In these days of small margins of profit the manufacturer can no longer afford to throw anything away until he is quite certain that its capacity as a revenue producer is exhausted. Applying this principle to the distillation of ammoniacal liquor in the column still, says the *Chemical Trades' Journal*, one is struck by the fact that in the process as ordinarily conducted the spent liquor leaves the still at a boiling temperature, containing the heat equivalent of a considerable quantity of fuel. These few remarks are intended to show how, in the case of the Davis still, this heat may be recovered and utilized. In the case of the Davis still the spent liquor escapes from the apparatus through a series of U-tubes. It is proposed to cause these U-tubes to pass through a water-tight box of any convenient shape and material, and the ammoniacal liquor to be treated is conducted through this box on its way to the still, so that it becomes heated by contact with the U-tubes, through which the spent liquor is escaping. In one works this arrangement has been already adopted, and answers very successfully. The temperature of the ammoniacal liquor is raised to 108° F., while the spent liquor only registers 112° F. as it escapes to the drain. Where other means are adopted for the pre-heating of the ammoniacal liquor, the "Economiser" (as the apparatus is called) may be employed to heat water for the boiler supply, or for any other purpose. In certain cases it may be desirable to substitute a coil of pipes for the series of U-tubes, but if this is done care must be taken to so arrange the coil that it forms a seal equivalent in its effect to the U tubes. These outlet tubes or coils may be best cleaned out by connecting temporarily with a high pressure water supply, communication with the still being, of course, cut off while the flushing or cleansing operation is going on. A mixed jet of steam and water, where it can be got, answers this purpose very effectually.

It may be thought by some that the saving to be effected by the use of the "Economiser" is insignificant. Compared with the differences between "ancient" and modern stills, this saving may appear a small one; but it must be remembered that the field of the economist is much more restricted in its area than was the case some few decades ago. We are very much nearer the goal of theoretical perfection, and our rate of progress must be expressed in smaller units. Those manufacturers who fail to appreciate small individual improvements are considerable losers in the aggregate, and are among the first to drop out from the struggle where the fittest only survive. The proverbial sweetness of little fishes has its parallel in the acceptableness of small economies.

The Market for Gas Securities.

The city share market during the week has remained in a quiet state, but the undertone is all in favor of higher prices. There was no considerable variation in values, and the trading was light. In connection with the purchase of the artificial lighting and gas fuel supply of Indianapolis, Ind., we note a rather curious denial by President Graham, of the Equitable Company of this city, who wishes it distinctly understood that that Company as a Company had nothing to do with the purchase. No one really supposed that such was the case; but we presume it was pardonable to infer (from the fact that a circular calling attention to the purchase was dated from the Company's office on Third avenue) that some of its directors were interested in the transfer.

Rumors are rife that the Citizens Company, of Brooklyn, will be called to account by the Fulton Municipal Company, in respect to the proposition of the owners of the former that they think it is time to make gas instead of peddling it. The increase to the Company's stock has been sanctioned by the required assent of the stockholders. Nassau gas is steady, at 120 to 122, the certificates being quoted at par to 107,

**WANTED,
 Management of Gas Works.**

By practical gas man of many years' experience. Is master of all branches of work about a small plant—main laying, services, retort setting, gasfitting, or repairs about the works. Best of references. 771-2 Address "W," care this Journal.

POSITION WANTED.

A Mechanical Engineer,

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked. Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal, 765-tf or Box 972, West Bay City, Mich

Position Wanted

As Superintendent or Assistant of a Gas Works,

By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address 770-3 "M.," care this Journal.

FOR SALE,

The Ironwork for 11 Benches of 5's, viz.:
 Cast Iron Hydraulic Mains, 17 Inch diameter, Inside.
 Dip Pipes, Bridge Pipes, Stand Pipes.
 Mouthpieces and Lids.
 Four Purifiers, 10 by 16 ft., with 10-inch Connections and dry Center Seal.
 Four Purifiers, 5½ by 10 ft., with 6-inch Connections and Wet Center Seal.
 Valves, 6-inch, 8-inch, and 10-inch.
 DAVID MOORE, Treas. Salem Gas Lt. Co.,
 770-tf Salem, Mass.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

SECRETARY, 123 Beale Street, San Francisco, Cal. 760-3 mos.

FOR SALE.

A Complete Water Gas Plant.

60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

6 PER CENT.

First Mortgage Bonds

**THE NEW
 HANDY BINDER.**

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filed in the Handy Binder, becomes a volume of great value, always convenient for instant reference. Handy Binder, Postage paid, \$1.00.

A. M. CALLENDER & CO., 42 Pine St., N. Y.

GREENOUGH'S

"DIGEST OF GAS LAW."

Price, \$5.00.

This is a valuable and important work, a copy of which should be in the possession of every gas company in the country, whether large or small. As a book of reference it will be found invaluable. It is the only work of the kind which has ever been published in this country, and is most complete. Handsomely bound. Orders may be sent to

A. M. CALLENDER & CO.,
 42 Pine Street, N. Y.

RAPPLEYE'S RHEOMETRIC GOVERNOR BURNER.

EXPLANATION OF CUT.—Gas passes through opening *A* in piston *B*, thence through opening *C* in inverted cup *D*, and through openings *EE* in guide-plate *F*; the flow being governed by the position of the conical valve *G* in respect to the opening *C*, a position which is automatically regulated by variations in the pressure of gas on piston *B*. Thus, if the pressure is excessive, the piston will be forced upward and the valve *G* elevated so as to restrict the freedom of the flow through opening *C*, the piston descending and the valve opening as the pressure is diminished.

This Burner is a Perfect Pressure Regulator, maintaining a uniform pressure at point of ignition at any pressure above $\frac{1}{8}$ in.

Careful Photometric tests show a gain of *fifteen per cent.* in illuminating power *over* the Argand burner. Warranted to give the same amount of light as other burners at from 25 to 50 per cent. less cost, and not to corrode or clog in any manner.

Manufactured in 2, 3, 4, 5, 6, 7, and 8 ft. sizes, and larger or smaller or intermediate fractional sizes to order.

Price, \$6 per Dozen. Special Price and Free Sample to Gas Light Companies on Application.

In ordering Burners state whether for Coal Gas, Water Gas, Oil Gas, or Natural Gas; and also give specific gravity and illuminating power of same. Special Burners will be adjusted on demand for any quality of gas, and warranted to consume any required amount of such gas.

OFFICE OF THE SUPERINTENDENT OF THE CITY GAS WORKS, }
RICHMOND, VA., March 10th, 1890. }

MR. H. W. RAPPLEYE, 1345 Arch Street, Philadelphia:

Dear Sir—In answer to your inquiry concerning your Burners, I will say that since the introduction of your Burners on our street lamps, about four years ago, they have given perfect satisfaction in every particular. I cannot recall a single instance where one had to be replaced for any defect whatever.

Very truly yours,

WM. C. ADAMS, Supt.

ARE YOU USING RAPPLEYE'S RHEOMETRIC GOVERNOR BURNERS? IF NOT, WHY NOT?

F. D. HARMON, PRES.

CHAS. C. ALLEN, SEC. AND TREAS.

P. W. MACKENZIE, CHIEF ENGR. & SUPT.

THE FUEL GAS AND LIGHT IMPROVEMENT CO. OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889,

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM.

The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. The Gas requires NO PURIFICATION. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE.

Works under our system can be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than $4\frac{1}{2}$ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon.

One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

GEROULD'S
System Gas Bookkeeping.

Approved and adopted by many of the prominent Gas Engineers of the Country.

Sample Sheets and Price-List furnished free on application to

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3	ft. square,	5	ft. deep.
No. 2,	"	125,000	" " "	4	" " "	"	"
No. 3,	"	250,000	" " "	5	" " "	"	"
No. 4,	"	500,000	" " "	6	" " "	"	"
No. 5,	"	750,000	" " "	7	" " "	"	"
No. 6,	"	1,000,000	" " "	8	" " "	"	"
No. 7,	"	1,250,000	" " "	9	" " "	"	"
No. 8,	"	1,500,000	" " "	10	" " "	"	"
No. 9,	"	2,000,000	" " "	12	" " "	"	"
No. 10,	"	3,000,000	" " "	15	" " "	"	"

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used *in every State in the Union*, and purifying daily over *thirty-five million cubic feet*. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but *three years*, and in that time has been introduced *more generally* than any invention ever designed for use in gas works. Over *two hundred* of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is *complete* without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for *mixing air* with oil gas. *No works* too small to use them profitably.

Prices given on all our specialties *delivered at any point in the United States*. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,

OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels
or 12,500 " " 60 " "		of merchantable Coke weighing 900 Pounds
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,

Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
37 in. high. 20 in. wide.	12 in. high. 17½ in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	38 in.

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
31 in. high. 17 in. wide.	9½ in. high. 14½ in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 16 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 8 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. ¼ in. supply pipe should be used where the pressure is 1 in. or over.

BRIEFLY TOLD.

THE MEETING AT TOLEDO.—"Toledo, O., March 19, 1890: Dear JOURNAL—Writing hurriedly at this hour, which marks the conclusion of the first days' business session of the Sixth Annual Meeting of the (I had almost written Baby Association, but fortunately remembered in time that Texas and the Southwest held the junior honors) lusty Ohio Association, I may say that it seems scarcely possible that a twelvemonth has been added to history since the last gathering, at Mansfield. Time has dealt kindly with its membership, in that the roll of a year ago remains intact, although the grim reaper has been exceptionally busy in the ranks of other Associations. You may depend upon it, however, that the death strokes which afflicted them have also awakened strongly in the breast of the Ohio Association that sympathy which kinship of the truest sort alone can call out. The cutting off of such men as King, Forstall and Cushing must be felt by all; and strongly, too. Indeed, I ought not dwell longer on this, for President Lindsley, in his annual message has alluded most appropriately to the matter. Many of the delegates came in last night, and it is but common justice to the Secretary and the Local Committee of Arrangements to say that their joint efforts for the accommodation of the visitors were of the most satisfactory kind. The Body House presented the appearance that such hotels always take on when they have been selected as the trysting places of the gas men. I do not know whether such an impression is the general one, but it always seems to me that gas men, whenever assembled on like occasions, look as if the world had used them kindly. The prevailing personal characteristics are: More than the average height, well above the average avoirdupois, and well beyond the average age. There is no gainsaying the fact that gray hair is fashionable at the Association gatherings. Not that the ubiquitous youngster does not also have a chance to show himself. He is there, but is usually not forceful. The first day's proceedings were marked by much earnest work, and President Lindsley proved that he is not only a good gas maker, but that he is a capable director of conventions as well. The attendance was perhaps not far short of 60, and there was a goodly contingent of visitors, including not a few from the East. Secretary Butterworth was more than pleased at this response to his earnest preliminary work, and Charlie Faben beamed with smiles—and a jolly smile is his. Few appreciate the real sacrifice that President Lindsley had to make in preparing for his duties in connection with this meeting. Severe illness in his family, with all that that implies, was his portion, and with rare fidelity to the Association's interests he served in double harness, without complaint. Is it any wonder that the Association prospers when its members make such sacrifices on its behalf? His address was of the practical sort, and his remarks in respect to the varied influences for good that mutual association has upon the gas industry are vigorous and bright. Take it all in all, it is a good paper, and will well repay a careful reader of its lines. As to the regular papers, they bore out the promise of their titles. Faben, as usual, in his treatment of 'Graduated vs. Uniform Rates,' was frank and outspoken. In fact, it seems to me that the single scale theory finds fewer advocates every year, and as the average rate for gas decreases, I think the chance for argument in favor of the all-round rule grows smaller. One of the best papers yet presented by Mr. Wilkiemeyer (and that is saying much, for everything that can be

traced to his pen in the shape of communications to the Ohio Association have been really models) was his compilation on the subject of the 'Municipal Control of Lighting.' Of course I cannot go at length into it; but let me quote a single sentence—not exactly as he wrote it, but so arranged that I can carry the meaning through without taking up too much space—in order to show the aptness of his reasoning. The lines are these: 'The capital of a city is derived primarily from the pockets of the people; secondarily, from the vaults of the city treasurer. It is not an exercise of solid political economy to allow the people's money to be invested in a commercial undertaking,' and "no man should be willing to be taxed in order that a city should secure capital with which to strangle private enterprise." If the political stranglers who are now agitating for the supply of gas and electric light by the cities and towns of Massachusetts could, through the medium of the constituents whose interests they misrepresent, be shown the potency of this argument, they might not be so willing to engage in an attempt through corporate force "to strangle private enterprise." Labor cannot look to its just due from public employment, for private capital has always been its savior. The paper by Mr. Hyde, Sr., on the new coal gas works at Cleveland, is after the manner of its author—precise, cool and accurate. To me, however, the moral of it all—and I think his view will be shared in more fully, when a score or more of Utopian fuel gas schemes have been exploded—is contained in its closing words. Having said that in his opinion the new Cleveland plant was of the best type, he quaintly remarks, "And is well provided to produce the most effective gas fuel, as well as the most practical medium of artificial light." In other words, the engineer of the near future will not require two plants for the manufacture and distribution of lighting and fuel gas—any more than he now does. Given a perfect manufacturing plant, his next step is to improve to the full the methods of using the product. The point of consumption is the one for the sharpening touches of the student and the inventor. Mr. Light's paper on the "Advantages of a Combined Coal and Water Gas Plant," strongly favors the affirmative side of the proposition; and Mr. Hedge's "Street Lighting Statistics" bears the evidence that care, thought and correspondence accompanied its compilation. The statistics are given in neat tabular form, and are likely to be hoarded for reference by all those who shall read his paper. I have not heard the remaining papers listed, but these will, of course, appear in due season, as will the contents of the "Question-box," which have been greatly increased since the publication of your last "Official Notice." The gas apparatus exhibition is a good one, and cannot fail to result in material benefit to those who have goods on display. The arrangement of it is admirable. To-morrow will be occupied largely in paying visits to the exhibition, to the showrooms and factory of the Central Chandelier Company, and to the plant of the Toledo Company's gas and electric light works. In conclusion, I may say that the Ohio Association's course is still onward and upward.—*.*"

"Thursday, 8 P.M.—The remainder of the proceedings may be classed as on a par, at least, with what I sent you respecting the instalment of the first day. The Association roll was increased by the addition of no less than 30 names, and this fact tells the story of the Society's vitality. It has been decided to hold the next meeting at Zanesville. The officers elected are: President, Chas. R. Faben, Jr.; Vice-President, H. Wilkie-meyer; Treasurer, Geo. W. McCook; Secretary, Irvin Butterworth—a right good working staff. The interest in the meeting was well sustained. The outing time was not over-enjoyable; and the banquet was as it should have been. Permit me to remark in closing that Lindsley is a most capable hand at directing the affairs of a meeting.—*.*"

A WEEKLY EDITION OF THE ELECTRICAL ENGINEER.—It gives us satisfaction to be able to say that the *Electrical Engineer*, hitherto published in this city as a monthly review of theoretical and applied electrical science, will, from and after April 1st, be printed weekly under its former management. This paper was conducted in a manner peculiarly acceptable to the interests which it represented, and as an earnest that this course is to be pursued in its entrance upon a wider field, we have only to remark that its old-time conductors, Mr. F. L. Pope and Mr. G. M. Phelps, are still to remain at the helm. They have, however, associated with them Messrs. T. Comerford Martin and Joseph Wetzler, whose names are guarantees that what was good before shall be even better in the future. We hope that the *Electrical Engineer* will reap the reward that comes from honesty of expression and unprejudiced treatment of the interests it seeks to serve.

MR. WILLIAM H. McCLAVE, of Newark, N. J., died at his home in that city on the morning of the 15th inst. He had been a resident of

Newark since 1850, and was a Director in the East Newark Gas Company.

MR. GREENOUGH ON MUNICIPAL LIGHT SUPPLY.—At an adjourned meeting of the Committee on Manufactures (Massachusetts Legislature) Mr. C.P. Greenough appeared in argument against the Bowers proposition to authorize the municipal authorities of cities, towns and villages to engage in the supply of artificial light. He declared that the proposition means spoliation by the Nationalists. The bill submitted contains no provision requiring the purchase of the gas companies, an omission which means ruin to the companies and to their stockholders. The scheme involves socialistic tyranny, and the petitioners do not represent the people, but only that portion of the people under their own hats. Mr. Greenough said that no cities, or towns ask for this legislation; it was only a part of the programme laid out by the Nationalists to place the railroad, telegraph, express and all other business in the hands of the Government. The proposed legislation was calculated to tempt towns to engage in speculative enterprises, and it would prove a source of political jobbery here, as it had in Philadelphia, Richmond, Wheeling, and elsewhere.

President Peaty's Views on the Status of English Lighting Methods.

The following is abstracted from the annual address of President Henry Peaty to the Midland Association of Gas Engineers:

During the past year, many things have happened which compel us to examine seriously the conditions of stability of our gas undertakings. Our rivals, if they have not actually increased in number, have developed in strength and activity. Some of them may be passed by without much consideration; to others, we must give our respectful attention. The language used formerly in describing electric lighting, and in estimating its value and prospects of success, must be considerably modified. Many of the defects which have been pointed out in past years, no longer exist; and those that remain have the attention of accomplished engineers, who are exerting every energy to effect their removal. We can no longer speak of the impossibility of bringing the light down to an illuminating power that would be generally useful; that it does not admit of regulation; that it is variable and uncertain (I am now speaking of the glow lamp supplied from accumulators); and that the color is more trying and wearying to the eyes. In many respects, it is a most beautiful light; and the way in which it can be adjusted to any portion of a room—ornamenting as well as illuminating—commends it to those who have a delight in beautiful adaptations, and who are not confined to the economical aspect alone. At present, it cannot compete with coal gas in economy; it is to some extent a light of luxury. But many people like luxurious appliances, and can afford to have them. There is such a thing as fashion. What is fashionable will be sought after; and, in many places, good and useful as gas has proved itself to be, and still is, the newer light will find a place. The gas will be removed, or relegated to the humbler offices of the house or mansion. Any one who has money and taste enough to adorn his principal rooms with valuable pictures and other decorations, would not hesitate to illuminate them, wherever practicable, with the light that would least interfere with their valuable contents. I do not anticipate that this method of lighting will take a large proportion of the lighting business of the country; but it is almost sure to encroach somewhat on our domain, and we shall have to bestir ourselves to make good any loss that may occur.

The use of oil lamps is extending; and though there is some inconvenience in the trimming and some risk, many prefer oil lamps to gas on account of their soft and agreeable light. It is claimed for the oil lamp that the light is cheaper, the wonderful improvement in burners enabling the consumer to get a most agreeable illumination at a moderate cost. The fittings have been improved to a remarkable extent; many of the designs of fittings, glasses and shades leaving nothing to be desired in the matter of decoration. Many of these fittings are cheap; and being portable, they are bought by consumers who would not go to the expense of gas fittings in their dwellings. The way in which we may compete for the custom of this class of consumers will be dealt with further on.

Of water gas—either used in manufactures, or in conjunction with oil gas for the purposes of illumination—I do not entertain the slightest fear. Whenever the conditions of the oil market allow gas to be made so as to compete with our ordinary coal gas, no one will be in a better position than ourselves to make use of it and supply it to the public. At present there is no firm of importers of oil who can quote a low enough price for either British, American or Russian oil to enable us to work it economically. When the supply of oil is sufficiently copious and low enough in price we shall be able and willing to deal with this mode of manufacture.

OFFICIAL REPORT.—REVISED BY THE SECRETARY.—[CONCLUDED FROM PAGE 362.]

TWENTIETH ANNUAL MEETING, NEW ENGLAND ASSOCIATION OF GAS ENGINEERS.

HELD AT YOUNG'S HOTEL, BOSTON, MASS., FEB. 19 and 20, 1890.

SECOND DAY—FEB. 20—MORNING SESSION.

REPORT OF COMMITTEE ON PRESIDENT'S ADDRESS.

Mr. Lamson—The committee to whom was referred the President's address would report as follows :

The committee heartily recommend to the Association a careful consideration of the many valuable and interesting matters contained therein. They coincide with the President's views in regard to the fairness and courtesy always displayed by the Gas Commission, and the value of the services of that body, both to the public and to gas companies. They respectfully refer back to the Association, without report or recommendation, that portion of the address advising the appointment of a committee by the Association for the consideration of legislation, etc. They further recommend the printing of at least 250 copies of the address for distribution among the members of other societies.

FRANK S. RICHARDSON, }
CHAS. D. LAMSON, } Committee.
HENRY B. LEACH, }

Mr. Lamson (continuing)—In presenting this report I would like to say that I am not the chairman of this committee ; that Mr. Richardson is the chairman, and that I was asked to present it for the reason that I yesterday afternoon felt called upon to make a few remarks with regard to a part of the address ; but I want this morning to commend this address most heartily to the Association, for I believe that it is written exceptionally well, and will prove a valuable paper for future reference. I also want to say a word with regard to two points mentioned in this report. First, the Gas Commission. They have been referred to by the President in pleasing terms. I most firmly believe in the Gas Commission, and in the value of their work. In a general way I have believed that their work has been in the right direction ; but I feel rather called upon to draw the attention of the Association to one matter which I understand they have in their report, and which they are bringing before the Legislature at this session. Last year there was legislation in the matter of the limit of the amount of carbonic oxide in gas. The limit that has been allowed in Massachusetts is 10 per cent. After much legislation last year it was left in this manner—that the limit should be 10 per cent., but the Gas Commission were allowed to increase that limit if they saw fit, if, when they granted a license to increase the limit, they would guarantee the safety of the gas which contained the increased limit. No three men would assume that responsibility, and no license has been granted. If I understand the recommendation of the Gas Commission to the Legislature this year it is something like this—that the Gas Commission generally shall have power to grant licenses to manufacture water gas in various towns in the Commonwealth, the limit of carbonic oxide being something like a sliding scale. That they may allow town A to manufacture water gas with a limit of 10 per cent., town B with a limit of 15 per cent., and town C with a limit of 20 per cent. ; that they shall use their careful judgment in the supervision of the matter, and that they may at any time, if they see good and sufficient reasons, revoke the license and prohibit a corporation in a town from making water gas, and I suppose refuse the right to make it, or the right to make it under the limit which they have granted. Of course, this Association can pass no resolution, or take any action to influence the Gas Commission, and do not wish to do so ; but I wish personally, in making the report and in speaking of the Gas Commission, to draw attention to that matter, and to this particular bill which they are introducing before the Legislature. It seems to me that all our Legislatures would do well to act in this matter, and to place a decided limit upon carbonic oxide. What that limit should be I am not prepared to say ; but whether the limit be left at 10 per cent., or increased to 15 or 20 per cent., I believe that it is for the good of the companies in Massachusetts, and also for the good and happy contentment of the Gas Commissioners for the years to come, that the limit shall be established by the Legislature and not by the Gas Commission. It will bring no end of trouble if the Gas Commission are going to allow one of you gentlemen to make 20 per cent., and limit another to 10 per cent. of carbonic oxide. They would hardly have time to attend to any other business during the year. I hope that when the question comes up, and they present it to the legislature—as they are supposed to be called upon to do very soon—they will see that it is a wise thing for them, and a good thing for the

companies, that they recognize some one limit that is, in their judgment, the right one, and let that limit be the same for all. In the latter part of this report of the committee we refer back to you the suggestion of the President that a committee be appointed to look to the question of legislation and to help out in the matter. I most firmly believe that the Association, as an Association, should let legislation alone—that they should not in any way, shape or manner touch it ; but let each one of us in the towns where we live watch the legislation and do what we can to influence it. But as an Association, I think that we would make a great mistake if we should in any way try to influence the legislation of this State.

On motion of Mr. Stiness the report was accepted and placed on file.

The President—That matter being left in that shape, no further action is necessary. A matter similar to that has been brought to the attention of the President. It is with reference to the preparation of statistics for a census report ; and perhaps without entering into a discussion of the matter, if Mr. Foot, the special agent of the Census Department, is in the room, or Mr. Graeff, will explain to us what action individual companies may be asked to take with reference to that matter, we should be glad to hear them.

Mr. Graeff—I do not know that there is much to explain. The only point which I desire to call to your attention is a matter in which I think every member of the Association is as intimately concerned as is any government official. This will be the first time the gas industry will be represented in the census of the country. An attempt in this direction was made 10 years ago, as you know, but unfortunately Major Dresser died before his work was completed ; and consequently the gas industry stands as yet unrepresented as regards statistical data. I think it is to the interest of every manager, superintendent and engineer who has the good of his business or profession (as you may choose to call it) at heart, that the best possible showing, consistent with strict facts, shall be made. I would only ask that each of you consider and bear closely in mind the fact that nothing which is sent in to the Census Office will be made public in any way. The schedules sent out will contain some questions which you might consider impertinent, provided any publication was to be given to them ; but there will be no way by which Mr. Taber can find out anything that Mr. Harbison has been doing, or by which Mr. Humphreys can find out how Mr. Prichard is making gas. The figures will simply be entered as statistics, and the nearest approach to a division will be by States. Therefore I ask you to bear in mind that all the statements which you may make, and all the answers which you may give, will be treated as strictly confidential—not merely so by the census enumerator as a man, and as one of yourselves, but by the other sworn officials of the government, who could not divulge them even they wished to. I think if that fact is borne in mind there will be no difficulty in obtaining the showing which the gas industry is entitled to. That is the only point I wish to bring before the Association.

Mr. George F. Goodno, of Dedham, Mass., then read the following paper, entitled

A POINT OR TWO IN REGARD TO ILLUMINANTS DURING CONDENSATION AND PURIFICATION.

It is with diffidence that I come before this body of experienced men to acquaint them with facts with which they are doubtless familiar, but in working up the subject I have gained considerable information myself, which may be some excuse for inflicting this upon your attention.

A phase of the question of the advisability of using iron sponge for purifying purposes has led to the assertion, supported by some short experiments, that lime absorbs quite an appreciable portion of the illuminants, thereby reducing the quality of the gas so purified to the same candle power as that purified by sponge with its contained carbonic acid. No one has ever held that there is any chemical combination between lime and the illuminants, any more than there is between sponge and the illuminants. If there is *any* absorption, it must be purely mechanical in either case, and there appears to be no reason why one should absorb more than the other.

A well-known engineer has shown by a series of careful experiments, on an average quality of gas, that the candle power is reduced about one candle by the presence of 1.32 per cent. of CO₂ in the unpurified gas, or what would be the same thing in regard to the CO₂, that purified by sponge as against that purified by lime. I endeavored to attack the problem from a different quarter, after the the following manner :

Four or five cubic feet of unpurified gas were stored in an improvised holder made from an old governor. A portion of this was passed through a layer of good, fresh sponge about one foot thick, and a sample collected for analysis. Another portion was passed through a like quantity of moistened lime, and a sample likewise collected for an-

alysis. By this means there was no doubt that the composition of the crude gas before either method of purification was the same. This can be readily seen to be a most important point, and one not strictly observed in other experiments on record.

The analyses made were to determine the amount of carbonic acid and illuminants only. The apparatus used was the Hempel, which was exhibited to you last year, and its use so clearly demonstrated by Mr. Jones. It meets the requirements of an experiment of this kind in a very satisfactory way.

The sponge gas was treated precisely like the lime gas in regard to temperature of operation, length of contact with the reagents, etc., so that any error occurring in one would appear in the other, and would not affect the relation between the analyses.

The samples were taken over a period of six weeks, as will be seen by the dates, and comprise a very wide difference in per cent. of illuminants. Taken as follows:

	CO ₂ .	Illuminants.
Nov. 1.—Unpurified gas.....	1.0	4.1
Purified with lime	0.1	4.1
" " sponge.....	1.0	4.1
Nov. 2.—Purified with lime0	4.1
" " sponge	1.0	4.1
Nov. 8.—Purified with lime0	3.5
" " sponge.....	.5	3.7
Nov. 10.—Purified with lime0	6.7
" " sponge.....	1.8	6.7
Nov. 15.—Purified with lime0	8.0
" " sponge.....	0.7	7.9
Nov. 21.—Unpurified gas.....	.8	5.1
Purified with lime0	5.1
" " sponge.....	.8	5.1
Nov. 23.—Purified with lime0	6.2
" " sponge6	6.2
Nov. 28.—Purified with lime0	6.7
" " sponge.....	.5	6.8
Dec. 14.—Purified with lime0	4.8
" " sponge.....	.6	4.8

A glance over these results shows the amount of illuminants in percents. by volume to be practically the same whether purified by lime or sponge. But the candle power does not vary with the percentage by volume of the illuminants, for at least two reasons, viz.:

First, because of the different specific gravities of the various illuminants, belonging as they do to the naphthaline, benzole, and other series of hydrocarbons. Some authorities have said that the candle power varies according to the percentage *by weight* of the illuminants; and this looks much more probable when we observe the different specific gravities of those constituents:

Acetylene89
Olefiant gas97
Benzole	2.72
Naphthaline	4.42

A very limited variation in volume of the last two would make, as will be seen, a very considerable difference in candle power. In fact it seems, from a study of a large number of analyses, that the volume per cents tell us very little about the illuminants and the illuminating power of a gas.

The second reason is the influence and character of the accompanying diluents, as shown by the reports of the State Inspector. Two analyses in these reports show this fact very conspicuously.

	Candle Power.	Illuminants.	Marsh Gas.
No. 1.....	19.4	5.14	45.12
No. 2.....	16.6	9.20	30.61

In the first the low per cent. of illuminants compared to the candle power and the remarkably high per cent. of marsh gas. The hydrogen was nearly the same in each. The per cent. of illuminants in the second being nearly double that in the first, while the marsh gas is only about two-thirds. Another factor in the case is that No. 2 contained 12.3 per cent. of nitrogen and 2.2 per cent. of CO₂, while No. 1 had 3.5 per cent. nitrogen and no CO₂.

Furthermore, the 19.4-candle power gas was purified by lime alone, while the other evidently was purified by sponge—as a whole, quite clear negative evidence with regard to the absorption of illuminating power by lime.

Another point in which I became interested with regard to absorption of illuminants of the gas is in its passage through condenser and washer. Our condenser is a coil of pipe exposed to the air, and the washer a rectangular iron box, with alternate shelves, and is familiar in small works.

I wished to determine if there was any loss of illuminants to the gas in its passage through these two pieces of apparatus, especially when there was a relatively large amount of water running through the washer. For this purpose a sample of gas was taken after passing through the exhauster; then, by a rough calculation of the capacity of the apparatus between there and the outlet of the washer, I determined very nearly by consulting the meter when the same gas could be sampled again. The two samples were then analyzed for illuminants. Several pairs were taken in this way, and different qualities of gas on different days. The results were as follows:

	CO ₂ .	Illuminants.
Before passing condenser and washer.....	1.4	4.3
After " " "	1.4	3.9
Before " " "	1.5	5.6
After " " "	1.5	4.9
Before " " "	1.0	4.1
After " " "	1.0	3.8
Before " " "	2.0	6.1
After " " "	1.8	5.7
Before " " "	1.4	4.3
After " " "	1.4	4.3

Average loss..... .36

I was then using about 4 or 5 gallons of water to the 1,000 cubic feet. The pressure of other duties prevented me from making further analyses, using less water, as I intended.

Discussion.

The President—You have the figures and the facts before you. Has Mr. Gifford any figures which he can compare with those given by Mr. Goodno?

Mr. Gifford—I have no figures, but I will say that I am pretty certain from my observations that these facts are very generally true, and in a good many cases the percentage is a great deal larger than he has stated.

Mr. Prichard—This paper is valuable in settling in my mind a point which has been often spoken of the relative absorption of illuminants in oxide and lime. I have in mind two papers, both taking opposite and different grounds from this paper; and it seems to me, from the care that Mr. Goodno has taken in his experiments, he proves that both those gentlemen are wrong; and he settles in my mind that there is no absorption of illuminants by the purifying material.

The President—I know it has been the prevailing idea that the use of iron sponge was a detriment to candle power. Has any one made any experiments to prove how much of a detriment it is?

Mr. Jones—I think that Mr. Goodno's paper is a valuable addition to the literature of gas purification. He has voiced an opinion which I have had for some years with regard to this matter; but my good friend Mr. Blodget, of Williamsburgh, tried a series of experiments, the results of which he put in the form of a paper and read before the American Association, which were directly contrary to Mr. Goodno's results. Granted that the absorption of illuminants by the passage through the lime is merely a mechanical action, I see no reason why 12 inches of lime should absorb illuminants, if 24 inches of sponge, closely packed together, does not absorb the illuminants. I have a few figures here which relate to another portion of Mr. Addick's paper, but which I think may be of interest. Last spring I was using at the North End station of the Boston Gas Company what is known as the Baby process—the bootleg retorts. We used the process for enriching our coal gas, using oil and steam in the presence of incandescent lime. I found that there was some loss by not running the water gas process on Sunday, on account of cracked retorts, etc.; and so I decided to run the water gas plant on that day. This gave me oil gas, which I put into the holders and mixed up with the coal gas of low candle power which was made during the early morning hours of Sunday. I thus had an opportunity to find the difference in candle power between the unpurified oil gas, and the condensed, washed, and purified oil gas as it went through the station meter of the works. It has been very aptly said that no man knows what there is in a gallon of oil, and I believe that that is true to-day. I hope that some day we will find out what there is in a gallon of oil, and naphtha as well. I have some figures giving the candle power of crude oil gas made in the bootleg retorts directly after it had passed a washer which was inadequate for the purpose, and the candle power after it passed through the station meter. One hour the candle power of the crude gas was 24.5, and at the station meter 21.5; the next hour the crude gas was 24.5, and the purified gas 21.5; the next hour, crude gas 23, and the purified gas 21.5; the next hour, crude gas 23, and the purified gas 20; showing that there was a loss of about 3 candles in fixing that gas in order to send it out to our consumers. Is there not some way

that we can get that 3-candle power back into the gas and deliver it to our consumers as it should be?

The President—Can anyone answer that conundrum?

Mr. Harbison—I suggest that Mr. Jones tell us next year at what points this loss occurs, if at more than one point, between the bootleg retort and the station meter; and if he will make his test at various points between those two points I think he will be able to solve the question.

Mr. Addicks—I would suggest the possibility that the loss is before you get to the scrubber and washer at all. In other words, that it is by reason of not heating the gas to a proper temperature.

Mr. Humphreys—We have been making some experiments in this same line, and I am sorry that I have not the exact figures with me. We make, as you know, a mixture of coal and water gas, and have been endeavoring to see whether there is any loss of candle power in the passage of the gas through the works. We have been making these experiments now running over three weeks, taking the candle power and analyzing the gas at points next to the hydraulic main, and prior to the condenser, and prior to the washer, and prior to the purifiers; and we do not find any loss either in candle power or in illuminants in the passage of gas through the works.

Mr. W. A. Wood—Have any members noticed a difference of candle power when using fresh sponge and when using old material? Our experience has been that when running on old sponge which has been used for several months we get a certain candle power, but if the box were filled with new material there would be a depreciation. There is a question in my mind whether the more active sponge does not effect some chemical change in the illuminants themselves.

The President—Possibly the greater heat of the reaction of the iron itself at its first start off might depreciate the illuminants.

On motion of Mr. W. A. Wood, the thanks of the Association were voted to Mr. Goodno for his paper.

The next paper was read by Mr. W. H. Snow, of Holyoke, Mass., entitled—

A CHAPTER OF DON'TS.

Mr. President and Gentlemen:—During a somewhat extensive experience in the past twelve months with an old stack of benches, some faults of construction were so forcibly brought to my notice that I jotted them down for future reference, in order to guard against a repetition of same in case of possible rebuilding. When the invitation came to prepare a paper for this meeting I wrote them out more fully, hoping some one might get a point or two for his benefit. The points are put in the form of "don'ts," as the writer does not wish to undertake to say what is the best way of obviating the faults. While he may have his own opinions in the matter, he prefers to leave the solution of the questions to the judgment and discretion of his hearers.

There is no portion of a gas works that it is of more importance to have well constructed than the stack of benches, with the bench settings. It is a case where the cheapest is not always the most economical. Sometimes in building a new stack a few hundred dollars invested above absolutely necessary expenditure will be returned more than a hundred fold. To begin at the beginning, look well to the foundations; don't neglect them; don't under any circumstances have them weak. Those who have never been there have no idea of how the heat strikes down through them. In excavating the past season to put in some deep furnaces under an old stack, it was surprising to find how hot the earth was under a bench that had not been run for a month, and had all been torn out for two weeks. The foundation was a solid block of masonry 3 feet in thickness, built of flagstone 6 and 8 feet long by 3 to 5 feet broad, and from 6 to 9 inches thick. The dirt was so hot for a depth of 3 feet under the flagging that it could not be handled until it had been cooled; in fact, it was sissing hot when water was run upon it. You probably are all familiar with the instances where bench work has been built upon piling, and the piles have burned off so much as to ruin the stack. The stones themselves get so much burned that they appear like rotten stone one can pick up in the fields; hence it is necessary not to have the foundations too thin. Don't use poor flagstones; anything or everything will not do. An expensive foundation is a good investment.

Next comes the brickwork, the arches and their covering. Don't scrimp on room. Don't be satisfied with low, narrow, shallow arches. There seems to be a growing demand in every succeeding year for more room in the retort house. Do you realize the economy in fuel and labor secured by large retorts? I have frequently seen a bench, with all the coal it was practicable to put into it, so hot that if there had been room to put it, it would have easily burned off 25 or 50 pounds more to a retort with no more expenditure of fuel or labor. If plenty of room can be had, next look sharply after the brickwork. Don't accept any second-

class bricks, don't allow any large joints, and don't have any red bricks anywhere near a flue. Have you ever, in the case of a stack that had settled and apparently shrunk, and appeared upon the point of collapsing, investigated the causes therefor? Were there not some soft burned brick, broken and ragged from the handling during the transportation, somewhere in the structure, either just at the top of the foundation, or in the piers supporting the arches, that were not strong enough to stand the strain of repeated contraction and expansion, and had crumbled, helping on the settle? Were there not places, perhaps out of sight, where there had been large joints? In leveling up, had not the masons, rather than spend the time and trouble to cut bricks to fit, filled up the spaces with a half-inch or more of mortar? There is but little strength or bond in fireclay mortar, so with large joints the conditions are even more favorable for settling than in the case of soft bricks.

Red bricks are another prolific source of trouble. My advice would be, don't use any, either in leveling up the foundations or filling up over the arches. By no means have any near the flues. While their use may have been perfectly practicable in the days of common old-style furnaces with lighter heats, with the changed conditions of the present heavy heats they will melt. How many of us have had occasion to cut from the bottom of the uptake flues a hard, lava-like substance, and traced the cause to the same red bricks? When they melt and run they must of necessity leave an empty space, to the detriment of the strength and stability of the block. I have recently seen on top of a stack with short chimneys a hole where the bricks had melted, extending from chimney to chimney, a distance of 17 inches, a foot wide and 15 inches deep. The safety of those chimneys was certainly jeopardized.

Don't by any means ever allow the tie-rods connecting the binder irons to be covered by the brickwork. They will most certainly burn off, the braces will spring out from place, and the arches begin to settle. What a feeling of discomfort possesses the manager when he observes this state of affairs and realizes that it is impossible to ever get them back into place again. I am glad to be able to state that the builders now-a-days appreciate this point and are keeping the rods uncovered.

There is a difference of opinion as to the desirability of short or tall chimneys. I will not attempt to say which is the better; but if the former are decided upon don't have them built directly over the up-take flues. What a source of trouble and expense such an arrangement is, those of you who have never had the experience have no idea. If it is in a double stack, the opportunities have to be watched for getting into empty arches to cut through back walls into the flues to clean them. With no such opportunity, there is a good chance of losing the bench before it is half used up. Be sure of a way of getting into the upright flues from the top.

After the stack is provided for there remains the most important part as affecting the results procured—the benches, the style of settings, and the furnaces. Don't put in old-style furnaces. It is positive extravagance so to do. It would be hard to tell which regenerative or recuperative furnace is the best, but it is safe to say any one of them is better than a common furnace. Our worthy Secretary requested me to write up my experience with recuperative furnaces; but my experience is so limited at present that I cannot give any facts or figures that would be of any real value to my hearers, though I am satisfied from it that no company can afford to heat their retorts in the old-fashioned way.

The first furnace we put in was in the fall of 1888, it being a half-depth recuperative one. With it we managed to burn our retorts all up inside of six months; but, notwithstanding this dismal result, we were able to gather some grains of comfort. The heat was there, the economy was there; we were on the right track. We found we must have a setting that would stand the great heat we could generate, as plain open settings would not do. With the retorts properly braced and protected, we could handle it. While the retorts were in good condition in this bench, we were able to make an average of 8,971 feet per retort, or 53,826 ft. for the bench in 24 hours, burning off 300 pounds of coal in four hour charges, with a consumption of 60 bushels of coke. We ran as high as 9,864 ft. per retort, or 59,184 ft. for the bench. The retorts were 14 in. by 26 in. by 9 ft. As was said, we were convinced we were upon the right track.

This last summer we excavated and put in three deep furnaces, starting the first one last October. We have burned off 2,000 pounds in four-hour charges, with a consumption of 60 bushels of coke in 24 hours (reckoning 59 pounds of coal as making a bushel of coke), making something over 60,000 ft. of gas to the bench, or 10,000 ft. per retort. Using 1,900 lbs. of coal to a charge is a comfortable every days' work, while 1,800 lbs. to a charge is only play. In this bench, the four upper retorts are 14 in. by 28 in. by 9 ft., and the two bottom ones are 14 in. by

26 in. by 9 ft. These furnaces are very simple recuperative ones, with both primary and secondary air supplies heated but very little compared with some of the more complex regeneratives.

Do we have any trouble with them? Yes, some. They require attention as well as common fires; but if the stokers were to be asked which style they preferred, they would undoubtedly choose these. We are able to run with clinkering twice a week; that is, either driving the secondary bars, or letting the fires down so that the fire-boxes can be cleaned all out. The latter we do upon Sundays, when not making gas, so we do not lose our heats. Of course, we run the slicing bars into the fires occasionally to break up the clinker. That is about all the trouble we have. The fires are very easily controlled; the labor of firing is comparatively light, as we fire with hot coke, so it is only a part of the charging. What have we gained? We have increased our make per bench from 45,000 ft. to 55,000 ft. per day. The latter figures are placed low purposely, as being a fair average for all the year around. We have reduced our coke consumption from 47 per cent. to 33½ per cent. These figures I do not give as anything wonderful, for they do not approach some that have already been given you in years past; but I consider them practical, every day results, that can be obtained with ease and comfort, without stopped stand-pipes or pitch in the hydraulic mains, and going to show the desirability of adopting some one of the improved methods of firing.

About the life of the benches I cannot say, as I have said, my experience is too limited; but if as much gas can be made under present arrangements in three months less time than formerly, adopting them will have been good business policy. There will be three months' labor that will not have to be paid for and three months' consumption of fuel saved.

If improved furnaces are adopted, look out for the settings; don't have them weak. Open settings, that will do for ordinary fires, will not answer for the increased heat. Do not allow bricks and tiles to be laid too wet; thereby avoid a prolific cause of cracks. The suggestions made at the last meeting of the American Gas Light Association, in answer to the question, "How should fire bricks and tiles be laid?" are good ones to follow.

I do not know that it ever has been done, but I believe it possible with sound foundations, first-class materials, good workmanship, plenty of room inside the arches, and the brick work properly braced and tied together, to build a stack of benches that will last a lifetime.

Discussion.

Mr. Allyn—As Mr. Snow has laid considerable stress on the matter of the economy in the consumption of coke, I would like to ask him whether he estimated his coke at the rate of 59 pounds to the bushel. It seems to me that that is a greater weight than any of us have ever reached.

The President—He estimates 59 pounds of coal as making a bushel of coke. The English find that a little over 60 pounds of coal produce a bushel.

On motion of Mr. Lamson the thanks of the Association were voted to Mr. Snow for his paper.

THE WORLD'S FAIR.

Mr. Prichard read the following report of the Committee on World's Fair:

The Committee appointed upon the World's Fair would report that they cordially approve the suggestion that the gas industries of this country be suitably represented at the proposed World's Fair; and they would recommend that Messrs. C. J. R. Humphreys, A. B. Slater and John P. Harbison be appointed a committee on behalf of this Association to act in connection with committees appointed by other Associations; and that such committee act without compensation, but that their actual expenses shall be paid from the treasury of the Association.

On motion of Mr. Stiness the report was received and accepted.

On motion of Mr. Neal the recommendations of the report were adopted and the committee appointed.

BADGES.

Mr. Stiness—On consultation, the Committee on Badges have decided to adopt the monogram of the New England Association. The Committee ask to be continued. They recommend that the badges be paid for by the members. It is perhaps proper that the badges be procured in the name of the Association, as it would be desirable for the Secretary to retain some in his possession. The price will not exceed \$3, and we will get them for as much less as possible. I move that in this matter the Committee be continued, and that when they make a report they report to the President; and if acceptable to the President and Board of Directors, that they be authorized to procure the badge. I do not feel

like throwing the responsibility of procuring the badges upon the Committee alone, without any consultation or advice.

On motion of Mr. Anderson the report of the Committee was accepted and the recommendations adopted.

QUESTION-BOX.

The President—I was afraid that, owing to the press of other business, our Question-box had been neglected. I was quite surprised the other day, on talking with some of the electric light gentlemen, that they alluded to the Question-box as one of the most interesting features of this Association. We can very well put in there questions as to anything which is troubling us, or as to which we are in any doubt, and get an answer to our queries. That seemed to the electric light men a wonderful thing. I will read the questions which I find in the box.

"What is the effect on meters of the use of crude oil as an enricher?"

Mr. Prichard—We find that when the oil is thoroughly fixed it has no effect that I am aware of.

Mr. Lamson—Crude oil has been used only for a comparatively short time, and I can hardly venture an opinion. We had all formed an opinion in advance with regard to the effect of naphtha on the meters—that it would be injurious; but I do not myself believe that it has been injurious to any great extent.

"How many days is it best to allow for the payment of gas bills?"

Mr. Fowler—In Westfield we wait 5 days.

Mr. Harbison—Five days, not counting in the day that the bill is delivered, Sabbaths or legal holidays.

Mr. Coffin—We allow 15 days, but about all the business is done in about the last two days.

Mr. Tilton—Ten days.

Mr. Cogshall—Ten days.

Mr. Allyn—Twenty-five days, with the addition of 25 cents per 1,000 after that.

Mr. Sherman—Ten days.

"What dissatisfaction, if any, is caused among regular customers by making a reduction to users of gas stoves?"

The President—As I understand that question, it is, supposing you allow a gas stove man to have his gas at one dollar, how much dissatisfaction is caused when he comes to pay for his illuminating gas at \$1.50? Is the practice adopted in any of our New England gas companies of making a differential gas price on gas for illumination and heating?

Mr. Anderson—Our practice has been to charge \$2.50 for illumination and \$2 for stove.

Mr. Fowler—Is there any difference made in the price of gas for power and for illumination?

The President—I think there is no question about that. Who has gas engines in use?

Mr. Goodno—We allow a discount of 50 cents per 1,000 from the regular price for stoves, engines, etc., and we find that it is gratifying to the consumer; and it does not seem to react the other way and make him complain of the higher rate. I have not heard anything of that kind.

Mr. Harbison—I do not believe in the theory or principles of making a price for different uses of gas. I do not think that it ought to make any difference to the gas company whether the consumer uses gas for power or for heat, or for illumination. If you do make a difference in your price for different uses, you are making trouble with your customers. You make one man pay more who uses a large quantity for illumination than his neighbor pays for a small quantity for running his gas engine. If you begin to make a different price for the use of gas according to what it is used for, it increases the number of meters, and that is very objectionable on account of the expense involved. But you must do that in order to determine the quantity used. I think that both the principle and practice are wrong. I think that gas should be sold for all uses at the lowest possible rate.

Mr. Neal—I think it is a very good plan to make special rates for special consumers. We do it for gas engines and we never have had any trouble arising from it.

Mr. Coffin—We have three or four gas engines, but I believe that to the largest (a ten-horse power engine) we do not sell over three thousand feet per month; whereas we have some consumers who use three times that amount for illumination. I think that a consumer would have a just cause to complain that a party using only one-third the gas that he did could buy it a lower rate.

Mr. Greenough—I agree with Mr. Coffin. I do not think it is fair to discriminate against our principal consumers of gas for the purpose of

building up a trade. The question has been very carefully argued on the other side of the water; and in Brussels at the present time, I think, they have a meter which works in different compartments, according to the amount of pressure put upon it; and that for the gas used in the day time they charge one price, and charge another price for the gas used in the night. According to that plan, those who use gas in the day time get it for less money, and I think it is fair; but I think it is not right to turn against our principal consumers by selling gas to the small consumers for a less price. The question was brought up in the South Metropolitan Company, in London, and argued fully by Mr. Livesey, who maintained that the principal purpose for which gas was made was for illumination, and that if anybody was to get his gas cheap it should be the person who used it for light; and that to sell it to any one else at lower prices was to discriminate against the ordinary consumers in an unfair way. I must say that I think he was right in that view.

Mr. Coffin—We have in use over one hundred gas stoves, and last year they averaged a little more than \$10 net, each; but after setting a separate meter, and doing all the additional work required, and then sell a party only \$10 worth of gas per year, if we were obliged to do that at much lower prices than our regular price, it would seem to me to be bad policy.

Mr. Todd—I think the better way is to have a sliding scale, and let the largest user of gas, whether for illumination, power, or heating, have the biggest discount.

“What is the best material and manner of repairing leaks temporarily in holders?”

Mr. Coffin—I am using red lead, making it quite soft, one component part being shellac.

Mr. Allyn—I know of no better cement than one made of glycerine and litharge. It sets very quickly, is elastic in a measure, and after it has set it is very hard and very tenacious.

Mr. Anderson—I have had a little experience in this line. My holder, where the sheets were riveted together on the side, rusted out in places 8 and 10 inches long, so that the gas came out freely. The iron was so rusty and corroded that it was almost impossible to hold the cement on the sides. I took a lot of canvas duck and shellacked it, laid it over the break, tapped the canvas in the center so as to allow the gas to escape while the canvas was setting on the larger portion of the break; and after it had set closely on the holder I had no trouble in sealing up the small hole I had made in the canvas. It ran along for a year without trouble.

Mr. Harbison—Some years ago, during a severe snow storm, the top of one of the Hartford holders broke, and in coming down cut a hole in the side of the holder 16 inches long, five sheets from the top. We put a plate of iron on the outside, and it has remained there to this day in good shape.

Mr. Tilton—I have, during the past year, repaired one holder by soldering, where the leak was considerable. I first scraped the sheet, then thoroughly tinned it, and made a complete and good job by using soft solder. I have repaired a dozen different places on the holder in that way.

The President—Those are all the questions there are in the box. Are there any others which any one wishes to ask?

Mr. Addicks—I would like to ask for a method of preventing the gasfitter putting on 2-foot tips to save gas bills.

Mr. Coffin—One way to do it is to do your own fitting, and do it at such a price that the gasfitter cannot touch it.

The President—We get over that difficulty in the same way.

Mr. Harbison—I think if gas companies will provide a supply of burners that they can recommend as giving a good light for the quantity of gas consumed, and sell them to consumers at cost, they will have very little difficulty from any party putting on inferior burners. We have adopted that course and found it to work very satisfactorily indeed.

Mr. Lanc—We have adopted the plan of furnishing the consumer with tips, and I think it pays to do so.

Mr. Anderson—I would like to ask the opinion of the Association as to what burner they consider the best to adopt to be sold to the consumer at cost. I have tried a number of burners of different kinds, and finally have come to the conclusion that the Bray burner gives the best satisfaction, and gives more light, for the amount of gas burned, than almost any other I have tried.

Mr. Addicks—We tested a large number at Chicago at one time, and found that they were apt to stop up.

Mr. Coffin—We adopted the Bray burner at one time, but found them hard to clean out.

Mr. Boynton—I would like to ask what is the effect of varying tem-

perature and varying density in the registry of candle power upon the jet photometer. Perhaps Mr. Jones can tell us.

Mr. Jones—I have no figures at hand which I would like to give in answer to that question.

Mr. Prichard—I suppose the gentleman's question has reference to whether it is plain coal gas, or a mixture of coal and water, or coal and oil. I think that Mr. Jones can explain better than anybody else why photometers have to be adjusted for different densities of gas.

Mr. Jones—The jet photometer which I make is adjusted for all ranges of density, so that the instrument is approximately correct, as all photometers are. There is a great deal of dissatisfaction or fault found with photometers in general. The water gas photometer is of course made for a gas of greater density than coal gas, and is adapted to ranges of from 520 to 620; coal gas photometers are adapted to gas of a density in the neighborhood of 425, and oil gas photometers are adapted to gases of greater density.

Mr. Todd—I would like to ask what the members think is the best burner for street lights where there is a greatly varying pressure—say from 35-tenths to 25-tenths. The tips must be 4-foot. What is the best burner to regulate the pressure on street lamps?

Mr. Coggshall—The Springfield burner.

Mr. C. S. Spaulding—The city of Boston uses the glycerine burner, which we are using in Brookline; and after being on for three years, and having had a record kept, I know that they will burn within 0.02 of what they did when they were put on.

Mr. Harbison—Some years ago the city of Hartford was well lighted, as far as the streets were concerned; and at that time we were induced to put on a couple of dozen of glycerine burners for the purpose of testing them. They were 4-foot burners. We watched them very carefully, and in 20 days found that at least half of them were burning 10 or 12 feet.

VOTES OF THANKS.

The President—The papers which were prepared for us have all been read and discussed; the questions found in the box have been answered, and the work before us, so far as it was laid out by our absent Secretary, has been, as far as I know, thoroughly gone through. Unless some member has some business which would properly come before us, a motion for adjournment is in order.

Mr. Harbison—Before a motion to adjourn is made I wish to return special thanks, in my own behalf, and in behalf of the members of the Association, to our President, Mr. Taber, who has filled the chair at this session, and has performed the duties of his office during the past year to our entire satisfaction. He has been exceedingly courteous in his treatment of members, very thorough in his management of the business, very calm and deliberate in his judgments and decisions, and it is due to ourselves that we should place on record a vote of thanks to our retiring President, and I so move.

Mr. Stiness—I second the motion.

The motion was put by Mr. Prichard (President-elect) and unanimously adopted.

The President—Gentlemen, there ought to be a vote of thanks to you, rather than that you should give me thanks for doing what I have done so incompletely. I thank you most heartily for the courtesy you have extended to me. The absence of the Secretary necessarily threw a great deal of extra work upon us, and that he was not able to get here in time was a matter of regret to me; but your uniform kindness has enabled me to get through with the business. There has been but one subject brought up that has in any way tended to disturb us, and that has been treated in such a kindly way, and with such open, fair-hearted criticism, that I am very glad indeed that it came before us. I welcome it as a fact of a good deal of importance that we can criticise each other honestly, honorably and amicably, and state what we think, and why we think it. I have great faith in the future of this Association. I notice that our papers are getting more and more practical, more and more pointed, and that we are all getting more and more in earnest in the matters that come before us; and I trust this spirit may continue from year to year. I would remind you that we have had a Secretary *pro tem.* this year, who has ably filled the duties usually so ably managed by Mr. Nettleton; and I move that a vote of thanks be given to him for his kindness in attending to the duties of that office.

The motion was unanimously adopted by a rising vote.

Mr. Humphreys—I am exceedingly obliged to you, Mr. President and gentlemen, for your kind vote of thanks. I have recalled during the past two days our meeting at Baltimore of the American Gas Association, of which I am Secretary. You will remember that then, through illness, I was unable to take my usual place; but I received so much help from my friends at that time that the work went on without any

hitch, and that has made me all the more willing to serve you in the capacity of temporary Secretary during this convention.

PLACE OF MEETING.

Mr. Greenough—I move you that the Executive Committee of this Association next year consider the advisability of finding larger quarters for our meeting. The time was when the parlor of the Tremont House was large enough to hold us; then we came to this place; and now we have outgrown our present quarters. The ventilation of this room has been so poor that a number of our members have gone out because they could not stand it here any longer. I do not think there will be any difficulty next year in finding some small hall where we shall be more comfortable than here.

The President—I might say, in that connection, that in the proposed gas stove exhibition that we had on hand this year (and which was so heartily seconded by every maker of gas stoves), the great difficulty was in finding a place suitable. It was suggested in the course of the discussion that some such change as is now proposed should be made—not that we are anxious to leave our old home, for we are all familiar with this room, but because we are growing larger every day, and really need a larger room for our meetings.

The motion was carried.

The President—I wish to bring up something which has not been referred to yet, and that is that I think a vote of thanks is due to the local press for their fairness and care in reporting our discussions. It does not, of course, call for any response from them, but I will say that they have been very careful and accurate; and I think that a vote of thanks is due to them for their politeness towards us.

A vote of thanks to the local press was passed.

Mr. Harbison—It has been suggested to me that there has been no vote of thanks proposed, nor any fit announcement made with reference to the postponement of the entertainment tendered to us, and which has been postponed on account of the weather.

The President—That announcement was made in the early part of this morning's session, but I will repeat that, owing to the storm, it was not thought best to accept the invitation; but the thanks of the Association are due for the generous offer.

The thanks of the Association were voted to the companies extending the invitation.

On motion the Association then adjourned.

IN MEMORIAM.

The Committee appointed to prepare a memorial of our late associate,
MR. OLIVER E. CUSHING,

respectfully submit the following:

Oliver Edwards Cushing was born at Chelmsford, Mass., in March, 1829, and died in Lowell, Mass., January 17th, 1890.

He was one of the original members of the New England Association of Gas Engineers, and also one of the first Directors, but declined to accept the office of President.

He was also one of the original members of the Guild of Gas Managers, of New England, and served as its President two years. He was elected a non-resident member of the Society of Gas Lighting, of New York, in 1876. He was elected a member of the American Gas Light Association at its second annual meeting, in 1874, and continued his membership in these several Associations up to the time of his death.

He entered the service of the Lowell Gas Light Company as agent, in 1860, and continued with the Company until his death.

Mr. Cushing's lifework as a gas engineer was marked by success; and in all the various relations which he sustained to the business of gas manufacture, whether as a member of the several Associations, or as an officer, his course was always marked by a quiet dignity of manner, coupled with good practical judgment, which made him an agreeable associate and a wise and prudent counsellor.

In his death we feel that this Association has lost one of its most valued and worthy members, and that his memory will always be cherished by the most kindly feelings of all his associates.

(Signed)

SAMUEL G. STINESS,
A. B. SLATER,
C. F. PRICHARD, } Committee.

The Meyer Valve Indicator.

This apparatus, herewith illustrated (which is covered by United States Letters Patent, granted October 8, 1889), is known to the trade as the Meyer valve indicator, and its claim for consideration at the hands of gas engineers—that is, in respect to its especial advantage for their use

—is that it indicates clearly, from a simple glance, the exact state of the valve opening. In short, it presents a picture of the interior of the valve in the position most convenient to the eye of the person operating the valve. It can be applied to any valve—gas, steam or water—in any position howsoever hidden, and does not get out of order. Many of

these indicators have been used for some time in this city and elsewhere, on valves from 12 inches to 30 inches diameter. For application in a valve room it is only necessary to know the size of the valve, the number of turns required to raise it completely, the diameter of the valve stem, and the distance from the top of the valve stem to the upper side of the flooring in the valve room.

Any additional information in respect to the Meyer apparatus may be readily obtained from Messrs. James R. Floyd & Sons, of this city, who are the sole manufacturers of the device.

The Manufacture of Oxygen for Industrial Use.

The *London Journal* reports that at a recent meeting of the Institution of Mechanical Engineers, in London, a paper on the above subject was contributed by Mr. Kenneth S. Murray. It described (with the aid of illustrations) the plant used by Brin's Oxygen Company, with which the author is connected, whose works in the Horseferry Road the members were afforded an opportunity of visiting. In view of the recent utilization of oxygen, manufactured by the Company's system, for the purification of gas at the Ramsgate Corporation Gas Works, on Mr. W. A. Valon's recommendation, and under his supervision, an abstract of the paper, and a short report of some of the remarks thereon, may be of interest.

The author commenced by referring to the discovery made by the eminent French chemist Boussingault, about 30 years ago, upon which the Brin process is founded—that monoxide of barium has the property of absorbing oxygen from the atmosphere when heated to 1,000° Fahr. (the result being a dioxide), and that the oxygen thus absorbed would be given off again at a temperature of about 1,700° Fahr.; the monoxide being apparently restored to its original condition. It was found, however, that the barium monoxide gradually lost its virtues as an agent for extracting and giving up again the oxygen in the atmosphere. The discovery consequently had no important industrial result for very many years, until the brothers Brin determined to turn the researches of their compatriot to commercial uses. The barium oxide, commercially known as baryta, is used in bleaching processes, and is therefore an article of commerce; but that which is placed on the market by manufacturers is not sufficiently pure for the purpose of oxygen manufacture. The baryta required was therefore made on the Brin Company's works; and its manufacture has been so far perfected that the difficulties encountered by Boussingault and others have been practically overcome.

The method of working is as follows: The baryta is placed in vertical steel retorts, and these are subjected to the heat generated by the burning of carbonic oxide from a gas producer, which forms part of the apparatus. The retorts are 9 ft. long and 7 in. in diameter; the metal being $\frac{1}{2}$ in. thick. In the plant described there are 24 retorts, which will hold 2,100 lbs. of baryta. Arrangements are made for

charging or emptying the retorts while in position. This is one of the recent improvements in the plant. Air is compressed in a suitable pump to a pressure of about 10 lbs. to the square inch, and is then delivered to the purifiers containing caustic lime and caustic soda, in order that the carbonic acid and moisture may be extracted. After leaving the purifiers, the air passes to the retorts, and the oxygen is absorbed by the baryta; the nitrogen escaping into the air through a release valve. When the peroxidation of the baryta has continued for the desired period (say, $7\frac{1}{2}$ minutes), the operation of the air pump is reversed by an ingenious automatic device which throws the purifiers out of the circuit by means of cocks, and the retorts are subjected to a vacuum of about 26 inches of mercury. Deoxidation of the baryta then takes place, and the gas thus obtained is stored in a suitable receptacle. The result is oxygen to the extent of about 96 per cent.

The cost of production, allowing for depreciation of retorts and baryta, is said to range from 2s. per 1,000 cubic feet in ordinary gas works, to 6s. 6d. in works especially erected for the production of oxygen only, where additional charges would have to be made for labor and rent. The demand for oxygen in retail business appears to be constantly increasing. In 1887, Brin's Oxygen Company sold from their works no more than 142,000 cubic feet for limelight and other purposes. The quantity sold in 1889 amounted to just 1,000,000 cubic feet, notwithstanding that the Manchester Oxygen Company have recently taken over the whole trade of the North of England.

The paper closed with a description of the high pressure cylinders in which the oxygen is sent out, and of the compressors used for charging them; and in connection with the industrial uses of oxygen, the author referred the members to the paper read by Mr. Valon before the Gas Institute in June last year.

In the course of the discussion on the paper, Dr. Thorne, the Company's Chemist, gave some additional information. He explained that the opinion which had been expressed as to the dependence of the process for its extensive application upon the successful manufacture of the steel storing cylinders, was incorrect; for the cylinders were only used in storing small quantities for such purposes as limelights, etc. Wherever the use of the oxygen was at all extensive, the gas works or steel works at which it was employed would have plant erected expressly for its manufacture, and then no compressive storing would be required. The introduction of oxygen into metallurgical processes had a great future before it, and at the present time a number of very important experiments were being carried on with regard more especially to the reduction of the refractory ores. It had been stated that difference of pressure was the key to the success of the process; but he reminded the members that there was nothing extraordinary in the fact that at different pressures different chemical operations took place. When the plant was first erected, the peroxidation was conducted at a dull red heat and the deoxidation at a bright red heat, both at the same atmospheric pressure. It was afterwards found that the same effects could be obtained, but far more economically, if the temperature at which the two operations were conducted was kept constant at a little below the mean of the two, and if the pressure was increased for the first operation and decreased for the second. Theoretically, 1 lb. of baryta would absorb and give off again $1\frac{1}{2}$ cubic feet of oxygen. With the old process, only about 0.6 or 0.7 cubic feet could be obtained practically; and even this occupied three hours. With the new process, although the same yield of oxygen was obtained, the cycle of operations only took 15 minutes; so that the new process was in the end much more economical. With regard to the industrial uses of oxygen, the purification of coal gas was a prominent feature among them. It was being tried at the Ramsgate Gas Works; and it was hoped that Mr. Valon, the Engineer of those works, would have been able to attend the meeting to speak on the subject. But he was unfortunately prevented from doing so on account of an attack of influenza which had confined him to his room. Dr. Thorne then described the plant in use at Ramsgate and explained the process of purification by oxide of iron. He stated that in carrying this out, a small quantity of air was sometimes mixed with the gas before it entered the purifiers, so as to make the process continuous so long as the oxide retained its purifying property. This, however, had the effect of detracting somewhat from the illuminating property of the gas, due to the nitrogen in the air admitted to revivify the oxide. It was found that by using a corresponding quantity of pure oxygen in place of air, not only was the revivification more effectually carried on, but that the loss of luminosity resulting from the mixture of air, gave place to a slight increase of lighting power. A further discovery was made that the oxygen could be employed with the lime process of purification, and the use of oxide done away with; for, if oxygen were employed in the

same way, the sulphur compounds could be removed by the lime process, and render auxiliary oxide purifiers unnecessary. Mr. Valon had stated that the total sulphur in purified gas treated in this way did not exceed 8 grains per 100 cubic feet. The quantity of oxygen passing over into the gas must be small, and then the illuminating power was increased; but if any considerable excess of oxygen passed, the lighting power was decreased. The proportion of oxygen found to give the best results had been stated by Mr. Valon to be 0.10 per cent. of the volume of the gas for every 100 grains of sulphur per 100 cubic feet of crude gas. Under these conditions, the sulphur remained fixed in the lime (partly as free sulphur), and did not move forward when the lime became saturated with carbonic acid, as was the case under ordinary conditions. The life of the lime was thus nearly doubled. A most important feature, so far as the public were concerned, was that the lime, when at last it became spent, was an almost odorless and dry substance. The advantage of this in a pleasure or health resort such as Ramsgate was, as Mr. Valon pointed out, very great. Having referred to some of the other commercial uses of oxygen, Dr. Thorne concluded by remarking that the industry was at present in its infancy; but he believed that in the future these uses would be found to multiply almost indefinitely. Sir James Douglass said he was more especially interested in the production of oxygen with the view to its application to the intensifying of light. Experiments had been made at the suggestion of Mr. Goldsworthy Gurney, who had offered to make a trial at Oxford Ness light. With the same sectional area, the intensity of the light had been increased $2\frac{1}{2}$ times. This was very satisfactory; but the application was not successful commercially, as the oxygen was too dear, and it was found better to pay for more oil than the oxygen. In replying at the close of the discussion, Mr. Murray stated that the price of oxygen was 2s. per 1,000 cubic feet when made and used at one place—for instance, in the case of a gas works, where special plant was erected and the oxygen used as it was made. Compressing the gas doubled the price; but in any case the figures varied with the conditions under which the oxygen was made.

Fire Danger from Outside Electric Currents.

The Boston Manufacturers' Mutual Fire Insurance Company have published the following circular:

Electric light was first introduced in a very few risks insured by this Company before the year 1881; in that year, and in the first six months of 1882, it was adopted in a very considerable measure. In this period of its early introduction, prior to April 1, 1882, we received notice of 23 fires which had been set by the electric current in only 61 mills which had then been equipped. No claim for loss was made on any of these fires, but they disclosed conditions which were very alarming to us. An immediate investigation was made, under the direction of Mr. C. J. H. Woodbury, and certain rules were adopted for putting up the apparatus, insulating the wires, and guarding against the dangers disclosed in these 23 fires. These rules were immediately submitted to all the electric light companies or manufacturers of electric lighting apparatus who had any standing in the community, and were at once adopted by them, as well as by all insurance companies. They have not been changed since that date except so far as new inventions have called for modifications.

Since April 1, 1882—a period of nearly eight years—we have received no notice of any fire which could be attributed to electricity in any risk insured by this Company, and of course no claim has been made upon us for a loss which could be attributed to this cause. Our experience, therefore, justifies the conclusion to which we came after the first two years of electric lighting—that under proper safeguards it is the safest method of lighting that can be introduced. Electricity has also been applied in some of the works insured by us as a motive power, and electricity is now applied to lighting or motive power in over 600 risks which are insured by the factory mutual companies.

Attention, however, has lately been called to the danger of wild currents of electricity generated on the wires which may be in use for lighting, for power, and for railway service in many cities. There appears to be very little doubt that the recent destructive fire in Boston originated in the diversion of a high-tension current of electricity from its own wire to an electric-clock wire, on which it was carried to the building in which the fire originated. There appears to be little doubt that this conflagration may be attributed to the lack of precaution in guarding against an outside current of electricity. Such currents may be carried from their proper wires to other points in all cities and towns in which electric light or power is widely distributed on the public streets or over private buildings.

In order to guard against this hazard, the owners and managers of mills and works insured are advised to establish the following rules for the protection of their premises. These rules, after having been drawn by us, have been submitted to experts in various branches of electric science who are of the highest authority. The forms have been modified by them, again considered on our own part, and are believed to be suitable for what may be called an emergency:

1. No foreign wires of any kind shall be attached to buildings insured by this company for the purpose of carrying electric currents across the yard to any point.

2. All electric wires which may be required by the insured shall enter the premises at one point near the headquarters of the night watchman, where they can be kept under supervision; each of the said wires shall be guarded by a protector against strong currents operating by opening the circuit, and by a lightning arrester.

3. Such protectors against strong currents shall be located in a dry, accessible place inside the building, and as near the point of entrance of wire as possible, and shall be without ground connection; such protectors shall be mounted on non-combustible and insulated supports, which shall be provided with a receptacle for the burning or melted parts of such apparatus.

4. The lightning arresters on all wires must be placed between the protector against strong currents and the electrical portion of the apparatus within the building to which such wires are connected. No ground wires for such lightning arrester shall be attached to gas pipes within the premises of the insured.

5. All electric wires which may enter the premises of the insured must be insulated, between the line wire on the insulator attached to the buildings outside and the protecting device within, with the best quality of waterproof insulation. Moreover, such wires must enter at a distance of not less than three (3) inches from any other wire or any conducting material.

6. If any wires carrying high tension or strong currents are to be carried over or under other wires on the property of the insured, they shall be attached to poles so near to each other, with one wire so far above the other, that if a break should occur the pendant wire between these poles may not be long enough to come in contact with the wire below; or, if not carried on poles, these wires shall be so placed or protected with guard wires as to render a contact between different wires impossible.

7. If the high and low tension systems are in use in the same yard, even when developed within the works, the wires must be kept separate; and so wide apart that no contact or cross arc can be made.

Thoughts on Electric Units.

A writer in *Electrical Industries* says that in mechanical work we use quite a variety of units for measurement, and these units are quite well understood by most intelligent mechanics. Electrical measurements are mechanical, and the units adopted are directly related to the mechanical units with which we are familiar. The variations are in sizes of the units and their names. The reasons for adopting new units for electric work are similar to those which induces us to measure coal by the ton, butter by the pound, gold by the pennyweight, diamonds by the carat. We understand that the carat is a certain small part of a ton, but we do not care enough about this relationship to learn what part of a ton a carat is. The human eye has a better idea of the "fitness of things" than to measure diamonds by the same units we do coal. Therefore when scientific men were called upon to establish units for electric measurements, they sought such sizes as the force demanded, and then worked to establish accurately some standards to represent the units adopted. As these units were new they required new names, and what better course could have been adopted than to apply the names of those men who had taught the world so much of electricity as to make a need for these new units of measurement?

An electrician knows that his units are certain small parts of the common mechanical units, but he doesn't think of this relationship, except in those calculations, involving horse power parlance, any more than the diamond dealer thinks of the relation between the carat and the ton. The units mostly in use are the ohm, the volt and the ampere.

We know that any conductor offers resistance to the passage of electricity, just as we know that pipes offer resistance to the passage of water, and a unit was established for measuring this resistance. It was called an ohm, in honor of the German mathematician who originated the simple formula so much used by electricians.

A unit was established to measure the force which "pushes" elec-

tricity through conductors. It is called a volt in honor of Volta, the great Italian electrician. We have two units for expressing the force which pushes water forward, used according to circumstances. If the water is flowing through pipe systems like city water works we use the "pound" to measure the pressure, but if flowing down streams, as used for water power, we use the "foot of head" as the unit.

A unit of quantity was also established, and was called an ampere in honor of a French electrician. There are many other units in use by electricians, but the three mentioned are those most in use, and a full understanding of these is of vast importance to the mechanic. When the uses of these units are well understood it then becomes easy to appreciate the others that have been adopted, but are much less frequently used.

These three units are directly related to one another. The ampere, for instance, is the quantity of electricity which would be forced through a conductor which had a resistance of one ohm by an electric pressure of one volt. To know the work to be done by an electric current we must know both the force and the quantity, which is the same as we require in water power calculations. To say, for instance, that 1,000,000 gallons of water pass a certain place in one day would not convey any idea of the power to be obtained therefrom. The hydraulic engineer must know the number of feet fall that he could obtain for this water. Tell this engineer that you have 1,000,000 gallons per day with a drop of 20 feet, and he could very soon tell you the horse power it would give. So also with electricity; to say that we have 10 amperes would give the electrician no idea of the work that could be done by the current. He must know the force behind it. If, however, you say that you have 19 amperes and a force of 100 volts, he could very soon calculate the amount of horse power obtainable, and he could also tell what could be accomplished with this current in the various ways in which it is used.

The ampere is in reality the measurement of the rate of flow, so to speak, of the electric current, and it does not really give an idea of the quantity passing, because for this we need also to specify the time. Perhaps the best comparison is that of a trotting horse. To say that a horse passes us at a 2:40 pace would give us no idea how far he travels, but to say that he travels at a 2:40 pace for 2 minutes and 40 seconds would give us the idea that he had traveled just one mile. Using the second as a unit of time, then if we have one ampere for 1 second we have in reality a unit of quantity, and electricians have called this coulomb. This term has not come into general use, however, and another unit of quantity has been adopted in practical work. In this case the hour is used for the unit of time, and to express this unit we simply connect the two terms by a hyphen, viz., ampere-hour, and this is the unit used for most electric meters. Unfortunately this unit conveys no idea of the work that can be done by the current. For instance, one ampere hour of electricity with pressure of 50 volts, would only be worth one-half as much as one ampere-hour with 100 volts, and if an electric light company furnishing electricity with a pressure of 50 volts should charge the same price per ampere-hour as another company supplying electricity at 100 volts, the former would be receiving twice the rental of the latter. This difficulty has given rise to the practice of registering the work in lamp hours when used for lighting, and the most satisfactory meters to the public are those which indicate the work in this way. In these cases the 16 candle power lamp is used for the standard.

There are two methods of distributing electricity in practical work, one in which the current is kept constant and the force is varied according to the amount of work to be done; the other in which the force is kept constant and the quantity is varied in proportion to the work done. Suppose we had at the top of a hill a supply of water which we wish to use for power, and suppose that on one side of this hill we could descend into a valley in the depth of 100 feet, and on the other side we could only descend 10 feet, and suppose, furthermore, that we wished to operate 10 water wheels from this water power. If we put these 10 wheels side by side and connect them by a pipe large enough to supply them all, the pressure of the water would remain constant and the quantity flowing would depend upon the number of water wheels working; or, in other words, upon the amount of work done. On the other hand, supposing we put these wheels on the other side of the hill, one wheel below the other, 10 feet apart, and connect them with a pipe one after the other. To make this comparison complete it must be considered that each wheel is on a shelf or terrace in so far as the pipe is not in a straight line up and down the hill, and because each wheel is supposed to require a head of 10 feet only. Now, in this case the quantity of water passing remains constant, whereas the pressure or total drop can be considered as practically proportional to the number of wheels working. To operate all 10 wheels on this system requires a total fall of 100 feet,

and the same water works all the wheels; whereas, to work the 10 wheels by the other system requires a fall of only 10 feet, but each wheel takes its own separate supply of water. Although this comparison is a little difficult, it is essentially the same as the two methods of distributing power by electricity. If, for instance, we have 10 lamps, each of which requires a current of 10 amperes in quantity with a pressure of 10 volts, and we connect these lamps one after the other, then the same current of 10 amperes would work all the lamps, but the force would be 10 times 10 volts, or 100 volts, whereas if we connect these lamps side by side, then each would require its own supply of electricity, the same pressure would work them all, but it would require 10 times as much electricity to supply them.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

A CORRESPONDENT at Freeport, Ills., writes: "Those who suppose that Freeport is sleeping are very much mistaken, in fact Freeport is wideawake. Especially so is this the case in the instance of our Freeport Gas Light and Coke Company, whose proprietor (Mr. Farwell) has decided to install a water gas plant, probably with a view to hastening the time for the distribution here of a fuel gas. A new gasholder will be put up this spring. A day or so ago Supt. Runner informed me that the Company had rented the corner storeroom in the building of the Y. M. C. A., which is to be fitted up as an office and show room. Mr. Farwell, aided by Supt. Runner, will here keep an assortment of burners, globes and electric light fixtures, and last—and most important of all—a good collection of cooking and heating stoves. Mr. Farwell is determined that the housekeepers of Freeport are to have ample opportunity for becoming conversant with the value of *illuminating gas* as a fuel for domestic purposes, and it may be taken for granted that he will popularize its use in this direction by selling it at a low figure.—T. T."

THE Augusta (Me.) Electric Light Company has reduced the rate for each 16-candle power incandescent light supplied to 75 cents per month. The former price was 93 cents.

AT a recent meeting of the Frostburg (Md.) Gas Light Company, Messrs. B. Stone, Lloyd Lowndes, A. E. Hitchais, F. C. Beal and Jas. Keene were appointed to make the necessary arrangements for the erection of an electric light plant to be operated in connection with the gas plant. We understand that provision will be made for an incandescent plant equal to the requirements of 750 lamps of 16-candle power each, and that the capacity of the arc system will be rated to 50 lamps of 2,000-candle power.

WE understand that the proprietors of the Stoughton (Mass.) Light, Heat and Power Company have decided to make a 12½ per cent. reduction in gas rates.

THE electric light plant at Huntingdon, Pa., which is operated as an adjunct to the local gas works, was put in service about a fortnight ago. A correspondent at Tyrone, Pa., sends us the following particulars concerning it: "The building containing the plant is a one-story brick structure located at the corner of Second and Allegheny streets, nearly opposite the Pennsylvania Railroad depot, and adjoins the gas works. The boiler room, which is at the eastern end of the house, contains two boilers, each of 70-horse power capacity. The dynamos are located in the western end of the house, are two in number, and are operated by the improved Ball engines (two in number) of 80-horse and 60-horse power, respectively. The former will operate the dynamos for supplying commercial incandescent lights, while the other will drive the machine that is to furnish the arc current for lighting the streets. The Thomson-Houston system was chosen. The plant cost about \$25,000, and is complete in every detail of modern practice. Mr. B. F. Africa is Superintendent, and Mr. Chas. E. Bates will have charge of the works. Both are competent young men.—C. H. D."

THE appointment of Mr. Samuel J. Fowler, of Westfield, Mass., to the Superintendency of the Springfield (Mass.) Gas Company has been followed by the naming of Mr. William T. Thayer to the position of Superintendent of the Westfield Gas and Electric Light Company. We understand, however, that Mr. Fowler will continue to act as Treasurer and General Manager of the last named corporation.

THE Selectmen of New Brunswick, Me., have been authorized to enter into a contract with the New Brunswick Gas Light Company for the lighting by gas of the public buildings of the town, and also such streets as are not lighted by electricity.

THE new holder on the 26th Ward works of the Philadelphia municipal gas plant was formally inspected by Councils and Gen. Wagner on the 21st inst.

A DIVIDEND of 1 per cent. on the capital stock of the Chicago Gas Trust Company has been declared. It is made payable on and after next Friday. The transfer books remain closed from March 15th to April 25th. The annual meeting of the Trust will be held on the 24th prox., and one of the important matters to be considered thereat will be a proposition to change the name of the corporation. This means, of course, that measures have been taken to re-adjust the affairs of the Trust.

IN the meantime, we might add that the Trust has given notice that it will, until further notice, through separate meters, furnish a supply of gas for fuel purposes, in quantities desired, at the rate of \$1.25 per 1,000 cubic feet, with 25 cents per 1,000 off for prompt payment.

THE buildings of the electric lighting annex of the Faribault (Minn.) Gas and Electric Light Company were destroyed by fire on the evening of the 13th inst. The total loss was \$9,075, apportioned as follows: Buildings, \$1,800; apparatus, \$7,275. The rather astonishing cause given for the conflagration is that a pile of wood which was placed *too close to the furnaces* took fire. Wood under those circumstances can usually be counted on to do its duty. But where was the engineer?

MR. ROBERT F. FITZ, who can travel incog. with ease, grace and dignity, has been appointed Superintendent of the Elgin (American) Gas Company, of Illinois. Mr. H. S. Whipple, formerly Superintendent at Elgin, goes to Rockford (Ills.) to take charge as agent there of the American Company's latest purchase. We congratulate Messrs. Whipple and Fitz on their promotions, and the American Company also on its good fortune in having such attaches.

A CORRESPONDENT, writing from San Francisco, Cal., under date of March 11th, forwards the following: "The City Council, on March 5th, granted to George W. King, of Los Angeles, Cal.—the right has been properly signed by the Mayor, and is therefore binding—and his assigns and legal representatives, the right to lay gas mains in that city. The conditions are: The life of the right is 50 years, the Company is not to charge over \$1.50 per 1,000 cubic feet to the city buildings (to include schools, engine and police stations, etc.), nor is any higher rate to be charged to private consumers. King is to file a bond, in \$20,000, for the proper replacing of the street pavements, is to lay 10 miles of pipe (distributing mains) within 1 year, and is to pay 2 per cent. of the *gross receipts* each year to the city, the payments to be made at the end of each 6 months. I have but one copy of the ordinance, else I would send you the thing complete. Mr. King was connected in some manner with the gas companies of your city, and claims to have been one of the first to introduce water gas there. He is in control of capital, and I believe he means business. I will send on word if there is anything new in the developments. The price of gas was reduced in Los Angeles, on March 1st, from \$2.25 to \$2 per 1,000; but the people seem to have been spoiled there because of the late gas war in that city, when gas sold for a time at as low as \$1 per 1,000.—RETORT."

THE following, respecting the fuel gas supply of the Louisville (Ky.) Gas Company, will be read with interest: The mains and plant of the absorbed Citizens Gas Company are employed on the work, and the streets on which the fuel gas supply may be obtained are the following: 7th, from Ormsby avenue to Chestnut; 6th, from Broadway to Main; 4th, from Broadway to Main; 2d, from Broadway to Main; Broadway, south side, from 4th to 7th; Broadway, north side, from 2d to 6th; Chestnut, from Brook to 10th; Walnut, from 3d to 6th; Jefferson, from 1st to 7th; Market, from Jackson to 12th; Main, south side, from 1st to 14th; Madison from Brook to Preston; Preston, from Madison to Market; 12th, from Main to Chestnut. The price to consumers on these streets will be 50 cents per 1,000 cubic feet, and the Company has also reduced the price of gas (of the illuminating sort) to parties not in the fuel gas district proper for purposes other than illumination to 75 cents per 1,000 cubic feet—a separate meter to be used. Therefore does it seem that Engineer Barret is to be credited with being the first in this country to have practically shown the way to the realization of the full benefit of a fuel gas that is bound to succeed—that is, the supply of a rich gas at a reasonable figure—indeed, at a low figure; for his illuminating fuel gas at 75 cents per 1,000 is bound to be a cheaper and better article than the non-carbureted fuel gas at 50 cents per 1,000. President Morris says that the Company will be able to furnish all the fuel gas needed, but will not make any extension of the fuel

gas mains until the demand justified it. The Gas Company has fuel gas in the district of the Kentucky Rock Gas Company, but does not now expect any consumers in such district, as the price of natural gas, with the discount off, is but 22½ cents per 1,000 cubic feet, while the artificial article is to be charged for at the rate of 45 cents per 1,000 with the discount off.

WE understand that Mr. Walter Woolcott, the urbane and clever Secretary of the Kansas City (Mo.) Gas Light and Coke Company, is now in the East, with a view to inspecting the various processes under which fuel gas is manufactured. He will visit the following places: Chicago, Ills., Jackson (Mich.), Cleveland, Akron, Pittsburgh, Pa., Jersey City, Louisville, Ky., and Tacony, Pa.

THE bill filed by F. M. Charlton against the Chicago Gas Trust Company to wind up its affairs and for the appointment of a Receiver was dismissed before Judge Collins, and a new petition or suit was filed. The new proceedings state that the Trust is about to pay to its stockholders the sum of \$250,000 in dividends, and complainant avers that if the Trust erected gas works, as the Supreme Court says it should, it could not pay the dividend just declared. In addition to the prayer in the first complaint Mr. Charlton asked that the payment of the dividend be enjoined.

AMONG new incorporations we note that of the Leavenworth (Kas.) Electric Light Company. The purpose of the organization is to supply light and heat by the use of gas, electricity, steam or hot air. The capital is put at \$100,000, and the Directors are: Messrs. Edward Carroll, McCown Hunt, Paul E. Harms, John Gimper and E. Henning.

MR. J. F. SCRIVER, Secretary of the Montreal (Can.) Gas Company, recently had a novel experience, as may be gleaned from the following bit of history. Edward Holloway, of 210 Peel street, had the worthy Secretary up in a local police court on a charge of assault. The alleged assault took place in the office of the Gas Company, to which premises Holloway had repaired for the purpose of asking for further grace in the matter of the payment of an overdue gas bill. In the course of the negotiations some exciting language was indulged in, and at last Mr. Scriver ordered Holloway to leave the room. On the refusal of the latter to obey the order, Mr. Scriver ejected him. The action for assault followed, but on hearing the evidence the Judge dismissed the suit with costs, holding that plaintiff should have left the premises when requested to do so.

ONE of the best arranged and most capably managed electric light plants within the borders of the State of Georgia is that owned by the Athens Gas and Electric Light Company; and it ought to be a good one, for \$50,000 was expended in its construction and equipment. It might also be said that the gas works are modern and complete. The electric annex contains two steel boilers of 70 horse power each, and two engines (one of 70-horse and one of 50 horse), which operate one 50-light arc machine, and one 650 light incandescent dynamo. The apparatus was furnished by the Thomson-Houston Company, and it is handsome and complete. Forty arcs are now in circuit, and the Company has application for 300 incandescent lamps, which it is now arranging to supply. Dr. J. A. Hunnicut, President of the Company, has great faith in its future.

THE Board of Public Works, Duluth, Minn., have extended the contract for public lighting, for a period of 3 years, with the Duluth Gas and Water Company.

WHEELING, West Va., is very much excited over charges brought against Oscar Seeley, Trustee of the City Gas Works, that three years ago he appropriated over \$1,000 worth of materials to his own use. Ex-superintendent Darral is said to have made the accusation.

SOME time ago we noted that the gas works at Reading, Pa., operated by the Reading Railroad Company, had been seriously damaged by an explosion. The Company, as a result of this happening, has decided not to rebuild the works, and to abandon the use of gas altogether. In the meantime the electric plant will be enlarged sufficiently to furnish all the light needed in depots, yards and shops.

THE lighting situation at Los Angeles, Cal., has been further simplified in the purchase by the Los Angeles Lighting Company (which is a consolidation of the Los Angeles Gas Company and the Lowe Gas and Electric Company) of the Los Angeles Electric Light Company. President Cline, of the Gas Company, has been chosen President of the newly-acquired corporation.

THE Methuen (Mass.) Gas Light Company has been incorporated with a capital of \$25,000. Its officers are: President, James F. Wall; Treasurer, Granville Parks. The stated objects are: "The manufacture and sale of illuminating and fuel gas and electricity for light, heat and power." It is presumed that this Company means business; for it will be remembered that a similar venture proposed there some time ago was never brought off.

THE officers of the Troy (N. Y.) Gas Company say that the public may rest assured that the Company will be ready to fulfil its contract with the city within the time specified—90 days from the date of contract—for the public lighting by electricity.

IN the matter of the failure of the Artificial Gas Company, of Greenville, Darke county, O., briefly alluded to in our last issue, we have the following further advices, by way of Dayton, Ohio: "One of the worst failures ever reported in Darke county is that which occurred about a fortnight ago in Greenville. The Artificial Gas Company, with its President and Secretary (John and Elijah Devor) are heavily involved. The matter was brought to a head by the filing of a suit by Mr. R. R. Dickey, of this city, who is well known to the fraternity of the West from his connection with the Dayton Company, who asked that the Greenville Artificial Gas Company be declared insolvent, and that a receiver for its affairs be appointed. Shortly thereafter John Devor made a voluntary assignment, and this act was duplicated immediately by Elijah Devor, both acting as individuals, the assignees being James A. Reis and Frank M. Eidson, respectively. These acts were followed later by the assignment of the Devor Gas Company as a corporation, Reis and Eidson being again named as assignees. The liabilities of the Company are put at \$50,000, and the assets are considerably under this figure. The liabilities include \$14,000 bonded indebtedness, and this sum is divided in the following manner: R. R. Dickey, of Dayton, \$4,000; Citizens National Bank, of Urbana, \$4,000; Second National, of Greenville, \$6,000. The bonds, however, are amply secured. The personal liabilities of the Devors are estimated at \$56,000, with perhaps assets of \$30,000."

IN our last we made note of an application to the authorities of Salt Lake City, by one Judge French, for an opposition charter. The Judge has thus unbosomed himself in respect to the project: "I have all the capital behind me necessary to carry out the plan and make it a success. I am somewhat familiar with the gas business now, being interested in two Eastern companies. This city needs first class gas works, such as we shall build if we are given the franchise, and I know it would be a good investment." Yes, Judge, it would, and it would further give you an excellent opportunity to harras the existing gas company, and perhaps to give you a chance at its treasury. Come to think of it, we were always under the impression that Salt Lake City had a pretty good gas works, and that its business was handled in a liberal and progressive fashion. In fact, we are still under that impression. Further, the Judge's plan may yet "gang aft," and we certainly hope they shall.

THE Woonsocket (R. I.) Gas Company is installing a new station meter.

THE Allegheny Heating Company, of Allegheny, Pa., has been awarded the contract for supplying natural gas to the public buildings in that city. The rate agreed on is \$25,000 per annum.

THE rates on cast iron pipe are not likely to be advanced this season, judging from the tenders made by several manufacturers in the competition for supplying pipe under contract to the Water Committee of Allegheny City. The successful bidders made the following propositions: 4-inch pipe, \$26.40 per ton; 6-inch, \$24.80; 8-inch, \$24.80; branches, 2½ cents per pound; sleeves, 2½ cents per pound.

MR. WILLIAM ST. JOHN, General Agent of the gas department of the Safety Car Heating and Lighting Company, of New York, who are the proprietors for the Pintsch compressed system of gas lighting for the States, has about convinced the Georgia Southern Railroad Company that the service of the Company would be improved were it to adopt the Pintsch system for the lighting of its cars. It is also rumored that the Pullman Company will light all its sleeping coaches by the same method.

CHARLES JENNEN, a resident of Clifton, Ohio, a village close to the city line of Cincinnati, has applied to the courts for an order setting aside the contract made by the village with the Cincinnati Gas Company for a supply of gas to the public lamps.

WE welcome to the East Mr. George C. Hicks, formerly of Chicago, Ills., who is to have personal supervision of the Boston Fire Brick Works, owned by Messrs. Fiske Coleman & Co., of 62 Congress street, that city.

THE Monroe (Mich.) Gas Light Company having completed its original term (30 years) of incorporation, has filed articles of association for another term of 30 years.

A RATHER odd suit, which is reported from Newark, N. J., is that of W. H. Ratcliffe and others, against Jennie A. Moorehouse and others. According to the papers in the case, the defendants have been attempting to invent a gas machine for the past 15 years, and some time ago they engaged a party to draw up plans for a new construction. When these were finished they awarded the construction of the machine to plaintiffs, who claim that defendants agreed to pay them at the rate of 50 cents an hour till the apparatus was completed. The latter assert that a fixed sum was agreed on. The difference is perhaps \$200.

AT last the Trustees of Cicero, Ills., have granted a franchise for the construction and operation of a gas works for that town to Messrs. Martin Maloney and W. A. Toles. The prices for gas are not to exceed \$1.40 per 1,000 cubic feet for illuminating gas and 60 cents for fuel gas, for a period of 2 years from the passage of the ordinance, and after that time, \$1.25 and 50 cents respectively. The ordinance provides that in all streets that are to be permanently improved, mains and laterals shall be laid before the improvement, and all service pipes, connections and meters to be put in at the expense of the Company. The works are to be completed and gas is to be supplied by November next, failing to do which the Company forfeits \$10,000 to the town, which sum will have to be deposited with the Town Treasurer before the ordinance is operative.

AT a special meeting of the Norfolk (Neb.) Council, Messrs. G. A. Brooks, of Bazile Mills, and certain Chicago capitalists, were granted a franchise for the construction and operation of a gas plant in Norfolk. The plant is to cost not less than \$50,000, and is to have a daily capacity of 100,000 cubic feet. Work is to be commenced on the plant within 6 months, and it is to be completed within 18 months. This place is a post village of Madison county, Neb., and is on the north branch of the Elkhorn river, at a point about 50 miles north of Columbus.

ACCORDING to a local authority, "The Superintendent of the Alexandria (Va.) city gas works reports that an expenditure of some thousands of dollars will be necessary to put the plant in complete order, if not to secure its safety. The gas works has always been the money maker of the corporation, and now that the establishment is relieved from the burden of lighting the streets, which, in the works' report of 1890 was carried on at a cost of \$6,116.79, it will pay into the city treasury about \$10,000 per annum. Heretofore the policy has been pursued of allowing the gas works to run down for want of the stitch in time that saves nine, until lately. A very large expenditure was made on the works for a new holder, etc., and now new benches are required in order that the establishment may be put in thorough order. There will, however, still remain the probable expense anticipated by Mayor Downham in his last message, when he said that 'as the gas pipes were laid many years ago they must, in the nature of things, be nearly destroyed by rust.'"

LAST Monday the shareholders of the Beverly (Mass.) Gas Light Company adopted a proposition to increase the capital stock in the sum of \$15,000, the money to be expended on plant betterment.

MANAGER LIVINGSTONE, of the St. Paul (Minn.) Gas Company, says that the proprietors will expend a large sum of money this year in extensions to the gas and electric divisions of their property. One item in the plans calls for the placing of about 16 miles of new gas mains.

RICHARD WELCH, Village Recorder of Litchfield, Minn., advertises for tenders for the construction of an electric lighting plant suitable to the needs of the district. Specifications can be examined at his office, and the competition will close at 7.30 P.M., of March 31st.

Hot Air Engine.

The principal features of the hot air engine invented, by Jerome H. Chase, of Buffalo, N. Y., are: It is provided with an ordinary and hot air chest in which is a slide valve of the usual form operated from the main shaft. Into the hot air chest leads a pipe provided with a valve and connecting with the upper end of a hot air reservoir, below which

is a heater placed above a furnace, all these parts being inclosed in a case supporting the cylinder. The reservoir is provided with a number of parallel plates extending through the bottom on to the bottom of the heater. Into the heater opens a pipe leading upward and connecting by a discharge valve with one end of an air compressor arranged alongside the cylinder and operated from the crosshead of the main piston rod. On the other end of the air compressor is a discharge valve opening into a pipe leading into the ash pit of the furnace. In the heads of the air compressor cylinder are placed inlet valves connected by pipes with a closed reservoir located inside of a cooler placed on the outer end of the main cylinder. Water flows through the cooler to cool the air.

When a fire is started in the furnace the air in the hot air reservoir is rapidly heated. When the pressure in the reservoir is sufficient the valve is turned to allow the air to pass to the hot air chest and cylinder and operate the piston in a manner precisely similar to that in the ordinary steam engine. The exhaust may be discharged into the open air or into a room to be heated. Through one pipe the compressor discharges air into the furnace to aid combustion and through the other into the heater, from whence it passes to the hot air reservoir. The arrangement of the pipes and valves is such as to permit the operator to increase or diminish the supply of cold condensed air to either the heater or furnace. It will be observed that the air in this engine is first rapidly cooled, then compressed and forced into a heater, where it is subjected to the intense heat of the furnace. Another noticeable feature is the fact that the engine is double acting.

The Quality of London Gas.

The following is abstracted from Dr. Williamson's report on the quality of the gas supplied to London during the last quarter of 1889:

Illuminating Power.—The average illuminating power, in standard sperm candles, at each of the testing stations, was as follows:

The Gas Light and Coke Company.

Jewry street, E.C.....	16.5
King street, E.C.....	16.3
Dorset Buildings, E.C.....	16.6
Ladbroke Road, W.....	16.6
Devon's Road, E.....	16.7
Carlyle Square, Chelsea, S.W.....	16.1
Camden street, N.W.....	16.3
Graham Road, E.....	16.6
Kingsland Road, E.....	16.4
Grove Gardens, Regent's Park, N. W.....	16.5
Hornsey Road, N.....	16.5
Lambeth Road, S. E.....	16.3
Millbank street, S. W. (cannel gas).....	20.8

Commercial Gas Company.

Parnell Road, E.....	16.3
Wellclose Square, E.....	16.1

South Metropolitan Gas Company.

Hill street, S. E.....	16.3
Foster Place, S. W.....	16.3
Stoney Lane, S. E.....	16.2
Lewisham Road, S. E.....	16.3
Burrage Road, S. E.....	15.8
Blackfriars Road, S. E.....	15.6

It will be seen from these results that the average illuminating power at the Blackfriars Road and Burrage Road stations of the South Metropolitan Gas Company was lower than the Parliamentary standard; and that it was above that standard at all the other testing stations. Several deficiencies in the illuminating power were reported during the past quarter—viz., at Jewry street, King street, Hornsey Road, Wellclose Square, Hill street, Stoney Lane, Lewisham Road, Blackfriars Road and Burrage Road.

Purity.—Sulphureted hydrogen was only once during the quarter reported to have been present in the gas—viz., at the Jewry street station of the Gas Light and Coke Company; and an appeal has been lodged by the Company against this return. The average amount of sulphur in other forms was considerably less than that allowed—viz., 22 grains—at all the stations, especially at Millbank street, Devon's Road, Parnell Road, and Lewisham Road, where it averaged less than half the quantity permitted. Ammonia has been present more or less frequently in the gas at all the stations, but only in slight quantities. There was no excess on any occasion during the quarter.

The Market for Gas Securities.

The city market for gas shares was in line with higher prices during the week, and Consolidated, on comparatively small transactions, moved up closely to 97, but reacted to 96½. There can be no doubt about it but that when the market for money shows signs of a settled or normal condition that Consolidated will go to par and over. Other city shares are also inquired after, and purchasers are making all the concessions in respect to quotations. Brooklyn presents nothing of interest, unless it may be noted that Metropolitan is now at par, bid. The Appeal Tax Court of Baltimore has readjusted the tax rating of the Consolidated Company, of that city, and Secretary Smoot is to be congratulated on the finesse displayed by him in the premises. It is somewhat strange to us that the "ad. of Secretary," offering to sell a controlling interest in several California gas works does not receive more attention from investors in such properties. One of the works thus offered ought to be a rare good thing. Buffalo (N. Y.) shares are being sought after.

Gas Stocks.

Quotations by Geo. W. Close, Broker and Dealer in Gas Stocks,

16 WALL ST., NEW YORK CITY.

MARCH 24.

All communications will receive particular attention.

**WANTED,
Management of Gas Works.**

By practical gas man of many years' experience. Is master of all branches of work about a small plant—main laying, services, retort setting, gasfitting, or repairs about the works. Best of references. 771-2 Address "W," care this Journal.

**POSITION WANTED.
A Mechanical Engineer,**

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked. Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal, 765-tf or Box 972, West Bay City, Mich

Position Wanted

As Superintendent or Assistant of a Gas Works,

By a man who can give the best of references. Thoroughly understands the manufacture and distribution of gas and the construction of works. Address 770-3 "M.," care this Journal.

For Sale, Cheap.

Thirty Benches of 5's, with Cast Iron Hydraulic Main, 5-inch Stand and Dip Pipes, Plugs, etc Also, Stays and Rods for Forty Benches, with Door Frames and Doors. Mouthpieces, Lids, Cotter Bars, etc. Four Iron 4-Wheel Side-Drop Retort House Coke Wagons. Four Good Coal Carts. Twelve Charging Scoops. Hoes, Rakes, and Firing Tools.

One Set Round Purifiers, 10 ft. diameter, 12-in. Seal, with Wet Center Seal.

Washers, Scrubbers, and

One Mackenzie Exhauster, 12-in. openings, 500,000 cu. ft. capacity.

Will sell whole or in part, to suit purchaser. Address

772-4 MUNICIPAL GAS CO., Albany, N. Y.

FOR SALE,

The Ironwork for Twelve Benches of 6's, viz.: Cast Iron Hydraulic Main.

7-inch Dip-Pipes, Stand-Pipes, and Bridge-Pipes, complete.

Floyd Mouthpieces and Self-Sealing Lids, 15x26 in Lids and Mouthpieces only in use over a year. Will be sold cheap.

ISAAC C. BAXTER,

772-tf

Detroit (Mich.) Gas Lt. Co

FOR SALE,

The Ironwork for 11 Benches of 5's, viz.:

Cast Iron Hydraulic Mains, 17 inch diameter, inside.

Dip Pipes, Bridge Pipes, Stand Pipes.

Mouthpieces and Lids.

Four Purifiers, 10 by 16 ft., with 10-inch Connections and dry Center Seal.

Four Purifiers, 5½ by 10 ft., with 6-inch Connections and Wet Center Seal.

Valves, 6-inch, 8-inch, and 10-inch.

DAVID MOORE, Treas. Salem Gas Lt. Co.,

770-tf

Salem, Mass.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

SECRETARY, 123 Beale Street,

760-3 mos.

San Francisco, Cal.

FOR SALE.

A Complete Water Gas Plant.

60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889,
For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. The Gas requires NO PURIFICATION. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE. Works under our system can be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than $4\frac{1}{2}$ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon. One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

Boston Fire Brick Works Manufacturers of Gas Retorts and Settings

Under the Personal Supervision of MR. GEO. C. HICKS late of Chicago.

GREENOUGH'S

"DIGEST OF GAS LAW."

Price, \$5.00.

This is a valuable and important work, a copy of which should be in the possession of every gas company in the country, whether large or small. As a book of reference it will be found invaluable. It is the only work of the kind which has ever been published in this country, and is most complete. Handsomely bound. Orders may be sent to

A. M. CALLENDER & CO.,
42 Pine Street, N. Y.

THE NEW HANDY BINDER.

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filed in the Handy Binder, becomes a volume of great value, always convenient for instant reference. Handy Binder, Postage paid, \$1.00.

A. M. CALLENDER & CO., 42 Pine St., N. Y.

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

GASHOLDER TANK CONSTRUCTION, ETC.

Gas Companies and others about to erect Gasholders will find it profitable to consult W. C. Whyte, who for over 30 years has made a specialty of

Tank Excavation and Mason Work.

Fifty Tanks now in operation show the sort of work done. Address

W. C. WHYTE, - No. 15 Cortlandt Street, N. Y. City.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

THE CLERK GAS ENGINE CO.,

Main Office, 1012, 1014, 1016, 1018 Filbert St., Philadelphia, Pa.

WM. W. GOODWIN, Prest.

E. STEIN, Sec.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's
OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,
OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

Every Meter emanating from our establishment will bear the State Inspector's Badge, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

GAS INTO POWER,

BY THE

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

BRIEFLY TOLD.

THE TOLEDO CONVENTION.—Perhaps it would seem unnecessary, in view of the extended telegraphic report forwarded us by "Three Stars," and printed in our issue for last week concerning the proceedings of the Toledo gathering of the Ohio Association, to say anything further about it; but it is likely that a word or two more will not come amiss. Broadly it may be stated that the meeting was a most successful one, and to President Lindsley's tact the Association is in no small degree indebted for that happy result. Although the paper list was rather less on the large numerical order than formerly, the plethoric question-box more than made up the requisite quantity of material for food-thought. In fact, had the paper list been larger the Association might have been embarrassed in its riches. As it was, out of the eight papers listed seven were read—the omitted one was that to have been contributed by Jos. M. Bate, of Canton, who reported by telegraph that he was detained at home because of a "fight" then on in his bailiwick between gas, electric light and kerosene oil—and these were supplemented by two others (one by Mr. M. A. Gemunaer, and the second by Mr. A. R. Foote), which were read in connection with Mr. Wilkiemeyer's remarks on the "Municipal Control of Lighting." Regarding the latter, we have only to say that "Three Star's" opinion of the value of Mr. W.'s paper but does him simple justice. We had hoped that Mr. Evan's would have given us something of a different nature in his record of "Another Year with Fuel Gas;" for from his Jackson experience, as gathered in the working of another twelve-month, fact and fancy ought now to be easily determined, at least in respect to the intrinsic merit of the fuel gas plan which is in fashion there. Apart from his comparisons in respect to the relative fuel value of illuminating gas and fuel water gas—and we imagine that his deduction that "illuminating gas as used for cooking and heating is worth but 30 per cent. more than fuel water gas, instead of 2½ times as much," will find but few indorsers—we would like to reply in answer to the following plaint of Mr. Evans—"I was painfully surprised to learn the opinions of some of the success of our Jackson plant, especially so in this case, because I am positive that the engineers in question never were in Jackson to investigate the system in use, but were only too willing to cry down something they knew nothing about"—that those, in this section of the country at least, who are most outspoken against the Jackson method, are the ones who have visited Jackson for the purpose of examining the system with a view to installing the system in their home situations, did it, in their opinion, even fairly meet the conditions under which it would have to be tried. The increased business of the fuel gas company at Jackson, Mich., is a very slender thread whereon to suspend the success of its lighting and fuel gas supply. The Company has the entire field to itself, and its business ought to grow, and "the fate" (to quote from the Evans paper) "of the now defunct Jackson" (or old Company) "Gas Light Company" is the common fate of all corporations whose proprietors part with their property in consideration of having received a good price therefor. It is time that the fact was plainly stated that the old Jackson Company was not driven from the field; it was bought and paid for by those whose interests would be subserved in the purchase. It may be taken for granted, however, that other experiments than those at Jackson will be required ere the ques-

THE GAS WORKS SAFE AT LOUISVILLE, KY.—The following is in reply to a telegram sent to Mr. A. H. Barret, Engineer of the Louisville Gas Company: "Everything and everybody safe and sound. Works and holders about two blocks out of line of tornado."

tion of fuel gas shall have even been partially solved; and it is not asserting too much to say that many an anxious eye is looking toward Louisville, where service and not interest colors the policy of those in charge of the experiment of supplying fuel water gas.

THE Association is to be congratulated on the excellent exhibition of gas cooking apparatus, etc., that was held under its auspices. It was most successful, and the arrangement of the showroom was worthy of all praise. The display will bear fruit in the sendout of many an Ohio city and town the coming summer, and the manufacturers will also share in the reward that the gas makers shall reap. The visit to the Central Chandelier Company's showrooms and factory was made in a rather desultory sort of way, but those who availed themselves of the privilege thus afforded were well repaid for their effort. The inspection of the Toledo Gas Company's properties was more generally shared in by the members, and we can dismiss this portion of the entertainment in the remark that the works are a credit to the Company, and are unmistakable evidences of the energy and capacity of its engineer.

The banquet tendered the Association and its guests by the Toledo Company was a most enjoyable affair. If President Lindsley was a success as a presiding officer, he was just as successful as a toastmaster, for certainly he left nothing to be desired in his direction of either. The toasts and responses were in happy frame and not a little of the glow of the occasion can be traced to the wit and brilliancy of Fred. R. Persons. In conclusion we have only to say that the Ohio's Sixth Annual was in all respects a success.

A BANQUET RESPONSE.—The toast at the Ohio banquet to the "GAS JOURNALS" was responded to by Mr. G. A. Hyde, of Cleveland. His handling of the subject is so well worthy of spreading before the fraternity that we herewith reproduce it in full—a glance at the roll call, which will be found elsewhere in this issue, will serve to enlighten the reader unfamiliar with the names referred to by Mr. Hyde.

"Had I the freedom of thought and flow of language of my illustrious brother, Capt. Harry White, or my distinguished and genial friend, Geo. Shepard Page, I could carry my impromptu speech in my head, and at my will and pleasure let it flow out onto my eager and attentive auditors; but my impromptu response is written and is offered for your consideration.

"About gas works, journals are portions of engines, shafting and exhausters, and a *Page* in the AMERICAN GAS LIGHT JOURNAL volunteers the information that they are a necessary part of the "Standard" washer-scrubbers used in gas works.

"The public *Journals* are the great and mighty disseminators of knowledge, truth and error, educating the people, forming public opinion, and recording passing events. The AMERICAN GAS LIGHT JOURNAL is the *Callender* of the best thought and transactions of the Gas Associations of America.

"If you are seeking *Light*, you will make no mistake if you consult the GAS JOURNAL, or go to Dayton.

"If you *Felt* that you were not *Strong* enough to make a success of your chosen profession, and were rather *Green* in the gas business, and *Wood* require a *Starr* to guide you along the uncertain *Track*, you should then consult the GAS JOURNALS.

"If you wish to know what's *Butterworth*, consult the GAS JOURNALS.

"If you desire to go fishing, and are *Spinning* about to find a *Birch* rod and *Bate*, the GAS JOURNALS will point you to the *Dell* where they can be found.

"If you wish to find the *Bird* that *Blinks* in the *Bowers*, or the *Crane* that *Hydes* in the *Hedges*, consult the GAS JOURNALS.

"If you are making investigations to ascertain the numerous products of the deep wells of Ohio, and desire to know which is the *Salter*, consult the GAS JOURNALS.

"The *Walker*, the *Turner*, the *Taylor*, and every other *Christian* brother, members of this grand Association from *Alexander* to *Zimmermann*, should, for their pleasure and profit, read and consult the *Printz*, the GAS JOURNALS.

"Now, my brother, fill your *Cantine*, but remember your failings and drink moderately; do *Credit* to this Association and go home sober, or else you may be gathered in by a *Kopp*.

"Many a gas man *Burns* his fingers through ignorance of the subject engaging his attention; but he *Can*, by consulting the GAS JOURNALS, escape such disagreeable results."

THE WAKEFIELD MANUFACTURING COMPANY.—On Wednesday, March 19th, there was introduced into the lower house of the Rhode Island Legislature a bill for the amendment of an act which seeks to

incorporate "The Columbian Land Company," the amendment being in the nature of granting to J. Edward Addicks, Samuel Little and others, the right to establish and operate gas works in the cities of Providence and Pawtucket, under the corporate title of the Wakefield Manufacturing Company. This is not in reality a brand-new measure, as one quite similar to it was "indefinitely postponed" at the May meeting of the Legislature. The bill, as said before, was presented to the lower branch on March 19th, was at once referred to the House Committee on Corporations, who reported it back on March 20th, when, under suspension of the rules, it was adopted without debate and forwarded to the Senate, which branch at once referred it to the Committee on Corporations. When the bill was considered in this Committee, its radical provisions were of such a nature that the Committee decided not to report it, but to subject it to the fullest investigation that wide publicity could assist. Accordingly, last Friday was named as a day for a hearing, the result of which we cannot ascertain in time for publication in this issue. Briefly stated, the bill authorizes the grantees to make and sell gas in Providence and Pawtucket without the preliminary (other than filing a bond of \$25,000 with the treasurer of each city) of securing the right to open and occupy the streets, from the local authority. In fact, the latter would have no more control over the doings of the Wakefield Manufacturing Company than, for instance, would the Mayor or Council of Chicago. The Wakefield proprietors are also authorized to "purchase, own, hold and dispose of the shares of capital stock of corporations in this State and in other States, and bonds and other securities of such corporations, provided, however, that nothing in this Act contained shall be so construed as to authorize said Wakefield Manufacturing Company to carry on a banking or stock brokerage business." In other words, the proposed Act is simply an omnibus license to the grantees to harrass the capital now invested in gas works in the cities named, and to prevent the local authorities from interfering in any way in the proposed spoliation. We hope that the good sense of the Rhode Island Senate will incline to protect Rhode Island capital from the clutches of this syndicate, who, wherever they have gained a foothold, have made cheap gas a slim possibility. In the meantime, we note that Mr. Addicks is now endeavoring to freeze out the stockholders of the old Wilmington (Del.) Gas Company, by virtue of the omnibus charter granted him by the Legislature of that State, and under which he proposed to "construct and operate" gas works in that city. We shall keep our readers posted in respect to the history of the proposed Rhode Island grab.

REPEALING THE CARBONIC OXIDE ACT.—The Committee on Manufactures, of the Massachusetts State Legislature, have presented a unanimous report recommending the removal of all restrictions as to the percentage of carbonic oxide that may be contained in illuminating or heating gas distributed in that State.

WE are in receipt of a copy of the argument recently made by Mr. C. P. Greenough, as counsel for remonstrants, before the Committee on Manufactures, of the Massachusetts Legislature, on the proposed bill to enable cities and towns of that State to supply, sell and distribute illuminating gas, etc. The argument is in masterly vein, and bristles with telling points, tersely told. The grouping of the statistics is admirably done, and we make no doubt that the well-trained lawyer will receive many inquiries for copies of his argument.

WE note that the ship *Belt* sailed last Friday from Newport News with a cargo of 1,734 tons of Breckenridge cannel for Rio de Janeiro. The shipment, of course, was made under direction of Messrs. Perkins & Co., of this city.

IT having been reported that Mr. Emerson McMillin was about to resign the Presidency of the Laclede Gas Company, we desire to say that the statement is a mere fabrication.

AN application has been filed for a charter for the operation of the Tuscaloosa (Alabama) Gas, Electric Light and Power Company, the incorporators of which have already secured by purchase the local electric light works. The Company is officered as follows: President, Geo. A. Search; Secretary and Treasurer, Jhon A. Daniel; Directors, Geo. A. Search, Robert Jenison, J. F. B. Jackson and W. Fitts.

A BILL has been introduced in the New York Legislature which seeks to establish the following maximum rates for gas in this State: In cities whose population is over 100,000 but under 500,000, \$1.75 per 1,000; between 500,000 and 1,200,000, \$1.25 per 1,000.

[COMMUNICATED ARTICLE.]

An Interesting Chapter in Photometrical Testing, and an Addendum.

By MR. T. S. CLEMINSHAW, Engr. Launceston Gas Company, Tasmania.

Whilst perusing Mr. W. J. Dibdin's excellent book on "Practical Photometry," it occurred to me that the question of gas-testing candles was scarcely exhausted, and with the hope that my experience may be worth recording in your issue I write this.

Having a large stock of gas-testing candles here when I first came, I thought they should be worked out before a fresh supply was ordered, and as soon as the new candles arrived (before the old stock was done) experiments were at once instituted in order to ascertain whether the abnormally high returns on the Evans photometer were correct or not.

The gas supply to the photometer room is derived from a special service laid on to a pressure register, and travels but a short distance from the 18-inch governor. The holder was not changed during any of the experiments, so as to avoid any chance of error from that source.

many gas engineers who, like myself, are their own gas examiners. Till then we must content ourselves with the standard means of testing, which takes an hour each time.

ADDENDUM.

I note in your issue of Jan. 6, 1890, page 3, that Mr. F. Egner, having been troubled by mineral oil in his exhauster, was driven to use lard oil. I called attention to this same matter in your esteemed paper* some years ago, and found my way out of the difficulty by using castor oil.

I have two Gwynne exhausters (10,500 feet per hour size), coupled, running with castor oil beautifully; and in the winter a Donkin (25,000 feet per hour size), running with "Globe" oil—a mineral oil—also beautifully; and yet if I use Globe oil on the two smaller exhausters they will stick me up in 24 hours. The black varnish which Mr. Egner speaks of was always present when the two exhausters were "stuck up."

The 25,000-ft. exhauster ran night and day for six months, at 65 rev-

MEMO.—It is a point sometimes made against the Evans closed-in photometer that the readings show a perceptible rise toward the third testing. I append the following tests to show that the difference, in my experience at least, is not so very great as could be imagined:

Folio.	Actual Observations		
	1st.	2d.	3d.
235.....	18.38	18.17	18.17
236.....	19.38	19.85	19.57

242.....	18.84	18.66	18.82
243.....	18.50	18.27	18.54
192.....	18.09	18.04	18.04

It will be seen that the apparently high power of the gas dropped at once when the new candles were employed; and this only confirmed my suspicions, and led me to infer that the candles had suffered from being kept so long (in a dry place), it being nearly 8 years since they left the maker's hands. There is no instruction as to the age of candles in the Referees' instructions. The photometer is an Evans closed-in pattern, and the usual method of testing employed is that given in the Referees' instructions.

In Mr. Dibdin's book (page 92) we read: "Whilst candles are, no doubt, unsatisfactory as a standard, they are not, when properly made and used, so bad as many of the published results have caused them to appear."

Again (on page 122), read: "The day cannot be far distant when a worthy substitute for the discredited candles will be found, and then those who deem them an excuse for the present neglect will never recover their lost ground."

Taking these two passages together, one is apt to be more distrustful than ever in candles as a standard for testing gas, and my only consolation lies in the probability that these two paragraphs were written at different times, with some long interval between, and that the writer must have suffered disappointment from the use of unsatisfactory candles when the last paragraph was penned.

I feel sure that the adoption of a perfectly reliable means of testing gas, in a few minutes, will be hailed with the greatest satisfaction by

olutions per minute, and only stopped twice, to pack the engine glands; so that there is some reason for sticking up other than the pitchy substance alone. It must have something to do with the internal construction of the exhauster.

[From Engineering.]

The Three-Lift Holder at Dawsholm Station of the Glasgow Corporation Gas Works.

Besides the extensions carried out during last year at the Tradeston Works, and which have already been described in our columns, an addition was made to the gasholder capacity at Dawsholm Works by adding a third lift to one of the existing gasholders. This work was executed by Messrs. Clayton, Son & Co., Limited, Hunslet, Leeds. It must, of course, be borne in mind that Mr. Foulis in this instance had not a free hand. To use a well-known Scotch saying, he had to "cut the coat to suit the cloth." The details of the design were regulated to a large extent by the existing holder, so that it must not be forgotten by the reader that the third lift was an addition to the holder built sixteen years ago. That the adaptation of the third lift to the old structure is admirable will be made evident by an examination of the plans, and to many the fact that it is only an addition may render the work more interesting.

The total height is slightly over 125 ft., including the depth of the tank, which is 30 ft. under the ground level. The depth of each of the lifts is about 30 ft. The diameter of the tank is 163 ft., while the diameters of the outer, middle, and inner lifts of the gasholder are respectively 160 ft., 157 ft. 8½ in., and 154 ft. 6¾ in. The original framing consisted of sixteen cast iron columns 65 ft. high, 3 ft. in diameter at bottom, tapering to 2 ft. 6 in. at top, tied together at top by lattice girders, and having guide runs bolted by distance brackets to the inner side of columns. These columns had to be heightened to the extent of 30 ft. For this purpose certain top pieces, caps and girders were removed, and two new lengths, each 15 ft. long and 31½ in. in diameter, were bolted to the remaining part of each column. The pieces removed with the caps and the girders were then replaced on the top of the new lengths, the joints being made by internal flanges turned true, and securely bolted by eight 1½-in turned bolts in each flange, having

* May 17, 1886, page 293.

strengthening brackets between each bolt hole. Bolted to the inner side of each column is a wrought iron lattice girder, which extends from the top of the pedestal to 18 in. above the capital of the column. The outer and inner members of those girders are formed of two angle irons 4 in. by 3½ in. by ½ in., with diagonal bars 2 in. broad and ⅝ in. thick riveted between them. The angle irons of the inner members are set to suit the curve of column, and firmly bolted thereto. The guide runs, which are of channel iron 5 in. by 3 in. by ½ in., are fixed to the lattice girder by bolts with countersunk heads.

Besides the top row of girders, two additional rows of girders were constructed at equal distances between top and bottom. These are of the lattice type, and 3 ft. deep, and of the same design as the top girders.

The top and bottom members of the girders are formed of two angle irons 4½ in. by 4½ in. by ½ in. and plates 12 in. broad and ⅝ in. thick forming flanges. Diagonal bars 4 in. broad and ½ in. thick are riveted between the angle irons. Wrought iron brackets formed of ¾ in. plates and angle irons, are bolted to the girders and columns at top and bottom of each end of the girders, and also at the base of each column. At top of each column a malleable iron strap is securely fixed, fitting tight round the column. To these brackets and straps one end of the bracing bars is secured, the other end being connected by wrought iron rings, 18 in. in diameter, with nuts and washers on the inside and outside, and over all is an ornamental plate.

In describing the holder itself we will proceed in the same way by narrating the successive steps in its construction. The covering having been removed, the top row of plates of the middle lift was cut to a breadth of 15 in., and a grip formed of ½-in steel plates bent so as to form a sort of lip, 1 ft. 8 in. deep and 1 ft. wide, having riveted to the outer edge a bar of half flat iron 1½ in. by ½ in. The design also shows an upright bar which is fixed so as to connect the grip just described with a similar arrangement at the bottom. These also serve as guides to the inner lift. The inner lift is entirely new, with the exception of the crown sheets and framing.

The top curb is formed of three angle irons and two ¾-in plates, 18 in. broad, the whole forming a continuous ring. The corner plates, which are attached to this curb, are of steel ½ in. thick bent to an appropriate curve, and strengthened by angle irons of mild steel 5 in. by 4 in. by ½ in. riveted to curb and plates, and to these angles the main principals are attached. These are made particularly strong, as against them are fixed the pulleys and their brackets.

Thirty-two semi-tubes removed from the middle lift of holder and lengthened, are fixed to the side sheets to connect the grip and top curb. The bottom of these tubes is fixed to a plate ½ in. thick and 22 in. broad, carried all round, and riveted to the bottom grip of the lift and fished at the joints, thus forming a continuous ring. The bottom row of plates next the grip and the plates at each upright semi-tube are ¼ in. thick, the row next the corner plates are ⅝ in. thick, and the row below ½ in., the intermediate rows are sheets No. 12 B. W. G. Opposite each of the upright bars of the middle lift a friction plate of cast steel is fitted to the outside of the grip of the inner lift. The plans of guide brackets and pulleys of inner, middle, and outer lifts respectively are so complete that it is not necessary to describe them at length.

The extensions of the Glasgow Corporation Gas Works which we have illustrated and described in the present and recent issues, including the principal parts of the plant needed in the manufacture and storing of coal gas, reflect the greatest credit on Mr. Foulis, who has designed them, and has himself superintended their construction.

In concluding this series of articles, descriptive and illustrative of the recent extension of the works of the Glasgow Gas Corporation, it may not be inappropriate to refer briefly to the progress made from a commercial point of view. Gas was supplied first to the citizens of Glasgow in September, 1818, by the Glasgow Gas Light Company, who continued without opposition until 1844. No record of the quantity of gas made was kept until 1827, as it was only in that year that meters were first utilized in Glasgow. In 1827 the quantity manufactured was 79,234,000 cubic feet. For two or three years the new light did not make much advance, if the make is to be regarded as a good indication of this, for in 1830 it did not much exceed 82,000,000 cubic feet. From this year onwards, however, the progress was very marked, and in ten years the quantity consumed was more than doubled, or to be precise, it was 173,863,000 cubic feet. In 1843, when a new company was organized, the consumption was about 217,000,000. The new organization of the City and Suburban Company started their works in 1844, and the effect was to greatly increase the consumption by widening the area of supply, etc. In 1844 the make was 276,500,000, 60,000,000 more than in 1843, and it increased to 333,000,000 in 1845. In 1850 the total reached

451,000,000, an addition in ten years of more than 200 per cent. The progress continued most marked, as the following figures show :

Year.	Make in Cubic Feet.	Price per 1,000 Cubic Feet.
1855.....	593,181,000.....	s. d.
1860.....	769,241,000.....	5 0
1865.....	990,094,000.....	4 2
1869.....	1,206,921,000.....	4 7

In 1869 the corporation took over the works of the companies, and it is interesting to note that the loss by leakage was 20 per cent. of the total make, and that since that time it has been at most a half of that loss. In a table appended we give statistics as to gas made by the Glasgow Gas Corporation. From this it will be seen at a glance that as the quantity of gas made increased the revenue decreased. In other words, the citizens are now consuming 600,000,000 cubic feet more per annum than they did in 1885, and yet they are paying £36,000 less for it. The figures testify to the care with which the works are managed :

Statistics as to Gas Made by the Glasgow Gas Corporation.

Year.	Quantity of Gas Made in Cu. Ft.	Price per 1,000 Cu. Ft. s. d.	Total Revenue.
1870.....	1,295,863,000.....	4 7.....	£235,701
1875.....	1,649,616,000.....	5 5.....	378,392
1880.....	1,859,582,000.....	3 10.....	341,274
1885.....	2,368,131,000.....	3 6.....	428,227
1886.....	2,442,880,000.....	3 3.....	401,306
1887.....	2,596,470,000.....	3 0.....	386,246
1888.....	2,705,444,000.....	2 10.....	383,566
1889.....	2,905,796,000.....	2 8.....	392,896

NOTE.—The gas works were transferred to the corporation in the year 1869. The price of gas is now 2s. 6d. per 1,000 cubic feet.

Device for Charging Inclined Gas Retorts.

Messrs. F. Morris and L. Van Vestraint, of England, have been granted protection by English Letters Patent (No. 16,489) for a device for charging inclined gas retorts. In noticing the apparatus the *London Journal* says: In setting inclined gas retorts, the inventors remark, they present their upper mouths at different heights, and in different vertical rows; and the present invention relates to means for charging retorts so set by the use of a shoot, which can be adjusted in length and in position in order to conduct the coal from a supply above to the mouth of any one of the group of retorts. For this purpose, at a convenient height above the highest tier of retort mouths, there is provided a frame or carriage that can be moved on rollers horizontally

along rails; and from this carriage there is suspended a tubular shoot made in several sections, fitted to slide freely along one another like the tubes of a telescope, and balanced by weights attached to chains passing over pulleys mounted on the next higher section. When it is desired

to charge any one of the retorts, its mouth is opened, the carriage is run along the rails until the shoot comes vertically over the retort mouth, and its sections are slid telescopically until the lowest one reaches the mouth, whereupon coal can be delivered into the upper end of the shoot so as to descend into the retort.

The illustrations show portions of two inclined retorts to the charging of which a shoot, according to this invention, is applied; also an elevation of the shoot to an enlarged scale.

The shoot, as already mentioned, consists of a tube made in three lengths or sections A_1, A_2, A_3 , of which A_2 can slide freely along A_1 , and A_3 along A_2 . The highest length (A_1) is carried by a carriage B having rollers which run along rails C . The lowest length (A_3) is connected to a counterweight E by chains D passing over pulleys mounted at the upper end of A_2 ; and the length A_2 is similarly connected to a counterweight F by chains G passing over pulleys mounted at the upper end of A_1 , or on the carriage B . To the lowest section (A_3) is hinged a curved shoot A_4 , which can be adjusted so as to direct the coal as desired into the mouth of any retort. The shoot is shown in position for charging the uppermost (H) of a row of inclined retorts; the dotted lines A_3 indicating the shoot extended to charge a lower retort K . The retorts being arranged in several vertical rows, the shoot can be moved by running the carriage B along the rails, so as to come immediately above a retort in any vertical row; and it can be extended telescopically to reach the mouth of the retort.

An Argument in Favor of the Municipal Ownership of Electric Lighting Plants.

[Contributed by Mr. Victor Rosewater, of the Johns-Hopkins University, to the *Independent*.]

Questions of an economic nature are becoming more and more topics for public discussion. The people, as a whole, are gradually awakening from that lethargy in which they were willing to allow anything and everything to take its own course, regardless of the public convenience. And now, in almost every city in the country, problems of rapid transit, adequate water supply, or proper illumination of the streets, are claiming the attention of the citizens. Probably no one of the larger cities has yet done entirely away with gas for outdoor purposes; but all have, to some extent, made use of the modern substitute. From this, the importance of the question whether such lighting should be undertaken directly by the municipal authorities or should be left to private enterprise ought to be clear to every one. Consequently, any investigation which will throw the light of general experience upon the matter should prove of great value and of general interest.

Some time last fall a committee of the Council of the city of Scranton, Pa., which had been appointed to investigate the matter of electric lighting and the differences which had arisen between the city and the local company, made its report. This committee, "in order to deal intelligently with the question in hand, had deemed it wise to correspond with other cities in the United States, and to gather such data as they might have to furnish for the guidance of their deliberations." The answers received as a result of this correspondence were tabulated for more convenient perusal, and now furnish not only the most complete, but also the most reliable statistics upon the subject which have been compiled up to this time. The following table presents the figures for those cities in which arc lights were supplied by contract with private companies. All lamps are 2,000-candle power, except in Newburgh, Norwalk, Richmond, Va., Northampton, Mass., Taunton and Concord, whose lights are 1,200-candle power. The area lighted is, in every case, the entire city. In Scranton alone the radius is a factor in the cost.

Name of Place.	No. Lights.	Cost per Annum.	Hours Lighted.
Alliance, O.	8	\$144.00	All night.
Ashland, Pa.	23	125.00	All night.
Asheville, N. C.	37	100.00	2 A. M.

Youngstown	180	72.50	All night.
Zanesville, O.	140	70.00	Except moonlight.

One need not have much knowledge of the subject to ascertain, by

glancing at these figures, that the charges do not conform to the cost of production. The predominance of even figures would point to a merely arbitrary rate, while the partiality shown for a charge of \$100 seems to indicate a desire on the part of the electric lighting companies to keep their books in the most simple manner. Where an odd figure is to be found, it may easily be inferred that the authorities and the company originally failed to come to an agreement. But the company, with great condescension, must have granted a reduction, or offered to "split the difference," to which fact may be assigned the frequent form of $2\frac{1}{2}$ or $3\frac{1}{2}$.

A great imposition may be discerned in the relative charges for large and small numbers of lights. In the 5 cities consuming the largest number of lights the average cost is far above that in the 5 cities consuming the smallest number. That something is radically wrong must be apparent. By one not initiated in the mysteries of city contracts the very opposite would be expected. And if the charges were governed by the cost of production, that is what the statistics would show. Every increase in the number of lights is made at a less than proportionate increase in expenditure. The capacity of the plant may be doubled without doubling the investment. This is the primary characteristic of a natural monopoly, and every business in which this state of affairs exists must necessarily be viewed as monopolistic in its nature. Whether the fact that large cities using many lights are paying more per light than small cities using few, is the result of ignorance, imposition, or corruption, the fact still remains, and the only remedy is enlightenment.

Before proceeding further it might be well to note one more peculiarity evinced by this investigation. The efficacy of competition as a regulating influence is something almost implicitly confided in by the American people. They do not recognize the monopolistic character of certain industries. Now, in many instances it was stated in the answers received from the various cities that the city was illuminated by contract with two and often three different electric lighting companies. But in no single case was any variation in the charge noted. Each company received the same price per light as the others. The only explanation which can be made is that by some combination the same price was fixed for each company, and that the latter divided the territory according to mutual agreement. The impossibility of competition in this line of business could not have been more clearly illustrated.

We may now ask what is the condition of affairs in those cities which own their own electric lighting plants? In the report of the Scranton committee the statistics are given as follows:

Name of Place.	No. Lights.	Cost per Annum.	Hours Lighted.
Martinsville, Ind.	30	\$40.00	Midnight.
Grand Ledge.	32	62.00	12 o'clock.
Huntington.	50	48.64	All night.
Decatur, Ills.	52	60.00	All night.
Dunkirk, N. Y.	55	36.50	All night.
Paris, Ills.	60	36.00	Except moonlight.
Easton, Pa.	64	100.00	All dark nights.
Aurora, Ills.	75	56.00	Except moonlight.
Painesville, O.	80	35.00	Except moonlight.
Ypsilanti, Mich.	80	23.61	12 P.M. not moonlight.
Madison, Ind.	85	48.00	All night.
Lewiston, Me.	96	42.00	All night.
Hannibal, Mo.	96	52.00	All night.
Little Rock.	110	47.50	When dark.
Bay City, Mich.	134	60.00	All night.
Topeka, Kas.	184	54.00	Eight hours.
Topeka, Kas.	184	72.00	All night.
Chicago, Ills.	292	65.60	All night.

The difference between this table and the one above it is surprisingly great. One cannot but wonder, upon comparing the two, why the great electric lighting companies are no richer. The averages under the two systems are instructive. The average price paid to private parties by the various cities is \$105.13 per light each year. The same service when performed directly under municipal management averages to the citizens a cost of \$52.12 $\frac{1}{2}$. Under the former method, Boston pays annually the enormous sum of \$180 per light, while the greatest cost under public control is \$100, paid by Easton, Pa. The lowest amount which corporate greed will take to loose its hold upon the public purse is paid in Cortland, N. Y., to the sum of \$50 per light each year. But Ypsilanti, Mich., by supplying herself with nightly illumination, has been able to keep the expense for the same work down to \$23.61.

The first and only conclusion to be drawn from a study of these figures is that cities can supply their own electric lighting much more cheaply and advantageously than they can obtain it from private parties.

Individual corporations cannot dispose of their product at the same price and retain a reasonable profit. The very fact that an increased number of lights are obtained at a less than proportionate increase of outlay is a strong argument in favor of municipal management. A greater number of lights are made necessary by the natural growth of a city. There is no reason why the sum thus saved, hitherto put into the coffers of private corporations, should not, by being turned into the public treasury, inure to the benefit of the people. Besides, it costs but little more to burn the lamps for ten hours than for six. If the lamps burn all night no more linemen nor other employes are required. Many cities, recognizing the advantages in owning certain enterprises, are manufacturing their own gas; many more are supplying themselves with water. In such places great saving could be effected by running an electric lighting plant in conjunction with the water works. This has been done in Dunkirk, N. Y., and has proven profitable to the city. If desirable, commercial lights might be sold; the revenue thus accruing would lessen the amount necessary to be raised by taxes. In this way the taxpayer would reap some direct benefit from the undertaking.

But it may be argued that various other considerations should be taken into account. Many municipalities stand in greater need of other improvements which demand their entire resources. To these it seems better to postpone the acquisition of an electrical plant and to leave the matter for the present in private hands. The changing condition of the electrical industry, the constant application of new inventions, the probable discovery of new processes, all advise that haste be made slowly. But that does not disprove the advisability of taking measures to obtain, without friction, municipal control of this industry in the near future. Where individuals have already invested their capital in such undertakings it is always more difficult to bring about the change; for they will take pains to prevent it as long as possible. As long as they can control the primaries and nominating conventions, the corporations are always "out of politics." They are for either party, but above all for themselves. The corruption which might possibly result from the extension of municipal functions to electric lighting and other monopolies of service, is not to be compared with the pernicious influence upon politics of private companies when seeking fat city contracts.

There are frequent complaints under the system of private management. In Scranton the local company persisted in furnishing a light of less power than that called for in their agreement. Investigation showed that instead of giving a 2,000-candle power arc light the lights had never been over 800-candle power and very seldom that, even under the most favorable circumstances. Very often they had run down to 400 or 500-candle power. The poles were placed in arbitrary positions, and the company failed to supply the lamps at intersections. This last neglect made necessary an increased number of lights, which increase, of course, is added to the profit of the company. The dirty condition of the globes furnished another cause for complaint. As far as the wires are concerned the public is well aware of the threatening danger. Everyone acknowledges that the wires ought to be placed underground; but the recent experience in New York city has shown the strength as well as the humor of the great corporations. Such trouble would be very unlikely to arise if these industries were under public control.

The advantages of public ownership of natural monopolies are beginning to be appreciated. The owners of the electric companies have perceived the trend of public opinion. One of them, in a recent work upon the subject, has enunciated the astounding principle that electric lighting, above all other industries, "is the field for private monopoly." But this proposition is far from being generally accepted. Theory as well as practice points to an opposite direction. At the banquet of the Boston Merchants' Association last winter the Hon. Seth Low, former Mayor of Brooklyn, and recently installed President of Columbia College, said, during his speech in favor of municipal ownership of these monopolies of service, "that the result of his experience in the Mayor's office for four years had been to change the whole current of his thoughts, which formerly ran away from that conclusion." In view of the general satisfaction expressed by the citizens of those cities operating their own electric lighting plants, one can scarcely fail to agree with the opinion expressed in the report of the Scranton committee to the effect that "the day is rapidly approaching when cities will no longer submit to so barefaced a fleecing process, but will own their respective plants, and thus reduce the cost of lighting to a minimum."

THE City Council of Florence, Ala., has granted a charter for the formation and operation of a gas works there. The grantees will begin construction work prior to mid-April, and they are, under the franchise, required to be in position to supply gas on or before October 20th.

[OFFICIAL REPORT.—REVISED BY THE SECRETARY.]

SIXTH ANNUAL MEETING, OHIO GAS LIGHT ASSOCIATION.

HELD AT THE BOODY HOUSE, TOLEDO, OHIO, MARCH 19 AND 20, 1890.

FIRST DAY—MARCH 19—MORNING SESSION.

The meeting was called to order by the President, Mr. Edward Lindsley, who announced that the first item of business would be the appointment of a committee on applications for new membership, and thereupon named the following as that committee: Fred. Persons, Geo. S. Harris and W. A. Ross.

On motion of Mr. Wilkiemeyer, the reading of the minutes of the last meeting was dispensed with.

REPORT OF EXECUTIVE COMMITTEE.

The Secretary—The report of the Executive Committee consists of the following recommendations to the Association. First, that the Association release from membership the nine members who have asked, in writing, to be dropped from the rolls. Those members are: Chas. M. Converse, late of Delaware, O., but now at San Francisco, Cal.; J. M. Critchlow, late of Pittsburgh, Pa., now at Titusville, Pa.; P. W. Huntington, Columbus, Ohio; W. H. Mandeville, Lima, Ohio; W. H. Gibson, Lima, Ohio; W. L. Rolston, Marietta, Ohio; A. J. Seamon, Wheeling, W. Va.; S. M. Dalzell, Cleveland, Ohio; Wm. F. Zimmermann, Pittsburgh, Pa. [Adopted.]

The Secretary read the following invitation from the Central Chandelier Company, of Toledo: "We extend through you a cordial invitation to all members of the Association to visit our new show rooms and factory while in Toledo," and further said: The Executive Committee recommend that the invitation be accepted with thanks; and they further recommend that, instead of attempting to visit the show rooms and factory in a body, our members go in groups and as may best suit their convenience.

The President—This show room is well worthy the attention of the membership, and is very convenient of access from the hotel, being, I think, less than a block away. I do not suppose that it would be convenient for the members to visit it in a body, but if they feel disposed to accept this invitation in the manner suggested by the committee, I think they will find it exceedingly profitable. [Adopted.]

The Secretary—The third recommendation is that the Association bear the legitimate expenses incurred by local companies in connection with annual exhibits of gas apparatus.

The President—This is a matter of some little importance, gentlemen. The Secretary has this year acted on his own responsibility. I think he has done wisely, and I believe you will all endorse him. But as an expenditure of money is involved, I think there should be some formal action by the Association. What action will you take, gentlemen, with reference to this matter?

Mr. Wilkiemeyer—Mr. President, I move the recommendation be adopted. As the exhibits are for the benefit of the gas companies entirely, we certainly ought to pay the small expense that has been incurred, and I move that recommendation be adopted.

The President—Gentlemen, it is moved and seconded that the legitimate expenses attending the exhibit, which is a very important feature of our meetings, be borne by this Association. This covers the ground, I believe. Are there any remarks?

A Member—Mr. President, had it not better be understood what you term "legitimate expenses?" What is covered by that? It may prevent confusion to have it definitely stated.

The President—I will call upon the Secretary to explain?

The Secretary—In the Committee meeting the legitimate expenses were designated to be those incurred in bringing goods for the exhibit from the depot, unpacking them, setting them up in the exhibit room, gas pipe connections, and, after the exhibit, disconnecting and repacking them, and hauling them to the depot; also, the rent of the room where the exhibit is held, and the cleaning up of the room. [Adopted.]

The Secretary—Fourth, that the Secretary may be instructed to ascertain, during the ensuing year, the wishes of each member regarding the adoption of a badge for the members of this Association. [Adopted.]

The Secretary—Fifth, that the Secretary be authorized to have printed, in advance of each annual meeting, the papers that are to be read at the meeting, and as soon as possible after the meeting, the papers and the discussions thereon shall be printed in pamphlet form and distributed to the members. [Adopted.]

The Secretary—Sixth, the Executive Committee recommends the election to honorary membership of Mr. Emerson McMillin.

The President—Gentlemen, you have heard the name of Emerson McMillin announced for honorary membership in this Association. As you all know, he is already an active member. That, perhaps, is a little superfluous to say. He is the father of this Association. I do not need to say more for him than that. You all know that we are largely indebted to him for our existence as an Association and for our maintenance thus far. The fraternity of gas men is also indebted to him, and likely to be in the future, for a measure of usefulness that we can scarcely find perhaps in any other man. We will lose an active member here, and perhaps we might lose something were our organization different from what it is. But I think we will not lose anything, and I think it is eminently fitting that we make Mr. McMillin an honorary member of this Association.

Mr. Gwynn—I move you, Mr. President, that the recommendation of the Committee be adopted. (The motion was duly seconded and carried.)

The Secretary—Seventh, that the Secretary's salary be increased to \$300 a year. [Adopted.]

REPORT OF COMMITTEE ON LEGISLATION.

The President—Next thing in the order of business is the report of the Committee on Legislation. Is that Committee ready to report?

Mr. Wilkiemeyer, on behalf of the Committee, reported: "The Committee on Legislation has had several questions propounded to it, but as it does not find its duties and powers sufficiently defined for action, it has hesitated in the matter, and taken no action. Provisions should be made at this meeting, by giving this Committee definite instructions, as to how and when it shall take action in matters appertaining to the welfare of the gas business. Expenses possibly would be entailed, and the Committee should be empowered to draw upon the Association's funds for all such legitimate expenses. Respectfully submitted,

March 19, 1890. A. J. STOLL,
EDWARD LINDSLEY, } Legislative Committee."
H. WILKIEMEYER,

On motion the report was received and placed on file.

ANNUAL REPORT OF SECRETARY, MARCH 19, 1890.

In the hands of Secretary at beginning of year.....	\$246.26
Received as dues and initiation fees.....	400.00
Total credits.....	\$646.26
Remitted to Treasurer, March 26, 1889.....	\$390.26
" " " 13, 1890.....	120.00
Total debits.....	\$510.26
Balance in hands of Secretary.....	\$136.00
Dues for 1888, still unpaid.....	\$6.00
" 1889, " 	39.00
" 1890, " 	225.00
Total dues unpaid.....	\$270.00

New members admitted at last meeting.....	22
Released from membership.....	12
Elected from active to honorary membership.....	1
Total honorary members elected.....	2
Present number of active members.....	128
" " " honorary members.....	9
Number of members deceased during past year.....	0

Respectfully submitted,

IRVIN BUTTERWORTH, Sec'y.

On motion of Mr. Persons the report was accepted and placed on file.

Mr. Cantine—Mr. President—How many members of this Association are required to form a quorum?

The Secretary—The Secretary can tell you as soon as the Constitution will tell him. The question has never come up before, and I am not familiar with that point.

The President—Three members shall be a quorum.

Mr. Cantine—That is about the number we have present, if I judge by the responses I have heard. I wish every member would vote aye or no. It would be more pleasant. About 25 per cent. of the moving I have been doing myself.

The President—I hope Mr. Cantine will receive more help in that direction. The Secretary has made a pretty good suggestion that comes in right here. There are quite a number of vacant chairs up here, and I think if the gentlemen in the back part of the room were more nearly in front we perhaps would feel a little more communicative. I wish the gentlemen in the back part of the room would occupy the chairs in front. (The members came forward and occupied front seats.)

LETTERS OF REGRET.

The President—Our Secretary has received some communications, the nature of which he will explain if you will now listen.

The Secretary—We have a number of letters from prominent gas men over the country expressing their regret at their inability to be present at this meeting. I will merely read their names, as the letters are too numerous and too long to be read :

W. E. Barrows, Philadelphia, Pa.; A. S. Bushnell, Springfield, O.; Samuel T. Bodine, Philadelphia, Pa.; T. M. Cox, Rochester, N. Y.; W. H. Denniston, Pittsburgh, Pa.; Frederic Egner, St. Louis, Mo.; A. C. Humphreys, Philadelphia, Pa.; G. A. Hyde, Jr., East Saginaw, Mich.; N. G. Keenan, Cincinnati, O.; Bement Lyman, Indianapolis, Ind.; A. S. Miller, Omaha, Neb.; Northrop Moore, Wyandotte, Kas.; Charles H. Nettleton, Birmingham, Conn.; C. F. Prichard, Lynn, Mass.; George G. Ramsdell, Vincennes, Ind.; Samuel G. Stiness, Pawtucket, R. I.; Louis Wagner, Philadelphia, Pa.; Adam Weber, New York City; William Henry White, New York City; William Enfield, Dallas, Tex.; E. C. Brown, New York City; Eugene Vanderpool, Newark, N. J.; A. B. Slater, Providence, R. I.; W. H. Pearson, Toronto, Ont.; C. J. R. Humphreys, Lawrence, Mass.; R. J. Monks, Boston, Mass.

The President—I suppose no action is required on this matter. We are glad to hear from these gentlemen, and would have been very glad to have welcomed them to our meeting. The next thing in order is the election of new members. Is the Membership Committee ready to report?

ELECTION OF NEW MEMBERS.

Mr. Persons—Mr. President, your Committee has 33 applications, upon which it reports favorably in each case. The names are :

A. P. Lathrop, Columbus, Ohio; E. P. Callender, New York City; Andrew Harris, Phila., Pa.; F. A. Wilke, Richmond, Ind.; D. E. Dangler, Cleveland, Ohio; Fred. Bredel, New York City; A. E. Rood, Toledo, Ohio; G. S. Fowler, Lima, Ohio; J. G. Stephens, Pittsburgh, Pa.; W. L. Ley, St. Louis, Mo.; A. H. Johnson, Oberlin, Ohio; O. F. Webster, Owosso, Mich.; W. P. Bonny, Erie, Pa.; Geo. Osius, Detroit, Mich.; J. M. Armstrong, Delaware, Ohio; L. Stockstrone, St. Louis, Mo.; H. E. Floyd, New York City; A. H. Jones, Columbus, Ohio; A. F. Nash, Windsor, Ont.; Geo. Whysall, Springfield, Ohio. E. N. Lewis, Defiance, Ohio; C. F. Adams, Chicago, Ill.; H. D. Harper, Chicago, Ills.; W. W. Douglass, Ann Arbor, Mich.; D. P. Russell, St. Louis, Mo.; L. Moore, Joliet, Ills.; Geo. M. Clark, Chicago, Ills.; G. A. Allen, Zanesville, Ohio; E. C. Brown, New York City; J. A. Faux, Pittsburgh, Pa.; Chas. A. Marden, Coshocton, Ohio; John M. Tryon, Van Wert, Ohio; G. A. Hyde, Sr., Cleveland, Ohio.

On motion, the Secretary cast the ballot of the Association in favor of the election of the foregoing applicants.

The Treasurer then read his report as follows :

REPORT OF TREASURER.

Herman Wilkiemeyer, Treasurer, in account with the Ohio Gas Light Association, March 19th, 1890.

	<i>Cr.</i>	
March, 1889, balance	\$717 90	
Interest collected on this account	2 33	
March 26th, received dues remitted by the Secretary.....	390 26	
March 15th, 1890, received dues remitted by the Secretary	120 00	
Interest earned on \$874.94 to date.....	34 05	
	—————	\$1,264 54
	<i>Dr.</i>	
Irvin Butterworth, salary, etc., as per voucher attached	\$169 47	
Ohio State Journal, printing, etc.....	44 00	
H. Wilkiemeyer.....	22 08	
	—————	\$235 55
Balance in the hands of the Treasurer.....		\$1,028 99

Respectfully submitted,

HERMAN WILKIEMEYER, Treas.

PORTSMOUTH, Ohio, March 19th, 1890.

On motion the report was referred to the Finance Committee.

ROLL CALL.

The President—The next item of business is the roll call.

Mr. Padan—I would like to ask what action the Association wishes to take in regard to the Committee on Legislation. Their report has been received and I would like to know whether the Committee is in existence, and whether anything further is expected of the Committee on Legislation?

The President—I suppose the Committee is virtually discharged.

The Secretary—Mr. President, I move you that the subject of the continuation of the Legislative Committee be deferred until after the discussion of Mr. Wilkiemeyer's paper. (The motion was carried.)

The President—You will now listen to the roll call. Gentlemen, if in the calling of the roll a name should be called of a member that is known to be in attendance by any member present, but who is just now absent from the room, I wish such member would respond for that name. We would like to make this roll represent those who are really here, and to that end if each member would bear in mind and respond, it will help to make it so. At this point the roll was called by the Secretary, and the following members were shown to be in attendance :

- | | |
|--------------------|----------------------|
| Jos. R. Thomas. | Murray McMillin. |
| Geo. W. Graeff. | Geo. Matt. |
| John W. Alexander. | John Mills. |
| Miller Booth. | Henry Padan. |
| Irvin Butterworth. | Jerome Penn. |
| W. W. Cantine. | Fred. R. Persons. |
| Geo. H. Christian. | J. H. Phillips. |
| G. N. Clapp. | W. W. Prichard. |
| D. M. Clark. | Eugene Printz. |
| A. D. Cressler. | Henry Ranshaw. |
| John Dell. | A. C. Reichelderfer. |
| Chas. H. Dickey. | D. T. Roots. |
| R. A. Dittmar. | W. A. Ross. |
| Chas. H. Evans. | E. M. Russell. |
| C. R. Faben, Jr. | E. E. Schaff. |
| O. N. Guldin. | James H. Smith. |
| J. W. Gwynn. | F. N. Sisson. |
| Jos. Gwynne. | John W. Skinner. |
| A. N. Hammond. | D. C. Spinning. |
| J. A. Harris. | Wm. Stacey. |
| H. L. Hurlburt. | A. J. Stoll. |
| Richard Lee. | S. S. Stratton. |
| Edward Lindsley. | L. A. Strong. |
| Geo. Light. | Geo. H. Tayler. |
| Hugh McCall. | R. Turner. |
| Geo. W. McCook. | E. C. Warren. |
| Wm. McDonald. | Chas. H. Welch. |
| John McIlhenny. | H. Wilkiemeyer. |

REPORT OF FINANCE COMMITTEE.

The report of the Finance Committee was then read as follows :

“Mr. President and Gentlemen of the Ohio Gas Light Association :—Your Committee have examined the report of the Treasurer and find it correct. It shows a balance on hand of \$1,028.99, for which the Treasurer holds a certified check.

GEO. H. TAYLER,
W. W. PRICHARD, } Finance Committee.”
M. McMILLIN,

The report was accepted and placed on file.

Mr. Ross—Mr. President, I would like to get the sense of the meeting as to whether it would be well to instruct our finance committee to investigate the matter of a possible reduction in the annual dues. It seems to me we are accumulating money unnecessarily. If our expenses for the ensuing year are such that we can make a reduction in the annual dues we should do so. My idea would be not to reduce the initiation fee, but the annual dues, so that we will not accumulate any more money in the treasury than we need. I make it as a suggestion.

The Secretary—Mr. President, if you will permit me, the expenses of the Association will be much larger in the future than in the past, and my impression is that we will not be able to add to our account in the treasury in the future to any great extent, but the tendency will be to reduce it. It is nice to have that surplus on hand, and I don't think the Association can afford to reduce the dues.

Mr. Ross—My object in making the suggestion was simply to draw out a little talk, to see what the sentiment of the members is; and if, as the Secretary says, we cannot make a reduction, the Finance Committee could make an estimate of what our expenses and probable income would be. They might make a report, and then the Association could take action afterward. I would then put it in the form of a motion, “That the Finance Committee be instructed to estimate what the probable expenses of the Association for the coming year will be, and what the probable income will be, and to report whether they think it possible to make a reduction without interfering with our business and have plenty of money to get through with.”

A Member—The funds seem to accumulate under the management of the Secretary, and pretty soon we can start a bank.

The President—Gentlemen, excuse me a moment. The motion has not been stated from the Chair, and possibly some in the rear part of the room may not fully understand it. I would make a suggestion, before stating this motion, that I believe it would add to the facility of doing our business if we would make our motions in writing, in the main—with motions of this character at least. With that suggestion, I will endeavor to repeat the motion of Mr. Ross, and he can correct me if I mistake it. The motion is that inasmuch as we seem to be rather accumulating funds, the Finance Committee take the matter under advisement and make a report as to whether the annual dues, but not the initiation fee, can safely be reduced. Is that the spirit of the motion?

Mr. Ross—Yes, sir.

The President—That is the spirit of the motion. Are there any further remarks?

Mr. Padan—I would like to ask if the motion is in order?

The President—It is not strictly in the order of our business, perhaps.

Mr. Padan—I do not mean the order of the business. The dues are prescribed in a by-law in the Constitution; therefore, I think it is not in order.

Mr. Booth—I think that motion is not out of order. It is only to refer the matter to the Finance Committee for them to make a suggestion in case they decide that the dues can be changed. If so, then a change in the by-laws would be in order. It is not to take definite action at all, as I understand it. After the recommendation would come the change in the by-laws. The motion, I claim, is in order.

The President—I think that is correct. It will be so ruled, that the motion is in order. Are there any further remarks?

Mr. Tayler—I would like to inquire of the Secretary how much that balance on hand will be reduced after the expenses of this meeting are paid?

The President—Perhaps the Secretary can give that information.

The Secretary—At a rough estimate I would say it would be reduced \$400. We will have expenses incident to the exhibition at this meeting, as well as those incident to the exhibition at Mansfield last year, which amounted to nearly \$100 there, and probably amount to more here.

The President—Are there any further remarks? [The motion was put and lost.]

APPOINTMENT OF COMMITTEES.

The President then announced the following committees:

On the Place of Next Meeting.—Messrs. Eugene Printz, G. A. Hyde and George Matt.

On Nominations.—Messrs. D. M. Clark, W. W. Cantine and A. N. Hammond.

(To be continued.)

Alavoine's Gas Washer.

U. S. Letters Patent (No. 422,173) were granted on February 25th, to M. F. A. M. Alavoine, of Beauvais, France, for an improvement in gas washers. The American patents are in supplement of those previously granted the inventor by the Governments of France, England, Belgium, Austria, Italy and Spain. Using the language of the Alavoine specification, the invention and its application are thus disclosed:

The invention relates to that class of purifiers which receive the gas directly from the retort, known as "barillet" purifiers; and the object is to provide the gas inlet of the purifier with a submerged screen or foraminous distributor, whereby the gas is compelled to pass through the wash water for a considerable distance before it escapes at the surface thereof. The volume of gas is divided by foraminous partitions or plates as it flows along the tortuous course from the point where it enters to the point where it leaves the water; but the construction is such that there is no appreciable loss of pressure.

In the accompanying drawings, illustrative of the improvements, Fig. 1 is a longitudinal vertical section of the purifier as a whole, the submerged distributing screen being represented in elevation; Fig. 2 is a

longitudinal vertical mid-section; and Fig. 3 is an under side plan view of the distributing screen detached, and on a larger scale than Fig. 1.

In Fig. 1 *W* represents the drum of the purifier; *V* the water therein; *P* the overflow outlet for the water; *T* the gas inlet; *U* the submerged distributing screen, as a whole; *S* the gas outlet; and *X* the outlet for the tar, *t*, which collects in the bottom of the drum.

The submerged purifying screen (illustrated in Figs 2 and 3) consists of a bell *D*, provided with an elevated central crown-plate *Dx*. In this crown-plate is fixed a collar *E* to receive the gas inlet pipe *T*. This collar extends below the plate *Dx* and to its inner end is secured a bell, *A*, of particular form, as seen in plan in Fig. 2. Exterior to the bell *A* on both sides thereof, are annular pendent partitions *C*, arranged as shown. *B* are end chambers within the bell *D*.

The dotted lines *xx* in Fig. 2 indicate the water level and the extent to which the screen will be submerged. The bell *D* will, of course, be full of water. The gas under pressure and directly from the retorts, descends through the pipe *T* and enters the inner bell *A* through the water. It rises and flows out from the bell *A* through the larger perforations *a* in the crown-plate or roof of said bell and enters the space under the plate *Dx*. Thence it flows downward into the annular space *O*, exterior to the imperforate wall of drum *A*, thence laterally through the perforations *c* in the pendent partitions *C* into the end chambers *B*. It rises in these chambers and escapes from the bell *D* through the finer perforations *b* in the roof of said end chambers. The gas now rises to the surface of the water and flows off at the gas outlet *S*. In its flow through the screen *U* the gas is submerged, and being divided or broken up by the perforations through which it must pass, every part of it is brought into contact with the water and thoroughly washed. The passage of the gas successively through perforations of less and less diameter prevents any material loss of pressure. In its passage through the purifier the gas parts with nearly all of its tar, the major part of its sulphydric acid, a large percentage of its carbonic acid, and a considerable proportion of its ammonia. The tar falls to the bottom, and may be removed at the outlet *X*, and the ammoniacal water overflows at the outlet *P*, which serves to preserve a uniform level of the water in the cylinder.

This apparatus is very uniform in its action, and the body of gas is so subdivided as to present every molecule or portion of the same to the water.

To avoid unnecessary repetition, in Fig. 2 is only represented a portion of the perforations *a* and *b*.

Having thus described his invention, M. Alavoine claims—

In a gas purifier, the combination, with the drum or water receptacle of the purifier and the gas inlet pipe *T*, of a foraminous gas distributing screen *U*, connected with said inlet pipe, said distributing screen consisting of the bell *D*, having endchambers *B*, provided with perforations *b*, an inner bell *A*, having perforations, *a*, in its roof, and pendent foraminous partitions between the wall of said inner bell and said chambers *B*, the perforations *a* being larger than the perforations *b* as set forth.

THE proprietors of the Cambridge (Mass.) Gas Company, in pursuance of the liberal policy that has always characterized their ownership and operation of that business, have announced that on and after April 1st the selling rate is to rule at \$1.60 per 1,000 cubic feet. This is a reduction of 15 cents per 1,000. That this method of treatment fosters the consumption of gas in beautiful Cambridge is best shown in the fact that the output increase averages 10 per cent. per annum.

SPECIAL ENGLISH CORRESPONDENCE.

COMMUNICATED BY NORTON H. HUMPHRYS.

SALISBURY, March 10, 1890.

Gas Managers' Spring Meetings.—The Institution of Gas Engineers.—Van Steenberg's Carbureted Water Gas.

Gas managers have already begun, as usual at this season of the year, to meet. Three of the spring assemblies of the District Associations are already matters of history, and three more will also have entered that category before these lines reach their destination. A prominent feature at these meetings is the inaugural address delivered by the newly-elected President for the year, which has gradually grown from a few commonplace remarks, possessing little more than local interest, to an elaborate literary effort, occupying one-half to three-quarters of an hour in delivery, and usually including a review of all matters of present special interest to the auditory, in addition to the results of special individual experiences. Anyone who carefully reads the Presidential addresses will acquire a fair idea of the various matters that are at present occupying the minds of gas engineers in this country, and of the progress of events in gas circles during the last twelve months.

The principal topics receive attention, of course, from each one, and thus an interesting insight is afforded into the effects of personal peculiarity, experience, and environment as influencing the particular view taken of the same subject. The labor question claims the first place, especially in regard to the operations of the "Gas Stokers' Union." On this subject there is perhaps a tendency to be rather too rosy as regards the future. Such may only be expected on account of the decisive nature of Mr. Livesey's action in shaking himself free from the chains of the Union. Without making any invidious comparisons, it may be said that few gas undertakings possess the resources that are at the disposal of the South Metropolitan, or the spirit of unanimity, harmoniousness, and fidelity to headquarters that animates the whole of the superintending and office staff. The Manchester Corporation, too, are to be congratulated on their success in resisting the unreasonable demands of the men. But while the Union has received a severe and crushing defeat in both these cases, it is useless to ignore the fact that in many other towns the victory has been on the side of the men, and that, chiefly by means of highly colored and grossly exaggerated representations of the nature of the work done, they have secured the support of influential persons, professors of religion, and others whose opinions are influenced by sentiment rather than by fact. So it can scarcely be concluded that further attempts will not be made, and it behoves the managers of gas works to consider the advisability of meeting this state of affairs, perhaps, by some sort of employers' union. The Gas Stokers' Union already recognize the causes which led to their defeat, and if they should try a strike again will take care to select a Company that does not possess a deservedly popular and honored Chairman, widely known for his sympathy and kindly dealing with the working classes, a thoroughly loyal superintending and office staff, and last, but not least, a reserve fund of forty thousand pounds. Mr. May, President of the Southern Association, gives some noticeable results, showing the economy resulting from the use of machinery in his retort houses. After several years experience in this direction he finds that the cost of wages, including all charges from the coal stove to the coke yard, also wear and tear of machinery, is just under 2d. per 1,000 cubic feet of gas made. Under the new labor arrangements most gas companies are paying more than double this amount. Water gas comes in for a fair share of attention, and the fact that it can be manufactured with the aid of a much smaller staff of workmen than that requisite for coal gas, apart from other considerations, is sufficient to secure for it a respectful hearing. Mr. May also gives some valuable records of his experience in admitting measured quantities of air at the inlet of the purifiers, by which means he is able to reduce the expense of removing sulphureted hydrogen, carbonic acid, and keeping the sulphur compounds under 20 grains per 100 cubic feet, to less than 0.25d. per 1,000 cubic feet of gas. This advantage is secured without any loss of illuminating power, as proved by careful experience. Mr. Peaty, President of the Midland Association, touches upon the position of oil and electricity, each of which he considers to have a definite field of usefulness. He searchingly criticises the action of municipal authorities, who, being owners of gas works, apply the profits obtained by the sale of gas to various public purposes, even including experiments with the electric light; and insists on the importance of selling gas at the lowest price that is practicable, so as place it in a good position as regards competition. The increased price of coal naturally directs attention to improved

carbonizing processes, such as the Coze inclined retort and the Dinsmore process. In respect to both inventions, gas engineers are in a waiting position, looking for the results of practical experiments on a working scale. These, in respect to the latter at any rate, will shortly be available. The same may be said of the plan of supplying cottages and small tenements with the necessary pipes and fittings free of charge, and slightly increasing the cost of the gas as a means of paying interest on the capital so invested. This plan is being tried at London, Ramsgate, Stafford, and other places, usually in connection with prepayment meters. Mr. W. W. Hutchinson, President of the Manchester District Association, directs attention to the magnitude of the gas industry as shown by the latest Government returns available, and also draws a strong but by no means exaggerated picture of the numerous difficulties with which the gas engineer of the present day has to contend. This gentleman also devotes considerable attention to the effect of the electric light upon the consumption of gas, showing conclusively that its production in London and various other towns has not interfered in any way with the steady increase in the demand for gas that has lately obtained. All these gentlemen allude in the course of their addresses to some remarkable statistics recently given by Mr. John West, of Manchester, President of the Manchester Association of Engineers, who, taking actual practical data, shows conclusively that gas at the prices now obtaining in our large towns is over four times as cheap, light for light, as the electric light. If improved regenerator burners be used, it is eight times as cheap. Taking as a standard the production of 16,000 candle hours, he shows that at 8d. per unit, the price actually charged by companies now supplying electric light, the cost of this quantity of light would be \$10.50. With regenerator gas burners it would be \$1.25 to \$1.50, and with ordinary burners \$2.50 to \$3. Mr. West also brings out the remarkable fact that the proprietors of several private installations, where the electricity is generated on the premises by means of a gas engine, are able to supply themselves very much cheaper than the rate above mentioned as charged by the electric companies. In some cases the cost, inclusive of interest on capital, wear and tear, etc., is less than one-half. Of course in many private installations a spare corner can be found for the gas engine and dynamos, thus avoiding the cost of special buildings; but the great advantage afforded by private as compared with central supply electric stations, is the avoiding the cost of conductors, and the leakage in course of distribution.

Our already lengthy list of technical societies has been increased by the formation of the "Institution of Gas Engineers," which has been promoted under the auspices of some of the gentlemen who retired from the Gas Institute a year ago. So far as can be gleaned from the editorial columns of the *Journal of Gas Lighting*, the object of the new Institution is to form a more select body than that afforded by the Gas Institute. Membership into the latter society is open to anyone that can reasonably be described as a gas manager, and secure a proposer and seconder; but the new Institute will only admit persons who "by training and profession are *bona fide* gas engineers." In the Gas Institute, proposal forms for membership are signed by a proposer and seconder, and afterwards examined by the Council, but this plan is to be improved upon in the new Institution. The new society is to be an "Association of technicians for the cultivation of the art and practice of gas engineering," and all persons who are "unskilled and consequently uninterested" are to be kept out. Speaking broadly, the effect of this arrangement will be to exclude the managers of small gas works, as well as those (and they are not a few) who have risen from the ranks. Much depends, of course, upon the definition of the word "training." What with district associations, the Gas Institute, and the Institution of Gas Engineers, the members of the craft will have no difficulty in filling up their spare time. It is also mentioned that the new Institution is in no sense a rival to its older confrere, but this is only true in a limited sense. The objects of both must necessarily run on very similar lines, and the chief hunting ground for recruits for the Institution will be amongst the members of the Institute. Both may exist, side by side, but only in a dwarfed and enfeebled condition as compared with what a single Institution might be. It now remains for the new Institution to show what special benefits it can secure, either for its members or for our industry at large, that could not have been afforded by the Gas Institute.

An experimental trial of the Van Steenberg water gas process is being conducted in London, under the supervision of Prof. Vivian B. Lewes, who is a well known authority on such subjects. According to some results lately published, it appears that he has succeeded in manufacturing 20½-candle gas with a consumption of 24½ lbs. of anthracite, and 2.80 gallons of naphtha (70° Beaume) per 1,000 cubic feet of gas.

A peculiarity of this process is that the naphtha is to a large extent reduced to hydrogen and marsh gas. There is only 7.6 per cent. of illuminants, and 40 per cent. of hydrogen against only 25 per cent. of carbonic oxide, while the quantity of carbonic acid in the crude gas is only 2.15 per cent. There is 17 per cent. of marsh gas, and the assistance of the atmosphere is called in to increase the bulk of the product, as shown by the fact that nearly 10 per cent. of nitrogen is present. The composition of gases from 76° naphtha, in conjunction with various carbonaceous fuels, is also given. Foundry coke yields a gas of 22½-candle power, low in respect to hydrogen and carbonic oxide, but rich in marsh gas and illuminants. Gas coke yields a gas containing 6 per cent. of carbonic acid, but, apart from this objection, of good quality, containing 39 per cent. of hydrogen and 26.7 of marsh gas in the purified gas, and possessing an illuminating value of 22.9 candles. The high proportion of carbonic acid is ascribed to the fact that the fuel will not heat up so well as anthracite. With the latter fuel the result is very similar to that obtained from the 70° naphtha. There is rather less hydrogen, and more marsh gas. It is remarkable that a noticeable proportion of free oxygen is present, in one case as much as 1.3 per cent., and this seems to indicate, especially in conjunction with the large proportion of nitrogen, that the gases are "exhausted" out of the producers with a considerable degree of vacuum.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

SOME time ago we noted that the plants of the Batavia (N. Y.) Gas Light Company and the Consumers Electric Light and Power Company had been purchased by a syndicate with a view to consolidating and reorganizing the same. The details of the plan have been carried out with the result that the Companies have been reincorporated as the Consolidated Gas and Electric Company of Batavia, with Messrs. Samuel D. Purdy, Henry Craft, Chas. H. Caldwell, Richard C. Garhart and Russell L. Kinney as the incorporators. The capital stock has been put at \$100,000, and the Company promises to be in every sense prosperous.

A CORRESPONDENT forwards the following: "Some days ago to a select coterie Gen. Hickenlooper was relating a story respecting the late Wm. Mattox, which story contained a moral illustrating the expediency of each man minding his own business. He was then, as now, living out on Dayton street, and on a lot, which he passed every day on his way to and from the office, Mr. Mattox was erecting a dwelling house. One day the General passed by as usual, and found the builder sitting on a brick pile, gazing contemplatively towards the cornice which was just being put into place by the workmen. He stopped and said: 'Mr. Mattox, I am afraid that you are going to get that cornice too heavy for the rest of the building.' 'I am sorry, mighty sorry, that you did not come along a few days sooner, General,' was the response; 'for I am trying to put this house up in full accord with the wishes of my neighbors, and if you had spoken just a little earlier I would have left the work without a cornice.'"

THE Gas Commission will on the 7th inst. open bids for the public lighting of this city. Much interest attaches to this competition, in respect to the course that the electric lighting companies have agreed on.

MR. H. D. FITCH, of Louisville, Ky., has purchased the plant and franchises of the Sherman (Texas) Gas Light Company, and will make important improvements on the works and mains systems. This purchase places Mr. Fitch in control of about ten gas works, mostly in Kentucky and the South.

FITCH evidently means to "boom" gas sales in Sherman, for about the first thing that he did in connection with his newly acquired property was to put the selling rate (for lighting and other uses) at \$1.90 per 1,000 cubic feet, net, prompt payment, of course, being an essential to sharing in the concession. Whether this was a "heroic slash" or not is best determined from the simple announcement that the old rate was \$3. In order to popularize the use of gas for cooking, the Company agrees to put in a cooking stove, of any size desired, and allow the same to remain on trial for 30 days. If at the end of that period the consumer is dissatisfied the stove will be removed, at the Company's expense; but if the consumer is satisfied he will be required to pay only the actual cost of the stove to the Company. That is the way to do it, Mr. Fitch.

AT the annual election of the Bay State Gas Company the following officers were elected: President, J. Edward Addicks; Vice-President, Henry C. Gibson; Secretary, W. H. Miller; Treasurer, F. B. Addicks.

WE understand that the sale (reported by us some time ago) of the Evansville (Ind.) Gas and Electric Light plants to an Eastern syndicate has not been consummated.

COL. JEROME CROUL and Mr. I. C. Baxter, of the Detroit (Mich.) Gas Light Company, have been having a busy time of it in arranging for the betterments that are to be made on that plant this season. Their journeyings, however, have not been fruitless, as will be seen from the following summary of the contracts that they have concluded. In the first place, Mr. James Gardner, Jr., of Pittsburgh, will put in two full-sized benches of the McIlhenny type, through retorts, that are to be erected alongside of the two large benches of the Arndt type which were installed last year, and which are carbonizing 4,700 lbs. of coal in four hours, or 2,350 lbs. to each side. All the ironwork for the new benches is to be furnished by the Bouton Foundry Company, of Chicago, the stand-pipes, etc., to be 8 inches. Each bench is to be fitted with a (separate) diaphragm hydraulic main. At the upper end of the retort house is to be erected a double set of the improved Lowe apparatus, each set to have a capacity of 400,000 cubic feet each 24 hours. The apparatus is to be adapted to the use of Lima crude oil, and to take hot coke, drawn from the retorts and "dropped" into the generator. Messrs. Morris, Tasker & Co. have completed for the Company a 600,000 cu. ft. holder, which is inclosed in a brick building, covered with an iron (trussed) roof, slated. All the light is admitted from the roof, which carries glass—½ in. thick by 6 ft. square panes. This material runs all around the roof of the building, and about 2 feet from the gutter line. The house carries two doors (no windows), and is surmounted by a large cupola, the ventilators to which are opened and closed automatically from below.

THE annual meeting of the Superintendents in the service of the United Gas Improvement Company, of Phila., Pa., was held at the Continental Hotel, in that city, on the morning of the 18th inst. The proceedings were of a most interesting nature, and the meeting was largely attended.

A CORRESPONDENT, writing from Joplin, Mo., under date of March 12, says: "The much talked of purchase of the Carthage gas works and electric light plant and the Joplin gas works by a Fort Scott (Kas.) syndicate has taken place, and articles of incorporation have been filed under which the Carthage Light and Fuel Company and the Joplin Light and Fuel Company, come into existence. Each enterprise is capitalized in \$100,000, and the owners of the properties are Messrs. H. C. Messenger, C. H. Malin, H. A. Malin, S. B. Malin and George B. Campbell. All of these gentlemen, save the first named, are residents of Fort Scott, and they have secured two valuable artificial lighting properties. They will take absolute possession at Carthage on April 1st, and at Joplin on April 15th. Mr. Messenger, who is in charge of the water works system, will also have charge of the syndicate's gas and electric light properties. The plants will be overhauled and enlarged, but perhaps the greatest expenditure will be in line of adding to the main systems."

MR. CORNELIUS E. DURKEE has been appointed Superintendent of the Saratoga Springs (N. Y.) Gas and Electric Light Company. Mr. Durkee is a capable and clever man, and the proprietors of the Company would be in far better position now did they commit their interests in that property to a competent manager at an earlier period in its history. Through gross mismanagement the Company has been brought in disrepute among the residents, hence Mr. Durkee's task is a trying one. He has pluck and capacity, and will likely succeed in hauling the chestnuts out of the fire for those whose penny-wise, pound-foolish policy thrust the fruit in the flames. It never yet paid the proprietor to be strong in the belief that an ignorant day-laborer could stand in the place of an intelligent gas maker. In other words, a day-laborer makes the most expensive sort of an "engineer."

MR. JOHN CARSCOT, who has filled, since 1869 (with credit to himself and with satisfaction to the taxpayers), the post of City Clerk, of Madison, Wis., was, on the evening of March 18th, presented with an elegant gold watch and chain, that had been purchased from a subscription list on which figured the names of those who had served as Mayors, City Attorneys and Aldermen during Mr. Carscot's term of office, as a testimonial to his worth. The interest that gas men have in Mr. Carscot, however, is to be found in the fact that he ceases to act as City Clerk of Madison in order that he may become Secretary of the Madison Gas Light Company.

A MARLBORO (Mass.) correspondent forwards the following: "The rumor that Mr. William Anderson, the efficient Manager of the Marlboro

Gas Light Company, has engaged his services to the East Boston (Mass.) Gas Light Company, and will enter upon his labors there on July 1st, is not denied by that gentleman. We are sure that all the patrons of the Marlboro Gas Light Company who have any recollection of the Company's manufacturing facilities and works previous to Mr. Anderson's taking control thereof on February 1st, 1887, will be sorry of his conclusion to relinquish his position. However, as he gets a large increase of salary, with less of detailed routine work, the move is a wise one on his part. Good men are scarce, but the East Boston Gas Light Company knew where such an one was located, and they are, in my opinion, lucky in securing him. A large number of Marlboro's citizens will wish Mr. A. the success he deserves and will undoubtedly meet with in his new location." We heartily share in the wishes of Marlboro's citizens, and congratulate Mr. Anderson on his promotion. That it is deserved goes without saying.

MR. DANIEL H. HENSLEY, Secretary and Treasurer of the Hamilton (Ohio) Gas Light and Coke Company, has been appointed postmaster of that city. The appointment gives great satisfaction.

THE dividend of 2½ per cent. declared on the preferred stock of the Laclede Gas Company is payable on and after to-morrow.

THE Gas Inspector of San Francisco (Mr. John G. Brown) reports that the average quality of the gas supplied in that city during the week ended March 17th was: San Francisco Gas Company, 17.38 candles; Pacific Gas Improvement Company, 17.50.

ADVICES from Salt Lake City, Utah, are to the effect that the negotiations which have been underway for some time looking to a change in the management of the Salt Lake Gas Company, have been completed. Under the agreement Messrs. T. W. Ellerbeck, Henry Dinwoodey and James Jack resigned from the Board of Directors, and Messrs. Thomas Marshall, Frank H. Dyer and P. L. Williams were chosen in their stead. The reconstructed Board then elected Thomas Marshall as Vice-President; Arthur Pratt was chosen Secretary; and Frank H. Dyer was appointed Treasurer and General Manager. At a meeting of the stockholders, to be held in April, a President is to be chosen, and there is little doubt that Mr. Williams will be the man. Manager Dyer says that the reorganized Company proposes to enlarge the works, extend the mains, and to generally improve the service. The scheme of betterment under consideration involves an expenditure of between \$100,000 to \$150,000, and the work will be completed this summer. It is also proposed to improve and enlarge the electric plant that is operated by the Company.

WE are indebted to Mr. Wm. Daley, Engineer and Manager of the "City of Dunedin Suburban Gas Company (Limited), of Caversham, New Zealand," for the following particulars respecting the workings of the respective gas companies mentioned. The reports go to show that the gas men on the "reverse side" of the world have nothing to complain about: "Wellington, Feb. 3d.—At the annual meeting of the Wellington Gas Company, the report of the Directors, recommending the payment of a further dividend of 6 per cent., making a total of 13½ per cent. for the year, was adopted. The chairman, in moving its adoption and the declaration of the dividend, alluded to the falling off in the consumption of gas through the loss of the street lighting and the general habits of economy made possible by modern improvements, but expressed his confidence that gas will have nothing to fear from competition with electricity in the long run. This was not his opinion alone, but also that of eminent gas engineers in England and America. Christchurch, Feb. 3d.—The Christchurch Gas Company held its 24th annual meeting this afternoon. The balance to credit of profit and loss account was reported as £10,210 5s. 10d. A dividend of 5 per cent. for the half year, making 10 per cent. for the year, was declared, and £210 5s. 10d. carried forward. The retiring Directors, Messrs. John Anderson, H. P. Cowlishaw, Joseph Gould and G. G. Stead were re-elected. In consequence of the reduction in the price of gas the profit is £2,872 less than last year, and £6,537 less than in 1887. Auckland, Feb. 3d.—The Directors of the Auckland Gas Company announced at the annual meeting to-day that the prospects of the Company were so good that they intended to reduce the price of gas from 7s. 6d. to 6s. 8d., or a reduction of 10d. per 1,000 cubic feet. The accounts showed a net profit for the year of £22,086, and there was a balance from last year of £13,169. Dividends were declared as follows: 8s. 6d. per share on fully paid up shares, and 4s. 3d. on half paid up shares, leaving £3,394 to be added to the reserve fund, and £3,310 to be carried forward. Messrs. T. Newman and J. Buddle were re-elected Directors."

MR. RUFUS RAND, Secretary of the Minneapolis (Minn.) Gas Company, denies the rumor that any agreement has been entered into whereby a controlling interest in the Company was to be transferred to an Eastern syndicate.

SAN FRANCISCO parties are negotiating for a franchise for the operation of a gas works in the town of Santa Clara, Cal.

CASE No. 1310, in the Fourth Session Court, Boston, Mass., is that of Jno. Justice vs. the Boston Gas Light Company, and is an action to recover \$4,000 damages to person. Plaintiff asserts in January, 1885, he was employed by the defendant at its branch works at Dorchester, and that while at work, and exercising due care, in "running a machine called an automatic stoker," his right hand was caught in the machine and crushed so seriously as to be rendered useless. He alleges that the accident happened because the room in which he was working was full of steam, caused by the "cooling off or drowning of coke" in the cellar, by which the room was made dangerous to work in. The defence is a general denial. Messrs. C. E. Gerry and A. P. Worthen for plaintiff, with C. P. Greenough and J. P. Parmenter for defence.

ASSISTANT CORPORATION COUNSEL DARROW, of Chicago, has prepared an opinion in which he gives it as his belief that the franchises of the gas companies composing the present Gas Trust can be forfeited to and by the city. Perhaps they (the franchises) can be forfeited, but not according to law. Mr. Darrow also asserts that the city has the right to fix the price of gas.

AN Eastern correspondent writes: "Savin Hill residents, particularly those of them who are yachtsmen, have had their pleasure much disturbed and their eyes offended—these yachtsmen of ours are very delicate fellows—by what they have been pleased to term the unaccountably filthy waters of Dorchester Bay. The "filthy condition" as alleged was traceable to the Bay State Gas Company's station at Commercial Point, but although the Board of Health probed the case, in the evident hope of interfering with the Gas Company, the Board nevertheless failed to satisfy itself that the Company was really at fault. The Company, however, in order to clear itself completely, will not pass any more refuse into the Bay, and will hereafter run its drains into a large settling tank. The cost of the tank will not be less than \$1,000."

THE Bergen County Gas Light Company, of Englewood, New Jersey, has reduced its selling rate to \$2.80. In noting this reduction a local authority says: "This will be satisfactory news to consumers, and I doubt not will lead to an increase in the consumption of gas. The Company's recent and very liberal action in the matter of reducing the rate on gas lamps for the public lighting should meet the hearty approval and support of the public. The erection of the gas works in 1869 was a public spirited venture on the part of our citizens who subscribed the necessary capital, and if they have received no great benefit from their investment, they have at least added to the comfort, convenience and safety of our homes, churches and public halls."

IT is likely that the Courts of Wheeling, West Va., will be appealed to in the settlement of matters arising out of a complaint recently made to the City Council by a number of residents of the Fifth Ward of that city, in which they allege that the Wheeling Electric Light and Railway Company's plant has become a decided nuisance. The plant is located in a rink building which is in a fashionable residence quarter, and petitioners assert that when the machinery is in full operation every building within a radius of 500 feet is badly shaken up. Capt. R. T. Deories, Supt. of the Baltimore and Ohio depot, says that the sleeping hours enjoyed by his family are limited to the time when the electric plant is quiescent.

THE Nebraska Fuel Company, of Omaha, Neb., has been incorporated with a capital stock of \$500,000. The organizers are Messrs. Evan A. Edwards, Robt. Laird, H. A. Biossart, J. D. Cook and J. Sterling Morton. All of these, save the latter, make acknowledgement of the articles in Lucas county, Ohio.

THE plant of the Kingston (Ont.) Gas Company was damaged by fire, on the night of March 20th, in the sum of \$500. There was no interruption to the gas service.

WE understand that articles have been filed which incorporate the Citizens Gas and Electric Company, of Cleveland, O. The incorporators are Jephtha Wade, Jr., Samuel P. Ely, William J. Ramey, Mars E. Waggar and Cyrus P. Leland. An ordinance is now before the Board of

Public Improvements, of Cleveland, granting the Company (which is capitalized in \$250,000) the right to lay gas pipes and to bury subways for electric wires in the streets of the city.

THE main offices of the Minneapolis Gas Company have been removed to the Masonic Temple building.

DESPATCHES from Ottawa, Ills., dated March 21, are to the following effect: "The Illinois Supreme Court to-day denied the rehearing asked for by the Chicago Gas Trust Company in the famous Trust case. The court holds that the pleas filed are insufficient. It is not enough to allege generally that the power of franchise in question was among the powers conferred by the charter. The pleas should set forth particularly and in detail the facts which show how the corporation power or franchise was conferred upon or acquired by the defendant. But if this technical objection be waived the eight pleas are demurrable for reasons which go to merits. Some of them aver that the charter confers the power to purchase 'the capital stock' of other gas companies, which means all the stock of such companies. Others of them are less explicit, but all of them aver that the charter granted power broad enough to authorize the purchase of a majority of the shares of the capital stock of other gas companies, and that under it such majority of shares has been purchased. All of them plead the right to so purchase a majority of said shares as an original and indisputable power or franchise without reference to the other power of making and selling gas. The language of the statements as set out in the pleas imparts an intension to create the Chicago Gas Company for two independent objects. Both were designated as of equal importance and to be carried out independently of each other, the first to build, erect, operate, etc., gas works in the city of Chicago or elsewhere in the State of Illinois; the second to purchase hold or sell the capital stocks or the property and plants and goodwill of other gas companies. The court holds that the manufacture and sale of gas is one business and the dealing in stocks another, and that under the general incorporation law of the State of Illinois a corporation cannot exercise other powers than those concerned in the management of a business for which it received its charter. The dealing in stocks is not a part of the business of the manufacture and sale of gas. The power sought to be conferred by the articles of association of the Chicago Gas Trust Company is something more than the right of purchasing certain stocks of other gas companies. An attempt has been made here to vest them with the tremendous power of the purchase and control, not only of all of the gas companies in Chicago, but in Illinois. This would lead to a suppression of competition and bring about a virtual monopoly. A corporation may be formed for any lawful purpose, but so far as the Gas Trust Company is organized for the purchase of stock of other companies it is not a lawful purpose. The lighting a city is a business of a public character, and any unreasonable restraint placed upon it is prejudicial to the public welfare. This Company seeks to make use of the privileges and franchises of other companies having the use of streets and of public property, and to exercise control of them as though issued by the City Council of Chicago. The public welfare would be endangered should such procedure be authorized."

THE Superintendent of the Empire Gas and Electric Lighting Company of Huntington, L. I., asserts that the financial trouble in which its President (Mr. Claassen, of the Sixth National Bank of this city) is involved, will not affect the Company in any way, and that the gas works will be completed within the time named in the franchise. We hope that such will be the case, although we must confess the current outlook is not in line with that belief, for construction work has been suspended quite a while.

THE proprietors of the Mechanicsburg (Pa.) Gas and Water Company have voted to make application for an amendment to their charter that will permit them to engage in the business of supplying electrical currents for light, heat and power purposes.

MESSRS. DIETERICK, DAWSON AND BENEDICT, of the syndicate that recently secured control of the artificial lighting plants of Indianapolis, Ind., have made a critical examination of their purchase and report themselves as highly pleased. Of course, we did not anticipate any other verdict, more particularly when it is remembered that Mr. J. Sommerville has been for years in control of the most important of the plant factors in the syndicate purchase. We understand that Mr. Fletcher, of the old Indianapolis Gas Company, will not consent to act as President for the Syndicate Company, as he is desirous of seeking recreation in foreign travel. The probability is that a resident of this

city will be named to the Presidency, and that the vice-Presidency and virtual management will be intrusted to residents of Indianapolis.

THE Edison Electric Illuminating Company, of Paterson, N. J., lately brought suit in the District Court against one Jacob Strief, alleging that 7 Edison lamps had been installed on defendant's premises, in consequence of an agreement by the consumer to pay for the service as per "meter bill." The first bill rendered for a month's use amounted to \$34.40, and payment of same was refused. In court defendant maintained that he had never "given an order for the installation of the lights, and that as he did not use them all, he did not see why he should be asked to pay for the installation of the lights and for *more current* than he used." The Court, however, found that even though there was no contract, still his usage of the lights made him responsible for the installation of them, and, of course, he must pay for the amount of current used as indicated by the meter of the Company. This showed the amount claimed (\$34.40) to be correct, and judgment was accordingly given for the plaintiffs.

Recent Patent Issues.

The following list of recent patents relating to the gas interests is specially reported by Franklin H. Hough, solicitor of American and foreign patents, 925 F street, N. W., Washington, D. C.

ISSUE OF MARCH 4, 1890.

- 422,449. Gas Cock Gauge. W. W. Robinson and W. S. Brockway, Milwaukee, Wis.
 422,692. Gas, Apparatus for the Manufacture of. J. D. Averill, Brooklyn, N. Y.
 422,587. Gas Burner, Regenerative. T. Gordon and W. R. Swift, Philadelphia, Pa.
 422,589. Gas Burner, Regenerative. T. Gordon and W. R. Swift, Philadelphia, Pa.
 422,483. Gas Regulator. G. W. Wright, Bapel, Ind.

ISSUE OF MARCH 11, 1890.

- 423,044. Oil Gas, Apparatus for the Manufacture of. W. B. Frink, Revere, Mass.
 423,385. Gas Pipe Alarm. A. Miese, Lima, Ohio.

ISSUE OF MARCH 18, 1890.

- 423,516. Oil Gas, Apparatus for the Manufacture of. H. H. Englemen, Defiance, Ohio.
 423,525. Gas Burner, Self-Lighting. J. W. Lyon, Brooklyn, N. Y.
 423,868. Gas, Production of Chlorine. C. Hornbostel, Brooklyn, N. Y.

ISSUE OF MARCH 25, 1890.

- 424,000. Gas Engine, Rotary. G. E. Hibbard, Chicago, Ills.
 424,027. Gas Engines, Igniting Apparatus for. E. F. Roberts, Rochester, N. Y.
 424,305. Gas or Air Pipes, Safety Device for. E. C. Jones, Boston, Mass.
 424,345. Gas or Oil Motor Engines, Igniting Apparatus for. N. A. Otto, Cologne, Prussia.
 424,199. Gas Regulator. W. Haskell, Smithport, Pa.

The Market for Gas Securities.

The city market for gas shares was featureless during the week, unless utter stagnation may be considered as such. Consolidated sold at 96½ to-day (Friday), which shows that these shares can now hold their own easily in the face of a sluggish market. Other city shares are not inquired after, but all are firmly held, at perhaps a trifle over the ruling nominal quotations. The Brooklyn situation is about as before, with hardly sufficient transactions reported to base quotations on. Baltimore Consolidated has again deceived its friends, and many local speculators are bewailing their fate. They have good reason for this, inasmuch as it was looked upon almost as a certainty that the Senate would indorse the action of the House in passing the bill regulating the gas supply of that city for a term of years. The Senate, however, has "indefinitely postponed" the bill, which means its death.

Eastern shareholders are agitated over the prospects of opposition at Providence and Pawtucket, R. I., mention of which scheme will be found in our Editorial columns. After awhile perhaps the gas stockholders will appeal to the lawmaking power to protect them from such strikes by the formation of Commissions similar to the Massachusetts system. The strikers are again at work in the direction of Washington, D. C., but it is not likely that they will be any more successful than those who have tried the same game in the past.

POSITION WANTED.

A Mechanical Engineer,

Experienced in Gas Manufacture, wishes a position as Superintendent of a Gas Works. Best of references given and asked. Salary, \$1,200.

"MECHANICAL ENGINEER," care this Journal, 765-tf or Box 972, West Bay City, Mich

FOR SALE,

The Ironwork for 11 Benches of 5's, viz.:
Cast Iron Hydraulic Mains, 17 inch diameter, inside.
Dip Pipes, Bridge Pipes, Stand Pipes,
Mouthpieces and Lids.
Four Purifiers, 10 by 16 ft., with 10-inch Connections and dry Center Seal.
Four Purifiers, 5½ by 10 ft., with 6-inch Connections and Wet Center Seal.
Valves, 6-inch, 8-inch, and 10-inch.
 DAVID MOORE, Treas. Salem Gas Lt. Co., 770-tf Salem, Mass.

GAS WORKS FOR SALE.

A CONTROLLING INTEREST IN SEVERAL

Interior California Coal Gas Plants,

now paying handsomely, are offered on very reasonable terms. This is an exceptionally good opportunity for practical gas men of limited means, wishing to remove to a mild and healthful climate, to acquire an established and paying business. Particulars given and full investigation solicited.

SECRETARY, 123 Beale Street, San Francisco, Cal.

For Sale, Cheap.

Thirty Benches of 5's, with Cast Iron Hydraulic Main, 5-inch Stand and Dip Pipes, Plugs, etc Also,
Stays and Rods for Forty Benches, with Door Frames and Doors, Mouthpieces, Lids, Cotter Bars, etc.
Four Iron 4-Wheel Side-Drop Retort House Coke Wagons. Four Good Coal Carts.
Twelve Charging Scoops. Hoes, Rakes, and Firing Tools.
One Set Round Purifiers, 10 ft. diameter, 12-in. Seal, with Wet Center Seal.
Washers, Scrubbers, and
One Mackenzie Exhauster, 12-in. openings, 500,000 cu. ft. capacity.
 Will sell whole or in part, to suit purchaser. Address 772-tf MUNICIPAL GAS CO., Albany, N. Y.

FOR SALE,

The Ironwork for Twelve Benches of 6's, viz.:
Cast Iron Hydraulic Main.
7-inch Dip-Pipes, Stand-Pipes, and Bridge-Pipes, complete.
Floyd Mouthpieces and Self-Sealing Lids, 15x26 in. Lids and Mouthpieces only in use over a year. Will be sold cheap. ISAAC C. BAXTER, 772-tf Detroit (Mich.) Gas Lt. Co.

FOR SALE.

A Complete Water Gas Plant.
60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Generator, Purifiers, and Holder. Can be removed to any part of the country, and set up at small cost. For further information apply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889,

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. The Gas requires NO PURIFICATION. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE. Works under our system can be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon. One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3	ft. square,	5	ft. deep.		
No. 2,	"	"	125,000	"	"	"	"	"	"
No. 3,	"	"	250,000	"	"	"	"	"	"
No. 4,	"	"	500,000	"	"	"	"	"	"
No. 5,	"	"	750,000	"	"	"	"	"	"
No. 6,	"	"	1,000,000	"	"	"	"	"	"
No. 7,	"	"	1,250,000	"	"	"	"	"	"
No. 8,	"	"	1,500,000	"	"	"	10	"	"
No. 9,	"	"	2,000,000	"	"	"	12	"	"
No. 10,	"	"	3,000,000	"	"	"	15	"	"

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used *in every State in the Union*, and purifying daily over *thirty-five million cubic feet*. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but *three years*, and in that time has been introduced *more generally* than any invention ever designed for use in gas works. Over *two hundred* of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is *complete* without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for *mixing air* with oil gas. *No works* too small to use them profitably.

Prices given on all our specialties *delivered at any point in the United States*. Correspondence solicited.

E. STEIN, Sec.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20. and 25 Horse Power. All Engines Guaranteed for One Year.

WM. HENRY WHITE,

No. 32 Pine Street, - - - New York City.

ENGINEER AND CONTRACTOR FOR THE

Erection and Extension of Gas, Water, and Electric Light Works.

SOLE REPRESENTATIVE OF THE

McILHENNY REGENERATOR FURNACE PATENTS

And the Martin Water Gas Process.

Edison Incandescent and American Arc Electric Light Plants Installed.

Correspondence with Gas Companies contemplating extending or improving their Plants respectfully invited. Plans and Estimates Furnished.

GAS COALS.

CANNEL COALS.

GAS ENRICHERS.

JAMES D. PERKINS. **PERKINS & CO.,** F. SEAVERNES.
 228 & 229 Produce Exchange, New York.
 Cable Address, "PERKINS, NEW YORK." Post Office Box 3695, New York.

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's
OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,
OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,
 Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to

Agency for U. S., Room 70, Nos. 2 & 4 Stone St., N.Y. City.

The Standard Oil Company,

REFINERS OF

NAPHTHA AND GASOLINES.

ALSO MANUFACTURERS OF

A Special Grade of Naptha for
 Gas Companies

The Most Economical, Efficient, and Durable Gas Stove Made.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
37 in. high. 20 in. wide.	12 in. high. 17 1/2 in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	36 in.

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE, also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves.
31 in. high. 17 in. wide.	9 1/2 in. high. 14 1/2 in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 16 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

“RADIANT” BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6 1/2 inches diameter, 8 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. 1/2 in. supply pipe should be used where the pressure is 1 in. or over.

BRIEFLY TOLD.

THE RHODE ISLAND GAS GRAB.—In our item columns will be found the latest news that we have respecting the attempt of certain capitalists to levy on the capital invested in the Gas Companies at Providence and Pawtucket, and interesting reading it will undoubtedly make. It is with satisfaction we note that the local authorities, who are ignored completely in the measure now under consideration in the Legislature, are disposed to resent not only the slight thus put upon them, but seem moved by the further impulse to protect the property that contributes so much to the comfort and convenience of the citizens. This is as it should be; and while we are not of the opinion that the Rhode Island Legislature or its chief executive officer—Governor Ladd—will authorize the grab in the consent of the State, we nevertheless believe that vigilance in watching the doings of the schemers will be necessary to defeat them. Another lesson that this attempt teaches is the absolute necessity that exists for the enactment of laws placing the gas business under the control of State Commissions.

SCANT JUSTICE.—In 1886 the authorities of Toronto entered into a public lighting agreement with the Consumers Gas Company, of that city, under which the latter was authorized to carry out an improved system of street lighting by gas, at a certain figure, the contract to last for 5 years, or until Jan. 1, 1891. In order to fully carry out the compact the Gas Company invested large amounts of money in lanterns and burners—the Lambeth type was most largely favored—and the expenditure on that account was supplemented by an investment of something over \$100,000 in new mains, which were put down in streets that were ordered lighted by the authorities, but in which the Company had not theretofore distributed gas. The service was fully up to the contract, but meanwhile the authorities became enamored of electric light, and taking advantage of a strained and peculiar construction of a clause in the contract with the Gas Company, it was not long before the latter was ordered to make wholesale discontinuance of its public gas lamps and lighting. So great had this drain become that Manager Pearson, of the Company, finally appealed to the authorities, and in a well-tempered argument showed that 279 ordinary and 106 Lambeth lamps (costing but \$13,454.50 per annum to maintain) had been discontinued, while the electric lights substituted cost \$19,764.03 per annum. As it was proposed to still further decrease the gas service, Mr. Pearson appealed to the authorities to stay their hands until the gas contract had expired. It was finally determined not to further decrease the number of gas lamps in use until the expiration of the contract; and we presume the Gas Company ought to consider itself fortunate in obtaining even this scant measure of favor.

HINTS FROM ALTON, ILLS.—When Mr. William Tracy took charge some months ago of the works of the Alton (Ills.) Gas and Electric Light Company, we had occasion to remark that he was sure to make his individuality felt in directing the affairs of the Company. Now that the several plant improvements have been completed, or at least have been so far advanced that advantage may be taken of the same in carrying on the business, we are treated to the following notice, published by Secretary and Superintendent Tracy, under authority of President Campbell:

"Commencing May 1st, the price of gas will be \$2.50 per 1,000 cubic feet. If bills are paid on or before the 6th day of the month, a discount of 50 cents per 1,000 feet will be allowed, making the net price \$2. An additional discount will be allowed large consumers, as follows:

Monthly Consumption.	Discount.	Net Rate.
5,000 to 10,000.....	5 per cent.....	\$1.90
10,000 to 15,000.....	10 ".....	1.80
15,000 to 20,000.....	15 ".....	1.70
20,000 to 25,000.....	20 ".....	1.60
25,000 to 30,000.....	25 ".....	1.50
30,000 and over.....	30 ".....	1.40

"All consumers using gas stoves for cooking purposes during months of May, June, July, August, September and October, will be allowed a discount of \$1 per 1,000 feet, if bills are paid on or before the 6th day of the month. With this very low price of gas in the city of Alton, we look for a liberal patronage." Of course there is no reason to doubt that this liberal policy will be well rewarded by the people of Alton in a largely increased use of gas by them. This is the second reduction in gas rates at Alton in the last two years, and it should be remembered that the Company is in no wise exposed to competition of any sort, since its proprietors are also in full control of the electric light supply of the city. In his letter to us on the subject, Supt. Tracy says that the consumption of gas is steadily increasing. He has orders on his books for the placing of 22 gas stoves in this month, which is a rather remarkable showing when it is remembered that the total number of stoves hitherto disposed of to users in the city was only 37. Our go-ahead Superintendent is now of the opinion that Alton will have 125 stoves in use by September 1st. This may only be a small straw in the direction of indicating the increasing popularity of gaseous fuel; but such are nevertheless quite as potent in proving the drift of sentiment as are the "larger sizes."

UNIFORM THEM.—We do not suppose that there is much room for argument over the proposition that the employees of a gas company whose duties call upon them to enter the houses of consumers should be uniformed. The last example we have of the necessity for this is reported from Baltimore, where an enterprising thief has, under the guise of a gas inspector, been robbing the houses to which he gained entrance.

[Communicated Article.]

Practical Hints on Purification with Lime.

By FREDERIC EGNER.

Having received a number of inquiries from brother gas men asking if the writer could explain the reason why the amount of gas purified to the bushel of lime used was, for a time, greatly reduced at their works, without any apparent cause therefor, he thought the following item of personal experience would perhaps be interesting to the readers of the JOURNAL. In each case the statement was made that the same kind of coal that had been used for years past was used then; and so it was with the lime, and even the men employed who handled the material; and yet the number of cubic feet of gas purified to the bushel was all at once reduced to less than one-half the usual average. The apparatus and method of operation would be described, and, so far as one could judge from that, everything was as it ought to be; yet still the fact remained that where perhaps 20 and more thousand cubic feet of gas were purified before to each bushel of 80 pounds of stone lime used, now not over one-half of that amount could be passed through the boxes when a change would have to be made.

In view of the above statements the writer was puzzled to account for this state of things for a time until the same happened at the works of which he had charge. It was in December, some years ago, when we had our first experience of the kind mentioned. All at once the purifiers had to be changed more frequently than the increased quantity of gas made warranted; and with each day the matter became worse, until we investigated thoroughly, and found the cause. We were using the same kind of coal—yes, even from the same pile—which we had previously used when purifying 22,000 to 25,000 cubic feet of gas to the bushel of unslaked lime. The lime was fully as good as at any time before; and the men who did the work were the same, and were known to be faithful, hard-working men. And while the trouble lasted these men worked much harder than ever, but for all that we had to employ nearly double the force, and certainly had to buy more than double the amount of lime.

Samples of the lime were carefully analyzed, and found very good, before using; the lime was examined after it was prepared for the boxes

and found to be apparently just right; the foreman of the purifiers assured us that he was doing everything as he had always done it, and there was no reason to doubt his honesty, as he and his men worked much harder than ever before. But the fact remained that the results grew no better, but worse, as the season advanced. So at last we resolved to remain in the purifying house for a time with the men, to see if after all the fault was not there, as nothing could be found wrong elsewhere which could cause the trouble. We did not have to stay long. Within less than half a minute after seeing the men slake the lime we knew where the trouble was, and applied the remedy at once.

The manner of preparing our lime used to be as follows: A bed of lime containing about 50 bushels was made on the floor something like bricklayers make their mortar beds. The unslaked lime was spread in a thin layer, not over 4 to 5 inches deep, and then nearly the whole quantity of water needed was poured over the lime by means of a large hose and some barrels which had been previously filled. As the lime slaked it was turned over, by means of long-pronged rakes made for the purpose. After having been well slaked, about one-tenth of its bulk of screened coke breeze was added, and the whole thoroughly mixed and moistened, until if a handful were taken and tightly squeezed it would stick together and show the imprint of the fingers; and thus prepared we would purify on an average over 22,000 cubic feet of gas to the bushel (80 lbs.) of unslaked stone lime, when using Pittsburgh coal. This was a somewhat tedious process of preparing lime, but it paid for the trouble.

Now, as the season advanced, our foreman, hoping to keep up with the increased demand without employing additional labor, made some *improvements*, as he believed, in the process of slaking lime. He would spread a hundred or more bushels on the floor in layers 8 to 10 inches deep. Then he would turn the big hose on the lot, and when the top of it was about the consistency of stiff mush he would have a man go over the bed with a small hose, at the end of which was a half-inch pipe, and with that he would prod around the pile, sticking it—with the water turned on—to the bottom at short intervals. Then he would spread the coke breeze as before and mix it all.

When mixed, the lime appeared to be all right, the same as when slaked properly; but it was nothing of the kind. The lime was more than half destroyed by the above described method. True, the man could slake treble the quantity of lime with the same labor, but it was misdirected labor, well intended on the part of the foreman, but ruinous as to results, as has been shown. Within two days after stopping the above "improved method," and insisting on the old way, we had our old results back, greatly to our good foreman's surprise, who could not see before any difference between his new way and our old way of slaking lime. But the results did not convince him, as they would almost anybody who may be similarly troubled, for a few years afterwards he repeated his experiment, with the same effect as before. But he was quickly found out, and we shall have no more trouble that way.

We had blamed wet coal, defective center seal, water gas made in connection with coal gas, possible furnace gases drawn in perhaps by running exhauster too fast—everything we could think of—with the falling off in our purification; but here it was, simply the improper slaking of the lime; but for all that it needs the frequent care of the Superintendent to insure the best results, like everything else connected with the manufacture and distribution of gas.

The Market for Gas Securities.

During the week, some improvement was manifested in the dealings in city gas shares, and Consolidated was in demand at something over last week's quotations. Transactions at close of week were done at 96½ to 97, with the tone all in favor of still better figures. Mutual is higher, and Equitable shows no change of moment. Chicago Trust is at 45½—ex-dividend, the payment of which may cause serious trouble. Baltimore Consolidated is unsettled, but it would seem as though the worst had been reached. Providence and Pawtucket (R. I.) shares have not been greatly disturbed over the appearance of the Wakefield Manufacturing Company as a possible competitor in the gas supply of those cities; and Wilmington shares hold their own, although Engineer Conde is out with a notice that the Oxyhydrogen Gas Company, of Wilmington, Del., is ready to take applications for services for intending consumers, the gas to be laid on next fall. This notice is intended as a stock argument—in other words, that the owners of the old Wilmington Company had better sell out. Why they should, we fail to see. They can hold their own easily in any contest that may arise.

[OFFICIAL REPORT.—REVISED BY THE SECRETARY—CONTINUED FROM PAGE 433.]

SIXTH ANNUAL MEETING, OHIO GAS LIGHT ASSOCIATION.

HELD AT THE BOODY HOUSE, TOLEDO, OHIO, MARCH 19 AND 20, 1890.

FIRST DAY—MARCH 19—MORNING SESSION.

The President then read the following address :

PRESIDENT'S ADDRESS.

Gentlemen of the Ohio Gas Light Association:—A year ago we adjourned our last session at the beautiful interior town of Mansfield. Your action at that meeting charged me with the duty of presiding at this. How wisely you bestowed your compliment remains to be seen. Personally I was then, and am now, fully conscious that you might have made a better selection, but with renewed thanks for your compliment, and the hope that your leniency for shortcomings will not be entirely withheld, permit me to extend you a hearty greeting and welcome to this our Sixth Annual Meeting in this thriving city of our Northwestern border. A year is not a long time, and relatively to most of us it doubtless seems short, yet is ample and sufficient to work important changes for us, either for weal or woe. What greater change than the sleep that knows no waking for those who go and also for some that remain? Man, as a gregarious animal, numbers among his keenest pleasures that of greeting the returning friend, and sorrows without comfort at the final parting. As an Association we mourn no break in our numbers, and have cause to thank a beneficent Providence that the year has been thus kind to us. But as part of a fraternity may we not properly pause a moment here and be reminded that death seeks a shining mark, when we recall such names as King, Cushing, Forstall, Parrish and Button? Their names were not on our roll, but all were able, and more than ordinarily bright lights in the fraternity that we call ours. They were well and favorably known to most of us, and perhaps between all of them and individuals of our membership existed ties of attachment of more than ordinary tenderness. May we not appropriately pause and bow the head in silent communion with our own thought, remembering with thankfulness that we are not called to make official record of our own departed? May this opening and coming year be as kind in this regard to us as an Association as the one just closed has been. As an Association representing the interests of companies whose industry is not without competition, and whose environments are necessarily exceedingly various and constantly changing, may we not on the whole be satisfied with the results of the past year, and take courage for the future in view of the present outlook? If we may judge from many individual reports, and from the sentiment voiced by our technical journals, most companies are rejoicing in an increased output of their main product, and those who have steadfastly pinned their faith to the straight coal process are comforted by a marked advance in the value of residuals; all of which tends to reassure investors in gas undertakings. Of our modern industries, some are tributary and some are fundamental. The former having served a temporary purpose, pass out of use and are forgotten. The latter are perhaps variously modified according to exigencies that may arise, but in a general way remain as factors of our civilization, and we tersely speak of them as having come to stay. Steam and gas seem to be permanent examples of the latter, coming into practical use and being developed on somewhat the same general lines; there have been times in the past when the future usefulness of both seemed to be menaced, and the faith of those most interested rudely shaken. That both have thus far stood the test of practicability goes without saying.

Concerning the gas industry and the immense investments involved, the discovery of petroleum, and the economical conversion of mechanical power into electric currents with their phenomenally rapid application to practical uses, seemed so to menace the future of gas that the observant looked on with bated breath, while timid gas men whistled to preserve their courage. Particularly was this true in the early eighties. An interview about that time with an eminent electrician and inventor, familiarly known as the "Wizard of Menlo Park," is still fresh in memory. The relative possibilities and probabilities of gas and electricity in the field of artificial illumination were discussed at length. Among his concluding remarks the man of electricity said, half reflectively, and with manifest candor, "Oh, yes, we shall doubtless let you down easy." This was about ten years ago; to-day, as then, we hear what is to be, and this is natural and in entire accord with that worthy ambition that constantly strives for something better, and without which there would be no advancing civilization, none of the pro-

gress of this progressive age. Our own industry, that industry in the interests of which we are gathered to-day, has been builded in the past and will be developed in the future upon these same general lines. Startling or sensational developments we should not expect, however wonderful or incomprehensible the process submitted for our inspection or investment may appear. But, on the other hand, we may reasonably look for advantage when scientific demonstration and practical accuracy unite to complete a process. In so far as intelligent and persistent industry obtain in the conduct of our affairs, so will the measure of success be. Looking backward over short periods of time, long strides of progress are not manifest, but over *several short periods*, aggregating say twenty years, the difference between then and now is very marked. Measured by the crucial comparisons of dollars and cents, the relation is very nearly as one to three; and so accustomed has the consumer become to frequent and considerable reductions that he continues to ask with the utmost assurance "When will the price of gas be reduced?"

It is significant of the general faith in the future of gas that so much capital is being invested in dependent industries, the managers of which, in their zeal for their specialties, are becoming most potent influences in the matter of educating the public to a higher appreciation of the possibilities of gas. But while the modern idea of combustion is in striking contrast with the phlogistic theories of a past age, the practiced application of the principles of combustion that we make is even more discreditable to our time, and the more especially since it is so well understood that the gaseous form is essential to combustion. It is comforting, however, to note that the industries above referred to, such as the manufacture of stoves, engines, regenerative lamps and various heating appliances, are being conducted with increasing recognition of the principles involved in combustion, and that the near future promises such increased efficiency as will materially hasten the day of cheaper gas, the millenium alike of the manufacturer and the consumer.

And this suggests the reflection that intelligent use on the consumer's part is more or less a factor in the solution of that problem. And further, the increasing and multiplied forms of devices for using gas make this a constantly increasing necessity, not that they are complex or difficult to manage, but to turn the key and strike a match is the beginning and end of all law in this regard with the average consumer.

And since gas from being a luxury has become a necessity, and the manufacturer and consumer from being more or less indifferent, if not actually hostile to each other, have come to the attitude of mutual citizenship, it would seem that this advance toward cheaper gas should be easily made. Or, to put the case a little differently, has the manufacturer performed his part fully when he contents himself with furnishing a good article? May he not go further in the interest of the company he represents and its patrons and dispense information that may not so readily be obtained from any other source?

In the March issue of a New York paper, under the head of "Gas Fuel," appears three columns of such valuable matter in this direction that I feel justified in calling your attention to it, although all present may have already carefully perused it. So much has been written within a few years past upon the subject of gas fuel, and especially since the extensive development and use of natural gas, that it seems almost superfluous to add anything here, and more particularly as we are promised a paper, entitled "Another Year with Fuel Gas," from Mr. C. H. Evans, and which will doubtless give us his practical experience. I had also hoped we might hear from Mr. Wood, some account of his experience with the Loomis system in Sandusky; but perhaps we look to St. Louis with the more eager expectation. That situation then seems exceptionally favorable, and the hands of our own McMillin will steady the helm. Referring to the other papers on our list, I learn with regret that we shall not hear from Mr. Bate on "Theory and Practice in Gas Management," and that he may not even be with us on account of sickness.

Opinions vary greatly, especially among those without practical experience, as to the advisability of gas companies engaging in electric lighting. That such combination is sometimes justified there is no doubt, and perhaps more especially so in the *small town* where there is a demand for both lights, but for either separately a limited one. Mr. Bower's practical experience will surely interest all of us.

"Graduated Versus Uniform Rates" is certainly not a new question for gas men to consider, but the chair ventures the suggestion that when Mr. Faben gets through with his paper new opinions are more than likely to have been formulated. Those of us who have read "Looking Backward," by Edward Bellamy, may have encountered difficulties with the thought that it should be possible for a sane man to clothe the government with such extraordinary powers, but whatever view Mr.

Wilkiemeyer presents in connection with "Municipal Control of Lighting" will command respect, whether all agree with him or not.

The lighting of streets is so important a part of the public service, whether by gas or electricity, that Mr. Hedges' "Statistics" may be expected to constitute a valuable addition to the literature of our meeting. That no two gas companies deliver their output under precisely the same conditions goes without saying, and to hear the "Advantages of a Combined Coal and Water Gas Plant," from a practical standpoint, as Mr. Light will present it, will undoubtedly interest all present. If Mr. Hyde's paper, "Our New Coal Gas Works," is as creditable to his literary ability as the works themselves are to his engineering skill, we are assured a literary treat. In addition to the papers thus briefly alluded to we have eleven questions published, all of which are interesting and of practical importance; so much so that it would seem that there should be no lack of interest so far as the literary programme is concerned, and the success of the meeting thoroughly assured. Many points of interest suggest themselves for presentation here, but with a feeling that the opinions of those who have prepared subjects for your consideration should by no possibility be forestalled, my remarks should be as clearly as may be apart from those likely to be presented by others. Again, most technical questions are very fully discussed in our journals from time to time and may not profitably be reviewed here. There are, however, some matters of interest to us as an Association, and possibly a few thoughts of general interest that may properly be presented by the Chair. A Legislative Committee was appointed at Mansfield, which seems an important one. When the members for this year are appointed, as an insurance of their usefulness, I beg to suggest that both their duties and powers be clearly defined.

The question as to whether under the present statutes gas companies can by vote of their stockholders amend their charters so as to enable them legally to engage in the manufacture of electric light, is one of great importance. I am credibly informed that the Attorney General has decided this question adversely, and for the reason that such amendment would be a substantial change from the original purpose of their organization. The correctness or validity of this decision, if it be such, might easily be tested by mandamus proceedings which it is believed would involve no great amount of expense. The other alternative involves incorporation under a new charter, and I believe has been the course of more than one company during the past year. That there is a growing sentiment particularly among legislators favoring the exercise of municipal control, not only as to street railway and water companies, but gas companies as well, seems an undoubted fact. That such control, so far as we know it in the United States, has not been in the past, and is not now, conducive to the furnishing of cheap gas to the consumer, history clearly proves. This and the fact that some sections of our State laws bearing on the business of gas companies are at variance with each other, would seem to justify an effort on the part of our companies and this Association to secure needed amendments or change. That this Association has been a factor of benefit to the gas interests of Ohio and territory outside of our borders none will deny.

There are 78 gas companies in the State aside from those using natural gas exclusively. Twenty-eight of these are, as yet, unrepresented in this Association. Our Secretary has sent yearly invitations and circulars since our organization. Although a baby Association, we are a lusty little chap, but nevertheless need and ought to have the help of the 28. On the other hand, if united with us, they would derive benefits many times the value of their cost; and I respectfully urge the members present to come up to the help of the Secretary and assist in bringing these outsiders into the fold.

And while in the invitation business, let me say, in a whisper, that there are also a small number who are identified with us by membership in our Association, but who never attend its meetings. To such I say, come up and help to receive and impart the mutual benefits to be derived from our Association, not the least of which are those that come by the mere fact of our coming together.

Not long since every gas company was a finished and completed thing in itself, and so far as the outside world was concerned was literally and metaphorically fenced in. Mystery and reserve their governing characteristics, they were alike unapproachable by consumers and reserved to each other. That such barbarism of the quite recent past has given place to the intelligent, enlightened, and vastly more profitable relations of the present, by virtue of the organization and successful maintenance of gas associations, may be stoutly averred and successfully maintained. A volume might be written and the story of their valuable work and influence still remain untold. None should erroneously suppose that that work and influence is confined to the time occupied by the annual gathering. On the contrary, much of the labor

performed and thought presented in our assemblies, together with valuable information and details from various sources, become crystallized for use in the intervening time. We employ and make a pretence of paying one man, whose time of service extends through the entire year, and to whose earnestness and faithfulness much of the crystalizing effect is due. Through him, by correspondence and otherwise, a large part of our vitally necessary work is performed. Right here pardon me if I step on delicate ground, but when you have carefully considered what shall be presented, I trust you will not be moved to censoriousness. We are all more or less, and within qualifying limits, responsible for the valuable results of our meetings, and but little more remotely for the success of this Association, which exerts so potent an influence on the gas business itself. As already intimated, the present attitude of gas men toward each other is a vast improvement upon that of the former times; but there is still room for more. No man, not even a gas man, can live wholly within and unto himself. To the best of us comes a time when we seek information, and what we seek we should be equally ready to impart. That there should be no office secrets it is not intended to assert, but in a general way, if information is sought—say as to the conduct of manufacture, or business policy, or data bearing thereon, either for local use or as statistics for the general good of the fraternity—are not those who neglect or refuse a reasonable answer short-sighted, and do they not stand in their own light? Surely they have everything to gain and nothing to lose by being freely communicative in such cases. It is a matter of regret that there is here and there one, partly buried in the forgotten past, that seems to think otherwise. It is believed, however, that such are not good gas men. From year to year our Secretary requests papers for our meetings, commencing a goodly time in advance, but generally the burden of anxiety upon that score is not removed until the very near approach of the meeting itself. Excuses are more plentiful than favorable replies, one has bought a farm, another a yoke of oxen, while a third must needs take a wedding trip. And this is not the worst phase of the matter, some totally ignore his letters answering neither one way or another. Such apathy and indifference reflect upon the courtesy and progressiveness of those refusing to respond, and if all were like them would presage ill for the future of the gas business in these days of competition. I trust I have not been simply censorious in these remarks; if I have been I wish to be forgiven. They have been suggested not in the belief that they apply generally, or to any considerable portion of our number, but somewhat with the thought in mind, that even where they appear to apply, it is more because proper recognition is deferred and finally forgotten in the press of multiplied duties, and possible neglect of system in matters of correspondence. May I add, this is the census year, and it is as incumbent upon us to be faithful in imparting such facts as deserve permanent record, as it is the duty of those appointed for such purpose to record them. You hardly need be reminded that the time for the Columbus Fair at Chicago is rapidly approaching, and that some responsibility rests on each of us to the end that the gas interest be represented there in a manner commensurate with the vastness of its magnitude.

In the past, and very generally in the present, the gas business has fallen into the hands of, and has been and is being directed by, men who have drifted into it by chance or from force of circumstances. Bright men for the most part (they never would have been gas men had they been otherwise), but nevertheless not especially educated or prepared for the practical duty of manufacturing and distributing gas. Other industries not as important in the magnitude of their financial investments, or yet in relation to public necessity, find it important, and even necessary for their successful maintenance, that the practical management be committed to men of special education, and that of a high order. Indeed, the general appreciation of the value of technical education is becoming more manifest every year; it is even becoming an essential part of the public school system. Right here in Toledo is a manual training school under the auspices of the Board of Education, the privileges of which are open to any pupil having entered the High School grade; and when such pupil graduates, to his usual scholarly attainments is added more than a fair knowledge of a half dozen different trades. If in the future gas shall realize the full measure of its possibilities, its management must be characterized by a high order of intelligence. This thought is not advanced here as an original idea—more properly as a new idea—but rather to emphasize its importance, and stimulate action that shall culminate in something tangible.

Gentlemen, some apology is doubtless due for the disconnected and perhaps somewhat irrelevant character of this presentation. Recent sickness in my family, and extraordinary attending cares connected therewith, have prevented the bestowal of such thought for the interest

of this meeting as would otherwise have been given. It may occur to some that the more careful consideration and presentation of the technical details pertaining to the practicalities of our industry should have been more particularly considered. Personally, I hold the opinion that the interest of our meeting is more particularly in the hands of the membership. The list of practical papers that we are to have from them fully insures success in that direction, and certainly so if we make the most of the opportunity that their reading will afford. It has often been remarked that cordiality and freedom particularly characterized the meetings of the Ohio Association. I sincerely hope that such will be the case on this occasion. I have already occupied your time at too great length, but feel that you will indulge me in saying that when gentlemen prepare papers for us, it is fair to presume they do it at some personal sacrifice of time and mental labor. Of course we thank them, but it is due to them and to ourselves that we make the most of the papers. To that end there should be the utmost freedom in discussion. Very often it brings to the surface points necessarily only partly brought out in the paper itself. Furthermore, failure in discussion is discourtesy to the writer and loss to the meeting at large. The meeting is in your hands, and will be a greater or less success as you elect to have it. Gentlemen, I thank you for your kind attention.

On motion of Mr. Printz, a vote of thanks was tendered to the President, and the address was referred to a committee (Messrs. Printz, Gwynn and Wilkiemeyer) to examine and report in regard to the suggestions contained therein.

The President—Gentlemen, the next thing on our programme is a paper, entitled "Theory and Practice in Gas Management," by Mr. Bate, of Canton. Mr. Bate will not be present, neither shall we have the paper. We have a paper by Mr. Geo. W. Bowers, and as he is not present, I would suggest that the paper be read by the Secretary.

The Secretary then read the paper by Mr. Bowers, which was on the subject of—

COMBINATION OF GAS AND ELECTRIC LIGHTING IN A SMALL TOWN.

This subject must be considered in two lights. To be able to discuss the matter thoroughly it will be necessary to take the actual experience of the old Hillsboro Gas Light Company and repeat part of its history. It may sound as though the present Company is, through its representative, throwing reflections upon the citizens of Hillsboro—which is not done with any intent—but it is necessary to make the comment so as to thoroughly discuss the title of this paper.

The population of Hillsboro is in the neighborhood of 4,000. The Company (in 1875) secured from this corporation a contract for the period of 10 years, as follows: Street lighting, \$31.50 per post; private consumption, \$4 per 1,000 cu. ft. The cost of plant was \$26,000, \$6,000 of which was a bonded indebtedness. The private consumption at this figure, after the first few months of experience by consumers, showed a falling off of revenue by the Company, and in the course of time the price of gas was reduced to \$3 per 1,000 cu. ft., which made a slight increase each year in the Company's revenue.

I am not an advocate of high prices for private consumption, nor was the Company, but we had to contend with the following: The people in this country have an idea that all gas companies are bloated monopolies, and do not take into consideration that companies of small towns that have in the neighborhood of three, four, or five thousand inhabitants, have not the field to draw from that a city company has, nor do they consider that the amount of gas consumed in a small village in one year would serve a large city for but a day. And, further, expenses must be cut to the lowest point by the people and merchants in places the size of Hillsboro, as business in said towns has not been and cannot be placed on an average with larger cities. Hence the coal oil factor is a measure of economy and a detriment to gas companies.

It is said: "Put the price of gas down and more will be used." Now let us illustrate: We were selling gas at \$3 per 1,000; if we put the price to \$1.50 it would take twice the amount of fuel, etc., to reach the amount of income that the Company was receiving under the \$3 contract. This subject was considered by the Company, and the sentiments of the people were canvassed, but no result in regard to cutting the price was reached. At the expiration of the 10-year contract, the Company made a proposition to reduce city lighting to \$20 per lamp and private consumption to \$2 per 1,000 cu. ft., and had a petition signed by the largest taxpayers and consumers of gas of the village, requesting the Council to make said contract. But, unfortunately, the Council and Gas Company locked horns, and this situation continued for the period of two months. The Company had \$32,000 capital at stake—there being an addition to construction account of \$6,000, with the bonded indebted-

ness paid off—and the club of an electric plant hanging over its head, as they accepted a contract of two years at \$16 per lamp, with the rate of \$1.50 for private consumption. We were willing to make the test in regard to increase in consumption at a lower figure, which was half of the former contract, and at the expiration of the first year our predictions that the amount of gas consumed would not be doubled were fulfilled, the same falling short of the figures of the previous year. At this reduced figure, the Company was still made the subject of complaint, whenever gas bills were presented, as being "too expensive," and "that the Company were robbers," etc. At the expiration of this contract the electric question was brought up again, no thought being given the local Gas Company's interest or investment at stake, as no contract could be reached by them with the city.

This state of affairs brought the Company around to investigate the matter of public arc lighting, with the incandescent for private use. In anticipation of supplying both gas and electricity the subject came up "What would become of the gas interests?" Lighting the streets by electricity would cause a loss to the gas revenue. Would the increased price of arc lighting overcome the gas loss, take care of the running expenses, interest, etc., and make a profit for the Company? In our figuring we found that arc lighting for the streets at the low price of \$10 per light per year, and gas, used at private consumption, at \$1.50 per 1,000 (taking the total amount of gas used the last year of the \$1.50 contract) that the Company would come out even, not making a penny. If we undertook this addition our only salvation was in the use of incandescent lights for private use, as the only expense attached to this part of the works would be the increase of fuel, the Company having necessary steam power and employees. This, for a certain number of lights, would allow us each year to pay a small dividend after setting aside an amount towards the cost of electric plant. We decided to try the experiment, and on the 22d of last March (1889) 60 arc lights were turned on in the village. We have not had experience with the incandescent light as yet, the same not having been put in. The past year corroborates our statement that without the incandescent lights we would not be able to make a penny, as we have not. Now, I hear you say if we put in the incandescent light it will make a deficit in our private gas consumption. That is true, but with our facilities we can make incandescent lights cheaper than gas, and by utilizing employees in the gas plant with the electrical works, the amount of gas manufactured is only averaging the regular cost of production. If you could supplant all gas consumption with incandescent light at a set price per month, it would be better to do so; as, for the same amount of revenue you would receive from gas, your profits would be larger, and you would have your gas plant for fuel purposes at a cheaper rate to consumers and a cheaper process of manufacture.

Now, then, why have we let the past year go by without the addition of incandescent lights? Here we must look at this question in two lights. What is the nature of your citizens in the locality in which you reside? Are they progressive, or does the same state of affairs exist with you that we have with us—the people being conservative? If they are a wide-awake, liberal, pushing class, and have improvements in their locality at heart, the combination of gas and electricity will be a success, but if they are of a conservative order, you will know not what obstacles you will have to surmount, or at what time your investment will be put in jeopardy. We have failed to put in incandescent lights for the reason that we have been unable to secure a certain number of lights (200) at a rental of 75 cents per month (lights to burn from early candle light to 1 o'clock at night). We may be asked "Why don't you sell it by meter measure?" I will here give an illustration and then await your verdict. We were called upon by three citizens some time ago to extend our mains on a certain street. Not being compelled to make extension unless the number of 5 consumers could be obtained, and yet feeling inclined to accede, we stated to the gentlemen that if the city would take three lamp posts we would comply with their request. This the city agreed to do at \$16 per lamp rental. We made our extension at the cost of \$350, received 1½ year revenue from the city, while the revenue from the three consumers is as follows:

The first consumer has been using gas constantly at an average of \$1.05 per month; the second never put gas in his residence, and the third consumed 15 cents in gas the last year. Now, gentlemen, here we are; what can you say? I claim that with 400 incandescent lights at a rental of 75 cents per month, contracted for, it would be an inducement for any company to install said plant; but no company under the sun wants to make an outlay under existing circumstances as given. We have our plant and must make the addition of incandescent light, and work up to a certain subscribed number of lights. We anticipate making this addition in April. Our rental to this city for public lighting is

the cheapest of any lights that I know of, taking in comparison the population we have with other places. We receive \$70 per lamp for 63 lamps, and are required to burn each and every night in the year with the exception of (when it is moonlight) after midnight we are allowed to shut down. This gives us on an average of eight half nights in each month that we do not run. In addition to this we have to furnish gas lighting for the city buildings free of cost. I advocate that a corporation should be liberal in its contract with gas or electric light companies for public lighting, and the benefit given to consumers in cheap rates.

Now, to a brief history of our electric plant: The first important step we made upon the introduction of the electric light in connection with our gas plant was the attempt to thoroughly post ourselves as to the state of the art in other places in visiting other successfully operating plants. We started out with the general proposition that the best was none too good for us. We selected the Thomson-Houston system, with the Ball engine, and after operating the plant one year we have as yet to regret our selection, and have won the honorable mention of probably having one of the best, if not the very best, lights in the country.

Our city was formerly lighted with 170 gas and gasoline lamps of 16-candle power, making 2,720-candle power per night. We have now 63 2,000-candle power arc lamps, making 126,000-candle power per night.

We make it a point to reduce the number of employees and tried to get first-class labor. To do so we found it practical to secure an engineer and electrician in one person. Our labor includes one engineer and one trimmer, and we utilize the night stoker in gas plant as fireman for the electric plant. His duties are not excessive, and as soon as we get our automatic stoker in operation his duties will be comparatively light.

The claims made for the Ball engine were 4 lbs. coal per horse power per hour. Our first statement upon first starting was:

3½ lbs. coal per horse power per hour.
4 lbs. coke " " "
2 $\frac{7}{10}$ lbs., $\frac{1}{4}$ coke and $\frac{3}{4}$ Jackson slack.

This estimate does not include steam raising. We have lost two hours time with engine, and two nights' run with one of our dynamos. We have found that it is necessary to furnish 1-horse power for each 2,000-candle power light, and possibly our system may be slightly in excess of other systems as to close power economy; but its great reliability and excellent operating success more than compensates for this slight loss of power. We use the St. Louis hydraulic $\frac{1}{2}$ -inch carbons, and can count upon 9 to 9½ hours in each carbon. Have had no accidents.

Now, as to the future: We are here and in good shape, with anticipations that our community will take hold of incandescent lighting, to no disadvantage to our private gas consumption; as it is known the country over that where one place of business is well lighted the next door neighbor must have a better light, either with gas or electricity, and thus we hope to increase either one or the other of our modes of lighting.

In regard to the people of smaller towns, it generally takes some time to get them interested in any matter of this kind; but we intend to treat them liberally, and hope by next year to give a successful account of a paying investment of the arc and incandescent addition to gas which makes a success of "Combination of Gas and Electricity in a Small Town."

Discussion.

The President—Gentlemen, this paper is, I may say, a matter of interest to all of us—perhaps of more interest to some than to others. As the author is not present, there may be a little inconvenience in discussing it, but I trust that all will discuss the paper with the utmost freedom.

Mr. Penn—I have had some experience with a combination of gas and electricity in the little town of Washington Court House. Our population is about twice that of Hillsboro. I do not know I can say anything that will add to what Mr. Bowers has said, but in regard to incandescent lighting, especially at the prices they have agreed to furnish it at in Hillsboro, I will say this: Our citizens come at me in this way—we get \$80 for a 1,200-candle power arc lamp, while they only get \$70 for a 2,000-candle power lamp—and say, "Why don't you furnish it as cheap as Hillsboro?" I say, "We don't have to." In Hillsboro some of the parent companies came in, got hold of the Council and treated them nicely, nicer than our gas men can afford to do, got up a fight for a franchise, and forced the Gas Company into buying an electric light plant at an unreasonable price. I thought, when that paper was being read, if there was not some way by which this Association could come to the assistance of the small gas companies when these parent companies come in and force them into buying a plant. They could certainly give them some assistance in the way of advice, if nothing more. We were more fortunately situated than they were in Hillsboro. When we

took hold of the matter I got our contract to run to '95. We put in an electric light plant simply because the people wanted it, and it was going to come anyhow. Another thing, we were enterprising. We wanted the town to boom, and we concluded to put in an electric light plant. Our gas plant was about up to its limits—it is a small works, with only 4-inch connections—and we felt that we had gone so far that we would either have to put in a larger gas plant or add an electric one. Taking all these things into consideration, we thought it advisable to put in electric light. We finished our addition last month when we put in a second machine. Of course I can't give any data as to what we are making. I made a rough estimate of what coke was required—I am using coke altogether—and I think it is as cheap, or cheaper than coal. My impression is that we will make a very good percentage on our investment; but, on the other hand, on the gas part of it, I find we are a little bit short. It is going to "hustle" us, as the saying is, to keep up the improvements for the gas required. Now we have a demand for an extension of mains. That thing is staring us in the face, and we are not getting anything from the city to amount to anything (only about \$1,000 a year), and, of course, that is not going to give us much revenue from the city contract. The private consumption will hardly pay all the running expenses and give us surplus enough to enable us to extend our mains as they should be. Now, of course, as has been stated before, the electric light no doubt increases the demand for gas light, and it is a benefit that way. I can state several cases in our town where parties who were using oil saw, as soon as we got electric lighting in, that there was such a contrast between it and oil that it made them sick to look at their light, and they ordered either electric light or gas. I have one case in mind where a bookstore was equipped with electric light. The next store was a boot and shoe store, the proprietor of which was a very close man, who watched dollars and cents very closely. I had been at him nearly two years to put in gas, but he adhered to the use of oil. He said gas was too expensive and he couldn't stand it; but as soon as the bookstore put in electric light, he came to me voluntarily and said he wanted me to put gas in his store. I did so, and he is a good customer. In several places where we put arc lights in the stores they have abandoned oil altogether. Another place in point was a clothing store, in a long deep room, with low ceiling—a very dark place; they used oil, all except the two front windows. Of course they wanted the people to know that they burned gas there. Their gas bill didn't amount to anything. I would a good deal rather have had their meter than to have had their trade. I put in arc lighting there and they said "Oil don't look well beside electric light, and we would like you to fix up gas burners for us." Now, next door there was a tailoring establishment, and, by-the-way, the proprietor is one of the stockholders in the Gas Company. He put in arc light. He was always a little bit on the kicking order about his gas bill—thought he didn't get enough gas for the amount of money, although he was a stockholder. I noticed since putting in the arc light that he burns two jets in the window and one back at the desk. I intended to have brought a paper showing comparisons in the case of these parties, but in my hurry at starting off left it. I could show you the names and the amount of gas used before they put in electric light, and the amount used since. Of course there are exceptions. This book store that I spoke about don't use any gas at all. They have a very high ceiling and one light lights up the whole store, except in the holidays, when they light the back part of the store with gas. We keep meters in all these places and give them the regular rate, whether they use little or much.

Mr. Booth—I believe Mr. Penn has gone pretty thoroughly over all the ground. He has had a little more experience than I have. We went into the electric light business in November, and put in two 35 light (2,000-candle power) T. & H. machines. We did it as a matter of policy. Other parties were making application for a franchise, and our contract for lighting the city ran out the first of last May. We decided if they came in it would cause a fight, and we determined to put in a plant of our own. We induced the Council to give us a franchise first—that we should have the first right on the streets. We started our plant up about the 1st of December. The first contract was for 36 arc lights. We get \$90 per year for all night lighting, except three nights in the month, at full moon, and since they were put up we have had an addition of eleven, or a total of 47 lights. We have only seven commercial lights. We have not been soliciting for commercial light at all. Of course if any person comes to us and wants a commercial arc we put it in. We have been at a loss to know whether it is policy or not—whether there is not more money for us in gas than electric lighting. I notice where we have put it in has been altogether in saloons. Our saloons are perhaps the best consumers we have, consuming from 5,000 to 15,000 feet a month of gas. They burn gas in addition and we

get about the same amount from arc light and gas together that we did for the gas. There is very little difference in the amount of their bills. The arc just takes off about the same proportion of gas as if they had burned all gas, and we get about the same money per month from our customers that we got before we put in the arc lamp. We can get coal pretty cheap down there, and we get \$1.20 for gas, net. Of course we have not run long enough to determine whether we can make any more out of it than we did out of gas. From the city for gas we only got \$15 per post. Our revenue from that with the number of posts we had, amounted to about \$2,300 a year, while we get now (with the 47 lights) \$4,200 for the electric light, which I think ought to give us a little profit. We started up in November, and we didn't get anything from the city till the 1st of December, when they commenced to pay us for the arc lights. We started up the 20th of November to run the lights, but we only charged for the gas rate to the first of December. From the 20th of November I figured to the 1st of January—a month and ten days—and we had a little margin in that length of time over the cost of running. Of course, that was a fair estimate. Our expenses were larger than they would be now. We had to get accustomed to the business. We are talking some of putting in the incandescent light, because the people want it. They have it around there, and our people say, "Why don't you put it in? You have a monopoly and you think no person will come in, and you won't give us the incandescent lighting." It has been our object to please our consumers, and, if possible, to give them what they want. We expect this summer to put in an incandescent lamp machine, and we think, if we can go over the river to Benwood, we can get enough to pay us to put in the plant, as they have no gas there. I am satisfied that when they try incandescent lighting at the price it is sold at now they will find it more expensive than gas, and I expect there will be more "kicking." We have some people of that sort, of course, in our town, like they have in other places. I was amused at Mr. Penn's statement about one of the stockholders "kicking on his bill." It put me in mind of some of our consumers who act in the same way. In regard to incandescent lighting, it is a question with us whether it is policy or not to put in a plant. I will say that our consumption has been greatly increased in the last year—say, by three million feet. Our meter sale to private consumers would run in the neighborhood of a little over ten millions. We lost somewhat on account of natural gas. A few of them put in the Lungren burner, and we have never been able to get them back. They were some of the best consumers we had, but they wanted cheaper light. Natural gas is very nearly played out. In a cold day there isn't enough there, but in the warm weather we have a pretty good supply. This winter, being open and warm, we have had enough gas for general purposes, except on the real cold days when we had to hunt up wood or coal to keep warm. If it had been a cold winter I don't think there would be much gas used in Bellaire now. Most of the factories there have been thrown out of natural gas, although a few of them use it yet. Only two of the glass factories I believe use it for melting. It is pretty nearly played out, and I understood the other day that the Natural Gas Company in Martin's Ferry had instructed their agent to make no new contracts with new consumers, either for lighting or heating purposes, as they thought they had about all they could take care of. I would like to hear from somebody who has had experience in regard to incandescent lighting, where there are gas companies, to give us that experience.

Mr. Wilkiemeyer—My remarks will be based on the teachings of observation, and not experience. At Portsmouth, O., we are entering the electric lighting field, and I must confess I feel a decided shakiness about the knees. The Directors of the Portsmouth Company placed at my disposal a certain amount of money for traveling expenses, etc. My instructions were, "Investigate the different systems of electric lighting and steam engines." One result I have achieved—their money I spent. I studied the different makes of engines, their utility, economy, and efficiency; and when near my journey's end—as yet not having arrived at any satisfactory conclusion—I visited Raleigh, N. C. There I found two Otto gas engines, 50-horse power each, speeding three 45-light dynamos. I had been told that gas engines would not give the steady power necessary; but the light was steady, and, I thought, superior to any I had seen in my travels. Incandescent lamps were fed from the same circuit, and only by very close observation could I see an occasional waver, which would not be taken note of by a person not intent upon discovering this defect. Credit should be given this Company—as I understand the case—for the enterprise displayed and their results. At the time they installed the electrical plant a 50-horse power Otto gas engine could not be had in this country. Nothing daunted, they imported one from London, England. Each engine is taking but 17 cubic feet of gas per horse power. At Portsmouth we are following

the footsteps of Raleigh (N. C.), Spencer (Mass.), and Norwalk (Conn.), by utilizing a gas engine—furnishing electric light, and still selling gas through the medium of the electric light. I expect to do this—operate 7 hours per night, and with the following most liberal figures attain the consequent results. Our engine is a 50-horse power Otto gas engine. Now, then, supposing it will require 20 cubic feet per hour per horse power, we have a consumption of 1,000 cubic feet each hour; for 7 hours, 7,000 cubic feet. We will need to charge, say, 5 extra retorts, taking a total of 1,560 pounds.

1,560 pounds of coal = 19½ bush., at 5½ cents.....	\$1 03
Cost of labor of charging the 5 retorts	35
Total.....	\$1 38

We will have returned in residuals—

9 galls. tar, at 7 cents.....	\$0 63
10 bush. coke, at 5 cents.....	50
	1 13
Total cost of fuel for the 7 hours' run	\$0 25

That electric lighting plants, to be a commercial success, need most careful watching and closest economy is evidenced from the following item; furthermore the market value of stock is its true value. The item is from a recent issue of the *Cincinnati Enquirer*, and reads as follows:

"Novel Auction Sale! Some parties Dumping Electric Light Stock, and others Taking it in.—A sale of electric light stocks and rights was held at auction yesterday at the Bodman Tobacco Warehouse that attracted considerable attention from the novelties that were offered and from a certain story that was in circulation. It was stated that the gas companies had suffered from the establishment of electric light plants, and now that the former were getting the best of the latter, probably by buying them out. It appears that there is an organization called The Ohio Edison Installation Company, so called because it has the right to install Edison electric light plants in the cities of Ohio. Some that it has established had to be sold out. The reason given for having the sale at the tobacco warehouse was because so many tobacco men were interested. The sales were \$74,500 Middletown (Ohio) Electric Light Company stock, 6 cents on the dollar; \$10,600 Tiffin (Ohio) Electric Illuminating Company stock, at 60 cents on the dollar; \$16,000 Piqua (Ohio) Electric Illuminating Company stock, at 23 cents on the dollar; and \$10,000 Circleville (Ohio) Electric Light Company second mortgage bonds, at 15½ cents on the dollar. There was offered \$8,000 of the stock of the latter Company that is in litigation, but there wasn't a bid on it.

"Besides the sale mentioned the Installation Company sold its entire rights in the Middletown Company for \$25, in the Piqua Company for \$35, and in the Tiffin Company for \$125.

"There were in attendance at the sale Messrs. H. H. Hoffman, Henry Worthington, J. Hamilton, E. C. Williams, Judge Harmon, J. O. Wiggins, H. R. Morehead, and many others."

I happen to know of the experience of Circleville. They made an investment in an incandescent electric light plant of \$55,000, and it was sold at receiver's sale for \$17,000. That seems to be an experience well worth looking at by gas companies. At Circleville they are now thinking of putting in an arc plant. The stockholders of the electric light company there have control of the Gas Company—I think they paid \$40,000 for the stock. Now that, with the \$55,000 that they have invested, makes \$95,000. With the arc light coming in there—the town has a population of about 6,000—what are they going to do?

Mr. Gwynn—They will go up.

Mr. Wilkiemeyer—Another thought comes from the reading of Mr. Bower's paper. Do not we, as gas men, make a mistake in cutting our prices under compulsion? Ought we not to make these prices before we are compelled to make them, and thereby gain the friendship of the people we are dealing with? When we fight we don't want to be beaten—neither party wants to be beaten. It creates bad feeling that is very hard to overcome, and I think that is where a mistake is made. If we economize as much as we can, working hard and doing all that we can to please the people, and giving them gas at the lowest price that we can possibly give it to them at, the people will not be unreasonable, and they will stay with you, and when the electric light company comes in they won't get anything from them. The Gas Company, of course, must have foresight enough to know that if electric light is wanted in that town, they must give it to them; but if you don't give it to them, and another company comes in there, don't run.

Mr. Booth—One remark made by Mr. Wilkiemeyer in regard to the cutting of the price of gas I favor very much. Our experience in that line was that in 1884 we made a contract with the city to furnish gas at

\$1.50 per 1,000, net, to city and private consumers. When natural gas came in two years later we voluntarily cut the price to \$1, although our contract with the city for \$1.50 lasted three years longer. When the natural gas failed so that it had to be abandoned, we advanced the price to \$1.20. There was no "kicking." We had a contract with them for coal gas at \$1.50, and they expected to pay \$1.50, but instead of that we only advanced it 20 per cent. and put it at \$1.20. I think it is a good plan for a gas company, whenever they find it is necessary to make a reduction, to make it without being forced, and thus get into the good graces of the consumers who won't think you are trying to take advantage of them all the time. I think it is a good plan to do things without being compelled to do them.

A vote of thanks was passed to Mr. Bowers for his paper.

The meeting then adjourned until 2 o'clock P.M.

FIRST DAY—AFTERNOON SESSION.

The Secretary—We have a telegram from Mr. J. M. Bate, who was to have read a paper here on "Theory and Practice in Gas Management," but who is unable to be present. His telegram reads as follows:

"Comrades of the Ohio Association:—Theory in gas management is a delusion. It is all hard practice. I am proving it by trying to engineer a gas lighting contract against an electric and gasoline combination. If any of you know how to pray, make a silent petition for me in this time of woe. Am sorry not to meet with you, but my spirit is there. Wishing you a successful meeting and a good time, I am yours, fraternally—John M. Bate."

We also have a telegram from Capt. Wm. Henry White, of New York, as follows:

"Accept my sincere wishes for a large and interesting meeting, and my regrets that I am compelled to be among the missing.—Wm. Henry White."

At this point Mr. Chas. R. Faben, Jr., read his paper, entitled—

GRADUATED VS. UNIFORM RATES.

The subject presented in this paper is one that has interested, at different times, many of the general managers of gas companies throughout the whole world. It has been the subject of discussion among them during conversation, and also in open convention at the meetings of many of the largest gas associations.

There are those who argue strongly in favor of a "uniform rate" to all consumers, large and small, for any and all uses and purposes to which gas can be applied, while others again have presented equally strong argument in favor of "graduated rates"—the amount of gas demanded, the time of day in which the gas was likely to be consumed, and the purpose for which it was to be used, being a governing factor in the rate per 1,000 cubic feet to be charged for such gas consumed, etc.; and yet we are almost without precedent and reliable data to govern our actions, should any one of the gas companies represented here to-day desire to engage in the practice of "graduated selling rates."

It is true, nearly every gas company operating to-day does make some comparatively small concessions in the lines indicated. Some companies make a lower rate, if a certain large quantity of gas be consumed in a given time, irrespective of the purpose for which it is used; others again make a special discount upon bills for gas consumed for heat and power purposes, irrespective of quantity used; and nearly every company makes a discount for prompt payment of bills, some of them being very liberal in this regard. Some have made great effort to introduce into common use gas stoves for cooking purposes, selling stoves at or below actual cost, renting stoves, etc., yet no company of my acquaintance has adopted the broad policy that the time and hour seems to demand.

Great inroads have been made upon the gas lighting business of the cities and towns of our country by the advent of the arc and incandescent electric light. Some of the managers of gas companies obtain all the comfort and solace they require when they state that the arc light has educated the community to demand more light, with the result that their output of gas is just as great, or that they have experienced a slight increase over the preceding year, etc. But this, I say, is not enough. Why should we stand comparatively still, while our competitors in the lighting business push forward, and are enabled to show a very large increase of lighting business in the same territory that we, as lighting companies, have so long occupied?

The earning capacity of the plant, and of the capital at present invested, should be largely increased, since the lighting business has been very largely increased, as clearly indicated by the amount of lighting that is being done at present, electrically.

If electric light companies offer a light that answers the purpose bet-

ter than gas, then we must look for another market for our product. If, to secure business, they make generous concessions to very large consumers of light, then, if we can afford to do so, we also should be prepared to make like concessions and secure the business. If a large and profitable increase of business is not to be secured to us in the field of lighting, then is not the fuel and power field the one for us to occupy? And is not the present the time for us to make the necessary move to secure the same?

As previously stated, we are almost without precedent and reliable data to govern our actions, should any of the companies represented here to-day desire to make a new departure, adopt a broad and liberal policy, and occupy the field as a "Lighting, Fuel and Power Company." From a newspaper of recent date I clip the following items:

"*Relative Cost of Producing and Distributing Fuel Gas.*—At a recent meeting of the Engineers' Club, of St. Louis, Mo., Mr. Emerson McMillin, President of the American Gas Light Association, and of the Laclede Gas Light Company, of that city, expressed his intention of endeavoring to solve the fuel gas question in St. Louis, in the near future, by making and distributing it from an existing plant in that city, and if the people supported the enterprise it would be continued and extended.

"Replying to the question as to the relative cost of manufacture and distribution, Mr. McMillin stated that in an extreme case which had come under his observation the distribution cost four times as much as the original cost of gas. In well designed and equipped works these items of expense should be about equal. The European practice was to estimate that one-third of the selling price of gas should pay the interest on the investment, one third the cost of manufacture, and one-third the cost of distribution. He called particular attention to the fact that mains used for distributing fuel gas could be used for probably 15 hours of the 24, while those used for illuminating gas were used probably 3 hours. The fixed charges, therefore, per thousand cubic feet of gas delivered, would be greatly reduced."

"*Fuel Gas in Kansas City.*—That gas will be manufactured especially for fuel purposes in Kansas City before the close of the present year is confidently expected. With all other modern conveniences in this age of advancement, the old-style way of using wood for heating and cooking is behind the times, and fuel gas seems to be destined to take the place of these bulky commodities to a very large extent. The Kansas City Gas Light Company's new gasholder, at the corner of Twenty fifth and State Line streets, with a capacity of 1,000,000 cubic feet, is nearly ready for business," said one of their officials recently. One of the purposes of the Company is, as soon as practicable, to manufacture gas for fuel.

"Officers of the Company believe that the time is not remote when they will feel justified in beginning the manufacture of a fuel gas which may be supplied to consumers at a cost not exceeding 75 cents per 1,000 cubic feet. The initial outlay for such an undertaking, including the cost of about 20 miles of mains to be laid in the thickly populated residence districts, would approximate \$200,000; but it is not unlikely that such a task may be begun before the end of 1890."

These two items are only a sample of many that are constantly before us, and they clearly indicate the great field that is open to us, if we will but make the proper effort to enter and occupy it—not in a small way, as if by experiment, but in the broadest sense of the term. We occasionally come across such a news item as the following: "*Fuel Gas at Montgomery, Ala.*—The Montgomery Light Company have a daily output of gas of 100,000 cubic feet, of which 40,000 cubic feet is sold for fuel purposes. They charge \$2 for illuminating and \$1.20 for fuel uses. Twenty (20) heating and 108 coking stoves and four engines are now supplied. The gas stove trade is handled by the Company, and stoves are sold at cost. They examine the stoves regularly, and have a rapidly growing stove trade. The monthly consumption of gas per stove, they find, averages 3,600 feet. They think of trying the rental plan this season."

Here we have the case of comparatively a small gas company who have given the matter some considerable thought and attention, and have decided to try an experiment, to wit, making a discount of 40 per cent. from price list to all persons who will adopt gas as a source of heat and power. No doubt there are many such cases in actual successful operation in the United States, but yet we have no compilation of these facts, and we are without data as to practical working results, and, therefore, are without the means to make deductions to govern our own particular case, should we decide to do so, but we must also resort to another "experiment."

The importance of having this sort of data properly compiled, together with the peculiar local conditions existing where the "experiment" is made, must be apparent to all; but how to collect this data, and in what form to present the same to existing gas light companies

in a clear, intelligible manner, so as to enable them to make a satisfactory "schedule" for their respective localities, I am unable to present in this paper.

Gas light companies would be justified in their action were they to make special rates for gas used for special purposes. Railroad companies make special rates on classification of goods carried. When sulphate of ammonia is shipped to a buyer, the rate is, say 40 cents per 100 pounds; but when the same material, in the same packages, in the same car, is shipped to the same buyer, and he intends to use the material as "fertilizer," the freight rate is only 20 cents per 100 pounds. If the experience, practice and business laws governing in the case of railroads, is good, why will not the same apply equally well with gas light companies, who are forced to depend upon purely local trade for patronage and support?

The saying that "large bodies move slowly" is applicable to the general policy exhibited by many of the gas light companies in their past history. We are sometimes told that the present generation of gas makers are living down the sins committed by their predecessors in the business.

This leads us to the question, Are we not, as the progressive gas-makers of the present committing sins that will entitle future generations of gasmakers to truly say of us that they also are living down the sins committed by us? A look at the past will convince most of us that we have sometimes blundered and committed great errors; that our prejudice was much stronger than we are willing even now to acknowledge.

Just review, to a moderate extent, the subject of "Water Gas." When the "Lowe Apparatus" was first presented to the notice of the average legitimate coal gas man, what was said of it? We said, "It is nothing new. It don't amount to anything." Prejudice was our master at the time.

We did not say to Mr. Lowe that the apparatus presented was crude, and that it simply needed to be improved by better proportioning its parts, and in some other small matters of detail. We said that it was no good, and that settled it. But Mr. Lowe and others, not acknowledged as great gas men at the time, thought differently, and they worked and labored upon "water gas apparatus" until they have produced systems that many of the former legitimate coal gas men have since adopted, and they now swear by carbureted water gas as against their original idol, coal gas. The present direct water gas apparatus produces the same volume of carbonic oxide that it used to produce, and carbonic oxide is just as poisonous as ever, but with more calm reasoning, and dismissing our prejudices, we can now see that the presence of carbonic oxide in our gas is not seriously objectionable, but is in a measure desirable as an ingredient in an illuminating gas.

The subject of electric light was also treated by gas companies generally with the same sort of biased reasoning. It was pronounced as being simply "A demonstration of a scientific principle," "The light for the rich," etc. To-day we are confronted with the propositions of the so-called "fuel gas company projects." They are not entertained by the existing gas light companies, any more than were the "water gas people" of a few years ago, and as they (the promoters) have faith in the "fuel gas business" (with the matter of light as a sort of a side issue), they are forced to apply for a separate franchise, if they desire to engage in business at all. I do not say these things as an indorsement of their processes nor their methods and practices, but simply to raise the question, Are we to-day repeating the same sort of a mistake that we did a few years ago upon the subject of "water gas?" If we are, then we should at once proceed to change position, and not again wittingly place ourselves on the wrong side of a very important subject.

The more common use of gas for fuel and power purposes is near at hand, but if the narrow policy that has been the practice of the average gas light company in the past, is to be continued as the true policy for future operation, then fuel gas companies yet to be formed, will be the ones to do that business, but if existing gas light companies will adopt a broad and liberal policy, incorporating some schedule of "graduated rates," the price charged per 1,000 cubic feet of gas to be based, in a measure, upon the value of the service rendered the consumer, then existing gas light companies will be the ones to do the business, and in this manner largely increase the earning capacity of the present investment.

Discussion.

The President—Gentlemen, probably there is no subject that has been presented here that has commanded more thought or been

more widely discussed in the past than this very question, and I trust we shall have a warm and earnest discussion that shall be fully as valuable to us as the reading of the paper has been. If I be permitted, I will ask Mr. Hyde to say something to us that shall reflect his views and opinions.

Mr. Hyde—In a city of the size of Cleveland, as a principle I think there should be one price in the ordinary use of gas; but as this paper indicates we should be looking to the future. We should not let time pass, and not take advantage of the privileges and opportunities that present themselves. The question of fuel gas has been brought before the various Associations, and has been discussed in the GAS JOURNALS, and whether we are to have a special gas fuel or to use the present illuminating gas or fuel, has been discussed somewhat. It seems to me that with our present coal illuminating gas plants, and with all the conveniences for manufacturing and distributing gas, we should take advantage of the means we have and deliver to our customers fuel gas. That, of course, necessitates having two prices for the gas. Now we are very well aware that as the prices of gas have been reduced from time to time the consumption has been largely increased. It would seem to me that a desirable way would be to have two prices for the illuminating gas, one for that used as fuel and the other for that used for illuminating purposes. The ordinary price for illuminating gas is too high for that same gas to be used for heating purposes to any great extent; and while we have the means and opportunities of making and distributing gas, if the consumption should be largely increased for the day-time, the outlay would be increased simply in the labor attending the manufacture of the gas at the works. Now I think a policy will have to be, or should be, adopted by gas companies to meet this desire to have fuel gas, by fixing the rate of all gas used for fuel purposes much lower than it is for illuminating purposes. What that should be—how low it should be—is a matter that will have to be considered and discussed before the rate will be fixed. We all know that since the use of gas for cooking purposes the send-out for the day is largely increased. In our city the increase has been quite extensive, and I feel sure that should the price be reduced largely the gas will be used for other purposes than simply for cooking. I suppose for the heating of houses, the amount is comparatively small, but I think, with the rate reduced to say perhaps half or two-thirds, and then attention given to the construction of heating furnaces, the day may be not far distant when our houses may be heated by our illuminating gas. We have the pipes and meters in the houses and a very small outlay would be required to attach it to the furnace, or to a furnace which may be designed for that purpose. Of course the ordinary coal furnace is not adapted to the consumption of gas with economy, as it could be by some study and experimenting which the ingenious gas men of the present day are putting on that subject. My opinion is gas men should give thought and attention to this matter, and the probability is only a short time will elapse until the consumption in the day-time will be equal to the consumption at night.

Mr. Penn—I am much interested in this question. I have for about three months been contemplating making a reduction in price, and have been waiting until this meeting so that I could hear the question fully discussed, as I am in hopes it will be. I have been thinking the proper way would be to make a uniform rate for illuminating gas to all consumers, both large and small, and a uniform reduced rate for all fuel purposes. I would like to hear the opinion of others before I adopt that schedule.

Mr. Tayler—I think the question of graduated prices is very largely a local question. In some places it would be exactly the thing, in others it would not. I am speaking of graduated prices for illuminating purposes. In my town (Warren) we have no large consumers. There are none large enough to make it any special object to reduce the price of gas to them—that is, to make a graduated rate; but I think the only way to use illuminating gas for fuel purposes is by reducing the price. For the last month or so I have been heating my office with gas in a new way, putting in pipes and heating by hot water—putting gas under my boiler; and while it is a very convenient way of heating, and one that perhaps a gas company could afford to use for its own heating, it would stagger some of our customers if the bill were presented to them. I find it takes about 1,500 feet a day to heat my office and shop. That, at any price that we could sell gas at in Warren, would not bring many customers. But if the price of gas could be put at something that approximated the price of coal, we could furnish gas for heating purposes. The question with me is—how to get down there. I don't see how we can make a coal gas in a town of our size at anything near the cost of hard fuel—without it would be a change in process, making an entirely different gas, and that means almost another gas works.

The Secretary—One of our consumers at Columbus said that he would agree to let us heat his house with our gas, by putting it under a boiler, as in Mr. Tayler's case, and heating the house with steam. He would agree to let us undertake it and allow it to re-

main there, if it did not cost him more than twice as much as coal. We made the experiment, using two or three kinds of home-made atmospheric burners under his boiler. Experiments were made to a considerable extent, and yet we could not come within the limit that we had fixed. It cost more than twice as much as coal.

A Member—At what price?

The Secretary—One dollar a thousand.

Mr. Christian—I would like to know whether Mr. Tayler used hot water circulation or steam?

Mr. Tayler—Hot water.

Mr. Christian—For how many hours?

Mr. Tayler—Twenty-four.

Mr. Christian—That is very favorable towards gas. I did not think it could be done for that. What sized rooms are those?

Mr. Tayler—Two rooms about 16 feet square. The shop is about 24 by 16, and hall-way is equal to a room 16 by 18.

Mr. Christian—Last Spring I went to Iowa to change a plant that had been making hydrogen gas—it was a town of about 12,000 inhabitants—and I don't think they had been using it more than a year. It was an illuminating plant, not one for fuel purposes. They used the Springer apparatus and made the hydrogen gas with the Springer cupola. They used hard coal, costing, I think, \$8 per ton. All the coal that we used after I went there they had when I went there. We changed from an oil process. They sold their gas at 60 cents a thousand feet and that winter they lighted a large hall with some of their burners. The expense, I think, with the gas at 60 cents, was about three times the cost with lighting with coal gas. Of course the soft coal was cheap. You could get coal at \$1.35 a ton, delivered, so that hydrogen gas at 60 cents in that town never could have competed with soft coal.

Mr. Evans—Mr. President, the subject has somewhat taken a fuel gas turn, and I may have a word to say. I don't think that fuel gas, as manufactured even at the lowest possible price to-day, can be used to heat an office by steam. Of course it is evident that to produce it you have to raise the temperature to the boiling point, or 212°, and that in the changing of that water from the boiling point of 212° steam it will equal a latent heat of 966°. So that in changing water into the form of steam you require a great deal of heat, and also pass the products of combustion out of your chimney at a high temperature, at least as high as that of your steam. So that as fuel gas is produced, or any other gas, I don't think that we to-day can compete with coal in this way. I would like to ask Mr. Faben if he is using graduated rates, or is making any attempts in that direction?

Mr. Faben—No, we are not. I said to the Secretary at the time it was in bad taste for me to write a paper indorsing some pet principle of his that I did not have in practice. But I think we should be excused a little as we are well supplied with natural gas. It would be senseless for us to attempt to do a fuel business, because you can buy natural gas for 12 cents a thousand, meter measure. The subject was an entirely new one to me, suggested by our Secretary, but in thinking the matter over the more important the whole subject seemed to be; and without making a very exhaustive and tiresome paper I hardly knew how far to go with it. One of the most important things that presented itself to my mind in the preparation of the paper was the lack of data as to the experience and experiments that are going on all over our country. Occasionally a newspaper will take it upon itself to send out a list of questions, asking the companies to kindly fill in the blanks. They will ask them how much of their gas is burned in day-time and how much at night, what portion of it is used for fuel, and what portion for light, and what portion for steam engines. Well, it is one of those matters that they have not given any particular attention to, or kept any account of, and the result is, as my friend here says, they keep their postage stamps. If some manner or mode was suggested whereby the data covering the experience of all those companies making these experiments in graduated rates could be compiled and published, so that every man could make his own deductions for his own particular case, it would be a good thing. There is a figure somewhere lower than the ordinary selling rates that could be adopted for fuel purposes. The best avenue I see presented now is through the eleventh census. We will see, for the first time, electrical statistics. The electricians are thoroughly alive to the importance of this matter in connection with their business. Ten years ago they were not in the business, and no data were required at that time. But the commercial growth of their business demands that they have a full and exhaustive compilation of the present condition of the electrical industry. We were in the business of gas making more than ten years ago, and the kind of information compiled and in store to-day on the condition of the gas business ten years ago, at the time of the collection of the last census, is very poor material—for what reason I cannot say, but another census is about to be taken. Now, if our business had been properly canvassed ten years ago, and we knew the condition we were in at that time, both in the matter of light and fuel service, we would know just exactly where we stand on the question to-day—not only as lighting companies, but how far we have progressed with the fuel business. The trouble has been that the majority of companies have not kept a very exhaustive record of what they were doing, and when a circular is sent out to them they cannot well fill it. I would like to impress on the minds of the members that each individual can make a very much closer guess in his community, than can the gentleman who sends the circular out; and if, in collecting the material for the eleventh census—the schedules sent out are rather exhaustive—if each man

will fill in the answers that are required, to the best of his ability, and those that he cannot give accurately, if he will write after them, "approximate," and any other data that might suggest itself to his mind, it would enable the census collector, at some later date, in his newer and later schedules, to incorporate those features.

The Secretary—Coming back to the subject of graduated rates, I would like to ask Mr. Faben if he would recommend that a company should fix a graduated rate based simply on the amount of consumption, leaving out of question the fuel part of the business?

Mr. Faben—I hardly understand the question, Mr. Secretary.

The Secretary—Would you give a lower rate to the man who burned 10,000 feet of gas than you would than to the man who burned only 1,000 feet, for illumination?

Mr. Faben—That certainly is in line with the modern practice of doing business. We have, as lighting companies, a well-organized and formidable competitor in the matter of electric lighting. Some of our members feel that incandescent lighting is still an experiment. I don't think so. I think the incandescent light will do a very large percentage of the nice lighting of the future; and I also believe that gas will be more commonly used than it was ever used before; but I don't think that we ought to content ourselves in doing just as much business as we did last year when the field is open to us to do a great deal more business. The fixed charges on a plant are the same, whether we send out one hundred million, or whether we send out two hundred million, provided that other hundred million is in a new field, and furnished during hours when our mains are now comparatively idle.

Mr. Prichard—We have used a graduated rate at Ironton for four years, and have had no reason to change or go back.

Mr. Printz—We at Zanesville have not what you would probably term graduated rates. We have a fixed charge of \$1.25 per thousand feet for gas consumed for all purposes. But we allow a discount of five per cent. on bills of \$25 per month, and ten per cent. on bills of \$50 and over. We have not made any graduated rate for fuel and for illuminating purposes. We thought if we made two rates that it would require, in a house where they were using gas for fuel and illumination, two meters. That would be an expense we didn't think we ought to incur. Again, we hardly thought it fair to allow a man a low rate for gas consumed for fuel. For instance, he consumed say \$5 worth in a month, and another man would consume twice that amount for illuminating purposes in the daytime. It is a question we thought of a great deal, and we settled in our minds the better way was to charge as low a rate as possible for all purposes. Mr. Tayler's idea of heating his office, and the figures he has stated, brought to my mind the fact that we have been heating our office at home. It is a room 17 ft. by 26 ft., and about an 11 foot ceiling. We heated it with a large reflector stove and the gas bill for six months, for heating and illuminating purposes, amounted to \$40. Although we paid the year before \$30 for steam heating purposes alone, we felt that we were really saving money by heating our office with our own gas. Quite a number of our people are using our gas for fuel purposes in a small way, for heating bath rooms or bed rooms, which they use just for a short time in the evening; and we have, all told—that is for heating and cooking purposes—some 400 stoves in use in our place, and the people are very well satisfied with the price we charge them, \$1.25 per 1000.

The President—If I may be permitted I would like to express just a thought here. All this is exceedingly interesting, but after all, the absolute cost developed into heat units is the thing that underlies the whole matter. I have given some attention to that thing, and I regret exceedingly that I have not brought the data with me. A stove designed for heating purposes alone was brought to my notice, and I placed it in a room some time ago, and kept a record of the gas consumed, and the temperatures. This room is say 18x26, and perhaps 10 feet high. It is an outside room, that is, all sides exposed, practically, to the open air, and is in a brick building. There are nine windows and an exterior side door so that it is a fairly exposed room. Of course this is not definite, but I give you these facts that you may form your own judgment. I was really quite surprised at the measure of economy that was manifested. It was more expensive than coal, perhaps, applied in an open grate, and certainly more expensive than steam or hot water circulation, but not so vastly out of reach as that we might not take to ourselves a little courage that there is a field for manufactured gas heating in the future.

Mr. Faben—Mr. President, Mr. Evans has had some experience with graduated rates, as I recollect it. I believe they sell fuel gas at 30 cents, and add about 33 per cent. for the same gas used for lighting purposes. He might tell us something of his experience in that line.

Mr. Evans—Mr. Faben is a little in error. We do use some graduated rates, simply to this extent: The consumer is obliged to burn 5000 feet of gas per month in order to get the lowest rates. It is billed to the consumers at 50 cents per thousand, if they burn under 5000 feet, with a rebate of 10 cents if paid on or before the 10th of the month. Over 5000 feet is billed to them at 40 cents a thousand, with a rebate of 10 cents, if paid on or before the 10th. We make no distinction between lighting and heating, although we contemplate doing this on our illuminating gas main that does not parallel our water gas. We have discussed this very point, and I was very much interested when I learned this subject was coming up, because it is one which I think has brought about a great deal of thought and study on the part of gas men, and I have yet to see the solution of it.

Mr. Tayler—I would like to ask Mr. Evans his opinion as to the practicability of using gas for heating by hot air or hot water circulation. In either case I imagine it is cheaper than steam.

Mr. Evans—I imagine that heating by hot air or hot water would be the best method, as you can send the product of combustion out at almost as low a temperature as the temperature of the room. The necessity exists of extracting all the heat, so that the products of combustion will leave the room at as low a temperature as possible. A great deal depends upon the application. If you can apply it to heating by hot water, so as to absorb all that heat, so that when it reaches the point of exit the temperature is low, and yet not so saturated with the products of combustion that it will condense at that point and stop your draft, then you have accomplished all that can be done. Of course, in my paper on fuel gas this thing will probably come up again, as I have gone into the matter, not very deeply, but as much as my time will permit. I will probably have something to say on that point when the subject comes up for discussion.

Mr. Faben—On the matter of data, I believe we have with us Mr. Graeff, who has been selected as the person to collect data of the gas industry. I would like to have Mr. Graeff, if he will, tell the Association what has been done in that direction and what he would like the Association to do to assist him in the collection of statistics.

The President—I think the Association would be glad to hear from Mr. Graeff, and co-operate with him as far as they can.

Mr. Graeff—Mr. President and gentlemen: So far as the first part of Mr. Faben's remarks is concerned—as to what has been done towards the collection of the statistics—I would simply say "nothing," except getting the schedules in order; because the data has to be collected, in the gas industries, for the year ending June 30th, and of course the schedules will not be sent out until the close of June. The preliminary schedule, which will be sent out prior to that time, for information upon which the other schedules will be partly based, will simply have in it a reference to the number of gas stoves and gas engines in the town, if they can be correctly or approximately reported. It is not expected they shall be closely ascertained. The regular schedule, so far, only contains inquiries as to the price of gas for lighting, and the price at which gas is sold for heating power purposes, with the quantities consumed in each direction, so far as can be ascertained, during the twelve months. But it strikes me that a request should go from this Association to the Superintendent of the Census, asking him that inquiry in this direction should be made as thorough as possible, and that the results obtained from such inquiries be made public as early as possible in a special report. I think he will very readily put on the possible little extra clerical force that will be necessary. I think that such a request will have considerable weight, and I would like to see it made. Of course you know that in the matter of these statistics, names of the companies are not made public.

Nothing is made public in the matter of particulars—the entire State of Ohio will appear as a unit, for instance, so that no one will know how much gas one company or another is selling, and no one will get at the minutiae of your business. Of course, you are guaranteed against that by the Government. But in a matter of this kind, the different rates at which gas is sold throughout the country could be very properly gathered together without "giving away" the business of any particular company. It strikes me that such a request would materially advance the matter—the point toward which Mr. Faben seems to aim. I will do all in my power to have such a request granted, if made.

The President—It would seem as though here was a suggestion that it might be well for us to act upon before we adjourn. In this very matter my attention has been called to a case that presented itself after the introduction of a stove, or stoves, that were put in at the graduated rate, maintaining the regular rates for illuminating, and with the special view of increasing the sale of gas by "booming" the fuel trade. A prominent consumer came in very shortly, who was very quick to "catch on" to the situation, and desired that his gas be passed through a stove as well as through a meter: I think the point is obvious. (Laughter).

Mr. Strong—Mr. President, I think this manner of graduated rates is one that is peculiar to each individual city. It is one thing to manipulate a gas company where you can have the situation to your own liking and quite another thing when you have not. This matter of graduated rates came up before our company a year ago. We had been giving a little concession prior to that for gas used as fuel, but not enough to cut any figure in the bills, or in the increase of gas so used. A year ago, with a change of process, we concluded to "burn our bridges." So we reduced the gas used as an illuminant to \$1.25, net, and for fuel to \$1. We did that for two reasons: First, the comparative economy which we secured by getting a larger number of consumers, if gas was reduced to a price that was unmistakably cheap, rather than to confirm itself by one or two or three years' demonstration, which would only gradually come to the surface. Second: We find in our community, which perhaps has as large an amount of total depravity as you find elsewhere, that the man who burns a large amount of gas in his house at \$1.25, or whatever the rate is, but in his place of business gets it for less money, he wants it as cheap all around. Now the larger consumer, who gets his gas at \$1 per 1000, for instance, but who pays for it in his house at the rate of \$1.25, is very apt to insist on the computation of the amount of gas burned, at the low price. Consequently, you are having continual annoyance, and, in case of competition, decided trouble. Now of course the arrangement that we adopted would require the setting of additional meters; but we increased

our consumption the last year about 30 per cent. on the gas sold. In our community I don't think any other scheme would have been satisfactory. We have secured such a favorable opinion among our consumers that I think this year we will perhaps double our use of gas stoves. I think we have now very nearly 140 gas stoves—perhaps two-thirds of these are gas ranges—and the experience of those who are using gas was so complimentary to the company that a great many now adopt some means of warming their kitchens, using the surplus heat of the hot air furnace for such purpose, thus abandoning their coal stoves the year through. Our winter consumption for fuel is only 25 per cent. less than our summer consumption was last year, for same purpose.

A Member—The day consumption?

Mr. Strong—I mean the day consumption on gas stoves. In other words, we have a number who are throwing away their stoves and depending upon the gas fuel to warm their kitchens by means of hot air or steam. I think the great increase gas companies can make in the amount of gas that is used, is in the direction of day gas, in cases where you have competition, as we have, by incandescent lighting.

Mr. Evans—It strikes me that if the price of gas is made low to large consumers (low per thousand feet) they would still have an inclination to save, whereas, if the price were based on their yearly consumption they would make it a point to reach those figures. For instance, a consumer who has been consuming 500,000 feet a year at \$1.40 per thousand, say, would make that bill aggregate \$700 a year; but if the price were reduced (for 600,000 feet burned) to \$1.30, the bill then would be simply \$780, or he would get the last 100,000 feet for \$80 or 80 cents a thousand. If the price was reduced still lower—for a consumption of 700,000 feet, say \$1.20, he would receive the last 200,000 feet for \$140, or 70 cents a thousand. You can carry that up to a million. For instance, if he used a million feet a year at \$1 a thousand, he will simply be paying \$1,000, and they will get the extra 500,000 feet for \$300, or 60 cents a thousand. These are the figures I have gone into, contemplating making some reduction, as I said before, in the illuminating gas in mains that do not parallel our water gas. It strikes me that the tendency would be for the consumer to use the gas so as to bring the amount up to a point where he would get low rates. He could then illuminate his house or a hotel, whatever it might be, as much as he saw fit. I would simply make them their rebates semi-annually, or at the end of the year, billing their gas at the regular rates and making this discount semi-annually, or, as I said before, at the end of the year.

On motion a vote of thanks was passed to Mr. Faben.

Mr. Faben—I move that the Secretary be instructed to communicate with the Superintendent of the Census, asking that the data on the consumption of gas for uses other than lighting be extensively gone into. I have not the exact wording of the proposed letter. The Secretary can frame that. [Adopted.]

At this point Mr. H. Wilkiemeyer, of Portsmouth, read his paper, entitled:

MUNICIPAL CONTROL OF LIGHTING.

Man was born free. The Creator endowed him with the fullest liberty. He had not lived long until he got into trouble and discovered he needed protection against himself. He was wild and savage, and he knew it. He also knew that he was capable of better things than those into which he was led by his unbridled, unrestrained instincts. He therefore, for the sake of bettering his condition, surrendered certain of his inherent rights and entered into the social compact. He said to his neighbor, "You stop reaping the grain which I have sown, and I will no more feast upon the cattle which you have herded and guarded from the wolves." The ideas of "mine" and "thine" became more firmly fixed. There was compensation in this arrangement for all parties connected therewith. While one party, on his part, was compelled to forego the pleasure of stealing the goods of his neighbor, on the other hand his own chattels were the more secure. By the surrender of certain of his inherent rights, other rights were rendered more stable: greater security, both in purse and person, was realized, and out of these mutual surrenderings Society was formed. Therefore it may be laid down as an axiom that societies, or communities, exercising corporate functions, were formed and exist as a police measure. The *rationale* of the construction of the social fabric precludes the exercise by the municipality of all functions but those that are police in their nature and tendency. Whenever a departure from this rule occurs, then liberty suffers, and another item of natural personal liberty is sucked into the great vortex of centralization of power. It is therefore wrong, on first principles, for a city to engage in any other occupation or business than that for which cities, or communities, or society, was originally established.

The centralization of affairs in the Government is eminently unwise, for there is no limit to the venture. If the city has an inherent and politic right to go into the lighting business, it has also the right to go into the coal, clothing and grocery business. The result would be either absolute anarchy or abject slavery.

Societies should continue to serve the purpose for which they were created. It is dangerous precedent for them to go further or assume more. By absorption of all business, the Government would become paternal in its nature. Ambition would have no place in our make-up, and we would be a nation of nonentities, no man depending upon himself or his neighbor. We would be an army without soldiers, or perhaps we would attain that delight-

fully philosophic, but lamentably impractical, condition described by Bellamy in his recent novel, "Looking Backward."

But the question as to the advisability of a city's owning and operating a gas light or electric light plant, instead of being philosophic and speculative, is pre-eminently an economic and practical one; and the practical phases of it only should be regarded. Enthusiasts and men who have machinery and lighting apparatus to sell to cities (in the absence of a multiplicity of private customers), have at great expense been flooding the popular and scientific prints with long articles from the pens of hired sophists. By their fallacious but plausible arguments many a fair municipality, which was prosperous and peaceful, has been plunged into a state of disquiet, and has had a white elephant imposed upon it in the shape of a gas or electric light plant, which must forever be fed and nourished from the public crib, or which will, when the novelty of the affair wears off and when officers become negligent, be cast aside to be of no future use except as an undying memento of the folly of following the advice of persons interested in the sale to the city.

Of course the smooth-tongued agent presents the matter in a glowing light. It is his business. He has studied the points, and he knows what to push most forcibly and what to pass by as not worthy of mention. It may safely be laid down as an axiom, that whenever a city embarks in a venture that even savors of money-making, it is exceeding either its legal powers or is encroaching upon rights never ceded by the people.

Old adages are good, and as they have stood the test of time they must be true. "What is everybody's business is nobody's business" and "every man to his own trade" are two trite phrases that seem particularly appropriate in the discussion of this question. The managers of a city plant, however honest, have not, and can not have, the same material interest in its economical and successful administration as would an individual owning the same. Expensive experiments are more likely to be made when the cash does not come from the pocket of the experimenter. His salary is secure, no matter upon which side of the ledger the balance stands at the end of the year.

He has the credit of the city at his back, and a few thousands in extravagance will not be remarked by the public.

Looseness and carelessness are almost inevitable in the management of a city lighting plant. On the contrary, when the owners of the plant are its managers, every cent of the expenditures is carefully, jealously scrutinized. Men are employed because they will work, and they must work to their full capacity or seek employment elsewhere. They are not employed and retained in well-paid positions for political reward, but for the work they do. No man can secure an agent who gives the same attention to his affairs as he does himself, nor can a city secure the same service which an individual gives to his own affairs.

It has been argued that a private gas or other lighting company has a monopoly. Granted. But they are entirely different in their nature from mercantile monopolies. Take a private corporation, engaged in the sale of any given commodity. It can, if it has a monopoly in the article, establish a given price, and say to the public, "Either buy from us at our price or go without. We own it all, and you will have to pay what we ask." It is not thus with a lighting company.

Corporations have ever been jealously guarded by the people, and their power and privileges curtailed. Under existing laws, a monopoly in lighting is impossible. The city may fix the price which it will pay for gas for a definite time, and the company must sell at that price if that price be fair. There are so many other ways of lighting than by gas and electricity, that it is impossible for a company dealing in either to be in the least arbitrary.

True, a certain company may be the only one that has gas or electric light for sale in a given locality, but even in such a case it never has a monopoly in the strict sense of the word, or even in the plain business sense of the word. No man nor set of men can control the price of light. If A asks too much for his electricity, I can buy from B, the gas man: If A and B combine and run up the price, I and my neighbors can buy a barrel of coal oil, and while we are burning half of it A and B will come to the conclusion that they have made a grievous business error, and will quickly come to terms.

The people of a city have it in their power to dictate absolute terms to a lighting company. The company has money invested in its plant, and it depends on the people for its income. When the people withdraw their patronage, the income from the investment ceases, and the venture from that moment becomes unproductive. Now, it is plainly within the power of the people to exercise power over lighting companies in more ways than one. The Creator has placed in the bowels of the earth, and within easy reach, oils, by the use of which, for even a day, great loss ensues to a company. The plan and principle of a lighting company is to extend the patronage; this can only be done by keeping the price down.

The adage of an ordinary monopoly is, "Charge the highest price the purchaser can afford to give." The adage of a lighting company is, "Sell at as low a price as you can afford to take, extend your patronage, and run your institution to its limit."

Another restriction of which the public may avail itself, is this: Whenever the citizens discover that an unfair advantage is sought to be taken by the light company, they can, under the laws, call a halt. No private company owning a light plant can afford, by

extortion, to drive the municipality, in which it is located, into a fight, which, in nine cases out of ten, means ruin. The value of the plant is virtually in the hands of the municipal authorities, and they can therefore exercise a summary and wholesome jurisdiction over the lighting company without investing a single dollar of the people's money. The claim, therefore, that a private lighting company is a monopoly, is erroneous. The municipality has arbitrary power, and would not, nor does not, hesitate to exercise the same when circumstances demand it.

It is said that a municipal lighting company can afford to sell at cost. But where the gain? Who supplies the money to pay the cost? Is it those who use gas and electric light? By no means. The men who live in a cottage and the cabin pay taxes. What does it avail them that a man who lives in a mansard can have his halls lighted by electricity at cost? They burn oil or tallow. Cost price is too high to enable them to indulge in electric light, yet they, the men who dwell in the humble houses of labor, the men whose brawn and muscle and brain made this country what it is, must be called upon to help pay for the illumination of the palaces of these princes and potentates of finance. It is unfair. There is no justice in it, and the system which compels them to do it is radically wrong. Let the man who wants an electric light buy it and pay for it if he is able; if not, let him burn gas. If that be too expensive for his pocket, then he should burn oil. If that be beyond his means, let him go to bed and get up aided by the tallow dip of our grand-mothers.

The system of taxing a poor man in order that a rich man may have his luxuries at a lesser cost, will never prevail in a land where justice has an abiding place. But, it may be urged, the owner of the small house must pay his proportion of the taxes, any way, and his taxes are lessened in proportion as the expenditures of the city are high or low; the city must be lighted, and if it is done at a lower cost by reason of the city owning the light plant, he benefits thereby. But the public, it has been estimated, forms only one-sixth of the patronage of a light company. And, therefore, he benefits himself to the extent of one-sixth, while he benefits his wealthy neighbors to the extent of five-sixths.

But is it an invariable fact that a city sells light at cost? Let us see if there are not reasons which lead, naturally, to their selling at a profit. The Superintendent and Directors desire to make as good a public showing as possible. They do not care to have it appear in their stated reports that the business which they have been conducting cost more than it brought in, so they, in order to demonstrate managerial ability, are naturally inclined to put up prices. This is not only true in theory, but in fact. In the city of Portsmouth, Ohio, for example, seven lamps are sold to the county and to the railroads. Each lamp, according to the statement of those in authority, costs less than \$30 per annum. Yet the county and railroads pay per year for each lamp the sum of \$100. Surely, no private corporation would be suffered to do thus, nor would it have the temerity to try, "soulless" though it be.

Capital is crystallized labor. Every dollar is made sacred by hours of labor. Every penny represents a drop of sweat that falls from the laborer's brow. Capital, as well as every expenditure of mind or matter, must bring its compensation. The legitimate purpose of capital is *investment*. The man or the policy which prevents the investment of private wealth in a town or city does a wrong to labor. Yet this is what a city does when it embarks in the business of selling light.

It is urged by some writers, as an argument in favor of municipal ownership of light plants, that the cost of light in cities owning their own plants is so much less, by comparison, than those lighted by private companies. But these writers invariably fail to tell us the tax rate in these cities. Why this omission? Can it be that the force of their argument would be lessened by the publishing of that very important factor? Is it because this important fact would give the lie to the assertion that a saving is made by the city's operating the light plant?

The capital of a city is derived primarily from the pockets of the people; secondarily, from the vaults of the city treasurer. It is not an exercise of solid political economy to allow the people's money to be invested in a commercial undertaking.

No industry is generated unless there is, as an object, a profit. The motive for private capital to invest in a certain line of business is destroyed, annihilated, when a city enters into the same line of business and conducts the business with no desire to make a profit. It is a dangerous principle, and one subversive of all our cherished ideas, that a city may forestall the investment of private capital and assume and arrogate to itself a certain line of business without profit as an object.

No man should be willing to be taxed in order that a city should secure capital with which to strangle private enterprise. If it is good policy to allow a city to embark in and run and manage a light plant, it is also good policy to allow it to own and manage street car lines, telephone service or a meat shop. It receives its capital from taxation. It has no interest to pay except upon the pledged credit of the municipality, nor is it taxed. It can exist forever without making a cent of profit. And when the credit of the city is pledged the citizen is taxed once for the principal and once for the interest. The city, which needs no profit, competes against private enterprise, and so successfully as to deprive it of all hope of a reward. It is driving private capital from one investment to another, because private capital must increase or decrease, while the city is doing all that is requisite when it comes out even.

It does not have to eat or wear clothes. It has no doctor bills or funeral expenses to pay, no school books or taxes or interest to pay, and it can live without making money. It is to the interest of the citizens that cities do not own and operate a light plant.

The President—Gentlemen, we have just listened to, I was going to say, as good a paper as I ever heard read; but I ought not to manufacture capital here for any man's paper. I will say you have listened to a good paper and it ought to be thoroughly discussed. I surely hope it will be.

The Secretary—Mr. President, I would not want to say anything that would block the discussion of Mr. Welkiemeyer's paper at once; but I will mention, as proof of the interest now being taken in this question, we have voluntarily offered to us at this meeting two further papers on this same subject. Before leaving Columbus, yesterday, I was surprised to have handed me a nicely type-written paper entitled "Municipal Control of Gas Works," by a gentleman connected with the Columbus Company. I had invited him to attend and help discuss this question, as I knew it was one in which he would naturally take an interest. He has given economic and social questions a good deal of thought. It is his bent, and his opinions are worthy of consideration. He was unable to attend, but had prepared a paper embodying his views. I read the paper on my way here. I thought it merited presentation in the same form in which the other papers have been presented, and on arriving here I immediately had enough copies printed to distribute one to each member. Furthermore I have a letter from Mr. Foote, of Washington, D. C., which reads:

"Dear Sir:—I expect to leave here Wednesday morning and to arrive in Toledo Thursday morning. Had expected to get off today, but find I cannot do it. I enclose you a copy of a paper I have prepared to be read before the Association. If by any mishap I should fail to be present, will you kindly ask Mr. Graeff, or someone else, to read it for me?
Yours respectfully,
ALLEN R. FOOTE."

The President—Gentlemen, I know nothing more of these papers than you know. You have heard the entire statement. It would appear to me that our interests might possibly be subserved by having the reading of these other papers and discuss this question afterwards. Mr. Wilkiemeyer is with us, and perhaps Mr. Foote may be. He will not be, however, in time for this discussion; yet a motion that should cover this ground would be a quite proper thing to entertain at this time, and I trust if anyone cares to hear from these other papers that he will make a motion that will recognize them.

Mr. Cantine—I move, Mr. President, that the discussion of this paper shall be postponed until those of the Columbus gentleman and Mr. Foote shall be read and then discuss the three, as they all bear upon the same subject. [Adopted.]

Mr. Cantine—Mr. President, during the distribution of these papers I would like to present to you the name of Mr. O. S. Webster as a member of this Association. He is a resident of Michigan, and he has been tried by fire as hot as that required to make gas. He and I suffered and bled for our country in the same regiment. He came down here and offered himself as a sacrifice, and I now introduce to you Mr. Webster.

The President—I have no doubt the Association will be glad to greet Mr. Webster. The blanks upon which his application should be made will be provided by the Secretary, and at the same time there are a number of others whom we desire to welcome to our ranks. I suppose we may defer that a little longer. I will now ask the Secretary to read Mr. Gemunder's paper.

The Secretary then read the following paper, by Mr. M. A. Gemunder, of Columbus, Ohio, which had for its title:

MUNICIPAL CONTROL OF GAS WORKS.

Leaving out of question the points raised by socialists who claim that the true function of government is to take charge of all lines of production, and looking rather at those put forward by individuals who acknowledge or allege that state agency is not equally effective in every department of industry, will at this time be more to the point, as the latter opinion is that which is held by the most numerous antagonists of private interests in the line of gas supply. Many of the most advanced thinkers have long ago given up the idea that the public can best be served by competing companies, and hence term the agencies which furnish such commodities as gas, water or electricity, natural monopolies.

It is further stated that as our commonwealth and national institutions are opposed to privileged classes, that is, guaranteeing some citizens benefits at the expense of others, and as it would be necessary to foster such, if competition were abolished, in order that the best service may ultimately be secured, it follows that expediency, as well as sound statesmanship, would demand that the people as a whole unite in controlling that which should minister equally to the welfare of all.

This seems plausible enough, but unfortunately the community as a whole, that is "all of us," never can operate either a gas, water or electric plant. The public can only work through special agents—that is, through "some of us"—and it is through the short coming of "some of us" that the expectations of "all of us" so frequently lack realization.

The main argument advanced by many advocates of municipal control, such as Professor Ely, of Johns Hopkins University, or

Mr. Keeler, in a recent article in the *Forum*, is an arrangement side by side of prices charged in various cities by public or private works for like services, and which are so selected and grouped as to show off private concerns to the poorest advantage. Now, any one connected with a gas company must know that such comparisons made in this manner are absolutely worthless. It can be readily seen that even greater differences in rates exist among the various individual plants worked exclusively by private capital, and as to public corporations, their own charges are not at all equal. There is no fixed or uniform difference in favor of any particular order of management which would appear thus at a glance. We all know that variation in price is very seldom due to any one particular factor. Admitted that Philadelphia (public) charges less than San Francisco (private), does that prove anything? If this difference would lead to the drawing of an inference, would it not be offset by the fact that Cincinnati and Columbus, both with private institutions, charge considerably less than Philadelphia?

The figure at which the public is supplied is the product of many factors, not only such as the cost of coal and the several crude materials used in distillation, but transportation, location of works, size of cities, number of consumers, width of streets, style of architecture of buildings, habits and general prosperity of people, and a host of minor conditions, many or all of which are peculiar to certain localities and very few common to all. It is not here contended, however, that no system of statistics may give rise to accurate conclusions, but only, that they must be very carefully sifted and examined and then accepted with due caution. Prima facie, as before stated, they are exceedingly treacherous. Discarding as insufficient the statistical method for want of proper data, and reasoning after the manner commonly called "on general principles," let us see if it leads to trustworthy results. Municipalities either do or they do not furnish increased blessings; if they do, then there must be a reason therefor; if they do not, failure must be due to some ascertainable cause. This is the problem:

A comparatively few years ago there was first demonstrated a law, that of the Conservation of Energy, which is of the utmost importance in physical science; it has done more to place that science on a firm basis than probably any other single discovery. This law, as you are probably all aware, asserts that: "The quantity of force which can be brought into action in the whole of nature is unchangeable and can be neither increased nor diminished."* With the full recognition and comprehension of this law, there was a sudden disappearance of all search after perpetual motion and such like phantoms, for it became evident that whatever extra energy appeared to come out of one end of a machine, it was only a question of how long or how well one looked before it would be discovered that it entered at some other end.

The critical spirit thus generated in the domain of physical science is at present also strongly permeating and affecting the manner of thought and examination in Social and Economic Science, also finding outlet in everyday life in the saying that "something out of nothing is not to be had."

All arguments for public ownership when analyzed yield simply the following: Municipalities would offer greater service for the same pay, or the same service for less pay than private organizations. That is, its labor is in some way more productive. More energy leaves the machine—where does that additional energy enter?—whence does it come?—We are certain that it must spring from some source, for Government can no more make something out of nothing than can the least important individual.

Suppose that the Government purchase a coal mine for the purpose of supplying itself with fuel. It will of course be acknowledged that after the purchase the coal will be just as deeply imbedded in the earth as before, the mere fact of the public having become the owner will not of itself raise it even in the slightest degree. Where then must the extra energy be looked for? Undoubtedly in the only remaining source, namely, the brains and muscles of those depleting the mine.

But, after all, as previously seen, these factors are furnished not by some unusually potent entity, but only by "some of us," very much like the "rest of us." Naturally, if these "some of us" are no better than the "rest of us," Government brings no new or unusual forces to bear, and it would be folly to state that its efforts entail superior results. This would surely be getting something out of nothing.

It may be replied, however, that there is a difference among the various individuals comprising "all of us," and if the best are chosen to perform a certain duty, their endeavors must yield the most satisfactory consequences.

This then brings us to a direct comparison between Government officials and private management. Here arise two questions:—

First.—Are the "some of us" chosen to perform certain functions really for the "best of us," for the purpose?

Second.—Are conditions such as to demand from them their utmost?

As to the first question, little attention need be paid. The reputation for ability and morals of the general run of Legislators, office holders and politicians is so well known as to require little comment. It is only in rare instances that they are selected, or, when selected, retained, because of any special fitness displayed. The Civil Service Reform movement of to-day will go far in bearing out this statement.

Mr. Donisthorpe, in a recent economic work, makes the following

*Helmholz.

pointed comment: "The art of Legislation is a very difficult and complicated study; much more so than farming or boot making for example, and yet, as has been remarked with amazement by thinkers of the weight of Socrates, Shakespeare and Spencer, whereas a lifetime is required for the mastery of the humblest handicrafts, almost any ignorant busybody is credited with intuitively understanding that most intricate art, legislation.

"Were I to walk into an engine room and point out to the engineer the intolerable waste of steam entailed by a hole in the boiler, and urge him to stop it, he might turn upon me with some such reply as this: 'Sir, that hole is called the safety-valve; if you would bring your mighty brain power to bear on some subject with which previous study has qualified you to deal without making an ass of yourself, you might be doing more good to the community and less harm to me. Good morning.' And yet this same engineer will walk into the great legislative laboratory where the complex parts of the machinery of state are forged, and with the serenest self-confidence take off his coat and set to work."

That this state of affairs is owing to the nature of things and is likely to remain thus for an indefinite time, is more than probable. The brightest and strongest characters and intellects will of necessity be monopolized in those productive channels which promise the greatest reward to industry, these of course existing largely outside the sphere of government.

An excellent illustration of this tendency was furnished some time ago, when President Cleveland was somewhat taken to task for what was considered unreasonable delay in filling some vacancies that had occurred in a very important commission; the President replied and justified himself by saying that although he knew of many men capable of filling these places, yet the salaries and incomes that their labors in other fields yielded them were so great that the remuneration offered by the Government, generous as it may seem, presented no temptation.

The first question may be dismissed without further discussion, as all are familiar with its bearings. The second is, however, of greater importance.

The testimony of all human experience is that man endeavors to satisfy his wants at the least possible expenditure of his energy, and consequently the greatest exertion is only concomitant with the greatest need of pressure.

Should A desire the performance of a piece of work and be unable to attend to it in person, he would be compelled to delegate B to carry out his plans. Under what restraints would B now consider himself for the performance of his duty? Evidently he would consider himself responsible only for ordinary reasonable care, and if he be honest, his sense of responsibility, together with the fixed amount of his reward, would prevent his taking any but ordinary chances, for fear of exceeding his authority, thus fixing upon himself a certain loss with no direct prospect of possible gain. His action must be conservative and not progressive, hence not in the highest degree productive.

Should, now, B sublet to C, then it must be plain that A's chances of receiving good service will also diminish. The only desire in B and C is not so much the fulfillment of A's plans, as it is to put in honest time, with the risk limitations already specified, at his expense. A, on the contrary, not only risks the loss of his expected benefits, but also the pay of B. The greatest anxiety for success is surely with A, and were conditions favorable so as to allow A to labor in his own behalf, it would not be hard to designate the source of the greatest energy.

The old maxim "if you wish a thing well done, you must do it yourself," has hardly arisen without a foundation in experience. Probably every one has had more or less occasion to appreciate its truth. Its application here is simply this:—

In all private corporations and business concerns, those who control and manage them are either those who directly own them or else stand in close relation to them. They are those who directly pay the penalty of a mistake, be it honest or otherwise, not only by being discredited in the eyes of one's neighbors, but capital earnings and very existence are at stake. It is here that employees are most carefully tested, and possible gains or losses most rigidly compared and weighed. Rewards and penalties being less remotely connected with conduct, cause and effect better apprehended, the greatest scope is given to productive energy and skill.

But how do matters stand in public hands? Here all action is of the delegated kind, and agents are held responsible for their trusts only in a more indirect way, and disaster for misconduct is far lighter and less certain in its effect.

Inducement to extraordinary action is lessened and it may be accepted as a certainty that the more we shift or separate those consequences which naturally follow any line of conduct from such conduct, the poorer will be the outcome.

All will probably remember the State's action in the Scott Law contest. Here legislators passed a law, taxing a certain class of business houses. This tax was in many instances promptly collected. The Supreme Court later declared this law unconstitutional and the collection of the tax unwarranted. Those who had paid the tax to the State expected naturally to be reimbursed, but here the courts again held that this could not be done without committing another wrong. Great loss to honest tax-payers was the result.

But how fared it with those whose ignorance directly caused this distress! Does any one even remember their names? Was the suffering in any way visited on them? Did they not draw their full pay and come up again for re-election the same as ever?

It may be said that they, as fellow-citizens, share public calamities; which would be true in the same way that a man loses by laying down a dime and taking up a dollar.

Would it not be more than probable that if the legislators who passed the act could have been given to understand that they would be held directly accountable for any wrong committed, their actions would have been much more painstaking and deliberate?

The *vicarious nature of all Government action* must always continue to be the cause of inferiority in all State and municipal management. It is and will ever remain the element of weakness that will prevent the raising of any superstructure with State or municipal management as a foundation. This doctrine I hold as of the utmost importance, and were it more generally appreciated, it would often save the community great loss.

Returning now to the mining example, if the coal fails, by reason of state ownership, to be raised nearer the surface, and as we see that the brains and muscles applied for that purpose are of a restricted and inferior kind, then it cannot be maintained that Government management can be the most productive. No extra energy can leave such a machine, for none has entered.

There is yet another argument that deserves consideration. It may be claimed by some, while acknowledging the greater economy in private supervision, that the chief object in municipal control is the prevention of excessive rates, which are the result of undue profits in monopolies; that the community could better stand a waste in production than a greater loss by extortionate charges.

Here again is an oversight. Every municipality, when franchises are granted, has the power to make such stipulations as regards rates, etc., as may be mutually agreeable. If it fails to possess the requisite wisdom and purpose to make this single agreement a good one, on what possible grounds can it be expected to make good the innumerable ones connected with the carrying on of even an ordinary enterprise with any better hope of success?

No city need be at the mercy of any corporation. It can easily secure for its franchise such a rate as will allow only fair returns on investments. Permit this rate to extend over a definite period of time, allowing the corporation the entire benefits resulting from any improvements introduced, this will prevent stagnation in efforts. At the expiration of the allotted time renew the contract at a new rate, which has as a basis the now-improved manner of production.

Private control has another great advantage, namely, it throws the entire cost of production on those who are the consumers and beneficiaries, and does not require any deficit to be made good by those who had no such advantages, which is the case where loss is repaired by general taxation.

Neither is the present generation of tax-payers saddled by any heavy debt, incurred in erecting works, in order that future generations may reap the benefit for nothing. That is to say, every one will pay his own gas bill.

The President—Gentlemen, the paper of Mr. Foote is not printed. A copy is in the hands of Mr. Graeff, and we will be pleased to have him now read it.

Mr. Graeff then read the paper of Mr. Foote.

MUNICIPAL CONTROL OF GAS AND ELECTRIC LIGHTING PLANTS.

That system of political economy is best which enables the poorest member of society to become richer. The breadwinner must have bread now. For this reason, economic systems, promising immediate benefit, quickly become popular with the masses. In political contests present advantages always strive for the mastery, with duty to principle. While an election is pending the wage-worker has many friends. Why? Because, by reason of numbers, his class holds the balance of power. There is always much talk about measures to make this or that thing cheaper, or, in general terms, to make living cheaper. The advocates of cheapness do not explain, and the wage-earner does not think far enough to see, that cheaper living means lower wages. With living and wages both made cheaper the economic condition of the wage-earner remains unchanged.

Civilization has entered upon an era of economic evolution. I say evolution, because progress in the development of an economic system, in accord with the requirements of natural economic law, cannot be induced, except by a condition of general and high degree of intelligence, an intelligence that will not permit the destructions of a revolution. Creeds of churches and codes of secular law have reached the limit of their power to benefit the people without taking into consideration the economic conditions under which they live. He teaches both religion and patriotism who teaches the principles of natural economic laws. The power given by nature to man to produce more than he consumes gives him the power to relieve himself from the law of necessity. It is his natural birthright to freedom. Benjamin Franklin's formula for making money plenty in the pockets of every man is based on natural economic law: "Earn money honestly, spend less than you earn, and save the difference." 'Tis simple, but not easy to do. The first requires strength; the second, courage; the third, intelligence. It is because of the lack of economic intelligence that there is any failure in justice in the distribution of the results of labor. For this reason, questions tending to create popular interest in economic science should be welcomed, not feared.

The new departure in the discussion of labor questions under-

taken by the Emperor of Germany; the recommendation of government ownership for all interstate railroads, by President Blackstone, of the Alton system; the effort to initiate government ownership of telegraphs, by Postmaster-General Wanamaker; the use of crop values as the basis for a national currency, advocated by President Livingstone, of the Farmers' Alliance; the monster petition to bear the signatures of 200,000 persons, asking the Massachusetts legislature to give cities and towns the right to establish their own gas and electric light works, to be presented by the nationalists; the use of land securities as the basis of a national currency, proposed by Senator Stanford of California, together with similar projects by others, make up the moraine of the oncoming economic evolution.

The advocates of municipal control of lighting give but one reason for their policy. It is that it will make the lighting service cheaper. The same argument will serve equally well, a movement for municipal ownership of gas plants; electrical plants; street car lines; ferries and telephone exchanges. More than this, it will suit just as well, a demand for the national ownership of railroads; telegraphs and the express business.

But why stop here? It will apply with still greater force to the national ownership of every productive or distributive industry. If a municipality can perform any service cheaper than it can be done by a private individual, a state can do it cheaper than the municipality, and the nation can do it cheaper than the state. If a single industry can be so handled, then every industry can. The logical sequence of municipal ownership is national ownership. The inevitable result of the control of one industry by government monopoly, will be a government monopoly of all industries. Those who do not wish to see the principal of municipal ownership carried to its logical conclusion, should not advocate it. Those who do not desire the national ownership of all industries, should present a united opposition to municipal ownership of any industry. No dam will ever burst if the first leak appearing, be effectually stopped. No great fire will ever occur, if the first blaze be instantly quenched. No great disaster will ever cause wide-spread destruction or suffering, if its initial cause be judiciously and promptly removed or overcome.

All theories must stand uncovered in the presence of facts. Economic theories are not relegated to the far off future for a demonstration of their correctness. The results of municipal ownership may be proven now. There are a sufficient number of undertakings of that character now in operation to render the demonstration complete. If the claims of those who advocate municipal ownership be true, they can prove them by accounts now being kept. I challenge any municipality in the United States owning a gas or an electric light plant, to submit the question of the policy of municipal ownership to the arbitration of provable facts. That this may be done, attention must first be given to the classification of items and the form of accounts of receipts and disbursements. The greatest difficulty in the way of a proper solution of this question, is the fact that there is no scientific classification of the items of accounts, made with a view of causing them to show all essential economic details, nor is there a close scrutiny to prove their accuracy. The people do not know whether the accounts are properly kept or not. They do not know whether or not, every item that enters into the cost of the plant, its operation and maintenance, is properly charged. Laxity in scrutinizing the methods in which the proceeds of the tax are expended, is a strong objection to indirect taxation. Wherever there is a lapse of vigilance, there is a lapse of virtue. Consider the lamentable failure of the vast majority of men to conform to the requirements of an exact science of economy and accounts, in the management of their private receipts and expenditures, then consider that such imperfectly developed economists are entrusted with the management of the accounts of municipal works, and a fair idea of the difficulties to be met with in this direction, may be formed.

Not one man in one hundred is able to give an exact account of every dollar of his private income and expenses at the end of a year. This is the reason why it is so difficult to carry into practical effect Benjamin Franklin's formula for making money plenty in every man's pocket. The accounts of partnerships are probably more carefully kept than any others. This is because those interested in them are few. They are vitally interested in the results of the business, and as a necessary consequence, give their accounts a most careful scrutiny. The accounts of stock companies are scrutinized much more closely than those of municipalities. The managers of such companies know that they have among their stockholders able critics, whose invested interests will lead them to give their accounts a most rigid examination. The history of the management of stock companies demonstrates the fact that, wherever there is a lapse of vigilance, there is a lapse of virtue. The human nature of managers of municipal works, is not different from, nor better than the human nature of men in the management of their private affairs. If men are not exact and honest with themselves in the management of their own finances how can they be made exact and honest in the management of municipal finances? The only safe-guard for the man and for the municipality, is the regular publication of accounts in approved forms, showing every dollar of income and expense, in items classified in accord with the requirements of a sound economy. The question of honesty is of minor importance in the demand for a scientific system of economic accounting. A system of accounting that will satisfy economic requirements, will satisfy all moral requirements. Morality has no existence apart from the principles of natural economic law.

Money may be spent honestly and not be spent economically. There can be no scientific demonstration of economic results, without a scientific record of economic operations. Upon such data only can economic policies be safely based. Those favoring municipal ownership can afford to wait until such data can be obtained, before committing their municipality to a measure of doubtful expediency, and one that may ultimately prove undesirable.

This demand for scientific investigation of, and basis for, economic action, is in the interest of the poorest member of society. It is in the interest of the whole people without distinction as to their economic condition. It is in the interest of the municipality, of the state, and of the nation. Every economist, every candidate for votes, that favors municipal control of lighting, and who is honest in the opinions he holds, cannot refuse to join those who oppose that policy, in demanding that all accounts be kept in accord with the requirements of a scientific classification of receipts and disbursements, to show all essential economic details. This demand is in the interest of good government and good morals.

I say to the people of all municipalities that have committed themselves to the principle of municipal ownership, you have entered upon an economic policy that will ultimate in industrial slavery. You sought escape from a limited monopoly, and have established an absolute monopoly. You are levying a tax on consumption, instead of possessions. This is the most inequitable form of taxation. Professor Richard T. Ely says, in "Problems of To-day," pages 6, 7, 10 and 11:

"Indirect taxes are chiefly taxes on commodities; in other words, taxes on what we eat and wear and consume in other ways. This is taxation on consumption; but does consumption of taxed commodities vary with income? Indirect taxation does not discriminate between the last dollar of the poor widow, and the dollar which is only one in an income of a million. Indirect taxes are imposed on people without creating so much discontent as direct taxes, and without causing so close a scrutiny of the method in which the proceeds of taxation are expended, because the mass of men do not realize that they pay taxes every time they purchase gas and electricity for lighting, when the municipality owns the plant."

Prof. Ely did not write "Gas or Electricity for Lighting," as given in this quotation. He wrote "Dry Goods or Groceries." I made the substitution, which does not change the principle or meaning of what he was saying, so as to make it more directly applicable to the policy of municipal ownership which, strange to say, he advocates. When the municipality owns the plant, the wage earner and the millionaire pay exactly the same rate for the gas they consume. The profit on that gas compels the wage earner to pay a tax a thousand times greater in proportion to his income, than the tax that is paid by the millionaire.

The policy of municipal ownership of lighting-plants can be successfully combated upon practical lines. Let the whole truth be known regarding the accounts of such plants, let the people become thoroughly educated as to the workings and tendency of such undertakings, and, speaking of one of them as representing the whole, the sale of the Philadelphia gas plant to private ownership and management, will become a political necessity.

Discussion.

The President—Gentlemen, that concludes the three papers upon this subject. I think it rarely falls to the lot of an Association to have more valuable subject matter presented than is contained in these three papers. I see only one possible misfortune in it, and that is that they are nearly in the same line. I trust a discussion will develop here that will bring out the full merits of what has been presented. The papers are at your disposal.

Mr. Cantine—Mr. President, I see only one trouble about the matter, and that is there is no one present who would take the affirmative. A great many people in this country have not anything and I would not like to have any person else have anything. They would like to divide up. They would like to be in the year 2000, and "look backward;" but, nevertheless, they would not keep their credit cards 30 days! Eleven months in the year they would starve. Now if any person thinks that municipal ownership of a gas plant is a good thing it would of course also be a good thing for the municipality to own everything else, and we would very soon come to the condition that Egypt is in, where the Khedive owns everything. He builds the railroads, runs the hotels and steamships, and everything else. Nobody owns anything. He has as many wives as he wants, whereas the poor man is satisfied with one poor little wench. Whenever the Khedive wants anything built, he builds it as Solomon built his temple. He pays no wages; there is not even a chance to get a little of the common stock of the concern, which is generally worth nothing! The individual detailed to work upon a railroad, canal, or hotel, or what not, has no prospect whatever. His poor wife brings him his scanty sustenance. She tills the ground and raises his living. If the people of the United States want to get into that condition they should start in and have the Government run everything, and thus remove all the opportunities of making a livelihood and reduce to a vassalage nine-tenths of the human family.

Mr. Wilkiemeyer—Mr. Cantine says this is a one-sided affair. Granted; yet it is an *affair* talked of, and also introduced in a number of places, and the agitation of this question will most likely give us many sleepless nights. Now then, let us seek the first cause of this affair. I will challenge you all to cite me a single case in the State of Ohio where the city controls a gas works or an

electric light plant in opposition to an already established plant, where the gas company was not prime mover by its unfair treatment, injudicious action, etc., all leading to those baneful and most distasteful words—"you *must*" being hurled at the people, and the people resenting in this manner.

The President—I hope the entire party won't take up the gauntlet at once!—(Laughter.)

The Secretary—Mr. Graeff must be familiar with this question; and I should think for the information of some of us, myself included, I would like to ask Mr. Graeff to give us, in brief, the arguments of those who favor municipal control; and, furthermore, if there has been some activity in this direction over the country—"if there's a cloud as big as a man's hand in the horizon, that may grow into something formidable"—I would like to know definitely what danger threatens us in this direction.

Mr. Graeff—Mr. President, I think I am very poorly equipped to answer that question. I think Mr. Wilkiemeyer has given a fair outline of the argument in this paper of his; but, as I see it, the argument is a very short one. It is simply the one against monopoly. A municipality can furnish gas cheaper than a private corporation can, for the reasons that Mr. Wilkiemeyer gives in his paper. Of course the municipality all the time has nobody to consult except the politicians who run it. I believe that is about the argument of the other side. But as regards this cloud the size of a man's hand, I am one of those who recollect that there was a time when that story first begins, when the cloud was not seen at all. Then, at the next observation, the cloud began to appear, and finally there came such a storm as startled those in that part of the country. I think this question of municipal control is growing at a rate at which I think Mr. Wilkiemeyer—and I think he has looked into it as much as any of us—does not appreciate. As he states, it is being agitated and pressed by those who have anything to sell to a municipality. I would like to see a full and fair discussion of this subject. I don't believe there is any question to-day that can be presented that is more important, not even the question of fuel gas; and with this question goes that other of legislative action in regard to gas companies. On that I trust we will hear something to-morrow. I would certainly like to see the discussion of this very full and free. I don't exactly agree with Mr. Wilkiemeyer on one point. He says the poor man pays for the gas burned by the rich man; that the man who lives in a cottage and burns oil when the municipality owns the plant, pays for the gas that the man who lives in the mansion burns. Well, now, my experience in Philadelphia is that the man who burns gas and pays his gas bills, pays for the street lighting of the man who burns oil. Philadelphia sells gas at \$1.50 and the city uses all the gas it chooses to consume for street lighting and other purposes. Therefore, instead of the man who burns oil paying for the lighting of the man who burns gas, in this case the man who burns gas is paying for the street lighting of the man who burns oil, which I think is fully as unsound as the ground on the other side which Mr. Wilkiemeyer takes.

Mr. Wilkiemeyer—Is not that an exceptional case?

Mr. Graeff—I hope it is.

Mr. Wilkiemeyer—If a private company had the plant in Philadelphia, what would it furnish gas at—\$1.50?

Mr. Graeff—I am not quite big enough a gas man to place myself on record, but I think no gas man who understands the condition of things in Philadelphia would say that we would not have gas at \$1.00 per thousand, if a private corporation owned that plant; but the city might then have to pay for its gas.

A Member—I don't think you understand Mr. Wilkiemeyer on that point. Where does Philadelphia get the capital to invest in that plant?

Mr. Graeff—The capital, of course, was raised, in the first place, by loans, which loans have been paid off from the profits on the plant.

A Member—How do they pay them off, with taxes gathered from the poor as well as the rich?

Mr. Graeff—They pay them from the profits resulting from the sale of gas. The works earn the money and pay off their own loans.

Mr. Cantine—Mr. President, not wishing to occupy much of the time, I happen to think of a case that is germane to this subject. I know a town about 20 miles from where I live that owns its own water works. In the town in which I live a New York corporation owns the water works. We pay, I think, \$6.00 a year for domestic purposes. In the other town I think they pay \$3.00. The people are very much better pleased, I think, in the town where the town owns the works. That is the non-taxpayers are. Those who use the water are much better pleased with the \$3.00 rate than those who pay \$6.00, but there is a *deficiency*, and the tax-payers are very much displeased for this \$3.00 rate. Now, there seems to be just about where the trouble all comes in. The tax-payer is very well satisfied with the gas works at their present prices. This I think has effected, probably, as much as anything else, the putting of the price down to where it is. Gas is sold in this country as cheap as it ought to be, considering the facilities for making it, etc. It is an open question whether the general public are better served under a municipal control than privately. I think not. In the former case all the ward heelers are employed as hangers-on, without caring to do any good for the corporation. It requires an immense amount of inspection in all these municipal plants at certain seasons of the year. It takes a great many men to inspect a few street lamps. Ten or 15 would be a good day's work for a man to go over, and see whether the lamps are properly cleaned. After

election is over, they don't get any more inspection for a while. Philadelphia used to require from \$800,000 to \$1,000,000 a year appropriated by the Council to meet deficiencies. Now I don't know at what particular time they commenced to pay this debt that Mr. Graeff speaks of, but that state of affairs was, I think, true eight or ten years ago.

Mr. Graeff—Mr. President, I think all the appropriations made by the city of Philadelphia for its gas works were made in the shape of loans, and I think the last of these loans has recently matured and been paid off, or there may be one still remaining. But as I understand it, all the money advanced was in the shape of loans to the Trustees of the work. I think that is correct.

Mr. Tayler—Mr. Chairman, Mr. Wilkiemeyer says he challenges any one to show any gas company in the State of Ohio that has not brought on its own troubles. I don't believe he is right. I am not speaking with reference to any particular plants, but on general principles. I think the facts are that the older companies, at least a great majority of them, did not provide against this in the way they ought to have done in earlier days; and, speaking generally, I think gas companies are to blame for the trouble they are *now* experiencing, but I don't think Mr. Wilkiemeyer's criticism applies to a new company that has started in, say, of later years, and has found the citizens already opposed to gas companies (simply because citizens are opposed to them all over the country) and found city councils ready to take all the advantages they can of them, simply because it has been done so before in other places, and in fact because it has become the general complaint all over the country. But I have no doubt that a great many gas companies are experiencing trouble of that kind who in fact are not to blame at all, and who have treated the community fairly.

Mr. Cantine—Mr. President, we don't need to own up that we have done anything wrong. I deny the soft impeachment that we have done wrong. We have not done anything of the sort. Simply because we, as corporations, have paid our debts, treated our men well, paid our taxes, never on the delinquent list, never any executions, never any companies went into liquidation, never made any assignments or re-organized under an order of any court and scaled our debts down and paid our debts off in stock that is worthless, but because we have simply walked up like gentlemen and paid our bills, and done what was right, we have incurred the enmity and hostility of that mean, contemptible spirit that this country is full of. That is all that is wrong. (Applause.)

Mr. Wilkiemeyer—Why do you pay your taxes?

Mr. Cantine—Because I am compelled to.

Mr. Wilkiemeyer—Why are the gas companies reducing their gas rates?

Mr. Cantine—Competition.

Mr. Wilkiemeyer—Competition! Because they have to?

Mr. Cantine—Yes, sir.

Mr. Wilkiemeyer—Now, then, suppose the gas companies, before the electric light people compelled them to come right down to business and go to work, and not sit in the office for customers to come around, but go around and bring them up, had done that before the electric light came in, how much of an advantage would the gas companies have over the electric light companies to-day?

Mr. Cantine—Not a bit. I sold gas, when I had an opportunity to, at 50 per cent. profit. I was not good enough to sell gas at cost and lower. I made hay while the sun shone. I made money out of it, and I don't deny it. I would do it over again. If I started in the gas business to-day, and could get \$3 or \$5 I would take it, and I wouldn't go around soliciting either, not a bit, unless I had to. Competition compels people to do lots of things they don't like to. I am here to tell you the truth. The chief reason that we sell gas for \$1.25 in our town to-day is simply because we have to; and we are on the upper side. We are not the under dog at all. We once sold gas for \$5, and we got that rate then just as easily as we get \$1.25 to-day. The thing amounts to just this, that we don't know so much about other business oftentimes as we do our own—that is a common thing, and we ought not—but I have been engaged in other lines of business, and I know, taking all the commercial businesses of the country, that there has been a gradual—well, I may almost say there had been a rapid scaling down of profits. Take the money that you have in your Portsmouth works, let somebody pay you cash for them, and you will lay awake at nights to consider what to do with your money. You can't put it in banking because you have to do a credit business. You don't dare to put it in merchandise, because they sell too many things at less than cost to realize a profit. Once we didn't have to do that. We sold women's blue calico dresses at 50 per cent. profit. You can buy the same at 20 or 25 per cent. less now, but the price wasn't lowered until it had to be. That is all wrong, you say. There is not very much in the way of business now that is right, and as we are a sort of bright and shining mark the public are shooting their little arrows and shafts and darts at us continually; but they don't puncture many of us, nevertheless. The only fear I have of the gas interests of this State is that they will swamp us with taxes. I think from the account of the meeting of the State assessors in Columbus, that they intend all of the property shall be appraised at its full value. You will find there will never be any diminution of the rate per cent. You had a very able paper on that once, Mr. Wilkiemeyer. Nearly all the cities and towns are taxed 2½ per cent.—26, 27, and even 30 mills on the dollar. You will get a worse black eye there than you have on the price of your gas. I move you, Mr. President, that the thanks of this Association be tendered to the authors of the three papers last read. [Adopted.]

SUNDRY MATTERS.

Mr. Printz—I would like to say that the committee on location of the next place of meeting would be pleased to receive applications from any member who would like to have the meeting in his city.

The President—You hear the request of the Chairman of the Committee. The next place of meeting is, of course, a matter of importance to us, and will have to be settled before we finally adjourn. I trust it can be settled to the satisfaction of the Association at large.

The Secretary—Mr. President, by resolution this morning the matter of the consideration of the question of providing for a legislative committee for the ensuing year was deferred until after these papers on municipal control had been read and discussed. I simply call your attention to the fact that this is the time for any action on that subject.

The President—A resolution would be in order that shall be expressive of the sentiment of the Association in this regard; and, for my own part, as it seems to me that an Association of this kind should have some such organization in connection with its movements, I will recommend that some step be taken in reference to this. If any one has a resolution to offer that shall meet the requirements, now is the time to present it.

Mr. Printz—Mr. President, I don't believe that there were many of us who fully understood the subject when it was up this morning, and I think the Committee have failed to make a full report, or didn't appear to know what they were wanted to act upon. As they have given the matter some study, I think it would be well to have the same members continued on that committee.

The President—The report of the committee is to the effect that, in their judgment, their powers and duties are not sufficiently or accurately enough defined; that is one thing. The whole thing indeed seems to be rather vague, and yet there seems to be a pretty thorough idea engrafted upon the mind of the Association at large that there is need of a committee of that kind. I believe that some questions have come up during the present year, when inquiry was made about the legislative committee. I was chairman of the committee, but I could see no possible opportunity for us to take any action in connection with that matter. A conference with the members of the committee also failed to elicit anything, so we were completely at a loss to understand just precisely how far our duties might extend. A report was made that certainly was vague and rather indefinite, but it was all that could be reported under the circumstances. Action was taken this morning that made this matter come up at this time, but if the body wishes further time to consider it, I think there is no impropriety in simply dropping the matter at the present time and bringing it up further on. If the Association so desires it, of course a resolution is in order.

Mr. Graeff—Mr. President, I suppose nearly every member of this Association knows that the electric light people are paying close attention to this matter. A year ago, at their National Convention at Chicago, they appointed a committee, giving the chairman of the committee power to choose his fellow members to give attention to this matter during the coming year. As a result about a dozen state associations have been formed among the electric lighting companies with the sole purpose in view, of guarding the electric lighting interests against adverse legislation. These associations are formed by the companies, not by individual members. They are banded together for mutual protection, as I say, against adverse legislation. The National chairman (Mr. A. R. Foote) of this electric light committee, will probably be here to-morrow, and I think if we would lay this matter over until then that he could probably tell us more particularly wherein lie the dangers that we will have to look after, and which we must guard against. He can probably give us suggestions which it will be wise for us to heed. I, therefore, move you that action on this matter be postponed until to-morrow morning. [Adopted.]

Mr. Cantine—While this matter is before the house I would like, Mr. President, to make the suggestion that very few who are connected with this Association (and possibly the same may be true of the electric light association) have legal minds, and it would be a very nice thing for us if our committee were empowered to employ, in any case of emergency, a first-class constitutional lawyer. Now in Mr. Gemuender's paper which our Secretary read, when the outsider called the engineer's attention to the fact that there was a hole in his boiler, he was very indignant that any person should interfere with his business, but he felt confident that he himself had sufficient ability to legislate. That class of people don't know much about legislation, but if we had a first-class attorney to take care of our interests, who was, like the Michigan peddler, "just middling honest," we would get along with this matter in that way better than with any committee. In case of any proposed legislation we don't know what effect the constitution would have upon it—whether it would be constitutional or not. If it would not be effective, a good constitutional lawyer would say the act would be not worth the paper it is written on, and he comes up and makes his argument, and that is generally the last of it. I think that is the best way to get rid of any obnoxious legislation—to show what its effect would be; to show that it would not be good for anything, and that would be the end of it.

Mr. Penn—I think Mr. Cantine is right. We organized an Electric Light Association in Columbus, and the Executive Committee was authorized to employ a lawyer to look after our interests. They have employed a lawyer temporarily, until our permanent

organization could take place in May. We took the same ground that Mr. Cantine has taken.

The President—Mr. Hedges not being here, we will now call upon our Secretary to read his paper.

The Secretary then read Mr. W. C. Hedges' paper, which was on the subject of

OHIO STREET LIGHTING STATISTICS.

Mr. President and Gentlemen of the Ohio Gas Light Association—What is popular opinion to-day may become unpopular opinion to-morrow. The subject of "Street Lighting Statistics," suggested to the writer, as regards the State of Ohio, by your Secretary, is one of the great questions of the day that interests gas men, not only of our own America, but of foreign countries likewise.

Circulars having been mailed, with a series of questions relating to city and commercial lighting, to eighty gas companies doing business in Ohio and Indiana, and general and aggregate statistics of the companies responding having been made up, the members of this Association will receive a copy of the same by applying to the Secretary.

We find thirty-five cities reported from Ohio, with a population ranging from six thousand and upward. The average net price to private consumers for illuminating gas in these cities is \$1.48 per thousand cubic feet.

Also, in thirty-one cities, ranging in population as stated, the average net price to private consumers for gas used by stoves and engines is \$1.33²/₃ per thousand cubic feet.

Of the forty-one gas companies responding to the circular, five fail to note the number of public street lamps in use. Eighteen companies report 4,436 public street lamps, making an average of 246¹/₂ lamps per company. Eighteen report no public street lamps in use. Twenty-two failed to report size of burners used in public street lighting. Nineteen give full report, showing, by average, that public street lamps burn five cubic feet per hour. Twenty-one companies fail to report as to the maintenance and care of lamps. Twelve reports said maintenance and care reported by the city. In eight of the cities this expense is borne by the gas companies.

It might be well to here call your attention to the fact that only two gas companies report that they are the owners of the lamps and posts connected with their works. One company is owner of lamps only. The cities where balance of companies are located are the absolute owners of lamps and posts. Twelve gas companies are owners of electric light works.

It is very interesting here to note the fact that most of our cities have their streets illuminated by the electric arc system, at an enormous expense, far exceeding the price of gas for street lighting.

As my design in preparing this brief recapitulation is simply to introduce the subject for discussion, I will now leave it to each one of you to deduce, from the gas and electric lighting charts accompanying this memorandum, the fact that the tread of the world is toward gas for light and fuel.

Discussion.

The Secretary—Mr. President, I would like to call the attention of the members, for the sake of having anything of this kind perfect in the future, to the fact that the value of these charts, upon which there has been considerable labor and expense, would be very much greater had the companies all freely responded to Mr. Hedges' circulars, and taken the trouble to fill out the blanks in detail. They are very imperfect. Some companies did not respond at all.

The President—Gentlemen, this matter is before you, together with the charts, and the suggestion of the Secretary, which I consider a pretty important point.

Mr. Printz—I think we certainly owe thanks to Mr. Hedges for the time and care he has taken. Certainly, the charts are very interesting, and yet I don't see how we can do very much in the way of discussion until we have had time to read them and examine them. At the same time I feel under very great obligation to Mr. Hedges for preparing them, and I move a vote of thanks to him. I did not wish to cut off discussion by making this motion. [Adopted.]

The Secretary—Mr. President, while we are on the subject of street lighting I will mention a matter of possible interest, simply—it could hardly be classed as discussion of this paper and these charts—that Columbus is lighted very lavishly and extravagantly with electric arc lights; that the lighting there costs about \$63,000 per annum, which is equivalent to over 60 cents per year for every man, woman and child in the city. The Gas Company, in conjunction with the Oil Lighting Company, there, have canvassed the matter very thoroughly, and have ascertained they can make a bid for lighting the city, leaving the electric lights on all the street car lines in the city and other central streets, at an expense of \$48,000 per annum, saving the city \$15,000 per year, and the city would be as satisfactorily lighted as at present. Notwithstanding that, I have very little hope of our getting such a contract made.

Mr. Printz—I would like to ask Mr. Butterworth if he has any objection to giving the Association the benefit of experiments he has made with Gordon lamps for lighting streets?

The Secretary—Well, that part of the results that will be interesting to you is simply that the lights were very much admired by the council committee on gas and lighting, and by citizens; and that is about as far as it has gone. The council committee on lighting claim that they cannot entertain a proposition from us for

lighting the streets, or cannot enter into any contract for the lighting of the streets, on account of the Burns law. That blocks all further discussion. The matter has come to a crisis there at present though, as some of you are probably aware. It might be interesting, if it would not take too much time, to detail the circumstances. A certain attorney had a bill against the city for services rendered. I do not know the terms of the bargain under which he performed these services, but the city declined to carry out the contract, or to pay him for the services rendered, because the Burns law rendered the contract nugatory. He said, "Gentlemen, if you refuse to pay this on account of the Burns law, I shall get an injunction on the electric light company's lighting the streets, which you are having done in violation of the Burns law." There was no money in the treasury when the contract was entered upon. He also enjoined the city from paying the Assistant City Solicitor for the same reason, and so the night before I left Columbus the streets were in absolute darkness. I don't know how they were last night. The matter will certainly have to be passed upon soon, one way or another, because the people won't go without light.

On motion, the meeting adjourned to 8 P.M.

FIRST DAY—EVENING SESSION.

The President—I will call your attention to the 13th question on this supplementary list: "*Is plate steel or cast iron the better construction for purifying boxes?*" That is a matter of considerable importance. At least I have recently had my own thought directed to it by others, as well as by natural impulse. We have here on the table an exhibition of the use of wrought iron in a stand-pipe, and the question as to its use in other constructions—purifying boxes, for instance—is one that ought to bring out information that should be valuable to us all. I presume no one would object to getting some information as to its value, not only for purifying boxes, but for stand-pipes and perhaps dip-pipes. I recall the fact that the new works at Cincinnati required a very general overhauling, so far as the dip-pipes were concerned, a very short time after they went into operation.

Mr. Hyde—Our new boxes, the boxes themselves, are made of cast-iron, the covering, of course, being of sheet-iron.

The Secretary—Did you consider the use of steel at all?

Mr. Hyde—No, sir; not in ours. We made our hydraulic main and the stand-pipes on one side of the house with wrought iron, and on the other side of the house the stand-pipes are cast iron. We tried to see which was better. We put up a thirty inch main in the condenser room of steel, but seeing that sample up there, and some other things that have occurred, I almost wish we hadn't done it. I don't know what the result is going to be, but I don't think I would be in favor of using it again.

The President—What are your dip-pipes?

Mr. Hyde—I don't recollect, but I think they are cast iron. The hydraulic is wrought iron or steel. Mr. Bredel put them up.

Chair—If I mistake not, Mr. Evans has some practical knowledge in the use of wrought iron mains, and possibly his knowledge may extend beyond that.

Mr. Evans—Mr. President, I have never seen any deterioration in our mains that would lead me to act any differently in putting in mains. In fact I don't think the wrought iron or steel would be affected. I see no reason why, if you get rid of the sulphur, it should be acted upon any quicker than cast iron; but I believe where heat and moisture exist with sulphur that the sulphur acts upon the iron to a greater or less extent. I don't know of any place where wrought iron or steel boxes are in use now except the covers.

The President—To my mind the New York Gas Light Company has a set of steel boxes. I would not assert it, for I am not positive about it, but as memory serves me they are steel boxes, lined with cement. I think Mr. Hyde was with me at the time. I don't know whether he remembers that or not.

Mr. Hyde—I don't recollect about it.

The President—I noticed it more particularly on account of that cement lining. I think they had been in use then some two or three years.

Mr. Webster—I believe we have used a set of wrought iron boxes five years. I don't see any giving out to them, or anything that would indicate anything of the kind. That is the extent of the time we have used them. I don't know how long they are going to last; but I don't see anything about them that indicates any wear.

The President—You say wrought iron—do you mean wrought iron or steel?

Mr. Webster—I think they are heavy boiler iron. That is my impression. They probably may be steel but am not positive. They are riveted together in pieces, the same as boiler iron.

The President—That is valuable testimony. An economic question comes in there that might be of a good deal of importance in a large works.

Mr. Cantine—Most works have plate iron or steel covers that seem to last pretty well, having just as hard usage and being subject to just the same deterioration that the sides and bottoms have. If the covers last, why should not the sides?

The President—In my own experience the covers would not last as long as good heavy cast iron.

Mr. Cantine—That is true, but we have all used them for twenty years without finding any holes in them. I know that is my ex-

perience. They are not over three-sixteenth of an inch thick, and had it been good three-eighths steel, the ordinary American citizen would not live long enough to have seen a set worn out.

Mr. Wilkiemeyer—I have no experience with steel, but with wrought iron I have some little. I took charge of a set of works one time, and when I came into the people's houses they had their doors open to get rid of the foul gas. When I examined into the matter I found that it was caused by the purifiers all being rusty, and I had to build cement walls around the inlets and outlets so as to purify the gas for a certain length of time until I could put in the wrought iron boxes, which I had to buy at once. When I took out the sheet iron boxes I could tear them in pieces like a rag.

Mr. Clark—We have a purifying box, twelve feet square, that has been in constant use since 1878, and I don't think we have ever paid out a dollar of expense on repairs. We have simply kept it coated well with paint. I was examining it the other day, and I saw no trouble with it except one or two rivets. We had it coated over with paint and I think to-day it is good for many years more. I think the top is three-sixteenths. It was a second-hand box, purchased in Philadelphia. In fact, our works were mostly second-hand works purchased in Philadelphia.

The President—You are speaking particularly of the lid being wrought iron?

Mr. Clark—The lid.

The President—You don't mean the body of the box?

Mr. Clark—Yes, the lid and the sides. That is the outside. The water-seal is wrought iron. The inside is cast iron, bolted together in sections, but the outside I think is wrought iron.

The President—I will read the 14th question: "*What treatment or care secures the longest life of a purifying box lid?*"

The Secretary—At Columbus we aim to keep the sides of the lids that dip into the water painted frequently. The part of the lid, of course, that rusts first, is right at the water line. We aim to keep a little "oil on the troubled waters" all the time, to prevent rusting.

Mr. Hyde—Crude petroleum put on to the sides where it dips into the water, or near the water line that Mr. Butterworth speaks of, is a thorough preventative of rust, inside and outside. Apply it occasionally, so that it keeps oily, and it cannot rust. Crude petroleum is the best thing that can be used.

The President—We have practiced, for a number of years and with a great deal of satisfaction, this method. We have taken some little pains to make these surfaces pretty clean, however, and then painted them over, as Mr. Hyde says, with crude petroleum, with a very decided advantage. Perhaps some of these questions may seem, at a glance, unimportant, because they are presented merely as questions. But any one of them would form a good subject for a paper.

Mr. Faben—Instead of painting the oil on, if the oil is merely put into the seal, the cover, in coming up, comes out of the oil last, and in going down enters the oil first, and maintains a constant coat inside and outside.

The Secretary—We put the oil on the surface of the water.

Mr. Geo. A. Light, of Dayton, then read his paper entitled—

ADVANTAGES OF A COMBINED COAL AND WATER GAS PLANT.

Mr. President and Gentlemen of the Ohio Gas Light Association—The subject I am to write upon is one that has received considerable attention, and I do not think I can furnish more information than has already been given in the Gas Light Journals, but I will try.

The gas company that manufactures a gas of fourteen to sixteen candle-power, can no longer satisfy the consumer. He wants something better for less money, and if the gas company can not furnish this he will try something else, and that something else is usually electric light. So the question is, "What is the best and cheapest plan of increasing the candle power of gas?"

There are several ways, but the water gas process is acknowledged to be the most satisfactory method of making a high candle power gas.

By using Lima crude oil in a water gas plant, gas can be made of a high candle power, say thirty candles, at less cost per thousand feet than by any other method. A coal gas plant can be run more satisfactorily, and the gas made at considerable less expense, where a water gas plant is being run in connection with it. No idle benches on Sunday or Monday, no extra benches under slow fire, ready for sudden increase in consumption. The variation in the output is supplied and controlled by the water gas plant. For instance, we will suppose the average daily consumption is 500,000 feet. The coal gas plant has four benches of sixes and four benches of fives, making 300,000 feet of sixteen candle-power gas per day. The water gas plant consists of two sets of Granger generators and superheaters, capacity 400,000 feet of thirty candle power gas per day. The 200,000 feet of water gas that is required to make up the daily output of twenty-two candle power gas, can be made in the daytime by running both sets (this I consider the best plan), reversing the night watch for extra work. If the output should suddenly increase on account of several successive dark days, the required amount of gas can be made and kept on hand by running an hour or two extra at night; or, if the increase be a gradual one, the extra gas required can be made at night until your increase in consumption justifies starting another bench.

When the output of a water gas plant making 30-candle gas is more than two-fifths of the total amount of gas made by the com-

bined plants, the candle power can be regulated by the amount of oil used per 1,000 cubic feet of gas.

In a city or town where natural gas is in general use it is a difficult matter for a coal gas company to dispose of coke at the price obtained for it before the introduction of natural gas.

The water gas plant is then a good customer for the coal plant. It decreases the amount of coke made and helps to keep up the price of that you have for sale by using a considerable amount of it. It requires 45 pounds of coke per 1,000 cubic feet of gas made (coke made from Youghiogeny coal).

An engineer or superintendent of a coal gas company, who has a water gas plant in running order, does not lie awake at night, planning how he will overcome the trouble his stokers are causing in the retort house, or will cause him by striking at the time he is least prepared for it. The water gas plant is the best "peace-maker" that I know of. The stokers know, or if they don't know, very soon find out that, in an emergency, two men in the water gas plant can make as much gas as twelve men in the coal gas plant, and that it requires but one skilled man for each watch, and they are generally old and tried employees.

Discussion.

Mr. Light—Now gentlemen, the reason I did not make this paper any longer is because the last issue of the AMERICAN GAS LIGHT JOURNAL contains two articles which I think thoroughly cover all the ground.

The President—You have heard a brief presentation of facts from the experience of one in daily practice. I trust the points thrown out may be the nucleus of a discussion that will be valuable to us in this connection.

Mr. Penn—I would like to ask Mr. Light if he would think it advisable for a small town like Washington Court House to put in water gas plant?

Mr. Light—Yes, abandon your coal gas plant. That is what we have done at Piqua.

The Secretary—Which costs the more in the holder, coal gas or water gas?

Mr. Light—Water gas.

Mr. Booth—What sized generator do you use?

Mr. Light—We have two. I think they are called six foot generators. I don't remember the exact size—I was trying to think of it this afternoon. It is a seven-foot shell.

Mr. Booth—What amount of gas do you produce to each run?

Mr. Light—Between 3500 and 4000.

Mr. Booth—Do you fire up every 15 minutes?

Mr. Light—No, we run ten minute runs—blow ten minutes and make gas ten minutes.

Mr. Booth—Can you get up heat in ten minutes?

Mr. Light—Yes, sir, with coke made from Youghiogeny coal. You cannot very well with hard coke.

Mr. Booth—That is your gas house coke?

Mr. Light—That is coke that comes out of our retorts.

Mr. Booth—At Bellair we have the Crichlow process.

Mr. Light—We have the McKay-Crichlow at Piqua, and we have a Granger at Dayton.

Mr. Booth—Ours was put up for a natural gas plant. In running natural gas there we would run thirty minutes.

Mr. Light—We don't use any natural gas at Dayton, but when I left we were preparing for it.

Mr. Booth—It would require about thirty minutes to get up a heat. Once in a while the natural gas would fail us, and we would get short. We would then make water gas and run about ten to fifteen minutes, but it took us longer than the time you specify to get up heat, and our experience was that it cost as much or more to make water gas as it does coal gas.

Mr. Light—With our Piqua plant we can make gas a great deal cheaper. We have one difficulty there, we can't sell coke at a reasonable price. We have between six and seven thousand bushels of coke there that they are using up in that way.

Mr. Booth—There may be a misunderstanding as to what I mean in regard to its costing more than coal gas. When we deducted the receipts from coke and tar from the cost of the gas the coal gas was cheaper than the water gas.

Mr. Light—Are you comparing candle power?

Mr. Booth—Well, you might have a little higher candle power.

Mr. Light—I think if you bring your coal gas up to 22-candle power, you will have to use cannel coal as an enricher.

Mr. Booth—We always made our ordinary coal gas of 16 or 17 candle power, except when we ran the Crichlow process, when we got a higher candle power.

Mr. Light—At Dayton we had to come to it or let the electric light get ahead of us.

Mr. Booth—At the present price of coke and tar I think coal gas, unless the coal costs too much, can be made at least as cheap as water gas.

Mr. Light—Have you natural gas in your town?

Mr. Booth—No, not much.

Mr. Light—You say you have a market for your coke?

Mr. Booth—Since natural gas has failed we sell our coke to the glass houses and cannot produce enough of it. We sell it cheap compared with what they do in some places. We only get four cents at the works. Of course the glass house hauls it away.

Mr. Light—We get ten and twelve cents in Dayton now for what we do not use up. Of course we could not get that unless we were using a good deal of it up in the water gas plant.

Mr. Rood—The gentleman spoke of using natural gas in the manufacture of illuminating gas. What proportion of natural gas can you use to advantage in making illuminating gas?

Mr. Booth—That is a question that I don't believe I can answer.

Mr. Rood—What effect upon your gas does an excessive use of natural gas have?

Mr. Booth—It will weaken the candle power, of course. If you use too much natural gas your candle power will be that much decreased. We aim to use, I believe, about 3 to 4 gallons of oil to the thousand feet produced, but when natural gas went through it was not measured. We opened the pipe.

Mr. Rood—Is it possible to enrich the natural gas passing through your generators so that it will make illuminating gas as acceptable as water gas?

Mr. Booth—Well, I never could discover any difference in the quality of the gas when you use the natural gas, from what it is when making straight water gas. Very frequently the natural gas would fail, so that we had to make half runs with water gas. Some days, altogether water gas.

Mr. Rood—Is it much cheaper to use natural gas in manufacturing your gas, than to make pure water gas?

Mr. Booth—There is not much difference. Of course we paid a pretty heavy dividend to the natural gas companies in order to get the natural gas.

Mr. Rood—What did you pay per thousand feet?

Mr. Booth—We paid twelve per cent. of our gross receipts. We did that to keep them out of the field.

Mr. Rood—Then you would not consider the use of natural gas a great advantage in making gas?

Mr. Booth—It was not in our experience. It cost more than coal gas, as I said, after deducting the price we got for the residuals.

Mr. Rood—But you made a gas of higher illuminating power?

Mr. Booth—Yes. We haven't run, however, for nearly two years, because we didn't get enough natural gas. We had to have pressure enough to force it into the holder. Whenever it got below that it would goback into the pipes, and we didn't think it good policy to make gas to go back into the natural gas mains, so we stopped.

The President—I see Mr. Faux is here, who, I think, can give us some experience in this direction that would interest us.

Mr. Faux—Mr. President, I came here to be a listener—a looker-on. I did not expect to have a chance to give my experience in this matter, but as it has been brought out I feel like saying something. In the matter of enriching natural gas, my experience is quite extensive. We spent a great deal of money, and tried to make it a success. I found that by using a small portion of natural gas there was no trouble in getting candle power, but if you used over a certain amount of it your gas would be smoky and red; and you couldn't hide it, no matter how much steam you put in it. For outside purposes, such as street lighting, it was very poor. Just as soon as the least draft of air would strike it, it would go off in a blue blaze. Of course people soon found out what did that. We tried that about a year. We used 5, 10, and sometimes 15 per cent. to see whether we could get anything out of it. We got the natural gas part of one year for 1.9 cents per thousand feet, through the station meter; that is, we paid the natural gas company 1.9 cents per thousand for every thousand feet of gas that we made that went through the station meter. The second year we paid six cents per thousand feet for natural gas. But we abandoned it entirely, from the fact that we could not make a success of it. As far as candle power was concerned, it was all right. I find other parties are using it, but I speak from my own experience only. The gas was not satisfactory to ourselves. This matter of water-gas comes up here, and I am glad it has been brought up. I am in the same position. Three years ago I took charge of the works on the Southside. They were using what I call a number one coal—that is, the best lump. They were paying \$1.54, I think, per ton, delivered. I looked over the matter—I was sent from the eastern part of the State—and my figures were set—that I must put gas in the holder at a certain price. I looked over this matter and found I couldn't do it with coal at \$1.54, and coke at three cents a bushel after it was crushed and screened. I thought I would try another coal. I think that cost me about \$1.25. My results were not satisfactory. The gas still was costing too much in the holder. I then came to the conclusion that, as I had this water gas plant, I would try something different. I tried 2,000 bushels of slack, just this common slack that they screen from the mines, and I found that I could get a pretty good yield out of it and by using a small quantity more of oil I could get the desired candle power. So instead of using \$1.54 coal I am to-day using 50 cent coal—costing me fifty cents delivered at the works—and with about $\frac{1}{2}$ or $\frac{3}{4}$ of a gallon of Lima crude, which costs me now 65 cents a barrel, I have my desired candle power, which runs from 22 to 24. All this is done with the aid of a water gas plant. If I hadn't this water gas plant I could not nearly get that candle power. So I think, in works of ordinary size, where they can combine the two, the water gas plant is the thing.

The President—What yield do you get from that slack as compared with your inch and a-half screened coal?

Mr. Faux—Well, I regulate that a little bit to suit myself. I can get all the way from 3.50 to 4.44 feet. If I am a little short of gas, I set the exhauster up pretty heavy. If I don't need the gas, I go the other way on the exhauster, about three-quarters of an inch. If my gas is poor from that slack, I just push in a little bit more oil at the other end.

Mr. Rood—The gentleman said he used different proportions of natural gas. What proportion of natural gas did you find you got the best results from?

Mr. Faux—When I used about five to eight or ten per cent., not over that, I could get fair results; but it didn't matter what the candle power was, as soon as a gust of wind struck it, it told on it, from the fact that there was no weight in it. It would blow off in a blue streak. For inside lighting, where there was no wind, it was very nice, but outside in the street it was not good. Our street lamps there are very peculiar. They have no bottom in them, as I say. It is so that the lighters can do the lighting with a stick. A draft of air would blow the lights out, and we had more "outs" when we were using natural gas than we have had since.

Mr. Rood—Did you find that five to eight per cent. of natural gas is an advantage?

Mr. Faux—Well, I don't know. It would depend considerably upon the price you could buy your natural gas for. If you could buy it cheaper than you could make coal gas, it would be an advantage. Otherwise, I don't think it would be.

Mr. Rood—Would it be of advantage to pay twelve cents a thousand feet, and use it in that plant?

Mr. Faux—That would depend upon the cost of coal in your locality.

Mr. Rood—Suppose you were not making coal gas at all, but were making water gas.

Mr. Faux—Then it would be an advantage, because your natural gas will run—well, our Pittsburgh natural gas is about eight candles. That is about the general run of it. We have that eight candle gas already made for that twelve cents and I don't think you can make water gas of eight candle power for twelve cents.

The Secretary—Mr. President, at Richmond, Indiana, Mr. Starr tells me that 25 per cent., by volume, of the gas in his holder is natural gas, and 75 per cent. water gas. He uses three gallons of oil to the thousand feet, enriching it, and he and his consumers are very well satisfied.

Mr. Rood—What candle power is his illuminating gas?

The Secretary—I forget; but it is high.

Mr. Rood—What advantages did you find in using an excessive amount of natural gas other than those you have mentioned?

Mr. Faux—I don't find any other advantages.

Mr. Rood—Are any hydrocarbons carried off through the mains that trouble you?

Mr. Faux—No, sir, we had no such trouble. I believe, if anything, it was a benefit rather than a detriment, because the hydrogen in the natural gas absorbed the carbon that laid in the mains in the shape of oil and tar. Answering Mr. Rood's previous inquiry, I remember that while using natural gas a tremendous number of our meters gave out, which I believe was caused in a great measure by the dryness of the natural gas, which seems to be of such a composition that it has an affinity for the oils in the diaphragm of the meter. Since we have abandoned the use of natural gas our trouble in this respect has not been one-third what it was during the time of its use. Our city is divided into three sections, and it would take two men two days to get the bad meters in, but I think last month not over two imperfect ones were reported.

Mr. Rood—My experience is similar to that of Mr. Faux with reference to meters. We are using some natural gas, and although I am not well enough acquainted with its use to say what the benefits or the troubles arising from it are. I may say we are having trouble from our meters.

Mr. Faux—I saw some of these questions before I came here, and hoped that Mr. Young or Mr. McElroy would be here.

Mr. Booth—We have had an experience similar to that mentioned in respect to meters.

Mr. Smith—What was the comparative price between water gas and coal gas?

Mr. Faux—I could not say that because the Southside has used water gas more or less all the time.

Mr. Faben—I don't think the effect on the meter, as between the coal gas or water gas, would be very different, if both of the gases were equally well made. One advantage in the mixture of coal gas with water gas I have not heard stated. The flame temperature of water gas is very high and the total heat of combustion comparatively low. A very small, energetic combustion and a small flame. If the ordinary run of burners are used in consuming it, a large burner would be apt to throw off smoke. A large burner would throw off free carbon (although the flame would continue bright, and would not indicate it), and free carbon would be deposited about the room. Now, if we can add to that gas a quantity of light carbureted hydrogen, that has a low flame temperature and a large total heat of combustion, requiring the large amount of air that it does for its combustion, by increasing the size of the flame—increasing the flame area without changing its illuminating quality—in that manner we will remove the smoke difficulty. The only objection to using a large quantity of natural gas would be to give the gas too large a percentage of light carbureted hydrogen, and, requiring that large amount of air for its combustion, the flame itself would be very apt to leave the burner tip with a little air disturbance—to spread itself, without the necessary amount of oxygen in the atmosphere to bring on combustion.

Mr. Cantue—It used to be said in the revival meetings of our country that "Honest confession was good for the soul." About this time last year a little competition stared me in the face, and I

struck out to get reinforcements. I contracted for a water gas plant, but the plant was a little too small to work nicely. It was a four foot cupola. It worked during the summer very nicely, but the manner in which it was connected with the old coal works made it impossible to work the two together. Having only one holder, it was a little difficult to do. When we are working one, the other would have to shut down. We met the enemy, and I don't know whether they are ours or we are theirs; but we have captured a good many of their pickets. We made a good gas—higher than the Jones photometer would indicate, but we had something that was not just as sweet a thing as water gas ought to be. It was the foulest institution the undersigned ever had anything to do with. We found it required from eight to ten hours to clean the thing. The rest of the time we made gas. We were always in that muss, and we are yet. It was no trouble at all for anybody on the street to find out what kind of business I was in; they didn't need to ask any questions. It was impossible to live in the same house with me. The odor was simply frightful. Now, we propose to get out of that scrape by making coal gas, and when the thing gets down to about the point the public will complain, we will start this thing up. I think I aged about ten years in six months. I used to grow old—to get a little old—when the holder was going down, and it was a question if it wouldn't strike ground; but this thing has hurried the matter up a little. I would like to ask Mr. Light whether we will be compelled to stay out nights with picks and shovels and bonfires to get rid of the naphthaline that will be made?

Mr. Light—That question, I think, hits the nail on the head. We don't use picks and shovels, but we keep portable boilers out. I think that is the best method to get rid of it. Every Fall-November is our worst month; for three or four nights we have to have a portable boiler out steaming out our pipes. It would seem impossible that 10 or 12 or 16 inch mains will be clogged up in that way; but they will. Nine times out of ten you will find the naphthaline just beyond the drip. Then we run in a barrel of naphtha, turn on as much steam as we can get in, say 50, 60 or 80 pounds, and leave it on 15 or 20 minutes. Going to the furthest lamp post away, where the grade is down to the drip, we put in another half barrel of naphtha and pump it out at the drip, and it will take up all the naphthaline with it that the steam has dissolved. We have done this for two years. I don't know whether we will have it next year or not. I have tried everything that I can think of to stop it. We have it now in the works. I saw it the day before I left. When we first put in our water gas plant I thought: "This settles the naphthaline question." That was the hobby at first; no naphthaline where there was a water gas plant. We ran four or five months and choked up the inlets and outlets of the holder. We had it in the works the most part of that season, but that season it did not show in the street. Next season it left the works (we have not had it in the works since to any great extent), but it appears now on the street every year. Why it changed is something I can't say. It seems almost impossible to control it. As to using picks and shovels, we used to dig down and cut our mains, but found the portable boiler to answer the purpose better. Of course it must be done at night. We can't do it in day time on account of teams and things of that kind. By the way, we have one particular place—talk about going to bed and going to sleep! We have a great many hydraulics. At one particular place where we cross the hydraulic, I suppose, it runs eighty feet under the water. I remember the first time we had it, last Fall, it stopped the main solid. We cleaned it out, and the following night it was stopped up again. The way we cut it out was by putting in between five and six barrels of naphtha. We had a good deal of naphtha on hand, and simply filled that pipe under the hydraulic and pumped it out again. I think that stopped four or five times. Sometimes not two days would intervene before it would stop up. It kept stopping up that way, until we finally cut it off and ran it across the top of the bridge, when we didn't have any trouble afterwards. But that shows the way it deposits. Inside of 24 or 36 hours it will stop up a 6 inch pipe. If anybody knows any way to get rid of it, I would like to know it.

Mr. Faux—Up to this Winter I was in the same condition as Mr. Light. Until last July I used benzine of 65° gravity, and sometimes I would have two men out all the time cleaning out lamp-posts and consumers' services. One day it would be in one part of the town and the next day in another part. About the time people would want to light up in the evening the telephone would begin to ring. I didn't know what in the world to do. It was naphthaline all the time, station meter, inlet and outlet of holder, etc. I remember one time there was a stoppage in the inlet of the holder, when we had to put a big piece of iron on the end of a rope, and let it down to break that stuff. Last July I began to use crude oil. I put in a scrubber, which consisted of a boiler 25 feet long and 44 inches diameter. There is about twenty feet of solid filling in that boiler, and the wood is cut two inches wide. It is an inch on the bottom, and runs to a point on top, making it the shape of a V. I began filling within two feet of the bottom, turning each row at a slight angle with the one below it. After I got my boiler filled some of the gas men thought I would never get any gas through that, but I was going to try it. I put on what I call a scrubber pump, that would throw a 1½ inch stream of water, hitched an engine to it, placed a barrel at the outlet and fed it with a small stream of fresh water about as thick as your finger, then pumped that liquor from this barrel into the top of the scrubber. Last Winter in condensing I would not allow my gas to get below 65°

if I could help it, no matter how cold the weather was. This Winter I let it go down as low as the temperature of the water would make it. I can't recall an instance where I have had a service stopped up by naphthaline this season. I have not seen a speck of naphthaline around the whole works, except in the bottom of the purifier when the material is taken out and thrown in the air. I noticed one morning that the temperature of the gas was down to 34°. It was condensed that low before it went into the holder. I can't say whether the pumping, and the condensing of that gas to that low temperature, have relieved me of naphthaline or not; but I have no signs of it anywhere.

Mr. Light—I don't think the remedy is in your scrubber; for we have the same identical thing. We pump the water over and over, and we have been doing that for the past two or three years. We aim to run at 60° temperature. Whether your relief is on account of the low temperature that you carry or not is a problem.

Mr. Faux—I am going to try to keep it at 45°, or as close as I can to that, to see whether that trouble will occur again. I want to find out what has been the cause of it. This is the first Winter that I have been free from naphthaline.

The President—I would like to inquire of Mr. Faux whether the extreme cold whether showed more or less naphthaline than warm weather?

Mr. Faux—Previous to this Winter?

The President—Yes, sir.

Mr. Faux—Well, I think during cold weather the changes of temperature would close me up. But this Winter I have experienced no trouble with these sudden changes.

Mr. Clark—I have had a little experience in the water gas business. About five years ago I took charge of the Elyria Gas Company, and my hair then was quite dark. In two years I felt a good deal as Mr. Cantine did. I threatened to resign and leave the Company. I would say to our President that I was disgusted and discouraged with the gas business, and wanted no more of it; but he encouraged me to hang on, and, as Mr. Light and Mr. Faux say, my pipes filled up, and how to free them I did not know—without taking a shovel or pick, or something of that kind. I labored day and night, and derived no especial benefit. Many visitors gave me advice, and I tried the remedies suggested, but without obtaining any lasting benefit. Finally a party came along who said he *could* make water gas. I replied, "You are the man I want; if you can get me out of this trouble I would like it." He took hold and ran his heats and everything entirely different from the party I had had, and the result was that my tar and lampblack ceased. We ran our heats about thirty minutes. We got a good cherry red on our generator, and a good straw color on our super-heater, and made 5000 feet to a run, and had less lampblack and tar. It began to let up at that time. I changed men again, and the last man thought he could improve on it somewhat, so he introduced hot water and steam when we had any trouble. The result was, if we had any trouble or stoppage we applied the steam and followed with hot water, and now to-day we have but very little trouble. In fact, we look at it as such a small matter that it is no bother at all. I lose no sleep, and we are working nicely. But I would say we have never used Lima oil. We have always used 63 naphtha, and experienced the same trouble earlier with the naphtha that they do now with the Lima oil. Now I am making a 22 candle power gas with 4½ gallons of naphtha and 50 pounds of anthracite coal. I find I cannot get as high candle power with coke as I can with anthracite coal. We used the Rochester coke—what they call 72 hour coke—and when we make gas from it I find we cannot get our candle power as high as we can with anthracite coal. Our generators and super-heaters being so small that we get too heavy heats—that is we have to get too heavy heats—which practice is very destructive to our works. I really begin to like to run gas works; before I was sick of them.

Mr. Hyde—Mr. Clark, what has remedied the difficulty?

Mr. Clark—Well, I used to lay a good deal of it to Mr. Benham, the Standard Oil Company man. I thought they were not preparing their naphtha right. I thought they had changed it. But he laid it to our man not understanding properly.

Mr. Hyde—Are not the high heats responsible for naphthaline?

Mr. Clark—High heats make the lampblack.

Mr. Hyde—And the naphthaline also?

Mr. Clark—Yes, sir. I think there is also something in the process by which they prepare their naphtha. I know we have no trouble now. They claim they are making their naphtha the same, and we have no trouble with it at all.

Mr. Light—I do not know of any gas apparatus that will cause more trouble than a water gas plant, unless it is run on correct principles. It is the easiest thing imaginable to choke it up suddenly. The least change will make lampblack on one side, and if the heats are too low you will make more tar than you should. My experience is that you cannot use too much water in your seal. I find that a way to get rid of that hard, pitchy, tar in the seal is by drawing the seal off completely. As soon as we put on a run we open the four-inch cock at the bottom and draw everything out. It cleans the seal out completely, so that there is nothing in there to thicken up. By running with careful heats there is no occasion at all for lampblack, and the lampblack is what causes the difficulty in a water gas plant.

Mr. Printz—I would like to ask Mr. Light if he had this same trouble with the naphthaline when he was using naphtha instead of Lima oil?

Mr. Light—We had the same trouble. We have been running

the plant two years. We commenced using crude oil there the latter part of March or April last year. We never run strictly on naphtha, except when we could not get the crude oil. We generally run two-thirds crude oil and one-third naphtha, but we have had the same experience both years. There were very few occasions when we had to run on naphtha alone, except when we were delayed in getting crude oil. The reason we abandoned naphtha altogether was because the Lima naphtha contains too much sulphur. We had to put the whole force at the works into the purifying house; and so we abandoned it altogether.

A Member—Did you have any trouble with your superheater getting clogged up with lampblack?

Mr. Light—No, the super-heater will not clog. The deposit of carbon that is formed on the brick on the inside is burned out by letting the plant stand idle at night, with a small draft on the generator. We leave a draft in the bottom of our generator and it heats up the super-heater during the night. In the morning when we fire up it throws out a perfect cloud of white, greasy substance. We have been running twelve hours a day since last June with one set, and we have never taken a brick out and never been inside of it.

Mr. Cantine—I was going to tell you of a little trouble I had about the stoppage of our inlet pipe. I tried steam and naphtha and benzine and gasoline, and all the other materials that come from distillation of coal oil. The quantity of gas in the holder was very small. Night came on and yet we couldn't get a foot of gas through. Steam had no effect on it. I didn't know what to do. I was about in such a dilemma as the man, alone in his house, who had the quinsy, and who looked through the cupboards for some kind of medicine, and couldn't find anything until at last he found some kerosene oil. He took a dose of that and it cured him. I dosed it with oil and then took cold water and put it in, and I have never since had any trouble with naphthaline. I never got anything but a tarry naphthaline. It looks like jelly. I don't know how it came nor how it gets into the inlet.

A Member—I don't think we have had any confessions from Mr. Faben yet on this subject.

Mr. Faben—I have not any to make. A double water gas set of our own selection was put in our place and was operated by the employees of the Company that placed it there. They had some trouble. When the apparatus was handed over to us we took new men who knew nothing about the gas business or water gas apparatus. They had everything to learn and nothing to forget. They did just what they were told to do—very closely observed the operation of the apparatus when under the charge of the gentlemen who put it there. I noticed the trouble that our friend Cantine speaks of would always occur when we had anything but uniform heats. When the apparatus was strikingly hot in some particular spot the men would perhaps not be able to introduce oil in that run because that part of it was too hot. As they hadn't put anything in there to cool it, the next run it only went that much higher, and they would have to use some heroic treatment; and that was to put in a good big dose of oil, and then they made lamp black. But our apparatus is different from many used and spoken of. We have an arrangement of the combined Lowe and Granger. It has three cylinders. The first cylinder is the generator. That is of good size. It has the diameter of a Granger set and it has the modified length of a Lowe set. With that apparatus—that particular form of generator—we are enabled to use soft coal. With a short blast, say six minutes, we can bring that fuel to a very high incandescence, and then make water gas for nine minutes. In the second cylinder we vaporize the oil. The oil is atomized, having been heated in a steam coil before entering, so that the very light portions of the crude oil are vaporized by the steam heat, and the heavy portions atomized in escaping through the fine orifice and getting in there. It is showered in, and any portion of the oil that is too heavy for atomization or evaporation under the conditions named, lodges on this brick work. The temperature of the brick work is maintained at a low degree, so as just to evaporate it and let it pass on with the incoming gas. We don't undertake to gasify that oil in there. It is simply to vaporize it. When it comes down to the bottom of the cylinder, there we have a volume of water gas wrought up with the vapors of crude oil. Then it enters the bottom of the super-heater. In the super-heater we attempt to gasify it. It has a large damper. The length of that cylinder and the primary proportion of vaporization of the oil properly enable us to gasify that oil first in passing through that super-heater without exposing it to a very sharp heat. A very moderate heat will do it by treating the oil in that manner. We can look into the super-heater during any portion of the run, and it is perfectly clear in there. The gas coming through does not cloud it up until towards the end of the run, and then, on account of the disappearance of heat, the vision is obscured. I have not had—I have been fortunate in that respect—any naphthaline trouble in or about the works, or in any street mains, or with any consumer.

Mr. Hyde—The secret of the cause of naphthaline is the high heats. I know, from experience with the manufacture of coal gas, that the original cause is the high heat, and then the rapid cooling afterwards.

Mr. Faux—In speaking of naphthaline before, I left something that I will explain now. I have what is called a Granger machine, that was built for benzine alone. That is, it takes oil in the bottom of the super-heater. With super-heated oil at 150 pounds pressure the engineer had considerable trouble. He almost blew up the whole works a number of times. The outlet of the super-

heater would elog up. I did not know what to do. He had his oil lown in the ash pan and all over everything. I was in a bad fix. I was like Mr. Cantine for a while—I felt like clearing out. I took hold of the machine, ran it myself for a week or so, and found there was something wrong. I didn't know what it was, but I made up my mind if I would change the machine it would do better. I took off the cap, deepened the fire and changed the inlet from the generator to the super-heater. Then it would go down the side blast pipe. In explaining this I suppose many of you have seen a cut of the Granger process. I came to the conclusion that if I could stop that from going down there I would have the thing about right. I let the machine cool down and got in there myself, I commenced to wall opposite the end of the super-heater blast pipe, and placed the brick in such a position that the oil could not get back into the pipe, compelling it to meet the hydrogen gas coming from the generator in the bottom of the super-heater. It worked perhaps for two weeks all right, and then it would back behind this wall. I studied the matter over. I had been looking up the new process—this new Granger machine that Mr. Faben has in operation—and I made up my mind I could get the results with this machine. I put a tuyere right under the second arch and sprayed my oil in there. I made a loose checker-work between the two arches where the oil has a chance to drop down and evaporate below. I now have no trouble. It is as clean as it ever was with benzine. There is no tar, and there is no trouble with the outlet or anything else. I run with very high heats in my super-heater, and there is no sign of naphthaline.

Mr. McDonald—Mr. President, I am not a gas man, as you know, but I have listened to this discussion. I think probably most of you agree with Mr. Hyde, that high heats have something to do with this; but from what I have heard of the discussions of water gas, I am of the opinion that the bringing of the oil to a high heat suddenly is the cause of the trouble. If the oil is brought to a high heat slowly, I think the trouble will be much less. I know it is generally conceded that it is much better to bring the oil up gradually, vaporizing it first and then introducing into the apparatus afterwards.

On motion, a vote of thanks was passed to Mr. Light.

AN INVITATION.

Mr. Faben, on behalf of the Toledo Gas Light and Coke Company, then invited the Association to a dinner, to be served in the Budy House on the following evening, which invitation was, on motion, accepted with thanks. The meeting thereupon adjourned.

SECOND DAY—MARCH 20—MORNING SESSION.

The President announced that a neat souvenir badge had been presented to each member of the Association by the Central Chandler Company of Toledo, accompanying their invitation to visit their show rooms and factory. The meeting took appropriate action expressing its appreciation of the memento and the invitation.

A letter was also read from Mr. Scott, President of the Board of Trustees of the Manual Training School, inviting the members of the Association to visit the school during their stay in Toledo. On motion, a vote of thanks was given Mr. Scott for his invitation.

A resolution introduced by Fred. R. Persons, endorsing the action of the National House of Representatives in selecting Chicago as the site of the World's Fair, was, on motion, adopted.

Mr. G. A. Hyde, sen., of Cleveland, then read his paper on

OUR NEW COAL GAS WORKS.

Mr. President and Gentlemen of the Ohio Gas Association—I esteem it an honor to be chosen a member of this Association and complimented in being requested by your Secretary to prepare a paper entitled "Our New Coal Gas Works."

The portion of the city of Cleveland lying on the east side of the Cuyahoga river is supplied with illuminating gas by the Cleveland Gas Light and Coke Company, and the west side by the People's Gas Light and Coke Company.

This paper relates to the former Company only. The old, or No. 1 Station is located at the extreme northwest corner of the territory supplied, and has proven to be a desirable location from which to suitably meet the requirements of that portion of the city.

Looking to the future, the question of duplicate feed pipes to, or the erection of supplementary works in the outlying district had to be considered, and, after due deliberation, a conclusion was reached that it would be best to erect supplementary works.

In furtherance of that plan a plot of land was purchased near the shore of the lake, at a point three miles eastward of the old works.

The plot contains about eight acres of ground, and is located between the main track of the Lake Shore and Michigan Southern Railroad and the Madison avenue branch of the Cleveland and Pittsburgh Railroad, thus affording excellent facilities for the receiving of material used in the construction or repair of the works, the receiving of coal and shipment of residuals. A brook runs through the grounds, which furnishes an abundance of water suitable for quenching coke and for the benches. Water for boilers and washers is obtained from the city water system.

As a basis for planning for the construction of the new plant, it was considered advisable to provide for the manufacture of 600,000 cubic feet of gas per day to meet present requirements; but, deeming it prudent to be mindful of the future, the houses and machinery were placed and distributed in manner to conform to a general plan contemplating a works having a capacity of 5,000,000 cubic feet.

The retort house, benches and coal shed were built for a capacity of 600,000 cubic feet, but they are placed so that they can be extended to the ultimate full capacity.

The boiler, exhaustor, condenser and washer houses are joined together in the order named. The boiler house is of a size sufficient for all future requirements, and incloses two boilers for immediate needs. The exhaustor house is ample for all future demands, and contains two exhaustors for alternate work, each having a capacity of 2,500,000 cubic feet. The condenser house has a capacity to contain apparatus capable of properly condensing 3,000,000 cubic feet, and is so arranged that additions can be easily made to provide for the further amount of 2,000,000 cubic feet. The apparatus now set will properly condense 900,000 cubic feet. The washer house now contains one set of tar and ammonia washers of about 1,200,000 cubic feet capacity, and has space for another set. Provision was made for extending this house to receive two more sets of washers.

The purifying house, with its one set of purifiers, 25 feet by 25 feet, and the revivifying house attached, can properly pass 1,250,000 cubic feet of gas, and the building and inlet and outlet pipes are so placed that they can easily be extended to the capacity of 5,000,000 cubic feet.

The station meter house contains one station meter, 12 feet by 12 feet, having a daily capacity of 1,700,000 cubic feet, and ample room remains in the building for placing two more of same size.

The first gasholder, having a capacity of 600,000 cubic feet, has two sections of 110 and 111½ feet diameter, respectively, each section 32 feet high, contained in a tank of 114 feet diameter and 32¾ feet depth, inclosed in a brick house surmounted with a non-trussed wood roof, covered with slate. Adjoining this building is the governor and valve house, being centrally located for connections with the present and all contemplated gas holders. The piping and valves are so arranged as to admit of inlet and outlet of each holder being controlled in this building.

Two tar and ammonia tanks are located convenient to the retort house and condenser and washer houses, each having a diameter of 40 feet and a depth of 35 feet. The pump house is adjacent to the last named tanks.

The retort house was constructed especially for the convenient use of regenerative benches. The floor consists of I beams covered with ribbed steel plates. Tracks and turntables are laid contemplating the use of steam charging and discharging machines, and the house is arranged for erecting overhead coal tracks and storage bins for supplying the charging machines.

A system of water piping for fire protection, connected with the city system, is distributed through the entire plant.

The main gas pipe running through the works is thirty inches in diameter, is exposed to view, and placed ten or more feet above the ground, or floors, from the retort house to the outlet of the station meter house, excepting for a short distance between the purifying house and the station meter house, where it is placed under the surface of the ground.

I wish to call attention to this feature of our work, as it differs from the usual custom. These pipes are easily reached in case of leaks, require no basements, and permit of free access to all the machinery.

The buildings are placed in the following order, viz.:

The coal house adjoins the Lake Shore and Michigan Southern Railroad, is 100 feet wide, has a branch elevated railroad track running lengthwise along its centre, allowing the "storage" coal on one side, and the "present use" coal on the other, and nearest the retort house.

A space of twenty feet intervenes between the coal and retort houses, thirty-seven feet between the retort house and the boiler, exhaustor, condenser and washer houses, and thirty feet between the last named and the purifying house, and attached to revivifying house. This last named house lies alongside of the track of the Madison avenue branch of the Cleveland and Pittsburgh Railroad.

The benches are of the Kloeene-Bredel Regenerative pattern, and were erected by Mr. Fred Bredel, of New York city.

The exhaustors were manufactured and placed by the P. H. & F. M. Roots Company, of Connersville, Ind.

The condensers are of the open-air plan, but divided into rows every two feet, each row containing twenty-four six-inch pipes, of twenty-four feet in height each, and having a daily capacity per row of about 150,000 cubic feet. This method was first introduced in our present old works in 1872, and proves satisfactory. It has the advantage of making it possible to give, at all times, the same condensing treatment to the gas, whether much or little is being manufactured, but which can not be done by a single line condenser, whether open-air or multitubular water condenser. By having valve at each end of each row, there is obtained the further advantage of being able to shut off by single rows for cleaning.

The tar and carbonic acid extractors and ammonia washers were furnished and set up by Mr. Fred Bredel, of New York city. R. D. Wood & Co. furnished and placed the set of four purifiers and dry centre valve. The Maryland Meter Company, of Baltimore, Md., furnished the station meter. The Stacey Manufacturing Company,

of Cincinnati, O., furnished the holder, and Helme & McIlhenny, of Philadelphia, a twenty-four inch Foulis governor for regulating the delivery of gas to the street mains.

Gas making at the new station was commenced December 1, 1889, and has been in successful operation since that date.

The paramount endeavors in the planning and construction of this plant have been to avoid display and useless expenditures for outward effect and complication, and have been concentrated in producing the simplest and most effective methods for manufacturing gas of a uniform good quality at the lowest cost.

In these days, and days to come, in which competition is to be met, the best machinery is the cheapest and most profitable. In the matter of apparatus and methods of operation, while others may be as good, we may be pardoned, I think, in believing that our new Coal Gas Works is of the best, and is well provided to produce the most effective gas fuel, as well as the most practical medium of artificial light.

Discussion.

The President—Gentlemen, you have listened to this paper by Mr. Hyde, and I don't think any comment from the chair is necessary. I think the end has been reached in that works; and I trust a free discussion will be had on the paper.

Mr. Printz—The description given by Mr. Hyde of his works is very vivid, so much so that we could almost carry the the works in our eye, and we can tell about what the works would look like. What I would like to ask of Mr. Hyde is the results which have been obtained in the new works—whether they have been superior to those in the old works, in the amount of gas produced per ton of coal, and also as to the saving in the amount of coke used—that is, the percentage of coke that has been used to carbonize say 100 pounds of coal; whether the difference has been very marked between that formerly used in the old works and that used in the new works.

Mr. Hyde—As the acceptance of the Bredel benches depended upon their results, a test was made to ascertain the percentage of coke used. Four benches were run a week, according to the contract, on 19 per cent. of the coke produced. That was the trial. We have been running three months. Of course it is in the beginning of the work, and under the management of those who have not been accustomed to use this kind of bench, and with those benches (as any benches, or any new work in new hands) it is necessary to run for a while to get accustomed to the methods. The other day, my son, who has charge of the works, reported that, as near as he could make out, they ran a week with 22 per cent. Of course they didn't include in the first test an occasional stopped stand-pipe, and that interferes with the record which might be obtained where you are making a trial, the first trial especially. We feel satisfied that somewhere about that amount of coke will be required to heat the benches, 22 per cent. In the old works I have run with our plan of old benches for a month with 25 per cent., and I have run six benches for six months or a year with 27 or 28 per cent. It would seem from the information which I am able at present to present, that there is a saving of probably 5 or 6 per cent. in the use of the Kloenne-Bredel benches. What the future will develop will be the experience of the manager, and we do not know now. It may be less than that, but I apprehend that 22 per cent. is about what we may expect. Does that answer your question?

Mr. Printz—Yes, sir. Another question that I would like to ask—were not the old benches you speak of extraordinarily good benches, or good settings, for the old style? That 22 per cent. you speak of is much below what we usually hear from the old settings.

Mr. Hyde—As far as I was able to determine that, and I made many inquiries in years past, with reference to the consumption of coke, our experience compared with that of every other gas works that I inquired of, was such that I can scarcely believe my own statement, because everybody else said otherwise? I could not understand why we were able to keep our furnaces at the right heat with so small amount, when every other company varied from 40 to 50, even 60 to 70 per cent. of the coke produced. I couldn't understand how we were able to run six months with 27 or 28 per cent. under, you might say, unfavorable circumstances—like charging benches and having them ready for use, and holding them for dark days, etc. But we seldom got above 30 or 31 per cent. It always had been for a long time, rather a mystery as how it came—whether the others were careless in their statement or what it was. I knew I was making the statement, and I knew the information I obtained was correct. Mr. McIlhenny was at our works a year ago, where we were constructing a bench, and he said: "I see the philosophy of your benches now. I never could understand it. Your furnaces are short and narrow and others are long and wide." That was partly in confirmation of what I had ascertained myself at one time. About 15 years ago we got a plan from New York for the erection of a set of benches that called for a length of 42 feet furnace, I think, and 14 inches in width. That was the grate-bar surface. Mr. Christy, our superintendent of the works, and myself noticed they were much at variance with ours, and we said, "Now, ours are all right, and what is the use of having anything better?" But we concluded to set up three benches on the new plan, and built the other nine on the old plan. Then we set to work to see if there was any difference in the practical use of them. We tried them on coal and on coke. We ran long enough to demonstrate the practical use of them on each

kind of fuel, and the result was that with the new style we used about 2,000 pounds of fuel per day; while with the 3½ (I think it is something like that), and 12 inches wide, we used about 1,600 pounds. That would be three-quarters of the quantity, and we produce the very same heat exactly. We could not use less than 2,000 pounds with the wide furnace, and we couldn't use more than 1,600 with the other, but the heats were the same, and the quantity of coal carbonized in the retorts was the same. We also tried the coke, but I cannot give the quantity. The results, however, were the same, or about in that proportion. So we demonstrated, to a certainty, and gave an explanation why we were using less fuel than others. But I can't now see how any company could use up to 50 and 60 per cent. when we were using 28 or 30. While in Massachusetts I called at several places and asked of them the quantities, and also told them our experience. They looked at me as though "that would do for a western man to tell a down-easter; but we don't take any stock in it." I was astonished to find they used so much. What did they do with it? that is the question. Mine, you would say, was absolute measurement. We filled so many retorts with coal and pulled so many out. It is not measured, but the retorts are charged alike, and a certain proportion of them used, so there is no mistake about the quantity. I think I have answered the question.

The President—You got the same yield from the short and narrow benches?

Mr. Hyde—Just the same with the same charges.

Mr. Smith—Any difference in the depth of the furnaces?

Mr. Hyde—No, sir; constructed the same and fed the same; treated the same every way.

Mr. Printz—I don't wish to monopolize the time of the meeting by asking all the questions, but I would like to ask another, and that is—the size of the retorts in the benches, the amount of coal you were charging into them, and the yield you were getting from these new benches?

Mr. Hyde—Now?

Mr. Printz—Yes, sir.

Mr. Hyde—It was understood that we were to get 9,000 cubic feet to a retort. We have averaged from nine to ten thousand.

Mr. Printz—Now, the size of the retort?

Mr. Hyde—The retorts are 15 by 26, by 9 feet 4 inches.

Mr. Printz—Charged every four hours?

Mr. Hyde—Yes.

Mr. Printz—What weight?

Mr. Hyde—333 lbs. we are charging now. I think that is the highest—333, 316, sometimes 300, depending on the condition or necessity.

The Secretary—Mr. Hyde, what disposition do you expect to make of your old works? What will be their ultimate fate?

Mr. Hyde—There can be no change made in the old works, except to use them as they are.

The Secretary—Indefinitely?

Mr. Hyde—Indefinitely. That is, we do not see now any reason why we should lift the benches up and have a basin where the benches are. It is not convenient. The width is not right, and the probability is that we shall use them as they are. They are not extravagant in the use of fuel. We have not thought of it, but I don't suppose there will be any change.

Mr. Printz—One further question I would like to ask, and that is as to the care in the handling of these new benches. Is it necessary to draw the clinkers from the furnaces as often as you do in the old set?

Mr. Hyde—I wish I could tell you something about the running. I have been busy about other things. My son runs the works. I am satisfied of this, that there is economy, of course, in being able to draw your coke out of your retorts to run it down into the basement instead of hauling it off in some other way. The tendency is to economize; to what extent I am not able to say. I wish I could state that, but they are new to us and I have been busy about other things and have not paid attention to it so as to be able to answer.

The Secretary—After you make increases to a considerable extent, do you anticipate any trouble from back pressure thrown by these Bredel tar and carbonic acid extractors and ammonia washers?

Mr. Hyde—No, sir, we don't anticipate any difficulty in that respect. We calculate to run about eleven hundred thousand and when we get to that we will have another set.

The Secretary—What pressure do they throw now, with your make at 600,000 feet?

Mr. Hyde—It is eleven inches.

The Secretary—That is the aggregate pressure before the exhaustor?

Mr. Hyde—Yes, sir.

The Secretary—What pressure, for instance, does the ammonia washer itself throw?

Mr. Hyde—I could not tell you that. I only noticed the other day that it was eleven inches before the condenser.

Mr. Cantine—Why, if water gas plants are so good and generally used and so popular, why did Mr. Hyde not put that in a plant of that type instead of this 5,000,000 coal gas plant?

Mr. Hyde—We think a good deal of water gas, but we don't use it. As far as we have been able to ascertain we thought it safe to use the process that we were familiar with. We know we make gas at not a high price, that is we make it cheap, and the method and process we are familiar with and we make it with ease, and everything has been satisfactory so far. The question of introducing a water gas plant has occasionally been brought to our at-

tention and we think some time we will put in a set. However, if we don't put it in any faster than we talk, it will be some time; for we have talked about it for ten years. We bought the right to use the process about ten or twelve years ago. I am satisfied of this, that it would be well to have a plant, because in Cleveland, as in other places, we occasionally have a dark day, and when it is dark, it is dark. We have repeatedly, or about once a year anyhow, consumed all the gas we make between sunrise and sunset as fast as we made it, and our supply for the night is what we had on hand at sunrise. So, if that day should be repeated we would be floored. In an emergency of that kind I think it would be desirable to have a water gas apparatus so that when we found the day was going to be dark we might commence making water gas to replenish. But from all we have been able to find out or learn, we have not decided to change yet, any way. We have got coal gas yet.

Mr. Evans—I would like to ask Mr. Hyde to state how much his gas costs him in the holder?

Mr. Hyde—That is a question that I could not answer before any public assembly.

The Secretary—I would like to ask Mr. Bredel, who is now present, the question I asked Mr. Hyde, as to what pressure his ammonia washers throw with that 600,000 feet daily make?

Mr. Bredel—All the way from three to five inches pressure.

The Secretary—Isn't that a good deal?

Mr. Bredel—No, the exhauster will take care of it all. You will have to push your gas so much harder. I don't see any objection to high pressure. I know of gas works where the pressure is up as high as 14 or 15 inches, and I don't see the objection to it.

The Secretary—As I understand it, your purifying boxes don't throw any pressure at all.

Mr. Bredel—No.

The Secretary—But after the make increases materially I should think these purifiers would throw the usual pressure, which is considerable, and then your aggregate pressure, it seems to me, would be rather high.

Mr. Bredel—Well, it might be that the purifiers afterwards will throw about an inch pressure. If they throw more there is something wrong. Your purifier is not large enough, or your purifying material is not good.

Mr. Printz—I would like to ask Mr. Hyde if that saving of five per cent. in the coke is sufficient to justify the extra expense incident to the cost of this Kloenne-Bredel furnace over the old settings?

Mr. Hyde—Well, I have not taken that into consideration. In investigating this matter of putting in the new works we concluded that we would have in a set of these benches for trial, but I have not investigated. After we get fairly going and have run several months, we shall settle all that conclusively. I, however, may say this, we expect to extend our retort house and put in the same kind. We expect this year to extend the retort house 500 feet, and expect to build a tank of 145 feet in diameter for the same works. We are contemplating the need of further extension.

Mr. Printz—I would suppose that there is not only this saving of five per cent. in the fuel, but the advantage which you obtain by the setting, in the handling of your coal and getting rid of your coke, would certainly be quite an inducement to make a change of this kind.

Mr. Hyde—Yes, sir, we expect that; but you asked a definite question, and I can't answer it. I would be pleased to if I could. Of course we expect to get benefit from the use of this or else we would not think of extending it.

The Secretary—With us the price of coke is so low that the study of the economies in coke saving is not a matter of any particular importance. Our coke nets us only 3½ cents, and although our regenerator furnaces consume more coke than they ought, we don't care very much. We use at least 30 per cent. of the coke we make in the furnaces.

Mr. Printz—One of our bashful members requests me to ask the price which Mr. Hyde gets for his coke.

Mr. Hyde—The ordinary price is seven cents for the coarse coke. For our crushed coke we get 8½ cents at the works.

Mr. Faux—Do you not expect your retorts to last much longer than under the old system of firing?

Mr. McIlhenny—I believe the usual way of measuring the life of a retort is by the quantity it produced during its life. If a retort is run hard and produces in a year five million feet, and another runs three years and only produces the same quantity, the one that runs a year has done as much work as the other one. It is a question of production rather than a question of time.

The President—That is undoubtedly true, but the factor comes in there, however, whether the one system maintains a more uniform heat than the other. I think we will all agree that that system that maintains the most uniform heat, even if it be somewhat higher heat, would perhaps be not more destructive to the retort than a lower and vacillating heat.

Mr. McIlhenny—Yes, of course. The regenerator system is like running a train without stops at stations. You don't have to stop and start the train again. You draw the hot coke into the furnace, and there is no cooling of the retorts by the cold coke being thrust in. Now you have a practical advantage in that direction, I think. You have a more uniform heat, of course, upon the bench, and better results. Besides, we all know that all kinds of material contract and expand more or less by heat and cold, and when you cool your bench down by throwing in cold coke there is more or less

contraction of the retort, and it takes some fuel to bring that heat up again to the condition the regenerator should maintain.

Mr. Faux—The reason why I brought out that question was this: I use natural gas. Three years ago when I took charge of the works, there were benches that had been dismantled and torn out. The retorts were good but they wouldn't heat with coal and coke any more. I refitted them, put natural gas under them and have run them now three years, and I find they are in very good condition. The reason I brought that out is to show that with the regenerator furnace and firing by gas, the life of a retort is much longer than by firing the old way. I believe in gas firing under a retort.

Mr. Bredel—Mr. President, I think the injury is due more to the solid pieces of coal that get in the ordinary furnace and, coming in contact with the retort, form a flux there and make the retort crack. Now in the regenerator furnace no flying ashes or anything can get into the retort and form a flux, and, as Mr. Faux says, naturally, this is an advantage in firing with gas. Another thing, if you open your filling door, there is not much chance for cold air to get in. Of course if any cold air gets in it will have to pass through the generator and will be warm by the time it strikes the retort and will not crack it.

The Secretary—Mr. Bredel, what is the proper temperature in your regenerator furnace when it is working right?

Mr. Bredel—That is a pretty hard question to answer. The proper temperature of the furnace itself, of the fuel, should not be much hotter than the coke coming out of the retort. In attempting to estimate this I use an apparatus of my own contrivance for that. You cannot call it a pyrometer, but I have used it quite satisfactorily. It is a very simple arrangement, but it is only for comparative heats. I take a small box and make little slots in it and take blue glass and cut them up into pieces of one inch square and put 20 to 30 in it. Then bore a little hole on both sides, about half an inch in diameter, look at the fire, and put so many blue glasses on until I can't see anything more. Then I rate by how many glasses it takes. In this way I have a comparative test.

The President—In the matter of economy in firing, the regenerative furnace has one advantage that I have not heard brought out yet, and it strikes me that it is much greater than many of us are perhaps apt to give it credit for, namely, the fact that the fuel is dropped in at the top. Of course there would be no current of air in that case, as with a door opening squarely in front. In the latter case you get a current of air through the ordinary furnace, that means a good deal of disaster. Of course every time the door is opened for stoking or charging or anything of that sort a current of cold air rushes in. I have no doubt the difference is very much greater in that regard than many of us think.

Mr. Hyde—I would like to make mention of a scheme that I have in mind. Whether it will ever be carried out or not at our works I don't know. In perfecting our method of handling coal and coke at our new works my scheme is to shovel the coal into a car from the coal shed, where, of course, it is unloaded; lift the car and dump it into a crusher for crushing it for the steam charger. It would pass through the crusher into another car. That car would be lifted high up into the retort house, and run around on the tracks on each side of the house to the dumping bins. Out of these bins the coal would be drawn into the steam chargers and be blown into the retorts. Then, after carbonization, withdrawn by steam with the steam stoker, and drawn into the chutes in front of the retorts down into the coke car—that car to run along on a track to an elevator, and be lifted and dumped into a bin; the coke drawn out of that bin over a screen that takes out the dust, and continuing a little further, takes out the pea, if you choose, then the nut and the dust and the pea are deposited in separate bins, and the coarse coke will run into a car. One shoveling in the works, after the coal is unloaded into the works, does the whole business. We have no track at present for delivering the coal into these bins, and have no bins as yet. But that is what we are thinking of doing, and if we do, one shoveling will do the whole work.

Mr. Dittmar—Mr. President, since we are on the different modes of manufacturing gas, and manufacturing it quickly, I want to ask Mr. Hyde whether he fully looked into the matter of the various processes of manufacturing before spending the amount of money he did for manufacturing coal gas?

Mr. Hyde—Only in a general way. Of course almost any one is familiar with the method of making gas by the water gas process. But we didn't go into that particularly. We had in view having a coal gas works, and we did not investigate perhaps thoroughly with reference to all the other methods.

Mr. Dittmar—As I understand you, you anticipate putting in a plant for making gas quickly. Did I understand you rightly?

Mr. Hyde—No; we expect to extend our present method.

The President—I think Mr. Dittmar partially heard what Mr. Hyde said with reference to water gas processes. Mr. Hyde did say they had had under consideration the matter of water gas, but that if they made progress as fast in the adoption of water gas in the future as in the past, it would likely be a good many years before it was put into operation—or something of that kind.

Mr. Dittmar—I judge, then, from that remark that Mr. Hyde is not very much impressed with these different processes of water gas manufacture.

Mr. Hyde—Well, I cannot say. You might draw that inference. We have not yet concluded to put in a water gas plant.

On motion, a vote of thanks was extended to Mr. Hyde.

(To be Continued.)

[Communicated Article.]

Doubts Versus Dogmatism.

By MR. B. E. CHOLLAR.

At the meeting of the Western Gas Association, held in St. Louis, in 1887, the writer read a paper on "The Rule of Inverse Squares," in which he endeavored to show, by a simple geometrical demonstration, that the commonly accepted law of light, as applied in the practice of photometry, exaggerates the value of a small light to the consequent disparagement of a larger one.

The paper, although prepared with some care, was intended by no means as an elaborate effort, but, on the contrary, was offered as an invitation to our scientific friends to take up the discussion of the subject with a view of clearing away the very serious doubts in the minds of many in regard to the truthfulness of the photometer.

It is unnecessary to say that the paper failed of its object. The criticisms were few in number and extemporaneous in nature. The general inference seemed to be, however, that the writer might possibly engage in a more suitable occupation than in that of questioning natural laws as they are laid down in the books.

The paper was disposed of in short order: but the doubts still survive. And the doubters persist in believing that a big light has some sort of an unrecognized value not possessed by a little one.

Where there is much smoke there must be some fire. Let us look again for the fire.

We will suppose a luminous point, trace an imaginary beam of light from it through a series of ideal lenses and note the result.

Although in reality it is altogether probable that there can be no such thing as a "ray" of light; yet the conception is correct, and the expression is so intelligible and convenient that we will make use of the term.

In the diagram let *A* represent the luminous point, situated in one of the conjugate foci of the lens *B*. The effect of the lens upon the light received by it will be to change the direction of the rays and converge them at *E*, which point we will make the principal focus of the lens *C*. At *E* the rays will cross without change of direction and diverge to *C*, where they will again be changed in direction and made parallel, in which relation they will continue until, by the lens *D*, they will be directed to the point *F*. The general form of the wave point of the diverging rays, from *A* to *B* and from *E* to *C*, will be convex in the direction of the light, while that of the converging rays *B* to *E*, and from *D* to *F*, will be concave. From *C* to *D*, the light rays being parallel, the successive wave points will be parallel planes. If, therefore, the light from the luminous point *A*, advancing with a convex wave point, decreases in strength in proportion to the square of the distance, it follows, conversely, that light from the surface *B*, toward a point or with a concave wave point, must increase in strength at the same rate.

Similarly, light made up wholly of parallel rays should neither increase nor decrease in strength.

Here we have severally—if the expression may be permitted—three distinct kinds of light; one of which decreases, another increases, while the third remains constant in strength as the distance increases. A luminous point can emit only the first, while a luminous surface sends out all of the three kinds of light, only one of which diminishes in proportion to the square of the distance.

The other two kinds alone possess the characteristics of what we call diffused light. Diffusiveness in light, therefore, is a quality produced by converging and parallel rays; hence if these rays are not governed by the law of inverse squares, diffused light is not; and it follows, in comparing a large light with a small one, that the photometer is a prevaricator.

The mendacity of the photometer lies in the scale graduated on the bar, and the law under consideration can be proved true by the photometer itself no more than a tape line can be proved correct by measuring backward over a distance already measured by the same tape.

It is well to be precise; but it is better to be correct. And it is hardly worth our while to spend time in looking for a light-standard of third decimal place precision, so long as the photometric bar may possibly be wrong in units.

In the meanwhile it appears to the doubters that the larger light is entitled to a credit over the smaller by reason of its size, and independent

of its brightness. In other words, that photometer experiments, as they are ordinarily made, should be corrected by an addition to the observed value of the larger light.

The Influence of an Idea.

The *London Journal*, in its issue for March 18, says that a curious illustration of the influence of a fermenting idea is to be observed in the progress of the improvement of gasholder design by the suppression or radical modification of the guide framing. It is some time since we devoted any space in the *Journal* to a review of this modern improvement, and meanwhile the change that was a few years ago regarded by most engineers as chimerical, has become a commonplace of engineering, as our advertisement pages testify. It will doubtless require time for all gasholder makers to fall in with the new movement, especially as the two best known arrangements for dispensing with the outer guide framing of gasholders are proprietary. Contractors who do not possess workable patents of this class will naturally disparage their value, in order to keep work in their own hands; but the commercial future of this reform in the principles of gasholder construction will settle itself. We have nothing to do with this part of the question, but desire for the present merely to call attention to the remarkable practical effect that a single idea has wrought in this branch of engineering; and we do this not for the sake of unduly magnifying the value of this particular idea, which may be great or small, but in order that any reader who may at any time start a similar idea may be encouraged. In most professions, and particularly in gas engineering, there exists a robust class of critics who claim to be nothing if not "practical." They weigh everything in the same balance, and pass ideas over their weighbridge just like trucks of coal. Anything by way of suggestion that cannot be weighed in this fashion, and its value determined forthwith in current coin, they dismiss as "theoretical"—which in their mouths is a term of contempt. These critics are eminently respectable and useful in their way; but it is well to occasionally remind them and the world that they do not know everything. There are matters which cannot be weighed on a weighbridge, or measured by a two-foot rule, but which may in the fulness of time set many weighbridges and rules to work. These are fundamental ideas. Nobody can tell for certain, when a strange suggestion arises in his own thought, or is communicated by his neighbors, whether it is likely to bear fruit or not. Technical journals and the records of the Patent Office bear witness of many suggestions that never come to anything. There is no recognizable hall mark on these productions of the mind. Not even their parentage serves to indicate their value; for the most striking thing about the life work of every eminent man is the amount of suggestion which he produces to waste. A Siemens or a Bessemer, whose ideas sometimes create new industries, make more failures than successful shots; so that not even the best accredited ideas can be accepted without practical test. On the other hand, the most obscure thinker may discover a clue to an industrial advance that has escaped others. It is his duty, therefore, to give his ideas a fair chance of being heard; and fortunately the means of publication are so generally available now-a-days, that nobody need despair of a hearing for aught he may have to say that is not obviously ridiculous.

The distinction between a fertilizing idea and its practical application is radical. The idea may be expressed in a few words; but the application may take years in working out. The property in the original suggestion and in its utilization may, and generally does belong to different people. Sometimes, but happily not always, the first discoverer essays to protect himself from the improver by patenting every imaginable modification of the embodiment of his idea; and when he has overlooked a weak spot that is taken advantage of by another, he is loud in his denunciations of the infringement. It is probable that more general good is effected when the discoverer keeps himself independent of the practical deviser of applications, whose genius is of a totally different character. We say this because it is possible that here and there may be found men who have in their minds more or less clearly defined ideas on various industrial problems, which they are not disposed to publish for what they are worth because they have a half-wish to keep them until they can clothe them in working shape. This day never comes. The man with the idea never succeeds in devising the practicable embodiment for which he waits; and so his idea perishes with him. It is not always that he keeps his idea to himself with a view to his personal gain. Such conduct would be undoubtedly selfish and short sighted, but not necessarily iniquitous. It may well be, however, that the man with the idea does not keep silence through selfishness, but simply through modesty. He has the idea, such as it is, but cannot himself see

what practical good it represents, and has no hope of acting upon it. He is afraid of the robust practical critics already referred to, who are sure to "sit upon" him for venturing to dabble in a "theory" which has no apparent connection with their experience; and so he keeps his own counsel, and the world is the poorer of a suggestion that somebody else might have been able to work up into a useful shape.

It will not perhaps be an undue exaggeration of the worth of the example if we cite the history of the movement for the suppression of gasholder guide framing of the usual description, in support of the foregoing observations. About this time three years ago there appeared in the *Journal* an article entitled, "Is Lofty Guide Framing Necessary for Large Gasholders?" which began with the statement that "the question as to what is the precise value of gasholder framing is one that has been raised several times by engineers with a propensity for diving after abstract principles of construction, but has not yet been settled, or even placed upon the road that may lead to settlement." The gist of the article lay in a suggestion that a gasholder might be maintained in a proper working position by means of the bottom curb. It was the first promulgation of the idea of guiding gasholders from the base. And now let us pause to point out that this was no more than an idea, stated simply for what it was worth, without any attempt to apply the principle. The time was apparently favorable for the suggestion, although there had not been any prior discussion of the subject. Within the week, Mr. V. Wyatt came forward to admit the force of the suggestion, and wrote the truly remarkable words for the time: "I quite anticipate the production of a self-sustaining gasholder in the future." The fulfillment of this prophecy at Northwich and Haslingden by two different methods of gasholder guiding not then thought of, is one of the most interesting developments of modern gas engineering. It is unnecessary to do more than mention the work of Mr. George Livesey in this connection; but his remarks on the original suggestion are instructive, in view of accomplished facts. He said: "If some practicable means could be devised whereby all the bottom rollers might be made to rise or fall equally, and none of them could either rise above or fall below the others, the holder would then, to all intents and purposes, have a solid foundation, and no columns or guide framing of any kind would be necessary." Mr. Harry E. Jones and Mr. F. D. Marshall must also be included among the few who realized the speculative value of the idea expounded in the *Journal* article; while nobody could say that he was satisfied with the only suggestion then offered for embodying the principle. Time passed; Mr. W. H. Y. Webber's paper was read and discussed at the Glasgow meeting (1887) of the Gas Institute; and still the idea remained "in the clouds," although an increasing number of engineers came to think there was "something in it." Months afterwards, the idea showed signs of bearing fruit. Mr. W. Gadd was first in the field with a printed device for maintaining the verticality of holders without lofty guide framing; Mr. Pease perfected a different means of attaining the same end; and the list of inventors who sought to solve the practical problem in various ways includes at least half a dozen other names, and might probably be largely extended. All this simmering effort, be it understood, followed the publication in these columns of a thoroughly unpractical "notion," which the original promulgator has never attempted to convert into an actual fact. In all probability the coming summer will witness a noteworthy expansion of the trade in gasholders without external guide framing. Which will be the favorite system to be followed in this and foreign countries, is not for us to anticipate. Whether the known devices will be supplemented or superseded by others, is another question that must be left to the future to answer. At any rate, an economy of about 30 per cent. in the cost of a holder is something that no conscientious gas manager, duly solicitous for the rightful application of his employers' capital, can affect to ignore. The revolution in gasholder design has been effected; and those engineers and contractors who are specially interested in the new departure will have plenty of work from this time forward. The men who have made the new principle workable in despite of all the opposing forces of ignorance, apathy and prejudice, deserve all the reward they will get.

In concluding this short notice of the origin and present position of the most striking reform in gas engineering practice that has been brought to pass since the existing type of gasholders was adopted, we repeat that our main object has been the encouragement of the expression of ideas by those who entertain them, irrespective of their apparent value, in a practical sense, at the time. It is not necessary to define the limits that separate from mere dreams those suggestions which have possibilities of usefulness. The line need not be drawn too closely, for the dreams of some men are worth more than the waking sense of others. Ideas relating to industrial developments are not more fre-

quently of the nature of dreams than many of the political projects that fill the daily newspapers; and it is hard to see why an engineer as well as a politician should not be allowed his occasional flight of fancy.

Professor Wolcott Gibbs on Illuminating Gas.

Professor Wolcott Gibbs some evenings ago delivered a lecture on illuminating gas before the Business Men's Association, of Newport, R. I. There was a large attendance of members and invited guests, among the latter being Professor Munroe, Major Livermore, Dr. C. A. Brackett, A. B. Almon, Colonel E. M. Neill, John Whipple, A. B. Emmons, E. P. Allan, W. E. Dennis, C. E. Hamnett, Jr., J. G. Topham, Dr. H. R. Storer, Rev. Mahlon Van Horne, James S. Bryer, Rev. Warren Randolph, W. A. Barber, G. P. Taylor and Captain H. B. Ryder. Mr. L. D. Davis, First Vice-President, was in the chair. The lecturer introduced his subject by giving the following figures showing the analyses of the average coal and water gas in use in Massachusetts:

	Coal Gas.	Water Gas.
Marsh gas.....	38	21
Hydrogen.....	47	32
Carbonic oxide.....	6	27
Illuminants	5	15
Impurities.....	4	5
	100	100

And then went on to say that marsh gas is a colorless, odorless and tasteless gas; not poisonous, but capable of producing death by suffocation. Hydrogen is also a gas, tasteless, odorless and colorless; not poisonous, but producing death by suffocation. It prevents the blood from being oxidulated. Carbonic oxide is a colorless gas, nearly or quite odorless, but is deadly poisonous. The illuminants are sometimes 2, 3, or 4 in number, and are very important in the manufacture of either gas, as without them the commercial qualities of the gases would be of little consequence. The impurities are composed partly of carbon dioxide or carbonic acid. They are of no great consequence, but are necessarily present from the nature of the materials used in the making of gas. Marsh gas, hydrogen and carbonic oxides burn with a very pale light, which makes them of little value in commercial use in the composition of illuminating gases. It therefore becomes necessary to have something to afford illuminating qualities. In some of the larger manufacturing of gas, oil is used to give a larger proportion of illuminating power. Passing hurriedly over the manufacture of coal gas, the speaker said that the manufacturing of water gas is one of the most beautiful processes in manufacturing chemistry, its simplicity exciting the admiration of experts. Coal or coke is heated to a high degree of temperature by means of air blasts and then a jet of steam is forced over the heated substances and decomposes into hydrogen and carbonic oxide, the gas being collected and cleaned. Pure or simple water gas is composed almost entirely of hydrogen and carbonic oxide, but this is of little value as an illuminant. The lighting qualities are imparted to it by the introduction of petroleum or naphtha. The process is simple; the plant occupies but a small space and requires little scrubbing or cleaning. It must be very cheap. But there are no side products as in the manufacture of coal gas. In the latter the coke, ammonia water and coal tar are of a considerable commercial value. The coke is used for heating purposes; from the ammonia water nearly all the ammonia used in the arts is obtained, and from the coal tar the hundred or more aniline dyes are produced. In taking into consideration the cost, the value of these side products is of much importance, yet the speaker thought that the fact that so many gas companies are using water gas shows conclusively that the manufacture of that gas would be much less expensive than that of coal gas.

Professor Gibbs devoted a large portion of the lecture to the consideration of carbonic oxide. This is usually admitted to be one of the most, if not the most, poisonous of gases. It is directly poisonous, acting upon the blood corpuscles, displacing the oxygen and taking its place, and thus paralyzing the corpuscles. He then read Sir Humphrey Davy's experiment of the effects of carbonic oxide upon himself, and those of Messrs. Nichols and Sedgwick, of Massachusetts, and of German and French chemists, which had been to determine the amount of the gas necessary to produce death. These experiments have shown that the presence of one-half of one per cent. of carbonic oxide is exceedingly dangerous, and will almost inevitably produce death. The experiments of Messrs. Sedgwick and Nichols were also directed to determine what per cent. of air will be displaced by a gas in a commonly ventilated room, where it is not absolutely air-tight. It was found that the air of such a room will contain $3\frac{1}{2}$ per cent. of gas. Taking his

table mentioned in the beginning, Mr. Gibbs showed that in the case of coal gas, which contains only 6 per cent. of carbonic oxide, the 3½ per cent. of this amount (.21 of one per cent.) is far below the danger limit; while in the case of water gas, 3½ per cent. of its proportion of carbonic oxide (27 per cent.) leaves a presence of .95, or nearly one per cent. of the poisonous gas, which is far above the danger limit.

The return petition before the Legislature for a law governing the amount of carbonic oxide in illuminating gas was for the purpose of keeping the proportion of obnoxious gas below the danger limit—10 per cent. In an analysis of the gas in use in Newport a few weeks ago the proportion of carbonic oxide was found to be 9¾ per cent., which is less than the required limit; the local company using a mixture of coal and water gas, which reduces the proportion of carbonic oxide. Mr. Gibbs said that coal gas and water gas in use as illuminants are both detectable by the odor, which is produced by the illuminants and impurities. The danger of the gas is from its escaping from the fixtures, which are not always tight, from carelessness in turning off the light and leaving the gas to escape, in the dropping out of the stoppers, and from the breaking of mains in the streets. The last is the most dangerous of all, as it has been found that in the passage of the water gas through the earth the gas is purified and loses its odor, so that it may come into our cellars and its presence be undetected until it affects our health. The dangers from the leaks of the common water gas are more pronounced than from coal gas, because of the presence of a greater proportion of carbonic oxide. There is no difference in the explosiveness of the two gases—that is, one will not explode more quickly than the other; but the water gas is more violently explosive than the coal gas, from the fact that the former contains more illuminants than the latter, and this causes the greater violence of the explosion. It is claimed that coal gas exhausts air much more quickly than does water gas. The products of combustion are the same in both, and about as much oxygen is required by one as by the other, and the difference in this respect is not worth noticing. In conclusion, Mr. Gibbs said that the State fixes the danger limit in kerosene and illuminating oils, and that it could take the same action in regard to gas.

At the conclusion of Professor Gibbs lecture Mayor Coggeshall spoke briefly in defense of the Newport Gas Company, saying that it did not desire to provide a dangerous gas for its consumers. He spoke of the advantage of public discussion. He was in favor of water gas, which he believed to be the coming illuminant.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

MR. WM. JOHNSON, for many years a collector in the employ of the Fuiton-Municipal Gas Company, of Brooklyn, N. Y., is dead. He was a faithful man, and much esteemed by his employers.

THE following action of Mayor Barker, of Providence, R. I., in respect to the proposed chartering by the Legislature of that State of the Wakefield Manufacturing Company, goes to show that the local authority is alive to the slight which would be put upon them in the event of the passage of the measure. The documents explain themselves:

CITY OF PROVIDENCE, EXECUTIVE DEPARTMENT, }
CITY HALL, March 27, 1890. }

Gentlemen of the Board of Aldermen: I have convened you to-day in order to present a message in relation to a proposed act of incorporation of the Wakefield Manufacturing Company now pending before the General Assembly of the State of Rhode Island.—Henry R. Barker, Mayor.

CITY OF PROVIDENCE, EXECUTIVE DEPARTMENT, }
CITY HALL, March 27, 1890. }

Gentlemen of the City Council: An act of incorporation has recently been presented in the General Assembly by which it is proposed to give to the Wakefield Manufacturing Company authority to produce, make, generate, sell, use and supply gas in the city of Providence for lighting, heating, mechanical and other purposes, etc. Section 4 of said act provides that "said corporation upon filing its bond in said cities of Providence and Pawtucket, in the sum of \$25,000, with the Treasurer of said city or cities to secure the putting of the streets of said city or cities, wherein it may choose from time to time to exercise the powers to it granted by this act, in as good order as said streets and highways were in at the places wherever said corporation may do work at the time of commencing work thereon, may open the ground in any part of said streets or highways for the purpose of laying, putting in and down and repairing pipes and other appliances for the use and the conducting of gas, and for any other purpose necessary or incidental to or convenient for the exercise of the powers granted by this act." It will be seen by

the provisions contained in this section that this Company, if the act is passed, will obtain the right to use any of the streets in which it may determine to lay and use its pipes without any control thereof being had by the City Council, either as to the streets used or the manner of their use. Deeming that such broad and extensive grants should not be conferred upon any corporation proposing to do business in this city without making it subject to such proper restrictions and limitations as the City Council may impose, I have brought the matter to your attention in order that you may take such action thereon as may by you seem best.—Henry R. Barker, Mayor.

THE following is extracted from the annual report of the Halifax (N. S.) Gas Light Company: The net income for the year was \$24,092.52, and the total expenditure on all heads was \$72,721.41. The following is a recapitulation of the balance sheet to Jan. 31, 1890:

Capital stock	\$400,000.00
Amount due by Company to wear and tear and contingent account	196,426.00
Dividend, payable April 1	12,000.00
Profit and loss account	15,493.00
Total	\$623,919.00
Gas works, etc., meters, materials, coals, electric light station and materials	590,754.00
Cash on hand and due Company	39,165.00
Total	\$629,919.00
<i>Profit and Loss.</i>	
Dividend, paid Sept., 1889	12,000.00
“ payable April, 1890	12,000.00
Balance carried forward	15,493.26
Total	\$39,493.26

FROM a local source we learn the following respecting the situation at St. Louis in the matter of the proposed 90 cent gas rate: "Interesting developments are expected after the 90 cent gas rate bill goes into effect, at noon of to-morrow—March 29. The bill, as probably your readers are aware, makes it a misdemeanor for any Gas Company in the city to sell gas at more than 90 cents per 1,000 cubic feet; and as the Laclède Gas Light Company, through President McMillin and Vice-President Thompson, has announced its intention to maintain the present rate (\$1.25), it is probable that Mr. McMillin, as President of the Company, will be arrested on charge of violating a city ordinance; and if this is done, St. Louis will likely be the center of some interesting lawsuits. When Mr. McMillin was interviewed by a local reporter (on March 27), that gentleman said the Laclède Company had not yet fully decided what action it would take to prevent the enforcement of the new law, but he said that one thing was positive, which is that the Company would not make the reduction called for in the ordinance. He did not think the Company would decide to take action in the matter immediately after the bill becomes a law, as there was no hurry. The Company will not collect from consumers for about a month, and the time for the collection of the rates after the 90 cent gas bill is in force will be time for action. What the Company would do would be the result of mature deliberation. It is probable that the citizens who object to the payment of the present gas rate will be the first to declare war, although the fact that one of the officers of the Company may be arrested on the charge of committing a misdemeanor under a city ordinance may induce the Company to bring matters to an immediate crisis, and not wait for the action of the city or the citizens. Regarding the reduced gas rate bill, Mayor Noonan said: 'The fact that I did not favor the provisions of the bill and vetoed it when sent to me by the Assembly will not deter me from doing my duty, which is to see that city ordinances are enforced. I do not know what my first step will be, as I do not know what turn circumstances may take, but I will instruct Counselor Bell to look after any cases arising in the courts out of the matter, and I may send instructions to the police. The reduced gas rate bill becomes a law on the 29th, and it is my duty to see that the law is observed. I will not stand passively by because in my opinion the bill was not equitable, but will see that every step is taken to insure its observance.' City Counselor Bell said: 'As City Counselor of St. Louis it is my duty to attend to all litigation arising from the non-observance of the city ordinances, and when the reduced gas rate bill becomes a law it will be my duty to insist upon its observance as energetically as any other. What steps I may take will be decided by the instructions I receive from Mayor Noonan, and the turn of affairs after the bill becomes a law. However, I do not expect to take the first steps in the matter. The Laclède Gas Company will

doubtless take out a writ of injunction to prevent the enforcement of the city ordinance relating to the reduction of the gas rate to consumers, pending litigation to have the ordinance declared illegal and invalid. This I conceive will be the only step that will prevent a more unpleasant and summary course of proceedings on the part of the city. If the Company does not take out an injunction, but, nevertheless, persists in charging the present rate, even after the new law has gone into effect, one of the officers may be arrested on a charge of misdemeanor, and the litigation commenced in this wise. As soon as the reduced gas rate becomes a law it will be enforced."

THE proprietors of the Stoughton (Mass.) Gas Company have announced a reduction in gas rates, from \$6 to \$4.95 per 1,000. The Company manufactures a "high candle power pure oil gas."

IN the Manufactures Committee, Massachusetts Legislature, many matters of general interest to the fraternity have either been considered or are under consideration during the present session of the Legislature.

THE Committee on Finance, Milwaukee (Wis.) Council has wisely adopted a resolution "indefinitely postponing" consideration of the resolution appropriating a certain sum for the purchase by the city of an "experimental electric lighting plant."

AT the annual meeting of the Middletown (Conn.) Gas Light Company the following officers were re-elected: President, A. B. Calef; Secretary and Treasurer, F. E. Camp; Superintendent, J. H. Jones.

THERE is every indication that at the annual meeting of the shareholders in the Montreal (Can.) Gas Company a proposition will be indorsed that will increase the capital stock in the sum of \$500,000. The sum thus raised is to be devoted to paying for plant betterment and extensions.

THE Select Council of Philadelphia has negatived the proposition to raise \$250,000, the said sum to have been expended in the installation of a municipal electric lighting plant.

WE understand that Chas. P. McGuire and associates have signed their names to an acceptance of the fuel gas charter recently passed for them by the authorities of St. Joseph. Under its conditions McGuire & Co. were allowed 25 days in which to accept the franchise, and an additional 60 days in which to file the bond of \$20,000 as a guarantee that the work be undertaken under the stipulations imposed.

MESSRS. R. D. WOOD & Co., of Philadelphia, will build the new gas-holder for the Citizens Gas Company, of Newark, N. J. We understand that its capacity is to be 400,000 cubic feet.

THE new plant of the Duluth (Minn.) Gas and Water Company, at Rice's Point, is completed.

WE obtain the following from a Newark correspondent: "Mr. Dusenbury, Secretary of the Newark (N. J.) Gas Company, when appealed to for information concerning the rumors that Mr. Vanderpool's present trip to Europe was to make arrangements for the sale of the Newark Company's plant to an English syndicate, said: 'It is not true that our Company contemplates selling out to a syndicate, nor are making any negotiations for that purpose. Some little time ago we were approached by a representative of an English syndicate with a question whether we would name a price for our concern. The reply was given that the concern was not for sale, and that no price would be named. Since that time the negotiations, if they could be called such, were entirely broken off. The visit of Mr. Vanderpool, our President, to Europe has nothing to do with this business. Mr. Vanderpool goes to Europe simply because this is a time when he can go conveniently. The objects of the trip are two-fold. One is that he goes for recreation, as he is a very hard working man; the other object is to inform himself in regard to all the new processes and discoveries in the manufacture of gas, and to see all the new appliances for the use of gas, such as stoves, burners, etc. This last is especially in view of the fact that we are putting a new show room in the rear of our office building, which is especially designed for the exhibition of stoves, burners and gas apparatus of all descriptions.' President A. A. Smalley, of the Citizens Gas Company, whose interests are, to say the least, in no wise inimical to those of the old Company—also said: 'No negotiations for the sale of the Citizens Gas Light Company have ever been made or proposed. No offers to sell have been made by us nor have any propositions for purchase been received. The Directors have no power to sell or to agree to sell without

the consent of the stockholders. No proposition has been made or advanced in any form for a consolidation of the Citizens with the Newark Gas Company. Neither Mr. Vanderpool, Mr. Murphy, nor anyone else at home or abroad, is authorized to represent the Citizens Company in any relation whatever."

GENERAL HICKENLOOPER says that there is not a word of truth in the recent statements circulated in Cincinnati to the effect that the Cincinnati Gas Light and Coke Company is interested in the fortunes of the local branch of the Thomson-Houston Electric Light Company.

THE following is the full text of the bill now before the Rhode Island Legislature, to charter the Wakefield Manufacturing Company, which seeks to supply and sell gas in the cities of Providence and Pawtucket:

Section 1. Charles H. Henshaw, J. Edward Addicks, Samuel Little, Michael M. Cunniff, Spencer Borden and their associates and successors and assigns are hereby created a corporation by the name of the Wakefield Manufacturing Company, for the producing, making, generating, selling, using and supplying gas in the cities of Providence and Pawtucket for lighting, heating, mechanical and other purposes, and also for the purpose of manufacturing, using and dealing in all machinery, lamps, pipes, apparatus and appliances pertaining to the use of gas, and also with power to purchase, own, hold and dispose of shares of the capital stock of corporations in this State and other States, and bonds and other securities of such corporations, provided, however, that nothing in this act contained shall be so construed as to authorize said Wakefield Manufacturing Company to carry on a banking or stock brokerage business, and for the purpose of transacting any other business connected with the purposes and powers herein authorized, with all the powers and privileges and subject to all the duties and liabilities set forth in chapters 152 and 155 of the Public Statutes, and in the statutes and amendments thereof and in addition thereto.

Sec. 2. Section 2 of said act shall be amended so as to read as follows:

Sec. 3. The capital stock of said corporation shall not exceed \$5,000,000, to be paid in amounts from time to time, and divided into such number of shares, the par value of such shares to be fixed and the transfer of such shares to be made in such manner as the corporation may, by vote of its by-laws, determine.

Sec. 4. Said corporation, upon filing its bond in said city of Providence or Pawtucket in the sum of \$25,000 with the treasurer of said city or cities, to secure the putting of the streets and highways in said city or cities wherein it may choose from time to time to exercise the powers to it granted by this act in as good order and condition as said streets and highways were in at the places wherever said corporation may do work at the time of commencing work thereon, may open the ground in any part of said streets or highways for the purpose of laying, putting in and down and repairing pipes and other appliances for the use and the conducting of gas, and for any other purposes necessary or incidental to or convenient for the exercise of the powers granted by this act.

Sec. 5. Said corporation shall have an office or place of business in the city of Providence, and there shall be an annual meeting of the stockholders in the city of Providence at such times as the by-laws shall prescribe for the choice of officers, and for such other business as may come before them, and this act shall take effect from and after its passage.

AT a meeting of the stockholders of the Terre Haute (Ind.) Fuel Gas Company the following Directors were elected: Messrs. R. S. Tennant, J. R. Kendall, C. M. Warren, H. P. Townley, W. Kidder, A. Z. Foster and Capt. J. B. Archer. The proprietors assert that their preliminary tests with the plant have answered all expectations.

THE Caloric Light and Fuel Company, to do a general lighting and heating business, has been chartered in Chicago, by Messrs. M. Goldsmith, H. G. Coffee and J. L. Kerr. It is capitalized in \$150,000.

ACCORDING to the Flint (Mich.) *Journal*, Bay City (Mich.) has been doing its own electric lighting at an annual cost of \$90 per year per arc, but now that a private corporation has offered to perform the work at \$60 per lamp the city proposes to retire from the field.

THE total revenue collected during the year for the inspection of gas meters in Canada was \$7,922, as compared with \$6,946 collected in the previous year. The total expenses of the department of inspection were \$18,538 as against \$20,894 for the previous year; 104 tests of Toronto gas were made, and on no occasion did it appear to be below the standard. Belleville gas was once below the standard, Cornwall 5 times, and Ottawa 19 times.

AT a meeting of the Rhode Island Senate Committee on Corporations (held Friday, March 27), a public hearing was had on an act in amendment of an act entitled "An act to incorporate the Columbia Land Company," in which Chas. A. Henshaw, J. Edward Addicks, Samuel Little, Michael M. Cunniff, Spencer Borden and their associates petition to be incorporated under the name of the Wakefield Manufacturing Company for producing gas in the cities of Providence and Pawtucket. The Senate chamber was crowded in every part with prominent citizens from all parts of the State. Senator Wilbour took the chair and called upon those in favor of the act. Mr. S. A. Cook, Jr., said they started with the assumption that an act whose purpose it is to introduce a new industry into the State for fair and honorable competition will be looked upon favorably by the committee. The course of legislation in the past would warrant that assumption. They could not understand the reason of the opposition to capital coming into the city, increasing the taxation value and giving additional employment, especially at a time when there was an outcry against money going out of the State. The course of legislation of the State had been to grant any fair business enterprise the right to enter the field. If this act is refused, it will, perhaps, be the only instance where a competitor asking for incorporation has been so treated. He argued that the Company could only succeed by offering a better product at a greater price, or the same product at a lower price. The granting of a charter forces no one to take the product. He considered it was the duty of the remonstrants in the first place to show why the charter should not be granted. Senator Wilbour said it was the custom to hear the friends first. Mr. J. E. Addicks protested to being considered a foreigner. As a Baptist he felt he had some part and lot in the State of Roger Williams, and as a citizen of Delaware, he ought to have some regard from the other little State. He was a competitive gas man, and had been a merchant all his life. It was not until he reached the gas business that he found it disreputable to enter the gas business. He had been in it six or seven years. As a result of his appearance before the Legislature, in Newport last year the price had been reduced and water gas introduced. He desired to come right in with his associates and enter into fair competition. There was enough business in the city for two companies. His standing as a man was open for investigation, and newspaper talk did not affect him. He had tried to interest Providence gentlemen in the movement, but the power of the old corporation was so great that no one seemed to have courage. There was money enough behind the Company to carry on the business. City Solicitor Van Slyck said the city through its officers desires to control the municipality and not give up the rights of its streets to any corporation however respectable. Here was a bill unparalleled in the history of legislation in the State. It would permit the corporation to do anything it liked, and the injury to Westminster street would cost more than the \$25,000. It was a street so laid down that a strip could not be taken up and put back in the same condition, and this was to be done by a corporation over which the city was to have no control. The State never had enacted such legislation. He was not here to oppose the granting of the charter, but to ask that it be fixed as it always is, giving the Constitutional authorities control. If the committee permits this bill, it should stand upon the consent of the City Council. The old bill was subject to the Board of Aldermen, but the Common Council had grown sufficiently to warrant it in taking control of its highways. Mr. William A. Roelker appeared on behalf of the Providence Gas Company. The first that was heard of Mr. Addicks in Rhode Island was at the last May session in Newport, when he petitioned for an Act which is the same as the one presented to-day, with the exception that the most objectionable features were omitted. The Act which they asked for at Newport had a section providing that they should use the streets subject to the Board of Aldermen. That was now stricken out, and a bond substituted. Another difference was the power to purchase stock of other corporations. No such clause was to be found in any other Acts incorporating similar companies. It must have been put there for a purpose. He rehearsed the methods by which the bill had reached the present stage, and questioned the parliamentary correctness and fairness. It seemed to him that when a bill came with such extraordinary provisions and passed in such an extraordinary manner, there was something suspicious about it, and should have most careful consideration. The Company he represented had served the community well, at fair prices. There were nearly 1,000 shareholders in the Company, and all but 100 live in Rhode Island; and the stock was equally divided between men and women. They are our own people, and have a right to ask for fair treatment, and that you will not put a club into the hand of a corporation. Mr. Addicks was mistaken in supposing the price had been reduced on account of his appearances at Newport. The result of that gentleman's operations in Chicago was a gas trust. The average price in

Boston to day was \$1.67, here it was \$1.40; that is how he has benefited Boston. Referring to the Delaware letter, he said it was a case of a highwayman's "stand and deliver." It was plain on the face of it what Mr. Addicks wanted. He wanted a club put in his hand with which to strike the citizens down. Lieutenant-Governor Darling, of the Pawtucket Gas Company, said their stock was largely owned in that city and neighboring towns, and the passage of the Act would be great hardship to them. Mr. S. G. Stiness, Superintendent of the same Company, said competition had always resulted in a combination sooner or later, and the cost of it would eventually have to come from the pockets of the public. The Providence Gas Company has not increased its stock for many years, and the Pawtucket Gas Company had not increased its construction expenses until they gave the city electric light. The public was reaping the benefit from the small capital upon which dividends had to be paid. The policy which had been pursued in the past would be that of the future. They had reduced the price of gas from \$3.50 to \$1.53. Mr. L. M. Cook appeared as a citizen against the admittance of this corporation. The changing of the title of the Act would not have given any idea but what it was to be a little manufacturing company in Wakefield. If there was any agreement that there was need of a Constitutional amendment, it was such Act as this. Every measure brought before the House should be printed. If they could have had that rule in the House of Representatives, the Senate would not have been troubled with the matter. Mr. John F. Lonsdale protested against the bill appearing before the Senate with the indorsement of the House. The sense of that body was not taken upon it, it being run through with a lot of other charters.

A CONTROVERSY has arisen between the Jersey City Gas Company and the United Gas Improvement Company, relating to taxes on the former corporation. We have been informed that the latter Company in leasing the former agreed to assume all taxes on that corporation and pay them a clean dividend of 10 per cent. annually on the amount of stock of the Jersey City Company. The question in dispute is relative to the State taxes, which the United Gas Improvement Company refuse to pay, and for which no doubt a suit will be instituted.

THE Woburn (Mass.) Gas Light Company has declared a semi-annual dividend of 4 per cent.

SUIT has been begun in the Supreme Court by Margaret Sullivan against the California Electric Light Company, of San Francisco, to enjoin it from operating machinery on the premises on Jessie street, near Third. The plaintiff owns a house adjoining the works, and alleges that the machinery makes so much noise that it is impossible to carry on an ordinary conversation in her house; also that the jarring of the machinery has shaken her house so as to cause the plastering to fall from the walls and ceiling. She has therefore been unable to lease or rent the house, and rather than let it remain unoccupied has been compelled to live in it with her family and suffer these annoyances in question. In addition to the injunction \$10,000 damages are asked for.

GREENFIELD, MASS., March 29, 1890.—The voters will have another field day Monday afternoon, when they will close up the business of the annual town meeting. Were it not for the proposed wrestling match between the stockholders of the Electric Light and Gas Companies to see which Company can secure the contract to light the streets for five years, the session would be a tame affair. Some committees are to report, including one on the subject of buying a new almshouse nearer to where the poor people live, but this scheme, like others that are not quite ripened, will be quickly shelved on a motion to carry it over until the next annual meeting. Not so with the illuminating question. An attempt was made last week to have the selectmen assume the responsibility, but when the subject was opened up and the town fathers saw some of its bearings, they with one accord begged to be excused, preferring that their wise constituents should father the job. As a result a dozen of the lawyers and business men have been bottling up their oratory for Monday's contest. The gas people will urge that inasmuch as they pay about \$450 in taxes against less than half that amount as paid by the electric light concern, it is no more than fair that they should be given a wee bit of the public patronage. There are a great many who will strenuously oppose the making of a contract with any company for 5 years, on the ground that many changes are likely to be made during that time which will cheapen the lights, and of which the town should have the advantage. Of course, the farmers will generally come in to oppose the appropriation of any very liberal sum for any kind of light. —*Springfield Republican*.

THE NEW HANDY BINDER.

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filled in the Handy Binder, becomes a volume of great value, always convenient for instant reference. Handy Binder, Postage paid, \$1.00.

A. M. CALLENDER & CO., 42 Pine St., N. Y.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889,
For the United States, England, Russia, France, Germany, Austria, and Canada,
No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. The Gas requires NO PURIFICATION. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE. Works under our system can be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon. One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

GAS vs. ELECTRIC LIGHT.

We would invite attention to the able and exhaustive argument of General A. Hickenlooper, President of the Cincinnati Gas Light and Coke Company, contained in a handsome pamphlet of 96 pages, entitled

"EDISON'S INCANDESCENT ELECTRIC LIGHTS FOR STREET ILLUMINATION. REPORT OF AN ARGUMENT DELIVERED BY A. HICKENLOOPER BEFORE THE COMMITTEE ON LIGHT, MUNICIPAL COUNCIL, CITY OF CINCINNATI, JULY 22, 1886."

This is a subject of special interest to all Gas Light Companies.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

S. LEWIS JONES, Asst. Sec.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

WM. HENRY WHITE,

No. 32 Pine Street, - - - New York City.

ENGINEER AND CONTRACTOR FOR THE

Erection and Extension of Gas, Water, and Electric Light Works.

SOLE REPRESENTATIVE OF THE

McILHENNY REGENERATOR FURNACE PATENTS

And the Martin Water Gas Process.

Edison Incandescent and American Arc Electric Light Plants Installed.

Correspondence with Gas Companies contemplating extending or improving their Plants respectfully invited. Plans and Estimates Furnished.

GAS COALS.

CANNEL COALS.

GAS ENRICHERS.

JAMES D. PERKINS. **PERKINS & CO.,** F. SEAVERN.
 228 & 229 Produce Exchange, New York.
 Cable Address, "PERKINS, NEW YORK." Post Office Box 3695, New York.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's
OCEAN MINE YOUGHIOGHENY GAS COAL.
 HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL, OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY, THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

Analyses, prices, and all further information furnished on application to
 Agency for U.S., Room 70, Nos. 2 & 4 Stone St., N.Y. C ty.

Every Meter emanating from our establishment will bear the State Inspector's BADGE, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

GAS INTO POWER,

BY THE

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

Gas Power the Leading Power of To-Day,
AND SOLVE AT ONCE THE QUESTION OF FUEL GAS.

[OFFICIAL NOTICE.]

Western Gas Association.

SECRETARY'S OFFICE, WESTERN GAS ASSOCIATION, {
QUINCY, ILLS., April 9, 1890. }

The Thirteenth Annual Meeting of the Western Gas Association will be held at St. Louis, Mo., on the 21st, 22d and 23d days of May. The Lindell Hotel will be used as our headquarters on this occasion.

The usual reduction in transportation rates has been secured and the necessary certificates for obtaining the same will be mailed to our members on or about the 10th of May.

On the 15th of February the Special Committee on the Assignment of Papers assembled at St. Louis for the purpose of choosing subjects and assigning authors for the same. It is a pleasure to state that the responses to the requests of this committee have, in almost every instance, been favorable. The Association can, therefore, rely upon the fact that the paper contributions to the Thirteenth Annual will be of a high order of merit. The list will be announced in these columns later on.

Although "The Western" contains on its lengthy membership list the names of a large number of executive officers of the gas companies that are embraced within its territory, the fact still exists—and it is a painful one—that there still remain a considerable proportion of our Western and Southern companies who have not yet sent delegates to our annual reunions. It is the intention of the Secretary to send a circular, calling attention to the great good accomplished by Gas Associations generally, to the President of each and every company that still remains unrepresented on our roll book, accompanied with a request that he shall send his Superintendent to our St. Louis meeting. These circulars will be issued at an early day, and will be mailed to every gas

company President from the Alleghenies to the Rockies, and from the Great Lakes to the Gulf. If any of our members, or those who are contemplating becoming members, can lend a helping hand in this movement, they will confer a favor upon the Secretary. Application blanks and copies of our by-laws will be mailed to those who desire them.

A. W. LITTLETON, Sec'y.

BRIEFLY TOLD.

OBITUARY NOTE—WALTER BURCHARD HOUSTON.—The American Association is again called on to sorrow over another vacancy in its ranks in the decease of Mr. Walter Burchard Houston, who died at his home in Rahway, N. J., on the 3d inst., after a long and painful siege of illness. Deceased, who was in his 26th year, became identified with the Rahway Gas Company, and so well did he serve his apprenticeship therein that the proprietors, appreciating his worth, finally named him to fill the triple place of Secretary, Treasurer, and Superintendent. He accepted these duties at a time when the fortunes of the Company were at a very low ebb; but imbued with the idea that hard work and liberal management would restore the property to its original position, he applied both restoratives with unflagging zeal. As is not infrequently seen, when his efforts had been crowned with success, even to the point of putting the Company on a dividend paying basis, he was not permitted to enjoy the full fruit of his labors; for about the close of the spring of 1888 he was seized with hemorrhage of the lungs which eventuated in chronic phthisis. In the hope of alleviating, if not conquering the symptoms of his disease, he journeyed to Arizona, but failed of the hoped-for relief. He returned home last fall, to linger until the summons should come, and death's messenger was never received with greater resignation. In fact, from personal knowledge of the circumstances, we cannot refrain from expressing our admiration respecting the placid, uncomplaining manner with which deceased bore the ills that afflicted him. He was elected to membership in the American Association at the meeting held in New York city, in October, 1887, and was much interested in its welfare. His illness, beginning as it did shortly after his election to the Association, alone prevented him from becoming prominent in its affairs. He was a progressive engineer, a close student and a thoroughly cultured gentleman.

THE BIDS FOR PUBLIC LIGHTING, NEW YORK CITY.—Early last week the Gas Commission met for the purpose of opening tenders that had been received from the various gas and electric lighting companies in response to the city's invitation for bids for lighting the streets for 1 year, from May 1st. The figures submitted are as follows:

Name of Bidder.	Price per Light.
Consolidated Gas Company.....	\$17.50
Mutual ".....	17.50
Equitable ".....	12 00
Central " (suburban).....	28 00
Northern " ".....	27 00
Yonkers " ".....	27 00
United States Company (arcs)....	39-42 cts.
Brush " ".....	39-42 "
Mount Morris " ".....	39-42 "
Harlem " ".....	39-50 "
East River " ".....	42 ½ "

The electric bids of course are on the basis of a charge per night, and the schedule for both classes is on the plan of 4,000 burning hours per annum. The Equitable's bid is for all lamps on its existing lines of pipe, and is a compulsory figure, inasmuch as its charter names that as the maximum rate that it may exact. Given in the order as they stand in the table, the electric companies bid on the following number of arcs: 314, 337, 175, 185 and 226. Much curiosity was awakened as to what advance the electric companies would make over the figures submitted by them in the preceding competition, and their propositions of a week ago may be averaged at a 20 per cent. increase. The alleged reason for the advance is the cost of subway rentals; but this cannot be accepted as the *only* one. The simple matter of profit and loss, in the instance of manufacture and distribution, beyond doubt shares with the subway rental in a fair attempt to account for the higher figures demanded. As the matter at present stands, it seems that the usual awards will be made to the gas companies, whereas the electric lighting apportionments cannot be made on the basis of the bid figures. In other words, owing to the increased rates demanded by the electric companies, the cost of their portion of the work will largely exceed the appropriation fund allotted by the city to carrying it on. The bids were referred to Secretary McCormick for tabulation and report.

A MODEL CIRCULAR.—Elsewhere we note that a concession had been made by the operators of the gas supply at Paterson, N. J., to their consumers, and since that item was written we have received a copy of the circular issued in making the concession known to the residents. As it seems to us to be a model circular, we herewith give its salient points in the belief that it may be of assistance to others when the time comes for them to take similar action.

“OFFICE OF UNITED GAS IMPROVEMENT CO., }
146 ELLISON ST., April 1, 1890. }

“We have amended our discount schedule so as to lower the net prices on monthly bills of from 5,000 to 50,000 cubic feet. Gross price being \$2 per 1,000 cubic feet, discounts are now allowed as follows, provided that bills are paid on or before the 10th of each month:

Monthly Consumption.	Discount.	Net Price.
5,000 cu. ft.	12½ per cent.	\$1.75
5,000 to 10,000	17½ “	1.65
10,000 to 20,000	20 “	1.60
20,000 to 50,000	25 “	1.50

“We thank the public for past patronage, and assure them of our desire to continue to serve them well and faithfully. In continuance of past and present policy (not as a new departure), we place as the four cardinal points of our business compass—1, good service; 2, square dealing; 3, courteous attention; 4, prompt response to complaints; and hope to merit and obtain increased business. Using the best methods and materials known to modern gas making, we cannot but feel that we are furnishing a superior article. If there should be any cases of dissatisfaction, the causes will be found to be local, usually in the house-pipes or burners, and we would desire to be informed of any such cases and to have a chance to propose the proper remedies. We intend in the near future to have a house-to-house inspection of burner tips, etc., and trust to have the co-operation of each consumer. In this our object will be, not to increase the size of the gas bills, but rather to increase the illumination. In endeavoring to produce the best light and the most light for the least money, consumers' interests and our own are mutual. We have provided blanks to be given to managers of mills, factories, public halls or other large consumers, who may wish to have a record of each day's consumption of gas. We advise consumers to frequently read their meters, and are always glad to explain the method, or to give other necessary explanation or information. Gas stoves are now in use by hundreds of families in our city, both for cooking and heating. The convenience attending their use, and the saving of time, labor, and trouble, are now too well known to need more than mention. When properly used, the cost is no more (sometimes less) than that of coal. We handle stoves at cost, and would prefer to sell them, making, if desired, very easy terms of payment. We also have stoves to rent at low monthly rates. We have other convenient arrangements, such as self-lighting burners; nursery burners, for quickly heating over an ordinary gas flame small quantities of water or other liquids; curling iron heaters; iron heaters for family use, for tailors, laundries, etc.; waffle and cake bakers, etc., etc.—UNITED GAS IMPROVEMENT COMPANY.”

NOTES.—Professor Chas. L. Robbe, of Trinity College, has been appointed Official Gas Examiner for Hartford, Conn. We congratulate the authorities and the Gas Company on his selection: for his past record is the best guarantee of his fitness, capacity and impartiality.—The proprietors of the Hartford (Conn.) City Gas Company have de-

termined to install an auxiliary water gas plant. In all probability the contract for same will be awarded to the United Gas Improvement Company, with instructions to erect a double set of the improved type of Lowe apparatus, each set to have a per diem capacity of 250,000 cubic feet.—Mr. Chris. Felt, a brother of Mr. Henry Felt, Supt. of Distribution to the Cincinnati Gas Light and Coke Company, has been appointed Superintendent of the Addyston Pipe and Steel Company's works.—The streets of Tyrone, Pa., have for the last three years been lighted by means of 25-candle power incandescent electric lamps, the contractors maintaining 100 of the same on the basis of a charge of \$1.33 per lamp per month, moonlight schedule. The number of lamps in use was 100. As the contract expires on May 1st, the authorities asked for tenders for another 3-year agreement with the following result—the bids were opened on April 7th. Tyrone Electric Light Company, 25-candle power lamps (100 in number), moonlight table, \$1.50 per month each; all night and every night, \$2; Jones & Underhill (Columbus, Ohio) for naphtha lamps, \$19 per lamp per annum; the Tyrone Gas and Water Company did not tender. In view of the increased rate demanded for electric light, Council deferred action in the matter of an award.—During the year Director Wagner reports that 5,241 new meters, and 10,076 new services, were placed through the Philadelphia Gas Bureau last year in that city; that the number of additional burners placed footed up at 113,474; and that the total number of gas consumers is 128,867.—Mr. J. W. R. Cline, whose promotion has been fairly won through a 15-year term of apprenticeship, so to speak, in the service of the Company, has been appointed Superintendent of the Springfield (O.) Gas Light and Coke Company, vice Nathan Kinsman, resigned. Mr. Kinsman, who has served the Company most acceptably for something like 35 years, retires on account of ill-health and advancing years. The fraternity will unite with us in the hope that rest and travel will speedily restore Mr. Kinsman to his old-time physical condition. Mr. Cline has acted as Assistant Superintendent of the works for some years.—Mr. George W. Harper has resigned from the Superintendency of the Fall River (Mass.) gas works, in order to accept a more responsible position in the same line of business at Kansas City, Mo.—Mr. R. B. Taber, as Clerk of the New Bedford (Mass.) Gas Light Company, gives notice that a special meeting of the stockholders is called for Wednesday next, to decide (1) whether the Company shall purchase the rights, privileges, etc., of the New Bedford Edison Electric Illuminating Company; (2) to authorize an increase of the capital stock; (3) to amend the by-laws so as to provide for increasing the Directorate to 11 members.—Messrs. John W. Wright, Thos. C. Young, John S. Latta, Jas. L. Armstrong, John E. Wright and Wm. J. Latta, have applied for a charter for a Company to be known as the Parkersburg Gas Company, “the character and object of which is to manufacture and supply gas for light only to the public at the Borough of Parkersburg, Chester county, Pa.”—The Brooklyn (N. Y.) Gas Company will construct an additional holder.—The Charlton suit against the Gas Trust has been withdrawn, and a sum of money equal to 1 per cent. on the common stock has been “disbursed” by the Trust's Treasurer.—Mr. W. C. Whyte, of New York, will build the tank for the new holder to be constructed by the Peoria (Ills.) Gas Light Company.

The Market for Gas Securities.

The city market for gas shares shows no change from the time of last writing, although investment inquiry was rather more on the brisk order than has ruled for some time back. To-day's (Friday) opening sales were effected at 96½ for Consolidated, and Equitable was sought for in a quiet way. Mutual, too, fully holds its own. In fact, it is undeniable that city gas shares are now attracting more attention from “safe” investors than has been the case for some time back. We hold to our prediction of a month ago that Consolidated will cross the par line before the summer is over. In Brooklyn shares no change of moment has occurred, and the situation there seems to be all in favor of the holders. The Edison Branch Company in Brooklyn may be written down as a very weak competitor of the gas companies—all large users of the incandescent light supplied from the Pearl street station are dissatisfied with the lighting service and its cost. The usual quarterly dividend of the Newark (N. J.) Company (2½ per cent.) has been declared, as also has the Citizens' (same city) allotment of 2 per cent. Chicago Gas Trust stock is in demand to-day at 45¼ to 45½, and the holders thereof have received a sum equivalent to 1 per cent for the last quarter, and are now engaged in an attempt at solving the riddle propounded in connection therewith by the Trust's Treasurer, who says that the aforesaid 1 per cent. is not in the nature of a dividend, but is a “disbursement.” Permitting it to go at that, we may remark that the meeting on the 24th inst. will undoubtedly witness a reorganization of the Trust that will bother even a Chicago lawyer to find a flaw in.

[OFFICIAL REPORT.—REVISED BY THE SECRETARY—CONTINUED FROM PAGE 484.]

SIXTH ANNUAL MEETING, OHIO GAS LIGHT ASSOCIATION.

HELD AT THE BOODY HOUSE, TOLEDO, OHIO, MARCH 19 AND 20, 1890.

SECOND DAY—MARCH 20—MORNING SESSION.

Mr. C. H. Evans, of Jackson, Mich., now read his paper on—
ANOTHER YEAR WITH FUEL GAS.

Mr. President and Gentlemen:—One year ago it was my privilege to present to this Association a paper on "Fuel Gas," and to-day I am called upon by our worthy Secretary to renew this subject.

Many of you, no doubt, have heard at the various Association meetings, or read in our gas journals, a great many papers and articles on this subject during the past year. Some of them have been of an encouraging nature, while others, and I might say the most of them, have been decidedly the other extreme; but if you stop to consider a moment you will remember that the words, "assume," "if," and "theoretically," occur at frequent intervals. No doubt the writers have given the subject much careful thought and study; but who among you can tell by theorizing what will occur in practice?

I could monopolize your time for hours on the theoretical possibilities of fuel gas, but that does not satisfy. Facts are what we want—facts demonstrated by actual results—and until such facts can be presented beyond all possibility of doubt, few gas managers would care to venture, in a business way, into the unknown—few would care to run the risk of success or failure, judging of the conditions from a theoretical standpoint.

There is no longer any necessity to theorize; there is no longer any reason to doubt; for 70 miles from this very city there is a fuel gas plant in operation, doing a business that ought to convince the most skeptical. A plant that is not of the mushroom order, but is built to stay, and is second to none of its size in the country in mechanical appliances for reducing labor to the minimum.

It may not be uninteresting at this point to describe what I am pleased to term our model purifying house. It is a brick building, approximately 40 ft. wide, 115 ft. long, and 30 ft. high to under side of roof trusses. Our boxes, 4 in number, are 20 ft. by 20 ft. by 4 ft. deep, and hold 1,000 bushels of purifying material, each. They are supported on iron girders 12 ft. above the cemented basement, which leaves this latter space entirely free from columns and gives ample room for re-vivification of purifying material. As the lower floor is level with the street, it is easy of access, and the numerous windows afford ample light with plenty of opportunity for rapid circulation of air. The covers are lifted and moved by hydraulic machinery, and the purifying material is handled almost entirely by a system of conveyors, which I will describe. There is a line of conveyors running over the purifiers, which are provided with two discharge openings, operated by slide valves over each box, and another line is suspended under the bottom of the boxes that has two openings, directly under the two discharge pipes in the bottom of each box—this line also has slides in the bottom at frequent intervals. A third line is placed in the center of the lower, cemented floor, the top being flush with its surface, and runs the entire length of the building, having slides or openings at desirable points. An elevator (similar to those used to handle grain), a steam drum and shovel, complete the list of machinery necessary for one man to do the work of six or seven. The *modus operandi* is simple. One man steps into the field, whenever it is necessary to clear a box, at, say, 7 o'clock in the morning, and starts the machinery. The cover is lifted by hydraulic device, the man steps into the box and lifts out the trays that are over the discharge openings. As these trays have rods attached to them that protrude above the material, the lifting out is easily accomplished. The material is shoveled through discharge pipes to conveyor below, which carries and deposits it at any point desired by simply opening the slides; the emptying is done in short order, and the man, after opening the two discharge valves over the boxes, descends below, hooks on his steam shovel to rope attached to drum, and drags the material required for filling to the center conveyor. It is carried along by the latter to an elevator at the end of the building, which receives it, elevating it to the floor above, depositing it in the conveyors over the boxes. This line conveys it to and deposits it in the proper box, and there is nothing left to do but level it off, and this is easily accomplished by 6 o'clock, with the labor of one man. The freshly deposited material below is leveled by a steam shovel and turned at proper intervals by a steam plow.

Our system of handling coal is somewhat similar to the above. The coal, which comes in on a side track, is shoveled direct into a hopper, connected to an underground line of conveyors, which carries the coal to our shed, where it is elevated and deposited at any desirable point. The same line of conveyors brings the coal to our generator house, where it is elevated and delivered into a scale hopper, which not only automatically weighs the coal, but rings a bell in the coal shed whenever the desired amount is in the hopper. The coal truck is wheeled under the hopper and filled by opening a slide.

It is somewhat alarming to contemplate the erection of a fuel gas plant, looking at it from the standpoint taken by Mr. John Young, in his recent paper read before the American Association; but as his estimates are taken and his conclusions drawn from his experience in the sale and delivery of natural gas, I am not surprised at the figures. In fact, I can easily credit the statements since I made a personal investigation of the appliances in use at Allegheny. No attempts had been made, that I could ascertain, to use the gas economically. The coal stoves and furnaces filled with broken brick, and the gas attached thereto, were in universal use. Under such conditions is it to be wondered at that such vast volumes of gas are required and such fluctuations in demand should exist? As an illustration of the differences that proper appliances make in the consumption of gas, I will give you the figures of gas consumed by two houses—one fitted up with a gas furnace, and the other with the gas attached to an ordinary coal furnace filled with brick. The former is a 14-room house, and was warmed throughout during the winter months with an average consumption of 39,000 cu. ft. per month. The latter was a 10-room house, and required a consumption of 125,000 cu. ft. per month.

In the manufacture and sale of illuminating gas the whole distribution occurs in practically 4 hours of each day, and necessitates a storage capacity at least equal to the output, or a manufacturing capacity equal to three times the output, if the storage be reduced one-half. The mains also have to be of sufficient size to supply the entire daily output in practically 4 hours.

Is it not plain to be seen that certain mains supplying a given quantity of illuminating gas would, if used to supply fuel gas, where they are in use 18 hours each day, distribute $4\frac{1}{2}$ times as much as the latter? Is it not consistent to claim a decrease in holder capacity in the same ratio? There is equally as wide a difference in the winter and summer output of illuminating gas as could possibly exist in the supply of fuel gas. Mr. Young must certainly have had some standard of comparison in mind when he said that the storage capacity of a fuel gas plant would have to be simply enormous; but he certainly could not have used the supply of illuminating gas as a comparison to draw his conclusions from. My daily record shows no such erratic demand as Mr. Young assumes must exist. He is generous enough to credit the possibility of getting 30,000 cu. ft. of fuel gas from a ton of bituminous coal, while the facts are, we are getting 40,000 cu. ft., and have every reason to expect 50,000 from improvements now in process of construction.

What constitutes the success of any business, if it is not the selling of its goods? The fact that people buy shows that there are certain merits in our gas, else why should they continue to use it? Why should our business continue to grow and our receipts to increase if the supply of fuel gas is not a success? Is it necessary the gas should be in every house in Jackson before it is entitled to the claim of success. Such seems to be the impression of some gas engineers.

I had occasion a short time ago to read a number of letters from different gas managers, which were in answer to inquiries of a certain party who proposed to introduce fuel gas into the city where he resided. I was painfully surprised to learn the opinions of some of the success of our Jackson plant. Especially so in this case, because I am positive that the engineers in question never were in Jackson to investigate the system in use, but were only too willing to cry down something they knew nothing about.

There seems to be a popular fallacy existing among a great many gas engineers that illuminating gas has $2\frac{1}{2}$ times the practical calorific value of fuel water gas. This is probably due to the assumption that the heat of combustion of a composition of gases is the same as that of its elements. The fact is usually the reverse. Thus, marsh gas, C H_4 , which forms more than one third of the bulk of coal gas, is composed of three parts (by weight) of carbon and one part by weight of hydrogen. In one pound of marsh gas the heat of combustion of its elements, when burned separately, is, for carbon, 10,914 units, and for hydrogen 15,381, making a total of 26,295 units as the combined heat which one pound of marsh gas ought to yield. But by actual experiments the heat evolved is only 23,616 units; hence marsh gas in burning evolves 2,672 units per pound less than its elements, or a loss of about 12 per cent.

Another serious drawback to the practical utilization of the heat in the combustion of illuminating gas, is due to the admixture of such vast volumes of nitrogen which of necessity must be taken in to obtain the proper amount of oxygen. This nitrogen not only absorbs the heat and detracts largely from the flame temperature of the gas; but by its insidious presence it casts off into the atmosphere unconsumed gases the moment a cold vessel is placed in contact with the flame. In fact, I can safely assert that the air dilution necessary for the complete combustion of illuminating gas, detracts from its theoretical value fully 50 per cent. This would not appear to be the case if the specific heat of the nitrogen which enters into the composition was subtracted from the theoretical heat evolved. But this is simply another illustration of the difference between theory and practice. As fuel water gas requires but 2.47 cu. ft. of air for the perfect combustion of a cu. ft., it is slightly affected, comparatively speaking, by the air dilution.

Many tests have demonstrated the fact that illuminating gas, as used for cooking and heating, is worth but 30 per cent. more than fuel water gas, instead of $2\frac{1}{2}$ times as much.

Let us review the oft-trodden ground and see if there is not some reasonable possibility of making the general sale of fuel gas a success. There are certainly elements of advantage in its use that ought to make it preferable even at a higher cost than a solid carbonaceous fuel.

First.—The cost, labor and inconvenience of handling a heavy material is avoided, the fuel being capable of easy distribution.

Second.—It is in a form also free from those material impurities which involve a large residual waste, besides impairing combustion.

Third.—It is also free (if it be a purely combustible gas) from those ingredients which, in the present methods of heating, involve even larger loss than the cause last mentioned.

Fourth.—It is in precisely the condition to unite perfectly and instantaneously with the oxygen of the air, thus securing a thorough combustion. Hence it gives an immediate and uniform result, and its flame temperature is constant.

Fifth.—The intense and steady heat of the flame just mentioned saves both time and money, by presenting an even fire surface ready at the moment of ignition.

Sixth.—It is a fire capable of concentration upon the precise point where the result is desired, and one that is thoroughly under control—the turning of a valve starting, graduating or stopping the combustion at will.

Seventh.—The general cleanliness of the system, no dirt or residuals being left.

Eighth.—The decided advantage from a sanitary standpoint of simply burning combustible gases in our dwellings, instead of attempting to make them as well, by means of the imperfect gas machines called stoves. In the one case, the only risk arises from the possibility of a leak, readily detected by the sense, and having simply mechanical remedies; in the other it is a much more serious risk, because the defect is a chemical one, consequent upon imperfect combustion, and the infusion of poison into the atmosphere is likely to be frequent and insidious, to say nothing of the deoxidization of the air by contact with red-hot iron surfaces.

These facts appear to be overwhelming arguments in favor of a gaseous fuel as against a gross form, and it is a matter of some considerable surprise to me that every family on our lines of main is not a consumer. But there is one class of people that always wait to see what their neighbor is going to do, and another class that is afraid of everything new. But, nevertheless, there are between eight and nine hundred families consuming our gas, and $\frac{2}{10}$ of all the business places in the city are lighted by our method of illumination. To this last feature I want to draw your special attention, for I do not believe a fuel gas business can be perfect and complete without an incandescent burner. The one we have in use at Jackson (the Fahnehjelm) has during the past year made such rapid strides towards perfection, that, to one who remembers it when first brought before the public, the change seems marvelous. The comb has now double the life it had a year ago, and emits a beautiful, straw-colored light, that is very attractive to the public, as the fate of the now defunct Jackson Gas Light Company will testify.

A series of photometrical observations, which I have made from time to time with the Fahnehjelm burner since its improvement, shows an average of 5-candle power per cubic foot of gas burned for the first 150 hours burning, and a gradual diminution until, at the expiration of 250 hours, it has decreased to a shade less than 3 candles per cubic foot of gas consumed.

I removed 4 burners from a chandelier in my house that had been in use for 38 days, in the months of December and January, and had been burned at least 190 hours. A photometrical observation of the burners

showed an illumination equal to 3.9 candles per cubic foot of gas burned.

One burner which costs the consumer 4 cents practically represents the oil that is used to carburet a thousand feet of water gas, as well as the additional amount of fuel expended in bringing to proper temperature the surface used to gasify the oil. In many places, the cost of carburation of oil reaches from 25 cents to 30 cents per 1,000, and in no instance has the cost reached so low a figure as is represented by our Fahnehjelm burner.

That fuel gas has established itself in the field to stay, I do not believe there is any longer need to doubt.

Discussion.

The President—You have listened to the paper of Mr. Evans, which I doubt not has been a source of satisfaction and instruction to those present, and I trust that the discussion shall bring out as much of value as the reading of the paper has.

Mr. Cantine—I believe all the courts of this country have decided that however credible a witness may be it will do him no harm to be corroborated. I was in Mr. Evans' works at Jackson, Michigan, at a time when he was not present. However, his Superintendent treated me very courteously. I believe his purification plant and apparatus are really better than he said. His description hardly makes the plant out as good as it really is. The coal benches were of about the usual type—having 3 benches and 12 cupolas on the same floor. The hot coke was drawn out from the retorts and was blasted up and made fuel gas by the use of steam. One question that puzzled me a little (perhaps Mr. Evans will kindly enlighten us) was that they made an excellent quality of coal gas, but the Superintendent didn't tell me what they did with it. I asked the question, and, I think, I got no answer.

Mr. Evans—I will say in answer that we have about 7 miles of mains that do not parallel our water gas mains, and we have on the former between 500 and 600 consumers of coal gas. The amount of gas necessary for these consumers is separated in the process of manufacture and delivered to them through the old Company's mains. The balance of the gas is sent back and into water gas. We have three generators in use.

Mr. Cantine—I understood the Superintendent to say that your price was 30 and 40 cents, according to the quantity used. Am I right?

Mr. Evans—Yes, sir.

Mr. Printz—I would like to ask Mr. Evans if they have shut down the coal gas works entirely?

Mr. Evans—Yes, sir; we have not only shut it down but taken it apart and sold it.

Mr. Printz—Then, again, I wanted to ask you what was the price of solid fuel—that is, of soft and hard coal—in your city?

Mr. Evans—The coal mined in Jackson carries considerable sulphur, hence very little of it is used for fuel purposes, except in the rooms. The bituminous coal used is brought from the Ohio region, and costs at retail to the consumer about \$4.50 to \$5 per ton. Anthracite coal in the summer season can be bought for \$6 or \$6.50 at the outside per ton.

Mr. Printz—I would like to ask whether you buy pea, nut or lump coal, and whether it is Youghioghney or native coal that you are using in your fuel plant. And another question as to the comparative cost between heating a house with your gas and with heating that same house with solid fuel?

Mr. Evans—We are now using Youghioghney nut. The cost of heating a house with gas, as compared with solid fuel, varies considerably—you would be surprised how much. In some instances it costs from 25 to 30 per cent. more, while in other instances it is just the reverse. It depends a great deal on the consumer. If they use the gas wastefully—that is, leave it on at times when they don't require it—it is likely to be more expensive than the solid fuel; but with the steady heat coming from the gas stove or gas furnace your house becomes thoroughly warmed, and not only thoroughly warmed but warmed uniformly through the whole of the 24 hours. There is no variation. In the use of hard coal the temperature goes down—it is only when it gets down to the point where you can notice it that someone is sent down to look after the furnace—then cold fuel is put on the fire and it is at least half an hour before you feel the effect. There is an interval of time when you have not been heating your room up to the proper degree of temperature. All these things have to be considered, of course.

Mr. Hyde—What appliances for heating houses do you use in Jackson—what kind of furnaces?

Mr. Evans—One made especially for it, or a furnace made especially for the gas, so that the products of combustion will go out of the chimney at the very lowest possible degree of temperature.

Mr. Hyde—What does it probably cost to heat the lower part of a house of 4 good-sized rooms?

Mr. Evans—Representing how many cubic feet of space?

Mr. Hyde—The rooms probably 16 feet square—or four rooms 14 by 16 each.

Mr. Evans—Say, 2,000 cubic ft. space—8,000 feet altogether. About \$32.

Mr. Hyde—For how long a time?

Mr. Evans—In the winter season—the heating season—I have made a great many experiments in that direction, and find that the safest figure I can reach is about \$4 per 1,000 cubic feet of space, heated under the general conditions.

Mr. Printz—Mr. Evans, does the Fahnehjelm comb hold its own with incandescent electric light as well as illuminating gas of 18 or 20-candle power?

Mr. Evans—I think I can safely say it does. I think the secret of illumination by incandescent electric light is the fact of the distribution of that light. It is hung around in different parts of the room and distributed thoroughly. The light from a chandelier emanates from one point, and the walls of a room, and every place where you look for the effect don't seem to have the light cast equally; at the chandelier there is an excess of light. I don't think any business places in the country are lighted as well as those lighted with the Fahnehjelm burner. I think it is due to the fact that the light is cheap that they want more of it. When the bills come in they are so reasonable that they feel they can afford more illumination.

Mr. Dittmar—Will Mr. Evans have objection to giving us the actual cost, delivered through the meter, of the gas at Jackson? Another question, while I am up, is whether he has had experience enough to give us the actual cost of a cook stove for one month—say, for a four-hole top—for a family of half-a-dozen? We people that are in the natural gas region would like to compare prices with those that are using the artificial fuel gas.

Mr. Evans—In answer to the first question, the cost of delivering to the meter is a very uncertain figure in the delivery of any gas—that the cost of the gas in the holder is quite uniform, but the cost of delivery is very irregular, which of course is due largely to the office expenses and the salaries of the officers of the company. In some cases they are paid three times as much as they are in other cases, and the office expenses consequently exceed in the same proportion. The cost of gas for a month, for a family of six, cooking on a four-hole stove, I should estimate to be about \$1.30, if used economically. In fact, the cook stoves that are in use show a consumption that varies from 16 cents a month to \$5. In the latter instance, it is due to the fact that the party who uses the stove cooks for 18 men—boarders, laborers—and the stove does all of the cooking—meats, bread, in fact everything.

Mr. Dittmar—Is that the ordinary cook stove—the old cook stove converted into a gas stove?

Mr. Evans—A cook stove made especially to burn gas.

Mr. Dittmar—Do you find any difference in the cost of the fuel where the old coal stove is converted into a gas stove and where they use a stove especially made for gas?

Mr. Evans—Yes, a decided difference; I should estimate it would cost three times as much at least.

Mr. Printz—I can readily see that the statement Mr. Evans makes is true in regard to the diffusion of the electric light. Latterly I have noticed that electric light people, in placing the incandescent burners, place them around the top of the room, near the ceiling, about 8 feet apart, so that their lights are divided and reach where you would like to see. Mr. Evans says that the gas is concentrated at the chandelier. A question I would like to ask Mr. Evans is as to the price charged for the illuminating gas and that charged for his fuel gas; and whether there is any difference made between the consumers who have only the illuminating gas and those that have both—whether you discriminate?

Mr. Evans—No; we make no discrimination at all in the prices of the illuminating coal gas. It is sold at \$1.35, net, and we aim to make a very good quality. We don't want it said that we reduce the quality of illuminating gas in order that the Fahnehjelm burner may be introduced in its place. We supply a 19-candle gas, which is about as high as you want to send out coal gas. We often carburet it by the use of a little oil, in order to bring it up to the right standard. Those who consume 5,000 feet of water gas a month get their gas at 40 cents a thousand, with a rebate of 10 cents a thousand if paid on or before the 10th. If less than 5,000, it is billed to them at 50 cents per thousand, with a rebate of 10 cents. I might state, as a comparison between the lights, that the incandescent electric light company had about 1,000 burners there a year ago. They now have 800 in, and I think in a short time they will have about 600, as there are about that many changing now.

The incandescent electric light is sold there now for about what they can get. In some places I know they are paying but 20 cents a month per lamp.

Mr. Printz—Is that the Edison incandescent?

Mr. Evans—Yes, sir.

Mr. Printz—Yesterday afternoon, during the course of a conversation with Mr. Evans, he made some statements and gave me some figures, and for the benefit of the discussion I would like him to make the same statement—that is, in regard to the yield of coal per pound that you get in these retorts, and the yield you get from the coke in your generator.

Mr. Evans—We are using in our benches Lima crude oil, and are aiming to keep a very uniform heat. We are able to keep any temperature we desire. We also use it under our boilers. We are now running our retorts on about 3½-hour charges, on 1,800 pounds. We obtain from every pound of coke that enters the generator at least 20 feet of gas; a great many days it runs up to even 30, but when I say 20 I take the average—not for a week nor for a month, but for two months or three months, because those who manufacture water gas know how that varies each day. From the bituminous coal in the retorts we can and do realize over 5 feet. The balance of the illuminating gas that we do not require to supply those that use illuminating gas is drawn back by the exhauster and forced through the generator tubes and sent out in the form of hydrogen into the water gas. The marsh gas is thus converted into hydrogen, and for the actual number of feet of illuminating gas that enters our generator we receive 30 per cent. more in the form of fuel gas.

The President—One feature alluded to in Mr. Evans' paper I may not have got exactly right. I only listened to it as it was read, without any further knowledge of it. The vital question with most of us, I think, in this connection is whether we have or are tending toward the realization of a perfect fuel gas system, and whether the conditions are met in the experience at Jackson thus far with reasonable certainty. The point is made that Mr. Young's experience with natural gas, and his comparison with illuminating gas, hardly represents the conditions. It has occurred to me that possibly Mr. Evans' experience has not been so very extended until the past winter.

Mr. Evans—I have had experience in the distribution of fuel and water gas for the last seven years. In fact, water gas was introduced into Lynn, as I said before this Association a year ago; but under the conditions I detailed then it could not be a success. However, from that I gained a great deal of valuable experience, which I would hardly want to go through again, I assure you. So that in starting into the fuel gas business in Jackson I had the benefit of that experience. As in everything else new, hardly a day passes that one does not learn something; and although I think we are achieving success there without doubt, we are not sitting down satisfied with what we have already obtained. In fact, we are erecting a generator there now—although we have no special use for it so far as adding to our present capacity is concerned—in which we propose to introduce bituminous coal direct. It will not only coke its coal, but will save the labor of drawing the coke from the retorts. I would be glad to give you a more clear explanation if I was at liberty to do so.

The President—The point in my own mind that I have not quite reached was with reference to the storage capacity that Mr. Young had concluded would be necessary. The winter that he had just passed through had been an exceptional one in the relation of the fuel supply to the necessities to be met, either by an amount of plant sufficiently large or capacious, with the necessary help to run it, or, on the other hand, a sufficiency of storage to supply the conditions. I think perhaps the conditions of supplying illuminating gas would not furnish exactly a criterion, but a wider range of conditions would have to be met. These features are only thoughts that occur to me, and I had hoped, perhaps, we might bring out still further light from Mr. Evans' experience. As we take the use of illuminating gas, its fluctuations depend very largely upon the variation of daylight. You know that means quite considerable. Mr. Hyde has already alluded to it, but how much greater it is when you consider the vastly larger output which will be necessary, in any event, for fuel purposes, and the fact that our temperature sometimes changes from about freezing to many degrees below zero within, I was going to say, 18 hours' time—say within 24. It seems to me here is a factor that the past winter furnished us no criterion to judge by at all.

Mr. Rood—Mr. Evans, did you ever experiment so as to get the exact comparison between your fuel gas and hard coal for heating, under similar circumstances?

Mr. Evans—Yes, sir.

Mr. Rood—For instance, take the same room and heat it to a certain temperature by your fuel gas and with coal?

Mr. Evans—I have done so.

Mr. Rood—What was the result?

Mr. Evans—It showed that 20,000 feet of the gas was equal to a ton of anthracite coal.

Mr. Rood—Was that by actual experiment?

Mr. Evans—Yes, sir; by metering the gas.

Mr. Rood—What is the price for your gas in Jackson?

Mr. Evans—The lowest rate is 30 cents a thousand.

Mr. Rood—Then your conclusion was that the cost under the same circumstances is about equal?

Mr. Evans—I think in the majority of cases it would be a trifle more, owing to the fact of their not understanding just how to manipulate their gas stoves and furnaces to get the best results. That, of course, is our greatest trial. In the use for cooking purposes gas does not cost one-quarter what coal does.

Mr. Rood—Have you had improved stoves and burners for your fuel gas during the last year and a half?

Mr. Evans—Yes, sir; I think it was about a year ago that we began to manufacture our own appliances, from our own patents, made from the result of experience.

The Secretary—I would like to ask Mr. Evans if he has tried any of the heating stoves made by the Century Gas Stove and Furnace Company.

Mr. Evans—No, sir; I have not. I have received their catalogues, and intend to make a trial of their goods; but I have not got to that point yet.

Mr. Rood—Is your present gas stove improved so that any fumes that may arise from the burning gas are carried off?

Mr. Evans—The heating stove?

Mr. Rood—Yes, sir.

Mr. Evans—In some instances the air is vitiated and saturated with carbonic acid if the room is too close; but no fumes come off from the burning gas.

Mr. Rood—Are your stoves arranged so that they are connected with the flues of the house—so that any impurities that may arise are carried off; or do they come into the room?

Mr. Evans—About half of them are connected with the chimney. That is left to the consumer. The conditions are explained thoroughly and they can do as they see fit.

Mr. Rood—Which would you recommend?

Mr. Evans—I would recommend connecting with the chimney in every instance. It does not take any more gas in any instance to heat a room when the stove is connected with the chimney than when it is not. The hydrogen in the gas is formed into moisture, saturates the air, increases its specific gravity, and requires more heat to heat that space than it would if the moisture and carbonic acid were carried off. By arranging your stove pipe with the proper sized damper you can pass the products of combustion out of that stove pipe at the temperature of the room or very nearly so.

Mr. Rood—It also acts as a ventilator in the room for ventilating the room to a small degree?

Mr. Evans—Yes, sir.

A vote of thanks was tendered Mr. Evans.

REPORT OF COMMITTEE ON LOCATION.

Mr. Printz—The committee in their conference this morning met with a very serious obstacle. There were no applications from the members to have the next meeting at their places, but several said they would like very much to have the Association meet in their cities only that the banquet feature would preclude them from asking it to do so. They made the statement that while they themselves would like very much to invite the Association to meet there and to give them a banquet, they individually did not feel able to do it, and while they were officers of their companies, they did not feel like taking the responsibility of asking the Association to meet there with the expectation of being furnished a banquet. They were afraid, in some cases, that their Directors, or the members of their company, would not sanction an invitation of that kind, and would not back them. Several, and I might say more than several, have expressed themselves to me in this matter that they were opposed to the banquet feature, and that their understanding when the Ohio Association was formed was that there was not to be anything of that kind. One or two said to me that the cost necessary to give a banquet would be as much as one per cent. on all their capital stock, and they did not feel like an expenditure of that kind. In two invitations—I could hardly say they were invitations, either—it was intimated that

the offerers were perfectly satisfied, and in fact would like to have the Association meet at their places, with the understanding that they were not to expect a banquet from their companies. If, after the place of meeting was selected, the companies which they represented saw fit to give a banquet, well and good; but they would not promise that there would be anything of that kind. Columbus has been named, so has Cleveland, and Zanesville is a third. The gentlemen representing Cleveland say they would like to have the Association meet there, but they would prefer to have a conference with their officials, and would rather have the meeting there the following year. The gentleman representing Columbus would like very much to have you go there. He has an eye open to the business interests of his city. Some others have spoken to me about Zanesville as being near the central portion of the State, a point which is very readily reached by railroads, and which all our members could get to in a very short time. They did not think we ought to go twice in succession to the northern portion of the State. They did not feel that we ought to go as far south as Cincinnati—that the Western Association had been there a very short while ago. For these reasons we have selected, and the Committee would report in favor of, either Zanesville or Columbus, with the understanding that a banquet is not promised. I can say, and Mr. Allen, who is Secretary of our Company, agrees with me, that if the Association chooses Zanesville we will agree to treat you well and see that you are entertained very well, but we will not promise a banquet. Mr. Butterworth, of Columbus, says the same thing. That is the report of the committee, Mr. President, and if the members please I would like to have them express themselves with regard to this banquet feature.

Mr. Cantine—Mr. President, what is the matter with Alliance? We have made about enough money out of our water gas plant in the last year to pay for a banquet. (Laughter.)

Mr. Printz—I am only sorry, Mr. President, that Mr. Cantine did not present his application.

Mr. Hyde—Mr. President, naturally, under the circumstances, I would not say anything about this business, because I am a new member. I am a member of the American and of the Western Associations, and have brought to myself some little notoriety in reference to this banquet business. I would not say anything now except that it has been brought out, by the report of the committee, that considerable opposition is manifested in regard to having a banquet. I want to say with reference to this (as I can now), that I have always been opposed to having any banquet, and, if we have a banquet, to having any liquors of any kind. There are some cities that can afford to provide a banquet. It is all right that they should, so far as that is concerned. They are perfectly able to, and perfectly willing; and those who go there are perfectly willing that they should furnish it and pay for it. But there are some who cannot do that. In some of the smaller towns, as the chairman of the committee has said, it would take 1 per cent. of their capital to pay for the banquet. Well, now, we ought to have a little regard for our brothers as well as ourselves. We should not engage in any methods that would compel others to do what they can't do, or what they are not able to do. The easy way to get along with that is to have none. Now we could have this evening our tea, or supper, or whatever you choose to call it, at the usual time, and adjourn to this room and have our little talk. That costs nothing. We are going to pay for our keeping here to-night anyhow, and if we have a banquet we are going to pay for that, too; and, besides that, we are going to pay for staying a day longer than we want to. There are three ways. Now if we could do it in this way—have our supper in the usual way, and have with it this entertainment, this "flow of soul," without the flow of liquor and wine, and have a good time, it would be all right. I have upon other occasions, and at other Associations, mentioned Cleveland. Mr. Lindsley and myself and a good many others belong to the Civil Engineers' Club of Cleveland. They are, like all these Associations, formed for getting good from each other and profiting by exchanging thought. When that club was started, in preparing for the first banquet that we had, the question was: "Shall we have liquor—shall we have wine at the banquet?" and a few said, with determination and positiveness, "No, not if we go." And so that has been left out, and we have had meetings now for 5, 6 or 7 years, and a better banquet or better entertainment cannot be had anywhere. Everything goes off in fine style, the entertainment is first-class, but we don't have any wine. Now I know it is not necessary (the wine question, however, is not under discussion, but I am willing to speak of that) to have wine if we have a banquet; and having in view the ability of what might be called smaller towns and cities to provide a banquet, I don't know but it would be well to say that we won't have any, and then we will all stand on the same basis; and any place, where the hotel facilities are such as to accommodate those who can

gather, is free to invite with cordiality this Association to come and see them.

Mr. Wilkiemeyer—Mr. President, I have a resolution to offer on this subject, which I will read:

“Whereas, It was the original determination of this Association, as expressed in a resolution unanimously adopted at its meeting for organization in Columbus, Ohio, September, 1884, that the feature of a banquet should not become a concomitant of its annual meetings; and,

“Whereas, The tendering of a banquet to our members and visitors in connection with our annual meeting, by local companies in the cities where meetings are held, having, contrary to the expressed determination of our charter members, gradually grown into a custom that might possibly occasion embarrassment in the future, and militate against the best interests of the Association; therefore,

“Resolved, That in the future this Association shall decline any tender of a banquet on the part of local companies in the cities in which it shall decide to hold its meetings.” [Seconded.]

The President—Gentlemen, you have heard Mr. Wilkiemeyer's resolution. Are there any remarks. This is a matter of some little importance. I think Mr. Wilkiemeyer has put it in tangible shape, and I trust it will be freely discussed.

Mr. Allen—Mr. President, as our town is one of the applicants for the next meeting, it would probably be better for me not to say any thing, but in order to do our Company justice I do want to say one thing. Our Company is not small or niggardly. If Mr. Printz or I should say to them, “We want to have a banquet,” they would reply, “Very well, go and have a banquet and we will pay for it.” They like to have us attend these conventions, and when anything comes up that they and we consider an advantage to our Gas Company, they say, “Go ahead.” Whether we could convince them that a banquet was necessary, or of advantage to our gas works or the gas business in general, I am unable at present to say. If there is anything in it that is doing us any good—were we learning anything that was for our own good directly or indirectly, we would have the “cheek” to say to them we wanted it; and even as it is, if we were to say to them that we wanted it they wouldn't “kick.” We ourselves want to stand in as good a light with our Company in the future as we do now, and as when we are away attending these conventions our folks suppose we are looking to their interests, we would not like to shake their confidence.

Mr. McDonald—Mr. President, I being one of the charter members of this Association, have always taken deep interest in its welfare. I am not in favor of places where the Association meetings are held feeling that they have to furnish the Association with a banquet. I have always felt that it would be wrong, and a detriment to the Association, if that were the case; but a resolution of that kind, which says we *will* not accept, to my mind, is not right. I think the banquet matter has been carried too far in many instances. I do not know but that I agree with Mr. Hyde that we could get along just as well without wine. Suppose we went to Zanesville, if you please, or to Cleveland, or to Columbus, and the gentlemen wanted to ask this Association to a social, pleasant time, that might cost \$10 or a \$100 to the proposers, we would be confronted with the fact that on our books stands a resolution saying we will not accept. That would place the Association in a bad position, I think. I would suggest to the Association that this resolution should be modified to the effect that it shall be dependent upon the vote of the Association at the meeting there and then held.

Mr. Graeff—I think that Mr. McDonald forgets that when he was a young man, and used to go out with one of his best girls, and a girl that would occasionally eat ice cream, and he had to press her occasionally to take some, and she refused, and he would say, “I saw you take some a few evenings ago with some other fellow,” then she would go. But if he had a girl that made it a maxim of her life that she wouldn't eat ice cream, she wouldn't go, and he was better off.

Mr. Cantine—I have the honor of belonging to an Association that at its annual reunion follows the policy of paying for its own banquet. It is the custom of all the towns where the reunion is held to provide a hall and all the facilities for having a meeting, but they don't give us a banquet, nor could they do so. Now, you will find that this will militate greatly against this Association after awhile. You will have exhausted all the hospitality there is. This banquet feature will place every company in a bad position. It will, first, have to tender a banquet, then you can decline or accept as you please—you will find there will be no failure to accept—so I think we had better place ourselves on an independent basis. Mr. McDonald represents a big Albany Company and sees no objection to doing these things; but the poverty-stricken gentlemen belonging to this Association find it a little hard on them. Now,

in our case, I have told you just how we stand and there would be no hardship. (Laughter.)

Mr. McDonald—I presume it is well known to all the members of this Association that the New England Association always pay for their banquet wherever they are. They always have one at mutual expense. I think \$3 per plate is their price. A very moderate amount of wine is furnished at these banquets, and every member feels it no hardship to pay the assessment.

Mr. Wilkiemeyer—The resolution offered does not prevent the Association from furnishing itself a banquet. It can do that.

Mr. McDonald—Suppose a dozen gentlemen in a town should organize and want to give the Association a banquet. Would this prevent the Association from accepting it?

Mr. Wilkiemeyer—The resolution says “local companies”—the gas companies. Now, if we go to a manufacturing center where we have half-a-dozen meter manufacturers, we would have no scruple at all about taking a banquet from them.

Mr. McDonald—I am ready to vote for the resolution. (Laughter.)

[The resolution was voted upon and adopted.]

Mr. Penn—Mr. President, I move that the next meeting of the Association be held at Zanesville, Ohio. [Adopted.]

Mr. Printz—I would say to the gentlemen that we have good hotels. Traveling men will confirm what I say in regard to the leading hotel of our place. We have quite a number of places of interest that we will be pleased to show to the members after they have finished their business meeting. I thank you.

Mr. Graef—How is the water there?

Mr. Printz—The water is muddy.

INTRODUCING THE NEW MEMBERS.

The President—Gentlemen, as the Secretary calls the list of new members I wish they would be kind enough to rise in their places and answer to their names.

(Thereupon the Secretary called the roll of new members, and as their names were called they rose in their places.)

The President—Gentlemen, I hardly know whether to introduce you to the old members or the old members to the new. I can say we are glad to receive you, and we welcome you to the privileges of the Association of which you are now members, and trust it may be a matter of mutual profit to us all.

(On motion, the meeting adjourned.)

SECOND DAY—AFTERNOON SESSION.

QUESTION-BOX.

The President—I think we will open our question-box. The first query is: “*At what point in the works is the best place for the exhaust-er?*” This is a matter I have heard quite earnestly discussed very recently, and I think we should be able to get some information that perhaps would be of value to us all.

Mr. Hyde—The exhauster at both of the works—the old and the new—at Cleveland, precedes the condensers; that is, it follows right after the retort house.

The President—You interpose no special apparatus between the exhauster and hydraulic main?

Mr. Hyde—At the old works we have a tar extractor or tar scrubber. At the new works there is nothing.

Mr. Evans—We have the exhauster within 30 feet of the hydraulic main—nothing intervening between the exhauster and hydraulic main.

The President—At the works with which I am connected that is substantially the case. We have a tar scrubber in the line between the exhauster and hydraulic, which is the only interposition.

Mr. Hurlburt—In Oberlin we tried it both ways. In the old works we had the exhauster beyond the condenser, and in the new works about 10 feet from the condenser. We don't calculate to have very much tar in our hydraulic mains; only water. It works a great deal better on the new plan than on the old. We have a reservoir in which the tar lodges, and we draw it off from that.

The President—I will inquire of Mr. Hurlburt if he notices any particular difference in the action as to the different points at which it was placed?

Mr. Hurlburt—The difference is in the condition in which we get our gas to the purifier. In using it now next to the hydraulic we have no trouble.

The President—The second question is, “*In a lighting territory covered by illuminating gas and the incandescent electric light, which seems to be in the ascendancy?*”

Mr. Hyde—At Cleveland gas has the ascendancy.

The Secretary—I think that at Columbus, in the territory covered by both our gas and the Edison incandescent electric lights, the gas bills amount to more than the electric light bills.

Mr. Booth—I will ask Mr. Butterworth whether they did not occupy that territory before the electric light company did?

The Secretary—Yes, sir; that would be the case in almost any city that has the incandescent light.

Mr. Penn—I don't think the Edison company is a competitor of the gas company.

Mr. Cantine (addressing the President)—What is the case in your city?

The President—Mr. Hyde has stated the case very fairly, and I don't know that I could add anything to it. The statements he made would perhaps be a little more true on our side of the river than on his. We are the smaller part of the city—a sort of attachment—separated by a geographical line in the shape of a river. I think the electric lighting there is relatively smaller than it is on the other side of the river. In fact, I don't know of an instance of incandescent lighting there, and the population is perhaps 80,000.

Mr. Cantine—My judgment, Mr. President, is that gas is largely in the ascendancy in all the smaller towns and cities. In cities with 15,000 or 20,000—at any rate, the smaller cities of 8,000 or 10,000 or 15,000—I think gas will always be in the ascendancy, and I doubt whether any company could maintain a plant for any great length of time with the incandescent light solely. They are difficult machines to handle. It is difficult to keep the energy at one thing. As far as some of them are concerned, the cables are so large that it makes the capitalization so great that they can't get their money out of it. I think in the smaller towns few of us have any apprehension of being smothered by the incandescent light. It is true the arc light will be used for lighting streets. It is a large light, and a very brilliant one; but I think there is no apprehension that the electric lamp will hurt us. We have in our town a little opposition, but it is growing less each month. In very many of the business houses they have gone back to gas, until there are only a few now using the electric light.

The President—I will read another question. It is in the same general line, and has been called for by a member who has to leave soon. It is this: "*What system of electric lighting is best for adoption by gas companies?*"

Mr. Penn—I would ask what the question means; whether it means incandescent or arc system, or some particular make of machine.

The President—Manifestly the question is of systems, as between the Edison, the Thomson Houston, the Brush, and Westinghouse. That would be my interpretation of it.

The Secretary—That is mine. It seems to me, Mr. President, that that system which would be best for adoption by an incandescent electric lighting company would also be best for adoption by a gas company; and since Mr. Penn has expressed the opinion that the Edison is hardly to be considered a competitor of gas, it must be some other system than the Edison. We will eliminate that, then.

Mr. Penn—I would say the reason I do not consider the Edison a competitor of the gas company is because it costs too much to install a plant to cover any considerable area. We all understand that—it has been discussed thoroughly before. Of course, other systems come in—the alternating system—which covers a large area, and they can run at a less expense than the Edison. That is the reason why I say the Edison is not a competitor of gas companies. While they give a good light, yet the expense of running is too great, especially where they have cheap scales, as in Columbus. As far as the other systems are concerned, I found out, when I was investigating as to what system to buy when that competition commenced with us, that they all had the best system—like the woman with the sewing machine. They all have the best sewing machine. It is pretty hard to say which is the best system.

The Secretary—But you would say it would be a high tension system.

Mr. Penn—That is the kind I would buy, if I bought.

The President—The next question is, "*Does a fine gas of 23 to 25-candle power help check the invasion of the incandescent electric light?*" Now, what are the opinions of those who have had experience in that regard? I would suggest that Secretary Butterworth could perhaps give us something on that score.

The Secretary—It would be hard to make a 25-candle power coal gas at Columbus that would not smoke. One would suppose that, theoretically, a high candle power gas would have a tendency to check or retard, in a measure, the invasion of incandescent electric lighting. Yet I have been told that in those cities where the candle power of gas is

highest, the incandescent electric light seems to thrive as well as in cities where the candle power of the gas is lower.

Mr. Graeff—I certainly think that a high candle power gas is one of the best means in the world of checking the incandescent electric light.

Secretary Butterworth—How about the progress incandescent electric lighting is making in Baltimore, Mr. Graeff? They have a high candle-power gas there.

Mr. Graeff—I am too good a friend of Frank Hambleton's to answer that question.

Mr. Evans—In my judgment the incandescent electric light has its field just as much as gas has, and there are people in certain manufacturing business, perhaps, or offices, who would pay a larger price for incandescent electric light than they would for gas. Some complain of the heat. Others say the electric light is preferable on account of its convenience—no matches, no danger of fire, touch a button and your light is ready, touch another one and it is out. I know that in Jackson, in trying to win back a very large consumer of the incandescent electric company, they wouldn't have anything to do with gas whatsoever, because a few years ago they had a fire. It is a very large dry goods store, with drapery goods largely, and a few years ago some lace happened to get into the gas flame and ignited, and the loss was some \$35,000. They were willing to pay a larger sum for incandescent electric light, and in fact refused to have anything to do with gas whatsoever. I think that condition exists more in large cities than in small cities. I don't think incandescent electric lighting is progressive in small cities at all. In fact I think it is going down hill. But in larger cities, where they can afford to pay for the luxury and convenience of it, I think it is advancing. I know it is in Chicago, and I made a great many inquiries in that direction.

The Secretary—But a high candle power gas would have a tendency to check it, even in large cities.

Mr. Evans—I believe so; yes, sir, with canvassing back of it.

Mr. President—The fourth question is, "*Should we not confine the work of our Association to the important interest it was established to promote, viz., gas lighting and the manufacture of coal gas?*" Now, we have some here who manufacture something besides coal gas. It would seem we ought to be able to bring out some points from this question.

Mr. Hyde—From the reading of this question two constructions could be placed upon it. It says "Gas lighting and manufacture of coal gas." Now, if it had said, "Gas lighting and manufacture of gas," it would be all right; or "coal gas lighting and manufacture of coal gas." As it reads we don't exactly know what the writer intended.

The President—May be that ambiguity was placed there purposely.

The Secretary—The question is ambiguous; but I think the author's idea was that technical light papers, or technical water gas papers should not be encouraged here.

Mr. Hyde—What was the object of this Association? Did it read "Coal gas" or "Water gas?" Was water gas left out?

The Secretary—The constitution simply says "Gas." The object of this Association was to be the "promotion and advancement of knowledge, scientific and practical, in all matters relating to the construction and manufacture of gas works, and to the manufacture, distribution and consumption of illuminating gas, to the end that its cost may be cheapened and its consumption increased."

Mr. Hyde—I would say we ought to do just what this question calls for—confine our work or the work of the Association to the important interests of manufacturing gas. I think that is what we are here for, and I think we should not be talking or discussing anything else than the manufacture of gas and things pertaining to it. We should not discuss railroads, or anything of that kind, but only the manufacture of gas.

The President—The next question has already been partially anticipated. It reads: "*Are cast iron pipes better and cheaper than wrought pipes for gas mains of two to four inches in diameter?*"

The Secretary—A manufacturer of cast iron pipes in Columbus said, when I showed him this question, that he would not recommend a 2-inch cast iron pipe, although he was a cast iron pipe manufacturer; that the tapping of a 2-inch cast iron pipe weakened it, and it was liable to break, etc. Even as to 3 and 4 inch pipes, it was a question with him whether cast was any more durable than wrought.

Mr. Penn—He was not interested in wrought iron?

The Secretary—He is a cast iron pipe manufacturer.

The President—I see Mr. Ranshaw here. In talking with him this morning he gave a little account of some purifying boxes made of sheet metal rather than of cast iron. I wish he would repeat, for the benefit

of the members, what he said to me; and perhaps he can add to that.

Mr. Ranshaw—I alluded to some wrought iron purifying boxes that had been in use not less than 20 years, and which are still in use. They were made out of, I believe, $\frac{1}{2}$ -inch boiler plate—the sides and bottom, if I remember rightly, are three-eighths—and the water seals are made in the ordinary way. These boxes are in use now in the Cumberland gas works. A number of others (smaller ones), 6 and 8 feet, were shipped to different parts of the country.

Mr. Penn—Mr. President, I would ask if wrought iron pipes will not rust out quicker than cast iron from the alkali of the soil? Some soil has more alkali than others. Does not that have an effect upon the wrought iron which it does not have upon the cast?

The President—I think all of us have noticed the difference in the life of wrought pipe according to the soil in which it is placed. For instance, I think Mr. Hyde could give us an account of the very rapid deterioration of pipe laid in a certain locality. We also know that many times a service pipe meets with disaster, and what causes the difference seems almost incomprehensible, but we generally find there is a made soil there—an ingredient in it or something that accounts for the change, if we investigate carefully. The same is true of natural soil, and there is no question that there is a vast difference between a sandy, gravelly soil and a clay soil, with reference to the life of wrought pipe. The life of a cast iron pipe has perhaps hardly been determined in the gas business. Some original pipes are still in the ground and come out all right on latest investigations.

Mr. Penn—What kind of soil is the hardest on pipes, clay or sandy?

The President—Well, my own idea of the thing is that a pipe will last longer in a clay soil, as a rule.

Mr. Penn—That is my experience.

Mr. Hyde—At Cleveland we have had a peculiar experience. At Newburgh, where the rolling mill has been in operation for 30 years, wrought iron service pipes will not last more than a year or so. They are eaten right through. Where there is ashes or coke dust, or pieces of coke, or refuse from a furnace, or anything of that kind, to make contact with the iron, it is very quickly eaten through. At Newburgh, in the eastern part of our city, all the service pipes are now laid in and covered with lime. We take a little trough, put something in it to hold up the pipe, pour it full of water lime, and then plaster it all over so that it is perfectly covered. That preserves it. I don't think I am mistaken in saying otherwise they will not last more than a year until eaten through. Cast iron is not affected that way. I think, as a rule in our city, that we would not wish to use wrought iron pipe of any size for mains. All our services are of wrought iron and, ordinarily in the sand, we experience no particular difficulty; but when we get into some place where ash or coke dust is found, as in Newburgh, we have to protect them. In the ordinary sand they will last apparently an indefinite length of time. We used to lay 2-inch cast iron mains, but it is useless to lay a 2-inch main. It is too small to be tapped. Our smaller mains, as a rule, are 4-inch, and we lay water works weight—a heavy weight—so that we can tap them with impunity. We don't cover our mains—that is, they are not coated with tar.

A Member—Is it not the sulphur that eats through those service pipes?

Mr. Hyde—I think so.

A Member—Wouldn't the use of oxide in your purifiers have the same effect on them that the ashes and stuff would on the service pipes that you speak about? You spoke about your purifiers lasting so long; do you use lime in them?

Mr. Hyde—Yes, sir.

A Member—Any oxide?

Mr. Hyde—No, sir, I think not.

A Member—Well, if you used oxide they wouldn't last any time.

The President—I would like to ask Mr. Hyde if possibly this condition in Newburgh may not be due to the fact that the iron works are located there?

Mr. Hyde—I think the whole atmosphere is filled with this sulphur gas—all the deposits and rain and everything are filled with it. The ground is permeated with these particles of combustion from the coal. One hundred tons of fuel are used every day in the mills at Newburgh.

Mr. Penn—They manufacture copperas, using sulphate of iron?

Mr. Hyde—Yes, sir.

Mr. Penn—That will destroy the iron very rapidly.

Mr. Cantine—Mr. Hyde has spoken about the difficulty of making a good tap in a two-inch main. We find no difficulty whatever in doing that, by the aid of a little device which we use. (Mr. Cantine here described his device.)

The President—I would say that in our experience we have found

more difficulty from the fact that the pipe is very much weakened—a three-inch pipe especially. It has been a long time since I have put in anything larger than an inch hole, and I dislike to do that. With the disturbances that come from water and sewer connections and the like, we find that very frequently a three-inch pipe is broken where it is tapped, no matter how thick it is. Even if tapped on the thick side of the pipe, the pipe is liable to be broken. Our 7th question reads, "Does it pay to coat gas mains with coal tar?"

Mr. Hyde—We do not think it advisable to coat gas mains—they last long enough anyhow, but there is another objection with reference to coating gas mains. Do not order your mains tarred at the factory where they are made, because if you do you will regret it. You perhaps all know that at the foundries where they coat the water mains, they dip them, and that coats the socket and the spigot—the whole main—inside and out. I suppose you all know that the gas puts the tar coating in such a condition that it will run. It finally is disintegrated, runs down into the bottom of the mains and flows on as far as it can and stops up everything. More than that, in pouring a lead joint, the hot lead melts the tar and the tar rises or comes to the top. The last lead that enters the socket holds that tar there—it is not simply a thin coating at the upper part of the bowl, but a thick quantity—the joint is driven up, and after a space of time, say six months or a year, the gas operates on that tar, liquefies it, and it runs out, and you then have an open joint. We had a most unfortunate experience of this kind. We laid a 24-inch main and a 16-inch main that way, and I suppose in the course of two years every joint had to be made over or caulked up. We had to dig down and cut the tar out, and then drive the joints up again? Through $1\frac{1}{2}$ miles of 24-inch pipe, and two or three miles of 16-inch pipe, I suppose every joint has been gone over the second time; and we thought it of so much consequence that in speaking with foundry men we say, "Don't ever dip a pipe for a gas main. If he orders a pipe dipped, tell him you will not do it, because if he is not posted he will get posted before he gets through with it, and you had better post him beforehand." We have taken some pains to advise foundry men not to dip pipe for gas men. Perhaps you all know about this, but if you don't, you had better regard it, or you will have experience that you will regret. We have had all we want of it.

Mr. Penn—I would like to ask if that applies to wrought iron pipes?

Mr. Hyde—It does not apply to wrought, because wrought iron is made with a thread.

Mr. Penn—I mean without coating on the outside. Will they last forever, like cast iron?

Mr. Hyde—No, sir; the wrought iron pipe ought to be coated. A mixture of red and white lead, I suppose, would be the best of anything. That seems to be indestructible and everlasting.

The President—What Mr. Hyde has stated with reference to the joints of tar-coated cast iron pipe I can indorse as true and worthy of the most careful consideration. Our Company has not so extended an experience as Mr. Hyde's people, but we have had all we want. On one occasion we had to put in some tar-coated pipe. We did not cut out, as Mr. Hyde describes, the joints in the first instance—that is, the upper part of the joints, where there is a kind of spongy mixture, more or less lead and tar. As it boils up there it forms a kind of porous condition of the lead, and you may caulk it up and within a year you must do it again; and if it were not cut out it would keep on doing that.

Mr. Hyde—I did not say we cut it out; we drove it up.

The President—Did not you find it necessary to take something out there?

Mr. Hyde—No, sir; we drove it up. We have latterly driven a heavy chisel in. We find it easy to do, and put a big wedge into the top of every single one of these pipes. Whenever we open them now we resort to that as a means of saving another opening.

(To be continued.)

Public Street Lighting in New York.

E. G. Love, Ph. D., Gas Examiner for this city, recently prepared the following interesting paper on this subject for the *School of Mines Quarterly*. Doctor Love wrote:

The first attempt to light the public streets of New York with gas was made in 1823, when a contract was executed with the newly organized New York Gas Light Company. The contract granted to the Company the exclusive privilege, for a term of 30 years, of supplying gas to that portion of the city lying south of Grand street. The cost of each public lamp was not to exceed the amount paid for 1 oil lamp. This contract expired by limitation in 1853, and another one was made for a period of

1 year. It was similar to the first, except that the exclusive right to the territory below Grand street was omitted, and the price to be paid for lighting the lamps was fixed at \$15.47 each per annum for 2,300 hours, with a corresponding increase in price for any extension in the number of hours.

The practice up to this time had been not to light the lamps on moon-light nights, but late in 1853 the Common Council directed that the public lamps should be lighted on every night of the year. This increased the number of hours of lighting to 3,833, and the cost of each lamp to about \$25 per annum. The number of hours lighting remained at the figure given until 1879, when it was increased to 4,000, and has been without change up to the present time.

Some 10 years after the introduction of gas lamps in the city, the Manhattan Gas Light Company was organized, and in 1833 obtained a grant and contract to light that portion of the city lying between Grand street and Sixth street, the same to continue for 20 years.

Owing to the rapid growth of the city, an extension of the lighting system became necessary. To this end the existing contract with the Manhattan Company was cancelled in 1848, and another one made for a period of 20 years, in which the territory was extended to Forty-second street. As in the former contract, the price per lamp was fixed at \$15 per annum for 2,300 lighting hours, or \$25 for 3,833 hours. This second contract was cancelled by mutual consent in 1865, and for the 8 years following the city's streets were lighted under short contracts or none at all. During most of this period the gas companies, profiting by a decision of the Court of Appeals, charged \$53 per lamp per annum.

In the years 1855, 1858 and 1868, the Harlem, the Metropolitan and the Mutual Gas Companies, respectively, entered the field, already sufficiently well filled, and received their grants to tear up the city's streets, under the mistaken idea that an increase in the number of companies and the amount of capital invested would give the consumer cheaper gas.

The amended city charter of 1873 authorized "the Commissioner of Public Works, in conjunction with the Mayor and Comptroller" (commonly known as the Gas Commission), to make contracts for lighting the streets, avenues and places of the city with gas, but limited the contracts to 1 year. Under this Act contracts were made for the year 1874 at greatly reduced rates, which have continued up to the present time.

For convenience in connecting the public lamps with the gas mains, the Gas Commission was authorized in 1878 to determine when the year for the lighting contracts should commence, so that now all contracts for lighting the public lamps date from May 1st to the April 30th following.

The contract prices in 1888 were \$17.50 per lamp by the Consolidated and Mutual Companies, and \$12 by the Equitable Company. In the case of the latter Company, the franchise fixes the price given as a maximum. Companies lighting the public street lamps beyond Harlem river receive \$28 and \$29 per lamp.

The first movement looking to the public lighting of New York by the electric light was a resolution adopted by the Common Council in February, 1879, requesting the Gas Commission "to have experiments made to test the practicability of lighting" the streets and parks of the city with the electric light, and to determine the relative cost of gas and electricity for this purpose. As the experiments were to be made without expense to the city, nothing was done under the resolution.

Early in November, 1880, however, the Brush Electric Light Company asked permission to erect lamp posts on Broadway, from Fourteenth street to Thirty-fourth street, for the purpose of demonstrating the suitability of the electric light for street illumination. This request was granted, and on the 15th of January following 22 arc lamps were lighted by the Company, and continued without expense to the city until the 1st of June. While these lamps were far from perfect, the experiment promised sufficiently well to warrant the Gas Commission in making a contract with the Brush Company. Fifty-five lamps were lighted under this contract, at the rate of \$7,400 per annum.

Another contract was made with the Brush Company for 1882, and also one with the United States Electric Illuminating Company. The price paid by the city was 70 cents per lamp per night, or \$255.50 per annum. This continued to be the price up to May 1, 1887, the number of lamps being increased each year. Thus, on the 31st of December, 1882, there were 128 electric arc lamps in use; in 1884, 647 lamps; in 1886, 711 lamps; and in 1888, 1,328 lamps.

Previous to 1887 the contracts were awarded to the two companies already mentioned; but a number of new companies now entered the field, and the contract price in 1887 varied from 19.9 cents to 50 cents per lamp per night. The prices paid in 1888 varied from 32 cents to 60 cents per lamp per night, the average being 35.2 cents.

To arrive at the comparative cost of gas and electric light for street illumination we may take the years 1885 and 1888—in the former the price being 70 cents per lamp per night, while in the latter it averaged 35.2 cents.

The number of gas lamps replaced by each electric light will naturally be subject to some variation, but the average, based upon the introduction of a large number of electric lights, is $4\frac{1}{2}$ gas lamps for each electric lamp. At the close of 1885 there were 708 electric lamps in use, equivalent to 3,185 gas lamps. The cost of the electric lamps at \$255.50 each, on the supposition that no reductions were made for extinguishments, would have been \$180,894. The price paid for the gas lamps replaced was \$17.50 each per annum, and if to this we add \$1.60 for supplies, etc., we obtain \$19.10 as the cost of each gas lamp, or \$60,852.60 for the total number of lamps replaced. The lighting by electric lamps, therefore, cost \$120,041.40, or 66 per cent. more than would have been paid for the less brilliant illumination by gas.

On the 31st of December, 1888, there were 1,328 electric lamps in use, at the average price of \$128.48 per annum, or a total cost of \$170,621.44. They replaced 5,976 gas lamps, costing, with supplies, etc., \$19.14 each per year, or a total cost of \$114,380.64. In this case, where the prices charged for both gas and electric lamps were about as low as we may expect to see them—for the present at least—the excess in cost of the electric lamps over the gas lamps was \$56,240.80, or about 33 per cent. It is therefore apparent that whatever may be the advantages of the electric light over the ordinary gas lamp for street illumination, we are obliged to pay liberally for these advantages; and it becomes a question to what extent it is desirable to replace gas lamps by the more intense but less reliable electric lamps at an increase of one third in cost.

As showing the demand for this greater illumination, it is interesting to note that in 1885 the Common Council passed various resolutions requesting the Gas Commission to light certain streets and avenues with the electric light. The Superintendent of Lamps and Gas estimated that had it been possible to comply with these requests it would have taken over 2,000 lamps, costing \$526,840, and have replaced gas lamps costing \$89,862.50; an excess in cost of the electric light over the gas lamps of \$436,977.50—more than one-half of the entire appropriation for public lighting.

As regards comparative illumination, it is not necessary to say that the electric light is much superior to gas; indeed, in New York the street lighting by gas is not what it ought to be. The first contract made with the New York Gas Light Company, in 1823, specified the burner to be used as one capable of passing 3 feet of gas per hour; and while repeated efforts have been made to increase the capacity of the burner to 4, 5, or 6 feet per hour, we are, in this respect, precisely where we were more than 60 years ago. And yet during this period the candle power of the gas supplied has been nearly doubled; so that to-day our street lamps give a light of from 10 to 16 candles for 3 feet of gas.

In the early days of electric lighting it was commonly said that the ordinary arc lamp gave a light of 2,000 candles, but such is not and it never has been the case. The arc lamp gives less light horizontally than in a downward direction, and when these lamps were first put upon the market some one measured, or, more probably, estimated the intensity in a horizontal direction at 500 candles, and then, to make a good showing, multiplied it by 4, making the 2,000 candles. While the 500 candles was pretty clever guessing, there was no good reason whatever for multiplying it by 4 any more than by 360.

As the amount of light thrown upon the walk and roadway is of more importance than that emitted in a horizontal direction, the present city contracts with the electric light companies require that the lamps shall give a light of at least 1,000 candles at an angle of 40° below the horizontal. Measurements which have been made of the lamps of some of the companies give from 1,300 to 500 candles.

Of late an attempt has been made by one of the gas companies to introduce a large regenerative gas burner—the Gordon—for street illumination. It has been tried on parts of Fifth and Madison avenues, and Forty-ninth and Fiftieth streets, with very satisfactory results, and without expense to the city. An arrangement was made to light Lenox avenue, from One Hundred and Tenth street to One Hundred and Twenty-ninth street, with 75 of these lamps, during the month of December. The expense of this installation, however, which is \$5 per lamp per month, will doubtless prevent its extension.

The recent extinguishing of most of the electric lamps, and the consequent darkness on many of our thoroughfares, calls public attention especially to this subject of street lighting, and shows the importance of keeping the gas lamps in a condition for immediate use, certainly until the electric light has become more thoroughly domesticated.

Thwaite's Gas Fired Boiler.

The boiler herewith illustrated is being introduced by the Gaseous and Liquid Fuel Supply Company, of Liverpool, Eng., and is the invention of Mr. B. H. Thwaite. The cut shows a 30-horse power steam generator designed to be heated with gaseous fuel, such as producer gas. The gaseous fuel is generated in a Thwaite gas generator, but the latter can be placed immediately below the steam generator. Where there is a series of these boilers it is advantageous to generate the gas in separate vessels.

The gas ascends into a vertical combustion chamber A, meeting a supply of air issuing radially and uniformly from air tubes B, at the level of which combustion ensues, the flame flowing upward inside refractory tube C, which becomes heated to bright incandescence. The flame passes over the upper edges of this combustion tube C, and descends the annular space D formed between the flue plate and tube, the ring of flame being in close contact to the water-covered surface of tube. The combustion is completed in the annular chamber E, which is provided with a secondary air supply by means of the radially-placed air tubes F. The gaseous products of combustion ascend through the tubular part of the generator G into the upper chamber H, when they are diverted and directed downward around the inverted tube I, around which they circulate in contact with the steam-covered surface of the boiler flue plate, superheating the steam and enabling the full practicable absorption of the sensible heat from the gases of combustion to be obtained. The arrows clearly show the direction of flow of gases to the chimney.

It will be seen that the maximum temperature and the flame combus-

tion is next to the water-covered surfaces, only the products of combustion with their sensible heat being next to the steam-containing portion of the generator. It will also be noticed that practically all the heating surface is vertical. The circulating arrangement of this generator is most simple and effective. An annular ring or curtain J is provided, dividing the ascending and descending currents. The latter flow next to the outer casing, sweeping the tube-plate and flowing with great velocity over the surface of the combustion flue. The velocity of circulation is such as to prevent the deposition of any calcareous material, all that is required to maintain the internal heating surfaces free from scale is to blow off the boiler once a week. The perfection of combustion enables the boiler to work without the necessity of cleaning the tubes. The rate of evaporation can be maintained almost absolutely constant. The boiler is provided with Heffner's safety Popp valve, which was tested at various pressures up to 95 pounds to the square inch in this boiler, and gave satisfactory results.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE proprietors of the Hoosick Falls (N. Y.) Gas Light Company have determined to reduce the net selling rate to \$2 per 1,000 cubic feet.

AT the annual meeting of the Royal Electric Company, of Montreal, Canada, the following officers were elected: President, Hon. J. R. Thibaudeau; Vice-President, W. J. Withall; Directors, the officers and Messrs. G. R. Robertson, E. A. Small, J. A. Strathy, W. Cassils and F. L. Beique. While the financial reports submitted were "generally considered satisfactory," we have it on good authority that the balance sheet shows no evidence of very pronounced earnings. Further, it would be rather strange if it did, since the local Gas Company's good and cheap gas seems to be in great favor with the residents, even though the city authorities are willing to strain a point—if not more—in favor of aiding and abetting the electricians in respect to the public lighting.

WE are informed that the Cincinnati Gas Light and Coke Company has arranged for the construction of a large gasholder, to be located at the corner of McMillan and Church streets, in the Walnut Hills district.

A SUIT that is attracting considerable attention in Philadelphia is one brought in the local Court of Common Pleas, (No. 2), by A. H. McNeal, the pipe founder of Burlington, N. J., against the Director of Public Works (Gen. Wagner) for \$50,000 damages "for defamation of character and injury to complainant's business reputation and credit." The suit, according to our local advices, is based upon a remark said to have been made by Director Wagner when, on the fifth of last November, he rejected a bid for gas pipe tendered by McNeal. This particular bid was considerably lower than that of any other tender submitted in the competition, and when it was opened the Director ordered that it be thrown aside, at the same time remarking, "This bid will not be considered, because this man McNeal has committed a criminal offence in altering a city contract which was awarded him some time ago." Our authority then goes on to say: "In explanation of what the Director meant, Richard P. White, counsel for Mr. McNeal, says that on March 5th, 1889, McNeal was the lowest bidder, by several thousand dollars, on a very large contract for gas pipe, the task of delivering which was to commence at once, and to be completed on the 1st of July following, under a forfeiture for delay. The contract was awarded to Mr. McNeal, who was notified by Chief Engineer Park, on the 7th of March, of the award. He answered at once that he was ready, but would not furnish any pipe until the contract had been signed. He wrote repeatedly to urge the preparation of the contract papers and finally, after they had been delayed over two weeks, he notified Director Wagner that he would not sign the contract unless there was included in it a provision extending the time for the delivery of the pipe for as long a time as the papers had been delayed, or for a release of the forfeiture. The Law Department, at the close of the month sent him a blank form of contract, before signing which Mr. McNeal inserted the clause upon which he insisted. The form thus signed, but unsigned by any one else, was returned to the Department of Public Works. Director Wagner refused to sign it with the clause inserted by McNeal, and ordered the pipe from the firm of R. D. Wood & Co., under a contract to have the pipe delivered by November 15, at a cost said to be \$2,005.29 more than the same pipe would have been delivered by McNeal, before August 1, if the Director had allowed McNeal for the delay claimed. Of course, it must be remembered that the foregoing is but a reflex of the opinion of Mr. McNeal's attorney, and take it all-in-all, I fail to see wherein the

Director has not the best of the thing all the way through in the matter of a plain business proposition, for I fail to see where Mr. McNeal could justly think himself entitled to alter a contract, the specifications of which were under the framing of the city authorities. At this point, however, one must cease to defend General Wagner, in so far as anything detailed above can be construed in excuse of the remark attributed to the General, that McNeal had committed a criminal offence. It, however, is but another instance of how far an irascible temper may embroil a man; and it may be taken for granted that Director Wagner is not over-choice sometimes in choosing words expressive of his dissent. I might be forgiven, too, for remarking that it is almost time he arrived at the knowledge that the language of the camp is not best suited for the expression of a business verdict.—QUAKER.”

FIFTY new passenger coaches, to be lighted by the Pintsch system of compressed oil gas, have been contracted for by the New York Central & Hudson R. R. Co., to be delivered at an early day.

IT is probable that Manchester, Va., will be lighted with gas in a few months. In any event, the scheme for the construction of a gas plant there has been revived, and one of those most prominently identified with the resurrection is Mr. John C. Robertson, General Manager of the Southside Land and Improvement Company.

THE Paterson (N. J.) resident whose monthly consumption of gas aggregates 5,000 cubic feet or upwards is to be granted a certain rebate from the present net price. The Gas Company will also institute a system for the regular inspection of consumer's burners, fixtures, etc.

THE proprietors of the Kansas City (Mo.) Gas Light and Coke Company have filed plans for the construction of a brick, boiler and engine house, to be located at 25th street and "State Line," the estimated cost of which is \$40,000.

THE residents of Everett, Mass., are clamoring for the right to operate an electric lighting plant on town account. They now pay \$90 per annum each for arc lights, and \$18 for incandescents (16-candle power), on a lighting table (moon-schedule) that ends at midnight.

THE Gas Lamp Committee, at a recent meeting of the Wilkes-Barre, Pa., City Council, submitted a resolution providing for the abandonment of all public electric lights, and the substituting therefor of gas and naphtha lamps. This proposition created quite a stir in the meeting room, and Mr. McCartney was quite pronounced in opposition to the measure. He thought that Wilkes-Barre would be disgraced in the event of its casting out electricity, and that no Alderman could give any good reason why such a course should be adopted. Mr. Lavin thought that Wilkes-Barre could not afford to bankrupt itself for the sake of maintaining electric lighting; and that the present system was decidedly inefficient. Again, if the system was to be followed it would have to be extended, since it would not do to make fish of the residents of one Ward and flesh of those in another. Mr. Long, on behalf of the electric light suppliers, said the rates charged were not excessive, and that the service was fully up to standard. Mr. Mahoney thought the city ought to be equally well lit in all of its divisions, and was decidedly opposed to having electric lights in one Ward and naphtha lights in another. He thought that an improved system of gas lighting would be acceptable to the citizens; not only so, but that it would be far cheaper than the present hybrid plan. Mr. Lavin said that under the present conditions one-third of the city absorbed three-fourths of the lighting appropriation. When the debate was closed, by means of a motion to lay the report on the table, the latter was determined on by a vote of 10 to 9. A pretty close shave for the electricians; but not so close as they may look forward to in the near future.

ALTHOUGH the figures would indicate something of the imposing order, we imagine there is more of buncombe in them than of real value, which opinion is advanced in connection with the suit of Col. James M. Clark, who asks for the appointment of a receiver for the Michigan Gas Company (nominal headquarters at Detroit), in a suit begun in the Circuit Court. For the transfer of Ohio rights and the franchise for the right to use the streets of Detroit he alleges that the Company was to give him \$30,000 and one-sixth of its stock. As they are said to have transferred \$2,500,000 in stock to the Interior Construction Company, he wants the matter looked into.

ACCORDING to the Indianapolis (Ind.) *Journal*, the Electric Lighting and Gas Heating and Illuminating Company, of that city, has filed

notice with the Secretary of State of its intention to extend and enlarge the objects of the Company, so as to include the business of mining, drilling, sinking and operating wells for natural gas, petroleum and minerals. This Company, which is the successor of the three corporations that recently operated the Indianapolis Gas Light and Coke, the Citizens and the Natural Gas Companies, is incorporated by Messrs. C. E. Benedict, Chas. F. Dieterich, E. J. Jerzmanowski (New York), and Messrs. Henry Decker, S. W. Pray and H. E. Pickett, of Indianapolis. The *Journal* intimates that Mr. Pray will be appointed Secretary, that Mr. Decker will act as Cashier, and that Mr. Pickett will act as General Manager of the natural gas plant.

A "VOTER," in writing to the Rutland (Vt.) *Herald*, says: "Below is a sample of how villages are deceived regarding the cost of putting in electric light plants, to be operated on municipal account, and Bangor (Me.) is selected as the instance. Its city charter enables it to use certain water power. Assuming this power to be sufficient, an estimate was made of \$17,000 to equip the city with a plant of its own, and afterwards \$3,000 was added for contingencies, whereupon the city committed itself to the scheme. The lowest bid received, however, was reported at \$26,000. The water power was found inadequate, requiring a steam plant in addition, costing \$5,000, and an additional \$10,000 is now required to make the plant answer the city's needs, or in all, \$41,000, as against the estimate of \$20,000 on which action was first based. Do the taxpayers of Rutland want to be burdened with more taxes for a wild scheme of this kind?"

REFERRING to the opinion of Assistant Corporation Counsel Darrow, of Chicago, in respect to the right of the city to regulate the price to be charged for gas by the various gas companies doing business there, it is found that his adverse decision rests on the basis that, while the City Council would without doubt have power to prescribe by any ordinance, giving to any gas company the right to use the streets, terms and conditions upon which such right could be exercised, it would not have power to control the charges of gas companies to private individuals when no conditions were imposed at the time of granting the right to said companies to occupy and lay their mains in the streets.

WE are called on to record the death of Mr. Thomas Earle, at one time a prominent figure in business circles in Jersey City, N. J. Deceased, who was in his 91st year, had for years acted as President of the Jersey City Gas Light Company, and when in control of its fortunes managed them judiciously. He had been City Treasurer for 15 years, and had been a member of the Board of Aldermen for 10 years. He was also Vice-President of the Hudson County National Bank.

THE Philadelphia Gas Improvement Company, of which W. L. Elkins, Jr., is President, is the corporation that is interested in the recent grant for a works to supply gas in the suburban Chicago towns of Cicero, Oak Park, Harlem and Austin. A plant with a capacity of 1,000,000 cubic feet per day is talked of; but this is probably a trifle, if not more, in excess of the real mark.

THE Iron City Gas Light Company (capital, \$5,000) has been incorporated at Pittsburgh by Messrs. J. B. Griggs, W. M. Cooper, J. M. King, H. L. Trees and J. H. Young.

THE proprietors of the Brattleboro (Vt.) Gas Company have decided to add a 650-light Thomson-House incandescent type dynamo to their present arc lighting outfit.

THE 2 per cent. dividend declared by the Citizens Gas Light Company, of Wakefield, Mass., is now payable.

MR. LINCOLN HAMMETT has resigned the position of Superintendent of the Warren (R. I.) Gas and Electric Light Company.

THE plant addition to generating house of the Spencer (Mass.) Gas Company, now in process of construction, will enable the Company to deliver 40,000 cubic feet of gas per diem.

AT the annual meeting of the Consumers Gas Company of Newburgh, N. Y., the following Board of Directors was chosen: Joseph H. Berry, Detroit, Mich.; O. H. Lawrence, Fitchburg, Mass.; and Capt. John C. Adams, Isaac L. Corwin, and Benj. McDonald, of Newburgh.

THE offices of the Birmingham (Ala.) Gas, Electric Light and Power Company have been removed to 1805 Second avenue, which change will greatly tend to the convenience of its customers.

OWING the large increase in its business, the Berlin Iron Bridge Company, of East Berlin, Conn., has made important changes, both in the instance of its officers and in the details of its business. Mr. Burr K. Field, who had served it as Vice-President and Treasurer, resigned the latter office, and Mr. F. L. Wilcox, of Berlin, was named to the vacancy. The new Treasurer was formerly Manager of the Kensington factories of the Peck, Stow & Wilcox Company, and is well and favorably known throughout New England as a brisk and safe financier. Mr. Field will devote his entire attention to the constructing department, which has of late years assumed very large proportions—its sales last year amounted to almost a million of dollars. All the other departments will, as heretofore, be under the direct supervision of the President and Chief Engineer, Mr. Charles M. Jarvis, ably assisted by Mr. Mace Moulton as Consulting Engineer, and Mr. S. W. Bowles, Jr., as Superintending Engineer. The Company's specialty, in which gas men are most interested, is its improved system of iron roofs for retort houses, etc.

THE Directors of the Lowell (Mass.) Gas Light Company have chosen Mr. George W. Farnham to succeed the late Oliver E. Cushing as Agent. This appointment is one that does credit to the proprietors of the Company, in that it is the promotion of a man who has for years faithfully served the corporation in lesser capacities. That he will fill the bill is beyond doubt, for everything committed to his care in the past was completed in honest fashion. We congratulate Mr. Farnham, and the Company, too.

MR. J. L. HALLETT, of Springfield, Mass., is on his way home from a few weeks outing, chiefly spent in Colorado and California. He is in robust health, is as bright as a button, and will soon be heard from again in connection with the gas business.

MR. E. A. VAN HORNE has been elected Superintendent of the Oswego (N. Y.) Gas Light Company.

THE proprietors of the Whitehall (N. Y.) Gas Company have leased the old Martin sawmill with the intention of installing therein an electric lighting plant.

THE Wilkes-Barre (Pa.) Council, at a special meeting held to consider the matter of awarding a street lighting contract—mention of earlier action in the premises will be found elsewhere in these columns—rejected the proposition to abandon electric lighting, and substitute gas therefor. A compromise resolution was agreed to under which the city will maintain 49 arc lights, at the rate of \$135 each per annum, and 180 or more gas lamps, to cost \$20 per annum each. This is a reduction of \$4.50 per annum on each electric light from the last contract rate; the gas rate remaining substantially the same. The contract is to run for a year, from first inst.

FROM a Montreal correspondent we have the following: "The annual meeting of the Gas Company was held on the afternoon of the 3d inst., and was largely attended. President Jesse Joseph occupied the chair, flanked by his astute understudy, Manager J. F. Scriver. The reports, which show how prosperous the Company is, were read and accepted, after which Mr. Joseph submitted to the shareholders a proposition to issue \$500,000 of new stock, and a resolution to that effect was unanimously adopted. The stock is to be called at the discretion of the Directors, and quite likely one-half will be emitted now, the other half to be called towards the close of the summer. This issue will bring the company's capital account to \$2,500,000, and the proceeds of the sale of the new stock will go to meet the loans made in improving the property and increasing the plant capacity during the last six years. The most important business, however, that was transacted was an announcement that from and after May first the price of gas was to rule at \$1.40 per 1,000 cubic feet. The retiring Directors were re-elected by acclamation. In conclusion, I might remark that the meeting was a most harmonious one."

"DEAR Journal:—About the most extraordinary thing in connection with current events in New England gas politics is an application for the incorporation of an opposition gas company at Marlboro, Mass., which town is, in all sincerity, just about big enough to enable the present Company to exist. Marlboro's citizens are a not over-liberal set, and I have no doubt that they can tell to a mill just what the value of a penny is. Under the circumstances, then, if the citizens happened to be the only factor in the case, it might be a good thing to advocate the licensing of the opposition company in order that the citizens might be called on eventually to pay the cost of the fight. On the other hand we are confronted with the fact that as the old

Marlboro Company has kept its promises it should be protected. This is where the State Commission will have a chance to show its capacity for protecting invested capital from the attacks of malice; and it is quite an open secret that the opposition attack at Marlboro has its inspiration—well, not from any desire to benefit Marlboro's mill-counters. The putative officers of the new company are: President, Hon. W. N. Davenport; Treasurer, E. L. Bigelow; Clerk, Frank Wall. Another bit of news is that the Springfield Company is likely to lose the lighting of the engine houses. The electricians are willing to do the work for \$800 per annum, as against the Gas Company's charge of \$1,300. The light-of-the-future suppliers say that 20 incandescent lamps of 16-candle power each will amply light each engine house—there are 8 of these in the city—but I am inclined to think that at least 24 lamps of this power would be required to light the houses with anything like a satisfactory result.—OBSERVER."

IT is pretty well understood that General Hickenlooper has so managed it that all the electric lighting enterprises in Cincinnati—save, possibly, the Queen City Company—are under control of the Cincinnati Gas Light and Coke Company. The names of the electric companies absorbed are: The Cincinnati Electric Light Company, the Brush, the Cincinnati Electric Light and Power Company, the Thomson-Houston, the First Edison, and the Edison General Electric Company. It is needless to say that the General dictated the terms.

THE Pottstown (Pa.) Light, Heat and Power Company has been awarded a contract for the public lighting of that place, arc lights to be employed. The contract is to run for three years.

THE Municipal Electric Light Company, which has the contract for the public lighting of St. Louis, expects to begin service under the agreement on or before the 21st.

THE conference committees from the Troy (N. Y.) Gas Company and the Troy Electric Light Company, appointed for the purpose of agreeing, if possible, on a rate or sum for the transfer of the property of the latter to the former, have been unable to solve the problem. It is reasonable to assert, however, that an agreement will finally be reached.

THE authorities of Stockton, Cal., and the local Gas Light and Heat Company have settled their differences in respect to a contract for the public lighting, which is of the electric type. The rate agreed on is \$13.75 per month for each arc burning on moon-table; also, the city to pay 7 cents per hour for each light that is kept burning any time in excess of the hours provided for in the schedule.

OUT of a total of 9,629 meters inspected last year by the Government of Canada, only 198 (or 2 per cent.) were rejected as outside the correct limit in respect to fast measurement. On the other hand, those reported slow were returned at 5.8 per cent.

THE street gamins of New Albany, Ind., have been amusing themselves so greatly of late in smashing the glasses of the gas lamps in that city that Superintendent Dunbar has been obliged to offer a reward that will lead to the conviction of any of the offenders.

MR. W. W. DASHIELL, has resigned from the service of the Bayonne and Greenville (N. J.) Gas Company to accept an important position with an extensive manufacturing establishment in Birmingham, Ala.

IT is likely that the Annapolis (Md.) Gas Company will build a new works.

THE offices of the East Chester (Mt. Vernon, N. Y.) Gas Company have been removed to the Cardner Building, First street and Third avenue.

MAYOR NEMES has signed a 5-year contract with the Atlanta (Ga.) Gas Company under which the latter is to put up and maintain 50 gas street lamps in the suburb known as the "West End."

AT a recent meeting of the Directors of the Bristol (Pa.) Gas Company it was ordered that the price of gas be reduced from \$2 to \$1.60 per 1,000 cubic feet, the new schedule to take effect on May 1st. This looks like business. The Bristol folks will also make a determined effort to popularize the use of gas for cooking.

THE Scranton (Pa.) Gas Company is improving its system of distribution, especially on the Main street division.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889,
For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. The Gas requires NO PURIFICATION. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE. Works under our system can be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon. One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

GAS vs. ELECTRIC LIGHT.

We would invite attention to the able and exhaustive argument of General A. Hickenlooper, President of the Cincinnati Gas Light and Coke Company, contained in a handsome pamphlet of 96 pages, entitled

"EDISON'S INCANDESCENT ELECTRIC LIGHTS FOR STREET ILLUMINATION. REPORT OF AN ARGUMENT DELIVERED BY A. HICKENLOOPER BEFORE THE COMMITTEE ON LIGHT, MUNICIPAL COUNCIL, CITY OF CINCINNATI, JULY 22, 1886."

This is a subject of special interest to all Gas Light Companies.

PATENTS.

FRANKLIN H. HOUGH

Solicitor of American & Foreign Patents.

925 F. ST., WASHINGTON, D. C.

(NEAR U. S. PATENT OFFICE.)

Personal attention given to the preparation and prosecution of applications for Letters Patent. All business before the U. S. Patent Office attended to for moderate fees. **No Agency in the United States possesses superior facilities for obtaining Patents**, or for ascertaining the patentability of inventions. Copies of patents furnished for 25 cents each. Correspondence solicited.

THE NEW HANDY BINDER.

This article may be described as elegant in appearance, strong, durable, and possessing many special qualities of its own. It allows the opening of the pages perfectly flat, whether one or several numbers are in the binder. Any number can be taken out and replaced without disturbing the others. The papers are not mutilated for subsequent binding in permanent form. The binder is supplied with gilt side title, and is an ornament to any desk or reading table. The JOURNAL, filed in the Handy Binder, becomes a volume of great value, always convenient for instant reference. **Handy Binder, Postage paid, \$1.00.**

Sugar House Work, and Special Castings of all Descriptions.

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per	24 hrs.,	3 ft. square,	5 ft. deep.			
No. 2,	"	125,000	"	"	4 "	"	"	"	"
No. 3,	"	250,000	"	"	5 "	"	"	"	"
No. 4,	"	500,000	"	"	6 "	"	"	"	"
No. 5,	"	750,000	"	"	7 "	"	"	"	"
No. 6,	"	1,000,000	"	"	8 "	"	"	"	"
No. 7,	"	1,250,000	"	"	9 "	"	"	"	"
No. 8,	"	1,500,000	"	"	10 "	"	"	"	"
No. 9,	"	2,000,000	"	"	12 "	"	"	"	"
No. 10,	"	3,000,000	"	"	15 "	"	"	"	"

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

Brenner Self-Sealing Retort Door.

WILLIAM B. LUNDIE, Superintendent of the 42d Street Station of the Consolidated Gas Company, of New York, writes, under date of Jan. 4, 1889:

"We have 320 Brenner Self-Sealing Lids in use at this Station, built by the Smith & Sayre Mfg. Co. They require very little attention, and are the best of the kind that I have seen, giving entire satisfaction."

GENERAL SALES AGENTS FOR

The Youghiogheny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogheny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

No. 40 St. Enoch Sq., Glasgow. No. 2 Talbot Court, London.

Proprietors of the BATHVILLE COLLIERIES (which produce the celebrated BOGHEAD CANNEL), Shields, Shieldmuir, Drumpeller, and other Collieries. This Firm offer

STANDARD CANNELS,

Unequaled as Gas Enrichers.

Also, WEST FAIRMONT GAS COAL, of W. Va.

“SUN DIAL” GAS STOVES,

The Most Economical, Efficient, and Durable Gas Stove Made.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Ex-
37 in. high.	12 in. high.	12 in. high.	24 in. long.	tension Shelves,
20 in. wide.	17½ in. wide.	15 in. wide.	21 in. wide.	36 in.
	12 in. deep.	13 in. deep.		

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast iron door.

All Fittings are Nickel-Plated.

“RADIANT” BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 8 inches high. Consumption, 6 feet per hour at 1 in. pressure.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Ex-
31 in. high.	9½ in. high.	10 in. high.	21 in. long.	tension Shelves,
17 in. wide.	14½ in. wide.	15 in. wide.	16 in. wide.	32 in.
	12 in. deep.	13 in. deep.		

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. ½ in. supply pipe should be used where the pressure is 1 in. or over.

[OFFICIAL NOTICE.]

Western Gas Association.

SECRETARY'S OFFICE, WESTERN GAS ASSOCIATION, }
QUINCY, ILLS., April 9, 1890. }

The Thirteenth Annual Meeting of the Western Gas Association will be held at St. Louis, Mo., on the 21st, 22d and 23d days of May. The Lindell Hotel will be used as our headquarters on this occasion.

The usual reduction in transportation rates has been secured and the necessary certificates for obtaining the same will be mailed to our members on or about the 10th of May.

On the 15th of February the Special Committee on the Assignment of Papers assembled at St. Louis for the purpose of choosing subjects and assigning authors for the same. It is a pleasure to state that the responses to the requests of this committee have, in almost every instance, been favorable. The Association can, therefore, rely upon the fact that the paper contributions to the Thirteenth Annual will be of a high order of merit. The list will be announced in these columns later on.

It gives me great satisfaction to be able to say to the members that the Executive Committee has decided upon a plan for the holding of an exhibition, on a large scale, of gas apparatus of all descriptions, the display to continue during the three days of the meeting. The exhibition room is located on the third floor of the new office building of the Laclede Gas Light Company, which room, besides being capacious and well lighted, is easily accessible on account of an excellent service of passenger and freight elevators. Beyond a doubt the members of the Association will recognize in this a most graceful and serviceable act on the part of the officers of the Laclede Company.

Although "The Western" contains on its lengthy membership list the names of a large number of executive officers of the gas companies that are embraced within its territory, the fact still exists—and it is a painful one—that there still remain a considerable proportion of our Western and Southern companies who have not yet sent delegates to our annual reunions. It is the intention of the Secretary to send a circular, calling attention to the great good accomplished by Gas Associations generally, to the President of each and every company that still remains unrepresented on our roll book, accompanied with a request that he shall send his Superintendent to our St. Louis meeting. These circulars will be issued at an early day, and will be mailed to every gas company President from the Alleghenies to the Rockies, and from the Great Lakes to the Gulf. If any of our members, or those who are contemplating becoming members, can lend a helping hand in this movement, they will confer a favor upon the Secretary. Application blanks and copies of our by-laws will be mailed to those who desire them.

A. W. LITTLETON, Sec'y.

BRIEFLY TOLD.

THE WESTERN'S THIRTEENTH ANNUAL.—Our readers no doubt have read with interest the current official notices now being printed in our columns over the signature of Secretary Littleton, respecting the Thirteenth Annual of the Western Association, which gathering is eagerly looked forward to, not by its own membership alone, but by almost

every gas man who is compelled by stern necessity or the travail of business to reside east of Chicago. At the outset, however, one's desire to foretaste the privileges and profits and pleasures of the coming convention at St. Louis, is lessened, in that a somber pall hangs dimly between the Association's last tryst and the one soon to be brought off, in that its President-elect—the lamented and esteemed E. J. King—having been called to "Sleep the sleep that knows not waking," will not sound the summons to duty. But in their grief his confreres may seek and surely find solace if not comfort in the knowledge that his example lives with them to stir them on to closer union in upholding the trusts committed to their care. It is also comforting to know that the reins that fell from the master's hands were grasped by one in every sense qualified to use them rightly in their capacity for direction. From the Secretary's notice it will be seen that he comes out in characteristic manner in the frank admission that the Special Committee on the Assignment of Papers has admirably answered the purpose for which it was formed, and we have from him the further satisfactory knowledge that those who were "named" by the Committee have not sought to evade the duty imposed on them. It is this spirit of union that has made the Western Association what it is, and it may be well understood that under the guidance of such sustained impulses the Western is not to be the thing of a day. Mention of the Association's superlative Secretary recalls the fact that he has been sadly bereaved in the recent death of his father, whose failing frame succumbed on the 12th inst., at his home in Lincoln, Ills. It is true that the senior Littleton had carried the burden of eighty years of life, but the burden seemed to rest so lightly that those nearest him imagined that more of life was to be his. We mention this, apart from our desire to tell the Secretary's friends of his bereavement, to follow it with the remark that despite his personal cares at such a time he still finds space wherein to prepare a herald of the coming meeting. We note with great satisfaction that the Executive Committee has determined upon an exhibition of apparatus connected with the manufacture, distribution and consumption of gas, and that said exhibition is to be held in the elegant and capacious lofts over the newly-finished offices of the Laclede Gas Light Company. Perhaps Egner may be said to be largely responsible for this determination—that is, in the matter of holding the exhibition—and it is certainly a most graceful act on the part of the Laclede Company to offer a house location for the display. We hardly suppose that any necessity exists for us to recall to the minds of the manufacturers of gas apparatus the advantages, of a purely commercial character, that are to be theirs from a practical participation in this exhibition. Mr. Egner has full charge of the arrangements for the exhibition, and this is a guarantee that fairness and absolute impartiality are to rule in the management of the affair. Exhibitors need not remove their goods until such time as will best serve their convenience—which is an extra inducement, perhaps, in the case of those who will contribute bulky articles to the display. In fact, we hope that every one of our advertisers will figure in the exhibition catalogue and on the floor or shelves of the exhibition room. It will pay them handsomely, too. Perhaps we may be forgiven for anticipating somewhat the matter that will appear in Mr. Littleton's succeeding official announcements, but in any event it may be whispered about that the Lindell is to be headquarters, and that the Local Committee of Arrangements have outlined a plan for the entertainment of the members, in the matters of banquet and outing, that is superb almost unto lavishness. More complete details of the meeting programme will follow in later issues.

ANNUAL MEETING, BRIDGEPORT, CONN.—The stockholders of the Bridgeport Gas Company elected the following Board of Directors on the 15th inst.: Messrs. Wm. R. Higby, Wm. D. Bishop, S. C. Trubee, H. L. Clark, Wm. H. Perry, H. Nichols, S. B. Beardsley, Wm. B. Hincks, and A. C. Hobbs. The following officers were elected: Prest., W. R. Higby; Sec. and Treas., F. B. Sammis; Supt., C. A. Gerdenier.

ON TO WASHINGTON ONCE MORE.—That picturesque party named Ingalls, who represents Iowa in a Senatorial capacity, has introduced, "by request," a bill to authorize the Commissioners of Washington, D. C., to provide illumination "by gas, or electric, or other lighting system." In furtherance of that proposition they are "authorized to purchase the plant of the Washington Gas Light Company, provided it can be bought at what it would cost to duplicate it," the assessment or valuation to be "set up by five experts." The bill also provides that if the Gas Company declines to sell, then the Commissioners are to put in and operate an independent plant for the general supply of gas to the residents, "the rate which may be charged therefor to be not in excess of 10 per cent. over the cost of production and distribution." The bill

also appropriates \$1,000,000 for the promotion of the objects named. Is it not time that the Washington Gas Light Company ceased to be a mark for such arrows as this? Every session we are treated to a like sortie; but there is some satisfaction in realizing that so far the attacking parties have met with defeat, and there is even greater satisfaction in the belief that as it was with the others so shall it be with this.

ANNUAL MEETING, ROCHESTER, MINN.—At the annual meeting of the Rochester (Minn.) Gas Light Company the following officers were chosen: President, C. H. Myers, of Dubuque, Ia.; Vice-President, Thos. Hennessy, Grand Forks; Secretary and Local Manager, A. T. Stebbins; Treasurer, O. Mulcahy, Grand Forks.

NOTES.—The proprietors of the Kingston (Can.) Gas and Electric Light Companies have agreed upon a plan for consolidation. As soon as the arrangement is perfected a bid of 35 cents per night per arc (2,000-candle power) for all-night lighting will be submitted to the authorities. Under the ruling practice the city pays 30 cents for a midnight service.—President Geo. W. Morris, of the Louisville (Ky.) Gas Company, says that the demand for artificial fuel gas in that city is as yet not up to the expectations of the proprietors.—The proprietors of the Portland (Me.) Gas Light Company have arranged with the special money order agencies of the American Express Company for the collection of gas accounts. The points at which payment may be made are six in number, and were selected with especial reference to the convenience of the consumers. The fees for the service are as follows: On bills of less \$5, five cents; \$5 to \$10, eight cents; \$10 to \$20, ten cents. This plan, which is now in operation in several cities, is rapidly gaining favor.—A correspondent informs us that 109 arcs are in use by the city of Omaha, Neb., and then goes on to say: "In some places gas and electric lamps are burning during the same hours, but they are localities which the inspector has not been able to visit. According as he discovers that the electric lamps illuminate the vicinity he orders the removal of the gas lamps, and from that moment pay for them ceases. Thus far 309 gas lamp have been discontinued. At the rate of \$31 per year, which was the old price, the cost of these lamps for a year would be \$9,579. At the present rate, \$25 per lamp, the cost would be \$7,725. The 109 lamps which supplant the gas lights cost \$18,100.—The Rhode Island House of Representatives, on Wednesday of last week, debated the bill which sought to restrict the gas companies of the State to the manufacture of a gas containing not "more than 10 per cent. in volume of carbonic oxide, or any sulphureted hydrogen." The debate was rather lively, in that it was spiced with a liberal portion of personalities. In the end the bill was "indefinitely postponed."—At the annual meeting of the Chucatanunda Gas Light Company, of Amsterdam, N. Y., no change was made in the executive management. This is not to be wondered at, considering the fact that an 8 per cent. return was made to the shareholders during the twelvemonth.

The Market for Gas Securities.

During the week speculation or investment demand for city gas shares assumed something like activity, if not briskness. Consolidated, on fairly large transactions, moved up sharply, going in the early transactions to 97 $\frac{7}{8}$. From this point it sagged off, but at no time did it go below 97, and to-day's opening transactions (that is, Friday) were made at 97 $\frac{1}{2}$. We look forward to a near crossing of the par line, and with no idea that a long stop will be made at the minimum three-figure quotation.

Other city shares are stronger. In Brooklyn the market appears to be all in favor of the holder, and the tone is undoubtedly in line with still higher prices. The reason for this state of affairs in Brooklyn is to be found in the bald truth that the Edison incandescent lighting supply is a failure, utter and complete. Frugal Brooklyn counts the cost of everything that it uses, and its verdict seems to be that gas is cheaper and better than Edison incandescent electric lighting.

Chicago Trusts are up to 48 $\frac{1}{2}$, and the 50 mark will soon be scored. The Managers of the Company have prepared a plan which will lead it into perfectly safe paths; but as the meeting to fix the thing will be held next Thursday, it may be as well to say nothing about the outcome now. Laclede common is woefully weak, being down to 13. Bay State gas is mending, and we believe that at anything under 25 it is a purchase. Muller sold at auction last week 54 shares of Jersey City gas at 170. Baltimore gas is a trifle stronger, at 49 $\frac{1}{2}$ to 49 $\frac{3}{4}$. A marked feature of the day seems to be the neglect exhibited by investors over bond issues, which, in our judgment, are all too low in quotations. In the meantime it is certain that any gas stock which has something like a reasonable prospect does not have to wait long for a purchaser.

[OFFICIAL REPORT.—REVISED BY THE SECRETARY—CONCLUDED FROM PAGE 521.]

SIXTH ANNUAL MEETING, OHIO GAS LIGHT ASSOCIATION.

HELD AT THE BOODY HOUSE, TOLEDO, OHIO, MARCH 19 AND 20, 1890.

SECOND DAY—MARCH 20—AFTERNOON SESSION.

The President—The next question is: "*What is the average life of a meter in constant use, with ordinary good care?*" I don't think any one need to be afraid of discussing this matter on account of the meter men that are present. I only see one or two just now.

Mr. Hyde—I would like to hear some of the meter men state how long a meter will last.

Mr. Graeff—I understand that Dr. McFadden has a meter in a house near him that was put in when he was a small boy, and he is waiting to see how long it will last, in order to answer your question. (Laughter.)

Dr. McFadden—I am not a member of your Association, and I don't like to impose upon you.

The President—We will be very glad to hear from you.

Mr. McFadden—I have known a dry meter to last 30 years, and if you ask me the average life of a dry meter I should want to know what kind of gas you made; for it depends very much on the quality of the article which passes through it. If your gas is sulphurous, as you all know, you will have corrosive action. We had some meters sent to us for repairs, that were made by a competing house. I went to the party and said, "With this gas you can't get these meters made here, or anywhere else, to last." The trouble was in the character of the gas. It formed a filmy oil which, as the gas moved, spread out like thin soap bubbles and burst, and with that came the oscillation of the light. I think myself that the different qualities of gas that have been made in the last 20 years have affected the life of meters differently. In my earlier days we knew nothing but coal gas, pure and simple. I think meters lasted much longer then. We have had meters come into our "hospital," or repair shop, in which the leathers had become as hard as buckboard. The oil is thoroughly extracted by some drying or dessicating substance in the gas. Some are corroded; and there are various diseases of meters. It would take more than one doctor to classify them all. We, as makers of meters, have not the experience which you gentlemen have, with the use of them. We always recommend that you treat a meter very much like you would a man. Keep him in constant service and he will wear better and last longer and behave more accurately. I know we have what we call lazy Monday, and we hate to go to work on Tuesday, and if we have a lazy Tuesday it seems to grow. Constant use and proper care I should advise for every meter. What the average life to-day of a meter is I could not answer. I have known them to last 30 years—a dry meter. The unfortunate thing for the meter makers is that they last too long.

The Secretary—The patient public are under the impression that Mr. McFadden's advice is being heeded by the gas companies, viz., to keep the meters in constant use night and day.

Dr. McFadden—There are public fallacies as well as public truths.

Mr. Hyde—Mr. McFadden spoke of one meter lasting 30 years. Recently a Glover meter was taken out at Cleveland—no meters have come from England since '61, that is 29 years ago—that was set prior to 1860, and it is good yet, apparently as good as ever, as far as we could see. I may also say that I believe that 15 years would be a fair average.

Dr. McFadden—I would like to ask Mr. Hyde if he thinks the character of the gas has not a very great influence on it?

Mr. Hyde—That has a great deal to do with it.

Mr. Matt—How about the location of the meter?

Mr. Hyde—That has something to do with it. How it is cared for, and all about it.

The President—In discussing the life of a meter, I would call the attention of the Association to the following questions in the question-box:

"If a meter gets gummed and sticks—does not work free—what is the best remedy, without bad results to the meter?"

"Do meters, when out of order, work in favor of or against the gas company?"

"What temperature will a meter work best in, giving best results to all?"

The Secretary—In answer to the second question, I believe it is almost the universal experience that meters, when out of order, register against the gas company.

The President—Our consumers, I think, have an opposite opinion, and

if there is any good ground upon which we can make this answer to that question I think we ought all to have just as much fortification as we can get. I presume each one works in his own way to that end. I hope this question will be discussed thoroughly.

Mr. Graeff—I think the only official record we have in this country is that made by the Massachusetts Commission which gives this answer—the answer made by the Secretary. I think the report showed that the meters worked slightly against the company.

The President—That, of course, is something we can place implicit confidence in.

Dr. McFadden—I think that every State inspection shows that the meter, when out of order, registers in favor of the consumer. There is one thing I would mention. Of course, no gentleman expects to carry his watch beyond 12 months without examination for repairs and cleaning. Meters cannot get that attention. With 30,000 or 40,000 meters in a city, in a large place, they cannot receive that attention which you give to your watch. But for accuracy of registering I don't think there is anything in the world to-day that is measured more accurately than gas. There is not a meter leaves a factory that I know of that does not leave it under a sworn inspection. If any gentleman will place before his mind 1,728 cubic inches, and vary it 2 per cent. above or 2 per cent. below, and place those three blocks before him, I don't think he could select which was the 1,728 inches—the difference is so slight.

Mr. Penn—My experience is that it has been against the gas company all the time. In testing meters, once in a great while you will find one that registers a little bit fast. That is a sure thing. There is one thing I can't understand about meters. We get a new meter and the customer will quit using it and go away for a short time, and when he returns and tries to start it his gas won't work. It is dead. Yet it is comparatively a new meter. I don't see why it should be so. I would like the meter men to explain that. If it was an old meter it would be a different thing.

Mr. McFadden—I would like to know if the meter registered at all after setting.

Mr. Penn—It registered when it was first put in.

Dr. McFadden—In transit meters are liable, as other things, to accident; but it is very rare that we hear of accidents in transit. It is remarkable that so few are injured by transit, but some are. It may be set and started and this injury received in transit may become apparent afterwards. I think it comes back to a question of a deposit upon the valve, evaporation taking place by the non use, it becomes sticky and gummy, and the valve of the meter does not work right, or, if working, it leaks; and just in proportion to that leak so is the loss to the company.

Mr. Persons—The only remedy for a meter in that condition is for the valves to be cleaned. Send it to the shop and have those accustomed to that work do it.

Mr. Penn—Do I understand it is the valve that sticks, or the diaphragm?

Mr. Persons—The valve—a gummy substance forms on its face.

The President—I don't know who proposed the second meter question; but it would seem to be in the mind of the writer of the question that a remedy could be applied apparently without taking the meter away.

Mr. Persons—I think I just answered that question. I don't know of any remedy except to have the meter repaired.

The President—You answered in that way, but I apprehend the writer had an impression there might possibly be another remedy.

Mr. Persons—When you send a man out to repair a meter he usually shakes it first, and if he succeeds in loosening the valve there will be a ridge left on the face of it which would make the valve "rock." It would pass gas and register against the company. It is not safe to do it. It ought to be sent to the shop.

Dr. McFadden—I think one of the important elements in the use of a meter is thorough purification of the gas. Prevention is easier than cure. We all know, for instance, that is, all who have had experience in the management of gas works—at least such was my experience—that gas not well purified is very offensive. Skunks are certainly sweet alongside of it. I have no doubt that if gas was thoroughly purified that meters would last longer and work more accurately.

Mr. Printz—While on the question of meters I would like to ask Mr. Evans if he finds any more trouble with the use of blue gas—that is, do the meters give out any sooner in using blue gas than with the ordinary illuminating gas?

Mr. Evans—I do not think we have any more occasion to repair the meters in using the blue gas than we would with coal gas. During some 8 years' experience in the distribution of fuel gas I knew what it was to have to repair meters, but I think there is no danger to be apprehended

from that direction at all. I know that in passing the unpurified gas as we did at Lynn through meters, it acted upon them very quickly. In fact I have known a meter to be perfectly useless inside of six months.

The President—This question as to temperature has not been brought out. It would involve somewhat the best location for a meter.

Dr. McFadden—In answer to the question of temperature allow me to say this: The same law that applies to the human organism applies to all things in nature. We doctors speak very frequently of the vicissitudes of temperature and their influence upon the human organism. Every gas man knows, and my gas experience taught me, that we might run a retort to the melting point without its cracking or leaking, but we could not afford to freeze it without breaking it. Now, meters should not be placed where hot steam would strike them. It has an injurious influence. It contracts the diaphragm, and extracts the oil; and I should say this, that every man is best in an even temperature. He don't want a change of 20° degrees in 24 hours, either up or down; and so with meters. The meter should stay at an even temperature. The best location is the cellar, away from the heater. So that a medium temperature for man or meter, is a good thing.

The President—The 9th question is, "*Is not illuminating gas, of the requisite candle power, sold at a reduced price for fuel, the true solution of the fuel gas problem?*"

Mr. Graeff—This is a question that will take about 5 years more to work out.

The President—I don't suppose it will be solved right here. There may perhaps be some views that members might like to express which we would all be glad to hear. If no one has anything to say upon that we will pass to the next question, "*Which is the correct method of tapping mains, on top or at the side?*"

Mr. Printz—I would answer that question by saying tap on the sides, for two reasons. One is that you don't weaken your pipe by a side tap as you do on top. Another is, if there is any stoppage you can clear your pipe easier by having a straight line than running it out and down with an angle.

Mr. Hyde—That is exactly the opposite reason given by our Mr. Heath why he would tap it on top. He taps on top. He would not tap on the side, and if there is any water in the main it doesn't run out on top while it might on the side.

Mr. Evans—Mr. President, I believe the top of the main is the place to tap them. For instance, if tapped on the top, there is always room to swing your service pipe in any direction you wish. If tapped on the side it is rigid.

The Secretary—If a second-hand opinion will be of any interest, I will state that I asked Mr. Felt, the Superintendent of Distribution of the Cincinnati Gas Light and Coke Company, what his opinion was as to this question, and he said it didn't make a particle of difference, according to his experience, whether the main was tapped on top or side. (Laughter.) He said it depended altogether on the depth of the main. If deep, tap on top; if shallow, tap on the side.

Mr. Evans—I have always noticed that they begin to excavate for the service about the same time they dig down for the main, getting the trench all open at the same time, then the workmen take hold of the pipe, pull it around so as to get it in line, and in a great many instances strip off a portion of the thread.

Mr. Printz—I admit there is a freer chance to swing your pipe sideways, but don't you meet with the same difficulty up and down if you tap on top? You have your elbow in there. Now, we don't think of making a tap in the pipe until we have the trench long enough, so that we can drop in a straight edge with a level in it, and get the proper elevation.

The President—To my mind the top of a main is, all things considered, the preferable place. Doubtless there are many instances where convenience might dictate otherwise. I have no doubt that any gentleman here who has had any practical experience in laying service pipes could refer back to his own experience and find examples of both practices. But, as has been stated, it seems to me that the tapping on the top of the main is, on the whole, the more economical plan, and the more convenient, as well as probably removing some difficulties in the way of disturbances. There is a little item of elasticity in the elbow connection that does not exist in the direct side connection. Perhaps that does not account for much.

Mr. Penn—I don't think I could tap on top at all in our town. Our mains are only about 30 inches deep. We could not get under the curbing at all; hence we use the side tap.

A TELEGRAM.

The Secretary—The President has suggested that I now read a tele-

gram received from Mr. Emerson McMillin, whom you yesterday elected to honorary membership. The telegram is as follows:

"To Irvin Butterworth, Secretary Ohio Gas Light Association.—I never accepted an honor with greater appreciation than the honorary membership in the Ohio Gas Light Association. Present my compliments to the President and members, with my sincere regrets that I cannot be present at a meeting of one of the best working Associations in existence.—EMERSON McMILLIN."

The President—There is also a little routine business that should be attended to now. There are three committees to hear from. Is the committee on nominations ready to report?

Mr. Cantine, on behalf of the Committee, reported the following nominations:

For President and Vice-President, Chas. R. Faben, Jr., and N. Wilkiemeyer; *for Secretary*, Irvin Butterworth; *for Treasurer*, O. P. Taylor and Geo. W. McCook.

We also suggest that whichever candidate (Mr. Faben or Mr. Wilkiemeyer) receives the highest vote shall be President, and the other shall be Vice-President. We would suggest the propriety of electing Mr. Butterworth by acclamation, and of voting by ballot for all the other candidates.

Mr. Wilkiemeyer—Allow me to make the suggestion that we cast the unanimous vote of the convention for Mr. Faben as the next President of the Association.

Mr. Cantine—That is a piece of magnanimity on the part of the gentleman making the motion that he will hardly be entitled to exercise.

Mr. Wilkiemeyer—No, sir; I certainly have a good running mate, and I want him to come under the line first.

ELECTION OF OFFICERS.

Mr. Alexander—I move the rules of the Association be suspended and that the Secretary be instructed to cast the ballot for Mr. Faben for President for the ensuing year. (The motion was seconded, put and carried.)

Mr. Graeff—I make the same motion in regard to casting the ballot for Mr. Wilkiemeyer, for Vice President. (The motion was seconded, put and carried.)

On motion the President cast the vote of the Association for Irvin Butterworth for Secretary.

A ballot was then taken for the election of a Treasurer, which resulted in the election of Geo. W. McCook. On motion his election was made unanimous.

REPORT OF COMMITTEE ON PRESIDENT'S ADDRESS.

Mr. Printz, from the Committee on President's Address, made the following report:

The Committee on President's Address have carefully considered the very valuable suggestions offered, and, in as forcible a manner as possible, would ask the members of the Association to carefully read and work out these suggestions, in the course of the year, to the very best results.

One suggestion in particular should be acted upon at once—*i. e.*, as to the Legislative Committee. This Committee should have definite instructions. It should closely look after all interests appertaining to the welfare of the gas industry, and give its attention to difficulties as they come up, and as they are brought before it. The expenses which this Committee may incur in the fulfillment of its duties should be paid by the Treasurer out of the funds of the Association. As to the scope of its powers the Committee alone should be the judge.

Respectfully submitted, EUGENE PRINTZ, }
H. WILKIEMEYER, } Committee.

Mr. Matt—I move that the report of the Committee be accepted and made a matter of record.

The President—Gentlemen, the report of the Committee is before you for your adoption or rejection, and I trust you will give it as careful consideration as the circumstances may permit. Are there any remarks?

Mr. Printz—Mr. President, Mr. Foote is here. He has given this matter considerable attention, and I would like him to make such remarks as he may feel disposed respecting this question.

The President—I think, perhaps, we had better dispose of the other matter first.

Mr. Printz—I think the information he would give us would probably assist us in determining what disposition we should make of this matter.

Mr. Wilkiemeyer—I think it would be best to discuss this question somewhat. It may be possible that we do not see the need of this Legislative Committee. Now, if we are better informed as to our needs, we may come to some definite conclusion. It is something that requires

thought, and then as we understand each other, the different members of the Association will know what best to do. I think Mr. Foote could give us a very good idea of this subject.

The President—A motion is before the house, but the vote thereon may be foregone, if there are no objections. As I said before, I had a desire to listen to Mr. Foote, and am glad to see him present. Mr. Foote, as you all know, is Chairman of the Committee on Legislation, of the National Electric Light Association. If there are no objections to deferring the vote upon this question, we will defer it, and I will invite Mr. Foote to make some remarks upon the subject of municipal control.

Mr. Rood—The motion before the house seems to be to receive the Committee's report and place it on file. This does not prevent us from afterwards taking up that report and discussing any recommendations they may make. It seems to me that it would be entirely proper to receive the report and then hear from Mr. Foote, or any other gentleman, upon the recommendations of the Committee.

On motion the report of the Committee was received and placed on file.

Mr. Foote, on invitation of the President, then made the following remarks :

Mr. President and Gentlemen:—Perhaps I can serve you best by offering an outline of my connection with this subject of legislation. A year ago, at the convention of the National Electric Light Association, the question was discussed of the municipal ownership of electric light plants. As a result of the papers read at that time a resolution was adopted creating what we term the "National Committee on Legislation," of which I was made Chairman. No instructions were given to that Committee. I was authorized to appoint one member for each State in making up the National Committee. The first object in view was to collect from each State all the bills that were offered in the Legislature of the State, and the discussion had on them, with a view of having them ready to be used in any other State. The plan of work as laid out was on this line—that I, as Chairman of the National Committee, should be furnished from each State with copies of all the bills that were introduced in the Legislatures, and the discussions had on them, with the objective point of having them ready to transfer to any other State where a similar question would come up, so that we would not be constantly threshing out the same old straw in the attempt to get at least some of the questions settled. As soon as we commenced to look into the subject we found there was a very great difference in the laws of each State, between the statutes touching the questions governing electric central station companies; that is, the general question of franchises, rights and powers of local councils over the action of the Company; the way of fixing prices; the way of making up contracts, and all these questions. In fact, every question of legislation that affects a central station company is either a question of State or municipal legislation. In order to unify the electric interests so they could work for their State, we instituted a movement to organize State associations. The membership of these State associations is confined exclusively to operating companies, and they are supposed to look after the legislation in their own States, being assisted in their work through the work of the National Committee. There are 10 or 12 of these State associations now organized. There were 10 in February. So far as the policy of having a Committee on Legislation is concerned, I hardly think there can be two questions about it. All this subject of legislation has to be gone through with by every company, more or less, in some phase or other, every year. The experience that is gained is what you might term a by-product that you now let go to waste. A company has a struggle with a local council over a question of renewing a contract, over a question of price, or something of that kind. When that comes up, if they have not the means of laying their hands on the information that had been brought out in similar struggles elsewhere, they are at a disadvantage. These questions occur all through the United States. If the company having a case in hand would make a record of its own case and transmit that record to the Committee on Legislation, in the course of time the chairman of that Committee would be in possession of data and facts and arguments that would meet any case that would come up, because there is a very great similarity in these cases. They follow a certain rut. To give you an illustration: Last Saturday I received a letter from a certain gentleman saying a town meeting had been called to take a vote on establishing a municipal plant, and wanted all the information he could get on the subject. I was able to send that party pamphlets containing the arguments made in four different States on that subject. At the cost of 25 cents for postage I furnished him arguments that would have cost him \$500, if he had to pay for them. They really cost more than that in the first place in attorneys' fees. I simply state that to show you the workings of this Committee. It can

be carried on with very little expense, and to very great advantage. So far as giving instructions to the Committee is concerned, I do not think the Committee need any instructions. I think the general understanding is that the Committee is to take cognizance of all questions that affect your interests in the line of legislation, whether that legislation be municipal or State. Any one of you having a case in hand should report it to the chairman of that Committee and advise, work with and aid him—the State Committee becoming a sort of a Committee on arbitration between each company and its local authorities. That is the outline on which we are working. Of course the work is still in its infancy. We have not accomplished very much, and still we have got sufficient results from it now to know its value.

So far as the question of municipal ownership is concerned I think there is more agitation going on and more work being done in the direction of trying to institute public plants than most of you are aware. All of the professors of political economy, so far as I know, of the universities, are favoring that issue—some to a greater and some to a less degree; but I think they all favor municipal control as a proper economic measure for the people; and, so far as I know, every professor of political economy who favors municipal control also favors free trade.

Last week I received a letter, from the Secretary of the Board of Transportation of New York city, that has in it quite a full detail of that city. They wanted all the data I could give them on the subject of municipal control of electric light plants and gas plants. I judge this information is being collected to favor the ownership of these plants by the municipalities. Of course, you are all aware of the extent of the Nationalist movement in that direction. They have clubs now in almost every State, and in almost every important city in the States. They are devoting their entire work to that line of development. They are making the move now to introduce a petition in the Massachusetts Legislature, with 200,000 signatures, asking for a general law of that State, authorizing the towns to erect gas and electric light plants. They have a petition before Congress to have the District of Columbia authorized to do so. They are working it in Cleveland. They are working the same thing in Minneapolis; and so all over the country that movement is being carried on. It is a very popular movement, of course, among the wage earners and laboring people, and it will spread and have a great deal of influence. I think the best way to meet that question is through State organizations. I believe to-day that the condition of the electric light and gas companies of Massachusetts is in better shape, and that they are better prepared to meet such issues than in any other State in the country, on account of that State Gas Commission; and, personally, I favor the creation of State Gas Commissions and Electric Light Commissions to take control of that subject. I don't know how familiar you may be with the Massachusetts law, but the short of it is that it creates a commission of three men, with a clerk, to devote their entire time to the work. They act as a Board of Arbitration. If there is any dispute between the local company and the local authorities either one can appeal to this Commission as a board of arbitration, and the decision of the board is final. They set themselves against rate competition, and against competition in the business. Where there is one company in a town, and that company is in shape to perform the service in that town, they do not give their permission to any other company to enter into business in that town. That is, in my opinion, a sound economic condition, and I think you could do no better than to institute your committee on legislation, and simply give them general instructions to look after your legislative interests in every detail and every particular. Then you must remember that they can do nothing whatever unless you cooperate with them. If each company in the State should send to the chairman of that Committee every case that is brought against them, every complaint they have to make, and every complaint that is made against them, with the action taken against them, so that the matter can be made a matter of record, so that it can be preserved and used, in the course of time you will have something that is very valuable to you indeed. It will be a record that will be satisfactory to any legislature or any council, or any board of fair-minded business men competent to examine such questions. I am obliged to you for your attention.

Mr. Graeff—Mr. President, I would like to ask Mr. Foote to give us some outline, if he will, of the manner in which these State associations of electric lighting companies work. It is very probable that it will become expedient, in the eyes of this committee of ours, to recommend the formation of some similar association of the gas companies of this State. I would like to ask Mr. Foote to give us an outline of how these State electric light associations work, so that we may be familiar with it in case the question should come up.

Mr. Rood—I would say a State association has been formed of the electric light men in Ohio, and the organization met last week in Col-

umbus. Hence the electric light people operating plants in the State of Ohio, independent of gas companies and with gas companies, have an association and also have a committee to look after legislation. It was brought about because there was legislation proposed before our Legislature that was going to do a very serious injury to electric light companies, if allowed to pass.

Mr. Graeff—Yes; this State association is simply one of the associations formed under this National Committee, of which Mr. Foote is Chairman. There are 10 or 11 others through the country, and I wish Mr. Foote to explain that plan for the benefit of the gas companies.

Mr. Foote—They are all on a uniform basis, as they admit to membership only operating companies. If a gas company is operating an electric light plant, it is admitted to membership. The tendency has been to make the initiation fee very small. It runs from \$5 a year to \$20; I think it would average \$10. To enable a company to become a member of the association an act of the company would be required—a resolution passed by its board of directors—then any member of that company, any officer or regular employee of the company, can represent the company in a meeting of the association. In fact, all the officers and all the employees of the company, if they choose, can attend the meeting; but they would have to designate some one of their number to cast the vote for the company, so that there would be but one vote by each company. To provide for the finances, an assessment is authorized to be made, which varies from one-eighth to one-fourth of one per cent. of the capitalization. In the State of New York, however, that is changed to \$1 on each horse power employed by the company. In case a gas company is a member, the assessment only applies to that part of its investment which it is using in the electric light business. This assessment is subject to the order of the executive committee of the association. So it gives them the means of raising a fund, if they have use for it, without waiting to call a meeting of the association, or without much delay. They can simply have a meeting of the executive committee, order an assessment, and collect the funds. So far as my observation has gone (and I have been present when eight of these associations were organized), there has been no disposition at all to hold back in the matter of finances. A proposition was made in the State of Massachusetts of making the assessment one-eighth of one per cent. Forty companies were represented at the meeting when the organization was effected, and authority was given the executive committee to raise this assessment from one-eighth to one-sixth of one per cent. by people who had not been what might be called workers of the association—showing that it was popular, and not brought about by those who had been instrumental in bringing the association into existence. You will see that varies somewhat from your Ohio Gas Light Association, because you admit members who are not engineers, but manufacturers, and who have interests other than the simple, direct interest of producing gas with profit from a plant. We are now considering a move to bring all these State associations into federation as a National association. That will be our next step, which will be considered during the next six months. We propose to continue the work of organizing State associations until we get a State association in every State, and then probably we will follow the line of the State commissions as being our best protection in the matter of legislation. That matter, however, has not been brought out before the association in any way for public discussion.

Mr. Rood—In what respect do the laws of Connecticut and Massachusetts differ?

Mr. Foote—Well, I can't answer you technically. Massachusetts has control of the companies through a commission which gives each company protection in its town against any infringement from an outside company—what we call "raiding companies." If I am rightly informed, in Connecticut any body of people can go to its Legislature and get a charter to do business.

Mr. Rood—A charter would have to be gotten through the Legislature instead of the State officers.

Mr. Foote—Yes, sir; I think so. I have a copy of the law under which the Massachusetts State law is operated which I could read, that would give you full outline of the points that we are talking about.

Mr. Evans—I would like to ask Mr. Foote if this power given the Gas Commission of Massachusetts to prevent the introduction of any other company into a city where one is already doing business has not been very recently conferred on them. I was not aware they had any such power.

Mr. Foote—The Act creating this Commission was passed in '85, I believe, and it has been amended several times. I can't tell whether this power was conferred by the original Act or whether it is an amendment; but it gives them supervisory power.

Mr. Evans—I was aware they had considerable power over the gas companies, some of which is a little expensive to the companies. For instance, every gas company there is obliged to keep its accounts according to the form devised by the Gas Commission. They must show in detail on these accounts every pound of coal and every gallon of oil they use, every pound of coke they sell; in fact, every expense in detail must be shown, including the salaries of their officers and the dividends. It makes public the company's business all over the State. All you have to do is simply to get a report of this Commission, which anybody can get by writing for it. I have written for it myself and received it. So that it not only makes your business public throughout the State, but all over the country, for that matter. I understood their power consisted only in obliging companies to manufacture their gas within certain limits, as to a certain per cent. of carbonic oxide that was allowed, a certain amount of sulphur and ammonia, and a certain standard of illumination.

Mr. Foote—I think that 90 per cent. of the companies in Massachusetts, if asked to-day, would say that the Gas Commission is a very great benefit to their business, and they would prefer to see it continued rather than discontinued. That is the information I have from those in that State whom I have come in contact with.

Mr. McDonald—I think, Mr. Chairman, that Mr. Evans is slightly mistaken. The matter he speaks of in regard to carbonic oxide, ammonia and sulphur, are matters of law in the State of Massachusetts. They are, possibly, in some measure under the control of the Commission; but these are matters of State law, and were established before the Commission was established. They are now agitating in the Legislature there a law which will permit of more carbonic oxide in the gas made than is now allowed in Massachusetts. I only speak of this to correct this misapprehension which he had in regard to where these limitations came from.

Mr. Graeff—Mr. President, I think that the Massachusetts law originally covered what it covers to-day in regard to the admission of new companies.

Mr. Evans—I don't think so, Mr. Graeff. I had occasion to look up the matter quite thoroughly when I was in Massachusetts.

Mr. Graeff—I know the Commission is popular to-day among the companies of the State, so far as can be gathered from talking with members from all sections of the State. I think Mr. Foote is right in saying that 90 per cent. of the companies would vote for the continuation of the Commission, but I understood that these electric light State associations were simply for the purpose of attending to the matters of legislation, and not for the discussion of all questions, such as our gas Associations discuss. Is that correct, Mr. Foote?

Mr. Foote—No, sir; not strictly. The legislative point is the "exciting cause," but where we create an association, the association is competent to do any business of interest to the companies in the State.

Mr. Evans—I understand that a petition signed by 20 consumers of gas of any town or city presenting this petition to the Gas Commission, claiming that your gas is of inferior quality, or that you are charging too high a price, can be acted on by this Commission, and that this Commission has power to compel you to reduce your rates.

Mr. Foote—That is true; yes, sir; and the record is that the power has never been abused to the disadvantage of the gas company.

The Secretary—Mr. President, I have given this subject no particular thought, but it occurs to me that for our present purposes the adoption of this recommendation that the committee on the President's Address has made, would be sufficient; that is to say, the appointment of a Legislative Committee that will perform such duties as the Committee on President's Address has suggested; and as Mr. Wilkiemeyer, of that Committee, mentioned apart from the report, viz., to take into consideration an association of companies rather than individuals, and make a recommendation at our next meeting, if such a thing is desirable. I think the adoption of such a plan as that would be sufficient for our present needs.

Mr. Rood—I am of the opinion that the adoption of the Committee's report would be a good thing for the Association. I think their report and recommendation are in the right direction, and I move you that we now adopt the Committee's report. (The motion was seconded.)

The President—Gentlemen, it is moved and seconded that we now adopt the Committee's report.

Mr. Hyde—Mr. President, it seems to me that there should be some limit as to the expenses. One question would be, "How much funds have you got, and how much latitude should we give this Committee?" If they are given unlimited authority, of course, we would naturally suppose they would be judicious in expenditure, but it seems to me there ought to be some understanding, some suggestion, as to the amount of

money that should be expended in carrying out this purpose. Now, it seems to me that it would be well for this Association to investigate and appoint a committee to report at the next meeting; but it does not seem to me they should have authority to attend to this matter in a sort of uncertain manner, according to their own judgment. It seems to me it would be all right for them to prepare a plan and recommend it to the next meeting that could be recommended to the gas companies. It seems to me that this business should be done with the gas companies—that there should be an association of gas companies' representatives. We are not strictly gas companies' representatives, only in a sense; but I don't think we should do anything more than to prepare a plan. Let this Committee prepare a plan, and then, when it is arranged, recommend it to our gas companies, and let our gas companies do anything or not, just as they please. I don't care whether they do or not. I have no interest in it. It is for our companies to do it. Whether our company does it or not is of no consequence to me. They don't send me here, and why should I do anything? I expect that is the case with all of you. You are not sent here by them. You might suggest a plan and recommend it to them, and if they say "We will operate under it," that is their business, not ours. That is my view of it.

Mr. Graeff—I think every member of a gas company here, every engineer or manager, has a direct interest in this matter, and I think this resolution is perfectly in order for adoption from that standpoint—looking to the protection of the interests which we have in it. Of course a committee of this character cannot undertake to combat adverse legislation as can a State association formed by the companies themselves. In the first place, that would require an expenditure of money which this Association could not dream of. But our committee can go ahead, as Mr. Hyde says, to perfect (and possibly go a little further than simply laying) plans, and putting them in shape so they can be carried out by the gas companies of the State, or whatever authority chooses to take hold of the matter; but I think the continuance of this Committee would be possibly the best thing this Association has done at this meeting.

The Secretary—Mr. Graeff, don't you think it would be well to limit the amount of expense that this Committee can incur?

Mr. Rood—If you will allow me to suggest, I think you can overcome that difficulty by inserting "subject to the approval of the executive committee" of your Association.

Mr. Foote—In my work I have to spend money and then get it appropriated afterward; so they have a pretty good hold on me. I always bring in a bill for what I spend.

The Secretary—A motion to adopt this report in full is before the house. I move that we amend by inserting the words "subject to the approval of the executive committee," in reference to incurring expense. (The motion was seconded.)

Mr. Rood—Mr. Chairman, as the mover of that motion, I will accept that amendment.

The motion, being then put before the Association, was carried.

Mr. Rood—Mr. Chairman, who are the Committee named?

The President—As I understand the action of the meeting at Mansfield, the Chair was empowered to appoint two members of that Committee, and the President who followed afterward furnished the third member. The third member of this Committee is now already appointed, and it only remains for the present Chair to appoint two other members. The Secretary tells me that that rule was adopted for future action, or until it should be rescinded. In the absence of any objection to that course I will announce two members of the Legislative Committee that are to be appointed by the Chair. They are Mr. A. J. Stull, President Gas Light Company, Sandusky, Ohio, and Mr. H. Wilkiemeyer, Secretary and Superintendent Gas Light and Coke Company, Portsmouth, Ohio. These were both members before, I think are very able men, and as well qualified as any appointees that could be made.

BACK TO THE QUESTION-BOX.

We will now discuss the 11th question:

"Is the Welsbach burner with natural gas a success, and what proportion of the lighting does it do in towns having both natural and artificial gas?"

Mr. Graeff—Mr. President, I think we have a couple of representatives here who can tell us what success the burner has made with natural gas. One of them is Mr. Hunt.

The President—We will be very much pleased to hear from Mr. Hunt.

Mr. Hunt—Mr. President, we are making some progress in Pittsburgh. We have 12 or 14 thousand there in use, all giving fair satisfaction. In Muncie we have about 6,000. In Findlay we have about 1,500, I think. So far they have given very good satisfaction, and we have them in

some smaller places in Ohio where they have got artificial gas. I think the number of Welsbach lamps in use altogether is something like 75,000—that is, on both artificial and natural gas. In the city here we have an exhibit of Welsbach burners consuming natural gas on about four ounces pressure.

Mr. Graeff—What candle power do you consider those lamps as giving, and how long will they keep that candle power?

Mr. Hunt—I think that candle power is not less than 35, and the lamps will last not less than 750 hours, and will maintain that candle power not less than 250 hours; at no time dropping down to less than 25 or 28-candle power.

Mr. Graeff—How many have you at Indianapolis, do you know?

Mr. Hunt—I think about 6,500 now. The business has reached such proportions there that Mr. Fletcher has expressed himself as interested in the plant, and I think has made some sort of a proposition for us to join in interest with him, or take some part in the business.

Mr. Graeff—Mr. President, I would like to ask Mr. Hunt what is the standing of this light in Mr. Fletcher's estimation? I understand Mr. Fletcher made an offer of \$20,000 for the right of the Welsbach lamp for Indianapolis. Is that correct, or can you answer the question?

Mr. Hunt—Those are secrets; but Col. Barrows wrote me some time ago, when a question came up as to the success of the Welsbach light, as to whether there was any possibility of doing business in Toledo. I explained the business to him, whereupon he said the business had reached the point in Indianapolis that Mr. Fletcher had offered them a handsome sum of money for an interest in it. Mr. Graeff's figures are not far out of the way. We have been working like heroes to introduce the Welsbach, and are meeting with very gratifying success.

The Secretary—How much longer do your lamps last with artificial gas than with natural gas?

Mr. Hunt—With the uniform pressure of natural gas I think the life is about the same. I made that statement, applying it to both natural and artificial gas. In Findlay, where we have a pressure varying from 8 to 20 ounces, the mantles last 500 hours. We get pressures there all the way from 8 ounces to 10 pounds.

The Secretary—How many Welsbach burners did you say you had in Pittsburgh?

Mr. Hunt—There are about 14,000 in use, I think, now.

The Secretary—How many employees are necessary to keep those in order?

Mr. Hunt—Well, I think a force of about 8 to 12 men, including the bookkeepers.

Mr. Rood—At Findlay, Mr. Hunt, what has been the position of the Welsbach burner as compared with incandescent light? Are you displacing the incandescent, or are both the Welsbach and incandescent lights growing?

Mr. Hunt—At a meeting of the Westinghouse Company in regard to the Allegheny business the statement was made that the Welsbach light was causing them a great deal of trouble and displacing a great many lights.

Mr. Rood—What is the condition at Findlay?

Mr. Hunt—At Findlay the incandescent people have made the price as low as 33½ cents for not less than 12 lights, and there they have procured some business.

Mr. Rood—How many incandescent lights have they there, probably?

Mr. Hunt—Not over 250 altogether. Their arc lighting business is a very handsome and profitable one, and increasing all the time.

A Member—Mr. President, I would like to ask Mr. Hunt if the burners are sold to consumers, or whether they are simply rented to them? As I understood, in questioning some consumers, they bought them for so much a burner, and natural gas was furnished by the Welsbach Company—the Welsbach Company supplied the burner, and they were paying for the Welsbach burner 15 cents per lamp per month.

Mr. Hunt—Mr. Stevens, from the Pittsburgh office, can answer that question more intelligently than I.

Mr. Stevens—We have two systems. In Pittsburgh we rent the lamps to our consumers. There are two kinds. Part of them use gas by meter and part of them by contract—we have it so arranged that they can use it through their meter. We have enough to do without it, and they don't pay us for the gas; but, if they are using the meter and wish to rent our light and have us furnish the gas, we will make connection behind the meter and furnish gas, too. To show that it is no "gouge" game with us, I put on, say, 24 lights, and put a meter in the house. We assume that our light will use or consume 1,500 feet of gas in a year. I put on 24 lights, and in a year they burn about 25,500 cubic feet. So that with the use of natural gas such a small amount is hardly taken into consideration.

Mr. Evans—How much does each burner burn?

Mr. Stevens—2½ feet with natural gas. Of course if the gas runs up to a higher pressure I suppose it would use a little more; the average on natural gas is about 3 feet, I think. I have made several tests on different occasions, and found it to run from 2.7 to 3.1—so I always say 3 feet. I also think I am giving a maximum estimate.

Mr. Rood—Do you sell or rent the burners?

Mr. Stevens—In some towns we sell them. In giving contracts to companies we grant them the privilege of renting or selling, as they see fit. The Pittsburgh department is run by our own Company, and therefore we rent the light. In some towns in Ohio the business is run by the Gas Company, and they rent the light. It lies with the company handling the light whether they will rent the burners or sell the light.

Mr. Evans—Is not it a fact, Mr. Stevens, that in Fort Wayne, Ind., they also have adopted that system of renting each burner at 15 cents a month and keep it in order; also that the Welsbach Company furnishes the burner to the consumer, and charges him 15 cents per month per burner, and keeps the burner in order?

Mr. Stevens—Well, I don't understand it that way. I think Mr. Hunt can answer that.

Mr. Hunt—I think the customer makes his own arrangement, paying 35 cents for the mantle, 5 cents for the chimneys, and 20 cents for the shade. The 15 cents is simply for rental.

Mr. Smith—That differs according to localities. In our place they charge 50 to 60 cents. The Company have represented to me that they were the agents.

Mr. Stevens—I would answer that question in this way, where companies take hold they cannot sell the mantle for 35 cents unless they make their rental plan in some way to make it up. The burner cannot be produced for less than that amount of money.

Mr. Rood—What is the price usually charged by the Welsbach Company to gas companies using the burner?

Mr. Stevens—Thirty-five cents. If a company starts out to rent its lights it has to make the rent high enough to cover its percentage on that mantle, because they pay 35 cents for it. They do that in Pittsburgh. That department there (I am not directly connected with it) rent their lights at so much a year. They have a schedule which covers the amount which would give a percentage on the mantle. They furnish the mantle in Pittsburgh for 35 cents, but they are getting a percentage on that mantle in the schedule they make. Where you sell the lamp outright to the company handling the light they furnish the mantles at not less than 50 cents, because it would not pay to handle them for less.

Mr. Rood—As a rule, though, the consumer pays for all the broken mantles or the renewals?

Mr. Stevens—Undoubtedly; you wouldn't expect the Company to buy the material and then give it away to consumers.

Mr. Graeff—Mr. Hunt, at Indianapolis the rental there covers what? Now, I got a schedule that the Indianapolis Company published last month. The schedule ran down, I think, to 50 lights per month, costing \$17.

Mr. Hunt—I think that includes rental of the light and the cost of the gas. I can tell in a moment by looking at the schedule.

Mr. Graeff (reading)—“Per month, 50 lamps, \$17.50.” What does that cover?

Mr. Hunt—That covers the entire cost of the light there. I think they have figured the gas and mantles in that.

Mr. Graeff—I judge, Mr. President, that was an opposition schedule to the electric incandescent.

Mr. Hunt—That is a fact.

Mr. Graeff—I think that has been created to compete with the incandescent electric lamps in wholesale quantities; therefore, that must cover everything. Of course, incandescent electric lighting covers everything, and this must cover everything, including shade and mantle.

Mr. Hunt—Yes, sir; and where there is a uniform pressure mantles last a satisfactory length of time.

The Secretary—I would like to ask Mr. Stevens if, at Findlay or Indianapolis, where a room contains a great number of Welsbach burners consuming natural gas, there is any complaint from unpleasant odors produced by them.

Mr. Stevens—Well, now, I don't know with reference to Findlay. There is a difference, as you all know, in natural gas. At one place we find that the natural gas has an odor, while at another it has none. Mr. Hunt made a statement about the life of a mantle. I believe that the gas in his field (the northwestern part of Ohio) is far harder on the life of our mantle than the gas in the other parts of Ohio and Pennsylvania. In my travels around (and I am “around” pretty nearly all the time),

I find in one field that the mantle will run, on an average, from 1,000 to 2,000 hours. Then I will strike another field where they will not run that length of time. It appears that in this field the gas has more sulphur substance in it. That will eat away the mantle. I found some of this trouble with it in Newark, Ohio, but I overcame that by several manipulations. There the mantles run very well now. The gas is not the same there that it is here—not as hard on the mantles. When I go further I find it still better. I find in some places a natural gas that you can run the mantles on as long as with artificial. I have run mantles for a year without touching them. I can give names of parties who have used them that length of time, and I can also give names of parties who have used them for 2,000 hours. I don't say that our mantle will always run that length of time; but it has run that length of time. It is a delicate thing, of course, and very easily broken. I admit all that; but with judicious management it is a fair estimate to say that the mantle will run 500 hours.

Mr. Rood—What is the shortest time you have known mantles to run?

Mr. Stevens—I have known them to break inside of 10 minutes.

Mr. Evans—What percentage break in 10 minutes?

Mr. Stevens—It would be very small.

Mr. Evans—What I want to get at is the liability to fractures—whether one has to use extraordinary care in handling or lighting them?

Mr. Stevens—Not after they are first started. I consider the mantles should be properly put on. I think a great many mantles are destroyed from not being properly handled, in the first place. To get the best results out of a mantle, I know from long experience that it should be started and tempered slowly at the outset. Then we will get a good result from the mantle. It is a good deal like taking a child and starting it. You have to take it gently at first.

AN INTERJECTION.

The President—I don't want to cut short this discussion, but I believe Mr. Faben is here. Mr. Faben, I would like to inform you of the exceeding satisfaction I have in saying that you have been unanimously elected President of the Ohio Gas Light Association, for the ensuing year.

Mr. Faben—Gentlemen of the Association, I thank you for the honor you have conferred upon me. At such a time it is usually fitting to make some pretty remarks, but we will have to forego that now. The Association heretofore has certainly been a useful organization—a voice: “That is so”—but that its usefulness has been as complete as could have been wished I question. The success of the Association does not depend entirely upon the officers, but does depend upon the individual effort of each member. We all come to the Association meetings. They are well attended. Good subjects are presented. The attendance is here. There is not a member present who has not his ideas and convictions on every subject presented. Yet they are very reticent about placing themselves on record. I do not say these things in a fault-finding sense; but, as your choice for President, I hope at our next meeting all those who have attended this will be present, and will come prepared to render every assistance possible, especially in the way I have suggested, in making the meeting as successful as the one just closing. I thank you again, gentlemen, for this honor.

The President—Gentlemen, are there any further remarks with reference to the Welsbach burner?

The Secretary—Mr. Hunt has called my attention to a letter that Mr. Phillipp, of Findlay, has written me, with reference to the Welsbach burner, which I will read:

“We have been using the Welsbach with natural gas about 14 months, and our satisfaction with it can best be expressed by the following resolution of our Board, passed August 28th, 1889: ‘Resolved, That the general adoption of the Welsbach light be made, owing to its excellence and its economy in the use of gas.’ Also, in the rules and regulations for the use of gas, of January 2d, 1890: ‘The adoption of the Welsbach light for manufacture is recommended by the Board.’ This practical testimony on the part of the Board of Trustees is conclusive to the fact that the Welsbach burner has given entire satisfaction, both as to economy and quality of light. Very truly yours, E. B. PHILIPP,
Sup't City Gas Works, Findlay, O.”

I wanted to say a while ago that as I had already given two or three second-hand opinions, I would also give one on this. A gentleman in Columbus noticed this question on our programme. His occupation is such as to indirectly interest him in gas, but he is not a gas man. He said: “I can answer that question”—he is a man of intelligence and observation—“I have been all over this State and Indiana, and the Welsbach burner, theoretically, is a success, but practically it is not.” That is simply his opinion; it goes for what it is worth. I think myself

that the Welsbach burner is a success, in a measure. It will occupy a certain field, more or less limited, more or less extended.

Mr. Evans—I would like to be made perfectly clear on this matter. As I understand Mr. Stevens the life of a burner is during the consumption of 1,500 feet of gas, and that the mantle is supplied by gas companies at 35 cents apiece. In other words, that 23½ cents represents the carburation of a thousand feet of gas. If I am in error I beg he will correct it.

Mr. Stevens—No; that represents the amount of gas consumed by the light.

Mr. Evans—I so understood it; yes, sir; which represented the life of the lamp.

Mr. Stevens—No, sir; when I spoke about the consumption of gas what I said was that our light would consume in one year 1,500 feet of gas—that is, in ordinary burning, house use. The life of a mantle has nothing to do with the consumption of gas.

Mr. Evans—I thought you had the thing so figured down that you could tell how long a mantle would last by the consumption of gas which was consumed by the burner.

Mr. Stevens—No, sir; you misunderstood me.

Mr. Evans—I think that represents 600 hours.

Mr. Stevens—I made the statement that our mantle would last about 500 hours, but I could produce lots of evidence that it would run 2,200 hours. That does not say that every mantle would run that long—nor can we say that every mantle would positively run about 500 hours; but I do not see any reason why they should not, and where there has been a fair and judicious handling of the light I have not seen a mantle that has burned out in that time. I have not been over this territory, yet, I believe, from what Mr. Hunt has told me about this gas, that it is stronger and has a harder effect upon our mantles than in other places.

Mr. Evans—Can you tell what is the average life of a mantle?

Mr. Stevens—Between 500 and 1,000 hours—700 to 750.

Mr. Evans—Why is it that they vary between 500 and a 1,000?

Mr. Stevens—The Welsbach people have spent several thousand dollars to find that out, and don't know themselves.

Mr. Evans—On the introduction of the burner into use, if you base your prices on that, I don't see how a gas company could figure satisfactorily.

Mr. Stevens—We cannot make any average of that except of the general life of the mantle, which is from 500 to 1,000. Of course, some times they run 2,000, and sometimes they come under 500. But as to the lamps lasting ten minutes, I think not one-half of 1 per cent. is that way.

Mr. Evans—I remember one instance where three out of six had to be removed inside of 20 days.

A Member—I experimented with two, one of which lasted 31 days and the other lasted 22 days. Each burned 4 feet of illuminating coal gas per hour.

The President—What constituted the day, Mr. Evans? How many hours?

Mr. Evans—Twenty-four hours.

Mr. Graeff—I have a dozen of them in my house that were put in there in the fall of '88, and the same dozen mantles are running there yet, with the exception of one which I undertook to run on a test, to see how long it would go without going to pieces. It ran 1,970 odd hours, when some ignorant assistant from the Welsbach Burner Company came up and put a new governor on. He thought that lamp was not looking quite as well as it ought to, and undertook to put another one on. At the expiration of that 1,970 odd hours I could read in the room, which is about 33 feet long, with the light on the opposite bracket. I could read at the extreme corner of the room, certainly 30 feet away from the light. That is what I said a year ago—that the Welsbach burner was a success (and I maintain it is to-day) on artificial gas. I don't know how it is on natural gas.

The Secretary—Mr. Evans, what are the results of any experiments that have been made with the Fahnehjelm comb in connection with the natural gas?

Mr. Evans—I do not think any success has been attained at all. I have made some little experiments, but they gave no satisfaction whatever. In one experiment I made with the Welsbach burner, in burning 4 feet of gas it showed on the photometer 19 candle power when first put on. The first one, at the expiration of 3½ days, showed about 3 candle power; while the other one, which lasted, I think, 22 days, showed between 4 and 5 candle power.

ADJOURNMENT.

Mr. Faux—Before we adjourn I move a vote of thanks be tendered the President for his efficient and courteous services rendered at this meeting. (The motion was put and carried.)

Mr. Hyde—I move a vote of thanks be extended to Mr. Butterworth for his very efficient services. (The motion was put and carried.)

On motion of Mr. Clark the convention adjourned.

Experience with Subsidized Gas Mains.

[A paper read by Mr. Wm. Drewry (Cleethorpes, England), at the March meeting of the Eastern Counties Gas Managers' Association.]

The subject of this paper, happily, is not the every-day experience of gas managers; but there are times when all are more or less liable to subsidences of mains from various causes. In order to give you as clear an idea of my situation as possible, it is necessary to briefly describe the face of the country as it was supposed to be a long time ago, and also its present state.

First, its ancient condition. Cleethorpes was a small village, situated on the east coast of Lincolnshire, on a large clay cliff, one end of which is practically connected with the Wold Hills; far away to the west, the other end jutting far out into the river Humber, and almost directly opposite Spurn Point, on the Yorkshire coast. The next projection we find was Lock Hill, at Grimsby. Whether this was formed in making the old harbor or not does not affect my paper. It lies about three miles northwards. Between these two hills the coast line fell back landwards for a considerable distance, and thus formed a large bay; and a stream (with a gravelly bottom) flowed through it, and there is to be seen to day a sea bank, nearly a mile inland from high-water mark. Time and the action of the wild sea waves have gradually dismantled the beetling cliff, and carried it towards the bay, which, together with sand and gravel, have filled up and brought forward the coast line almost straight with the two points before mentioned—its present state. A road was made across this filled up bay some 40 years ago, from Cleethorpes to Grimsby, and buildings sprang up, by degrees at first, afterwards rapidly.

The Cleethorpes Gas Company was formed for Cleethorpes. Grimsby being at that time almost as far from the new district as Cleethorpes, and being another parish, a race took place between the two rival companies which should get there first, ending, of course, in a lawsuit, resulting in a parliamentary boundary, which meant to each, "thus far shalt thou come, and no farther," and here shall thy Bills be stayed. The name of the district was New Clec, but now it is in the borough of Great Grimsby. The Cleethorpes Gas Company laid a 5-inch main over 2 miles along the Grimsby road, afterwards replacing it by an 8-inch—the one before you. As a proof that I am in the main correct in the description of the country, I do not hesitate to say that there are thousands of houses to-day standing on sea sand, and, of course, gas mains laid in the same; also that water can be seen draining out of the gravel bed and returning to the sea. When the tide is up, it flows inward through the gravel to some extent; and, of course, returns when the tide falls. There are several brickyards, out of whose pits black wood and parts of trees, and, I have been informed, even stags' horns, are sometimes again brought to the light of day. Two years since, it was decided to lay a main sewer along the aforesaid road, and as the Grimsby Tramway Company had previously put down a single line in the center of the road, with numerous switches, it was, unfortunately for us, considered necessary to lay the sewer between the line and our main. In order to avoid the former with its traffic, our main was undermined to a considerable distance; and it was suspended in the most thoughtless manner—in fact, the main was more or less visible all along the road. At the point where the operations commenced, all unknown to us, from the above reasons, the gas supply was placed in the utmost jeopardy. Our solicitor at once wrote to the Board, calling their attention to the danger and responsibility, which had good effect for a while.

All went well until the 8th of August, when the ground subsided some few hundred yards further down the road. (See Fig. 1.) This was over part of the bay before mentioned. It happened in this way: The trench was timbered, but not low enough. The ground was sand and gravel, and the trench made a deal of water, which had to be pumped out before any pipes could be laid, very few of which could be got in at once. By pumping the water and throwing out the loose sloppy sand and gravel, the latter began to purge out from behind the backings as the bottom of the trench was lowered; making still more room for the ground behind the timber to drop, which it did, forcing the boards below the walling until they almost met. I do not think the main dropped then, because it was much nearer the surface than the sewer, and was held up by the timber, which was all right at the top. The pipes were put in as quickly as possible, you may be sure; but the timber was drawn too early—causing the ground to crack on each side and fall in as far as it could, in some instances only very little, in others a

foot and even more. We at once bared the main, when it was found to have subsided, as shown in Fig. 1. Several of the joints were drawn. These were at once stopped temporarily, as we were suspicious of further subsidence. I then had to think of the best means I could to lift the main back to its proper position, as we were almost innocent of the

Fig. 1.—Plan Showing a Subsided Gas Main. Fig. 2.—Subsidence and Fracture of a Gas Main. Fig. 3.—Shows Method of Repairing.

same; and I could only turn out my men, some with bottle jacks, some with blocks, and others with that earliest mechanical power of all, the lever, giving the passer-by the impression that the job had been let at random to a marine store dealer, to accomplish in any way he chose, and with anything that first fell to his hand out of his miscellaneous collection. I should mention that it occurred in the height of the Cleethorpes season, and that thousands of people passed daily along the road from all parts of the country. Having several spare retort handles and crossbars, I got four of the T-handles made into hooks and the crossbars into nuts, with two handles (see Figs. 1 and 2). We then got some strong chains, and there being plenty of timber on the spot we placed two planks across the trench (edgeways, as shown), with an iron clasp to prevent them parting, a washer under the nut well oiled, and posted a man at each screw—giving the two in the center orders to slightly tighten their chain and the two outside to keep gently following as they felt their chain slackening. We took care to follow up the main with suitable backings in its upward movement; and fortunately we did, for two chains broke, and, but for that precaution, the last fall would have been worse than the first. After restoring the main to its original position, lead joints were made, and so completed.

Subsidence No. 1.—Another gang of men commenced a mile or so further down the road, and thinking the ground was sound (it looked very good clay), never put in a strut at all, until the walls of the trench showed unmistakable signs of meeting, but luckily left our main in position. Subsidence and fracture No. 2.—On the 17th of August another and more dangerous slip occurred. We lifted the main at once, and found it broken in two. We ran lead joints and temporarily repaired the broken part, and filled up for Sunday, it being close to a switch of the tramway, and interfered with the working of the cars. In truth, that was partly responsible for the mishap. As soon as possible we got a muff (shown in Fig. 3) and placed it in position, built up two clay collars and mouths to a sufficient height, and then poured into one pure Portland cement, rather thin at first and afterwards thicker, until the water and thin cement flowed out of the other mouth, the solid settling at once in the cavity, a hole having been previously drilled in the top of the muff to let out the air and also to watch the cement. After hardening a little the clay collars were removed and the faces trowelled up. A perfectly sound joint was made; and there has not been the slightest escape of gas since, as far as I know.

Conroy's Cut-Off and Relief Apparatus for Gas Mains.

U. S. Letters Patent (No. 424,761) were granted, on April 1st to Jas. C. Conroy, of Pittsburgh, Pa., for improvements in cut-off and relief apparatus for gas mains. According to the specifications the objects of the invention are, first, to provide a simple and convenient means for shutting off gas by control of an electrical circuit or equivalent connection from a line or section of piping, and for relieving the cut-off line

from pressure immediately when the passage in the main is closed; second, to provide means for immediately, if desirable, letting on the gas after it has been cut off, and for closing the escape passage; and third, to provide, in combination with the gas main, an automatic shut-off, an escapement way, and a bye-pass having a valve for closing the escapement-way, and opening said bye-pass; also, in combination with such improved apparatus, to afford facilities for controlling the operation of the same from the gas office.

In the drawings Fig. 1 is a side view illustrating an arrangement of pipes, valves and valve operating mechanism in accordance with the invention; Fig. 2 is a longitudinal central section through the pipes and valves; Fig. 3 is a side view of the valve operating mechanism, with dotted lines showing the action thereof; and Fig. 4 is an end view of the same.

Referring to parts, A denotes the gas main or line of pipe through which the gas normally flows; B indicates an escape or relief pipe connected at its lower end with said main and its upper end extending to a suitable position for safely discharging the gas into the air, said upper end being open and covered by a hood or cowl B'; C indicates a bye-pass pipe that connects with the main at opposite sides of the escape pipe, as at C', and centrally with said relief pipe; D indicates a rotating valve or stopcock located at the junction of the relief pipe B with the main A, and having a three-way port therethrough. The normal position of the valve D in the main is, with its straight ports leading directly through and its third port at the bottom, as shown in Fig. 2; E indicates a rotating valve or stopcock located at the junction of the relief pipe B with the bye-pass C and provided with a two-way port. The normal position

of the valve E is with its port open in line with the relief pipe, or with the bye-pass closed, as shown in Fig. 2.

Any suitably arranged mechanism can be employed for operating the respective valves D and E, but the inventor prefers to employ an automatic mechanism which can be controlled from a central station by electric or other suitable connection, and in the present instance he shows an electrically actuated mechanism arranged substantially as follows: A lever or arm F is attached to the axis of the valve, and to the outer

end of the arm there is connected, by a hinge or pivot *g*, a link *G* that carries a weight *H*. This weight is preferably loose or free to slide on the link, but retained thereon by a head or nut at *h*. Above the arm and supported by a suitable bracket *K* is arranged a trap lever *I*, pivoted or fulcrumed at *i*, and having its shorter arm fitted to engage with a loop or detent on the weight *H* for sustaining said weight elevated, while the opposite end of said trap lever *I* is held down by the escape lever *J*. (See full lines, Figs. 3 and 4.) The lever *J* is fulcrumed at *j*, and is in turn retained by the armature *m* in front of the electro-magnets *M*, which magnets are connected by wire *n* with the central gas office, where suitable batteries and circuit breaking and closing apparatus are combined therewith for sending through the magnets *M* the requisite impulse for moving the armature *m* and releasing the escape lever *J*. In connection with the valve or its operating arm there is provided a lug or finger *f* that comes into contact with a stop or projection *P*, which prevents movement of the valve past the desired position.

The operation is as follows: When the magnet draws back the armature *m* the escapement lever *J*, being thereby released, drops down and allows the trap lever *I* to swing upward and release the weight *H*. (See dotted lines, Fig. 3.) The weight then slides down the link *G* and against the end of the arm *F*, thus giving a stroke to start the valve in case it does not move freely. The link, weight and arm then swing downward, and as the arm descends the link *G* turns over on its hinge *g*, so that the weight can again slide outward thereon and against the head *h*, thus giving a second blow or shock for insuring the complete movement of the valve.

The valve *D* is operated when it is desired to cut off the flow of gas through the main. This instantly closes the main and simultaneously brings one port of the valve into line with the passage of relief pipe *B*, thus giving vent therethrough for relieving the pressure in the section cut off.

When the valve *D* has been closed and it is again desired to let on the gas to the cut off portion of the main, it is done by operating the valve *E*, which valve closes the passage through the escape pipe *B*, and opens the passage through the bye-pass pipe *C*.

The stop-lug *P* is preferably furnished with contact points *r*, from which a wire or wires *R* lead to and connect with an annunciator in the gas office. The finger *f* completes the electric circuit at *r* when the weight *H* falls, and thus sends back a signal to the gas office that the valve has properly operated.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE sub-committee of the Committee on Manufactures of the Massachusetts Legislature (who are accompanied by Messrs. C. P. Greenough, of Boston, and J. L. Sargent, of Lowell) have been inspecting the various gas works in Virginia that are under municipal control—of course, the inspection was ordered with a view to the acquirement of practical knowledge respecting the degree of success attained by such management, the information to be applied to shaping the policy of Massachusetts in the instance of gas and electric light supply in that State. The Richmond works seem to have interested the committee most, and the inspection there appears to have resulted in the verdict that the plant is well managed; but as gas men are quite well conversant with that fact, they will not be surprised at such an expression of opinion. Another hint, though, in connection with the inspection may be found in the fact that the Mayor of Richmond admitted "that it was more costly to run than a private system would be."

AN explosion occurred recently at the gas works at New Rochelle, N. Y., which cut gas off from the town for an evening or two. Mr. C. C. Van Benschoten, Manager of the works, was slightly injured.

At the annual meeting of the Fulton Municipal (Brooklyn, N. Y.) Gas Company the following Directors were chosen: Benjamin Brewster, H. H. Rogers, Wm. Rockefeller, H. R. Bishop, James Jourdan, E. C. Benedict and J. F. Freeman.

THE new rate at Doylestown, Pa., is \$1.60 per 1,000 cubic feet, with 5 per cent. off for prompt payment. The former gross rate was \$2 per \$1,000.

At the annual meeting of the Rome (N. Y.) Gas Light Company the following result was reached: Trustees, Messrs. G. N. Bissell, J. D. Higgins, Calvin Petrie, T. H. Stryker, E. H. Walworth, H. T. Utley and W. R. Huntington; President, G. N. Bissell; Vice-President, T.

H. Stryker; Secretary and Treasurer, W. R. Huntington; Inspectors of Election, John C. Bissell and Howard E. Ketcham.

No reasonable man can deny that the gas distributed by the proprietors of the Atlantic City (N. J.) Gas Company is as good, in respect to illuminating power, as any gas distributed by any other illuminating gas company in that State. There, however, our commendation of its business methods must cease; for the Company pays no attention whatever to the consumers' burners, which, as a rule, are of the most imperfect sort. In further connection with that forest of hotels (they are all frame structures) we may mention that the incandescent electric light is rapidly losing whatever prior hold it may have had upon the affections of the residents.

THE proprietors of the Malden and Melrose (Mass.) Gas Light Company have decided to construct another gasholder (200,000 cubic feet capacity) on their Malden property.

THE Directors of the Hackensack (N. J.) Gas Light Company have announced the following schedule to take effect on May first:

Monthly Consumption.	Net Rate per M.
5,000 cubic feet and under.....	\$2.50
5,000 cubic feet to 10,000.....	2.25
Over 10,000 cubic feet.....	2.00

WE are indebted to a Troy (N. Y.) correspondent for the following: "Negotiations which have been pending for a week or ten days, looking to a purchase of the Troy and Edison electric light plants operated by the Troy Electric Light Company, by the Troy Gas Company, were concluded on Saturday, April 12, when the agreement and papers of sale were signed in the office of Smith & Parmenter. By the terms entered into by Albert E. Powers, for the Troy Electric Light Company, and A. N. Brady, for the Troy Gas Company, the latter receives, on May 1st, all of the stock in the Company represented by Mr. Powers, paying for the same the sum of \$190,000. The obligations of the Troy Electric Light Company must not exceed \$189,000. Stockholders will suffer loss, as the original plant, independent of the Edison works at the railroad depot, cost \$250,000. The Troy Gas Company by this sweeping purchase obtains a monopoly of the commercial, private and public lighting of Troy and Lansingburgh."

ASSOCIATED Press despatches (dated 14th inst.) brought the news that the plant of the Madrid (Spain) Gas Company was badly damaged through an explosion.

SOME time ago we noted a reduction in gas rates that had been made by the Alton (Ills.) Gas and Electric Light Company, and predicted that President Underwood and Superintendent Tracy would likely be surprised at the gas boom that would ensue when the "folks about town" fully comprehended the liberality of the Company's move. That the prediction was well founded would seem from the following extract from a letter (under date of April 11th) at hand from Superintendent Tracy: " * * *. The reduction in price of gas here has given us more than we can possibly attend to. I have three men connecting meters and gas stoves, and took on eight new consumers last week, and have at least a month's work before me on stoves and new services, with more coming." Well, Mr. Superintendent, we are of the opinion that you won't tire of your activity.

THE City Council of Florence, Ala., has finally agreed to grant to Mr. C. W. Butterworth and associates a franchise for the construction and operation of a gas works at that point. The grantees are to expend at least \$40,000 on the plant, which is to have a capacity equal to the requirements of a city of 25,000 population. The system is to be completed within 6 months. This place is the capital seat of Lauderdale county, Ala., and is on the north bank of the Tennessee river (the latter is spanned here by a substantial bridge), at the head of steamboat navigation, and at the lower end of the Mussell Shoals. It is 70 miles west of Huntsville, and can easily be reached by rail. It is a briskly thriving place, and bids fair to be in a short time a great manufacturing center. Population, about 7,500.

MR. FRANK M. DUNLAP, formerly at Detroit, Mich., has secured a position with the Brunswick (Ga.) Light and Water Company.

A VERY pleasant family reunion was that which was held in Belleville, Ills., on April 7th, on the occasion of the anniversary of the birthday of Mr. John Eimer, President of the Belleville Gas Light and Coke Company.

AT the special meeting of the stockholders of the Louisville (Ky.) Gas Company, convened for the purpose of passing on an amendment to its charter relinquishing its exclusive right to manufacture fuel gas in the city, 9,588 shares were represented, and all favored the adoption of the amendment.

THE Worcester (Mass.) Gas Light Company will build a new retort house on Quinsigamond avenue, that city. The structure will be 102 by 68 ft., and 43 ft. in height. Messrs. Pellet Brothers are to do the mason work.

GALESBURG, Ills., "points with pride" to its \$1.50 gas rate. So it should.

THE proprietors of the White Plains (N. Y.) Gas Company and of the White Plains Electric Light Company have agreed to consolidate their forces under the corporate title of the White Plains Gas Light Company.

THE St. Thomas (Ont.) Gas Company has bargained with the Westinghouse Company for an incandescent electric lighting plant rated to a capacity of 750 lamps of 16-candle power each. The Company's service rate will be 1 cent per hour per light.

THE use of gas for purposes other than illuminating is rapidly spreading in the Eastern States. Mr. Hallett's paper on what he did at Springfield in this line is bearing fruit.

FROM the annual report of General Wagner, Director of the Department of Public Works, Philadelphia, Pa., we make the following extracts in respect to his mention of the workings of the Gas Bureau: The output was 52,980,000 cubic feet less than in the previous year, but this reduction was not caused by reduced consumption, the quantity sold and paid for, as well as the quantity sold for which bills are not yet due, being greater than ever before. An increase of 39,877,914 cubic feet, or over 1 per cent. of the whole output, sold to consumers, and a decrease of 92,858,514 cubic feet, or nearly 2½ per cent., in leakage, and in the consumption of gas furnished the city free of cost, produce large figures when they enter into the receipts and expenditures. The figures are increased still more by reason of the increased production of gas per pound of coal carbonized, amounting to 7,548,500 cubic feet. When, in addition to this, the report shows that 5,241 new meters, and 10,076 new services were introduced last year, that 113,474 lights were added, and that the number of gas consumers is 128,867, it can be reasonably inferred that the days for the use of gas manufactured by the Department of Public Works of the city of Philadelphia are not yet numbered. If it is claimed that some of the gas falls below the standard it is only necessary to state that all the gas stations are connected by large mains, and that no portion of the city can be supplied exclusively with gas from any particular works. When the works passed under the control of this department it was found that they were deficient in all that constituted first-class works of a construction suitable to make good gas and at the lowest prices. Labor saving machinery had never been introduced, and but two stacks with modern appliances for carbonizing coal had been built. The men numbered 2,257, and the cost for skilled and unskilled labor, especially for the latter, was startling. The manufacturing capacity was insufficient to meet the demand at the period of greatest consumption, and the pipes and mains were totally inadequate to distribute the gas made. In fact the works were short of everything but men. At the close of a little more than two years of the new management, by the introduction of labor-saving machinery, the rebuilding of old stacks with benches of 6's instead of 3's, and with the modern "regenerative" furnaces and appliances, and by the introduction of water gas, the manufacturing capacity has been increased from 13,000,000 to 20,000,000 cubic feet in 24 hours; the holder capacity has been increased from 12,000,000 to nearly 15,000,000 cubic feet; and greater length of pipe and mains, especially the latter of large size, were laid than ever before in the same period of time.

Appended is a table showing the maximum daily capacity of the works, as follows: Ninth Ward, 6,600,000 cubic feet; Twenty-first Ward, 200,000 cubic feet; Twenty-fifth Ward, 4,000,000 cubic feet; and Twenty-sixth Ward, 4,300,000 cubic feet—a daily total capacity of 15,100,000 cubic feet. This does not include the plant of the Philadelphia Gas Improvement Company. Fourteen thousand three hundred and thirty-three meters and 26,924 new services have been introduced, the Director said, and the number of lights and of consumers has been increased from 1,886,599 to 2,206,013 of the former, and from 114,386 to 128,867 of the latter. The number of men employed has been reduced from 2,257 to 1,518 during the same period. All the expenses of the works, including extensions amounting to \$506,312.58, and which would have been

charged to capital account in any manufacturing establishment, were paid out of the current receipts, and a balance of \$1,435,796.16 of actual cash remains in the city treasury. Because of the improvements already made, and of others contemplated and under contract, the results of the past two years are but a slight indication of the profits to accrue to the city from her gas works in the immediate future.

The most important event of the year, and perhaps in the history of the Philadelphia gas works, was the completion of the water gas plant, of which a detailed report was made a year ago. The buildings and machinery were finished and gas was delivered as agreed upon, the first passing into the city's holders on January 22d, 1889. The total quantity purchased during the year was 919,647,000 cubic feet, reducing the output of coal gas to 2,231,507,000 cubic feet; total output, 3,151,156,000 cubic feet. The tests made in the contract prove this gas to be of the standard contracted for, and the mixed gas, produced by its passage into the holders simultaneously with the gas made from coal, gives satisfaction to the consumer. It is but proper to state that very few complaints of the quality of the gas furnished come from those parts of the city in which the largest proportion of this gas is burned. The new 20-inch main under contract to be laid from the Twenty-fifth Ward works to the holder station at Ninth and Diamond streets, and on York street from Ninth street to Ridge avenue, will deliver larger quantities of this gas in the northwestern part of the city. If gas is needed in excess of the quantity named in the contract, "not exceeding 3,000,000 cubic feet per day," this plant can readily be increased to double these figures. It is well also to recollect that the city has the option of purchasing these works at any time. A decrease in the output of coal gas because of the quantity of water gas used caused a reduction of 210,666,305 pounds of coal carbonized.

In commenting on the foregoing facts and figures, showing a condition of the management of the city's gas works which must satisfy any reasonable man that the past year has been not only a year of large profit to the city and of general improvement to the works, but also a year of the manufacture of the best gas ever distributed from these works, a local critic says: "We cannot shut our eyes to the fact that there is a widespread belief that exactly the opposite of all this is the case; that the works are badly managed; that the product is poor and getting worse; and that the whole property had better be sold or given to some one who can do things better than the present official. There are those who contend that the gas furnished is bad, and no matter what the place or the occasion, the burden of their tale is the 'bad gas,' by which they claim the people of our city are being robbed. Where this is the result of personal or political ill-feeling caused by disappointed desires for gain of money or of place, it would be a waste of time to even attempt the effort to convince to the contrary—the story has been told so often that the teller actually believes it true; but, where it is the result of an honest misapprehension of the facts as they are, it is due to the citizen, as well as to the officials of this department, that the truth should be published."

Of the operations of the new Bureau of Lighting the Director reports that during 1889 there were in the city 1,045 electric arc lights, 6,476 gasoline lamps, 380 lamps supplied by the Northern Liberties Gas Company, 10,074 under the Bureau, 50 electric lights under the Board of City Trusts, and 149 lamps under charge of the Bureau of Correction—a total of 26,174, the cost to the city for lighting and maintaining being \$467,652.27.

The lighting by electric arc lights is done under annual contracts with 7 different companies, dividing the city into districts suited to the location and the capacity of the power stations of the several companies. The number of lights at the close of the year was 1,045, maintained at a cost to the city, per lamp per night, of from 55 to 45 cents, with an average cost of 48½ cents. The contracts for 1890 have been made at an average cost of 47¾ cents per lamp per night for an estimate of 1,245 lamps.

The territory lighted by underground wires has not been extended during the year, but the continued satisfactory service rendered in the districts so lighted during the past year proves that there are no insurmountable difficulties in the way of putting electric light wires underground, and they will be so placed whenever ordinances requiring it shall be enacted.

MR. W. ELIOT FETTE and his associates in the management of the Dedham and Hyde Park (Mass.) Gas and Electric Light Company are again to the fore with a practical exposition of their opinion in respect to the policy of selling gas cheaply. The latest exemplification of their belief is shown in the action taken by them on the 15th inst., when it was resolved to reduce the gross rate to \$2.50 from \$3 per 1,000 cubic feet, prompt payment—that is, on or before the 15th of each month—to secure to the user a rebate of 20 per cent. This net rate (which is an

"all round" one) of \$2 per 1,000 is a remarkably liberal one for the locality.

A CORRESPONDENT, writing from Austin, Ills., under date of 12th inst., says: "It looks now as though a new gas works for the town of Cicero, Ills., which includes within its precincts Austin, Oak Park, Ridgeland, Clyde, and some others of Chicago's suburban villages, will be built here this summer. In any event the Globe Light and Heat Company, a branch of the Philadelphia concern of that name, has accepted the last franchise granted them by the Town Board of Trustees; and Mr. Tolles, its Manager, and one of the grantees of the franchise, tells me that some of the pipe is already on the way here. I understand that the Hanlon-Leadley apparatus will be put in here, as the Philadelphia Company controls that process. If anything comes up that I think will interest you in this matter, as the work progresses I will keep you informed.—B."

A THOROUGH working test of the washer recently invented by Mr. N. C. Dye, of Rutland, Vt., is being carried on at the Bay State Company's Boston works. So far, we understand, the results are excellent.

THE Brooklyn Gas Light Company has notified City Works Commissioner Adams that it will accept the proposition of the city to pay only \$19.80 per annum for each gas lamp to be maintained in the Company's district. In the lighting competition for the current year the Company submitted a bid of \$22 per post. This is a square backdown on the part of the Company, and would seem to indicate a trifle of weakness in its management; for the latter certainly ought to have known at the time of the general competition whether or not the supply could be under taken on the basis of the figure now accepted.

It is with the greatest satisfaction that we note that the Sage of Indianapolis is to retain his place as Superintendent of the Company that he has served for years with such great success.

It is refreshing to note that the Youngstown (O.) *Telegram* has just put itself on record in the following remarks: "A New York philanthropist has investigated 560 complaints against gas companies, all charging chicanery or dishonesty, and he reports that he did not find a single instance where a company wilfully sought to defraud. He adds that no other business in the world is conducted on more straightforward principles."

ON and after May 1 the Saratoga (N. Y.) Gas Company's selling rate will be \$2.25 per 1,000, with 5 per cent. off for cash.

A RECENT issue of the Omaha (Neb.) *World-Herald* contains the following: "A Gas Company, which is entirely under control of Omaha men, and known as the Nebraska Gas and Fuel Company, has made a move by which it is proposed to illuminate the streets of the southern portion of the city. Caspar E. Yost, the Vice-President, appeared before the Board of Public Works, and upon his application permission was granted to lay mains in the following streets and alleys: Second street, between Poppleton avenue and Hickory street; Hickory street, between Second avenue and Fourth street; alley between Pine and Hickory, to Fourth street; Pine street, from alley between Woolworth avenue and Williams street; alley between Woolworth avenue and Williams street, from Fourth to Fifth; Fifth street, from alley between Woolworth avenue and Williams street, to Poppleton avenue; Poppleton avenue, from Fifth to Sixth streets; Sixth street, from Poppleton avenue to alley between Pierce and Williams; alley between Pierce and Williams, from Sixth to Tenth streets; Tenth street, from alley between Pierce and Williams, to Pierce street; Pierce street, from Tenth to Eleventh; Eleventh, from Pierce to Williams; and Williams, from Eleventh to Thirteenth streets. The work is to be in accordance with the ordinance dated December, 1888, and to be governed by the rules and inspections of the Board of Public Works. In order that the city may know the work is being performed in a proper manner, Mr. Donovan has been appointed inspector for the city. The Company has recently purchased the old buildings of the Boyd Packing Company, and will at once commence putting the buildings in shape so they may be used as the works for the gas plant, and in the meantime mains will be laid in all the streets and alleys asked for in the above petition."

SOME time ago we noted that Mr. S. B. Conde, the Engineer in charge of construction work on the plant of the "Oxy-Hydrogen Company," of Wilmington, Del., was endeavoring to secure applications from the residents of that city for gas to be supplied from the mains of the "Oxy-Hydrogen Company," when the latter was actually in the field as a competitor of the old Wilmington Coal Gas Light Company. One of

Engineer Conde's appeals takes the form of a circular, and it is so rich in its terms that we think our readers will receive both amusement and instruction from a perusal of it. Mr. Conde says: "After April 15th the Oxy-Hydrogen Company will be prepared to take orders for gas of a superior quality to that now furnished to the citizens at 75 cents per 1,000 feet, net, if promptly paid within 10 days from the time of delivering the bill. The works will be ready for delivering gas next fall, and service connections will be made as fast as the mains of the Company are extended. Mains will be laid first upon the principal streets, and gas takers upon those streets are invited to give early orders, so that we may have some guide in laying the first arrivals of pipe." In the meantime we might say that President Betts, of the old Company, does not seem to be greatly disturbed over the situation, to which he still undoubtedly holds the key.

THE premises No. 239 E. 17th street, this city, were badly damaged by an explosion of illuminating gas on the morning of the 14th inst.

It is reported that the Westinghouse Electric Company, of Pittsburgh, is negotiating for the purchase of the Brush Company's plant and system in Baltimore, Md.

THE McComb (O.) Gas and Fuel Company has been incorporated with a capital of \$50,000.

THE Village Board, of Ilion, N. Y., has received the following bids in response to an invitation for tenders for the public lighting by arc lamps, 2,000-candle power each, to be maintained on a moon table: Thomson-Houston Company, 29 cents per lamp per night; Ilion and Mohawk Electric Light Company, 28½ cents per lamp; Ilion and Mohawk Gas Light Company, 28 cents.

Coal Miners' Strikes and London Fuel Supply.

Engineering, in commenting on the disturbances occasioned by the recent strike of the English coal miners, remarks that the fact that fuel is the chief factor in all manufacturing and industrial enterprise is acknowledged universally, but it was never brought home to the minds of all sections of the community so vividly as during the few days over which the coal miners' strike extended. Within a few hours, comparatively speaking, there was a dearth of fuel, in some industrial centers there was positively a coal famine. Prices went up in London from 3s. to 3s. 4d. a ton in the space of two working days. In some manufacturing districts the advanced prices realized reached 10s. per ton. As a matter of fact coal is so essential in all trades and occupations, and in the economy of social life, that utter stagnation and ruin would result if the supplies were cut off for only a few weeks. The immediate result of the strike was the stoppage of some iron works, where large quantities of coal are consumed; then followed the stoppage of some mills and factories in the textile trades where the tonnage consumed weekly is so great that storage rooms for stocks is not possible. There was something approaching to consternation in connection with some of the large gas works of the country where enormous quantities of coal are needed from day to day at the bare prospect of two or three weeks' strike. Happily all anxiety is over, and industrial England breathes freely again. But the lessons taught are not to be forgotten nor lost sight of by all concerned.

Petroleum in Servia.

The Belgian Minister at Belgrade, in his last report to the Belgian Foreign Office, says that up to the present time no petroleum in a liquid state has been discovered, but the country is exceedingly rich in bituminous schist. The following are the principal places in which it is found: The Department of Pojarevatz by the side of the river Pec, between the villages Zelenik and Lechuitza, stretching towards the villages of Vodkovitch and Kakova Bara, up as far as Snegatine; the Department of Kniajevatz, in the whole of the southwest basin of the Timok, from Sorlingue, near Kniajevatz. Bituminous schist has also been found in Brehatz and Nina, while in the neighborhood of Trgovichte there is a veritable mountain of schist. In the Department of Nisch it is found at Zelachnitza, and it is frequently met with in the Departments of Alexinat and Tchoupria, particularly in the basin of the Montnitza and Vitchevatz, which extends to the north as far as the river Ressava, and to the south as far as Rajagne. In the Department of Valievo it is found in the basin extending from Kaloubara to Ligne. Up to the present no one in Servia has engaged in the business of extracting petroleum from these deposits of schist.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889,
For the United States, England, Russia, France, Germany, Austria, and Canada,
No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. The Gas requires NO PURIFICATION. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE.

Works under our system can be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon.

One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

LACLEDE FIRE BRICK MANUFACTURING COMPANY,

ST. LOUIS, MO.

Exclusive Agents in the United States

FOR THE

Coze System of Inclined Retorts.

Reliable
Simple, Durable.

Thousands now in use and giving perfect satisfaction. Write for Catalogue and Prices.

ROOTS' NEW GAS EXHAUSTER.

We will take pleasure in furnishing estimates on complete plants, including **GAS EXHAUSTER, ENGINE,** and **GAS GOVERNOR,** all connected, complete, on same bedplate. Also, estimates for **GAS VALVES, BYE-PASS VALVES,** and **PIPE FITTINGS,** arranged in any manner to suit the exhauster room or main connections.

All flanges of pipe and valve fittings faced off, with bolt holes drilled, all ready to go together.

S. S. TOWNSEND, General Agent, } 22 Cortlandt St., N. Y. P. H. & F. M. ROOTS CO., Connerville, Ind.
COOKE & CO., Selling Agents,

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

CONNELLY & CO., No. 111 Broadway, New York City.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time.

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

PROPRIETORS OF THE

OAKHILL GAS RETORT & FIRE BRICK W'KS

Our immense establishment is now employed almost entirely in
the manufacture of

Materials for Gas Companies

We have studied and perfected three important points. Our re-
torts are made to stand changes of temperature, the strongest
heats of the furnace, and the abrasion of feeding and emptying.
We have the exclusive Agency for the West of the celebrated

**Kloenne-Bredel Full Depth and
Semi-Recuperator Benches,**

And also furnish and build

Our Own Styles Semi-Recuperator Furnaces
for the use of Coal or Coke as fuel.

Every Meter emanating from our establishment will bear the State Inspector's BADGE, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

GAS INTO POWER,

BY THE

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

ENTERED AT THE POST OFFICE AT NEW YORK, N. Y.
AS SECOND CLASS MATTER.

Published on each Monday of the year, at No. 42 Pine Street, N.Y.

Terms of Subscription, Including Postage.—For the United States and Canada, \$3 per annum. European countries, \$4.50 (19 shillings—22½ francs). All payments to be made in advance. Single copies, 10 cents.

Remittances should be made either by post-office order, registered letter, or bank draft on New York, payable to the order of A. M. Callender & Co.

Collections are invariably made directly from this office, for subscriptions, advertisements, etc. We have agents to solicit the same, but they are not authorized to receipt for money.

Correspondence.—Wishing to make this JOURNAL a gazette of intelligent discussion to those of our readers who may wish to gain or give information on the subjects to which its columns are devoted, correspondence is solicited for publication from all who make the study of those subjects a pleasure or a profession.

The American News Company, Nos. 39 and 41 Chambers street, New York, are agents for this JOURNAL. Newsdealers will send orders to them.

Books.—We will forward by express, at publisher's lowest rates, any book—scientific or otherwise—to any address in the United States or Canada. No books will be sent C. O. D.

Western Gas Association.

SECRETARY'S OFFICE, WESTERN GAS ASSOCIATION, }
QUINCY, ILLS., April 22d, 1890. }

The Thirteenth Annual Meeting of the Western Gas Association will be held at the Lindell Hotel, St. Louis, Mo., on the 21st, 22d and 23d days of May. The hall in which the business sessions of the Association will be conducted is within the hotel building, is very commodious, quiet, and in every way excellently well adapted to our requirements. The hotel management has granted on this occasion the following rates: For single room and board, \$2.75 per day; for room with bath, \$3.50 per day. These rates will apply to members in attendance, their families and visiting brethren. In this connection I am instructed by the Local Committee of Arrangements to give our members warning of the fact that in order to secure suitable accommodations, their rooms *must be engaged in advance*. Your Secretary has been in the habit of making an announcement to this effect with exceeding regularity from year to year, and just as regularly no one, or at least only very few, pays the slightest attention to the warning. The necessity of engaging quarters in advance, however, is in this instance very urgent. Now that the old Planters' House has been closed, the Southern and Lindell Hotels often have more business thrust upon them than they are capable of handling, and of late it has been no unusual occurrence for them to deny would-be guests admission, unless their rooms had been previously spoken for. But all of our members can be accommodated without the slightest jar or friction, if they will but take the trouble to address a line to the "Proprietor of the Lindell Hotel, St. Louis, Mo.," telling him the kind and price of room or rooms desired. This should be done at least one week in advance of the first day of the meeting.

In addition to the reduction in transportation rates granted by the Central Traffic Association, the Trunk Line Association has also joined in the movement. As the boundary of the latter Association extends as far east as the western border of the New England States, our Eastern friends will be enabled to avail themselves of the reduced fares.

I am authorized to state that Mr. R. D. Walsh, Chairman of the Local Committee of Arrangements, has kindly consented to take charge of all articles destined for the Gas Exhibit, and will cheerfully surrender a generous portion of his time to the interests of exhibitors. Communications, consignments of gas stoves, apparatus, burners—anything, in fact, intended for the Exhibit—may be directed to Mr. Walsh, in care of the Laclede Gas Light and Coke Company. Exhibitors can rest assured that not only will their wares receive careful handling and be displayed to the best possible advantage, but that they themselves will be accorded the most courteous treatment at the hands of Mr. Walsh and his efficient committee.

The "Paper List" for our Thirteenth Annual will be as follows:

"Relative Value of Gaseous Fuels," by B. E. Chollar.

"Effects of Natural Gas Competition," by James Somerville.

"An Argument in Favor of the Adoption of a Uniform System of Estimating the Cost of Gas in the Holder," by George G. Ramsdell.

"Impressions of British Gas Works," by George T. Thompson.

"Mixed Gases," by E. G. Cowdery.

"Wrought Iron, Cast Iron, or Steel—which is the Best Material for Street Mains?" by Eugene Printz.

"What Policy Should the Gas Interest Adopt in Connection with the Approaching World's Fair?" by Walton Clark.

"On the Abuse of the Patent System as Bearing on the Gas Industry, with a Remedy," by Frederic Egner.

The attention of the Board of Directors is called to the fact that Section I., of Article VII., of our By-Laws reads as follows: "The Board of Directors shall meet as such at least once in each year, on the day preceding the annual meeting of the Association, at which time they shall determine in regard to the propriety of the various papers, drawings, models, or other matters constituting the special order, being laid before the Association." The Board of Directors elected at our last meeting is composed of the following-named gentlemen, who are, therefore, particularly requested to assemble at the Association's headquarters on Tuesday morning, May 20, at 10 o'clock:

J. B. Howard, E. H. Jenkins, Z. T. F. Runner, John Gimper, C. W. Butterworth, E. G. Cowdery, J. S. Ambrose, J. W. Dunbar, and B. E. Chollar.

Application blanks, copies of our By-Laws, and any information not contained in these communications will be cheerfully furnished by

A. W. LITTLETON, Sec'y.

BRIEFLY TOLD.

ANOTHER INSTALMENT FROM THE WESTERN'S SECRETARY.—Secretary Littleton's current circular not only shows how rapidly everything is shaping for the coming convention of the Western Association, but also furnishes the best of proof as to what an entertaining time the members are to enjoy at their Thirteenth Annual. It certainly seems a trifle on the strange order that those who propose to visit St. Louis in mid-May should have to be urged, solely on the score of serving their own comfort, to secure their rooms in advance; but Mr. Littleton has not put this in any too forcible a way. On the contrary, he might have gone a trifle further in his advice, and yet have been within the pale of safety. We trust that his warning in respect to the closing of the "Planters' House" will be appreciated at its full meaning. It is also with pleasure that we note that the Trunk Line Association has joined the Central Traffic Association in a rate schedule, which will save many shekels to the Eastern delegation. So far, we can safely say that the proposed exhibition of gas apparatus will be a success, and Chairman Walsh is prepared to do his full duty in connection with the reception and arrangement of the goods consigned by intending exhibitors. The paper list reminds us that the Western is evidently a Gas Association, in that we fail to notice anything on the schedule which calls for an electric lighting discussion. Of course the Secretary's hint as to the time for the assembling of the Board of Directors will no doubt be all-sufficient.

PUBLIC LIGHTING AWARD, NEW YORK CITY.—The Gas Commission and the local electric lighting companies are still at wide divergence in the matter of rates to be paid and charged for the arc lighting of this city for the ensuing year, and it is not altogether improbable that the gas companies may be given opportunity during the twelvemonth of showing what can be done in the way of public illumination on a large scale by means of high candle power gas lamps and burners. There can be no doubt, however, that the electrical suppliers will not receive anything like the figures bid by them (the average rate might be put at 39½ cents per lamp per night), simply because the appropriation is not sufficiently elastic to admit of such a proceeding. So far the Commission has made but one award of any kind, and that is the allotment of about 3,600 lamps on the Equitable's lines, to be paid for at the rate of \$12 per annum each. The Mayor seems inclined to oblige the Standard Company (no bid was submitted by it) to stand by the provision of its charter, which says that "Said Company shall supply gas to the public lamps situated on the line or lines of the mains of said Company when required by the said city of New York, at a maximum rate of \$12.50 per annum for each lamp." This would not be a particular hardship were it not for the fact that it is further stipulated that that sum is to include payments on "gas lighting, extinguishing, and all maintenance and repairs." The Commission will in all probability settle the whole matter some time this week.

NOTES.—The proprietors of the Georgetown (D. C.) gas works are about to remodel their retort house, and after much investigation have decided to install 5 benches of sixes to be constructed and operated under the Flemming improved plan. Messrs. Gautier & Co. are to furnish

the fireclay materials, the iron work to be supplied by Messrs. Floyd & Sons. The same parties are under contract to erect four benches of 6's of the Flemming type at Elizabeth, N. J. The Flemming principle is meeting with deserved favor.—The plant of the Champaign and Urbana (Ills.) Gas Light and Coke Company was, on April 17th, sold at auction, for \$40,000, to satisfy a mortgage on the concern, held by Mr. Wm. Walter Phelps. The purchaser was Mr. Thomas R. White, of this city.—The Beaver Falls (Pa.) Gas Company will arrange to supply gas in the outlying districts of Barnardtown, College Hill, etc.—As previously intimated, Mr. Chas. F. Dieterich has been elected President, and Mr. Samuel Pray Secretary, of the Consolidated Indianapolis Gas Company.—The Laclede Gas Light Company has applied to Judge Valliant, of the Circuit Court, for an injunction restraining the city from carrying out the provisions of the 90-cent gas ordinance.—A gas plant is to be erected at Benton Harbor, Michigan.

OBITUARY RESOLUTIONS, SOCIETY OF GAS LIGHTING.—The following is from the records of the March meeting of the Society of Gas Lighting:

"The committee appointed to prepare a memorial of our late associate Oliver E. Cushing, respectfully submit the following: Oliver Edwards Cushing was born at Chelmsford, Mass., in March, 1829, and died in Lowell, Mass., January 17, 1890. He was one of the original members of the New England Association of Gas Engineers, and also one of the first Directors; but declined to accept the office of President. He was also one of the original members of the Guild of Gas Managers, of New England, and served as its President for two years. He was elected a non-resident member of the Society of Gas Lighting, of New York, in 1876. He was elected a member of the American Gas Light Association at its second annual meeting in 1874, and continued his membership in these several Associations up to the time of his death.

"He entered the service of the Lowell Gas Light Company, as Agent, in 1860, and continued with the Company until his death.

"Mr. Cushing's life work as a gas engineer was marked by success; and in all the various relations which he sustained to the business of gas manufacture, whether as a member of the several Associations, or as an officer of his Company, his course was always marked by a quiet dignity of manner, coupled with good practical judgment, which made him an agreeable associate and a wise and prudent counsellor. In his death we feel that this Society has lost one of its most valued and worthy members; and that his memory will always be cherished by the most kindly feelings of all his associates.

F. C. SHERMAN,
A. B. SLATER,
C. J. R. HUMPHREYS, } Committee.

"Whereas, The members of the Society of Gas Lighting being desirous of expressing their feelings upon the death of their fellow member, Theobald Forstall, at the meeting held March 27, 1890, it was

"Resolved, That in the death of our friend, the Society loses an energetic worker in the field to which we are devoted, the profession loses an able, conscientious and devoted engineer, and the gas interest one whose constant thought was centered not only on the development and advancement of the important interests which he directed, but also in the general application of theories and practices to the art of gas lighting.

"Resolved, That we extend every sympathy to his immediate family in their bereavement, and that we express by these resolutions our deep sense of the loss our Society sustains by his death.

"Resolved, That a copy of these resolutions be placed upon our minutes, and that a copy be sent to the family of deceased.

FRED. S. BENSON,
D. D. FLEMMING,
A. M. SMITH, } Committee."

The Market for Gas Securities.

The local stock market was noticeably strong yesterday and to day (Friday), and in common with the rest of the list, Consolidated moved up sharply. To-day opening transactions were made at 98½, which is an advance of 1½ points from the quotation of a week ago. We look for the par mark before many days. Equitable is in good demand at advancing figures, and Standard is also inquired after. Mutual may also furnish a good purchase, even at current rates. Chicago Trusts fluctuate somewhat, but the stock is cheap, and very cheap at anything below 50. We have no positive advices as to what was done at the meeting yesterday, but presume that the plan arranged for was put through. Consolidated, of Baltimore, is fairly strong, the upward movement evidently hingeing on the intrinsic merit of the shares. Laclede common is yet woefully weak. We repeat our advice to purchase Boston common at ruling figures.

Some Facts Connected with the Manufacture of Water Gas.

[A lecture delivered by Dr. A. W. Wilkinson, Chemist to the New York Mutual and Equitable Gas Companies, before the Society of Gas Lighting, and reported for the Society and the JOURNAL by Mr. Edmund T. Davis.]

I am a little surprised, gentlemen, that you should call upon me to address you, under the impression that I know anything about gas making, hence the best that I can do will be to give you a little of my experience in gas works. At one time I had to teach, in the City College, how to make gas; and for that purpose I had a diagram of a gas works plant, where I showed retorts, hydraulic mains, condensers, scrubbers, purifiers, etc., and I used to repeat that same old story every year. At that time I thought I knew something about making gas; but now I do not think that I know much about it. My little experience dates from the time when Messrs. Stern, Stevens & French brought to this country Tessie du Motay's new process for making oxygen and pure hydrogen gas, who proclaimed, in the city of New York, with a great flourish of trumpets, that they were going to make gas so cheap that the then existing gas companies would have either to adopt the process or go out of the business. A charter was procured in Buffalo, and the works were built—they had previously built small works in New York. Of course, we could not demonstrate that we could make oxygen very cheap in New York, for the simple reason that we made it in such small quantities, but we claimed that it would be made cheaper when we could make it in larger quantities. In Buffalo we had complete works for making oxygen, also complete works for making pure hydrogen, and it did not take long to demonstrate that we could not make oxygen cheap enough to make it a commercial article. The oxygen and hydrogen were to be used as we use oxygen and hydrogen for the calcium light; but instead of using lime we were going to use magnesia. Very soon we found that we could not make the light cheap enough, and that plan had to be abandoned.

The hydrogen was made in this way: We had a cupola for making water gas—there was nothing extraordinary about it. It was simply a vessel lined with firebrick, into which we introduced a quantity of coal, fired it, and, after it had reached a sufficiently high temperature, we passed through it steam, when the steam would be decomposed, making water gas. This was passed to the holder, and from the holder it was passed through retorts containing hydrate of lime, the object of that being to relieve the water gas of the carbonic oxide, thus making a pure hydrogen gas. This pure hydrogen gas was to be used with oxygen, as before stated. We used it hardly a dozen nights before we had to give it up—the expense was too great. Then the question arose "What can we do with the hydrogen?" It was suggested we should have a carbureter in every house, so as to render a portion of the hydrogen illuminating, and the balance of the hydrogen was to be used for heating purposes. You practical men will see the difficulty that would arise by attempting to cart around naphtha and placing a quantity in every house. Of course, that plan had to be abandoned almost as soon as it was tested. At that time I was called upon to advise what could be done with the works they then had on hand. It was suggested that the gas should be carbureted at the works. M. Tessie thought that if we carbureted the hydrogen there at a low temperature it would carry the naphtha without condensation; but if we made any quantity you will see the difficulty attending that plan. I suggested that the hydrogen should be passed through the carbureter, and then through a red-hot retort, thus making a fixed gas. From that point we succeeded in making a gas which was very satisfactory; but we found that the hydrogen was altogether too expensive; in fact it cost more to pass the hydrogen through the hydrate of lime in the retort than ordinary coal gas cost in the holder. Consequently we had to abandon that plan. We finally passed the water gas direct from the cupola to the holder, then through the carbureter, and then through the retort, and made gas in that way. But we found that it was difficult to get men to properly manage the works, whereupon the whole thing fell through.

That was my first experience in the making of what was known as water gas. Baron Jerzmanowski afterwards built works in Troy; but two or three years passed by before we made another attempt in New York to construct works for making illuminating water gas. Mr. Stern was a very active and persevering man, and forced every undertaking to success. He came to me one day and asked if I would meet some gentlemen who proposed putting money into water gas works. I told him I would give them all the information that I could. The first question asked was, "How cheap can you make gas?" I replied that we could make a high candle power gas at 50 cents per 1,000 feet; men who were posted thought that \$1 per 1,000 feet would be very satisfactory. He succeeded in getting the money and built the works. From that grew

up the process that is used at the Municipal, the Mutual and other works—the process being, first, by making water gas in a cupola, then passing it through a carbureter to give it a sufficient quantity of the vapor of naphtha for the candle power required, then passing it through the retort so as to break up the naphtha into a gaseous form, and then purifying it, after which it is ready for the holder. The process of Tessie du Motay which we started in with, proved a failure, but from it we developed the process which is now used by several companies.

About (or before) this time, Mr. Lowe had suggested a process for making water gas. He filled a cupola with coal, and fired it (passing the products of combustion down through loose brickwork) in a vessel called a superheater, and when the brick were very hot shut off the air and turned on steam, and on the top of the coal threw naphtha, which in going down through the hot brickwork would become more or less a fixed gas. You see the difficulty of making gas in that way. In our way of making gas you have a better control over the products which you obtain. Of course, you are all familiar with the Lowe process. You know that you start with more heat than you require, then you will have it just about right; but finally you have less heat than you require to decompose the naphtha. What we look for in our way of making gas is to make all the gas we can from the coal in the cupola. That is the first step. That, of course, is water gas. The next thing is to give that gas a sufficient amount of the vapor of naphtha to make the candle power we wish. The next thing is to fix that naphtha, or make gas of it.

If you will compare the two you will see that we have two distinct processes for making what is known to-day as water gas. Several modifications of Lowe's apparatus have been made, but in every case the principle has remained the same, and has been so decided by the highest courts, and his patents sustained.

We have made improvements in the different parts of the apparatus originally designed by us, but the principle upon which the gas was first made remains the same. I will now proceed to give in detail the process.

If we pass steam through red-hot carbon we will produce, in the first place, carbonic acid, CO_2 ; then, as the carbonic acid passes through the red-hot coal, we shall make carbonic oxide, or CO ; the hydrogen of the water, or from the decomposed steam, will be set free, and at the same time a little light carbureted hydrogen is formed, or compounds of carbon and hydrogen— CH_4 by the old formula. There is in the coal a little sulphur, which will go off as sulphureted hydrogen. There is no ammonia.

To repeat, as we decompose the steam by red-hot coal we will get carbonic acid, carbonic oxide, hydrogen, light carbureted and sulphureted hydrogen. All of these gases, with one exception, are combustible gases. If we examine illuminating gas we will find, first, a combustible gas; second, a gas capable of giving illumination. Either of these gases above named will answer the purpose, excepting carbonic acid. Of course hydrogen would be the best, everything considered; but pure hydrogen is too expensive to be thought of. Practically we have to take these three—carbonic oxide, hydrogen, and light carbureted hydrogen—as our carrying or combustible gas. Of these we need from 85 to 95 per cent. of all the gas we make for illuminating purposes. The gas that gives illumination is a compound of hydrogen and carbon, and when derived from naphtha it is in the proportion of 3 of carbon to 5 of hydrogen. We need this mixture for perfect combustion. You might ask, Why not leave out this 85 per cent. and make pure oil gas? You cannot get a burner that will burn that gas perfectly.

The important question is, "Where can you get these combustible gases cheapest?" You get them when you decompose soft coal; you get them when you decompose wood; or you can get them by passing steam through red-hot carbon. Thus the engineer has a choice. There may be places where it is cheaper to distil coal to get those gases; but there are other places where wood would serve a better purpose, and be cheaper; and there are still other places where hard coal would be a preferable substance to use.

The carbonic oxide has been the gas which has caused the most trouble in water gas. Carbonic oxide is a poison—a very virulent poison. We used to experiment with carbonic acid and with carbonic oxide by taking a pigeon and putting it in a jar of carbonic acid; it would die, but not very quickly—if we kept it for only a certain length of time and then let it out it would recover; but if we put the pigeon in a jar of carbonic oxide it would die very quickly—if there for a short time it would not recover. That has been the trouble with water gas—the carbonic oxide was so poisonous. But we do not make this to breathe; we make it to burn. And any engineer who would carry on his works so carelessly as to allow that gas to escape in quantities that would be dangerous to

life does not attend to his business. We make this gas to sell, to be burned; and when it is burned it is perfectly safe.

Now, how much gas can we make from coal? for that decides the whole thing. You will probably be surprised when I tell you that we can make from coal in the cupola (leaving out the steam) more pounds of these three gases than we have pounds of coal in the cupola. I have done it. That is, I have made more pounds of gas than I have had pounds of coal in the cupola. If I put 100 pounds of coal in the cupola and under the boiler, I can get out of it 75 per cent., or 75 pounds in the shape of gas. If we take the absolute amount of carbons in these two gases, we find we can actually send out one-half of the weight of the carbons that we use, in the shape of gas. I mention these facts for the reason that it has been suggested that we use gas for heating purposes. In doing that we shall have a leeway of one-half of the carbons. In other words, we can give you one-half of the carbons in the shape of a gas which will be ready for use. We have to use a certain amount of coal to produce the gas. You have to burn up a certain amount. Consequently we are pretty near the end of the route as regards the amount of gas that can be made. This is a suggestion to be considered in connection with the question of what we can do with water gas as a heating agent. Can we afford to use it in that way? Can we afford to sacrifice one-half of the carbon for the sake of the other half? And what prices can we charge? If a man can get a ton of coal for \$5, we must charge him more than double the amount for the ton of coal in the shape of gas.

These are facts that are now coming before the people. In the Western States where they do not have natural gas this is a question that they are thinking of very seriously: "Can we make this artificial gas cheap enough for them to use it for fuel purposes, instead of coal?" You can judge for yourselves whether or not you can do it here.

At the Mutual works we make water gas, purify it and measure it—that gives us an opportunity of knowing how many feet of gas we are making from a ton of coal; and I have seen made there as high as 65,000 feet per ton of coal in the cupola. If you figure up the weight of the gas you will find that it is very nearly the weight of the coal that you use. Where do we get the extra weight? We get it from the oxygen which comes from the steam. If we take the coal burned under the boilers and in the cupola, we can make 45,000 feet from a ton of coal. If we reckon the weight of 45,000 feet of gas we will find that it makes a good many pounds. It is working very close. It is working so close that we have but very little leeway out of a possible 100. Shall we manufacture this gas for heating purposes? I think it is coming to that. They say now that in the West you cannot hire a servant girl in a house where they do not use gas for cooking; they will not use coal; they have got to have gas, or they will not go into the house. The great convenience of it will undoubtedly force us ultimately to the making of water gas for domestic purposes, for heating our houses and for doing our cooking. The question will arise right away, how does this gas compare with natural gas for heating purposes? Take the composition of water gas as 5 per cent. of carbonic acid, 40 per cent. of carbonic oxide, something like 50 per cent. of hydrogen, and only about 5 per cent. of light carbureted hydrogen, and see how much oxygen they require. We find that there is only about two-thirds (hardly that) of the heating qualities in this water gas that there is in natural gas or in coal gas. Consequently we cannot say that pure water gas will do the same amount of heating that natural gas will. Some assume that a foot of gas ought to be the same in both cases. But it is not the same. All of you are familiar with the fact that you can drive an engine better with coal gas than you can with water gas, for the simple reason that it calls for more oxygen than this water gas does. But, if for any cause we are able to make that gas very cheap, it is possible it will become the future gas for heating purposes.

Now, leaving the heat out of the question, let us look and see what we can do with it for light. I have already told you that we can have in the cupola as high as 65,000 feet of gas from a ton of coal—taking the cupola and the boiler together we can average almost 45,000. Upon looking over the books I find that the average for the year was about that, so that it is not impossible to do it. I think we can take as the average 45,000 feet to the ton. That then gives you a basis upon which to figure your illuminating gas, and what you will use to give illumination. You can do this by using very rich cannel coal. If you pass this gas through a retort distilling cannel coal you will get a very pretty gas; but in this country, where we have petroleum in abundance, we can use that instead of cannel coal—if we use crude oil it will work just as well. I do not know but what we can make more with crude oil than we can with naphtha; it is heavier, has greater gravity. The naphtha boils at a very low temperature, and the crude oil boils at a much higher tem-

perature, consequently you require more heat to decompose the crude oil than you do the light naphtha. At one time engineers had the idea that naphtha did not add to the volume of gas. At the Mutual works we have a means of measuring the water gas, and we also measure it again after the naphtha gas has been added, and find that the increase is from 33 to 40 per cent. In other words, that instead of taking 1,000 feet of water gas we only required 650 feet of water gas, and the balance of the 1,000 is made up from naphtha. At the Mutual works we have averaged over 80 feet for every gallon of oil that we used in the works. Now, with 80 feet from every gallon you can easily figure the cost of your gas. We find that we can make a 30-candle gas with 4½ gallons of naphtha; we are doing it right along—it seldom ever reaches as high as 5 gallons. In the winter time we require more than we do in the summer. The average is 4½ gallons right straight through for the year. At first we thought we had to have retorts filled with all sorts of brickwork, so as to make the gas tumble about in all sorts of directions to break the naphtha into gas. Now, we know that if we have the retort perfectly polished and heated to the right kind of heat we can decompose it better.

We measure very carefully every bit of waste oil that we have at the works, and there is not one quarter of one per cent. of the oil that we use that comes back to us in the shape of waste products. We can use that under our beuches, or we can burn it in our lime kiln.

So much, then, for the decomposition of the naphtha. You might ask: "Why not pass the oil through the retort by itself?" If you do, you deposit lamp-black and make a heavy oil, and you will not get anything like the full value of the naphtha in that way. You possibly might make 40 or 55 feet of gas per gallon; but in the presence of hydrogen or of water gas you can decompose it so that you have almost a perfect decomposition. Those are the points that we are working for—to convert all of the oil into gas without any waste whatever; and it only requires a little care and attention to enable us to do it.

Now, as to the candle power. We find it is as easy to make 30 or 35 candle power as it is to make 16 candle power; and in fact, if we should get down to 16 or 20 candles it would look so poor that we would be ashamed of it. We have to make high candle power; and when you make that high candle power you do not necessarily have smoke. You can make it brilliant and white, as you all know; and there is no tendency to smoke when made in this way. The gas burns perfectly free; and we could easily carry the candle power up to 35 without smoke, if we take proper care in decomposing the oil.

As to purification. When we look over these gases we find that the carbonic acid is about the only one to be taken out. That will hurt the candle power, but not so much as it hurts the candle power of coal gas. At the Equitable works they carry as high as six per cent. of carbonic acid in their gas, and it costs them only half a gallon more of oil to make up the candle power. In other words, if we use lime to take that out we can use one-half gallon less of oil. Consequently, it is cheaper to let that gas go than it is to undertake to take it out.

Prof. Horsford at one time, in looking over an analysis of water gas, said that if there was nothing else to recommend this gas the purity should recommend it to every company. In water gas we should not get more than 3 to 5 grains of sulphur per 100 feet; and it seldom reaches as high as that—it must be very poor coal that will give us as much as 3 or 5 grains per 100 feet—and no ammonia. Consequently, when we burn the gas in a room, we have less impurities than any other gas. Compare this with coal gas, where we have from 20 to 40 grains of sulphur and from 5 to 7 grains of ammonia to the 100 feet.

When sulphur burns it burns into sulphurous and sulphuric acid and when ammonia burns it burns into nitrous and nitric acid; 40 grains of sulphur will make 88 grains of sulphuric acid and 5 grains of ammonia will make 18 grains of nitric acid. These acids are very unhealthy to breathe, and we need not wonder that our wives and children, who are confined in close, well-lighted rooms, look pale, have headaches, sore throats, and, finally, consumption. We send them to the country where they do not get the gas and they get better; we bring them home, light more gas to make it more cheerful, and poison them by slow poison, and, finally, when we carry them to their last home, we thank God we tried to make it cheerful, we burned all the gas we could, we have sacrificed those most near and dear to us to save some drunken "bum" who might, in his stupor, blow out the gas and die an hour sooner than he would with coal gas.

In a dry goods store, where the goods are piled on shelves, if you burn coal gas containing these impurities, you will find after a time that the burning of the gas will bleach the edges of the goods—this is done by the acid that is produced by burning sulphur and ammonia—but with the use of water gas we do not have it to anything like the same extent. They tell us they prefer to have water gas because it

does not bleach or fade their goods. Therefore, water gas has these qualities to recommend it.

A few words as regards the construction of the cupola to make this gas to the best advantage. Of course, we have to make a cupola from which we shall get the greatest amount of gas out of our material per man. I have made cupolas 5 feet in diameter, 6 feet in diameter, and 8 feet in diameter. The small cupolas will make slightly more gas per pound than the larger ones, but it takes just as much labor to handle the small cupola as it does the larger one, and, consequently, we have to make them just as large as we can in order to get satisfactory results. I have never made one larger than 8 feet in diameter. As to the depth of carbon in the cupola, if we only have a short column of coal for the steam to pass through we shall get more carbonic acid; the greater depth of coal we have in the cupola the more carbonic acid will be converted into carbonic oxide. That is what we work for. We want to get just as much carbonic oxide in the gas as we can. We want to get all the carbonic acid converted into carbonic oxide.

Lately we have been passing the steam through 8 feet of red-hot carbon, and for the last few weeks we have been running the carbonic acid down to 3 per cent. in the water gas; and in the commercial gas it would be about 2 per cent. You can let that amount go. Consequently we do not need the lime purification; but with gas made in this way there are always some traces of oil still sticking to the gas. We get some vapor of naphtha. We have to pass that through some sort of purifier. If iron oxide is cheap we pass it through it. If there is sulphureted hydrogen in it, the iron will take care of that. At the same time it will act as a filter—you will find that the iron will become moistened with whatever stray oil there is; and it is desirable to filter that out. There is not much of it. You can run a box for a month and still not have it very wet; but we cannot let that oil go through. If we do we will find a quantity of oil condensed in the mains. I do not care anything about purification—leave all the purification out, except the purification which we get by filtering it (we can filter the gas until we clean it completely of the stray oil), and then we have got an elegant gas. What it may lack in candle power from the presence of carbonic acid we can make up by using a little more oil.

As regards the effect of cold upon this gas. I have passed the gas through 60 feet of inch lead pipe covered with ice and salt, and have lost but a candle or two by doing so. We all know how well it will stand exposure to cold, the reason being that the gases that we make—those heavy hydrocarbon gases of the C_2H_2 type—at this very low temperature do not crystallize.

At the Mutual works I have never seen an ounce of naphthaline made. At the Baltimore works the men said that they did not know anything about naphthaline, and never had seen it. We do not make it for the simple reason that we do not carry the heat high enough to make those solid bodies. We carry heat just sufficient to make a gas, which, if reduced by cold, will still be a liquid.

With regard to the cost. You are all perfectly familiar with the handling of coal gas, and know just what you can do. In the making of gas in this way we, so to speak, make it by machinery—just as a great many articles are made by machinery—and thus save hand labor; and so this gas is made by machinery. The labor is very much less than that of handling ordinary coal gas. When we first started we drew the charges out of the cupolas once every day. We cleaned out generally once in 12 hours. Now we do not clean out the cupola once a week. We open the ashpit door, take out the ashes, rattle the coal down, and go on again; and we run for a week or 10 days without change. We find that that is a great saving. The men who wheel in the coal and dump it in the cupola do not have very hard work, nor is it skilled work. The men who handle the valves do not have very heavy work. You are all familiar with the fact that you can make some 15,000 or 25,000 feet of coal gas per man; but with this way of making gas our books show that every man engaged in the gas making—taking them all into consideration—can make from 100,000 to 110,000 feet. When we first started we thought that one man had all that he could attend to in attending to two cupolas. This year one man attends to four cupolas. All he has to do is to change the valves every 10 minutes. We find that he might just as well occupy his time in attending to four cupolas as in attending to two cupolas; and consequently we have made more gas per man by giving him more cupolas to attend.

Then, again, we find we have made more gas per retort for the amount of coal burned, because the setting has been better. At first we had a very heavy setting—such as would support 200 or 300 pounds of coal. Now we put in just a skeleton setting.

You may ask what our benches will do. We find we can run,

through a bench of six retorts, 400,000 to 450,000 feet of gas in a day. I was in Washington recently and found that there they were running 600,000 feet per bench per day, and were doing it just as easily as we were running 400,000 or 450,000. I believe that with a properly constructed regenerator furnace we might run 700,000 or 800,000 feet to the bench.

As regards fuel. When I first went to the Mutual works I was told it was impossible to heat the benches properly without coke, and that interfered with this way of making gas, because we always had to have coke for the benches. We tried all sorts of arrangements to burn hard coal, and they were more or less successful. Finally we came down to so simple a thing as just lengthening the stack. We put about 30 feet of pipe on the stack, and then we were able to burn hard coal better than we had burned coke, and the men would rather attend the fires with hard coal than they would with coke. So that we are out of the woods in that respect. We do not have to have coke, and we can use hard coal. In fact, we use nothing but hard coal all through the works—under our benches, in the cupolas, and in the boilers. We can use a very cheap variety of coal. We never use better than pea coal, we use up all our screenings, and have no waste.

There are a few things which I have learned practically in handling works of this kind. In the first place we want a boiler that will give high pressure steam, and as hot as you can make it. We want that boiler to be as close to the cupola as we can get it. A good many times the water gas process has been a failure because the steam had to be carried so far that when it got to the cupola it was not in a shape to do its work. Place the boilers as close to the cupolas as you can get them, so that the steam only has to travel 7 or 8 feet to get to the first cupola. We find that the first cupola will make more gas in proportion than the others that are further away.

Not only do we want hot steam, but we find that if we can dry that steam we are still better off. When M. Tessie first came out here with his cupola we then used about 40 pounds of steam. He thought that it was absolutely necessary to use superheated steam. Anybody who has had experience with superheated steam knows the difficulties in the way of its use. We do not superheat our steam now. We get hot steam at 100 pounds pressure, and get it into the cupola as soon as possible from the boiler. In that way we have had a great deal of success. Anyone who will undertake to run a boiler which is 200 or 300 feet from the cupola will have very poor success. You want to put them as close together as possible and get your steam as hot as you can.

We have made certain improvements in the making of water gas. One improvement is by introducing the steam a part of the time at the top of the cupola—in blowing up the cupola the top of the cupola soon becomes very hot; pretty soon the whole top of the cupola was red-hot, and, of course, the valves and covers would warp. I suggested the idea of putting the steam in at the top for half of the run instead of introducing all the steam at the bottom and driving the heat all to the top. I found that I could make about 5,000 feet more of gas per ton of coal by doing so, and at the same time did not burn out my cupolas. In fact the repairs of the cupolas are very slight indeed. We find that per 1,000 feet of gas the repairs to the cupolas are hardly worth mentioning.

Of course, you may get hold of coal which will clinker; but even with such coal, if you pass the steam both ways, a part of the time below and a part of the time above, it will break up the clinkering so that it will give but very little trouble.

Then, again, as regards the grate bars. We never burn them out. We have the same bars in now that were there at first. They are $1\frac{1}{2}$ -inch square iron bars.

When we first made the gas there was any quantity of trouble with the valves. We found that this red-hot gas coming in contact with the valves soon burned them out; but it did not take much thought to put these valves all under water, and we have had no trouble with them since. The gas is taken out red-hot, but it has to strike the water before it can touch the valve; consequently we have no more trouble with the valves.

In making this gas we do not require skilled workmen. The best men we have came there as common laborers. It does not seem to require any extraordinary knowledge to enable them to handle the valves. In making gas through the retort, a man learns to make it in a very short time, and without any trouble. Of course, if he is careless he can soon fill the standpipe full of carbon and the hydraulic main full of pitch; a little attention will save all this.

We can make high candle power, any candle power we want, just simply by opening or shutting the valve that lets in the naphtha; you can easily control that.

For vaporizing naphtha, we need a carbureter large enough, and well

supplied with steam, to vaporize the naphtha, so that when mixed with the gas it will decompose easily.

I have been making some experiments with crude oil and with the Lima oil, and I find that I can make gas just as well with that. Of course it requires more heat in the bench to do it, but it can be done; and if naphtha should go out of our reach to-day, and the crude oil remain, it would not interfere with us a single day. We should make gas just the same, and just as good.

As I have already said, it seems ridiculous for me to undertake to talk to you about gas making; I have told you about all that I know about the art. I know there are men here who have had years of experience, and are, therefore, better posted in every way than I am, and who can give us all the details. If there are any questions which you would like to ask, suggested by anything I have said, I shall be happy to answer you. Mr. Bradley can tell you many things that I have not thought of, and he ought to be made to talk.

Discussion.

Mr. Bradley—I think that you have covered the ground pretty well.

Mr. Benson—It might be of interest, now, if we could get Mr. Bradley to cross-examine the witness on the points suggested.

Mr. Bradley—I do not think I can add anything to what Dr. Wilkinson has said.

Mr. Benson—Of course it is understood beforehand that there shall be no questions asked the Doctor which would tend to criminate the witness.

Dr. Wilkinson—I have been in the position oftentimes in the college of not only having to ask questions, but also to answer them; and oftentimes some of these boys would ask very difficult questions, that I have had to get out of in some way.

Mr. Benson—You remarked that if naphtha should go out of your reach, and crude oil remain, you would still be able to make gas about as cheaply, and with as little difficulty. I would like to ask you if the residuals of crude oil would not be more difficult to take care of; and whether or not the present regulations of the Board of Health would not tend to embarrass you somewhat in the manipulation of the residuals.

Dr. Wilkinson—We have always worked on the principle of never allowing any waste; and if we should use crude oil to-day we would not make any more waste than we do now. With crude oil, as pumped out of the earth, of course there comes a lot of dust that will remain in the retort, and that will accumulate after you have made a good many thousand feet. We would have that to contend with. The oil that we now have is pretty clean, and consequently we have nothing in the way of sediment to dispose of, as we would have if we were using all crude oil. Otherwise than that, we would have no great waste, and there would be no more heavy oil, tar, or pitch than from gas made from naphtha. There is no necessity of making a particle of waste oil. If they only attend to the benches properly they need not make any heavy oil at all. We might filter a little out in the purifying boxes, and it is possible we might get a little from the street; but it would be so exceedingly small as to be of no account. We made a careful estimate a few winters ago of the actual amount of heavy oil that we made, and that coming in from the street—I had every particle of it collected—and I found that while we were using 15,000 gallons of oil per day we did not get 200 gallons of oil back. So that it is possible to work up almost every particle of it, with the exception that I have mentioned—that if you use heavy oil a little sediment will accumulate.

Mr. Thomas—I do not suppose there would be any particular objection to using the ordinary crude oil, but Lima oil might be objectionable.

Dr. Wilkinson—I will tell you what we have found. Within the last year or so we have been using naphtha that was not as good as the naphtha that we used to get; and the stuff made a smell in the gas that we could not take out with either iron or lime. We found that lime would work better than iron, but still an odor remained which was very much like the odor of a skunk. Now, as long as that gas burns it is all right. The odor is that of sulpho-hydrocarbon; the amount of the sulphur is exceedingly small. You might take a bushel of onions and you would not get a grain of sulphur out of them; and yet you know that a bushel of onions is capable of making a great deal of a stink. And so it is with this oil. The amount of sulphur in it is exceedingly small, but what there is there is in the shape of a very rich smelling body. When a servant girl lights the gas her usual way of proceeding is to turn the gas on and then hunt around for a match, and when she finds it she will light the gas; and in the meantime the gas has been escaping in the room. A gas with such a pungent odor in it does not take very

much of it in the room to be noticeable. That odor is probably owing to the naphtha made from the Lima oil. It is probable that we get in the light naphthas some of those very strong smelling bodies; but if we burn it all, it is all burned up, and the odor is not noticeable. It is only when the gas is allowed to escape that it gives trouble.

Mr. Thomas—As between the ordinary crude oil and the Lima oil, what would be the difference in the amount of lime that it would be necessary to use in purification, in order to eliminate all of the odor?

Dr. Wilkinson—It is not all in a shape that will combine with lime chemically. With ordinary sulphureted hydrogen, when we pass it through the hydrate of lime we form the sulphide of calcium; but this sulpho-hydrocarbon does not combine with lime, neither does it combine with the oxide of iron, and we cannot filter it out in that way because we cannot combine it. We purify as thoroughly as we can the water gas, so that we get rid of every trace of sulphureted hydrogen. After the naphtha gas is added it passes through lime. Mr. Kennedy gave orders to fill those boxes with lime instead of iron. We do not change the boxes because the gas gives a test of sulphureted hydrogen, but we changed because the oil began to accumulate there and make a back pressure. It did not seem to have the power of combining with this gas. It is not a pure, simple gas; if it were we could get rid of it easily. It is a compound gas, that will not combine with any ordinary substance which we use in purification.

Mr. Flemming—What is the temperature of the gas as it comes from the retorts?

Mr. Wilkinson—It is only a little above red heat. It hardly reaches a red heat until it has passed two thirds the length of the retort. As it goes off in the stand-pipe it is not hot enough to make a cherry red heat.

Mr. Flemming—Do you think that the whole body of gas as it passes the retort is acted upon and changed at all?

Mr. Wilkinson—Yes; I judge by the fact that if it was not we should have the oil condensed out.

Mr. Flemming—Why do you prefer naphtha to crude oil?

Mr. Wilkinson—Simply because one boils at less than 212° and the other at 600°.

Mr. Flemming—The cost of one is nearly double that of the other, is it not?

Mr. Wilkinson—Yes; but with one we should have to use more coal under the retort. In other words, instead of making between 400,000 and 500,000 feet to the bench we would not be able to make more than 300,000. We would have to use more coke. We cannot have the cake and the penny too. If we get light naphthas they will decompose easily; if we get a heavy oil we have to use more coal. So that although you can use this Lima oil at 2 cents as against 4½ cents for naphtha, still it is not all profit. You have got to burn more coal and you lose money there. The chances also are that your stand-pipes will stop; you will fill the hydraulic main, and you will give the man more work outside of the benches than you would in using naphtha. I have figured that up, and although the figures are in favor of using the heavy oil, they are only slightly in favor of it; yet I should prefer naphtha for the sake of keeping a less number of men busy about the works. One advantage that we claim for the process is that you can make a pure gas cheaply, and at the same time get rid of a good many men at the works. When you can make 100,000 feet to a man instead of 20,000, you get more work for your money; and the fewer men you have about the works the better off and the happier you are.

Mr. Nettleton—I understood you to say that practically there was no need of purifying this gas, and yet, as far as my information goes (I know nothing about it practically), it costs fully as much to purify water gas as it does to purify coal gas. Within the year I have heard the statement made that it costs *more* to purify water gas than it does to purify coal gas. Is there anything about your process which makes the gas freer from sulphur or sulphureted hydrogen than is the gas made by the ordinary process?

Mr. Wilkinson—If we take ordinary hard coal the amount of sulphur that there is in it is about one-half the amount we get in ordinary soft coal. Now, with ordinary soft coal, if you get 10,000 or 12,000 feet you will get about all the sulphur that there is in the coal in the 10,000 or 12,000 feet; but as we put the coal in the cupola and make 60,000 feet we divide the sulphur into so much smaller quantities per thousand feet that the amount of sulphur becomes unimportant. I have a very perfect apparatus for testing the quantity of sulphureted hydrogen contained in the gas, and I cannot get a sufficient rise in the tube to show one-tenth or one-twelfth of one per cent. of sulphureted hydrogen, and that quantity is so very small that it is not worth noticing. Then, again, as regards the carbonic acid. Where you make a very high candle power gas the carbonic acid does not have the deleterious

effect that it does with a gas of lower candle power. We reckon that one per cent. of carbonic acid in 16-candle gas would take off about one candle. At the Equitable works they run six per cent. of carbonic acid, and I know that it does not take off one-sixth or anything like it. The deleterious effect of carbonic acid on high candle power gas is not so marked as it is on low candle power gas. Then, again, you do not need to have carbonic acid as high as 5 per cent. You can run with much less than 5 per cent. If you burn a little more coal you need not make any. Keep your cupola hotter and you can run it almost without any carbonic acid. You are to put the cost of the coal in the cupola as against the cost of lime in your boxes. If we have no sulphur, no ammonia and no carbonic acid worthy of consideration, what is the use of purification?

Mr. Nettleton—I must have been misinformed; but I think it is the impression among coal gas men generally that you cannot purify more than 6,000 feet of water gas (made by the cupola process) from sulphurated hydrogen with a bushel of lime.

Mr. Flemming—My experience is 2,500.

Mr. Bradley—We purify more than 2,500, but not more than 6,000; and it will run nearer to 4,000.

Mr. Nettleton—Is it because of the trouble with carbonic acid?

Mr. Bradley—Yes. Dr. Wilkinson is right in the statement which he makes about the quantity of carbonic acid. I was running 4,000,000 feet per day for six weeks with less than one per cent. of carbonic acid; but I found that in doing so I was burning more coal than I was saving in lime. So I finally established the rule of about from 2 to 3½ per cent. of carbonic acid as being about the balance between the coal and the purification.

Dr. Wilkinson—When I said that we made 5 per cent. in the water gas from cupola I meant that we were running then just about two-thirds water gas and one-third gas made from oil. Of course, there is no carbonic acid coming from the oil; and, consequently, this amount would be reduced by adding one-third more gas to it.

Mr. Humphreys—I think you said you made about 45,000 feet per ton of coal. Did you include the use of coal under your retorts?

Dr. Wilkinson—No; when I said that I was speaking about gas as a heating agent—as heating gas—where you take the amount of coal under the boiler and the amount of coal in the cupola. Putting those two tons of coal together you can make from each ton 45,000 feet. That has been measured.

Mr. Thomas—It is carbureted afterwards?

Dr. Wilkinson—Yes.

Mr. Thomas—I understood you to say that in making this gas you tried to get as much carbonic oxide in it as possible. What was that for when you admit that the CO is a virulent poison?

Dr. Wilkinson—The people must learn to take care of themselves. We tell them that the gas is made to be burned and not to be breathed. I was speaking of how much more we can make. By making so much carbonic oxide we, of course, make less carbonic acid. Now, there is something in the burning of the gas. If you have a gas that is rich in carbonic oxide you have a gas that is whiter than it is when made without the carbonic oxide; and it is so for purely a physical reason—the carbonic oxide burns with a blue flame, and the two burning together have a tendency to produce a white light. If you have them properly proportioned they will produce a white light. That is one reason why we get a whiter light by having the carbonic oxide than we do when we do not have it.

Mr. Nettleton—You made the statement that the ammonia in the gas is transformed into nitric acid. Can you show the chemical formula on the board?

Dr. Wilkinson—Take the old formula, NH_4O ; now, when that burns you will see that the hydrogen will burn into water, and the nitrogen at this high temperature is bound to take on oxygen and become NO_2 and NO .

Mr. Nettleton—But that does not necessarily make nitric acid, does it?

Dr. Wilkinson—Yes; it will always make more nitric acid than the lower oxides.

Mr. Nettleton—Why does it not make nitrous oxide?

Dr. Wilkinson—Because the temperature is too high. The oxidation is so rapid at that point. You can show it very well if you burn it in a glass jar. You may see the red fumes of NO_2 .

Mr. Nettleton—How much nitric acid can you produce from 5 grains of ammonia per 100 feet of gas?

Dr. Wilkinson—Taking the chemical equivalents, nitrogen is 14 and oxygen is 8, and 14 grains of nitrogen combining with 40 grains of oxygen will make 54 grains. That will be the atomic weight of the nitric acid— NO_3 . Now, when you have the ammonia you have not got to add

oxygen to burn it, so that 5 grains of ammonia would nearly equal 18 grains of nitric acid. The oxygen you get from the air.

Mr. Thomas—Natural gas is credited with being chemically combined in the proper proportions for heating purposes; and, in fact, it is claimed that none of the manufactured gases equal it in that respect. Some crude experiments which have been made, by simply taking air and carbureting it through the aid of oil, have determined that there is the same heating quality in that gas that there is in the natural gas, with a larger quantity of nitrogen and oxygen in it. It is a surprise to me how that can be.

Dr. Wilkinson—The hydrogen, weight for weight, gives the greatest amount of heat of any body. Here we have a more condensed gas; we have two equivalents of hydrogen, and we have carbon added to it. That virtually would be the same as the natural gas—and really it has more heating power than almost any other gas that you can get; but it has not so much as gas distilled from coal.

Mr. Thomas—The experiments which I have referred to were made in a crude manner, by simply taking the gas under pressure and delivering it from the same pipe, so that under the circumstances it was as nearly equal as possible. As the thing seemed, better results were obtained from the carbureted air than the natural gas.

Dr. Wilkinson—We can determine that without making any experiments, for we know how much oxygen will combine with hydrogen. Every pound of hydrogen requires eight pounds of oxygen for combination, and the heat developed in every case is in proportion to the amount of oxygen required to burn it. Now, if you will give me a body and tell me how many pounds of oxygen are required to burn it, I will tell you how much heat you will get from it. It is a positive quantity, right straight through. Carbonic oxide does not require half as much oxygen to burn it as hydrogen does. All that you have to do is to add one equivalent of oxygen to carbonic oxide and it burns it; whereas this gas carbureted hydrogen requires 3 equivalents of oxygen—or thrice as much. Carbonic oxide is a very poor heating body as compared with light carbureted hydrogen.

Mr. Humphreys—You spoke of the necessity of using dry steam. How does wet steam act?

Dr. Wilkinson—It simply puts out your fire, that is all. It deadens your fire right down. To decompose wet steam you require a very high temperature in your coal. I have made several attempts to get at the temperature, but I cannot say how high it is. It is a bright white heat when you start. The minute you begin to deaden that coal and bring it down to anything like a red heat, it will not decompose the steam. You see in the books a statement of the temperature that you have to have in the coal in order to decompose steam, but I find that possibly it is much higher than is there stated. I suppose we could decompose steam into carbonic acid and hydrogen at a temperature not much above a cherry red heat; but if you want to make it into carbonic oxide and hydrogen you have to have a higher heat. If the steam is the least bit wet you will soon deaden your fires, and you will find that during the 10 minutes you are passing the steam you cannot make anything like the amount of gas that you can if you have the steam dry. You need not necessarily have the steam at high pressure. All that you need is to have it dry. You know that we can have steam red-hot, and yet without a pound of pressure on it. You can heat steam as you can heat anything else—without having it under pressure. Suppose you have a long pipe, and that you heat it red-hot; you pass steam through it; you leave the end of the pipe wide open; the steam will come out of that end of the pipe just as hot as the pipe itself is. That steam will decompose very readily. In all our works it is heat that we are after. In order to make gas we must have heat—and heat at high temperature. Now, in making gas through our retorts I do not care how much heat you get on the bench; you may give me all the heat you can possibly obtain by a regenerator furnace, and I can pass gas enough through that to keep the heat down. If Mr. Flemming will show how we can burn hard coal under regenerator benches, I know where there is a place for 10 benches. Heat is what we are working for.

Mr. Flemming—I think you will get more heat there than you want.

Mr. Humphreys—You spoke of 80 feet to the gallon of oil. What was the candle power of that gas?

Dr. Wilkinson—We cannot separate that. That 80 feet is made in the presence of the water gas going through the retort. You cannot take that same amount of oil and put it through the retort and get 80 feet out of it in a way that will enable you to test it. It will only make 80 feet in the presence of the water gas, or hydrogen.

Mr. Strecker—What influence has the water gas upon it?

Dr. Wilkinson—In the first place, it keeps the particles moving. You can imagine the particles of naphtha are broken up into fine globules.

Now, aside from splitting up those particles, we cannot make gas without dropping something, and that something is carbon. Naphtha is made of carbon and hydrogen. As we decompose the naphtha and make gas out of the liquid, we have to drop something, and that something will be carbon. Now, as pure hydrogen is there, that hydrogen will seize upon that carbon to form a combination with the carbon, forming light carbureted hydrogen. I know that to be a fact. It used to be stated that there would be no combination between the free hydrogen and the carbon—that the carbon would drop. But this is not so; the carbon will combine with that free hydrogen. It is a principle in chemistry with which you are all familiar that if you want to produce a combination of bodies, one or both must be in a nascent state. Now, the hydrogen has already been produced in a free state, but the carbon which would drop out from the naphtha is in a nascent state, and the hydrogen will seize upon it and form light carbureted hydrogen. So that we get more light carbureted hydrogen in our commercial gas than we ought to get, and we get less hydrogen than we ought to have.

On motion of Mr. Benson a vote of thanks was given to Dr. Wilkinson.

A Method of Increasing the Consumption of Gas for Cooking and Heating Purposes.

[A paper read by Mr. F. G. Dexter, of Wantage, at the last meeting of the Southwest of England District Gas Managers' Association.]

It seems to be the orthodox rule in assemblies of this kind for the author of a paper or address to occupy the first five minutes or so in lamenting his inability to properly perform the task in hand, and calling the attention of the meeting to the fact. I believe that the final impression of this kind of thing is that the author himself would be about the last individual to sincerely believe it. At any rate, if he failed to demonstrate forthwith the diametrically opposite fact, his audience might be safely left to arrive at that conclusion in a much shorter space of time; for the fact remains that the aforesaid five minutes are generally more profitably spent by the members in arranging chairs, making a liberal use of the pocket-handkerchief, and a few other kindred attentions. As a new member of the Association, I am particularly conscious of the honor conferred upon me in the invitation to present a paper. Without apology, therefore, I give you—not a theory or proposition, but the actual results brought about by the adoption of a scheme (hitherto untried, I believe) to effect the subject of this paper.

On taking charge of the Wantage Gas Works last August twelvemonth, I found a state of things calculated to gladden the heart of any manager. To enumerate the difficulties encountered would afford scope for a lengthy paper in itself; and therefore I will content myself with briefly mentioning those bearing more immediately on the subject in hand. The annual output was about 8 million cubic feet, with a leakage of 20 per cent. The mains and services were allowed to look after themselves, until their existence was demonstrated in a more or less unpleasant manner. No record had been kept either of the position or age of the mains and services, whether forming part of the works or of the distributing system. The ideal depth seemed to be 6 inches, with two large firms manufacturing traction and semi-portable engines wholesale, with free license to turn the "kittens" into the street at will. All stores were purchased (I might have "obtained," but I can guarantee that they were paid for) from local tradesmen, who were also entrusted with the required repairs at the works, as well as all meter fixing and service and main laying. Under these circumstances, my first winter's experiences were particularly agreeable. Complaints from consumers were rife on all sides, from defective mains, services, and interior fittings, although, of course, "the gas" was the scapegoat; and as this was sent out well purified, and of 17-candle average quality, it was hard to bear without the means of putting the actual defects right, except at great expense with insufficient workmen, and only at such times as might suit their employers' purposes.

By the close of October I had had enough, and at the next Board meeting (on Nov. 5) I introduced a report condemning the whole system; proving the indifferent and costly way in which fitting work and repairs, both for ourselves and the customers, was carried out, and advocating thorough reform, including—(1) Additions to the staff for stoking and yard work. (2) The engagement of a thorough mechanic and fitter. (3) Power to hold an exhibition of cooking, heating, and lighting apparatus in the Town Hall during the following summer. (4) Full license to hold the necessary stock and stores of apparatus and fittings, and to let cooking stoves out on hire. (5) To undertake gas-fitting in any shape or form which might appear advantageous. (6) To lower the price of gas used for cooking and heating purposes, ex-

cepting by the use of boiling-burners only, by 10d. per 1,000 cubic feet (from 4s. 2d. to 3s. 4d.). I will not attempt at this time to describe the meeting; suffice it to say that my report was adopted.

The exhibition was held from the 18th to the 21st of June (four days). This was, I suppose, of the usual character. At the head of the room a lady lecturer demonstrated twice daily on plain and fancy cooking; including on one evening the preparation complete of a five-course dinner for five or six persons. A test meter, facing the audience, was fixed to record the consumption of gas in the stove used; the cost being given at the close of the lecture. Opposite, at the bottom of the hall, eight different sizes of ranges were shown, both enamelled and plain; while on either side were arranged a variety of other apparatus—including fires, bath-heaters, boiling-burners, coffee-roasters, airers, washing machines, grillers, &c.—any of which could be instantly lighted up. Arranged round the walls on brackets were various types of lamps and burners, illustrating flat-flame, Argand, and regenerative lighting. Pamphlets and papers were widely distributed, and posters adorned the walls. Specimens of some of these are on the table for the inspection of any who may be interested. Admission was entirely by invitation ticket. I may here mention that the whole of the cooking and heating apparatus exhibited were Messrs. T. Fletcher & Co.'s, and that I have kept exclusively to that firm's manufactures.

To my mind it is of primary importance that a gas company's goods and work should be second to none. For this reason I will supply no other form of globe than the improved open bottom, and no other than the governor type of burner. The small galleries attached to brackets, etc., supplied from the manufacturers, are removed and thrown away. It is high time gas companies with fitting businesses combined to put pressure on manufacturers to stop, or at any rate to limit, the sale of these abominations. At present they are supplied with every bracket and chandelier manufactured as part cost; and customers naturally object to give up an article once paid for to incur the expense of a second.

The exhibition being held so late in June, little fixing of apparatus could be effected before the close of the quarter. From then, however, until now the work has rapidly proceeded; my fitter, until a few days ago, being on overtime until 8 and 9 at night. At the close of the exhibition, some 25 appliances were on order; while up to the present time upwards of 60 (omitting boiling burners, etc.) have been fixed. This record, out of some 200 consumers, speaks for itself. A great deal of ordinary fitting work has also come in; and I see no reason to doubt the continuance of public favor and confidence. The net effect has been to return to us the whole of the extra wages, while we have also effected all our own main and service laying, meter fixing, and tool and general repairs.

It is our practice to let out on hire cooking stoves only—the rental varying from 1s. per quarter for a stove suitable for four persons, to 3s. 3d. per quarter for one to cook for 15 or 20 persons, and the minimum term of hire being 12 months; but they are sold to consumers at a discount of 33½ per cent. Fires, bath heaters, and all other apparatus, are supplied at 25 per cent. discount.

In fixing gas appliances I charge cost price, and sometimes under, for those which affect the day consumption; and in all other cases allow for an ordinary profit. Every case of gas fitting I personally inspect beforehand; instruct my man respecting the work, if necessary, and inspect again both while in progress and after completion. Should any difficulty subsequently arise, it is always put right without further expense to the consumer. Every opportunity is also taken to instruct consumers in the proper use of any apparatus they may have. By this means satisfaction has ruled the day; and although it has necessarily entailed a great sacrifice of leisure time on my part, I feel that the results have well repaid the labor and risk.

In connection with my report to the Board I mentioned a reduction of 10d. per 1,000 cubic feet for gas used for cooking and heating purposes. With gas at 4s. 2d., and no immediate prospect of a reduction on ordinary ground, I felt that a secondary and lower rate was essential, in order to popularize the exhibition movement, and give a decided impetus to the consumption. You will the more readily understand this when bearing in mind that Wantage is supposed to be the oldest town in England, and now only numbers about 4,000 or 5,000 inhabitants; so that the prospect of the growth of the consumption of gas for lighting purposes by the influx of new consumers is not reassuring.

Some here may consider the drop of 10d. per 1,000 feet too great under the circumstances, or may, perhaps, entirely discountenance a secondary rate. I do not. What is more, I believe that, however good the results due to the exhibition movement in any town may be, that a lower rate for heating and cooking gas would pay better. A consumer seems naturally to expect a reduction. The use of gas for cooking and heating

purposes is very young compared with its primary function—lighting, and some incentive, some inducement to try it for other purposes should be offered. The very fact that gas is delivered at less cost to us should influence the question. Take a consumer adopting some apparatus; the consumption is always largely increased, and often doubled. What does that gas cost the distribution department? Nothing. You use the same main, the same service and the same meter. The leakage is unaltered, unless the pressure is augmented; but the bulk of such gas being used in the day affords little excuse for that. In my own case the works are the property of the town. No surplus profits are made; the selling price (4s. 2d. per 1,000 feet) being practically the cost of working and delivery to the consumer under our circumstances. Say, for argument's sake, our leakage is 10 per cent. It is known well enough that services cause the bulk of the loss from leakage; and each service presumably goes to a consumer. Therefore all extra gas delivered through such service, being free from leakage, costs us one-tenth less. It can be sold at 3s. 9d. per 1,000 feet apart from any question of increased economy in production at the works, which every manager knows must follow.

With a differential charge for gas, therefore, the question arose as to how the relative quantities used for heating and lighting respectively were to be determined. I was aware of the double-index meter system, and also that separate meters might be put in to take the cooking and heating consumption. But neither plan commended itself to my mind, on account of the expense involved, and the difficulty in the latter case of inducing consumers to face the outlay of the duplicate service. After careful consideration, I determined to try the following plan: In the great majority of cases the consumption of any individual consumer for lighting purposes remains fairly uniform from year to year; the consumption for any particular quarter comparing pretty closely with that for the corresponding period of the previous year. At any rate, should any fluctuations occur in the shape of an increase, they are not slow to require an explanation. Taking, therefore, the four quarters ending March 25, 1889, as the basis for lighting purposes, it was agreed that the adoption of any stove, fire, or other apparatus, would necessarily make the total consumption greater; and that whatever increase there might be in each quarter over and above the four quarters to March 25, 1889, should be chargeable at the lower rate. The effect of this is that a great many consumers have adopted some kind of appliance who would not have entertained the idea had a duplicate service and meter rent been necessary, to say nothing of the horror some have of the idea of the house being turned upside down "for those gas men." Again it is a direct incentive to a more liberal use of gas for lighting purposes; this extra consumption of course going in at the lower rate. In the case of an account heavier than usual—from late hours, inclement weather, or what not—it is useful to be able to point out how much heavier it might have been had not the consumer adopted some apparatus, and so become entitled to have all the increase charged at the lower scale. On the other hand, since no reduction is allowed except on an increase over the 1889 consumption, the works are protected from a diminution of income from these consumers, as far as it is possible to go; so that in the case of a consumer adopting, say, the albo-carbon light, the reduction on the lighting consumption has to be made good by a part of the heating consumption—the balance only coming in at the lower rate. But in other words, a consumer effecting economy in his lights gets the reduction on the consumption charged at the heating and lower rate first, and not until the whole extra consumption of a fire or stove has been wiped off, can the actual lighting rate be affected. Of course, this in some cases makes the cost of the fire or stove appear remarkably small. The consumer, however, in getting such conveniences so cheaply is well satisfied; and so am I. In the case of new consumers, duplicate meters and services are generally put in; but in some cases they prefer the account to be proportioned by us. In such instances, while dealing as fairly as possible, you may be sure my award does not unnecessarily prejudice the legitimate income of the works, nor make the cooking and heating figure appear too costly.

Such, then, is the plan adopted; and to complete this paper, and justify the steps taken, I have only to give you the result. Although the appliances were being fixed during the September quarter, and consequently had not developed the full effect we shall experience in the future, our registered consumption for that period is 30 per cent. higher. Appliances were being fixed at intervals through the Christmas quarter; and although it is with us by far the heaviest quarter for lighting purposes, yet the registered consumption was up 15 per cent. The total quantity of gas registered for heating and cooking apparatus in the Christmas quarter was 36 per cent. in advance of our September figure; and I therefore believe that another summer quarter will give us a 40 per cent. advance. I am sorry this meeting is being held a little too early

to enable me to give the exact figure for the present March quarter, which closes in a fortnight's time; but from my books I find the increased output well maintained, and expect that if any difference is found it will be still higher. I would add that the output is really greater than the figures given. Several new consumers have been obtained, and the public lighting greatly augmented by the adoption of Sugg lamps in the Square, and other improvements; but the figures given are purely the exhibition of results.

This, gentlemen, is all I have to say on this subject at present. The scheme of arranging the consumption is, I believe, a novel one. Whether or not it is applicable to large towns I leave to the judgment of those engaged in them. It is, I think, well enough adapted to small places with limited capital and stunted growth; while the excellence of the results can hardly be questioned. The paper is offered primarily to put heart into those managers who have not yet dared to move from the customs of bygone days, or "to brave the lion in his den" over that bone of contention, the "gas works fitter," and the little tit-bits of income one meets with. To those I would say that, if no opposition were offered, one could be sure there was little to be gained. Go and do likewise, is my advice. There are doubtless others who have long since successfully engaged in the work. If any such can find in this narrative food for reflection, or some stray new idea, so much the better. The best among you can at least leave with the pleasing reflection of how much better he has done.

Cowell's Device for Carrying off Leakage from Gas Mains.

On April 8th U. S. Letters Patent (No. 425,369) were granted to Hiram Cowell, of Zanesville, Ohio, for a device or system for carrying off leakage from gas mains. In the drawings Fig. 1 is a side elevation of a section of a gas main, showing the covering on the joints and the escape pipe for carrying off any gas that may leak out; and Fig. 2 is a longitudinal sectional view of one of the joints, showing the manner of adjusting the escape pipe.

A designates a main such as is usually employed for conveying gas through the streets in cities. Around each of the joints *a* is placed a covering *a'*, which may be of any elastic material, but preferably of rubber. The covering may be made in the shape of common hose, in which case it would simply be slipped over the joints and cemented and held in place by means of a clamp, or by wrapping wire around it at each end, as shown in the drawings at *a''*. This would prevent the escape of gas at the ends, and cause it to escape through the pipe *B*, which extends through the covering and to within a short distance of the joint. To each of the pipes *B* is secured a T-joint *b*, into which is fitted a pipe *C*, which connects all of the escape pipes *B* all along the main. At long intervals in the length of the main are other escape pipes *D*, which allow the gas to pass out into the air.

In covering very large mains it will be found very difficult to obtain rubber tubing of sufficient diameter to slip over the mains. In that case sheet rubber may be used and the edges and ends cemented to prevent the gas escaping.

This device may be also applied to the smaller gas pipes in a house, and also to prevent the escape of sewer gas.

MR. DAVID MORRIS, formerly in charge of the works of the New Westminster (British Columbia) Gas Company, is engaged in the construction of the new water works at Moscow, Idaho, the franchise for which was secured by Mr. G. H. Sutherland, of Walla Walla, Wash. The works are to cost \$25,000, and are to be completed on or before July 1st.

SPECIAL ENGLISH CORRESPONDENCE.

COMMUNICATED BY NORTON H. HUMPHRYS.

SALISBURY, April 10, 1890.

An Important Problem.—The Gas Institute Meeting.—The Profits of Electric Lighting.—Oxygenated Oil Gas.—Spontaneous Combustion of Coal.

The question of the effect of a moderate dose of air, say not exceeding 2 per cent., admitted at the inlet of the purifiers, upon the illuminating power of the purified product, is one possessing great interest. There is no doubt as to its benefit in prolonging the active life of the charge of material, whether oxide or lime, and thus reducing the expense and the annoyance involved in a change of the contents of a purifier; but opinions seem to differ as to the effect upon the illuminating power. In my own practice, the proportion of sulphureted hydrogen remaining in the gas by the time the inlet of the purifier is reached, is reduced to about 5 grains per cubic foot by careful and thorough washing and scrubbing. About 1½ per cent. of air admitted at the inlet of the exhauster is sufficient to maintain the *in statu quo* of the oxide purifier, as it is assisted by the small proportion of oxygen already present in the crude gas, and the most searching experiments fail to show any effect, deleterious or otherwise, exercised by the air upon the illuminating power. Several other gas engineers, who also carefully measure in a small quantity of air, find their experience to agree with this; but there are some who insist that air cannot possibly be united with the gas without exercising a deteriorating effect similar to that observed when air and ordinary purified gas are united together.

That the use of the above small proportion of air admitted under the circumstances usually prevailing in a gas works, at some point anterior to the purifiers, may be resorted to without any injurious results, is therefore a proved fact, so far as some gas works are concerned, at any rate. But the explanation of this fact is a matter of conjecture only at present. The only observed data is that the air increases the temperature of the purifying material to the extent of a few degrees. A charge of purifying material certainly absorbs hydrocarbons from the gas. As much can easily be shown by experiment. And it is easy to imagine that, especially where the purifiers are exposed to a low temperature, that a few degrees of warmth may materially reduce such absorption. I question whether it is due to any special chemical property of the material. The effect of a sudden cooling is sufficient to account for it. We are always very careful to guard the gas against "shock" in the way of a sudden reduction in temperature while in the condensers. But if such gas, after being condensed and washed by appliances situated in a sheltered locality near to the retort house, is conveyed to a purifier house at some distance and in an exposed place, it may perhaps enter the purifier at a temperature of 10° or 20° higher than that of the material. The sudden and complete chilling that follows upon the intimate contact with a large surface of cold material would then produce those effects that have been so carefully guarded against in the condenser. Of the 1.5 per cent. of air, we know that the whole of the oxygen is absorbed and retained in the purifiers, leaving only 1.2 of nitrogen to pass on with the gas. It has recently been suggested that a portion of the nitrogen may also be retained. When alkalinized carbon at a high temperature is exposed to air and steam, some of the nitrogen is retained in the form of cyanides. A considerable quantity of cyanide accumulates in oxide of iron used for the purification of gas, and it is also possible that some of the nitrogen may remain as ammonia. If the nitrogen is retained in the purifier it cannot, of course, injure the gas in any way.

The reason for referring to this subject is because I notice, from the reports of American Gas Managers' Associations, that some of the members are experimentally inclined, and in these days when we are all perturbed at one time or another as to "what to write a paper about," a suggestion may not be unacceptable. Unfortunately there is no convenient method by which the percentage of nitrogen present in a gas can be directly and accurately determined. But as the specific gravity of nitrogen is more than twice that of coal gas, a few experiments with a delicate specific gravity apparatus, such as the Lux balance, would soon afford some information as to the quantity of nitrogen remaining in the gas. Other methods of proceeding will also be obvious to those who are interested in this question. The purifying materials, for instance, might be examined for nitrogenous products.

The arrangements for the June meeting of the Gas Institute, which is to be held at Ryde, Isle of Wight, are in a forward state. Seven papers have already been promised by gentlemen whose names are quite sufficient to show that the prestige of the Institute, as compared with its previous proceedings, will be fully maintained. A noticeable feature of the

programme, and one that will no doubt prove a great attraction, is that of the seven papers above named no less than four are devoted to new inventions of an important character. Mr. W. Gadd will describe the Northwich gasholder, as erected according to his patent system, without exterior guide-framing of any kind; Mr. Pease has something to say about his wire rope system of guiding gasholders; Mr. Coze, of Rheims, will treat of his well known setting of inclined retorts; and Mr. T. Duxbury will read a paper on the Dinsmore process. Looking at the activity that has lately prevailed in respect to oil and water gas, something on these subjects should also be forthcoming. In any case, however, there will be plenty of useful material for discussion. Mr. Geo. Garnett, of Ryde, is the President, and his name is a sufficient guarantee that the social and recreative part of the gathering will be efficiently provided for. Few people know how to arrange for the comfort of a party, whether of 600 or 2,000, better than Mr. Garnett.

The supply of electricity for lighting purposes is not yet a paying affair. The London Electric Supply Association have a plant that cost a round quarter of a million sterling. During the past year it was the means of earning them about £26,000 as gross rental. Of this nearly £20,000 was required to cover the cost of coal, oil, wages and repairs at the generating station. Coal cost £10,500, which is a much larger proportion of the revenue than obtains in the case of coal gas. That sum expended in gas coal would be the means of producing £50,000 or £60,000 worth of gas. Oil and waste cost £2,750, which shows that the machinery requires a tremendous lot of lubricating and cleaning. After paying distributing and other charges a balance of £1,250 remains as profit, which is equal to one-half per cent. on the capital. No wonder the electric light people show such a marked preference for dealing in sales of concessions and patents, or the supply of apparatus. I shan't buy any electric lighting shares at present. No, thank you. Six per cent. gas securities suit me better.

The supply of pure oxygen gas at low prices, now rendered practicable by Brin's Oxygen Company, has directed attention to the various methods in which it can be applied in practice. Amongst other things, it has probably been the means of originating the oxygenated oil gas scheme. Oxygen in quantity has a considerable depreciating effect on the luminosity of ordinary coal gas, but it is claimed that this objection diminishes as the quality of the gas increases. It should be understood that the oxygen is to be used in quantity considerably less than that necessary to form an explosive mixture. A rich oil gas, of 80 to 100 candle power, is very apt to smoke, even with every precaution in burning; but the addition of 20 per cent. of pure oxygen to such gas is claimed to be a means of overcoming this difficulty without at the same time lowering the illuminating value. The oxygenated oil gas thus formed is a sort of concentrated coal gas, yielding five or six times as much light. One thousand cubic feet of it is therefore equal in value to 5,000 or 6,000 cubic feet of coal gas, and the intrinsic value of it, taking the latter at 60 cents per 1,000 cubic feet, would be over \$3. At this price the mixture would afford a large profit, as, with the prices of oil and oxygen at present prevailing, it would not cost more than \$2 per 1,000 cubic feet. The scheme, however, appears to be applicable on the small rather than on the large scale. It may overcome the difficulty of burning rich oil gases, but it does not touch upon the difficulties connected with their distribution to any distance. Provided that the claims of the inventors can be realized in practice, something more will be heard of this scheme in connection with the supply of gas to lighthouses, gentlemen's country residences, or factories situated in districts where coal gas cannot be obtained at a moderate price.

A paper on the spontaneous combustion of coal was recently read before the Institution of Naval Architects, and it is worthy of careful study by all who are interested in the storage of large quantities of coal. The author is Prof. Vivian B. Lewes, who is known as being at present engaged upon an investigation of Van Steenberg's water gas. The principal cause of spontaneous combustion is defined in the following terms: "When the carbon of the coal absorbs oxygen (from the air), the compressed gas becomes very chemically active, and soon commences to combine with the carbon and hydrogen of the bituminous portions, converting them into carbonic acid and water vapor." The prevalent idea is that the presence or otherwise of pyrites or brasses is largely concerned in determining the liability to spontaneous combustion. But it is shown in the paper that the heat produced in this manner is far too small to raise the coal to igniting temperature, or anything near it. The igniting point has been carefully determined by the author, and found to range from 700° F. for cannel to 870° for anthracite. A fruitful cause of spontaneous combustion is the manner in which coal is treated previously to stacking, which usually leads to a large amount of disintegration and consequent formation of fresh surfaces for ex-

posure to the air. Coal loaded into trucks is frequently conveyed some hundreds of miles by rail, being exposed to a great deal of rough jolting during the act of shunting, etc. It is then shot violently down a slope into the hold of a ship. The large amount of slack and dust thus formed is usually the source of trouble, as it not only offers additional facility for the absorption of oxygen, but is a great hindrance to ventilation. If coal was stacked without all this rough treatment, in the same mechanical state in which it is taken from the pit, there would be no risk of firing. As an indication of rise of temperature in the stack of coal, the introduction of electrical alarm thermometers at suitable intervals throughout the mass is recommended. These could be set to ring a bell as soon as a certain temperature was reached, and the bell would continue to ring until the temperature was reduced below the limit. A safeguard against undue rise of temperature could be provided by the use of steel cylinders 1 foot long by 3 inches in diameter, containing carbonic acid compressed to several hundred atmospheres, and closed by a fusible plug melting at 200° F. As soon as the melting point of the plug was reached the carbonic acid would escape rapidly, and in the act of expanding would absorb a large quantity of heat. Prof. Lewes claims that one such cylinder to every 8 tons of coal would be an absolute preventative of undue rise of temperature. According to this, there need be no more trouble or loss on account of the spontaneous combustion of coal cargoes.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE Walla Walla (Wash.) Gas and Electric Company's new buildings for the housing of its incandescent electric lighting system are well under way.

SUPERINTENDENT EDWARDS, of the San Jose (Cal.) Electrical Improvement Company, has, through frequent tampering by unknown parties with the Company's wires and lights, been compelled to offer a reward of \$250 for the arrest and conviction of the offenders.

THE Drain National Gas Company has been incorporated by Messrs. C. M. Idleman, M. C. George, F. A. E. Starr, R. L. Durham and Geo. B. Markle, with a capital stock of \$100,000. This place is in Douglass county, Oreg., at a point 229 miles north of Portland. It is on the line of the old Oregon and California Railroad.

"I SEND you the following resolutions that were recently adopted at a special meeting of the stockholders of the New Bedford (Mass.) Edison Electric Illuminating Company. This move puts Mr. Taber's Company in complete control of the artificial lighting supply of his city—perhaps I should have said the artificial lighting supply on a wholesale basis, for it is beyond question that a few candles and some quantities of 'oil' are still retailed in the celebrated old whaling port. The resolutions are: 1. That this corporation sell its real estate, licenses, privileges, rights and franchises, together with so much of its other property, machinery and material as will altogether amount to the sum of \$150,000, valued as the same stands upon the books of the company, and receive in payment therefor 1,275 shares of said New Bedford Gas Light Company, reserving, however, the corporate power to wind up and dispose of its assets not herein conveyed. 2. That the President and Treasurer be and are hereby authorized to execute, acknowledge and deliver in behalf of the corporation all deeds, papers and instruments necessary to carry out said sale. 3. That John W. Macomber and Chas. R. Price be appointed Trustees of the corporation and of its shareholders to receive from the New Bedford Gas Light Company the shares of stock to be paid by said New Bedford Gas Light Company as the consideration of the sale heretofore voted, and to distribute the same among the stockholders of this corporation in proportion to their respective interests, and to sell at public auction so many of said shares so received from the New Bedford Gas Light Company as may be necessary to an equitable distribution of the same. 4. That the Directors be authorized to take such action with reference to all assets and liabilities of the corporation as are not sold to the New Bedford Gas Light Company under the provisions of the vote heretofore passed, for the purpose of winding up the affairs of this corporation, and distributing the remaining property among its shareholders, as they shall deem best for the interests of said shareholders."—OBSERVER."

"SAN FRANCISCO, Cal., April 14th, 1890.

"Dear JOURNAL—The trial of the action brought by Simon Goldstein and Hernian Cohn against Messrs. Will & Finck to recover \$1,050 for an alleged theft of gas, was begun, on the 13th inst., before Judge Hunt and a jury. The complaint in the case sets forth that the defendants are doing business at 818 and 820 Market street, and the plaintiffs, in the ad-

joining shop, at 822 Market street, carry on their trade. It is charged that for 10 months past defendants secured the lighting of their stores free of expense by secretly attaching their pipes to the plaintiffs' meter, thus securing gas for 52 lights of the value of \$2 a night. The plaintiffs claim to have sustained \$1,000 actual damages, and also that they have expended \$50 in endeavoring to discover the unlawful connection. I have heard of gas being stolen from gas companies, and often burned off the same meter, but this market street instance strikes me as an entirely new sample of 'gas steal.' In that belief I venture to send the above facts.—RETORT."

THE first move in the shaping up of the future management of the Troy (N. Y.) Electric Light Company, since its acquisition by the Troy Gas Company, is the election of Mr. Charles E. Davenport, Secretary of the Gas Company, to succeed Trustee George H. Morrisson, of the Electric Company. Doubtless the next one of the new owners to assume a Trusteeship will be Mr. A. N. Brady, and in all probability he will replace Mr. Chas. P. Kimball.

MR. L. F. McDONALD, Mayor of Belfast, Me., notifies electric lighting contractors that the City Council will, until 6 P.M. of Monday next, receive bids for the public lighting of that place, under the following conditions: 40 incandescent electric lamps, of 64-candle power each, and 6 arcs of 1,200-candle power each, the lights to burn from sunset to midnight of each night in the year. Proposals are invited for a 1, 2, 3 or 5-years' contract, and also for a service based on all-night lighting. Again, proposals will be received for 20 arcs, to be burned from sunset to midnight throughout the year. The party to whom the contract is awarded must have the lights in duty 90 days after the contract is signed.

THE stockholders of the Randolph (Mo.) Coal and Gas Company have agreed to increase the capital stock to \$200,000 from \$75,000.

THE officials of the St. Paul (Minn.) Gas Company entertained at least 500 people at the premises No. 100 East Third street, that city, on the afternoon of the 16th inst. The entertainment was somewhat after the nature of a lesson in cooking, differing therefrom only in the fact that the edibles cooked were afterwards (at once would be better) consumed by the visitors in attendance. Of course, the cooking was done by gas in gas ranges, boilers, heaters, etc., and there can be no doubt about it that this object lesson will be worth at least \$5,000 in good, hard cash to the St. Paul Company, ere 1890 becomes 1891.

AT a meeting of the Board of Directors of the Charleston (W. Va.) Gas Company, held on the 16th inst., it was agreed that the Company should erect an electric light plant at once, and operate the same under the authority conferred by the Company's charter.

"I NOTE your reference to the possibility of Manchester, Va., having a gas works, and agree with you that the possibility is likely soon to become a certainty. In connection with this I send you the following from a local paper known as the *Leader*, dated the 12th inst.: 'Mr. John C. Robertson, on behalf of himself and others, presented a petition to the City Council last night asking for franchises to construct a gas plant in Manchester for the purpose of manufacturing illuminating and fuel gas. The petition came in the shape of an ordinance reported from the Committee on Light. The ordinance provides that mains shall be laid on the same streets now occupied by water pipes, and on such other streets as the Council may direct, certain conditions being complied with. It is provided that the city shall receive gas at not exceeding \$1 per 1,000 feet, and the citizens shall not be charged in excess of \$1.25 per 1,000: further, that when the price of gas in other cities east of the Alleghenies is less than \$1.25 a similar reduction shall be made here. The Company is to enjoy exclusive franchises for a period of 25 years. In the debate that followed Chairman O'Brien, of the Committee on Light, said he did not expect the ordinance to be adopted right away, and agreed with others that it should go over for a few days. Mr. Bradley thought the 25-year exclusive feature was too lengthy a concession, which view was shared in by Messrs. Perdue and Falconer. It also looked as though the sentiment of the Council was in favor of stipulating in the ordinance that the city should have the right to at any time purchase the plant.'—R."

THE new Collins Cove and Beverly Harbor plant of the Salem (Mass.) Gas Company, which is complete in every particular, is now in active operation, and is a success in every way you can ask the question.

SOME months ago we published an opinion of the District or Lower Court of New Orleans in the matter of the New Orleans Gas Light

Company vs. the Harmony Club, in which the basis of claim was that defendants resisted payment of a bill for meter rent, presented by the plaintiff. The latter had been using gas but subsequently changed to electricity, insisting nevertheless that defendant should not remove the gas meter, and that payment to the plaintiff should only be made for such gas as was passed through the meter when the electric light failed, etc. The decision of the inferior court was adverse to defendant, who thereupon applied to the Supreme Court for an appeal, with the following result—in view of the importance of the case we report it in full. The decision was rendered by Judge Fenner, the associates concurring: "*Harmony Club vs. New Orleans Gas Light Company*.—Appeal.—We are confronted with a challenge to our jurisdiction, *ratione materiae*, over this appeal which we are bound to determine. The facts are simple and undisputed. The Harmony Club had upon its premises, furnished by the Gas Company, what is called a 45-light meter, adequate to the supply and registry of all its gas burners. In common with many other gas consumers it adopted the system of electric lighting and its use of gas became only occasional and greatly reduced. The Gas Company adopted certain rules applicable to this class of customers, the meaning and effect of which are that it would only furnish meters proportioned by size to the amount of gas consumed. That a 45-light meter would only be supplied or continued when the monthly gas bill was at least \$8; or if less, upon the payment of an extra rental of \$4 per month. A copy of these rules was served upon the Club, and notice was given that unless complied with its meter would be removed and replaced by a smaller one. The Club being unwilling to comply and denying the right of the Gas Company to adopt or enforce such rules, instituted this suit for an injunction prohibiting the latter from removing or interfering with the meter then on its premises. The Gas Company responds, affirming its right to adopt and enforce the rules in question. This is the sole issue involved in the case. If it should be determined that the Gas Company has the right to adopt and enforce the rules, the injunction necessarily fails. If *per contra* it has no such right the injunction stands. What is the amount or pecuniary value involved in such a suit? It is not pretended that the Gas Company will interfere with the meter if the Club consumes gas to the amount of \$8 per month, or, if consuming less, it pays \$4 additional for the rent of the meter. It is not denied that the club is bound to pay for the amount of gas, large or small, actually consumed by it. Therefore, the only value possibly involved is the right of the Company, in a certain contingency, to charge \$4 per month for the use of its meter, or \$48 per annum. If this were a right *in perpetuus* it would be difficult to find an investor who would pay \$2,000 for the privilege of collecting \$48 per annum; but in point of fact, the Gas Company's charter expires in 35 years, and a simple calculation would show that if collected in that period the gross amount would not exceed \$1,700. Moreover, the Club is not the owner of the building, but a lessee, and is only interested during the term of its lease, the extent of which is not shown, but is presumably limited. We are not concerned with the damage which the Club might have suffered had its gas supply been cut off or diminished, as threatened. No such damages have accrued or will accrue. If the injunction herein be perpetuated that will prevent such injury. If it be dissolved the act of the Gas Company will be declared lawful and no such claim can arise. We have repeatedly held that the jurisdiction of this court must be tested in such cases by the pecuniary amount or value in dispute, according to the nature of the action as disclosed by the substantial allegations of the pleadings, and not by the mere jurisdictional allegations or affidavits of the parties—*Belding vs. Baldwin*, 38 Ann., 394; *State ex rel vs. Miscar*, 34 Ann., 834; *Wilkins vs. Gault*, 32 Ann., 929; *Cran Case*, 32 Ann., 1,191. Most of the cases quoted by appellant only concern the right to sue and enjoin, neither of which rights is controverted here. We decline to follow him into the records of the cases of *Callory vs. Water Works Company*, 35 Ann., 799; *Long vs. same*, 36 Ann., 942; and *Ernest vs. same*, 39 Ann., 551, in order to determine whether or not we had jurisdiction in these cases. The opinions show that no such question was raised or passed upon. Had it been we should have applied to them the same rules now stated. If inadvertently and in the absence of suggestion to that effect, we exercised jurisdiction which we should have declined (which we by no means admit), such error neither harms nor benefits the plaintiff here, whose right must be decided according to law. It is therefore ordered that this appeal be dismissed at appellant's cost."

THE deadlock over the election of a President for the Bridgeton (N. J.) City Council has been brought to a happy termination in the selection of Mr. Benjamin F. Harding, of the Bridgeton Gas Company. The mantle could not have been placed on worthier or stouter shoulders.

MR. JAMES LAMBERT VIALLE, one of the most popular collectors in the service of the Bay State Gas Light Company, of Boston, Mass., died at his home in that city, on the 16th inst. He was in his 62nd year, and was well liked by his employers.

THE betterments recently completed on the plant of the Danvers (Mass.) Gas Light Company have enabled it to distribute an excellent quality of gas. The last test made by Inspector Hinman gave it a candle power of 18.1, and the ammonia content was less than 2 grains per 100 cubic feet.

THE Waltham (Mass.) Gas Light Company is extending its mains, and the business of the Company keeps on increasing in most gratifying manner.

THE Citizens Gas Light Company, of Newark, N. J., is not averse to bringing on a lawsuit in respect to its right to remove gas meters from the premises of those who have changed from gas to incandescent electric lighting, but who insist on retaining their gas meters as an insurance against possible failure of the electric light. Early this month the Company did remove a meter from the barber shop of F. Beck, 9 New street, whose use of gas was confined to a quantity sufficient to maintain a cigar lighter. The barber agreed, however, to pay for a certain quantity of gas each month, and his meter was replaced. The Company, however, intends to have a test case of this right made, and, judging from the rulings in the Supreme Court of Louisiana, in respect to the complaint of the Harmony Club, there is small doubt that the right would be sustained.

MR. WM. BRUCE, of the Elmira (N. Y.) Gas Company, will visit Europe this summer. He expects to remain abroad for four months.

THE new gas rate at Rockford (Ills.) is \$1.80 per 1,000. The American Gas Company are to be congratulated on their having secured this property, which so long stood as a monument to the genius of the late Thomas Butterworth.

AT the annual meeting of the Flint (Mich.) Gas Light Company the following Directors were chosen: J. W. Begole, Ira H. Wilder, Wm. Hamilton, Wm. A. Atwood, J. C. Wilson, A. D. McColland and Robt. J. Whaley. The officers chosen were: President, J. W. Begole; Treasurer, Ira H. Wilder; Secretary, Giles N. Denham.

THE Poughkeepsie (N. Y.) *News Press* says: "The Electric Light Company are not furnishing good service in the government building here. They are obliged by the terms of their contract to pay for all gas used in the post office and in the revenue collector's office, in consequence of the incandescent lamps failing to give sufficient light. The gas bills on these accounts have been frequent and large of late. Further, the incandescent electric lights in the post office building do not come up to the standard of 16-candle power."

THE County Board of Equalization has reduced the assessment of the Kansas City (Mo.) Gas Light and Coke Company on personal property from \$160,000 to \$107,000, because it was shown that the Company returned its machinery—retorts, scrubbers, etc.—as personal property, while the Board had also assessed the same under the heads of buildings and contents.

THE attempted general strike at the North Side works of the Chicago Gas Light and Coke Company was a complete failure. Only 7 of the employees went out. The proposed strike was ostensibly based on the discharge by the Company of Richard Williams and Charles Peters, their confreres claiming that the men had been discharged without just cause; but the real cause for discontent is the desire of the men to have fewer hours of work.

DISPATCHES from Circleville, O., bring the news that Howard Jones, Henry Worthington, George C. Harrington, Fannie M. Moore and Samuel Moore have filed a petition in the Common Pleas Court praying that the Circleville Gas and Coke Company be put in the hands of a receiver and its affairs closed up. They alleged that the defendants, L. H. Sweetman, Jos. P. Smith, B. Hathe and L. Abt, owners of one-half of the Gas Company's stock, are also stockholders in the Circleville Edison Electric Company, and that they use the information so obtained to the injury of the Gas Company.

THE Legislative Committee appointed by the Kentucky Senate and House to investigate charges that the Louisville Gas Company had interfered in local elections, seems to make haste slowly. At any rate, they have named two dates on which to take testimony at the Galt

House, but the announcements were followed by postponements. Among the witnesses cited are: President Morris, Vice-President Barret, Treasurer Lee, Asst. Treasurer Porter, Directors Harry Bishop and J. M. Atherton, Gas Inspector Bate, Ex-Mayor Reed, Mayor Jacobs and other city officials.

LAST week we noted that the stockholders of the White Plains (N. Y.) Gas and Electric Light Companies had voted to consolidate their interests, and we are now able to say that the deal is a fixed fact. The officers chosen are: President, Samuel Conover; Treasurer, Edward R. Phelps; Secretary and Superintendent, Richmond E. Slade; Directors, S. Conover, Edward R. Phelps, Samuel R. Pullen, R. E. Slade and Wm. H. Albro. The corporation is hereafter to be known as the Citizens Gas and Electric Light Company, and it is capitalized in \$100,000.

THE City Council of Annapolis, Md., has adopted an order granting the right to the Annapolis Electric Light Company to lay gas mains through "the streets, lanes and alleys of Annapolis, for illuminating and other purposes, provided the same be laid so as not to obstruct the proper use of the streets," etc.

A DRAUGHT of the plans for the proposed new Smith avenue plant for the Troy (N. Y.) Gas Company has been completed.

WE understand that operations have been resumed on the plant of the Empire Gas and Electric Light Company, of Huntington, L. I., which work was temporarily suspended on account of certain financial difficulties in which its President (Mr. Claassen) became involved.

THE North Attleboro (Mass.) Gas Company wants to perform the public lighting of that town by means of Gordon lamps.

AT the session of the Rhode Island Senate, held April 18, Senator Pond called up the special order granting the Electric Power and Machine Company power to lay gas pipes in the city of Woonsocket. Senator Garvin asked for information in respect to the animus of the motion, and Senator Andrews said it was simply a local affair. He incidentally remarked that the "Woonsocket Gas Company was accidentally given the power to put in electric light last year, consequently it was only fair that the electric light company should be put in position to compete." To this Senator Garvin made the somewhat common-sense reply, "that it was a very different matter from competition between two gas companies. Because a mistake was made last year there was no reason for carrying it further." Continuing, he said: "There appeared to be only two objects for asking for these powers—either to allow the two companies to consolidate, or to have competition. If the first was carried and the Legislature passed this bill, it would become a party to the watering of stock, and thus help to increase the cost of gas to the citizens of Woonsocket. There was no argument in favor of having two companies, so far as the price of gas is concerned. In Fall River, Mass., the price of gas is \$1.57, while the average cost in cities of that State having but one gas company was \$1.49. Rhode Island should have a Gas Commission similar to that in Massachusetts, but in the absence of a Commission the State should adopt a positive policy in respect to the supply of gas and electricity, and that policy should be not to allow the placing of two gas companies in one city. The only argument in this Woonsocket case was that no one so far objected to the grant, and that the City Council favored it. The Legislature, however, did not know what the City Council might do; it was like giving a razor to a baby." Senator Pond sarcastically alluded to the last speaker by comparing him to the Spanish hero who went around fighting windmills. He went over the history of the two cases again. It was only the question of putting one company on the same footing as the other. There was nothing hidden in it, and if granted the City Council would treat it in a business way. There was scarcely a city of any importance on the face of the earth that did not have more than one gas company. Senator Garvin suggested that his colleague, Pond, would have been closer to Senatorial dignity had he, instead of indulging in personalities, attempted to show what benefit the people of Woonsocket would gain in the passage of this act. When the debate terminated a motion to adopt the act was agreed to by a vote of 15 to 6.

WE are indebted to a correspondent (who writes under date of 16th inst.) for the following interesting particulars regarding the artificial lighting supply of Helena, Montana:

"Yesterday the preliminaries were arranged for the consolidation of two of Helena's largest lighting plants, involving over \$250,000. The Helena Gas Light and Coke Company (C. W. Cannon, President) and

the Helena Steam Power and Lighting Company (H. M. Parchen, President) will be merged into one Company. At a meeting held yesterday the terms were agreed upon, and the perfection of the organization is soon to follow. The building now occupied by the Helena Steam Power and Lighting Company is to be vacated and the machinery removed to a new building 50 x 75 feet, to be built at once near the gas works. One of the stockholders of the new Company stated that it was the intention to expend about \$150,000 in improvements in enlarging the gas works and purchasing additional machinery, which will make the plant the finest in the West. The present works of the consolidated Company, together with the improvements agreed upon, will give the plant when completed and improved a cash valuation of over \$500,000. One important move will be the extension of gas mains to many of the rapidly filling suburbs. The consolidation makes a Company to which the costs of improvements are not a strain. The men interested have ample funds to further any enterprise in the way of spreading light which they may undertake. In the directory will probably be found some of Helena's most prominent names."

The Council Bluffs Gas and Electric Light Company has concluded to branch out, and will enlarge its works and better fit itself for the production of gas, in spite of the fact that the consumption of that article in the city does not run on the average above 30,000 feet per day. The coal gas plant will certainly be improved by the addition of a new boiler and other fixtures, and it is probable that a plant for the manufacture of water gas will be put in. This plan has been under consideration for a long time past, but has been regarded as something which could possibly be acquired now. But the members of the Company, after consulting together, have almost reached the conclusion that it will be a good thing in the long run to put the water gas plant in now, and it is probable that the contracts for the erection of the necessary buildings will be let within a few weeks; and when this has been done the work will be pushed as rapidly as possible. The new plant will cost, if erected, from \$25,000 to \$30,000.

MR. JOHN P. HARBISON, acting for the Hartford (Conn.) City Gas Company, has entered into a contract with the United Gas Improvement Company, under which the latter will install on the Hartford works a water and fuel gas plant, to have a capacity of 500,000 cubic feet. The plant will be completed in about three months.

The Cheapest Light.

At the session of the National Academy of Sciences, held in Washington, April 17, Professor Langley read a paper "On the Cheapest Light." In all artificial lights, he said, there is an enormous waste of energy. Thus, in heating a poker to incandescence at least 15-16ths of the amount of coal burned is required to raise the temperature sufficiently to emit light. It is as if we had to strike all the low notes of a piano before we could sound an upper one. If, while using such an instrument, we should hear the singing of a bird, we should realize that Nature had provided a far simpler apparatus.

We find an analogous case in the simplicity and economy of natural compared with artificial methods of producing light. The paper gives an account of observations on a firefly (*Pyrophorus noctilucus*), many specimens of which were secured from the West Indies, and the spectrum of light emitted by them was studied with the aid of the spectroscope, while the heat emitted was measured by Langley's bolometer.

The spectrum from light from this insect is very short, extending only from F to C, and culminating in green, so that the heat rays are entirely absent, not heat enough being emitted to raise the temperature of the bolometer 1-200,000 of a degree Centigrade in 10 seconds' exposure.

That the absence of heat rays is not caused by the faintness of the light is shown by comparing it with light from a candle reduced to the same amount, which is accompanied by two or three hundred times as much heat.

In all ordinary methods of illumination there is a loss of at least one hundred, probably several hundred times as much heat as is utilized, most of the energy being consumed in raising the temperature of flame to at least two thousand degrees.

The light of the firefly is not a vital, but a chemical process, in other words, combustion, as is proved by the fact that nitrogen quenches and oxygen enhances it, and that it is attended by the production of carbon dioxide; though, as respects heat, it is even more economical than sunlight. It seems that chemistry should find means to imitate this process, giving us a form of combustion wherein the energy of fuel is all converted into light instead of being mostly wasted in heat.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889, and later dates.

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE. Works under our system may be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon. One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3	ft. square,	5	ft. deep.
No. 2,	" "	125,000	" " "	4	" " "	" "	" "
No. 3,	" "	250,000	" " "	5	" " "	" "	" "
No. 4,	" "	500,000	" " "	6	" " "	" "	" "
No. 5,	" "	750,000	" " "	7	" " "	" "	" "
No. 6,	" "	1,000,000	" " "	8	" " "	" "	" "
No. 7,	" "	1,250,000	" " "	9	" " "	" "	" "
No. 8,	" "	1,500,000	" " "	10	" " "	" "	" "
No. 9,	" "	2,000,000	" " "	12	" " "	" "	" "
No. 10,	" "	3,000,000	" " "	15	" " "	" "	" "

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time

Made in Sizes of 5, 10, 15, 20, and 25 Horse Power. All Engines Guaranteed for One Year.

 Cable Address, "PERKINS, NEW YORK." Post Office Box 3695, New York.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's
OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,
OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,
Gas and Cannel Coal Contractors,

222 Sutter Street, San Francisco.

HELME & McILHENNY,

(Established 1848.)

GAS METER MANUFACTURERS,

Nos. 1339 to 1349 Cherry Street, Philadelphia, Pa.,

WET AND DRY GAS METERS, STATION METERS, EXPERIMENTAL METERS, METER PROVERS,

Center Seals, Pressure Registers, Governors, Indicators, Photometers, and all other kinds of Apparatus for use in Gas Works.

FOULIS' PATENT STATION AND DISTRICT GOVERNORS.

REPAIRING DEPARTMENT.—We employ a special force of skilled workmen repairing meters of all makers.

WM. WALLACE GOODWIN, President and Treasurer.

E. STEIN, Vice-President.

H. B. GOODWIN, Secretary and Superintendent.

THE GOODWIN GAS STOVE AND METER CO.,

Successors to W. W. GOODWIN & CO.

1012, 1014 and 1016 Filbert St., Phila., Pa.

142 Chambers St., New York City.

76 Dearborn, St., Chicago, Ills.

WALDO BROTHERS, Agents, 88 Water Streets, Boston, Mass.

MANUFACTURERS OF

DRY AND WET GAS METERS,

Station Meters (square, cylindrical, or in staves), Glazed Meters, King's and Sugg's Experimental Meters, Lamp Post Meters, etc., etc. Meter Provers (sizes 2, 5, and 10 feet), Pressure Gauges of all kinds, Pressure Registers, Pressure and Vacuum Registers, Pressure Indicators (sizes 4, 6, and 9 inch), King's Pressure and Vacuum Gauges, Dry and Wet Center Seals, Dry and Wet Governors, Exhauster Governors, Photometers of all descriptions. Letheby's Sulphur and Ammonia Test Apparatus complete. Also, Testing and Chemical Apparatus of all kinds, and of the most perfect description, for all purposes relating to Gas.

Manufacturers of the "SUN DIAL" GAS STOVES, for Cooking and Heating.

Goodwin's Improved Lowe's Jet Photometer.

Agents for Bray's Patent Gas Burners and Lanterns.

Special attention to Repairs of Meters and all Apparatus connected with the business. All work guaranteed first-class in every particular. Orders filled promptly.

G. B. EDWARDS, Manager, New York.

S. S. STRATTON, Manager, Chicago.

D. McDONALD & CO.,

GAS METER MANUFACTURERS.

(Established 1854.)

51 Lancaster St., Albany, N. Y. 34 & 36 West Monroe St., Chicago, Ill.

STATION METERS, EXPERIMENTAL METERS, METER PROVERS, PRESSURE & VACUUM REGISTERS, PRESSURE GAUGES, ETC.

Also STAR GAS STOVES, RANGES, and HEATING STOVES.

We use only the very best materials, and employ the most skilled labor, and by our long experience (36 years) and personal supervision of every detail, we feel justified in assuring the public that our goods will give perfect satisfaction. Every Meter emanating from our establishment will bear the State Inspector's BADGE, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

WM. WALLACE GOODWIN, President. E. STEIN, Vice-President. H. B. GOODWIN, Sec. & Supt. G. B. EDWARDS, Mang'r, New York. S. S. STRATTON, Mang'r, Chicago.

THE GOODWIN GAS STOVE AND METER CO.,

1012-18 Filbert St., Phila., 142 Chambers St., N. Y., 76 Dearborn St., Chicago.

Agents, WALDO BROTHERS, 88 Water Street, Boston.

SOLE MANUFACTURERS OF THE

"SUN DIAL" GAS STOVES,

The Most Economical, Efficient, and Durable Gas Stove Made.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
37 in. high.	12 in. high.	12 in. high.	24 in. long.	36 in.
20 in. wide.	17½ in. wide.	18 in. wide.	21 in. wide.	
	12 in. deep.	13 in. deep.		

This Stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 42 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
31 in. high.	9½ in. high.	10 in. high.	21 in. long.	32 in.
17 in. wide.	14½ in. wide.	15 in. wide.	16 in. wide.	
	12 in. deep.	13 in. deep.		

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 3 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. ½ in. supply pipe should be used where the pressure is 1 in. or over.

Western Gas Association.

SECRETARY'S OFFICE, WESTERN GAS ASSOCIATION, }
QUINCY, ILLS., April 28, 1890. }

The Thirteenth Annual Meeting of the Western Gas Association will be held at the Lindell Hotel, St. Louis, Mo., on the 21st, 22d and 23d days of May. The hall in which the business sessions of the Association will be conducted is within the hotel building, is very commodious, quiet, and in every way excellently well adapted to our requirements. The hotel management has granted on this occasion the following rates: For single room and board, \$2.75 per day; for room with bath, \$3.25 per day. These rates will apply to members in attendance, their families and visiting brethren. In this connection I am instructed by the Local Committee of Arrangements to give our members warning of the fact that in order to secure suitable accommodations, their rooms *must be engaged in advance*. Your Secretary has been in the habit of making an announcement to this effect with exceeding regularity from year to year, and just as regularly no one, or at least only very few, pays the slightest attention to the warning. The necessity of engaging quarters in advance, however, is in this instance very urgent. Now that the old Planters' House has been closed, the Southern and Lindell Hotels often have more business thrust upon them than they are capable of handling, and of late it has been no unusual occurrence for them to deny would-be guests admission, unless their rooms had been previously spoken for. But all of our members can be accommodated without the slightest jar or friction, if they will but take the trouble to address a line to the "Proprietor of the Lindell Hotel, St. Louis, Mo.," telling him the kind and price of room or rooms desired. This should be done at least one week in advance of the first day of the meeting.

In addition to the reduction in transportation rates granted by the Central Traffic Association, the Trunk Line Association has also joined in the movement. As the boundary of the latter Association extends as far east as the western border of the New England States, our Eastern friends will be enabled to avail themselves of the reduced fares.

I am authorized to state that Mr. R. D. Walsh, Chairman of the Local Committee of Arrangements, has kindly consented to take charge of all articles destined for the Gas Exhibit, and will cheerfully surrender a generous portion of his time to the interests of exhibitors. Communications, consignments of gas stoves, apparatus, burners—anything, in fact, intended for the Exhibit—may be directed to Mr. Walsh, in care of the Laclede Gas Light and Coke Company. Exhibitors can rest assured that not only will their wares receive careful handling and be displayed to the best possible advantage, but that they themselves will be accorded the most courteous treatment at the hands of Mr. Walsh and his efficient committee.

The "Paper List" for our Thirteenth Annual will be as follows:

- "Relative Value of Gaseous Fuels," by B. E. Chollar.
- "Effects of Natural Gas Competition," by James Somerville.
- "An Argument in Favor of the Adoption of a Uniform System of Estimating the Cost of Gas in the Holder," by George G. Ramsdell.
- "Impressions of British Gas Works," by George T. Thompson.
- "Mixed Gases," by E. G. Cowdery.

"Wrought Iron, Cast Iron, or Steel—which is the Best Material for Street Mains?" by Eugene Printz.

"What Policy Should the Gas Interest Adopt in Connection with the Approaching World's Fair?" by Walton Clark.

"On the Abuse of the Patent System as Bearing on the Gas Industry, with a Remedy," by Frederic Egner.

"The By-Products of Experience," by Allen R. Foote.

The attention of the Board of Directors is called to the fact that Section I., of Article VII., of our By-Laws reads as follows: "The Board of Directors shall meet as such at least once in each year, on the day preceding the annual meeting of the Association, at which time they shall determine in regard to the propriety of the various papers, drawings, models, or other matters constituting the special order, being laid before the Association." The Board of Directors elected at our last meeting is composed of the following-named gentlemen, who are, therefore, particularly requested to assemble at the Association's headquarters on Tuesday morning, May 20, at 10 o'clock:

J. B. Howard, E. H. Jenkins, Z. T. F. Runner, John Gimper, C. W. Butterworth, E. G. Cowdery, J. S. Ambrose, J. W. Dunbar, and B. E. Chollar.

Application blanks, copies of our By-Laws, and any information not contained in these communications will be cheerfully furnished by
A. W. LITTLETON, Sec'y.

BRIEFLY TOLD.

THE PAPER LIST FOR THE ST. LOUIS CONVENTION.—A glance over the list of papers that are to be presented at the meeting of the Western Gas Association is all that is necessary to force the conviction that the literary part of the proceedings will be more than ordinarily interesting, which is high praise when one bears in mind the always excellent contributions that the Western has been favored with. First on the list comes Mr. Chollar's name, who proposes to deal with the "Relative Value of Gaseous Fuels." Now, it must be admitted that Chollar has a peculiarly attractive method in his penciling, and when the fruit from the latter has been turned out of the basket it cannot be charged with the taint of unsoundness. His subject is one that is in full accord with the thought of to-day, and as he has neither a process to sell nor a pet theory to propel, we can safely count on true independence of opinion from him. Mr. Jas. Somerville will also be welcomed again with heartiness to the arena of disquisition, the records of which bear ample testimony to his carefulness and thoroughness. Next we have Geo. G. Ramsdell, who has in other days—and not so long ago, either—proved his value in the field of argument. His subject, too, is one that bears the charm of novelty. We hoped some time ago that Mr. Thompson would have, through the columns of the JOURNAL, given our readers the benefit of his "Impressions," but, it is without any symptoms whatever of jealousy, that we congratulate the Western on being the first to have an itemized account of the Thompson tour through Europe. If we mistake not, this is Mr. Cowdery's "first appearance" as a paper contributor, and as he is well grounded in his subject, through careful, prolonged and extensive practice at Milwaukee, we confidently look forward to an excellent paper from him. Mr. Eugene Printz will beyond doubt show to good advantage in the matter of determining which is the best iron material for use in street mains, and Mr. Clark will, we imagine, have something original to suggest in his remarks on the correct attitude to be assumed by the gas interest in respect to its connection with the World's Fair. Mr. Egner's name is so familiar to our readers, that no doubt they are at one with us in the knowledge that he could not write uninterestingly, even did he try to so do. Mr. Foote closes, and with seeming appropriateness, a list that is headed by a C(h)ollar. Take it in any light, one cannot avoid the conclusion that the meeting at St. Louis is to be enlivened by an excellent lot of papers on subjects well outside the usual scope, that are to be prepared by authors of unexceptional capacity.

THE GAS APPARATUS EXHIBIT AT ST. LOUIS.—Messrs. Walsh and Egner of St. Louis, are devoting much attention to the matter of arranging for the exhibition of gas appliances that is to form a prominent feature of the Western's meeting. We can only repeat our hope formerly expressed that every one of our advertisers will be represented in the display; and to give the matter as wide publicity as possible, we herewith reprint a circular, dated from the Engineer's office of the Laclede Gas Light Company, on April 29th. The circular reads:

"To Manufacturers of Gas Appliances.—It is the intention of the local Committee of Arrangements of the Western Gas Association to have, in connection with the annual meeting, an exhibition of gas appliances.

Mr. Emerson McMillin, President of the Laclede Gas Light Company, has kindly given the use of the third floor of the large new office building of that Company to the Committee for an exhibition hall. The same is supplied with freight and passenger elevators, gas, water and closets. Exhibitors will be under no expense whatever, except that of sending and removing their exhibits. It is not necessary to remove exhibits as soon as the convention is over. On the contrary, exhibitors may continue to show their goods at the hall to the public or customers, or sell them from the hall, or use the exhibits as samples merely, for an indefinite time, and remove whatever they desire to take away at their leisure and convenience. The hall is located in the center of the business districts of the city of St. Louis—a city of over one-half million of inhabitants; a city as large as New York city of 30 years ago; a city which is the visiting point annually of many thousands of people from Mexico to the Canadas, the Pacific coast and the Gulf. It is not the unimportant border town that many Eastern people who have never been here seem to imagine. This opportunity to exhibit during the convention, and more or less permanently after that time, should not be neglected by manufacturers. Those not represented may regret it when too late. Such as wish to exhibit should address, without delay, the undersigned, and send on their goods, so as to be sure and have them in place on May 20th, next.—Very respectfully, FREDERIC EGNER."

A CORRECTION.—In Mr. B. E. Chollar's paper in the JOURNAL (April 7, p. 485), entitled "Doubts versus Dogmatism," some inexcusable typographical errors occur; and as the admission is made that they are inexcusable, we have but to point them out and correct them. In the eighth paragraph, which is chiefly devoted to an explanation of the diagram accompanying the paper, the words "wave point" occur four times. In each instance these should read "wave front."

NOTES.—We are in receipt of telegraphic advices from Providence, R. I., which are to the effect that the Wakefield Manufacturing Company's "little bill" has been indefinitely postponed by the Rhode Island Senate, and we are glad of it.—There can be little doubt that important changes will soon be perfected in the capitalization and scope of the United Gas Improvement Company. As we understand it the capital is to be increased to \$50,000,000, about 50 per cent. of which is to be held in England. The Company will largely extend its business.—The municipal gas works for Hamilton, Ohio, are virtually completed.—Important plant betterments are being made at the gas and electric lighting stations of the Neenah and Menasha (Wis.) Gas and Electric Light Company.—The Pratt and Ryan Water Gas Construction Company, with a capital of \$100,000, has been incorporated with place of business at Chicago. That is a reconstruction of the old firm of Henry C. Pratt and Co.—The Fresno Republican, of Fresno, Cal., is making a great howl over the imperfect burners maintained in the public lamps, and thinks the Gas Company ought to change them. Why should the authorities not attend to it? It is their duty to do so.—The strike at the Elizabeth (N. J.) gas works was a complete failure. The men were "out" 3 days, and were glad to get back on the old terms.—Mr. Frank Seaverns, of Perkins & Co., will sail for Paris on the 10th inst. No pleasure trip for Frank this time.—The proprietors of the Watkins (N. Y.) Gas Company have reduced the selling rate to \$2.25 per 1,000. Former price, \$2.75.—The San Diego (Cal.) Gas and Electric Light Company has adopted a novel plan to head off competition. Briefly stated the scheme is this: the Company agrees to reduce the price of gas to \$2.50 from \$3.50 per 1,000, provided the consumer will sign a contract to take gas from no other Company for the period of 5 years. The agreement also provides that if during the five years the City Council shall pass, and the Gas Company accept any ordinance by virtue of which the price of gas to all private consumers is reduced below the price named in the agreement, then consumers shall not be required to pay any price in excess of that named in the ordinance, but shall have the benefit of any general reduction in price which may be made.

The Market for Gas Securities.

Consolidated sold above 99½ during the week, and to-day (noon, Friday) is bid for at 99. Prudent observers of the market and careful investors look for 105 before July 1st. Of course, dividend time is approaching, and the shares are carrying the earnings virtually for the old months. Other city shares show no marked change. Brooklyn shares are strong, the highest figures for years being now recorded in one or two of them. Chicago Trusts are up to 51½-52, and Chicago gas, the successor to the Trust, ought to sell at 60 before July 1st. The general market presents no feature of interest, other than that a good demand for shares is certain.

[A Paper read before the Society of Gas Lighting.]

Labor-Saving Appliances for the Manufacture of Coal Gas.

By MR. WM. MOONEY, C. E.

Assuming at the outset that coal will be used for the manufacture of illuminating and fuel gas for many years to come, and that the present methods of purification will also continue in use for some time yet, I venture in this paper to call attention to the use of labor-saving appliances in the handling of the coal, coke and purifying materials.

I am aware of the fact that one not actually engaged in gas making is apt to suggest improvements, so-called, that the practical engineer at first thought may not think of much value; but these notes may encourage thought in the direction, now so earnestly sought, of cheapening the cost of manufacture, and thereby reducing the cost of gas to the consumer, and encouraging him to use it for other purposes than illumination.

The subject treated of in this paper might properly be called the substitution of machinery for hand labor in the manufacture of gas; and the subject may be divided into the following parts:

- 1st.—Handling and storage of coal.
- 2d.—Delivery of the same in the retort house.
- 3d.—Charging and drawing the retorts.
- 4th.—Handling and storage of coke.
- 5th.—Handling of purifying materials—lime and oxide of iron.

That the methods of manufacture used in the manufacture of coal gas are a fit subject for improvement nobody can deny, some of the methods being as old as the business itself.

Improvements, it is true, have been made on certain lines and the cost of manufacture reduced; but these improvements only show more plainly the need of radical changes. For obvious reasons the changes suggested here can apply only to large or medium-sized works.

Handling and Storage of Coal.—Economy in this line has always been a study by engineers and others, and while considerable progress has been made in economical handling and storing, yet there is still room for improvement.

Works that have been badly located, without much thought as to the coal supply, or future growth, thus putting a tax on the manufacture for all time, and saving possibly a trifle in the first cost of the land, can do but little towards economy in the direction indicated above; but improvements, to some extent, can be made almost anywhere.

The inventions of Mr. C. W. Hunt, in apparatus for the handling of coal, have simplified to a wonderful extent the old methods, and the increased amount of coal delivered per man has been as ten to one, with less strain on the laboring man.

The cable system adopted some years ago by the Manhattan Gas Light Company, of New York, and still in use for out-door storage, seems to be simple in its working and a great saving over the old systems.

The only suggestions to be made for improved methods under this heading are the use of link belt elevators and conveyers, which are used with great success in handling anthracite coal. It is probable that gas coals will in time be unloaded from vessels and carried horizontally to the storage piles by means of bucket elevators and conveyers as grain is handled at present.

Delivery of Coal to the Retort House.—This subject is more or less closely allied to the previous one, and in many cases is a part of the same system. At the works of the Newark Gas Light Company the coal is hoisted from the vessel, by the Hunt system, to an elevated hopper, from which it is delivered into cars, from which it is dumped either into bins inside of the retort house, or delivered into the coal sheds through openings in the roof. A platform elevator raises the cars when coal is to be carried from the coal shed to the retort house. Where charging machines are used the coal is also raised in cars on platform elevators. It is possible that, where the coal shed and retort house are properly located, the platform elevator will in time be superseded by the bucket elevator, and the cars will give way to the horizontal conveyer.

Charging and Drawing Retorts.—In this branch of the manufacture of coal gas the whole system is at fault. The horizontal retort is substantially the same as it was at the inception of the business. Whether the lately introduced inclined retort will be a success remains for the future to decide.

The carbonization of coal by the cupola system has never had a fair and thorough test. The many patents covering this system all seem to lie dormant, and perhaps, when some of them have expired, some further experiments may be made in this direction. There are no really formidable obstacles in the way that may not be overcome by patient experiment combined with a liberal expenditure of money.

When coal can be carbonized in cupolas by a continuous process coal gas can be made cheaper than by the intermittent water gas processes. At the same time, the coal gas can be enriched by naphtha or oil without any special apparatus. However, as horizontal retorts are likely to be used for an indefinite time, improvements in the manner of drawing and charging them are still in order.

The stoking machines invented by Capt. A. Q. Ross have taken the lead, in this country at least, and are without doubt, since recent improvements, as perfect machines for the purpose as can be devised. It is hoped that some simple machine may yet be devised which can be made cheap enough to warrant its use by small companies. No suggestions for improvements in this department are made, and probably no changes will be made, except the radical change to the cupola system, as noted above. The many improvements due to the introduction of so-called regenerative furnaces do not properly come within the scope of this paper.

Handling and Storage of Coke.—Much attention has of late been paid to the proper treatment of this valuable by-product, and the sales to private consumers have been increased by proper crushing and screening. The care of the salable coke is of great importance, and there is room for improvement in this direction. The quenching of coke in barrows, while accomplished in one place, is unsuccessful in others, the barrows being most of the time in the repair shop.

Different places seem to require different treatment of coke to make it salable. In one place it must be crushed and screened, while in another it is simply screened by the screening shovels.

At the Milwaukee (Wis.) gas works a system of coke handling has been introduced which seems to be a step in the right direction. The entire product of coke is removed from the retort house cellar entirely by machinery.

The coke falls from the mouthpieces, through the usual apertures in the floor, into conveyers, which travel at a short distance below the iron floor. At the end of the range the coke drops into conveyers of larger size, which carry the coke to the outside of the building, where it is quenched by water from a perforated pipe extending over the conveyer.

By means of a bucket elevator the coke is then elevated and piled, and the only men employed are the engineer who runs the engine, and one man who attends the swivel spout at the top of elevator.

A horizontal conveyer running under the coke pile conveys the coke to another elevator which delivers it to a series of fixed screens, which deliver the different sizes into pockets, from which it is drawn, as wanted, into the delivery carts.

Where four different sizes of coke can be sold or used a revolving screen is found to work well; the coke being crushed in the usual crusher, and the different sizes, viz., broken, screened, pea and breeze, delivered from the screen into separate pockets ready for delivery into carts.

The whole of the coke handling machinery at Milwaukee is moved by a 50-horse engine.

Handling of Purifying Material, Lime and Iron.—Having lately designed a purifying house for a works where they proposed using all means possible for the economical handling of material, a brief description of the same will be given. As a preliminary to making the drawings, a visit was made to one of the most extensive and complete breweries in the city of New York—not, however, for bibulous purposes, but to inspect the manner of handling automatically the materials used in that special business.

It was found that the entire moving of the grain and malt both before and after using was done by machinery. All upward and downward movements are performed by bucket elevators and shoots, and all lateral movements are, with one exception, made with screw conveyers—the exception noted being the spreading of grain on floors to dry, which is done by means of iron buckets travelling on an overhead railway.

It is but natural to suppose that if the materials used in gas works had to be moved to as great a height as the brewers' materials are we should have adopted their methods long ago.

In the purifying house alluded to it was proposed to place the four boxes (which were 24 by 30 by 5 feet deep) in a square in the usual manner, although they were to be operated by a valve system, which would have worked them to advantage placed in line. Directly over the center of each pair of boxes an iron lattice girder was placed, at the proper height to clear the carriages. To the centers of each of these girders were attached the wheels carrying the elevators, which worked inside of an iron enclosure between floor and girder, and a brick enclosure in cellar. The fresh oxide was received at the top into a hopper, and carried to the boxes on each side by screw-conveyers. These conveyers terminated over the center of each box with swivel pipes, by which the material could be spread over the outside surface of box.

The conveyers, which were continuous steel screws, about 12 in. in diameter, were driven by suitable shafting and gearing secured to the girders, and driven by an engine in an adjoining building. The elevator was kept supplied by barrows emptying the revived material into the boot or hopper at bottom. The foul oxide was dropped into the basement, through suitable openings in the bottom of boxes, which were secured by lids with cotter bars and screws, closing them gas tight.

It was proposed to spread the material over the concrete floor of basement by manual labor, using the basement for a revivifying room.

At the East End station of the Cincinnati Gas Light and Coke Company the revivifying floor is located at the end of the purifying room, and the floor is about one foot higher than the top of the boxes. A platform on wheels, running on tracks laid on the floor of purifying room, extends over each box, by means of which the material is brought in barrows and placed in any part of the box.

The foul material is dumped through openings in the bottom of boxes, and is taken up to the revivifying room by platform elevators.

The following suggestions for improved methods may or may not be practicable, but are here given for what value they may have:

The purifying house to have a high and well ventilated and lighted basement, with room for clear passage under the connecting pipes. Directly under each purifier are hoppers to receive the foul material, which is carried by conveyers to belt elevators against the side walls, and thence to the revivifying room, which will be located directly over the purifiers. This room might be suspended from the roof trusses or supported on columns and girders. It would have large openings on all sides filled with louvres, and the roof will have large ventilators. The belt elevator will deliver the foul material into hoppers, from which it can be spread on the floor, by swivel spouts or by manual labor. In the floor of the room there will be openings directly over the center of each purifier, through which the material can be delivered by swivel pipes to all parts of the boxes.

This arrangement may look, at first sight, more extensive and complicated than it really is, and there is no reason why the purifying material cannot be as easily and cheaply handled as brewer's grains.

Another partial improvement, where the basement under the purifiers is used for a revivifying room, and the fresh material raised by platform elevators, may be suggested as follows:

The trays, instead of being supported on bearing bars, to rest on spindles at the corners with dowels and corresponding holes in the trays; the trays to be made smaller than usual. In emptying the box, after breaking down and opening the doors in the bottom, which would be a little larger than usual, the whole contents of the box—oxide, trays and spindles—would be dumped into the room below, the trays and spindles, after cleaning, to be brought up in barrows on the platform elevators.

Bucket elevators and screw conveyers are no new things, both being found in the most ancient grist mills, the primitive screw conveyers being made with wooden pins inserted into a wooden shaft.

The whole outfit of link-belt elevators, horizontal conveyers of different kinds, swivel pipes, and, in fact, the whole apparatus for moving or raising any material, can be obtained and their erection contracted for by well-known establishments, eager to introduce their systems into any new industry.

If any of the suggestions contained in this paper appear to be too radical, it must be remembered that the radical is generally the pioneer or leader (sometimes too far ahead of the times, at which period he is called a crank), but generally not far in advance of the practical man who reaps the crop, the seed of which was sown by his radical predecessor.

Jones' Safety Device for Gas or Air Pipes.

U. S. Letters Patent (No. 424,305) were granted, on March 25, to Edward C. Jones, of Boston, Mass., for "new and useful improvements in safety devices for gas and air pipes." Reproducing the language of the specification, the inventor says:

This invention relates to improvements in safety devices for gas or air pipes; and its object is to prevent explosions of illuminating, producer or heating gases when accidentally mixed with atmospheric air while being conveyed from the gas works to the holder or consumer.

Producer gas for heating purposes, when mixed with a small quantity of atmospheric air, forms a very explosive compound when brought in contact with a light or fire, and when a leak occurs in the pipe a very dangerous accident may happen, causing injury to the pipes or their surroundings if the escaping gas is ignited.

The invention, although particularly designed for preventing explo-

sions in producer gas pipes, is also very well adapted for blast pipes of water gas generators for the purpose of preventing the gas from the generator from backing into the blast air-pipe and exploding the compound gas.

In fact the invention is useful for any and all purposes where there is any danger of explosions from illuminating or heating gases being mixed with atmospheric air in the right proportion for causing an explosion when brought in contact with a fire.

The invention is constructed as follows, reference being had to the accompanying drawings, where—

Fig. 1 represents a vertical section of a valve provided with my improved safety device. Fig. 2 represents an end view of the same, parts of which are shown in section. Fig. 3 represents a modification of the device, showing, in connection with the safety-plug, a cut-off or slide arranged at a right angle to said plug for the purpose of allowing the safety-plug to be cleaned or repaired without shutting off the gas supply from the pipes. Fig. 4 represents a horizontal section on the line XX (shown in Fig. 3). Fig. 5 represents an end view and partial section of a modification, showing a pair of safety plugs arranged side by side within the valve chest for the purpose of substituting one plug for the other in case the plug in use should become foul or clogged up; and Fig. 6 represents a cross section on the line Y Y in Fig. 5.

Similar letters refer to similar parts wherever they occur on the different parts of the drawings.

a represents a valve-shell of any well-known form or construction, having on its interior seats against which a vertically sliding plug b is adapted to be lowered by means of a screw shaft c and hand wheel d, and which is also adapted to be raised out of the way, for a purpose hereinafter specified. I do not, however, limit myself to any particular means for lowering and raising the valve, as it will be obvious that other means may be employed. e e represent the gas-supply pipes as usual connected in a suitable manner to the ends or flanges of the valve shell. The plug b has a transverse perforation b', of a size about equal to the interior bore of the pipes e, which perforation coincides with the pipes e e when the plug b is closed against its seat, as shown in Figs. 1 and 2. The said perforation is covered by a fine wire gauze or netting B, which is preferably secured to said plug by means of a ring b'' and suitable fastening screws, as shown in Fig. 2; but this is not essential, as said wire gauze or netting may be secured

to the plug for the purpose of covering its perforations in any other suitable or equivalent manner.

It is well known that wire gauze or netting serves as a means to prevent explosion of gases from passing by such wire screen, and thus it will be seen by the arrangement, as shown and described, an explosion of gas taking place from any cause on one side of the valve and its wire gauze or netting will be prevented from going beyond the latter, thus preventing accidents and damage. Should the wire gauze or netting become foul or clogged with impurities, all that is necessary to do is to raise the plug *b*, so as to establish a free passage for the gas through the valve shell until such time when it may be convenient to shut off the gas pressure for the purpose of cleaning the plug screen or replacing it with a fresh one, as the case may demand.

The modification shown in Figs. 5 and 6 is substantially like the one shown in Figs. 1 and 2, with the difference that in the said Figs. 5 and 6 I have shown the valve shell provided with two plugs of the kind described, instead of one only, as shown in Figs. 1 and 2, each of said plugs being operated independent of the other to enable one to be used at a time, the other one being raised out of position, as shown.

When one plug becomes foul or clogged the other one is forced against its seat and the first one raised out of position, thus enabling the safety device to be used a longer time as compared with the device shown in Figs. 1 and 2, where only one plug and netting is shown.

In Figs. 3 and 4 the device is substantially like that shown in Figs. 1 and 2, with the addition of a solid gate or cut-off *f*, arranged at a right angle to the perforated plug *b*, so as to permit the latter to be raised, when foul or clogged, to the position shown in Fig. 3, after which the horizontal gate *f* is closed, as shown, enabling the operator to remove the top of the valve-shell above the gate *f*, as well as the plug *b*, for the purpose of cleaning the wire gauze or netting *B* without the need of shutting off the gas supply from the pipes *e e*.

Profit Sharing.

In view of the impending labor troubles in this country we are of the opinion that the following, from a paper read by Mr. G. P. Norton before the Liverpool Chartered Accountants' Association, will be read with interest:

Profit sharing will ultimately stand or fall by its own merits, whatever may be our attitude toward it. Amongst the many theories propounded to solve the great labor problem it bids fair at an early date to take a prominent place. The "bonus scheme" of Mr. Livesey at the South Metropolitan gas works has forced it to the front as a prime factor in the controversy. The example of the great London dock strike, combined with the general revival of trade, has awakened the old cry for less work and more wages into such clamorous and persistent energy that just at present more than ordinary efforts are required either to stifle or satisfy. The time-worn dispute seems to be at length resolving itself into a question to what degree it is possible to lessen work and increase wages. Very pertinently Mr. Ruskin's question to the discontented workers comes in: "Do you think the time will ever come for everybody to have *no* work and *all* wages?" It is evident there must be a halting place, and a method of adjustment must be discovered. The problem is undoubtedly one of enormous difficulty, but the time seems ripe for the introduction of any just and effectual scheme.

The rapid progress of the co-operative movement indicates one of the most likely directions in which a permanent settlement will eventually be found; but co-operation leaves the employer out of its plans altogether. For this reason it is not likely to become universal. Account must be taken of the "provision in nature which has made the few strong, wise, and able, and the many weak, foolish, and incompetent." It is desirable, moreover, that those endowed with such superior qualities should have full power to exercise them. The tendency of the English form of co-operation is to reduce all to a dead level—an endeavor after an impossible equality. On the other hand, the employing class has to a large extent forgotten its duties. Instead of regarding trade as a calling, a life's work, what many "want and mean is to make money as fast as possible out of their businesses, and then clear out and turn (so-called) gentlemen." I am afraid this spirit is not altogether absent from the members of our own profession, and the feverish haste to grow rich, at all hazards, has not in a few instances spoiled a promising career and brought about ruin and disgrace.

The co-operative movement could only partially solve the labor problem. Profit sharing between the employer and the employed is closely allied to the principle of co-operation, and in course of time will probably be adopted generally as one of its methods. At present co-operation is an effort of the worker to solve the labor problem in his own way, and chiefly for his own benefit. Profit sharing may become a parallel movement by which the employer will seek to retain the privileges due to mastership, and at the same time secure the goodwill of his work-

people. There is undoubtedly a vast field for the application of profit sharing, providing that it can be shown to be feasible, and an improvement on existing methods. Should it be generally adopted, and there are clear indications of a movement in that direction, the assistance of chartered accountants will be required in a variety of ways. Fortunately a large amount of reliable evidence is available in regard to the experiments already made, which will enable us to judge as to the merits of the various methods under which profit sharing has been worked. It is by no means of modern theory, but rather the outcome of the ancient practice of *product* sharing. In agriculture we find an illustration in the well-known *metayer* system. In the fisheries the "catch," whether good or bad—in many places—has long formed the basis upon which the crew has been paid. In trading ships the sailors have shared the profits of the voyage. In fact, the principle, in different forms, can be traced everywhere, and has been applied to almost every class of undertaking. In course of the development of trade product sharing has, for the most part, fallen into disuse. The division of labor, the difficulty of exchanging the products of labor, and the convenience of payment by a recognized medium of exchange, combined with other causes, have led to the general substitution of the existing wages system. The chief attraction to the worker of payment by wages is that it provides a fixed and certain income, without risk of loss. For this consideration he has forgone his right to participation in profit; and any modification of the system is not likely to succeed, unless this feature is retained. Payment by wages has, however, been tried and found largely wanting, while its particular failings are all absent from the old method of product or profit sharing. In the haste to provide for the exigencies of rapid change and development, the virtue of the old order of things has been lost sight of. Carlyle observes that "The world has been rushing on with such fiery animation to get work, and ever more work, done, it has had no time to think of dividing the wages, and has merely left them to be scrambled for." It is no uncommon thing, however, for old customs to be revived in new shapes, in order to set right prevailing systems which have grown unendurable.

The chief defects of the wages system are that it takes too small account of degree of industry and skill, and it does not offer sufficient inducement for individual effort. "The ordinary employer pays the least he can for labor; and labor, for the most part, gives the least it can in return." Payment by time wages fails notoriously in producing the *quantity* of work of which labor is capable, and the piecework system was introduced to remedy this defect. The remedy, however, produced another evil, for while the quantity was increased the *quality* deteriorated, because of the workers' undue haste and want of care. Quality prizes have been offered and fines for bad work have been imposed, but the difficulty remains; and the expense of supervision is everywhere a subject of complaint. Again, neither piecework nor time wages offers any adequate motive for care and economy in dealing with materials, implements, and machinery. Besides the objections just mentioned, the wages system, as a whole, involves the constant antagonism between employer and employed which finds vent in lockouts and strikes.

Many attempts have been made to perform the work of adjustment with less friction. The sliding scale has been applied, as an automatic regulator, to collieries and mines; but the practical difficulties in the way of working the scale have rendered it, to a large extent, ineffective. Arbitration and the intervention of disinterested parties have done much to make peace, but these remedies ought not to be required. The desideratum, then, it would appear, is a system which will not only remove the antagonism between the employer and the employed, but will make their interests mutual; and so distinctly mutual that the employee shall be able to appreciate the fruits of his extra zeal, skill, carefulness, and economy. The advocates of profit sharing, appealing to the past, as well as to the success of modern experiments, claim that their system answers all requirements. It rewards the worker for his extra exertions, and it gives him a share in the savings effected by his own economy and ingenuity. It is a sliding scale in itself, easily and accurately adjusting the division of fluctuating profits. The claim to these advantages will doubtless be readily allowed, but the manner in which the participation is to be carried out, so as to satisfy both the employer and the employed, requires much consideration.

In the first place, the importance attached by the worker to a fixed and certain payment in wages has already been mentioned; and it is generally agreed that under existing conditions the wages paid should not be less than the regular market rate, the profit sharing being in addition. The next step is to satisfy the employer that his income will not be decreased in order to provide the workers' share of the profits. Now, the strongest argument in favor of profit sharing (assuming that it can be maintained) is that it *creates* the fund which it proposes to distribute,

Mr. Sedley Taylor, in his work on "Profit Sharing," remarks that "the system, far from being a scheme for enriching workmen out of the pockets of the employers, has at its command potential energies capable of opening an entirely new source of profit." That is to say, the zeal of the workmen is aroused, and he puts forth his utmost efforts. There is less waste of time and, therefore, increased production. The cost of superintendence is diminished; for each worker has not only a personal interest in doing his best, but his conduct is under the immediate scrutiny of his fellow-workers, who will lose by his indiligence. The solidarity of interests caused by profit sharing promotes amongst the workers themselves a general surveillance more vigilant and effective than could be obtained from the highest paid overlooker. There is more thrift, more care exercised, and the awakened ingenuity of the worker is brought into full play. Thus, partly earned and partly saved, a fund is raised over and above the ordinary profits, and it is this fund which the worker shares.

An employer contemplating the adoption of the system might be deterred for fear lest, having launched upon a scheme of which he has had no previous experience, he should find it difficult to retrace his steps, if necessary. He may also be reluctant to grant a privilege entailing the possibility of his employees contending for it as a right. The entire control of the whole scheme may, however, be expressly reserved to the employer, with full power either to modify or to discontinue it. The workers' claim to a share in the profits need not receive any legal recognition, and misconduct, or leaving the firm of his own free will, may be made conditions under which his share is wholly forfeited.

The dislike and danger of publicity is another difficulty, but this has been overcome in a very simple manner. The employer privately determines a minimum of profits, after exceeding which he agrees that participation shall commence. This minimum, called a "reserve limit," is revealed to a chartered accountant, who vouches the workers' share. The participation may be regulated by varying percentages (for instance, on the first £1,000 above the "reserved limit" the workers may have, say, 33 per cent., and on the second £1,000, 25 per cent., and so on). It will be necessary for the accountant to have a very clear understanding at the outset, not only of the details of the scheme, but as to the manner of dealing with items in regard to which differences of opinion might be held, as to whether they are chargeable against revenue or capital. The rate chargeable for depreciation, the charge (if any) to be made for proprietor's management, the interest payable upon capital and loans, and the limits within which profits are to be placed to a reserve fund, should especially be settled. In fact every point upon which a conflict of opinion could arise should be guarded by express written instructions. Otherwise it is conceivable, especially where profits are liable to considerable fluctuation, that the accountant's position might often be one of extreme difficulty.

The success of experiments in profit sharing thus far has varied according to the degree of intelligence of the workers. For this and other reasons a partial application and subsequent gradual extension of the principle is often preferable to a full adoption of the system all at once. A nucleus of managers, overlookers, and the *elite* of the workmen being first admitted to participation, the privilege may be extended according to personal merit, length of service, or other qualifications. The *noyau* or nucleus of the *Maison Leclair* has been an important element in the development of that establishment, and the principle wherever adopted has had an educational and moral influence on the remainder of the workers, which has largely contributed to the success of the system.

Another important factor, applicable to joint-stock concerns, is the gradual acquisition by the employees of a portion of the capital of the business. In many establishments a part of the employees' bonus is retained to be applied in the purchase of shares. The celebrated *Familis-tère* of Guise, France, the establishment of M. Godin, retains the whole bonus for this purpose, and further provides that the older workmen shall release their shares to the younger, so that the ownership may remain always in the hands of the actual workers. Where it is possible, shares thus acquired should be inalienable and not subject to be charged for debt, voluntary or otherwise.

The schemes upon which the profits are shared vary widely. Some of the French establishments have most elaborate methods of division; such as would, probably, be wholly unsuited to the ordinary English mind. Only a plain scheme, easily comprehended, even though less effective, would be likely to find ready acceptance in England. The methods of participation may be classified under three general heads. (1) Immediate participation; (2) Deferred participation; (3) Mixed participation. In immediate participation the workers' share is paid in cash.

In deferred participation the share is retained, and either applied towards the purchase of shares in the capital or passed to the credit of a provident, mutual or pension fund. In mixed participation a part of the workers' share is paid in cash, and the remainder is treated as in deferred participation. The basis upon which the profits are divided is determined by the particular circumstances of each case. Important considerations, such as the relative amount of wages paid compared with the volume of trade done, and the degree in which labor is able to exert its influence on the production, render it impossible to conform to any strict rule. After providing for the reserve fund and a fixed rate of interest on capital, the remaining profits are, in the majority of cases, divided in defined proportions between capital, management and labor. The proportion due to each individual worker is usually based on his wages, but the division in some cases is quite arbitrary; the employer allocating the shares according to his own ideas of merit.

The general introduction of profit sharing into Great Britain has undoubtedly been retarded by the abandonment of the experiments made by Messrs. Briggs & Co., at Whitwood Collieries, Normanton, and by Messrs. Fox, Head & Co., at the Newport Ironworks, Middlesborough. The time at my disposal prohibits the narration of the circumstances which led to the adoption and ultimate abandonment of the system by these firms, but their history has been fully dealt with by Mr. Sedley Taylor, Mr. Gilman, and others. Suffice it to say that both attempts were made at times of bitter antagonism between masters and men, and amongst a class of operatives of low average intelligence. Nevertheless, while the system was in force decided advantages were obtained both by the employers and the employed. The scheme was adopted as an antidote to trade unionism, and it failed because of its being placed in deliberate and unwise opposition to labor organizations. The evidence of these cases is rather in favor of the principle of profit sharing than against it, but the fact of the abandonment has certainly produced a distinctly adverse impression. After a long interval the system appears to have received fresh impulse, and during the past few years, and especially in the past few months, several British firms have announced their intention of admitting their employees to participation. A noteworthy example is that of Wm. Thomson & Sons, Limited, woollen manufacturers, Huddersfield. Mr. Geo. Thomson is a disciple of Mr. Ruskin and an enthusiastic supporter of co-operation. He converted his business in 1886 into an industrial partnership, under which, after charging 5 per cent. upon capital and placing 10 per cent. of the profits to a reserve fund until the fund amounts to 10 per cent. of the capital, the employees are entitled to five-ninths of the net profits. The remaining four-ninths may be applied as the Committee of the Society directs, and have actually been distributed to co-operative societies dealing with the concern, by way of bonus on purchases. The workers' bonus is retained and applied in the purchase of shares in the capital of the business. Mr. Thomson has informed me that "the general result has been most satisfactory upon the work and workers, and that a sense of real fraternity pervades the mills." Messrs. Thos. Bushill & Sons, printers and stationers, of Coventry, who are very active in the support of the system, have introduced profit sharing into their business, which is still carried on under a private partnership. A "reserved limit" has been communicated to a chartered accountant, who certifies the sum due to the workpeople in respect of bonus. The amount of profit made by the firm is thus kept secret. Cassell & Co., Limited, the great publishing house, have introduced a system of deferred participation, as well as methods by which their employees may become shareholders in the capital of the Company. Amongst the remaining British profit sharing firms may be mentioned Blundell, Spence & Co., Limited, color and varnish manufacturers, of Hull, and Tangyes, Limited, engineers, Birmingham.

While the instances of successful profit sharing are sufficient to show that it is a practical scheme, and one under which large fortunes can be accumulated, it is only fair to point out that the most marked successes have been achieved by men of exceptional business capacity. Their prosperity has not depended on profit sharing. Nevertheless it is satisfactory to know that men of distinguished ability have chosen this method of attaining their ends. That they have grown rich under the system is a complete answer to the objection that a man who can make a business wants to make it for himself.

Profit sharing does not, like co-operation, tend to cramp individuality. It secures to the industrial "captain" his place as leader, and the rights and emoluments which should accompany that position. The employer may be satisfied under its operation, while the worker, who has always resented his exclusion from the prizes of industry, may be contented also. And again, it can be so worked as to give effect to the principle of "permanent contract," instead of "temporary," between master and man. In removing the causes of discontent it should also do much to

check the impracticable, and often mischievous, scheming of socialists. Profit sharing is not a visionary scheme, it is one of those slow evolutionary processes having its beginning far back in the history of mankind, and it is admitted on all hands to be right in principle. If, however, it effects any practical improvement in the relations between the employer and the employed, it must have a fair chance. The scheme must be employed in cases where the elements of success are present, and not as a last resource to retrieve failing fortunes. To promote its adoption in Great Britain, the example of a few leading commercial men is required—men whose business is not likely to fail, and whose income is such that they can well afford to be generous if need be. To them all the compensating advantages of the system are assured, and from the experience of others there is every reason to expect that from a pecuniary point of view the venture will not prove impolitic. The system should commence amongst the more enlightened of both masters and men, and be allowed to win its way gradually. The employer should be thoroughly informed on profit sharing generally, and his particular plan should be well thought out in all its bearings. Every opportunity and every convenient agency should be utilized for explaining the benefits of the scheme to his employees; and it need hardly be remarked that no occasion is more suitable for enforcing such counsels than when they are accompanied by the tangible illustration of a bonus at the period of stock-taking. If higher motives fail, it is not improbable that the extreme irritation and worry caused by a strike and the fear of its repetition, or the desire to be remembered as a prime mover in a great industrial reform, will bring one of our prominent traders into the field, and we shall then have the scheme thoroughly tested. There is no doubt that numbers would follow a really good start. Amongst our great English traders there are many whose generous spirit has not been entirely buried in the competitive rush of the times. These will readily take up the scheme, provided they are satisfied they will not make fools of themselves, and that its general adoption will be a national benefit. The desire to be masters in the true sense, so admirably described by Mr. Ruskin, will, to all thoughtful and right-minded men, prove more potent than the vain ambition to become members of an unpopular and purposeless plutocracy.

The Waste of Raw Material in Gas Manufacture.

The *London Journal*, in an article on this subject, says that an interesting question arises out of the recent reports that have appeared concerning the working of the various oil and water gas schemes now before the public. It is with regard to the duty rendered from the raw material by different methods of gasifying solid and liquid hydrocarbons; and it will be impossible to treat the present discussions and explanations of these systems as exhaustive unless this question of their respective duty is cleared up by satisfactorily scientific handling on the part of some competent authority. What we mean by the duty of a gasification method is precisely the same as is meant by the same term when used in connection with steam power plant. And, though there is no such absolute datum in gas making as Joule's equivalent supplies to the mechanical engineer, whereby an accurate balance sheet of engine performance with relation to fuel consumption may be prepared, yet it is possible to prosecute analytical investigations of gas making systems on nearly the same lines, and with precisely the same object—to determine the loss by exchange. We know that nature does not give change without charging for the accommodation. When a known weight of coal is put into a steam boiler furnace, which is intended to convert the heating power of the fuel into the mechanical power of the engine, there is a heavy percentage of the potentiality of the coal lost in the process of transformation. Similarly, when a ton of coal is carbonized in gas making retorts, the product is a redistribution of the original atoms in the three states of solid, liquid, and gas, which, if they could all be put into the balance against the coal from which they were derived, would "kick the beam." Theoretically, the arrangement should not entail any loss of weight; but practically there is a loss, although not a very considerable one. In the manufacture of coal gas, a little apparent deficiency (say) in the weight of gas obtained may generally be ascribed to a change in the relative proportions of the other products; but, except within narrow limits, there is no room for increasing the weight of the gas at the expense of any other product. In brief, the amount of preventible waste in practical gas making is not serious, because what does not appear as gas is mostly to be found as coke, tar, and water. The most obvious waste is the carbon deposited in the retorts and hot ascension pipes, which the gas maker usually begrudges as being not only troublesome in itself, but as eminently an example of "matter in the wrong place."

We do not, at the moment of writing, recall any attempt on the part of chemist or gas engineer to determine the exact proportion of waste of the raw material which is capable of being represented as carbon deposited in retorts and pipes. It would not be an easy thing to do with any respectable degree of accuracy, even if the result were worth the labor. There is a certain interest attaching to this question of the proportion of the lost carbon in coal carbonization, however; because it rises into great prominence in connection with the carbonization of oil, which is the next raw material to coal for the manufacture of illuminating gas. All who have ever tried to carbonize oil for gas making in closed retorts, as coal is carbonized, have been confronted sooner or later with the difficulty of the wasted carbon. If oil, whether mineral or vegetable, is run into a retort and gasified, the hot surfaces on and in contact with which the process is effected are speedily coated with a deposit of carbon, which becomes graphitic if the heat is sufficient, and not only represents a serious loss of weight of material, but also prevents the satisfactory continuance of the manufacturing operations. A mineral oil which in a clean, hot retort will commence by yielding (say) 110 cubic feet of 70-candle gas per gallon will, if the process is attempted to be carried on continuously, drop in a very short time to a yield of not more than 60 or 70 per cent. of the first production, while the furnace will fail to keep the retort hot enough to prevent even worse results. If persisted in, the process would eventuate in a retort full of carbon, ranging all the way from graphite where it touched the walls, to loose, greasy soot in the centre. Gasification would have meanwhile altered to the vaporization of a constantly diminishing proportion of the raw oil, until even this would cease. The technical history of oil gas manufacture is a record of attempts to rectify this trouble, which is done in the production of Pintsch's gas by carbonizing the oil in the first stage in a metal tray placed loosely in the retort, and therefore easy to remove and clean. Notwithstanding this device, which is necessary in order that gasification may be conducted continuously in the same plant, the initial loss from deposited carbon, is, of course, constant, and averages nearly one-half of the weight of the raw material. There is a little tar produced when oil is carbonized; but this is the only true residual. The carbon thrown down in the retort is, of course, pure waste; and this waste is so great in the ordinary way of working, notwithstanding all the care that may be used to keep the retorts as clean as possible, that, as already remarked, the gas obtained scarcely weighs half as much as the oil consumed in its production.

Yet, with all its wastefulness, this was the only system of making illuminating gas from common mineral oil before the modern development of water gas was brought to a success by Lowe and his rivals and imitators. This development consists, as everybody knows, in the gasification of oil in immediate contact with the incandescent fuel of a water gas generator, or in a current of the hot gases immediately after these leave the generator. The combination is called illuminating water gas, or more shortly water gas, with the qualification of luminosity left to be understood. Let us, for the purpose of this article, however, regard the resultant gaseous mixture as an oil gas, with its illuminating power diluted, and its bulk correspondingly increased, by the addition of a non-luminous but inflammable cheap diluent. The change of standpoint will give us some fresh ideas on the general subject. From this point of view, then, we see the generator as a means of gasifying mineral oil. If preferred, the water gas can be made in a generator, and afterwards used to dilute oil gas produced in a retort. This was, indeed, the earliest system of water gas working, and the employment of a combustile diluent was a great advance on the crude practice of letting down an unmanageably rich oil gas by an admixture of air. It was evidently a further improvement when the retort was abolished, and the oil gasified upon the same glowing mass of fuel from which the diluent was obtained. If nothing else was gained by the change, the consumption of fuel for heating the retorts and the prime cost of maintenance of this portion of the old plant were saved. Were there any other advantages, however? Was the production of gas from the oil consumed improved in quantity or in quality when the operation of gasification was shifted from the closed retort to the live fuel and hot current of gas from the generator? In other words, does the modern water gas generator return a higher duty, regarded as a mass of gasifying mineral oil, than a Pintsch's retort? This is a point not fully cleared up.

The question possesses practical importance, more particularly in connection with the future of the system of utilizing oil gas in which Mr. E. Tatham (whose process was described in the *Journal* a fortnight ago) is a pioneer. For it will be observed that, although Mr. Tatham proposes to burn his rich oil gas by the aid of oxygen, instead of diluting it with water gas or anything else detrimental to the illuminating

power, he requires to make his gas first. If it is produced in the closed retort, he must submit to the loss incidental to that method of manufacture; but what if the oil is gasified on a bed of live coke? There is no necessity for the simultaneous production of a great bulk of water gas with the oil gas, but only for making just so much as may be required to prevent the oil from being burnt up in the glowing mass of fuel with such stray oxygen as may linger from the blowing up operation. It is quite possible that the duty of a generator used in this way may not be much higher than a closed retort—a suspicion that gains colors from an examination of water gas data. It appears, for example, that 3 gallons of petroleum, weighing about 25 pounds, go to the production of 1,000 cubic feet of 22 candle gas. Now, if this oil were well carbonized in a clean retort, it would make 300 cubic feet of gas rated at about 70-candle power. Increasing the bulk of gas in this way therefore brings down the luminous value pretty much the same as would be the case if the lighting gas and the diluent were separately prepared. It would be satisfactory if Professor Lewes could clear up the doubt surrounding this question, by showing authoritatively how much of the weight of 1,000 cubic feet of Steenberg water gas, as prepared under his supervision for illuminating purposes comes from the oil, which would give the ratio of loss, and how much from the coke, which would also indicate the proportion of fuel lost during the operation of "blowing up," on making producer gas. This would, in short, settle the point, now doubtful, of the comparative efficiency of retort and cupola for gasifying oil.

If it should appear, upon examination, that the wastefulness of a generator for oil is at all commensurate with that of a closed retort, it will go far to establish the deduction that the quickness with which the fluid form of hydrocarbon may be fractionally gasified, has to be paid for by an inevitable waste of carbon, which renders this form less desirable economically than the solid form, although the latter is not so tractable. It would be noteworthy if it should be shown that coal is, after all, the least wasteful form in which a gas making material is obtainable; and, from what can be learned at present, such a conclusion is distinctly probable. Oil may be so low priced in some localities that the unavoidable loss of half its weight in the process of gasification may be commercially insignificant; but the idea would nevertheless remain to irritate engineers, and perhaps to inspire inventors with vain hopes of the possibility of more economical methods.

Life and Efficiency of Electric Arc Light Carbons.

By L. B. MARKS, in *The Crank*.

Ten years ago the electric arc lighting industry in this country was of little commercial importance; but a decade has seen its transformation into one of enormous proportions.

The engineer has devoted himself with assiduity to the perfection of almost every part of the electric light plant: the engine, the dynamo, the lamp mechanism—these have been experimented upon under a variety of conditions, until to-day it may be reasonably doubted that an increase in their efficiency can be more than trivial.

But there is one factor in the system which, as far as the literature on the subject goes, seems to have been relegated to a secondary position, although its prime importance in the production of a perfect light cannot be overestimated. The publication of facts concerning the laws of life and efficiency of arc light carbons has been very limited in extent, and it is the purpose of this article to briefly set forth the results of investigations made in this direction in the laboratory of Cornell University.

The conclusion has been drawn from a multitude of experiments that when the current and difference of potential between the terminals of a lamp are kept constant, with carbons of the same manufacture and type, the *life* of the carbon varies directly as its diameter and inversely as the resistance of the pencil.*

On the other hand, it has been determined† that "the *efficiency* of the carbon varies inversely as the diameter." Hence we see that invariably large efficiency is attained only at a sacrifice of life and vice versa.

Now it is found that carbons which are admirably adapted to one system of electric lighting are very inefficient when burned in another. Those systems which are operated by a small current and a long arc, as the Brush, are technically called *high tension* systems, while those which make use of a large current and a short arc, as the Weston, are known as *low tension* systems.

Recent experiments prove that, generally speaking, a *molded* carbon

is superior for high tension and a *forced* for low. Forced carbons are made by pressing the crude mass through a die of given size, after the fashion of "squirting" lead pipe. But by whatever process of manufacture a carbon pencil is produced, its adaptability to a system depends mainly upon the molecular structure and conductivity of the rod.

Practice shows that "the requirement of the low tension system seems to be a carbon that is hard, and a good conductor, the latter being the more important."* In the high tension system, hardness and low resistances are undesirable. There is a tendency to burn unsteadily and "go out" when a hard pencil is used in this system, and a soft one becomes necessary.

A microscopical examination of the various types of carbons was made, in order to ascertain what relation, if any, exists between the structure of the rod and its efficiency. Transverse sections of the carbons were cut, mounted on glass slides, and viewed through a microscope having a magnifying power of 50 diameters. In each case the enlarged image of the carbon surface was photographed. A complete set of microphotographs was thus obtained, covering the principal types of forced and molded carbons now used in this country.

The study of these photos leads to the assumption that every change in the molecular structure of the carbon is accompanied by a change in the efficiency of the latter. In accordance with this statement a high tension carbon having a more compact structure than another will have a different efficiency. Similarly a low tension pencil in which the particles are symmetrically grouped in parallel ranges, differs in efficiency from one in which the striations are absent. In fact, from the relation found to exist between the structure of a pencil and its action when burned in an arc lamp, it is in many cases possible, by a simple microscopical examination, to *predict* with some degree of accuracy the efficiency of a forced or molded carbon.

The interdependence of efficiency and molecular structure is a subject about which little or nothing has been published. For the present the facts stated above must be taken for granted, as no exact law has yet been formulated. In general, however, it may be said that high efficiency with a low tension carbon is secured by a dense structure, while a loose arrangement of the particles is preferable for a high tension carbon.

It will be seen that because of the more compact structure of the forced pencil its electrical resistance is less than that of the molded rod, and hence, as was stated before, the former is better suited to a low tension system. Yet the manufacture of molded carbon for low tension plants has been and is now carried on to a large extent. Low resistance of the pencil for this purpose is absolutely essential, and although this factor is not attained by virtue of the structure, an approach to the same end is secured by thickly copper-plating the carbons.

On the other hand, in one of the manufactories of this country an attempt is made to decrease the resistance of a molded pencil by submitting the latter to great pressure in the molds. By applying a stress of 6,000 pounds per square inch the requisite density of structure is obtained.

Altering the amount of pitch in the carbon is still another method which is used for regulating the resistance of the pencil.

Summarizing we find that the difference between a high and a low tension carbon may be the result of one or more of four variations in the method of manufacture.

1st.—Variation in the direction of application of stress; e. g. "forcing" and molding.

2d.—Variation in the amount of pressure applied.

3d.—Variation in the "mix" or composition of the pencil.

4th.—Variation in the thickness of the copper coating.

Thus it appears that there is a diversity of means to the same end. The discussion of the methods employed in the manufacture of high and low tension pencils respectively can be found elsewhere.†

We have seen from the microscopical examination of the pencils and the results of actual tests that a slight difference in the molecular structure of the carbon may make a difference of several per cent. in the efficiency.

Hence, though we may fail to find a substance better suited to the purpose than the carbon point, there remains sufficient room for improvement in the manufacture of the latter.

In the foregoing remarks the direction in which this improvement must take place has been pointed out. And it is confidently hoped that in the near future the application of methods to increase the life and efficiency of the carbon will advance the electric arc light one step further towards the attainment of a perfect source of artificial illumination.

Notes on the Action of Lubricants.

Prof. J. E. Denton, in the April issue of the *Stevens Indicator*, calls attention to the action of lubricants, as observed by him :

If we "feed" oil to a journal with an ordinary cup, which has its rate of feeding restricted so that the amount of oil supplied to the journal is no greater than is common—say, on a locomotive crank-pin, or in lubricating fast-running shafting, the resistance to rotation produced by friction will be from 3 to 20 per cent. of the force or load to which the rubbing surfaces are subjected. If the rubbing surfaces are in a very smooth condition the 3 per cent. limit is realized, but in proportion as the surfaces are less smooth the friction approximates to the greater limit. The average engine bearing, which is smoothed by natural wear unattended with considerable "end play," may be assumed to create a frictional resistance equal to from 5 to 10 per cent. of the total load on the bearings—that is, the "coefficient of friction" is from 0.05 to 0.10. The idea is somewhat prevalent that modern experiments with oil-testing machines have demonstrated that a journal wears *itself*, if run for a long time without mishap, to such a condition that a coefficient of friction of a fraction of 1 per cent. is finally secured. As a matter of fact the journals of testing machines which have given such a low coefficient have been nursed by long running, under a flood of oil, to an exceptional state of smoothness, attainable only by maintaining a constant "end-play," or reciprocating motion of the brasses over a considerable fraction of the length of the journal. If such bearings are supplied with a restricted amount of oil, and the end-play motion stopped, the coefficient of friction immediately increases from the fraction of 1 per cent. to 3 or 4 per cent. In the case of railroad car bearings there is a natural realization of the low coefficients, because the supply of oil is superabundant, and there is an "end play" motion which gives to the journal and brass a highly polished surface practically unattainable on engine bearings.

Writers on lubrication for a number of years past have apparently assumed that the coefficients of friction of car service were attainable on all journals, and amongst other results of this error has been a general condemnation of the laws of friction given by the eminent scientist of the last half century, General Morin, whose work from a practical standpoint is still worthy of all respect.

Morin experimented* with shafting from about 1½ to 2½ inches in diameter, weighted with heavy pulleys or discs, so as to produce pressure up to about 200 pounds per square inch. The bearing surfaces were of cast iron, the speed about 100 revolutions per minute. The friction was measured with his well-known form of recording dynamometer. Lard oil was used and the method of feeding was made to conform to that used in practical service.

His conclusions were as follows :

Friction during motion is—1st, proportional to pressure; 2d, independent of the area of the surface of contact; 3d, independent of the velocity of motion.

It is the object of this article to show that these simple laws are still realized as nearly as is necessary for the estimation of the friction of practical machinery.

The modern theory of the action of lubricants conceives the frictional resistance to be made up of two parts—viz., a part representing the friction due to metallic contact of infinitesimal irregularities of the bearing surfaces, and a part representing the force to overcome the viscosity or fluid friction of the lubricant itself. The first part is believed to vary in direct proportion to the pressure or load on the bearings. The second part increases very slowly with the pressure. Hence the total friction, which is the sum of the two parts, may increase rapidly with the pressure if the film of lubricant is so thin as to permit considerable metallic contact, or slowly with the pressure, if the supply of lubricant is so superabundant as to practically destroy metallic contact by causing a thicker film of oil to maintain itself between the rubbing surfaces, and thereby make the principal resistance to rubbing simply the force necessary to agitate the particles of oil—i. e., the force due to the viscosity of the oil.

The following tables show experimental results for these two cases. The same figures hold for any oil of about the same viscosity as lard oil. The apparatus used was a small Thurston oil testing machine with a journal 1½ inches in diameter and 1½ inches long. The same brasses were used with both the journals of Table I., but the area of bearing differed slightly.

The results of Table II. apply to both journals of Table I. The rate of feed for Table I. was determined as follows: An ordinary oil cup

having a screwed needle or spindle to adjust the rate of feeding was restricted in its rate of feeding, so that when tightly closed against the atmosphere no oil would run out by gravity, but the slight suction produced by pressing the outlet against the hand and quickly withdrawing it would draw out a drop of oil.

TABLE I.—Friction with Restricted Supply of Lard Oil.

PART I.—Hardened Steel Journal-Composition Brasses.					PART II.—Soft Steel Journal-Composition Brasses.				
Pressures in Pounds		Coefficients of Friction.		Temp. Fahr. Degrees.	Pressures in Pounds.		Coefficients of Friction.		Temp. Fahr. Deg.
Per sq. in.	Total on Bearings.	300 Revs. per Min.	900 Revs. per Min.		Per sq. in.	Total on Bearings.	300 Revs. per Min.	900 Revs. per Min.	
40	88	0.050	0.047	102	13	26	0.070	0.10	100
65	136	0.055	0.050	102	50	100	0.056	0.076	100
115	236	0.054	0.055	102	100	200	0.058	0.075	100
215	436	0.051	0.063	102	200	400	0.060	0.075	100

TABLE II.—Friction with Superabundant Supply of Lard Oil.

Pressures in lbs. Total on Bearings.	Coefficients of Friction.—300 Revs. per Minute.	900 Revs. per Minute.	Temp. Fahr., Degrees.
13	0.060	0.100	100
50	0.038	0.053	100
100	0.032	0.027	100
200	0.045	0.024	100

When the cup was screwed into the upper brass of the machine, the suction,* due to the revolution of the testing journal, would draw out sufficient oil to satisfactorily lubricate the bearings. To produce the superabundant feed for Table II., the adjusting needle was removed from the cups and the latter left open at the top to the atmosphere. Thereby the oil was free to flow to the journal through a hole ¼-inch diameter under two inches of head. The rate of consumption under these circumstances was about a pint per hour. The consumption in the case of Table I. could not be discerned in less than several days' usage. From the inspection of Table I., it is evident that the friction practically follows the laws of Morin, the coefficient being constant for pressures above about 40 pounds per square inch, and so nearly independent of the speed that exceptions to this rule are ascribable to differences of condition of bearing surfaces, and the margin of error in the determinations—about 10 per cent.

A study of Table II., shows. 1st: that while the friction at the light pressures approximates to that given in Table I., for pressures above 40 pounds per square inch, it is considerably less for the superabundant supply; and, 2d, that the friction does not increase proportionally to the pressure, but follows an irregular law evidently depending upon the speed.

Thus, for 300 revolutions the coefficient first decreases and then increases as the pressure changes from 100 to 200 pounds, whereas, at 900 revolutions there is a continued decrease of coefficient. The apparent irregularity is, however, interestingly in accordance with the theory of friction outlined above. Thus, at 13 pounds pressure the coefficient of friction is 50 per cent. greater at 900 revolutions than at 300, because at both speeds sufficient thickness of film is maintained to make the portion of the friction due to viscosity preponderate very largely over that due to metallic contact. The same conditions also apply to the figures at 50 pounds pressure.

But at 100 and 200 pounds pressure, the difference in the suction effect of the two speeds in drawing oil between the rubbing surfaces, evidently makes so much difference in the thickness of the film of oil, that the decrease in friction due to the less degree of metallic contact at high speed, preponderates over the increase of friction due to viscosity. Hence, increase of speed produces exactly the opposite effect upon the coefficient of friction at the higher pressures that it does at the lower pressures. The absolute value of the pressure at which this change of effect takes place would, of course, differ with such variations of proportions and arrangement of journals and feeding orifices as would modify the suction effect due to velocity of rotation.

In practical service the only bearings which receive a supply of oil approximating to that used for Table II., are car journals when freshly supplied with oil and dynamo bearings for which the oil is filtered and repeatedly reapplied.

Steam engine and general machinery lubrication realizes the conditions of Table I.

* This method of adjusting the rate of feeding is common in lubricating shafting and locomotives, etc. The oil is thereby consumed at as slow a rate as is grease, and affords excellent lubrication.

In a succeeding article it will be shown that Morin's laws, if applied to the calculation of the friction of steam engines, afford results in satisfactory agreement with prony brake determinations of this friction.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

THE Sioux City (Ia.) Gas Light Company's amended rate schedule became operative on the 1st inst., and cannot fail to produce a marked effect on the sendout. The prices now in force are :

Monthly Consumption.	Net Rate per 1,000.
Under 5,000 cu. ft.	\$1.90
5,000 to 10,000 cu. ft.	1.80
10,000 to 25,000 cu. ft.	1.70

On all gas used for purposes other than illumination, to be registered on a separate meter, the net rate is \$1.50 per 1,000, but all gas bills unpaid 10 days from date of presentation will thereafter be reckoned on the basis of a charge of \$2 per 1,000.

THE franchises and plant of the Decatur (Ala.) Gas Light Company have been sold by the New York Contract Company to Decatur capitalists. The latter have determined to extend the main system to North Decatur.

IN mid-April the employees of the Elizabethtown (N. J.) Gas Light Company notified Superintendent Engel that unless an increase in pay (it figured out something like a 12½ per cent. raise all round) was granted them by April 23d, a strike would be ordered. Manager Kean refused—and properly so—to accede to the modest (?) demands of his force, whereupon the men "went out." The Company had no difficulty in securing the necessary substitutes.

THE Hon. Wilbur F. Lunt, as attorney for the Biddeford and Saco (Me.) Gas Company, has commenced an action against the city authorities of Biddeford to recover \$5,000 damages for injuries to mains and wastage of gas, traceable to the careless operations of the city's street department.

THE following common-sense circular has been issued by the proprietors of the Van Wert (O.) Gas Light Company to the residents of that city :

"Ten years ago gas was first turned into the mains of this Company. During that time there has not been a single night that gas has not been furnished to our patrons. Occasionally the service has not been as perfect as we could desire, but these occasions have been rare, and the causes thereof have been removed, so that we now feel safe in assuring our consumers that the liability for suspended or defective service has been reduced to the minimum. Our business has had a continuous and healthy growth and has never been on a more satisfactory basis than the present time. In view of this fact we have adopted a new discount schedule which will materially reduce the net price of gas on monthly bills of over 1,000 cubic feet. The gross rate of \$2 per 1,000 will be maintained, and all discounts will strictly depend on the prompt payment of bills. All gas passing through any one meter, after May 1st, 1890, will be subject to the following discounts :

Monthly Consumption	Discount, per Ct.	Net Price.
1,000 cu. ft. or less.	10.	\$1.80
1,000 to 3,000 cu. ft.	15.	1.70
3,000 to 5,000 "	20.	1.60
5,000 to 10,000 "	25.	1.50
10,000 and upwards.	(Special.)	

In dealing with several hundred customers it is impossible to make repeated calls in collections. One call will be made at the place of business or residence of each consumer. Bills not then paid must be sent to our office on or before the 10th of the month succeeding the month of consumption, otherwise the gross price will be collected. We urge consumers to frequently read their meters, minute instructions for which are printed on the reverse side of monthly bills. We shall at all times be glad to give any other explanation or information. The meter is the *arbiter* between the Company and the consumer. It is constructed on scientific principles, and is supposed to measure correctly. It is as much the standard of measurement as the merchant's scales ; it is owned by the Gas Company, and is on the premises of the consumer ; neither could tamper with it if he would. Using the best methods and material known to modern gas making, we cannot but feel that we are furnishing a superior article. Should there be any cases of defective service the cause will be found to be local, and we shall desire to be informed of such cases and to be consulted towards proper remedies. We thank our customers for past patronage and assure them of our desire to con-

tinue to serve them well and faithfully. By good service, square dealing, courteous attention and prompt response to complaints, we hope to merit and obtain a large increase of business."

THE Easton (Pa.) Gas Company will soon be out with an announcement of cheaper rates.

THE Davis & Farnum Manufacturing Company have quite a number of contracts on their ledgers, and the probability is that several other plums are about to come their way. Among the list we note the following : An iron roof and ten benches of 6's (complete) for the new retort house of the Lowell (Mass.) Gas Light Company ; a double-lift holder (capacity 200,000 cubic feet) to be put up in Malden for the Malden and Melrose (Mass.) Gas Light Company ; a single-lift holder (capacity 100,000 cu. ft.) for the Gloucester (Mass.) Gas Company ; a tank (35 ft. by 19 ft.) for the Providence (R. I.) Company ; and alterations to the benchwork of the Nassau (Brooklyn, N. Y.) Gas Company. These items, together with their general run of work on water works and sugar houses, including flanged pipe, gas and water pipe, specials, etc., ought to keep Treasurer Farnum and Traveler Davis on the go this summer.

THE following is the summary of the results of the annual meeting of the Chicago Gas Trust Company, held at the Company's office, 101 Lake street, on the afternoon of April 24th. Among the prominent out-of-town stockholders present were Vice-President Benedict, of this city, Chas. F. Dietrich, E. J. Jerzmanowski, P. A. B. Widener and W. L. Elkins ; 206,325 shares out of the 250,000 were represented. Perfect unanimity of thought and expression prevailed, and each vote was unanimous. The supplementary deed of trust transferring the stock of the four Companies in the Trust to the Fidelity Insurance Trust and Safety Deposit Company, of Philadelphia, by the Board of Directors, was ratified, as was also a proposition to change the name of the corporation to that of the Chicago Gas Company. The Directors chosen were : Messrs. W. H. Gebhard, E. C. Benedict, R. M. C. Graham, H. J. Davison, Chas. F. Dieterich, John Sloane, E. J. Jerzmanowski, C. R. Cummings, S. A. Kent, N. K. Fairbank, W. L. Elkins, P. A. B. Widener and C. K. G. Billings. The officers chosen were : President, C. K. G. Billings ; First Vice-President, E. C. Benedict ; Second Vice-President, E. J. Jerzmanowski ; Secretary, T. B. Wells ; Assistant Secretary, C. K. Wooster.

As was intimated in the last issue of the JOURNAL, the Citizens Gas Light Company, of Newark, N. J., has notified its meter setters to remove all meters from stores and residences where the electric light has superseded gas. A general howl along the line is the result ; but it is quite certain that the parties affected will either have to agree to burn a certain quantity of gas per month, or else pay a meter rental.

THE Girard (Kansas) Gas and Electric Company has been incorporated by O. T. Boaz, J. A. Bendure, J. T. Leonard, S. P. Christian and Austin Hawley. It is capitalized in \$25,000. This place is the capital of Crawford county, Kansas, and is on the Missouri River, Fort Scott & Gulf Railroad, at a point 26 miles south by west of Fort Scott. It is also connected by rail with Joplin, Mo. Coal of fairly good quality is mined there. Population, about 6,200.

THE American Gas and Ventilating Machine Company, with principal offices at Auburn, Me., has been incorporated with a capital of \$500,000. The business to be prosecuted is the manufacture of machines for compressing air and generating gas. Its officers are : President, Geo. H. Barrows, of Somerville, Mass. ; Treasurer, Wm. P. Hammond, Charlestown, Mass.

ON and after May 1st the offices of the St. Paul (Minn.) Gas Light Company will be in the handsome building of the New York Life Insurance Company, corner 6th and Minnesota streets, that city.

THERE was a lively contest this year at Paducah, Ky., for the public lighting of that city, which is not to be wondered at when it is remembered that the successful bidder would have the work until 1894. The bidders included the Thomson-Houston Electric Arc and Incandescent Company, the Excelsior Electric Company (arc), the Ohio Gasoline Street Lighting Company, and the Paducah Gas Light and Coke Company. Mr. H. W. Meyers, Superintendent of the latter Company, seems to have convinced the Council that gas was not only the light of the present, but was to remain the light of the future—for four years at any rate—for his Company was awarded the contract to maintain 300 gas lamps (5-ft. burners), moon schedule, on the basis of a gas rate of \$1.25 per 1,000 cubic feet. Twelve of the City Fathers were present, and 11

of them voted for gas. The Paducah Company's rates are : For public uses, \$1.25 per 1,000 ; for illuminating (private) purposes, \$1.75 ; for cooking, heating, and power uses, \$1.50. Supt. Meyers will put down 3 miles of new street mains this season. He is a good one.

WE are in receipt of a handsomely printed circular sheet containing the names of no less than 112 housekeepers of East Saginaw, Mich., who are using either gas stoves, ranges, fires, etc., furnished by the Gas Company of that city. This of itself would look "numerous enough" to fully testify to the fact that gas as a cooking and heating agent is away above par in the locality noted. Supt. G. A. Hyde, Jr., however, to whom we suppose the credit of compiling such an effective advertising method is due, clinches this testimony in the remark that the list is but a partial one. Well, he ought to have success ; for it took some courage to put the cooking and heating gas rate in a place like East Saginaw at \$1 per 1,000. He is a son of his father, and no mistake.

SOME days ago the Wabash Railway Company entertained by invitation a select party, for the purpose of showing its guests how well the Pintsch system of compressed gas lighting answered for the ordinary illumination of a swiftly moving train. The trial train was made up of 5 coaches, and the trial trip covered 50 miles. The affair was most successful.

AT the annual meeting of the Ottawa (Can.) Gas Company the financial reports rendered were indorsed as satisfactory by the shareholders. The officers chosen were : Directors, Robt. Blackburn, Senator Clemow, S. Howell, Thos. Patterson, Jas. McLaren, and Allan Gilmour. President, Robt. Blackburn ; Managing Director, Senator Clemow ; Secretary and Treasurer, Alex. Spittall.

AT a meeting of the Board of Directors of the Charleston (W. Va.) Gas Light Company, it was ordered that the President (Mr. Frank Woodman) of the Company be authorized and directed to take immediate steps to erect an electric light plant, for arc and incandescent lighting, under the authority conferred by the charter of the Company, of such capacity as he may upon investigation approve ; and to advertise for bids for same.

SOME time ago we noted the formation of a gas company for Fort Benton, Mich., to which we may add that the concern bears the title of the Excelsior Gas Company. The proprietors have determined to install a water gas plant, which will be completed and put in operation as soon as possible.

MRS. ANNIE RILEY, through Messrs. Doherty & Doherty, has taken an action, *in forma pauperis*, for \$5,000 damages against the Montreal Gas Company. The declaration states that plaintiff's husband, John Riley, who was a stoker in defendant's employ, when coming out of the workshops, at an early hour in the morning, fell into an excavation in the yard and sustained injuries that eventuated in his death.

THE people of Windsor, Ont., are to vote on a proposition empowering the local authorities to invest \$15,000 in an electric lighting plant, to be operated on municipal account.

MR. JNO. CABOT'S specialtes in trays for gas works still hold the market. The Church grooved slat tray for iron oxide is a great success.

THE proprietors of the Joplin (Mo.) Gas and Coke Company are out with an announcement of cheaper gas, the concession to affect all gas consumed from first inst. Under its terms the gross rate is cut from \$2.50 to \$2 per 1,000, and prompt payment—*i. e.*, accounts must be settled 8 days from presentation—secures the following rebates :

Monthly Consumption.	Discount per Cent.	Net per 1,000.
Under 5,000 cu. ft.	5 "	\$1.90.
5,000 to 7,500 cu. ft.	10 "	1.80.
7,500 to 10,000 cu. ft.	15 "	1.70.
10,000 and over	20 "	1.60.

Where a separate meter is placed for the registration of fuel gas, a net rate of \$1.50 per 1,000, irrespective of monthly consumption quantity, is operative ; but a meter rental of 25 cents per month is charged. This latter item seems to us to be in line with imperfect policy, and we hold to the opinion that the consumers would be better satisfied were they called on to pay the \$1.60 per 1,000, without the rental feature. The company maintains a handsome assortment of cooking and heating appliances, which it disposes of at net cost. One excellent feature of the Joplin cheap gas announcement is, that it is made to take up about one-quarter page of one of the local dailies ; and it is printed in such

a bold manner that one is led to exclaim, "Well, the Joplinite who cannot read that while in motion, must be a very swift runner."

THE case of Roland H. Smith *vs.* the Pittsburgh Gas Company, was decided about a fortnight ago, in an opinion filed by Judge Acheson, who upholds defendant. In general terms the suit was for infringement of letters patent (granted November 17, 1885, to Smith,) for a process of producing illuminating gas. Judge Acheson's opinion, which is a very lengthy one, goes into the merits of the case with great minuteness, and the summing up is as follows : "I do not see how it can be denied that the process practiced at Beaver Falls was the same as that described in the Smith patent, and was an anticipation. What more does the patent disclose than was there known and prosecuted? As to the proper proportions in the admixture of the natural gas and the fluid hydrocarbon the patent is silent. It gives no instance whereby the excessive employment of the enriching agent may be avoided. Nor can the transaction at Beaver Falls be deemed an unsuccessful and abandoned experiment within the meaning of the patent law. An illuminating compressed gas was there actually produced, and for a long time was extensively used. The cessation of the use was not because the product was impracticable, but by reason of the unsatisfactory nature of the product, in that the compressed gas burned with a smoky flame. And here it must be observed that there is testimony in the case tending very strongly to show that smokiness is a defect inherent in gas produced by combining natural gas and petroleum gas, for the reason that natural gas is deficient in hydrogen. I will not, however, discuss that subject. It is enough here to say that in my opinion the defence of anticipation has been made out."

THE Kentucky State Senate has granted the Louisville Gas Company the right to manufacture and distribute electrical currents for lighting and power purposes. We might also note that the Senate Committee, appointed to investigate the charges of corrupt interference by the Company in municipal and State elections, was, upon request of its Chairman, Senator Poyntz, discharged from further service in that direction. Thus ends the investigation farce, which termination might lead one to exclaim : "What were they (the Committee) born for, when they were so soon done for?"

THE proprietors of the Inter-State (St. Louis, Mo.) Gas and Water Works Company have agreed to include the "erection, management and maintenance of electric light plants" in the objects for which the Company was originally chartered to uphold.

THE Village Trustees of Glens Falls, N. Y., have awarded a 3-year contract for the public lighting of that place to the Glens Falls Electric Light and Power Company, at its bid rate of 26 cents per arc per night, on an all-night schedule. Much dissatisfaction exists over this determination, because another and lower bid for the service, from the Glens Falls Gas Light Company, was entirely disregarded. The contract for the naphtha lighting was awarded to the New York and New Jersey Globe Gas Light Company at its bid of 7 cents per lamp per night.

THE Committee on Manufactures, of the Massachusetts Legislature, have presented a report in the matter of their investigations at Alexandria and Richmond, Va., and Philadelphia, as to the operation of gas and electric lighting plants by municipalities. The Committee considered it inadvisable to recommend the adoption of municipal control of gas and electric light works in the cities and towns of Massachusetts. In Richmond, they say, it is evident that a limited number of citizens are paying a high price for gas without corresponding advantages to the city. As to Philadelphia, they say, if the offer of \$1,200,000 rental and 17,000 street lights free had been accepted, the city would certainly get its gas as cheaply as it does now, and instead of an actual loss of \$104,145, would have an actual profit of \$1,851,000.

It is said that the Fahneltjelm Incandescent Gas Light Company will attempt to secure a fuel gas charter for Rockford, Ills.

THE sales of gas at Atlantic City, N. J., during the month of March amounted to 3,000,000 cubic feet, which is an increase of about 25 per cent. over the quantity consumed in March, 1889.

MR. ALEX. L. MCKAIG, of the Fuel Gas and Electric Engineering Company, of Pittsburgh, Pa., is to be married to a Miss Rogers, of London, England. The ceremony will take place in June.

MR. H. P. TALMAGE, of Netherwood, a suburb of Plainfield, N. J., has been lighting his mansion on Belvidere avenue with gas produced

from some type or another of an automatic gas machine. He will probably resort to other means of obtaining artificial illumination, as the apparatus "exploded, with a loud report," on the evening of Sunday, April 20.

SUPT. EVANS, of the Spencer (Mass.) Gas Company, is using Lima crude oil for enriching purposes.

IN a recent issue of a St. Louis newspaper we find the following: "Gas bills to private consumers for the month of April," said Mr. J. D. Thompson, Vice-President of the Laclede Gas Light Company, "will be made out at \$1.25 per 1,000 cubic feet. It will be time enough to reduce the rate to 90 cents when the court of last resort decides that we must do so. The Carondelet Company will probably charge what it has been charging right along, \$2 per 1,000. The Carondelet Company is not a large one, and the bulk of its business, probably, is in the supply of gas to the public lamps."

IN respect to the petition of the Laclede Company for an injunction restraining the city of St. Louis from attempting to enforce the provisions of the 90 cent gas ordinance, we have the following advices: The Laclede Gas Light Company has anticipated the city in the litigation to test the validity of the new gas ordinance fixing the price of gas at 90 cents per 1,000 cubic feet, and which went into effect on March 10 last, by commencing an injunction suit in the Circuit Court to restrain the city from enforcing the new ordinance. The Gas Company, with Gibson, Bond & Gibson, Boyle, Adams & McKeighan, and Lubke & Muench as attorneys, filed a petition in the Circuit Court about a fortnight ago, asking the court to declare the ordinance invalid and of no effect, so far as the Laclede Company is concerned, and to enjoin the city from attempting to enforce it. The petition sets out the incorporation of the Laclede Gas Light Company by the General Assembly of the State of Missouri, by an Act approved March 2, 1857, and an amendatory Act approved March 26, 1868; that the Company under the grants thus given it has laid 135 miles of pipe, has a large and valuable plant, and has been supplying gas to consumers, and that this right is in no manner dependent upon or subject either in respect to the right of vending gas or the price at which it shall be vended, or in the manner of collecting its bills for gas consumed, to any control, legislation, supervision or dictation on the part of the city or any of its officers, agencies or instrumentalities.

It is then stated that on January 1 last there was existing in St. Louis a corporation known as the St. Louis Gas Light Company, the incorporation of which is set out in detail, which corporation expired by limitation on the date last named; that said Company had a contract with the city to supply gas to consumers at not less than \$3.25 per 1,000 cubic feet, and to light public lamps, etc.; that on January 30, 1886, while said contract was in force, the city desiring a modification thereof to the extent of a reduction in the price of gas, after certain negotiations, adopted an ordinance, which was approved by the Mayor reducing the price of gas to \$1.25 per 1,000 cubic feet to consumers, and a reduction in the price to public lamps, and extending the franchise of the St. Louis Gas Company for 30 years from Jan. 1, 1890, which ordinance the St. Louis Gas Company duly accepted, and executed a bond in the sum of \$100,000 to the city, as required by its provisions, to abide by its conditions, which conditions caused the Company to surrender \$1,574,244 in the form of reductions to consumers, and \$116,000 by way of rebate for public lamps, between the time of the extended franchise and January 1, 1890. The sale of the St. Louis Gas Company to the Laclede Gas Company on December 24, 1889, is then set out. It is then asserted that in purchasing said Company the Laclede Company succeeded in all the rights, privileges and franchises of the St. Louis Gas Company, including the conditions in the ordinance extending the franchise of the St. Louis Gas Company; and the city was obligated in like good faith to perform all the obligations of the ordinance.

It is then alleged that the city is attempting to evade the obligation of this ordinance, and in February last passed an ordinance attempting to fix the price of gas to consumers at 90 cents per 1,000 cubic feet for illuminating gas, and 45 cents per 1,000 cubic feet for fuel and power purposes; that in passing said ordinance the Municipal Assembly did not hear evidence or investigate or consider judicially the question of the reasonableness of the price of gas, but determined the same arbitrarily and finally without notice to the plaintiff; that this notice is in effect an attempt to deprive plaintiff of its franchise and property without due process of law, and that the attempt to impose a fine of \$250 for violating the provisions of the ordinance is a violation of article 8 of the Consti-

tion of the United States, and article 2 of the Constitution of the State of Missouri.

The matter was presented to Judge Valliant, who granted a temporary injunction restraining the city until the 29th inst., at 2 o'clock P. M., from interfering with the Gas Company or its property in any manner. At that date, if the pleadings are perfected, the case will probably be heard upon its merits. The case, succinctly stated, is nothing more than a modified revival of the old tripartite contract litigation so disastrous to the city in times past. The ordinance granting an extension of the franchise of the St. Louis Gas Light Company was nothing more than a modification of that contract.

THE Providence (R. I.) Gas Company will maintain 15 additional public lamp posts in the village of Auburn.

MR. SHELTON, of the United Gas Improvement Company, Philadelphia, is designing a plan for an auxiliary water gas plant for the Pittsfield (Mass.) Gas Company. The capacity desired is 150,000 cubic feet per diem.

ON and after July 1st the price of gas in Lynn, Mass., is to rule at \$1.60 per 1,000 cubic feet. The present rate is \$1.80. That the Company is progressive is shown in the following table of rate reductions for the last decade:

Date.	Rates.
Jan. 1, 1881, from.....	\$3.00 to \$2.50
July 1, 1884, "	2.50 to 2.00
Oct. 1, 1886, "	2.00 to 1.80
July 1, 1890, "	1.80 to 1.60

AT an adjourned Council hearing in the matter of the petition of certain parties who seek the right to operate the Citizens Gas Company, in the town of Marlboro, Mass., much interesting testimony was volunteered. We give the following summary of the proceedings:

Messrs. E. L. Bigelow, W. N. Davenport, and C. F. Morse appeared for the petitioners. J. W. McDonald, Esq., in behalf of the Marlboro Gas Light Company, remonstrated against granting. The petitioners gave as their reasons for the request that they wanted cheaper gas, and also wanted the present gas works removed so far away that they would not be offensive to the denizens of Main street. Mr. Bigelow stated they had made inquiries where water gas had been used, and found it worked well both for heating and illuminating purposes. He said it could be furnished for from \$1 to \$1.50 per thousand, which would be quite a saving from the present price charged in town. Mr. Bigelow said that on pure business principles he wished to procure gas at a less price, and also furnish it to others at less cost. Mr. McDonald asked if the Company had been chartered. Answer, yes. Mr. Davenport exhibited the charter, which had ten signatures, with a capital stock of \$50,000. In answer to the question if the stock had been paid in, he replied no; no money had been paid out except the expense of procuring the charter. The reply to the question if the Company had a certificate for doing business was that permission had not been granted yet by the Gas Commissioners. Mr. McDonald asked what processes they proposed to adopt in making gas. If the old Company would furnish it as cheaply, would the new Company still insist on their petition? Would the new Company be satisfied if the old Company removed their plant farther from the Main street? Do you propose laying mains in the same streets occupied by the old Company and compete for the same patronage? Don't you think with so many pipes in the ground, and sewage soon to be put in, that it would make too many? The answer to the first was that substantially the same processes would be adopted as the old, though the manufacture of water gas might be introduced if feasible. Several places were cited where it had been used with good results. The second and third questions were answered by Mr. Morse that they should still insist on their petition. The fourth question was answered in the affirmative. The answer to the fifth query was in the negative. The petitioners stated one thing contemplated was the furnishing of fuel gas. The petitioners said they would furnish same guarantee as the old Company. They thought competition would give cheaper gas and not give so much chance for a corporation to monopolize the price as with one company. Mr. McDonald asked what the petitioners knew about the manufacture of gas and the expense, from a practical standpoint, and their reply showed little knowledge in that respect, only what they had gained by talking with individuals. The petitioners said they would produce a man thoroughly acquainted with the manufacture of water gas if the Board desired. By request of Mr. McDonald the hearing was adjourned.

Steel-Melting by Water Gas.

A contemporary states that under the auspices of the British Water Gas Syndicate, Limited, experiments in steel melting by water gas were conducted at the Leeds Forge recently, in presence of a number of gentlemen interested in steel melting. The object of the experiment was to prove the utility in the way of economy of time required to melt an ordinary charge of pig iron into Siemens steel by means of water gas mixed with producer gas, as against the older practice of using merely producer or Siemens gas; and also in the economy of fuel required for the purpose. It was stated that under the old-fashioned system the Leeds Forge had only been able by one furnace to produce from 9 to 11 charges per week, with a consumption of fuel of about 10 cwt. to the ton of ingots produced. Experiments have been going on for some time; and on March 20, for instance, work was conducted at a speed of from 20 to 22 charges per week, with a consumption of less than 5 cwt. of fuel per ton of ingots produced, and similar or even better results were expected from the experiments on March 21. At this establishment similar apparatus to that here employed is being made for several firms in different parts of England. The system is said to have been adopted with success on the continent. For instance, the Hørde Steel Works Company, in Westphalia, are converting all their steel by means of water gas, and are also heating large armor plates with it, and puddling iron in six puddling furnaces. They are also said to be melting pot steel in large furnaces, where 48 crucibles of steel are operated upon with water gas at the same time. The largely increased output of puddling iron may be gathered from the fact that whereas under the old system the output per man per shift was 14 cwt. in England, at Hørde, where water gas is used almost exclusively, the quantity turned out per man per shift is 40 cwt. Besides, the product is said to be superior, owing to the high melting point at which water gas does its work. The practical men present at the experiments were afforded every opportunity for obtaining samples of the gases going into and issuing from the furnace, and of the materials used in the charge, and of the charge at the various periods of its conversion into steel; so that by analysis they might be able to form their independent judgment as to the improved action which takes place under the influence of water gas. The charge, consisting of 9 tons 6 cwt., was completely converted into mild steel within the space of 5 hours 4 minutes, and when tapped it was to all appearances in a more fluid and better condition than that usually obtained under ordinary producer gas. The gentlemen present were satisfied at this practical demonstration both as to facts and figures on a large scale of the application of water gas for this special purpose.

With regard to the above described experiments a correspondent to the *Iron and Steel Trades Review* writes as follows:

From the notices of the experiments made at the Leeds Forge, in melting steel with water gas, which have appeared in last week's technical journals, it may be inferred that the steel was made on the open hearth of a Siemens furnace (with four regenerators), and that the fuel employed was a mixture of producer and water gas. A charge was made, it appears, in 5 hours with a consumption of fuel equivalent to 5 cwt. per ton of steel produced.

These figures are very interesting to steel makers, but it would be well if they could be supplemented by information on the following points, viz.: whether the water gas employed was mixed with gas from a Siemens producer, or with the gas sometimes called producer gas, which is made in the water gas apparatus; also whether the consumption given as five cwt., represents the fuel consumed in the production of water gas, or of producer gas, or of both combined.

No one will doubt that gas made in the Siemens producer may be enriched by the addition of water gas (hydrogen and carbonic oxide free from nitrogen), and that by using such enriched gas in the Siemens furnace a higher temperature may be obtained than by using producer gas alone; but it may be questioned whether this can be done profitably, both as regards cost of fuel and wear and tear of furnaces.

With regard to the melting of a charge in five hours at the Leeds Forge, in the Siemens crucible steel melting furnace, which was introduced about 1867, five to six charges have always been made per 24 hours in regular work; and if similar materials, viz., pig iron and puddled bar or scrap, be used in an open-hearth furnace, steel should be melted as quickly in one case as in the other, and this, indeed, has been reported from the Continent. If the puddled bar is charged red hot, the working should be even more rapid, as in pot furnaces cold materials are exclusively employed. The notices concerning the use of water gas at the Leeds Forge refer to the fusion of pig iron and scrap, and it follows from what has been said that there is no evidence of improvement by the use of water gas, as, of course, the melting of steel in crucibles, and on the open hearth, to which reference has been made, is effected with gas from the ordinary Siemens producers.

The statement that the normal production of puddled iron in an

ordinary puddling furnace is as low as 14 cwt. per shift can only be looked upon as a clerical error, inasmuch as 32 cwt. per shift is the usual figure for a forge mixture, and the consumption of fuel 25 cwt. per ton of puddled bar, as may be found in the standard works on iron and steel of Percy or Bauermann. A return which I have seen from the Pather Works, Glasgow, of the day and night shifts on the 24th of last month confirm these figures, the production of bar iron from an ordinary puddling furnace being given as 32 cwt. per shift, and the consumption of fuel 23 cwt. per ton of puddled bar. At the same works a double Siemens furnace of the new type has lately been set on work for puddling iron, and the production is returned as 34 tons of puddled bar per shift, which is fully equal to the ordinary furnace, while the consumption of fuel is reduced to 1 cwt. per ton for puddled iron. It would be interesting to learn the consumption of fuel in puddling with water gas.

Discharge of Steam through Orifices.

The *Engineering Record* says that while the question of steam discharge through orifices has been ably investigated from a theoretical standpoint, there is a lamentable deficiency of experimental data on the subject. The following table, calculated for steam pressures ranging from 10 to 150 pounds per square inch above the atmosphere, will therefore prove valuable. It has been calculated by means of a formula given in a Report on Safety Valves in the Transactions of the Institution of Engineers and Shipbuilders in Scotland, and stated to agree with the results of experiments for pressures not lower than 10 pounds per square inch with a surprising degree of exactness:

Velocity of Efflux of Steam into the Atmosphere.

Gauge Pressure.	Velocity of Discharge in Feet per Second.	Pounds of Steam Discharged per Minute per Sq. In. of Opening.	Gauge Pressure.	Velocity of Discharge in Feet per Second.	Pounds of Steam Discharged per Minute per Sq. In. of Opening.
10	861	22.2	70	894	73.5
15	867	26.6	75	895	77.6
20	871	30.9	80	896	81.9
25	874	35.3	85	898	86.0
30	877	39.5	90	899	90.3
35	880	43.8	95	900	94.4
40	882	48.0	100	902	98.6
45	884	52.3	110	904	106.9
50	886	56.5	120	906	115.2
55	888	60.7	130	908	123.5
60	890	65.0	140	910	131.9
65	892	69.3	150	912	140.2

For obvious reasons no table can be calculated for the flow of steam through pipes since the element of pipe length there must be considered, and no two cases in practice would have the same length of pipe. In Robert Briggs' "American Practice in Warming Buildings by Steam," however, extensive tables are given for different conditions, to which it may be interesting to refer.

An Ingenious Device for Lighting the Bottom of the Sea.

In the investigations that were undertaken by the Prince of Monaco in deep sea soundings, an ingenious method was adopted to obtain specimens of the living creatures existing at the bottom of the ocean. The apparatus used was shown at the Paris exhibition. The cage in which the submarine animals were caught, according to *Le Genie Civil*, consisted of a cylinder of wire having three conical entrances, like those of a lobster pot, and weighted for submersion with detachable weights. It was, however, very unlikely that at these immense depths, where the darkness is practically total, any fish would voluntarily find their way into the trap, and steps were taken to attract them by a light placed inside it. Obviously, no light was available but an electric light, but to get an electric light to burn a mile or two under water was not easy.

The only resource was to supply the incandescent wire from a battery in the trap. Here, however, another difficulty occurred. It was necessary to enclose the battery, which had to be of considerable power, in a box of some kind, and as the hydrostatic pressure at such depths was six or seven hundred pounds to the square inch, it was found impossible to make a box which was not crushed before it reached its destination. At last, however, this trouble was overcome by the curious device of connecting the box with a balloon. The balloon was made of cloth dipped in indiarubber, and so arranged that the air in it was in communication with that in the battery box.

On sinking the apparatus, the hydrostatic pressure, being virtually uniform all round the balloon, compressed it equally on all sides, forcing the air out of it into the battery box, until the pressure inside the box and balloon exactly balanced the pressure outside. This process went on to any extent, so that at the bottom of the sea, although the balloon was reduced by the enormous force exerted on it to a small fraction of its original size, it still kept the internal and external pressure equal. On raising the apparatus again it expanded as the pressure diminished, and brought the battery box to the surface uninjured. So successful was this device that, not content with capturing deep-sea fish, the prince and his assistants propose on their next expedition to send down a photographic apparatus and bring back negatives of the bottom of the ocean, as seen by the electric light.

Gas Stocks.

Quotations by Geo. W. Close, Broker and Dealer in Gas Stocks.

16 WALL ST., NEW YORK CITY.

MAY 5.

All communications will receive particular attention. The following quotations are based on the par value of \$100 per share.

Table of Gas Stocks with columns for Company Name, Capital, Par, Bid, and Asked prices.

Out of Town Gas Companies.

Table listing various gas companies and their financial details, including Boston United Gas Co., Bay State Gas Co., Buffalo Mutual, etc.

Advertisers Index.

Table listing advertisers and their page numbers, categorized by Gas Engineers, Gas Works Apparatus and Construction, Gas and Water Pipes, Processes, Inclined Retorts, etc.

GASHOLDER TANKS.

Table listing gas holder tanks and their locations, such as W. C. Whyte, New York City.

GASHOLDER PAINT.

Table listing gas holder paint products, such as The Government Waterproof Paint Co.

RETORTS AND FIREBRICK.

Table listing retorts and firebrick products and manufacturers, such as J. H. Gautier & Co., Jersey City.

SCRUBBERS AND CONDENSERS.

Table listing scrubbers and condensers, such as G. Shepard Page, New York City.

REGENERATIVE FURNACES.

Table listing regenerative furnaces, such as Bartlett, Hayward & Co., Baltimore, Md.

GAS GOVERNORS.

Table listing gas governors, such as Connelly & Co., New York City.

SELF-SEALING MOUTHPIECE DOORS.

Table listing self-sealing mouthpiece doors, such as Smith & Sayre Mfg. Co., New York City.

TAR AND CARBONIC ACID EXTRACTOR.

Table listing tar and carbonic acid extractors, such as Geo. Shepard Page, N. Y. City.

CEMENTS.

Table listing cements, such as C. L. Gerould & Co., Brooklyn, N. Y.

GAS ENRICHERS.

Table listing gas enrichers, such as Standard Oil Co., Cleveland, Ohio.

GAS METERS.

Table listing gas meters and manufacturers, such as John J. Griffin & Co., Phila., Pa.

EXHAUSTERS.

Table listing exhausters, such as The P. H. & F. M. Roots Co., Connersville, Ind.

GAS COALS.

Table listing gas coals and suppliers, such as Penn Gas Coal Co., Phila., Pa.

CANNEL COALS.

Table listing cannel coals, such as Perkins & Co., New York City.

VALVES.

Table listing valves and manufacturers, such as Ludlow Valve Manufacturing Co., Troy, N. Y.

GAS ENGINES.

Table listing gas engines, such as Schleichler, Schumm & Co., Phila., Pa.

ENGINES AND BOILERS.

Table listing engines and boilers, such as Jarvis Engineering Co., Boston, Mass.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889, and later dates.

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used. Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE. Works under our system may be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon. One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

LACLEDE FIRE BRICK MANUFACTURING COMPANY,

ST. LOUIS, MO.

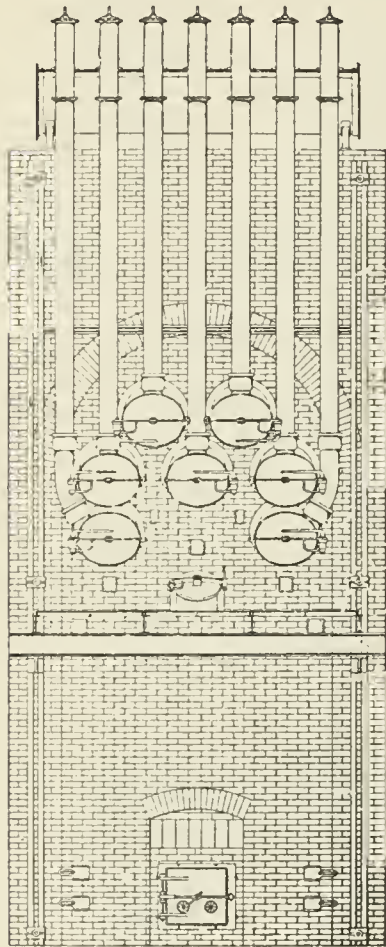

Exclusive Agents in the United States

A Successful Competitor of the Incandescent Electric Light for Interiors, etc. Is especially applicable for the lighting of Offices, Stores, Factories, Mills, Show Windows, Libraries, and all situations where an increased illumination is desired.

More than 25,000 Lungren Lamps are now in use. Testimonials, references, or any desired information will be cheerfully given.

Lungren Lamp.

THE SIEMENS-LUNGREN CO., N.E. Cor. 21st St. & Washington Av., PHILADELPHIA.

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE." Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR. Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER. Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time.

Made in Sizes of 5 10 15 20, and 25 Horse Power. All Engines Guaranteed for One Year.

PROPRIETORS OF THE

OAKHILL GAS RETORT & FIRE BRICK W'KS

Our immense establishment is now employed almost entirely in the manufacture of

Materials for Gas Companies

We have studied and perfected three important points. Our retorts are made to stand changes of temperature, the strongest heats of the furnace, and the abrasion of feeding and emptying. We have the exclusive Agency for the West of the celebrated

Kloenne-Bredel Full Depth and Semi-Recuperator Benches,

And also furnish and build

Our Own Styles Semi-Recuperator Furnaces for the use of Coal or Coke as fuel.

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,

OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY, THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

(Established 1848.)

GAS METER MANUFACTURERS,

Nos. 1339 to 1349 Cherry Street, Philadelphia, Pa.,

WET AND DRY GAS METERS, STATION METERS, EXPERIMENTAL METERS, METER PROVERS,

Center Seals, Pressure Registers, Governors, Indicators, Photometers, and all other kinds of Apparatus for use in Gas Works.

FOULIS' PATENT STATION AND DISTRICT GOVERNORS.

REPAIRING DEPARTMENT.—We employ a special force of skilled workmen repairing meters of all makers.

WM. WALLACE GOODWIN, President and Treasurer.

E. STEIN, Vice-President.

H. B. GOODWIN, Secretary and Superintendent.

THE GOODWIN GAS STOVE AND METER CO.,

Successors to W. W. GOODWIN & CO.

1012, 1014 and 1016 Filbert St., Phila., Pa.

142 Chambers St., New York City.

76 Dearborn, St., Chicago, Ills

WALDO BROTHERS, Agents, 88 Water Streets, Boston, Mass.

MANUFACTURERS OF

DRY AND WET GAS METERS,

Station Meters (square, cylindrical, or in staves), Glazed Meters, King's and Sugg's Experimental Meters, Lamp Post Meters, etc., etc. Meter Provers (sizes 2, 5, and 10 feet), Pressure Gauges of all kinds, Pressure Registers, Pressure and Vacuum Registers, Pressure Indicators (sizes 4, 6, and 9 inch), King's Pressure and Vacuum Gauges, Dry and Wet Center Seals, Dry and Wet Governors, Exhauster Governors, Photometers of all descriptions. Letheby's Sulphur and Ammonia Test Apparatus complete. Also, Testing and Chemical Apparatus of all kinds, and of the most perfect description, for all purposes relating to Gas.

Manufacturers of the "SUN DIAL" GAS STOVES, for Cooking and Heating.

Goodwin's Improved Lowe's Jet Photometer.

Agents for Bray's Patent Gas Burners and Lanterns.

Special attention to Repairs of Meters and all Apparatus connected with the business. All work guaranteed first-class in every particular. Orders filled promptly.

G. B. EDWARDS, Manager, New York.

S. S. STRATTON, Manager, Chicago.

D. McDONALD & CO.,

GAS METER MANUFACTURERS.

(Established 1854.)

51 Lancaster St., Albany, N. Y.

34 & 36 West Monroe St., Chicago, Ill.

STATION METERS, EXPERIMENTAL METERS, METER PROVERS, PRESSURE & VACUUM REGISTERS, PRESSURE GAUGES, ETC.

Also STAR GAS STOVES, RANGES, and HEATING STOVES.

We use only the very best materials, and employ the most skilled labor, and by our long experience (36 years) and personal supervision of every detail we feel justified in assuring the public that our goods will give perfect satisfaction. Every Meter emanating from our establishment will bear the State Inspector's BADGE, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

GAS INTO POWER,

BY THE

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

Gas Power the Leading Power of To-Day,
AND SOLVE AT ONCE THE QUESTION OF FUEL GAS.

“Otto Gas Engine Works,”

SCHLEICHER, SCHUMM & CO.,

151 Monroe St. (Kent Building), Chicago.

[OFFICIAL NOTICE.]

Western Gas Association.

SECRETARY'S OFFICE, WESTERN GAS ASSOCIATION, }
QUINCY, ILLS., May 7, 1890. }

The Thirteenth Annual Meeting of the Western Gas Association will be held at the Lindell Hotel, St. Louis, Mo., on the 21st, 22d and 23d days of May. The hall in which the business sessions of the Association will be conducted is within the hotel building, is very commodious, quiet, and in every way excellently well adapted to our requirements. The hotel management has granted on this occasion the following rates:

For single room and board, \$2.75 per day; for room with bath, \$3.25 per day. These rates will apply to members in attendance, their families and visiting brethren. In this connection I am instructed by the Local Committee of Arrangements to give our members warning of the fact that in order to secure suitable accommodations, their rooms *must be engaged in advance*. Your Secretary has been in the habit of making an announcement to this effect with exceeding regularity from year to year, and just as regularly no one, or at least only very few, pays the slightest attention to the warning. The necessity of engaging quarters in advance, however, is in this instance very urgent. Now that the old Planters' House has been closed, the Southern and Lindell Hotels often have more business thrust upon them than they are capable of handling, and of late it has been no unusual occurrence for them to deny would-be guests admission, unless their rooms had been previously spoken for. But all of our members can be accommodated without the slightest jar or friction, if they will but take the trouble to address a line to the "Proprietor of the Lindell Hotel, St. Louis, Mo.," telling him the kind and price of room or rooms desired. This should be done at least one week in advance of the first day of the meeting.

In addition to the reduction in transportation rates granted by the Central Traffic Association, the Trunk Line Association has also joined in the movement. As the boundary of the latter Association extends as far east as the western border of the New England States, our Eastern friends will be enabled to avail themselves of the reduced fares.

I am authorized to state that Mr. R. D. Walsh, Chairman of the Local Committee of Arrangements, has kindly consented to take charge of all articles destined for the Gas Exhibit, and will cheerfully surrender a generous portion of his time to the interests of exhibitors. Communications, consignments of gas stoves, apparatus, burners—anything, in fact, intended for the Exhibit—may be directed to Mr. Walsh, in care of the Laclede Gas Light and Coke Company. Exhibitors can rest assured that not only will their wares receive careful handling and be displayed to the best possible advantage, but that they themselves will be accorded the most courteous treatment at the hands of Mr. Walsh and his efficient committee.

The "Paper List" for our Thirteenth Annual will be as follows:

- "Relative Value of Gaseous Fuels," by B. E. Chollar.
- "Effects of Natural Gas Competition," by James Somerville.
- "An Argument in Favor of the Adoption of a Uniform System of Estimating the Cost of Gas in the Holder," by George G. Ramsdell.
- "Impressions of British Gas Works," by George T. Thompson.
- "Mixed Gases," by E. G. Cowdery.
- "Wrought Iron, Cast Iron, or Steel—which is the Best Material for Street Mains?" by Eugene Printz.
- "What Policy Should the Gas Interest Adopt in Connection with the Approaching World's Fair?" by Walton Clark.
- "On the Abuse of the Patent System as Bearing on the Gas Industry, with a Remedy," by Frederic Egner.
- "The By-Products of Experience," by Allen R. Foote.

The attention of the Board of Directors is called to the fact that Section I., of Article VII., of our By-Laws reads as follows: "The Board of Directors shall meet as such at least once in each year, on the day preceding the annual meeting of the Association, at which time they

shall determine in regard to the propriety of the various papers, drawings, models, or other matters constituting the special order, being laid before the Association." The Board of Directors elected at our last meeting is composed of the following-named gentlemen, who are, therefore, particularly requested to assemble at the Association's headquarters on Tuesday morning, May 20, at 10 o'clock:

J. B. Howard, E. H. Jenkins, Z. T. F. Runner, John Gimper, C. W. Butterworth, E. G. Cowdery, J. S. Ambrose, J. W. Dunbar, and B. E. Chollar.

The social features of the Thirteenth Annual, as provided by the Entertainment Committee, will be as follows:

On Thursday evening there will be a grand moonlight excursion and supper on the Mississippi, the handsome steamer *Oliver Bierne* having been engaged for the occasion. A trip will be made up the river as far as the Chain of Rocks, giving a view of the new water works now in process of construction, and also of the recently completed Merchants' Bridge. On returning, the steamer will run down below Carondelet, affording a beautiful twilight view of the full 16 miles of the city's front along the Mississippi. Supper will be served, and there will also be music and dancing, the boat returning to the wharf at 10 o'clock.

On Friday, at 10:30 A.M., carriages will be in readiness at the hotel for delegates and their guests. A drive will be taken through the western portion of the city as far as the Fair Grounds, where a luncheon will be served at the Jockey Club House. After a series of entertainments, beginning at 2 o'clock P.M., which have been generously tendered by the Board of Directors of the Fair Grounds, parties wishing to take a drive through the parks may do so at their pleasure, in carriages provided by the committee.

Ladies accompanying delegates can obtain carriages at any time during Wednesday and Thursday for such purposes as they may desire.

From the above it will be seen that the time-honored custom of serving a banquet on the second night of our reunion will be departed from. This is an innovation which the committee feels assured will receive a hearty welcome from the "Toast-Responders;" and possibly from many others for the mere sake of a change, if for no other reason.

Application blanks, copies of our By-Laws, and any information not contained in these communications will be cheerfully furnished by

A. W. LITTLETON, Sec'y.

(Since writing the foregoing, your Secretary has received word that the lines operated by the Southern Passenger Association will grant the same rates as those which will be given by the Central Traffic and Trunk Line Associations, viz., one fare and one third for the round trip. These fares can be obtained on the certificate plan. Any railroad ticket agent within the territories of these three passenger associations will take pleasure in informing a member as to the steps that are required for securing these reduced fares. It is hoped that every delegate who can do so will avail himself of the reduction.)

BRIEFLY TOLD.

THE ENTERTAINMENT PROGRAMME FOR THE ST. LOUIS MEETING.—Secretary Littleton's current circular foreshadows with great distinctness the round of pleasure that is to be the portion of the Western's members and guests at the meeting to be held next week in St. Louis, and it will also be noted that the programme this year differs considerably from any that has so far been carried out. The time-honored banquet in formal state on the evening of the second day will not be held this year, and we are inclined to the view that the change, especially when we know that a most charming river trip is to be the enjoyable substitute, will be heartily indorsed by all. But one fear as to complete success can be entertained, and that fear is connected with the nature of the weather on the night of the 22d inst. Given good atmospheric conditions, and the outing on the Mississippi is bound to be a grand success. The balance of the programme for entertainment conjures up great expectations and reflects great credit on the originality and cleverness of those who have the preliminaries in charge. Another very satisfying announcement is found in the determination of the Southern Passenger Association to join in the offering of a reduced rate for passenger transportation. It gives us great satisfaction to be able to add that in every shape and manner the promise of a most successful meeting is assured.

EXIT THE WAKEFIELD MANUFACTURING COMPANY.—Following up our brief note of a week ago in respect to the defeat in the Rhode Island Senate of the scheme proposed by Mr. Addicks for the incorporation of the Wakefield Manufacturing Company, we may say that the matter came up on April 30th in the shape of a report from the committee

which had the matter under consideration, to indefinitely postpone the proposed grant. The Senate concurred in this, and a motion for reconsideration of that action was adopted. While this does not completely "kill the bill," in that it may be resuscitated before the next Senate, it may be looked on as extremely improbable that the measure, in its present framing, will ever be again considered. In the meantime the greed of the "Wakefield Company" schemers may actually deprive them of the "free assistance" that they so earnestly invoke in the nature of English capital. Without this latter sinew the paths of certain speculators or traffickers in "good gas situations in America" might have been much harder than they now are, and some of the "good gas situations" might still be in control of those who worked the situations up from poor to good ones. In any event, the leader in the April 22d issue of the *London Journal of Gas Lighting*, which is based on the Wakefield Manufacturing Company's application to the Rhode Island Legislature, sounds an alarm that tends to show that English capital, or rather its controllers, can make the separation between piracy and honest business practice.

MR. TODD'S POLICY.—When Mr. J. R. Todd resigned from the management of the Natick (Mass.) Gas Company to take charge of the gas plant at Middletown, N. Y., every one who knew that gentleman was certain that his success at Natick would be duplicated, at least, in his new field. And so it has been, not only duplicated, but excelled. This pleasant announcement is incited through our receipt of a circular which carries the intimation that the Middletown Gas and Electric Light Company, through Mr. Todd, had arranged for a repetition of the exhibition of gas cooking and heating stoves, similar to the display that was held by the Company in 1888 and 1889. Hearing is impressive, but illustration is the real way of making the picture. The Company hired a suitable apartment in the Dill Building, in Middletown, fitted up a complete exhibit of gas cooking, etc., stoves, and for one week (the display closed last Saturday) showed the beauties and value of cooking by gas to Middletown's housewives. Of course, we do not offer this as anything markedly out of the way, for many such exhibitions have been given in other places; but it takes courage to carry out plans of this kind in a locality like that of Middletown, for the "Managing Director" is apt to veto these on the ground that they cost too much. In any event, Mr. Todd must have all the credit for the results achieved in this direction in his present location, for when he took charge there the Middletown Company had *one* heating stove on its lines, and not a single cooker. Now, however, the lines carry gas to over 100 stoves, with the prospect that before the summer season of 1890 is ended that number will be returned at not less than 150. Again, as an evidence of Mr. Todd's careful guidance, from July 1st to December 31st, 1888, the increase in the Company's gas accounted for was 25 per cent. over the corresponding 6 months in 1887, and a further gain of 15 per cent. is shown in the same respect in the 6 months of 1889 over 1888. Surely this is the kind of management that ought to be appreciated by the proprietors of the property.

NOTES.—The stockholders of the Randolph Gas and Coal Company have assented to an increase in its capital stock of \$125,000. The present capitalization is \$200,000.—Manager Tracy, of the Poughkeepsie, (N. Y.) Gas Company, is availing himself largely of printer's ink for the popularizing of gas for purposes other than illumination. For instance, we are in possession of a recent issue of the *Evening Enterprise*, in which one and one-half columns are devoted to argument, figures and testimonials respecting the utility and convenience of gas cookers.—Manager L. C. Grapuer, of the Red Bluff (Cal.) Gas and Electric Light Company, is expending between \$4,000 and \$5,000 on betterments to the retort house plant. The electric light apparatus will not be added to.

The Market for Gas Securities.

The event of the week in city gas shares was the rise to par of Consolidated, which was bid for at noon to-day (Friday) at 100½. The figures thus given prove the position taken by us in respect to it. It will go higher, and not a better stock for investment purposes is at present on the market. Other city shares are strong and higher, too. Old Brooklyn gas sold on Wednesday of this week, at auction, at 116. Other Brooklyn shares are also in demand. The feature in out-of-town shares is the continued rise in Chicago gas, which is bid for at 58¾. Laclede common is at 24¾ to 25, and Bay State gas also moved up sharply. We have hitherto been quoting this stock on the basis of \$50—the stock is half stock—per share, when it should have been quoted, in accordance with our practice, on the \$100 basis. It is bid for at 79. The market in general is strong.

Fields for Scientific Research.

At the annual meeting of the Liverpool Physical Society perhaps the most striking feature of an extraordinarily good meeting was the address of the President, Prof. Lodge, who referred at length to the fields of greatest promise for scientific exploration. An abstract of the address is appended.

Running over some of these open paths we come across a fruitful field in the study of the effects of light on a great number of things. That light affected chemical combinations has long been known, and it is the foundation of photography, but we now find there is scarcely anything which light does not affect. It affects selenium enormously, bringing down its electrical resistance to half or one-third what it is in the dark; it may affect other bodies in a similar way. It affects metals, charging them electrically in a curious way, especially such metals as zinc. It seems to disintegrate or evaporate surfaces long exposed to it. It affects the electric field, causing a short spark to occur much more easily in ultra-violet light than in the dark. And quite recently, by Shelford Bidwell, it has been found to affect the magnetism of an iron rod in a sensitive condition. Of none of these phenomena has the investigation more than begun. Then, in the region of photography, there is a good deal to be done, not only in understanding the photographic process itself, but in photographing rays hitherto intractable. The photography of ultra-red rays a good way below the visible spectrum is, so far as I know, in the hands of Capt. Abney, who discovered how to do it. But others should now take it up and develop it. Celestial photography, with plates sensitive to obscure rays, might reveal a number of unsuspected and invisible semi cool worlds. The electric spark has lately been a favorite subject for photography, and much good work may be done by obtaining judicious photographs of lightning on fixed and on moving plates. A double-nozzled camera, with two plates, one fixed, the other spinning rapidly on an axis perpendicular to its plane (kept spinning at an approximately slow speed, say, clockwork), so that the same flash it depicted on both plates simultaneously, would give much valuable information. For some flashes a very moderate speed of rotation, or even a wiggling camera, suffices, but for others a speed of 30 revolutions a second gives an image apparently the same as if the plate were still. What is known as the Hall effect in various substances has not yet been exhaustively observed or measured. It has not even been observed as yet in insulators, though it ought, one would think, to be there; nor has its connection with the Faraday effect, the rotation of the plane of polarization of light by magnetism, been at all satisfactorily or finally made out; while its discrimination from, or assimilation to, certain known thermo-electric facts is at present hanging in suspense. Perhaps, however, these matters are rather too complex to be suitable for mention under present circumstances.

A simpler and more qualitative research is the effect of magnetism on a number of things. For instance, on living organisms. A person in a magnetic field is not known to feel anything. Reichenbach thought he had found people who were optically sensitive to a magnet, so that they could see whether an electro-magnet is excited or not. It may be so, but subsequent observation has not gone to confirm it. But, even if all persons are insensitive (by no means a likely conclusion without experimental proof), other animals may not be. Phosphorescent things—a glow-worm, or some of the luminous sea beasts of Dr. Herdman—may be fit subjects for experiment. How, again, does a gymnotus or electric eel behave in a powerful magnetic field?

I can imagine a fine field for a physicist to encamp on Puffin Island, under the auspices of the Biological Society, and bully some of the microscopic and other animals with electric and magnetic and optical appliances. Even if they declined to take any notice, the fact ought to be ascertained; but if any of them were properly sensitive, development of the fact might be surprising. Then, again, plants; sensitive and other muscular plants are well known to set up electric currents and to be under electric control; magnetism might be applied to plants also; and about their electric phenomena there is much more to work out. Heaps of experiments on plants and on germinating seeds could be made by an ingenious physical experimenter, and, though they might be more sluggish in their response than animals, some remarkable developments might ensue. A change of physical surroundings in the course of a few generations might bring about noteworthy changes of structure. Seeds growing under inverted circumstances as regards light have, I suppose, already been experimented on. I do not know. I am not familiar with the subject, and the biological suggestions I throw out are therefore vague. But this I feel, that so long as the origin of life is wrapped in mystery, experiments on the simplest form of protoplasm—subjecting it to a variety of kinds of circumstances,

electrical, magnetic, optical, thermal, mechanical, and chemical—may any day, though not perhaps for a few centuries yet, result in an astounding discovery, which will throw our present idea of evolution into the shade.

A number of experiments and observations can also be made on crystals and crystal formations by those who have suitable opportunities. The accidental formation of twin crystals, and the beautiful optical phenomena which develop themselves at the twinning surface, are matters of quite recent discovery, or, at least, of recent attention. So also is the perfectly astounding fact that a crystal, such as Iceland spar, for instance, can be mechanically twinned or pushed over into its perverted form by the pressure of a knife judiciously applied. Effects of magnetism on chemical action have now been discovered, and it is known that a piece of magnetized iron is less easily attacked by an acid than ordinary iron, provided, at least, the iron is pointed so that its lines of force are very diverging, or its field rapidly varying. But many other facts remain to be ascertained in connection with these subjects. The electrical properties of flame are only partially worked out, and their power of discharging static electrification has had fresh light thrown on it quite lately by some experiments of Worthington. The study of phosphorescent substances is yet in its infancy. Why should not a phosphorescent substance give out a really useful amount of light? Why is the process by which the glowworm maintains so brilliant a speck of illumination?

Many amateurs possess an induction coil, having, indeed, often made it themselves. Approximately the same number of amateurs do not know what to do with it when made. They use it to illuminate vacuum tubes, which they buy at a shop, nicely colored. Well, don't buy them, but make them, and omit the colors. Read the researches of Mr. Crookes, and other more recent investigations on the subject by Schuster, and Moulton, and Wiedemann and others, and you will find in the electrical phenomena of high vacuum an unlimited field for profitable experiment. More than this: A whole continent of practically unexplored territory has just been opened by the discovery of Hertz that electro-magnetic waves in air can be easily produced and detected. Some may know and some may not know of these brilliant investigations into the propagation of electro-magnetic waves. But any one with an induction coil, an empty room, and some bits of metal can repeat many of them. Any repetition of known experiments is the natural prelude to the discovery of new ones.

The Hertzian receiver is a microscopic spark gap. This serves, but it is by no means necessarily the best, as it is certainly not the most metrical method. Gregory has tried a kind of metallic thermometer with some success. In Germany, I hear, a kind of bolometer or wire resistance thermometer has been successfully used. Quite lately Fitzgerald writes me that a galvanometer in circuit with a simple wire makes these waves apparent. This will simplify their investigation very much. That is always the way. Once a thing has been done, hundreds of ways of doing it turn up. For instance, the telephone. The transmission of speech by electricity seemed a mighty achievement, and so it was; but now, almost anything will transmit speech—a flower pot full of cinders has been made to talk. The great electro-magnetic waves excited by any kind of electric discharge are now under easy control, and they can be reflected by mirrors, refracted by prisms, concentrated by lenses. They can be polarized and analyzed. Diffraction and interference effect can be detected in them. Everything optical has its counterpart in this new region, for they are to all intents and purposes light, as Clerk Maxwell predicted nearly a quarter of a century ago, from refined and abstract mathematical investigation.

The whole of this great field now lies open to the explorer, and only a few have entered it. Here and there a mathematician, here and there an experimentalist, is at work upon it, but there is plenty of room, and every fact is of interest. These electric waves have been obtained as long as 2,000 miles and as short as a foot; they can easily be lengthened, they cannot so easily be shortened. If shortened to the 10,000th of an inch they would affect the retina and be visible. At present they belong to the region of the infra-red. Whether they affect the human frame at all is unknown. Apparently they do not, but further experience may show that they do.

WESTERN capitalists are negotiating with the authorities of Yankton, Dakota, for the right to operate a gas works there. This place is on the left bank of the Missouri river at a point 61 miles west-northwest of Sioux City, and 140 miles north-northwest of Omaha. It is beautifully located on a level plateau, at elevation of 1,200 feet from sea level. The river is navigable for steamboats, and it is also reached by the Southern Dakota Railroad. Population, about 9,000.

Leisner's Apparatus for Manufacturing Gas.

On April 29th U. S. Letters Patent (No. 426,823) were granted to George Leisner, of Philadelphia, Pa., for an improved gas making apparatus, the rights for which were subsequently assigned to the United Gas Improvement Company, of the same city. The Leisner specification is as follows:

My invention relates to apparatus for generating water gas, and has for its object to provide a generator of improved construction whereby the gas may be driven off from the coal with which the generator is fed and saved more effectually and with better economical results than has heretofore been the case in apparatus with which I am familiar.

The novel features of my invention will be best understood as described in connection with the drawings in which they are illustrated, and in which Fig. 1 is an elevation in section of a water gas apparatus embodying my improvement; Fig. 2 is a section through the generator and the parts superimposed upon it on the line $x x$ of F. 1; and Fig. 3 is an enlarged view of the valve used to close the conduits $e e'$.

A is the generator, provided with the usual grate a to support the fuel, an air-blast conduit a' , leading into its lower part, a steam conduit a^2 , also leading into its lower part, a door a^3 at its bottom to per-

operative purposes the generation of gases in the retort and in the generator were totally independent of each other.

By referring again to the drawings, b^2 is a movable grate arranged, as shown, to extend across the retort b and afford a support for the coal inserted in it, and having a handle b^1 , by which it can be withdrawn in part or in whole, so as to let the fuel supported by it fall in part or altogether into the generator A .

b^3 is a valve extending across the retort b beneath the grate b^2 , and provided with a handle b^3 , by which it can be withdrawn in whole or in part at will. Its function is to close the communication between the generator and the retort. The use of the movable grate and valve enables me to entirely close the retort chamber b with respect to the generator when fuel gas is being generated therein, such gases passing through pipe C' into the chamber C , surrounding the retort, and escaping through the conduit D , while the gases generated from the coal in the retort b escape through the conduit E , and can be saved from and without admixture with fuel gas, while at the same time as soon as the generator begins to manufacture water gas by merely withdrawing the valve b^3 such water gas will pass up into the retort b , mingling with the gases driven off from the coal and passing with such gases through conduit E to such point of storage, use, or further treatment as may be de-

Fig. 1.

mit the exit of ash from time to time, man-holes a^4 conveniently arranged, and stoking-hole a^5 . Upon the top of the generator is supported the structure B , containing a substantially vertical retort b , situated immediately above and in free communication with the generator. This retort is provided at its top with an opening, closed by lid b^1 or in any convenient way, through which fuel can be introduced from time to time. A chamber C is also formed in the structure B , so as to surround the vertical retort b , and this chamber C is placed in communication with the generator in any convenient way, as by a conduit or pipe C' . A conduit D leads off from chamber C to a system of regenerative superheaters or fixing chambers (indicated in the drawings at K and N), and a conduit E also leads off from the retort chamber b .

All of the above-mentioned parts of the apparatus are substantially shown in various patents, publications, and structures with which I am familiar; but in all such older structures the fuel inserted in the vertical retort is supported by and forms a continuous body with the fuel in the generator, and no provision is made for passing water gas through the vertical retort, or for saving all of the gases driven off from the coal. I am aware, also, that coal has been fed through vertical retorts externally heated, with closed bottom and gas passages leading from them, and that such retorts have been arranged in convenient proximity to generators, so that the coke formed in them could be from time to time withdrawn and fed into the generator; but in such cases, also, no provision was made for passing water gas through the retort, and for all

sired. Preferably I provide a valve c' in the passage leading from the generator to the chamber C , so that during the generation of water gas the passage may be closed to compel all the gases to pass through the retort b , or partly closed, so that the greater part of the gas will pass through said retort chamber and a small portion into the chamber C . I prefer also to lead an air-blast pipe c , Fig. 1, into the chamber C , so that the gases passing into it may be ignited and combustion kept up around the retort b . Where it is desired to maintain combustion in the chamber C during the generation of water gas, as well as during the generation of fuel gas, I provide escape pipe d in conduit D , and a valve d^2 to close said conduit, so that the products of combustion can be led off through the passage or escape d . A valve d' should be inserted in the conduit d , so that it can be closed whenever the main conduit D is open.

My invention is intended for use in connection with the ordinary system of regenerative fixing chambers by which water gas, together with other rich carbonaceous gases or vapors, are converted into a fixed gas. When so used, the conduits D and E both lead into the fixing chambers, as shown in the drawings. The conduit E may lead directly into the fixing chambers, as is shown by the dotted continuation of said conduit, or it may lead into the conduit D , as is shown by the full lines. In this combination I provide a conduit $e e'$, leading from conduit E , and valves to control this passage and to control the conduit E on the farther side of this passage. As shown in the drawings, the pipe e leads into the bottom of box F , through the top of which the continuation e'

of the conduit, consisting of pipes $e e'$, also leads. A lever G is secured to the end of a shaft g , which passes through the wall of the box F , and has secured to it on the inside of the box an arm g^3 , holding a cup g' , the said cup arranged directly beneath the open end of the pipe e' . The lower part of box F is filled with tar or some material of like nature, so that when the lever G is thrown up and the cup g' down it will fill itself with tar, which, when the lever is pulled down and the cup pulled up, as shown in Fig. 3, will make a seal on the bottom of the pipe e' . On the outer end of the lever G a slot g^2 is formed, through which and a similar slot in a pivoted lever I a pin h , attached to a rod H , passes. The lever I is pivoted at i , and attached, as shown in Fig. 1, to a link j , extending from a sliding valve J , situated in the conduit E . The above described arrangement is such that the valve's conduit $e e'$ and conduit

Fig. 2.

E are simultaneously actuated in opposite directions—that is, so as to either open the conduit $e e'$ and close the conduit E , or to open the conduit E and close the conduit $e e'$.

The regenerative fixing chambers or superheaters (shown to the right of Fig. 1) are of the common character in water gas apparatus, and need not be particularly described. The gases pass from the generator into the top of the superheater K , where they mingle in the combustion chamber at the top thereof with air introduced through the gas passage k' , the burned gases passing down through the brickwork and out from the bottom of the chamber through passage L into a combustion chamber at the bottom of the superheater M , where more air is introduced through the gas pipe m' , and the burning gases pass upward through the brickwork and out at the passage m^2 , from which connection is made to any convenient stack which will carry off the products

Fig. 3.

of combustion. When the generator is sufficiently ignited and the superheater sufficiently hot, steam is passed into the bottom of the generator and the water gas resulting introduced into the superheaters in the same way as the fuel gas previously introduced. Air, however, is of course shut off from the superheaters, and in general, oil is introduced, as by pipe k^2 , to be vaporized and combined into a fixed gas with the water gas by the action of the superheaters, the gases being drawn off fin-

ally through m^2 and conveyed to a point of storage or use. The parts marked k^1 and m^1 in the drawings are manholes to permit convenient access to different parts of the superheaters.

My preferred mode of operating the improved apparatus is, after having properly charged the generator with fuel, to thrust the grate b^2 across the lower portion of the retort b and close the valve b^3 . I then charge a quantity of coal into the retort b and close the charging orifice at the top. The air blast is then or previously, if desired, turned on in the generator, and the fuel gases pass through the conduit C' , the valve c' of which is open, into the chamber C , into which chamber, also, air is introduced through the blast pipe c , so that combustion shall ensue around the retort b . The air introduced at this point, however, need be but small in quantity, as it is not desired to consume any large proportion of the gases in the chamber C , which, together with the retort b , can be heated to a considerable and essential degree even without combustion in chamber. The gases leave the chamber C through the conduit D , and are delivered by it into the regenerative chambers K and M , in which they are completely burned, in order to heat the chambers for subsequent operations. While this is going on the conduit consisting of the pipes $e e'$, leading from pipe E , is opened and the pipe E closed in advance thereof, as shown in Fig. 1, so that all gases distilled from the coal in the retort b pass through the pipes $e e'$, which convey them to a convenient receiver. (Not shown in the drawings.) This operation is continued until the fuel in the generator is thoroughly ignited and the superheating chambers heated to a high degree. The air blast is then shut off from the generator and steam introduced, the valve b^3 opened, the conduit $e e'$ closed, and the valve J in the conduit E opened. The water gas generated in generator A can then pass upward through the retort b , and out of said retort it passes, together with coal gases driven off from the coal, into conduit E , whence it is delivered, either directly or by means of a connection with conduit D , into the regenerative fixing chambers or superheaters, through which it passes and is finally delivered to a receiver (not shown), oil, if desired, being injected to enrich the gases. Preferably I also close the valve c' when making water gas, so that no gases will pass from the generator into the chamber C . If desired, however, the valve c' can be adjusted so that a small portion of the water gas will pass from the generator into chamber C , and, the air blast through c being continued, combustion will ensue, or, rather, be maintained, around the retort b . Where this is done it is necessary, in order to prevent admixture of products of combustion with the gases passing into the fixing chamber, to provide a take-off pipe d in conduit D , and a valve d^2 by which the conduit can be closed on the farther side of the take-off. A valve d' is of course provided in the take off pipe d , so that it can be closed when the valve d^2 is opened.

If desired, a portion of the water gas may be passed through the conduit C' , chamber C , and conduit D , while another portion is passing through the retort b , as already described. All that is necessary is then to cut off the air blast through c , so that no combustion will take place in chamber C .

The inventor makes the following claims for originality of design :

1. In a gas generating apparatus, a water gas generator A , in combination with a substantially vertical retort situated above it and opening freely therein, a feed opening at the top of the retort, a movable grate b^2 , arranged in the retort to sustain the coal, a valve b^3 , arranged in the retort to control the communication between it and the generator, a conduit leading from the retort, a chamber C , communicating with the generator and surrounding the retort, and a conduit leading from the chamber C .

2. In a gas generating apparatus, a water gas generator A , in combination with a substantially vertical retort situated above it and opening freely therein, a feed-opening at the top of the retort, a movable grate b^2 , arranged in the retort to sustain the coal, a valve b^3 , arranged in the retort to control the communication between it and the generator, a conduit leading from the retort, a chamber C , communicating with the generator and surrounding the retort, an air supply pipe c , leading into chamber C , and a conduit leading from the chamber C .

3. In a gas generating apparatus, a water gas generator A , in combination with a substantially vertical retort situated above it and opening freely therein, a feed-opening at the top of the retort, a movable grate b^2 , arranged in the retort to sustain the coal, a valve b^3 , arranged in the retort to control the communication between it and the generator, a conduit leading from the retort, a chamber C , communicating with the generator and surrounding the retort, a valve controlling the communication between chamber C and the generator, an air supply pipe c , leading into chamber C , and a conduit leading from the chamber C .

4. In a gas generating apparatus, the combination of a water gas generator A , a substantially vertical retort b , situated above the generator,

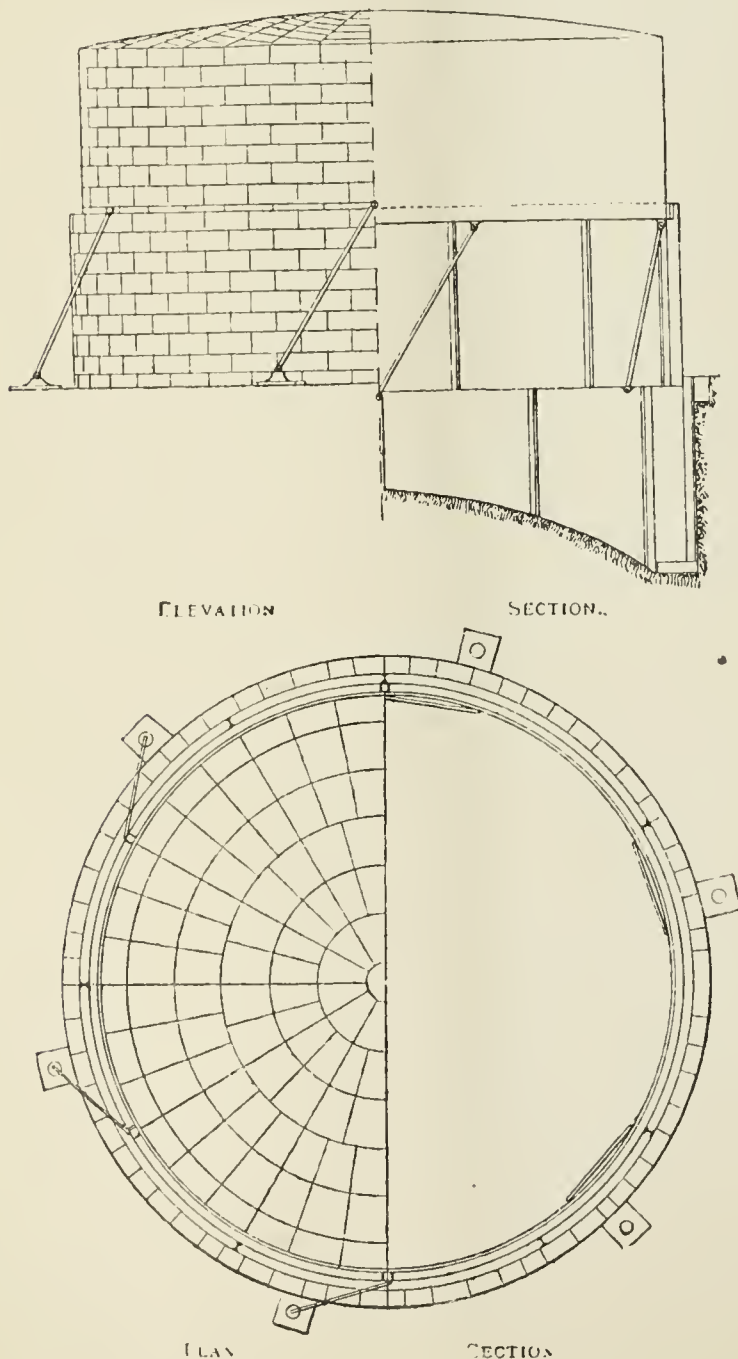

having a feed-opening at its top, and opening into the generator at its bottom, a movable grate b^2 to sustain the fuel in retort b , a valve b^3 , to regulate the communication between the generator and retort, a chamber C , surrounding the retort b and connected with generator A , a valve arranged to close and regulate the connection between the chamber C and generator A , a conduit D , leading from chamber C to regenerative fixing chambers, a conduit E , leading from retort b to said fixing chambers, a passage e , leading from conduit E , a valve controlling passage e , a valve controlling conduit E on the further side of passage e , and one or more regenerative fixing chambers connected to conduits D and E .

5. In a gas generating apparatus, the combination of a water gas generator A , a substantially vertical retort b , situated above the generator, having a feed opening at its top, and opening into the generator at its bottom, a movable grate b^2 , to sustain the fuel in retort b , a valve b^3 , to regulate the communication between the generator and retort, a chamber C , surrounding the retort b and connected with generator A , an air supply pipe c , leading into chamber C , a valve arranged to close and regulate the connection between the chamber C and generator A , a conduit D , leading from chamber C to regenerative fixing chambers, a conduit E , leading from retort b to said fixing chambers, a passage e , leading from conduit E , a valve controlling passage e , a valve controlling conduit E on the further side of passage e , and one or more regenerative fixing chambers connected to conduits D and E .

Terrace's Parallel Motion for Gasholder Guiding.

In returning to the subject of gasholder guiding the *London Journal* says:

In the *Journal* for Jan. 8 of last year an illustrated description was given of an arrangement devised by Mr. James B. Terrace, of Brechin, N. B., for guiding gasholders by means of sets of spur wheels keyed

upon spindles long enough to reach the distance at which the guide columns are ordinarily placed round the tank of a gasholder. Mr. Terrace now sends to us for publication a drawing representing a double-lift gasholder, 60 feet diameter (the inner lift 58 feet), each lift being 18 feet

deep, the working movement of which is controlled by means of a number of long connecting links situated at regular intervals round the tank, instead of the ordinary guide-framing. A model of the arrangement has, it is said, been made—2 feet in diameter, with each lift 8 inches deep—and is found to work very satisfactorily indeed.

One-half of the drawing is in section, showing the inner lift connecting links *inside* the holder. One end of each link works into a bearing fixed on the bottom curb of the inner lift, the other end working into a bearing fixed on the bottom curb of the outer lift of the gasholder. These links, six in number, control the action of the inner lift only; and when the holder is being filled one end of each link rises from the horizontal to an angle of 60° , and remains at this angle as long as the two lifts are cupped. The other part of the drawing is not in section, and shows the outer lift connecting links *outside* the holder. One end of these links works into bearings fixed on the bed plates anchored on the ground outside the stone coping of the tank. The other ends work into bearings fixed on the top curb of the outer lift. These links—also six in number—control the action of the outer lift; and when the holder is being filled one end of the links rises from the horizontal to an angle of 60° , when it is filled to its utmost capacity.

In addition to the ordinary working of the gasholder, the links cause a rotary or side-way motion to take place. All the bearings to which the links are connected, therefore, require to be on the double-joint or ball-joint principle. With this side-way motion of the holder, the bottom curb guide rollers could, however, be dispensed with, as the points of contact deviate in the circuitous path along the upright guides.

The controlling links may be placed otherwise than described above; and in the case of a three-lift holder, two tiers could control the three lifts—one set being used for the inner lift only, and the other set for the second and outer lift. The links for the latter two lifts would be connected to bearings fixed on the top curb of the second lift, the other ends working into bearings fixed on bed plates or columns anchored on the ground outside the stone coping of the tank.

Mr. Terrace claims that, when these controlling links are placed outside the holder, they not only keep it in proper equilibrium during its working movements, but act as strong supports. While some of them are in tension, the others are in compression; and so they relieve the bottom curb of the holder of a large amount of the strain which, in the case of some recent inventions, it is called upon to bear.

Notes on Some Coals in Western Canada.

[Abstracted from a paper read by Mr. Wm. Hamilton, F.G.S., at the Ottawa meeting of the Am. Inst. M. E.]

With the exception of the Vancouver Island coal, all the Western coal fields owe their present development to the completion, in the autumn of 1886, of the Canadian Pacific Railroad. While it could not be expected that a very great deal could have been accomplished in three years, enough has been done to pretty thoroughly establish the coal bearing areas and their correspondence with those which have been developed to the south of the boundary along the lines of the transatlantic railroads in the United States.

This summer I visited some of the important developments in the coal areas of Washington Territory, largely with the object of being better able to appreciate the corresponding coal bearing areas in British Columbia to the north.

In Western Canada, coal bearing rocks have been found in three zones.

1. In the plains to the east of the Rocky Mountains and in the eastern flanking ranges, the coal occurs in the Cretaceous formation (including the Laramie).

2. In the interior plateau of British Columbia, the coal is found in the Tertiary formation.

3. On the coast of British Columbia, Cretaceous and Tertiary rocks are found carrying coal, and on the Island of Vancouver the well-known Nanaimo coal has been worked for years in the first-named formation.

In all of these zones the coals vary from lignites up to higher grades, the factor determining quality being the amount of pressure to which they have been subjected. The intensity of this pressure is generally shown by the disturbance which the coals exhibit, and, in many cases, is almost directly in proportion to the distance of the deposits from mountain ranges. This seems to be also the opinion expressed by Mr. Bailey Willis in connection with his census report on the coals of Washington. It has been elsewhere stated that super-imposed strata has been thought to have been an important factor in these changes; but my observations for several years in all these areas lead me to the conclusion that it is

pressure alone from distortion and upheaval that has altered these Western coals into the many varying grades in which they are found to exist.

In the first zone an enormous amount of coal occurs in the territory between the western borders of Manitoba and the Rocky Mountains. I shall merely note some of the seams, which are reached by rail, as examples of the character of the coals in the area mentioned. In the plains they are all lignites, changing to a high grade lignite at the Galt mines (which are reached from the Canadian Pacific Railroad by a branch railroad 110 miles long), into a bituminous coking coal at the Bow River mines (where a 7-foot seam cuts across the main line of the Canadian Pacific Railroad), and finally the maximum result of the metamorphic influence is reached in the Cascade Valley, where the pressure of the mountains, on both sides of the Cretaceous trough, has altered the coal which it contains into an anthracite.

The following analyses, passing from east to west, convey some idea of the types of these coals :

TABLE A.
Eastern Zone.

Approximate distance from mountains, miles	234	128	36	28	0
a.—Medicine Hat, lignite (Geological Survey), fair coking.					
b.—Crawfoot, “ “ “ “					
c.—Galt, “ “ “ “					
d.—Bow River mines, bituminous, “ “					
e.—Cascade Valley, anthracite, “ “					

In the interior plateau of British Columbia lignite and coal have as yet been found in only a few places. The following are the only occurrences yet discovered worthy of notice :

At Princeton or Allison's some 20 feet of alternating lignite and shale seams occur, lying at a gentle dip. The lignite can be obtained of a workable thickness, but the greater part of the bed is too much mixed with shale. The character of the lignite, as indicated by the analysis, is that of an inferior coal.

The lignite found at Marble Canyon, Hat Creek, is of a better description, as shown by the analysis. It is said to be of very considerable thickness. I did not think the quality sufficiently good to justify a visit to the place, which has been described in the Reports of the Geological Survey.

At Kamloops, close to the Canadian Pacific Railroad, coal of a very fair bituminous character has been found; but as yet, seams of only about a foot in thickness have been opened up. The vicinity is being tested by a shaft.

In the Nicola Valley, some 40 miles from the railroad, a seam of bituminous coal, about 5 feet in thickness, has been exposed. This coal has been subjected to a greater amount of metamorphic influence than any yet discovered in this zone. It lies adjacent to a mountain, which is probably a result of the disturbance that has altered it into a good coking bituminous coal.

TABLE B.
Interior Zone.

	a.	b.	c.	d.
Water....	15.75	8.60	6.26	36.065

Coke.....	None.	None.	Fair.	Very good.
a.—Allison's lignite.				
b.—Hat Creek lignite (Geological Survey).				
c.—Kamloops, bituminous.				
d.—Nicola, bituminous (Geological Survey).				

On the Pacific coast zone, on the main shore, there has as yet been located a very small amount of coal and lignite, in the districts which correspond to the large areas developed along the Puget Sound to the south of the international boundary. And, as has been ascertained to the south of the line, the coal which has been found near the coast is merely a lignite, but that which occurs inland, near the Cascade Range, has

been altered into a bituminous coal. A sample of the latter type is found in a 2-foot, somewhat dirty bed of coal, which has been opened on the slope of Sumas Mountain. Still further inland, the cretaceous conglomerates occur near Chillawack, but all the coal which they have so far been found to contain consists of a few small masses forming part of the conglomerate, and some very thin strings of a coaly matter. The analysis from the above-mentioned Sumas Mountain seam is as follows:

Analysis of Sumas Mountain Coal.

Water.....	4.62
Volatile combustible matter.....	35.68
Fixed carbon.....	42.00
Ash.....	17.70
Total.....	100.00
Coke.....	Fair.

On Testing Materials.

Mr. Paul Kreutpointer, of Altoona, Pa., writing in a contemporary, considers that the financial benefits of testing materials manifest themselves in the decrease of supplies required for a given purpose. But it performs also an educational mission of considerable magnitude by forcing the consumer as well as the producers to acquire and exercise thought, skill, knowledge, care and attention. Testing of materials has become a special branch of science and a profession on account of its importance as an economic factor in the industrial world. No engineer can claim thoroughness in his profession who does not possess at least a fair knowledge of the properties of metals and the principles of testing them. Engineers have frequent occasion, in the absence of time or proper appliances, or both, to make what may be called emergency or field tests. Knowledge of the structure of metals and the effects of heat and work on the same are prime requisites to success in testing, handling and working metals. A designer may be a genius in mathematics, yet his work will be deficient in value at times if a text book is the only source of his metallurgical wisdom.

Quality of Metal.—Since materials like iron and steel are apt to vary in quality chemically and physically, testing serves two objects; it must be descriptive as well as comparative. By descriptive testing is meant to obtain, by a simple tensile, bending transverse or other test, a brief description of those qualities of a metal which are supposed to indicate its fitness for a given purpose in everyday service. For instance, the result of a tensile test made on a bar of iron taken at random from a lot of, say, two tons, will give us a sufficient description of the qualities of this particular lot of iron to enable us to consider that iron fit for use in car work. We are not the least concerned in this case how this iron compares in quality with link, stay-bolt or chain iron. As soon as we push our inquiry to the point, how does this metal compare with some similar metal as to quality or usefulness, then testing becomes comparative in intent and purpose? Comparative testing is essentially the basis of calculations of safe stresses and the designing of structures.

What is Quality?—The work of investigating and testing materials would be simple if conclusions could be drawn from one quality as to all the other qualities and properties of a metal. Unfortunately this cannot be done, as our present knowledge of the properties of metals is still too limited in that direction. Hence, we are confined in our investigations to the slow and often expensive work of comparative testing whenever the question as to the better quality of a metal is raised. The qualities and properties of metals are determined by their chemical composition and the manner and extent of mechanical treatment.

The farther a metal has been removed from its original raw state, the more numerous the manipulations it underwent through heating and cooling, hammering and rolling, the more complex has the nature of this metal become. To ascertain the respective qualities and properties thus imparted or acquired, chemical analysis or physical testing is resorted to. The latter may include tensile torsion, bending, transverse, crushing, shearing, drop hammer, nicking or fatigue test, including also etching and microscopic examination. Before making use, however, of any or all of these means to ascertain the quality and properties of a given material, it is well to determine beforehand whether the result obtained shall be merely for the purpose of general information, or whether it is to be applied to any definite purpose, and thus the work done be of relative value. The quality or quantities so obtained are the relative qualities of materials, since those qualities bear a close relation to the work we expect the metal to perform. On the contrary, if the object of testing is merely to gain general information, without its application to useful work, we ascertain the absolute quality of a metal and nothing more. In other words, we learn that a given piece of metal

can carry a load of so many thousand pounds or stretches so many per cent. in a given length before rupture takes place. This then is the absolute quality of a material.

How to Test and What to Test.—Next in importance to the understanding of the import of testing is the knowledge how to test and what to test. To inquire into the tensile strength of metal when we ought to know its torsional resistance or transverse deflection under a given load is obviously erroneous, and if the result is applied to practical purpose, may result in disaster. Or again, an elaborate tensile test is made where a cheap and quick bending test would answer all the purposes of a test. In this or similar cases no harm may result, but testing thus becomes a very expensive luxury. An example of the misapplication of the principle of testing as a guide to quality in the absolute groove or marine test section still prescribed by the Treasury Department as a measure of quality for boiler steel on river steamers. Only thorough knowledge of the properties of metals and of the effects of the form of test section on the result will prevent a misapplication of the economic principle of testing or the retention of antiquated usages and specifications. Wherever testing is carried on as a routine work on a large scale there will necessarily also be done a considerable amount of special and comparative testing. Under such circumstances the question of what to test assumes considerable importance on account of the cost of preparation of test-pieces, help, wear and tear of machinery and possible delays to the service. It would be a mistake to test, therefore, material which may be subject to no strain, perhaps has to carry its own weight only, and might even serve its purpose better if the material did not stand specification, because it would then be too hard. Zeal or desire to appear scientific, want of confidence in the ability or judgment of subordinates or a natural tendency to express everything in mathematical formulas and figures will often be the cause of what might be called "surplus" testing. In all such cases of unnecessary testing the result of the work done is equal to ascertaining the absolute quality of a material—a result which, as explained before, has no practical value.

Value of Testing.—In dealing with so complicated a subject as metallurgy and the products of metallurgical processes, it is essential to success that we look at the question of the value of testing not only in its scientific aspect, but also consider it in the light of purely a business transaction. The aim must be to make money through the medium of testing by saving waste with the least expenditure of money. The employment of cheap and incompetent labor or antiquated, unreliable machinery and appliances, will not do it, however. To try and apply a hard and fast rule, or, in other words, fit the conditions of the service and the qualities of materials to the specifications, is equally erroneous. Like the merchant who watches the quotations of the market, so the one in charge of specifications must watch the changes in methods of producing metals, in a general way at least. Division of labor, for instance, and specialization of product are as powerful factors to success nowadays in a steel mill as in a machine shop. As a natural consequence the product of a mill for a given grade, be that grade high or low, is remarkably uniform during long periods of time. Division of labor makes the furnaceman as much an adept in selecting and handling raw materials as the machinist in turning or planing certain shapes. On that account a manager hesitates to change men from one furnace to another. This fact can be made use of to reduce the cost of testing since it permits the reduction of the number of test pieces. If six test pieces represent the qualities of a heat or a day's work as well as five times that number it is certainly money in one's pocket not to test more than six pieces. There are other reasons besides which strengthen the position here taken. Some of the highest authorities on testing have long since argued that, as the elastic limit of material is its true measure of value in regard to its ability to do useful work, therefore the testing of metals to their ultimate strength and elongation is of no particular value, because no engineer ever expects to see the structures break which he designed. The only merit of the present method of testing up to ultimate strength and elongation is the simplicity of performing such tests.

On the other hand, the argument is advanced, and with good reason, that the amount of "commercial" testing to be done daily in the test department of a large concern, be it a steel mill, railroad, shipyard or bridge works, prevents the introduction of the method of taking the elastic limit as a routine work. A way out of this difficulty might be found in the fact alluded to above, that specialization tends to uniformity of product. Sometimes it also tends to deterioration of quality of product, but with this question we are not now concerned, except to say that in this case also the above fact holds good, for it has been found that material deteriorated in quality is equally uniformly bad. Consequently it would be quite safe to dispense with a large percentage of

"commercial" testing in favor of taking the elastic limit as a routine work. The time gained by dispensing with three-fourths of the work now done could thus be utilized to great advantage. Moreover, if the elastic limit were provided for us in specifications it would often be found that metals from different makers, which test alike as far as ultimate strength and elongation are concerned, would differ in their elastic limit. In other words, one metal would be found less fit to do useful work and therefore be inferior in quality, which inferiority, however, was not revealed with the prevailing method of testing. There can be no doubt of the importance and value of this additional advantage gained by the suggested change in method. Thus it will be seen that routine testing would become at once descriptive and comparative; descriptive as to quality for every day use and comparative as to quality of materials from different makers or different classes of materials.

What has been said will indicate the value and usefulness of systematic and scientific testing and the knowledge of the qualities and properties of metals. Indeed, the diffusion of such knowledge should receive very much attention in colleges, trade and industrial schools and shops. Alexander Holley, whose correctness of views and knowledge on metallurgical subjects no one questioned, used to say that our factor of safety was a factor of ignorance.

Professor Ledebur expresses the same sentiment when he says, in one of his recent works: "The question whether every one who makes use of iron (and steel) for his purposes possesses also the requisite knowledge of its qualities and properties must still be answered in the negative. This may seem paradox in the face of the fact that metals have been so extensively used for a thousand years. The reason, however, is that, first, changes in our industries have taken place during the last 30 years which necessitated the production of certain kinds of metals which were entirely unknown before. Second, because iron (and steel) is now used for many purposes where formerly only wood or stone was used; and, third, because only quite recently science has undertaken a thorough study of the mechanical properties of metals and the raw materials of which they are made."

Of the correctness of these statements there is ample evidence. The time-honored nursery tale of the recrystallization of iron under shocks and vibrations is still rehashed with evident satisfaction as a bit of traditional unscientific knowledge. Some even assert that steel also is possessed of this wonderful property of crystallizing while in a cold and solid state.

The penalty for the want of this indispensable, thorough knowledge of the chemical and physical properties of metals in this age of iron and steel, and the apparent indifference to acquire or diffuse such knowledge, is a heavy tax on our industries and the community at large, in the shape of wanton waste of our resources through excessive wear and tear of materials and their improper treatment. Since metals form the basis of our national industries and prosperity, we cannot afford with impunity to neglect the study of their properties, practically as well as scientifically.

The Construction of Gasholder Tanks.

The *London Journal* asserts that while a marked accession of interest has been imparted to the subject of gasholder design by recent suggested reforms of the established ideas of engineers relating to the conditions of gasholder stability, it is to be noticed that the construction of tanks has not been discussed with a view to any alteration of method for several years past. True, Mr. V. Wyatt not long ago offered a suggestion with regard to the building of gasholder tank walls in sections instead of in vertically-placed rings, as the common practice is, and claimed some economy for the method; but there is no sign of his plan being adopted anywhere. The exception in favor of Mr. Wyatt's as yet abortive suggestion only goes to prove the force of the remark that for many years—ever since, in fact, concrete was successfully taken into the service for tank building—nothing has been attempted by way of fundamentally improving, cheapening, or expediting the construction of gasholder tanks. The position of the gas engineer now contemplating the addition of another holder to his storage room therefore remains as it has been any time for the last 20 years. The first thing that occupies his thoughts is the tank—where it is to go, and of what it is to be made. In connection with all but the smallest works the tank is the care of one season and the holder of the next; and in some very large establishments the ground must be broken three and even four seasons before the prospective holder will be ready for work. Few engineers are so favorably circumstanced that the questions arising out of the situation and construction of a tank give no trouble. In the majority of instances the need for a tank brings the engineer face to face with an aggravating

array of contrary conditions. He may have settled in his mind for some years the site, dimensions and construction of his next tank, only to discover at the instant of taking the work definitely in hand some insuperable obstacle to the realization of his ideal. He may have reluctantly to confess that he wants an altogether bigger holder than he had vaguely promised himself; or experiences of a disturbing kind may have upset his half-formed plans. If he is a conscientious man, he desires to obtain the largest accommodation for his outlay; and perhaps he has little knowledge of any but local customs in building. Locality largely helps to settle the character of the work; but with all regard to this consideration, it remains true that the skill of the engineer is the most important factor in determining the cost.

Some men who undertake the designing of work of this order have very little notion of comparing cost with result; hence we see examples of tanks of equal capacities constructed for widely different sums in similar situations. One engineer thinks of nothing but making what he calls "a good job," and is utterly oblivious of the blame attached to the designer who wastes material. Another will have brickwork in a stone country, or *vice versa*; and will carry clay for miles, because he is afraid of cement rendering at half the cost of puddle. Another man is so nervous of water that he buys a costly wrought iron tank, merely because the last holder in the same place was so provided; and all the time cheap fuel and powerful pumps would enable him to get down a masonry tank at considerably less expense. There is nothing that tests the knowledge and judgment of a gas engineer like the making of a large tank in a given place. To do the work satisfactorily he needs to know how all the tanks in the neighborhood were built, and what they cost. He must be equally familiar with examples of the cheapest and dearest tanks in the country, in order to decide what of the former he may follow or even improve upon, and what of the latter can be avoided.

"Penny wise and pound foolish" ways must both be known and guarded against. The extravagance of material which is not conducive to strength, because lavished in the wrong place, is as abhorrent to the true engineer as weakness where substance of material is required at any cost. All possible materials and methods of construction must be weighed and compared, and the great question of "to pump, or not to pump," intelligently solved. It is hardly to be wondered at that so many tanks up and down the country fail, or when good, cost very much more than they ought, seeing the number of factors that go to the satisfactory selection of a design, to say nothing of the after troubles that may, and very often do, arise in connection with the nature of the subsoil or the character of the contractor. It seems a hard condition to lay down, that no engineer is justified in breaking ground for a tank unless he is humanly certain that his plan of construction is the best and most economical that could be arrived at in view of all the circumstances, and that in the event of unforeseen difficulties arising with the ground or the contractor he could take hold of the job and finish it for his employers. Yet short of this competence, there is no safety. In tank construction, above all enterprises, it is necessary to be prepared for the worst; so that unless a gas manager feels honestly capable of standing the test here laid down, he had far better confine his cares to the ordinary duties of his office and advise his directors or committee to put the extra work in the hands of a consultant.

The question may well be asked whether the conditions of tank construction, and more particularly for large works of the kind, have been altered of late by the introduction of mechanical improvements in excavating, building, etc. The sinking of foundations for great modern works, such as the Forth Bridge, the Eiffel Tower, and less notorious structures has brought out a number of devices unknown to the last generation of engineers, some of which are undoubtedly available for gasholder tank construction. One reads of and sees appliances for sinking shafts vertically and for cutting tunnels horizontally; and it would be gratifying if the excavation of ground for tanks could be effected by more expeditious and cheaper means than by the navvy and his timberings. Probably something could be done by way of pneumatic or mechanical sinking in the case of metallic tanks of large size; but no suggestion has been offered for reducing the labor of excavating the trench for a brickwork or concrete circular wall. Hoists and steam trollies for removing the soil, mechanical puddlers and concrete mixers, stone breakers, rock drills, and a variety of appliances of a like supplementary character will reduce the cost of digging out and walling a gasholder tank, as of a dock or railway cutting; but there is nothing specially to aid the tank constructor. The indispensable navvy is still the great agent in this class of work.

The capabilities of cement concrete as a material for the construction of gasholder tank walls are gaining acceptance every day, although not by any means so easily as might be supposed by those who have long

learnt its value. Puddling a tank to make it water-tight is so immemorial a device, however, that were it a less admirable one than it really is in suitable localities, it would long persist in spite of modern innovations. Far be it from any engineer to speak disrespectfully of puddle where it can be had as cheap as anything else; for a good puddled tank will remain sound until the end of time. Cases have actually been heard of where cement renderings, and even worse—cement sandwiched between inner and outer brick walls—have been used in tanks dug in solid clay that would have been as tight as a bottle almost without any puddling; but only the richest gas companies can afford to support the national manufactures in this lavish fashion. It is exceptional, however, for good clay to be met with throughout the whole depth of a large tank excavation; and where there is any doubt about the puddle, cement is fortunately a ready substitute. A concrete tank can be made out of almost any kind of "hard core;" and as it can be backed up against the solid earth of the cutting—must, indeed, be so built—there is a saving of excavation attendant upon its use.

The necessary thickness of a concrete tank wall is not to be hastily settled; but it is probable that the thickness may be reduced in a remarkable degree if plenty of iron is built into the wall. This latter is a most important—indeed it is the most important—element in the making of a staunch concrete tank wall. Stout bars of flat iron, curved to the radius for which they are required, and with their ends simply hooked together to form complete rings, laid on edge in the thickness of the wall, are the great safeguard for the structure. It may be said to be a point for consideration whether the weight of iron or of concrete shall preponderate in any particular example; but if this way of putting the question is regarded as open to the charge of exaggeration, it is better to incur this reproach than to run the risk of confusion of ideas between the weight of iron bars desirable to reinforce a slight concrete wall and the thin iron hoops commonly used to bond brickwork. Experiments made in the small way in forming concrete tanks for a variety of manufacturing purposes, have demonstrated the advantage of this mixed iron and concrete construction when the iron has been used more liberally and the concrete kept lighter than has ever been attempted for gasholder tanks. The fact that the expansion or contraction of iron for changes of temperature is practically the same as that of cement concrete removes the fear of fractures from this cause even in regard to structures of the combined material subjected to greater variations of temperature than are met with in gasholder tanks.

The modification of the guide-framing of gasholders, from heavy cast iron columns, concentrating their weight upon even heavier piers forming part of the tank wall, to the lighter standards required for the lattice framing lately in vogue, is a great relief to the tank builder. The idea was held that the piers helped the wall; but this service could only have been performed against the bursting pressure of the water, and not against the crushing force of the earth when the tank was empty, which was the greater danger. As against this problematical assistance, the piers (by unequal settlements) frequently pulled the tank walls out of the perpendicular, giving serious trouble to the gasholder maker. Now that guide columns are spoken of as likely to be dispensed with altogether, tanks should be easier as well as cheaper to make. In concluding this brief review of the conditions of modern gasholder tank construction, it should be remarked that several large examples of this class of work will be commenced during the present season in different parts of the country, full particulars of the most important of which will be given in the *Journal* in due time. From these it will appear whether any new procedure has been introduced into this branch of engineering since the latest designs already published were carried out.

Coal Fields of the State of Washington.

By W. J. WOOD, C. E.

The coal fields of the State of Washington, or, I might say more correctly, the coal measures of the Puget Sound basin, consist of alternating beds of sandstones and shales, interstratified with many beds of carbonaceous shales and coal, showing that the period or age is of tertiary formation.

It is found that they lie in a wide trough between the Cascade and Olympic ranges, and east of the Cascade mountains are found also extensive coal basins of older formations. The lignites of this country, however, are found in the central part of the trough lying west of the Cascade mountains and north of Green river, and stratigraphically in the upper series, while south of the above mentioned places and lower down in the measures will be found the true coals, or those resembling them. It is the prevailing theory that the tertiary rocks rest uncon-

ormably on the cretaceous—that is to say, that they were separated from each other by a lapse of time, during which the folding of the older coals and elevation of the mountains took place, and that probably after the development of the latter formations there was a general submergence, depositing the tertiary strata, which follows the cretaceous, and I have found in my examinations hints of the latter formations in various positions. But it is not improbable that in some places there may be a more or less complete strata of passage beds between the cretaceous and tertiary, as we find by comparison on the eastern slope of the Rocky mountains, where I observed hints of it three years ago in Colorado, Wyoming and Montana coal fields. I might add that it is quite possible that there may be two unconformable series of tertiary rocks. However, much of the disturbed strata observed by volcanic flues, recent drifts and a dense forest is not so materially affected or altered by geological changes as one might suppose, while undoubtedly many changes and faults have taken place which, as a matter of course, is a natural consequence in a volcanic and mountainous country. But, on the other hand, we find it adds greater advantage for mining purposes, as also in qualities, to find the measures more or less influenced by geological manœuvres, making them practically available for commercial value and rendering the same easy to mine, while, at the same time, we also find the measures in which the veins are described tilted about suitably in various degrees of angles, from 20° to 85°, as seen in the Wilkinson, Green river and Raging river coal fields, and east of the mountains, so as not to interfere with the working of the coal beds, providing proper mining methods are used. I have seen many mines where a suggestion would result in the mining of the coal in better shape for marketable use. The region over which this deposition occurred has since been the scene of mountain making and upheavals of stupendous volcanic eruptions and enormous erosions. Thus we see that the diversities and changes in coal measures which have occurred in the form of anticlinal axis, etc., are preferable in schemes of the working mines to the ordinary flat-vein coal fields, as natural ventilation can be had. The lifting of coal, also water, can all be done at a small cost, if the field to be operated is studied in advance.

Another feature which is to be added to the Washington coal fields, and one which is important, is the timber resources, which exist in vast quantities and in places very heavy, and are composed of fir, cedar, hemlock, spruce and maple. The same can be used for timbering in mines, where large sticks are required for props, etc. The timber resources in this State invariably accompany the coal measures, the latter being without exception overlaid with good standing timber, while in many other States the contrary is the rule, as in the Montana and Wyoming coal fields, where the timber is very light and sparse.

The definition of the boundaries and extent of the Washington coal fields, although a great many areas have been given, is correspondingly difficult, and in some locations and directions is an impossible task, although a description of the boundaries and approximate area will not be amiss, and will be near enough for exactness. The coal fields or the carboniferous area extend from beyond the British boundary south almost to the Columbia river, and from the Pacific ocean eastward to the foot hills of the Cascade ranges, and east of the Cascade ranges, beginning at the foot hills, 25 miles to a point or line running north and south parallel with the ranges, varying from 800 to 5,000 ft. in altitude above the sea level, but buried, on the one hand, beneath recent gravel beds and overflowed, on the other, by eruptive masses; within the boundaries of the above described lines of 8,000,000 to 10,000,000 acres of mineral lands there are probably from 600 to 700 square miles of coal lands, of which a slight portion only is yet developed. The coal ranges in quality from a semi-anthracite up through the other qualities of coals, such as bituminous blacksmithing, lignites, gas and coking coal, and is in inexhaustible quantities. The best sections are those of the Wilkinson and Green river fields, where large amounts are shipped yearly, as also from the Franklin mines, Roslyn and Cle-Elum coal fields and a great number of other successful operating mines which could be mentioned, some of them turning out from 50,000 to 200,000 tons annually. There are over 20 mines in operation, with the prospect of the opening of three new coal fields this year.

While there are many varieties and qualities of coal, there are also many different analyses, but an analysis of one is approximately that of all. In this case it is a bituminous coal having upward of 59 per cent. of fixed carbon and, in some cases, as high as 66 per cent.; volatile matter, 28 per cent.; ash, less than 5 per cent.; sulphur, none. With the lignite we have excellent grades and qualities, which surpass the lignite seen in many other sections of the country. Where I have observed, the quality and grade of the lignites in these sections is probably due to action of a volcanic nature influencing the character of

the coal, thus producing a hard, brilliant coal of moderate heating power. It finds a ready market in all cases where the demand for cleanliness and cheerfulness overrules the economy of the greater heating power of the more highly bituminous coal.

On the semi-anthracite of the Natchez and Cowlitz Pass coal fields extensive measures and croppings of large veins of coal have been discovered, the strike and pitch of which extend for several miles, forming anti and monoclinax axes in basins of unknown area, and showing good analysis of the strongest indication for the best uses and purposes of coke making. This section of the country lies dormant in one of the most secluded and remote parts of the mountains. A railroad has been talked of to open up these fields of coal, as it is deemed desirable to tap these fields, owing to the coking and bituminous qualities thus recommended. The coal in this region is probably the result of volcanic rocks running in contact with the coal measures, as faults and as intrusive dikes. They have modified the character of the coal from its original state by pressure and heat, and the influence of a superficial flow would in both these respects be less than that of molten rock before extrusion. Thus the beds of coal have been altered to semi-anthracite of a brilliant luster and an anthracite fracture, and in some places the change is sufficient to produce a bituminous or coking coal.

Here we have reviewed the several kinds of coal, qualities and probable area. In conclusion, I would add that, while at present the Washington coal is generally used for steam and domestic purposes, the general quality of other coals so far discovered in this State is found to be adapted more particularly for making gas and cooking purposes. In either case the coal is very desirable and valuable.

Preservation of Wood by Chemical Means.

Probably the best preserved wood in the world which has been used by man is that found in ancient Egyptian temples at least 4,000 years old. The wood appears to be tamarisk or chittin-wood, and is found as dowel-pins connecting stone work. In removing the old London Bridge, in 1829, piles driven 800 years before were found in good condition. Most of the wooden parts of the roof of Westminster Hall were in good preservation after an equally long period. But if wood may be thus long preserved by accidents of nature, surely chemistry, whose resources are nearly as wide as those of nature herself, can reproduce the accidental conditions, if they are thoroughly understood. It would be difficult to mention any cheap chemical agent which has not, at some time, been proposed as a wood preservative. No less than 57 patents have been taken out in England on various methods of timber preservation. Of these, however, it is well to remark that many were patents on minor detail of the same processes, and also that most of the methods were impracticable.

A solution of corrosive sublimate was used in France early in the 18th century for impregnating wood for protection against insects and decay. It was tried by the Dutch Government in 1730 for protecting its ships against the teredo worm. Owing to the solubility of the sublimate in water, especially in sea water, the process was a failure for wet situations. Mr. J. H. Kyan obtained a patent in England in 1832 for a method employing a solution of one part corrosive sublimate in 50 parts water, and for a long time kyanising was quite popular. It has met with considerable success for timber to be placed in comparatively dry situations. The disadvantages of corrosive sublimate are its inefficiency on account of solubility in water, and its poisonous effect on workmen handling lumber impregnated with it. It is also very expensive, and therefore not practical in many instances.

Mr. J. J. Lloyd Margary in 1837 introduced and patented in England the substitution of copper sulphate (blue stone) for corrosive sublimate. It had the advantage of cheapness, and was regarded as one of the most successful of all metallic salts as an antiseptic for timber. This method is still used in France. The objection of solubility applies here also. Mr. Chas. Payne sought to avoid this by first impregnating the timber with iron sulphate, and then with some salt like calcium chloride or sodium carbonate, which reacting with the iron sulphate would give an insoluble precipitate within the cells of the wood. The process is of historical interest only, as it was an utter failure, probably by reaction taking place before the second solution had penetrated the wood, thus preventing its own entrance any deeper, and the resulting timber being protected only quite near its surface. Dr. Boucherie, in 1837, in France, proposed zinc chloride, which is a powerful antiseptic, but extremely soluble in water. The process is known as burnettising, since it was introduced in England by Sir Wm. Burnett. For dry situations, owing to its cheapness and efficiency, it is more largely used than any of the foregoing methods—principally in Holland, Germany and this country.

The way the metallic salts effect the desired end is by forming a chemical compound with the fermentable constituents of the wood—that is, by coagulating the albumen, etc., or, according to the more recent theory of putrefaction, their preservative powers depend on their being poisonous to the bacteria, thus acting as germicides. As early as 1756 attempts were made both in England and America to impregnate woods with vegetable tars or portions of such tars. Coal tar was probably first proposed by Franz Moll, who took out a patent in 1836. He recommended the use of oils both lighter and heavier than water. This was never carried out, as it was obviously wasteful to inject the lighter oils which would soon evaporate.

Various modifications have been continuously made from time to time—mainly in the composition of the creosote used and in the machinery for impregnation. Of course, every creosoting company has its own particularities as regards details, but in general the timber is placed in iron cylinders, sufficient melted creosote added to cover the timber, a partial vacuum produced by an air pump, the whole kept at a temperature of about 110 to 120° F. for several hours, when the air pump is stopped and the pressure pump put on till a pressure of 6 to 16 atmospheres is made in the cylinders, the heat still continuing, and the process being completed in from 12 to 48 hours, depending on the size of the timber. The advantage of the vacuum at beginning of process lies in that water and all liquids boil at a lower temperature under decreased pressure, and consequently the little moisture in the wood is evaporated at a temperature too low to injure the wood. The timber being thus more thoroughly dried, the tar enters more readily and penetrates deeper.

Another quite common plan is merely boiling the wood in coal tar tanks. This is not so good, since nothing like the 10 or 15 pounds of tar per cubic foot forced into the wood under pressure can be obtained by the open tank process. Still another method—and a poor one, too—is painting the wood with boiling tar. To ensure perfect preservation the proper kind of tar should be disseminated all through the wood. As to what is the proper kind of tar, authorities differ, some favoring the lighter tar oils, since these contain a higher proportion of tar acids—carbolic, cresylic, etc.—which they claim prevent decay by killing the germs of putrescence, or by coagulating the albumen, etc., of the wood. Others say that it cannot be these acids which effect the preservation of the wood, since they are volatile and soluble in water, and therefore do not remain in the wood, but that the wood is preserved by some constituent of the heavier oils. This last view seems to be the correct one, since actual experiment has proven the heavy oils equally as good, if not better, than the lighter oils containing 10 or 12 per cent. of the tar acids. The best authorities now believe the active principle in creosote wood preservation to be acridine—found in the heavier oils only. Now, acridine is a deadly germicide, and it coagulates the albumen. The oily body of the tar prevents the entrance of germs and of moisture into the interior of the wood, and this must play no unimportant part in the success of the creosote method.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

GAS was turned on to the mains of the Hamilton, Ohio, municipal gas works on the evening of the third inst.

WE can also say that Mr. Jas. R. Smedberg, under whose supervision the Hamilton works remained from their inception, has been appointed Superintendent of the plant.

ARTICLES have been filed with the Secretary of State of New Jersey, incorporating the Knapp-Campbell Gas Company. It is capitalized in \$2,000,000. The officers chosen to serve in the first year are: Directors, A. Blumenthal, G. Blumenthal and F. B. Spooner, of this city, H. D. Campbell, of Brooklyn, N. Y., J. L. Berg, of East Orange, N. J., and Reed Campbell and D. H. Knapp, of Norwich, N. Y. President, Albert Blumenthal; Vice-President, David H. Knapp; Treasurer, Gustave Blumenthal; Secretary, James L. Berg. We presume this Company is formed for the purpose of exploiting the Knapp gas making apparatus, a description of which will be found in our issue for December 9, 1889, p. 823.

THE proprietors of the Vineland (N. J.) Gas Light Company, which corporation can now be said to be freed from the financial entanglements that so sorely emmeshed it a year or two ago, have completed a most systematic and thorough overhauling of the main system, carried out under the intelligent direction of Mr. A. W. Tarbell, of Waltham, Mass. The betterments also included the placing of a street governor,

and general repairs to carbonizing apparatus. To show that Mr. Tarbell's plan of main overhauling answered his expectations and the desires of the Company may best be proved by the following. The final meter tests by sections of mains showed a total leakage (on the 5 miles comprising the system) of 34 feet per hour. This means, on comparing the result with that proved before the work of repair was undertaken, to the Vineland Company an annual saving of 700,800 cubic feet of gas, or a reduction in the leakage account of from 25.33 per cent. in 1889, to about 7 per cent. in 1890, without mentioning anything in the saving sure to result from checking the day pressure almost 50 per cent. Money may be made in the carbonizing house, but it is surely lost in the street department, if the service of the latter is imperfect. Look to your street mains.

MR. E. T. ROWELL, of the Massachusetts Gas Commission, has been elected President of the Railroad National Bank, of Lowell, succeeding Mr. Jacob Rogers, who will spend the summer in Europe.

THE East River Gas Company has filed a certificate of incorporation. It is capitalized in \$1,000,000, and will manufacture and sell gas in Long Island City and Newtown, Queens county, L. I. The Trustees returned for the first year are: Philip Burkhard, L. I. City, Isaac L. Egbert, Clinton Tabor and Franklin Everhard, of New York, and A. D. Ballard, of Yonkers, N. Y. Quite likely this Company is a corporation that either has taken or will take over the franchises and rights of the present Company doing business in the localities named.

CORRESPONDENCE from Indianapolis, Ind., dated May 2d, is to the following effect: "The power of electricity as a death-dealing agent was demonstrated at the works of the Brush Electric Light and Power Company, here, at midnight last night, when James Clark, an employee, was instantly killed by a shock. Clark had charge of two dynamos, and also assisted in operating the switchboard. The engine operating one of the city circuits had been running 'hot' all evening, and the night engineer gave Clark orders to change the city circuit to one of the commercial engines. A circuit is changed by shifting the wires on the switchboard. Attached to the end of each wire is a wooden handle through which the insulated wire passes. This handle fits into a brass neck and ring with which the wire is hooked on to the switchboard. In shifting the current Clark unhooked the city wire with his left hand and the commercial with his right. As he did so one of his fingers accidentally came in contact with the metal at the end of the wooden handle on the commercial wire. The current, 4,000 volts, threw him backward a distance of 20 feet. Death was instantaneous."

QUITE a rumpus was raised by certain citizens of Memphis, Tenn., in respect to a petition that had been submitted to Council by the Equitable Gas Light Company for the right to cross Horn Lake road in front of its works by means of a railroad track of standard gauge. The Company, however, was enabled to show beyond doubt that less inconvenience and danger would be occasioned to residents of the vicinity under the proposed practice (in the matter of transport of materials) than was the case under the existing methods, whereupon Council acquiesced in the petition.

THE Columbus (O.) Gas Light and Fuel Company has, in response to an invitation from the authorities, submitted a bid for the public lighting, and suggests therein the possibility of the city using gas to better advantage than could be the case with electricity. The agents by which this could be accomplished are named as the Gordon lamp and an "open burner" of the ordinary type, to consume 8 cubic feet of gas per hour. The letter to the Board of Public Works, which is signed by General Manager Irvin Butterworth, for the Gas Company, then goes on to say: "If granted a 10-year contract, this Company would agree to furnish as many of the above lamps, of either or both kinds, as your Board should see fit to order (the number, once ordered, not to be decreased during that time), and maintain, clean, light, extinguish and furnish gas to them, all at the rate of \$45.75 per year for Gordon lamps, and \$21.40 for the 8-foot open burners, if lighted during all dark hours—that is to say, 2,500 hours per year; or at the rate of \$57.80 for the Gordon lamps and \$26.20 for the open burners, if lighted all night and every night during the year. Herewith submitted is a map of the city, upon which are marked the locations of the various kinds of lamps—electric, Gordon, open burner and gasoline—for the purpose of illustrating the saving which may be effected in the street lighting of the city. It will be observed that the electric lights remain upon all the street car lines, and that the gasoline lamps are necessarily marked upon the outlying portions of the city, and in other places not at present supplied by the

Company's mains. It is likely that if we should be given a 10-years' contract we would be warranted in making liberal extensions to our present system of mains, if your Board should desire that we light a larger area than is now covered by them. Upon the plan illustrated upon the map there would be: 152 electric lights at \$80 per year, \$12,160; 145 Gordon lamps, at \$45.75 per year, \$6,633.75; 544 open burners, at \$21.40 per year, \$11,641.60; and 1,100 oil lamps, at \$15.75 per year, \$17,325, making the total cost for lighting per year \$47,760.35; present cost, \$76,000; saving per year \$28,239.65. Of course, your Board could modify the above number or arrangement of the lights in any manner that you might find would conduce to a better result, and the total cost would be affected in accordance with the foregoing prices, and could easily be calculated. The price herein named for gasoline lamps we are authorized to quote by Jones & Underhill, of this city. We believe that the above, or some similar arrangement of the lamps, would light the city better than most cities in the country are lighted. The lighting would be more thoroughly distributed, and there would be no dark alleys and corners. We believe it would give the people fully as good satisfaction as the present lighting. You will bear in mind that our proposal contemplates the assumption on our part of the first cost of the lamps, the expense of their maintenance and care, and the cost of lighting and extinguishing, the city being at no expense, except for the lamp posts, of which it already possesses a large number not at present in use. Furthermore, the 'all dark hours' lighting would be a total of 2,500 hours per year, whereas, ordinarily, the lighting under the new light schedule is calculated at 2,100 to 2,200 hours per year. In the case of the open burner gas lamps, as heretofore mentioned, they will be made to consume 8 cubic feet of gas per hour. Such lamps in other cities never consume more than 4 to 6 feet, as you will see by the chart which accompanies this map. In fact, an examination of this chart will show you that our proposed charge for the open burner lights is far the most liberal of any charge made in the cities therein reported, and the gas consumed by the Gordon lamps is not only to be charged for at the same rate per 1,000 feet, but the gas consumed by them gives a great deal more light per foot consumed than the open burners. A comparison of the cost of street lighting in Columbus with what is paid in other cities, shows that our streets are being extravagantly lighted. The cost in Columbus is equivalent to 76 cents per capita per annum, whereas, for example, it is 60.5 cents in Grand Rapids, 59 cents in Mansfield, 48 cents in Detroit, 40 cents in Cincinnati, 35 cents in Indianapolis, and 22 cents in Allegheny. We would guarantee to save the city 25 per cent. of what the streets could be lighted for by electricity." The proposal was referred to a committee.

A MEETING of the shareholders of the Birmingham (Ala.) Gas, Electric Light and Power Company is to be held in that city on the 2d prox., to determine whether or not a mortgage of \$300,000 shall be put on the property, and to consider the advisability of "selling its electric light plant and privileges, easement, and franchises appurtenant thereto."

MESSRS. WHITE AND CALL, acting for the proprietors of the Marquette (Mich.) Gas Light Company, have published the following circular: "The price of gas has been reduced from \$2 to \$1.50 per 1,000 cubic feet, and gas bills will hereafter be rendered at the latter rate. This price, we believe, is lower than in any city in the West or Northwest, where the population and the rate of gas consumption are not greater than in Marquette. We are now making an excellent quality of gas, and with proposed additions and improvements to be presently made to our plant we expect to offer gas to our customers for cooking and heating purposes, and believe many of the housekeepers of the city will be glad to avail themselves of its use, and will be pleased with its cleanliness, convenience, and economy." Gas at \$1.50 per 1,000 would be reasonable almost anywhere; hence it is more than reasonable at Marquette.

AT the annual meeting of the Cumberland (Md.) Gas Light Company the following result was reached: Directors, Messrs. E. T. Shriver, John McIlhenny, Robt. Shriver, Harrison Swartzwelder, and James Gardner; President, E. T. Shriver; Secretary and Treasurer, Webster Bruce; Superintendent, J. F. Seamon.

THE title of the Grand Rapids (Mich.) Gas Light Company has been changed to that of the Grand Rapids Gas Company.

THE ordinance by which the price of gas was fixed at \$1.25 per 1,000 to the city and \$1.35 to the public of Toledo (with 10 cents per 1,000 off for prompt payment) expires on Oct. 8, 1890, and the Mayor suggests that the "Common Council and the Gas Committee should be prepared, before

the 1st of October, with a new ordinance establishing the price of illuminating gas for a period of 3 or 5 years." He urges this early attention because in his opinion the proper determination of that question will require considerable study and investigation. And a lot of gammon, too, Mr. Mayor, on the part of the city.

A SPECIAL from Harrisburg, Pa., dated April 30th, says: "Judge Simonton to-day handed down two opinions in the Commonwealth's cases against the Philadelphia Electric Lighting Company and the Brush Electric Light Company, of Philadelphia. Both of these Companies claim to be manufacturing companies, and, as such, exempt from taxation under the recent act removing the tax from manufacturing companies. The opinions discuss at great length the means by which electricity and electric light are produced, and quote extensively from the testimony of Professor Henry Morton, President of the Stevens Institute of Technology, whose testimony as an electrical expert was taken in these cases. But Judge Simonton adheres to his opinion promulgated in a somewhat similar case about one year ago, that producing electric light is not a species of manufacture. He held that neither electricity nor electric light was a material substance, and that there could be no manufacture unless some material substance was produced. It is expected that these cases will all be argued in the Supreme Court, on appeal, at its meeting here next month."

THE authorities of Revere, Mass., have granted a contract to the North Shore Electric Light Company under which the latter will, for a period of 3 years, maintain 175 incandescent lamps (26-candle power) at a rate not to exceed \$16 per annum each, on an all-night table; also, 15 arcs, of 1,200-candle power each, to burn from sundown to 12:30 A.M., at the rate of \$72 per annum each.

THE public lighting by gas of New York city, for a year from 1st inst., has thus been allotted by the Gas Commission:

Company.	No. Lamps.	Price per Lamp.
Consolidated.....	17,150	\$17.50
Mutual.....	280	17.50
Equitable.....	3,600	12.00
Central.....	2,675	27.00
Northern.....	2,200	28.00
Yonkers.....	557	28.00

WE presume that the enthusiastic supporters of the movement for municipal control of electric lighting stations and gas works will find little food for consolation—it might set them thinking, however—in the fact that the Bay City (Mich.) Common Council has about decided to sell out the municipal electric lighting station now owned and operated by the city.

THE West Arlington Improvement Company will probably construct a gas works at West Arlington, Md. D. MacIneston, of New York, is President of the Improvement Company.

THE new Methodist Church building at Downingtown, Pa., is to be lighted by gas. There was quite a contest between the local Gas and Electric Light Companies over the contract.

THROUGH the courtesy of Mr. T. R. Parker, of San Jose, Cal., we are informed of the death in that city, on April 27th, of Mr. John Fullagar, formerly Superintendent of the Cincinnati (Ohio) Gas Light and Coke Company. The cause of death was heart failure. In his brief note to us on the sad affair Mr. Parker wrote: "Thus ends the life of an energetic man, a kind father, a firm friend and a congenial gentleman." We hope in due time to give to our readers some account of Mr. Fullagar's life.

IN a suit brought in the United States Circuit Court, Boston, Mass., before Judge Colt, the Electric Gas Lighting Company sued Charles E. Fuller, the action being a bill in equity brought for infringement of letters patent, No. 225,071, granted to Henry F. Packard, and No. 232,304, granted to C. N. Sanford for improvements in electric gas lighting apparatus. The patents relate to that form of electric gas lighting where the burner is operated by hand, and which does away with the use of matches. The Sanford device is substantially like the Packard. The apparatus covering both of the patents is called the Packard-Sanford burner, and it appears to have been the first burner of this class which obtained any large degree of commercial success. The defence mainly relied upon is that there was no invention in what Packard did, in view of the state of the art at the time. Judge Colt says: "The Court finds in none of the prior devices the combinations referred to in the third and fourth claims of the Packard patent, and

recognizing the prior state of the art. I think it called for the exercise of the inventive faculty as distinguished from mere mechanical skill to produce the Packard device. Upon the question of infringement I have no doubt."

WE understand that the Selectmen of Marlboro, Mass., have granted the promoters of the Citizens Gas Light Company a franchise.

GOVERNOR BRACKETT having signed the bill repealing what is known as the carbonic oxide law of Massachusetts, water gas can be made in that State without any restriction whatsoever.

ADVICES from Boston are to the effect that on the morning of the 2d inst. Attorney General Waterman forwarded to the House of Representatives, in reply to its order, an opinion that cities and towns have no right to make and sell gas for private use, nor to make it for their own use. He examined the status of cities and towns separately. As to towns he says: "I can find no law or statute by which towns have been authorized to enter into business of a commercial or private nature, such as requires an investment of capital and the employment or particular application of skilled labor or scientific knowledge therein. And I am of the opinion, for the reasons above stated, that under existing statutes towns have no authority to construct and maintain within their own limits and for their own use systems of lighting by gas or electricity; nor can they in connection with such systems sell gas or electricity for private use in such towns." Regarding cities he also gives his reasons and concludes that "cities as well as towns have no authority to construct and maintain either gas or electric light works."

THE Duluth (Minn.) Gas and Water Company has ordered 500 tons of gas and water mains from the West Superior pipe works.

THE May term Grand Jury of Chicago, has found an indictment against Charles V. Henkel, on a charge of embezzling \$2,000 from the Globe Light and Fuel Company of 195 Michigan street, that city.

THE proprietors of the Westfield (Mass.) Gas Light Company have voted to reduce the gross price of gas, to consumers of 20,000 cubic feet per month, to \$2.37 per 1,000, and to consumers of less than that quantity to \$2.50, prompt payment to entitle the consumer to a rebate of 10 cents per 1,000.

WE were recently in receipt of the following circular, copies of which have been extensively distributed throughout the central West. We cheerfully give to Messrs. Hayes & Co. this free advertisement, in the full knowledge that it will curtail their receipts. The circular reads: "Do you burn gas? Do you desire to save 25 to 40 per cent. on your monthly bill?—If so, send 50 cents either in stamps or by postal note to the undersigned, and by return mail receive a simple device which has proved this result can be achieved in any business place, hotel or residence in this country. The device and manner of applying it is very simple. It is neat, safe and clean, saving your ceilings from being disfigured by smoke. Once attached, they last the lifetime of the fixtures. The information imparted to you with this device will enable you to change all the burners you may control at a mere nominal cost and the time it will take to adjust them. The question has been asked, Have the public any rights which the gas companies are bound to respect? We answer, Yes. With our device you will only receive what you pay for, and pay for what you receive, and the company will have no way to doctor the meter to produce other results. The thousands already in use justify the above statement. If you personally have no need of this information, please hand this to some friend who may desire to avail himself of this privilege, and greatly oblige C. H. Hayes & Co., 1615 Hough avenue, Cleveland, O. In writing us, give full post office address, which will lessen the chances of delay and miscarriage." Naturally, wishing to keep up with the best practice of the day in the matter of how to burn gas properly or to the best advantage, we at once applied by letter to Mr. G. A. Hyde, of the Cleveland Gas Light and Coke Company, for information respecting the Hayes device, and received from that gentleman the following response: "Replying to yours of the 3d inst., we had received a similar circular and inquiry from another party recently, and sent a person to purchase the device advertised. It proved to be nothing more nor less than the stuffing of a burner with cotton to accomplish the desired result." Perhaps Hayes & Co. will not be grateful for this advertisement.

MR. E. A. VAN HORNE has handed in his resignation to the proprietors of the Utica Gas Company, in order that he may accept the position of Superintendent of the Syracuse (N. Y.) street railway system.

MR. WM. LAWLOR, Superintendent of the Lincoln (Neb.) gas works, was badly burned about the face and shoulders while making an inspection of some repairs that had been made to a boiler in the generating room of the works. The accident occurred on the morning of April 28th.

AN attachment for \$136,063.53 has been sued out in the Circuit Court of Chicago by Robert Fulton Cutting against Nicholas C. Miller, who is plaintiff in the suit to set aside his sale of the Lake Gas Company to the syndicate headed by C. R. Cummings. Mr. Fulton's claim is based on a judgment recovered by him against Miller in the Supreme Court, this city, on March 11.

THE annual meeting of the Wilmington (N. C.) Gas Light Company was held on the morning of April 29th, Mr. D. G. Worth acting as Chairman, Mr. J. C. Chase acting as Secretary. The election for Directors resulted in the following choice: Capt. John F. Devine, Dr. A. J. De Rossett, and Messrs. E. S. Martin, Donald MacRae, Geo. W. Kidder, G. H. Smith and Geo. R. French. The Directors subsequently effected the following permanent organization: President, E. S. Martin; Secretary and Treasurer, R. J. Jones; Superintendent, J. W. Reilly. The Company enjoys a most prosperous business.

THE formal transfer of a majority of the shares in the Troy (N. Y.) Electric Light Company to the Troy Gas Company was made on the afternoon of April 29. It is possible that Joseph A. Powers will be retained as Manager.

THE Waukegan (Ills.) Light, Heat and Power Company has been incorporated, with a capital of \$60,000, by Messrs. William Stubbs, De Witt Stearns and W. L. Duston.

ACCORDING to the city's books, Rochester, N. Y., maintains 2,719 public lights of all classes. Of these 846 are ordinary gas lamps, paid for at the rate of \$18.25 each per annum; 1,083 are of the arc electric type, and which cost 28½ cents each per night; and 790 are of the incandescent electric type (20-candle power), charged for at 4½ cents each per night.

THE proprietors of the Chattanooga (Tenn.) Gas Light Company, in order to encourage the use of gas for cooking, heating and power, have agreed to allow, from the first inst., a discount of 40 cents per 1,000 on bills for gas used in stoves and gas engines. This is equivalent to a net rate of \$1.30 per 1,000.

THE cases of the Laclede and Carondelet Gas Light Companies against the city of St. Louis to enjoin the latter from enforcing the ordinance reducing the price of gas to 90 cents per 1,000 cubic feet, have been ordered continued in Judge Valliant's court until the 20th inst. The court granted a restraining order against the city. In the meantime City Counsellor Bell has filed three petitions in the Supreme Court asking for a writ of mandamus against the Gas Companies to show cause why they continue to disobey the ordinance.

Correspondence

Electric Lighting at St. Louis.

ST. LOUIS, MO., May 4, 1890.

To the Editor AMERICAN GAS LIGHT JOURNAL:

On May first St. Louis was lighted for the first time with electric lights; arc lights being used on the streets and incandescent lamps in the alleys. It is safe to assert that never before was St. Louis so brilliantly lighted as it has been since the advent of electricity. When the city was lighted with gas a moonlight schedule was followed. That is to say, when the moon was shining brightly the gas was not turned on. During the past few evenings we have had a clear sky with a bright moon, with all the electric lights going and all the gas lamps lighted to help them. The moon can't continue much longer to aid the electric light, and must retire from business for a time, of course; but the gas lamps are kept burning by order of the Mayor until the electric lights shall have burned satisfactorily for at least 5 nights. To date they have not done so. The city was to be fully lighted by electricity, January 1st. Then the contractors obtained an extension of time until May first, when they claimed to be ready, after a number of trials with the light, the result of which is thus briefly told. There seems to be, after all, a good deal of uncertainty and not a little humbug connected with the electric light. If gas lighting were as dangerous to human life and property as electric lighting has proved to be the daily newspapers would protest all over the land; but, strange to say, the newspapers have nothing to say now. The electric light is probably a newspaper pet, the same as the gas company and the plumber are its old-time chestnuts for bad jokes and abuse, at times when other matter is "short."

Position Wanted

As Superintendent or Assistant of a Gas Works,
 By a man who can give the best of references. Thoroughly
 understands the manufacture and distribution of gas and the
 construction of works. Address
 779-5 "M.," care this Journal.

POSITION WANTED

As Superintendent of Gas Works.

Eleven years' experience in the manufacture of coal gas. Best
 of references given.
 W. L. CARVER, Supt.,
 Carthage, Mo.
 778-8

WANTED,

By a New England Gas Company,

**A Man to Repair Meters, take
 Meter Readings, etc.**

776-5 Address "H. R.," care this Journal.

FOR SALE,

**The Ironwork for Twelve Benches of 6's, vis.:
 Cast Iron Hydraulic Main.**

**7-inch Dip-Pipes, Stand-Pipes, and Bridge-
 Pipes, complete.**

Floyd Mouthpieces and Self-Sealing Lids, 15x26 in.

Lids and Mouthpieces only in use over a year. Will be sold
 cheap. ISAAC C. BAXTER,
 772-tf Detroit (Mich.) Gas Lt. Co.

FOR SALE.

A Complete Water Gas Plant.

60,000 Cu. Ft. Daily Capacity.

Fully equipped; all the latest improvements; includes Gener-
 ator, Purifiers, and Holder. Can be removed to any part of the
 country, and set up at small cost. For further information ap-
 ply to BRADFORD GAS LT. & HEATING CO., Dunkirk, N. Y

FOR SALE,

**One Eight-Inch Steam Jet
 Exhauster.**

Kerr Murray make, and one of the best. Address
 J. B. HOWARD, Supt. Key City Gas Co.,
 776-tf Dubuque, Iowa.

Fuel and Its Applications.

By E. J. MILLS, D.Sc. F.R.S., and F. J. ROWAN, C.E., assisted
 by others, including Mr. F. P. Dewey, of the

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889, and later dates.

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used.

Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE.

Works under our system may be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon.

One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

GAS vs. ELECTRIC LIGHT.

We would invite attention to the able and exhaustive argument of General A. Hickenlooper, President of the Cincinnati Gas Light and Coke Company, contained in a handsome pamphlet of 96 pages, entitled

"EDISON'S INCANDESCENT ELECTRIC LIGHTS FOR STREET ILLUMINATION. REPORT OF AN ARGUMENT DELIVERED BY A. HICKENLOOPER BEFORE THE COMMITTEE ON LIGHT, MUNICIPAL COUNCIL, CITY OF CINCINNATI, JULY 22, 1886."

This is a subject of special interest to all Gas Light Companies.

Prices.

25 copies.....	\$7.50	100 copies.....	\$22.50
50 copies.....	12.50	250 copies.....	50.00

THE WALKER TAR AND CARBONIC ACID EXTRACTOR.

A very general demand exists, in both large and small Gas Works, for an apparatus that will be absolutely efficient in the removal of the tar which passes the hydraulic main and condenser. Many attempts have been made to accomplish this, but, I believe, without success, until the introduction, five years ago, in England, of the C. & W. Walker Patent Tar and Carbonic Acid Extractor. During these years this apparatus has been adopted by many of the most prominent Engineers, not only in England, but also on the Continent of Europe and in other parts of the world. It is only necessary to give here a partial list in order to convince any intelligent American Gas Engineer that this machine must have succeeded fully in accomplishing the desired results.

The following Engineers have personally given permission to refer to them:

G. C. Trewby, Esq., Engineer-in-Chief of the Gas Light and Coke Co., London. The manufacturing plant at Beckton is built in complete sections of 3,000,000 cubic feet capacity each. A Walker Tar Extractor has been fitted to each one of these sections. This was done after a long and thorough trial on one of its sections. The Tar Extractor has been supplied to other works of the Gas Light and Coke Co., including those of which John Methven, Engineer of the Gas Light and Coke Co. at the Nine Elms Station, is in charge. Also to G. E. Stevenson, Peterborough Gas Works; B. Green, Mitcham and Wimbledon Gas Works; W. H. Smith, Bedford Gas Works; F. Linging, Norwich Gas Works; J. T. Browning, Colchester Gas Works; S. B. Darwin, Portsmouth Gas Works; J. McCrae, Dundee Gas Works; W. J. Wells, Stamford Gas Works; J. M. Darwin, Longton Gas Works; J. Paterson, Warrington Gas Works; and J. Coulter, of the Dundalk Gas Works. All of the foregoing gas works are located in Great Britain.

Mr. Charles A. Gerdenier, Superintendent of the Bridgeport (Conn.) Gas Light Company, writes as follows, under date of Dec. 3, 1887:

"The C. & W. Walker Tar and Carbonic Acid Extractor has been in operation at these works for the past six weeks, and is an unqualified success. It removes every particle of Tar from the gas in once passing through the apparatus, and a large percentage of the Carbonic Acid. I also feel quite sure that it prevents the formation and deposit of Naphthaline, because since I started the Washer I have had no stoppages from this cause. These works have been seriously troubled with Tar for many years, and I have used several kinds of apparatus and every expedient which has come to my attention for dealing with the difficulty, but without success. The Walker apparatus occupies comparatively small space, is less expensive than other systems, and requires but little attention. I carry 2½-inch seal, and have an automatic tar delivery valve. This Tar Extractor is indispensable to gas makers."

I have taken the Agency for the United States for this apparatus, and am now prepared to make contracts to erect it on the premises of any Gas Company. It would be manufactured in the following sizes:

No. 1,	50,000 to	100,000	cu. ft. per 24 hrs.,	3 ft. square,	5 ft. deep.
No. 2,	" "	125,000	" " "	4 " " "	" "
No. 3,	" "	250,000	" " "	5 " " "	" "
No. 4,	" "	500,000	" " "	6 " " "	" "
No. 5,	" "	750,000	" " "	7 " " "	" "
No. 6,	" "	1,000,000	" " "	8 " " "	" "
No. 7,	" "	1,250,000	" " "	9 " " "	" "
No. 8,	" "	1,500,000	" " "	10 " " "	" "
No. 9,	" "	2,000,000	" " "	12 " " "	" "
No. 10,	" "	3,000,000	" " "	15 " " "	" "

This Tar Extractor will perform its work with about one-fourth the usual back-pressure heretofore required. It is simple in construction, and can be supplied at a very reasonable price—less than any other ever before introduced. Satisfactory results will be guaranteed in every instance.

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE."

Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR.

Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER.

Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time!

Made in Sizes of 5, 10, 15, 20, and 25 Horse Power. All Engines Guaranteed for One Year.

GENERAL SALES AGENTS FOR

The Youghioghenny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest. M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghioghenny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE. Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

BRECKENRIDGE CANNEL,

OF KENTUCKY.

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

JAMES & WILLIAM WOOD,

Gas and Cannel Coal Contractors,

"SUN DIAL" GAS STOVES,

The Most Economical, Efficient, and Durable Gas Stove Made.

GAS COOKING STOVE, No. 8 C.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
37 in. high. 20 in. wide.	12 in. high. 17½ in. wide. 12 in. deep.	12 in. high. 18 in. wide. 13 in. deep.	24 in. long. 21 in. wide.	36 in.

This stove has four burners on top, and double oven burner. Consumption of gas with all burners in use, 12 feet per hour, at 1 inch pressure. The top is made in sections, so that a greater variety of cooking utensils may be used. By lifting out the covers and crosspieces and putting in a suitable forked ring, which is sent with each stove, a wash boiler or other large utensil may be set over two burners. Our No. 87 GRIDDLE also fits in the same position. The roasting oven is provided with a cast-iron door.

All Fittings are Nickel-Plated.

GAS COOKING STOVE, No. 7 B.

SIZE.

Stove.	Oven.	Roaster.	Top.	Length over Extension Shelves,
31 in. high. 17 in. wide.	9½ in. high. 14½ in. wide. 12 in. deep.	10 in. high. 15 in. wide. 13 in. deep.	21 in. long. 16 in. wide.	32 in.

This Stove has three boiling burners in the Top or Hot Plate, and one single oven burner.

This cut represents our New Style Cooking Stove. As will be seen, it has an ornamented cast-iron Base and Front, and extension shelves. The Oven Burner, which is atmospheric (unless otherwise ordered), is of an entirely new and improved pattern (patent). The ovens are of greater capacity than those of the old style. The Top, in conjunction with the Outlet Pipe, is designed to carry off all the products of combustion, if desired, but they are also supplied with a loose ring which converts it into an ordinary open top stove.

The consumption of this Stove is 35 cubic feet per hour at 1 inch pressure, with all Burners in use.

All Fittings are Nickel-Plated.

"RADIANT" BOILING STOVE, WITH REGENERATIVE BURNER.

Size, 6½ inches diameter, 8 inches high. Consumption, 6 feet per hour at 1 in. pressure.

HOT PLATE, No. 111.

Size, 36 in. long, 12 in. wide, with three double burners, 6 taps. Consumption, with all burners in use, 36 cubic feet per hour, with 1 in. pressure. ½ in. supply pipe should be used where the pressure is 1 in. or over.

ENTERED AT THE POST OFFICE AT NEW YORK, N. Y.
AS SECOND CLASS MATTER.

Published on each Monday of the year, at No. 42 Pine Street, N. Y.

Terms of Subscription, Including Postage.—For the United States and Canada, \$3 per annum. European countries, \$4.50 (19 shillings—22½ francs). All payments to be made in advance. Single copies, 10 cents.

Remittances should be made either by post-office order, registered letter, or bank draft on New York, payable to the order of A. M. Callender & Co.

Collections are invariably made directly from this office, for subscriptions, advertisements, etc. We have agents to solicit the same, but they are not authorized to receipt for money.

Correspondence.—Wishing to make this JOURNAL a gazette of intelligent discussion to those of our readers who may wish to gain or give information on the subjects to which its columns are devoted, correspondence is solicited for publication from all who make the study of those subjects a pleasure or a profession.

The American News Company, Nos. 39 and 41 Chambers street, New York, are agents for this JOURNAL. Newsdealers will send orders to them.

Books.—We will forward by express, at publisher's lowest rates, any book—scientific or otherwise—to any address in the United States or Canada. No book will be sent C. O. D.

Western Gas Association.

SECRETARY'S OFFICE, WESTERN GAS ASSOCIATION, }
QUINCY, ILLS., May 14, 1890. }

The Thirteenth Annual Meeting of the Western Gas Association will be held at the Lindell Hotel, St. Louis, Mo., on the 21st, 22d and 23d days of May. The hall in which the business sessions of the Association will be conducted is within the hotel building, is very commodious, quiet, and in every way excellently well adapted to our requirements. The hotel management has granted on this occasion the following rates: For single room and board, \$2.75 per day; for room with bath, \$3.25 per day. These rates will apply to members in attendance, their families and visiting brethren. In this connection I am instructed by the Local Committee of Arrangements to give our members warning of the fact that in order to secure suitable accommodations, their rooms *must be engaged in advance*. Your Secretary has been in the habit of making an announcement to this effect with exceeding regularity from year to year, and just as regularly no one, or at least only very few, pays the slightest attention to the warning. The necessity of engaging quarters in advance, however, is in this instance very urgent. Now that the old Planters' House has been closed, the Southern and Lindell Hotels often have more business thrust upon them than they are capable of handling, and of late it has been no unusual occurrence for them to deny would-be guests admission, unless their rooms had been previously spoken for. But all of our members can be accommodated without the slightest jar or friction, if they will but take the trouble to address a line to the "Proprietor of the Lindell Hotel, St. Louis, Mo.," telling him the kind and price of room or rooms desired. This should be done at least one week in advance of the first day of the meeting.

In addition to the reduction in transportation rates granted by the Central Traffic Association, the Trunk Line Association has also joined in the movement. As the boundary of the latter Association extends as far east as the western border of the New England States, our Eastern friends will be enabled to avail themselves of the reduced fares.

I am authorized to state that Mr. R. D. Walsh, Chairman of the Local Committee of Arrangements, has kindly consented to take charge of all articles destined for the Gas Exhibit, and will cheerfully surrender a generous portion of his time to the interests of exhibitors. Communications, consignments of gas stoves, apparatus, burners—anything, in fact, intended for the Exhibit—may be directed to Mr. Walsh, in care of the Laclede Gas Light and Coke Company. Exhibitors can rest assured that not only will their wares receive careful handling and be displayed to the best possible advantage, but that they themselves will be accorded the most courteous treatment at the hands of Mr. Walsh and his efficient committee.

The "Paper List" for our Thirteenth Annual will be as follows:

"Relative Value of Gaseous Fuels," by B. E. Chollar.

"Effects of Natural Gas Competition," by James Somerville.

"An Argument in Favor of the Adoption of a Uniform System of Estimating the Cost of Gas in the Holder," by George G. Ramsdell.

"Impressions of British Gas Works," by George T. Thompson.

"Mixed Gases," by E. G. Cowdery.

"Wrought Iron, Cast Iron, or Steel—which is the Best Material for Street Mains?" by Eugene Printz.

"What Policy Should the Gas Interest Adopt in Connection with the Approaching World's Fair?" by Walton Clark.

"On the Abuse of the Patent System as Bearing on the Gas Industry, with a Remedy," by Frederic Egner.

"The By-Products of Experience," by Allen R. Foote.

The attention of the Board of Directors is called to the fact that Section I., of Article VII., of our By-Laws reads as follows: "The Board of Directors shall meet as such at least once in each year, on the day preceding the annual meeting of the Association, at which time they shall determine in regard to the propriety of the various papers, drawings, models, or other matters constituting the special order, being laid before the Association." The Board of Directors elected at our last meeting is composed of the following-named gentlemen, who are, therefore, particularly requested to assemble at the Association's headquarters on Tuesday morning, May 20, at 10 o'clock:

J. B. Howard, E. H. Jenkins, Z. T. F. Runner, John Gimper, C. W. Butterworth, E. G. Cowdery, J. S. Ambrose, J. W. Dunbar, and B. E. Chollar.

The social features of the Thirteenth Annual, as provided by the Entertainment Committee, will be as follows:

On Thursday evening there will be a grand moonlight excursion and supper on the Mississippi, the handsome steamer *Oliver Bierne* having been engaged for the occasion. A trip will be made up the river as far as the Chain of Rocks, giving a view of the new water works now in process of construction, and also of the recently completed Merchants' Bridge. On returning, the steamer will run down below Carondelet, affording a beautiful twilight view of the full 16 miles of the city's front along the Mississippi. Supper will be served, and there will also be music and dancing, the boat returning to the wharf at 10 o'clock.

On Friday, at 10:30 A.M., carriages will be in readiness at the hotel for delegates and their guests. A drive will be taken through the western portion of the city as far as the Fair Grounds, where a luncheon will be served at the Jockey Club House. After a series of entertainments, beginning at 2 o'clock P.M., which have been generously tendered by the Board of Directors of the Fair Grounds, parties wishing to take a drive through the parks may do so at their pleasure, in carriages provided by the committee.

Ladies accompanying delegates can obtain carriages at any time during Wednesday and Thursday for such purposes as they may desire.

From the above it will be seen that the time-honored custom of serving a banquet on the second night of our reunion will be departed from. This is an innovation which the committee feels assured will receive a hearty welcome from the "Toast-Responders," and possibly from many others for the mere sake of a change, if for no other reason.

Application blanks, copies of our By-Laws, and any information not contained in these communications will be cheerfully furnished by

A. W. LITTLETON, Sec'y.

(Since writing the foregoing, your Secretary has received word that the lines operated by the Southern Passenger Association will grant the same rates as those which will be given by the Central Traffic and Trunk Line Associations, viz., one fare and one-third for the round trip. These fares can be obtained on the certificate plan. Any railroad ticket agent within the territories of these three passenger associations will take pleasure in informing a member as to the steps that are required for securing these reduced fares. It is hoped that every delegate who can do so will avail himself of the reduction.)

BRIEFLY TOLD.

THE DAY IS AT HAND.—Before this number of the JOURNAL shall have been completely distributed the Thirteenth Annual of the Western will be over and its record a part of history. Look at it as we may, at the time of writing, however, we are in the full knowledge that the session is to be a memorable one. Every arrangement for the mental and social side of the occasion has been made, and made with thoroughness and cleverness. The Eastern delegation will be on hand in greater numbers than ever before, and they go in the certainty that a royally fraternal time is to be their portion.

THE GAS STATISTICS BRANCH OF THE ELEVENTH CENSUS.—The following, from Superintendent of the Census explains itself. We hope that the proprietors of gas works will see to it that the returns respecting the gas industry are as full and complete as it will be possible to have them. The compilation cannot fail to benefit all, and that benefit will

be in exact proportion to the completeness of the figures submitted. Supt. Porter's letter is as follows:

"DEPARTMENT OF THE INTERIOR, CENSUS OFFICE, }
WASHINGTON, D. C., May 14, 1890. }

Census of Manufactures.—On the 2d day of June the work of collecting statistics of manufactures for the report of the Eleventh Census will be inaugurated throughout the entire country. The value of this report must depend wholly upon the accuracy and thoroughness with which manufacturers answer the questions propounded. The personal interests of every manufacturer are involved in the character of the report on Manufactures. It will be quoted for the next ten years as the official announcement of the *exact* industrial condition of the country, and will be the basis for any future legislation that may be enacted in regard to the wants of our people, whether engaged in agricultural or mechanical pursuits. Therefore it is of vital importance to each manufacturer that an accurate report shall be made. The Superintendent of census has taken every possible precaution in the preliminary work to make this census complete and satisfactory, and the earnest co-operation of those engaged in productive industry is all that is now necessary to secure valuable results. Every manufacturer should bear in mind that his answers to the questions relating to his business are held strictly confidential, are not disclosed to any competitor or to other persons, and are not used by the Government as predicate for the purposes of taxation or license, or in any way adversely to affect his individual business. This assurance is printed on each schedule over the signature of the Superintendent of Census. The expert Special Agent in charge of this branch of census work, Mr. Frank R. Williams, has personally visited the principal manufacturing centers and consulted representative manufacturers, the publishers of trade journals, and practical business men generally, for the purpose of ascertaining the proper scope of the inquiry for each branch of manufacture. The questions contained in the census schedules are those suggested by the manufacturers and other persons most interested in the progress of the country, and cover ground absolutely essential to the proper presentation of its industrial conditions and resources.—ROBT. P. PORTER, Supt. of Census."

NOTES.—In a letter to the publishers, dated Alton, Ills., May 12, Secretary Tracy, of the Alton Gas and Electric Light Company, writes: "Alton at this time is experiencing quite a boom. We are building a \$30,000 opera house, an I. O. O. F. temple, and a public library. In fact you can hardly visit any part of the city without witnessing some evidence of growth in the shape of new residence buildings, etc. With all this bright outlook the Gas Company shares its part. I will lay about one-half mile of 3-inch main as soon as I can get the pipe. I will also put in a hot tar scrubber and substitute iron sponge for lime. A comparison of April 1889 and 1890 shows an increase in gas sales to private consumers of 29 per cent., and from appearances at this time, next April will show an increase of at least 50 per cent. over the April just closed." The light of the present seems to hold its own.—At the annual meeting of the Easton (Pa.) Gas Company the following Directors were elected to serve for 3 years: Samuel Boileau, Robt. I. Jone and Wm. A. Seitz. At the Directors' meeting the following officers were elected: President, S. Boileau; Treasurer, Edward Hilliard; Secretary, W. G. Stewart; Supt., W. H. Ward.—The furnaces of the Pennsylvania Tube Works, Pittsburgh, will be remodeled to burn producer instead of natural gas. The cost involved in fitting the works for the change will not be less than \$120,000.—A gas company for Norwich, N. Y., has been incorporated by Messrs. Dudley Farlin, J. White Sprong and E. F. Murray. It is capitalized in \$50,000.—Mr. Lucius D. Rhodes, Superintendent of the Holyoke (Mass.) Water Power Company's gas works, died at his home in that city on the 7th inst. He came to Holyoke in 1863, from the works of the Hartford (Conn.) Gas Company, and his record in the former place speaks for itself. He was in his 61st year.

The Market for Gas Securities.

The upward movement in Consolidated gas continued through the week, and the stock is bid for to-day (Friday) at 105 $\frac{1}{4}$. We would advise caution now in the matter of its purchase; that is, in respect to purchase on speculative account. For investment purposes it is worth at least 110. Mutual gas is very strong, the bid figure being 115 with no shares offering. Brooklyn stocks are steady. The event of the week, perhaps, was the rise in Chicago Trusts, which sold up to 67 $\frac{1}{2}$. To-day the stock is bid for at 63 $\frac{1}{4}$. We would not advise purchase at anything above 60, for the present at least. Bay State is up to 84, and will soon be in the dividend list. Laclède common is up to 27 $\frac{1}{4}$, and the preferred, at 64 to 70, looks to be a purchase.

Did Dr. Wilkinson Confine Himself to Facts?

By MR. JAMES SOMERVILLE.

Dr. Wilkinson, in his lecture on "Some Facts Connected with the Manufacture of Water Gas," as published in your issue of April 28th, makes a statement regarding coal gas which appears to me, coming from such a source, ought not to remain any longer uncontradicted. In speaking of the purity of water gas, he says, "Compare this with coal gas, where we have from 20 to 40 grains of sulphur, and from 5 to 7 grains of ammonia to the 100 feet."

If he had said seven-tenths of a grain of ammonia, and from 8 to 10 grains of sulphur per 100 feet, he would have been much nearer the truth. Ammonia is too valuable a product to allow any of it to be retained in the gas. There is no sulphureted hydrogen, and the amounts of sulphur compounds that may escape the action of the lime and oxide are so small that the resultant sulphurous and sulphuric acid from the combustion of the gas is practically harmless to health.

The bleaching of the goods to which he refers is not due to the impurity of the gas, but to the stratum of highly heated air to which they are constantly exposed. The same result has been observed in houses in which gas was never used. As for those poor people whom he so pathetically describes as dying of slow poison, this distressing condition is not due to impure gas, but to the want of oxygen or fresh air, and it seems to me it would have been more in keeping with his profession if, instead of decrying the use of gas, he had insisted upon a proper system of ventilation.

Our friends, the enemy, are not slow to pick up such statements and use them to the disadvantage of our industry.

An Odd Experience in a Purifying Room.

By IRVIN BUTTERWORTH.

Last fall this Company (the Columbus, O., Gas Light and Coke Company) purchased a lot of new oxide, two car loads of the Connelly sponge and three of Prof. Douglas's ferric oxide, from Michigan. The material was put into use in the usual way, the two oxides soon becoming thoroughly mixed together until the material was homogeneous. We endeavored to revive the spent material by blowing air through it in the "off" boxes, by means of a rotary blower operated by a gas engine. The cover was not removed, and the air was blown into the inlet, passing up through the oxide in the same manner as the gas passes, and escaping through the small cap-hole in the cover.

This plan of revivification worked successfully for some time, and we did not have any trouble whatever from the heating of the oxide, though we had to empty and refill boxes occasionally, on account of back pressure caused by the caking of the material.

But the oxide soon began to apparently lose its efficiency, and after being revived in the above manner would soon pass the sulphureted hydrogen, necessitating two or three changes daily, and the almost constant running of the blower. Our material, we noticed, had begun to assume a dark, greenish appearance, and that which we would remove from the boxes and expose to the air would not go through the chemical heat of revivification, nor change its color from the dark green to the characteristic brown of properly revived oxide. In fact, it did not seem to reoxidize a particle. And yet, by frequently changing boxes and keeping our blower in operation almost night and day, we have been able to purify our gas.

I should mention, as having a possible bearing upon our ability to do this, that during about 16 or 18 hours out of every 24 we scrub our gas through hydraulic main liquor, of about 2 ounces strength; and we also constantly introduce into our gas at the exhauster about 1 per cent. of air.

About three weeks ago, as an experiment, we discontinued the running of the blower, and tried the effect of throwing the material out of the boxes and exposing it to the air in the old way, with the effect of increasing, slightly, the length of time that the boxes would run without changing, but not tending, to any perceptible degree, to bring the dark green material back to the proper color, nor promoting its revivification to any very noticeable extent.

An analysis of our purifying material (which has been lightened by the admixture of about one-third its bulk of sawdust) shows that it now contains over 10 per cent. of sulphates of iron. This, of course, accounts for its dark green color. Just how much iron it contains in other forms, and what the total percentage of sulphur is, we do not as yet know; but an analysis is about to be made to determine these points.

In the meantime, we are able to purify our gas by making two or three changes daily.

Three or four questions present themselves, viz.:

1st—As our material does not show any of the evidences of revivification on being removed from the boxes when foul, how, or by what agent, is our gas being purified?

2d—If it is sesquioxide of iron in our material that is performing this work, why does the material not show some of the usual evidences of revivification?

3d—Have any gas companies who revive their oxide by blowing air through it had any experience similar to ours?

4th—Has the blowing of air through our oxide been the cause of our trouble, and if so, how could this plan have a different effect in this respect from that of exposing the material to the air?

Notes upon Distributory Plant.

[Read by Mr. W. J. Warner, of South Shields, before the North of England Gas Managers' Association. Reprinted from the London Journal.]

I very much regret not having been in a position to comply with the request of your Committee to contribute on the present occasion a paper to this Association. Though not in possession of matter of sufficient importance for a paper, I had a few notes which I thought might interest you, and draw forth some expression of opinion, which, backed by observation and experience, might be of value at a time when an attempt is being made by the users of steam rollers to remove from themselves the responsibility attached to such use.

In a paper on the subsidence of gas mains, by Mr. Drewry, of Cleethorpes, read at the recent meeting of the Eastern Counties Association, the writer gives his experience with mains laid in loose soil subjected to tidal influences and disturbed by sewerage works—resulting in a considerable subsidence of the main and its ultimate fracture. Reference was made in the discussion of the paper to the general disturbance of gas mains by "the necessities of domestic civilization," so termed by Mr. C. E. Jones, of Chesterfield—viz., the "water-carriage system, sewers, the multiplicity of telegraph, telephone, and electric lighting poles, and electric lighting mains." It will be observed that reference here is only made to the disturbance of the ground from these operations—the actual doing of the work. Beyond these disturbances within, if they may be so termed—the cutting of the trenches, inadequate shoring, improper filling in, and the disturbance of the joints by such operations—there is the disturbance from without, or from the surface of the ground—the road making operations, the general traffic over the ground, and the passing of heavy loads over the surface of the road.

Having a record, extending over some years, of the defects found in mains and pipes other than those of an ordinary character, I have arranged them in a tabulated form. Though this scarcely covers the whole of the ground, yet it may be of some value as a contribution to the subject. These entries of the whole are divided into five divisions, with the number of breakages in each, and the percentages, the sizes of the smallest and largest pipes, and the mean diameters, as follows:

No.	Cause.	No. of Breakages.	Percentage of Whole.	Sizes of Pipes.		
				Max. Inch.	Min. Inch.	Mean. Inch.
1.	Bad castings	7	6.48	12	1½	3.79
2.	Drainage operations	51	47.22	6	¾	2.29
3.	Heavy weights passing over roads . . .	16	14.82	12	2	3.62
4.	Steam roller passing over roads	17	15.74	6	¾	2.40
5.	Unknown	17	15.74	8	1	3.00

Two of the latest reports are as follows: "March 11, 1890.—Jarrow district: Escape in a ¾-inch service; connecting piece drawn from main by pressure of steam roller; the pipe end quite bright; pipe bedded in soft clay." "April 2, 1890.—Shields district: Escape up lamp pillar; opened out the service, and found it extended from the end of the main; a connecting piece drawn from the socket; the end of pipe was as bright as silver; steam roller was there a few days prior to escape being reported; pipe laid in clay." I am told there have been other cases in these districts; but until that reported on March 11, when the pipe was taken out of the ground "quite bright," attention was not directed to the matter as the cases were only considered as ordinary disturbances of service pipes. But these cases of brightly burnished pipes attracted attention and were reported to me shortly after the other case was found. One of the pipes I have here on the table; the other, unfortunately, has been mislaid.

The general experience of an excessively heavy weight passing over mains and pipes is drawn joints and fractured pipes, caused through the pipes being laid in a yielding soil, or in one of varying densities, or over an unequal rocky surface. It is not, I believe, an uncommon opinion that the disturbance of the mains and pipes is confined to the direct downward pressure of the weight—that is to say, that a heavy casting, or traction engine, or a heavy steam roller passing over mains and pipes will affect only those immediately under the weight. But may there not be other disturbances from the same cause not so obvious, being further removed, but still directly traceable to this downward pressure? There must of necessity be a lateral disturbance of the subsoil. In a case under my own observation there were yards of guttering, curb, and concrete pavement forced up along a line parallel with the track of a steam roller about two yards away from the nearest edge of the roller; thus proving, if proof were necessary, in the clearest manner, that there are other disturbing movements than those of the direct downward pressure of the moving weight. The injury then may be more remote, and the cause of a more complex character than is generally assigned to such disturbing influences.

The ultimate effect may be a general and permanent settlement of the plant till a further disturbance of the ground takes place; but there may be (and it is to this that we should direct attention) such an elasticity in the ground and plant, or in the plant alone, that a prejudicial action may be maintained by the ordinary traffic over the road, and so affect the joints of the pipes. In other words, the compression of the ground in which the pipes are laid may not only cause an immediate disturbance of the joints and breakage of the pipes, but may throw such strains upon the plant that there may be a deteriorating action continued, accompanied by a constantly increasing quantity of gas unaccounted for—an increase which might baffle every attempt to discover the cause of the loss, but which may be accounted for by a general deterioration of plant from the vibratory action of a steam roller. If the pipe shown may be taken as a true indication of the otherwise unseen action upon the mains and pipes, the fractured pipes and the drawn joints of mains, though more dangerous, are of little consequence when compared with this action, as they will soon tell their own tale and get repaired. But the other necessitates a constant, careful watchfulness and expense, which, I may say in passing, is not dreamed of by the promoters of electric lighting. Whether such deterioration is going on, and whether it will be continuous, must be a matter of observation. Doubtless, with the repeated rolling of the ground it will become more consolidated, and therefore better able to resist undue action and excessive pressure when so consolidated. A general inspection, repairing, and testing of the plant may again reduce the unaccounted-for gas to a moderate percentage of the make.

Though, in the percentages given, the steam roller injuries are lower than the drainage operations, yet the roller may have helped to swell the latter. However, this fact stands plainly out—that nearly 70 per cent. of the injuries to the distributory plant of a gas undertaking arise from the operations of local authorities; and if there be a still further general deterioration it behoves such authorities to carry on their work with much greater watchfulness than has been sometimes done—to shore, and fill in their drainage trenches with more care; and to use the roller over the ground in the forming of new roads before the pipes are laid, thus avoiding any greater settlement than there must of necessity be. I would also suggest that, in the carriage of excessive heavy weights over the roads—such as a casting drawn by a team of 25 horses—there should be a previous notice given to the local authorities, and the route to be taken decided on and registered. Such a course is justified by the fact that about 16 per cent. of the injuries recorded were caused by this work; and we may fairly assume that a portion of the percentage of “unknown” was from the same cause.

Now what is the remedy—that to which I directed attention some years since, viz., districting and sub-districting a town, as far as it can practically be done, and isolating and testing the mains. Since my paper was read I believe much has been done in this direction. Papers have been read upon the subject abroad; and the latest patent is that of the combination syphon test-box for this purpose, by Mr. Lyon, of Colsham. In the meantime closer attention should be given to the syphons than I believe is generally done. They should be sounded at regular intervals, and the depth of water found entered in a book and compared. Thus the syphons may become indicators of the condition of the mains; and through them the leakage traced to its source. This will not, however, be equally serviceable in all soils. Then there is that beautiful, sensitive and serviceable machine—the governor, which may be made to do excellent service in this work if closely observed, as it will give a very good indication of an increased flow of gas into a district; and for

such work I believe that form which is manipulated by counterbalance weights is the best.

Discussion.

Mr. W. Ford (Stockton) said he was afraid that what little information he could contribute was almost all contained in the paper which Mr. Warner had so carefully prepared. Mr. Warner made no remark as to whether, since steam rollers had come into vogue, he had adopted the ordinary method of laying service pipes and mains deeper. Some years ago they had very great trouble with the steam roller in Stockton; and it necessitated considerable relaying of their pipes. Since then they had had very little trouble. Mr. Warner said that something more than downward pressure was to be attributed to the steam roller. It was natural that the surface might be a movable subject; but still the underground might be quite firm, and the service pipe or main would receive no damage from the steam roller. If ordinary care was exercised in the laying of mains a great amount of trouble and anxiety to gas companies and corporations would be avoided. He was, however, only stating his own experience of the last 14 or 15 years. In consequence of the precautions they had taken in the deepening of their mains and service pipes the leakage, which, before the era of the steam roller (some 16 to 21 years ago), was 24 per cent., had been reduced to an average of 5 per cent. for the last few years. So that he thought, with care, where steam rollers were in existence, gas managers might reduce the leakage, independently of the action of the local authorities.

Mr. Pettigrew, Gas Engineer to the North-Eastern Railway Company, said he found that his services were often pulled out but seldom drawn. The weight actually dragged them out, and broke the mains at the place where they were connected. He had found pipes, 6, 8, 12, 14 and 20 inches in diameter, drawn sufficiently for his hand to be passed between the two; but this was caused by subsidence of the soil. He had constantly to be cutting out and putting pieces into the mains, but not into the services. Their services were laid in pitch boxes, not deep; and they always discovered, where a weight went across a pipe, it was downward action that took place—the pipe was broken, but never drawn.

The President said he was sure they were very much obliged to Mr. Warner for his paper. Four or five years ago he had some experience of the action of the steam roller. Some time previously a new sewer had been laid in the street, below the gas and water mains; and evidently a subsidence took place below these, or rather on one side of them. When the roller was put to work there, it broke first the water and then the gas pipe. The water pipe was 3 inches in diameter, and the gas pipe 2 inches. The water carried the gas down into the sewer below. It was a street something like 500 yards in length, and the gas entered the cottages on one side of the street through the drains. They did not observe the escape in the street; and when they became aware of its existence they could not find it. They had to cut the street at both ends and isolate it, and follow the main until they found the leakage. This was caused by the subsidence of the subsoil, and the steam roller running over the top. The result might have been disastrous; but happily they discovered it before very serious consequences took place. He did not understand Mr. Warner to say that the service was drawn asunder, but that there was a motion, an actual draw, by the passage of the roller over them—a sort of lateral motion. He himself had seen the curb of a street puff up by the passage of a steam roller 3 or 4 feet from it; and in that case there must have been a lateral motion of the soil underneath the surface. He had a 2-foot main laid some little time ago, and the trench was filled up during wet weather. No portion of it was less than 4 feet deep; and yet the pressure of the steam roller lifted the pavement 5 feet away. This must have been a lateral motion. Gas pipes should be laid very carefully. He thought Mr. Warner's paper would be worth perusal, and they would no doubt profit by it.

Mr. Pettigrew said that at the last meeting of the Association he put before the members a pipe modelled to prevent drawing, and he thought it would be a very good thing to design a pipe which, when it moved in a lateral direction would tighten itself.

Mr. Warner showed a service pipe which had been drawn from the socket and burnished by the action it had undergone. He thought the burnishing must have been done by moving backwards and forwards. He exhibited it, he said, just as it was removed from the ground; and it was proof positive that there must have been vibration upon it. This was not the only case. He had one similar to it; and on looking through some pipes on the previous day he saw there were others. It was not simply a breakage; but a breakage first and then a vibration upon it. Alluding to Mr. Ford's remarks, he said it would be almost a matter of impossibility to take up 60, 80 or 100 miles of mains and relay them. But, of course, as mains were relaid, or new ones were being laid, precautions could be taken to place them at a greater depth. As, however,

their President had remarked, this would not meet their case entirely. Though he went down 4 feet, yet there were deeper trenches—sometimes three times that depth—for sewage pipes. It would not avail them to go further down, unless care were taken in filling in the trenches. The nature of the ground had something to do with it, undoubtedly. A surveyor of a Tyne district told him a short time since that he knew of a case where a steam roller sank to below the axle. If this were to happen how could their pipes escape damage? He congratulated Mr. Ford upon his being able to bring his unaccounted-for gas so low. He did not know that it was a general experience; but he himself nearly approached 5 per cent. a few years ago. He, however, found the leakage had been growing year after year since the steam roller began to be used. With reference to this percentage, though it was scarcely the matter under consideration, he might remark that it depended entirely upon how they dealt with it—upon what, for instance, they considered the amount consumed in public lighting. Until they obtained fixed figures for this, he thought they were not able to deal with the percentage except upon broad grounds.

Mr. Ford observed that his decrease had been accomplished under similar conditions to those under which he had 24 per cent. of leakage.

Mr. Warner remarked that there was still the question of whether the quantity had increased or decreased as well as the percentage. He was not altogether clear with regard to Mr. Pettigrew's observations. He thought he showed first that he did not know of any drawing of the joints of pipes.

Mr. Pettigrew said that his remark was that it was the weight—the vertical pressure—which caused a pipe to loosen, not the drawing pressure; that the pressure bent the pipe downwards and generally broke it.

Mr. Warner did not see that, as a rule, the pipes should be broken. It was the joint which gave way. The President's remarks were, of course, above criticism; but he might say that they bore out entirely his own experience in these matters. He thanked the members for their reception of his paper.

Mr. Hall (West Pelton) said he wished to add that he found an efficient method of preventing the drawing of service pipes to be to place (after the connection was made, and the trench filled in to the level of the pipe) several stones alongside the connection, and then when a subsidence took place the pressure came upon the stones, and not upon the pipe. If the place were opened years afterwards there would be a cavity but no fracture. He had found this in numbers of cases. The subsidence did not take place in the solid ground, but where the connection was made.

Gas Engines With Electrical Ignition.

In the report made to the Franklin Institute, by its special delegate to the Paris Exhibition (Mr. Carl Hering) on the electrical exhibits at that exhibition, we find the following respecting gas engines on display that are started by means of electrical ignition:

The ignition of the gases in gas and petroleum engines by an electric spark appears to be coming into use more generally, judging from the large proportion of engines exhibited in which this way is preferred to the gas flame ignition. There were exhibited twenty-one different systems of gas and petroleum engines, counting the various different exhibitors of the Otto engine as one exhibit. Of these, thirteen (or sixty-two per cent.) used electrical ignition, and only eight (or thirty-eight per cent.) used the gas flame ignition.

Historical.—The following abstract regarding the history of electrical ignition is taken from a paper of Mr. Delamère-Deboutteville, read before the Institution of Mechanical Engineers, July 3, 1889. In 1844, John Reynolds used a platinum wire heated by means of a battery. A mechanical contact maker and breaker started and stopped the current at the proper moment. In 1850, Shepherd used an electro-magnetic generator in place of a battery. In 1857, Barsanti and Mattenni used a Bunsen battery, with a de la Rive multiplier, the sparks from which were used. In 1860, Lenoir replaced the de la Rive multiplier by a Rhumkorff induction coil. The primary current passed continually, and the secondary was closed when the spark was required. There was difficulty in timing the spark exactly.

General.—The heated platinum wire is apt to become cooled at the moment of the passage of the gases, and it cannot be timed sharply, besides requiring considerable battery power. It therefore seems to be abandoned. All the engines exhibited used the spark. The chief advantages of the spark over the gas flame, appear to be, its very high temperature, which is of importance, especially when poor gases are used; it is independent of cold or moist air; it reduces the temperature of the valve chest and parts, and thereby facilitates lubrication of those

parts and does away with incrustations there; in some of the systems it can be very definitely timed, which is claimed to be very important as there is said to be a considerable difference in the power if the time of ignition varies one-twentieth of a second. The disadvantages of using electricity in place of the gas flame depend upon the particular system used; in general it introduces something with which the ordinary mechanic is not familiar.

The systems exhibited are here divided for convenience into four classes. All in common use this ignition only, having no means for gas ignition, showing that they can rely entirely on the spark. In all but one, the spark is made to pass in the cylinder, in the other it is in a special chamber. The insulation of the parts entering the cylinder are variously of porcelain, plaster of paris, or asbestos, in order to stand the heat and the mechanical pressure of the explosions.

First System.—In the first system, a battery, generally two or three large Bunsen or bichromate cells, is used with an ordinary Rhumkorff induction coil having a simple hammer vibrator; the vibrator acts all the time while the engine is running, and the spark of the secondary coil is operated by various means. In all of these the spark passes between two *fixed* points in the cylinder. The advantages of this system over some of the others are that there are no moving parts entering the cylinder; that there are numerous sparks generated instead of a single one, as in some of the others; and that the spark can be well timed. The disadvantage is that the vibrator acts all the time, which is bad for the contacts of the vibrator, and consumes battery power continually.

Details.—In the Engine exhibited by E. Rogers (French Section) the secondary circuit is normally open at a sort of switch outside of the cylinder, which is operated by the moving parts of the engine, and is closed the instant the spark is required for the explosion. When the switch is closed the only break in the secondary circuit is in the cylinder, where the sparks are therefore produced. It is evident that no premature explosions can take place.

In the engines of Louis Charon and those of Solomon Freres and Tenting (French Section) the secondary circuit is continually short circuited outside of the cylinder, except the instant when the spark is required. Premature explosions cannot take place unless this short circuiting switch is exceedingly dirty. They used two large cells.

Those of Thomas Powell (French Section) differ essentially from the others, in that the spark passes continually in a spark chamber, which is closed by the slide valve. When ignition is to take place, a port in the slide valve makes this spark chamber communicate with the cylinder, thus igniting the gases. The length of the spark is 1.5 mm., or about one-sixteenth inch. They claim that the instant of ignition can be more accurately and definitely timed by these ports in the slide valve. There is probably more possibility of premature explosions, as in the flame ignition engines, causing it to "sneeze." They use only one cell of two carbon plates in bichromate solution, the zinc being in sulphuric acid in a porous cup.

Second System.—In the second system a battery and induction coil are used as before, but the primary circuit, instead of the secondary, is closed when the spark is required. The vibrator, therefore, acts only while the primary circuit is closed, thus economizing battery power. It has the same advantages as the first system, except that the spark is not so definitely timed, and is not so sure, as it is necessary that the vibrator starts itself and responds promptly; to do this it must be well adjusted, and its contact must be very clean; it is difficult, if at all possible, to clean it while running.

To this class belong the engines of the Societe des Moteurs a Gaz Francais, A. F. Noel (French Section), and of the Societe Anonyme des Moteurs Inexplosibles au Petrole et au Gaz (Belgian Section). In these the primary circuit is operated by a contact piece on the shaft or other moving part, and a brush sliding thereon, usually made adjustable in order to time the spark. The one exhibited by Rouart Freres and Cie (French Section), was a double-cylinder engine, and in addition to the above there was a second contact piece on the revolving shaft connected to the secondary circuit, and having two brushes, the object of which was to switch this secondary circuit alternately to each of the two cylinders. They used only two large one gallon bichromate cells. The frame of the engine was used as a ground return circuit for both the primary and the secondary currents.

Third System.—In the third system a magneto machine is used to generate the spark without an induction coil. The armature of the magneto, usually a simple Siemens H armature, is kept from revolving by a strong spiral spring. For each explosion it is revolved on its shaft through 90° against this spring and allowed to snap back into its normal position, during which rapid return motion it generates a momentary current. An instant after the armature is released, and at the moment

when its current is a maximum, the circuit is broken in the cylinder, producing there a single bright spark. The advantages are that no battery is required, there is no coil with a vibrator to keep in order, and it is always ready to start; as the high rate of rotation necessary to generate the current is produced by a snap movement, no great speed of the engine is required at starting, as would be the case if a dynamo was used in place of a magneto. A disadvantage is that only one spark is produced in place of a number of them as in the other systems, but as it is a much more powerful spark, and quite positive, it does not appear to be an objection. In this system there must be moving parts entering the cylinder to break the circuit there.

The engines of Gotendorf and Cie, and of E. Delahaye (French Section) were of this class. In the latter, the exact time of the spark may be adjusted by a cam movement. The engine of W. C. Horne (British Section) also belongs to this class, it differs from the other two in that the H armature is normally in the stable position into which the magnets would pull it, the spring assisting it to return to the position, while in the other two the normal position is the unstable position, in which it is held against the magnetic pull by the spring, which must, therefore, necessarily be much stronger. The spark is produced between two steel springs in the cylinder, operated by means of a rod passing through a stuffing box. This rod has a rotary motion instead of a longitudinal one, thereby facilitating the construction of the fire-proof stuffing box.

Fourth System.—In the fourth system a dynamo or magneto is turning all the time, generating the current which is broken in the cylinder directly without a Rhumkorff coil. The disadvantages of this system are that in starting the engine, sufficient speed must be produced by hand before the dynamo will generate sufficient current to produce a spark.

In the engine of E. Durand (French Section), a small simple magneto is used generating an alternating current. Both wires are insulated, that is, the frame of the engine is not in circuit. The circuit is broken in the cylinder by a revolving rod, as in the engine of Horne. No self induction coil is used.

In the Baldwin Gas Engine (United States Section) the current is generated by a small shunt-wound dynamo of about one-eighth horse power. It is driven directly from the fly-wheel by a friction pulley, the pressure being produced by its own weight. There are two friction pulleys of different sizes, the smaller one, for high speed, is used only for starting. There is a self induction or spark coil in circuit, and the circuit is closed except when the spark is required. The breaking of the circuit is operated by an insulated pin passing into the cylinder and having a longitudinal motion. It is difficult in this arrangement to keep the contacts in the cylinder clean, especially as the tendency of this particular construction is to destroy its own contact.

Dye's Apparatus for Washing Gas.

On January 28th U. S. Letters Patent (No. 420,378) were granted to Nathaniel C. Dye, of Rutland, Vt., for an improved method and device for washing gas. In his specification the inventor says :

My invention consists of an improved method and a novel apparatus for washing, scrubbing and cooling gas, as will be hereinafter described and specifically claimed.

In the accompanying drawings, Fig. 1 is a vertical central section of

a main gas pipe provided with the improved gas washer, scrubber and cooler; Fig. 2 is a horizontal section of the same; and Figs. 3 and 4 are diagrams of two types of gas generators and purifiers having a main pipe provided with the improved gas washing, scrubbing and cooling apparatus.

The letter A in the drawings represents a main pipe of a gas genera-

tor; B, a gas washer and cooler; G, a gas generator, and C, a gas purifier.

Between the gas generator G and purifier C of a gas works the main pipe A is placed, and it conducts the gas from the former to the latter. Into this pipe A the nozzle portion b of the gas washer and cooler B is secured by means of a screw-thread b' on the said nozzle portion and a corresponding screw-thread a in the pipe A. A prismatic formation b³ on said nozzle portion serves to facilitate the use of a wrench for fastening or unfastening the nozzle portion. The nozzle b³ extends into and slightly beyond the inner surface of the pipe A, and is there provided with a longitudinal slot b⁴, forming a narrow flat orifice, which

terminates at the inner surface of the pipe A. This nozzle portion b is connected by means of pipe or conduit b⁵ with an elevated reservoir B', from which the water is conducted under pressure through said pipe or conduit b⁵ into the nozzle portion b and through the slot b⁴ into the pipe A, and thus a transverse diaphragm or unbroken sheet b⁶ of water is produced, which strikes the whole inner surface of pipe A, and, rebounding, is dashed into spray in the manner described. Through this diaphragm or water-sheet b⁶ and the spray thereof the gas from the generator is forced, and being thus thoroughly mixed with the same is freed by the current and the spray of such impurities as readily unite with water, and it is at the same time cooled down to such a degree that the remaining tar and nearly all the other impurities are precipitated or concentrated, and thereby separated from the gas.

In connection with the invention it is proposed to use lime as a purifier, the slaked lime being placed in trays or sieves within purifier boxes, and the gas, after having been washed, scrubbed and cooled, as herein described, is passed through the lime on its way from the generator to the gasometer.

The pressure necessary for producing a powerful current of water may be secured from a highly elevated reservoir, a force pump, or other suitable means, and this pressure may be varied to suit circumstances. A pressure of about 65 pounds to the square inch has been found to work very satisfactorily. While the pressure at the head or source of the water is 65 pounds to the square inch, there is very little pressure comparatively in the thin sheet of water which stands across the main gas pipe,

and through which the gas passes from the generator to the purifier, for when the water leaves the end of the nozzle it is in a body of only about one-eighth of an inch thick, as seen in the drawings, and runs off as rapidly as the pressure in the nozzle will cause it to flow, and it is immediately carried away with the condensation of the gas vapor through the siphon at the bottom of the pipe, and thus the gas pipe is always free

from water—accumulated water, which would be liable to retard the flow of gas and cause a back pressure. The resistance of the thin sheet of water is not more than sufficient to keep the sheet in a diaphragm form and in slight contact with the inner surface of the pipe, and thus insure the subjection of the entire volume of gas to the washing, scrubbing and cooling action of the cool water.

If desirable, several nozzles *b* may be employed at suitable distances apart, so that the water will flow through several transverse water sheets *b*⁶ in succession, and thus be subjected to a more effective treatment of cleansing and cooling.

In practice it is often found necessary to run in water gas works about 6,000 feet of gas in 20 to 25 minutes through an 8-inch pipe, and the gas leaves the superheater while it is red-hot, or oftentimes at a white heat. The gas in this condition strikes the diaphragm of water, about 5 feet from the superheater, and hence I generally employ two or more, but sometimes only one, diaphragms of water. This depends upon how fast gas is generated in a given sized generator and under a given amount of heat. When the gas strikes the first diaphragm of water, the water strikes every particle of gas vapor, or nearly every particle. Should there be any vapor that has not come in contact with the first diaphragm and spray from it, the second one would take up what escaped from the first, and so on, according to the number of spaced water diaphragms within and along the pipe between the generator and purifier. The solid sheet or sheets of water completely fill the circular space across the pipe to the extent of the thickness of the sheet or sheets, leaving no space for the gas to pass except it passes through the diaphragm or diaphragms of solid water. This operation is different from that of spraying or jetting water upon gas in the pipe, because the gas in the sprinkling method has freedom, in part, to pass between the jets of water, and thus it is not all subjected to the action of the water in its passage to the purifier.

In the water mains of Rutland, where I have introduced my invention, 65 pounds pressure to the square inch being used, I have found one nozzle sufficient; but where the pressure of the water in the water mains is but 25 pounds to the square inch, two or more nozzles might be necessary. All depends, as above stated, upon the amount of gas generated. It is a very convenient arrangement to apply, as I have shown, one or two nozzles immediately between the gas generator and purifier, as the gas can be washed, scrubbed and cooled, and then at once passed directly into the purifier.

It is obvious that if the gas mains be made of squared or any other appropriate form than cylindrical, the same result of forming a complete diaphragm of water across the pipe would be produced if the slit in the end of the nozzle is extended entirely across the nozzle from the inner surface of the pipe on both sides of the nozzle.

Before entering the purifier the gas is relieved of water and tar by means of an escape or drip pipe *a*, provided in the pipe *A*, which for that purpose enters the purifier from below. This drip cup may be in the form of an inverted siphon, forming a gas trap, which allows only tar and water to escape in the manner illustrated. In Fig. 4 I have shown a construction which I have successfully employed. It consists of a generator *G*, superheater *S*, sealing tank *T*, and lime purifier *C*, supplied with water nozzles *b*, between the superheater and sealing tank. It will be readily seen that the sealing tank serves the same purpose as the above-described inverted siphon drip pipe *a*. Before entering the purifier the gas is again relieved of any water and tar precipitated during its passage beyond the bottom of the purifier by means of an inverted siphon drip pipe *a*, as above described. In this apparatus I may also employ one or more nozzles *b* in the pipe *A* between the generator and superheater, and provide in the lowest portion of the pipe a drip pipe *a* as described.

Progress of the Electric Light in Australia.

Mr. E. J. Erskine, writing on this subject in the London *Electrician*, says the first introduction of the electric light into New South Wales was in 1881, when Mr. H. H. Kingsbury, who two years previously had introduced the telephone into this Colony, carried out an installation of arc lamps at the Redfern railway station for the government. At the present time there are upward of 5,000 incandescent and 500 arcs in the colony. In 1883 the Legislative Assembly was lighted by the same firm with incandescent lamps; Edison machines were used with great success, but lately it has been deemed necessary to increase the light, and new machines of the Manchester type have been installed. But it was really in 1887 that the advantages of the electric light were properly recognized. In this year Her Majesty's Theater Company decided to adopt this system of illumination for their new building, and a plant

for 900 lamps was installed, Manchester machines being used. In 1888 Messrs. Harrison and Whiffen appeared in the field as agents for Crompton & Co., and secured the contract for lighting the town of Tamworth, where they installed a plant on the continuous current system, which has given satisfaction in the town. In 1888, also, an impetus was given to the electric lighting business through the opening of a number of skating rinks in which the proprietors desired to have the electric light; but as these installations were nearly all of a temporary nature, the work was not of a character to be encouraged, switches, cut-outs, ampere or voltmeters being conspicuous by their absence. It would be more satisfactory to all parties concerned if the fire underwriters' rules were more stringently enforced; as, although we have so far been very fortunate in Australia, having had no accidents that could be attributed to the electric light, it is more by good luck than by good management; and now that the number of installations is increasing, it is most necessary that every precaution possible to prevent accidents should be taken.

Last year was a busy year in electrical circles in all the Colonies; in Melbourne, on account of the extensions of central stations, and in New South Wales, on account of the number of country boroughs which called for tenders; but perhaps the most important event of the year was the introduction into New South Wales of the first alternating current transformer plant installed by Messrs. Kingsbury & Co. in Young. This plant is on the Thomson-Houston system, and the success has been such that the firm has received the contracts for Penrith and Lambton. It should, however, be mentioned that although this is the first introduction of the alternating current in New South Wales, both the Thomson-Houston and Ganz & Co. have been working the system in Melbourne for some time with great success.

So far as motive power is concerned there appears to be a general leaning towards engines of the semi-portable type, and it is an exception when a plant is erected with separate boilers and engines. The standard of work done by firms in Sydney has been gradually improving during the last few years, and now it has reached a creditable pitch; the installations at the office of the *Daily Telegraph*, and that in the new hotel in Bent street—being the latest addition in Sydney—are in every respect highly satisfactory; also the temporary lighting of the Centennial Hall with arc lamps reflects great credit on the contractors. Perhaps the first thing that would strike an electrician coming here and going round the different installations would be the deplorable lack of ventilation and space in the engine and dynamo room, with one or two exceptions—a state of things highly detrimental to efficient working of the plant. Architects might be forgiven for not knowing that ventilation is a great advantage in a dynamo room from a commercial standpoint; but they should not lose sight of the fact that the attendant requires air to make it possible for him to look after his machinery. In one case the attendant is nearly suffocated by the fumes from some accumulators. It seems to be the general impression that any hole is good enough for electrical machinery.

Up to the present there is no central station lighting in Sydney; whereas in Melbourne there is a considerable amount of lighting done from the stations in operation, and there are other stations in contemplation. The reason for this difference in progress between the two largest cities in the Southern hemisphere may perhaps be accounted for by the fact that in Sydney the Gas Company has a monopoly of the lighting; and although two bills have at different times been introduced to enable companies to erect central stations and supply light and power, they have never got beyond the first stages, and have then been allowed to lapse. In Brisbane there has lately been a considerable movement toward the electric light; and central stations will, I think, shortly be an accomplished fact in the Northern Colony. If so, Sydney will have been left behind by all her neighbors, as at present there are no rumors of a central station here. However, the New South Wales country municipalities are, to a certain extent, making up for the indifference shown by the metropolis, as at the present time there are two of the interior towns lighted; in three others the work is in progress, and seven others are either considering or calling for tenders. Under these circumstances it must be admitted that the outlook is very promising.

So far as traction is concerned, very little has been done in any of the colonies. Some time ago a trial was made of a car on the Julien principle, but, although the trial was successful, nothing more was heard of it. At the present moment an electric tramway is talked of for Balmain, a suburb of Sydney, and I believe it is to be on the Sprague system. Victoria once more takes the lead in the matter of electrical tramways, having one at Box Hill which is giving satisfaction, although I hear the rails through which the return is made are not all that could be desired, the joints being very primitive, and therefore the resistance very great.

There is one matter that is doing a considerable amount of damage to the electrical industry. I refer to the exaggerated reports that appear from time to time in the daily papers, copied from home papers, of the dangers of electric lighting in general, and of overhead wires in particular. Many persons in the country districts reading these articles immediately imagine that the introduction of the electric light is nothing more or less than the introduction of a new kind of plague.

The subject perhaps most under consideration here at present in the country municipalities is whether arc or incandescent lighting should be adopted for street lighting. The great argument relied on by the advocates of arc lighting is, that whereas it requires 500-horse power to obtain 100,000-candle power with incandescent lamps, the same number of candle power would be obtained with 50-horse power with arc lamps. Of course this is absurd; but they will not understand that the two systems cannot be compared by their nominal candle power. So far the five municipalities who have decided on the electric light have adopted the incandescent with good results, and it certainly hardly seems necessary in towns of 6,000 inhabitants to go to an enormous expense of lighting the town with arc lamps, the night traffic being quite insignificant.

In Victoria the railway authorities are turning their attention to lighting their trains by electricity, and once more the younger Colony will be ahead of New South Wales, as the system now in vogue here is an elaborate system of gas illumination, the installing of which involved a large outlay; and it is, therefore, not probable that the authorities will, for some time, at any rate, consider the question of electric lighting, which would necessarily entail another large expenditure.

The prospects of electric lighting in the other Colonies, viz., New Zealand and Tasmania, should be very good, the abundance of water power which is at the disposal of engineers giving every opportunity for the electric light to compete with any other system of illumination.

The Identity of Light and Electric Radiation.

According to the *Gas World*, during the past couple of years a very remarkable series of investigations has been carried on by Prof. Hertz, of Berlin, on the above subject. The phenomena of induction—an object at a distance becoming electrified across the intervening space through the influence of a charged body—are very well known, and are, indeed, quite familiar; and Clerk Maxwell showed, 25 years ago, that this action is not, as gravitation appears to be, instantaneously propagated throughout space, but travels with a definite velocity; and he went on to measure this velocity by methods with which we need not concern ourselves here, but which brought out the startling result that the velocity of propagation of electric induction is the same, at least within one per cent. or so, as the velocity of light. On the other hand, it is known that heat, light, and the ultra-violet radiation present us with a series of ether waves, the length of which ranges from $\frac{1}{1000000}$ to $\frac{1}{100000000}$ inch. But there ought to be circumstances under which less frequent waves than these—waves of greater length—would be formed; and if they were formed they would obey the same wave-motion laws as are followed in the phenomena of light, radiant light, and actinic radiation. Up to Hertz's researches, however, these longer ether-waves had not been observed, though Clerk Maxwell's result afforded a very emphatic hint in what direction to look for them. Hertz has found them; and by so doing he has added another to the links which bind the various parts of physical science into one general science of matter and energy. Lecturing lately in Berlin, Hertz gave an account of some of his experiments; and we propose to give our readers a short sketch of the interesting results at which he has arrived.

After overcoming some considerable preliminary difficulties in realizing the results which he foresaw, Hertz succeeded in arranging two conductors so that a continuous spark jumped across the 0.12-inch space between them, and in producing, in a similar gap between two wires, a spark due to induction. This secondary spark was sometimes increased by putting a reflecting wall of metal or other conducting material behind the primary spark; but it was sometimes diminished and brought to naught; and the maximum spark was produced when the reflecting wall was at about 6.6 or 19.8 inches behind, the minimum when it was at about 13.2 inches; whence it followed that the phenomena of wave interference were in play, and the wave length was about 26.4 inches. By the use of a zinc mirror, of parabolic form and large size, with the primary spark at its focus, the reflection was rendered more manifest; and by means of such a mirror and an opposite reflecting metallic plate, as many as four model points can be obtained in the axis of the mirror. At each of these there is no effect on the secondary wires when there placed, and midway between them the spark-inducing action is at its maximum. The wave length being 26.4 inches, the number of com-

plete waves must be (taking the velocity to be the same as that of light) $\frac{1}{2}$ thousand millions per second—very much less frequent than the slowest heat wave yet observed (20 million millions per second). In wires the wave length appears to be only 23.2 inches; somewhat less than in air. These phenomena only occurred in the axis of the mirror, just as with light, and Hertz felt justified in speaking of electric radiation.

But then, having got so far, he proceeded to see whether this electric radiation was subject to the ordinary well known optical laws.

He first tried to produce shadows, and found that with a metallic screen of zinc, tinfoil, or even gilt paper, the radiation could be obstructed; but that it traversed insulators, such as a wooden door, which are therefore transparent to it. There were phenomena pointing towards diffraction; there was no sharp shadow; indeed, there could not have been, any more than sound waves of the same length (about B in the treble clef) could produce a sharp shadow on a small screen.

The next step is a decidedly astonishing one—namely, the discovery of the polarisation of the electric radiation. The conductors producing the primary spark were arranged parallel to one another and vertical; then the throbs in the conductors were vertical; the throbs in the primary spark were vertical; and hence the radiation waves were up and down ones. Keeping that in view, the mirror may be so shaped that two such mirrors will, in the crossed positions, act like a polariser and an analyser in polarised light; and a piece of tourmaline, to be placed between these "crossed prisms" so as to restore some light, may be imitated by means of a wooden framework over which are stretched parallel wires. Just as in the optical phenomena light is seen to pass through or to be shut off, so here the waves were either allowed to pass and produce the secondary spark, or else were cut off while the secondary spark disappeared. Hertz concludes from some other phenomena that, not only is there an electric disturbance in the vertical plane in the case supposed, and at right angles to the ray, but that there is also at right angles to the electric undulation, and also to the ray, a magnetic periodic disturbance; which is exactly a somewhat unintelligible phenomena predicted by Clerk Maxwell in ordinary light.

After polarisation, reflexion is easy to understand. We have already seen phenomena of reflection in this series of experiments; Hertz has established the fact that the law of equality of the angles of incidence and reflexion is obeyed by conducting mirrors.

Refraction, too, may be rendered manifest by the use of a huge prism of hard pitch, which is transparent to the waves, but refracts them as if they were light waves passed through a prism whose refractive index is 1.69; the optical refractive index of bodies of this class is between 1.5 and 1.6; but this divergence is not great, when regard is had to the experimental difficulties and the crudity of the material employed.

There is about all this a simplicity and directness which give it high rank as an experimental research.

Spontaneous Combustion in Coal Ships.

[Read by Prof. Vivian Lewes at a meeting of the English Institution of Naval Architects.]

The author first referred to the Royal Commission of 1875, and stated that in the nine years following the report 57 coal laden vessels were known to have been lost from the spontaneous ignition of their cargoes, while 328 were missing from unknown causes. It is said that the increase of steam pressure and consequent increase of temperature has made spontaneous ignition of coal cargoes more likely to occur. The paper next dwelt with the composition of coal, pointing out that its volatile constituents or hydrocarbons consist essentially of compounds containing carbon and hydrogen, together with a little oxygen and nitrogen. The ash which is left after the coal is burnt consists chiefly of sulphate of lime or gypsum, silica, and alumina, whilst in nearly all coal is to be found iron disulphide, known as coal brasses or pyrites. This has been formed by the gradual reduction of the sulphates by carbonaceous matter in the presence of iron salts. Of these constituents of coal the only ones which play no part in spontaneous heating are the mineral constituents other than the pyrites.

Carbon possesses to an extraordinary degree the power of attracting and condensing gases upon its surface, this power varying with the state of division and density of the particular form of carbon used. The absorptive power of newly-won coal varies, but the least absorbent will take up $1\frac{1}{2}$ times its own volume of oxygen, whilst in some coals more than three times their volume of the gas is absorbed. This absorption is very rapid at first, but gradually decreases, and is influenced very much by temperature. The absorption is at first purely mechanical, and itself causes a rise of temperature, and the rate varies with the amount of sur-

face exposed, so that when coal or charcoal is finely powdered, absorption becomes more rapid, and rise of temperature at once takes place. If charcoal is kept for a day after it has been made, out of contact with air, and is then ground down into a powder, it will frequently fire after exposure to air for thirty-eight hours; while a heap of charcoal powder, of 100 bushels or more, will always ignite. In the case of coal, this rise in temperature all tends to increase the rate of the action which is going on; but is rarely sufficient to bring about spontaneous ignition, only about one-third the amount of oxygen being absorbed by coal that is taken up by charcoal, while the fact of the action being much slower, tends to prevent the temperature reaching the high ignition point of the coal. Air-dry coal absorbs oxygen more quickly than wet coal.

The action of the bituminous constituents is next considered in the paper. All coal contains a certain percentage of hydrogen, which is in combination with some of the carbon, and also with the nitrogen and oxygen, and forms with them the volatile matter in the coal, and the amount present in this condition varies very largely, being very small in anthracite and very great in cannel and shale. When the carbon of the coal absorbs oxygen, the compressed gas becomes very chemically active, and very soon commences to combine with the carbon and hydrogen of the bituminous portions, converting them into carbon dioxide and water vapor. This chemical activity increases rapidly with rise of temperature, so that the heat generated by the absorption of the oxygen causes it to rapidly enter into chemical combination, which is accompanied by evolution of heat, and this further rise of temperature again increases rapidity of oxidation, so that a steady rise of temperature is set up. This taking place in the centre of a heap of small coal, which, from the air and other gases inclosed in its interstices, is an admirable non-conductor of heat, will often cause such heating of the mass that if air can percolate slowly into the heap in sufficient quantity to supply the necessary percentage of oxygen for the continuance of the action, the igniting point of the coal will be soon reached.

The action of pyrites is next considered by the author. It is found in coal in several different forms, sometimes as a dark powder distributed throughout the mass, or in larger quantities forming thin golden-looking layers. Sometimes it occurs as large masses and veins, often 1 in. to 2 in. in thickness, but these masses rarely find their way into the screened coal for shipment. If the air is dry the pyrites undergo but little change at ordinary temperatures; but in moist air they rapidly oxidize when in a finely divided condition, the first action being the formation of ferrous sulphate and sulphur dioxide, together with the liberation of sulphur, the relative amounts of the two latter being regulated by the temperature and the supply of air, whilst longer contact with moist air converts the ferrous sulphate into a basic ferric sulphate generally termed "misy." It is during this process of oxidation that the heat supposed to cause the ignition is evolved. But when it is considered that some of the coals most prone to spontaneous combustion contain only eight-tenths of a per cent. of iron pyrites, and rarely more than 1½ per cent. the absurdity of imagining this to be the only cause of ignition becomes manifest. If 100 pounds of coal were taken, and the whole of the pyrites in it concentrated in one spot and rapidly oxidized to sulphate, the temperature would barely be raised to 100° C., if all loss of heat could be avoided.

The author had carefully determined the igniting point of various kinds of coal, and found that—

Cannel coal	ignites at 698°	F. = 370° C.
Hartlepool coal	" 766°	F. = 408° C.
Lignite	" 842°	F. = 450° C.
Welsh steam coal	" 870.5°	F. = 477° C.

So that no stretch of imagination could endow the small trace of pyrites scattered through a large mass of coal, and undergoing slow oxidation, with the power of reaching the needful temperature.

Dr. Richters fully realizes this point, and discards the idea of the pyrites doing anything more than adding their mite to the causes which bring about rise of temperature. In this, however, Professor Lewes thinks he is mistaken, his (Prof. Lewes') experiments pointing to the fact that the pyrites may increase the liability to ignition when present in large quantities, and do so by liberating sulphur under certain conditions. Sulphur has an igniting point of 482° F., or 250° C., so that the presence of free sulphur would lower the ignition point of the coal by considerably over 100° C. Also the pyrites as they become oxidized to ferrous sulphate swell in size, and so tend to split up the coal into small pieces, and by extending a large extent of fresh surface to the air cause energetic chemical action.

On examining the evidence to be obtained as to the conditions under which spontaneous ignition of coal in ships usually takes place, it is found that liability to ignition increases with:

1. The increase in tonnage of cargoes.

Thus, in cargoes of under 500 tons the cases reported amount to a little under ½ per cent. for shipments out of Europe; from 500 to 1,000 tons, to over 1 per cent.; from 1,000 to 1,500 tons, to 3.5 per cent.; 1,500 to 2,000 tons, to 4.5 per cent.; and over 2,000 tons, to no less than 9 per cent.

a. The larger the cargo the more non-conducting material will there be between the spot at which heating is taking place and the cooling influence of the outer air.

b. The larger the cargo the greater will be the breaking down action of the impact of coal coming down the shoot upon the portions first loaded into the ship, and the larger, therefore, the fresh surface exposed to the action of the air.

2. The ports to which shipments are made; 26,631 shipments to European ports in 1873 only resulting in 10 casualties, whilst 4,485 shipments to Asia, Africa, and America gave no less than 60.

This result is partly due to the length of time the cargo is in the vessel, but a far more active cause is the increase in the action brought about by the increase of temperature in the tropics.

3. The kind of coal of which the cargo consists. The author is of opinion that East Coast coal is more dangerous than South Wales coal; but so much depends on the amount of small coal present that a well-loaded cargo of any coal would be safer than a cargo of Welsh steam coal in which a quantity of dust had been produced during loading. The idea that the percentage of pyrites present is any indication of the liability to spontaneous combustion must be entirely discarded, as experiment shows that many coals poor in pyrites frequently ignite, whilst others rich in them are perfectly safe.

A much surer guide is to be found in the quantity of moisture present in an air-dried sample of coal, which is a sure index to the absorptive power; the higher the amount of moisture held by the coal after exposure for some time to dry air, the greater will be its power of absorption for oxygen, and the greater, therefore, its liability to spontaneous heating and ignition.

4. The size of the coal; small coal being much more liable to spontaneous ignition than large, on account of the increased surface exposed.

5. Shipping coals rich in pyrites whilst wet; which increases the rapidity of disintegration.

6. Ventilation of the cargo. The so called ventilation which has from time to time been introduced into coal ships is undoubtedly, the author says, one of the most prolific causes of spontaneous ignition. For ventilation to do any good, cool air would have to sweep continuously and freely through every part of the cargo (a condition impossible to attain), whilst anything short of that only increases the danger, the ordinary methods of ventilation supplying just about the right amount of air to create the maximum amount of heating. The reason of this is clear. A steam coal absorbs about twice its volume of oxygen, and takes about 10 days to do it under favorable conditions; and it is this oxygen which in the next phase of the action enters into chemical combination and causes the serious heating.

7. Rise in temperature in steam colliers due to the introduction of triple expansion engines and high-pressure boilers. It has been fully pointed out that anything which tends to increase the initial temperature increases the rapidity of chemical action. The average increase of temperature in the stokehold in two of the Indian troopers from the use of the triple expansion engines was found to be about 5°.

Having discussed the chemical and physical conditions which lead to "spontaneous ignition," the author proceeds to formulate precautions.

The coal should be large, and it is better if free from pyrites. When air-dried it should not contain more than 3 per cent. of moisture.

No coal should be shipped to distant ports until at least a month has elapsed since it was brought to the surface at the pit's mouth. Every precaution should be taken to prevent breaking up the coal whilst being taken on board, and on no account must any accumulation of fine coal be allowed under the hatchways. When possible the coal should be shipped dry.

The coal compartments should be made gas-tight, as far as the bulkheads separating them from the rest of the ship is concerned. When the coal has all been taken in, it should be battened down, and the hatches should not be again opened until the vessel reaches her destination, the only ventilation allowable being a 2-inch pipe just inserted into the crown of each coal compartment, and led 12 feet up the nearest mast, the top being left open. This would be quite sufficient to allow free egress to any gases evolved by the coals, but would not allow undue access of air. The author next proceeded to describe an automatic alarm apparatus he had devised for indicating when the temperature in a cargo of coal had risen to a dangerous extent. It consists of a long bulb of

glass, containing mercury, and has an insulated wire inserted into the quicksilver, and making contact with it, whilst the stem attached to the bulb has a second wire in it, so arranged that when a rise of temperature causes expansion of the mercury, in rising in the tube it makes contact, and the wires from these tubes are in connection with an electric bell, index board, and battery in the captain's room. The author also describes an arrangement of flasks containing liquid carbonic acid gas which he proposed to distribute in the coal cargo. These flasks would be closed by an alloy, which would fuse at 200° F. In this way the gas would be liberated upon the coal becoming heated to a dangerous extent, and the intense cold produced by the expansion of the liquid into gas would cool down the coal to a safe temperature.

When once coal in a cargo has fired, pumping in water is of practically no use, as the fire is, as a rule, near the bottom of the mass of coal, and the flow of the water is so impeded, that in percolating through the interstices of the heated coal, it is converted into steam before it can reach the seat of combustion. The most effective way to apply water would be to have four 3-inch pipes laid along the floor of the coal compartments, about 6 feet apart, these tubes having a $\frac{1}{4}$ -inch hole bored in the upper side every foot or so, and each pair of pipes coming through the bulkhead, and connecting on to two 6-inch pipes passing through the side of the vessel, the sea water being prevented from entering by means of screw valves. As soon as the alarm thermometer gave notice that heating had reached a dangerous point, these valves could be opened and the lower portion of the cargo drenched with salt water. This, evaporating rapidly, would give large volumes of water vapor, which, passing up through the heated coal, would lower its temperature. It would be found beneficial to dress the coals with a little tar or tar oil, which would close the pores and to a great extent prevent oxidation.

The discussion on Professor Lewes's paper was commenced by Dr. Elgar, who referred to a paper he read on "Losses at Sea" at the Liverpool meeting of the Institution in 1886. In that paper he had pointed out that the number of lives lost in coal-laden vessels, of over 300 tons, during the period of 1881 to 1883, was more than one-third of the total number lost in all the foundered and missing ships. The author stated in his paper that: "In the nine years immediately following the report of the Royal Commission on Spontaneous Ignition of Coal Cargoes, viz., 1875 to 1883, 57 coal laden vessels were known to have been lost from spontaneous ignition of their cargoes, while during the same period 328 were missing from unknown causes, a large percentage of these losses being undoubtedly due to the same cause; and these again, form but a very small percentage of the cases in which the cargoes have heated and fired, but in which the vessels have been saved."

The speaker pointed out, with regard to the 328 vessels thus lost that there were other dangers attending coal cargoes besides spontaneous combustion, such as explosions of coal gas, shifting of cargo, collision, etc. From the paper he read at Liverpool, it would be seen that out of all the known losses registered during three years, 23 only were due to spontaneous combustion of coal, and of these 22 were sailing vessels, and only one a steamer. The speaker pointed out that many of the sailing ships thus lost were built of wood, and that wooden ships could not be kept dry, and he asked if the wet would not tend to generate heat in a coal cargo. Out of 86 coal laden vessels reported as foundered and missing, 33 were steamers and 24 of these went down with all hands. The remaining 9 were lost by springing leaks at sea or by shifting of cargo and taking in water through the deck openings. Sixteen of the remainder were iron sailing ships, and of these 11 went down with all hands, and 3 were lost through shifting of cargo. There were also 34 wood and 3 composite vessels. Dr. Elgar further pointed out that the firing of coal cargoes was not often the cause of loss of a ship or of the lives of the crew, notwithstanding the imminent peril in which ships are often placed in consequence. It took a considerable time for the fire to fully develop itself, and it appeared to be generally possible to get the ship into port. All ships registered in the United States were obliged by law to have steam pipes fitted throughout the holds for extinguishing fire, and the speaker was of opinion that some similar arrangement could be used with advantage in coal laden vessels.

CORNING, this State, is to have public electric lighting, the Mayor having been instructed to close a contract with the Corning Gas Company, under which the corporation is to maintain 50 arcs (1,200-candle power), to burn all night, and to be paid for at the rate of \$100 each per annum. The contract is to last for 5 years, and the Company agrees to have the system in operation on July 1st.

ITEMS OF INTEREST FROM VARIOUS LOCALITIES.

MR. J. D. HIGGINS, Superintendent of the Rome (N. Y.) Gas Light Company, has completed the betterments to that plant, and the result is apparent at every gas burner tip in the city. He planned the scheme carefully and carried it out with dispatch.

AT the annual meeting of the South Side Gas Company, of Pittsburgh, Pa., the following officers were elected: President, George Trautman; Secretary, W. H. Aldred; Treasurer, W. L. Elkins, Jr.; Directors, George Trautman, W. H. Aldred, Robert Brown, M. Maloney, Geo. W. Elkins, Joseph Stewart, Dr. John M. Dixon, Joseph G. Walters and R. V. Messler.

MR. LEON APPERT not long since described before the Societe d'Encouragement (France) a method for manufacturing glass pipes of large size for the distribution of gases, liquids, etc., and claimed that under his system the mains could be manufactured at a fairly low cost. The advantages claimed for glass pipes in this connection are non-porosity and negative electric conducting property. Again, the smoothness and non-porous character of the material enable the pipes to be cleaned easily. The weight of the glass pipes, too, is not so great as that of cast or wrought iron pipes.

ACCORDING to the Burlington *Hawkeye*, from which paper the following particulars are taken, it is a settled fact that Burlington, Ia., is to have a fuel gas company. Continuing, our authority says: "That was settled on the 5th inst., when a body of influential citizens met at the parlors of the Commercial Club and associated themselves together and signed the articles of incorporation of the new Company. The latter will be known as the Citizens Fuel Gas and Lighting Company, of Burlington, Ia., and its object the manufacture and sale of gas for power, fuel, lighting and other domestic purposes to the citizens of this city and vicinity. For this purpose it shall have power to acquire, receive and hold from the city such franchises, charters and rights as may be agreed upon, including the right to occupy the streets and alleys and public grounds of the city for the laying down of street mains and the erection of public lamps; also to hold and acquire the necessary real estate, and generally to do and perform everything necessary to be done in order to properly and successfully establish, carry on, conduct and maintain the business proposed. The life of the Company began May 5th, and is to continue for 20 years. The authorized capital stock is \$300,000, and the Company may commence business when \$100,000 is subscribed. After commencing business new stock may be subscribed only as authorized by vote of the shareholders. Shares are of the value of \$100. The Company is under the control and management of a Board of Directors, to be 5 in number. The officers will consist of a President, Vice President, Secretary and Treasurer. The annual meetings are to be held on the second Wednesday of January in each year. The highest indebtedness shall not exceed two-thirds of the capital stock, and the private property of the stockholders shall be exempt from corporate liabilities. The incorporators are W. D. Gilbert, M. A. Johnson, Chris. Mathes, Chris. Starker, James W. Smither, Chris. Geyer, D. D. Robinson, R. M. Raab, T. W. Barhydt and Philip M. Crapo. These names are a satisfactory assurance that the new Company is on a solid foundation and in the hands of men who will do all in their power to make the project a success. Mr. Branch, representing the Fahnehjelm Company, of Chicago, has been in the city in consultation with the present incorporators, and to him is due in great measure the success of the enterprise. This Company has offered entirely advantageous terms and has done everything possible to assure the members of the Burlington Company of the practicability and economy of the Fahnehjelm system. A petition was presented to the Council last night by Alderman Epstein setting forth the fact that the Company had been formed in answer to the popular demand for a cheaper illuminant, and that the Burlington Gas Light Company had declared they could not furnish their product at lower prices than now received. They, therefore, asked that a Committee of the Council be appointed to confer with the Fuel Gas Company for the purpose of determining what franchise, contracts, rights or other privileges could be granted the new Company. The committee appointed consists of Messrs. Epstein, Mercer and Bonn, who may be depended upon to make every reasonable concession to the new Company. It is the expectation that a franchise will be asked for at the next regular meeting of the Council. We believe but few realize fully the significance of the step taken by the Fuel Gas Company. Not only will the cost of gas for fuel and illumination be cut in halves, which will effect a large saving to the consumer, but manufacturers will be attracted to a place

where they can obtain such a low priced, pure and convenient fuel. It is a matter upon which the city as a whole may well congratulate itself not only for the direct benefits to be derived, but as an evidence of the enterprise and prosperity of her citizens. This is a trump card, which commercial agent Merrill will not fail to play to advantage in his approaching onslaught on the eastern manufacturers. No one is more delighted over the result than Mr. Merrill. He has labored assiduously to bring it about, and is now planning how to make use of it to further other interests. We welcome the new Company, and predict for it a brilliant and prosperous career." All of which is submitted as evidence that it is easy to gull some folks, even though the latter be engaged as newspaper agents in promoting the "best interests of an enterprising city!" The delightful childishness of the Hawkeyed Man, in respect at least to the blessings disguised in the shape of opposition gas charters, is simply touching. The old Company that knows to a dot the capacity for gas absorption of the city, cannot sell gas at anything like the figures that new hands to the business in the district are prepared to dispose of it when "they are ready," etc. Mr. Branch, we are told, "has done everything possible to assure the members of the (new) Burlington Company of the practicability and economy of the Fahnehjelm system. "Well, why could not Mr. Branch have used his powers of persuasion on the old Company, that was already in the field." Perhaps this might be answered in the remark that the old Company already knew the flimsiness of the wares that Mr. Branch had for sale; again, that Mr. Branch thought with good reason he would have better success with "green enthusiasts" than with seasoned operators. The long and short of it is that Burlington is to be appealed to to support a set of schemers, who have, however, so far not been very successful in the matter of "finishing" their dupes. In taking leave for the present of this case we must say we are one with our *Hawkeye* cotemporary in his belief that "but few realize fully the significance of the step taken," etc.; they will, however, get a better appreciation of the step and its tendency at some future time, say, for instance, when the final settlement is made in the adjustment between the conflicting capitalists—always providing that the Fuel Gas Company will assume other shape than that of an enterprise on paper.

MR. W. W. PRICHARD, of the Ironton (Ohio) Gas Company, writing under date of the 8th inst., says that there is nothing either new or strange in the gas business in his locality. Business there, however, is good, with a satisfactory increase over last year.

DISPATCHES from Peoria, Ills., say that Governor Hill, of New York, has granted the requisition asked for in the case of Lafayette Cole, who is charged with absconding with \$6,000 of the moneys of the Peoria Gas Light Company, of which corporation he was Secretary and Treasurer. Cole, after a preliminary hearing, was admitted to bail in \$7,000.

AT the annual meeting of the stockholders of the Cincinnati (Ohio) Gas Light and Coke Company the only change made in the former Board of Directors was the selection of Samuel J. Broadwell to fill the vacancy occasioned by the death of T. D. Lincoln.

THE proprietors of the Woodstock (Vt.) Gas Company have at last determined to rearrange and improve their distributing system.

"THE stockholders of the Perth Amboy (N. J.) Gas Light Company held their annual meeting on the afternoon of the 5th inst., and the following gentlemen were in attendance: Patrick Connery, J. Kean, Jr., U. B. Watson, Wm. Hall, Geo. A. Seaman, N. C. J. English, David Hayes, J. L. Kearney, W. H. McCormick, Wm. Ahrens and M. A. Brown. After the reading of the annual reports, the first five on the above list were nominated and elected Directors for one year. At a subsequent meeting of the Directors Mr. Connery was elected President, and Mr. Hall Secretary and Treasurer. Messrs. Watson and Seaman were instructed to consider and report on the advisability of engaging a Superintendent. I am pleased to note this determination, even though it is arrived at at a rather late period.—R. T. S."

Mr. A. G. Glasgow, who has been connected with the Kansas City (Mo.) Gas Light and Coke Company for the past two years, has resigned in order to take the General Inspectorship of the United Gas Improvement Company. He is succeeded in Kansas City by Mr. Geo. S. Clarke. A notable incident connected with Mr. Glasgow's departure from Kansas City was his reception at the depot, just before the arrival of the train that was to convey him East, by a deputation of employees from the Gas Company, who handed him a handsome silk umbrella. Mr.

Clarke made the presentation speech, and to say that Mr. Glasgow was surprised over the affair is to put it very mildly.

THE following explains itself: "ST. JOSEPH GAS AND MANUF'G CO., ST. JOSEPH, MO., MAY 5, 1890.—Dear Sirs:—I have this day resigned the position, heretofore held by me in this Company, of Secretary and Treasurer, in order to devote all my attention to my own business in St. Louis, Mo., where I shall hereafter be associated with Mr. John G. McNair, in real estate and loans. I bespeak for my successor, Mr. Jas. O. Starks, the same kindness you have always extended to me in my business relations. Very truly yours, J. H. FARISH." We are sorry to lose Brother Farish from the ranks, and Mr. Starks can always command us.

A SLIGHT fire occurred on the 6th inst., in the generator room of the Jackson (Mich.) Fuel Gas Company's plant. The damage was confined principally to the roof. Loss about \$600.

THE annual meeting of the Metropolitan Gas Light Company, of Elizabeth, N. J., resulted in the following choice of officials: Directors, Chas. G. Francklyn, Richard Irwin, John W. Gordon, W. Lewis Boyle, G. Wredenfield, C. K. Dutton, W. M. Oliver, Jas. S. Green and Henry Mactier; President, Chas. G. Francklyn; Secretary, W. M. Oliver; Treasurer, Wm. F. Van Pelt. The determination was reached to go right on with main extensions, and it was the general opinion of the officials that the Company would be ready to supply gas on July 1st. September 1st would be nearer the mark, we think.

THE mains of the New Britain (Conn.) Gas Company are being extended through Bassett, Division, South Main, Whiting and Maple streets. In fact, from the reports that we have of work of this kind from almost all sections of the country, it would seem as if we were to have a regular boom in the matter of increased sendout.

THE capital stock of the Mansfield (Ohio) Gas Light Company has been increased to \$150,000 from \$90,000.

AT the annual meeting of the Altoona (Pa.) Gas Company, the following officers were chosen: President, John Lloyd; Treasurer, W. D. Couch; Managers, W. H. Wilson, Enoch Lewis, H. C. Dern, T. Blair Patton and R. E. Pettit.

THE Syracuse (N. Y.) Gas Light Company, as an earnest of its disposition to deal in the future as it has in the past with the residents of its city, is out with an announcement that on and after June 1st the gross rate to ordinary consumers will rule at \$1.60 per 1,000 cubic feet, subject to a discount of 20 cents per 1,000 when bills are paid on or before the 15th of the month in which they are presented. The price to the city is to rule at \$1.30 per 1,000. We congratulate the Company and its guiding genius, Mr. A. C. Wood, on this latest proof of good business management.

THE employees of the Peoples Gas Light Company, of Manchester, N. H., have demanded an increase of wages, the increase asked for averaging about 25 cents per day. The proprietors are averse to granting the concession, and the men assert that if their demand is not acceded to a strike will be the result.

MR. CHARLES MONSON, of New Haven, Conn., who died at his home in that city on the 5th inst., at the advanced age of 90, will be remembered by gas men as the inventor of the extension gas fixture. He was a brother of the late Dr. Alfred Monson.

AT the annual meeting of the Bangor (Me.) Gas Company the following Directors were elected: T. U. Coe, F. A. Wilson, A. C. Hamlin, C. P. Stetson and John F. Colby. At the Directors' meeting the following officers were chosen: President, T. U. Coe; Secretary, W. S. Dennett; Clerk and Treasurer, Henry Boardman; Superintendent, A. H. Parker. The Company prospers despite the attempted competition of electric lighting.

THE "small boy" and the larger hoodlum in the Wollaston district of the Quincy (Mass.) Gas Company possess a decided antipathy to glass-encased gas lanterns, for the breakage to the latter is simply enormous. The Company, however, must be to blame for this state of affairs, since it could easily under the law bring the offenders to their senses. The Public Statutes, chap. 203, sec. 76, provide that "whoever wilfully or maliciously extinguishes a lamp, or breaks, or mutilates, or destroys, or removes a lamp or lamp post erected on a bridge, sidewalk, street, high-

way, court or passage, shall be punished by imprisonment in the jail not exceeding 6 months, or by a fine not exceeding \$50."

THE Pacific Gas Engine Company has been incorporated at San Francisco, Cal., by Messrs. Wm. G. Barrett, C. L. Barrett, E. C. Bartlett, W. A. Cavanaugh and John L. Boone. It is capitalized in \$100,000.

BECAUSE of the fall of an elevator at the Potrero Station of the San Francisco gas works two employees (Terence Hoey and Edward Kelly) were badly injured. While ascending the elevator, which was raising a heavy load of coal, at a height of 30 feet above the ground, a part of the machinery gave way and the men were thrown to the bottom of the shaft.

AT a meeting of the stockholders of the Peoples Gas and Gaseous Fuel Company, of Harrisburg, Pa., the following Directors were elected: David Flemming, Jr., T. D. Greenawalt, W. T. Hildrup, W. W. Jennings, S. J. M. McCarrell, W. T. Hildrup, Jr., Wm. T. Kirk. The officers chosen were: President, David Flemming, Jr.; Secretary and Treasurer, Geo. R. Flemming.

MR. COSTIGAN brought up recently before the Canadian Parliament another gas inspection amendment act. The bill as at first proposed called for an inspection of gas meters every 5 years; but he explained that he had decided instead of taking this means of increasing the revenue to increase the fees and leave the time of inspection as at present. He asserted that the deficiency in the revenue was about \$30,000. Mr. Jones advised Mr. Costigan to leave the matter alone, as there was a surplus in the treasury, and economy, which did not seem to be a marked virtue in the Department, might be practiced as a means of equalizing revenue and expenditure. Mr. Mitchell indorsed Mr. Jones' view on the ground that this would simply mean a tax upon consumers. As the 5 years' inspection system was to be continued, a mere increase in fees would not lead to an improvement in the accuracy of meters. Means, he thought, should be taken to compel the gas companies that made great dividends on watered stock to supply better gas. Mr. Lister denied that the gas companies in the smaller towns made other than fair dividends, and as this bill seemed a means of harassing the companies, he also advocated leaving the bill over. It was, however, not only read a second time, but was also put through its final stages.

TREASURER RICHARDSON, of the North Adams (Mass.) Gas Company, informs us that he is just completing the new electric annex to the Company's possessions, the buildings for which have been erected close to the generating house of the gas plant. The electric equipment comprises three 45 arc light machines and one 500-light alternating incandescent machine, all of the Thomson-Houston type. A 150-horse power Hazleton boiler is to furnish the power, and the apparatus has been most carefully placed. On May 5th the Company was awarded a contract for the public lighting of North Adams for a period of 3 years, on the basis of 70 arcs, to be paid for at the rate of 30 cents each per night, the lights to burn every night and all night. In the meantime we might remark that Treasurer Richardson does not intend to push electric lighting at the expense of his gas sendout, which continues to increase in gratifying percentage. This leads us to say that Treasurer Richardson is to be congratulated over the fact that the gas sendout in North Adams this year will not be less than 22 millions cubic feet, which is just 5½ times more than the quantity sent out in 1880. The selling rates, also, have been decreased from \$3, in 1880, to \$1.65 to \$1.85 at the present time. The distributing system of the Gas Company will be increased this season by the placing of 1½ miles of 6 and 10-inch pipes.

THE visiting gas man to this city who will have occasion to hunt up the local headquarters of the Goodwin Gas Stove and Meter Company, must bear in mind that Manager Edwards has removed himself and his shingle from 142 Chambers street to No. 113 same street.

WE are indebted to "Observer" for the following, which is from the Manchester *Mirror and American*, of the 10th inst.: "Manchester has been congratulating herself for several months that among all the manufacturing and industrial centers of the country she alone had been spared by the professional agitator and his inevitable accompanist, the prolonged strike. The fond delusion that on account of previous exemption she would escape from any future labor trouble was rudely shattered early this afternoon by the announcement, which spread with the utmost rapidity, that the employees of the Peoples gas works had gone out on a strike. The affair, as is natural in such cases, was grossly exaggerated, and from rumors flying about one would have been led to

believe that the whole of South Manchester had knocked off work. Investigation soon revealed the true condition of things, and although matters at the works are bad enough this afternoon, the state of affairs is much less ominous than was at first given out, and owing to the energetic efforts of Agent W. G. Africa the trouble promises to be tided over with but little, if any, inconvenience to the general public. The history of the strike is as follows: For some time there has been a growing feeling of discontent among the employees of the works over the wages paid by the Company. The men, so one of them informed the newspaper man that investigated the subject, had to work 13 hours per day, and as their duties were both of an arduous and confining nature, it told on their systems to a remarkable extent. Add to this the fact that a portion of their labors had to be performed in the night and a part in the day, practically spoiling the entire 24 hours, the informant stated that the men feel they have a grievance and one that could only be remedied by the addition of at least \$1.75 per week to their pay, and they had accordingly requested Mr. Africa to raise their wages from \$2 to \$2.25 a day. There appears to be some discrepancy about the time set for this raise to go into effect between the statements of the men and that of the Agent; but in any event matters were brought to a head at noon of to-day, by 26 of the employees of the works banking their fires and leaving the establishment in South Manchester to itself. The entire force on duty, with the exception of a few yard hands, are included in the ranks of the strikers, and hence, while their numbers may be small, their importance as a factor in furnishing Manchester's illuminating vapor makes the strike as formidable as many in which larger bands of breadwinners have an interest. Mr. Africa was seen with reference to the situation, and expressed himself in forcible terms as to the attitude of the Company. 'There will be no surrender,' said he; 'not even a compromise. We raised the pay of these employees, when the Peoples Company took charge of the plant, from \$1.75 to \$2, and that is all that we shall pay. We can get men enough to work for these wages that are competent to fill the position.' Mr. Africa further asserted, in reply to inquiries, that the men had applied to him yesterday for the proposed increase, and that on his refusal to grant the raise they had all given a two weeks' notice, which they abruptly terminated this noon, as seen above. With reference to the supply of gas now on hand, Mr. Africa stated that the daily consumption in the city amounted to 240,000 cubic feet, and that the stored supply could be made to last 3 days. He had also at the works at the South End a water gas plant, on the use of which injunction proceedings are now pending. He has telegraphed to Philadelphia and got this injunction raised temporarily, and if he cannot secure men enough to run the coal gas plant within the necessary 3 days, he will put his water gas apparatus into action and furnish the city with gas of that sort until the present difficulty is abated. One man with 2 helpers can, in one-half day, make gas enough to last the public a whole day, so that there does not appear to be much danger of this supply giving out. The above is the situation, with both sides standing firm, at the hour of going to press."

THE bonds of the Grand Forks (N. Dak.) Gas Company have been purchased by Messrs. E. H. Rollins & Sons. The price paid was at the rate of 80 per cent.

THE site for the new gas plant at Florence, Ala., has been selected. It is quite close to the local depot of the Louisville and Nashville Railroad.

THE Central Gas Improvement Company, to manufacture and distribute gas and electricity for lighting and other purposes, has been organized in Chicago by Messrs. Calvin Dickey, G. M. Trowbridge and J. O. Noris. It is capitalized in \$100,000.

GENERAL MANAGER McMILLAN, of the La Crosse (Wis.) Gas Company, is meeting with great success in his plan of introducing gas stoves, large numbers of which are now in use in his city. Being a believer in the efficacy of printer's ink, he has availed himself largely of the columns of the local papers for the purpose of displaying the different styles of cooking and heating stoves, hot water heaters, etc. For instance, half of the front page of the *Republican and Leader* has for some time been devoted to a handsomely illustrated advertisement, in which nine well arranged cuts display as many different styles of cooking and heating devices. Mr. McMillan's plan of booming the stove trade is so unique that we herewith give a summary of it. Stoves to the number of 100 will be virtually given away on the following basis: The purchaser selects the style of stove desired, when the Company will set it in place and properly connect it with gas. The stove will be billed at an agreed-on price, and the connections will be charged for at cost. As soon as the bill is paid the gas will be turned on, whereupon the stove

becomes the property of the consumer. Gas may then be used for any purpose without charge until the quantity so consumed, at \$2 per 1,000 cubic feet, will equal in value the amount advanced for stove and connections, after which bills for gas will be made out at \$1.50 per 1,000, and collected monthly in the usual manner. Surely, that is a liberal proposition.

MESSRS. GEORGE A. BROOKS AND HENRY MCGURRIN have laid before the Council of Norfolk, Neb., the following proposition, which is favorably viewed by the authorities: The contractor to expend \$65,000 in the construction of a gas plant, if the city will agree to contract to take gas for 25 public lamps the first year, 50 the second, 75 the third, and 100 the fourth and fifth years after the completion of the plant.

THE officers of the Roanoke (Va.) Gas and Water Company are: President, F. J. Kimbell; Secretary and Treasurer, H. E. Gerhard; Manager, J. C. Rawn.

MESSRS. W. Z. LARNED, C. A. Du Vivier, W. H. De Forest, George Manley, and Jonathan Bonnel, have given notice as incorporators of the Summit (N. J.) Gas Light Company, the enabling act for which was passed by the Legislature in 1873, that subscription books have been opened, and that subscriptions for the shares will be received to-day at the office of Mr. A. L. De Coster, township of Summit. It is understood that the majority of the stock will be taken by the proprietors of the Citizens Gas Light Company, of Newark, under whose auspices the new plant will be constructed.

Ingenious Expedient in Hydraulic Engineering.

F. S. Pecke, a civil engineer at Watertown, N. Y., lately accomplished in a very simple, cheap and expeditious way what is usually a difficult and expensive operation—the laying of a long line of pipe in deep water. He had occasion to lay nearly 1,000 feet of suction pipe at Rouse's Point. The water was needed for manufacturing purposes, and as it was found that water near the shore was more or less roily and impure, it was necessary to have the inlet a considerable distance out into the lake. He purchased for the purpose a steel pressure pipe of 8-inch diameter, manufactured by the Spiral Weld Tube Company, at East Orange, N. J., and used for couplings cast iron flanges, weighing, with bolts and gaskets, about 65 pounds to the pair. Plugging the end of the first length he pushed it out on the surface of Lake Champlain and connected the second length; pushing this out in turn until the whole line was coupled. It then presented the unusual spectacle of a line of 8 inch pressure pipe, nearly 1,000 feet long, floating with a displacement of only 3½ inches of its diameter. When the requisite length had been connected, the line was towed to position, the plug at the end removed, and the pipe sank easily in 16½ feet of water, without breaking a joint or receiving any injury. No buoys or floats were used in the operation, and no apparatus of any kind. The pipe is now in use as the suction of a steam pump, and gives perfect satisfaction. Work of this kind usually involves the use of expensive and troublesome flexible joints, and Mr. Pecke's ingenious expedient is worthy of record.

Useful Memoranda and Information for Engineers.

Loss of Water by Waste.—Water leaking through a hole just large enough to pass a needle through during 24 hours at a 14-pound pressure would be sufficient to supply a house for the day. The waste through a ¼-inch pipe under the same conditions would be 1,140 gallons.

An experienced inspector says: The most common defects to be found about the engine come from improper working or regulation by the governor, as the journals and bearings of the governor are quickly worn out if not looked after. The governor should be regularly cleaned, washed off and well lubricated. Engineers often think that their pistons and valves are not working to the best advantage, when the fault is really with the governor. Sometimes pistons leak, an effect of unequal and excessive wear. Belts being too tight cause a deal of trouble, a little sag being a good thing for bearings, as they very often get hot because the belts draw too tight.

As to boilers, laminated plates over furnace and bridge wall cause endless trouble, complaints from this outnumbering all others. The next thing to demand notice is deposit, which 90 per cent. of boilers are subject to. This causes bagging, burnt plates, opened seams and rivet checks.

Another bad fault comes from having feed and blow of the boilers at the front end. This allows the back end to become covered with sedi-

ment due to poor circulation. This should never be so. There should always be some means by which the boilers can be thoroughly cleaned and inspected. The man-hole plate in the front head is an excellent thing.

Another great fault in construction is not leaving room enough to clean boilers. Where there is any trouble or labor in getting at the parts the engineer does not give the boiler the attention it requires, and will not clean any more than is actually necessary, but where parts are easily accessible, and there is no trouble in keeping the same in good condition, the engineer will take pride in this part of his work.

Circular bridge walls should be condemned, for the reason that they are of no use and do not add to the combustion. As the fire is perfectly level—the bridge wall should also be level—that part of the shell directly over the bridge wall can be readily examined by the engineer or inspector at any time.

Steam gauge pipes should also have stop-cocks and blow-off cocks, so that the sediment and dirt can be blown out of the gauge pipes, the gauge taken down, tested and replaced while there is steam on the boiler.

Many boilers are injured by having fire lines too high—that is, above the gauge cocks; this will cause cracks, lamination and checks. The metal should not be exposed to fire where there is no water on the opposite side.

After the engineer gets the engine working well and in good order he should not tinker with it, but let him put his screw wrench on the shelf and not take it down until it is actually necessary.

Gas Companies Should Control the Introduction of Gas Stoves.

CHICAGO, ILLS., May 13, 1890.

To the Editor AMERICAN GAS LIGHT JOURNAL:

In answer to numerous inquiries and letters asking my views regarding the above proposition, I thought it best to briefly submit through your JOURNAL, not only my own opinion but such information as I have gathered from gas companies and the fraternity at large, offering the same for what it may be worth. In the past few years, in the way of business, I have visited nearly every gas company in the country, and have done considerable missionary work in the gas stove field by persuading companies to buy out the stock of stoves from local dealers and operate themselves, and I have yet to learn of a single instance where the company failed to make the system a success. I give you a few reasons why gas companies should manage the stove trade.

1st. It is the gas company's interest to increase the day consumption of their product. That means increased profits and larger dividends, as well as the regular and economical working of apparatus, lessening cost of production, wear and tear, repairs, etc.

2d. For a gas stove to work successfully it should be properly connected to the right sized pipes, and necessary instructions imparted how to use it. Adjust the burner to economize the gas and have perfect combustion, and other minor points adequate to satisfy the purchaser. All gas stoves and ranges must be looked after when complaints are made, and it is imperative that they be kept clean. None are better qualified to attend to these details than employees of gas companies, who usually are experts, and have all the facilities. It should be made a part of their duties.

3d. Many companies in view of these considerations are offering very liberal inducements to encourage the consumption of gas as fuel by granting a reduced rate, selling at wholesale price, when used in large quantities; also by selling gas stoves at cost prices, piping them with a separate meter attached free of charge. In some cities the company manufacture their own stoves and rent them out at a low rental by the month. Some operate a stove store detached from their business, and, as before stated, these methods have invariably proven successful. Some recent experience in introducing hotel ranges on a large scale has forcibly impressed the necessity of having expert gas men to see to having stoves and ranges properly set up, kept clean, and educate the novice how to operate them.

The consumer may soon, when that happy millenium arrives, come to the gas office with smiles, and instead of imprecations shower blessings on the gas people as public benefactors, paying his increased gas bill without a murmur; and, of course, we as manufacturers of gas stoves cannot help from cheerfully joining with the public and sing a hosanna of praise to the gas fraternity. Very truly yours, S. S. STRATTON.

THE FUEL GAS AND LIGHT IMPROVEMENT CO.

OF AMERICA.

Owner of the Mackenzie Patents of Dec. 31, 1889, and later dates.

For the United States, England, Russia, France, Germany, Austria, and Canada,

No. 32 Park Place, New York City.

This SYSTEM is an ABSOLUTELY NEW DEPARTURE IN THE MANUFACTURE OF FUEL AND ILLUMINATING GAS. The COST OF GAS IN THE HOLDER by our System is at least THIRTY PER CENT. LESS than that made by any other process of the day. The Gas contains neither SULPHUR nor other impurities, nor is there any resultant LAMPBLACK OR TAR RESIDUUM. The Gas is manufactured WHOLLY from LIQUID HYDROCARBONS, such as Lima, Penn. Crude, and Fuel Oils, Naphtha, etc. Neither PERISHABLE PIPES nor other RETORTS, NOR THEIR EQUIVALENTS, are used.

Neither COAL, COKE, nor any other HARD CARBONS enter into the manufacture or composition of the Gas, thereby requiring LESS LABOR THAN ANY OTHER METHOD. The APPARATUS is extremely SIMPLE, SUBSTANTIAL, and DURABLE.

Works under our system may be CONTINUOUS or ALTERNATING. If alternating, the Nitrogen present will be less than 4½ per cent. If continuous, the limited amount of Nitrogen present is neutralized by Carbon.

One gallon of Lima oil by our process EQUALS ALL THE COAL required for making 1,000 feet of carbureted Water Gas.

LACLEDE FIRE BRICK MANUFACTURING COMPANY,

ST. LOUIS, MO.

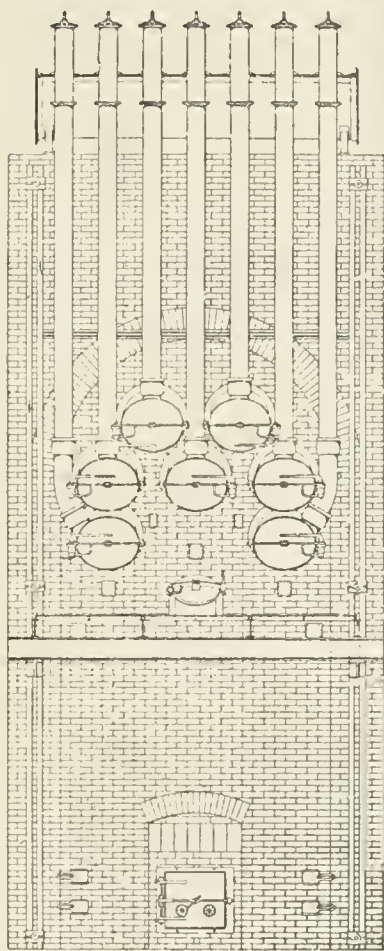

Exclusive Agents in the United States

FOR THE

**Coze System of
Inclined Retorts.**

**IT IS THE COMING BENCH
FOR MAKING COAL GAS.**

*It will Save from 50 to
60 per ct. in Labor.*

WELSBACH SYSTEM OF Incandescent Gas Lighting.

OFFICE, DREXEL BUILDING, PHILA., PA.

At the Fall Session of the Board of Supervisors of Winnebago County, held at the County Court House, Oshkosh, Wis., Nov. 26, 1889, the report submitted by Mr. C. W. Cook, Chairman of the Committee on Public Buildings, recommending the use of the Welsbach Incandescent Gas Burner in the Buildings under their charge, was unanimously adopted, because of the extreme economy in the consumption of Gas and the superior character of the light obtained.

JEWEL GAS STOVES

MANUFACTURED BY

GEORGE M. CLARK & COMPANY,

Nos. 157 & 159 Superior Street, - - - Chicago, Ill.

EVERY CONCEIVABLE SIZE AND STYLE,

CONNELLY & CO.,

SOLE MANUFACTURERS OF THEIR PATENTED SPECIALTIES.

"IRON SPONGE."

Saves money, saves labor, and is the most efficient purifying agent ever offered as a substitute for lime. Now used in every State in the Union, and purifying daily over thirty-five million cubic feet. Should be used in every gas works. Its own saving will pay for it many times over.

AUTOMATIC GOVERNOR.

Has been on the market but three years, and in that time has been introduced more generally than any invention ever designed for use in gas works. Over two hundred of them now in use. Sensitive; reliable; perfectly automatic; reduces leakage; satisfies consumers, and gives great relief to the Manager. No gas works is complete without one of these machines.

STEAM JET EXHAUSTER.

Designed particularly for small works. Combines Exhaust Tube, Steam Governor Gas Compensator, and Bye-Pass Valves in the most compact form possible; occupies but little space; uses very little steam; operated by ordinary workmen; saves formation of carbon in retorts; increases yield 10 to 15 per cent. Specially adapted for mixing air with oil gas. No works too small to use them profitably.

Prices given on all our specialties delivered at any point in the United States. Correspondence solicited.

A. J. DOTY, Supt.

The utility and convenience of the Gas Engine being no longer an open question, it only remains now for intending purchasers to select the BEST. We claim for the CLERK GAS ENGINE that it is equal to any other manufactured as regards steadiness in running, simplicity, and ease of keeping in repair, and that it gives the greatest amount of power for the least money (both in first cost and expense of running) of any engine made. In support of this claim we refer to the test of the Gas Engines made under the direction of the American Institute of New York, in December, 1885, and heretofore published in these columns. These engines are especially adapted for continuous running under heavy loads, and we can refer to Engines which have run 22 hours a day for months at a time!

Made in Sizes of 5, 10, 15, 20, and 25 Horse Power. All Engines Guaranteed for One Year.

ENGINEERS.

GENERAL SALES AGENTS FOR

The Youghiogeny River Coal Company's

OCEAN MINE YOUGHIOGHENY GAS COAL.

HON. W. L. SCOTT, Prest.

M. H. TAYLOR, Vice-Prest.

This Colliery is located at SCOTT HAVEN, PA., in the center of the Youghiogeny Gas Coal District, and produces the ONLY RELIABLE YOUGHIOGHENY COAL for gas purposes. (See Map on p. 87 of this JOURNAL, Feb. 16, '85.)

POINTS OF SHIPMENT,

Locust Point, BALTIMORE.

Pier No. 62, PHILADELPHIA.

Also, SOLE AGENTS for the

**BRECKENRIDGE CANNEL,
OF KENTUCKY.**

Within the past two years we have delivered this Cannel to over ONE HUNDRED COMPANIES IN THIRTY-THREE DIFFERENT STATES, and it is now in use in some of the large Gas Works

On the Continent and in South America,

where it successfully competes with the Australian Shale. It is the ONLY AMERICAN GAS CANNEL of sufficiently high grade to warrant EXPORTATION TO EUROPE AND SOUTH AMERICA, and it is the only economical substitute for OIL OR NAPHTHA. ONE GROSS TON will produce

10,000 Cubic Feet of 75 Candle Gas,	} equal to {	750,000 Candle Feet of Gas, and 26 Bushels of merchantable Coke weighing 900 Pounds
or 12,500 " " 60 " "		
or 15,000 " " 50 " "		

This is the ONLY GAS CANNEL that will produce a REALLY MERCHANTABLE COKE. It can be delivered in parcels of one carload or more to any point in the United States or Canada. Cargo shipments of any size required can be made from NEW YORK, PHILADELPHIA, BALTIMORE, or NEWPORT NEWS. Samples will be sent and particulars of price, etc., forwarded upon application to above address.

We use only the very best materials, and employ the most skilled labor, and by our long experience (36 years) and personal supervision of every detail we feel justified in assuring the public that our goods will give perfect satisfaction. Every Meter emanating from our establishment will bear the State Inspector's BADGE, and will be fully warranted by us. Our Annual and Calendar will be sent to Gas Companies upon application.

GAS INTO POWER,

BY THE

OTTO GAS ENGINE.

GAS POWER.—A Source of Revenue to Gas Companies ready to engage in Electric Lighting, building of Water Works, Electric Street Railways, etc.

Coal for producing Gas is less in amount than that for producing Steam, both being measured on an equal amount of work performed. And, further, with Gas,

50 to 90 per Cent. of Value of Coal is Returned

by sale of Coke and Tar, according to the market value of these products.

Labor for handling fuel is reduced, by its becoming centralized and confined to the gas house, and frequently has not increased after the addition of a power station.

With Gas Power, cost of fuel is strictly limited to the time of use.

MANY VALUABLE
AND RECENT
IMPROVEMENTS.

SIZES,
1-3 to 100
HORSE POWER.

Wherever Gas Companies tried Gas Power with Steam Power together in one Station, the use of Steam was subsequently abandoned or restricted, and Gas Power made to take its place.

Where Gas Companies adopt Gas Power for Electric Plants, Water Works, Sewerage, etc., they not only choose the most economical power for their use, but secure to themselves the numerous advantages of increased production, without increase of expense, and benefit thereby their entire manufacture. They induce consumers, by their example, to abandon Steam for Gas Power, and, by establishing special rates, make

Gas Power the Leading Power of To-Day,
AND SOLVE AT ONCE THE QUESTION OF FUEL GAS.

WITH this issue of the JOURNAL we present to our subscribers an excellent photographic likeness of Mr. Frederic Egner, President-elect of the Western Gas Association, and Chief Engineer of the Laclede Gas Light Company, of St. Louis. Mr. Egner is so well known to the fraternity at large in his capacity as an engineer, and to our readers as an able writer, through the many valuable articles that have been penned by him in our columns, that we deem any biographical notice unnecessary. It is all-sufficient to say that he is a credit to the fraternity in every sense and respect.

AN ADVANCE BUDGET FROM "THREE STARS."

St. Louis, Mo., May 21, 1890.

DEAR JOURNAL:—I cannot do better, I think, in beginning this summary of the first day's proceedings of the Western's 13th annual, than to bluntly say that if the other twelve "first days" were good, this, the "thirteenth first day," is simply "best." Of course, good weather being necessary to the perfect enjoyment of any sort of gathering "when one is away from home," I am glad to say that clear atmospheric conditions are not lacking, although some would not likely complain were the mercury in the temperature measurers less disposed to rise. In other words, 'tis rather hot. The attendance is simply grand, something over 150 having responded to roll call, with the more than likelihood that "another hundred" will report to-morrow. The Eastern delegation is out in great force, and our reception, in respect to heartiness and hospitality, cannot well be transcribed "over the wires." One must have participated in it to appreciate it. Slater, of Providence, modest as ever, despite the result in the legislative arena of his State, smiles benignly over the gas man from Hartford, and Humphreys, of Lawrence, insists on reminding Capt. White, of New York, of how much he is indebted to him for that "lift" at Baltimore last fall, while the Captain has his hands well occupied in the attempt to keep Weber, of New York, from bubbling over in his effervescence. Brother Down, of New York, as usual, is quiet and observant, and Leach, of Taunton, bears his honors—he was elected to Honorary Membership in the Association to-day—with true Bay State dignity. But if I am to say something about all the "Eastern boys" that have reported, your space (perhaps the patience of your readers, too) would be all too small. Forgive me for adding that Turner, of Charleston, looking every inch a gas man, is with us, and I will go on with a word or two about the business proper. President Faben, having had the satisfaction of listening to fully 150 respond to their names at muster roll, had the further pleasure of knowing that by the close of the day no less than 50 new members had been elected; and it goes without saying that Secretary Littleton is almost "puffed up with pride" over the result. So he ought to be, for he worked like a beaver to secure it. The President's address is a most valuable document; we all knew beforehand, however, that it could be nothing else. I will not attempt to foreshadow it here. You will print it later on, when it shall speak for itself, and speak forcibly, too. So far, Chollar's paper on the "Relative Value of Gaseous Fuels" is one of the very best papers that I have ever heard read before any Association, and stamps him as a man of great resource. Some of the deductions are brought
