history of the old company is that of fair-dealing, which clothed it with power that was never abused. And much of that history can be traced to the master hand of one known to his fellows as the “Sage of Indianapolis”—James Somerville.

WHEN General Manager Ellison, of the St. Paul Gas Company applied to the Building Department of the city for a permit to restore the structure recently damaged by explosion, he was astonished to find that a protest against the reconstruction had been lodged by several property holders in the vicinity of the works. The objection was based on the ground that the works were a menace to life and property; also that their operation tended to reduce the value of the surrounding holdings. The permit, however, we are informed was granted, the inspector alleging, and very properly, “that the gas plant was built many years before most of the residences were constructed, and that the Company has rights and privileges that cannot consistently be overlooked.”

AT a recent meeting of the Fredericksburg (Va.) City Council Mr. McCracken presented a resolution (which was adopted) containing an act for the construction and operation of a gas works on municipal account. The act is now before the Legislature.

WE understand that the City Council of St. Joseph (Mo.) has agreed to the proposition for a charter for an opposition gas company, under the pledges submitted by F. F. McGuire and his backers. The leading points in the ordinance are: The City Engineer is to have supervision over all street excavations and the subsequent repaving. Any injury resulting to persons or property, by reason of the construction of the works, to be settled for by the Company. The Company shall have on the ground, by August 1, 1890, three miles of pipe for distributing gas, one mile of which shall be laid, and shall also have begun the construction of its plant, and shall within 18 months after the acceptance of the franchise be prepared to furnish gas along at least 10 miles of pipe. The Company shall deposit \$20,000 cash with the Comptroller as a guarantee of good faith, 60 days from the acceptance of the franchise, the money to remain on deposit until the Company shall have given satisfactory evidence of having invested \$150,000 in the plant, a bond of \$20,000 to

be deposited at the same time. The maximum price of gas to be 75 cents per 1,000 cubic feet for fuel purposes, and \$1 per 1,000 for illuminating use. The city hall, engine houses and calaboose are to be lighted free of charge. The ordinance is to be accepted within 20 days after its passage. If the Company ever consolidates with any other Company the price of gas is not to exceed that named in the ordinance. The gas is to be odorized. This ordinance may give trouble to the authorities of St. Joseph in the near future.

OWING to the unprecedented rise in the Kentucky river, gas was shut off from Frankfort on the evening of March 1st.

THE Van Buren (Ark.) Investment Company has been incorporated by Messrs. W. H. H. Shibley, Geo. R. Wood, J. N. Brown, W. H. Ross and W. P. Brown. It is capitalized in \$50,000. One of the purposes of its formation is to construct and operate a gas and electric light works. This place is the capital of Crawford county, Ark., and is on the north bank of the Arkansas river, at a point about 9 miles northeast of Fort Smith. Population, about 4,000.

PRESIDENT ALLSTATTER, of the Board of Trustees of the Hamilton (O.) municipal gas works, is of the opinion that the works will be in operation on or before April 22d.

THE Philadelphia *Record* of March 3d contains the following: "The purifying house of the large gas works connected with the saw works of Henry Diston & Sons, at Tacony, Pa., blew up shortly after 8 o'clock yesterday morning. The building in which the explosion took place was constructed of brick, 1 story high, and located some distance from the other buildings. It was completely wrecked, together with the machinery. All the gas used in the blast furnaces and for lighting the works and the streets and residences of Tacony was purified in the destroyed building. The watchman noticed something wrong at an early hour in the morning, and started off to find one of the engineers. Before the latter arrived the explosion occurred. The loss to the buildings and machinery will not be great, but the loss to the works will be considerable, owing to the loss of time before new machinery can be procured and set up. In the meantime Tacony will be without gas."

THE Fairfield (Iowa) Gas and Electric Company, with a capital stock of \$50,000, has been incorporated.

IN the reorganization of the Monroe (Mich.) Gas Light Company the capital has been put at \$40,000.

THE Columbus (O.) Gas Company is experimenting, on a practical working scale, with the Gordon regenerative street lamp as an agent for street lighting.

IN response to the invitation of the Troy (N. Y.) authorities to tender for public lighting, the Troy Gas Company proposed the following: Not less than 280 arcs (1,200-candle power), 38 cents per light per night; 2,000-candle power, 42 cents per light. If a 3-year contract be allowed, the respective prices to be 37 cents and 41 cents; if for 5 years, the rates to be 37 cents and 39½ cents, respectively. Under the gas lighting head of the specifications, the Troy Gas Company offered the following: 310 Gordon lamps and 625 boulevard lamps (ordinary pattern), to be maintained under the schedule, at \$39,420 for 1 year's service; 370 Gordon lamps and 625 boulevard lamps, \$44,238; 450 Gordons and 620 boulevard pattern, \$49,056; 625 ordinary street lamps, 8½ cents per night each. Gas to public buildings, \$1.50 per 1,000. It would perhaps be a surprising thing were Troy the first city in this country to adopt a sensible plan of lighting streets by gas—that is, in respect to a new, but eminently satisfactory system.

MR. GEO. D. CURTIS, well known to the fraternity of Central New York, from his connection with the Albion Gas Company, has removed to Atlanta, Ga.

THE ordinance regulating the price of gas in St. Louis, which was vetoed by Mayor Noonan, has been passed over the veto by the Municipal Assembly. The vote was 9 to 3.

CAPT. D. H. HENSLEY, Secretary of the Hamilton (O.) Gas Light Company, has been appointed local postmaster.

MESSRS. T. F. OAKES, Crawford Livingston and General H. H. Sibley have been elected Directors in the St. Paul Gas Light Company. The first named is supposed to represent the recently-acquired interest in the Company secured by Mr. Henry Villard.

THE Rockford (Ills.) Gas Company has been purchased by the American Gas Company, of Philadelphia.

THE Poughkeepsie (N. Y.) Gas Light Company has brought suit against Wm. O'Riley for \$52.50, which sum the plaintiff claims is due because of defendant's negligence in the construction of a sewer through Main street. On account of faulty shoring the Gas Company's main was fractured, thus causing a loss of 45,000 cubic feet of gas. The defense interposed is a general denial, coupled with the statement that, as the work was being done on city account, O'Riley is not the real defendant.

Coke Brick for Furnace Linings.

The *Iron Age* says that at the last meeting of the German Society of Iron and Steel Metallurgists, F. Burgers, of Gelsenkirchen, presented a short statement of his experience with a special brick used to line the bosh and hearth of blast furnaces. It is a matter of frequent occurrence that linings 3 to 4 feet thick are soon reduced to a few inches. Then streams of water must be used to keep the walls from being destroyed. The chief reason for this rapid destruction of the refractory material is the fact that the cinder dissolves it, fluctuating in its composition, as it does frequently, from an acid to a basic cinder. Experiments made showed that the best refractory firebrick, varying in composition, were destroyed in one or two hours when placed in the cinder run. This circumstance led Burgers to seek for another material. His attention was directed to coke. The first experiment, begun in 1882, was directed to binding with clay, coal, coke, and graphite, and using the mixture in a form of brick. Dr. Otto & Co., a leading firm of German manufacturers of firebrick, furnished a series of samples which, however, were defective in this point—that in binding the brick the carbon had been partly removed; but even this sample gave good results.

In 1885 Pourcel, in describing the manufacture of ferromanganese, at Terrenoire, stated that the hearth and bottom of the furnace were made of graphite brick. He used as a raw material retort graphite containing 1 to 2 per cent. of ash, ground it, mixed it with tar, formed it into brick, and then heated it. A part of the tar cokes and binds the graphite to a solid brick. Burgers had experiments made with ground coke, low in ash, instead of graphite, obtaining good results.

In 1885 No. 2 furnace of the company with which Mr. Burgers is connected was lined with this coke brick, with excellent results. They have been introduced also with the Rheinische Steel Works, and at Rombach. At Mechernich the same material has been used for lining lead furnaces. During the course of a brief debate upon the subject, Burgers stated that the cost of the brick is about 100 marks per ton.

Recent Patent Issues.

The following list of recent patents relating to the gas interests is specially reported by Franklin H. Hough, solicitor of American and foreign patents, 925 F street, N. W., Washington, D. C.

ISSUE OF FEBRUARY 4, 1890.

- 420,726. Gas Regulator. C. P. Kolm, Knapps Creek, N. Y.
420,751. Gas Washer. W. T. Walker, Bishopswood Road, Highgate, England.

ISSUE OF FEBRUARY 11, 1890.

- 421,217. Gas Burners, Heating Attachment for. J. A. Wilson, Baltimore, Md.
421,263. Gas Furnace for Melting Metals. H. H. Garrett, Pittsburgh, Pa.

ISSUE OF FEBRUARY 18, 1890.

- 421,606. Gas Burner. A. G. Morey, LaGrange, Ills.
421,473. Gas Engine. H. J. Baker, Chicago, Ills.
421,474—421,475 and 421,477. Gas Engines. J. C. Beckfeld and A. Schmid, Allegheny, Pa.

ISSUE OF FEBRUARY 25, 1890.

- 421,924. Gas Burner. T. Gordon, Philadelphia, Pa.
422,299. Gas and Air Mixer. J. W. Danforth and R. W. Clark, Buffalo, N. Y.
422,173. Gas Washer. F. A. M. Alavoine, Beauvais, France.

WE understand that the bill regulating the gas supply of Baltimore, Md., has passed the lower branch of the State Legislature, the vote being decisively in its favor. The only substantial amendment to the bill is that which reduces the time (for which the grant to the Consolidated Company is to be exclusive) to 15 years from 25. Well informed people give it as their belief that the Senate will indorse the bill.

A. M. CALLENDER & CO.,

PROPRIETORS,

The Market for Gas Securities.

The city market for gas shares shows no marked change in quotations over those reported for last week. In general the tone is weaker, although this is to be attributed more to lack of inquiry for securities than to any real cause concerning either the management or business of the properties affected. Brooklyn shares are steady to strong, with but little stock offering. Baltimore gas keeps fairly steady, and the probability is that still higher figures in it will shortly be recorded. The measure introduced into the House giving to the Company the exclusive right to manufacture gas in Baltimore for a term of years, in consideration of certain moneys annually paid to the city treasury, has passed that branch of the Legislature, and this seems to us to be equivalent to its final enactment, for it is more than rumor that the Senate will interpose no objection. The Governor also favors the measure, if certain unofficial utterances of his about it are to be accepted as indicative of his leanings. President Morris, of the Louisville Company, has officially announced that to-day that Company will be ready to furnish a non-illuminating fuel gas, at the rate of 50 cents per 1,000. This experiment will be watched with interest, and Mr. Barret, will come in for no small share of congratulation should his studies in this direction lead to success.

It is more than likely that the Troy (N. Y.) Gas Company will absorb the Troy Electric Light Company's plant. In any event the city's public lighting has been awarded the Gas Company, and as the contract calls for both gas and electric lighting, the contractors might do worse than absorb their competitor, a competitor, however, that was never over strong. Mr. Thomas Turner has been re-elected President of the Charleston (S. C.) Gas Light Company, and the Directors are: Messrs. A. S. Johnson, W. B. Smith, John S. Riggs, Geo. W. Williams, Morris Israel, H. E. Young, G. L. Buist and John C. Simonds.

GAS vs. ELECTRIC LIGHT.

We would invite attention to the able and exhaustive argument of General A. Hickenlooper, President of the Cincinnati Gas Light and Coke Company, contained in a handsome pamphlet of 96 pages, entitled

"EDISON'S INCANDESCENT ELECTRIC LIGHTS FOR STREET ILLUMINATION. REPORT OF AN ARGUMENT DELIVERED BY A. HICKENLOOPER BEFORE THE COMMITTEE ON LIGHT, MUNICIPAL COUNCIL, CITY OF CINCINNATI, JULY 22, 1886."

This is a subject of special interest to all Gas Light Companies.

THE NEW HANDY BINDER.

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filed in the Handy Binder, becomes a volume of great value, always convenient for instant reference. Handy Binder, Postage paid, \$1.00.

A. M. CALLENDER & CO., 42 Pine St., N. Y.

GREENOUGH'S

"DIGEST OF GAS LAW."

Price, \$5.00.

This is a valuable and important work, a copy of which should be in the possession of every gas company in the country, whether large or small. As a book of reference it will be found invaluable. It is the only work of the kind which has ever been published in this country, and is most complete. Handsomely bound. Orders may be sent to

A. M. CALLENDER & CO.,

42 Pine Street, N. Y.

PATENTS.

GUARANTEED ESTIMATES of Cost of Gas Furnished on Application.

GASHOLDER TANK CONSTRUCTION, ETC.

Gas Companies and others about to erect Gasholders will find it profitable to consult
W. C. Whyte, who for over 30 years has made a specialty of

Tank Excavation and Mason Work.

Fifty Tanks now in operation show the sort of work done. Address

W. C. WHYTE, - No. 15 Cortlandt Street, N. Y. City.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used *in every State in the Union*, and purifying daily over *thirty-five million cubic feet*. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but *three years*, and in that time has been introduced *more generally* than any invention ever designed for use in gas works. Over *two hundred* of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is *complete* without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for *mixing air* with oil gas. *No works* too small to use them profitably.

Prices given on all our specialties *delivered at any point in the United States*. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

Address as above, or D. D. FLEMMING, Jersey City, N. J.

FRED. BREDEL,

CONTRACTOR FOR THE COMPLETE

Erection and Equipment of Gas Works.

SOLE PROPRIETOR OF THE

KLOENNE PATENTS

FOR NORTH AMERICA.

REGENERATIVE FURNACES.

(900 Retorts are now fired in America by the Kloenne-Bredel System.)

SELF-SEALING MOUTHPIECES.

(Over 800 Now in Use.)

Standard Condensers. Washer-Scrubbers.

TAR WASHERS FOR WATER GAS PLANTS.

(In use in the works of the Chicago Gas Lt. Co.)

GASHOLDERS.

Bredel's Automatic Gas Governor.

Refers, by permission, to Mr. Eugene Vanderpool, Newark, N. J.; Mr E. G. Cowdery, Milwaukee, Wis.; and Mr. Theo. Forstall, Chicago, Ills. For further information, address

FRED. BREDEL,

No. 208 East Seventeenth Street, N. Y. City.

COMPOUND Condensing or Non-Condensing.

18 SIZES, 5 to 500 H. P.

Not yet equaled by any form of Engine for
HIGH FUEL DUTY AND SIMPLICITY.

STANDARD 13 Sizes in Stock.
5 to 250 H. P.

3000 in use in all parts of the Civilized World.

JUNIOR 6 Sizes in Stock,
5 to 50 H. P.

An Automatic Engine cheaper than a Slide Valve.
WELL BUILT. ECONOMICAL. RELIABLE.

Over 300 Sold the First Year.

All the above built strictly to Gauge with
INTERCHANGEABLE PARTS.

REPAIRS CARRIED IN STOCK.

SEND FOR ILLUSTRATED CATALOGUES.

Post Office Box 3695, New York.

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

Gas Power the Leading Power of To-Day,
AND SOLVE AT ONCE THE QUESTION OF FUEL GAS.

Ohio Gas Light Association.

OFFICE OF SECRETARY,
COLUMBUS, O., February 22, 1890.

To Members of the Ohio Gas Light Association:

Gentlemen—As previously announced, the Sixth Annual Meeting of this Association will be held at Toledo, O., beginning at 10 A.M., March 19, 1890, and continuing two days. Boody House will be the headquarters of the meeting, the various sessions of which will be held in a very suitable room in the same hotel. Members and others desiring to attend are advised to write well in advance for rooms.

The following papers have been promised for the meeting:

1. "Theory and Practice in Gas Management," J. M. Bate, Supt. Gas and Coke Company, Canton, O.
2. "Municipal Control of Lighting," H. Wilkiemeyer, Supt. Gas Light and Coke Company, Portsmouth, O.
3. "Combination of Gas and Electric Lighting in a Small Town," George W. Bowers, Sec. Gas and Electric Light Company, Hillsboro, Ohio.
4. "Our New Coal Gas Works," G. A. Hyde, Engineer Gas Light and Coke Company, Cleveland, O.
5. "Advantages of a Combined Coal and Water Gas Plant," Geo. Light, Asst. Supt. Gas Light and Coke Company, Dayton, O.
6. "Another Year with Fuel Gas," Chas. H. Evans, Manager National Gas Company, Jackson, Mich.
7. "Ohio Street Lighting Statistics," W. C. Hedges, Secretary Gas Light Company, Mansfield, O.
8. "Graduated versus Uniform Rates," Chas. R. Faben, Jr., Supt. Gas Light and Coke Company, Toledo, O.

The following questions have been proposed for the "Question Box:"

1. At what point in the works is the best place for the exhauster?
2. In a lighting territory covered by illuminating gas and the incandescent electric light, which seems to be in the ascendency?
3. Does a fine gas of 23 to 25-candle power help check the invasion of the incandescent electric light?
4. Should we not confine the work of our Association to the important interest it was established to promote, viz.: gas lighting and the manufacture of coal gas?
5. What system of electric lighting is best for adoption by gas companies?
6. Are cast iron pipes better and cheaper than wrought pipes for gas mains of 2 to 4 inches in diameter?
7. Does it pay to coat gas mains with coal tar?
8. What is the average life of a meter in constant use, with ordinary good care?
9. Is not illuminating gas of good candle power, sold at a reduced price for fuel, the true solution of the fuel gas problem?
10. Which is the correct method of tapping mains, on top or at the side?
11. Is the Welsbach burner with natural gas a success, and what proportion of the lighting does it do in towns having both natural and artificial gas?

Other interesting questions have been proposed, which will be presented at the meeting, and members are requested to come prepared to participate in the discussion of the above papers and questions.

Provision has been made for an exhibit, in connection with the meeting, of all kinds of gas appliances and apparatus, a large room on the ground floor, a few doors from the hotel, having been secured for this purpose. No charge for floor space will be made to exhibitors, and those desiring to avail themselves of this excellent opportunity of displaying their specialties will consign their goods and address their communications to Mr. Chas. R. Faben, Jr., Supt. Gas Light and Coke Company, Toledo, O., who has the matter in hand, and who will arrange the exhibit to the best advantage of all concerned.

In addition to this exhibit there will be other objects of much interest to our members and visitors, and the meeting promises to be in every way successful. It is hoped that every member will show his appreciation of what has been done, by being present; and gas companies not heretofore represented at our annual gatherings will be profited by sending a representative to this meeting.

A cordial invitation is constantly extended to all who may desire to become members of the Association, to do so, and the Secretary would be pleased to hear from any such persons.

IRVIN BUTTERWORTH, Sec'y.

BRIEFLY TOLD.

OPPOSITION AT ST. JOSEPH, MO.—For some time back our item columns have contained the various chapters of history that were made in connection with the attempts to establish an opposition gas company at St. Joseph, Mo., and we think that taken in its entirety the history is very amusing, in that it furnishes a record of duplicity, cunning, ignorance and rapacity. Some months ago one W. S. Crosby, of Chicago, at the instigation of certain parties who will not be named here, received a hint that St. Joseph, Mo., was a likely situation for an opposition gas company, and it cannot be gainsaid that the hint was a good one, for the old St. Joseph Gas and Manufacturing Company had always been a steady dividend payer. In fact the only circumstance that could cloud the brightness of the schemer's chances was the possibility that the local authorities, remembering the liberality with which the city and citizens had been treated by the old Company, would refuse to assent to a plan that must necessarily depreciate its property. However, Crosby and his backers made application for a charter to the Council, the provisions of which have already appeared in the JOURNAL—in fact their precise nature is not of great moment, since they were founded on the skeleton plan that serves as the basis for all documents of a like nature. In due time, and upon "mature thought," the Council laid the application on the "suspense hook," which was supposed to end the matter. In passing it might be remarked that such a course was adopted chiefly on the ground that the old Company should be protected, because of its good record, and because it was managed by home capitalists. This last argument seems to have shown to certain local parties a way of whipping in on their own account, and in due course of time one McGuire appeared before the Council in the guise of a home rule advocate for an opposition charter. If we mistake not, still another of the same stripe petitioned for like recognition. The newcomers seem to have been able to "convince" the Council that their prayer should be answered. In any event they have carried the day, and whether it is McGuire or Allerton—or whether there is any real difference in their interests or not we cannot say—the franchise has been granted as per the conditions printed on pages 328 and 329 of our last issue. It would seem as if Crosby ought to feel rather sad about this time—unless, indeed, he is a friend of "McGuire's." This does not seem altogether improbable, especially when one remembers that the charter awarded is much more favorable in its provisions than that asked for by Crosby. In fact, under the new charter the proprietors cannot fail to make a good thing out of it, should they ever be able to induce Mr. Turner and his fellows of the old St. Joseph Company that it would be worth their while to buy it. In connection with this we herewith publish the following letter from Mr. J. H. Farrish, Secretary of the St. Joseph Gas and Manufacturing Company, which requires no particular comment, save in respect to his implied doubt as to whether we "find subscribers in the far East interested in the misfortunes of a Western Company." To that we can only reply—and in such reply feel that we are right—there is no sectionalism in the gas business, for what affects one affects all, hence all are interested. Mr. Farrish writes: "To the Editor AMERICAN GAS LIGHT JOURNAL: Inclosed find clippings which tell the tale. The original projector of the Jackson fuel gas scheme for St. Joseph—Mr. W. S. Crosby—got left, a franchise having been granted to a St. Joseph syndicate. Our Common Council, for reasons best known to themselves, have concluded that it is best for the city to have two gas companies hereafter. The new

franchise does not limit the new Company to any kind of gas or known process of manufacture; we do not, therefore, know what to expect. We shall keep you posted from time to time, provided you find subscribers in the far East interested in the misfortunes of a Western Company.

"Very truly yours, J. H. FARRISH."

"Since the above was written the bill has been vetoed by the Mayor, and passed over his veto. It is now a law.—J. H. F."

WHAT ADVERTISERS SAY.—We are not given greatly to the practice of telling how we are regarded by our advertisers and subscribers in the matter of the wares of the former and the needs of the latter, in so far as each may be served in those respects by an appeal to our columns. In this instance, however, we will transgress the rule by the submission of the following letter, which goes to show plainly the value of advertising in a technical paper, which has neither friends to protect nor enemies to punish. In other words, a paper that seeks to serve honestly the people who support it.

"H. W. Rappleye, Constant Volume Gas Burner, }
"Office, 1345 Arch St., Philadelphia, March 12, 1890. }

"Messrs. A. M. Callender & Co., 42 Pine street, N. Y.—Gentlemen: Herewith I hand you my check to your order for \$— (amount of inclosed bill), which please receipt and return. I also inclose additional 'ad.' which you will please insert in next issue. Somehow (unexplainable to me) the JOURNAL reaches a line of trade which I have heretofore been unable to secure. Yours very truly, H. W. RAPPLEYE."

Results from the Van Steenberg Water Gas Apparatus.

The Van Steenberg process of gas manufacture, which in its American type is well and not most favorably known to our engineers, is being illustrated in a practical way in England, at Humphrey's Hall, Knightsbridge, the trial run having been committed to the care of Prof. Vivian B. Lewes. This gentleman has compiled the following figures, which explain themselves:

TABLE I.—Giving Full Details of the Make of Carbureted Water Gas by Van Steenberg's Plant (Feb. 11, 1890).

Quantity of gas made.....	8,400 cubic feet.
Time occupied—	
In blowing.....	58 minutes.
In gas making.....	48 "
Fuel consumed—	
Anthracite.....	205 lbs.
Naphtha (70° Beaume).....	23 galls. 6 pts.
Illuminating power of gas made (corrected)	20.5 candles.

Analysis of Gas.

	Unpurified. Per Cent.	Purified. Per Cent.
Hydrogen.....	—	40.33
Marsh gas.....	—	17.08
Illuminants.....	—	7.59
Carbonic oxide.....	—	25.00
Carbonic acid.....	2.15	0.50
Oxygen.....	—	0.17
Nitrogen.....	—	9.33
Sulphureted hydrogen.....	2.84	nil
		<u>100.00</u>
Total sulphur (by Letheby test).....	6.67 grains per 100 c. ft.	
Sulphureted hydrogen in unpurified gas	23.80	" "
Sulphureted hydrogen in purified gas..	nil	
Ammonia.....	nil	
Bisulphide of carbon.....	nil	

Consumption of Materials per 1,000 Cubic Feet of Gas Made.

Naphtha.....	2 galls. 6½ pts.
Anthracite.....	24½ lbs.

TABLE II.—Showing the Composition and Illuminating Power of the Gas Made by the Van Steenberg Plant from Various Carbonaceous Fuels with 76° Naphtha.

	Foundry Coke.		Gas Coke.		Anthracite.	
	Unpurified.	Purified.	Unpurified.	Purified.	Unpurified.	Purified.

		Candles.		Candles.		Candles.
Illuminating power (corrected)	22.4	—	22.9	—	21.8	—

NOTE.—The low carbonic oxide in the make from gas coke is due to the fuel never being so hot as with anthracite; and the result is an increase in the percentage of carbonic acid in the unpurified gas.

OFFICIAL REPORT.—REVISED BY THE SECRETARY.—CONTINUED FROM PAGE 326.]

TWENTIETH ANNUAL MEETING, NEW ENGLAND ASSOCIATION OF GAS ENGINEERS.

HELD AT YOUNG'S HOTEL, BOSTON, MASS., FEB. 19 and 20, 1890.

SECOND DAY—FEB. 20—MORNING SESSION.

The Association met, pursuant to adjournment.

The President—The representatives of the Boston Gas Company are asking whether the Association will accept the invitation to visit the works to-day, and I have given them to understand that on account of the storm we cannot probably visit them. It may not be necessary to put the matter to a vote, but at the same time if I am wrong I would like to be made right. I told them, knowing the grounds down there to be very bleak, that I did not think it would be prudent for us to visit them, although we are very sorry to give it up. [It was therefore informally agreed on, for the reasons stated by the President, that the Association would not make the visit.]

IN THE MATTER OF BADGES.

Mr. Stiness—For the Committee on Badges I desire to report that the committee had an informal meeting yesterday, and that they recommend a gold badge, similar in appearance to the monogram on the programme of this meeting, the badge to be made either in the form of a button or as a pin with a patent fastener. The cost will be about \$3. It was also the opinion of the committee that the badges should be paid for by the members purchasing them, and not out of the funds of the Association. I did intend to introduce a resolution—if you will pardon me I will state it now—to the effect that the committee be continued, and that the Secretary be requested to obtain the names of those who will take a badge. Personally I make a very decided protest against appropriating the small amount we have in our treasury for the payment of badges.

The President—I think we will defer further business on this subject, and listen to the paper, by Mr. Ralph Woodward, of Waltham, Mass., entitled—

SOME NOTES TAKEN IN A SMALL GAS WORKS.

The subject of the management of small gas works has been so often written on, and in this Association so fully treated, that I feel I can add but little to the volume of experience that has already been handed in; but, owing to the persistency of our Secretary, I stand before you. My paper will be nothing more than its title suggests—some notes jotted down from time to time.

Most of us have some "hobby" we are particularly fond of riding. To many it is purification, others enrichers, and others leakage and condensation. There is hardly any subject more profitable in discussion than this last—leakage and condensation.

In this State alone, last year we had as "gas unaccounted for," 267,865,892 cubic feet, or 0.083 per cent., and the weather has been particularly favorable to a small leakage. We have all worked on this question and much has been done; but our work is only relatively satisfactory. Large leaks generally make themselves known by their very offensiveness, and are easily remedied, but small ones are sometimes very troublesome to locate. Probably our greatest loss from leakage comes from this latter cause.

To how small a percentage is it possible to reduce leakage? It depends on many conditions—age of mains, kind of joints used, depth of main, etc. With a good system of valves and with appliances for frequent testing and systematic work, much can be accomplished. As has been said, small leaks give us our greatest annoyance. I have in mind one street, not over a half mile in length, that, after the winter of 1887-8, when tested with prover, showed a leakage of 25 cubic feet an hour—219,000 cubic feet per year. After careful examination and repair we had been unable to find a leak that would amount to more than one cubic foot an hour, but had found a plenty of small ones, you may be sure.

In the system under my care we have nearly 17 miles of mains, and it is mostly small pipe, which, as you will agree, is more susceptible to leakage than larger pipe; and on this system we have 112 street valves, so arranged that any section between them can be separately tested.

The average distance between our valves is 800 feet, and while in old systems it may not be expedient, yet, in laying out new work, valves should be put in about 500 feet apart, and always at street intersections. We use "long-end" valves with a 3/4-inch pipe running to either side, and a 10-light test meter, with index on top, to read amount passed an

hour by observations of one minute, and keep a careful record from year to year of the leakage of each street.

With such a system, and a thorough knowledge of the probable day consumption of the district under test, leaks can be located with great precision. Our loss last year was 55,435 cubic feet per mile of main; small, compared with many works, but enough to demand an inquiry how it can be still further reduced,

How much do we lose by actual leakage? How much by defective meters? And how much by condensation?—by which we mean shrinkage or loss from difference in temperature. It has been stated that our loss from shrinkage in this region will average 2 1/2 to 3 per cent. If we can count on this loss for a surety, the remainder of our loss by "gas unaccounted for" will, in many cases, be but a small factor. Our gas is measured at the works at an average temperature of, say, 60° F. I question if the average temperature of house cellars is far below this.

Too little stress has been laid on the regular testing of meters, which are tested at intervals, but usually at intervals too far apart. From all meters tested by me last year we have the following results:

Correct or within 2 per cent. limit.....	159
Slow, average 6.6 per cent.....	82
Fast, average 4.9 per cent.....	21
Failed to register.....	4
Total	266

Average, 1.68 per cent. slow.

Our practice is to give every new consumer or tenant a new meter, or one known to be correct; thus my list includes all meters brought in, whether they have been in use six months or six years. We can safely count on an average of 2 per cent. loss, in our Company, from slow meters where they have been in constant use over five years.

Our Company has suffered, to a great extent, from the effect of having a system of drains and sewers laid through our city. Our mains have been broken, long stretches of mains have had to be removed and again relaid, and sewers crossing these new trenches break from unequal settling. I mention this only as an instance of the loss and annoyance we are subjected to, and few of us have any redress.

Some companies run a main for gas under each sidewalk. This surely would solve this difficulty.

Our Company has made a creditable record in its sale of gas stoves, but nothing that can be called satisfactory. We put our stoves on a month's trial, and, if then wanted, sell at bare cost, fitted up. Two difficulties in extending the introduction of stoves, that lie in the stoves themselves, are: They cost too much for the amount of work that can be done; and many of them give a disagreeable odor when burning.

In a series of tests made with Lungren lamps under different pressures, and adjusting the flame to burn at its minimum and keep lighted, we found, with the pressure we carry, that a 12-foot lamp could not be kept burning safely with less than 1 cubic foot an hour. Customers objected to this extra amount in their bills, so we had to set our lamps to shut off entirely during the day. I might say that our lamps were easier to keep in good repair when kept lighted.

The disposition of residuals is always a good theme for discussion. The electric light, for many of us, has helped solve the coke question, and if good sales can be made outside, tar can be used for fuel with good results.

We find 82 gallons of tar equal to 1 chaldron of coke, and with us it is economical to use. The advantages with tar are: First, high flame temperature; second, more perfect combination of combustion; third, ease of regulation; fourth, no clinkering and consequent loss of heat.

The Company with which I am connected supplies a manufacturing city whose mechanics are mostly of the best class. They earn good wages, own their own houses, to a large extent, live very comfortably and enjoy many luxuries; yet, comparatively speaking, few use gas either for lighting or cooking. Their houses are always piped for gas, our mains run by their doors, and they surely can afford, at present prices, to use gas; and should we once get them on our system as customers they would not leave us.

What hinders them? An impression I think prevails generally that it is expensive to introduce gas—that is, for running services and setting meters. Our practice is now to carry our pipes to the street line of an abutter, and he to pay all other expenses beyond; but it was not many years ago when a would-be consumer had to help pay for the pipe in the street.

Last year our average charge to abutters was \$2.88 for service and \$2.40 for setting meter, and we make both inlet and outlet connections to meter and pipe back to the "riser." These are surely not extrava-

gant rates; but could we not afford to still further lessen these petty charges?

Our business is to sell gas, and not a stone should be left unturned to help introduce its proper and economic use. How many thousand old iron burners and narrow-necked globes are in use to-day?

The electric light has only proved a blessing in disguise, but kerosene oil is, and has always been, our strongest competitor.

Discussion.

The President—Do any of you wish to question Mr. Woodward with regard to his paper? It is the general impression of gas men that meters, after 5 years' use, lose 2 per cent. Has any one any figures to state as to the amount of loss?

Mr. Stiness—I suppose there is a liability, after 5 years of continuous use, to lose a little; but I believe the practice in most companies now is not to leave them in for that length of time without a thorough test, and making repairs if needed. Mr. Woodward states that he charges for services and setting meters. That is one item which in my opinion should be stricken from the charges of every gas company. I do not charge for services; and if a street is to be opened we cover it as soon as possible with a gas main. I believed a good many years ago that it was poor policy for a gas company to make a man mortgage his house for the sake of lighting; and we have acted on this idea in doing away with all charges of this kind. I believe it would be to the interest of all gas companies to discourage all charges of this kind. I know it is the policy with many companies in Rhode Island and Massachusetts to seek the consumer, and not to compel the consumer to seek the gas company. In our company we do not allow the meters to run for 5 years without testing them. We make a thorough test, and we know that the meter is right when it is put in again.

Mr. Sherman—Are your joints made of cement, or of lead?

Mr. Woodward—All cement joints.

Mr. Sherman—If made of lead I think you would have a much larger leakage. My experience with lead joints is that they require a great deal of attention.

Mr. Woodward—We have no lead joints, except those which cross the bridges in the city; and those have to be relaid very often.

Mr. Allyn—In Cambridge the practice has been similar to that mentioned by Mr. Woodward. We charge the consumer, as near as we can get at it, the actual cost of the service inside the street line, and the cost of connecting meters. When I went to Cambridge the practice prevailed there (I think it still prevails in Boston) that when a consumer applied to have gas introduced into his house, a meter was sent him, and he obtained the gas fitter to make the necessary connections. We found so many places where improper connections had been made, that we stopped that plan, and the company now connects all its meters. There is no doubt but that the plan of changing meters at stated times is a good one, but in attempting it we have met with a good deal of opposition from consumers, who seem to think as soon as we send to a house to take the meter out, we do so because they believe the company is not getting royalty enough for the use of the meter, and will put in one that will work a little faster. I have no figures with me to show the average variations of meters taken out; but we had two extreme cases this winter. One meter had been in constant use in a house for 25 years, and the other for 30 years. On being tested they were both found to be within 1 per cent. of correct.

Mr. Humphreys—Will Mr. Woodward state what day pressure he carries? He speaks of it being necessary to adjust the Lungren lamps to use a foot in the bye-pass.

Mr. Woodward—Perhaps our pressure is a little different from that of other works, but we have to carry almost as much day pressure as we do night pressure, on account of supplying large factories. From the time they extinguish lights at night, until 6 o'clock in the morning, we run on low pressure; but on account of these variations we found that we could not get along with less than 1 foot per hour, on an average, in the Lungren lamps, when turned down low.

Mr. Sherman—Did I understand you to say that the average temperature at which you register your gas is 60° F.?

Mr. Woodward—That is average temperature at the station meter for the year.

Mr. Sherman—What is it in the summer?

Mr. Woodward—The temperature given is the average of the year.

Mr. Sherman—I do not think you credit your loss account with enough for condensation. I think most of us register our gas at very much above 60°, on the average, and we do not credit the loss account with the loss which comes from condensation. When the account is made up it is all charged to leakage account, when in most cases 2 per

cent. of it, and sometimes more, should be attributed to the difference between the temperature at the station meter and that at the consumer's meter.

Mr. Woodward—Our leakage for the last year was 3½ per cent., so that we have not a very large margin to charge off to the difference in temperature.

Mr. Addicks—How do you test the meters?

Mr. Woodward—We test them all in the shop. We go to a house, put in a new meter, bring the old one to the shop, let it stand over night near the prover, and test it in the morning.

Mr. Addicks—The Boston Gas Light Company has sometimes, after testing a meter in the house of the consumer, brought it to the shop and re-tested it, and a difference between the two tests of 4 or 5 per cent. has been found. In some cases where the consumer claimed that the meter was wrong, and asked for a test, we have tested it in the shop and found it correct.

Mr. Sherman—I would like to ask Mr. Woodward how much gas he sells per ton of coal. His leakage is remarkably low. Does he know what the average is?

Mr. Woodward—I cannot state that; but the average yield last year was about 5.2 feet.

Mr. Sherman—In the reports of the Commissioners is there a record of any lower leakage than yours?

Mr. Woodward—I have not seen any; but I judge there will be some small accounts of leakage, because the State Commissioners reported that the average leakage had dropped from 13 per cent. last year to 8 per cent. this year. There is a very great difference.

Mr. Sherman—What is the proportion of your street light consumption to the other consumption?

Mr. Woodward—I have not figured it in that way. We keep the numbers of hours that we burn the street lights.

Mr. Sherman—How many street lights have you?

Mr. Woodward—We have 186 street lights.

Mr. Cogshall—Does the yield of 5.2 include the enricher?

Mr. Woodward—That includes the enricher. Last year we used gas oil as an enricher. We did not use any during the summer, but when we were using it we never ran over 2½ gallons per ton of coal.

On motion of Mr. Allyn a vote of thanks was tendered to Mr. Woodward.

Mr. W. R. Addicks, of Boston, Mass., here read the following paper, on the—

VAPORIZATION AND FEED OF OIL TO GENERATOR AND RETORT.

If what follows serves to bring out future united investigation and discussion of this subject, it will be all that I desire. I wish to treat it at the present writing from a practical standpoint only.

I consider oil the most important factor in a water gas works, and in a coal gas works nearly as much so. In a water gas apparatus bad handling of this product will produce lampblack or tar—the tar well nuisance and fouling of scrubbers, condensation in large quantities in purifying box bottoms and drips, and even both of these substances in the very burners. The same material badly handled in a coal gas retort will produce similar troubles, though possibly to a much less extent.

In addition to the troubles hinted at above, which make life a burden to the gas superintendent and the telephone—an invention of Bell indeed—with oil at 3 to 6 cents per gallon, it increases most seriously the cost of gas in the holders, works' repairs, and the distribution department. I have endeavored to name the important points; your own experience, especially if you have gone through the experimental stage—but even after that stage—will make each of you think of many other points.

I divide my subject under the following heads, which state the principal features to be thought of in the vaporization and feed of oil to gas generator and retort:

A. Oil should be fed under constant pressure.

B. The quantity being fed should be ascertainable at any time.

C. (1st) Any treatment oil receives must be gradual in its changes. It must never be shocked. (2d) After being once brought to a given temperature, this must never be lowered until the oil has become a fixed gas at normal temperatures and pressures.

D. It should be fed to the apparatus at a pressure only just sufficient to permit the oil to enter in sufficient quantities.

E. The quantity fed to a generator (and the same is true of a given number of retorts) should be a constant proportion to the number of thousands of feet of gas being manufactured at the time.

In considering these heads, I will repeat them as separate texts.

A. *Oil should be fed under constant pressure.* When elevated supply tanks are in use, the best automatic device I know of—and I believe everything should be made automatic when possible—is that devised by Mr. Jos. Flannery, at the 132d street station of the Standard Gas Light Company, in New York city.

Fig. 1 illustrates roughly the principle of this, and a possible construction of it.

Fig. 1.

The ball and cock *A* rises and falls as the oil is fed, by pump *B*, through inlet *C* and to tank *D*, and drawn off through the outlet *E*. The rising or falling of ball and cock *A* cuts off or admits steam to steam cylinder of pump *B*, by means of cord *f* and valve *G*, preferably of Huntoon regulator pattern. The apparatus is complete of itself.

Where elevated tanks are not desired, either from questions of expense of elevators or from regulations of Fire Commissioners, a system devised by the writer can be used. This is not, as used to day, as absolutely constant as the method above, but it can be made so; and where a new apparatus is made, with duplicate pump and tank, etc., in proportion to quantity of oil desired, it will be so.

In Fig. 2 pump *A* draws oil from main tank *B*, through suction *C*, delivers through supply *D*, upon which is an "Ashton Relief" *E*, discharging back into main tank *B*. Pressure governing tank has compressed air *F*, oil under pressure *G*, and water *H*. Pressure is indicated by gauge *J*, and height of oil, which is variable, by glass gauge *K*, and height of water, which should be constant, by glass gauge *L*. Brass pipe *M*, connecting with regulator *N*, which feeds steam to steam cylinder on pump *A*, regulates the pressure on the pressure tank *G*, the regulator being the principal feature. *O* is the draw-off pipe to free the top of the water from dirt, *P* a drain pipe, and *R* the outlet of tank leading to oil meter, hence to vaporizer, and, last, to the gas machine.

It is intended that the pump and pressure tank shall be placed wherever the storage tanks are located. The pipe leading to the generator house should be of small size, as under pressure it is not required of large size. The whole apparatus is entirely automatic. Excess of pressure takes care of itself; want of pressure would soon be known in the generator house. We have thus obtained the fulfillment of the demands of constant pressure.

B. *The quantity being fed should be ascertainable at any time.* The sight-feeds are probably old friends to all, and there is no necessity of going into any details as to them. Suffice to say they are poor

guessers; or, rather, they permit a gas maker who is a good guesser to make a poor guess as to what he is doing.

I use at the Bay State works an oil meter marked in gallons, having one dial marked one gallon to one revolution of the hand. This, therefore, indicates quarter gallons, and, by estimation, any proportional part desired. This gives an easy reading for the gas maker.

I am sure everyone who has had experience with oil meters will at once say they are not accurate. Well, this is true of the meters in use thus far. I am hoping that the "Hersey," the one I am at present trying, may prove accurate. But even with their inaccuracy they are indispensable, in my opinion. The gas maker can come very closely, indeed, to the exact number of gallons he is feeding per minute. The make of his machine he knows, and so he can run the number of gallons per thousand he is ordered to, or follow out orders for so many gallons at end of each coaling, if he cannot be trusted to use his judgment to the former extent.

So we have now obtained the second condition within reasonable practical accuracy.

C.—(1st.) *Any treatment oil receives must be gradual. It must never be shocked.* Remarks: This will readily be permitted to stand as an axiom, I think; it is evident if oil is thrown cold into a hot apparatus a large quantity of lampblack will at once be formed, followed by a still larger quantity of tar, and some oil in the condition desired for carbureting or enriching.

(2d.) *After being brought to a given temperature this must never be lowered until the oil has become a fixed gas at normal temperatures and pressures.* Remarks: This likewise is an axiom, for would it not be a waste of heat to permit a partially vaporized oil to be cooled in any way?

D.—*It should be fed to the apparatus at a pressure only just sufficient to permit the oil to enter in sufficient quantities.* Remarks: I state this as I have seen oil fed to an apparatus under very high pressure through a (comparatively) minute opening in a spray.

Fig. 2.

You all know that any liquid released under pressure, in expanding to the volume which it must occupy at the pressure and temperature of its released condition, must absorb heat; consequently, in this apparatus the designer called upon the heated chamber to furnish still more heat when the chamber was already overtaxed in this respect. This machine I refer to was popularly known as the "tar machine," which, I think, illustrates my point effectively. It is for this reason I make the condition "D" a vital one. It could be done successfully by

providing considerable preheating; but I consider it bad practice. I have endeavored to obtain the results demanded by the condition, "C," (1st and 2d) and "D" in a partial way only, by means of a vaporizer, though I believe that heat imparted to the oil, such as waste heat, after the products of combustion leave the superheating chamber, is desirable, though not vital, and I believe it is not for this reason.

Granting that oil at 32.5° F. is a vapor, then the quantity of heat necessary to take it 500° higher is comparatively small. I will try to illustrate by arguing from the known to (at least to me) the unknown.

A—Heat units raise 1 lb. water, 32°, to water 212° at pressure 14.7 lbs.	180.52
B—Heat units raise 1 lb. water, 212°, 14.7 lbs. to steam, 14.7 lbs. and 212° F.	966.08*
C—Heat units raise 1 lb. steam, 212°, 14.7 lbs., to steam 300 lbs. and 417° F.	62.56

D—Heat units to raise 1 lb. water, 32° F., 14.7 lbs., to steam, 300 lbs., 417° F. 1,209.16

A is 14.9 per cent. of D.

B is 80.0 per cent. of D.

C is 5.1 per cent. of D.

A + B is 94.9 per cent. of D. (A + B is the condition we are seeking.)

NOTE.—Total heat, steam, 212° F., and 14.7 lbs., is 1146.6, with volume 1644. Total heat, steam, 417° F., and 300 lbs., is 1209.2, with volume, 97.

Granting that oil, being a fluid, follows the same law as water, if we bring oil to a vapor we have attained the result of greatest moment. I have obtained this by means of steam-jacketing the oil pipe from the oil meter to the entrance to the heating chamber. The details of construction are indicated in Fig. 3.

In Fig. 3, A is an oil meter, B is the oil pipe, which increases in diameter in each section when passing through steam jackets C₁, C₂, C₃, C₄, C₅, to inlet to generator D, where it would be, preferably, between 2 and 3 inches diameter. Jackets have inlets for steam in top stuffing

Fig. 3.

box E, and outlets for exhaust in bottom stuffing box F, the exhaust being automatically handled by means of trap G. At the bottom of each section of oil pipe is a drip-pipe H, which collects, by settling, the heavier matters or dirt which cannot be vaporized readily. I question if they are in any way actually needed.

*Made up of units to overcome external resistance, 71.83
Made up of units to overcome internal resistance, 893.81

The oil might be still further carried through heated chambers of temperatures of 600° to 800°.

In the Flannery machine it goes direct into an oil retort, and thence through the superheater, the oil retort being the cooler. The step from 312° to 1,500° of the retort is a great one; but I have pointed out that this is not so sudden as may seem at first sight. Practice bears me out; for at the Bay State works lampblack is unknown, and tar nearly so when naphtha was used. Since crude oil has been used, tar and condensation have appeared in considerable quantities, due to insufficient superheater area. I am at present working to get some exact figures on vaporization of oil, which, with the vaporizer, is an easy matter. Any figures that any members of the Association may have as to the latent heat of vaporization, and the specific heat of naphtha and crude oil, and of oil vapor, would be of service to anyone studying this subject. I believe this subject deserves all the time for investigation that can be spared.

NOTE.—Naphtha will be all vaporized at 300° F., in which case steam of 80 lbs. pressure will give all the preheating desired. With crude oil it is necessary or desirable to heat further, if the circumstances will permit of it with success.

Discussion.

The President—The subject presented in this paper is an interesting one to all of us, and I hope that we may have a full discussion. I think, perhaps, Mr. Shelton has had as much experience as any in the use of oil for gas, and we shall be glad to hear from him.

Mr. Shelton—I have been extremely interested in Mr. Addicks' paper, and I think he deserves a hearty vote of thanks for the thoroughness with which he has gone into a subject which is sometimes overlooked by those engaged in the management of gas works. I think we are not apt to go very deeply into these details of temperature and various qualities of oil. We get the crude oil, pump it in the machine, and if it makes tar, lampblack, or what not we blame it on the gas maker. We do not give enough thought to the why, and wherefore, and reason of it. On the whole I agree with Mr. Addicks thoroughly. I believe in raising the oil gradually to a high temperature, and I think the remarks he has made, although directed mostly in the direction of water gas, apply equally well to the use of oil for enriching in retorts. It is a subject in which coal gas men are interested. I cannot entirely agree with him as to the non-desirability of heating the oil beyond steam heat. I think the utilization of the heat of the producer gas, or of the sensible heat of the hot gas passing off from the superheater, is a matter of very great importance. There is still another point—that in utilizing the heat of the superheater you are killing two birds with one stone. You are not only increasing the heat of the oil, and taking so much work off the superheater and the generator, but you are taking heat away from the hot gas. On the whole, I agree with the exhibition which Mr. Addicks has made, and congratulate him upon the thoroughness with which he has done it.

Mr. Addicks—I will say further that I think if you can get up some practical arrangement to heat the oil by using the waste gases it would certainly be desirable to do so. If you can save one per cent. in that direction I would not hesitate to do it. One point I made with respect to that, was that the amount of heat necessary to do this work is such a small item comparatively, I thought it would not cost more than the interest on the money invested and the cost of repairs thereafter. I think Mr. Shelton told me at one time he did something of that kind; and if he would explain it to us now it would be a gratification to me, at least.

Mr. Shelton—I agree that when we can only save one per cent. we ought to do it. We ought to save anything that we can. It has been the experience of the company that I am connected with that we can obtain a comparatively cheap and effective apparatus to heat the oil—to make the gas by the heat of the gas that is being made. In other words, by utilizing the heat of the gas passing out by interposing some means whereby to heat the incoming oil. It is more a question of the efficiency and durability of the apparatus than of the first cost of it. We have found that a very simple arrangement will fill the bill. It is cheap, it does not have to be cleaned at great expense, and the cleaning is done once a month to once a week, depending upon circumstances. In short, it has fully repaid our putting it in.

Mr. Addicks—Mr. Jones told me that he would be here, and I would rather have him make a statement as to his success in operating this plan. When he took charge of the North End works they had 18 retorts in operation where they now have 12; and the candle power is higher than before with 18. He saves about one-third of the coke, and has a better gas than he had before; he also did away with all the sight feeds that we so often see continually dripping in various works.

Mr. Neal—I am quite interested in this paper, because I am using the Granger-Collins water gas plant, and have tried to use crude oil, but without success. I have a great deal of trouble in the superheaters, from the deposition of lampblack, and they require constant care. I spray the oil in at about 40 pounds pressure in the generator, and it meets the gas just as it is passing from the generator into the superheater. I would like to ask Mr. Addicks if he is acquainted with the Granger process?

Mr. Addicks—Yes.

Mr. Neal—The oil is sprayed in at a very heavy pressure. It is previously heated in a cylinder by steam pipes, which raises it to a very high temperature. It seems to work very well; but I think that perhaps naphtha will work better than crude oil, although it is more expensive.

Mr. Addicks—I think it is a fortunate thing that you do heat it, because if you put it in cold, and sprayed it, it would have a worse effect. I think that the preheating which you give it now serves to counteract the spraying in at high pressure.

Mr. Neal—Do you think I could adopt that method so we could use crude oil in works of that kind?

Mr. Addicks—I think it is a matter for experiment with each style of generator.

Mr. Shelton—I would corroborate that also. I think crude oil is harder to handle than naphtha. Naphtha is a uniform and homogeneous substance, and you can take a single superheater and make gas without trouble. If you make tar or lampblack it is your own fault; there is no necessity for it. But with crude oil you have all sorts of things to contend with; and you have to handle it with a great deal more care. In Mr. Neal's case, where he has the Granger apparatus and a single superheater, it is necessary to watch the heats very closely so as not to crowd the apparatus in using crude oil. In that case I think heating the oil to the highest degree possible holds true of crude oil. That crude oil can be successfully used with the Granger apparatus or with any single form of superheater apparatus I would verify by calling upon Mr. Jenks, as I have the impression that he has used a great deal of oil in the same way that Mr. Neal desires, and with entire success. I think he would prefer to use naphtha if there was no difference in price; but a little difference in price is enough to cause him to favor crude oil.

Mr. Jenks—I was about to ask Mr. Addicks if he thought that the raising of the temperature of the oil before passing it into the apparatus compensated to any degree the lack of superheating surface before reaching the scrubbers.

Mr. Addicks—Unquestionably.

Mr. Jenks—That being the case, I would say "Amen" to an apparatus of that kind, and for this reason. Mr. Neal has facetiously referred to Woonsocket and its gas engine. We have a gas engine in Woonsocket. We also have a double set of water gas apparatus known as the Granger-Collins style, and we are very well pleased with it. There is, however, this feature about it, that in the use of Lima crude oil (and that is what we have always used) we find we have to be extremely careful, not on account of the stoppage in the superheater, however (for I have never seen a speck of lampblack in the superheater), but on account of the lampblack and tar collecting in the wash-box, or seal, as coal gas men would call it, between the superheater and the scrubber. There we have to clean periodically, perhaps, on an average, once a week. Sometimes we find it quite heavy, at others comparatively light, depending on the care that the gas maker has exercised in the operation of his apparatus during the time which has intervened. Mr. Shelton is quite right when he says I would indorse the use of Lima oil, especially when you consider the fact that naphtha costs twice as much. But my opinion is that the setting which the U. G. I. Company are now putting in, known as the double superheater setting, is far in advance of the setting we now have, especially when it is desired to use Lima oil. I think if Mr. Neal had another superheater he would get along without any trouble whatever. While I should like another superheater connected with our works, nevertheless I do not propose to change to naphtha on account of the difference in price. I would rather put up with the extra trouble that the heavy oil occasions.

Mr. Sherman—I would like to ask Mr. Addicks how many gallons of crude oil he uses to a given candle power; say, 22-candle power?

Mr. Addicks—I can only say in reply to that, that we are using naphtha and crude oil, and are getting above 5-candle power per gallon of naphtha. With the vaporizer our candle power went at once up to 6-candle power per gallon of naphtha used. When using crude oil we use it half-and-half, so that it is hard to determine exactly what we do. We are now running about 5-candle power, or a little over, to the gallon. That is our result so far. What the candle power is definitely, after it gets from the works, we have very little opportunity of knowing

thoroughly and satisfactorily. I should say, though, that 5-candle power to the gallon would be a fair estimate for half-and-half.

Mr. Jones—I would like to call the attention of coal gas engineers to the advantages of vaporizing oil before putting it into the retort where it is used as an enricher. I regret very much that I was unable to be here to listen to Mr. Addicks' interesting paper; for I well know that he would not read any other kind of paper. Some time ago I began vaporizing, at the North End gas works, the naphtha before putting it in the retort; and the result has been that I am enabled to use the same amount of naphtha for enriching our gas with 12 retorts that I was before obliged to put into eighteen retorts, and with the further advantage that when I slack off the lid of an oil retort the retort is hot. Before, when I slacked off the pipes through which the oil was passed in, portions of the retorts were black, thus showing that by putting liquid naphtha into the retort we were overworking the retort. There certainly is an advantage in vaporizing oil before it is put into the retort, in the saving of fuel alone. At the North End works I am saving fuel in that way. I am getting better results from the naphtha used, and the naphtha is being converted into commercial gas; and I am positive that less of it is condensed out in passing through the apparatus. I think this matter is well worthy the consideration of all gas engineers who are using naphtha for enriching.

Mr. Prichard—Will Mr. Jones describe his vaporizer?

Mr. Jones—It is the vaporizer that has been already described by Mr. Addicks—a coil of naphtha pipes with a steam jacket.

Mr. Allyn—How do you introduce it into the retort?

Mr. Jones—Through an inch pipe, directly from the vaporizer. There is a main pipe leading from the vaporizer, and from that I take a pipe to each retort. The vapor is carried through a series of pipes inside of the retort. It is the well-known method of breaking up naphtha. There is one wrought iron pipe within another. The vapor traverses nearly the length of the retorts four times before passing up the stand-pipe.

Mr. Neal—How do you obtain your pressure—by gravitation or mechanically?

Mr. Jones—The pressure of the liquid when expanded to a vapor will carry it into the retort.

Mr. Lane—Have you done anything with crude oil?

Mr. Jones—I have not.

Mr. Sherman—How many gallons of naphtha will one retort take care of per hour?

Mr. Jones—We use 2,000 gallons in 12 retorts, and under the old method it would have taken 18 retorts to work it off properly.

Mr. Sherman—How much is that per hour for each retort? As we have used it we have thought that it would take care of about 7 gallons per hour without vaporizing.

Mr. Addicks—That brings up a question that I wanted to ask—and that is how many gallons went into the retort per hour? He is only using a 1-inch pipe—I have recommended 2½ to 3 inches—but we put in four gallons per minute.

Mr. Lane—With us we use five gallons on an average, and introduce it in much the same way.

Mr. Neal—Does Mr. Jones introduce the naphtha by spraying it over the coal?

Mr. Jones—No; the vapor is introduced into oil retorts.

Mr. Learned—What is the relative value of crude naphtha at 68, as compared with crude oil at 40 B?

Mr. Jones—As I have had no experience with crude oil at the North End station, owing to the locality, I cannot reply to that question.

On motion of Mr. Allyn, a vote of thanks was tendered to Mr. Addicks.

The next paper read was that by Mr. E. H. Yorke, of Brockton, Mass., entitled

PROBLEMS CONSTANTLY BEFORE THE GAS MANAGER.

Mr. President and Gentlemen:—By invitation of our Secretary, and feeling it to be the duty of every member of the Association to contribute to the success of the meetings, the writer reluctantly—because of their being abler hands in the Association to intrust the preparation of papers—consented to prepare a paper. Although able papers have been presented, touching, it would seem, on almost every theme, and the ground has been pretty thoroughly tilled, still even if old topics are again presented in a new garb, and the soil again turned over, it ought to yield a rich return. Your attention, therefore, is invited to some problems which are of necessity uppermost in the minds of every gas manager.

The life of a gas manager is one essentially of study. The complex and diversified character of his business calls for a broad and compre-

hensive knowledge of mechanical, scientific and commercial principles and methods.

Starting in his undertaking of managing the affairs of his company, he finds a capitalization, plant and income established by those before him, and which, even if of unequal proportions, he must deal with, so as to secure a reasonable return on the capital invested. Although limited in his opportunities for securing patronage by the confines of the town or city and its neighborhood in which his plant is established, he must so manage as to secure a sufficient sale of his product to meet his operating expenses, keep his plant in repair and order, and have a margin left for dividends. To these imperative requirements he will naturally supplement efforts to improve and increase the efficiency of his plant, to reduce the cost of his product to the lowest possible point, and to increase the revenue of his company. The successful accomplishment of these ends involves careful study and reflection, close application and untiring industry; for in no other way can the solution of the many problems that will constantly present themselves to him be accomplished. Of the larger and more important of these problems, that of cost of production will claim his constant attention. The competition of other forms of lighting makes it imperatively necessary that the cost of production shall be at the lowest possible point, if the general use of gas is to be maintained. While the wide difference in the conditions in the different works admits of no general standard of cost of production being established, there are, however, certain details in the operations, the cost of which should be as low in one works as in another; and if the gas manager finds that another manager, in one of these details, has attained a lower cost, there is obviously an opportunity for him to lower his cost by the employment of the same means and methods.

In entering upon a contemplation of the problem before him he will naturally commence with the cost of materials; and in this detail of the cost of product can accomplish much by calculation and effort. In coal, the yield of gas, quality of gas, and amount of sulphur will be the leading factors, in determining which coal is the cheapest in the end. To illustrate: Assuming that coal A and coal B cost the same in the market, and coal A yields 400 feet of gas per ton more than coal B, and this gas is worth 15 cents, but the cost of purification is one cent per thousand, and enriching two cents more with coal A than coal B, it is obvious that coal B is the cheapest coal in the end. And thus with materials for enriching and materials for removing the impurities from the gas and details of expense of carriage and handling can the minimum of cost be attained by study and effort. Assuming that he has purchased his materials at the lowest possible cost, the next step will be to consider the economical treatment and realization of the maximum of values in them.

As coal is the basis of his product its manipulation comes first for consideration. Having secured a coal whose qualities average the highest, the first item of expense will be the moving of this coal and depositing in retorts or generators. In doing this there should be the least expenditure of manual labor and the economy secured, by a utilization of the laws of gravity, should be substituted, not with complicated and expensive machinery, whose maintenance is costly, but with simple and durable arrangements. Having placed his coal in his carbonizing chambers, at the minimum of cost, the next thing in order will be the realization of the greatest production of gas from the coal. Practice and experience have demonstrated that five cubic feet of gas is about all the gas the coal contains per pound, to be yielded by destructive distillation, and having secured this result the gas manager may reasonably dismiss this item in the cost as admitting of no further reduction.

His next inquiry must be with reference to the kind of apparatus required to produce the necessary results. If he contemplates the introduction of apparatus of new forms in substitution for the old, he will need to consider the outlay required, the advantages and economies to be secured, and should have unquestionable evidence that he is adopting apparatus that has proved good; inasmuch as expensive experiments are alike unprofitable to himself and his company. He will need to carefully analyze every detail, and the requirements in all its parts, and be fully assured before adopting the new apparatus that every requirement is fully met, and that it does not possess even a single fault which would make its use impracticable when put into practical operation. He should especially guard against allowing the advantages represented to obscure to his vision the defects, if any exist. It will be well for him to profit by the researches and experience of other managers, and the more information he acquires relative to their investigations the better he will be able to arrive at correct conclusions. But it will not be wise for him to be guided by the experience of a *single* manager; for he will find, while seeking information, this most anomalous

state of things—namely, that while one manager has introduced a plan or apparatus and pronounces it a success, and is enabled with it to accomplish profitable results, that another engineer, held to be equally able, having tried the same plan, condemns it.

Returning to the point in his inquiries as to the best and most economical kind of apparatus for him to employ, he must determine which of the two processes—namely, coal gas or water gas—will best accomplish the desired end. The two primary factors in this question will be the cost and quality of the gas by the two systems. His investigations in this connection will develop these facts, namely: That with the water gas system he can distribute a gas of greater brilliancy without it smoking, when used in ordinary burners, than he can with the coal gas system. This will commend water gas in this particular, for his experience, doubtless, has convinced him, in these days of lavish illumination, that the more brilliant his gas the more successful it will be in its competition with other forms of lighting, and the more generally it will be used.

In steadiness of flame, he will find that the water gas flame is much more steady than the coal gas, and this will commend water gas; but as a slight off-set to this superiority of water gas he will find that its flame area is less than that of coal gas.

Thus far the weight of evidence has been in favor of his adopting water gas; and he must now examine it in other particulars to see if it possesses any defects which would overbalance its advantages. He will find that water gas contains at least 28 per cent. of CO, which increases its specific gravity to at least 40 per cent. above that of coal gas. He will find that the effect of this increased specific gravity is somewhat of a disadvantage in a two-fold way—to wit, the capacity of his mains for distributing a given quantity of gas will be 21 per cent. less than with coal gas, and the registration of gas by his meters will be diminished in like proportion; but this disadvantage will be partly off-set by diminished leakage. Of the character of the CO, while known that its effects are somewhat more detrimental to health than pure carbureted hydrogen, when breathed in excessive quantities for an extended period, but as numerous cases of asphyxiation have shown but little practical difference in the effect, the presence of CO in the gas need not be regarded as a serious objection.

The cost of the two gases will come next for consideration. He will find, on a make of 100,000 cubic feet per day, that the cost of the respective gases, at outlet of hydraulic main and superheater (the expense beyond will be the same with both gases), will be as follows, to wit:

Water Gas.

Materials—41 lbs. of fuel in generator, at \$4.92 per	
2,240 lbs.	09 cents.
10 lbs. of fuel for steam.....	02½ "
4 galls. of oil, at 5 cents	20 "
Labor.....	03 "
Wear and tear.....	01 "
Total.....	35½ cents.

Coal Gas.

Coal, less residuals.....	20 cents.
Enricher.....	05 "
Labor	08 "
Wear and tear	02½ "
Total.....	35½ cents.

He will, therefore, find, in the matter of cost, that one gas can be made, practically, at as low a cost as the other. His decision, therefore, must rest on other considerations.

He has already determined, in point of brilliancy and steadiness of flame, that it will be best for him to manufacture water gas, but in point of specific gravity, that coal gas would be best. This places him in a position where the conclusion is obvious that the best ends will be served by employing both processes, and manufacturing a gas of part water gas and part coal gas. His conclusion to employ a water gas plant will be strengthened by other advantages of value, which its possession will secure to him, namely, he will not require as much storage room for coal and coke, with the attended cost of construction and expense of repairs. He can manufacture the requisite volume of gas, with smaller purifiers and less holder room; he can better meet the fluctuations in consumption, and thereby increase the surety of his supply, than he can if he employs the coal gas system alone; and, finally, the possession of a water gas plant will diminish his dependence on labor; and organized attempts of labor, to force him to a compliance with its views, will be of but little avail. Having determined this detail in the problem before him, he will next consider the kind of benches he shall employ to car-

bonize his coal at the minimum of cost. The primary considerations in this question will be the cost of the bench, per 1,000 feet of gas, that it produces during its lifetime, its operating without trouble, its effective use of fuel, and its production of gas, per wages for labor. Taking up this question in its details, he must, first, determine whether he shall employ the horizontal or inclined plan of setting retorts. The economy of labor in the inclined system will commend it; but if he concludes to adopt the horizontal system, he must, first, determine the size of retorts he shall employ. The disadvantages of retorts of greater dimensions than 16 x 28 inches, 9 feet long, and the poor economy in using those of smaller dimensions, will commend this size to him. In number per bench, he will find that 7 will be more economical than a less number, while a greater number would bring disadvantages in furnace requirement and height of retorts.

At this point in his inquiries he must determine the kind of furnace that it will be best and most economical for him to employ. Whether simple furnaces and direct heating, or the employment of the regenerative principles, or the conversion of his coke into gaseous fuel in separate chambers, and burning these gases under his retorts, or the utilization of his tar for fuel purposes, will best answer the ends, can only be determined by a very thorough consideration of the principles involved and the action and effect shown by the different plans when used in practical operation. While he will not expect to be able to carbonize his coal with as low a number of heat units as is theoretically sufficient, he will hardly be satisfied to use a simple furnace and direct heating when its use requires at least 50 per cent. of his make of coke to carbonize his coal. He will, therefore, turn to the regenerative principles as a means for securing the greatest economy of fuel. The elements in this question (if he concludes to use a furnace of moderately simple construction) are: First, width and length of furnace, which should have a superficial area of at least 960 square inches; second, a depth sufficient to maintain a fire at least 30 inches deep; third, primary air flues of as large dimensions as the circumstances will allow, in order that excessive draught shall not be necessary; fourth, secondary flues of such form that the air currents will have to pass through a continuous flue of at least 28 feet in length; fifth, a continuous circuit for combustible gases, of at least 30 feet in length, with exits for secondary air at successive points; sixth, stack draught sufficient to maintain a vacuum of at least four-tenths of an inch. Supplementary to those essential elements will be the need that the combustion of the coke shall be moderately slow, the speed of the combustible gases not over 35 per second, and the temperature of the waste gases not over 500° F. If he secures a bench of this description, and is successful in the management of it, he will carbonize his coal with 25 per cent. of his make of coke, and will be able to work off 300 pound, 4-hour charges, will secure 63,000 cubic feet per bench, and may reasonably dismiss this detail, in the cost, as having accomplished the minimum of cost.

The next element in the cost of product for his consideration will be the cost of purification of his gas; and under this head may be included condensing and washing. How best to accomplish a thorough separation of the ammonia and tar from the gas without extracting a portion of the heavy hydrocarbons admits of much consideration. In the removal of the sulphur and its compounds and CO₂ the item of expense will be for materials for purification and labor in handling them. He will find that the cheapest effective purifying agent for extracting the sulphur is a mixture of coarse sawdust and oxidized iron borings. The removal of the CO₂ can be accomplished with lime, and if he have purifiers of a superficial area of 30 square feet per 15,000 feet of gas made, he can purify 50,000 feet of gas per bushel of lime. If he can find a means of revivifying his oxide in his purifiers he will have accomplished the minimum of cost in purification. But should he be unable to revivify his materials *in situ*, that plan which requires the least labor will obviously be the least expensive.

Beyond this point no large opportunities exist for effecting a material reduction in the cost of production; but it will be well for the gas manager to remember that in the minor details of expense ways and means can be found for reducing the cost of them.

While but a general outline of this problem and its solution has been attempted, its treatment has been sufficient to suggest the conditions, means and ends in the question of cost of production.

The next problem constantly before the gas manager, and which stands second in importance to cost of production, is the problem of how to increase the revenue of his company. In considering the opportunities and means for accomplishing the solution of this problem, it will be well for him to start with a consideration of the conditions of supply and management essential to its solution. Quality of gas; this should be as high as it will be judicious for him to distribute; for a high illu-

minating power will favorably influence the increased use of gas. Uniformity in quality is important, and variations in quality should be carefully avoided. The pressure on all the mains should be ample for all requirements; as insufficient pressure, due to mains inadequate in capacity to pass the requisite volume of gas, will obviously cause dissatisfaction among the consumers and effect a reduced sale of gas. Obstructed services, stiff meters, and riser-pipe elbows filled with rust should be sought for and remedied. Attention to consumers' burners, in seeing that they are of proper size and construction, and are properly adjusted, will do much towards increasing the general and satisfactory use of gas, while the judicious and free distribution of burners will materially assist this and return large profits for the outlay.

Cheerful and prompt attention to complaints, courteous treatment of consumers and an accommodating spirit are essential. The sentiment of the community in its relations to the gas company is an important factor. The management should be such that the company will be regarded as fair in its dealings, liberal in its spirit, and progressive in its aims and purposes. But dissatisfaction with the size of the bills will arise among the consumers, even if all the foregoing principles and methods are practiced. With these dissatisfied patrons much pains must be taken, and the reason why their bills are of such amounts made clear to them. It will be well to explain the principle and operation of the meter and its dial, and show them how errors in reading the indices will correct themselves. If this is not sufficient to satisfy them, the meter should be removed and tested on the meter prover in their presence. The imparting of this information will do much towards eradicating that element of distrust, the mystery surrounding the gas meter and gas bills, and which materially retards the more liberal use of gas.

Having determined on the principles and methods which he purposes to employ to establish conditions favorable to the retention of present consumers and addition of new, he will next turn to a consideration of the opportunities that exist, and means which he can employ to secure new users. In his examination of the opportunities for securing new patrons, he will find in that great body of non-users, which exist in every district supplied with gas, a prolific field for effort. In viewing this non-use of gas by many residents of his community, and in seeking for the reasons therefor, he will find them to be: First, the subject of gas not occurring to their minds; second, deficient appreciation of the value and advantages of gas; third, an opinion that it is too expensive. Of the various uses to which these non-users may apply gas, that of lighting, ventilation, heating of rooms, of irons for tailors and hatters' use, of coppers for tinware, of water for the bath, in cooking in families, restaurants, hotels and bakeries, and in gas engines for power purposes, will suggest themselves. These conditions in the non-use of gas call for his pursuance of the following, namely: First, he must bring to the minds of these non-users, the subject of gas; second, he must present its advantages in point of quality and volume of light, cleanliness, convenience and safety; third, he must present a simple statement of cost per burner per hour, and an approximate cost when used under stated conditions.

Of the means and methods which he may employ, it will be well to start with an exhibit at the company's office of the different kinds and sizes of burners, gas stoves, and a gas engine in operation, together with a generous supply of printed matter. Circulars through the mails and the columns of the press will serve as means to draw attention to gas and disseminate information relative to its advantages. Self-lighting burners furnish a minor means for promoting the use of gas, inasmuch as they enhance its convenience. The economy and advantages of the regenerator lamp will contribute to securing new uses, and its introduction, even at a low rental, will bring large returns in profit on sales of gas. The quality of light, steadiness and complete combustion of the gases, make the incandescent gas burner a useful agent in promoting the use of gas, and, finally, in appliances, the gas stove and gas engine offer a means to the gas manager of the largest character for increasing the revenue of his company.

In *methods*, that of personal solicitation will be the most effective; and in view of the field for effort and all the conditions, the employment of a thoroughly informed man, of good address, to solicit new takers ought to be attended with highly profitable results. This solicitor would find large opportunities for employing his talents and energies in increasing the use of gas for the various purposes to which it is applied, and doubtless would be able each year to secure a large number of new takers. He also could comprehend in his duties the inspection of consumers' lighting, and could do many things which would effect the retention of present consumers, the increased use of gas by them, and their better satisfaction with gas and the expense of its use.

One more important means suggests itself to the gas manager for in-

creasing the revenue of his company, and that is in extension of mains. This will be constant with the growth of the town or city, and as it involves a permanent increase in the capital invested in plant, and creates a constant expense in interest, leakage, care, repairs, depreciation, and liability for damages, it calls for very careful consideration. A presentation of all the details of this question would reach beyond the limits of this paper, and the author has, therefore, undertaken but a cursory consideration of the main factors in it and the means which may be employed in accomplishing an increase in the revenue of the company.

The next important problem constantly and permanently before the gas manager is the problem of electric lighting, its present and prospective effect on the gas business, and how best to deal with it. Now, that several years have elapsed since the general introduction of the electric light, both arc and incandescent, the use of it from its novelty and sentimental considerations, is rapidly fading away, and it is being weighed and measured by the hard and practical measurements of commercial estimate of value.

That people like and turn to new things is a self-evident proposition. The control of such a mysterious and subtle agent as electricity had a charm and fascination for most people. Everything electrical has been at the "top round" of popularity for several years; but, unless the signs are wrong, people are beginning to put the electric light in the balance and weigh it for its worth. The moving of a lever and the instant illumination of space remote has lost its charm. The practical turn of mind of people has commenced to assert itself, and the future of electric lighting is to-day somewhat problematical.

Such, then, is the status of the subject which is the basis of the problem now before the gas manager. In entering into a consideration of the details of this question, he will commence with the cost of generating and distributing electricity, and to avoid the confusion of the two lights, the arc and incandescent, will first consider the latter.

Information sufficient for his purpose will be acquired from the results as shown by established electric plants, and which show that the operating expenses have about equalled the revenue, although the charges for light have been about 50 per cent. above the cost of gas lighting—the number of candles being the same in both cases. Reasons for this will be found in the excessive wear and tear of the electric system. For these reasons the conclusions will be forced upon him that as a means for the profitable employment of capital, the business of furnishing electric light offers no inducement. In examining that aspect of the question which relates to the future of the incandescent electric light, he finds that these objections to its use present themselves, namely, that it is not a reliable light, due to the very nice conditions necessary for its perfect operation; that the lamp has a most uncertain lifetime, and subjects its user to much annoyance and trouble by its frequent breaking; that it steadily diminishes in candle power, in exact ratio to the time it is used. Its claims for superiority over gas are, that it is more convenient, gives off no heat, and doesn't vitiate the atmosphere of rooms. Examining these objections in detail, he finds that users are not much influenced against it because of its unreliability, or the frequent breaking of the lamp bulbs, or its inherent quality of diminishing in candle power.

The matter of its increased cost above gas lighting, if the considerations of its claimed advantages have weight, will not effect its general use any more than the increased cost of gas over other lighting agents did when gas came into use, although the difference is less in comparison between electricity and gas. The conclusion, therefore, appears obvious in view of the extent that the incandescent light is established and used, and the length of time that it has been in use, that the probabilities point to its continued use. The gas manager, therefore, is confronted with these facts and this additional one, namely, he sees the steadily and increasing investment in electric lighting, which he realizes may be a menace to his business, hence it would be well for him to enter the field and retard this accumulation of outside inimical capital. If he now establishes an electric plant, and the events of the future should demonstrate that the electric incandescent is to do the lighting, he is in a position to maintain his business and find employment for the vested capital of his company.

Of the arc light there is but little to be said. Its value for out-of-door illumination cannot be questioned. It occupies a field distinctly its own, and meets requirements in street lighting which cannot be met with gas. It is strongly entrenched in its position, and modern civilization will not consent to its displacement by any of the other forms of illuminants. Its position, therefore, is a prominent one, and must be recognized as such by the gas manager, and the earlier (if he has not already done so) he establishes an electric light plant, and secures a portion of the lighting (commercial and municipal) the better he will consult the ultimate interest of his company. He may not succeed in making any money

for his company by distributing electricity, although from the advantages of his position, he will probably be able to earn enough to meet his operating expenses, with a margin for depreciation, but he will do that which it is eminently his duty to do, namely, to preserve and protect his company's interest.

In conclusion, while doubtless but little instruction will be found in my treatment of these problems, and issue will be taken with some of the conclusions, still if it directs attention to the subjects, and suggests new consideration of them, it will serve the useful purpose for which we are all assembled here to-day, namely, the consideration of the problems constantly before us. I thank you for your kind attention.

On motion of Mr. Stiness, a vote of thanks was tendered to Mr. Yorke.

(To be continued.)

Notes on Fuel Gas.

[Read by Mr. G. W. GOETZ, at the Washington Meeting of the American Institute of Mining Engineers.]

As is well known, the general use of natural gas in Pittsburgh and vicinity for domestic and industrial purposes has shown the great advantages and benefits to be derived by the use of a gaseous fuel. In order to ascertain and bring together all the facts relating to a large and economical production, purification, distribution and consumption of fuel gas made out of coal, the Fuel Gas and Electric Engineering Company, Limited, was organized under the presidency of George Westinghouse, Jr.

Interviews with leading authorities, in this country and in Europe, and a careful perusal of the enormous literature on this subject, brought out so many conflicting statements as to show the necessity of experiments, on a large and practical scale, to get accurate data to base ideas upon, and to ascertain the practical difficulties and merits of the respective processes proposed. A large number of experiments were made as to the possibilities of water gas, illuminating gas, producer gas and oil as fuels. A bench of retorts, producers, water gas apparatus, condensers, scrubbers, meters, a laboratory, and a holder, with a capacity of 50,000 cubic feet, being at disposal, it was possible to test the properties of the different gases obtained and to make mixtures of them in any desired proportion. All these experiments were controlled by carefully made gas analyses.

Interesting experiments on the diffusion of gases in a large holder when two gases of different specific gravity enter the holder alternately or at the same time were also made, as well as a large number of tests on the combustion of different gases. Mr. Frederick Siemens' statements on luminous flames and on heating by radiation were fully corroborated by carefully made tests; and gas burning devices, based on the radiation of heat from luminous flames, were developed which will give an efficiency of 84 per cent. of the original heat units in the gas, 54 per cent. of which results in radiant heat and is reflected on the floors of a room. Producer gas is undoubtedly the cheapest fuel gas that can be made, and answers all purposes where the air necessary for its combustion can be heated by the off-going heat of the furnace. Tests have shown, however, that producer gas carries too much nitrogen to permit its distribution to a community, since, in consequence of the presence of this constituent, its calorific power is too low, and its flame extinguishes so easily as to be dangerous for household use. It was important to know how many cubic feet of producer gas 1 ton of coal will give. Conflicting statements as to this point will be found in the literature of the subject, the figures ranging from 150,000 to 250,000 cubic feet per ton. To get at the actual figures by a practical test a ten days' run, night and day, was made. Pittsburgh coal of the following average composition was used:

	Per Cent.
Water	1.26
Volatile matter.....	36.22
Fixed carbon	57.98
Sulphur	0.70
Ash	3.78

In order to get a gas very low in carbonic acid, a much larger depth of fuel than is generally carried in producers was required; and, as it is impossible to poke by hand such a deep fire, a pneumatic rammer was placed upon the producer. This rammer consists of a cast iron ring so constructed that it will not only exert a pressure upon the coal, but also force the coal to the periphery of the producer—which is desired, because the gas has a tendency to creep up along the walls. The ring is raised by air pressure and allowed to fall upon the fuel, the stroke given depending upon the blow desired to make the fuel sink regularly.

A producer of the above type can burn from 12 to 15 tons of coal in 24 hours. A positive air blast is used, and steam is admitted under the grate, the admission of both being controlled by valves at the top of the producer. The result of a 10 days' run, carefully metered, showed that 1 ton of Pittsburgh coal will give, on an average, 131,280 cubic feet of purified producer gas, corrected for barometer and temperature. The gas from the producer passed through scrubbers, condensers and meters, and thence into a holder of 50,000 cubic feet capacity. The carbonic acid in the gas was at times as low as 1.4 per cent., but the average percentage was about 3.4 per cent., at a pressure of 4 inches of water. With a pressure as low as is generally carried on producers in connection with steel melting furnaces, the carbonic acid could have been easily kept at 1 per cent. with such a deep body of fire in the producer. The average composition of the gas was:

CO ₂	3.4
CH ₄	3.1
H.....	9.2
C ₂ H ₄	0.8
CO.....	25.3

The remainder was mainly nitrogen. This experimental determination of the amount of producer gas obtainable from 1 ton of Pittsburgh coal, will enable engineers to judge what they are likely to get from other coals. An interesting fact as to the heat units required to puddle 1 gross ton of pig iron was determined by the engineers of the above company. The experimental gas furnace employed, with regenerators for air only, was designed and superintended by W. F. Zimmermann.

The ordinary single handed puddling furnaces used in Pittsburgh consume about 36,000,000 British heat units per gross ton of pig iron, whereas when gas is employed about 14,000,000 heat units will do the same work. It was found that 13,250 cubic feet of natural gas, with 1,100,000 heat units per 1,000 cubic feet, will puddle 1 gross ton of pig iron, whereas by using a gas with nearly 300,000 heat units per 1,000 cubic feet, 47,000 cubic feet were consumed, and by using a gas with 266,000 heat units 54,000 cubic feet were used to puddle 1 gross ton of pig iron. The number of cubic feet of gas consumed, multiplied by the respective heat units in 1,000 cubic feet, will, in each instance, give somewhat above 14,000,000 heat units.

These results clearly show that if all circumstances as to the production and consumption of heat could have been considered in these experiments the amount of gas used in each case would have been exactly inversely proportional to the heat units contained in the gas. This result could, of course, be expected from the laws of heat, but it is, nevertheless, an interesting fact to have it experimentally demonstrated on a large scale. This result on puddling, and similar results on the consumption of different gases to evaporate water, combined with many other considerations, has led to the important conclusion that it is not advisable to distribute a gas for domestic use with a comparatively low amount of heat units per 1,000 cubic feet. The higher the heat units per 1,000 cubic feet the better, especially when the gas is to be widely distributed.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE Salem (Mass.) Gas Light Company is soon to occupy its new plant on Bridge street, which is very complete. Mr. John W. Leighton, of Boston, has been chosen President. One particular advantage of the new establishment is the facility with which supplies can be handled.

THE following letter will prove of interest:

SPRINGFIELD GAS AND ELECTRIC LT. CO., }
 SPRINGFIELD, MO., March 7, 1890. }

To the Editor AMERICAN GAS LIGHT JOURNAL:—I notice your remarks in your valuable JOURNAL, of March 3d, about the Laclde Gas Light Company adopting the Coze system of inclined benches. I am pleased to see it because it proves to me that I have not gone far astray in adopting this system here. My excavation is almost ready, and I hope to lay the foundation stone next week, and hope to have the bench under fire at the time of the convention, so that, if it cannot be seen in St. Louis, if the members will come to Springfield I will be glad to see them and show them what I now call improvements upon the original Coze bench in St. Louis. I have had the honor to place the first order for this style of bench with the Laclde Firebrick and Manufacturing Company.

Yours, truly,
 JOHN GIMPER.

AT the annual meeting of the Memphis (Tenn.) Gas Light Company the Directors chosen were Messrs. William A. Williamson, W. S. Bruce, Napoleon Hill, Enoch Ensley, N. M. Jones, John S. Bransford,

and R. Dudley Frayser. This selection shows that Mr. Samuel Prichitt has been succeeded by Mr. Bransford, while Mr. R. D. Frayser takes the place of Mr. Henry Craft. It has been well known for some time that Mr. Prichitt was not enjoying the best of health, but it was hoped by his friends, a wish that was also shared by the stockholders in the Memphis Company, that he would still consent to remain in harness. His declination, however, was positive, and we join with the fraternity in an expression of regret over the first step in his retirement from the active practice of his profession, whose membership will ever hold him in affectionate regard. Mr. N. M. Jones was re-elected President, and Mr. Joseph Craig will also retain the position of Secretary.

WHILE regretting his declination to longer serve on the executive management of the Memphis Company, we are on the other hand able to congratulate Mr. Prichitt on the fact that he is to retain his connection with the Nashville Company, of which enterprise he is virtually part and parcel. The Directors chosen at the last meeting (6th inst.) the Nashville Company are: Messrs. Samuel Prichitt, T. D. Craighead, S. M. Murphy, V. L. Kirkman, Thomas Plater, Jas. Simmons and M. M. Gardner.

JOHN DEVOR, President of the Greenville (O.) Gas Light Company, has made an assignment. Among those who figure on his list of creditors we are sorry to note the name of R. R. Dickey, of Dayton.

FROM a recent issue (6th inst.) of the Chicago Tribune we take the following: "F. M. Charlton, through Beck & Charlton and L. P. Wilcox, solicitors, has filed a bill in the Chancery Court asking for the appointment of a receiver to take charge of the property of the Chicago Gas Trust, to sell its assets, franchises and privileges, and to wind up its affairs, under the direction of the Court. In the meantime it is asked that its officers, directors, agents, and confederates be enjoined from buying or selling the stocks of the associated gas companies, and from exercising any supervision or control over their acts. The grounds are that the Trust is not carrying on the business of manufacturing and selling gas and electricity as it lawfully might, but on the contrary is continually purchasing and selling the stock of the four companies composing it; that it controls their management by holding a majority of the stock of each, and that by its manipulations the interests of the stockholders are suffering. In 1887 the Chicago Gas Trust Company was organized under the general law. Its purposes as set forth in the charter were to build, erect, purchase, lease, establish, maintain, and enlarge works in the city of Chicago and elsewhere for the manufacture, supply, sale, and distribution of gas and electricity, and to purchase and hold the stock, property, plant, and goodwill of other companies. The capital stock was \$25,000,000, consisting of 250,000 shares of \$100 each. Charlton claims that he is a holder of shares in the Trust, which would be of great value to him if the Company would erect the necessary buildings and apparatus for the manufacture and distribution of gas and electricity. He claims that the officers of the Trust never had any intention to carry out the object set forth in the first clauses. On the contrary, it has conspired with the officers of the Chicago Gas Light and Coke Company, the Peoples Gas Light and Coke Company, the Consumers Gas Company, and the Equitable Gas Light and Fuel Company, of Chicago, to control a majority of the shares in each, and thereby to suppress competition, to destroy their diversity of interest, and to build up a monopoly in the manufacture and sale of gas in Chicago. By reason of this combination and conspiracy, and because the Trust does not go ahead and make and distribute gas, Charlton claims that his stock is more than 50 per cent. below par, and is likely to become, through manipulation of the markets, practically worthless. Further, it is set forth that the Trust organized for the purpose of crushing 'competition,' is not only destroying the value of the stock owned by him, but is creating a monopoly dangerous and injurious to the best interests of the people. He claims that under the decision of the Supreme Court, in the case of 'The People, ex rel. Peabody vs. The Chicago Gas Trust Company,' rendered last November, the Trust should be enjoined." Mr. Charlton and his attorneys have managed to put together a goodly share of claptrap in their "complaint."

THE authorities of Salem (Ohio) have determined to abandon the use of incandescent electric lamps for lighting the streets. Arc lights will take their place.

THE shareholders of the Belleville (Ills.) Gas Light and Coke Company and of the Belleville Electric Light and Coal Company will, on April 1st, vote on a proposition to consolidate.

ONE of the Helena (Montana) City Fathers created a hearty laugh in the meeting room a fortnight ago by gravely remarking that the local Gas Company was to be commended for its liberality in reducing the gas rate from \$3 to \$2.50 per gallon. A rather condensed way of putting it.

CONSIDERABLE plant additions will be made to the Omaha (Neb.) Gas Manufacturing Company's system.

DR. MORFIT is responsible for the introduction of an ordinance in the First Branch of the local government of Baltimore to regulate the "laying of gas and other pipes, railroad tracks, electric light, telephone and telegraph wires, in, upon, under or over the streets, lanes and alleys," of the city. Hereafter when any corporation or person is desirous of using the streets for the purposes named they must first obtain written permission from a board, composed of the Mayor, City Commissioner and City Comptroller, to be granted upon such terms and conditions, and subject to the payment to the city for any such privilege of such "equitable sum of money as may be determined by the board." The ordinance was referred, in which state it is hoped it will remain; for, certainly, a rarer gem in the line of a plan for extortion, it has not been our fortune to encounter.

A SUIT for \$5,000 damages has been instituted by Albert I. Thompson against the Worcester (Mass.) Gas Light Company, who asks for this sum because of personal injuries received by him through an explosion of gas on the evening of February 25. Plaintiff alleges that a gas meter had been set in a faulty manner by the agents of the Company in a certain place in the Esterbrook Building, and because of that faulty construction, plaintiff (whose duties obliged him to ignite a match close to the meter) received a severe shock and serious burns in the explosion of gas that followed. Defendant replies that plaintiff acted wrongly in lighting the match, because he must have known that such an act—he was aware that gas was escaping either from the meter or from some break in the service close to it—would imperil his person; also, that if there was a defect in the setting of the meter, it was his or the tenant's place to notify the Company. The case will be tried at the April term of the Superior Court.

THE street lighting service of Lincoln, Neb., calls for the maintenance of 298 gas lamps and 224 gasoline lamps. The city owns all the gas lamps, posts, etc., and the Gas Company furnishes gas and lights and extinguishes, receiving pay therefor at the rate of \$1.75 per lamp per month—moon table. The gasoline lamps, posts, etc., are owned by the contractors, who maintain and repair the same, and also furnish lighting material, and light and extinguish, for the sum of \$1.33½ per lamp per month. The City Engineer estimates that each gas lamp—the city making all needed repairs to same—is a tax on the treasury in the sum of \$2.16½ per month.

THE proprietors of the Helena (Montana) Gas Light and Coke Company have reduced their selling rate from \$3 to \$2.50 per 1,000 cubic feet.

THE City Council of Omaha, Neb., have passed an ordinance creating the office of City Electrician.

THE Boston *Advertiser* says, in a Washington "special," dated the 6th inst.: "The recent Patent Office decision in the interference case of Wm. Stanley, Jr., against M. M. Slattery, better known as the Fort Wayne case, is one of great importance as affecting almost every electric light plant in the United States. The case was one concerning the right to use a converter in electric lighting, each party claiming prior invention of a system in which an adaptation of the converter to the dynamo by the length of its primary coil is a distinguishing element, and one which was not disclosed in some or all the prior publications in evidence. In the Patent Office decision it is held that the entire case turns on the fact that it is not regarded as essential to the invention in issue that in the construction of the converter the length of the primary coil should be made the one variable element to be adjusted to other conditions presented; on the contrary, it is believed to be sufficient to satisfy the terms of the issue that the length of primary coil be suitable to the other conditions presented, whether the length of coil be varied to fit the conditions, or the other conditions are varied to fit the length of the coil. It is thought that if the issue were of narrower construction the primary examiner would have required further terms of limitations to the claims involved. In accordance with this rule, priority of invention was awarded to Stanley, whose patent is the property of the Westinghouse Company."

MR. GEORGE W. MORRIS, President of the Louisville (Ky.) Gas Company, has notified the residents that the Company is ready to distribute

a non-illuminating fuel gas at the rate of 50 cents per 1,000 cubic feet. Perhaps Mr. Barret could be prevailed on to write something for the JOURNAL respecting the fuel gas plans prepared by him for his Company.

THE Fremont (Neb.) City Council has decided to submit a proposition to the people to vote \$10,000 for the construction of a municipal electric lighting station.

MR. THOS. FLANAGAN, has been elected Superintendent of the electrical department of the Portsmouth (N. H.) Gas Light Company. He has practically filled the position for some time past, and is in every sense equipped to carry on the duties of his post.

THE Oswego (N. Y.) Gas Light Company has reduced the gross rate to \$1.85 per 1,000 cubic feet, with 10 cents off for prompt payment, or a net rate of \$1.75. The Company has also notified its consumers that it will hereafter supply incandescent electric lights on an all-night circuit without any change in price of service—60 cents per month for each 16-candle power lamp.

THE following is from the annual report of Mr. W. C. Adams Superintendent of the Richmond (Va.) City Gas Works, respecting the operations of the gas department for the year 1889. Having called attention to the fact that despite the more general use of electricity for illuminating purposes, the receipts for gas were only \$1,832.64 cents less than in 1888, Mr. Adams goes on to say: "I would especially call attention to the limited purifying surface of the works. This is a most important factor in the manufacture of gas, and unless something is done to increase the capacity for purifying we will have serious trouble from impure gas during the next winter. The new retort house containing 10 benches of 6's was completed last April, and the results from these benches have been perfectly satisfactory. The walls of the old retort house were raised 10 feet, and a new roof put on, which conforms the old building to the new, and adds greatly to the comfort of the men. We are still in urgent need of a new holder, and as soon as practicable one should be constructed. The use of the incandescent electric lights reduced the revenue of the department to a slight extent last year, but we are gradually regaining our customers, and I think we will send out more gas in 1890 than in any preceding year since the works were started. I would recommend that efforts be made to increase the consumption of gas by the use of gas stoves. This branch of the business admits of large development and would greatly add to the revenues of the gas department. In Springfield, Mass., over 1,900 heating and cooking gas stoves are now in use. I think the time is near at hand when we will be able to reduce the price of gas to \$1.25 per 1,000 cubic feet. We should at once adopt a graduated scale of prices, by which large consumers could be offered inducements to continue the use of gas, for unless we do we will find that more of our best customers will substitute electricity for gas. It is the large consumers that are leaving us, and we must meet the competition that confronts us, or continue to witness a falling off in our gas receipts."

AT a meeting of the Committee on Manufactures (Massachusetts Legislature), held on the 5th inst., a hearing was had on the petitions of Charles E. Bowers and others and Michael Doyle and others for legislation authorizing cities and towns to manufacture and distribute gas and electricity. Mr. C. P. Greenough appeared for the Boston Gas Light Company, E. W. Burdett for the Massachusetts Electric Light Association, and ex-Senator John C. Crosby for the North Adams Gas Light Company. Mr. Bowers submitted a bill which provides that any city or town may establish or purchase and maintain plants for the manufacture and distribution of gas or electricity for light, heat and power, upon the two-thirds vote of the City Council, in two successive years, in cities, ratified by the people, and in towns by the two-thirds vote of the legal voters at two annual meetings. The bill further provides for the issue of bonds, outside of the limit of indebtedness, the amount of such bonds to be not over 5 per cent. of the town's or city's indebtedness. The plants may be enlarged with the consent of the council or selectmen as above. Assessments may be made upon the owners of premises, but their payment is not obligatory unless gas or electricity is supplied, and the city or town is not to be compelled to furnish gas or electricity to any person or corporation, except by the order of the Gas Commissioners, after proper hearing. The bill provides that the business shall be given in charge of a manager, and that the net profits shall not exceed 8 per cent. Mr. Bowers, in support of his project, referred to the Danvers bill rejected by the Legislature of last year, and read from opinions expressed by the Boston Ex-

Executive Business Association, and various other parties, in favor of municipal control and against corporate monopolies. In Philadelphia, where the price to consumers is \$1.50 per 1,000 feet, the net profit of the municipal gas works in 1888, taking into account what is distributed for city purposes, was \$1,006,134. Included in the Bowers references were extracts from the *Forum*, the *Nationalist*, and the *North American Review*. He said that petitions had been received from between 12,000 and 13,000 people, from 116 towns, in favor of the proposed legislation. Miss L. J. Robinson raised the point that the early laws tended to protect the people in their individual rights, and that they should not be "trampled upon" by corporate monopolies. Frank Parsons favored any bill which should give to each community authority to elect the manner in which gas and electricity should be manufactured and distributed. He claimed that neither corporate monopoly nor private competition could be depended upon in justice to the people, and said that municipal ownership was the only equitable system, as had been shown in the experience of cities which had adopted it. Speaker Barrett appeared in response to the vote of the town of Melrose, which desires to be allowed to manufacture and sell gas and electricity to its inhabitants. Mr. Barret said that there was a feeling in the community, no doubt intensified by the consolidation of the gas and street railway companies, which had increased prices or at least had not diminished prices commensurate with increased advantages, that the different cities and towns should be allowed to choose for themselves in what manner gas and electricity should be manufactured and distributed. This was a question of principle and not one of profit. It did not make any difference whether the town or city made money or not. The only question of importance is whether or not the cities and towns should be allowed this privilege. Mr. Lane and Levi S. Gould, of Melrose, ex-Mayor Raymond, of Salem, P. F. Shevlin, of South Boston, Dr. James Waldock and Frank C. Coffin also addressed the committee either upon the general question or upon some especial or local phase of it. The hearing was then adjourned.

MESSERS. R. D. WOOD & Co., of Philadelphia, Pa., have been awarded the contract for the construction of the new holder at the works of the Citizens Gas Light Company, Newark, N. J.

ALL the preliminaries in respect to the purchase of the Rockford (Ills.) Gas Light Company by the American Gas Company, of Philadelphia, have been completed. The transfer involved the payment of about \$300,000.

WE are in receipt of a copy of a circular recently issued to the gas consumers of Warren, Ohio, by the proprietors of the Warren Gas Light Company, from which we learn that the net rate for gas, from and after the first prox., is to be \$1.50 per 1,000 cubic feet. This is a concession of 30 cents per 1,000, and insures very cheap light to the residents of Warren. This is the fifth reduction that has been made by the Company since 1878, and that it is likely to be tried again is evident from the language of the last paragraph of the circular which reads: "We wish again to impress upon you the fact that the faster the consumption of gas increases in Warren the sooner can the price be further reduced." That the use of gas for purposes other than lighting finds favor in Warren, we may note that over 100 stoves are now in use there.

THE Adams (N. Y.) Gas Light Company has thus perfected its organization: President, N. M. Wardwell; Vice-President, A. B. Hudson; Secretary and Treasurer, E. C. Bessie; Superintendent, R. P. White.

IN the reorganization of the Kenton (O.) Gas and Electric Company the capital stock has been put at \$50,000.

THE capital stock of the Toraya (Philadelphia) Patent Gas Company is \$20,000, and the original Board of Directors comprised Messrs. Jose F. Toraya, Jose Vivo and Chas. C. Haines.

THE electric light plant recently determined upon by the proprietors of the Johnstown (N. Y.) Gas Company is being installed.

AT a meeting of the Troy (N. Y.) Contracting Board, the subject under consideration being the bids for public lighting, City Engineer Fuller moved that the contract for street electric lighting be awarded to the Troy Gas Company, for 5 years, at 39½ cents per light per night, for lights of 2,000-candle power. The motion was adopted. Comptroller Roche then moved that the Troy Electric Light Company be authorized to keep on with the public lighting at the ruling figure of 43½ cents per night for each lamp until the Gas Company is ready to go on with the

new contract. There is small doubt that the Gas Company will soon absorb its rival.

AT a meeting of the Directors of the National Gas and Electrical Construction Company, Boston, Mass., Benjamin F. Butler was elected President, and Fred. Whittemore, Clerk.

AT a meeting of the Engineers' Club (Philadelphia, Pa., March 1) Mr. Henry G. Morris described a new method of sinking dies, and followed his remarks by presenting a beautiful specimen of the results accomplished. He stated that these results could be obtained by this process at a cost entirely insignificant when compared with the cost by the old method.

THE City Council of Macon, Ga., has decreed that the electric lighting towers (6 in all, 150 feet each in height, and erected at a cost of \$5,000) must be torn down by May 1st. The reason given is that the "towers are dangerous."

C. O. FRENCH, Solicitor for the Utah, Nevada and San Francisco Railroad, has applied to the City Council, of Salt Lake, for a franchise for the construction and operation of a gas plant. He proposes to supply illuminating gas for \$2 and heating gas for \$1 per 1,000 cubic feet. While not positive about the matter, we are inclined to think that French is backed by certain parties who are interested in the Jackson (Mich.) plant.

Economy of Fuel in the Distillation of Ammoniacal Liquor.
