4. *Fagara Piperita*; *Ash-leaved Fagara*. Leaflets crenate; stem shrubby, scarcely a fathom in height; branches round, prickly, purple; prickles scattered, horizontal; leaves many from the ends of the twigs, unequally pinnate, with about six pairs of leaflets; these are alternate and opposite, subsessile, ovate, emarginate, smooth, half an inch in length; flowers among the leaves terminating, paniced, small, white; capsule wrinkled, one-celled, containing one smooth black seed. The bark, leaves, and fruit, being aromatic, are frequently used in soups instead of spice. The bruised leaves, made into a cataplasm with meal of rice, are laid upon the parts afflicted with rheumatism, and on buboes. The root, which is woody, with a corky yellow bark, and a sharp subaromatic flavour, is warm, diaphoretic, and emmenagogue, and is much esteemed in intermittent fevers, rheumatism, &c.—Native of China, Cochin-china, and Japan.

5. *Fagara Horrida*; *Spiny Fagara*. Leaves pinnate; pinnae ovate-crenate; spines of the branches armed with spinules. This is a small upright tree, smooth in all its parts; branches alternate, striated, flexuose, upright, from ash-coloured purplish, elongated, almost simple.—Native of Japan, where the natives call it *Sai-katfi*.

6. *Fagara Tragodes*; *Prickly-leaved Fagara*. Joints of the pinnae prickly underneath. A shrub, branching, almost erect, five feet in height; prickles in pairs, subulate, recurved, strong, subaxillary, brown, shining; there is one similar, but smaller, on the back of each joint of the leaves; flowers small, axillary, aggregate.—It flowers in February, and is a native of St. Domingo.

7. *Fagara Emarginata*. Leaves pinnate; leaflets ovate, emarginate, veined; racemes terminating, compound; flowers three-stamined. The trunk of this tree is of the size of the human leg, sometimes beset with many short prickles. It rises twenty feet high, and its branches are inclined towards the ground. The wood is white, solid, and odoriferous, with a pretty large pith; flowers white, small, like those of Elder, three-petalled; fruit round, the size of black pepper; seed black, smelling somewhat like Bay-berries. The smoke of this wood in burning is odoriferous, and probably occasioned the fine scent which Columbus perceived near the south-shore of Cuba, on his discovery of that island.—Native of Jamaica, and other West India islands.

8. *Fagara Spinosa*. Leaves pinnate, sessile, ovate, acuminate; both they and the branches spiny underneath; flowers three-stamined.—Native of Jamaica.

9. *Fagara Acuminata*. Leaves pinnate; leaflets entire, elliptic, acuminate, shining, coriaceous; flowers in cymes, three-stamined.—Native of Jamaica.

10. *Fagara Octandra*; *Downy Fagara*. Leaflets tomentose; branches thick, few, long, irregular; leaves pinnate, tomentose on both sides, winged, deciduous, coming out from the ends of the smaller branches with the flowers, or a little after them; racemes many, simple, an inch or an inch and a half long; flowers very small, with white calices, and yellowish corollas; fruit green, the size of peas: when broken, the valves distil drops of balsam. It is an inelegant tree, frequently more than twenty feet in height, abounding in a balsamic glutinous juice, much like that of *Burseria* in its qualities. The wood is very white, and light. The natives of some of the West India islands make saddles of it, in one piece; they have no pad, and only a sheep's-skin thrown over them when they ride. Jacquin calls it *Elaphrium*, from the lightness of the wood.—Native of Curaçao and the adjacent islands, where it flowers in July and August.

Fagonia; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets lanceolate, erect, patulous, very small, deciduous. *Corolla*: petals five, heart-shaped, spreading; claws long, slender, inserted into the calix. *Stamina*: filamenta ten, subulate, erect, longer than the calix; antheræ roundish. *Pistil*: germen five-cornered, superior; style awl-shaped; stigma simple. *Pericarp*: capsule round-acuminate, (five-cornered, according to Gærtner,) five-celled, five-lobed; ten-valved; the cells compressed. *Seeds*: solitary, roundish. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five, cordate. *Capsule*: five-celled, ten-valved, with one seed in each cell.—This genus consists of herbaceous plants, with a woody base. The leaves are either simple or ternate; the stipules in the two first species become thorns. The flowers are solitary and axillary. In order to propagate them, sow the seeds upon a warm border of fresh light earth in autumn, where they are designed to remain, for they do not bear transplanting well: in frosty weather shelter the plants with mats, or some other covering; thin them out to the distance of ten inches or a foot, and keep them clean from weeds. It is, however, a better plan to sow them in pots, and place them under a frame in winter; in the following spring, shake them out of the pots, and plant them in a warm border; thus they will flower early, and ripe seeds may be obtained.—The species are,

1. *Fagonia Cretica*; *Cretan Fagonia*. Thorny: leaflets lanceolate, flat, even. This is a low plant, spreading its branches close to the ground, a foot or more every way. The flowers are solitary, from the forks of the stem, or terminal, of a beautiful purple, with yellow stamina. It flowers in July and August, but, unless the season proves warm, does not ripen seeds in England.—Native of the island of Candia.

2. *Fagonia Arabica*; *Arabian Fagonia*. Thorny: leaflets linear, convex. This is a low plant, with a shrubby stalk, from which come out several weak branches, armed with long thorns; the leaves are thick, narrow, and convex on their under side; the flowers come out as in the first sort.—It was discovered in Arabia by Dr. Shaw. This and the following species seldom flower in the first year; and on that account require shelter, like the first, for two winters.

3. *Fagonia Hispanica*; *Spanish Fagonia*. Without thorns. This differs from the first species, in being smooth; the branches having no thorns; it will also live two years, whereas that is annual.—Native of Spain.

4. *Fagonia Idinca*. Thorny: leaves simple, oval; flowers yellow. Annual.—Grows in Persia.

Fagraea; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, bell-shaped, five-parted; divisions obtuse, incumbent, membranaceous at the end. *Corolla*: one-petalled, funnel-shaped; tube round, gradually widening to the top, long; border twisted, five-parted; divisions oblong, oblique, obtuse, entire, patulous. *Stamina*: filamenta five, filiform, equal, inserted into the tube, shorter than the corolla; antheræ ovate, twin, vertical, convex outwards, four-furrowed, flat on the inner side, easily bipartite. *Pistil*: germen superior; style filiform, the length of the corolla; stigma peltate, orbiculate, flat. *Pericarp*: berry ovate, fleshy, covered with an epidermis, two-celled. *Seeds*: orbiculate, smooth. ESSENTIAL CHARACTER. *Calix*: bell-shaped. *Corolla*: funnel-shaped. *Berry*: two-celled, fleshy. *Seeds*: globular. *Stigma*: peltate.—The only known species is,

1. *Fagraea Zeylanica*. Stem becoming shrubby, erect, somewhat four-cornered, a finger in thickness, and two feet high; leaves fastigiately opposite, petioled, frequent, obovate-oblong, very obtuse, entire, coriaceous, a hand broad, and a span long; petioles semicolumnar, an inch in length; flowers terminating, subumbelled, peduncled; the umbel has about three flowers; peduncles one-flowered, bracted, half an inch in length; bractes opposite, ovate, obtuse.—It is a native of Ceylon, flowering in December and January.

Fagus; a genus of the class Monœcia, order Polyandria.—GENERIC CHARACTER. *Male Flowers*, fixed to a common amentaceous receptacle. *Calix*: perianth one-leafed, bell-shaped, five-cleft. *Corolla*: none. *Stamina*: filamenta many, the length of the calix, setaceous; antheræ oblong. *Female Flowers*, in a bud of the same plant. *Calix*: perianth one-leafed, four-toothed, erect, acute. *Corolla*: none. *Pistil*: germen covered with the calix; styles three, subulate; stigmas simple, reflex. *Pericarp*: capsule (which was the calix) roundish, very large, covered with soft spines, one-celled, two or four valved. *Seeds*: nuts one or two, ovate, three-cornered, three-valved, acuminate. *Observe*. In the third species, or Beech, the male flowers are in a ball; in Chestnut they are in a cylinder. ESSENTIAL CHARACTER. *Male*. *Calix*: five-cleft, bell-shaped. *Corolla*: none. *Stamina*: twelve. *Female*. *Calix*: four-toothed; styles three. *Capsule*: (which was the calix) muricate, four-valved. *Seeds*: two.—The species are,

1. *Fagus Castanea*; *Common Chestnut Tree*. Leaves lanceolate, with acuminate serratures, naked underneath. This tree will grow to a very great size, and spread its branches finely on every side where it has room, but planted closely, will shoot up straight to a great height. The leaves, which are large, and of a lucid green, end in a very long taper point, and the serratures terminate in a tender kind of prickle; they are about four or five inches long, and two wide, somewhat wrinkled, having several transverse veins, prominent on the under surface, and proceeding from a strong midrib. The aments or catkins of male flowers are pendulous at the ends of the branches, very long, and resemble those of Walnut. They have a strong spermatic smell; and the flowers, which are sessile, are collected in remote little balls. The proportion of male flowers to the females is prodigious. The stamina are about nine in number, some say from five to eighteen. In the female flowers, the number of styles varies from four to seven, but six is the most common. The calix becomes an echinate capsule of four valves, of a silky smoothness on the inside, and containing two nuts, sometimes three, or only one.—This tree has long been naturalized in the southern countries of Europe, and is said to have been brought by the Roman emperor, Tiberius Cæsar,

from Sardis to Lydia in Italy, whence it was transplanted into France, and latterly into England. It is indigenous in many parts of Asia, in China, Cochin-china, Japan, &c. The Chestnut abounds now in the mountainous parts of Italy, in the south of France, Switzerland, the Valais, and many parts of the Alps towards Italy, in Corsica, and Sicily, where it grows half way up the side of Mount Ætna, as well as in Carniola, some parts of Germany, Portugal, and Spain. Mr. Miller supposes it formerly to have been more plentiful than at present in England, but it is probable that the timber in various old buildings in London, which he supposed to be Chestnut, was nothing but Oak of a different grain, and inferior quality. Evelyn makes little doubt that the Chestnut-tree is a native of Great Britain; and Dr. Ducarel, who is of the same opinion, among other ancient records to which he appeals, produces a deed of gift from King Henry II. to Flexley Abbey, of the tithe of all his Chestnuts in the forest of Dean. The Hon. Daines Barrington, on the contrary, thinks that it is not a native. It certainly is not in the woods north of the Trent; and, though it has been long in the southern parts, yet, says Hunter, there is no appearance of its being indigenous. This tree seems to be very long-lived, and grows to a very great size. The famous *castagno de cento cavalli*, or Chestnut of a hundred horses, on Mount Ætna, as measured by Mr. Brydone in 1770, was 204 feet in circumference; but some maintain that it is not one tree, and even Brydone himself confesses that it had the appearance of five distinct trees, but that he was assured the space was once filled with solid timber, and that no bark could be discovered on the inner parts. Kircher, who wrote a century before, declares, that a whole flock of sheep might be commodiously enclosed within it, as in a fold. In the same neighbourhood is another tree, called *il castagno del galea*, which is undoubtedly single, and measured at the same time seventy-six feet round, at two feet from the ground; but it should not be forgotten, that both these monstrous trees grow upon a deep rich soil, formed from the ashes of the volcano. The most remarkable of these trees in England, is that at Tortworth, the seat of Lord Ducie, in Gloucestershire. Even in the year 1150, says Bradley, it was styled the great or old Chestnut-tree of Tortworth; and in all probability is at least one thousand years old. It fixes the boundary of the manor; and in the year 1720, girted fifty-one feet, at a man's height from the ground. It divided at the crown into three limbs, one of which then measured twenty-eight feet and a half in circumference, five feet above the ground. The soil in which this tree grows is a soft, and somewhat loamy clay, and its situation on the north-west side of a hill. Lord Ducie has a beautiful painting of this ancient tree, from which an etching was made in the year 1772, under which is the following inscription: "The east view of the ancient Chestnut-tree at Tortworth, in the county of Gloucester, which measures nineteen yards in circumference, and is mentioned by Sir Robert Atkyns, in his history of that county, as a famous tree in King John's time; and by Mr. Evelyn, in his *Sylva*, to have been so remarkable for its magnitude, in the reign of King Stephen, as then to be called the Great Chestnut of Tortworth; from which it may reasonably be presumed to have been standing before the conquest." When the above-mentioned etching was made, it was barely included within the garden-wall, which bore hard upon it; but the present Lord Ducie removed the incumbent, and applied fresh earth to the roots, which seems to have enlivened it. So late as the year 1788, it produced great quantities of fruit, which, though small, were sweet, and well-flavoured. Mr. Lysons, however, who measured this famous tree in 1791, says, that

FAGUS CASTANEA — Common Chestnut Tree.

FERRARIA UNDULATA — Cape Ferraria.

T. Dixon sculp.

it measured only forty-four feet four inches round in the thickest part; and adds, that there does not seem to be any authority, to shew at what period it became remarkable for its size, except a very vague tradition; and it could never have been a boundary of a manor, for it stands in the centre of it. There are some fine Chestnut-trees on the banks of the river Tamar in Cornwall, at an old house belonging to the Edgcombe family, and at Beechworth Castle in Surry; there are not fewer than seventy or eighty trees, measuring from twelve to eighteen or twenty feet in girth. At Wimley, near Hitchin Priory, in Hertfordshire, a Chestnut-tree, in 1789, girted somewhat more than fourteen yards, at five feet above the ground; its trunk was hollow, and in part open, but its vegetation was vigorous. In the park adjoining to the garden, at Great Canford, in Dorsetshire, are four large Chestnut-trees, one of them measuring thirty-seven feet round, still bearing fruit plentifully, though much shivered and decayed by age. There was an old decayed tree at Fraiting, in Essex, whose very stump yielded thirty sizeable loads of logs. Another, in Gloucestershire, contained within its bowels a pretty wainscoted room, enlightened with windows, and furnished with seats. Ben Jonson, in his poem on Penshurst, makes mention of a Chestnut, planted at the birth of the celebrated Sir Philip Sydney. There have been, and still are, many fine Chestnut-trees in Ireland, as an avenue at Dunganstown: some of these were cut down in 1793, one of the trees measuring fourteen feet three inches, another fifteen feet, and a third sixteen feet six inches round; the length of one was twenty-four feet, and of another thirty-six. —The Chestnut, says Mr. Gilpin, in maturity and perfection, is a noble tree, and grows not unlike the Oak. Its ramification is more straggling, but it is easy, and its foliage loose. This is the tree which graces the landscapes of Salvator Rosa, who painted in the mountains of Calabria, where it flourishes. This tree deserves our care as much as any of the trees which are propagated in this country, either for use or beauty, being one of the best sorts of timber, and affording a goodly shade. The leaves continue late in the autumn, turning then to a golden colour, and are not so liable to be devoured by insects, as those of the Oak, which renders that tree very unsightly during a great part of the summer. On this account, the Chestnut is more valuable, as an ornament for parks and plantations; and there can be no better food for deer, and many other animals, than their nuts, which most of them prefer to acorns; but yet there should not be many of these trees planted too near dwelling-houses, because, when in flower, they emit an odour which is very offensive to most people. The shade of the Chestnut, like that of the Ash, is injurious to other plants; it should, therefore, be planted in thickets, or in detached plantations. Or, if these trees be planted in large wilderness quarters, next the walks, or in woods by the side of the ridings, and left untrimmed, as they ought to be, they will feather to the bottom, and hide the naked and crooked stems of other trees. To recommend the restoration of this noble and useful tree, which has unaccountably lost ground among us, we must observe, that it may be cultivated in England so as to afford an equal profit with any other sort of timber-tree; since the wood is equal in value to the best Oak, and for many purposes far exceeding it, particularly for casks, for which it is much used in Italy, and for pipes to convey water under ground. In Italy it is planted as coppice-wood, to make stakes for their vines, which will continue seven years. It must therefore be very proper for stakes in espaliers and dead hedges, for hop-poles, hurdles, &c. The timber was formerly used for all the same purposes as Oak, in building, mill-work, and household fur-

niture; and lately, some of it that was finely variegated, has been successfully employed for doors, and the balustrades of a staircase: a colour being given to it, by rubbing it over with alum-water, then laying on with a brush a decoction of logwood chips, and lastly a decoction of Brazil-wood, which process has produced a strong resemblance to Mahogany. Some persons assert, that the timber of Chestnut is brittle, and decays at heart; whilst, according to others, it will last longer than Oak, is not subject to cracks or flaws, and is never attacked by spiders or other insects. Old Chestnut is certainly brittle, and liable to crack, and therefore should never stand longer than whilst it is in a growing state. If cut when it squares only six inches, it will be as durable as Oak of six times its size and age, having very little sap in proportion to other trees. The durability of it, when exposed to the weather, has been sufficiently ascertained, from its use for gate-posts at Wellington in Somersetshire, of which the following is an authentic account. In or about the year 1763, some gate-posts of Oak, and others of Chestnut, were to be repaired; they had the appearance of being put in at the same time, but the latter were much more sound, inasmuch that some of them were adjudged good enough to remain as gate-posts, and were still to be seen there in 1788. Such as were too small were taken up, and set as posts to fix rails to. At the same time some new posts of Oak were put in, there not being a sufficient quantity of the old Chestnut posts; which, twenty-five years afterwards, were found to be sounder than the Oaken posts, which were then new. One side of the Chestnut posts was the outside of the tree; but the timber was as sound there as in any other part, which would not have been the case with Oak, the sap of which, next the bark, soon decays. These Chestnut gate-posts had been put down many years before 1745, and have, therefore, probably resisted the weather for above half a century. Another account says, that a chestnut-branch, about thirteen inches square, which, in the year 1726, was put down as a hanging-post for a gate, and carried the gate fifty-two years, when taken up appeared perfectly sound, and was put down for a clapping-post in another place. A large barn, built of Chestnut timber, in 1743, was sound in every part in 1792. At the former period, also, several posts and rails were put down, which, after standing thirty or forty years, appeared to be so sound, as in general to allow of being set up in some other place. In 1772, a fence was made of posts and rails converted from young Oaks and Chestnuts of the same age and scantling. In 1791, this fence was removed, and the Chestnut-posts were found as sound as when first put down; but the Oaken ones were so much wasted just below the surface of the ground, that they could not be used again without a spur.—The nuts are the usual, and, in some places, almost the only food of the common people in the Apennine mountains of Italy, and in Savoy, some parts of the south of France, and in Portugal. They are not only boiled and roasted, but made into puddings, cakes, and bread. They are reckoned a very flatulent and indigestive diet; although in Italy there are instances of men's living to the age of eighty, and even a hundred years, who have fed wholly upon Chestnuts. They are brought even to fashionable tables in desserts. Mr. Ray observes, that the Italians eat them with orange or lemon juice, and sugar, and that they are there sold commonly about the streets, roasted upon a portable furnace; by which we may infer, that this *luxury* was unknown at London in the last century. These nuts are also used for whitening linen-cloth, and for making starch, and are excellent for feeding hogs. The leaves likewise make useful litter, and, when mixed with the dung of the cattle,

form a good manure. It is hoped that the above interesting account will have some tendency to encourage the growth of this noble, though neglected tree. Mr. Peter Collinson, who thought it a native of this country, assigned the great profit arising from Chestnuts, when cut for hop-poles, as the reason why large trees are so rarely met with in our woods. Let us hope, however, that it will once more be suffered to rear its head as a timber-tree amongst us. An arrêt of the council of Paris was published in May, 1720, ordering that all the great roads in France should be planted with Chestnut, or other such fruit or 'orest trees as are suitable to the nature of the ground, at thirty feet distance from each other, and within six feet of the top of the ditch. The principal plantations which have been made of late years in Great Britain, are in the northern parts of the island. The Earl of Fife has planted above 60,000 trees in the county of Murray; George Ross, Esq. 4000 in Cromarty. In England, Mr. Windham's plantations, at Felbrigg in Norfolk, made in 1676, are well known. Mr. Joseph Mace has planted six acres, seventeen perches, with above 3000 trees, at Ashford in Biddenden, Kent. John Sneyd, Esq. 8000, at Belmont in Staffordshire, from 1784 to 1786; and Mr. Joseph Cowlshaw, six acres in Carlton forest, with above 1800 of these trees, mixed with Larch, Ash, &c.—There are several varieties of the Chestnut which have accidentally arisen from seeds; but the difference is chiefly in the size of the fruit and leaves. One sort, however, which has variegated leaves, is admitted into the nurseries as a curiosity. The Striped Chestnut is among the most beautiful of the variegated trees, the blotches being of a rich shining gold colour, strongly marked. The Dwarf Branching Chestnut is no more than a variety of the common sort.—The Chestnut-tree is propagated by planting the nuts in February, in beds of fresh undunged earth. The best nuts for sowing, are such as are brought from Portugal and Spain, and are commonly sold in the winter for eating, provided they are nut kiln-dried, which is generally the case with most of those brought from abroad, which is done to prevent their sprouting or shooting in the passage; therefore, if they cannot be procured fresh from the tree, it will be much better to use those of English growth, which are full as valuable, either for timber or ornament, as any of the foreign nuts, notwithstanding their fruit is much smaller; these should be preserved until the season for sowing, which is the beginning of March, in sand, where mice or other vermin cannot come at them, for they will soon destroy them. Before you plant them, it will be proper to put them into water to try their goodness, which is known by their weight; those that swim upon the surface of the water should be rejected as good for nothing; but such as sink to the bottom you may be sure are good. In setting these seeds or nuts, the best method is to form a drill with a hoe, as is commonly practised in setting kidney-beans, about four inches deep, in which you should place the nuts at about four or six inches' distance, with their eye uppermost; then draw the earth over them with a rake, and make a second drill at about a foot distance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, for the conveniency of clearing the beds. When you have finished your plantation, set traps to destroy the mice and other marauders, or else they will infallibly destroy your work. In April these nuts will appear above ground; observe therefore to keep them clear from weeds, especially while young; in these beds they may remain for two years, when you should remove them into a nursery, at a wider distance. The best season for transplanting these trees, is either in October, or at the end of February, but October is the best season: the

distance these should have in the nursery, is three feet row from row, and one foot or eighteen inches in the rows; be careful, when about to transplant them, to take them up without injuring the roots, nor should they remain long out of the ground; but if they have a downright tap-root, it should be cut off, especially if they are designed to be again removed: this will cause them to put out lateral roots, and render them less subject to miscarry, when they are removed for good. The time generally allowed for them to remain in this nursery, is three or four years, according to their growth; but the younger they are transplanted, if designed for timber, the better they will succeed; during this time be careful to keep them clear from weeds, and to prune off lateral branches, which would retard their upright growth; where you find any that are disposed to grow crooked, either by their upper bud being hurt, or from any other accident, you may, the year after planting, in March, cut them down to the lowermost eye next the surface of the ground, which will cause them to make one strong upright shoot, and they may be afterwards trained into good straight trees: but this should not be done, unless the plants have absolutely lost their leading shoot; for although the stems of the trees should be very crooked, as is generally the case with them when young, yet when they are transplanted out, and have room to grow, as they increase in bulk they will grow more upright, and their stems will become straight, as has been frequently observed where there have been great plantations made of them. But in doing this, care must be taken not to disturb or break their roots, which might probably destroy them. They require no other manure than their own leaves, which should be suffered to rot upon the ground; and, in the spring of the year, the ground should have a slight digging, when these should be buried between the roots, yet not too close to the trees, which might be injurious to their young fibres. After remaining three or four years in the nursery, they will be fit for transplanting, either in rows to grow for timber, or in quarters for wilderness plantations, avenues, clumps, or the orchard; but if you intend them for timber, it is by far the best method to sow them in furrows, as is practised for Oaks, and let them remain unremoved; for these trees are apt to have a downright tap-root, which being hurt by transplanting, is often a check to their upright growth, and causes them to shoot out into lateral branches, like the Oak, Walnut, &c. Let it be observed, however, that where the fruit is more sought after, then it is certainly the better way to transplant them: for, as transplanting is a check to the luxuriant growth of trees, so it is a promoter of their fructification, as may be proved by observing low Shrubby Oaks, Walnuts, &c. which generally have a greater plenty of fruit than any of the larger and more vigorous trees; and the fruit of such trees is much superior in taste, though the seeds of vigorous trees are vastly preferable for plantations of timber; for it is a constant observation, that, by saving seeds from dwarf trees or plants, from time to time, they may be rendered much lower in their growth than in their natural size: but where the fruit is most desired, then they should be taken from such trees as produce the largest and sweetest nuts, which are commonly found upon such trees as spread the most, and have horizontal roots; for the weaker trees being less capable of furnishing a supply of nourishment, and having a greater quantity of fruit upon them, to which this must be distributed, together with their roots near the surface of the ground, by which means the juices are better prepared by sun, air, &c. before it enters their vessels, it is certain that their juices are better digested, and their fruit better matured, than those can possibly be which grow upon strong

vigorous trees, which have long tap-roots running several feet deep in the earth, and consequently take in vast quantities of crude unprepared juice, which is buoyed up to the extreme parts of the tree; and these seldom have many lateral branches to digest and prepare their juice, by perspiring and throwing off the crude part before it enters the fruits. This remark will, in all probability, extend to all sorts of fruit-trees, and is often the occasion of the good and bad qualities of the same sorts of fruits growing on the same soil. What has been related about grafting this tree into the Walnut to promote its bearing, or render the fruit fairer, or inoculating Cherries into the Chestnut for later fruit, is very whimsical and silly, since neither the Chestnut nor the Walnut will receive its own kind in any other way than by inoculating or inarching, and it is the latter only by which the Walnut can be propagated; nor was it ever known that any two trees of a different genus would take upon each other so as to produce either a good tree or good fruit; therefore we may justly explode all those different graftings of various trees upon each other, so much talked of by the ancients, at least we may suppose those trees are not known by the same names now, that they are mentioned by in their writings; for, says Mr. Miller, "I have made many trials upon them, which, though performed with the utmost care, and in different seasons, have very seldom succeeded."—But to return: If you design a large plantation of these trees for *timber*, after having two or three times ploughed the ground, the better to destroy the roots of weeds, make your furrows about six feet distance from each other, and lay the nuts in them ten inches apart, covering them with earth about three inches deep; and when they come up, you must carefully clean them from weeds: the distance allowed between each row is for the use of the horse-hoeing plough, which will despatch a great deal of this work in a short time; but it should be very carefully done, so as not to injure the young plants; therefore the middle of the spaces only should be cleaned with this instrument, and a hand-hoe must be used to clean between the plants in the rows, and also on each side, where it will be unsafe for the plough to be drawn; and in hand-hoeing there must be great care taken not to cut the tender rind of the plants. If in the following spring the spaces are carefully stirred with the plough, it will not only make the ground clean, but also loosen it, so as that the sun and moisture may more easily penetrate the same, which will greatly promote the growth of the plants; and the oftener these ploughings are repeated, the cleaner will be the ground, and the greater the progress of the plants, which cannot be kept too clean while they are young. When these have remained three or four years, if the nuts succeed well, you will have many of these trees to remove, which should be done at the seasons before directed, leaving the trees about three feet distance in the rows; at which distance they may remain for three or four years more, when you should remove every other tree to make room for the remaining, which will reduce the whole plantation to six feet square, a distance sufficient for them to remain in until they are large enough for poles, when you may cut down every alternate tree, selecting the most unpromising, within one foot of the ground, in order to make stools for poles, which in eight or ten years' time will be strong enough to lop for hoops, hop-poles, &c. for which purposes they are preferable to most other trees, so that every tenth year there will be a fresh crop, which will pay the rent of the ground, and all other incumbent charges, and at the same time a full crop of growing timber left upon the ground. But as the larger trees increase in bulk, their distance of twelve feet square will be too small; therefore when

they have grown to a size for small boards, you should fell every other tree, which will reduce them to squares of twenty-four feet, which is a proper distance for them to remain for good; this will give air to the underwood, which by this time would be too much overhung by the closeness of the large trees, by which means that will be greatly encouraged, and the small timber thus felled will pay sufficient interest for the money at first laid out in planting, together with the principal also; so that all the remaining trees are clear profit, for the underwood still continuing will pay the rent of the ground, and all other expenses; and how fine an estate the succeeding generations will find in the course of fourscore years, when the timber-trees shall have arrived at maturity, every one may easily conceive.—In raising Chestnut woods for *timber*, Mr. Boutcher advises for the first two years to take a line of Beans between the drills; and at the end of two years, early in the spring, to remove every second plant in the rows, which will leave them about two feet and a half asunder, at which distance they may remain for three years. Then remove every second row, and every second tree in the remaining rows, which will leave them at the distance of eight feet by five; these plants will be useful for stakes and poles. The ground may now be levelled, and dug for any kitchen-garden crops; in the February following cut them down, reserving only the straightest and most vigorous, at the distance of twenty-five or thirty feet. Dwarf crops may be taken between the rows for two years more, after which the trees will soon cover the ground. Both Mr. Boutcher and Dr. Hunter prefer February to October for transplanting. Mr. Marshall advises the nuts to be set by the dibble, six inches asunder, in a quincunx order; because drills serve as conductors to the field-mouse. Mr. Hanbury contends for planting a Chestnut wood from the nursery: he advises to plant out the trees when they are five feet high, because they will not be so large as to require staking, nor so small as to be within the reach of hares, rabbits, &c. the distance to be two yards, which is far enough asunder for poles; when they are large enough for this use, they should be cut down, leaving a sufficient number of the most thriving trees for timber, this will be in fourteen years; if they are cut within a foot of the ground, there will be stools for another crop in ten years more. If the plantation be large, the first fall of poles may be begun so early, and the latter deferred so late, that the year after the last fall, the stools of the first-cut poles shall have sent forth others ready for a second cutting. Thus the proprietor will enjoy the benefit of an annual sale, and the country will not be glutted with too great a quantity. Mr. Hanbury prefers this method, because when the tree is raised from nuts, it is subject to a tap-root, which strikes beyond the reach of nourishment, and grows slower in consequence; and because while they are in the nursery a vast quantity will stand in a small space; whereas when they are raised from the nuts, the whole wood must be kept clear of weeds till the plants are grown of a sufficient size to need no further weeding.—In making a plantation of Chestnut-trees for the *fruit*, the ground should have three or four ploughings in the preceding summer and winter; and if one good digging be added a little before planting, it will be a great improvement. Plant your trees in rows six feet distant every way, dig the ground annually, and when the branches begin to meet, take up every second row, and every second plant, which will leave all the trees at twelve feet distance, while the wood of those that are taken up will be found of great use for many purposes. Having dug or half-trenched the land, if it be of good quality it may for some years be cultivated with Potatoes, Cabbages, and Turnips

When the branches begin again to meet, they must be reduced as before, and left twenty-four feet asunder, at which distance they may remain. The wood of this last felling will saw into small boards, and being about twenty years old, must be rooted out, for the Chestnut shoots vigorously from stools. The remaining trees, having produced fruit for several years, will now bear vast quantities, and make great returns of profit.—The Chestnut will thrive on almost any soils, and in all situations, if there be no standing water; it succeeds best in a rich loamy land; but will flourish very well on gravel, clay, or sand. All mixed soils suit it, as well as exposed places, and the declivities of hills. In foreign countries, where the Chestnut is cultivated for the fruit, they graft cions from trees bearing the largest and fairest fruit, upon stocks raised from the nut. These grafted trees are, however, unfit for timber, and are called *marronniers* by the French. The varieties with striped or blotched leaves are maintained by budding, and inarching upon common Chestnut stock. The Chestnut-tree has its name *Castanea*, from a town of the name of Castanis, in Thessaly, about which this tree grew in great abundance: it has the same appellation in all the European languages; the Germans call it *castanienbaum*; the Swedes and Danes, *castanientræ*; the French, *chataignier*; the Italians, *castagno*; the Spanish, *castano*; the Portuguese, *castanheiro*; the Russians, *keschtan*.

2. *Fagus Pumili*; *Dwarf Chestnut Tree*, or *Chinqua Pine*. Leaves lanceolate-ovate, acutely serrate, tomentose underneath; aments filiform, knotty. This seldom grows above twelve or fourteen feet high, but produces abundance of nuts, which are generally single in each capsule. This tree is very hardy, and will resist the severest of our winters in the open ground, but is very apt to decay in summer, especially in a dry soil. But although it delights in moisture, yet, if the wet continues long upon the ground in winter, it frequently destroys the trees. It is very common in the woods of America, but rare in England.—The nuts of the Chinqua Pine, or Dwarf Virginian Chestnut, should be put up in sand as soon as they are ripe, and shipped off immediately, otherwise they will lose their vegetating quality. When the nuts arrive in England, they should be put into the ground as soon as possible; and if the winter should prove severe, cover the ground with leaves, tan, or pease-haulm, to prevent the frost from penetrating to the nuts.

3. *Fagus Sylvatica*; *Common Beech Tree*. Leaves ovate, obscurely serrate. This tree will grow to a very large size, lofty, and spreading, the trunk straight, and covered with a whitish bark; the leaves are smooth and glossy, waved on the edges, rather than serrate, or slightly sinuate-toothed, three inches and more in length, and two or upwards in breadth; the petioles reddish, slightly grooved above, four or five lines in length, pubescent, as is also the midrib of the leaf; stipules reddish-brown, shining, lanceolate, conspicuous. It retains the old leaves through the winter. The male catkins come out in bunches from the ends of the small branches; they are roundish, obtuse, half an inch long, and almost as broad, on peduncles from half an inch to fourteen lines in length, pendulous, round, and pubescent; calix cut half way into six sharp villose yellowish segments; stamina uncertain, four, six, eight, nine, eleven, or twelve, from the bottom of the calix; the female aments come out from the same place, a little above the others, they are erect, and on round, whitish, villose peduncles, four lines or upwards in length; the common involucre has two flowers, is four-cleft, and covered with soft spines; calix superior, six-leaved, tomentose; germen three-celled, with two rudiments of seeds in each cell; styles three, or, according to Gærtner,

one-cleft; stigmas awl-shaped, and slightly hooked, yellowish and smooth; at the top of the germen there are also six whitish villose segments, shorter than the styles. The fruit is composed of two nuts joined at the base, covered with an almost globular four-valved involucre, with soft spines on the outside, but within very smooth and silky; the nuts, when ripe, are one-celled and triangular, and contain one or two angular seeds.—The Beech is very well adapted to form lofty hedges, to surround plantations or large wilderness quarters, or for screens, where there is not room for trees to extend their branches naturally. Although the timber of this tree is not so valuable as that of many others, yet as it grows very fast in chalky or stony ground of little value, with a clear smooth bark and straight trunk; as it will thrive on such soils and in such situations as better trees will scarcely grow on; and as it will resist winds on the declivities of hills better than most other trees; the planting of it should be encouraged, especially as it affords an agreeable shade, and the leaves both make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees, when they turn brown or orange, and frequently hold on all the winter. In parks, therefore, and other plantations for pleasure, this tree deserves to be cultivated among those of the first class, especially where the soil is adapted to it. But though the wood of the Beech be brittle, and decays soon in the air, yet it will endure long under water, and serves for a great variety of uses, as will appear from the following account: It is of great use to turners for making trenchers, dishes, trays, buckets, &c. to the joiner, for stools, bedsteads, and other furniture; to the wheel and millwright; it makes shovels and spade-graffs for the husbandman; and is useful to the bellows-maker: floats for fishermen's nets, instead of corks, are made of its bark. It is good for fuel, billet, bavin, and coals, though one of the least lasting; and the very shavings are excellent for fining of wine. When the timber lies altogether under water, it is scarcely inferior to Elm. Baskets for Strawberries are made of the bark; of the thin lamina or scale of the wood, scabbards for swords, band-boxes, hat-cases, &c. The leaves are used abroad, on account of their elastic quality, instead of straw, for the *paillasse*, to lay under their mattresses. To the above enumeration of its uses by Mr. Evelyn, we may add many other. It is now in much repute among the cabinet-makers, for chairs, both plain and painted; for bedsteads, with the posts frequently stained the colour of mahogany. In the country it is much used for rafters, in building. Much of it is cut out into quarters and planks for various purposes; and barn floors are frequently laid with it. The millwright uses it for cogs, &c. and the wheelwright for spokes and fellies; it goes to the dock-yards for wedges, and may be used in ships' bottoms from the keel to the floor-heads; and is known in the coal mines under the name of Newcastle railing. Being of an even grain, and without knots, it makes beautiful benches and railing for public rooms, and many sorts of inside work in houses. It is formed into gun-stocks, tool-handles, mallets, carpenters' planes, heel-pieces, pegs for heels; and into sounding-boards for harpsichords, by the musical-instrument makers. The soap-cask coopers cut it into staves for dry goods, for which purpose a considerable quantity is imported as ballast from Bremen and Dantzic, in slabs and clapboards about five feet in length. It is said that these coopers consume from twenty to thirty thousand of these clapboards yearly, except in time of war, when the importation is stopped. It is excellent fuel, and in burning affords a large quantity of potash. Much of it is sent to the metropolis, under the name of

London billet, for the use of the bakers, glasshouses, &c. The stackwood, which is made up of the branches, is burnt chiefly into charcoal; the nuts or mast, as they are commonly called, fatten swine, but the fat is not firm; and they are greedily devoured by mice, squirrels, and birds: they are said to occasion giddiness and headache, but, when dried and powdered, to make wholesome bread; they are sometimes roasted as a substitute for coffee; and the poor people in Silesia use the expressed oil instead of butter. At the beginning of the last century, Aaron Hill had a project for paying off the national debt with the oil of Beech-nut; but they seem to yield so little oil in northern countries, that Linneus informs us, that scarcely any oil can be expressed from them. If the soil be tolerably good, Beech will become fit to be felled in twenty-five years; the woods are then drawn, as it is called, that is, the trees fit for firewood or billet, poles, timber, &c. are taken down, and no crooked trees are suffered to remain. Formerly it was the custom to leave the old stools to produce new trees, but as these seldom grow well and handsome, now during the winter the old stools are grubbed up, and the plants which spring spontaneously from the mast are encouraged, to supply the places of the trees which are taken down. Once in six or seven years this operation of drawing the woods may be repeated; and thus there is a constant and regular succession of trees fit to cut. The price which firewood or billet fetches in Buckinghamshire, is nearly fourpence the foot solid measure; the poles and better stuff, for gun-stocks, wedges, &c. sell for fivepence the foot; and the largest trees, for millwrights, sell for sixpence or sevenpence; stackwood is fifteen or sixteen shillings per load, and faggots fifteen or sixteen shillings the hundred. Cæsar's assertion, that the *Fagus* was not in Britain when he visited the island, can hardly be controverted but by supposing that his *Fagus* is not the Beech. But whatever may have been the case in Cæsar's time, the Beech is now no uncommon tree in many considerable tracts of Great Britain, particularly on that large ridge of chalk-hills which runs from Dorsetshire, through Wiltshire, Hampshire, Surry, Sussex, and Kent, branching out into Berkshire, Buckinghamshire, and Hertfordshire; on the declivities of the Cotswold and Stroudwater hills in Gloucestershire, and on the bleak banks of the Wye, in the counties of Hereford and Monmouth; and it is, in short, to be found in almost every county of England. Some plantations of it have been lately made by the Earl of Fife, in the county of Murray, where his lordship has planted nearly two hundred thousand of these trees. George Ross, Esq. has also set 13,000 of them in Cromarty. In England, John Sneyd, Esq. has planted above 14,000 at Belmont in Staffordshire, between the years 1784 and 1786; and in 1788, the Bishop of Llandaff planted 2000 at Ambleside.—The Beech is a native of the greater part of Europe, and the southern provinces of the vast Russian Empire; but it is not fond of very high and cold situations, being seldom found in the northern provinces of Sweden. Mr. Lightfoot doubts whether it be indigenous in Scotland; and Mr. Marshall thinks it not a native of the northern counties of England. It prospers in a chalky and rocky soil, but not in light sands, and thrives prodigiously in sheltered bottoms, but seldom flourishes in a western exposure. In some parts of Herefordshire, where the soil is a strong clay full of flints, this tree grows to a great size, and is extremely beautiful. Beech, says the late Mr. White, is one of the most grand and lovely of all the forest-trees, whether we consider its stately trunk, its smooth silvery rind, its glossy foliage, or graceful spreading pendulous boughs. No tree, says another writer, is more beautiful, when stand-

ing singly in parks or ornamental grounds, as it throws out its branches very regularly, and feathers almost to the ground: in woods or groves it grows clear of branches to a great height. Mr. Gilpin is not inclined to rank the Beech much higher in picturesque beauty than utility. Its trunk, he allows, is often highly picturesque, being studded with bold knobs and projections, and having sometimes a sort of irregular fluting, which is very characteristic; the bark too wears often a pleasant hue; it is naturally of a dingy olive, but is overspread, in patches, with a variety of mosses and lichens; its smoothness also contrasts agreeably with these rougher appendages. This is all the merit Mr. Gilpin allots to the Beech; for, says he, we rarely see it well ramified, and in full leaf it has the appearance of an overgrown bush. Virgil, indeed, was right in choosing it for his shade, for no tree forms so complete a roof, although its bushiness gives it a great heaviness. The Beech, therefore, is most pleasing in its young state; it is then light and hairy, with spiry branches often hanging in the most easy and beautiful forms; and some of the finest oppositions of tint arise in the autumn from the union of this tree with the Oak. Although this tree is supposed not to be a native of Ireland, several fine Beeches are mentioned in that country; as at Tiny-park, the seat of Sir Skeffington Smyth, three noble trees together, the smallest fourteen feet round; the next, fifteen feet six inches at the butt, and fourteen feet eight inches at seven feet from the ground; the third, is sixteen feet three inches round, and continues nearly of the same girth for thirty-six feet. The celebrated Arthur Young, in his "Travels in France," speaks of a Beech at Chantilly, as the finest he ever saw, straight as an arrow, and not less than eighty or ninety feet high, forty feet to the first branch, and four yards in diameter at five feet from the ground.—The Beech derives its Latin name *Fagus*, from a Greek word which signifies to eat, either because mankind lived on Beech-mast before the use of corn, or because it was the food of the common people: the appellation is the same in all the northern languages, and in all the dialects of the Sclavonian; in German *Buche*, *Buke*, or *Boke*; in Danish, *Bog*; in Swedish, *Bok*; in Russian and Polish, *Buk*; the French *Hêtre*, is from the German *Hester*, which signifies a young Beech; the Italians call it *Faggio*, from the Latin, which the Portuguese have softened into *Faya*, and the Spaniards into *Haya*, although they sometimes call it *Fagos*.—There are some planters who suppose that there are two species of this tree, the Mountain Beech and the Wild Beech; the first of which has a whiter wood than the second; but this difference arises only from the soil. There are also seeds of a Beech brought from North America, by the name of Broad-leaved Beech; but the plants raised from them proved to be the common sort. There are two varieties in the nurseries, one with yellow, and the other with white stripes. In Germany they have another variety, with dark red leaves, which is called the *Purple Beech*. There are also some trees in our woods with rougher bark, which the woodmen call *Hay Beech*.—The Beech-tree is propagated by sowing the mast, the season for which is any time from October to February, only observing to secure the seeds from vermin when early sowed; if this be carefully done, the sooner they are sown the better. Since Beech-mast, however, keeps very well, and is greatly relished by field mice and other vermin, many planters prefer spring sowing; in which case the seeds should be spread on a mat in an airy place for a few days to dry, and then put up in bags. A small spot of ground will be sufficient for raising a great number of these trees from seed; they must be kept clean from weeds, and if they come up very thick, draw the strongest

the autumn following; and thus if a seed-bed be husbanded carefully, it will afford a three years' draught of young plants, which should be planted in a nursery; and if designed for timber-trees, at three feet distance row from row, and eighteen inches asunder in the rows; but if designed for hedges, two feet row from row, and one foot in the rows, will be sufficient. In this nursery they may remain two or three years, observing to clear them from weeds, and to dig up the ground between the rows at least once a year; but be careful not to cut or bruise the roots, and never to dig the ground in summer, when it is hot and dry. The Beech will prosper on stony barren soils, but then the nursery for the young plants ought to be upon the same soil, for if they be raised in a good soil and a warm exposure, and afterwards are transplanted into a bleak barren situation, they will seldom thrive. See *Nursery*. For hedges, the Beech may be kept in a regular figure, if sheared twice a year, at least when it shoots strong; in which case, if the hedges be neglected but a season or two, it will be difficult to reduce them again. The varieties with striped leaves may be continued by budding or grafting upon the common Beech, observing not to plant them in too good a soil, which will frequently cause the leaves to become plain.—The above directions being in some respects imperfect, we subjoin the following from Mr. Boutcher: Being provided with mast from the straightest and freshest trees in September, as soon as the husks are quite dry, mix them with sand, and lay them under an old frame or other covering, to protect them from frost and wet. The beginning of March, sow them in beds four feet wide, in shallow drills eighteen inches asunder, covering them one inch deep; if the season be dry, give them frequent but moderate waterings, from the time of their appearance above ground, until the middle of August. In March, next season, with a spade made very sharp, undermine the roots, and cut them over between four and five inches under ground. In the following autumn or spring, either raise the whole, or give them another cutting under ground; when gently raising such as are too thick, leave the remainder at proper distances to stand another season: plant such as you have raised, after smoothing the bruised and broken roots, and cutting away some of the small hairy fibres, in lines two feet asunder, and nine or ten inches in the line; here they may remain two, or, if the land be poor, three years. Next autumn or spring treat the rest in like manner; trim off only cross ill-placed branches, and those sparingly. From this nursery they must be removed to another, and planted in rows three feet and a half asunder, and eighteen inches in the rows; here they may remain three years, in poor land four, observing always to prune moderately at removal, and to leave abundance of small branches. These plants will now be fit for common and extensive plantations; but such as are designed for removal when large trees, must again be transplanted in rows five feet asunder, and two feet distance in the rows, to remain in good ground three, in poor ground four years. From this remove them again into rows eight feet asunder, and six feet in the row, to remain four years; if required of a still larger size, plant them ten feet asunder every way. Mr. Young informs us, in his *Irish Tour*, that Mr. Mahon made a plantation of all sorts of forest trees in his park, in order to see how far the deer would let them escape; they devoured every tree except the Beech, not one of which they touched, either in leaf, branch, or bark; many of these Beeches, of not more than thirty years' growth, were three or four feet in girth, and from thirty to forty feet high.

4. *Fagus Ferruginea*; *American Beech Tree*. Leaves ovate-oblong, remotely and acutely serrate, acuminate, tomentose underneath. The leaves of this are much more

distinctly serrated, and broader, than in the foregoing species; and the fruit smaller, of a tawny colour.—Native of North America.

5. *Fagus Cochinchinensis*. Leaves ovate, crowded; capsules three-celled, three-valved. This is a small tree, about five feet high, with branches ascending a little; leaves obscurely serrate, smooth, petioled; male flowers in terminating aments, with a five-cleft calix and corolla, and twelve stamina; female flowers below on the same branch, with a five-cleft calix, and no corolla; capsule muricated, three-celled, three-valved, one-seeded. The seeds are of the same form and colour with the common sort, but very small. The corolla of the male flowers being very thin and membranaceous, may be considered as a nectary. There appears to be some doubt whether this be a distinct species from the common Beech.—Native of Cochinchina.

Falkia; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, somewhat inflated, five-cornered, shorter by half than the corolla, five-parted; angles widened in the middle, compressed, standing up; divisions ovate, acute. *Corolla*: one-petalled, bell-shaped, crenate, ten-parted; border spreading. *Stamina*: filamenta five, filiform, inserted into the tube of the corolla, erect, unequal, shorter than the corolla; antheræ ovate, compressed. *Pistil*: germina four, superior, smooth; styles two, capillary, divaricate, the length of the corolla; stigmas capitate, obtuse, simple, orbiculate, peltate. *Pericarp*: none. *Seeds*: four, globular, arilled at the bottom of the calix. *Observe.* This genus is allied to *Convolvulus*, having the herb and flower of the same structure, but differing in the seed. **ESSENTIAL CHARACTER.** *Calix*: bell-shaped, five-cleft. *Corolla*: bell-shaped; stigmas orbicular, peltate. *Seeds*: four, arilled.—The only discovered species is,

1. *Falkia Repens*; *Creeping Falkia*. A perennial plant, flowering from May to August; and a native of the Cape of Good Hope.—It is generally increased by parting the roots, planting in loamy earth, and watering freely in summer.

Fan, Palm. See *Chamarops*.

Feather, Prince's. See *Amaranthus*.

Feathered Columbine. See *Thalictrum*.

Feather Grass. See *Stipa*.

Felwort. See *Gentiana*.

Fences.—In hotter climates than England, where walls are not wanted to ripen fruit, the gardens lie open, where they can have water, fence, or prospects, or else they bound their gardens with groves, in which are fountains, walks, &c. which are much more pleasing to the sight than a dead wall; but in colder countries, and in England, we are obliged to have walls to shelter and ripen our fruit, although they deprive us of the pleasant prospect of the garden. Since, therefore, we are under the necessity of having walls to secure our gardens from the injury of winds, as well as for the conveniency of partitions or enclosures, and also to ripen our fruit, brick walls are accounted the warmest and best for this purpose; and these walls being built in the shape of pannels, with pillars at equal distances, will save a great deal of expense, because they may be built thinner than when built plain without these pannels; for then it would be necessary to build them thicker every where; and it must be allowed that the panels are an ornament to the wall. Stone walls are preferred by some persons, and especially those of square hewn stone; but where they are designed for fruit, they should be faced with brick. Those that are made of rough stones, though they are very dry and warm, yet, by reason of their unevenness, are inconvenient to nail up trees to, except pieces of timber be laid in them here and there,

to fasten a trellis to them. But in large gardens, it is better to have the prospect open to the pleasure-garden, which should be surrounded with a fosse, that from the garden the adjacent country may be viewed; but this must depend on the situation of the place, for if the prospect from the garden be not good, it had better be excluded by a wall, or any other fence, than remain exposed to view. And where a garden lies near a populous town, and the adjoining grounds are open to the inhabitants, if the garden be open, there will be no walking there in good weather, without being exposed to the passers by, which is very disagreeable. When fosses surround a garden situated in a park, they are extremely proper, because hereby the prospect of the park will be enjoyed in the garden, which will thus be rendered much more agreeable than those which are confined. There have been numberless inventions for making these fosses, but there are none in all respects preferable to those which have an upright wall next the garden, which, where the soil will admit of a deep trench, should be six or seven feet high, so as to be above the reach of boys; and from the foot of this wall, the slope on the outside should rise with a gradual easy slope, to the distance of eighteen or twenty feet; and where it can be allowed, if it slopes much farther, it will be easier, and less perceptible as a ditch to the eye, when viewed at a distance. But if the ground be naturally wet, so as not to admit of a deep fosse, then, in order to make a fence against cattle, if the wall be four feet high, and slight posts of three feet and a half high are placed just behind the wall, with a small chain carried on from post to post, no cattle or deer will ever attempt to jump against it, therefore it will be a secure fence against them; and if painted of a dark lead colour, they will not be discerned at a distance; at the same time that the chain will secure persons walking in the garden from tumbling over; and if another chain be carried through the posts at one foot from the ground, it will more effectually prevent cattle from creeping under. In places where no good prospects can be obtained from a garden, it is common to make the enclosure of park-paling, which, if well performed, will last many years, and has a much better appearance than a wall: this pale may be concealed by plantations of shrubs and evergreens within, or else by a quick hedge, which may be trained up so as to be an excellent fence by the time the pales begin to decay. There are some persons who make stockade fences round their gardens to keep out cattle, which, when well made, will answer the purpose of a fence; but these being very expensive in the making, and not very lasting, has prevented them from being brought into common use. As to park fences, they are generally of paling, which, if well made of winter-fallen oak, will last many years; but a principal thing to be observed in making these pales is not to make them too heavy, for when they are so, their own weight will cause them to decay; therefore the pale should be cleft thin, and the rails should be cut triangularly, to prevent the wet from lodging upon them; and the posts ought to be good, not placed too far asunder, burning that part of them which goes into the ground. If these directions be observed, the pales will last upwards of forty years in good order. The common way of making such fences, is to have every other pale nine or ten inches above the intermediate ones, so that the fence may be six feet and a half high, which is enough for fallow deer; but where there are red deer, the fence should be one foot higher, otherwise they will leap over. Some enclose their parks with brick walls; and in countries where stone is cheap, the walls are built with this material, some with, and others without mortar. A kitchen-garden, if rightly contrived, will contain walling

enough to afford a supply of such fruits as require the assistance of a wall for any family; and this garden being situated on one side, and quite out of sight of the house, may be surrounded with walls, to screen those persons in the kitchen-garden from the sight of those in the pleasure-garden; and being locked up, the fruit will be much better preserved than it can be in the public garden; and the having too great a quantity of walling is often the reason why so many defective trees are frequently seen in large gardens, where there is not due care observed in their management. The borders of pleasure-gardens are also, in general, too narrow for the roots of fruit-trees, which it is therefore useless to plant there. The height of garden-walls should be from ten to twelve feet high, which is a moderate proportion; and if the soil be good, it may in time be furnished with bearing wood in every part, especially those parts planted with pears, notwithstanding the branches being trained horizontally from the bottom of the walls. The White Thorn, the Holly, the Black Thorn, and the Crab, are separately recommended for outward fences to a good ground, but it is said to be injudicious to intermix them. The White Thorn is the best to plant, because it is the most common, and may be clipped so as to render it the closest and hardiest fence of any other tree, and being very durable, is preferred to all others for outward fences, or for the division of fields, where they are exposed to cattle. The Black Thorn and Crab make very good fences, and are to be raised like the White Thorn; but if the kernels of Apples or Crabs be sown, it is the best to sow the pumace with them, and they will come up the sooner, that is, in the first year, if sown in the autumn soon after the fruit becomes ripe. If Crab-stocks be planted while young, in the same manner as the quick, they soon make excellent hedges; and so will some sorts of plums, especially such as are thorny. The Black Thorn is not so much esteemed for fences as the White Thorn, because it is apt to run more into the ground, and is not certain as to the growing, especially when the plants are not set while very young; but then, on the other hand, the bushes are by much the better, and are also more lasting than the White Thorn, or any other, for dead hedges, or to mend gaps; nor are they subject to be cropt by cattle as the others are. The richer the mould is, the better they will prosper, but yet they will grow on the same sort of soil that the White Thorn does. The Holly will make an excellent fence, and is preferable to all the rest, except that at first it grows slowly; but when once it does grow, it makes amends by its height, strength, and thickness. It is raised of young seedling plants or berries, as the White Thorn is, and the berries will lie as long in the ground before they come up. It delights most in strong grounds, but will grow upon the driest gravel among rocks and stones. French Furze will often do well upon dry sandy banks, where few other plants will grow; but they must be kept very clean at the bottom, and cut thin, and never suffered to grow too high, nor should they be cut in dry weather, or late in autumn, nor early in the spring; the doing either of which, is likely to make it die in patches, which is irrecoverable; it will never break out from old wood if cut close in, after it has been suffered long to grow out. Fences may likewise be made of Elder; if the soil be tolerably good, you may put sticks of Elder, or truncheons ten or twelve feet long, slopeways in your banks, so as to make a chequer-work; and they will make a fence for a garden the quickest of any thing, and be a good shelter. But these fences are improper for a fine garden, because they shoot very irregularly, and are ungovernable; the roots of these trees also spread very far, and draw away all the heart of the ground,

so as to starve whatever plants grow near them: add to this the scattering of the berries, which will fill the ground near them with young plants, and if not weeded out in time, will spoil every thing about them, so that this sort of fence is seldom planted where a hedge of White Thorn can be had. Elder planted on a bank, the side of which is washed with a river or stream, will make an extraordinary fence, and will preserve the bank from being undermined by the water, because it is continually sending suckers from the roots and lower branches, which is of great advantage where the stream washes away the bank. For middle fences in a garden, the Yew is the most governable and durable plant. For surrounding wilderness quarters, Elm, Lime, Hornbeam, and Beech, are very proper.—For farther particulars, see the article *Hedges*.

Ferraria; a genus of the class Monadelphia, order Triandria.—GENERIC CHARACTER. *Calix*: spathe of several inflated leaves; perianth none. *Corolla*: petals six, regular, cohering by their claws, oblong-acuminate, revolute, curled and fringed, alternately smaller. *Stamina*: filamenta three, sitting on the style; antheræ roundish, twin, rough, hairy. *Pistil*: germen inferior, roundish, three-cornered, obtuse; style simple, erect; stigmas three, bifid, cowled, fringed and curled. *Pericarp*: capsule oblong, three-cornered, thicker at top, three-celled, three-valved. *Seeds*: numerous, roundish. ESSENTIAL CHARACTER. One-styled. *Spatha*: inflated. *Petals*: six, regular, waved and curled. *Stigmas*: three, cowled. *Capsule*: three-celled, inferior.—The species are,

1. *Ferraria Undulata*; *Cape Ferraria*. Border of the corolla thrice as long as the claws; lobes of the anthers close. Root tuberous, roundish, compressed, in shape like that of the Indian Corn-flag, but larger; in the centre of the upper side it has a hollow like a navel, whence comes out the stalk; the outer skin is of a light brown colour, and the inside white. It lies inactive every other year, and sometimes will remain two years without putting out either leaves or fibres. Stem a foot and a half high, taper, and about the thickness of a man's little finger. It has lanceolate leaves the whole length, placed alternately, and embracing; the lower leaves are from four to five inches long, and an inch and a half broad towards their base, ending in obtuse points; they are a little keel-shaped, and of a light green colour. Flowers axillary, solitary, from the upper part of the stem, wrapped in a double sheath, out of which the flowering bud rises about an inch. The sheath is composed of a double row of keel-shaped leaves, the inner row being shorter than the outer, and situated obliquely to it. The petals are of a pale sky-blue on the inside, and of a dirty white on the outside. The antheræ are situated below the division of the filamenta, and are terminated by small silky hairs. The above described plant is one of the most singular and beautiful vegetable productions; and it is much to be regretted that its flowers are only of short duration, opening in the morning, and finally closing in the afternoon of the same day; a strong plant, however, will throw out many flowers in

succession. It flowers from February to May.—Native of the Cape. Both this and the third species are propagated by offsets, sent out from the roots; in the same way as the *Ixia*, and should be cultivated in the same manner as is directed for those and the African *Gladjolus*, being too tender to thrive in the open air in England, nor do they succeed well in a green-house; therefore the best method is to make a border four feet wide, either in the front of the green-house or stoves, covering it with a proper frame and glasses, so that the plants may enjoy the free air in mild weather, but be protected from frost. In such a frame, most of the African bulbous and tuberous-rooted plants may be brought to great perfection.

2. *Ferraria Pavonia*; *Mexican Ferraria*. Scape one-flowered; root bulbous; leaves sheathing, the lower ones longer and narrower; spathe two-leaved, compressed; corolla bell-shaped; filamenta sheathing the style; antheræ three, linear; germen pedicelled; stigmas two-parted, filiform; capsule linear.—Native of Mexico.

3. *Ferraria Antherosa*. Claws of the corolla equal to the border; lobes of the antheræ divaricated. It resembles the first species; but differs in the greater length of the claws of the petals, the shape and greater size of the anthers, and the stigmas being more toothed at their base.—Native of the Cape.

Ferreola; a genus of the class Diœcia, order Hexandria.—GENERIC CHARACTER. *Male*: *Calix*: perianth one-leaved; a little ventricose, hairy, three-cleft; clefts ovate, acute, erect, shorter than the tube, the third still shorter and blunter. *Corolla*: one-petalled, tubular, smooth, somewhat fleshy; border three-cleft; clefts erect, acute, hirsute on the outside, with long white hairs, pressed close, within naked. *Stamina*: filamenta six, short, inserted round a semiglobosa receptacle, upright, much shorter than the tube of the corolla; antheræ oblong, acute, erect, white, longer than the filamenta. *Female*. *Calix* and *Corolla*, as in the male. *Pistil*: germen oval; style short; stigma flat, three-notched. *Pericarp*: berry round, smooth, red, pulpy, size of a large pea. *Seeds*: two, large, on one side flat, on the other round. ESSENTIAL CHARACTER. *Calix*: one-leaved, three-cleft. *Corolla*: one-petalled, three-cleft. *Male*: filamenta six, inserted into a semiglobosa receptacle. *Female*: germen oval; berry round, smooth, two-seeded.—The only known species is,

1. *Ferreola Buxifolia*. Trunk irregular, covered with a dark rust-coloured bark, dividing into very numerous irregular branches; leaves alternate, short-petioled, oval, entire, very smooth, shining, firm, about half or three-quarters of an inch long, and half an inch broad. Among the mountains, this grows to a small tree; but in the low countries it is only a shrub. It flowers during the hot season. The ripe berries are well tasted, and universally eaten. The wood is dark-coloured, remarkably hard and durable, and where its size will admit, is employed for such uses as require the most durable heavy wood.—Native of Coromandel.

Ferula; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal, manifold, globular; partial similar; involucre universal, caducous; partial many-leaved, linear, small; proper perianth, scarcely observable. *Corolla*: universal uniform; floscules all fertile; proper consisting of five oblong straightish petals, nearly equal in size. *Stamina*: filamenta five, the length of the corolla; antheræ simple. *Pistil*: germen turbinate, inferior; styles two, reflex; stigmas obtuse. *Pericarp*: fruit oval, plane-compressed, submargined, marked on both sides with three raised lines, and bipartite. *Seeds*: two, very large, elliptic, flat on both sides, and marked

with three distinct streaks. *Observe.* The peduncle of the primary umbel sometimes throws out opposite lateral flower-stalks. **ESSENTIAL CHARACTER.** Fruit oval, plane-compressed, with three streaks on each side.—All the plants of this genus have roots which will continue several years; these have thick strong fibres which run deep in the ground, and divide into many smaller, spreading to a considerable distance every way: the stalks are annual, and decay soon after they have perfected their seeds. As these plants spread very widely, so they should have each four or five feet room; and ought not to stand near to other plants, which their roots will utterly deprive of nourishment. They are all propagated by seeds, which should be sown in the autumn; for if they are kept out of the ground until the spring, they frequently fail, and those which succeed remain a year in the ground, so that much time is lost. The seeds may be sown in drills, which render it easier to keep the ground clean: these drills must be at least a foot apart, and the seeds scattered two or three inches asunder. When the plants come up, they must be kept clean from weeds; and where they are too close together, they should be thinned, to allow them room to grow, for they will not be strong enough to remove till they have had two years' growth; then in the autumn, as soon as their leaves decay, the roots should be taken up with great care, so as not to cut or injure the tap or downright root, and then planted in the places where they are designed to remain, for after this transplanting they should not be removed. They succeed best in a soft, gentle, loamy soil, not too wet; and are very rarely injured by the hardest frost.—The species are,

1. *Ferula Communis*; *Common Fennel-Giant*. Leaflets linear, very long, simple. This, if planted in a good soil, will grow to a great height, and divide into many branches. The lower leaves spread more than two feet every way, and branch out into many divisions, which are again subdivided into many smaller; they are of a lucid green, and spread near the ground. From the centre of the plant comes out the flower-stem, which, when the plants are strong will be nearly as large as a common broom-stick, and ten or twelve feet high, with many joints; there issues from it, when cut, a fetid yellowish liquor, which will congeal on the surface of the wound. This stem is terminated by large umbels of yellow flowers, which come out at the end of June, or the beginning of July. The seeds ripen in September, and the stalk decays soon after. The stalk is filled with a light pith, which when dry easily takes fire: this pith the Sicilians use for tinder; and hence arose the fable of Prometheus. The leaves of this plant decay soon after the seeds are formed; but the roots continue several years, especially in a dry soil, and annually produce flowers and seeds.—Native of Italy, the south of France, Sicily, and Greece. In Apulia, where it abounds, it is grateful to the buffaloes, which form the principal wealth of the farmers. When it arrives to a considerable size, they use it to make stools and bee-hives. All the parts of this plant have a very strong smell, and abound with a milky juice, which is aerid to the taste, and concretes into a gummy substance, resembling galbanum or assafoetida, which are produced by two other plants of the same kind. "It is not," says Meyrick, "much regarded in medicine, but its smell and taste indicate that it possesses considerable virtues, which, from its affinity with the above-mentioned antispasmodic and nervous drugs, I am led to conclude are of a similar nature."

2. *Ferula Glauca*; *Glaucous Fennel-Giant*. Leaves superdecompound; leaflets lanceolate-linear, flat; stem from three to four feet high, terminated by an umbel of yellow

flowers, appearing in July, and succeeded by oval compressed seeds, ripening in autumn.—Native of Spain, Italy, and Sicily.

3. *Ferula Tingitana*; *Tangier Fennel-Giant*. Leaflets lacinate, the little jags three-toothed, unequal, brilliant; leaves large, spreading near the root, of a very lucid green, divided and subdivided into many parts. The leaflets are much broader than in the other sorts, and divided at the end into three unequal segments; the stems are strong, eight or ten feet high, terminated by large umbels of yellow flowers; and the fruit lenticular-bracted, calicled, of a dirty bay colour.—Native of Spain and Barbary.

4. *Ferula Ferulago*; *Broad-leaved Fennel-Giant*. Leaves pinnatifid; pinnae linear, flat, trifid. Height seven or eight feet. The umbels are large, and the flowers yellow.—Native of Sicily.

5. *Ferula Orientalis*; *Narrow-leaved Fennel-Giant*. Pinnae of the leaves naked at the base; leaflets bristle-form. This is much humbler in its growth than any of the preceding species, the stalks seldom rising much more than three feet high. The lower leaves branch into many divisions, with fine bristle-shaped leaflets. The umbel of flowers, and the seeds, are small.—Found by Tournefort in the Levant.

6. *Ferula Meoides*; *Spiguel-leaved Fennel-Giant*. Pinnae of the leaves appendicled on each side; leaflets bristle-form. This has very branching leaves, with angular channelled foot-stalks. At every joint are two opposite branches; those towards the bottom are nine or ten inches long, and the others diminish gradually to the top: these side-branches send out smaller ones at each joint in the same manner, having very fine leaves on them, like those of *Spiguel* or *Meum*, standing quite round in shape of whorls. The flower-stalks are three feet high, having a pretty large umbel of yellow flowers at the top: these are succeeded by oval flat seeds, which ripen in the autumn.—Native of the Levant.

7. *Ferula Nodiflora*; *Knotted Fennel-Giant*. Leaflets appendicled; umbels sessile. This plant is about three feet high; involucre very short, and reflex; rays of the universal umbel to fourteen, of the umbellule to twelve; petals yellow.—Native of Istria, Austria, and Carniola.

8. *Ferula Canadensis*. Lucid. See *Angelica Lucida*; from which, however, the specimen in Gronovius's *Herbarium*, afterwards in the possession of the late Sir Joseph Banks, is very different.

9. *Ferula Assafoetida*; *Assa-fœtida*. Leaves alternately sinuate obtuse. The *Assa-fœtida*, as described by Dr. Hope, is an umbelled plant, three feet high, upright, branching, glaucous, with a yellow flower; root perennial; root-leaves six, procumbent, three-lobed, ovate, many times pinnate; leaflets gashed, subacute, subdecurrent; common petiole flat above, with a raised line running longitudinally through the middle of it; stem two feet high, roundish, annual, slightly streaked, having only one pair of imperfect leaves about the middle. The branches are naked, and spreading; the three lower ones alternate, and supported by the concave membranaceous petiole of the imperfect leaf; the four middle ones are in whorls, the uppermost from the top of the stem, eight in number, the inner ones erect; all these support a compound sessile terminating umbel, besides from three to six branchlets placed on the outside, bearing the compound umbels: in this manner the lower branches support five, seldom six branchlets, the middle ones three or four, the upper ones one or two. The universal umbel has from twenty to thirty rays; the partial from ten to twenty, with subsessile florets. There is no involucre, either general or partial.

The florets of the sessile umbel are fertile, of the peduncled umbel mostly abortive; petals equal, flat, ovate, at first spreading, then reflex, with the tip ascending; filamenta awl-shaped, longer than the corolla, curved in; antheræ roundish; fruit oblong. Every part of the plant, when wounded, pours out a rich milky juice, resembling the imported drug in smell and taste; and at times a smell like garlic, such as a faint impregnation of *Assa-fœtida* yields, was perceivable at the distance of several feet.—*Assa-fœtida* is the concrete juice of the root, and is procured by the peasants who live in the neighbourhood of the mountains of Persia, in the province of Chorasán and Laar. It seldom flowers till it arrives at twenty or thirty years of age; and when it does, and has ripened its seeds, the plant perishes. In the latter end of April, when the leaves begin to decay, the Persians go in search of the plants, and after having cleared away the earth from the roots, to the depth of six or seven inches, they twist off the leaves, and then earth up the root again nearly to the top, which they cover with weeds, in order to keep off the heat of the sun, that would otherwise greatly prejudice, if not totally destroy it. In this state they leave the plant for the space of a month or six weeks; at the end of which time they take away the covering, and with a sharp knife cut about an inch in length from off the top of the root. They then cover the wounded root again with weeds, and leave it for two or three days; at which time they return, and find the wound covered with the exudated juice of the root; this they carefully gather, and preserve in vessels. They then clear away the earth a little lower from the root, cut a second slice from its top, and cover it up again with weeds for another gathering; which having made, they cover them up for eight or ten days more, and during this time they spread the gum which they have already collected in the sun to harden, and then carry it home. Four or five men generally go in a company, for the purpose of collecting this gum, and it is no uncommon thing for them to carry home forty or fifty pounds weight at each excursion they make. When the roots have remained covered up eight or ten days, they pay them another visit, take off the weeds, and collect the gum. They then cut another slice from the roots, and after that a third; this is done at the distance of two or three days betwixt the times of cutting, and the whole process is managed as in the first gathering. When they have thus made their third collection in this second expedition, they cover up the roots again for three or four days, and return home with their stores. They then return, and cut them three several times as before, after which they leave them to perish.—*Assa-fœtida* is well known by its peculiarly nauseous fetid smell, the strength of which is the surest test of its goodness: this odour is extremely volatile, and of course the drug loses much of its efficacy in keeping. It is imported in large irregular masses, composed of various shining little lumps or grains, partly whitish, partly brownish or reddish, and partly of a violet hue: those are accounted the best which are clear, of a pale reddish colour, and variegated with many fine white tears. It is a gummy resin, but has the gum in largest quantity. This drug is an excellent medicine in all nervous and hysteric disorders. It removes flatulencies, helps the colic, promotes the menses, expels the after-birth, and is a powerful sudorific. It is likewise serviceable in asthmatic and hypochondriacal complaints, convulsions, and other fits. Joined with opium, it considerably diminishes the efficacy of that narcotic drug; and applied externally in form of a plaster, it softens and disperses hard swellings. Though *Assa-fœtida* has been used in medicine for many ages, having been introduced by the Arabian physicians

nearly a thousand years ago, yet there was no satisfactory account of the plant which produces it, until Kæmpfer described and figured it in his *Amœnitates Exoticæ*, published in 1712. Kæmpfer travelled over a great part of Asia, towards the end of the last century, and was in Persia, upon the spot where this drug is collected; where it is called *Hingisch*. His plant differs in many respects from that above described; and as his fidelity has never been impeached, we must conclude that this gum, like many others, is the produce of more than one species. According to Kæmpfer's account, the root of the *Assa-fœtida* is perennial, tapering, ponderous, increasing to the size of a man's arm or leg, covered with a blackish bark, and near the top beset with many strong rigid fibres: the internal substance is white, fleshy, and abounds with a thick milky juice, yielding an excessively strong, fetid, alliaceous smell: stem simple, erect, straight, round, smooth, striated, herbaceous, six or seven inches in circumference at the base, and rising luxuriantly to the height of two or three yards or more; root-leaves six or seven, nearly two feet long, bipinnate; pinnules alternate, smooth, variously sinuated, lobed, and sometimes lanceolate, of a deep green colour, and fetid smell; umbels compound, plano-convex, terminating, many-rayed; seeds oval, flat, foliaceous, reddish-brown, rough, marked with three longitudinal lines, having the garlic smell, and a sharp bitter taste. It varies much from soil and situation, not only in the form of the leaves, but in the quality of the juice.

Fescue Grass. See *Festuca*.

Festuca; a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: glume many-flowered, two-valved, upright, containing the floscules in a slender spikelet; valves awl-shaped, acuminate, the lower smallest. *Corolla*: two-valved, lower valve largest, of the same form with the calix, but larger, roundish, acuminate, ending in a dagger-point; nectary two-leaved; leaflets ovate-lanceolate, acute, gibbous at the base, or one-leaved, plano-concave, horizontal, emarginate. *Stamina*: filamenta three, capillary, shorter than the corolla; antheræ oblong. *Pistil*: germen turbinate; styles two, short, reflex; stigmas simple. *Pericarp*: none. *Corolla*: very closely shut, growing together, and not gaping. *Seed*: single, slender, oblong, very sharp at both ends, grooved longitudinally. **ESSENTIAL CHARACTER.** *Calix*: two-valved; spikelet oblong, roundish, with acuminate glumes.—For the propagation and culture of this genus, see *Grass*.—The species are,

1. *Festuca Bromoides*; *Barren Fescue Grass*. Panicle directed to one side; spikelets upright, one valve of the calix entire, the other acuminate. It is about half a foot high; the culms are inclined; the leaves thin and smooth, the lower part of them quickly drying up: the panicles branch at the base; they are composed of smooth flattened spikelets, containing six or seven flowers; the outer valve of the corolla terminates in a long awn; the calix has the outer base very small, the inner is large, and ends in an awn like the corolla. Annual: flowering in June and July.—Native of England and France, where it is found on walls, and in sandy pastures.

2. *Festuca Ovina*; *Sheep's Fescue Grass*. Panicle directed to one side, contracted, awned; culm four-cornered, almost naked; leaves bristle-shaped. This is a small grass, scarcely exceeding six inches in height; perennial, flowering in June and July. Floscules three to six in each spikelet, generally acuminate, or acuminate awned; culms somewhat angular, with two or three coloured joints; root-leaves hirsute; stem-leaves smooth; lower spikelets peduncled, linear, four-flowered, with the rudiment of a fifth; glumes unequal, the larger ovate, the smaller sharp. It is chiefly found on dry sandy

soils, and in elevated situations; and is common on all our finest sheep-downs. This grass has been much celebrated for feeding sheep; Linneus asserts, that it is their principal food, and that they have no relish for hills and heaths that are without it. Gmelin says, that the Tartars choose to fix during the summer wherever there is the greatest plenty of this grass, because it affords a most wholesome nourishment to all kinds of cattle, but chiefly sheep. It certainly is a very sweet feed, as far as it goes, on sheep-downs. Mr. Anderson does not scruple to affirm, that it is capable of affording an immense quantity of hay, and that it promises to be one of the best grasses our country produces, and to make a most valuable acquisition to the farmer. This, however, seems to be carrying our prejudices very far indeed, for in its native soil, on dry elevated heaths and commons, its foliage is hard and wiry, and its produce very trifling. In such situations, it is of a puplish-brown colour in summer. In a rich moist soil, indeed, the foliage retains its verdure, and becomes much longer; but being after all but a small plant, it can never be productive, and consequently cannot have any pretensions to be considered as fit for a hay-grass. Were the Sheep's Fescue to be sown in such a soil, the grasses and other plants natural to that soil would quickly overpower it; and it is not merely the grass, but the nature of the soil in which it grows, the elevated situation, and the dry salubrious air, that are acceptable to sheep. Mr. Curtis, who has combated the vulgar notion of the excellence of this poor wiry grass for feeding cattle, particularly sheep, has however found out that it is excellent for the purpose of making a fine grass-plot, requiring little mowing: when it has once got possession of the soil, it will form so thick a turf, as to suffer few intruding weeds, and may be kept in order with little trouble. For this purpose it must be sown about the middle of August, in an open but not too dry situation, broadcast, and that thickly, on ground nicely prepared and levelled.—There is a variety which grows in Sweden, and on the mountains of Wales, Yorkshire, and Westmoreland.

3. *Festuca Rubra*; *Purple or Red Fescue Grass*. Panicle directed to one side, scabrous; spikelets six-flowered, awned; floscule at the end awnless; culm semicylindric. Red Fescue Grass is distinguished from the preceding by its greater size, its red colour when ripe, and the culm being cylindric, only flattened a little on one side. The leaves are covered with a woolliness on the upper side, barely perceptible to the naked eye; culms smooth, but rough within the panicle. According to Villars, the stiff hard leaves, those of the stem, like those next the root, fine, and of a shining green, with the brownish-red shining colour of the flowers, distinguish this from the innumerable varieties of other species; the glumes of the corolla are smooth.—Found on high heaths and dry pastures; perennial, and flowering in July.

4. *Festuca Amethystina*. Panicle flexuose; spikelets directed to one side, inclined, nearly awnless; leaves bristle-shaped.—This species was found near Paris; and is probably no more than a variety of the second species.

5. *Festuca Reptatrix*. Branches of the panicle simple; spikelets subsessile; root perennial, the thickness of a goose-quill, creeping very far under ground, covered with broad rudiments of leaves; culms more than a foot and a half in height; leaves involute, filiform. Panicle oblong, with alternate very simple branches, pointing one way; spikelets alternate, very many, lanceolate, six-flowered, alternate, acuminate, awnless.—Native of Arabia and Palestine.

6. *Festuca Duriuscula*; *Hard Fescue Grass*. Panicle directed to one side, oblong; spikelets oblong, of an even smooth surface; leaves bristle-shaped; root perennial. Culm twelve

or eighteen inches in height; branches of the panicle alternate; spikelets peduncled, linear, compressed, six-flowered, ascending. It is early and productive; and from these circumstances, and from its natural place of growth, appears to be a proper grass for sheep pastures. It varies much in size and breadth of leaf, as well as in the colour of its panicle; but in all situations it is very distinct from the *Ovina*. All these grasses form an admirable pasture for sheep, and seem to flourish most when they are bit the closest, but are in general unproductive.—Native of dry pastures, flowering in June.

7. *Festuca Dumetorum*; *Pubescent Fescue Grass*. Panicle spike-form, pubescent; leaves filiform; culms a foot or eighteen inches in height, filiform, cylindric, with two swelling knots; root-leaves a foot long, cylindric, scarcely apical; stem-leaves shorter, channelled; glumes terminating in a minute awn; bulbs very often produced within the sheaths of the culm.—Grows in woods and hedges, flowering in June and July.

8. *Festuca Elatior*; *Tall Fescue Grass*. Panicle directed to one side, upright; spikelets mostly awned, the outer ones cylindric; leaves from a foot to eighteen inches long; florets about eight; calicine glumes unequal, acuminate, of the corolla nearly equal, pointed, the outer a little larger and longer, the inner often bifid. Hudson, who joins the Meadow with the Flote Fescue, doubts whether this be a distinct species, since it has so many things in common with them; but Curtis, although he allows it to be very similar, asserts that it is specifically different: he says, that it grows to a great height in marshes, is hardy, and very productive, but too harsh and coarse for hay; yet allows that it may perhaps be a good grass for soils which cannot be drained of their too great moisture, or are very liable to be overflowed.—It is found in moist meadows and woods, but most frequently in wet situations, as by river sides, and in Osier grounds. It grows in large tufts, and is conspicuous by the breadth of its leaves, the height of its stems, and the drooping of its panicle, at least before it flowers. In very luxuriant spots the leaves are sometimes half an inch wide, but in general this grass varies little, except in size, and sometimes in having awns. Perennial, flowering in June and July.

9. *Festuca Myurus*; *Wall Fescue Grass*. Panicle spiked; calices extremely minute, awnless; flowers scabrous; awns long; culms aggregate, cylindric, a foot or eighteen inches in height; spikelets subsessile, linear, with five floscules in each; glumes very unequal; awns longer than the spikelets; according to Haller, growing from below the tip. It is annual; and is called *Capon's-tail Grass*.—Found upon walls and barren places, flowering in June.

10. *Festuca Spadicea*; *Bronze-flowered Fescue Grass*. Panicle erect; spikelets ovate, four-flowered; glumes acuminate, awnless; leaves bristle-shaped, smooth, pungent; root perennial. Culms three feet high, erect, strict, round, striated, very smooth, with one or two purple joints; leaves involute-setaceous, strict, very smooth, striated, mucronate, pungent, glaucous, widened into a membrane at the base, sheathing, whitish; peduncles angular, subflexuose, erect; spikelets compressed, usually four-flowered, smooth. Dr. Smith, whose sagacity and attention in developing this species are eminently conspicuous, informs us, that he has learnt from Savoy, that this grass is likely to become of considerable use, and that large quantities of it are now in cultivation.—Native of the south of France, Switzerland, &c.

11. *Festuca Phœnicoides*. Raceme undivided; spikelets alternate, almost sessile, cylindric; leaves involute, mucronate, and pungent; root creeping. Culms two feet high and upwards,

straight, branched at the base; spike from two inches to a foot or more in length; spikelets remote, two inches long, sharpish, from six to eight flowered; glumes mucronate.—Perennial; native of the sandy shores of Provence.

12. *Festuca Fusca*. Panicle erect, branched; spikelets sessile, keeled, awnless; culm lofty, branched; leaves from broadish sheaths, narrow, longitudinally involute, long, subulate.—Native of Palestine.

13. *Festuca Decumbens*; *Decumbent Fescue Grass*. Panicle upright; spikelets subovate, awnless; calix larger than the floscules; culm decumbent, from a foot to eighteen inches in length, somewhat bulbous at the base, having three knots, lying on the ground, but when in flower, ascending obliquely; root perennial; root-leaves narrowish, flat, hairy on the upper surface, especially at the base; stem-leaves the same, only shorter; sheaths villose above; nectaries two, obtuse.—It flowers in July and August, and is frequent on moorish ground, in both dry and wet pastures.

14. *Festuca Pauciflora*. Panicle effuse; spikelets with about four flowers, awned, and scabrous; leaves villose; culm round, streaked, upright, two feet high; calices marked with lines, lanceolate, with long awns.—Native of Japan.

15. *Festuca Fluitans*; *Flote Fescue Grass*. Panicle branched, erect; spikelets subsessile, cylindrical, awnless; root perennial, striking deep into mud; culm from one to three feet in length, or even much longer in water, creeping at bottom, and sending forth young shoots, afterwards nearly upright, and covered with the sheaths of the leaves as far as the panicle; valves of the corolla equal in length, the lower nerved; the nerves towards the top frequently coloured, at top membranaceous, rather blunt, with uneven points, the upper valve more pointed, flat, and bifid; nectary a small heart-shaped gland, resembling a scale, placed horizontally at the bottom of the germen; stigmas very much branched, but the styles not feathered to the germen, as in Schreber's figure, and in the *Flora Danica*; seed shining, olive-coloured, with two little horns, and naked. When it has nearly done flowering, the branches of the panicle generally project from the main stalk in an acute angle: in every situation the spikelets are always pressed close to the stalk or branches of the panicle; this circumstance, joined to the length and roundness of the spikelets, sufficiently characterizes this species; which being common in ditches, watery places, and slow streams, flowering all the summer, and having the parts of fructification beautiful, and large enough to be distinctly discerned by the naked eye, without the trouble of dissection, is peculiarly adapted for the investigation of the student. It appears that horses, cows, and hogs, are fond of this grass. Mr. Stillingfleet informs us, that having been told of a field of four acres, always under water, maintaining five farm horses in good heart from April to the end of harvest, without any other food; he obtained some of the grass, and found it to be the *Flote Fescue*, with a mixture of Marsh-bent. Cows, in spring, are frequently enticed into bogs, by endeavouring to get at the sweet young shoots of this grass, which appear earlier than those of most other grasses. Professor Kalm, observing that swine go a great way into the water after the *Flote Fescue*, and that they eat the leaves with great eagerness, had small bundles of it gathered and dried for hay, which they greedily devoured; hence he concludes, that wet and swampy places might be rendered useful by cultivating this grass. It has been recommended to be sown on meadows that admit flooding; but Mr. Curtis remarks, that this grass will not flourish, except on land that is constantly under water, or converted into a bog or swamp.—The seeds are small, but very sweet and nourishing, and are

collected in many parts of Germany and Poland, under the name of *Schwaden*, or manna-seeds, and are reckoned a delicacy in soups and gruels. When ground to meal, they make bread very little inferior to that prepared from Wheat; the bran is given to horses that have the worms, but they must not be suffered to drink for some hours afterwards. Geese, and other water-fowl, are very fond of the seeds; so are also fish: trout in particular thrive in those rivers where this grass grows in plenty. Schreber says, that the seeds are collected not only from this grass, but also from *Panicum Sanguinale*, or *Cock's-foot Panic-grass*, which is cultivated in several parts of Germany for this purpose. The common method of gathering and preparing them is as follows: At sun-rise, they are gathered or beaten from the dewy grass into a horse-hair sieve, spread on a sheet, and are dried for a fortnight in the sun; they are then beaten gently with a wooden pestle, in a wooden trough or mortar, with straw laid between them and the pestle, till the chaff comes off, and then they are winnowed: after this, they are once more put into the mortar or trough in rows, with dried Marigold flowers, Apple and Hazel leaves, and pounded till they appear bright; they are then winnowed again, and being made perfectly clean by this last process, are fit for use. The Marigolds are added, to give the seeds a finer colour. The most proper time for collecting the seed is in July. A bushel of seed with the chaff, yields only about two quarts of clean seed. Mr. Curtis has observed a disorder in the ear of this grass, similar to that which has been noticed by the French in Rye, and called by them *Ergot*.

16. *Festuca Pratensis*; *Meadow Fescue Grass*. Panicle directed one way, oblique; spikelets without awns, almost linear; leaves flat. This has been often confounded with the eighth species, from which it differs, in having only half its height or little more; the leaves only half the breadth; the panicle shorter, and containing about half the number of flowers. The panicle is but once branched, droops but slightly, leans to one side when in flower, and the flowers all grow in one way. This is also more common and less local than the *Elatior*, being found more dispersed in open meadows, and does not form such large tufts; they differ a fortnight or three weeks in their time of flowering. Mr. Curtis, who has cultivated it, recommends it among the six grasses, which he prefers before all others, and particularly for land either moist or moderately dry. This, says he, comes nearest in appearance to *Lolium Perenne*, or *Ray Grass*, to which, however, it seems in many respects greatly superior, at least for the purpose of forming or improving meadows; it is larger, and more productive of foliage; is strictly perennial, very hardy, and is found in all situations, from the sand-pits at Charlton, to the Osier grounds at Battersea, and abounds in the very best meadows about London; in short, there is no grass more likely to supply the deficiencies complained of in *Ray Grass*. One quality it has, which bids fair to introduce it quickly into general use; it produces more seeds than any of the others, which are easily gathered, and readily grow. In one respect it is inferior to *Vernal Meadow Fox-tail*, and *Smooth-stalked Meadow Grass* (*Poa Pratensis*;) it does not produce its flowering-stems earlier than about the middle of June, a fortnight or three weeks later than *Meadow Fox-tail Grass*; yet it cannot be considered as a late grass, for the most of the *Agrostis* genus, and *Meadow Cat's-tail Grass*, (*Phleum Pratense*;) flower at least three weeks later.

17. *Festuca Cristata*. Panicle spiked, lobed; spikelets ovate, broad, six-flowered, hirsute; culms many, scarcely the length of a finger.—Native of Portugal, on barren hills.

18. *Festuca Calicina*; *Bearded-leaved Fescue Grass*. Pa-

nicle contracted; spikelets linear; calix longer than the floscules; root annual; leaves bearded at the base; root-leaves collected into a tuft; culms filiform, narrow, of a finger's length. According to Cavanilles, who observed it near Madrid, a short fibrous root produces slender culms from four to six inches in height, somewhat prostrate at the base, but from the first joint upright; joints purple; valves of the corolla awnless, the outer ovate, striated, white, and scariose at the tip, including the inner; the genitals so minute as not to be visible to the naked eye.—Native of Spain, where it flowers in May, and here in June and July.

19. *Festuca Misera*. Panicle condensed; glumes awned, scabrous; culm kned, broken; leaves ensiform, smooth, a finger's length; panicle resembling a spike, mostly pointing one way, smooth, a finger's length; calicine glumes containing few flowers.—Native of Japan.

20. *Festuca Spinosa*; *Thorny-branched Fescue Grass*. Becoming shrubby: branches and branchlets thorny; pedicels prickly; culms perennial, the size of a pigeon's quill feather, solid, proliferous. The branches crowded, upright, simple, thorny at the end; leaves with dilated sheaths, ending in an awl-shaped, pungent, very short leaf; flowers distich.—Native of the Cape of Good Hope.

21. *Festuca Uniglumis*; *Sea Fescue Grass*. Panicle almost simple, condensed, directed one way, awned; calix one-valved; floscules distant; root annual; culms many, from six inches to a foot in height, oblique, round, smooth, somewhat branched; leaves petioled, somewhat involute, sharp, naked, much shorter than the petiole, which is sheathing, ventricose, and naked.—Native of the sea-coast, where it is found in loose sand, flowering in May and June.

22. *Festuca Cambrica*; *Welsh Fescue Grass*. Panicle directed one way, oblong, upright, branched; spikelets awned, smooth; leaves flattish, naked; root perennial; culm about a foot in height, oblique, round, leafy, smooth, having two or three joints; root-leaves somewhat erect, ensiform, sharpish, channelled; stem-leaves two or three, petioled, sharpish, nerved. It flowers in July and August, and grows on the highest mountains about Llanberis, in Wales.

23. *Festuca Indica*; *Indian Fescue Grass*. Panicle contracted, upright; spikelets compressed, somewhat awned, with about six flowers. This species has the appearance of a *Poa*; culms three feet high and more, the thickness of a pigeon's quill, streaked, leafy. It is distinguished at a distance by its bluish-green colour; one half of the panicle flowers and expands, contracting again, whilst the other half flowers.—Native of Tranquebar, in the East Indies, where it is found in the Rice-grounds, with erect culms in flooded, and decumbent culms in dry lands.

24. *Festuca Scabra*; *Rugged-flowered Fescue Grass*. Panicle directed the same way, squeezed close, erect; spikelets compressed, six-flowered; florets rugged. This grass is a foot and a half high or more, with a round, smooth, striated culm, and involuted leaves; spikelets lanceolate; calicine glumes smooth; outer valves of the corolla rugged, acute, villose, when viewed by a magnifier.—Native of the Cape.

25. *Festuca Pungens*. Spike glomerate, ovate; spikelets six-flowered, columnar, lanuginose; leaves involute, rigid; culm creeping; branches erect, divided at top, commonly into four divaricated branchlets, a span long, and the thickness of a pigeon's quill; the internodes an inch in length; leaves alternate, in two rows, spreading very much, pungent, smooth, very finely streaked; sheaths twice as long as the joints, covering the culm, broader than the leaves, ciliate, bearded at the throat on each side, without any ligule or strap; spike compound, sessile, terminating.

26. *Festuca Loliacea*; *Darnel Fescue Grass*. Spiked: spikelets alternate, sessile, compressed, awnless. In deference to the judgment of Mr. Curtis, who has bestowed so much laudable attention on this useful tribe of grasses, the *Darnel Fescue Grass* is here given to a distinct species, though Mr. Hudson regarded it as a variety of the *Fluitans*, and others of the *Pratensis*. In root-stalk, leaves, and habit, it comes so near *Lolium perenne*, or *Common Ray Grass*, as scarcely to be distinguished from it; but it is usually higher by about one-third; the flowers in general grow in a simple spike, from eight inches to a foot in length, bending a little towards the top; the spikelets are sessile, nearly an inch long, diverging from, and for the most part placed obliquely to, the rachis, sometimes on peduncles of different lengths, the lowermost about an inch long, nearly round, flattened a little on the sides, running out to a point, the uppermost shorter and somewhat broader, containing from ten to fifteen flowers; calicine valves unequal in size, the innermost frequently small, lateral, and sometimes wanting.—It abounds in moist fertile meadows, and flowers about the same time with the *Pratensis*. It is a hardy perennial, of very quick growth, producing a crop somewhat similar to Ray Grass, but larger, and succeeding best in a moist soil; it is, however, harsh and stalky. This and the eighth species (*Elatior*) do not seem to produce seeds, at least in a state of cultivation: may not this circumstance arise from their running so much at the root?

Feverfew. See *Matricaria*.

Fever Root. See *Triostium*.

Feuillea; a genus of the class Diœcia, order Pentandria.—**GENERIC CHARACTER.** *Male*. *Calix*: perianth bell-shaped, one-leafed, half five-cleft, rounded at bottom, spreading at top. *Corolla*: one-petalled, wheel-shaped; border half five-cleft: divisions convex, rounded; navel closed with a double little star, respecting the sun's motion, the rays alternately longer and shorter. *Stamina*: filamenta five, subulate; antheræ twin, roundish; nectary consists of five compressed threads bent in, and alternate with the stamina. *Female*. *Calix*: perianth as in the male, but with a germen at the base. *Corolla*: as in the male; the star of the navel is formed of five heart-shaped plates. *Pistil*: germen inferior; styles three or five, filiform; stigmas heart-shaped. *Pericarp*: berry, or rather pome, very large, fleshy, with a hard skin, ovate, obtuse, surrounded with the calix. *Seeds*: compressed, orbicular nuts. **ESSENTIAL CHARACTER.** *Male*. *Calix*: five-cleft. *Corolla*: five-cleft. *Stamina*: five. *Nectary*: five converging filamenta. *Female*. *Calix*: five-cleft. *Styles*: three. *Pome*: hard, three-celled, corticose.—The species are,

1. *Feuillea Trilobata*. Leaves lobed, dotted underneath; stem angular, the thickness of a thread: at the axils of the leaves are tendrils and bulbs.—Native of the East Indies.

2. *Feuillea Cordifolia*. Leaves heart-shaped, angular, petioled, alternate; stem suffrutescent at bottom, divided at top, with herbaceous branches, climbing frequently to the tops of trees, roundish, and very smooth; flowers racemed, dusky yellow; the fruit is a globular, corticose, hard, many-seeded pome; the nuts are orbicular, compressed, rugged, and ferruginous, enclosing a very white kernel: the whole plant is very bitter. There is a remarkable analogy between the fruit of this plant and that of the *Faba Ignatii*. It is frequent in the inland parts of Jamaica, and is generally found climbing among the tallest trees in the woods: the seeds are very oily, and often burnt by the negroes instead of candles. The kernels are extremely bitter, and commonly infused in rum for the use of the negroes: a small quantity

of this liquor opens the body, and provokes an appetite, but a larger dose works both by stool and vomit. Browne calls it the *antidote cocoon*; as it is frequently taken when there is any suspicion of poison, and often on other occasions. Some think this to be a variety of the first species; and Swartz affirms, that they are not so much as varieties.

Ficus; a genus of the class Polygamia, order Diœcia.—**GENERIC CHARACTER.** *Calix*: common obovate, very large, fleshy, concave, closed with many semi-lanceolate, sharp, serrate, inflex scales. The inner surface is covered with floscules, the outer of which, or those which are nearer to the edge of the calix, are male, these are fewer in number; the rest, lower down, are female, and more numerous. *Male*, each on its proper peduncle. *Calix*: perianth proper, three-parted, erect; divisions lanceolate, erect, equal. *Corolla*: none. *Stamina*: filamenta three, bristle-shaped, length of the calix; antheræ twin. *Pistil*: rudimenta caducous, intorted. *Female*, each on its proper peduncle. *Calix*: perianth proper, five-parted; divisions lanceolate-acuminate, straight, nearly equal. *Corolla*: none. *Pistil*: germen oval, the size of the proper perianth; style subulate, inflex, coming out from the germen at the side of the tip; stigmas two, acuminate, reflex, one shorter than the other. *Pericarp*: none, except the perianth enlarged and become pulpy. *Seed*: single, roundish, compressed. **ESSENTIAL CHARACTER.** *Receptacle*: common turbinate, fleshy, converging, concealing the floscules, either on the same or on a distinct individual. *Male. Calix*: three-parted. *Corolla*: none. *Stamina*: three. *Female. Calix*: five-parted. *Corolla*: none. *Pistil*: one. *Seed*: one.—Linneus tells us, that he removed this genus from the class Cryptogamia to Polygamia, on account of the different structure of the fructification, the spreading *umbilicus*, navel, or opening of the receptacle in some species, its want of genuine affinity to the plants of the class Cryptogamia, and by the advice of baron Munchausen, a very acute botanist. Some modern authors have again removed the genus into the class Triandria. There are two treatises on this genus; one in the first volume of the *Amœnitates Academicæ*, in 1744, and the other by Thunberg, in 1786.—The species are,

1. *Ficus Carica*; *Common Fig Tree*. Leaves palmate-subtrilobate, rugged underneath; fruits smooth, pear-shaped, umbilicated. The common Fig-tree seldom exceeds two yards in height; the trunk is about the thickness of the human arm; the wood porous and spongy; the bark ash-coloured, full of chinks, and rugged; branches smooth, with oblong white dots, erect or ascending, flexuose, or bent back; stipules in pairs, sessile, ovate, acute, ferruginous, caducous; leaves deciduous, a span long, in three or five deep rounded lobes, of which the central one is the largest, they are of a deep green; petioles round, grooved, about an inch in length; fruits axillary, solitary, the size of a pear, on very short round peduncles, generally of a purplish colour, with a soft, sweet, and fragrant pulp. The first Figs introduced into England, are still remaining in the archbishop's garden at Lambeth; they are of the white Marseilles kind, and still bear delicious fruit: they cover a surface of fifty feet in height, and forty in breadth; the circumference of the trunk of the southernmost is twenty-eight inches, of the other twenty-one. On the south side of the building is another tree of the same age, the circumference of which is twenty-eight inches at the bottom. Tradition says, they were planted by cardinal Pole; which is very probable, for it is generally allowed, that Fig-trees were brought into England in the reign of Henry the Eighth; and it seems likely, that the cardinal, who had resided long in Italy,

should be fond of cultivating those fruits to which he had been there accustomed. To the objection arising from their great age, it may be replied, that we do not well know how long a Fig-tree will flourish, if properly cultivated. There is also a concurrent tradition of an older tree, and instances of two very ancient ones, with the time of their plantation well ascertained. The first at Mitcham, in the garden of the manor-house, formerly the private estate of archbishop Cramer, and still belonging to one of his descendants: it is also of the white sort, and is confidently asserted to have been planted by that venerable prelate: the branches are very low, but the stem, which measures thirty inches in girth, has every mark of great age. The other is in the dean's garden at Winchester, where, in the year 1757, there was a very ancient Fig-tree, the fruit of which was of the small red sort: it was enclosed in a wooden frame, with a glass door and two windows on each side of it, for the admission of sun and air: the frame protected it from wind and rain. On the stone wall to which the tree was nailed, there was a plastering, and several inscriptions, one of which stated, that "in the year 1623, king James the First tasted of the fruit of this tree with great pleasure." Since the above time, this tree has been suffered to perish, for the want of necessary repairs to the frame-work. At Oxford also, in the garden of the regius professor of Hebrew, is a Fig-tree brought from the East, and planted by Dr. Pococke in the year 1648, which is in a thriving condition, and bears a black Fig. In 1792, though this last-mentioned tree bore marks of great age, and had its trunk perforated by insects, and damaged by time and weather, yet the branches of the new wood were clean, made vigorous shoots, and produced a number of small figs, which were touched by the frost, and were then falling off. Turner, in his Herbal, says, that the Fig-tree was cultivated in England in the year 1562; Gerarde says in 1597, and adds, "that the fruit never cometh to kindly maturity with us, except the tree be planted under a hot wall, whereto neither north nor north-east winds can come." Parkinson also, in 1629, says, that "if you plant it not against a brick wall, or the wall of an house, it will not ripen so kindly; that the dwarf Fig is more tender, and is therefore planted in great square tubs, to be removed into the sun in the summer time, and into the house in winter." In his time only three sorts were known: 1. The Figs of Algarva, sweet and delicate, bluish when ripe; 2. the white ordinary sort, that cometh from Spain; 3. the Dwarf Fig, not higher than a man's shoulders, bearing excellent blue fruit, but not so large as the first. Mr. Miller informs us, "that there are many varieties in the warm countries, which have been obtained from seeds, and might be increased, if the inhabitants were careful in propagating the trees from the seeds of the best sorts." In England, we had not more than four or five sorts, till within a few years past; for as the generality of the English were not lovers of this fruit, there were few who troubled themselves with the culture of it. We shall here introduce such of the varieties as are best worth cultivating, placing them in the order of their ripening: 1. The brown, or chestnut-coloured Ischia Fig.—This, says Mr. Miller, is the largest of any I have yet seen; it is short, globular, with a pretty large eye, pinched in near the footstalk, of a brown or chestnut colour on the outside, and purple within; the grains are large, and the pulp sweet and high-flavoured: this sort very often bursts open when it ripens, which it does at the end of July and the beginning of August. It has ripened well on standards in a warm soil, and if planted against hot walls, two plentiful crops of fruit may be annually ripened. 2. The Black Genoa Fig. This

is a long fruit, which swells pretty large at the top, where it is obtuse, but the lower part is very slender towards the stalk; the skin is of a dark purple colour, almost black, and has a purple farina over it, like that of some plums; the inside is of a bright red, and the flesh is very highly flavoured: it ripens early in August. 3. The Small White Early Fig. This has a roundish fruit, a little flattened at the crown, with a very short footstalk; the skin thin, and, when fully ripe, is of a pale yellowish white colour; the inside white, and the flesh sweet, but not high-flavoured: this ripens in August. 4. The Large White Genoa Fig; which is a large globular fruit, a little lengthened towards the stalk; the skin is thin, of a yellowish colour when fully ripe, and red within. This is a good fruit, but the trees are not good bearers. 5. The Black Ischia Fig. This is a short fruit, of a middling size, a little flattened at the crown; the skin is almost black when ripe, the inside of a deep red, and the flesh very highly flavoured: the trees produce a good crop of fruit, but the birds are great devourers of them when not protected. This ripens in August. 6. The Malta-Fig; which is a small brown fruit much compressed at the top, and greatly pinched towards the footstalk; the skin is of a pale brown colour, as is also the inside; the flesh is very sweet, and well-flavoured. If this sort be permitted to hang upon the trees till the fruit be shrivelled, it becomes a fine sweetmeat. 7. The Murray, or Brown Naples Fig. This is a pretty large globular fruit, of a light brown colour on the outside, with some faint marks of a dirty white; the inside is nearly of the same colour: the grains are pretty large, and the flesh is well-flavoured. It ripens in the latter end of August. 8. The Green Ischia Fig. This is an oblong fruit, almost globular at the crown; the skin is thin, of a green colour, but, when it is fully ripe, it is stained through by the pulp to a brownish cast: the inside is purple, and will stain linen or paper; the flesh is high-flavoured, especially in warm seasons. It ripens towards the end of August. 9. The Madonna, commonly called the Brunswick, or Hanover Fig; is a long pyramidal fruit of a large size: the skin is brown; the flesh is of a lighter brown colour, coarse, and has little flavour. This ripens at the end of August and the beginning of September: its leaves are much more divided than those of most others. 10. The common Blue or Purple Fig; is of an oblong shape, and a great bearer: the fruit ripens in August. 11. The Long Brown Naples Fig. The leaves of this tree are deeply divided; the fruit is long, and somewhat compressed at the crown; the footstalks are pretty long; the skin is of a dark brown when fully ripe; the flesh inclining to red, and well-flavoured, with large grains: it ripens in September. 12. The Yellow Ischia Fig. This is a large fruit, of a pyramidal form; the skin is yellow when ripe, and the flesh is purple, and well-flavoured; but the trees do not produce much fruit here: they grow very luxuriant in branches, with large leaves, which are but slightly divided: it ripens in September. 13. The Small Brown Ischia Fig; which is a small pyramidal fruit, with a very short footstalk; the skin is of a light brown, the flesh inclining to purple, of a very high flavour. The leaves of this tree are less divided than any of the other sorts. It is not a good bearer, and ripens late in September. 14. The Gentile Fig. This is a middling-sized globular fruit; the skin when ripe is yellow, and the flesh inclines to the same colour; the grains are large, and the flesh well-flavoured; but it ripens very late, and the trees are bad bearers, so that it is not propagated much in England.—There are several sorts which have been lately introduced from Italy, but some of them rarely ripen their fruit, and others are very unproductive, and not worth propagating; and therefore not worth enumerating here.

Those above specified continue in succession during the season for these fruits, and are preferable to the others; and few persons will care to fill their gardens with a greater variety of these trees than are of real use, especially as they require good walls, and a very large share of room.—The common Fig-tree is, in all probability, originally a native of Asia, though it has been introduced into Europe in the very early ages. It has the same name slightly varied in all the European languages. The Germans call it *feigenbaum*, or *figenboom*; the Danes, *figentræ*; the Swedes, *fikonstrû*; the French, *le figuier*; the Italians, *fico* or *figo*; the Spaniards, *figuera*; the Portuguese, *figueira*; the Russians, *финик*; the Poles, *figa*; the Turks, *ingar*; and the Arabs, *tin*.—Native of Asia, Barbary, the southern parts of Europe, and Louisiana.—The dried figs, sold by the grocers, are the fruit of this tree, cured by first dipping them in a scalding lye, made from the ashes of the tree which produces them, and afterwards exposing them to the heat of the sun. The fruit is accounted grateful to the stomach, moderately nourishing, and is more easily digested than any of the other sweet fruits. They are a useful ingredient in medicines intended for disorders of the breast, and in opening electuaries. Applied externally, either by themselves, or in conjunction with other ingredients of a similar nature, they greatly forward the suppuration or ripening of inflammatory tumors.—The first, second, third, ninth, and tenth varieties, will ripen their fruit on standards, where they are in a warm situation; but the others require the assistance of walls exposed to good aspects, or they will not bring their fruit to maturity in England. Fig-trees generally thrive in all soils, and in every situation; but they produce a greater quantity of fruit upon a strong loamy soil than on dry ground; for if the season prove dry in May and June, those trees which grow upon very warm dry ground are very subject to cast their fruit; therefore whenever this happens, such trees should be well watered, and mulched, which will prevent the fruit from dropping off; and the fruit upon these trees are better flavoured than any of those which grow upon cold moist land. Those fig-trees bear the greatest quantity of well-flavoured fruit, which grow upon a chalky land, with a foot or more of a gentle loamy soil on the top. They also love a free open air; for although they will shoot and thrive very well in close places, yet they seldom produce any fruit in such situations; and all those which are planted in small gardens in London, will be well furnished with leaves, but seldom bring any fruit to maturity. These trees are always planted as standards in all warm countries; but with us they are generally planted against walls, there being but few standard Fig-trees at present in the English gardens; however, as some sorts ripen their fruit well upon the standards, and the crop of figs is often greater upon them than upon those trees placed against walls, it is worthy of our care to plant them either in standards or espaliers: the latter would probably succeed best in England, if they were managed as in Germany, where they untie the Fig-trees from the espalier, and lay them down, covering them in winter with straw or litter to defend their shoots from the frost. This covering is gradually taken away in the spring, but not wholly removed till the danger of frost is over, by which management they generally obtain a very great crop of figs; whereas in England, where trees are sheltered by warm walls, in mild springs the young figs are pushed out early, and the cold that frequently returns in April and May causes the greater part of the fruit to drop off; so that our crop of figs is generally more uncertain than that of most other sorts of fruit; and it frequently happens, that trees which are planted against north and east aspected walls, produce a greater

quantity of fruit in England, than those which are planted against south and south-east aspects; which may happen, from the latter putting out their fruit so much earlier in the spring than the former; and if cold frosty nights follow their coming out, the most forward figs are generally so much injured as to drop off the trees soon after. In Italy, and other warm countries, this first crop of figs is little regarded, being few in number; for it is the second crop of figs produced from the shoots of the same year, and which rarely ripen in England, that form their principal crop; nor are there above three or four sorts which ever ripen their second crop, however favourable the weather may prove: therefore it is the first crop that must be attended to in England; so that when these trees are growing against walls with the most favourable aspects, it will be a good method to loosen them from the wall in autumn; and, after having divested the branches of all the latter fruit, to lay the branches down from the wall, fastening them together in small bundles, so that they may be tied to stakes, to keep them from lying upon the ground, the damp arising from which might cause them to grow mouldy in frosty weather; and they will also be secured from being broken by the wind. When they are thus managed in autumn, if the winter should prove very severe, the branches may be easily covered with peas-haulm, straw, or any other light covering, which will guard the tender fruit-bearing branches from the injuries of frost; and, when the weather is mild, the covering must be removed, otherwise the figs will come out too early; for the intention of this management is to keep them as backward as possible: then, in the spring, when the figs are beginning to push out, the trees may be fastened up to the wall again. The above plan has been very successful; and great crops have also been produced in some gardens, after very sharp winters, when they have in general failed in other places, by covering up the trees with reeds made into pannels, and fixed up against the walls. In pruning Fig-trees, the branches must never be shortened, because the fruit is all produced at the upper part of the shoots of the former year; if these be cut off, there can be no fruit expected; besides, the branches are very apt to die after the knife; so that when the branches are too close together, the best way is to cut out all the naked ones quite to the bottom, leaving those which are best furnished with lateral branches at a proper distance from each other, which should not be nearer than a foot; and when they are well furnished with lateral branches, if they be laid four or five inches farther asunder, it will be better. The best season for pruning Fig-trees is in autumn, because at that time the branches are not so full of sap, and will not bleed so much as when they are pruned in the spring: at this season the branches should be divested of all the autumnal figs, for the sooner they are removed, when the leaves begin to fall off, the better will the young shoots resist the cold of the winter. There are some seasons so cold and moist, that the young shoots of the Fig-trees will not harden, but are soft and full of juice; when this happens, there is little hope of a crop of figs in the succeeding year, for the first autumn frost will kill the upper part of these shoots for a considerable length downwards: whenever this happens, it is the best way to cut off all the decayed part of the shoots, which will prevent the infection from destroying all the lower part of the branches; for by this method a moderate crop of figs has sprung from the lower part of the shoots, where, if the shoots had received no injury, there would have been no fruit produced; because it is chiefly from the four or five uppermost joints that the shoots come out, and for this reason as many of the short lateral branches should be preserved as possible, those

being the most productive of fruit; for where the long straight shoots are fastened up, there will be no fruit but at their extremities, so that all the lower part of the trees will be naked, if there be not a particular regard had to supply young shoots in every part of the trees. Those trees which are laid down from the espaliers, should not be fastened up again till the end of March, for the reasons before given, and those against walls may remain some time longer; and when the large shoots of these are nailed up, if the small lateral branches be thrust behind them to keep them close to the wall, it will secure the young figs from being injured by the morning frosts; and when this danger is over, they may be brought forward to their natural position again. During the summer season, these trees will require no other pruning, but to stop the shoots in the spring, where lateral branches are wanting; and as the branches are often blown down by wind, whenever that happens they should be immediately fastened up again, otherwise they will be in danger of breaking; for the leaves of these trees being very large and stiff, the wind has great power over them, so that when not well secured they are frequently torn down.—Those trees which are planted against espaliers, may be protected from the injury of frost in the spring, by placing reeds on each side the espalier, which may be taken down every day, and put up again at night; but this need not be practised in warm weather, but only during cold winds and frosty mornings; and although considerable trouble and expense attend this management, yet the plentiful crop of figs, which it seldom fails to obtain, will amply compensate for both: the best way of making this covering, is to fasten the reeds with rope-yarn, in such a manner, that they may be rolled up like a mat, that the whole may be expeditiously put up or taken down; and if these reeds be carefully rolled up, and placed under a dry shed, after the season for using them is over, they will last for several years.—Several persons have lately planted Fig-trees in standards, which have succeeded very well. This practice was revived by the observation that some old standard Fig-trees, which had been growing many years, had generally produced much more fruit than any of those trees which were growing against warm walls: indeed, standard Fig-trees are in much greater danger of having their branches killed by severe frost, but in mild winters they generally fare better than those against walls; so that where these standard-trees can be covered in very hard winters, abundance of fruit is sure to be produced. They may be covered by fastening as many of the branches together as can be conveniently brought into a bundle, and winding some hay-bands, straw, peas-haulm, or any such light covering as can be readily procured, which should be removed gradually in the spring, so as not to expose the shoots all at once to the open air; and if something of the same kind be laid round the stems, and upon the surface of the ground near the roots, it will still more effectually secure them from the danger of frost; but when this method is adopted, great care should be taken that no mice or rats harbour in this covering, for these vermin will eat off the bark from their shoots, and kill them. It has often been observed, that the trees placed against walls have suffered most by these mischievous animals, by having their largest branches deprived of all the bark near the ground, which absolutely killed the trees; and this has generally been remarked to happen in the winter season. The common blue and white Figs, which are the sorts that have been the most generally cultivated in England, are not so proper to plant for standards as some other sorts more recently introduced; for they are more tender, and are often killed to the root,

when some other kinds growing in the same situation have received very little injury from the frost; indeed the white sort is generally a bearer, and the fruit is very sweet; but to those palates which are accustomed to figs, that sort, owing to its want of flavour, is not much esteemed. The first and third kinds have succeeded best. Their branches are seldom hurt by frost in winter, and their fruit will always ripen well; for in favourable seasons, many of these sorts, which were growing against walls, have ripened their second crop of fruit tolerably well. Mr. Miller says, "I have planted many of these sorts of Fig-trees against north-east and north-west aspects: some of these which were first planted, have produced a good quantity of well-tasted fruit, but were ripe much later; which has encouraged me to plant many more of these trees to the same aspects, and also to increase my number of standard-trees." We are aware, that what has been here advanced, in relation to the pruning and dressing of Fig-trees, will be condemned by great numbers of people, who refuse to give themselves time to consider, and examine the reasons upon which this practice is founded, or to make a single experiment to ascertain the truth of it, because it is vastly different from the practice of most gardeners, who generally imagine that Fig-trees should never have much pruning, or at least that they ought always to be suffered to grow very freely to some distance from the wall. It cannot be denied, that great quantities of fruit have been obtained by this latter and more common method, but then it has only been after mild winters; for it is very certain, that in sharp frosts few of these projecting shoots escape great injuries, when left uncovered; whereas it rarely happens, that those shoots which are closely nailed to the wall in autumn, or laid down and covered, suffer the least damage; and the fruits are always produced a fortnight sooner upon these branches, than they are upon those which grow from the wall: but although the trees which are suffered to grow rude from the walls, may produce a good quantity of fruit for a year or two, yet afterwards the trees will only bear at the ends of the shoots, which will then be so far from the wall, as to receive little benefit from it; nor can the trees be reduced to any regularity, without cutting away the greatest number of their branches, by which a year or two will be lost before they will come to bear again. The season, as well as the method of pruning here laid down, is also widely different from the common practice and opinion of most gardeners, and will therefore of course be objected against. Yet, if any one will make the experiment, he will confirm the truth of what has been here advanced; for as one great injury to this tree proceeds from the too great effusion of sap at the wounded parts, the autumnal pruning prevents that evil; since it is well known, that during that season, all the parts of European trees which cast their leaves, are less replete with moisture than at any other time of the year; for by the long continuance of the summer's heat, the juices of the plants having been exhausted in the nourishment and augmentation of wood, leaves, fruits, and also great quantities being evaporated by perspiration, the root not being able to send up a supply equivalent to this great consumption, the branches must contain a much smaller quantity of sap than in the spring, when it has had several months' supply from the root, which, though small in proportion to the quantity supplied when the heat is greater, yet as there is little or no waste, either through perspiration or augmentation, there must be a greater quantity contained in the branches, which is very easily observed by breaking or cutting off a vigorous Fig-tree branch at both seasons, the sap being milky, may be readily discerned; when that cut in autumn shall be found to

stop its bleeding in one day's time, or less, whereas that cut in the spring will often flow a week or more, and the wound be proportionably less disposed to heal.—Of late years some of these trees have been planted against fire-walls, and have succeeded very well, where they have been properly managed; but where they have been kept too close, and drawn by glasses, they have not produced much fruit: therefore, whenever this is practised, the heat should not be too great; nor the glasses or other coverings kept too close, but at all times, when the weather is favourable, a good share of free air should be admitted; and if the trees be young, and their roots are not extended beyond the reach of the covering; they must be frequently watered when they begin to shew fruit, otherwise it will drop off; but old trees, the roots of which are extended to a great distance, will only require to have their branches now and then sprinkled over with water. If the trees be properly managed, the first crop of fruit will be greater than upon those which are exposed to the open air, and will ripen six weeks or two months earlier. A plentiful second crop may also be obtained, which will ripen early in September, and sometimes in August, which is about the season of their ripening in the warmer parts of Europe; but the fires should not be used till the beginning of February; because, when they are forced too early, the weather is frequently too cold to admit a sufficient quantity of fresh air to set the fruit; but the covers should be put over the trees a month before, to prevent the shoots from being injured by the frost.—It may not be improper in this place to mention the great pains which the inhabitants of the Levant are at in the culture of their Figs; and without which, it is generally admitted by all travellers, who have noticed this subject, as well as by Pliny, and other old naturalists, that their fruit will fall off, and be good for nothing. Pliny (says Monsieur Tournefort in his travels) observed, that in Ceos, now called Zia, they used to dress the Fig-trees with great care; they still continue to do so. To understand aright this husbandry of Figs, called in Latin *caprificatio*, we are to observe, that in most of the islands of the Archipelago they have two sorts of Figs to manage: the first is called *ornos*, from the old Greek *erinos*, a Wild Fig-tree, or *caprificus in Latin*; the second is the domestic or Garden Fig-tree. The wild sort bears three kinds of fruit, *formites*, *cratitres*, and *orni*, of absolute necessity towards ripening those of the Garden Fig. The *formites* appear in August, and continue to November, without ripening: in these breed small worms, which turn to a sort of gnats, nowhere to be seen but about these trees. In October and November, these gnats make of themselves a puncture into the second fruit, which is called *cratitres*; and do not appear till the end of September; and the *formites* gradually fall away after the gnats are gone: the *cratitres*, on the contrary, remain on the tree till May, and enclose the eggs deposited by the gnats, when they pierced them. In May, the third sort of fruit, called *orni*, begins to put forth from the wild Fig-trees. This is much larger than the other two, and when it grows to a certain size, and the bud begins to open, it is pricked in that part by the gnats of the *cratitres*, which are in a proper state to go from one fruit to another to discharge their eggs. It sometimes happens, that the gnats of the *cratitres* are slow to come forth in certain places, while the *orni* in those very places are disposed to receive them; in which case, the husbandman is obliged to look for the *cratitres* in another place, and fix them at the end of the branches of those Fig-trees, the *orni* of which are in a fit disposition to be pierced by the gnats; if they miss the opportunity, the *orni* falls, and the gnats of the *cratitres* fly away. None but those that are well acquainted with this sort

of culture, know the critical moment of doing this; and in order to know it, their eye is perpetually fixed on the bud of the fig; for that part not only indicates the time that the flies are to issue forth, but also when the fig may be successfully pierced: if the bud be too hard, and too compact, the gnat cannot lay its eggs, and the fig drops when the bud is too open. These three sorts of fruit are not good to eat; their office is to ripen the fruit of the Garden Fig-trees in the following manner. During the months of June and July, the peasants take the orni at a time that their gnats are ready to break out, and carry them to the Garden Fig-trees; if they omit the precise moment, the orni fall; and the fruit of the domestic or Garden Fig-tree not ripening, will, in a very little time, fall in like manner. The peasants are so well acquainted with these precious moments, that every morning, in making their inspection, they only transfer to their Garden Fig-trees such orni as are well conditioned, or they would run the risk of losing their crop. It is true, they have one remedy, and that is but an indifferent one; it is to strew the *ascolimbros*, a very common plant there, and in the fruit of which there is a sort of gnats proper for piercing; probably they are those of the orni, which are used to hover about and plunder the flowers of this plant. In short, the peasants so well order the orni, that their gnats cause the fruit of the Garden Fig-tree to ripen in the compass of forty days. These figs are very good fresh; when they would dry them, they lay them in the sun for some time, and then put them in an oven to keep them the rest of the year. Barley-bread and dried figs, are the principal support of the peasants and monks of the Archipelago; but their figs are very inferior to those dried in Provence, Italy, and Spain: the heat of the oven destroys all their delicacy and good taste; but then, on the other hand, this heat kills the eggs which the flies of the orni discharged therein, which eggs would infallibly produce small worms, that would prejudice these fruits. What an expense of time and pains is here for a fig, and that but an indifferent one at last! I could not, says Tournefort, sufficiently admire the patience of the Greeks, busied above two months in carrying these flies from one tree to another. I was soon told the reason; one of their Fig-trees usually produced between two and three hundred pounds of figs; and ours, in Provence, seldom above twenty-five. The way in which these flies accelerate the maturity of the fruit of the Garden Fig-tree, is probably by tearing the vessels, while depositing their eggs, and thus causing the nutritious juice to extravasate: perhaps too, besides their eggs, they leave in the fruit some sort of liquor, proper to cause a gentle fermentation, and thereby make the flesh of the fig tender and delicate. Jussieu doubts whether the succulency and turgescence of the esculent fig be owing to the defluxion of the nutritious juice, occasioned by the punctures of the insects, or to the impregnation of the seeds from the farina, conveyed by them. The sexual botanists have adopted the latter cause, and regard it as one of the main props of their system. Here, as in similar cases, two purposes are answered at once, the impregnation of the seed, and the ripening of the pulp. Our figs in Provence, says Jussieu, and even at Paris, ripen much sooner for having their eyes pricked with a straw dipped in olive oil. Plums and pears pricked by some insects, likewise ripen much the faster for it, and the flesh round such puncture is better tasted than the rest. It is not to be disputed but that considerable change happens to the contexture of fruits so pricked, just the same us to parts of animals pierced with any sharp instrument. It is scarcely possible well to understand the ancient authors, who have written upon *caprificatio*, or husbanding and dressing the wild Fig-tree, without being well apprised of the above detailed circum-

stances, the particulars whereof, says Tournefort, were confirmed to us, not only at Zia, Tinos, Mycone, and Scio, but in most of the other islands. Fig-trees are propagated in England, either by the suckers which are sent out from their roots; or by layers, made by laying down their branches, which in one year will put out roots sufficient to be removed; or by planting cuttings, which, if properly managed, will take root: the first is a bad method, because all those trees which are raised from suckers are very subject to send out great quantities of suckers again from their roots, and the branches of the suckers are not so compact as those of the layers, but are fuller of sap, and in greater danger of being injured by the frost; those plants which are propagated by layers are the best, provided the layers be made from the branches of fruitful trees; for those which are made from the suckers or shoots produced from old stools, being very soft, and full of sap, are in danger of suffering by the frost, and these will shoot greatly into wood, but will not be very fruitful; for when trees have acquired a vicious habit while young, it is seldom that they are ever brought to be fruitful afterwards; therefore the shoots which are laid down, should be such as are woody, compact, and well-ripened, not young shoots, full of sap, whose vessels are large and open. The best time for laying down the branches is in autumn; and if the winter should prove very severe, if they be covered with some old tan, or any other mulch, to keep the frost from penetrating the ground, it will be of great service to them; by the autumn following, these will be sufficiently rooted by removing, when they should be cut off from the old plants, because the branches at that season, not being so full of sap as in the spring, will not bleed so much as when cut off at that season. If the place be ready to receive them, the layers should be transplanted in autumn where they are to remain; but if not then, the layers may remain till the spring, provided they are separated from the old plants in autumn. As they do not bear transplanting well when they are large, it is the better way to plant them first in places where they are to remain; and after they are planted, the surface of the ground about their roots should be covered with mulch to keep out the frost; and if the winter should prove very severe, it will be proper to cover the branches with reeds, pease-haulm, straw, or some other light covering; which will prevent their tender ends being killed by the frost, which frequently happens where that precaution is not taken. The other method of propagating these trees is by cuttings, which should be taken from the trees in autumn, for the reason before given: these must be chosen from such branches as are compact, whose joints are near each other; and they should have a part of the former year's wood at the bottom, with the top of each left entire, not shortened, as is usually practised with other cuttings; then they should be planted eight or nine inches deep, in a bed of loamy earth, in a warm situation, covering the surface of the ground three or four inches thick with old tanner's bark, to keep out the frost; and in severe frost, their tops should be covered with straw, pease-haulm, fern, or other light covering, to protect them from it. This covering should be removed in the spring; but the tan may remain, for that will prevent the drying winds of the spring, and the sun in summer, from penetrating the ground, and will be of great use to secure the cuttings from injury; these cuttings will be rooted sufficiently by the following autumn, when they should be transplanted, and treated in the same manner as the layers. If fruitful branches of these trees are cut off, and planted in pots or tubs filled with good earth, and if these be plunged into a good hot-bed of tanner's bark in the stove, they will put out fruit early in the spring, which will ripen in the middle of May.

2. *Ficus Sycomorus*; *Egyptian Fig-Tree*, or *Sycamore*. Leaves cordate, roundish, quite entire, tomentose underneath; fruits sessile. This is also called *Pharaoh's Fig-Tree*: the stem is often fifty feet thick, and spreads out its boughs very much, so that it is of great use in a scorching climate, to shade those who travel through the deserts; leaves like those of the Mulberry; the fruit is produced from the trunk and larger branches, and is shaped like the common fig; it is pierced by an insect called *cynips sycomori*, a little before it ripens, in two different ways; either the scales which cover the calix wither, and are bent back, as in the common fig, for the admission of the insect; or, which is more common in this species, a little below the scales on the side of the involucre the fruit is affected with a gangrene, which extends itself, and frequently occupies the space of a finger's breadth; it withers, the place affected becomes black, the fleshy substance in the middle is corroded for the breadth of a quill, and the male blossoms which are nearest appear naked, opening a way for the insect, which makes several furrows in the middle of the fruit, but never touches the stigmas, though it frequently eats the germina. The gangrenous part is at first covered with the blossoms, but the hole is, by degrees, enlarged, of various sizes, in different fruits, the margin and sides being always gangrenous, black, hard, and turned inwards; the fruit tastes pretty well; when quite ripe it is soft, watery, and somewhat sweet, with a very little portion of an aromatic flavour; though fleshy enough, yet little of it is good, the insects having eaten much of it. We call this the Sycamore-tree, and Mulberry Fig-tree; this, and not the Great Maple, is the true Sycamore.—Native of Egypt, the Levant, and Cochin-china. This, and all the rest of this genus, except the first species, are easily propagated by cuttings during the summer season. When the cuttings are taken from the plants, they should be laid in a dry shady place for two or three days, that the wounds may be healed over, otherwise they are apt to rot; for all these plants abound with a milky juice, which flows out whenever they are wounded; for which reason the cuttings should have their wounded part healed over and hardened before they are planted; after which they should be planted in pots filled with sandy light earth, and plunged into a moderate hot-bed, where they should be shaded from the sun, and in warm seasons should be gently watered two or three times a week, but must not have too large a share of moisture, for that would infallibly destroy them. When the cuttings have taken root sufficient to transplant, they should be each planted in a separate small pot, filled with light undunged earth, and plunged into the hot-bed again, being careful to shade them until they have taken fresh root; then they should have a large share of free air admitted to them at all times when the weather is favourable, to prevent their drawing up weak, and to give them strength before the cold comes on. In autumn the pots should be removed into the stove, and plunged into the tan-bed, where they should constantly remain, and must be treated in the same manner as other tender plants from the same countries; for although two or three of the sorts may be treated in a hardier manner, yet they will not thrive well under any other than the above-described management.

3. *Ficus Nymphaeifolia*; *Waterlily-leaved Fig-Tree*. Leaves ovate-cordate, mucronate, quite entire, smooth, glaucous underneath. This rises with a strong, upright, woody stem, twenty feet high, sending out several side-branches, which have large, oval, thick, stiff leaves, as big as those of Yellow Waterlily, waved a little about the edge, blunt with a point, hanging down, as it were, peltate, smooth, whitish underneath, about fourteen inches long, and nearly a foot broad, having

several transverse veins; the footstalks are a span long and more, compressed, smooth, and frequently turned next to the branches.—Native of the East Indies. For its propagation and culture, see the second species.

4. *Ficus Religiosa*; *Poplar-leaved Fig-Tree*. Leaves ovate-cordate, cuspidate, smooth; fruits sessile. This is a large tree, with a short trunk, and very long spreading boughs; leaves ever-green, of a light green, six or seven inches long, and three inches and a half broad towards the base, diminishing gradually to the top, where they run out into a narrow point, an inch and a half long; the fruit comes out on the branches, is small, and of no value. This tree is treated by the Hindoos with great veneration, their god Vishnu being born under it; but the Christians profanely call it the Devil's tree.—Native of the East Indies and Cochin-china. For its propagation, see the second species.

5. *Ficus Benjamina*; *Oval-leaved Fig-Tree*. Leaves elliptic, obtuse, smooth; fruits acute, sessile. This is a middle-sized tree; branches slender, flexuose, streaked, and wrinkled; fruits globular, scattered on the branchlets.—Native of the East Indies: See the second species.

6. *Ficus Bengalensis*; *Bengal Fig-Tree*. Leaves ovate-cordate, quite entire, smooth, blunt, coriaceous; stem arborescous, erect, a fathom in height; branches like the stem.—Native of the East Indies. For its propagation, see the second species.

7. *Ficus Pedunculata*; *Willow-leaved Fig-Tree*. Leaves ovate-oblong, cordate, quite entire, sharp, smooth; fruits globular; peduncles in pairs, elongated.—Native of South America. For its propagation, see the second species.

8. *Ficus Lucida*; *Shining-leaved Fig-Tree*. Leaves ovate-cordate, quite entire, smooth, blunt, three-nerved at the base; branches upright.—Native of the East Indies. See the second species.

9. *Ficus Indica*; *Indian Fig-Tree*. Leaves oblong, rounded at the base, smooth and even, quite entire, somewhat glaucous underneath, impressed with dots above; fruits almost globular. This vast tree is entirely smooth, the branches spreading very wide, bowed down, the lower ones rooting, ash-coloured; fruits aggregate here and there on the branchlets, peduncled, the size of a hazel-nut. The English call it Banyan-tree; and *arbor de rayz*, or the rooting-tree, is the Portuguese name; and it propagates itself, as Mr. Evelyn observes, by letting a kind of gummy string fall from its branches, which takes root, and thus spreads over a vast circumference. This, however, is the case with the third, fourth, fifth, sixth, and tenth species, and probably with some others. One of these trees growing near Mancee, twenty miles west of Patna, in Bengal, was 370 feet in diameter; the circumference of the shadow at noon was 1116 feet; and the circumference of the several stems, which were fifty or sixty in number, 921 feet. There is a vast tree of this kind near Fort St. David's in the East Indies, which is computed to cover nearly 1700 square yards, under the shade of which, it is said, ten thousand men might commodiously stand: another very celebrated Banyan-tree grows near Gonbroon on the Persian gulf. The Gentoos are almost as sensibly hurt, if any one cuts up or lops off any of the branches, as if he had mutilated or destroyed a cow, which he holds in so much veneration. On this account Linneus named the fourth species of this genus *religiosa*, which is said to be sacred to the Hindoo idol *Vishnu*, who is believed to have been born under it. Both Strabo and Pliny mention this tree: the former says, that the branches grow horizontally about twelve cubits, then taking a direction to the earth, where they root themselves; and when they have attained maturity

continue to propagate in the same manner, till the whole becomes like a tent supported by many columns. Milton seems to have had the descriptions of these classical writers in his eye :

“ Branching so broad and long, that in the ground
The bending twigs take root; and daughters grow
About the mother tree : a pillar'd shade,
High over-arch'd, with echoing walks between.
There oft the Indian herdsman, shunning heat,
Shelters in cool; and tends his pasturing herds
At loop-holes cut through thickest shade.”

From the manner of its growth, Gerard names it the arched Indian Fig-tree.—Native of the East Indies and Cochin-china. For its propagation and culture, see the second species.

10. *Ficus Virens*; *Round-fruited Fig-Tree*. Leaves oblong, acuminate, quite entire, smooth and even, narrowed and rounded at the base, eight or nine inches long, and two broad. This species rises to the height of thirty or forty feet, sending out many slender branches, which put out roots: the fruit is not larger than a hazel-nut, of a scarlet or carnation colour, the taste sweetish, and not unpleasant; and is much sought after by the wild pigeons.—Native of the West Indies. See the second species.

11. *Ficus Venosa*; *Waved-leaved Fig-Tree*. Leaves ovate, somewhat cordate, sharp, quite entire, smooth and even, impressed with dots on the upper surface; fruits the size of a pepper-corn.—Native of the East Indies. For its propagation, see the second species.

12. *Ficus Costata*; *Upright Heart-leaved Fig-Tree*. Leaves ovate-cordate, with a deep narrow sinus, quite entire, smooth, sharp, green on both sides.—Native of the East Indies. For its propagation, see the second species.

13. *Ficus Racemosa*; *Red-wooded Fig-Tree*. Leaves ovate, quite entire, sharp, impressed with dots; stem arboreous; branches round, smooth, ferruginous, upright; branchlets scattered, short; fruits in racemes, globular, almost the size of a plum.—Native of the East Indies. For its propagation and culture, see the second species.

14. *Ficus Pertusa*; *Laurel-leaved Fig-Tree*. Leaves ovate, smooth; calices bifid; berries globular, umbilicated with a hole. This is a small tree, the fruit of which is red, the size of currants, scattered in racemes, very abundant, pedicelled.—Native of South America. For its propagation and culture, see the second species.

15. *Ficus Retusa*; *Blunt-leaved Fig-Tree*. Leaves obovate-oblong, extremely obtuse; branches angular; fruits sessile, globose, smooth; when young, enveloped in a calix; the size of a currant when full grown.—Native of the East Indies. See the second species.

16. *Ficus Pumila*; *Dwarf Fig-Tree*. Leaves oblong-ovate; blunt, smooth, netted underneath; stem jointed, creeping; fruits peduncled; branches few, like the stem; the small branches at the leaves surrounded with an elevated streak; peduncles axillary, filiform, solitary; calix inferior, three-leaved; fruits ovate, smooth, the size of a plum.—Native of China and Japan. For its propagation and culture, see the second species.

17. *Ficus Toxicaria*; *Poisonous Fig-Tree*. Leaves cordate-ovate, somewhat toothletted, tomentose underneath. This is a middling-sized shrub, with round, smooth, ferruginous branches; fruits ovate, tomentose, the size of a plum, on thick tomentose peduncles.—This tree is said to be extremely poisonous; it grows near Padan, in Sumatra. See the second species.

18. *Ficus Maculata*; *Spotted Fig-Tree*. Leaves oblong, acuminate, serrate; stem and branches upright; fruit middle-

sized, turbinate, brown, axillary, solitary.—Native of America. See the second species.

19. *Ficus Trigona*; *Triangled Fig-Tree*. Leaves elliptic; calices bifid; berries with a triangular navel. This at top is a leafy tree, with round, wrinkled, tomentose branches, and very short branchlets.—Native of Surinam. See the second species, for its propagation and culture.

20. *Ficus Hispida*. Leaves oblong, petioled, sharp; fruits strigose, hispid. The whole of this plant is clothed with very minute thinly scattered hairs; branches round, striated, ash-coloured, smooth; peduncle in the axil of the leaves, filiform, hispid, with short, rigid, yellowish, shining bristles.—Native of Java. See the second species.

21. *Ficus Stipulata*; *Trailing Fig-Tree*. Leaves obliquely cordate, obtuse, smooth; stem decumbent, scaly; stipules scattered, awl-shaped, spreading, rufescent.—Native of China and Japan. For its propagation and culture, see the second species.

22. *Ficus Heterophylla*; *Rough-leaved Fig-Tree*. Leaves oblong, undivided, three-lobed, and sinuate, scabrous; stem hispid; fruit ovate, peduncled, scabrous; branches, according to Thunberg, round, flexuose, elongated, little subdivided.—Native of the East Indies, near rivulets and watery places: where it is called *Nir Atti*, Water Fig; scarcely accessible on account of the prickly rattans. For its propagation and culture, see the second species.

23. *Ficus Microcarpa*; *Small-fruited Fig-Tree*. Leaves oblong, on short petioles, three-nerved, veined, very smooth; fruit globular, small, sessile.—Native of Java. See the second species.

24. *Ficus Coriacea*; *Leathery-leaved Dwarf Fig-Tree*. Leaves oblong, smooth, and even, attenuated at the base, cordate, leathery; veins immersed.—Native of the East Indies. For its propagation and culture, see the second species.

25. *Ficus Scabra*. Leaves cordate-ovate, oblique, entire, scabrous underneath; fruits turbinate, without calices.—Native of the isles of Tanna and Namoka, in the South Sea. For its propagation and culture, see the second species.

26. *Ficus Aspera*. Leaves half a foot long, obliquely cordate, sinuate-toothed, rough on both sides; fruits turbinate; the edge of the calix obscure, and growing to them. This is a tree four or five fathoms in height, with jointed branches; fruit fleshy, juicy, and sapid. Thunberg describes it as of a globular form, and about the size of a plum.—Native of the isle of Tanna; where it is also cultivated for the fruit, which is sweet and pleasant; the young leaves boiled are eaten as greens. For its propagation and culture, see the second species.

27. *Ficus Tinctoria*. Leaves obliquely ovate, obtuse; fruits turbinate, caliced at the base.—Native of the Society Isles. For its propagation and culture, see the second species.

28. *Ficus Septica*. Leaves oblique, oblong-ovate, acuminate; peduncles in pairs, caliced at the tip; fruits warted.—Native of the island of Tanna. The Otahaitians call it *matte*. Loureiro has given the same name to a Cochin-chinese fig, on account of its septic qualities, which the inhabitants of that country employ as an antidote against worms, and for eating off proud flesh.—For its propagation and culture, see the second species.

29. *Ficus Granatum*. Leaves ovate, quite entire; peduncles terminating in pairs, horizontally diverging; fruits caliced, globular. This is a tall shady tree, with a multangular torosa trunk; all the branches ascending, long, roundish, somewhat jointed, brown ash-coloured, unequal; branchlets round, jointed, leafy only at the end.—Cultivated in the isle

of Tanna for its fruit, which is sweetish, but watery, and almost insipid, is larger than the common figs, and slightly downy. See the second species.

30. *Ficus Obliqua*. Leaves lanceolate, very smooth, cartilaginous at the edge; peduncles in pairs, very short; calices caducous, the length of the fruit.—Native of the islands of Namoka and Tanna.

31. *Ficus Prolixa*. Leaves lanceolate-oblong, acuminate, dotted underneath; peduncles in pairs, calicled at the tip.—Native of the Society Isles. See the second species.

32. *Ficus Caliculata*. Leaves ovate, quite entire, obtuse, opposite; fruit globular, calicled. This rises with many shrubby stalks to the height of twelve or fourteen feet, and divides into many smaller branches; leaves four inches long, and three broad, of a light green, upon short footstalks, jointed to a cup in which the fruit sits; which is the size of a nutmeg, and of a deep yellow, but not eatable.—Native of La Vera Cruz. See the second species.

33. *Ficus Americana*. Leaves ovate-oblong, veined, quite entire; fruits axillary, peduncled, clustered: the fruit is of a pale yellow colour, and spherical.—Native of Jamaica.

34. *Ficus Erecta*. Leaves oblong, acute, smooth, netted beneath; stem decumbent, with upright branches; fruits peduncled, scattered on the branchlets, erect, subglobular, the size of a hazel-nut. It differs from the sixteenth species, of which it was supposed to be only a variety, in having larger leaves, less netted, and thinner; and smaller, sweeter, and more eatable fruits.—Native of Japan.

35. *Ficus Stipulata*. Leaves obliquely cordate, obtuse, smooth; stem decumbent, scaly.—Native of Japan.

36. *Ficus Ariculata*. Leaves heart-shaped, acuminate; fruit eared, racemed, terminating. This is a large tree, with oblique branches; calices of the receptacle three-leaved, permanent. Besides the aperture at the top, common to the whole genus, there are four distant holes on the shoulder of the fruit, fenced round by prominent cartilages, resembling ears.—Native of Cochin-china, where the fruit, before it is ripe, cut in slices tastes like cucumber, and is eaten in salads. See the second species.

37. *Ficus Politoria*. Leaves oblong-ovate, quite entire, rugged; fruit roundish, in spikes; stem erect. This is a shrub six feet high, upright, and branched; fruit very small, saffron-coloured.—Native of Cochin-china, where the dried leaves are used in polishing small works in wood or ivory.

38. *Ficus Simplicissima*. Leaves palmate: stem quite simple; fruit compressed, spheroidal, saffron-coloured, small, sessile, axillary, solitary.—Native of Cochin-china.

39. *Ficus Cannabina*. Stem-leaves hastate, gashed; branch-leaves ovate-lanceolate, subserrate; stem suberect, six feet high, covered with a smooth bark-like hemp.—Native of Cochin-china. See the second species.

40. *Ficus Populifolia*. Leaves finely cordate, acute, smooth on both sides, veined, two inches long; fruits in pairs, pedicelled; branches round, smooth, with a wrinkled bark; fruit globular, smooth.—Native of the East Indies.

41. *Ficus Mollis*. Leaves oblong, quite entire, villose underneath; fruits axillary, sessile, tomentose; branches round, villose, tomentose towards the top.—Native of the East Indies.

42. *Ficus Salicifolia*. Leaves lanceolate, acuminate; fruits in pairs, axillary, peduncled. The whole of this plant is very smooth and even.—Native of the East Indies.

43. *Ficus Sagittata*. Leaves heart-shaped, oblong, acute, rugged on both sides; stem creeping; petioles scarcely two lines in length; stipules lanceolate at both ends.—Native of the East Indies.

44. *Ficus Denticulata*. Leaves oblong, undivided, three-lobed, and sinuate, toothletted, rugged; fruit peduncled, muricated, globular; branches angular at top, and hairy.—Native of the East Indies.

45. *Ficus Truncata*. Leaves oblong, undivided, and lobed, quite entire, rugged; fruits peduncled, oblong, truncated, rugged; branches angular, smooth, and even.—Native of the East Indies.

46. *Ficus Serrata*. Leaves oblong, undivided and palmate, repand-toothed, rugged; fruit peduncled, globular, very rugged.—Native of the Cape of Good Hope.

47. *Ficus Palmata*. Leaves cordate-ovate, and lobed, serrate; fruits pear-shaped, peduncled, smooth; branches round, smooth.—Native of the Cape of Good Hope.

48. *Ficus Cordata*. Leaves subcordate, ovate, acute, smooth, coriaceous; stem shrubby, erect. This is a middling-sized and entirely smooth shrub. Fruits sessile towards the ends of the branches and branchlets, in the axils of the leaves approximating, globular, the size of peas.—Native of the Cape of Good Hope.

49. *Ficus Falcata*. Leaves oblong, sickle-shaped, smooth; stem filiform, rooting, brown.—Native of the East Indies.

50. *Ficus Punctata*. Leaves oblong, emarginate, smooth, dotted underneath; stem flexuose, rooting, climbing, scarcely the thickness of a goose-quill; fruits obovate, nearly the size of the common fig.—Native of the East Indies.

51. *Ficus Nitida*. Leaves elliptic, acute, smooth; fruits retuse, umbilicate, sessile; stem entirely smooth; branches striated and wrinkled, from erect spreading; fruits at the ends of the branchlets sessile, globular, retuse, the size of peas.—Native of the East Indies.

52. *Ficus Reflexa*. Leaves elliptic, obtuse, smooth; branches recurved, and wrinkled; fruits globular, sessile, scattered, and aggregate on the branches, smooth, the size of peas.—Native of the East Indies.

53. *Ficus Drupacea*. Leaves obovate, cusped, smooth; fruits ovate, wrinkled, sessile; branches round, grooved, smooth; fruits toward the ends of the branches, smooth, the size of plums.—Native of the East Indies.

54. *Ficus Reticulata*. Leaves elliptic, somewhat angular, cusped, smooth, netted underneath; fruits globular, solitary, peduncled, larger than peas; branches round, wrinkled, purple, smooth, upright.—Native of the East Indies.

55. *Ficus Sinuata*. Leaves elliptic, sinuate-toothed, cusped, smooth; fruits globular, aggregate, peduncled, scarcely the size of pepper; branches round, striated, ash-coloured, smooth, erect.—Native of the East Indies.

56. *Ficus Capensis*. Leaves ovate, acute, smooth, serrate; fruits peduncled, smooth. This is a vast lofty smooth tree, with spreading branches; fruits scattered, turbinate, the size of a hazel-nut.—Native of the Cape.

57. *Ficus Glomerata*. A large tree; the fruit clustered, top-shaped, the size of a pigeon's egg, and eaten by the natives.—Grows in Bengal.

58. *Ficus Oppositifolia*. A small tree, with hollow, jointed, hairy branches; leaves opposite, oblong, slightly serrated, two to six inches long; fruit the size of a large nutmeg, covered with down.—Native of the East Indies.

59. *Ficus Comosa*. A middling tree, with a large, spreading, shady top; fruit sessile, in pairs, roundish, the size of a gooseberry.—Native of the Circar mountains.

60. *Ficus Finguere*; or *Wild Fig Tree*.—This tree is found in Madagascar, and produces by incision a milky juice, which becomes a true elastic gum.

Field Basil. See *Thymus Acinos*.

Field Madder. See *Sherardia*.

Fig, see *Ficus*; and *Fig*, see *Cactus*.

Fig Marigold. See *Mesembryanthemum*.

Fig, Pharaoh's. See *Ficus Sycomorus*.

Figwort. See *Scrophularia*.

Filago; a genus of the class Syngenesia, order Polygamia-Necessaria.—**GENERIC CHARACTER.** *Calix*: common, of imbricate chaffs, containing in the disk several hermaphrodite florets; in the circumference, among the lower scales of the calix, solitary female florets. *Corolla*: hermaphrodite, funnel-form, with a four-cleft erect border; females, scarcely visible, filiform, very narrow, cloven at the mouth. *Stamina*, in the hermaphrodite: filamenta four, capillary, small, anther cylindrical, four-toothed at the top. *Pistil*: in the hermaphrodite; germen scarcely any; style simple; stigma acute, bifid. In the females: germen ovate, largish, depressed; style filiform; stigma acute, bifid. *Pericarp*: none. *Seeds*: in the hermaphrodites none; in the females obovate, compressed, smooth, small; down none. *Receptacle*: disks naked, without chaffs, but at the sides there are calcine chaffs, separating the florets.—*Observe*, the above character is taken from *Filago Pygmæa*, or *Acaulis*, which Gærtner separates under the name of *Evax*. *Filago, Germanica, Arvensis, Montana*, and probably other species, agree with each other, and are distinguished from that by the following character. *Calix*: common, round, or five-cornered, imbricate; scales ovate-lanceolate; the outer acute, tomentose, the inner shining, coloured, acuminate. *Corolla*: compound; corollets hermaphrodite, tubular, few in the centre of the disk; females tubular, numerous in the remainder of the disk; and a few others, almost apetalous among the outer scales of the calix: proper in the hermaphrodites funnel-form, with a four-cleft spreading border; in the females of the disk funnel-form, with a slender tube swelling at the base, and a four-cleft erect border; in the other females hardly conspicuous, with a very slender tube, and a sharp cloven border. *Stamina*: in the hermaphrodites; filamenta four, very short; anther tubular. *Pistil*: in the hermaphrodites; germen small, abortive; style capillary, the length of the border; stigmas two, from upright spreading: females in the disk, have on oblong germen, a capillary style longer than the border, and two spreading stigmas: females within the calix have an oblong germen, a capillary style longer than the border, and two long spreading stigmas. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites barren, crowned with down: in the females of the disk oblong, crowned with a short simple down; in the females within the calix, oblong, naked. **ESSENTIAL CHARACTER.** *Calix*: imbricate; female florets among the scales of the calix. *Down*: none. *Receptacle*: naked.—The Cudweeds are herbs covered with a hoary or cottony down; the flowers are usually glomerate at the end of the stalk, and are sometimes surrounded by a leafy ring. They are of the same natural genus with *Gnaphalium*.—The species are,

1. *Filago Acaulis*; *Pigmy Cudweed*. Flowers stemless, sessile; floral-leaves larger. This is a very small plant, entirely covered with a white woolly nap, growing in a tuft: it has a little bristle-form stem, a line or two, sometimes half an inch, or at most an inch in height, erect, quite simple; leaves mostly close to the ground, longer than the stem and flowers, quite entire, linear; one or two flowers terminate the stem, or are sessile among the leaves; calix scarcely a line in length; the scales brown or reddish, brown about the edge, ash-coloured in the middle; the corollets are rose-coloured, and the central ones yellowish. Cavanilles, with a truly laudable zeal, has defended Linneus from the intemperate

and ill-founded attack of Monsieur Lamarck concerning this plant, and has retorted it upon the assailant. He informs us, that he has found caulescent plants about Madrid, accompanied by innumerable others absolutely stemless, both flowering, fruiting, and perishing, without any change from one to the other.—Willdenow states this to be the only species of *Filago*, the rest being *Gnaphaliums*.—Native of the south of Europe, and the Levant: it is found in dried pools of standing water, is annual, and flowers at the end of summer. This plant, together with all of the same genus, except the last species, are considered as weeds, and never cultivated, except in botanic gardens. They may be propagated from seeds sown in the autumn or spring, where they are to remain, and require no culture, except thinning where they may be too close, and to be kept clear from weeds.

2. *Filago Germanica*; *Common Cudweed*. Panicle dichotomous; flowers rounded, axillary, hirsute; leaves sharp; root annual, spindle-shaped. Several stems rise immediately from the root, from six to twelve inches in height, the central one thickest and longest, clothed with numerous, linear-lanceolate, waved, sessile, downy leaves; at the summit a sessile flowering head, beneath which are two or more branches bearing flowers, and these again proliferous. The lower lateral branches overtopping the principal central head, gave rise to the old name of *herba impia*, (herb impious,) or *Wicked Cudweed*.—Native of most parts of Europe, in barren pastures, corn-fields, and by way-sides; flowering in July and August. It varies with a very simple erect stem, and axillary sessile flowers. This plant is astringent, and a powder or decoction of it has been sometimes given to cattle in the bloody flux; and has been successfully tried in similar complaints of the human body. English farmers formerly gave it to their cattle, to restore the faculty of chewing the cud, whence it acquired the name of *Cudweed*. Petiver calls it *Childing Cudweed*; and Hill, *Forked Cudweed*. Bruised, and applied to recent wounds, it stops the effusion of blood, and speedily heals them; and taken inwardly, either in powder or decoction, it not only stops violent purgings, but relieves the whites and other female complaints.

3. *Filago Pyramidata*; *Pyramidal-flowering Cudweed*. Stem dichotomous; one or two inches high; flowers pyramidal, five-cornered, axillary; female floscules serrate; branches radical, bifid at the top; leaves lanceolate, bluntish, pressed to the stem, quite entire; calcine scales three or four, terminated by a thread, and between them a female flower, besides six males or imperfect hermaphrodites in the centre. It is probably no more, says Krocker, than a variety of the foregoing species: it differs however from it, in having a more simple stem, with only one branch or two at the end, and more erect; it is also more white and tomentose: the flowers are only at the end in the uppermost fork; the leaves are more numerous, and pressed close to the stem. It is annual, like the foregoing, and flowers in August.—Native of the south of France, Spain, and Silesia.

4. *Filago Montana*; *Least Cudweed*. Stem subdichotomous, erect; two to six inches high; flowers conical, terminating, and axillary; root annual; leaves numerous, lanceolate, sessile, downy, pressed to the stem, three or four lines long; calix pyramidal, five-cornered, sessile, or on very short peduncles, of a whitish green colour, shining at the top: in the very centre are four complete florets, and about fifteen in the disk, and four or five in the circumference, within the scales of the common calix, with pistil only, all fertile; anthers of the complete florets four, with two bristles at the base; border of the florets four-cleft: seeds of all the florets

in the centre, sprinkled with very short glandular hairs, and crowned with a capillary down; those of the florets in the circumference without down. The smallness of the heads or clusters, and the few flowers which compose them, readily distinguish this species from the second.—Native of most parts of Europe, in sandy pastures, especially in high grounds; also on walls, and other dry barren places. It flowers in July and August.

5. *Filago Gallica*; *Grass-leaved Cudweed*. Stem dichotomous, erect; flowers subulate, axillary; leaves filiform; root annual, often very long. The whole plant downy, but the down shorter than in the second and fourth species, and of a silvery white; leaves about an inch long, half stem-clasping, awl-shaped, submentose, yet smooth, and not hirsute.—Native of France, Switzerland, Germany, and England, in gravelly and sandy soils, flowering in July and August. With us it was first observed near Castle-Heveningham in Essex, and since on heaths in Derbyshire.

6. *Filago Arvensis*; *Corn Cudweed*. Stem paniced; flowers conical, lateral; root annual. The whole plant very woolly, inasmuch that the heads of the flowers are in a manner buried: stem erect, a foot high or more, branched only at the top; leaves linear-lanceolate, two lines broad, five to seven long, and quite entire.—The flowers are female in the circumference, androgynous in the centre, very small, and whitish.—Native of Sweden, Germany, France, Switzerland, and Carniola, in sandy soils, flowering in July and August.

7. *Filago Leontopodium*; *Lion's-foot Cudweed*. Stem very simple; head of flowers terminating, radiated with very hirsute bractes. This plant is about six inches high, hoary all over, and terminated in an elegant lanuginous star, formed of oblong spreading leaflets of unequal lengths. In the centre of this is a head of flowers, which are hermaphrodite; the corolla yellow, and five-cleft; the antheræ acuminate; the style whitish, the germen streaked, smooth, dilated at the end, and crowned with little bristles, which, when viewed with a magnifier, appear feathered; the stigma longer than the antheræ. Round this principal head, on radiating very lanuginous bractes, sit other small heads, in number as far as seven, in which some of the flowers are female, small, four-cleft, with a long style, and a bifid stigma; others are incomplete, yellow, and destitute of genuine stamina, style, and germen. The middle head, therefore, is that of a Gnaphalium, and the side ones are those of a *Filago*. Perennial: flowering in June and July.—Native of the mountains of Germany, Dauphiny, Switzerland, the Valais, Austria, Carinthia, and Carniola.—There is a variety which differs from the other, 1. in having a slender root, and short leaves; whereas that has a large root, and oblong leaves: 2. in having flowers of a very dark brown violet-colour; whereas in the other they are pale yellow.—This is a native of Italy, as on Monte Baldo near Verona, and of Germany.

Filbert. See *Corylus*.

Filix, or *Fern*. The plants that pass under this general denomination, constitute the first order of the class Cryptogamia, in the system of Linneus, called *Cryptogamia Filices*. The fructification in this natural order differs essentially from all others, at least in its situation; being generally disposed, either in spots or lines on the under surface of the fronds or leaves. There being no certain distinctions in the fructifications sufficient to establish the genera, and the parts being too small to be observed without the assistance of powerful magnifiers, the genera are chiefly distinguished by the dispositions of the seeds under their covers. The general structure of the fructification on this order is the following.—The *calix* is a scale springing out of the leaf, opening

on one side. Under this scale, commonly supported by little footstalks; but sometimes sessile, are globules for the most part encompassed by an elastic ring; these burst with violence, and scatter a powder, which is supposed to be the seed. These globules or seed-vessels are covered by a very fine, thin, semitransparent skin, which bursts open before the seeds are ripe: the ring or cord endeavours to become straight, and by its elasticity tears open the capsule, which then forms two hemispherical cups like those of *Anagallis*. This curious mechanism may be observed by the assistance of a good single microscope, with a reflecting speculum, during the months of September and October, in *Pteris Aquilina*, or common Brakes, and *Asplenium Scolopendrium*, or Hart's-tongue. The powder which is dispersed in this operation is so minute, as hardly to be visible to the naked eye. That it is the seed, has been proved by actually raising plants from that of the Hart's-tongue by Morison; and lately in the most satisfactory manner by Mr. John Lindsay, surgeon in Jamaica, from *Polypodium Lycopodioides*. Hedwig thinks that he has detected male flowers or antheræ; either sessile, or else on a very short filamentum, scattered over the back of the frond, of an ovate or subglobular form. From this singularity of the fructification being on the back or lower side of the leaf, was named the order in which they ranged the Ferns *Epiphyllasperma* and *Dorsifera*. Since the late discoveries of Hedwig and others, Equisetum, Salvinia, Marsilea, Pilularia, Isoetes, which stood among the Ferns, together with *Lyco-podium* and *Porella*, which were placed in the order of Musci by Linneus, have been united to form a new order, entitled *Miscellanea*, which now stands first of the class Cryptogamia in Linneus's *Genera Plantarum*, as published by Schreber.—The uses of the Ferns are little known. Few of them are esculent. They have a heavy disagreeable smell. In large doses they destroy worms, and some of them are purgative. The ashes produced by a slow incineration of the green plants, contain a considerable portion of the vegetable alkali, and are generally sold under the name of ash-balls, to make lye for washing linen. Common Brakes cut down, when fully grown and dried, make a very good litter; and this, with some others, forms a thatch more durable than straw. South America and the West Indies furnish abundance of species, many of which grow to a great size, and others are very ornamental plants in our hot-houses. For particulars concerning the genera and species of this order, see *Acrostichum*, *Adiantum*, *Asplenium*, *Blechnum*, *Ceanopteris*, *Hemionitis*, *Lonchitis*, *Marattia*, *Menisium*, *Onoclea*, *Ophioglossum*, *Osmunda*, *Polypodium*, *Pteris*, *Trichomanes*.

Finochio. See *Anethum*.

Fir Tree. See *Pinus*.

Fissidens; a genus comprehending several species of Moss, belonging to Linneus's genera of *Mnium*, *Bryum*, and *Hypnum*.

Filt-weed. See *Eryngium*.

Flacourtia; a genus of the class Diœcia, order Polyandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, five-parted; parts roundish, obtuse, almost equal from spreading erect. *Corolla*: none. *Stamina*: filamenta numerous, (fifty to a hundred,) longer than the calix, and fastened to its thickened bottom, spreading, capillary; antheræ roundish. *Pistil*: the rudiment of a germen and stigma at most. *Female*. *Calix*: perianth five-leaved; leaflets roundish, erect, lying over each other at the edge, blunt. *Corolla*: none. *Pistil*: germen superior, ovate, large; style none; stigma flat, stellate, with rays from five to nine. *Pericarp*: berry globular, fleshy, umbilicate with the stigma, many-celled. *Seeds*: in pairs, obovate, compressed, obscurely

grooved. **ESSENTIAL CHARACTER.** *Male.* Calix: five-parted. *Corolla:* none. *Stamina:* very numerous. *Female.* Calix: many-leaved. *Corolla:* none. *Germen:* superior. *Styles* five to nine. *Berry* many-celled.—The only known species is,

1. *Flacourtia Ramontchi.* This is a small tree, or rather shrub, very bushy, thorny, and growing to the height of eight or ten feet: stem erect, branching, round, leprous, ash-coloured; branches with their subdivisions alternate, patulous, round, thorny, dotted with tubercles, bay-coloured; suckers at first without thorns, but some acquiring them, scarcely pubescent, purplish; leaves alternate, petioled, spreading, ovate or oval, sharp, crenulate, serrate, almost entire at the base, smooth and shining, of a firm texture, and resembling those of the plum; racemes terminating, erect, peduncled; flowers two to seven, pedicelled. The fruit is the size and shape of a small plum, green when young, of a beautiful red when ripe, and finally of a dark violet colour; the skin is very thin, and the flesh transparent red, of the same consistence with our common plums: in the middle are a dozen or fourteen small kernels, the size of those in the apple, and nearly of the same shape; they are bitterish, like our apricot kernels, and covered with a tender shell. The natives eat the fruit, which is sweet, but leaves a slight sharpness in the mouth. An island on the coast of Madagascar is covered with these trees; and because they resemble the European plum-tree, the French sailors have named that island, *Isle aux Prunes*, or *Plum-tree Island*.

b *Flag, Common.* See *Iris*.

c *Flag, Corn.* See *Gladiolus*.

d *Flag, Sweet.* See *Acorus*.

e *Flagellaria;* a genus of the class Hexandria, order Trigynia.—**GENERIC CHARACTER.** *Calix:* perianth six-leaved, equal; leaflets ovate, permanent, the outer ones sharper. *Corolla:* none. *Stamina:* filamenta six, filiform, almost the length of the calix; antheræ oblong. *Pistil:* germen ovate, very small; style length of the stamina, trifid; stigmas three, simple, flattish, permanent. *Pericarp:* drupe roundish, one-celled, crowned with the flower. *Seed:* a round stone or nucleus. **ESSENTIAL CHARACTER.** *Calix:* six-parted. *Corolla:* none. *Berry:* one-seeded, (two cells of the nucleus small and abortive.)—The plants of this genus are propagated by sowing the seeds in small pots of light earth, and plunging them in a bark-bed: when they are fit to transplant, place them singly in small pots, shading them till they have stricken root, and gently supplying them with water.—The species are,

1. *Flagellaria Indica.* Stem round, climbing; leaves ovate, terminated by a tendril. Loureiro describes it as twenty feet high; the flowers white, in a loose terminating raceme; calix six-parted; stamina eight, short; fruit a smooth red berry, juicy, and enclosing one seed. The leaves, he says, are astringent, and esteemed vulnerary.—Native of the East Indies, Cochin-china, and of Guinea.

2. *Flagellaria Repens.* Stem angular, creeping; leaves jointed in pairs; flowers terminating, with a long bundled spadix, and a linear common spathe. The stem is twelve feet high, creeping upon trees by lateral fibres, but preserving its original root.—Native of Cochin-china.

f *Flax.* See *Linum*.

g *Flax, Toad.* See *Antirrhinum Linaria*.

h *Fleabane.* See *Conyza*.

i *Fleagrass.* See *Carex*.

k *Fleawort.* See *Plantago*.

l *Flix-weed.* See *Sisymbrium Sophia*.

m *Flos Adonis.* See *Adonis*.

Flower de Luce. See *Iris*.

Flower Fence. See *Adenantha*.

Flowering Fern. See *Osmunda Regalis*.

Flowering Rush. See *Butomus*.

Fluellin. See *Antirrhinum* and *Veronica*.

Fly Honeysuckle. See *Halleria* and *Lonicera*.

Fly Orchis. See *Ophrys*.

Fœniculum. See *Anethum*.

Fontanesia; a genus of the class Diandria, order Monogynia.—**GENERIC CHARACTER.** *Calix:* four-parted, inferior, very small, permanent, blunt at the ends. *Corolla:* two-petalled; petals two-parted; parts ovate, obtuse, concave. *Stamina:* filamenta two, long, filiform, inserted into the claws of the corolla; antheræ oblong, two-grooved. *Pistil:* germen ovate; style compressed, shorter than the stamina; stigmas two, inflex-hooked. *Pericarp:* capsule not opening, subovate, emarginate, compressed, membranaceous, in the centre two-celled, (very rarely three-celled,) three-winged. *Seeds:* solitary, oblong-columaar. **ESSENTIAL CHARACTER.** *Calix:* four-parted, inferior; petals two, two-parted; capsule membranaceous, not opening, two-celled; cells one-seeded.—The only known species is,

1. *Fontanesia Phillyrioides.* Stem frutescent, erect, twelve feet high; branches opposite, erect, the younger ones quadrangular; leaves evergreen, opposite, veined underneath, the lower ones ovate; petioles short, knee-jointed; flowers axillary, yellow. The corolla may be considered as one-petalled and four-parted, with two of the parts more deeply cut, for the filamenta are inserted into the corolla. It is allied therefore to *Fraxinus* and *Chionanthus*; but it differs from the first in having a two-celled fruit, and from the second in the fruit being a capsule, and not a drupe.—Native of Syria, between *Ladicea* and *Mount Cassius*.

Fontinalis; a genus of the class Cryptogamia, order Musci, or Mosses.—**GENERIC CHARACTER.** *Capsule:* oblong, with the mouth ciliate; opening with an acuminate lid; covered with a sessile, smooth, conical *veil*; and included in a pitcher-shaped, imbricate *perichætium*.—Linneus mentions only four species, which are all natives of England, and may be found in Mr. Hudson's *Flora Anglica*. The three first are water-mosses, and the last grows on trees. Dr. Withering has enumerated two more species; and several others have been discovered by Swartz in the West Indies, and one in Cochin-china by Loureiro.

Fool's Parsley. See *Æthusa*.

Forcing. See *Stoves*.

Forskallea; a genus of the class Octandria, order Tetragynia; or of the class Decandria, order Pentagynia.—**GENERIC CHARACTER.** *Calix:* perianth four or five leaved, erect; leaflets linear-lanceolate, parallel, acute, permanent. *Corolla:* petals eight or ten, rude, spatulate, concave, erect, withering, shorter than the calix: the claws the length of the border. *Stamina:* filamenta eight or ten, filiform, one within each petal, elastic, the length of the calix; antheræ twin, roundish. *Pistil:* germen four or five, distant, oblong, woolly; styles bristle-shaped; stigmas simple. *Pericarp:* none; (according to Gærtner, capsules five, woolly, ovate, acuminate at both ends, compressed, one-celled, not opening.) *Seeds:* four or five, oblong, compressed, attenuated to both ends, interwoven with wool. *Observe.* The number varies in the parts of fructification, and is extricated with difficulty, on account of the wool in which they are involved. Gærtner says, the number of capsules varies from three to five. **ESSENTIAL CHARACTER.** *Calix:* four or five leaved, longer than the corolla; petals eight or ten, spatulate. *Pericarp:* none. *Seeds:* five, connected by wool.—The species are,

1. *Forskahlea Tenacissima*; *Clammy Forskahlea*. Hairy-hispid: leaves elliptic, awnless; calicine segments oblong-lanceolate, sharp; root annual; stem nearly two feet high, panicled, round, hispid, red, with alternate branches; petioles round, shorter than the leaves; flowers axillary, in pairs, sessile, rough, hairy. The bristles of the stem and leaves are finely hooked, by which they stick to whatever comes in their way. It flowers in July and August.—Native of Egypt.

2. *Forskahlea Candida*; *Rough Forskahlea*. Scabrous: leaves elliptic, waved, awnless; calicine segments ovate, obtuse; stem shrubbyish, smooth, resembling that of the foregoing, whitish, and woody at the base; flowers axillary, sessile, smaller than in the first species; petals white. Perennial: flowering in June and July.—Native of the Cape of Good Hope.

3. *Forskahlea Angustifolia*; *Narrow-leaved Forskahlea*. Strigose: leaves lanceolate, the teeth thorny-bristle-shaped; calicine segments lanceolate-subulate. Annual, adhering like the others; stem red; pistils three.—It flowers in July and August.

Forstera; a genus of the class Gynandria, order Diandria.—GENERIC CHARACTER. *Calix*: perianth double; outer inferior, three-leaved, lateral; leaflets oblong, sharp; inner superior, six-cleft; leaflets erect, oblong, concave. *Corolla*: one-petalled, tubulous-bell-shaped; tube length of the calix; border six-parted; divisions oblong, obtuse, patulous, reflex at the tip, equal; nectary two small scales, obovate, petaliform, fixed to the style on both sides under the stigma. *Stamina*: filamenta two, very short, each fixed to the style between the stigma and a scale of the nectary under the stigma. *Pistil*: germen inferior, oval; style cylindrical, erect, the length of the tube of the corolla; stigmas two, broad, spreading, somewhat bearded. *Pericarp*: capsule oval, one-celled. *Seeds*: numerous, shaped like saw-dust, fixed to a columnar receptacle. ESSENTIAL CHARACTER. *Perianth*: double; outer inferior, three-leaved; inner superior, six-cleft. *Corolla*: tubular.—The species is,

1. *Forstera Sedifolia*. Stem herbaceous, ascending, a hand in height, somewhat branched; leaves imbricate, sessile, obovate, sharpish, quite entire, smooth, pressed to the stem, from spreading reflex at the tip, thickish, shining, with a broad keel; peduncles solitary, one-flowered, terminating, erect, red, long; flowers white, except at the throat and inside of the calix, where they are red.—Native of New Zealand, where it is found on the tops of the highest mountains.

Fothergilla; (so called, in memory of John Fothergill, M.D. an eminent physician, and patron of botany, who cultivated a variety of the most curious plants in his garden, near London:) a genus of the class Polyandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, close, truncate, short, permanent. *Corolla*: none. *Stamina*: filamenta very many, filiform, thicker at top, long; antheræ minute, erect, quadrangular. *Pistil*: germen ovate, bifid; styles two, subulate, terminating, the length of the stamina. *Pericarp*: capsule hardened, two-lobed, two-celled; lobes two-valved. *Seeds*: solitary, bony. ESSENTIAL CHARACTER. *Calix*: ament ovate; scales one-flowered. *Corolla*: calixform, one-petalled, five-cleft.—The only known species belonging to this genus is,

1. *Fothergilla Alnifolia*. This tree has the appearance and leaves of Alder: leaves alternate, petioled, wedge-shaped, entire, serrate at the tip; serratures very large and few, the upper surface green, the lower hoary, the younger ones white, with nap underneath; flowers in a close spike at the end of the stem, like an oblong head, and white; capsules

large, ovate, very hirsute, sharp, two-celled; the valves opening into four points until the seeds are ripe. The flowers come out in the beginning of spring, at the ends of the branches, in the form of white oblong spikes or catkins, of no great beauty.—Native of North America. There is a variety called the narrow-leaved *Fothergilla*, which Jacquin describes as a branching shrub, with ferruginous round branches; leaves oblong, obscurely crenate at top, on short petioles, alternate, smooth; spike at the end of the branchlets, sessile, ovate, close; flowers sweet-smelling, honied, sessile; capsule two-celled; seeds solitary.—Native of Carolina.

Foxglove. See *Digitalis*.

Fox-grape. See *Vitis Vulpina*.

Foxtail-grass. See *Alopecurus*.

Fragaria; a genus of the class Icosandria, order Polygynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, flat, ten-cleft; divisions alternately exterior, and narrower. *Corolla*: petals five, roundish, spreading, inserted into the calix. *Stamina*: filamenta twenty, subulate, shorter than the corolla, inserted into the calix; antheræ lunular. *Pistil*: germina numerous, very small, collected into a head; styles simple, inserted at the side of the germina; stigmas simple. *Pericarp*: none; common receptacle of the seeds (vulgarly called a berry) ovate, pulpy, soft, large, coloured, truncate at the base, and deciduous. *Seeds*: numerous, very small, acuminate, scattered over the surface of the receptacle; (according to Gærtner, a little compressed, smooth, glittering.) ESSENTIAL CHARACTER. *Calix*: ten-cleft. *Petals*: five. *Receptacle* of the seeds ovate, and like a berry.—The species are,

1. *Fragaria Vesca*; *Esculent or Wood Strawberry*. Creeping by runners. This species is sufficiently distinguished by the long slender runners which it throws out from the root, and by means of which it increases abundantly, by its ternate leaves, and its remarkably fleshy receptacle, commonly called a berry, but having the outer surface studded with the seeds. From the first and last of these characters, it obtained the English name of *Strawberry*; for it is a plant whose running stems are strewed (anciently *strawed*) over the ground, and the fruit of which is usually termed a berry. Monsieur Duhamel observes, that in our European Strawberries there are generally four stamina to each petal, but in the American five or six: so that when the flowers of the latter have the regular number of petals, they have from twenty-five to thirty stamina; but when they have seven petals, the number of stamina is from thirty-five to forty-two. In the European Strawberries, when any supernumerary petals are placed in a row before the regular ones, each diminishes the number of stamina by one or two; but when they are placed behind the regular petals, the number of stamina is not diminished. The common Wood Strawberry of Europe has the leaflets oval-lanceolate, acutely serrate; the petioles woolly, the runners slender, smooth, often tinged with purple; peduncles with two or more flowers. The fruit is small, and usually red; in England it seldom has much flavour, because the plants are generally too much shaded in woods and hedges. The mountainous Strawberries of warmer and drier countries, though they usually grow among bushes, yet enjoying more sun and a drier soil, are much higher flavoured, and larger, than ours. The subordinate varieties of this are, 1. The White Wood Strawberry, which ripens rather later in the season, and is by many persons preferred to it for its quick flavour; but as it seldom produces such large crops of fruit as the red sort, it is not very generally cultivated. 2. The Alpine Strawberry is a larger plant than that which grows

in our woods, the stem higher, the leaves broader, the fruit larger, red, and usually much pointed, sometimes white. It is well-flavoured; and the plants being great bearers from June till the autumn frosts put a stop to them, the Alpine Strawberry is therefore very valuable. The reason of its long continuance in fruit is, that the runners which it throws out during the summer, shoot up into flower and fruit the same year, more freely than the others. Mr. Miller, who considers it as a variety of the Scarlet Strawberry, says, that the Dutch gardeners call it *Everlasting Strawberry*. It has been cultivated ever since the time of Richard the Second.

3. The Rough-fruited or Prickly Strawberry, is only a mere accidental variety. The flower is greenish, the fruit harsh, rough, and prickly, of a greenish colour, with some show of redness. John Tradescant the elder, first took notice of it in a woman's garden in Plymouth: her daughter had gathered it in the country, and set the root there. Merret afterwards observed it in Hyde Park and Hampstead-wood.—The *Hautboy Strawberry* has been long cultivated in the English gardens, and differs much from the others in leaves, flower, and fruit. There is an improved variety of it, commonly called the *globe hautboy*, the fruit of which is larger, and of a globular form; which, when neglected, will degenerate into the common hautboy; but where the soil is good, and the culture well managed, the plants will produce plenty of large and well-flavoured fruit. Mr. Miller, we know not upon what authority, asserts that the hautboy came originally from America; it is certainly very liable to degenerate, and to produce dry effete fruit. This degeneracy, according to Monsieur Duhamel, is owing to there being two sorts of plants, one bearing male, the other female, or rather imperfect hermaphrodite flowers; for they have thick short filaments, with very small effete antheræ. The former of these being reputed useless, are carefully destroyed, and hence not only the seeds become abortive, but the receptacle, which we commonly call the fruit, small and juiceless. This may be remedied, either by planting a few of the male plants, or of the Scarlet or Pine Strawberry, among the hautboys. M. du Chesne, who has written a treatise in French on the subject of Strawberries, having sown the seeds of hautboys, had about an equal number of male and female plants. Parkinson's Bohemian Strawberry seems to be the hautboy; but he says nothing about the high musky flavour peculiar to it: and Ray says, it differs in nothing from the Wood Strawberry, but in being nearly twice its size in all the parts; and that the fruit is not so pleasant, but sweeter. Parkinson, however, gives a very different account; he says, "that it is the goodliest and greatest, both for leaf, next to the Virginian, and for beauty far surpassing all, for some of the berries have been measured to be near five inches about." The *Chili Strawberry* has hairy oval leaves, of a much thicker substance than any sort yet known, standing upon very strong hairy foot-stalks; the runners from the plants are very large, hairy, and extend to a great length, putting out plants at several distances. The peduncles are very strong; the leaves of the calix long and hairy. The flowers are large, and often deformed, and so is the fruit, which is very large; and, when cultivated in very strong land, the plants produce plenty of fruit, which is firm, and well-flavoured; but as it is not productive, it has been generally neglected. Frezier says, that the fruit usually attains the size of a walnut, but is sometimes as large as an egg; that it is of a paler red than the European Strawberry, and not so quick in its flavour. The *Virginia* or *Scarlet Strawberry* is the sort which is first ripe, which, if the fruit were not thought by good judges to be preferable to all others, would probably recommend it. The leaves are of a

dark green, and of a more even surface than the others; the flowering-stems are shorter; and the fruit is frequently concealed among the leaves. It was brought from Virginia, where it grows naturally in the woods. The *Pine Strawberry* has lately been introduced into the English gardens. The leaves have a great resemblance to those of the Scarlet Strawberry, but are larger, of a thicker substance, and the indentures of their edges are blunter; the runners are much larger, and hairy; the peduncles are stronger; the flowers much larger; and the fruit approaches in size, shape, and colour, to the Chili Strawberry. As this produces a great quantity of fruit, when the plants are kept clear from runners, and the fruit is very large, it is worthy of cultivation. Duhamel says, it is raised from the seed of the Chili Strawberry. The flower is very large, and the fruit has something of the smell and taste of the pine-apple. It varies in the form, some being ovoid, others oblate-spheroid, others again irregular: they are much smaller than the Chili Strawberry. They are smooth and shining; the shaded side yellowish-white, with a tincture of red, and the seeds red; the side towards the sun pale red, composed of a mixture of reddish-brown and yellow; the seeds red-brown. The flesh is less firm than that of the Chili Strawberry, but it is juicy, and has a pleasant perfumed taste. The *Carolina Strawberry* greatly resembles the preceding, but is much smaller and less hairy; the flower-stems are shorter; the flower-buds more lengthened out, and less swollen; the divisions of the calix larger, and the little ones seldom divided; the petals rather smaller, and seldom more than five in number; the fruit smaller, more regular in the form, of a higher colour, and the perfume not so pleasant. The Pine varies but little when raised from the seed, whereas this varies much in the flower, fruit, &c.—Strawberries, either eaten alone, or with sugar, or with milk, are usually esteemed a most delicious fruit: they are grateful, cooling, subacid, juicy, and have a delightful smell. Taken even in large quantities, they seldom disagree with the stomach. They promote perspiration, impart a violet scent to the urine, and dissolve the tartarous incrustations upon the teeth. Persons afflicted with the gout or stone, have found great relief by using them profusely. Linneus informs us, that by eating plentifully of them every day, he kept himself almost free from the gout. Hoffman affirms, that he has known consumptive people cured by them. The bark of the root, like that of the Tormentil, and the rest of its congeners, is astringent. The leaves, says Meyrick, are cooling and diuretic: an infusion of them is good in the strangury; and, when made strong, in the jaundice: when dried and reduced to powder, they are astringent, and useful in fluxes of the bowels; and a strong decoction of them sweetened with honey, is a good gargle for sore throats. It would be unpardonable not to inform our fair readers, that they have likewise the credit of being a cosmetic, or beautifier of the skin.—*Propagation and Culture.* Strawberries in general love a gentle hazelly loam, in which they will thrive, and bear greater plenty of fruit than in a light rich soil. The ground should also be moist; for if it be very dry, all the watering which is given to the plants in warm dry seasons, will not be sufficient to procure plenty of fruit; nor should the ground be much dunged, for that will cause the plants to run into suckers, and grow luxuriant, and render them less fruitful. The best time to remove these plants is in October, that they may get new roots before the hard frost sets in, which loosens the ground; so that if the roots of the plants be not well established in the ground, the first thaw will often turn them out of it; therefore the sooner they are planted, when the autumnal rains begin, the less danger will there be of

their miscarrying; and sometimes those which are well rooted will produce a few fruit the first year. There are some who transplant them in the spring; but where that is done they must be well supplied with water in dry weather. The ground in which they are planted should be thoroughly cleansed from the roots of Couch and other weeds, for as the Strawberry plants are to remain three years before they are taken up, if any of the roots of those bad weeds are left in the ground, they will have time to multiply so greatly as to fill the ground, and overbear the Strawberry plants. The ground should also be well trenched, and made level; then the usual method is to lay it out into beds of four feet broad, with a path of two feet or two feet and a half wide between each, which are necessary for conveniently gathering the fruit, for weeding and dressing the beds, and for watering the plants. After the beds are marked out, there should be four lines drawn in each, at a foot distance, which will leave six inches' space on each side, between the outside rows and the paths; then the plants should be planted at about a foot distance from each other in the rows, in a quincunx order, being careful to close the ground to the roots of the plants when they are planted; and if rain do not fall soon after, the plants should be well watered, to settle the earth to their roots. The distance here mentioned must be understood for the Wood Strawberries only; for as the other sorts grow much larger, their distances must be proportioned to their several growths; hence the scarlets and hautboys should have but three rows of plants in each bed, which should be at fifteen inches' distance, and the plants in the rows should be allowed the same space from each other; and the Chili, and other large Strawberries, must have only two rows of plants in each bed, which should also be two feet apart in the rows; for as these grow very strong, if they have not room to spread, they will not be very fruitful. In choosing proper plants the great art entirely consists; for if they be promiscuously taken, the greater part will prove barren, or, as it is generally termed, blind, producing plenty of flowers, but no fruit. These flowers, when examined, will be found to want the female organs of generation, most of them abounding with stamina, but there are few if any styles; so that it frequently happens among these barren plants, that some of them have a part of an imperfect fruit formed, which will occasionally ripen. This barrenness is not peculiar to Strawberries, but is common to all those plants which have creeping roots or stalks; and the more they increase from either, the sooner they become barren: and this in some degree runs through the vegetable kingdom; for trees and shrubs which are propagated by cuttings, taken from plants also raised from cuttings, are generally barren of seeds in two generations. In fruit-trees, it often happens that those sorts which have been long propagated by grafts and buds, have no kernels. But, to return to the choice of Strawberry plants; they ought never to be taken from old neglected beds, where the plants have been suffered to spread or run into a multitude of suckers, nor from any plants which are not very fruitful; and those offsets which stand nearest to the old plants should always be selected in preference, before those which are produced from the trailing stalks at a further distance. The Wood Strawberry is best, when the plants are taken fresh from the woods, provided they be taken from fruitful plants; because they are not so liable to ramble and spread, as those which have been long cultivated in gardens. When these plants have taken new root, the next care is, if the winter prove severe, to lay some old tanners' bark over the surface of the bed, between the plants, to keep out the frost; this care is absolutely necessary to the Chili Straw-

berry, which is frequently killed in hard winters, where it is exposed without any covering; therefore where tanners' bark cannot easily be procured, saw-dust or sea-coal ashes may be used; or in want of these, if decayed leaves of trees, or the branches of evergreen trees with their leaves upon them, are laid over the beds, to prevent the frost from penetrating deep into the ground, it will secure the plants from injury. In the succeeding summer the plants should be constantly kept clean from weeds, and all the runners should be pulled off as fast as they are produced; if this be constantly practised, the plants will become very strong by the following autumn; whereas when this is neglected, as it frequently is, and all the runners are permitted to stand during the summer season, and then pulled off in the autumn, the plants will not be half so strong as those where that care has been taken, and there will not be near the same quantity of fruit upon them the following spring, nor will the fruit be near so large and fair; but where proper care is taken of the plants the first summer, there is generally a plentiful crop of fruit in the second spring.—As this fruit is very common, and there are but few persons who cultivate it with proper care, we shall still further dilate upon this subject, and give ample directions for cultivating them with success. The old plants of Strawberries are those which produce the fruit, for the suckers seldom produce any till they have grown a full year; hence it appears how necessary it is to divest the old plants of them, for whenever they are suffered to remain, they rob the fruitful plants of their nourishment in proportion to their number, for each of these suckers sends out a quantity of roots, which interfere, and are so closely matted together as to draw away the greatest part of the nourishment from the old roots, whereby they are greatly weakened; at the same time, these suckers render each other weak, and consequently barren. Where the old plants have been constantly kept clean from suckers, they have remained very fruitful for four or five years; but it is the best way to have a succession of beds, that after three years' standing they may be taken up, because by that time they will have exhausted the ground: and it invariably follows, that Strawberries planted on fresh land are the most fruitful. The next thing to be observed is, to remove the strings or runners from the plants in autumn, and to clear the beds from decayed leaves and weeds, which should be buried in the dug-up paths, laying some earth over the surface of the beds between the plants, which will strengthen and prepare them for the following spring; and if after this there be some old tanners' bark laid over the surface of the ground between the plants, it will be of great service to them. In the spring, after the danger of hard frost is over, the ground between the plants in the beds should be forked with a narrow three-pronged fork, to loosen it, and break the clods, and in this operation the tan which was laid over the surface of the ground in autumn will be buried, which will be a good dressing to the Strawberries, especially in strong land: then about the end of March, or the beginning of April, if the surface of the beds be covered with moss, it will moisten the ground, and prevent the drying winds from penetrating, thereby securing a good crop of fruit; the moss will preserve the fruit clean, that when heavy rains fall after the fruit is full grown, there will be no dirt washed over them, which frequently happens, so that the fruit must be washed before it is fit for the table, which greatly diminishes its flavour. The soil in which the Chili Strawberry is found to succeed best, is a very strong brick earth, nearly approaching to clay; in this kind of soil they have produced tolerably good crops of extremely well-flavoured fruit; and if some care be taken to pull off the runners, there is

little doubt that they would prove as productive as the haut-boy: this is not advanced upon theory, but has experimental proof for its foundation.—*Forcing.* Some persons are so fond of Strawberries, as to be at any expense to obtain them early in the year; and when their great medical virtues are considered, it will not be deemed an useless or trifling addition to the present article, to detail the practice of those who have best succeeded in the early raising, forcing, or management of these fruits. Where there are any hot walls erected in gardens for the producing early fruit, it is very common to see Strawberries planted in the borders, that the fire which is applied for ripening the fruit against the walls, may also serve the purpose of bringing forward the Strawberries: but where this is the practice, the Strawberry plants should be annually renewed, taking up the plants as soon as the fruit is over; then all the earth of the border should be taken out at least two feet deep, and fresh earth brought in, which will be equally good for the wall trees; but, as was before observed, that the old plants only are those which produce the fruit, there should be a sufficient number of plants brought up in pots to supply the borders annually, and the same must be done if they are to be raised in a common hot-bed, or in stoves. We shall therefore begin with instructions for raising and preparing plants for those purposes. The sorts most proper for forcing early are, the Scarlet, the Alpine, and the Wood Strawberries, for the Hautboy grows too large a plant for this purpose. In the choice of plants, there should be an especial care taken to have them from the most fruitful plants, and those which grow immediately to the old plants: they should be taken off in autumn, and each planted in a separate small pot filled with loamy soil, and placed in a shady situation till they have taken root, after which they may be removed to an open situation, where they may remain till the middle or end of November, when the pots should be plunged in the ground up to their rims, to prevent the frost from penetrating through the side of the pots; if these be placed near a wall, pale, or hedge, exposed to an east aspect, or north-east, they will succeed better than in a warm situation, because they will not be forced too forward: the only care they require is, to secure them from being turned out of the pots after frost. The spring following, the plants will be so far advanced as to have filled the pots with their roots by the end of April, when they should be turned out of the pots, and their roots pared; then planted into penny pots filled with the like loamy soil, and plunged into the ground in a shady situation, where they should remain the following summer, during which time they must be duly kept clean from weeds, and all the runners must be taken off as fast as they are produced; likewise if there should be any flowers come out, they should be pinched off, and not suffered to bear fruit, which would weaken the plants, for there cannot be too much care taken to have them as strong as possible, that they may produce plenty of fruit, without which they are not worth the trouble of forcing. About the middle of October, or earlier if the autumn proves cold, the pots should be removed into a warmer situation, to prepare them for forcing; for they should not be suddenly removed from a very cold situation immediately into the stove or hot-bed, but with a gradual preparation. Where they are designed for the borders near a hot-wall, they may then be turned out of the pots, and planted into the borders, that they may have time to get fresh rooting before the fires are made to heat the walls: when these are planted, they may be placed very close to each other; for as they are designed to remain there no longer than till they have ripened their fruit, they will not require much room, as their roots will find sufficient

nourishment below, and also from the earth which is filled into the spaces between the balls of earth about their roots; and it is of consequence to get as much fruit as possible in a small space, where there is an expense to force them early. If the fires be lighted about Christmas, the Strawberries in these borders will be ripe by the end of March; or, if the season should prove very cold, it may be the middle of April before they will be fit for the table. In the management of the plants, there must be care taken to supply them with water when they begin to show their flowers, otherwise they will fall off without producing any fruit, and in mild weather there should be fresh air admitted to them every day; but as fruit-trees against the wall must be so treated, the same treatment will agree with the Strawberries.—If the Strawberries are to be forced in a stove, where there are pine-apples, and no room to plunge them in the tan-bed, then the plants should be transplanted into larger pots in September, that they may be well rooted before they are removed into the stove, which should not be till December; but if in the beginning of November they be placed under a frame where they may be screened from the frost, it will prepare the plants better for forcing; and those who are desirous to have them very early, make a hot-bed under frames, upon which they place their plants the latter end of October, which will bring them forward to flower, and then they remove the plants into the stove; when these plants are removed into the stove, they should be placed as near to the glasses as possible, that they may enjoy the full sun and air, for when they are placed backward, the plants will draw up weak, and the flowers will drop without producing fruit. As the earth in the pots will dry pretty fast when they stand upon the pavement of the hot-house, or on shelves, the plants must be duly watered, but with discretion: they will produce ripe fruit in February, which is as early as they are likely to be required, except it be for medical purposes. When the fruit is all gathered from the plants, they should be turned out of the stove; nor should those plants which are in the borders near the hot walls be left there after their fruit is gathered, but immediately taken up, that they may deprive the fruit-trees of as little nourishment as possible.—Where there is no conveniency of stoves or hot-walls for this purpose, the fruit may be ripened upon common hot-beds; and though they may not be quite so early as with the other advantages, yet great crops of them have ripened in April upon common hot-beds under frames: the plants were prepared in pots after the manner before directed, and were placed in a warm situation in the beginning of October; the hot-bed was made about Christmas in the same manner as for Cucumbers, but not so strong; and as soon as the first violent steam of the dung is over, some old rotten dung laid over the hot-bed to keep down the heat, or, where it can be easily procured, cow-dung is preferable. The plants should then be turned out of the pots, and placed upon the bed as closely together as possible, filling up the interstices between the plants with earth, and afterwards admitting fresh air every day. If the heat of the bed be too great, the plants should be raised up, to prevent their roots from being scorched; if the bed be too cold, the sides of it should be lined with some hot dung. The first bed will bring the plants to flower by the end of February, or the beginning of March, by which time the heat of the bed will be spent; therefore another hot-bed should be prepared to receive the plants, which need not be so strong as the first; but upon the hot dung should be laid some cow-dung, about two inches thick, which should be equally spread and smoothed; this will prevent the heat of the bed from injuring the roots of the plants, and

upon this should be laid two inches of a loamy soil : when the whole has laid two whole days to warm, the plants should be taken out of the first hot-bed, and carefully turned out of the pots, preserving all the earth to their roots, and placed close together upon this new hot-bed, filling up the vacancies between the balls with loamy earth : the roots of the plant will soon strike out into this fresh earth, which will strengthen their flowers, and cause their fruit to set in plenty ; and if proper care be taken to admit fresh air to the plants, and supply them properly with water, they will have plenty of ripe fruit in April, full two months before their natural season.—The Alpine Strawberry will supply the table the whole summer, especially if the plants be watered in dry seasons, the neglect of which frequently causes the blossoms to fall off without producing fruit. Thus may a succession of this delicious and salubrious fruit be obtained from March and April, and even earlier, by means of a hot-house forcing frame, hot walls, or hot-beds, and in the open air from June to October and November, when the weather is mild ; for not only the Alpine, but the White Wood Strawberry, will continue bearing in tolerable abundance till the autumn frosts come on with some degree of severity, especially if the situation be warm, and the soil in which they grow not too light. There are some persons so curious as to raise the plants from seeds, by which they have greatly improved some of the sorts : and Mr. Miller thinks, that if the practice were more common, it would be found of singular service, where the fairest of the fruit of each kind are chosen. To obtain the seeds, the ripe fruit must be bruised in a vessel of water, and the pulp carefully washed away, leaving the seeds clean. They should then be gradually dried ; when they may be sown in the spring on a border of rich light earth, keeping them watered and free from weeds during the summer.

2. *Fragaria Monophylla* ; *Simple-leaved Strawberry*. Leaves simple. The scape or flowering-stem of this is longer than it usually is in the common Wood Strawberry ; the petals are smaller, and the calices gashed. This, however, is frequently the case with the common wild sort in woods, and the others are very inconsiderable differences, especially in a genus so liable to variation as this. Other petty distinctions, such as that the leaves are smaller in winter, and their ribs less branched, the runners more slender and productive, the fruit more oblong or pyramidal, will not induce us to separate this from the foregoing species. Even the remarkable difference of simplicity in the leaves, cannot make us regard it as any thing more than a singular variety ; for plants raised from the runners will sometimes have ternate leaves, and so also will seedling plants. It agrees with its parent, the common Wood Strawberry, in the time of flowering and fruiting ; nor do the form, size, or flavour of the fruit, differ more from that than might be expected to result from cultivation. For its propagation and culture, see the first species.

3. *Fragaria Sterilis* ; *Barren Strawberry*. Stem decumbent ; flowering-branches lax. The name of *sterilis*, or barren, is not given to this species because it does not produce perfect seed, for it certainly does, but because the receptacle is not fleshy and eatable. To distinguish this from the esculent Strawberry, with all its varieties, it is sufficient to observe, that though the branches be trailing, yet they never creep or throw out roots ; that the leaves are ovate or obovate, bluntly serrate, silky, and silvery, white underneath, with very hairy petioles ; that the flower-stems are small, weak, and hairy, sustaining one, or at most two flowers, with smaller and whiter petals than the foregoing. The whole plant is smaller, weaker, and more hairy ; the petioles and leaflets extremely

hairy ; the latter on the flowering plants very small, about half an inch in length, on the young plants twice as long ; stem covered with brown scales ; peduncles from an inch to an inch and a half long, terminated by one flower, and having a single leaf in the middle it, from the axil of which springs another flower ; peduncles and calices tinged with red ; corollas three, eighth of an inch in diameter ; petals roundish, frequently emarginate. This species is very distinct from the other, and, according to the observation of Curtis, Leer, and others, its fructification has a greater affinity with *Potentilla*, between which genus and *Fragaria*, this seems to be a link. The flowers appear earlier than in the other, namely, in March, and it is common in woods and hedges, and on some heaths, in Switzerland and Germany, as well as in Great Britain ; found also in Japan.

Frankenia ; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix* : perianth one-leaved, subcylindric, ten-cornered, permanent ; mouth five-toothed, sharp, patulous. *Corolla* : petals five ; claws the length of the calix ; border flat, with roundish spreading laminae ; nectary with a channelled acuminate claw inserted into the claw of each petal. *Stamina* : filamenta six, length of the calix ; antheræ roundish, twin. *Pistil* : germen oblong, superior ; style simple, length of the stamina ; stigmas three, oblong, erect, obtuse. *Pericarp* : capsule oval, one-celled, three-valved. *Seeds* : very many, ovate, very small. *Observe*. Stamina five to ten ; fruit three-celled. ESSENTIAL CHARACTER. *Calix* : five-cleft, funnel-form. *Petals* : five—*Stigmas* : three. *Capsule* : one-celled, three-valved.—The species are,

1. *Fraukenia lævis* ; *Smooth Frankenia*, or *Sea Heath*. Leaves linear, crowded, ciliate at the base ; root perennial ; stem and leaves thinly sprinkled with white globular particles ; flowers at the ramifications of the stem, and in the middle of a bundle of leaves, solitary, sessile ; calix with five, six, or seven ribs, and as many teeth, but rarely more than five ; corolla purple ; petals wedge-shaped, a little scalloped at the end ; nectary a yellow scale ; filamenta flat on one side, convex on the other ; style deeply trifid. The flowers are elegant in form and colour, like those of a little red pink or campion. The stamina and pistil much resemble the *Lychnis*, to which the plant is nearly allied, though so different in habit.—In the salt marshes near Leghorn, this plant is often found. It has been found in England, at Bursledon-ferry, in Hampshire ; on the coasts of Essex, Sussex, and Kent, in abundance, particularly in the islands of Shepey and Thanet ; near Thurington in Essex ; between Maldon and Goldhanger ; in Selsey island, Sussex ; and near Portsmouth. It also occurs at Lovingland, just over the water at Yarmouth, at Tid Goat near Wisbeach ; and near Lynn in Norfolk. It flowers in July and August.

2. *Frankenia hirsuta*. Stems hirsute ; flowers in terminating bundles ; leaves like those of *Thyme*, ciliate, especially at the base ; flowers violet-coloured.—Native of the south of France, Apulia, Crete, Siberia, and the Cape of Good Hope. This appears to be but a variety of the former.

3. *Frankenia Pulverulenta* ; *Dusty Frankenia*, or *Sea Heath*. Leaves obovate, retuse, mealy underneath ; stems lying flat, slender, branching, with the knots about a finger's breadth from each other ; leaves four at a joint, with very short hairs underneath ; flowers in the axils of the leaves, sessile ; calix tough, rigid, with five angles ; teeth upright. Annual. Gerard and Ray name it *Valentia Knot-grass*. It flowers in July, and is a native of the south of France, Italy, and Spain. It has also been found on the coasts between Bognor and Brightelmstone.

Fraxinus; a genus of the class Polygamia, order Diœcia; or class Diœcia, order Diandria.—GENERIC CHARACTER. *Hermaphrodite*. *Calix*: none, or a perianth one-leaved, four-parted, upright, sharp, small. *Corolla*: none, or petals four, linear, long, sharp, upright. *Stamina*: filamenta two, upright, much shorter than the corolla: antheræ upright, oblong, four-furrowed. *Pistil*: germen ovate, compressed; style cylindric, upright; stigma thickish, bifid. *Pericarp*: none, except the crust of the seed, (capsule two-celled, leafy, and flattened at top, according to Gærtner.) *Seed*: lanceolate, flattened, and membranaceous, one-celled. *Female*, the same as the male, except that it has no stamina. *Observe*. The first species has neither calix nor corolla. The female has frequently hermaphrodite flowers, and the hermaphrodite has females interspersed. The third species has a calix and corolla, and is always hermaphrodite. **ESSENTIAL CHARACTER.** *Hermaphrodite*. *Calix*: none, or four-parted. *Corolla*: none, or four-petalled. *Stamina*: two. *Pistil*: one. *Seed* (or *Capsule*:) one, lanceolate. *Female*. *Pistil*: one, lanceolate.—The species are,

1. *Fraxinus Excelsior*; *Common Ash Tree*. Leaflets lanceolate, serrate, sessile; flowers without petals. The leaves have generally five pairs of leaflets, (four to six,) and one odd one, of a dark green. The flowers are produced in loose spikes from the side of the branches, and are succeeded by flat seeds, which ripen in autumn. The lateral buds produce the flowers, and the terminating one the leaves. Bractes linear, one on the outside at the base of each pedicel: filamenta broad and flat, not so long as the antheræ, which are of a blackish purple colour. There are not only hermaphrodite and female flowers, but also male ones, so that this species should seem referable to the order Diœcia. Care should be taken in observing the flowers; for in those which are hermaphrodite, the germen which lies between the two stamina does not grow till some days after they appear, so that they seem at first to be male flowers. What Linneus calls a seed, others call a capsule: the seed being covered with a leathery kind of crust, which does not split or open. Its usual time of flowering is in April, before the leaves, sometimes so late as May, from lateral buds, below the leaf-buds, and are greenish, and inconspicuous. Both are sometimes much injured by spring frosts. If a wood of these trees be rightly managed, it will turn greatly to the advantage of its owner; for by the underwood, which will be fit to cut every seven or eight years for hoops, or every fourteen years for hop-poles, &c. there will be a continual income, more than sufficient to pay the rent of the ground, and all other charges, and still there will be a stock preserved for timber, which, in a few years, will be worth forty or fifty shillings the tree. The Ash is, however, a very improper tree for hedges, and the borders of arable land; the drip of it is very unfavourable to all other vegetable productions; it exhausts the soil very much, and the root spreads widely near the surface. Nor, though it be a handsome tree, ought it on any account to be planted for protection or ornament, because the leaves come out late, and fall early. The fertile trees also generally exhaust themselves so much in bearing keys or fruit, that their foliage is scanty, and their appearance unsightly. The trees, however, which bear female flowers only, have a full and verdant foliage, and make a handsome figure, though late in the season. It is well calculated for standards and clumps in parks and plantations, and for groves and woods. It will grow in very barren soil, and in the bleakest and most exposed situations. It is hardy enough to endure the sea winds well, and may therefore be planted on the coast, where few trees

will prosper. If planted by ditch sides, or in low boggy meadows, the roots act as underdrains, and render the ground about them firm and hard; the timber, however, is in this case but of little value. It was natural that our remote ancestors, when the island was overrun with wood, should value trees rather for their fruit than their timber: it is no wonder then, that by the laws of Howel Dda, the price of an Oak or a Beech should be 120 pence, while the Ash, because it furnished no food for swine, was valued only at four pence. The *Edda* of Woden, however, holds the Ash in the highest veneration; and man is described as being formed from it. It is probably owing to the remains of Gothic veneration for this tree, that the country people in the south-east part of the kingdom split young Ashes, and pass their distempered children through the chasm, in hopes of a cure. They have also a superstitious custom of boring a hole in an Ash, and fastening in a shrew-mouse; a few strokes with a branch of this tree is then accounted a sovereign remedy against cramps and lameness in cattle, which are ignorantly supposed to proceed from this harmless animal. In many parts of the Highlands of Scotland, at the birth of a child, the nurse or midwife puts one end of a green stick of this tree into the fire, and while it is burning receives into a spoon the sap or juice which oozes out at the other end, and administers this as the first spoonful of liquor to the newborn babe. It is not common to see the Ash of a very great size, although instances of large trees are not wanting. Dr. Plot mentions one of eight feet in diameter, valued at thirty pounds. Mr. Marsham informs us of another in Benel church-yard, near Dumbarton, in Scotland, which, in the year 1768, measured sixteen feet nine inches in circumference, at five feet from the ground. Mr. Evelyn says, that some trees sold in Essex, were one hundred and thirty-two feet in length. Mr. Arthur Young, in his Irish Tour, mentions some of seventy and eighty feet in height, which were only of thirty-five years' growth. The trunk of one on the bank of the Avonmore, was above fourteen feet round, and carried nearly the same dimensions for eighteen feet. An Ash at Dunganstown was twelve feet round, and quite clear of branches for thirty feet, where it measured ten feet round, and the arms extended in beautiful forms twenty-eight yards. At Tiny Park was another, the circumference of which, in the smallest part, somewhat exceeded nineteen feet, or six feet four inches in diameter. At Luttrellstown, the seat of the Earl of Carhampton, are several Ash-trees, from eleven to thirteen feet six inches round, one of which was sold for thirteen pounds. At Leixlip Castle, is a row of eighteen Ash-trees, on a very bleak exposure, measuring from nine to twelve feet round, with fair stems of considerable height, and fine branching heads. At Donirey, near Clare Castle, in the county of Galway, is an old Ash, that at four feet from the ground measures forty-two feet in circumference, and at six feet high, thirty-three feet: the trunk has long been hollow, so that a little school has been kept in it, although the few branches that still remain are very fresh and vigorous. Near Kennity Church in the King's County, is an Ash, the trunk of which is twenty-one feet ten inches round, and it is seventeen feet high before the branches, which are enormously large, break out. When a funeral of the lower class passes by, they lay the corpse down for a few minutes, say a prayer, and then throw a stone, to increase the heap, which has long been accumulating round the root. Finally, in the church-yard of Lochabar in Scotland, Dr. Walker measured the trunk of a dead Ash, which, at five feet from the surface of the ground, was fifty-eight feet in circumference.—The timber of the Ash is next in value to the Oak, and in some places equal to it. It is hard and

tough, and of excellent use to the coach-maker, wheelwright, and cartwright, for ploughs, axle-trees, fellies, harrows, and many other implements of husbandry; for ladders, oars, blocks for pulleys, &c. It is excellent for tenons and mortises, and is in great request among coopers, turners, and thatchers; no wood equals it for palisade hedges, hop-yards, poles, and spars, handles and stocks for tools, spade-trees, &c. When it happens to be curiously veined, the cabinet-makers use it, and call it green ebony. From a remark in Harrison's Description of England, prefixed to Hollingshead, it is plain that the Ash was then esteemed the properest tree for hop-poles. Poles are accounted to be their greatest charge. The Ash makes very sweet fuel, with little smoke, but is apt to crack and fly in burning. Ash pollards are of great service where fuel is scarce; a few of them will produce many loads of lop. The loppings make the most agreeable of all fires, and will burn well either green or dry. It should nevertheless be borne in mind, that if the branches be suffered to grow too large, the lopping will proportionably injure the tree. The Ash has no equal for drying herrings. The ashes of the wood afford very good Potash; and the bark is good for the tanning of nets, and of calf-skins; a slight infusion of it appears of a pale yellowish colour, when viewed against the light, but when looked down upon, or placed between the eye and an opaque object, it is blue. This blueness is destroyed by the addition of an acid; and alkalies recover it again. It will give a good, though not a beautiful, green to cloths which have been blued. In the north of Lancashire, they lop the Ash to feed the cattle in autumn, when the grass is upon the decline, the cattle peeling off the bark. In Queen Elizabeth's time, the inhabitants of Colton and Hawkshead fells, remonstrated against the number of forges in the country, because they consumed all the loppings and croppings, which were the sole winter food for their cattle. In forests, the keepers browse the deer on summer evenings with the spray of Ash, that they may not stray too far from their walk. The leaves have been gathered to mix with tea; and poor people in some places have made a considerable advantage by collecting them for this purpose. Withering prescribes an infusion of the leaves made pretty strong, and taken to the quantity of an ounce and a half, as a good purge, and says that a decoction of two drachms of the bark, or six drachms of the leaves, has been used to cure agues. Vander Mye informs us, that the distilled water of the bark has been given in pestilential diseases with success. A decoction of the bark is very serviceable in the jaundice, dropsy, and other complaints of the liver and other viscera. It has likewise the credit of being singularly useful in the gravel and stone, and not without some degree of probability. A strong lye made from the ashes of the wood is an excellent lotion for scabby heads. If cows eat of the leaves or shoots, the butter made from their milk will be rank; which is always to be remarked in the butter made about Guildford and Godalming, and in some other parts of Surry, where there are Ash-trees growing about all their pastures; whereas in good dairy countries they never suffer an Ash-tree to grow. The truth of this is, however, disputed, and certain it is, that there is no taste in Ash-leaves to countenance the assertion; and it is said, on the contrary, that this is the next tree after the Elm, which the Romans recommended for fodder. Cream is apt to turn bitter at the fall of the leaf, and the reason is generally thought to be, that the cattle then pick up the decayed leaves, particularly the Ash; but the case is the same in the great low pastures, which are open and without trees, as in upland inclosures, which abound in them. The only way to avoid the ill taste in butter at that season, is

to churn oftener, and to use the butter whilst it is new. The Germans and Dutch call the Ash *esche* or *asche*; the Danes and Swedes, *aske*; the French, *le frêne*; the Italians, *frassino*; the Spaniards, *fresno*; the Portuguese, *freixo*; in Russia, *jas*, *jasen*, *jassen*, which name prevails in the dialects of the Sclavonian; the English is from the Saxon *æsc*. Ray says, it derives its name from the colour of the bark. We must be careful, however, not to confound, as some have done, this tree with the Mountain Ash, which is totally different from it. This has the epithet *excelsior*, from the loftiness of the trunk; that of *mountain*, from the loftiness of the situation which it delights in.—The varieties of this species are: 1. That with simple leaves, which, however, sometimes has them lobed and even ternate. 2. With pendulous branches, called the Weeping Ash. An uncommonly fine tree of this sort has been growing nearly forty years at Gamlingay in Cambridgeshire; and it is not uncommon in trees of considerable age, especially when growing by the water-side, to see the branches hang down. This variety is now become common in the nurseries, but they are engrafted, and carry too much the appearance of art; imitations are seldom successful, and none of the weeping Ash-trees will ever vie with the Babylonian Willow. 3. With variegated leaves, both yellow and white, or gold-striped and silver-striped, as the nursery-men call them. Micheli mentions some other varieties, but none of sufficient consequence to be enumerated here.—It is pleasant to observe, that amidst the deplorable destruction of valuable timber, the planting of this so extremely useful tree has lately not been neglected: twenty acres have been planted by William Wollaston, Esqr. at Great Finborough, Suffolk; thirty-five by Thomas White, Esqr. at Butsfield, Lanchester, Durham; sixteen acres by Mr. David Kay, at Frindsbury, Kent; 63,000 trees have been planted by Edward Loveden, Esqr. at Buscot, near Farringdon, Berks; 6000 by John Sneyd, Esqr. at Belmont, Staffordshire, between 1784 and 1786; 2000 by Dr. Richard Watson, bishop of Landaff, near Ambleside in Westmorland, in 1788; 42,000 by George Ross, Esqr. Cromarty; and 57,600 by the Earl of Fife, in the county of Murray. The facility with which the Ash is propagated, and adapts itself to any soil or situation, even the worst, the quickness of its growth, and the general demand for timber in every part of the country, for a variety of rural and economical purposes, recommend this tree very much to the planter. As a further encouragement, Mr. Boucher has given an instance of the great profit of an Ash plantation, in a small experiment, which he thus relates:—On half a rood of heavy meadow, chiefly barren red clay and moss, he planted Ash-trees six years old, and eight feet high, in rows four feet asunder, and two feet distance in the row; after four years he cut them down, within five or six inches of the ground; having more than he wanted, in seven years he sold half for pollards and hoops, for 40s. In six years he cut them again, and sold them for 50s; and at the end of six years more, at the same price. There remained then twenty trees intended to stand for timber, but he was obliged to sell them at twenty-three years' growth for 7s. a tree. Thus would an acre of indifferent ground, properly situated for sale, yield in twenty-three years £115. 10s. without any other expense than digging the ground, for the first five or six years, and cutting the coppice. Care should be taken to cut them slanting with a sharp instrument, leaving all the wounds smooth and clean. Observe, no price is mentioned for the first cutting, which he used himself; and that he found he should have had at least one-third more for the price of the last cutting; he also found that he had planted too thick, and that he should have had more wood if the rows had been

six feet asunder, and the sets three feet distant in the rows.—*Propagation and Culture.* The common Ash propagates itself plentifully by the seeds which scatter in the autumn, so that when they happen to fall in places where cattle do not come, there will be plenty of the plants come up in the spring. But where any person desires to raise a quantity of the trees, the seeds should be sown as soon as they are ripe, and then the plants will come up in the following spring: but if the seeds be not sown till spring, the plants will not appear till the year after; therefore the ground should be kept clean all the summer where they are sown, and not disturbed, lest the seeds should be turned out of the ground, or too deeply buried to grow; for many are too impatient to wait a year for the growth of seeds; so they dig up the ground, and thereby destroy the seeds. When the plants come up, they must be kept clean from weeds during the summer, and if they make good progress in the seed-bed, they will be fit to transplant by the autumn; on this account therefore there should be some ground prepared to receive them, and as soon as their leaves begin to fall they may be transplanted. In taking them up, they should be tenderly treated, in order not to break or tear off their roots: they should be taken up with a spade, and not drawn up, according to the general practice; for as many of the plants which rise from seeds outstrip the others in their growth, so it is frequently practised to draw up the larger plants, and leave the smaller to grow a year longer before they are transplanted; and to avoid injuring those that are left, the others are drawn out by hand, whereby many of their roots are torn or broken off; therefore it is much the better way to take all up, little or big, together, and transplant them out, placing the larger ones in rows together, and the smaller by themselves: the rows should be three feet asunder, and the plants a foot and a half distance in the rows; in this nursery they may remain two years, by which time they will be strong enough to plant where they are to remain, for the younger they are planted out, the larger they will grow, so that where they are designed to grow large, they should be planted out very young; and the ground where the plants are raised should not be better than that where they are designed to grow, for when they are raised in good land, and afterwards transplanted into worse, they very rarely thrive, so that it is much the best method to make the nursery upon a part of the same land where the trees are designed to be planted, and then a sufficient number of trees may be left standing upon the ground, and these will outstrip those which are removed, and will grow to a larger size. Those who live in the neighbourhood of Ash-trees may supply themselves with plenty of self-sown plants, provided cattle be not suffered to graze upon the land, for they will eat off the young plants, and not suffer them to grow; but where the seeds fall in hedges, or where they are protected by bushes, the plants will come up and thrive. To the above short and imperfect directions of Mr. Miller, it cannot be unacceptable to add the following from Evelyn, Dr. Hunter, and Mr. Boucher: If you would have a considerable wood of Ash at once, prepare your ground as you would for corn, and sow good store of keys, some crab-kernels, &c. with oats: take off your crop of corn in its season, and the year following the ground will be covered with young Ashes, which will either be fit to stand, or, as Mr. Evelyn preferred, to be transplanted for divers years after; and you will find these far better than any you can gather out of the woods, especially suckers which are worth nothing. The sooner they are removed the better: and Ashes of two years thus taken out of the nursery, will often outstrip those taken out of the hedge: you may keep the keys in sand for a winter before you sow them, in a covered airy place. Gather the

seeds or keys from healthy young thriving trees, in October or November; having prepared the beds, lower them about an inch, by raking some of the earth into the alleys; sow the seed moderately thick, and then throw the earth back again lightly with a spade, or sift it over them an inch thick, and rake it level. In spring, with a very small light iron rake, the teeth about an inch asunder, remove the moss, pull up the weeds, and sift a little earth over them again. The second spring, in the first open weather in February, rake off the earth as before very gently, sift fresh over them half an inch thick, and in March and April the young plants will appear in abundance: in October, sift some coal ashes half an inch thick over them. Next spring prepare some beds six feet wide, with a path of two feet between each; plant all of a size in each bed at one foot square, first shortening the tap-roots, and also the side ones. They must then be planted out into your nursery, in three rows three feet asunder, and each planted at one foot distance, where they are to remain till they are finally planted out. Mr. Boucher recommends the seeds being spread in an airy loft, and turned till dry, which will be in three or four weeks, and then mixed with sand, to be sown the beginning of April, on fresh mellow soil, on beds three and a half feet broad, with alleys eighteen inches, and covered three quarters of an inch deep. The seeds will not appear till the succeeding spring; during this time the beds must be kept clean, and in February they must be raked over; if a little rich mould be thrown upon them, it will much promote the growth of the seedlings. In the following February or March remove them, and plant them in drills eighteen or twenty inches asunder, and eight or nine inches in the drill. In October remove them again, planting them in lines three and a half feet asunder, and fifteen or sixteen inches in the line, where they may remain for three years. The trees will now be seven or eight feet high, of a proper size for extensive plantations; where large ones are wanted, remove them every fourth year. Stocks for budding should be planted out in the nursery, a foot asunder, and two feet distant in the rows; when they are one year old, and about the thickness of a bean straw, they will be of a proper size for working: a little after Midsummer is the time for the operation, and care must be taken not to bind the eye too tight; they need not be unloosed before the end of September. In March the head of the stock should be taken off a little above the eye, and by the end of the summer following, if the land be good, they will have made strong shoots: the variegated sorts can be increased only in this manner.

2. *Fraxinus Rotundifolia; Manna Ash Tree.* Leaflets roundish, acutish, doubly serrate, subsessile; flowers with petals. The shoots of the Manna Ash are much shorter, and the joints closer together, than those of the common Ash; the leaflets are shorter, with deeper serratures on their edges, and of a lighter green; the flowers come out from the sides of the branches, are of a purple colour, and appear in the spring before the leaves come out. This tree is of humble growth, seldom rising higher than fifteen or sixteen feet in England. The lower parts of the mountains in Calabria abound with the Manna Ash, which grows spontaneously and without any culture, except that the woodmen cut down all the strong stems that grow above the thickness of a man's leg. Towards the end of July, the gatherers of manna make an horizontal gash, inclining upward, in the bole of the tree: as the liquor never oozes out the first day, another cut is given on the second, and then the woodman fixes the stalk of a Maple leaf in the upper wound, and the end of the leaf in the lower one, so as to form a cap to receive the gum a

FRITILLARIA — The Yellow Crown Imperial

P. 574.

FRAGARIA — The Chili Strawberry.

it distils from each gash; the season continues about a month, and the men have only about three earlines, or thirteen pence halfpenny, for every rotolo, which is equal to thirty-three ounces and a third, and is sold for twenty-four earlines and three quarters, or somewhat more than ten shillings; if it be in tubular pieces, the price rises one-third, these pieces are called *manna in cannohi*; and these regular tubes are produced by applying to the incision thin straw, or small bits of shrubs, upon which the manna runs as it oozes out.—Manna is one of the mildest and safest purgatives known, excellently adapted for young children, and weak constitutions; it sheathes sharp acrimonious humours, and is good in disorders of the breast attended with fever and inflammation, as well as in the pleurisy, hooping-cough, gravel, and bilious complaints. It is apt to gripe the patient during the operation, but that inconvenience is easily removed, by adding a small quantity of some warm carminative substance to the dose.—These trees succeed best when planted in an eastern exposure, in order to warm the juices in the morning, and to inspissate those which the heat has sweated out in the evening. This, and the remaining plants of the genus, are commonly propagated in the nurseries by budding or ingrafting upon the common Ash, but are not so valuable as those which are raised from seeds, because the stock grows much faster than the grafts; so that the lower part of the trunk, so far as the stock rises, will often be twice the size of the upper; and if the trees stand much exposed to the wind, the grafts are frequently broken off from the stock after they are grown to a large size.

3. *Fraxinus Ornus*; *Flowering Ash Tree*. Leaflets ovate-oblong, serrate, petioled; flowers with petals. Miller makes two species out of this. The first is a low tree, about the same height as the preceding; the leaves are much smaller and narrower than those of the common Ash, but are serrate, and of the same dark colour; the flowers have petals. The second, has only or chiefly male flowers; the leaves have but three or four pairs of leaflets, which are short, broad, smooth, of a lucid green, and irregularly serrate; the midrib is jointed, and swells where the leaflets come out; the flowers grow in loose panicles at the ends of the branches, are of a white herbaceous colour, and appear in May.—This species is generally planted for ornament, the flowers making a fine appearance when they are in beauty, for almost every branch is terminated by a large loose panicle, so that when the trees are large, and covered with flowers, they are distinguishable at a great distance.

4. *Fraxinus Americana*; *American Ash Tree*. Leaflets quite entire; petioles cylindric; the fruits or keys are the same as in the common Ash, but smaller and narrow.—It was first raised from seeds imported from New England.

French Honeysuckle. See *Hedysarum Coronarium*.

French Marigold. See *Tagetes*.

Freshwater Soldier. See *Stratiotes*.

Friar's Cowl. See *Arum Arisarum*.

Fringe Tree. See *Chionanthus*.

Fritillaria; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: six-petalled, bell-shaped, spreading at the base; petals oblong, parallel; nectary an excavation or pit in the base of each petal. *Stamina*: filamenta subulate, approximating to the style, the length of the corolla; antheræ quadrangular, oblong, erect. *Pistil*: germen oblong, three-cornered, obtuse; style simple, longer than the stamina; stigma triple, spreading, blunt. *Pericarp*: capsule oblong, obtuse, three-lobed, three-celled, three-valved. *Seeds*: very many, flat, semiorbicular on the outside, in a double row. ESSENTIAL

CHARACTER. *Corolla*: six-petalled, bell-shaped, with a nectarous cavity above the claws; stamina the length of the corolla.—The species are,

1. *Fritillaria Imperialis*; *Imperial Fritillary*, or *Crown Imperial*. Flowers in a raceme with a coma over them, but naked below; leaves quite entire. It has a large round scaly root of a yellow colour, and a strong odour of a fox; the stalk rises to the height of four feet or upwards, it is strong, succulent, and garnished two-thirds of the length on every side with long narrow leaves ending in points, which are smooth and entire; the upper part of the stalk is naked a foot in length, then the flowers come out all round the stalk upon short footstalks, which turn downward, each sustaining one large flower: above these rises a spreading tuft of green leaves, which are erect, and called the coma. This plant flowers in the beginning of April, and the seeds ripen in July. The principal varieties are: 1. the common crown imperial, of a dirty red colour; 2. yellow crown imperial, of a bright yellow; 3. bright red crown imperial, called *fusai*; 4. the pale yellow crown imperial; 5. the yellow striped crown imperial; 6. the large flowering crown imperial; 7. the broad-leaved late red crown imperial; 8. the double and triple-crowned imperial crown; 9. the double red crown imperial; 10. the double yellow crown imperial; 11. the silver-striped-leaved crown imperial; 12. the yellow striped-leaved crown imperial. The variety with yellow flowers, that with large flowers, and those with double flowers, are the most valuable: but that which has two or three whorls of flowers above each other makes the finest appearance; though it seldom produces its flowers in that form until the second or third year after its removal, the stalks will be taller, and frequently have three tiers of flowers one above another, which is called the triple crown: the stalks of this sort frequently run flat and broad, when they produce a greater number of flowers than usual; but this is only a luxuriance of nature, not constant, though many of the writers have mentioned it as a particular variety.—As this is one of the earliest tall flowers of the spring, it makes a fine appearance in the middle of large borders, at a season when such flowers are much wanted to decorate the pleasure-garden; but the rank fox-like odour which they emit is too strong for most people, and greatly decreases them in value. The beauty, however, of the plant, and the splendour of the magnificent pendulous flowers, will ever ensure it a place in large gardens and plantations. The singular nectary cannot fail to arrest the attention of a curious observer; it is a white glandular cavity at the base of each petal, and has a drop of limpid nectarous juice standing in it when the flower is in vigour. Another of the wonders of nature may be observed in the peduncles, which bend down while the plant is in flower, but become upright as the seeds ripen. This circumstance, however, is by no means peculiar to this plant, but common to it with many others. The Crown Imperial has the same name in all the European languages: the Germans call it *kaiserkrone*; the Danes, *keiserkrone*; the Swedes, *keisarkrona*; the French, *la couronne imperial*, or *la fritillaire imperial*; the Italians, *la corona imperiales*; and the Spaniards, *la corona imperial*.—*Propagation and Culture*. This species may be propagated by seeds, or offsets from the root; the first is too tedious a process for most English florists, because the plants so raised are six or seven years before they flower; but the Dutch and Flemish gardeners, who have more patience, frequently raise them from seeds, and so obtain some new varieties, which amply repay them for their labour. The method of propagating these flowers from seeds being nearly the same as for the Tulip, the reader is requested

to turn to the article *Tulipa*, where there are full directions for performing it. The common method of propagating them here, is by offsets sent out from the old roots, which will flower strong the second year after they are taken from the roots; but in order to have plenty of these, the roots should not be transplanted oftener than every third year, by which time each root will have put out several offsets, some of which will be large enough to flower the following year, so may be planted in the borders of the flower-garden, where they are to remain, and the smaller roots may be placed in a nursery bed, to grow a year or two, according to their size; therefore they should be sorted, and the smallest roots planted in a bed together, which should remain there two years, and the larger by themselves to stand one year, by which time they will have acquired strength enough to flower, so that they may then be removed into the pleasure-garden. The time for taking up these roots, is in the beginning of July, when their stalks will be decayed, and they may be kept out of the ground two months; but they should be laid singly in a dry shady room, but not in heaps or in a moist place, which will cause them to moulder and rot. The offsets should be first planted, for as they are small, they will be apt to shrink when kept long out of the ground. As the roots of these plants are large, they must not be planted too near other flowers; and when they are planted in beds by themselves, they should not be nearer than a foot and a half in the rows, and two feet row from row; they should be planted six inches deep at least, especially the strong roots; they delight in a light soil, not too wet, nor loaded with dung, for if any dung be laid upon the borders where they are planted, it should be buried pretty deep, so as to be two or three inches below the roots.

2. *Fritillaria Persica*; *Persian Fritillary*, or *Persian Lily*. Raceme almost naked; leaves oblique. It has a large round root; stem three feet high, the lower part closely garnished on every side with leaves, which are three inches long, and half an inch broad, of a gray colour, and twisted obliquely; flowers in a loose spike at the top, forming a pyramid; they are shorter than the other sorts, spread wider at the brim, and are not bent down; they are of a dark purple colour, and appear in May, but seldom ripen their seeds in England. Bauhin says, the root is about the size of an orange, of a taste extremely bitter, but without any remarkable smell. There is a variety called the Small Persian Lily, which Mr. Miller describes as a distinct species, has a much shorter stem and smaller leaves; the stem branches out at the top into several small peduncles, each sustaining one dark-coloured flower.—The plants of this, and the second, third, fourth, and fifth species, are propagated either by seeds or offsets from the old roots. By the first method new varieties will be obtained, together with a stock of roots, which will accumulate more in three years, than those obtained by the latter method would in twenty or thirty years; we shall therefore first treat of their propagation by seed: Having saved some good seed from the fairest flowers, procure some shallow pans or boxes, which must have some holes in their bottoms to let out the moisture; fill these with light fresh earth, laying a few potsherds over the holes, to prevent the earth from stopping them; then, having laid the earth very level in the boxes, &c. sow the seeds pretty thick upon it, and cover them with fine sifted earth about a quarter of an inch thick: the time for this is the beginning of August, for if the seed be kept much longer out of the ground, it will not grow; then place the boxes or pans where they may have the morning sun until eleven o'clock, observing, if the season prove dry, to water them gently, and to pull up all the weeds as soon

as they appear, for if they be suffered to remain until they have taken deep root in the earth, they would draw up the seeds also out of the ground whenever they are pulled up. Towards the latter end of September you should remove the boxes, &c. into a warmer situation, placing them close to a hedge or wall exposed to the south; if they are sown in pots, these should be plunged into the ground, but they are best in tubs; these should be covered in severe frost. In this situation they may remain until the middle of March, by which time the plants will come up an inch high; you must therefore remove the boxes as the weather becomes hot, into a more shady situation, for while the plants are young, they are liable to suffer by being too much exposed to the sun, and in this shady situation they may remain during the heat of summer, observing to keep them clear from weeds, and to refresh them now and then with a little moisture, but be careful not to give them much water after their leaves are decayed, which rots their roots. About the beginning of August, if the roots be very thick in the boxes, you should prepare a bed of good light fresh earth, which must be levelled very even, upon which you should spread the earth in the boxes in which the small roots are contained, equally covering it about one-fourth of an inch thick with the same fresh earth; this bed should be situated in a warm position, but not too close to hedges, walls, or pales, which would cause their leaves to be long and slender, and make the roots weaker than if placed in a more open exposure. In this bed they may remain until they flower, which is generally the third year from sowing, at which time you should put down a mark to the roots of all such as produce fair flowers, that at the time of taking them out of the ground, which ought to be soon after their green leaves are decayed, they may be placed in a bed amongst the old roots of this flower, which for their beauty are preserved in the best gardens: but the other less valuable flowers may be planted in the borders of the parterre-garden for their variety, where, being intermixed with other flowers of different seasons, they will make a good appearance. The fine sorts of these flowers should remain undisturbed three years, by which time they will have produced many offsets, and should be taken up when their leaves are decayed, and planted into a fresh bed, taking such of their offsets as are large enough to produce flowers, to plant in the flower-garden; but the smaller roots may be planted into a nursery bed until they have obtained strength enough to flower; but you must never suffer these roots to lie out of the ground when you remove them, but plant them again immediately, otherwise they will perish. During these three years which the roots are to remain in the beds, the surface of the earth should be stirred every autumn with a trowel, observing not to go so deep as to bruise the root, and at the same time lay a thin cover of very rotten dung or tanners' bark upon the surface of the beds, which being washed into the ground, will cause the flowers to be larger, as also the roots to make a greater increase: observe also to keep them constantly clear from weeds, and those roots which you preserve with care, should not be suffered to seed. When a stock of good flowers are obtained, they may be preserved and increased in the same manner as other bulbous-rooted flowers, which is by offsets sent out from their roots, which should be taken off every other year from the finest sorts; but the ordinary flowers may remain three years undisturbed, in which time they will have multiplied so much, as that each root will have formed a cluster, so that if they be left longer together, the roots will be small, and the flowers very weak; therefore, if these are taken up every other year, the roots will be the stronger. These roots may

be treated in the same manner as Tulips, and other bulbous-rooted flowers, with this difference only, that the roots will not bear to be kept out of the ground so long; therefore, if there should be a necessity for keeping them out of the ground any time, it will be best to put the roots into sand to prevent their shrinking. As these flowers come out early in the spring, they make a handsome appearance in the borders of the pleasure-garden, where they are planted in small clumps; for when they stand singly in the borders, they make but a poor figure.

3. *Fritillaria Pyrenaica*; *Black Fritillary*. Lowest leaves opposite, some of the flowers having a leaf interposed between. The leaves of this species are broader, and of a deeper green, than the common Fritillary; the lower ones opposite, but those above alternate; the stem is a foot and a half high, terminated by two flowers of an obscure yellow colour, and spreading more at the brim than those of the common Fritillary, but turned downwards in the same manner.—It flowers three weeks after the common sort, and is a native of France and Russia. For its propagation and culture, see the preceding species.

4. *Fritillaria Meleagris*; *Common Fritillary*, or *Chequered Lily*. All the leaves alternate; stem one-flowered; root a solid bulb or tuber, about the size of a hazel-nut, white, or yellowish-white, roundish, compressed, divisible into several, enclosed by the withered wrinkled bulb of the preceding year, as in a case; stem from six to twelve, fifteen, and even eighteen inches in height; flower usually single, sometimes two, or even three, on the top of the stem, large, pendulous, at first somewhat pyramidal, but afterwards bell-shaped; petals chequered with purple and white, or purple and greenish yellow; in our wild ones the colour is a dull red chequered with a deeper, but without mixture of either green or yellow. It flowers in April and May, and, if the season be mild, at the beginning of the former month, or even the end of March. Many varieties have been sent from Spain, Portugal, and Italy, and many others have been raised from seed by the florists, which differ in the size and colour of their flowers; these amount to a considerable number in the catalogues of the Dutch florists; but as new varieties may be continually produced, and these flowers are no longer in such esteem as they formerly were, it would be useless to enumerate them. Gerarde calls it the *Turkey-hen*, or *Guinea-hen flower*, and *Chequered Daffodil*. The curious and indefatigable Parisian herbalist, John Robin, sent him many plants for his garden, where they prospered, as he informs us, and were then greatly esteemed for ornamenting the English flower-gardens, and the bosoms of the ladies. The Germans call this flower *kiebitzey*; the Dutch, *kievitsbloem*; the Danes, *vibeæg*; the Swedes, *vipaugg*; the French, *la fritillaire, meleagre*, or *panachee, le damier*; the Italians, *fritillaria, giglio variegato, meleagride, fritillaria scaccheggiata*; and the Spaniards, *la fritillaria, el meleagro*. For its propagation and culture, see the preceding species.

5. *Fritillaria Cantoniensis*. Leaves three-nerved, the upper ones opposite; flowers in pairs, axillary; stem annual, quite simple, hard, slender, round, upright, a foot and a half high; flowers pendulous, the whole dusky purple, and without smell.—Native of Canton in China.

Frog-bit. See *Hydrocharis*.

Fuchsia; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, funnel-form, coloured, superior, deciduous; tube ovate at the base, contracted above it, then gradually widening, patulous, angular; border short, four-parted; parts ovate, acuminate, spreading. *Corolla*: petals four, ovate, acuminate,

sessile, spreading; the same length with the parts of the calix. *Stamina*: filamenta four (or eight) filiform, erect, inserted into the tube of the calix below the middle, and a little longer than the tube; antheræ twin. *Pistil*: germen inferior, ovate, below the insertion of the calix constricted; style simple, the length of the stamina; stigma obtuse. *Pericarp*: berry ovate, four-grooved, four-celled. *Seeds*: many, ovate, fixed in a double row to a columnar receptacle in the middle of the berry. ESSENTIAL CHARACTER. *Calix*: one-leafed, coloured, bearing the corolla, very large. *Petals*: four, small. *Berry*: inferior, four-celled, with many seeds.—The species are,

1. *Fuchsia Triphylla*; *Three-leaved Fuchsia*. Peduncles one-flowered; leaves by threes, lanceolate, entire, pale green, a little firm or coriaceous, sessile. Root woody, branched, reddish; stem herbaceous, upright, quite simple, reddish-green, leafy, two feet high at most; flowers large, very fine, of a very bright scarlet, having eight stamina, not projecting beyond the flower; and the berry is a little larger than an olive, fleshy, soft, reddish-black, somewhat pubescent, of a very pleasant taste; the seeds are small and brown.—Found at St. Domingo, and at Carthagen in New Spain. It is propagated by seeds, which must be sown in pots filled with rich light earth, and plunged into a hot-bed of tanners' bark, where they are to be treated like other seeds from warm countries. In a month or six weeks the plants will begin to appear, when they should be carefully cleared from weeds, and frequently refreshed with water to promote their growth; and when they are about two inches high, they should be taken out of the pot, and separated carefully; then plant each into a small pot filled with light rich earth, and plunge them again into a hot-bed of tanners' bark, being careful to screen them from the sun until they have taken new root; after which they must have fresh air admitted to them every day, in proportion to the warmth of the season, and should be frequently watered. As the season advances and becomes warm, the glasses of the hot-bed should be raised higher, to admit a greater share of air to the plants, which will prevent them from being drawn up weak; and when they are grown so tall as to reach the glasses, they should be removed into the bark-stove, and plunged into the tan-bed. They are too tender to thrive in the open air of this country, even in the hottest part of the year; they should always, therefore, remain in the stove, observing to admit a large share of fresh air in summer, but to exclude the external air in winter; with this management, they will produce their flowers, and make a beautiful appearance in the stove among other tender exotic plants.

2. *Fuchsia Coccinea*; *Scarlet-flowered Fuchsia*. Leaves opposite, ovate, toothletted; petals obovate, obtuse. This is a shrub, growing to the height of six or seven feet. The leaves are commonly opposite, on short petioles, of a fine green, having the veins tinged with red, with a fine down on them; peduncles axillary, one-flowered, longer than the leaves; flowers pendulous, bright scarlet, with a four-parted calix, four petals, and eight stamina. This is a plant of peculiar beauty, producing its rich pendant blossoms through most part of the summer; the petals in the centre of the flower are particularly deserving of notice; they somewhat resemble a small roll of the richest purple-coloured riband.—It flowers from May to July, and is a native of Chili. It may be propagated in the same way as the first species. Though it will not succeed well in the winter, nor be easily propagated unless in a stove, yet it will flower very well during the summer months in a good green-house or hot-bed frame. It is easily increased by layers and cuttings, as well as seeds. For further particulars, see the first species.

3. *Fuchsia Multiflora*. Peduncles many-flowered.—Found in South America by Mutis. For its propagation and culture, see the first species.

4. *Fuchsia Excorticata*. Peduncles axillary, one-flowered; leaves ovate, alternate. This is a very smooth tree. Leaves on long petioles, hoary underneath, very finely serrate; flowers pendulous, very large.—Native of New Zealand. For its propagation and culture, see the first species.

5. *Fuchsia Involucrata*. Flowers involucre.—Native of Jamaica. For its propagation, &c. see the first species.

6. *Fuchsia Rosea*. Flower-stalks axillary, single-flowered; leaves fasciculate, unequal and alternate, lanceolate, entire; flowers drooping, with rose-coloured petals and calix.—Found in precipices at Valparaiso, in Chili.

Fucus; a genus of the class Cryptogamia, order Algæ.—GENERIC CHARACTER. *Male Vesicles*: smooth, hollow, with villose hairs within, interwoven. *Female Vesicles*: smooth, filled with jelly, sprinkled with immersed grains, prominent at the tip. *Seed*: produced in clustered tubercles, which burst at their summits. This genus comprehends most of those plants which are commonly called *Sea-Weeds*. Fifty-eight species are enumerated in the *Systema Vegetabilium*, and sixty-eight British species in Dr. Withering's *Botanical Arrangements*. Turton gives a catalogue of 149 species. They may be all used to manure land; or they may be burned to make kelp, which is an impure fossil alkali. Many of them form very beautiful specimens for the *Herbarium*, and are often seen disposed on paper, so as to form a sort of picture. Some of the species are eaten, either fresh out of the sea, or boiled tender, with butter, pepper, and vinegar. If the *Fucus Saccharinus* be washed in spring water, and then hung up in a warm place, a substance like sugar exudes from it. The *Fucus Palmatus* is called by the Irish *dullesh*; by the Scotch, *dills*; and in Northumberland, *dulls* or *dulse*. Being soaked in fresh water, it is eaten either boiled or dried, and in the latter state has something of a violet flavour. It is sold dried in the streets of Dublin, being said to sweeten the breath, and to kill worms. The poor in the north of Ireland eat it boiled. For the fructification, and mode of propagation, of these and other marine plants, the reader is referred to Reaumur, in *Act. Gall.* 1711; Gmelin, *Hist. Fucorum*; and Gærtner, *De Fructibus et Seminibus*.

Fuirena; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: ament oblong, cylindrical, imbricate; scales channelled, wedge-shaped, three-keeled, awned at the tip; awn cylindrical, straight, shorter than the glume; flowers between the scales, solitary, very small, sitting on a tubercle; glume, besides the amentaceous scales, none. *Corolla*: glume three-valved; valves petal-shaped, obcordate, somewhat membranaceous, flat, quite entire, ending in an awn that is bent in. *Stamina*: filamenta three, linear, inserted into the receptacle between the corolline valves; antheræ linear, erect. *Pistil*: germen large, three-cornered; style filiform; stigmas two, revolute. *Pericarp*: none, except the withered corolla, enclosing the seed. *Seed*: three-cornered, naked, without any villose hairs. ESSENTIAL CHARACTER. Ament imbricate, with awned scales. *Calix*: none. *Corolla*: with three petal-shaped obcordate glumes, ending in a tendril. The only known species is,

1. *Fuirena Paniculata*. This is a lofty grass. Leaves on the stem, with loose, pitcher-shaped, hairy sheaths; panicles terminating and axillary, composed of cylindrical scabrous spikelets; these are oblong, about three lines in length, conglomerate, blackish, imbricate with obovate, concave, rigid

scales, having three keels uniting at top into an awn.—Native of Surinam and Jamaica.

Fumaria; a genus of the class Diadelphia, order Hexandria.—GENERIC CHARACTER. *Calix*: perianth two-leaved; leaflets opposite, equal, lateral, erect, acute, small, deciduous. *Corolla*: oblong, tubular, ringent; palate prominent, closing the throat; upper lip flat, obtuse, emarginate, reflex. *The Banner*: nectary, the base of the upper lip prominent backward, obtuse; lower lip entirely similar to the upper, keeled towards the base. *The Keel*: nectary, the keeled base, but in this less prominent; throat four-cornered, obtuse, perpendicularly bifid. *The Wings*. *Stamina*: filamenta two, equal, broad, one within each lip enclosed, acuminate; anthers three at the end of each filamenta. *Pistil*: germen oblong, compressed, acuminate; style short; stigma orbiculate, erect, compressed. *Pericarp*: silicle one-celled. *Seeds*: roundish. *Observe*. The stamina are almost the only part of the fructification observed to be constant in this genus. ESSENTIAL CHARACTER. *Calix*: two-leaved. *Corolla*: ringent; filamenta two, membranaceous, with three anthers on each.—The species are,

* *Corollas with two Spurs*.

1. *Fumaria Cucullaria*; *Naked-stalked Fumitory*. Scape naked. Root scaly, the size of a large hazel-nut; flower-stalk eight or nine inches high; root-leaves in pairs, triternate, gashed, smooth, and slender, with red petioles; raceme terminating, simple, the flowers four or five, pendulous; pedicels one-flowered, with a pair of bractes to each, opposite, ovate, red, small; calix ovate, pressed close, small, white; corolla white; border yellow, two-lipped; lips equal, concave, reflex, ovate, entire; throat closed, yellow, the sides widened at the edge, and moistened with nectareous juice. Perennial. It flowers in June and July, and is a native of Virginia and Canada.—It is propagated by offsets from the roots, and loves a shady situation and a light soil. The best time to transplant it is in autumn, when the leaves are decayed, for it shoots pretty early in the spring, so that it would not be safe to remove them at that season.

2. *Fumaria Spectabilis*. Flowers two-lobed behind; stem leafy, erect. This is a fine plant, with very large handsome flowers. The branches proceed from the axils of the leaves, and are but few. The raceme has no bractes. The corolla is the size of the last joint of the thumb, divided at the back of it into two equal rounded lobes.—Native of Siberia.

3. *Fumaria Fungosa*; *Spongy-flowered Fumitory*. Flowers bigibbous at the base; siliques linear, ancipital, covered by an inflated fungous corolla; leaves climbing. Annual: flowering from June to September.—Native of North America.

** *Corollas with one Spur*.

4. *Fumaria Nobilis*; *Great-flowered Fumitory*. Stems simple; bractes shorter than the flower, undivided; root-leaves seven to nine, a span in length, bipinnate; scapes one or two, oblique, five-cornered; raceme very blunt; the flowers directed one way; bractes ovate-lanceolate, entire. Flowers double the size of the fifth species, white, with a yellow border, smelling like Cowslips.—It flowers in May, and is a native of Siberia. Both this and the next species are propagated by offsets, as other bulbous-rooted flowers; they are very pretty ornaments to borders in a small garden. They are extremely hardy, but do not increase very fast, seldom producing seeds with us; and their bulbs do not multiply very much, especially if they are often transplanted. They love a light sandy soil, and should be suffered to remain three years undisturbed, in which time they will produce several offsets. The best season for transplanting them is from May till August, when the leaves begin to die off.

Common Fumitory.

P. 588.

GALEGA OFFICINALIS — *Goat's Rue.*

5. *Fumaria Bulbosa*; *Bulbous Fumitory*. Stem simple; bracts the length of the flowers. There are three varieties of this species, which are specifically united by a fleshy, simple root. Linneus informs us, that they are all natives of different provinces of Sweden: the first, in Scania, both with a red and a white flower; the second, in most of the woods of Up-land; and the third, on the coast of Roslag and Finland. As this species is found in most parts of Europe, from Sweden to Italy, Linneus remarks, as a singularity, that it does not grow wild in England. Mr. Miller, however, says, that the Solid-rooted *Bulbous Fumitory* is common in many of our old gardens; but that the hollow-rooted one is now rarely to be found in them. See the preceding species.

6. *Fumaria Sempervirens*; *Glaucous Fumitory*. Siliques linear, panicle; stem erect, a foot and a half high, round, and very smooth, sending out several branches at top; leaves smooth, branching, pale, divided like the common sort, but the leaflets larger, and more obtuse; flowers in loose panicles from the sides of the stem, and at the extremities of the branches, of a pale purple colour, with yellow chaps or lips. Annual. It flowers during summer; pods taper, narrow, an inch and a half long, containing many small, black, shining seeds. Native of North America.—This, with the seventh, eighth, ninth, tenth, twelfth, thirteenth, and fourteenth species, will come up without any trouble, if the seeds be permitted to scatter; and require no other care but to thin them where they are too close, and to keep them clean from weeds. These thrive best on old walls and buildings, and on rocks.

7. *Fumaria Lutea*; *Yellow Fumitory*. Siliques cylindrical; stems diffusèd; angles obtuse. The root strikes deep into the ground; stems many, succulent, diffusèd, about six inches high; leaves on long branching petioles, composed of many irregular leaflets, trifid at the top; peduncles axillary, naked, longer than the leaves, supporting eight or nine flowers, of a bright yellow colour, in a loose spike. The leaves continue green all the year, and the flowers in succession, from April to October; so that this plant well deserves admission into every garden. It is peculiarly proper for rock-work, old walls, and buildings, in which the seeds often lodge of themselves, being thrown to a considerable distance by the elasticity of the pods.—Native of Barbary.

8. *Fumaria Sibirica*; *Siberian Fumitory*. Siliques oval; stems patulous; leaflets oblong; leaves alternate, superdecompound, with oblong leaflets; flowers yellow; pods oval, compressed, smooth, elastic. Annual, and a native of Siberia. See the sixth species.

9. *Fumaria Capnoides*; *White-flowered Fumitory*. Siliques linear, four-cornered; stems diffusèd, acute-angled; leaves superdecompound; the terminating leaflets larger, and semi-trifid; the middle segment lobed; petioles three-cornered; racemes naked; pedicels shorter by half than the corollas, blackish at the tip; corollas whitish, with the wings yellow at the tip, and drawn to a point. There is a succession of flowers from May till October; and this, like the seventh species, is proper for walls, old buildings, and rock-work.—Native of the south of Europe.

10. *Fumaria Enneaphylla*. Leaves triternate; leaflets cordate. This has weak trailing stems, which are much divided; and leaflets divided into three parts, each of which has three heart-shaped lobes; the flowers are produced in small loose panicles from the sides of the stalks; they are of a greenish white, and appear during most of the summer months.—Native of Spain and Italy, upon old walls and rocky places.

11. *Fumaria Officinalis*; *Common Fumitory*. Pericarps one-seeded, racemèd; stem diffusèd; root annual; leaves

alternate, petioled, glaucous, smooth, somewhat fleshy, superdecompound, the last divisions bifid or trifid, the extreme segments lanceolate; flowers alternate, in very long spikes, on very short pedicels, under each of which is a lanceolate membranaceous bracte, purple at top. The calix has little teeth about the edges; corolla reddish, tipped with deep purple, sometimes pale purple or white. It is a common weed in corn-fields, gardens, and on ditch-banks, flowering from April to August, and even later.—Cows and sheep eat it, and the latter are supposed to derive considerable benefit from it. The leaves are succulent, saline, and bitter. The expressed juice, in doses of two or three ounces, with whey, is useful in hypochondriacal, scorbutic, and cachectic habits. It corrects acidity, and strengthens the tone of the stomach. Hoffman preferred it before all other medicines, as a purifier of the blood. There is no doubt of its utility in obstructions of the viscera, and the diseases arising from them. The celebrated Boerhaave frequently prescribed it in the black jaundice and bilious colics. Some people smoke the dried leaves in the manner of tobacco, for disorders of the head; and frequently find relief. Dr. Cullen has experienced its good effects in many cutaneous disorders: and there is a disorder of the skin, which, though not attended with any alarming symptoms of danger to the life of the patient, is thought to place the empire of beauty in great jeopardy; the complaint is frequently brought on by neglecting to use a parasol, and may be known by sandy spots, vulgarly called *freckles*, scattered over various parts of the face. Now, be it known to all whom it may concern, that the infusion of the leaves of the above-described plant, is said to be an excellent specific for removing these freckles, and clearing the skin.

12. *Fumaria Capreolata*; *Ramping Fumitory*. Pericarps one-seeded, racemèd; leaves climbing, subcirrhose. This seems to be a mere variety of the preceding species. Mr. Hudson could perceive no difference, except in the colour of the flowers, which in this is white, with a purple tip. It climbs, not by tendrils, but by the bending or twisting of the petioles; but Louis Gerarde attributes this wholly to its situation in hedges, or among bushes. Dr. Stokes, however, has observed the stem sometimes trailing, and interweaving its branches among the grass, very much branched, sometimes three feet long; the blossoms pale red. The stems are longer and weaker; the leaves more distant, and not so finely divided; the extreme divisions broader and blunter than the foregoing; the spikes of flowers are on longer peduncles, but with fewer flowers on a spike. It must, however, in candour be confessed, that all these differences may be owing to situation.—Native of Provence, Silesia, and Britain.

13. *Fumaria Spicata*; *Narrow-leaved Fumitory*. Pericarps one-seeded, spiked; stem erect; leaflets filiform. Annual. The stalks more erect than in the common sort; the leaves are very finely divided, and the flowers grow in a loose spike; they are of a deep red colour, and appear about the same time. The flowers grow very close together in the spike; and the leaves are glaucous, and smaller than those in the other species, like Camomile. Both stem and leaves are covered with a glaucous bloom. There is little or no bitterness in the leaves.—It flowers with us in July and August, and is a native of Spain, Portugal, Italy, and the south of France.

14. *Fumaria Claviculata*; *Climbing Fumitory*. Siliques linear; leaves tendril-bearing. Root annual; stems three-cornered, slender, and unable to support themselves, purplish at the base; flowers few, (about five in number, seldom more than two coming to perfection,) in short terminating spikes; corolla pale, greenish-white, or straw-coloured; seeds generally three, in oblong pointed smooth pods.—Native of

Denmark and Britain, in woods and moist hedges, boggy and rocky places in a sandy soil, on the banks of lakes and rivers, and on the thatch of cottages. It is found on Blackheath, and about Charlton and Greenwich; at Snaresbrook near Woodford, in Essex; on the banks of the Trent near Ouseley, in Staffordshire; in the hedges between Bala in Merionethshire and Pimble-meer; above great Malvern tower; about Birmingham; on the rocks of Stonehall near Rawdon, seven miles from Leeds; at Thorpe near Norwich; at Kendal in Westmoreland; near Whitwick in Leicestershire; and in the quarries at Innerkeith in Scotland. It flowers from the end of May to the end of July.

15. *Fumaria Vesicaria*; *Bladdered Fumitory*. Siliques globular, acute, inflated; leaves cirrhose; pericarp double, composed of the third or outer involucre, arising from the germen itself, and of the capsule within the involucre; involucre large, somewhat leathery, inflated, globular, acuminate at the end, two-valved; the valves cohering with the capsules by means of a thready cellular substance; capsule placed in the axis of the involucre, oblong, acuminate to both ends, a little flattened, membranaceous in the middle, very thin, diaphanous, but at each side thickened, suberous, opaque, one-celled, valvless, bursting irregularly by the involucre when it opens; seeds numerous, rounded, kidney-form, towards the navel slightly flattened, dark-coloured, very smooth, and shining, fixed to the thickened edges of the capsule. The flowers are in loose panicles, from the sides of the stalks, of a whitish yellow colour. It flowers in July. Native of the Cape of Good Hope.—This is propagated by seeds, which should be sown upon a moderate hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a small pot filled with light earth, and plunged again into the hot-bed, where they must be shaded from the sun till they have taken new root; after which, they should have a large share of air admitted to them at all times in mild weather, to prevent their drawing up weak; and, as soon as the season is favourable, they should be inured to bear the open air, to which they may be removed in the beginning of June. At that time they may be taken out of the pots, preserving all the earth to their roots, and planting them in a warm border, where their stalks should be supported with sticks, to prevent their trailing on the ground; and in July the plants will flower, and continue a succession of flowers till the frost destroys the plants. The seeds ripen in autumn.

Fumitory. See *Fumaria*.

Fumitory, Bulbous. See *Adoxa*.

Funaria; a genus of Moss, the same with the *Koeltreutera* of Hedwig; founded by him on the *Mnium Hygrometricum* of Linneus and others. It has an angular veil, a double fringe with oblique or twisted teeth, and a very slightly prominent lid.

Fungi or *Fungus*, (from *σπογγος*, on account of its spongy nature,) Mushrooms: Cryptogamia Fungi, the last order in the last class in the Linnean System, and kept together as one class under every arrangement. Hitherto we know so little about the fructification of Funguses, that we are obliged to take the characters from the general external form. It is evident that they are vegetables, and produce seed, by which they have been propagated; and they seem to belong to the class Monœcia. Hedwig has made some important discoveries respecting the fructification of Funguses, by the use of powerful magnifiers. He thinks he has discovered stamina in the threads, which appear on the edge of the capor pileus, on the membrane or valve, or on the stem itself. The seeds

are a dark powder in the gills of the Agarics; in the Boletti they are within the membranes that line the tubes; in Peziza Cyathoides they appear to be enclosed in a sort of pod. The black powder in the Lycoperdon and Mucor was mistaken for animalcules by Baron Munckhausen, and thus the Fungi were on the verge of migrating into the class of the Zoophytes. Mr. Ellis, however, has shewn satisfactorily that the motion of the globules which caused the Baron's mistake, was occasioned by a number of very minute animalcules feeding upon them, and these, being much smaller than the globules, are difficult to detect. Many of the Fungus tribe are much esteemed in foreign countries, as a luxurious food, on account of their high flavour. In England, we generally confine ourselves to the Agaricus Campestris, which is exclusively the mushroom, the morell, and the truffle, and for which we refer our readers to the articles *Agaricus*, *Phallus*, and *Lycoperdon*. In Russia, we are informed, that they are eaten almost indiscriminately, and salted down for winter use. That many have imbibed disease, and some even lost their lives, from eating voraciously or incautiously of Funguses, is certain: it is doubtful, however, whether many of them be really poisonous in the strict use of the word; but the difficulty lies in the discrimination. A great variety of insects feed on the different species, particularly the larvæ or maggots of many of the fly genus. Some Funguses have been found of considerable use in stopping hæmorrhages; and the acrimonious qualities of others will, probably, at some future period, be turned to good account. For farther particulars of this tribe, see *Agaricus*, *Boletus*, *Clathrus*, *Clavaria*, *Helvella*, *Hydnum*, *Lycoperdon*, *Mucor*, *Peziza*, *Phallus*, and *Sphæria*.

Fusanus; a genus of the class Polygamia, order Monœcia. —GENERIC CHARACTER. *Hermaphrodite*. *Calix*: perianth one-leaved, turbinate, half five-cleft, (according to Berg, four-cleft,) clefts ovate-acute, from flat spreading, with the tips gibbose-uncinate, somewhat concave. *Corolla*: none. *Stamina*: filamenta four, linear, grooved in the middle, a little longer than the germen, inserted into the calix near it, and occupying the sinus of it; antheræ roundish, compressed, four-lobed, erect. *Pistil*: germen large, turbinate, almost inferior, wide at top, from flat somewhat concave, striated, quadrangular, with four hollowed sinuses, on each side of the germen, solitary; style thick, very short, subquadrangular; stigmas four, obtuse, cruciform, small. *Pericarp*: a drupe. *Male*. *Calix*, &c. as in the hermaphrodite, but the fruit abortive. ESSENTIAL CHARACTER. *Hermaphrodite*. *Calix*: five-cleft. *Corolla*: none. *Stamina*: four. *Germen*: inferior. *Stigmas*: four. *Male*. *Calix*, &c. like the hermaphrodite. *Fruit*: abortive.—The only species hitherto discovered is,

1. *Fusanus Compressus*; *Flat-stalked Fusanus*. This is a tree, with compressed and ancipital branches; leaves opposite, obovate, blunt with a point, flat, quite entire, smooth, on short petioles; racemes from the axils of the branches, erect, compressed, scarcely longer than the leaves. The number of parts in the flower, four or five. The fruitful tree has a three-leaved involucre at the base of the germen, with five glands. According to Jussieu, it is a glaucous shrub, with opposite branches.—Native of the Cape. It is propagated by cuttings, planted early in the summer, in a good loamy earth, in pots, set in a glass-case or hot-bed, shaded and watered gently till they have struck root.

Furze. See *Ulex*.

Fustick-wood. See *Morus Tinctoria*.

GÆRTNERA; (so called, in memory of Joseph Gærtner, M.D. F.R.S. author of a most excellent work on the fruits and seeds of plants,) a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-parted, permanent; divisions oblong, obtuse, spreading, nearly equal. *Corolla*: petals five, roundish, large, flat, spreading, torn and ciliate on the edge, nearly equal, with very short claws. *Stamina*: filamenta ten, filiform, very slightly coalescent at the base; nine slender, somewhat erect, shorter than the corolla; the tenth thicker, the length of the petal, bent in at top. Antheræ parallel-piped; nine equal, small; the tenth on the longer filamentum a little larger. *Pistil*: germen superior, three-toothed, small; style filiform, lateral, bent in, the length of the greater stamina, permanent; stigma sharp. *Pericarp*: capsule woody, having four wings, one-celled; wings lanceolate, widening towards the tip, obtuse; one very large, upright; two smaller, patulous; the fourth very small, ascending. *Seed*: single, roundish. **ESSENTIAL CHARACTER.** *Calix*: five-parted, the leaflets having on the outside a single marginal gland. *Corolla*: five-petalled, somewhat unequal, toothletted, furnished with very short claws. *Seed-vessel*: nearly globose, with four wings.—The only known species is,

1. *Gærtnera Racentosa*. Four of the petals are white, and the fifth yellow; the seed-vessel is nearly globular, or inversely parabolical, leathery, thin, of a yellowish bay colour, marked on the side with the rudiment of the style; on the top it has a small triangular crest, and on the edge it has three very long leathery wings of an ovate-lanceolate shape, the middle one larger than the others; seed kidney-form, globular, wrinkled, gibbous, ferruginous-reddish. It is a large climbing woody shrub, flowering in the wet and cold season. It is cultivated all over the coast of Coromandel, on account of the beauty and fragrance of its flowers.—Native of the East Indies, in the Circar mountains.

Gahnia; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: glume one-valved, ovate-lanceolate, convolute, two or five-flowered; (according to Linneus, two-valved, one-flowered; valves lanceolate, channelled, acuminate, the outer larger, broader.) *Corolla*: glume two-valved, shorter than the calix; valves ovate-lanceolate, acuminate, concave, the outer a little longer; nectary two-valved, hyaline, involving the filamenta; outer valve larger, ovate-concave, three-toothed at the tip, half the length of the corolline glume; inner ovate, entire, very small. *Stamina*: filamenta six, capillary, short, after flowering elongated; antheræ linear, acuminate. *Pistil*: germen oblong; style filiform, erect, longer than the calix, bifid; stigmas in each division of the calix two, capillary, curved back. *Pericarp*: none. *Seed*: according to Forster, single, oblong; according to Linneus, subangular, smooth, surrounded by the elongated filamenta, so as to be double the length of the corolline glume, permanent. *Observe.* Forster asserts, that the flowers are panicled; calicine glumes in the lowest panicles frequently none; stamina in the flowers seven and eight, but the uppermost flowers are always six-stamined. **ESSENTIAL CHARACTER.** *Glume*: two-valved, irregular. *Nectary*: two-valved, involving the filamenta. *Stigma*: dichotomous.—The species are,

1. *Gahnia Procera*. Panicles spiked, several elongated; florets six-stamined; culm half a fathom in height, round, smooth, upright, reclining at top, the thickness of a pigeon's quill; leaves sword-shaped, longer than the culm, narrow, bristle-shaped at the tip, reclining, concave at the base, sheathing, rough at the edge with rows of minute spinules, alternate; flowers purple, in involucre half an inch in

length; seeds brown; number of the stamina in the lower flowers seven or eight, but the upper ones have always six; the lower panicles are often destitute of involucre, and therefore bear naked flowers.—Native of New Zealand.

2. *Gahnia Schœnoides*. Culms flexuose; panicles compound, spiked, rigid, subsolitary.—Native of Otaheite.

Galanga, Galangale. See *Kämpferia*.

Galanthus; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: spathe oblong, obtuse, compressed, gaping on the flat side, withering. *Corolla*: petals three, oblong, obtuse, concave, lax, patulous, equal; nectary cylindrical, three-leaved, half the length of the petals; leaflets petal-shaped, parallel, emarginate, obtuse. *Stamina*: filamenta capillary, very short; antheræ oblong, acuminate, ending in a bristle, convergent. *Pistil*: germen globular, inferior; style filiform, longer than the stamina; stigma simple. *Pericarp*: capsule oval-globular, obtusely three-sided, three-celled, three-valved. *Seeds*: several, globular. **ESSENTIAL CHARACTER.** *Petals*: three, concave. *Nectary*: of three small emarginate petals. *Stigmas*: simple.—The only known species is,

1. *Galanthus Nivalis*; *Snowdrop*. The bulb of the Snowdrop is coated and truncate; leaves yellowish at the base, callous at the tips; scape half a foot or a span in height, acipital, striated, involved at the base in a pair of leaves; sheath whitish, truncate, involving the leaves and scape. The peduncle usually comes out from the left cell of the spathe, is weak, and wrinkled below the germen; flowers solitary, pendulous; petals milk-white. There are two varieties, one with semi-double, and the other with double flowers.—Native of Austria, Switzerland, Silesia, and England, where it is found in meadows; common in orchards, where it is probably a relic of cultivation: it is seen at the foot of Malvern hills, where no traces of buildings or gardens are to be found; also near Cirencester; but it is very doubtful whether this, and several other bulbous plants, were originally indigenous. It flowers usually in February; and hence is in some places called the *Fair Maids of February*. These flowers are highly valued for their early appearance in the spring, for they usually flower when the ground is covered with snow: the single sort comes out first, and though the flowers are but small, yet when they are in bunches they make a very pretty appearance: therefore these roots should not be planted single, as is sometimes practised by way of edgings to borders, for when so disposed, they produce very little effect. When twenty roots or more grow in a close bunch, the flowers have a fine appearance. As they thrive well under trees or hedges, they are very proper to plant on the sides of the wood-walks, and in wilderness quarters, where, if they be suffered to remain undisturbed, the roots will multiply exceedingly. The roots may be taken up when the leaves decay, and kept out of the ground till the end of August; but they must not be removed oftener than every third year.

Galardia; a genus of the class Syngenesia, order Polygamia-Frustranea.—**GENERIC CHARACTER.** *Calix*: common, of two rows of scales; scales linear, flat, acute, about twelve in each row; the outer longer, reflex, the inner erect. *Corolla*: compound radiate; corollets hermaphrodite, numerous in the convex disk: females about twelve, much longer, spreading in the ray. Proper in the hermaphrodites, tubular funnel-form, with a five-toothed border; in the females ligulate, wider outwards, half three-cleft. *Stamina*: to the hermaphrodites, filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: to the hermaphrodites, germen turbinate-angular; style filiform, the length of the corollet; stigmas two, spreading. Females, germen very

small; style none; stigma none. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites, solitary, angular, crowned with the five-leaved calicle; leaflets lanceolate, erect, awned: in the females, none. *Receptacle*: convex, (Jussieu says, flat,) chaffy; chaffs bristle-shaped. **ESSENTIAL CHARACTER.** *Receptacle*: chaffy. *Seed*: crowned with the five-leaved calicle. *Calix*: of two rows of scales, almost equal.

—The only known species is,

1. *Galardia Alternifolia*. Stem from a foot to eighteen inches high, straight, branched, slightly hispid, tinged with purple; root-leaves oblong, spatulate, with large notches, a little rough to the touch, spread on the ground; stem-leaves alternate, embracing, oblong, having a few blunt indentures along the edge, bright green, and slightly villose, the upper ones are almost entire; peduncles simple, naked, long, terminating, bearing one handsome flower, purple and yellow, two inches in diameter. This fine plant has been cultivated for some years in the royal gardens at Paris: the seeds were brought from Louisiana. It is an annual, flowering in July and August, and continuing to the end of October.

Galax; a genus of the class Pentandria, order Monogynia.

—**GENERIC CHARACTER.** *Calix*: perianth ten-leaved; outer leaflets alternate, shorter, lanceolate, reflex; inner longer, lanceolate, acute, upright. *Corolla*: one-petalled, salver-shaped; tube cylindric, length of the calix; border flat, five-cleft; segments obtuse. *Stamina*: filamenta short, antheræ roundish, converging with the throat of the corolla. *Pistil*: germen ovate, villose; style filiform, semibifid, length of the stamina; stigmas roundish. *Pericarp*: capsule ovate, one-celled, two-valved, coloured, elastic. *Seeds*: two, large, convex, ovate, callous, as it were single, two-lobed. **ESSENTIAL CHARACTER.** *Calix*: ten-leaved. *Corolla*: salver-shaped. *Capsule*: one-celled, two-valved, elastic.—The only known species of this genus is,

1. *Galax Aphylla*. This plant is a native of Virginia, as yet very rare, and little known in Europe; leaves all radical; stem naked, simple, probably woody; flowers in a loose terminating spike.

Galaxia; a genus of the class Monadelphia, order Triandria.—**GENERIC CHARACTER.** *Calix*: spathe one-valved, membranaceous, converging. *Corolla*: one-petalled, superior; tube filiform, long, erect, a little widened at top; border six-parted; parts obovate, obtuse, spreading, the three outer ones having a nectareous pit. *Stamina*: filamenta three, united in a cylinder, antheræ ovate. *Pistil*: germen inferior, obtusely triangular, smooth; style filiform, a little longer than the stamina; stigmas three, filiform, many-parted, spreading. *Pericarp*: capsule oblong-subcylindric, three-grooved, three-celled, three-valved. *Seeds*: very many, globular, very small. **ESSENTIAL CHARACTER.** Spathe one-valved. *Corolla*: one-petalled, six-cleft; tube capillary. *Stigma*: many-parted.—The species are,

1. *Galaxia Ovata*. Leaves ovate; root filiform, fixed to an ovate, netted, comose bulb, there are usually several of these conglomerate; stem none; root-leaves heaped, sheathing, ovate, obtuse, slightly veined longitudinally, flat, smooth, the edge somewhat cartilaginous; the calix is a very thin sheath; the corolla is variegated with yellow, purple, and violet; the capsule is smooth. It flowers from June to September.—Native of the Cape of Good Hope.

2. *Galaxia Graminea*. Leaves linear-filiform; root as in the preceding species; flowers radical, among the sheathing leaves, in bundles, sessile, with a long capillary tube, the length of the leaves; corolla yellow, varying with a yellow tube, and a violet-coloured border.—Native of the Cape.

Galega; a genus of the class Diadelphia, order Decandria.

—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, short, half five-cleft; teeth subulate, nearly equal. *Corolla*: papilionaceous; banner large, ovate, reflex at the end and on the sides; wings oblong, having an appendage, and being almost the length of the banner; keel oblong, compressed, straight towards the end, gibbous below, sharp above. *Stamina*: filamenta diadelphous, (simple and nine-cleft;) antheræ oblong. *Pistil*: germen slender, oblong; style slender, shorter than the germen, ascending; stigma a very small dot at the end. *Pericarp*: legume very long, compressed, acuminate, scored with oblong streaks between the seeds. *Seeds*: several, oblong, kidney-shaped. **ESSENTIAL CHARACTER.** *Calix*: with subulate teeth, nearly equal; legume with oblique streaks between the seeds.—The species are,

1. *Galega Officinalis*; *Officinal Galega*, or *Goat's Rue*. Legumes stiff, upright; leaflets lanceolate, streaked, naked; root perennial, composed of many strong fibres, which are frequently jointed; stems channelled, hollow, from two to three, and even to five feet high; leaves unequally pinnate, composed of five to seven or more pairs of smooth entire leaflets; flowers terminating, in loose spikes, they are of a pale blue colour, appear in June, and are succeeded by taper pods about an inch and half in length, and ripening towards the end of August. There is a variety with white, and another with variegated flowers.—*Goat's Rue* is esteemed as a cordial, sudorific, and alexipharmic. Mr. Boyle celebrated its virtues in pestilential and malignant diseases. The leaves, gathered just as the plant is going into flower, and dried, with the addition of boiling water, make an infusion, which being drank plentifully, excites sweating, and is good in fevers. Gerard calls it *Italian Fitch*, and *Goat's Rue*. Native of Spais, Italy, Hungary, and Africa.—This plant is propagated by seeds, sown either in spring or autumn in an open situation. When the plants come up, keep them clean from weeds, till they are strong enough to remove, then take them carefully up, and plant them in a spot well dug and cleared, in rows a foot and a half distant, one foot asunder in the rows, watering them till they have taken new root. Hoe the ground frequently between the plants, and dig it in the spring between the rows. If the stalks be cut down every year before the seeds are formed, the roots will continue the longer, especially on a light dry soil: or if the seeds be permitted to scatter, the plants will come up without any further care.

2. *Galega Cinerea*. Legumes stiff, spreading; racemes opposite to the leaves; pedicels solitary; leaflets villose underneath; stipules lanceolate. This is a small herbaceous plant, somewhat of an ash colour, seldom growing above eleven or twelve inches in height.—It is common among the bushes in all the savannas about Kingston in Jamaica.

3. *Galega Littoralis*. Legumes in racemes, the whole villose-tomentose; leaves unequally pinnate, the midrib villose, grooved, two or three inches long; leaflets about six pairs, oblong, attenuated at the base, blunt, quite entire; flowers flesh-coloured, inodorous.—Native of Carthage, in America, and found every where between the tropics.

4. *Galega Virginiana*. Legumes back-sickled, compressed, villose-spiked; calices woolly; leaflets oval-oblong, acuminate; root perennial; stem annual, three feet high; leaflets generally seven or nine. The whole plant is covered with a silvery down; flowers red, in spikes at the ends of the branches. Native of North America.—Though this plant is tolerably hardy, it is nevertheless difficult to preserve it in gardens, for the seeds rarely ripen in England, and the plants are often destroyed in winter by the frost. The only method, says Mr. Miller, by which I have been able to keep

these plants, has been by potting them, and placing the pots under a common frame in winter, where they enjoyed the free air in mild weather, but were protected from frost; they have been kept in this way for three years, but never ripened seed in our climate.

5. *Galega Villosa*. Legumes back-sickled, villose, pendulous, racemed, lateral; leaflets smooth lanceolate, thirteen to seventeen, blunt, with a point, streaked at an acute angle, the lower ones shorter and obovate; stem round.—Native of the East Indies. This, with the following species from the East and West Indies, may be propagated by seeds sown on a hot-bed in the spring: when the plants are strong enough, transplant each of them into a separate small pot, and plunge them into a hot-bed of tanners' bark, shading them until they have taken new root; then treat them as other tender plants, preserving them through the winter in the bark-stove. If they are brought forward early in the spring, and the summer proves warm, the seeds may ripen in England: they will flower in July, and ripen their seeds in September.

6. *Galega Spinosa*. Legumes solitary, back-sickled, compressed; stipules spinescent; leaflets wedge-shaped, hoary; stem diffused; peduncles axillary, solitary, short, one-flowered; flowers upright, small.—Found in Coromandel, by Koenig.

7. *Galega Maxima*. Legumes stiff, ascending, smooth; stipules lanceolate; leaflets oblong, smooth, streaked. This is the largest plant of the genus. Stem angular, smooth, changing situation variously between the joints; calices smooth.—Native of Ceylon.

8. *Galega Grandiflora*; *Rose-coloured Galega*. Legumes spreading; stipules ovate-lanceolate; leaflets oblong, almost naked, awned; stem shrubby, round, branched, having very minute hairs scattered over it; leaves unequally pinnate; peduncles terminating, erect, elongated; flowers at the top, opposite, approximating, nodding; bractes ovate-oblong, acute, purplish, deciduous; calix tomentose, silky; corolla purple; banner smooth above.—Native of the Cape.

9. *Galega Palleus*; *Pale-coloured Galega*. Legumes stiff, spreading, ciliate; stipules awl-shaped; leaflets nine to eleven in number, oblong, sharp, pubescent underneath. It flowers in July.—Native of the Cape of Good Hope.

10. *Galega Piscatoria*; *Woolly Galega*. Legumes stiff, ascending, subvillose; stipules awl-shaped; leaflets eleven to thirteen in number, oblong, blunt, somewhat hairy underneath; peduncles ancipital. It flowers in June and July.—Native of India, and the South Sea islands.

11. *Galega Purpurea*; *Purple Galega*. Legumes stiff, ascending, smooth, racemed, terminating; stipules awl-shaped; leaflets oblong, smooth. The stem is less angular and straighter than that of the seventh species, and reddish; the flowers narrower than the leaves; bractes ovate; flowers with capillary peduncles. Mr. Miller says, that this plant was annual here; that it had an herbaceous stalk two feet high; that the leaves had eight or nine pairs of leaflets; that the peduncles came out opposite to these; and that the flowers were small, purple, in a loose spike, and succeeded by slender erect pods. It flowered in July and August. The seeds were received from Ceylon, and many other parts of the East Indies.

12. *Galega Caribbæa*. Legumes stiff, smooth, pendulous, racemed; leaflets smooth, mucronate; stem shrubby. This is an upright, branched, slender shrub, two feet high; stipules bristle-shaped, entire; racemes axillary, loose, simple, stiffly spreading; solitary, longer than the leaves, six-flowered, or thereabouts; flowers inodorous, red and white variegated; seeds black, shining.—Native of the Caribbee islands.

13. *Galega Cœrulea*. Racemes terminating, many-flowered, contracted; leaflets eight to ten pairs, elliptic, blunt; stem scabrous; branches ferruginous, tubercled with black dots, on the top of the stem, tomentose; stipules awl-shaped; racemes upright; flowers numerous, heaped, blue.—Found in South America, by Mutis.

14. *Galega Tinctoria*. Spikes lateral, peduncled; legumes stiff, pendulous. This is a very handsome plant; the stems naked, flexuose, smooth, angular; leaflets eleven, emarginate, oblong, blunt, smooth above, silky underneath, hairy, streaked, the lower ones shorter; peduncles from each axil naked, spiked at the end, the length of the leaves, smooth; calices subvillose. It is from this plant that the inhabitants of Ceylon prepare their indigo, which yields a dye of a pale blue colour.—Native of Ceylon.

15. *Galega Senticosa*. Legumes in pairs, lateral, smooth; leaflets emarginate, silky underneath; stem shrubby. This is a woody shrub, with a roundish stem and a brown bark; leaflets usually nine, obovate, streaked.—Native of Ceylon.

16. *Galega Pulchella*. Legumes straight, villose, pendulous, racemed; stipules awl-shaped; standard above, and leaves underneath, villose; root annual, or biennial; stem reddish-brown, somewhat villose, at a small distance from the root, producing branches which subdivide into others; branchlets streaked, somewhat angular, villose, and sometimes so copious that they seem to weigh down the whole plant.—Native of the Cape of Good Hope.

17. *Galega Frutescens*. Leaflets ovate; flowers panicled, axillary; stem shrubby.—Discovered at Campeachy.

18. *Galega Tomentosa*. Legumes stiff, ascending, villose, racemed, opposite to the leaves; pedicels in threes; leaflets silky underneath; stipules awl-shaped; stem villose-tomentose, angular; flowers remote, on villose pedicels.—Native place uncertain.

19. *Galega Toxicaria*; *Poisoning Galega*. Spikes terminating, peduncled; legumes cylindrical, pedicelled, spreading; stem and leaflets hoary-tomentose. This is a spreading shrubby plant, rising generally to the height of five or six feet: the leaves and branches, well pounded, and thrown into a river or pond, very soon affects the water, and intoxicates the fish, so as to make them float on the water as if dead; most of the larger fish recover after a short time, but the greater part of the small fry perish on these occasions.—It is a native of South America, from whence it has been introduced into Jamaica, and cultivated there on account of its intoxicating qualities.

Galenia; a genus of the class Octandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth very small, four-cleft, concave; divisions oblong. *Corolla*: none. *Stamina*: filamenta eight, capillary, scarcely the length of the calix; antheræ twin. *Pistil*: germen roundish; styles two, simple, reflex; stigmas simple. *Pericarp*: capsule roundish, two-celled. *Seeds*: two, oblong, angular. **ESSENTIAL CHARACTER.** *Calix*: four-cleft. *Corolla*: none. *Capsule*: roundish, two-seeded.—The species are,

1. *Galenia Africana*; *Upright or Shrubby Galenia*. Erect, shrubby; leaves linear, fleshy; stem four or five feet high, sending out many weak branches; flowers in loose panicles from the sides and at the ends of the branches, very small, greenish-white, and making little appearance.—It flowers from June to August, and is a native of the Cape of Good Hope. Neither this nor the next species can endure the rigours of an English winter in the open air, but must be placed in the green-house, or under a frame, with other hardy exotic plants, where they may have a large share of air in mild weather, for they only require to be protected from the

frost. In the summer they may be exposed in the open air, with other plants of the same country, and in dry weather they must be frequently watered. They may be both propagated by cuttings, which, when planted during any of the summer months, and frequently watered, will take root in five or six weeks, and may then be treated in the same way as the old plants.

2. *Galenia Procumbens*; *Trailing Galenia*. Leaves ovate, channelled, with spreading recurved points.—Grows at the Cape of Good Hope.

Galeopsis; a genus of the class Didymia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, five-toothed, ending in awns the length of the tube, permanent. *Corolla*: monopetalous, ringent; tube short; border gaping; throat a little wider than the tube; at the length of the calix, above the base of the upper lip, putting out on each side an acuminate toothlet, concave underneath; upper lip roundish, concave, serrate at the tip; lower trifid, the lateral divisions roundish, the middle one larger, emarginate, notched. *Stamina*: filamenta four, subulate, concealed beneath the upper lip, two of them shorter; antheræ roundish, bifid. *Pistil*: germen quadrifid; style filiform, length and situation of the stamina; stigma bifid, acute. *Pericarp*: none; calix stiff, straight, containing the seeds in the bottom. *Seeds*: four, three-sided, truncate. *Observe*. The first species has the upper lip of the corolla scarcely notched; it is reflex a little at the tip. ESSENTIAL CHARACTER. *Corolla*: upper lip notched a little, vaulted; lower has two teeth above.—All the species, except the fourth, are annual, and must be propagated from seeds; but being common weeds, are seldom cultivated in gardens: they are not, however, very injurious weeds, nor very difficult of extirpation.—The species are,

1. *Galeopsis Ladanum*; *Red Deadnettle*, or *Nettle-hemp*, *Narrow-leaved All Heal*, or *Ironwort*. Internodes of the stem equal; whorls remote; calices not pungent; leaves petioled, of a pale green colour, linear-lanceolate, almost naked; root annual; stem upright, a foot high, purplish, somewhat hairy; or nearly smooth, brachiate, the knots scarcely swoln; corolla reddish purple, and somewhat villose; upper lip toothed, lower lip bent back, irregularly notched, with two oval yellow spots within, but underneath and on the outside many small white globules. It is common in corn-fields in a calcareous soil, flowering from June to August.

2. *Galeopsis Villosa*; *Hairy Deadnettle*, or *Nettle-hemp*; *Yellow Ironwort*. Internodes equal; whorls remote; leaves lanceolate-serrate, villose; root annual, branched; stem thicker, higher, and more branched, than the foregoing, purplish, obscurely quadrangular, grooved, and villose.—Native of Germany, Switzerland, and England, as in sandy corn-fields of Cambridgeshire, Nottinghamshire, Yorkshire, and Lancashire; and about Bangor in Wales: flowering in July and August.

3. *Galeopsis Tetrahit*; *Common or Hemp-leaved Deadnettle*. Internodes thickened at top; upper whorls almost contiguous; calices somewhat pungent; root annual; stem upright, covered with stiff hairs, swoln under the joints; flowers sessile, seventeen or eighteen in a whorl, each whorl supported by a pair of leaves, and subulate, thorny bractes; corolla twice as long as the calix, either purple or white, with a spot on the lower lip, variegated with purple and yellow: every part of this plant is rough with very sharp prickles, and has a strong smell when bruised. In Yorkshire it is called *dea-nettle*, which is probably a corruption of *dead-nettle*.—There is a variety, the flower of which is large and elegant, about twice the size of the above; the corolla is four times as long as the

calix, straw-coloured, and the lower lip spotted with purple. Haller, Miller, Pollich, and Krocker, make it a separate species; but the structure of the whole plant is the same, only the parts are much larger and softer. There are several other varieties, but none worth enumerating.—Native of Germany, Switzerland, and Sweden: it is found in the northern counties of Great Britain; also at the bottom of Bibton lane, near Woodford. It grows in corn-fields, and on the borders of them, on waste grounds, in coppice-woods, &c. flowering in July and August.

4. *Galeopsis Galeobdolon*; *Yellow Deadnettle*, or *Nettle-hemp*. Six flowers in a whorl; involucre of four leaves; (flowers six to twelve, with an involucre of as many leaves as flowers.) There has been a great diversity of opinion respecting this species; some have asserted it to be of another genus: we shall however leave it where Linneus has placed it. Root perennial; stems several, somewhat hirsute, furrowed, those producing flowers are nearly upright, from a foot to two feet in height, the barren stems, after flowering time is past, extend to a great length and creep. It flowers in May and June, and is found with variegated leaves.—It is a native of Sweden, Germany, Switzerland, Austria, Carniola, Italy, and England, where it is frequent, as in Charlton, Hampstead, and some other woods near London: in Kent, Essex, Cambridgeshire, Suffolk, Norfolk, Worcestershire, Staffordshire, and Warwickshire.—This plant is perennial, and may be propagated plentifully by the runners which it throws out too abundantly. When the foliage is variegated, it makes a beautiful appearance in a garden. This being a wood plant, it should not be much exposed to the sun.

Galium; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, four-toothed, superior; in some species none. *Corolla*: one-petalled, wheel-shaped, four-parted, sharp, without any tube. *Stamina*: filamenta four, subulate, shorter than the corolla; antheræ simple. *Pistil*: germen twin, inferior; style filiform, half two-cleft, length of the stamina; stigmas globular. *Pericarp*: berries two, dry, globular, united. *Seeds*: solitary, kidney-form, large. *Observe*. Some species have two styles. ESSENTIAL CHARACTER. *Corolla*: one-petalled, flat. *Seeds*: two, roundish.—Most of the plants of this genus being destitute of beauty, and being subject to spread, and overrun whatever plants grow near them, are seldom cultivated, except in botanic gardens; the perennials may be easily propagated by parting their roots either in spring or autumn; and they will grow in almost any soil and situation. If the annuals be permitted to scatter their seeds, they will maintain themselves in a garden without any culture, except that of preventing other weeds from overgrowing them.—The species are,

* *With a smooth Fruit.*

1. *Galium Rubioides*; *Madder-leaved Ladies' Bedstraw*. Leaves in fours, lanceolate-ovate, equal, scabrous underneath; stem erect, purplish-brown; the panicle of flowers is short and conglomerate; corolla white; seeds very smooth and glossy. Perennial.—It flowers in July, and is a native of the Palatinate, Silesia, and Idria.

2. *Galium Palustre*; *White Ladies' Bedstraw*. Leaves in fours, obovate, unequal; stem flaccid, branched from the joints, a foot long, the corners set with sharp hooked prickles pointing downwards; root slender, creeping, perennial; flowers numerous, white, on lateral and terminating peduncles, which are usually trifid, and subdivided.—It flowers in July, and is common on the banks of rivers, ditches, and moist meadows.

3. *Galium Trifidum*. Leaves in fours, linear; stem pro-

cumbent, scabrous; corollas trifold; root annual, very small and slender; peduncles usually in threes, very slender, the length of the leaves, one-flowered; the flowers very small, white, and three-parted; stamina three; fruit very small, smooth and even. It flowers in July.—Native of Denmark, Silesia, and Canada.

4. *Galium Montanum*; *Mountain Ladies' Bedstraw*. Leaves in fours, or thereabouts, linear, smooth, and even; stem weak, scabrous; flowers in trifold corymbs, white, purplish on the outside before they expand; antheræ brown. The flower is among the largest of this genus; peduncles branched, many-flowered, ending in a kind of convex umbel; the peduncle swells under the seeds.—Native of Germany and Switzerland.

5. *Galium Procumbens*; *Trailing Ladies' Bedstraw*. Leaves on the flowering-stem in sixes, lanceolate, and slightly hairy; the rest generally in fours, obovate; stem prostrate, smooth. Perennial. The stems and branches are matted together, and spreading on the ground; flowering-stem from two to six inches high, twisted, appearing cylindrical to the naked eye, but, when magnified, to have four rounded corners.—It flowers from June to August; and is found in Dudley wood, in marshes, and on heaths and mountains.

6. *Galium Lucidum*. Leaves four to six, rigid, subulate, bowed upwards; flowers panicle, terminating, larger than the fruit, which is wrinkled; stem very much branched next to the root: flowering-stems upright, simple, sharply quadrangular, herbaceous, green; flowers in a terminating panicle; corolla white, larger than the fruit, which is oblong-ovate, bowed in, black, and wrinkled.—Native of dry places in the county of Nice, and probably of Dauphiny.

7. *Galium Tinctorium*; *Dyeing Ladies' Bedstraw*. Leaves on the stem in sixes, and linear, on the branches in fours; stem flaccid; one or two flowers on a peduncle. This species abounds in the woods of Canada; the roots are employed by the Indians in dyeing the quills of porcupines red. The French women in Canada sometimes dye their clothes with these roots, which are but small; the colour produced from which, is unchangeable by either air, water, or sun.

8. *Galium Uliginosum*; *Marsh Ladies' Bedstraw*. Leaves in sixes, lanceolate, serrate-prickly backwards, mucronate, stiff; corollas larger than the fruit; root perennial, creeping, slender; stems from procumbent erect, often putting out roots at the base, from a finger's length, to a foot or eighteen inches; the corners rough, with very minute prickles; two or more branches springing from each joint; flowers in panicles at the ends of the stem and branches, in trifold divisions; peduncles very short; at the base of these a pair of leaflets or bractes; corolla white, larger than the fruit. It flowers in July and August, and is a native of Sweden, France, Germany, Switzerland, and Great Britain, where it is found on wet heaths, in bogs, low meadows, by river sides, and in other watery places.

9. *Galium Spurium*; *Corn Ladies' Bedstraw*. Leaves in sixes, lanceolate, keeled, scabrous, prickly backwards; joints simple; stem quadrangular, prostrate, hardly branched, prickly downwards at the corners; peduncles axillary and terminating, bowed in, three-flowered, all the flowers hermaphrodite; seeds globular, smoothish; style bifid; stigmas globular; bractes subulate at the base of the pedicels. It is an annual plant, and flowers in June and July, and even later in the stubble after the corn is off. It is very common in the corn in Cambridgeshire, especially where the soil is calcareous, as about Gogmagog hills, Linton, &c. It is also found in various parts of Oxfordshire, and, according to Hudson, in the isle of Thanet; near Leatherhead, and other places in Surry; near Stamford; and in the Isle of Wight.

10. *Galium Tricorne*; *Three-horned Ladies' Bedstraw*. Leaves from six to eight, the upper surface smooth, the rib underneath rough; peduncles lateral, almost naked, trifold; pedicels bowed back; fruit tubercled; umbels on peduncles, generally two to a whorl, opposite, dividing into three branches, not leafy at the base; fruit roughish, beset with minute tubercles, but which do not end in hairs.

11. *Galium Anglicum*; *English Ladies' Bedstraw*. Leaves about six, lanceolate, acuminate, reflex, ciliate, prickly; stems from a foot to eighteen inches high; flowering branches opposite, spreading, rough with prickles, pointing backwards; corollas smaller than the fruit; root annual, branched; panicle terminating; peduncles trifold; corolla greenish-yellow, small. The prickly hairs at the edge of the leaves point forwards, and sometimes there are a few scattered hairs on the surface; peduncles smooth, generally dividing into three, one of them supporting two flowers, sometimes dividing simply into two or three; flowers herbaceous; seed small, roundish, and not so rough as in most other species.—Found on walls at Hackney and Eltham by Sherard; and by Mr. Crowe, on the walls of Binham church in Norfolk. Hudson observed it in sandy ground, between Dartford and Northfleet, and on a wall at Farningham in Kent.

12. *Galium Saxatile*; *Rock Ladies' Bedstraw*. Leaves in sixes, obovate, obtuse; stem very much branched, procumbent. It is scarcely a hand high; root large, producing a prodigious number of angular stems; peduncles one-flowered, very short, scarcely emerging from the leaves, even when the seed is ripe; seed very large, wrinkled.—Native of Spain and Switzerland, where it is found on mountainous rocks.

13. *Galium Pyrenaicum*; *Pyrenean Ladies' Bedstraw*. Leaves in sixes; flowers lateral, opposite, subsessile, solitary; stems weak, of a finger's length, and branched; the internodes scarcely the length of the leaves, which are smooth, somewhat convex, and mucronate.—Native of the Pyrenees.

14. *Galium Minutum*; *Small Ladies' Bedstraw*. Leaves in eights, lanceolate, mucronate, serrate, prickly, smooth, incurved; fruits reflex; stem quite smooth, not scabrous even about the edge; fruits fleshy, large, with the peduncles reflex, whence they are conglomerate. Perennial.—Native of Russia.

15. *Galium Pusillum*; *Dwarf Ladies' Bedstraw*. Leaves in eights, hispid, linear, acuminate; fruit smooth; peduncles dichotomous; root branched, perennial; stems numerous, from three to ten inches high, branched, the corners commonly rough with prickles: they form large tufts, covered with numberless milk-white flowers, which are very conspicuous at a distance. Not only the corners of the stem, but the edges and midribs of the leaves, are rough, with short spreading hairs.—Native of Provence. It has been found on the lime-stone hills near Kendal in Westmoreland, flowering in August; and also near Matlock Bath, in Derbyshire, flowering in July.

16. *Galium Verum*; *Yellow Ladies' Bedstraw*, or *Cheeserennet*. Leaves in eights, linear, grooved; flowering-branches short; root perennial, creeping, slender, somewhat woody, of a yellow colour; stem from one to two feet high, upright, slightly four-cornered, somewhat flexuose, scabrous, pubescent, below slightly, above more obviously, pale green, branched towards the top; the joints cylindrical, subovate, whitish, surrounded with a slight margin; branches brachiate, opposite, alternately much shorter; flowers in a panicle, numerous, small, with a peculiar odour. The panicle about a span in length, interruptedly branched; the branches

many-flowered, unequal, leafy, with single leaflets on the pedicels; corolla yellow. It is observed by Dr. Withering, that the segments of the corolla are greatly expanded, that the style is cloven more than half way down, and that not only the corolla, but the stamina and pistil, are yellow.—It is an almost universal opinion, that the flowers and herb of this plant will curdle milk. Both Dioscorides and Galen attribute to it this quality; and Matthiolus informs us, that the Tuscans use it for this purpose, in order that the cheese they make from the milk of goats and sheep, may eat the sweeter. Gerarde, who was himself a Cheshire man, says, that in his county, especially about Namptwich, they use it in their rennet, esteeming that to be the best cheese that is made with it; and in some of the Western Isles, they curdle milk with a strong decoction of this herb. Though, says Mr. Miller, no coagulation has followed the experiments which I have seen tried, yet I should not, perhaps, have ventured to dispute the fact, were I not supported by Bergius and Krockner, who could not succeed in coagulating milk with this herb alone. It has been probably put into the milk designed for cheese-making, not so much for the purpose of curdling it, as of giving it a flavour; or, as Matthiolus expresses it, to make it eat the sweeter. The French prescribe the flowers in hysteric and epileptic cases. Both flowers and leaves are sensibly acid to the taste, and the flowering-tops, committed to the still as soon as gathered, afford, says Lewis, a pretty strong acid liquor, in a moderate heat. Hence it appears, that the restringent and refrigerating virtues ascribed to this plant, are not grounded on mere conjecture. An infusion of the plant in boiling water, is esteemed useful in the gout, rheumatism, and sciatica. The leaves and branches dried, and reduced to powder, are sometimes taken internally for spitting of blood, and other hæmorrhages, with success; and have also been said to cure cancerous ulcers. The flowers, digested for six weeks in oil of olives, make it a more efficacious ointment for burns and scalds. Made into syrup, they are said to promote the menses; and a bath or fomentation of them cures the scabs in the heads of children. The flowering-stems, when boiled in alum-water, yield a dye of a good yellow colour. The roots, though small, afford a very fine red dye, not inferior to madder; indeed, an ingenious gentleman, who was conversant in dyeing, assured Mr. Curtis, that the roots produced a brighter colour than madder; and, on that account, the experiment of their cultivation may be well worth trying, especially as the rest of the plant may be successfully used in dyeing yellow. They were cultivated a few years since, under the direction of the committee of privy council for trade. The roots were supposed on an average to weigh seven ounces; and the produce, when dried, to be twelve hundred and a half per acre.—This plant is common in most parts of Europe, in pastures, and by the sides of fields and roads, in a dry soil, flowering from June to August and September. It will flourish in the most unremitting drought, when not a blade of grass is to be seen. The best soil for it is a sandy loam; heavy soils will not answer. Prepare the land as for flax; sow four pounds of seed on an acre. In April, hoe out the plants to six inches square. The crop will require three or four hoeings more in the first season. In May or June, take up as many plants as will leave the rest at the distance of one foot square; and in March following take up again as many as will leave the rest standing at two feet square; and in the fourth, take up the whole crop in March; keeping it always free from weeds. Besides the names set down in the title, Gerarde says, it is called *Maid's-hair* and *Petty Muguet*, which last is derived from the Freuch, *petit muguet*. The common name, *Bedstraw*, is

from the verb to *strew* or *straw*, for, before the invention of feather-beds, a variety of herbs were used to *strew beds* with, of which this was undoubtedly one.

17. *Galium Erectum; Upright Ladies' Bedstraw*. Leaves mostly in eights, lanceolate, with fine prickly serratures; panicles trichotomous; stem flaccid; root perennial, branched. Stems several, rather upright, swelled at the joints, roughish at the corners, a little hairy, branched; flowering-branches opposite; panicle terminating, dividing into three; flowers white; seeds small. It flowers in June and July, and is found in meadows, and moist pastures. Mr. Bryant observed it on Heydon common in Norfolk.

18. *Galium Mollugo; Great Ladies' Bedstraw*. Leaves in eights, ovate-linear, subserrate, spreading very much, mucronate; stem flaccid; branches spreading. The whole plant is smooth to the touch; root perennial, creeping; stem two, three, and four feet high, and even more, generally depressed, unless supported by the weight of the branches, quadrangular, (by which it is distinguished from the next species,) thickest just above the joints; flowering-branches very much extended, sustaining abundance of white flowers, the four segments of which are lanceolate and pointed; they rise from the whorls of leaves, generally two long and two short ones from each whorl, forming in the whole a panicle. There are several varieties.—It is common in hedges and bushy places, flowering from June to August. It is called *Wild Madder*, and *Great Bastard Madder*. The roots yield a red dye like the true madder, and of brighter colour: it is also remarkable, that the animals feeding on this plant, as well as those feeding on madder, have their bones dyed red.

19. *Galium Sylvaticum; Wood Ladies' Bedstraw*. Leaves in eights, smooth and even, but scabrous underneath; a pair of floral leaves on capillary peduncles; stem smooth and even. Stems lofty, weak, smooth and even, very obscurely cornered or roundish; peduncles elongated, the outmost often two-flowered, and near these two leaflets; flowers very minute, nodding before they open. The root is perennial, yellowish on the outside, and affords a very fine red dye like the last.—It flowers from June to August, and is a native of woods in Germany, Switzerland, and the south of Europe.

20. *Galium Linifolium; Flax-leaved Ladies' Bedstraw*. Leaves in sevens or thereabouts, linear-lanceolate, smooth and even; peduncles capillary; stem upright, four-cornered. It flowers in June and July, and is perennial.—Native of the south of Europe.

21. *Galium Rigidum; Rigid Ladies' Bedstraw*. Leaves whorled, linear, scabrous above; panicles divaricate; stem upright, roundish, hairy, and roughish. Perennial; flowering in June.

22. *Galium Aristatum; Bearded Ladies' Bedstraw*. Leaves in eights, lanceolate, smooth and even; panicle capillary; petals awned. Perennial. The whole plant is smooth and even; stem a foot high: leaves eight or nine in a whorl, nicely lanceolate, by no means stiff. It flowers in July.—Native of Italy, on Monte Baldo and Cenisio.

23. *Galium Scabrum; Rough Ladies' Bedstraw*. Leaves about eight, scabrous, mucronate. Perennial; stems upright, closely beset with very short soft hairs. There is no appearance of prickles on the stem or leaves: flowering-branches opposite, one always shorter than the other; peduncles smooth.—Found by Dr. Stokes in a hedge-row in a marly soil on the side of Red House lane, near Worcester; and by Professor Jacquin, in Austria. It flowers in August.

24. *Galium Sylvestre*. Leaves six to nine, linear-lanceo-

late, quite entire, awned; stems angular, decumbent; root small, very slender, creeping; panicles terminating, and axillary, short; peduncles branched, not very leafy, bifid or trifid; corolla white; style very deeply cloven; seeds minute, round, cloven. Haller informs us, that it is common by the way-sides, in corn-fields, and stony parts of France, Germany, and Switzerland: it is also found in the Alps, where it becomes a more humble creeping plant.

25. *Galium Hierosolymitanum*. Leaves in tens, lanceolate-linear; umbels fastigiatae.—Native of Palestine.

26. *Galium Glaucum*; *Glaucous Ladies' Bedstraw*. Leaves linear; peduncles dichotomous; stem smooth and even; root perennial, somewhat creeping, branched. Stems slender, weak, prostrate, glossy; leaves five or six in a whorl, glossy, glaucous underneath, hardly scabrous on the edge, the lower ones turned back: flowers white, in subtrifid small umbels. This plant flowers in our gardens from June to September, and is a native of mountain woods, and fissures of rocks, in the south of Europe, Tartary, and Siberia.

27. *Galium Cinereum*. Leaves in sixes, linear, rigid, serrate, prickly; stems smooth, flexuose, filiform, somewhat woody at bottom; branchlets upright, leafless, with about three flowers. Perennial. This is an elegant species, covered with a glaucous bloom: when this bloom is wiped off, the plant is of a shining, not a dark green. The stems are obscurely quadrangular; the leaves of a long elliptic form, wider at the end, and terminating in a remarkable white prickle. A panicle of flowers terminates the stem and branches, the extreme peduncles bearing usually three flowers, one of which is abortive; seeds large, dirty white, smooth, but, when full ripe, wrinkled.—Native of Piedmont and Dauphny.

28. *Galium Tenuifolium*. Leaves six to eight, linear, grooved, rigid, slightly and finely serrate, with a small prickle at the end; stems diffusely branched, each branch terminated by a panicle; peduncles two or three flowered. Perennial. The peduncles are very much branched, capillary, and longer than the leaf, divaricate; segments of the corolla large, white, and awned; seeds slightly wrinkled, but neither hairy nor rough, the colour of them black.—Native of the county of Nice, Provence, and Dauphny.

29. *Galium Purpureum*; *Purple Ladies' Bedstraw*. Leaves linear-bristle-shaped; peduncles capillary, longer than the leaves; stem upright, very much branched, and so leafy that the leaves can hardly be numbered. They are usually in eights, smooth, and keeled underneath; branches ascending, and from their axils innumerable: peduncles above the leaves upright, sustaining few flowers; these and the stems are dark purple. The roots will dye red. Perennial.—It is found near Ripa and Chiavenna; by Lago Lugano; and in the counties of Nice and Montserrat.

30. *Galium Rubrum*; *Red Ladies' Bedstraw*. Leaves linear, patulous; peduncles very short; root perennial, slender; stems slender, prostrate, nearly a foot in length, rough with small prickles. The whole plant is of a pale green; the flowers, which are very small, are of a pale purple colour, or white, disposed in panicles at the end of the stem and branches.—It flowers in July and August; and is a native of the Palatinate, Silesia, Carniola, and Italy.

** With a hispid Fruit.

31. *Galium Boreale*; *Cross-leaved Ladies' Bedstraw*. Leaves in fours, lanceolate, three-nerved, smooth; stem upright; root perennial, long, slender, dark purple. Stems a foot or eighteen inches in height, obscurely quadrangular, stout, much branching at the top, the lower part smooth, the upper slightly hairy; flowers copious, in a terminating panicle, formed of racemes or corymbs, growing gradually smaller;

corolla white, with ovate segments; styles two; fruit covered with long, soft, whitish hairs, slightly incurved upwards. This is one of the species, the roots of which afford a beautiful red dye. The process is thus described by Haller: The roots are gathered in spring, they are ground with malt-dust, and infused in small beer, which then constitutes the dye in which the macerated woollen yarn is boiled, after having been previously dyed yellow in a decoction of Birch leaves.—It flowers in July and August: and is a native of Lapland, Sweden, Silesia, Switzerland, Carniola, and various parts of Britain: it is found in the mountains of Westmoreland and Wales; near Pooley bridge, by Ullswater: and near the ferry at Winandermere, in Cumberland; in some parts of the county of Durham; and on the rocks near the sides of many lakes and rivers in Scotland.

32. *Galium Pilosum*; *Hairy Ladies' Bedstraw*. Leaves in fours, nearly oval, hairy, nerveless; seeds hairy.—It flowers in June and July, is perennial; and a native of North America.

33. *Galium Rotundifolium*; *Round-leaved Ladies' Bedstraw*. Leaves in fours, ovate, obtuse, terminating in a very short prickle, ciliate about the edge, three-nerved; root perennial, slender, creeping, cinnamon-coloured. Stem procumbent, weak, a foot long, slightly grooved; branches alternate, green at bottom, pubescent, with very short hairs, and leafy, frequently purplish above, naked, and jointed; peduncles naked, an inch or two in length, bifid, seldom trifid, diverging, each terminating in a solitary flower, and filiform; corolla white; seeds white, bearded with long hairs. It flowers in July and August.—Native of Silesia, Switzerland, Savoy, Austria, &c.

34. *Galium Maritimum*; *Sea Ladies' Bedstraw*. Leaves in fours, hispid; peduncles one-flowered; fruits villose; root perennial; stem brachiate, rough with hairs, very much branched, the last branches dichotomous; peduncles capillary, shorter than the leaves, usually one-flowered, seldom bifid; flowers small.—Native of the Levant, and probably of Montpellier, the Pyrenees, and the county of Nice.

35. *Galium Bermudianum*. Leaves in fours, linear, obtuse; branches very much subdivided; whorls of leaves very distant; flowers dark purple; seed lanuginose.—Native of Virginia and Maryland.

36. *Galium Græcum*; *Candia Ladies' Bedstraw*. Leaves about six, linear-lanceolate; stems woody; the whole plant rough with hairs; peduncles longer; the leaves subdivided, forming a kind of umbel of few flowers, capillary.—Native of the islands of the Archipelago.

37. *Galium Aparine*; *Common Rough Ladies' Bedstraw*, *Cleavers*, or *Goose-grass*. Leaves in eights, lanceolate; keels scabrous, with prickles pointing backwards; joints villose; root annual; stem four feet high or more, weak, and supporting itself on other plants, brittle, jointed, the joints villose at the base; the angles are set with pellucid prickles, pointing downwards; it is very branched, and the branches are opposite; flowers few and small, on rough peduncles; calix none; corolla whitish, scarcely longer than the germen, divided to the base into four ovate-acute segments.—This plant is reckoned to purify the blood, and is therefore a common ingredient in spring broth. The expressed juice of the herb, taken to the amount of four ounces, or a quarter of a pint, night and morning, during several weeks, is very efficacious in removing many of those cutaneous eruptions, which are commonly, though improperly, called scorbutic. It has been much celebrated in scrofulous and cancerous sores; but it must be confessed, that the experiments made in our hospitals have not confirmed its celebrity. The juice

of the stem and leaves is acknowledged nevertheless to be of a cooling nature; it increases the urinary discharge, and is therefore esteemed in the jaundice, dropsy, suppression of urine, gravel, and other disorders that arise from obstructions of the viscera. Linnæus says, that this plant is very apt to infest crops of peas; and that the Swedes use the stalks as a filter, to strain their milk through. Dioscorides observes, that the same use was made of it in his time; and it certainly is not a bad substitute, to take hairs out of the milk, where a sieve is not at hand. The seeds have been used instead of coffee. The roots, like most others of this genus, will dye red; and are found to tinge the bones of the birds that eat them, of that colour. As it is an annual weed, it is easily destroyed, if it be cut or plucked up early, for it begins to seed in June.—It is common in hedges and cultivated grounds. The well-known property of adhering to whatever it comes in contact with, has given this plant the names of *Cleavers*, *Clevers*, *Clivers*, and *Catchweed*, or *Scratchweed*; from the same idea, it also derived the more elegant appellation of *philanthrophon*, among the Greeks and Romans; from its roughness, it has been called *Hariff*, or rather *Hairough*; and from being a favourite food or medicine of geese, *Goose-grass*, *Goose-share*, and *Gosling-weed*.

38. *Galium Parisiense*. Leaves linear, in sevens; peduncles two-flowered; root annual; stems a foot high, weak, scarbous backwards; flowering-branches opposite, shorter; peduncles naked, two or three flowered; corollas yellow, small.

39. *Galium Megalosperrum*; *Large-seeded Ladies' Bedstraw*. Leaves in fives, elliptic, acuminate, finely serrate; peduncles two-flowered; fruits large, wrinkled. This plant forms a tuft: the stems do not exceed a finger's length; branches alternate; from the last whorl they produce two-flowered peduncles; flowers pale yellow; fruits dirty white.—Native of Monte Cenisio.

40. *Galium Saccharatum*. Supposed to be a variety of the 37th species. Ray says, the leaves are smooth, and fruits warted, but not lappacious or tenacious.—Native country unknown.

41. *Galium Umbrosum*.—Native of Zealand.

42. *Galium Viscosum*; *Clammy Ladies' Bedstraw*. Lower leaves in fours, obovate; upper ones in sixes, linear-lanceolate, serrate; keel and stem smooth; root annual; stems several, ascending, a finger or a hand in height, smooth, even, made four-cornered by a pale decurrent line, branched from all the lower axils, ending at length towards the top in opposite peduncles, an inch long. In a rich soil, the stems are frequently a span high, and spreading. Corolla yellowish, white; seeds minute, viscid.—Native of the mountains of Tunis.

43. *Galium Paschale*. Leaves in nines, or thereabouts, linear-lanceolate, rugged backwards; peduncles axillary, elongated, trichotomous; stems weak, a foot and a half high or more, simple, smooth, even. The whorls are very remote, eight or nine-leaved; the leaves an inch and a half long, mucronate, smooth, even, except at the edge; the seeds minute.

44. *Galium Aparinoides*. Leaves in sixes, oblong, on the edge and along the keel prickly backwards; joints smooth; stem herbaceous, weak, half a foot high, prickly backwards at the corners, with equal joints; peduncles three, from the ends of the branches, bifid.

45. *Galium Album*; *White Ladies' Bedstraw*. Leaves in eights, or thereabouts, oblong, unarmed, rugged on the edge; stem pubescent, even, the thickness of a pigeon's quill, erect, branched, a cubit in height, unarmed, purplish-brown at the joints; the internodes a span in length; fruit hispid.—Native of Smyrna.

46. *Galium Microcarpum*; *Small-fruited Ladies' Bedstraw*. Leaves in sixes, or thereabouts, lower ones oblong, upper ones bristle-shaped; peduncles trifid; stems several, filiform, a hand and sometimes a finger high, erect, rugged at the corners below, but even above, branched at the base, dichotomous or trichotomous at top; peduncles terminating, capillary, in threes, bifid; pedicels one-flowered; two bristle-shaped leaflets at the base of the peduncles; flowers purple; fruit minute, whitish, hispid.—Native of the dry mountains of Tunis, and of Spain.

47. *Galium Tuberosum*. Leaves in fives, lanceolate; peduncles heaped, axillary; root a small, oblong, irregularly-shaped, white, farinaceous tuber; stem herbaceous, a foot and a half high, rufous, procumbent, simple; flowers white, on longish, one-flowered, heaped, axillary peduncles; fruit roundish, rough.—It is cultivated in China and Cochinchina for the roots, which are reckoned very salutary, and are eaten boiled, either whole or in meal.

48. *Galium Cruciatum*; *Crosswort*. Leaves in fours, ovate, hairy; stem simple above, hairy; bunches of flowers lateral, with two leaves; flowers polygamous; fruit smooth; root perennial, creeping, slender. The flowers are yellow, formed exactly like the Galiums, except that some are only male, and some of the hermaphrodites are five-cleft; the style is deeply cleft; and there are two germina, one of which is generally abortive; the fruit is globose, smooth, and sheltered by the reflex leaves.—Crosswort is often found about hedges and in thickets, flowering early in the summer.

Galopina; a genus of the class Tetrandria, order Digynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: monopetalous, quadrifid, superior, revolute. *Stamina*: filamenta four, capillary, long, inserted into the receptacle, deciduous. *Pistil*: germen inferior; styles two, a little shorter than the stamina, growing out; stigmas simple. *Pericarp*: none. *Seeds*: in pairs, naked, subglobular, muricate. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: four-cleft. *Seeds*: two, naked.—The only known species is,

1. *Galopina Circæoides*. Root annual; stem herbaceous, round, red, smooth, seldom branched, erect, but weak, about two feet high; branches alternate, spreading, resembling the stem; leaves opposite, petioled, oblong, acute, entire, smooth, pale underneath, an inch or a little more in length. In the axils of the leaves are others similar, but smaller; flowers terminating, in a loose diffused panicle: peduncles and pedicels opposite, capillary, smooth, with two opposite bristle-shaped bractes.—Native of the Cape of Good Hope.

Garb. See *Salix Babylonica*.

Garbanzo. See *Cicer Arietinum*, p. 298; to which we wish to add, that the pulse called Garbanzo is highly esteemed in Spain, as fodder for cattle; and at the table, in soups and other dishes, but principally with that standard dish in all families, the *olio*. The Garbanzo plant has a very considerable root, not penetrating far into the ground, and therefore not impoverishing the soil; its branches are numerous, and the large sort throws out shoots three feet long; it varies in colour, white, reddish, or rather gray, and the seed of each is of the same colour respectively. Each pod contains but one seed, or at most two, not round, but rather pointed; whence it is compared to a sheep's head, and has the trivial name *arietinum*. In Castile, they say that the best sort has the surface wrinkled like the face of an old woman, the broad back of a porter, and the bill of a parrot; the colour also should not be white, but a pale hue; and it should be light, soft, and flat. This pulse does not succeed so well in the hotter parts of Spain, as in the cold northern districts of Fuente Saucó, Mentrída, and others. It is generally sown

in the open fields, in the same manner as other pulse: a soft rich soil is best for it, but a stiff clay is not unsuitable. The Spaniards have a proverb, that rain never hurts Garbanzos. There are two principal sorts, or rather varieties; the large or winter, and the small or summer Garbanzo: the former should be sown the first week in October, that it may acquire a good root, and spread out luxuriantly for fodder; the latter must be sown about the end of February. The Spaniards consume large quantities of the Garbanzo as fodder for their cattle. It is reckoned to be tolerably nutritive, and is used either by feeding it on the ground, by cutting it green, and giving it to them in the stall or stable, (which is the best,) or dried after the manner of hay. The large sort furnishes an early fodder for cattle, sheep, and lambs, at a time when no other is to be had. It is a good preparation for other crops, because it is destructive of weeds, and shades the surface of the ground.

Garcinia; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets roundish, concave, obtuse, spreading, permanent. *Corolla*: petals four roundish, concave, spreading, a little larger than the calix. *Stamina*: filamenta about sixteen, upright, placed in a cylinder, simple, shorter than the calix; antheræ roundish. *Pistil*: germen superior, suboval; style scarcely any; stigma flat, spreading, peltate, eight-cleft, obtuse, permanent. *Pericarp*: berry coriaceous, globular, large, crowned with the stigma, of six or eight pulpy cells, with membranous partitions. *Seeds*: solitary, imbedded in the pulp, convex on one side, angular on the other. *Observe*: Jussieu remarks, that the clefts in the stigma, and the number of seeds, vary from five to eight: Gærtner says, six or eight, and the cells of the pericarp as many; he adds, that there is no other difference between this genus and *Cambogia*, except the form of the stigma, and the number of stamina. ESSENTIAL CHARACTER. *Calix*: four-leaved, inferior. *Petals*: four. *Berry*: eight-seeded, (or five, six, or eight,) crowned with the peltate stigma.—The species are,

1. *Garcinia Mangostana*; *Mangostan*, or *Mangosteen*. Leaves ovate; peduncles one-flowered. The Mangostan rises with an upright stem nearly twenty feet high, sending out many branches on every side, which are placed opposite, and stand oblique to each other, and not at right angles; the bark of the branches is smooth, of a gray colour, but on the tender shoots it is green, and that of the trunk is of a darker colour, and full of cracks; the leaves are entire, seven or eight inches long, and about half as much in breadth as in the middle, gradually diminishing to both ends, of a lucid green on their upper side, and of an olive colour on their under, having a prominent midrib through the middle, with several small veins running from that to both sides of the leaf: the flower is like that of a single rose, composed of four roundish petals, which are thick at their base, but are thinner towards their ends, they are of a dark red colour; the fruit is round, the size of a middling orange; the shell of the fruit is like that of the pomegranate, but softer, thicker, and fuller of juice; it is green at first, but changes to a dark brown, with some yellowish spots; the inside of the fruit is of a rose-colour, and divided into several parts by thin partitions, as in Oranges, where the seeds are lodged, surrounded by a soft juicy pulp of a delicious flavour, partaking of the Strawberry and the Grape, and is esteemed one of the richest fruits in the world. As these trees naturally grow in the form of parabolas, and the branches are well garnished with large shining green leaves, they have an elegant appearance, and afford a kindly shade in hot countries, where they are highly deserving of cultivation, and indeed in any coun-

try where there is warmth enough to ripen the fruit, which is esteemed the most delicious of all the East Indian fruits. A large quantity may be eaten without any inconvenience, as it is the only fruit which sick people are allowed to eat. It is given with safety in almost every disorder; and we are told, that Dr. Solander, in the last stage of a putrid fever, at Batavia, found himself insensibly recovering by sucking this delicious and refreshing fruit; the pulp has a most happy mixture of the tart and sweet, and is no less salutary than pleasant, for which reason, in hot climates, it is allowed with the sweet orange in any quantity, to those who are afflicted with fevers, either of the putrid or inflammatory kind: the dried bark is used with success in the dysentery and tenesmus; and an infusion is esteemed a good gargle for a sore mouth, or ulcers in the throat. The Chinese dyers use this bark for the ground or basis of a black colour, in order to fix it the firmer.—Native of the Molucca Islands, whence it has been transplanted to Java and Malacca. The head is so fine and regular, and the leaves so beautiful, that it is looked upon at Batavia as the tree most proper for adorning a garden, and affording an agreeable shade.—As there are but few of the seeds which come to perfection, (for the greatest part of them are abortive,) so most of those which have been brought to Europe have failed; therefore the surest way to obtain the plants, is to sow the seeds in tubs of earth in the country, and when the plants have obtained strength, they may be brought to Europe; but there should be great care taken in their passage to screen them from salt water, and the spray of the sea, as also not to give them much water, especially in a cool or temperate climate, for they are very impatient of wet. When the plants arrive in Europe, they should be carefully transplanted, each into a separate pot filled with light kitchen-garden earth, and plunged into the tan-bed, observing to shade them from the sun till they have taken new root; then they must be treated in the same manner as the other tender plants from hot countries. It may be increased in England by cuttings, in the same manner as is directed for *Gardenia*.

2. *Garcinia Celebica*; *Celebes Mangostan*. Leaves lanceolate; peduncles three-flowered. This is not a lofty tree, but it has an elegant spreading head; the fruit resembles that of the common Mangostan, but sometimes grows to a larger size; it is of a yellowish red or saffron-colour, like the pomegranate, and is not crowned with a star, but with a little crown, which is hollowed above, and broader there than at its origin.—Native of the island of Celebes, about Macassar, whence it has been transplanted into Amboyna and Java, where, however, it seldom bears ripe fruit.

3. *Garcinia Cornea*; *Thorny Mangostan*. Leaves lanceolate, veinless; peduncles one-flowered, drooping. The trunk of this tree is lofty, but not very thick; it is covered with a black bark, adhering firmly to the wood; the branches extend wide, and divide into many short branchlets, which have a pair of leaves at each joint; the flower comes out from the branch between the upper leaves, hanging on an incurved peduncle, having the form of a small rose, but of a yellow colour; fruit solitary, growing close to the branch, the size of a plum, crowned by a sort of wart like the head of a nail, it is of a dusky brown or smoky colour on the outside, and within it has a mucous pulp, in which lie a few seeds in shape of a half moon; it has a resinous smell when fresh. The wood is heavy, and very hard, like horn; hence Rumphius calls it *Lignum corneum*, or *hornwood*: it is used for the handles of tools, and the young trees are employed in building, the old being too hard to work.—Native of the high mountains of Amboyna.

Gardenia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-cleft, superior; divisions upright, permanent. *Corolla*: one-petalled, funnel-form, or salver-form; tube cylindrical, longer than the calix; border flat, five-parted. *Stamina*: filamenta none; antheræ five, inserted into the mouth of the tube, linear, streaked, half the length of the border. *Pistil*: germen inferior; style filiform, or club-shaped; stigma standing out, ovate, obtuse, two-lobed, often furrowed. *Pericarp*: berry dry, one, two, or four celled. *Seeds*: very many, flattened, imbricate, in rows. *Observe*: According to Thunberg, the most natural number of the parts of the flower is five; but they vary as far as nine in the antheræ, as likewise in the divisions of the calix and corolla. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled, contorted or twisted. *Stigma*: lobed. *Berry*: inferior, two to four celled, many-seeded.—The species are,

**Without Thorns.*

1. *Gardenia Radicans*; *Rooting Gardenia*. Corollas obtuse; calix angular; leaves elliptic; stem rooting, decumbent, smooth, the thickness of a reed, about a foot high, putting out roots at bottom; branches opposite, tubercled with rudiments of leaves, flexuose, upright; flowers solitary, subsessile, at the ends of the branches.—It is commonly cultivated in Japan, where it flowers in June and July.

2. *Gardenia Florida*; *Fragrant Gardenia*; or *Cape Jasmin*. Corollas salver-shaped; calicine segments vertical, lanceolate-subulate; stem large and woody, sending out many branches, which are first green, but the bark of which afterwards becomes gray and smooth; the branches come out by pairs opposite, and have short joints; the leaves also are opposite, close to the branches, five inches long, and two and a half broad in the middle, of a lucid green, having several transverse veins from the midrib, entire, and of a thick consistence; the flowers are produced at the ends of the branches, sitting close to the leaves; when fully blown, the double flower is as large as a middling-sized rose: it has a very agreeable odour on the first approach, something like that of the orange-flower, but, on being more closely smelt to, like the common double white Narcissus. It varies with single and double flowers; the flowers appear in July and August.—Native of the Cape of Good Hope, Cochin-china, China, Japan, Surat, Amboyna, and the South Sea islands. There are hedges of it in Japan, and the Japanese are very fond of it near their houses, and in the walks of their gardens: both in Japan and China the fruit is used for dyeing yellow; the mucilage pressed out with the seeds, yields a fine yellow colour; that from the seeds only is lighter, but tinges water of a lively yellow, and is said to dye silk of a deep orange, or even scarlet, but not of the deep China scarlet.—This plant is easily propagated by cuttings, during the summer season, planted in pots plunged into a moderate hot-bed, covered close with bell or hand glasses, and screened from the sun. When they have taken root, they should be carefully parted, and put each into a separate small pot, plunging them again into the hot-bed, and shading them until they have taken new root, after which they should be gradually inured to the open air. Though the cuttings strike freely, and make strong shoots a year or two after, yet in three or four years they are apt to be stunted in their growth, the leaves turn pale and sickly, and the plants frequently die soon after. The other sorts are propagated in the same manner.

3. *Gardenia Thunbergia*; *Starry Gardenia*. Corollas salver-shaped; calices bursting laterally, with the segments dilated at the tip; leaves elliptic. This is a tree about two fathoms in height, smooth, and branching very much;

branches alternate, round, having rings on them from the rudiments of leaves, ash-coloured, smooth, erect, branchleted; flowers on the branchlets terminating, solitary, sessile, erect; berry ovate, somewhat wrinkled, smooth, greenish, turning white, one-celled, five-valved, the size of a hen's egg, continuing several years without opening or falling, having a woody hard bark, and scarcely any pulp.—Native of the Cape of Good Hope.

4. *Gardenia Latifolia*; *Broad-leaved Gardenia*. Corollas salver-shaped; calicine segments subulate, obtusely keeled; leaves obovate-roundish.—Native of the East Indies.

5. *Gardenia Gummifera*; *Gummy Gardenia*. Corollas obtuse; calix rough with hairs; leaves oblong, obtuse. A gum resin, very much like gum-elemi, exudes from the clefts of the bark, and from the leaves.—Native of Ceylon.

6. *Gardenia Muscœnda*. Corollas acute; calix rough with hairs; leaves ovate, acute. It is shrubby, with round branches, rough with hairs; stipules between the leaves, solitary, dilated at the base, subulate; flowers axillary, and at the ends of very short branches, solitary, sessile.—Native of South America.

7. *Gardenia Genipa*. Leaves oblong lanceolate; peduncles axillary, many-flowered; corollas salver-shaped, with an abbreviated tube. Swartz describes this as a thornless shrub, with oblong-lanceolate leaves, axillary, many-flowered peduncles, and salver-shaped corollas, with a short tube.—Native of South America.

8. *Gardenia Rothmannia*; *Spotted-flowered Gardenia*. Corollas funnel-shaped; calicine segments subulate; leaves oblong; stem arboreous, erect, branching very much, a fathom and a half in height; branches and branchlets opposite, somewhat angular, striated, rugged, erect, ferruginous; flowers on the branchlets terminating, solitary, sessile; berry ovate, fleshy, angular, with about twelve obscure lines, smooth, two-valved, one-celled, pulpy, the size of a small pear, black when ripe, opening on one side, and falling from the tree when dry; pulp soft, like that of the tamarind: the wood of this is very hard; flowers white, smelling very sweet, especially during the night.—Native of the Cape.

***Thorny.*

9. *Gardenia Spinosa*; *Thorny Gardenia*. Stem shrubby; branches round, smooth, spiny, rigid; leaves from buds below the spines, several, subsessile, ovate, obtuse, entire, smooth, spreading, unequal; flowers sessile, hirsute, axillary, solitary; corolla funnel-shaped, white.—Native of China, near Macao.

10. *Gardenia Dumetorum*; *Bushy Gardenia*. Thorns opposite, longer than the leaves; germen smooth. This is a very thorny shrub, with very stiff, round, smooth branches; thorns in pairs, an inch long, simple, horizontal, decussated, straight, very stiff, smooth, coming out above the origin of the twigs; leaves obovate, entire, very smooth, opposite, a little smaller than those of Box; flowers solitary, small, fragrant, on short pedicels at the end of each twig.—Native of the East Indies. See the second species.

11. *Gardenia Micranthus*. Stem shrubby; branches round, villose, spiny; branchlets capillary, few, rough with hairs, spiny; flowers sessile, smooth, axillary, two or three, the size of a grain of rice; style capillary, white, the length of the corolla; stigma globular.—Native of China, and the isle of Ceylon.

12. *Gardenia Scandens*; *Climbing Gardenia*. Climbing; flowers peduncled; stem shrubby; branches round, smooth, ash-coloured, spiny, climbing; leaves from the buds below the spines aggregate, ovate, bluntish, entire, smooth, spreading, unequal, on very short petioles; stipules bristle-shaped;

flowers axillary, solitary; style filiform, the length of the tube.—Native of Macao.

13. *Gardenia Uliginosa*; *Boggy Gardenia*. Branches thorny at the end; tube of the corolla hirsute within. This is a shrub with brown squarish branches; the twigs short and growing by pairs, having leaves and two thorns at the end; leaves elliptic, obtuse, smooth.—Native of the marshes in the East Indies.

14. *Gardenia Armata*; *Armed Gardenia*. Spines of the branchlets terminating in fours; calicene segments linear, wedge-form; flowers crowded; leaves roundish; teeth of the calix lanceolate-subulate; corolla salver-shaped; the berry is two-celled, and even when ripe, a very thin partition yet remains. This is a small tree, about ten feet high. The flowers are commonly four together, and extremely odorous.—Native of South America and the West Indies.

15. *Gardenia Aculeata*; *Round-leaved Gardenia*. Thorns opposite; both they and the flowers shorter than the leaves; branches smooth. Browne calls it the Indigo Berry, and describes it as a small shrub rising by a branched stalk, and shooting commonly to the height of seven or eight feet; the main stem tough and hard; the branches somewhat prickly at the ends; the leaves of an oval form, and growing in tufts; the pulp of the berries, which are generally numerous on the smaller branches, is very thick, and stains paper or linen of a fine fixed blue colour. Native of the West Indies.—This plant is propagated by seeds, sown early in the spring, in pots filled with light fresh earth, and plunged into a hot-bed of tanners' bark, observing to water the earth frequently but gently. When the plants come up, admit fresh air to them every day when the weather is warm, and refresh them often with water. In a month's time they will be fit to transplant; shake them carefully out of the pots, place each in a small pot filled with light fresh earth, and plunge them into a hot-bed again, screening them from the sun until they have taken new root, after which they must have air and moisture according to the warmth of the season. The plants may remain in the hot-bed till towards Michaelmas, when the nights begin to be cold; then they should be removed into the stove. During the two first seasons, while the plants are young, keep them constantly in the stove, and wash their leaves whenever they contract filth; after they have acquired strength, expose them in summer to the open air, for two or three months, in a warm situation; but in winter, place them in a stove, in a moderate warmth.

Garidella; a genus of the class Decandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, small; leaflets ovate, acute, deciduous. *Corolla*: petals none, unless the calix be taken for them; nectaries five, long, equal, two-lipped; outer lip bifid, flat; divisions long, linear, blunt; inner lip shorter, simple. *Stamina*: filaments usually ten, subulate, shorter than the corolla; antheræ upright, blunt. *Pistil*: germina three, ovate, upright, acuminate, connected; styles scarcely any; stigmas simple. *Pericarp*: capsules three, superior, connected, oblong, acuminate, compressed, one-celled, two-valved; the inner suture more convex. *Seeds*: several, short, about twelve in each cell, ovate-acuminate, wrinkled, black or brown. *Observe*. This genus approaches very near to *Nigella*; the capsules are so closely united, as to seem one three-celled three-valved capsule. ESSENTIAL CHARACTER. *Calix*: five-leaved, like petals. *Nectary*: five, two-lipped, bifid. *Capsules*: three, connected, containing many seeds.—The only known species is,

1. *Garidella Nigellastrum*; *Fennel-leaved Garidella*. It is an annual plant, which rises with an upright stalk a foot

high, dividing into several slender branches, having very fine cut leaves, like those of Fennel, at their joints; the stalks are terminated by one small flower, of a pale herbaceous colour. It flowers in June and July, and the seeds ripen in September.—Native of the south of France, and of Italy. It is propagated by seeds, sown in autumn on a border of light fresh earth. When the plants come up, weed and thin them to the distance of four or five inches; or if the seeds be permitted to scatter, the plants will come up without further care. They do not well bear transplanting.

Garlic. See *Alium Sativum*.

Gaultheria; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth double, approximating, permanent; outer two-leaved, shorter; leaflets half-ovate, concave, obtuse; inner one-leaved, five-cleft, bell-shaped; segments half-ovate. *Corolla*: one-petalled, ovate, half five-cleft; border small, rolled back; nectary of ten subulate, upright, very short bodies or glands, surrounding the germen within the stamina. *Stamina*: filaments ten, subulate, bent in, shorter than the corolla, inserted into the receptacle; antheræ two-horned, with the horns bifid. *Pistil*: germen roundish, flattened; style cylindric, the length of the corolla; stigma obtuse. *Pericarp*: capsule roundish, obtusely five-cornered, flattened, five-celled, five-valved, opening into five parts at the top, covered all round with the inner perianth, changed into a roundish coloured berry, previous at the top. *Seeds*: very many, subovate, angular, bony. ESSENTIAL CHARACTER. *Calix*: outer two-leaved, inner five-cleft. *Corolla*: ovate. *Nectary*: with ten dagger points. *Capsule*: five-celled, covered with the inner calix, now become a berry.—The species are,

1. *Gaultheria Procumbens*; *Trailing Gaultheria*. Leaves obovate, pointed, slightly serrated, smooth, corroded about the tops of the branches; stem shrubby, trailing. This plant has the appearance of *Pyrola*, or *Vaccinium*, with a creeping root: it is a small, evergreen, trailing shrub, a span high, and scarcely branched; flowers solitary, axillary, pendulous, peduncled; inner calix and corolla white, or of an herbaceous colour, and rarely succeeded by fruit in England.—Native of Canada, where it is found upon a dry, sterile, sandy soil. The natives use the leaves instead of tea. The method of propagating this plant in an English garden, is, to set it in a light sandy loam, with a mixture of peat earth. It is very hardy, and bears flowers and fruit most part of the year.

2. *Gaultheria Antipoda*. Leaves scattered, roundish, serrate-toothed; stem shrubby, diffused.—Native of New Zealand.

Gaura; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, superior, deciduous; tube cylindric, long, thicker at the base, containing four oblong glands growing to it; border four-cleft; divisions oblong, acute, reflex. *Corolla*: petals four, oblong, rising towards the upper lip, equal, with narrow claws, placed on the tube of the calix. *Stamina*: filaments eight, filiform, broader at top, straight, shorter than the corolla; nectareous gland of a conical form within the base of each; antheræ oblong, versatile. *Pistil*: germen oblong, inferior, four-celled, many-seeded; the seeds fixed to a columnar receptacle; style filiform, length of the stamina; stigmas four, columnar, ovate, spreading. *Pericarp*: drupe ovate, four-cornered, the corners flattened; Gærtner says, dry, often with one cell only, and one seed, with the vestiges of the partitions and the abortive seeds. *Seed*: nut with one seed, oblong, angular; or, according to Gærtner, solitary, one or four, sub-ovate, narrowed at top, convex on one side, angular on the other, of a yellowish-bay colour, with a brown callus at the

base. **ESSENTIAL CHARACTER.** *Calix*: four-cleft, tubulous. *Corolla*: four-petalled, rising towards the upper side. *Nut*: inferior, one-seeded, four-cornered.—The species are,

1. *Gaura Biennis*; *Biennial Gaura*. Stem four or five feet high, sending out several branches; leaves oblong, smooth, pale green, sitting pretty close; flowers in close tufts at the ends of the branches, pale rose-coloured, appearing in September, and, when the autumn proves favourable, ripening the seeds towards the end of October.—Native of Virginia and Pennsylvania. If the seeds be sown on an open border soon after they are ripe, they will more certainly succeed than when they are sown in the spring. When the plants come up, keep them clean from weeds, and thin them if they be too close. In autumn they must be transplanted where they are to stand.

2. *Gaura Fruticosa*. Stem shrubby; leaves linear-lanceolate; stamina and style direct. The flowers of this are not near so large as those of the first species; nor the corolla so much expanded.—Native of South America.

Gelder Rose. See *Viburnum*.

Geniostoma; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth inferior, turbinate, five-cleft, permanent; divisions short, sharp. *Corolla*: one-petalled, funnel-form; tube widened, longer than the calix; throat villose, bearded; border five-parted, spreading; divisions ovate, sharpish, the length of the tube. *Stamina*: filamenta five, short, in the throat of the corolla, antheræ oblong, standing out. *Pistil*: germen ovate; style filiform, longer than the tube; stigma cylindric, blunt, grooved. *Pericarp*: oblong, two-celled. *Seeds*: very many, subangular, placed on a filiform receptacle. **ESSENTIAL CHARACTER.**

Calix: turbinate, five-cleft. *Corolla*: one-petalled, with a villose throat, and a five-parted border. *Capsule*: oblong, two-celled, many-seeded.—The only known species is,

1. *Geniostoma Rupestris*. Stem shrubby, climbing without tendrils.—Native of the isle of Tanna, in the South Seas.

Genista; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, small, tubular, two-lipped; upper lip two-toothed, more deeply divided, lower three-toothed, nearly equal. *Corolla*: papilionaceous; banner oblong, remote from the keel, the whole reflex; wings oblong, loose, shorter than the others; keel straight, emarginate, longer than the banner. *Stamina*: filamenta ten, connate, emerging from the keel; antheræ simple. *Pistil*: germen oblong; style simple, rising; stigma sharp, rolled in. *Pericarp*: legume roundish, turgid, one-celled, two-valved. *Seeds*: several, usually kidney-form.

ESSENTIAL CHARACTER. *Calix*: two-lipped, two and three toothed. *Banner*: oblong, reflex downwards from the pistil and stamina.—All the shrubs of this genus are propagated by seeds, which, if sown in the autumn, will succeed much better than if sown in the spring, and a year will be thereby saved. As these plants send out long, stringy, tough roots, which run deep into the ground, they do not bear transplanting well, especially if they are not removed young; therefore the best way is, to sow a few seeds in those places where the plants are designed to remain, and to pull up all except the most promising plants, as soon as they are past danger; after this, the plants will require no other culture, but to keep them clean from weeds. But where this cannot be practised, the seeds may be thinly sown upon a bed of light earth, and when the plants come up they must be kept clean from weeds till the following autumn, when they should be carefully taken up, and transplanted where they are designed to grow. Such as do not produce

seeds here, may be increased by layers.—The species are,

* *Unarmed, or without Thorns.*

1. *Genista Canariensis*; *Canary Genista*, or *Cytisus*. Leaves ternate, pubescent on both sides; branches angular; calix trifid, the lowest segment three-toothed; flowers in corymbs, five or six together, they are sweet-scented, and appear from May to September.—Native of Spain and the Canaries. This, with the third and sixteenth species, require the protection of a green-house.

2. *Genista Candicans*; *Hoary Genista*, or *Montpellier Cytisus*. Leaves ternate, villose underneath; peduncles lateral, leafed, sustaining about five flowers; legumes hirsute. This species rises to the height of seven or eight feet, sending out many slender-growing branches, the upper parts of which, for more than a foot in length, send out small flowering branches on their sides, supporting five yellow flowers, which appear in June and July. The seeds ripen in autumn; the flowers are scentless.—Native of Spain, Italy, and France.

3. *Genista Linifolia*; *Flax-leaved Genista*, or *Broom*. Leaves ternate, sessile, linear, silky underneath. This is a small shrub, with branches that are knotty from indentations left by the fallen leaves; the branchlets or shoots are leafy, angular, upright, and silky; flowers in racemes at the ends of the branches; calix three-parted, the lowest segment trifid.—Native of Spain and the Levant.

4. *Genista Triquetra*; *Triangular Genista*, or *Broom*. Leaves ternate, the upper ones simple; branches three-sided, procumbent. This is a hardy evergreen trailing shrub, producing a vast profusion of bloom, which renders it eminently conspicuous in May and June; it rarely produces seed. When tied up properly, and trained to a stake, it may vie in point of beauty with most of our ornamental shrubs.—Native of Spain, Italy, and France.

5. *Genista Sagittalis*; *Jointed Genista*, or *Broom*. Branches ancipital, membranaceous, jointed; leaves ovate-lanceolate. This species sends out several stalks, which spread flat on the ground, and divide into many flat branches, which are jointed, and their two sides are edged like a broad-sword; they are herbaceous, but perennial; at each of the joints is placed one small sessile spear-shaped leaf, ending in a point, of a deep green colour, and smooth; the flowers are produced in close spikes at the ends of the branches, and are succeeded by short hairy pods, which contain three or four kidney-shaped seeds. It flowers in June, sometimes in May, and ripens seeds in September.—Native of France, Germany, Switzerland, Savoy, Austria, Carniola, Italy, and Spain.

6. *Genista Tridentata*; *Three-toothed Genista*. Branches three-sided, membranaceous, somewhat jointed; leaves three-cusped; legumes woolly, white.—Native of Portugal.

7. *Genista Tinctoria*; *Common Dyer's Genista*, or *Broom*. Leaves lanceolate, smooth; branches streaked, round, upright; the roots creep far and wide; stems many, angular, tough, from a foot to eighteen inches or two feet in height, sometimes more; branches subdivided, ending in short spikes of yellow flowers, with stipules between them.—When cows feed on it, their milk, and the butter or cheese made from it, are said to be very bitter. A bright yellow colour may be prepared from the flowers; and for wool that is to be dyed green with woad, the dyers prefer it to all others. A drachm and a half of the powdered seeds operates as a mild purgative. A decoction of the plant is sometimes diuretic, and therefore has proved serviceable in dropsical cases. A salt prepared from the ashes, is also recommended in the same disorder.—Native of most parts of Europe, particularly in

dry gravelly or sandy soils, flowering in July. In the old writers it is called *base broom*, *green weed*, or *green wood*, *dyer's weed*, and *wood-waxen*.

8. *Genista Sibirica*; *Siberian Genista*. Leaves lanceolate, smooth; branches equal, round, upright. This resembles the foregoing.—Native of Siberia.

9. *Genista Florida*; *Spanish Dyer's Genista*, or *Broom*. Leaves lanceolate, silky; branches streaked, round; flowers in bundles, directed one way, terminating, succeeded by short pods, which turn black when ripe, and contain four or five kidney-shaped seeds. This rises with woody stalks two or three feet high: it flowers in June and July.—Native of Spain.

10. *Genista Pilosa*; *Hairy Genista*, or *Broom*. Leaves solitary, lanceolate, obtuse, somewhat hairy; peduncles the length of the calix; standard hairy on the outside; branches diffused; root long, running obliquely, and furnished with many small fibres; stem a foot in length or more, much branched, tough; the old branches naked; the young ones clothed with numerous minute, oval, or oval-lanceolate leaves, entire, smooth on the upper surface, beneath covered with long, white, silky hairs; flowers in short spikes on the summits of the branches, on short hairy peduncles.—Native of Sweden, Germany, Austria, Carniola, Hungary, Switzerland, France, Italy, and Spain. It was not known to be growing wild in England, until discovered by the late Sir John Cullum and Mr. Dickson, about Lackford, four or five miles from St. Edmundsbury in Suffolk. Mr. Woodward also observed, that Cavenham, and other heaths near Bury, appear yellow with the great plenty of these flowers, the flowering branches standing up; at other times it is difficult to find this shrub, the stem and branches being so closely procumbent, that they are often found even beneath the moss. It flowers in May.

11. *Genista Humifusa*. Leaves lanceolate, ciliate; branches prostrate, streaked, villose.—Native of the Levant.

** *Thorny*.

12. *Genista Anglica*; *English Genista*, *Petty Whin*, or *Needle Furze*. Thorns simple, awl-shaped; flowering-branches abbreviated, unarmed; leaves lanceolate, acute; legumes straightish; stem much branched; branches tough, without leaves, furnished with extremely sharp slender thorns, from a quarter to half an inch in length. The yearly shoots grow in bundles, on the summits of the old ones, and sparingly from the sides: flowers few, small, pale, and yellow. They appear from May till the end of July.—Native of Dauphiny, Denmark, and Britain, where it is found growing on the heaths, and generally in moist spongy ground.

13. *Genista Germanica*; *German Genista*, or *Broom*. Thorns compound; flowering-branches elongated, unarmed; leaves lanceolate, hairy; legumes oblong, straightish; stems about a foot and a half in height, very much branched. The old branches have no leaves, but strong branched thorns; the younger ones are full of green hairy leaves; flowers in a spike, long, and almost sessile; banner cordate, reflex, and thus much shorter than the keel, which is straight, and much longer than the wings. It flowers in the end of May, or the beginning of June, and ripens its seeds in September.—Native of Germany; Switzerland, as about Lausanne, Basil, Savoy, on Mont Saleve; near Geneva, where it was observed by Ray. It is also found in dry woody parts of Dauphiny, Piedmont, Carniola, and Arragon.

14. *Genista Hispanica*; *Dwarf Prickly Genista*, or *Broom*. Spines decomposed; flowering-branches unarmed; leaves linear-lanceolate, hairy; legumes ovate, straight. It rises with woody stalks, two or three feet high, sending out many

taper-channelled branches, which grow erect; flowers yellow, in terminating spikes, succeeded by short pods, which turn black when ripe, and contain four or five kidney-shaped seeds.—Native of Spain, south of France, and Carniola. It flowers in June and July, and the seeds ripen in autumn.

15. *Genista Lusitanica*; *Portugal Genista*, or *Broom*. Stem leafless; thorns decussated. The woody stems are leafless; the younger stems are leafy, and covered with decussated spines. It flowers from March to May.—Native of Portugal.

16. *Genista Scandens*; *Climbing Genista*, or *Broom*. Spines simple; stem climbing; leaves bipinnate. This is a large shrub, with a very long, round, climbing, branched stem, having many short recurved spines scattered over it; flowers in large, loose, terminating, pendulous racemes; corolla yellow, with an oblong reflex banner; calix of the same colour.—Native of Cochinchina, near rivers, mounting to the top of large trees, and covering them with its golden flowers.

17. *Genista Hirsuta*. Spines ternate, decussated; leaves simple, lanceolate; spikes terminating, hirsute. This is a very thorny rigid shrub, with round branches, leafless below, extremely hirsute at top; spike of flowers from the ends of the branches, an inch in length, imbricate, very hirsute.—Native of Old Castile.

Gentian. See *Gentiana*.

Gentiana; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, sharp; divisions oblong, permanent. *Corolla*: petal one, tubular at bottom, imperforate, at top five-cleft, flat, withering, various in form. *Stamina*: filamenta five, subulate, shorter than the corolla; antheræ simple. *Pistil*: germen oblong, cylindric, length of the stamina; styles none; stigmata two, ovate. *Pericarp*: capsule oblong, columnar, acuminate, slightly bifid at the tip, one-celled, two-valved. *Seeds*: numerous, small, fixed all round to the walls of the capsule; receptacles two, each fastened longitudinally to a valve. *Observe*. The figure of the fruit is constant; but, both that and the flower vary much in the different species, as well in number as in form. Some species exclude a fifth part of the number in the flower. One adds three parts of the number in the flower. One species has the neck of the corolla spreading; a second has the neck closed with hairs; a third has the segments of the corolla ciliate; a fourth has a bell-shaped, upright, plaited border; in a fifth, it is starred with small segments, interposed between the larger ones; some have a bell-shaped, and others a funnel-shaped corolla. ESSENTIAL CHARACTER. *Corolla*: monopetalous. *Capsule*: superior, two-valved, one-celled; with two longitudinal receptacles.—The species are,

* *Corollas five-cleft or thereabouts, and somewhat bell-shaped*.

1. *Gentiana Viscosa*; *Clammy Gentian*. Corollas five-cleft, one-styled; panicles trichotomous; bractes perfoliate; leaves oblong, three-nerved. See *Lyacum Viscosum*.—This, together with the thirty-fourth and thirty-fifth species, with a few others not at present in cultivation, require the protection of the green-house.

2. *Gentiana Lutea*; *Yellow Gentian*. Corollas usually five-cleft, wheel-shaped in whorls; calices spathaceous; root thick, of a yellowish-brown colour, and of a very bitter taste; lower leaves petioled, oblong-ovate, a little pointed, stiff, yellowish-green, having five large veins on the back, and plaited; stem three or four feet high or more, with a pair of leaves at each joint, sessile, or almost embracing, of the same form with the lower ones, but diminishing gradually to the top; flowers in whorls at the upper joints; fruit short,

swelling in the middle; seeds often barren.—Native of Lapland, Sweden, Germany, France, Italy, and North America. Haller observea, that it occupies large tracts of country, where it is left untouched by any kind of cattle. Our old English authors call it Felwort and Bitterwort. Before hops had established their reputation, this, with many other bitter herbs, was used occasionally in brewing: Mr. Houghton, at the end of the seventeenth century, assures us, that he had often sold it for that purpose. Gerarde says, that Master Isaac de Laune, a learned physician, sent him plants of this sort for the increase of his garden, from Burgundy; and it is named in English, Felwort, Gentian, Bitterwort, Baldmoyne, and Baldmoney. The root of this species of Gentian, imported from Switzerland and Germany, is the principal bitter now employed in medicine, though the roots of several other sorts are said to be equally efficacious, and are even preferred by some. As the intense bitters are generally admitted to be not only tonic and stomachic, but also anthelmintic, antiseptic, emmenagogue, antiarthritic, and febrifuge, this root has a better claim to the possession of these powers than most of the kind. Many dyspeptic complaints, though arising from the debility of the stomach, are more effectually relieved by these bitters than by Peruvian bark; and Gentian, joined with equal parts of Tormentil, or galls, has constantly succeeded, as we are told by Dr. Cullen, in curing intermittents, if given in sufficient quantity. As a simple bitter, Gentian is rendered more grateful to the stomach, by the addition of an aromatic; and for this purpose, orange-peel is generally used. Meyrick says of it, the dried roots are kept in the shops, and are the principal ingredient in most of the bitter tinctures and infusions. A tincture made with two ounces of the root, one ounce of dried orange-peel, and half an ounce of cardamom-seeds bruised, in a quart of brandy, is an excellent medicine in disorders of the stomach, which it strengthens surprisingly; and is no less efficacious in restoring an appetite, and promoting digestion. It is likewise useful in the decline of putrid and malignant fevers, in disorders arising from obstructions of the viscera, in intermittent fevers and agues, and also for the worms.—This plant delights in a light loamy soil, and a shady situation, where it will thrive much better than in a light dry soil, or on an open exposure. It is propagated by seed, which should be sown in pots soon after it is ripe, for if it be kept till the spring, it will not succeed; these pots should be placed in a shady situation, and kept clean from weeds. In the spring the plants will appear, when they must be duly watered in dry weather, and kept clean from weeds until the following autumn; they should then be carefully shaken out of the pots, so as not to break or injure their roots; and a shady border of loamy earth should be well dug and prepared to receive them, into which the plants should be put, at about six inches' distance each way, observing to let the top of the roots be a little below the surface of the ground, then press the earth close to the roots: after this, they will require no further care, except to keep them constantly clean from weeds; and if the following spring should prove dry, they must be duly watered, which will greatly forward their growth. In this border the plants may stand two years, by which time they will be fit to transplant where they are designed to remain; therefore in autumn, as soon as their leaves decay, they may be removed; but as the roots of these plants run deep into the ground, like carrots, there must be great care taken, in digging them up, not to cut or break their roots, for that will greatly weaken, if it does not kill them. After the plants are well fixed in their places, they require no other culture, but to dig the ground about them early in the spring, before they begin to shoot,

and in the summer to keep them clean from weeds. The roots of these plants will continue many years, but the stalks decay every autumn: the same roots do not flower two years together, nor seldom oftener than every third year; but when they flower strong, they make a fine appearance, and as these delight in shady moist ground, where but few ornamental plants will thrive, they should not be excluded from any good garden.

3. *Gentiana Purpurea*; *Purple Gentian*. Corollas usually five-cleft, bell-shaped, in whorls; calices truncate; root as thick as a man's arm, and two feet long, white within, and striated on the outside, extremely bitter, and used medicinally in some countries, instead of the second species, with great success. The stem is smaller than that, about a foot or a foot and a half only in height; the leaves somewhat broader.—Native of Denmark, Switzerland, and Silesia. This, and the following, to the thirteenth species, may be cultivated in the same manner as the second species.

4. *Gentiana Macrophylla*; *Long-leaved Gentian*. Flowers five-cleft, sessile, in whorls; root-leaves equal to the stem, which is almost naked; root creeping, with a transverse stock, and abundance of whitish fibres; root-leaves often a span in length, standing up above the stem, broad, lanceolate, five-nerved, sheathing at the base; flowering-stem coming out on the side of these, procumbent at bottom, but gradually rising, having only one or two pairs of leaves, besides the floral ones on the top; calix small, membranaceous, unequally four-toothed; corolla small, of a livid pale colour, the border pale blue, four or five cleft; the segments very short, and sharpish. The herbaceous part is hardly bitter.—It flowers in July and August, and is a general inhabitant of Siberia, especially the eastern part, where, Professor Pallas says, it is easily raised from seed.

5. *Gentiana Campanulata*; *Bell-shaped Gentian*. Corollas bell-shaped, seven-cleft, streaked, unspotted; calices seven-cleft; root yellow on the outside, very bitter, fusiform, branched; stem smooth and even, from dark blue becoming green, erect, two spans in height, round, but alternately somewhat ancipital between the joints; flowers almost sessile, in two or three whorls, in each axil from one to three.—It flowers in July, and is found on Mount Garten in Richenau in Carinthia.

6. *Gentiana Punctata*; *Spotted-flowered Gentian*. Corollas bell-shaped, five-cleft or thereabouts, dotted; calices five-toothed; segments of the border commonly seven, sometimes eight, but very seldom six, always shorter, narrower, contiguous, rounded, blunt, without any auricles at the base; and finally, the bellying of the corolla is blunter, and almost the same over the whole bell.—Native of Austria, Silesia, Italy, &c.

7. *Gentiana Pannonica*; *Rough Gentian*. Corollas bell-shaped, six or seven-cleft, dotted; calices usually six-cleft; stem-leaves lanceolate, acuminate; root yellowish on the outside, whitish within, intensely bitter. The whole plant is smooth and shining; stem from half a foot to two feet in height, round, or slightly angular, erect, a finger thick at the base, which is covered with shentling scales, having a bifid or trifid mouth; leaves opposite, broad ovate or lanceolate, acute, quite entire, bright green, somewhat plaited, having five prominent pale nerves on the back, attenuated into connate petioles, flowers from the axils, on very short peduncles, three, four, or five, seldom more on each side, forming whorls, supported by bractes resembling the leaves. There are commonly two or three whorls, with flowers much more numerous in the upper one; but in smaller plants there is

only one.—Native of Switzerland, the Tyrol, Silesia, and the Carpathian mountains.

8. *Gentiana Septemfida*; *Seven-cleft Gentian*. Corollas seven, and five-cleft, with ciliate segments interposed; leaves ovate-acuminate, somewhat stem-clasping. Stem a foot or eighteen inches in height, round, smooth, quite simple; leaves spreading, five-nerved; flowers from the upper axils, usually two together, and three at the top of the stalk, crowded together into a corymb, on short peduncles, the same size as in the next species, the upper one flowering first. The whole plant is smooth, but both herb and root are very bitter.—Native of the mountains of Persia, near the Caspian sea, and of the Chersonesus Taurica.

9. *Gentiana Asclepiadea*; *Swallowwort-leaved Gentian*. Corollas five-cleft, bell-shaped, opposite, sessile; leaves stem-clasping; stem upright, nearly a foot high; leaves smooth, about two inches long, and three-quarters of an inch broad at the base, where they embrace, and end in an acute point; they are of a fine green, have five longitudinal veins joining at both ends, but diverging at the middle, and diminishing in size as they are nearer the top; flowers in pairs, opposite, on short peduncles; they are pretty large, bell-shaped, and of a fine blue colour. It flowers with us in July and August. This is the most tasteless and least bitter of the genus. Native of Switzerland, Hungary, Stiria, Austria, Silesia, Piedmont, Barbary, Mount Caucasus, &c.—It requires a light loamy soil, with the same treatment as the second species. Clusius states, that he introduced it as a flower into his garden, but that it drooped, and lost much of its native vigour and elegance.

10. *Gentiana Triflora*; *Three-flowered Gentian*. Corollas bell-shaped, five-cleft, aggregate-sessile; leaves linear; floral-leaves four, two longer and two shorter; root fibrous; root-leaves none; stem upright, very straight, a span high, round, furnished with very small leaves at bottom, becoming gradually longer higher up, decussately opposite; they are stiff and somewhat rigid, blunt at the end, and turned back at the edge; the largest are nearly three inches in length. Flowers at the end of the stalk, in threes, and sometimes another pair of them from the next axil of the leaves; calix purplish, unequally five-cleft, subspathaceous, cut more deeply on one side; the segments linear, and sharp, alternately larger and smaller; tube of the corolla angular, whitish; the border dark blue, with subcordate blunt segments, distant at the base from each other, with a right-lined interval; filamenta unequal; anthers upright; germen fusiform, with a bifid stigma. It is really different from the next species, with which it may easily be confounded, from having a flower of the same colour, by its being so stiffly upright and bitter.—It flowers in July and August, and is a native of eastern Siberia.

11. *Gentiana Pneumonanthe*; *Marsh Gentian*, or *Calathian Violet*. Corollas five-cleft, bell-shaped; flowers peduncled; leaves linear. Stem upright, about a foot high; leaves smooth, an inch and a half long, and less than a quarter of an inch broad; they have no petioles; flowers on the top of the stalk, three or four in number, on peduncles, alternately above each other; they are large, and being of a deep blue colour, make a fine appearance; calix cylindric, or very obscurely angular, with linear leaflets, often reflex at top, scarcely a third of the length of the corolla, which is plaited in angles of different shades of blue; the tube paler, and dotted within; stigma revolute, and remarkably long. It has the bitterness, and other qualities, of several among its congeners.—Native of Sweden, Denmark, England, Switzerland, Carniola, the Palatinate, Silesia, Piedmont, in the temperate parts of Russia, and all Siberia, in moist meadows

and marshes. Ray found it near Lindau in Germany. It is not common in the southern parts of Great Britain, but much more so in the north. It has been found between Clapham and Engleton, on Longfield downs near Gravesend, near Greenhithe, Cobham, Hellingstone, and Dartford, in Kent. Gerarde observed it near Bath; and Parkinson, in divers parts of the west of England. It abounds in Lincolnshire and Yorkshire, on boggy heaths, as on Nettleton Moor, near Castor, in Tattershal park, and near Doncaster. Stillingfleet saw it on Stratton Strawless heath, near Norwich; it has also been observed near Milnthorp in Westmoreland; and is common all over Lancashire. This species does not strike its roots so deeply into the ground as the Yellow Gentian, and may be transplanted with less hazard, especially if it be removed with a good ball of earth to the roots. It will flower annually in a strong moist soil.

12. *Gentiana Saponaria*; *Soapwort-leaved Gentian*. Corollas five-cleft, bell-shaped, ventricose, in whorls; leaves three-nerved. This usually rises sixteen inches high, with upright straight stems, having long, sharp-pointed, opposite leaves, spreading horizontally; from the axils of these come out four or five blue flowers. It flowers in August and September.—Native of North America.

13. *Gentiana Villosa*; *Hairy Gentian*. Corollas five-cleft, bell-shaped, ventricose; leaves oblong, acuminate, slightly villose; flowers bell-shaped, ventricose, erect, pale yellow, or white on the outside, and variegated with lines on the inside.—Native of Virginia.

14. *Gentiana Acaulis*; *Dwarf Gentian*, or *Gentianella*. Corolla five-cleft, bell-shaped, higher than the stalk; root large, woody, branched; a set of ovate-lanceolate leaves spreads on the surface. Stem from one to three inches in height, with one or two pairs of leaves on it, and terminated by one very large upright handsome flower. There is sometimes more than one flower, in gardens, where the plant is strong and healthy. This plant, in its natural alpine situation, has little or no stem, whence its trivial name; but it acquires one in a state of cultivation. It flowers in our gardens in April and May, and sometimes a second time in autumn. The flowering time in the Alps, is in June, July, and August. Ray observed it growing upon the highest parts of Mount Jura.—Native of Switzerland, Austria, Carniola, and Silesia. This species is commonly propagated by parting the roots; but it must not be often transplanted or parted: in order to have it flower strong, it should have a loamy soil and a shady situation. It may also be increased by seeds sown in autumn; in a good soil the plants will be strong enough to flower the second year, and these seedling plants will flower much stronger than those which are propagated from offsets. Ray observes, that although it be a native of the highest Alps, yet it readily admits cultivation; and that it was much sought after in his time, by gardeners and florists, for the beauty of the flower. It is still much esteemed for the brilliant azure of its flower, so large in proportion to the size of the plant. The other alpine *Gentianellas* may be increased and treated in the same manner. In common with other alpine plants, they love a pure air, an elevated situation, and a loamy and moderately moist soil; so that it is absolutely impossible that they should ever flourish in the neighbourhood of London.

15. *Gentiana Nana*. *Tufted Dwarf Gentian*. Corolla five-cleft, bell-shaped, bearded on the throat; stem-leaves ovate; root small, annual, very slender, bitterish; stems in tufts, from an inch to a span in height, seldom branched, decumbent at bottom, then upright, jointed, leafy, terminated by one flower; root-leaves four, seldom more, spreading on

the ground; both they and the stem-leaves smooth, quite entire, bright green, sessile, flat; calix cloven to the base, green, smooth, the segments equal, lanceolate.—Native of Dauphiny, Savoy, Piedmont, and Silesia.

16. *Gentiana Exaltata*; *Crowned Gentian*. Corollas five-cleft, crowned, notched; peduncle very long, dichotomous, terminating.—This rises with an upright branching stalk, nearly two feet high; leaves oblong, smooth, acute-pointed; the upper part of the stalk divides into several forks, between which are six or seven long naked peduncles, each sustaining one large blue flower.—Native of the West Indies. Dr. Houston found abundance of it at La Vera Cruz, in low moist places, where the water stagnates, remote from the coast. This plant is propagated by seeds, sown on a hot-bed soon after they are ripe. They must be treated in the same manner as other tender annual plants from hot countries. If the seeds be sown in autumn, in pots placed in the tan-bed in the stove, they will succeed better than when sown in the spring; the plants will flower early, and good seeds may be obtained.

17. *Gentiana Decumbens*; *Creeping Gentian*. Corollas five-cleft, bell-shaped; root-leaves very long, ten or more in a bunch, linear-lanceolate, three-nerved; stalk decumbent; root perennial; stems one or two, coming out on the side of the bunch of leaves, decumbent at bottom, then rising, a span or foot in height, naked at bottom, a pair of leaves in the middle, bearing leaves and flowers at the end; stem-leaves linear; flowers sessile, commonly three, terminating among the top leaves, and two pairs opposite, accompanied also with leaves, seldom in threes. Sometimes the plant is larger, the root-leaves nearly an inch in breadth, and the flowers more in number; and sometimes there is a little axillary branch with one flower on it at the lowest pair of sessile flowers. It varies with a white and purplish corolla; is generally bitter and aromatic, and therefore medicinally used in Thibet.—Native of farther Siberia, where it begins to flower in July, and continues till stopped by the frost.

18. *Gentiana Algida*; *Cold Gentian*. Corollas five-toothed, bell-shaped, sessile, dotted; root-leaves in bunches; root perennial; stem very straight, round, from a finger's length to a span in height, with two or three pairs of broad, lanceolate, three-nerved leaves on it, slightly sheathing it at the base; flowers three or four together, sessile among the upper leaves, with sometimes an accessory one or two from the next axil; calix purplish, cylindrical, cut on one side, when the flower is in maturity cloven half way down; the segments linear, two alternately larger than the rest; seeds gray, scariose, and wrinkled. The leaves next the root are collected into a bunch; they are pale green, juicy, tender, and linear-lanceolate. The whole plant becomes pale in drying. It is intensely bitter, and proper to be used medicinally.—Found on the snowy alpine tops of eastern Siberia, and other parts of the Russian empire, flowering in August.

19. *Gentiana Saxosa*; *Stony Gentian*. Corollas five-cleft, bell-shaped; leaves spatulate; root perennial; stem herbaceous, single, very seldom subdichotomous, slender, round, grooved, erect, smooth and even, a hand or a span in height; peduncles two or three together, seldom four, from the top of the stem, one-flowered, angular, from upright spreading, two inches long; flowers white, and upright.—Native of Dusky Bay in New Zealand.

20. *Gentiana Montana*; *Mountain Gentian*. Corollas five-cleft, bell-shaped; leaves heart-shaped, sessile.—Found also in Dusky Bay, New Zealand.

21. *Gentiana Glauca*; *Blue Gentian*. Corolla five-cleft, bell-shaped; flowers sessile; leaves ovate-rounded; root filiform, slender, woody; root-leaves in a ring, thickish, with

nerves scarcely visible; stem simple, round, upright, from two to four inches in height, having three or four pairs of sessile leaves on it, which are somewhat fleshy, and smaller than the root-leaves; flowers usually three, seldom one only, at the end, together with an accessory pair from the uppermost axils.—There is a variety of this, in high exposed rocky situations, with two or three flowers sitting close to the root-leaves, without any stalk. The former flowers from June to August, and ripens its seeds in September. It is a native of the highest mountains of Kamschatka.

** *Corollas five-cleft, or thereabouts, and funnel-shaped.*

22. *Gentiana Verna*; *Green Gentian*. Corolla five-cleft, longer than the stalk; root-leaves crowded, larger than the others. This is a little plant, hardly two inches high. A perennial yellow branched root, puts up several simple stalks, each supporting one flower; root-leaves spread in a ring, smooth, ovate-lanceolate; on the stalk two or three pairs; calix five-cornered, half the length of the corolla; segments of the corolla slightly serrate, either blue or beautifully deep azure, and between each a small horned whitish blue process; capsule fusiform, long, bursting when touched. Linneus observes, that this plant is scarcely bitter. It varies with a white flower. A beautiful blue colour may be extracted from the flowers, as they are more commonly found.—Native of Switzerland, Savoy, Piedmont, Austria, Carniola, and Silesia. Ray found abundance of this plant on the mountains near Geneva. It flowers early in the spring, both in moist meadows, and in alpine situations. Clusius declares, that this plant rejects all culture.

23. *Gentiana Pyrenaica*; *Pyrenean Gentian*. Corolla ten-cleft, equal; the outer divisions wider than the others. This plant strongly resembles the preceding species, but the corolla is regularly ten-cleft; the segments blunt; the alternate or outer ones green on the outside, within all blue; leaves linear or linear-lanceolate; stalk perennial, procumbent, with upright branches, bearing one flower the length of the branch.—Native of the Pyrenees.

24. *Gentiana Altaica*; *Altaic Gentian*. Corolla ten-cleft; the clefts alternately smaller, and serrulate; stalk shorter than the flowers; root slender, two or three inches long; both root-leaves and stem-leaves closely imbricate, subulate-linear, sharp; stem usually single, but sometimes two or three, about an inch in length, somewhat naked under the flower, with one pair of leaves near it. This is very nearly allied to the preceding species, and, like that, is almost void of bitterness.—Native of the snowy cliffs of the Altaic Alps.

25. *Gentiana Pumila*; *Small Gentian*. Corolla five-cleft, subserrate; leaves lanceolate-linear; stems one-flowered; leaves sharp, scarcely four lines long, and one broad; stem one-flowered, about an inch in height, with two pairs of leaves, one near the calix, which is cloven half way down, and is angular, with five raised lines; tube of the corolla yellowish, not plaited; segments quite entire, with horned processes.—Native of the mountains of Dauphiny, Austria, and Carniola.

26. *Gentiana Bavarica*; *Bavarian Gentian*. Corolla five-cleft, serrate; leaves ovate-obtuse; root-leaves spreading in a ring perfectly round; stem often prostrate, three inches or more in height, with eight or ten pairs of ovate leaves on many; flower solitary, large; calix half the length of the tube of the corolla, divided not more than a third of the way down, into five sharp segments, frequently violet-coloured; segments ovate, moderately acuminate, a little serrate, of the finest sky-blue; the processes, shortly horned, arise from a white line of the tube. It varies with a white flower, like most of the others. The Siberian plant is taller and larger in

all respects than the German. They flower early in the spring. The latter is found near the lake Baikal, and the Carpathian mountains, in the Russian empire; and the former, in Switzerland and Germany.

27. *Gentiana Aurea*; *Golden Gentian*. Corollas five-cleft, extremely acuminate; throat beardless and awnless; branches opposite; root annual. Stem erect, a span high; branches at the root several, small, very upright; root-leaves ovate, smooth, small; stem-leaves similar, larger, sessile, bluntish; flowers terminating, few in a head; calices narrow, subpeduncled, divided into five awl-shaped segments; tube of the corolla the length of the calix; border yellow; the segments quite entire, without any teeth interposed.—Native of the mountains about Bourdeaux, and of Norwegian Lapland.

28. *Gentiana Nivalis*; *Winter Gentian*. Corollas five-cleft; branches one-flowered, alternate; root annual, small; stem one-flowered, but frequently branched, having one flower coming out from each axil, regularly one above another, often alternately, but sometimes in pairs; root-leaves ovate, bluntly lanceolate, few; stem-leaves a little longer, ovate-acuminate, as far as eight pairs: calix five-cornered, half the length of the corolla, cut one-third of the way; segments ending in a long and very sharp point, they are lanceolate, greenish on the outside, deep blue within, having a tinge of green. It varies, like most of the others, with a white corolla: the fading from blue to white is indeed very common in flowers. Haller observes, that it is a genuine alpine plant, common in the mountains of Lapland, between Savoy and Piedmont, on mount Cenis. Linneus also remarked it upon the Pyrenees, adorning them, as he expresses it, with the splendour of its deep vivid blue flowers; and Mr. Dickson saw it on Ben Lawers in Scotland.—This, with the two following species, being partial to spongy ground, cannot easily be cultivated in gardens. The seeds must be sown in pots, or in a shady situation, upon a moist boggy ground, in the autumn. When the plants come up, the surface of the ground should be covered with moss, which should be kept continually moist.

29. *Gentiana Aquatica*; *Water Gentian*. Corollas five-cleft, terminating, sessile; leaves membranaceous at the edge; root annual, filiform, somewhat branched, white; root-leaves spreading in a ring, very much crowded together, ovate-rounded; stem-leaves imbricate, ovate-sharpish, decussated. Stems from two to twenty, usually simple, but sometimes branched, dichotomous, in the flowering plant very short, but in the fruiting plant lengthened out, the leaves becoming more remote, and produced into an oblong form; flowers small, blue, varying to green and white; calix largish, five-cornered; the segments awl-shaped, sharp, equal. It approaches very nearly to the preceding species, and grows to a larger size in northern than in southern countries. Being very bitter, the Daurians use it as a medicine. It flowers in the middle of May, and is found from the river Jenisca to the eastern ocean, in sandy wet meadows, and especially by lakes and rivers: it is also found in China and Japan. See the preceding species.

30. *Gentiana Utriculosa*; *Bottle Gentian*. Corollas five-cleft, salver-shaped; calices plaited and keeled; root slender, fusiform, fibrous, yellow, annual, but, according to Allioni, perennial; root-leaves spreading on the ground in a four-cornered tuft, but soon decaying; stem upright, a finger's length or a hand in height, sometimes higher, slightly angular, smooth; branches opposite, each with the stem terminated by one flower; leaves seven pairs or more, ovate, blunt, quite entire, connate, sessile, upright, bright green, smooth; calix five-cornered; the corolla is sometimes six-cleft. Ray re-

marks that this species differs from all the *Gentianellas* which he had observed, in having the tube of the corolla no longer than the calix, but the segments of the former spreading immediately over the top of the latter, as in the Pink. Mr. Miller observes, that after the top flower decays, there are frequently two smaller flowers come out from the side of the stalk, at the two upper joints; as these flower after each other, there is a succession of flowers till autumn: it varies with white flowers.—Native of the mountains of Switzerland, Germany, Austria, Idria, and Italy, flowering in June. Ray says, he found it in abundance, passing from Munich to Augsburg.

31. *Gentiana Exacoides*; *Healing Gentian*. Corollas five-cleft, salver-shaped; calices membranaceous and keeled; stalk dichotomous; leaves cordate. The whole of this plant is only about a finger's length; stem simple, slender, upright, angular; leaves small, roundish, broad-veined, connate, two or three pairs; flowers terminating in a loose, broad, ventricose, membranaceous, striated calix; segments of the corolla oblong, narrow, equal, yellow.—Native of the Cape.

32. *Gentiana Centaurium*; *Centauray Gentian*, or *Lesser Centauray*. Corolla five-cleft; stem dichotomous; pistil simple. The whole of this plant is smooth and glaucous; root fibrous, annual, woody, yellowish; stalk from four inches to a foot in height, upright, hexangular or quadrangular, generally simple, but frequently putting out upright simple branches, some way above the root, and sometimes branching all the way to the top; leaves next the root oblong, or wedge-shaped, narrowed at the base, blunt at the end; stem-leaves lanceolate, pointed, upright, the uppermost often bent inward; floral-leaves linear, all sessile, three-nerved, quite entire; flowers in a corymb, upright, and subsessile; calix upright, slightly adhering to the tube of the corolla, permanent; segments awl-shaped, connected by a membrane, at the base two very short awl-shaped bractes; corolla tube one-third longer than the calix, slightly coloured, streaked; border generally rose-coloured or pink, plaited at the base, the fissures keeled on the outside, and the segments on the inside; there are no ears or processes between the segments. Gerarde remarks, that the flowers, which he describes as growing at the top of the stalk, in a "spokie bush or rundell, of a red colour tending to purple, in the day-time, and after the sun is up, do open themselves, and towards evening do shut up again." This plant is not uncommon with a white corolla. It is often found in boggy places, with a very short stem, and remarkably branched. This plant is extremely bitter, with a disagreeable flavour; so that, as Haller observes, it was called *fel terræ*, or gall of the earth, by the ancients: he also determines it to be the *graveolentia centaurea* of Virgil, to which Lucretius gives the more significant epithet of *tristitia*, expressive of its extreme bitterness. This herb forms the basis of the famous Portland powder, which prevents fits of the gout when taken in a large quantity, and a long time together; but is said at the same time to bring on hardness of the liver, palsy, and apoplexy. An infusion of the whole plant is, however, an excellent stomachic medicine, as it strengthens the digestive faculties, excites an appetite, opens obstructions of the viscera, removes the jaundice, kills worms, and cures the ague. A decoction of the whole plant destroys lice, and cures the itch.—For its propagation and culture, see the second species.

33. *Gentiana Pulchella*; *Neat Gentian*. Corolla five-cleft; tube elongated; style simple; stalk quite so; stem scarcely an inch high; root-leaves commonly in fours, ovate; stem-leaves opposite, obovate, all naked, quite entire; flower terminating, solitary; calix five-cornered; segments acute, membranaceous.—Native of Sweden.

34. *Gentiana Verticillata*; *Whorled Gentian*. Corollas quinquefid, in whorls eight together; stem scarcely a hand high, round, and somewhat woody; branches opposite, extremely simple, four-cornered, compressed, smooth and even; leaves subsessile, lanceolate, smooth and even, longer than the internodes of the branches; flowers sessile.—Native of the East Indies. For its propagation and culture, see the first species.

35. *Gentiana Maritima*; *Procumbent Sea Gentian*. Corolla five-cleft; styles twin; stem dichotomous, few-flowered; the calix is permanent, and not easily separable from the corolla. There is a variety with two flowers at top, one terminating, the other lateral, sometimes bifid or three-flowered, the lateral flowers equally peduncled, the middle one sessile. It is an annual plant, flowering in May in its native countries, but with us in July and August.—Native of the sea-coast of the south of France and Italy; about Naples; near Tefflis in Persia; and every where on the shores of the Euxine, where it usually has white corollas; it has been found also in the Azores. See the first species.

36. *Gentiana Spicata*; *Spiked Gentian*. Flowers alternate, sessile; corollas five-cleft. This is an annual plant, with an upright stalk, about a foot high, sending out several branches towards the top; the flowers are produced from the side and the top of the stalk, in loose irregular umbels, they are white, and about the size of those of common Centaury; it frequently has purple corollas.—Native of the south of France and Italy.

37. *Gentiana Verticillaris*; *Rounded Gentian*. Flowers in whorls; corollas five-cleft; stalk extremely simple; root perennial; stems several, a hand high, jointed; leaves lanceolate; leaves sessile; the nectary a roundish scale, annexed to the base of each filamentum, within the tube of the corolla.—Native of America.

38. *Gentiana Quinquiflora*; *Five-flowered Gentian*. Corollas five-cleft; stalk acute-angled; leaves ovate, stem-clasping; stem undivided and four-cornered, with the corners membranaceous; leaves three-nerved, sharp; peduncles opposite, being at the end; five flowers on very short pedicels.—Found in Pennsylvania by Kalm.

39. *Gentiana Scilloides*; *Squill-like Gentian*. Corollas five-cleft; stalk one-flowered, prostrate, branched; leaves obovate, obtuse, three-nerved. It is a foot in height, tender, and very smooth, with but few branches; leaves subpetioled, small, the upper ones more so, remote; peduncles long, naked, terminating, one-flowered; bractes in pairs, below the flower, opposite, awl-shaped, upright; calix linear; tube of the corolla funnel-form, longer than the calix; border flat, beardless, yellow.—Found by Masson in the Azores.

40. *Gentiana Aphylla*; *Leafless Gentian*. Corolla five-cleft, salver-shaped; stalk leafless. This is a very small, filiform, annual plant, scarcely branched; stem upright, simple, four inches high, tender, shining, straw-coloured, with opposite, very short remote stipules at the joints; flower terminating, solitary, erect, yellowish, inodorous.—Native of the mountainous woods of Martinico, where it is found in the hollow of trees, scarcely pervious to the light.

41. *Gentiana Amarella*; *Autumnal Gentian*. Corollas salver-shaped, five-cleft, (sometimes four or even three cleft.) bearded at the throat; segments of the calix five, equal; root annual, twisted, yellowish; stem square, erect, bearing several pairs of sessile, ovate, three-nerved, dark-green leaves, and clothed from top to bottom with flowers, on short, axillary, forked side-branches, one being terminal; calix pale, with green ribs, and divided half way down into five, lanceolate, nearly equal segments; tube of the corolla twice as long as the calix; segments of the border five, rarely three

or four, horizontal when the sun shines, the orifice crowned with a purple upright fringe, which conceals the stamina. A variety, under the name of the *Taller Autumnal Gentian with centaury-like leaves*, is said, in Ray's *Synopsis*, to have been found near Welwyn in Hertfordshire, and Belchamp St. Paul in Essex; but it does not differ in any thing essential from the other.—It flowers from July to September, though Ray says earlier. It is not uncommon in calcareous soils, and in dry pastures, in most parts of Europe.

42. *Gentiana Auriculata*; *Eared Gentian*. Corollas four and five cleft, bell-shaped, villose within, the alternate segments cordate. Upright, almost simple, a foot or less in height; root slender, somewhat woody; stalk subquadrangular, a little contracted; root-leaves smaller than the others, ovate, attenuated towards the base; the lower stem-leaves resembling these, the rest very remote from each other, oblong, five-nerved, sessile; the uppermost somewhat clasping, and more lanceolate, they are all paler underneath, and sometimes purplish; flowers five on the top of the stalk, between two pairs of leaves, on very long peduncles, and sometimes from the next axils accessory little branches, having two or three flowers, and one pair of leaves.—Near the sea it branches very much, and grows large; the farther it recedes from the sea, the smaller it becomes, insomuch, that in mossy wet situations inland, it is hardly an inch high, slender, and one-flowered. The maritime plants have generally the corolla violet or reddish; on open heaths, at a distance from the sea, it is pale blue or white; and in marshes, commonly blue. It is found throughout all Kamtschatka, the islands towards Japan and America, and on the shore of America itself. The herb, both fresh and dry, is used by the natives as a stomachic and antiscorbutic, and against vernal diarrhœas, caused by feeding on fish; it is not, however, so bitter as some of the other species. It flowers in the beginning of August, and perfects its seeds in September.

*** *Corollas not five-cleft.*

43. *Gentiana Campestris*; *Field Gentian*. Corollas four-cleft, bearded at the throat; calix four-leaved, the two outer segments very large. Although both Linneus and Scopoli pronounce this and the forty-first species to be one and the same, others have no doubt of their being perfectly distinct; the calix consists of four separate leaflets, the two outer oval-lanceolate, very large, the inner lanceolate, something membranaceous, but one-fourth the breadth of the outer; the flowers also are larger than those of the *Amarella*, though the plant is generally smaller. Haller describes it as extremely branched, and there are specimens in England branched from the root to near the top; the branches long, with leaves and flowers scattered the whole length; but *Amarella* has the branches short, even the lower ones not exceeding the length of the leaves from which they sprang, the upper ones in general are much shorter: it is rather paler in colour, and never so tall as *Amarella*; the stem being less drawn up, the flowers fewer, and on longer flower-stalks, they appear more corymbose: but the essential mark of distinction is in the calix being deeply divided into four unequal segments, two external, opposite, oval, very large, completely enfolding and concealing the two others, which are lanceolate, and not a fifth part of their breadth. Linneus and Pallas say, that the poor natives of the countries where it is found, use this species instead of hops, and as a medicine, in common with many others of the same genus. In the *English Botany*, it is observed, that it grows in pastures, more particularly towards the sea, and that it is not so much confined to a calcareous soil as the *Amarella*. Linneus says,

that it flowers in summer after the solstice, and with us in September and October. Various months are set down by others, as from April to June, and August: Dr. Withering has seen it flowering in a garden in October.—Native of most parts of Europe, from Lapland to Sicily; and is often found in Russia, and in Siberia, near the lake Baikal. In England it is observed near Kendal, and other places in the north; near Bury, in Suffolk, and Stratton heath in Norfolk; also in Cornwall, Cheshire, and Wales.

44. *Gentiana Ciliata*; *Fringed-flowered Gentian*. Corollas four-cleft, ciliate at the edge; root small, round, straight, biennial; stalk from two to eight inches long, reddish, angular, smooth, leafy, sometimes simple and one-flowered, sometimes with opposite branches, terminated by upright, sessile, solitary flowers; leaves sessile, the lower ones shorter, obovate, or spatulate, the rest linear-lanceolate, acuminate, longer, quite entire, upright, smooth, not veined. The corolla varies in different countries; in America, it is much ciliated, in Italy but little, in Iceland and Norway it is only serrate.—Native of Switzerland, Norway, Denmark, Germany, Austria, Carniola, Italy, Siberia, Caucasus, and Canada. It flowers in August and September; and till October in Italy, and even till winter. It is used as a medicine by the natives, and deserves admittance into every garden for the beauty of its flowers. For its propagation and culture, see the fourteenth species.

45. *Gentiana Cruciata*; *Crosswort Gentian*. Corollas four-cleft, beardless; flowers in whorls, sessile; leaves lanceolate, three-nerved, connate; flowers few from the lower axils, but more crowded from the top of the stalk. At each bunch of flowers there are two small leaves; calix short, truncate, with the teeth remote and short; corolla of a fine blue colour. The root is perennial, and puts up several stalks, from a span to a foot high and more. The leaves being in pairs, and each pair crossing the next at right angles, has given occasion to the trivial name *cruciata*, and the English name *Crosswort Gentian*. In the English gardens, it flowers in June, and sometimes in May; in other parts, it flowers in July and August.—Native of Switzerland, Germany, Austria, Carniola, Hungary, the Apennines, Siberia, and various parts of the Russian empire. For its propagation and culture, see the fourteenth species.

46. *Gentiana Sessilis*. Corollas four-cleft; flowers stemless; leaves ovate.—Native of Chili.

47. *Gentiana Filiformis*; *Least Gentian*, or *Marsh Centaury*. Corollas four-cleft, beardless; stalk dichotomous, filiform; root white, woody, simple, or with large fibres; root-leaves small, narrow, oblong; stalk about three inches high, simple or branched, at each joint a pair of small, narrow, sharp leaves; flowers at the end of the branches on long pedicels, yellow, small, almost always closed, seeming, as far as could be discerned, to have five petals; capsule elliptical. Every part of the herb is smooth; the flowers expand only in bright sunshine. The time of flowering is July.—It is a small annual plant, growing in the bogs of Denmark, France, and England. Mr. Ray first noticed it, in rotten marshy ground, near St. Ives in Cornwall. Dr. Pulteney sent it out of Dorsetshire; and it has since been found in Hampshire and Devonshire.

48. *Gentiana Heteroclita*; *Irregular Gentian*. Flowers four-cleft, irregular; stalk brachiate; root annual, fibrous; stalk erect, a span high, dichotomous, quadrangular; leaves sessile, ovate, quite entire, smooth, somewhat fleshy; the lower ones roundish; under the upper ramifications awl-shaped, very short; flowers sessile, solitary in the divisions of the stem, of a purple colour.—Native of Malabar.

49. *Gentiana Scandens*; *Climbing Gentian*. Stem shrubby, climbing; corollas bell-shaped, five-cleft, in elongated pendulous panicles; stem large, woody, round, with many very long climbing branches, without spines or tendrils; leaves ovate-lanceolate, quite entire, smooth, ash-coloured, opposite; flowers lateral, with a small fine-toothed calix, and a bell-shaped corolla, with a wide tube, on the outside ash-coloured, dotted with white, within filled up with dense purple hairs; border spreading, white, bluntly five-cleft, short; the segments usually lacinate, plaited; capsule roundish.—Native both of China and Cochin-china, climbing trees and hedges. It has an unpleasant fetid smell, which is lost in drying, and a very bitter flavour. In the Chinese plant, the leaves are often cordate, slightly emarginate at the base. It is tonic and stomachic.

50. *Gentiana Fimbriata*; *Fringed Gentian*. Corollas bell-shaped, ten-cleft, alternate segments fringed and smaller; stem round, erect, simple; leaves lanceolate, connate at the base, two inches long, very smooth, three-nerved; flowers from the upper axils and at the end of the stalk, the lower ones solitary on each side, sometimes only in one axil, the terminating ones four, sessile; corolla large, an inch and a half wide.—Native of Virginia.

51. *Gentiana Diffusa*; *Branched Gentian*. Stem branched, dichotomous, divaricate; leaves ovate-oblong; peduncles capillary, one or two flowered. Stem herbaceous, four-cornered, with decurrent lines, smooth; leaves sessile, opposite, an inch long; the upper ones subcordate, all very smooth, ending in a short dagger-point, and three-nerved; peduncles at the ends of the branchlets commonly in pairs, one longer, two-flowered, the other shorter, one-flowered; at the base, on each side, is a bristle-shaped leaf; calix tubular, smooth.—Native of the East Indies.

52. *Gentiana Albens*; *White Gentian*. Leaves ovate, stem-clasping; calices ovate; stem trichotomous.—Native of the Cape.

53. *Gentiana Dubia*; *Doubtful Gentian*. Corollas four-cleft; calix lanceolate; panicle terminating, trichotomous, superdecompound.—Native of the Cape.

Geoffroya; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, half five-cleft; the two upper divisions diverging, spreading. *Corolla*: papilionaceous; banner roundish, emarginate, flat, reflex; wings the same length with the banner, blunt, concave; keel compressed, the same length and figure with the wings. *Stamina*: filamenta diadelphous, (simple and nine-cleft,) the length of the keel; antheræ roundish. *Pistil*: germen roundish; style subulate; stigma obtuse. *Pericarp*: drupe ovate, large, with a longitudinal groove on each side. *Seed*: nut subovate, woody, rather flattened, with a longitudinal groove on each side, acute, two-valved. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Drupe*: ovate. *Nut*: flattened.—The species are,

1. *Geoffroya Spinosa*; *Thorny Geoffroya*. Thorny; leaflets oblong. It is described by Jacquin as an inelegant tree, twelve feet high, upright, branched; thorns few, awl-shaped, frequently an inch long, thick on the trunk and branches; leaves pinnate; mid-rib smooth, grooved above, four inches long; leaflets commonly seven on each side, with an odd one, oblong, blunt, smooth, quite entire; racemes simple, dense, axillary, three or four inches long; flowers on very short peduncles, with corollas of a dirty fulvous colour, diffusing widely a most fetid odour. The drupe does not ill represent the fresh fruit of an almond; the rind is very slightly tomentose, and of a greenish yellow colour;

the pulp is soft, sweet, yellowish, has a nauseous smell, and stains the hands with a rust colour, not easily washed out; the nut or stone is whitish, adheres close to the pulp, and contains a white kernel that has a farinaceous astringent taste. A plant with papilionaceous flowers, and a drupe for a fruit, is certainly a great singularity.—Native of Carthage in New Spain.

2. *Geoffroya Inermis*; *Smooth Geoffroya*. Without thorns; leaflets lanceolate. This tree rises to a considerable height, and towards the top sends off several branches; the wood is hard enough to admit of being polished. The external bark is smooth and gray, internally it is black and furrowed; leaves pinnate; leaflets opposite, oblong, ovate, or lanceolate, acuminate, smooth above, nerveless beneath, on short petioles; flowers in clusters, upon large branched spikes; calix very slightly five-parted, with short ovate divisions; corolla pale rose-colour; keel of the corolla ovate, spreading, very slightly divided into two parts. The fruit is a large subovate drupe, enclosing a woody nut.—Native of Jamaica, where it has the name of *Cabbage-bark*, or *Worm-bark-tree*. The bark, which has a mucilaginous sweetish taste, and a disagreeable smell, was first noticed as a vermifuge by Mr. Peter Duguid; but Dr. Wright, who resided a long time in Jamaica, has communicated the fullest information concerning this tree: according to him, the bark is powerfully medicinal, and its anthelmintic effects have been established at Jamaica by long experience. It may be administered in decoction, syrup, powder, or extract; but must be cautiously used, in small doses at first, gradually increasing them as the case may require.

Geranium; a genus of the class Monadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: five-leaved; leaflets ovate, acute, concave, permanent. *Corolla*: petals five, obcordate or ovate, spreading, regular; nectary five honied glands, fastened to the base of the longer filamenta. *Stamina*: filamenta ten, awl-shaped, connected slightly at the base, spreading at top, shorter than the corolla; antheræ oblong, versatile. *Pistil*: germen five-cornered, beaked; style awl-shaped, longer than the stamina, permanent; stigma five, reflex. *Pericarp*: capsule five-grained, beaked; the cells opening inwards, each having a simple naked tail fixed to it. *Seeds*: solitary, ovate-oblong. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled, regular; nectary five honied glands, fastened to the base of the longer filamenta. *Fruit*: five-grained, beaked; beaks simple, naked, neither spiral nor bearded.—This genus, as constituted by Linneus, having become very unwieldy through modern discoveries, it is found very convenient to divide it; and a division is commodiously made from this remarkable circumstance; namely, that in some species all the ten filamenta are fertile; whilst in others, three or even five of them are castrated, as Linneus terms it, that is, are destitute of antheræ. Hence three genera are now constituted out of one genus: *Erodium*, with five fertile stamina only; *Pelargonium*, with seven; and this, retaining the old name, with all the ten fertile. There are also other marks of discrimination, recited in their respective essential characters. These three artificial genera or families, however, form but one natural family, agreeing in their five-leaved calices, their five-petalled corollas, their pentacocous rostrated fruits, and their general habit and structure. They also agree in their inflorescence, the peduncles being curved downwards before flowering-time; but when the flowers are about to open, the general peduncle first, and then each pedicel, becoming erect.—The annual sorts of *Geranium* may be increased by seeds; and if these be permitted to scatter, the plants will come up

without any further care. The perennial sorts, which are more numerous, may be increased the same way, or by parting the roots in autumn. They may be planted in almost any soil or situation, and require no other culture but to keep them clean from weeds. Many of them, indeed, are common weeds, but even some of these have beauty enough to recommend them to a place in a garden, particularly the second, eighteenth, twenty-first, and twenty-second species. Most of the *Erodiums* are also hardy, and may be increased in the same manner; the annual sorts by seeds, and the perennial by dividing the roots. Some of them require the protection of a green-house. The seeds of the *Glaucophyllum* should be sown on a moderate hot-bed in spring; and when the weather is warm, the plants should be carefully transplanted on a sheltered border.—The species are,

* *Peduncles one-flowered.*

1. *Geranium Sibiricum*; *Siberian Crane's Bill*. Peduncles commonly one-flowered; leaves five-parted, acute; leaflets pinnatifid; root perennial; stem herbaceous, annual, diffusely dichotomous, jointed, almost round and smooth. At the divisions on each side, is a lanceolate acuminate stipule; calicine leaflets somewhat hirsute, with short awns; petals pale purplish, without any streaks, scarcely longer than the calix, either quite entire, or slightly emarginate.—It flowers in June, and is a native of Siberia.

2. *Geranium Sanguineum*; *Bloody Crane's Bill*. Peduncles one-flowered; leaves five-parted, trifid, orbiculate; root perennial, somewhat woody. The whole plant set with white spreading hairs; stems a foot or more in height, lax, spreading, branched, round, jointed, swelling at the joints; calicine leaflets oval, with membranaceous reddish edges, and terminated by a short red awn; petals obcordate, very large, pale red, with deeper veins, hairy at the base. The whole plant frequently turns red or purple after flowering.—Native of many parts of Europe, in thickets and rocky pastures, flowering most part of the summer, and often introduced into gardens, as an ornamental plant.—Mr. Miller insists, that the Lancashire Bloody Crane's Bill is a distinct species; the plants, which he raised from seeds, having always continued the same. The stalks are shorter, and spread flat on the ground; the leaves are much less, and not so deeply divided; and the flowers are much smaller, of a pale colour, marked with purple. It grows naturally in Lancashire and Westmoreland. There are also other varieties of this species, but none of sufficient importance to be inserted here.

3. *Geranium Spinosum*; *Shining Crane's Bill*. Peduncles one-flowered; stem fleshy, knobbed; spines solitary, strict. This is a low succulent plant; root simple, scarcely fibrous; stem suffruticose, erect, branched, fenced all round with broad, smooth, irregular tubercles, from the centre of which arises a long sharp black spine; leaves opposite, subsessile, wedge-shaped, reflex, sinuate-crenate; flowers solitary, peduncled; calix awned; corolla purple, spreading, larger than the calix; petals quite entire.—Native of the Cape.

4. *Geranium Emarginatum*. Peduncles one-flowered; leaves ovate, emarginate, crenate.—Native of the Cape.

** *Peduncles two-flowered, shrubby.*

5. *Geranium Anemonifolium*; *Smooth Crane's Bill*. Leaves palmate; leaflets pinnatifid; stem shrubby. The whole plant is remarkably smooth. From a thick root arises a very short stem, the thickness of a finger, and succulent, whence spring branches two feet long, with very long leafless internodes; root and stem-leaves numerous, subpeltate, palmate, five-lobed; lobes pinnate; pinnules gashed, having little notches ending in a very short awn; petioles longer

than the leaves, thick, red, declining; stipules membranaceous, reddish, kidney-form; flowers in the forks, and at the ends of the branches, on erect peduncles; they are of a fine crimson, as large as a half-crown; petals quite entire; capsules smooth. It flowers from May to September.—Native of Madeira.

6. *Geranium Macrorrhizum*; *Long-rooted Crane's Bill*. Calices inflated; petals entire; pistil very long; scape dichotomous; root perennial; the thickness of a finger, becoming woody, dark purple on the outside, round, single, or branched, having many long, round, thickish fibres; hence springs a bundle of leaves, and several almost upright stems, or rather scapes; these are all very soft and smooth, like the leaves of the Marshmallow, with a very short close down. Most of the leaves are large, subpeltate, seven-parted; flowers large and elegant, of a deep red or bright purple colour. The whole plant emits an agreeable odour when rubbed.—It flowers in May or June, and was first imported from Italy, where it is a native.

*** *Peduncles two-flowered, perennial.*

7. *Geranium Canescens*; *Silky-leaved Crane's Bill*. Leaves subpeltate, five-parted, canescent underneath; lobes gashed; petals emarginate. It flowers in May and June.—Native of the Cape.

8. *Geranium Incanum*; *Hoary Crane's Bill*. Calices awned; petals entire; arils hirsute; leaves subdigitate, pinnatifid. Herbaceous; stems filiform, somewhat knotty, having bristle-shaped scales at the knots; lower leaves scattered, prostrate, on long petioles, five-parted, multifid, hoary underneath, with linear segments; peduncles scattered, either opposite to the petioles or axillary, long, with bristle-shaped bracts, either all two-flowered, or else the upper ones four-flowered.—Native of the Cape.

9. *Geranium Tuberosum*; *Tuberous-rooted Crane's Bill*. Leaves many-parted; segments linear, subdivided, obtuse; root tuberous; plant low, scarcely branched; flowers very abundant, terminating, appearing in May; calix awned.—Native of Italy and Silesia.

10. *Geranium Phœum*; *Dark-flowered Crane's Bill*. Peduncles solitary, opposite to the leaves; calices slightly awned; stem erect, nearly cylindrical, eighteen inches to two or three feet high, below woolly, and having a few long shining hairs on them; petals waved; leaves soft, the younger ones silky, ribbed; the lower on long petioles, in pairs, the upper solitary; lobes mostly five, unequally toothed, the lateral ones lobed; the lower leaves have frequently six or seven lobes, and the uppermost only three or four; peduncles very slender; petals ovate, somewhat five-cornered, acuminate, waved at the edge, blackish purple, shining; claws white, marked with five lines, and woolly; arils hairy.—Native of Switzerland, Hungary, Stiria, and of Great Britain, where it is found about Clapham and Ingleton in Yorkshire, and at Tovel, near Maidstone, in Kent.

11. *Geranium Fuscum*; *Brown Crane's Bill*. Peduncles two-flowered, opposite to the leaves, in pairs; stem patulous; petals quite entire. Linnaeus unwillingly separates this from the preceding species, with which it agrees in many circumstances, and particularly in having the whole corolla spread out, and dark-coloured; it differs, however, in having the leaves rigid; the corolla more reflex and smaller; the petals suborbiculate, mucronate, quite entire, flat; the peduncles not solitary, two-flowered, but two distinct.—Native of the south of Europe.

12. *Geranium Reflexum*; *Purple-flowered Crane's Bill*. Peduncles and leaves alternate; petals reflex, lacinated, the length of the calix, which is awnless; stem a foot high,

dichotomous, or bifid, patulous, pubescent; upper leaves alternate, five-lobed, wrinkled, tomentose, not spotted; flowers drooping, on peduncles opposite to the leaves; calix awnless; petals red, somewhat gashed, not longer than the calix, reflex, gaping at the base.—Native of Italy.

13. *Geranium Lividum*; *Wrinkled-leaved Crane's Bill*. Leaves half-seven-lobed, gashed; calices simple, hairy; petals flat, somewhat waved. This is allied to the two last: stipules hirsute, green, those of the stem large, on the petioles small; flower much larger, flat; the petals marked with a very small star, acuminate, broad, perfectly flat, elegantly plaited, and serrate at the edge, pale blue, with a livid centre; root thick, woody, rufous.—Native of Switzerland.

14. *Geranium Nodosum*; *Knotty Crane's Bill*. Petals emarginate; stem-leaves three-lobed, entire, serrate, lucid underneath. An herbaceous plant, having knobs like little bulbs at the origin of the branches and peduncles; peduncles axillary, very long, simple; calix streaked, awned; corolla purple; capsules smooth.—Native of Dauphiny, and the mountains of Cumberland, flowering in July and August.

15. *Geranium Striatum*; *Streaked Crane's Bill*. Leaves five-lobed, light green; lobes widened in the middle; petals two-lobed, netted, veined; root perennial, sending up many branching stalks a foot and a half high; peduncles long and slender; the lobes of the leaves are gashed, and have a ferruginous or purplish brown spot at their base; calices awned. It flowers in May and June.—Native of Italy.

16. *Geranium Argenteum*; *Silvery-leaved Crane's Bill*. Petals emarginate; leaves subpeltate, seven-parted, trifid, tomentose, silky; root perennial, thick; flower-stalks four or five inches high, with one or two small leaves on them like those below, but sessile, and terminated by two pretty large pale flowers.—It flowers in June, and is a native of Monte Baldo and Dauphiny.

17. *Geranium Maculatum*; *Spotted Crane's Bill*. Stem dichotomous, erect; leaves five-parted, gashed, the uppermost sessile; root perennial; flowers pale purple.—It flowers in June, and is a native of Carolina and Virginia.

18. *Geranium Pratense*; *Meadow Crane's Bill*. Leaves subpeltate, many-parted, wrinkled, acute; petals entire; root perennial, sending up many stalks, which rise nearly three feet high, and are forked, and tinged more or less with red; hairs on the upper branches white, terminated by minute dark red globules; bracts four, lanceolate, acute; flowers mostly two, on very short downy peduncles; calicine leaflets lanceolate, ribbed, membranaceous at the edges, thick set with fine white hairs, tipped by scarlet globules, and ending in an awn; petals very large, inversely ovate, marked with from seven to nine whitish lines, and a little hairy at the base. The common colour of the petals is a fine blue, but it varies to white, and sometimes to variegated or striped. It has been found with double flowers.—Native of meadows in most parts of Europe.

19. *Geranium Palustre*; *Marsh Crane's Bill*. Peduncles very long, declined; leaves five-lobed, gashed; petals entire; the branches of this species are extremely divaricated, bifariously and obtusely angular. It resembles the twenty-first species in the leaves, but may be distinguished from it by the greater length of the peduncles, which are also recurved before the flowers open, and are not erect, but declined.—Native of Germany, Russia, and Denmark.

20. *Geranium Aconitifolium*; *Aconite-leaved Crane's Bill*. Leaves subpeltate, seven-parted; petals entire, veiny-lined; stems smooth, scarcely a foot high, forked; stipules in pairs at the origin of each branch; a pair of bracts also to each peduncle, which is downy; calicine leaflets ribbed, hairy

awned; petals white, or slightly tinged with pale purple, marked with dark purple lines; antheræ violet, the ends of the calix, the bractes and the upper part of the peduncles are also purple.—Native of Switzerland and Dauphny, flowering in May.

21. *Geranium Sylvaticum*; *Wood Crane's Bill*. Leaves subpeltate, five-lobed, gash-serrate; stem erect; petals emarginate; peduncles sometimes with more than two flowers; bractes four, awl-shaped, small; calicine leaflets ribbed, membranaceous at the edge, mucronate; hairs on the peduncles, and the edges of the leaves, which end in small globules; stamina all nearly equal; aril hairy, with a brown elevated keel, but not rugged.—It flowers in June and July, and is a native of mountainous woods and thickets, in many, and particularly in the northern, parts of Europe. In England it has been observed in Durham, Westmoreland, Cumberland, Lancashire, and Yorkshire; about Aysgarth Force, Wensley-Dale; near Hales Owen in Shropshire; Holtwood at Leziate; and near Lynn in Norfolk.

22. *Geranium Pyrenaicum*; *Mountain Crane's Bill*. Leaves rounded, five-lobed or three-lobed, gashed; petals two-lobed. This species is twice as large as the common sort, and always nearly upright; stem hairy, forked twice or thrice; peduncles solitary, from the forks, upwards from the bosom of the leaves, and longer than the leaves themselves; calicine leaflets broad and short, terminated by a red gland; aril even, sharply keeled, scarcely pubescent.—Native of the south of France, near the Pyrenees; and of England, where it is found about Chelsea, Battersea, and Brompton, in the neighbourhood of London; near Enfield, Oxford, Bingley, and Keighley in Yorkshire.

**** *Peduncles one-flowered, annual.*

23. *Geranium Molle*; *Common Crane's Bill*, or *Dove's Foot*. Peduncles and floral-leaves alternate; petals bifid; calices awnless; stem somewhat erect; root-leaves roundish, hoary, and veiny underneath, deeply divided into seven segments, which are jagged; stem-leaves alternate, divided into fewer, narrower, and more pointed segments; stipules at each joint four, membranous, and withering; peduncles the length and form of the petioles, opposite to them and bifid; pedicels nearly three times shorter, with smaller stipules, some of the hairs on which appear glandular when viewed with a glass; calicine leaflets ovate, three-ribbed, hairy, unequal, terminated by a reddish and somewhat blunt point. It is the most common of all our Geraniums, on dry banks, under walls, in corn-fields and in pastures, beginning to flower in April, and continuing through the summer. It is frequently confounded with the next species.

24. *Geranium Rotundifolium*; *Round-leaved Crane's Bill*. Petals almost entire, equal to the calix, which is somewhat awned; leaves kidney-shaped, lobed, gashed; sinuses glandular; stems much branched, straggling, but scarcely prostrate; peduncles alternate on the stem, and arising from the axil of a leaf, which is always smaller, and on a shorter foot-stalk than its opposite. The leaves are rounder, and of a paler colour; the seeds are dotted, so as to appear reticulated; hairs on the aril spreading. These marks distinguish it from the preceding species. The filaments are clearly distinct at the base; the petals are flesh-coloured or purple, varying to white, emarginate, or obcordate. When fresh gathered, it has a pretty strong scent of musk, but it soon goes off.—It is found on walls, roofs, banks, and in sandy pastures, about Islington, Hackney, Battersea, Wandsworth, Mortlake, and Kew, near London; at Church Brompton, in Northamptonshire; about Bath and Bristol; and is common all over Suffolk.

25. *Geranium Pusillum*; *Small-flowered Crane's Bill*.

Petals emarginate; arils even, with hairs pressed close; stem pubescent; leaves roundish, seven-lobed; lobes trifid, obtuse, some of them more deeply divided; the sinuses rather acute, veiny, villous, soft, pale green; the root-leaves on very long petioles; the stem-leaves opposite, unequal, nearly as long as the peduncles, their lobes more acute; stipules lanceolate, broad at bottom, red, shining; segments sharp, edged with hairs; flowers very small, purplish blue, on peduncles from the axils, about an inch long; corolla a little longer than the calix, bell-shaped, and open; petals obcordate; filaments five, longer, with ovate blue antheræ, five shorter and sterile; seeds kidney-shaped, smooth, reddish; aril pale brown, even, with white hairs pressed close to it. It forms a larger tuft than the twenty-third species, and, like it, sometimes varies with white flowers; it is also equally common in many places, particularly on the west side of London, in neglected gardens and fallow fields, flowering in June and July.

26. *Geranium Lucidum*; *Shining Crane's Bill*, or *Dove's Foot*. Calices pyramidal, angular, raised in wrinkles; leaves five-lobed, rounded; stems and leaves smooth and shining, whence it derives its significant trivial name: they are, however, slightly hairy. In rocky situations, the leaves are only half an inch broad, and not so much divided; flowers on short spreading peduncles, with very minute bractes; petals rose-coloured, emarginate. The aril has several rugged longitudinal ribs, and is hairy at top. The whole plant is sometimes red.—It flowers from June to August, and is a native of most parts of Europe, on walls, roofs, banks, in rocky and shady places, and in a chalky soil among corn.

27. *Geranium Columbinum*; *Long-stalked Crane's Bill*. Peduncles longer than the leaf; leaves five-parted, multifid; calices five-cornered, awned; arils smooth. Slender, mostly procumbent, with small, rigid, close-pressed hairs; pedicels much divaricated; petals reddish blue or pale purple, marked with three lines, emarginate, the little tooth between the lobes not very pointed, antheræ blue. It flowers from June to August.—Native of most parts of Europe, in corn-fields and pastures, and under hedges.

28. *Geranium Incanum*; *Hoary Crane's Bill*. Peduncles two-flowered; calices awned; petals entire; arils hirsute; leaves subdigitate, pinnatifid.—Native of the Cape.

29. *Geranium Dissectum*; *Jagged Crane's Bill*. Peduncles shorter than the leaf; leaves five-parted, trifid, and multifid; petals emarginate; arils villous; stalks many, about a foot long, spreading, roundish, pale green, here and there reddish, beset with short white hairs pointing downwards, jointed, with alternate spreading branches; flowers small, purplish red, on peduncles shorter than the leaves; bractes two, red, minute; calicine leaflets three-ribbed, awned, beset with glandulous hairs; corolla a little shorter than the calix; petals oblong-cordate, emarginate. This plant varies greatly in size, also with flesh-coloured and white flowers. It flowers in May and June, until August.—Native of most parts of Europe, by road-sides, on banks, in fallow fields, and on the borders of pastures.

30. *Geranium Carolinianum*; *Carolina Crane's Bill*. Leaves five-parted, gashed; calices awned; petals emarginate; arils hirsute. This greatly resembles Dove's-foot Crane's Bill, Number 23, but is smaller, and the branches are shorter; the flowers are very small, of a pale blue colour; seeds black, with short erect beaks.—Native of Carolina.

31. *Geranium Bohemicum*; *Bohemian Crane's Bill*. Petals emarginate; arils rough with hairs; cotyledons trifid, with the middle cleft truncate; stems many, branched; leaves five-lobed, crenate, on long footstalks, mostly opposite; flowers on long, slender, axillary peduncles; corolla

of a fine blue colour. In flowers from June to August.—Native of Bohemia.

32. *Geranium Robertianum*; *Stinking Crane's Bill*, or *Herb Robert*. Leaves quinate and ternate, gashed; calices ten-angled; stems spreading, branched, blood-red, hairy, particularly in young plants; stipules four at each joint, two on each side; peduncles very long; pedicels short; calicine leaflets ovate-lanceolate, nerved, hairy, ending in a long awn; petals rose-coloured, varying to white, spreading, and equal; the lamina somewhat heart-shaped; the claw long and linear, the middle part of it prominent, grooved, and spreading into three whitish nerves. The whole is beset with pellucid hairs, but becomes smoother as the plant grows older; it is commonly red at the joints, and the whole plant is frequently red. It has a disagreeable rank smell when bruised. In the variety of this plant, which occurs near Swanving in Dorsetshire, and on the shore of Selsey island, the whole plant is shining, and the leaves smaller, and more deeply divided.—A decoction of this plant has been found to afford relief in the stone and gravel; it is considerably astringent, and is given to cattle when they make bloody water, or have the bloody flux. This plant, says Meyrick, is an excellent vulnerary or wound herb, whether used externally or internally. An ointment made of the green leaves and hog's lard, is good for sore breasts, and has been found serviceable to anoint scrofulous or cancerous swellings with. Cattle have certainly been cured of what the farmers call the black water, and of the bloody flux, by a decoction of this herb, after all other medicines have proved ineffectual; and there is little doubt but its effects on the human body would be equally salutary in similar circumstances. The whole plant should be gathered, root and all, and dried for use; it is a most excellent astringent; scarcely any plant is in that respect equal to it: it may be given dried or powdered, or in decoction. It stops overflows of the menses, bloody stools, and all other hæmorrhages. It is to be observed, that nature seems to have set her stamp upon several herbs, which have the virtue to stop bleedings; this and the Tutsan, the two best remedies the fields afford for outward and inward bleedings, become all over as red as blood at a certain season. The name *Stock-bill* is set down in Dr. Withering's arrangements; which is probably a corruption of *storkbill*.—Native of all parts of Europe, in woods, under hedges, in hollow trees, on walls, and the roofs of houses, among rubbish, and in stony places, flowering from April through the whole of the summer.

Geranium. See *Erodium*, and *Pelargonium*.

Gerardia; (so called, in honour of John Gerard, the celebrated English botanist,) a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, upright, sharp, permanent. *Corolla*: one-petalled, ringent; tube round, longer than the calix; upper lip upright, blunt, flat, broader, emarginate; lower lip reflex, three-parted; divisions lateral, emarginate; middle shorter, two-parted. *Stamina*: filamenta four, scarcely the length of the tube, two a little shorter; antheræ small. *Pistil*: germen ovate, small; style simple, short; stigma blunt. *Pericarp*: capsule ovate, two-celled, two-valved, gaping at the base; partition contrary. *Seeds*: ovate, solitary. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Corolla*: two-lipped; lower lip three-parted; the lobes emarginate; the middle segment two-parted. *Capsule*: two-celled, gaping.—The species are,

1. *Gerardia Tuberosa*; *Tuberous Gerardia*. Leaves sub-ovate, tomentose, repand, the length of the stalk; root-leaves as on the spike; bractes imbricate, one-flowered; border of the corolla wheel-shaped.—Native of South America.

2. *Gerardia Japonica*; *Japanese Gerardia*. Leaves ovate, gash-pinnatifid, petioled; stalk simple; flowers axillary, peduncled, solitary; peduncles many times shorter than the leaves; corolla purplish; stalk villose.—Native of Japan.

3. *Gerardia Delphinifolia*; *Larkspur-leaved Gerardia*. Leaves linear, pinnatifid; stalk somewhat branched; stem a foot high, obtusely four-cornered, upright, even, with few alternate branches; flowers axillary, from the middle to the top of the stem, opposite, directed one way, on very short peduncles; corollas oblong, with a gaping mouth, and a five-lobed rounded border, the two upper lobes shorter.—Native of the East Indies.

4. *Gerardia Scabra*; *Rough Gerardia*. Hispid, scabrous; leaves oblong, pinnatifid.—Native of the Cape of Good Hope.

5. *Gerardia Purpurea*; *Purple Gerardia*. Leaves linear; root annual; stalks a foot high, filiform, either very simple, or brachiate, smooth; flowers opposite, on one-flowered filiform peduncles, or else sessile; calices smooth, small, bell-shaped, five-toothed; corollas very deep purple, either wheel-shaped or bell-shaped, or tubular.—Native of North America.

6. *Gerardia Tubulosa*; *Long-tubed Gerardia*. Smooth: leaves linear, entire, sharp; tube of the flower longer than the calix.—Native of the Cape of Good Hope.

7. *Gerardia Flava*; *Yellow Gerardia*. Leaves lanceolate, pinnate-toothed; stalk extremely simple, about a foot high; spike terminating, lax, consisting of opposite large yellow flowers: there is no fifth stamen.—Native of North America.

8. *Gerardia Pedicularia*. Leaves oblong, doubly serrate; stalk panicled; calices crenate; corollas pubescent on the outside, oblong, patulous.—Native of North America.

9. *Gerardia Glutinosa*. Leaves ovate-serrate; bractes linear, hispid; stem roundish, upright, with short branches; racemes terminating, solitary, composed of opposite flowers, on very short peduncles; calices five-parted, sharp, the uppermost division largest; a filiform bracte or two, of the same length with the calix, is close to it, hispid, like that, with glutinous hairs.—Native of China.

10. *Gerardia Nigrina*. Scabrous: leaves lanceolate, serrate at bottom; stalk four-cornered. This was formerly made a distinct genus by Linneus, under the name of *Nigrina*, but he was afterwards of opinion that it could not be separated from the *Gerardias*.—Native of the Cape.

Germander. See *Teucrium*.

Geropogon; a genus of the class Syngenesia, order Polygamia Equalis.—GENERIC CHARACTER. *Calix*: common, simple, many-leaved; leaflets lanceolate-subulate, keeled, upright, longer than the corolla. *Corolla*: compound, subimbricate, uniform; corollules hermaphrodite, outer as many as there are leaflets in the calix, inner fewer, shorter, proper, one-petalled, ligulate, truncate, five-toothed. *Stamina*: filamenta five, very short; antheræ cylindric, tubular. *Pistil*: germen oblong; style filiform, the same length with the stamina; stigmas two, bowed back, filiform. *Pericarp*: none; calix oblong, upright, gaping. *Seeds*: of the ray subulate, the same length with the calix; down with five patulous awns; of the disk subulate, shorter; down feathered. *Receptacle*: with bristle-shaped chaffs. *Observe*: there is a species with a caliced calix. ESSENTIAL CHARACTER. *Calix*: simple. *Receptacle*: with bristle-shaped chaffs. *Seeds*: of the disk, with a feathered down; of the ray, with five awns. For the propagation and culture of this species, see *Tragopogon*.—The species are,

1. *Geropogon Glabrum*; *Smooth Geropogon*, or *Old Man's Beard*. Leaves smooth. It has an upright stalk more than a foot high, with long grass-like leaves; the stalk branches at

top into two or three divisions, each terminated by one flesh-coloured flower. The whole plant is smooth, and abounds with a milky bitterish juice: calix usually seven-leaved.—It is an annual plant, and a native of Italy.

3. *Geropogon Hirsutum*; *Rough Geropogon*. Leaves hairy; stalks upright, a foot high. It seldom divides into branches, but is terminated by one flower: annual.—Native of Italy.

3. *Geropogon Caliculatum*; *Perennial Geropogon*. Calices calicled; root perennial; stems ascending, several, branched, a foot or more high, villose, and leafy; flowers terminating, nodding before they open; leaves sub-linear, acuminate, the lowest stem-leaves and the root-leaves channelled beneath, and hairy on both sides, the upper ones flat, and a little hirsute only on the back; corolla yellow on both sides; receptacle naked.—It flowers in June, and is a native of Italy.

Gesneria; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, superior, five-cleft, sharp, permanent. *Corolla*: one-petalled, incurved and recurved; tube thickish, with a contracted neck and funnel-form throat; border five-cleft, blunt; upper divisions concave, three lower flat, spreading. *Stamina*: filamenta four, shorter than the corolla; antheræ simple. *Pistil*: germen inferior, flattened; style filiform, the same in situation and length with the stamina; stigma capitate. *Pericarp*: capsule roundish, and crowned with the patulous calix, subbilocular; partition in the middle, longitudinally interrupted. *Seeds*: extremely numerous, and very small; receptacles on each side fastened to the partition. *Observe*: If the capsule be cut transversely near the top, it appears to be one-celled; if through the middle, two-celled. **ESSENTIAL CHARACTER.** *Calix*: five-cleft, sitting on the germen. *Corolla*: incurved and recurved. *Capsule*: inferior, two-celled.—The species are,

1. *Gesneria Humilis*; *Low Gesneria*. Leaves lanceolate, serrate, sessile; peduncles branched, many-flowered; root diffused, creeping; stem branched, naked at bottom; peduncles branched, three-flowered.—Native of Carthage, in New Spain. This, like all the plants of the genus, is propagated by seeds, which must be procured from the country where they naturally grow. They should be brought over in their capsules, for as they are very small and light, when they are separated from the partition to which they adhere, they soon lose their vegetative power. These seeds should be sown in pots filled with light earth, and plunged into a hot-bed of tanners' bark as soon as they arrive, for they sometimes lie long in the ground: those which Mr. Miller sowed in autumn, came up in the following spring; therefore when they happen to arrive here at that season, the pots in which the seeds are sown should be plunged into the tan-bed in the stove, and during the winter the earth should be now and then gently watered, to prevent it from becoming too dry, but at the same time it must not be made too moist. In the spring, the pots should be removed out of the stove, and plunged into a fresh hot-bed, which will bring up the plants soon after. When these are fit to remove, they should be each planted in a separate pot, and plunged into a good hot-bed of tan, observing to shade them till they have taken new root, and afterwards treat them in the same way as other plants from the same countries. In autumn they must be plunged into the tan-bed in the stove, where during the winter they should have but little water given to them, for if they receive much wet, it will destroy them: in this stove the plants must constantly remain, for they will not thrive when taken out of the tan. In the summer, free air should always be admitted to them during warm weather, and

they should at that time also be frequently refreshed with water, but in small quantities. As the plants advance in growth, they will require larger pots, but there must be care taken not to overpot them, for they will not thrive in large pots. With this management, the plants will flower in the second year, and may be continued three or four years; but they are not of long duration in their native country.

2. *Gesneria Acaulis*; *Stemless Gesneria*. Leaves lanceolate-ovate, serrate, subpetioled, crowded at the end; peduncles three-flowered, shorter than the leaf; stem round, woody, having a clay-coloured bark, with some furrows in it, rising three or four inches high, having at the top very many oblong leaves, standing very thick, without any order, on foot-stalks a quarter of an inch in length, covered with a reddish wool-like moss. They are seven inches long, and an inch and a half broad near the farther end, whence they narrow to a point, and also grow gradually narrower to the foot-stalk; from the axils come out small peduncles, branched, sustaining scarlet flowers an inch long, which are followed by a short, fungous, cornered seed-vessel, having no distinct cells, containing many small, oblong, yellowish seeds. Browne calls it, *Small-twisted Gesneria with scarlet flowers*, and observes, that the stem is always simple, creeping along the rocks, and bearing a pretty large tuft of leaves at each extremity, with single flowers springing from each axil.—Native of Jamaica. For its propagation and culture, see the first species.

3. *Gesneria Tomentosa*; *Woolly Gesneria*. Leaves ovate-lanceolate, crenate, hirsute, seven or eight inches long, and two and a half broad in the middle; peduncles lateral, very long, corymbiferous. This rises with a shrubby stalk to the height of six or seven feet, dividing into two or three irregular branches, covered with a russet wool; corolla irregular, subcampanulate, gibbous at the base and under the limb; the two upper segments approximate, so as to form one as it were that is bifid, arched in the middle, spotted on the inside with yellow and dark purple; the three lateral ones are spreading, ovate-acute, the lowest ventricose underneath; the tube is spotted within; the two interior filamenta are longer than the two others, and are bowed in towards the pistil; antheræ convex. This plant bears some affinity to the saxifrages, in the situation of the receptacles, and in the opening of the capsule. Browne calls it the *Hairy erect Gesneria with open flowers*.—Native of Jamaica. For its propagation and culture, see the first species.

4. *Gesneria Craniolaria*. Leaves wedge-shaped, oblong, tooth-lacinate; peduncles terminating; corollas bell-shaped. It rises with a shrubby stalk to the height of ten or twelve feet, dividing upwards into a few branches, which are garnished with spear-shaped leaves, cut on their edges, these are soft and hairy; the flowers are produced from the side of the branches, growing several together on the same foot-stalk, they are shaped like those of the Foxglove, of a greenish yellow colour, with brown spots on the inside; the flowers have a swelling tube, which is recurved; and the brim is slightly divided into five unequal segments. They appear in July, but are not succeeded by seeds in England.—This sort grows naturally at the Havannah, and in some other islands of America.

5. *Gesneria Grandis*. Leaves broad-lanceolate, very long, toothletted, rough-haired above, rugged beneath; peduncles terminating; stem arborescent.—Native of Jamaica.

6. *Gesneria Scabra*. Leaves ovate-lanceolate, serrate, rugged; peduncles axillary; corollas cylindrical, recurved.—This is a shrubby plant, and a native of Jamaica.

7. *Gesneria Corymbosa*. Leaves ovate, acute, serrate

scariose, sharp; peduncles many-parted; flowers in corymbs, shrubby.—Native of Jamaica.

8. *Gesneria Exserta*. Leaves ovate-lanceolate, crenate, smooth; peduncles three-flowered; genitals twice the length of the corolla; capsules ovate, shrubby.—Native of Jamaica.

9. *Gesneria Calycina*. Leaves lanceolate-ovate, acuminate, serrate, smooth; peduncles three-flowered; genitals longer than the corolla; calices bell-shaped; capsules cylindric.—It is a shrubby plant, and a native of the West Indies.

10. *Gesneria Ventricosa*. Leaves elliptic, acuminate, crenate, smooth; peduncles four-flowered or thereabouts; segments of the calix awl-shaped, elongated; corollas ventricose.—This also is a shrubby plant, and a native of Jamaica.

11. *Gesneria Pulchella*; *Fair Gesneria*. Herbaceous: leaves ternate, ovate, acute, serrate, villose; peduncles axillary, one-flowered. Browne describes this as having a slender even stem, seldom rising above ten or fourteen inches in height, and throwing out a beautiful single reddish flower from the axil of each of the upper leaves; filamenta longer than the corolla, and somewhat twisted as they rise.—Native of Jamaica. This sort deserves to be cultivated in the flower-gardens of America. It thrives best in a cool gravelly soil, well furnished with moisture, and intermixed with rich mould.

12. *Gesneria Pumila*. Stemless: leaves ovate-wedge-shaped, crenate, subsessile; peduncles subbiflorous, shorter than the leaves.—Native of Jamaica.

Gethyllis; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none, unless a sheath obliquely truncate. *Corolla*: one-petalled, superior; tube long, filiform, radical; border expanding, flat, six-parted; divisions oblong. *Stamina*: filamenta six, inserted into the mouth of the tube, shorter than the border, usually divided; antheræ linear, spirally bent in. *Pistil*: germen inferior; style simple, longer than the stamina; stigma capitate. *Pericarp*: berry club-shaped, blunt, radical, (sessile in the bulb itself, and proceeding from it,) somewhat fleshy, one-celled. *Seeds*: nestling, one upon another in three rows, globular, smooth. *Observe*. In some flowers, particularly those of the second species, the filamenta are divided above the base, with as many antheræ; but two antheræ are seldom seen on a single filamentum; so that the same flower may have eight, ten, or more antheræ. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: six-parted. *Berry*: club-shaped, radical, one-celled. All the plants of this genus have the habit or air of *Colchicum*, but are sufficiently distinguished from it, by having a monopetalous corolla, and a berry for a fruit. There is but one flower on a naked stalk; and the fruit has a grateful odour, with a pleasant taste.—The species are,

1. *Gethyllis Villosa*; *Hairy Gethyllis*. Leaves linear, filiform, spiral, villose; segments of the corolla ovate-oblong.—Native of the Cape of Good Hope.

2. *Gethyllis Ciliaris*; *Fringed Gethyllis*. Leaves linear, spiral, ciliate, three or four inches high; flower the height of the leaves, greenish-white, the size of a daffodil; segments of the corolla ovate-oblong.—Native of the Cape.

3. *Gethyllis Spiralis*; *Spiral Gethyllis*. Leaves linear, spiral, smooth; segments of the corolla oblong. It has been long known in Europe.—Native of the Cape of Good Hope.

4. *Gethyllis Lanceolata*; *Lanceolate Gethyllis*. Leaves lanceolate, flat; segments of the corolla lanceolate.—Native of the Cape of Good Hope.

Geum; a genus of the class Icosandria, order Polygamia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, ten-cleft, uprightish; segments alternately very small, sharp. *Corolla*: petals five, rounded; claws the length of the calix,

narrow, inserted into the calix. *Stamina*: filamenta numerous, subulate, length of the calix, into which they are inserted; antheræ short, broadish, blunt. *Pistil*: germina nuncrous, collected into a head; styles inserted into the side of the germen, hairy, long; stigmas simple. *Pericarp*: none; common receptacle of the seeds oblong, hirsute, placed on the reflex calix. *Seeds*: numerous, compressed, hispid, awned, with a long style. ESSENTIAL CHARACTER. *Calix*: ten-cleft. *Petals*: five. *Seeds*: with a kneed awn.—This genus consists of perennial herbaceous plants. The leaves are usually unequally pinnate, with the terminating leaflet larger than the rest; the stipules fastened to the petiole; and the peduncles terminating or axillary, supporting few flowers, sometimes only one.—The species are,

1. *Geum Virginianum*; *American Avens*. Flowers upright; awns hooked, naked; stem-leaves ternate, the upper ones lanceolate; petals shorter than the calix; stem a foot and a half or two feet high, branching at top into small peduncles, each terminated by a small white flower.—It flowers in July and August, and is a native of North America.

2. *Geum Strictum*; *Upright Avens*. Flowers upright, yellow; awns hooked, naked; stem-leaves pinnate; leaflets and stipules gash-cleft; petals longer than the calix; stems upright, round, a foot and a half high and more, most of the branchlets ending in one-flowered peduncles; root-leaves pinnate, and petioled, with the outmost leaflet very large, rounded and lobed; the side ones ovate, differing much in size, all sessile, and unequally serrate; sometimes the extreme leaflet is trifid palmate; sometimes, but more rarely, all the leaflets are deeply gashed; stem-leaflets lanceolate, and acute. It flowers in May and June. The whole plant is covered with whitish hairs; the fruit is also hairy.—Native of North America.

3. *Geum Urbanum*; *Common Avens*, or *Herb Bennet*. Flowers upright; awn hooked, naked; stem-leaves ternate; root-leaves lyrate-pinnate; stalks from one to two feet high, nearly upright, somewhat flexuose, slightly angular, hairy, branched at top; peduncles single, nearly upright, round, somewhat hairy, supporting one flower; corolla small, yellow, with very short claws; filamenta yellowish, at first bent in, afterwards upright, half as long as the larger segments of the calix; antheræ roundish, yellow, turning brown, having hairs about the edge visible only in a glass; germina hairy; styles smooth, purple, fixed to the top of the germen.—The roots have a mildly astringent aromatic taste, somewhat like that of cloves, whence this plant has the name of *Caryophyllata*. They should be gathered in dry warm situations, for in shady moist places they have little virtue. Gathered in the spring, and put into fresh ale, they communicate a pleasant flavour, and prevent it from turning sour. Infused in wine, it is esteemed to be a good stomachic; but in water, Haller declares it to have been attended with bad effects, producing delirium, when given to those labouring under malignant fevers. The roots chewed in the mouth are said to relieve an offensive breath. Meyrick describes it to be of a mild, austere, aromatic nature, perfectly adapted to strengthen the head and stomach. A drachm of the powder taken in a glass of wine dissolves and disperses inward congealed blood, occasioned by falls and bruises: it is also efficacious in the bloody flux, and other profuse purgings and spittings of blood. Boiled in water, in the proportion of an ounce to a pint and a half, until one-third of the fluid be wasted, or, which is better still, infused in half a pint of red-port for the space of twelve hours, and the whole quantity taken at the coming on of an ague-fit, has frequently been known to cure that disorder. Hill calls it a cordial and sudo-

rific, and says that it is good in nervous complaints, and that he has known it alone to have cured intermittent fevers, even where the bark has been unsuccessful. The root has been found useful in several chronic disorders, as a general tonic and astringent; and experiments evince its antiseptic power to exceed that of the Peruvian bark.—This, like all the other plants of the genus, may be propagated by seeds, which should be sown in autumn; for when they are sown in the spring, they do not grow the same year.

4. *Geum Japonicum*. Flowers upright; fruits hirsute; awns naked; leaves with three lobes or more; stalk round, flexuose, upright, hirsute, a foot high or more, sometimes, but seldom, a little branched at top; branches alternate, very short, somewhat tomentose; flowers terminating the stem and branches, solitary.—Native of Japan.

5. *Geum Rivale*; *Water Avens*. Flowers nodding; awns hooked, villose; petals retuse, roundish-wedge-shaped; leaves pinnate; root creeping, reddish, astringent, aromatic, smelling like cloves; stem a foot high, upright, round, and branched, bending at top, but becoming erect as the fruit ripens; peduncles purplish, hirsute, with hairs terminating in a red globule, becoming less bent as the seeds ripen. It flowers from the end of May till autumn, and varies with yellow flowers, which frequently become double and profuse. The powdered root is beneficial in diarrhoeas and hæmorrhages; and is much used by the Canadians in the cure of tertian agues. It will cure malt-liquor of its ropiness.—Native of most countries in Europe, where it is found in moist pastures and woods, and indicates, according to Linneus, a barren soil, unfit for corn. It is also found in the Levant, and in North America. With us it is more common in the north; as, on the water of Leith near Edinburgh, and other parts of Scotland, on moorish grounds; near Settle and Ingleton, in Yorkshire; in Lancashire, and generally by the sides of rivers, and on mountains, in many parts of the northern counties; near Chevely and Wood-Diton in Cambridgeshire; in Wolverton wood near Lynn; at Marham near Swaffham, and near Norwich in Norfolk; in a bog near Sudbury in Suffolk; near Aston in Warwickshire; and upon Snowden, and various parts of Wales.

6. *Geum Hybridum*; *Mule Avens*. Flower nodding; calix leafy, longer than the polypetalous corolla. This seems to be a mule plant, produced between the foregoing and subsequent species: it is much taller than the first, and a larger plant. The lower leaves are interruptedly pinnate, with three pairs of leaflets, besides the smaller ones, and that at the end, which is very large; calix duskier purple, tinged with green; corolla yellow, only tinged with purple at the edge, about the same length with the calix, having sometimes more petals than five.

7. *Geum Montanum*; *Mountain Avens*. Stem one-flowered; awns straight, villose; leaves pinnate, hairy; outmost leaflet very large and roundish, the lower ones gradually smaller; root-leaves in a tuft, on petioles of different lengths; these are hairy, and have several pairs of leaflets on them, the lowest very small, the succeeding ones gradually larger, and the pair immediately under the great terminating leaflet much bigger than any of the rest; the extreme leaflet is two or three inches in length and breadth, obscurely lobed, gash-serrate, and veined; flowers large, solitary, spreading, upright; calix wide, hairy, green. The small mountain avens is made a distinct species by Mr. Miller, who says that it is a very low plant, with flower-stalks about three inches long, bending on one side, each terminated by one bright yellow flower.—In its native places it flowers in June and July, and in our gardens from May to September.—Native of

the mountains of Switzerland, Austria, Silesia, and Dauphiny.

8. *Geum Potentilloides*; *Siberian Avens*. Stem one or two flowered; awns straight, naked; calices of the fruit upright; leaves pinnate-toothed. On account of the ripe calix being bell-shaped, the corolla yellow and five-petalled, the receptacle elongated, the awns naked and jointed, this approaches nearer to a *Geum* than a *Dryas*. Receptacle cylindrical, slender, excavated, naked, a little shorter than the calix; seeds numerous, obovate, gibbous on one side, thence comprised into a straight keel, shagreened on all sides with raised dots, of a brown ferruginous colour; awn straight like a needle. It flowers in June.—Native of Siberia.

9. *Geum Reptans*; *Creeping Avens*. Stems one-flowered; awns straight, villose; leaves pinnate, gashed, hairy; runners creeping; root large and woody; flower much larger than the seventh species; calix green, with the segments often reddish; petals yellow, emarginate, marked with lines much larger than the calix; the whole corolla sometimes two inches in diameter.—It flowers in June and July, and is a native of Switzerland, Austria, Silesia, Savoy, and Piedmont.

Ghinia; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, permanent; mouth expanded, five-toothed, acuminate. *Corolla*: one-petalled, irregular; tube long, narrow; border two lipped; upper lip largest, roundish, concave, ascending; lower three-parted; segments roundish; the middle one largest, bent down, emarginate. *Stamina*: filamenta four, inserted into the tube above the base, two longer than the others; antheræ with oblong cells, one at the end, fertile in the longer filamenta, barren in the shorter, the other inserted towards the middle of the filamentum, in the shape of a scale. *Pistil*: germen roundish; style the length of the tube; stigma four-lobed. *Pericarp*: drupe turbinate, angular, longer than the calix, which is permanent. *Seed*: nut angular, four or five celled, with one seed in each cell; according to Swartz, four-cornered, four-spined at the end, four-celled, with solitary kernels. ESSENTIAL CHARACTER. *Calix*: five-toothed; teeth acuminate. *Corolla*: two-lipped. *Stamina*: four, with two barren antheræ at the end of the shorter filamenta. *Pericarp*: a drupe containing a four or five celled nut, with a seed in each cell; Swartz calls it a fleshy four-celled nut.—The species are,

1. *Ghinia Spinosa*. Fruits four-spined; stem slender, woody, branching, nearly three feet high; leaves oval, sharply indented, light green, on short footstalks; flowers distant, sessile, in a loose spike, on slender, naked, axillary peduncles, six or seven inches in length; corollas small, bright blue; seeds two, terminated by short awns, and inclosed in the calix.—Annual, and a native of the West Indies.

2. *Ghinia Mutica*. Fruits without spines; stems strong, straight, and a little woody; leaves rounded or subovate, deeply toothed, having short hairs on both surfaces; petiole three or four lines in length; spikes axillary, opposite; flowers solitary, few, alternate, pedicelled, with a small linear bracte at the base of each pedicel; corolla blue.—Native of Guiana, and the island of Cayenne.

Gilliflower; See *Dianthus*.

Gilliflower, Stock. See *Cheiranthus*.

Gilliflower, Queen's, or Dame's Violet. See *Hesperis*.

Ginannia; a genus of the class Enneandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth double; outer one-leafed, bifid, acute; inner one-leafed, cup-shaped, four or five cleft; segments oval, concave, obtuse, spreading, one larger than the rest. *Corolla*: petals three, oblong, obtuse, fringed, spreading, inserted into the larger segment

of the calix at the base. *Stamina*: filamenta nine, filiform, flexuose, longer than the corolla, inserted into the mouth of the calix; antheræ paralleliped, versatile. *Pistil*: germen oblong, compressed at the bottom of the calix, affixed to a pedicel, with a membranaceous wing at top; style filiform, flexuose, the length of the stamina; stigma obtuse. *Pericarp*: legume long, straight, one-celled, two-valved, pedicelled. *Seeds*: very many, oval, flattened, smooth. **ESSENTIAL CHARACTER.** *Calix*: double, both one-leaved. *Petals*: three, fringed, spreading. *Germen*: pedicelled, with a membranaceous wing at top.—The only known species is,

1. *Ginannia Guianensis*. This is a shrub, growing to the height of fifteen feet, beginning to be branched at one or two feet from the ground; leaves alternate, entire, smooth, ovate-oblong, acuminate, subsessile, the largest six inches long, and two inches and a half wide; stipules minute, in pairs at the base of the petioles; flowers terminating, few, red, large, and handsome, on a short peduncle, on which are four or five soft green scales or bracts; legume reddish, linear, compressed, three inches long.—Native of the forests of Guiana, flowering in February, and fruiting in May.

Ginger. See *Amomum*.

Ginkgo; a genus hitherto imperfectly described, the only known species of which is,

1. *Ginkgo Biloba*, or *Maidenhair Tree*. This tree grows to a prodigious size; with a trunk frequently as thick as the largest Oak; the branches are alternate, and spreading; leaves alternate, petioled, in bundles at the knots or tubercles of the branches, not much unlike the leaves of *Maidenhair*; of the fructification, we yet know very little with certainty. The flowers are male and female, separate, probably on different trees. They come out in April, before the leaves, and from the same bud with them, towards the end of the branches, on aments or catkins, as *Kæmpfer* describes them, pendent, and longish, abounding in pollen. The fruit grows on a thick fleshy peduncle, an inch in length, and, having figured them single, *Kæmpfer* describes them as round or oblong, of the size and appearance of a damson or damascene plum, with a warted surface, becoming yellow as the fruit ripens, and a fleshy, juicy, white pulp, adhering very closely to the nut, which resembles that of the pistachia, but is almost double the size, and more of the form of an apricot stone; the shell is woody, thin, brittle, and whitish, and the kernel is white, rather firm, sweet, with a mixture of austerity or bitterness when raw, but is agreeable when gently roasted on the coals, before the skia is taken off; and in that state, is supposed to help digestion.—Native of Japan and China.

Ginora; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved; tube bell-shaped; border six-cleft; segments lanceolate, spreading, coloured, permanent. *Corolla*: petals six, roundish, spreading, longer than the calix, with long claws inserted into the neck of the calix. *Stamina*: filamenta twelve, subulate, patulous, as long as the calix, and inserted into it; antheræ kidney-shaped. *Pistil*: germen roundish, flattened; style subulate, the same length with the corolla, permanent; stigma obtuse. *Pericarp*: capsule flattened and roundish, shining, coloured, somewhat four-grooved, four-valved, one-celled, gaping at the tip. *Seeds*: very many, minute; receptacle roundish, large. **ESSENTIAL CHARACTER.** *Calix*: six-cleft. *Petals*: six. *Capsule*: one-celled, four-valved, coloured, containing many seeds.—The only known species is,

1. *Ginora Americana*. It grows upright, to the height of three or four feet, and divides into smooth branches, round,

except that they are compressed at the origin of the twigs and leaves, all woody; leaves lanceolate, acute, quite entire, smooth, spreading, an inch and a half long, on very short petioles; peduncles slender, spreading, solitary, an inch in length; flowers handsome, almost an inch in diameter, without any scent; calix red; corolla blue; capsule dark red, outwardly resembling a berry. It is an elegant shrub, with the appearance of *Myrtle*.—Native of Cuba, by river sides, where it is called *rosa del rio*, or *river rose*.

Ginseng. See *Panax*.

Gisekia; a genus of the class Pentandria, order Pentagynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate, concave, blunt, scarious at the edge, permanent. *Corolla*: none. *Stamina*: filamenta five, subulate, ovate at the base, short; antheræ roundish. *Pistil*: germen superior, roundish, retuse, five-parted; styles short, bowed back; stigmas blunt. *Pericarp*: capsules five, roundish, somewhat flattened, scabrous, blunt, approximating. *Seeds*: solitary, ovate, smooth. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: none. *Capsules*: five, approximating, roundish, one-seeded.—The only known species is,

1. *Gisekia Pharnaeioides*; *Trailing Gisekia*. Stalks herbaceous, decumbent, smooth, round, scored with a line on the upper side, a foot long, with remote joints; branches of the base alternate; leaves opposite, petioled, elliptic-lanceolate, quite entire, blunt, smooth and even, spreading; peduncles mostly axillary, solitary, round, naked; umbel simple, many-flowered; flowers green on the outside, white within, hanging down, except on the day of flowering; fruit blackish. It is an annual plant, flowering here in June; and a native of the East Indies.

Githago. See *Agrostemma*.

Glabraria; a genus of the class Monadelphica, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, five-cleft, shorter by half than the corolla. *Corolla*: petals five, lanceolate, blunt, equal; nectary surrounding the germen, consisting of five subulate, upright, coloured bodies, the length of the calix. *Stamina*: filamenta thirty, capillary, interposed between the nectaries, in sixes, connected at the base, the same length with the calix, antheræ kidney-shaped. *Pistil*: germen subglobose; style filiform, the length of the stamina; stigma simple. *Pericarp*: drupe juiceless, one-celled. *Seeds*: a bony oval nucleus. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Petals*: five. *Nectary*: composed of five bristles, the length of the calix. *Stamina*: thirty, always in sixes. *Pericarp*: a drupe.—The only known species is,

1. *Glabraria Tersa*. A large tree, resembling *Laurus Camphora*, or the *Camphor-tree*. Leaves alternate, petioled, ovate, lanceolate, quite entire, smooth, acuminate, subtomemose underneath, even nevertheless, and glaucous; flowers white, in little axillary balls, forming a sort of raceme, leafless, and much shorter than the leaves. The wood of this tree is very light and pale-coloured, not being liable to the rot, or to the attacks of insects: it is much used in the East Indies for house and ship building.

Gladiolus; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: a spathe, two-valved, inferior, shorter than the corolla; valves oblong, permanent, the outer one larger, inclosing the inner. *Corolla*: one-petalled, superior; tube cylindrical, bent; border somewhat bell-shaped, six-parted; segments oblong, from erect patulous, the uppermost and lowest lateral, either without or within. *Stamina*: filamenta three, inserted into the orifice of the tube, filiform, shorter than the corolla; antheræ ovate, incumbent. *Pistil*: germen inferior, triangular; style fili-

form; stigmas three, rolled back, and spreading, blunt, villose. *Pericarp*: capsule ovate, three-cornered, blunt, three-celled, three-valved. *Seeds*: very many, smooth. Gærtner observes, that *Antholyza* may be very well placed in this genus. **ESSENTIAL CHARACTER.** *Corolla*: six-parted, irregular, unequal. *Stigmas*: three.—The species are,

1. *Gladiolus Communis*; *Common Corn Flag*. Leaves sword-shaped; flowers distant; root round, compressed, yellowish, covered with a brown furrowed skin; hence spring two sword-shaped leaves, embracing each other at the base; and between them rises the flower-stalk, growing nearly two feet high, having one or two narrow leaves embracing it like a sheath, and terminated by five or six purple flowers, one above another at some distance, ranged on the same side of the stalk. Mr. Miller makes three species of this. 1. That above described, with the flowers disposed on one side of the stalk, varying with white and flesh-coloured flowers, which Gerarde calls the Italian Corn-flag: 2. the Italian, or *Utrinqve Floridus* of Caspar Bauhin, with flowers on each side the stalk, of which, he says, there is also a variety with white flowers, called by Gerarde and Parkinson, the French Corn-flag: 3. the Great Corn-flag of Byzantium, which has larger roots, but of the same form; the leaves are also much broader and larger, with deeper channels. The flower-stalks rise higher; the flowers are much larger, of a deeper red colour, and the sheaths are longer. It makes a fine appearance when in flower, and is worthy of a place in every good garden, especially as the roots do not increase so rapidly as to become troublesome. Parkinson, besides the French, Italian, and Byzantine Corn-flags, has three varieties, the bluish, white, and small purple.—The Common Corn-flag requires no care; for when it is once planted, it will multiply fast enough. The Byzantine Corn-flag has latterly supplanted it. This is propagated by offsets, which are sent off from the roots, in the same manner as Tulips. The roots may be taken out of the ground at the end of July, when their stalks decay, and may be kept out of the ground till the end of September, or the beginning of October, at which time they should be planted in the borders of the flower-garden, where they will thrive in any situation, and being intermixed with other flowers of the same growth, add much to the variety.

2. *Gladiolus Imbricatus*; *Netted Corn-flag*. Leaves sword-shaped; flowers imbricate, small, all directed one way, of a purple or crimson colour.—Native of Russia.

3. *Gladiolus Alatus*; *Winged Corn-flag*. Leaves sword-shaped; the side petals very broad; stem a span high, thickish, flexuose between the flowers; upper lip of the corollas sickle-shaped, narrow; side petals or wings of the same length, rhomb-shaped, very broad; lower lip three-parted; the leaflets ovate and equal.—Native of the Cape of Good Hope. This, and all the other Cape sorts, may be increased by offsets, which should be planted in a warm border of kitchen-garden earth; and in winter they should be covered with glasses or mats, to guard them from the frost. A slight shelter has preserved those in pots under a common frame, and even some that were planted in the full ground, when the frost has not been severe. But it has always been remarked, that those plants, which were hardily treated, grew much stronger than those which were placed in a moderate degree of warmth; so that where it is convenient to cover a warm border with glasses in the winter, if these roots be planted under them in the full ground, and only protected from frost, there will be a greater probability of their flowering, than under any other mode of culture. They may also be propagated by seeds, which are often perfected in England: the seeds should be

sown at the end of August, in pots filled with light earth, and placed in a shady situation till the middle of September; the pots should then be placed so as to enjoy the sun during the greater part of the day, until October, when they must be removed under a hot-bed frame, where they may be protected from frost and great rains, but enjoy the free air in mild weather. In the spring, the young plants will appear, and will require a little water once in eight or ten days; but it should be very sparingly given. In May, when the danger of frost is past, the pots should be removed to a sheltered situation, where they may have the morning sun till noon, and, if the season prove dry, be now and then refreshed with water. Towards the latter end of June, the leaves of these plants will decay; the roots should then be taken up, and may be mixed with sand, and kept in a dry room till the end of August, when they should be planted again; and, as the roots are small, four or five may be set in each halfpenny pot filled with light earth, and placed where they may have only the forenoon sun till the middle of September, when they should have a warmer situation, and in October should be placed under a hot-bed frame as before, and treated in the same way during the winter. In the spring, they must be placed in the open air till their leaves decay, when they may be again taken out of the ground, and treated in the same manner as before; but as the roots will have grown to a larger size, when they are planted again, they should each have a separate halfpenny pot, because they will not now be large enough to flower, and may be treated as the old roots.

4. *Gladiolus Tubiflorus*; *Long-tubed Corn Flag*. Leaves linear-lanceolate, villose, somewhat plaited, longer than the scape; tube very long; spathes hirsute; stem round, villose, a finger's length; flowers sessile, mostly on one side; bractes three at the base of each germen, hirsute, acuminate; the outer an inch and a half long, the inner half that length; stigmas somewhat wedge-shaped, villose above. It flowers in June.—Native of the Cape. See the preceding species.

5. *Gladiolus Plicatus*; *Hairy Corn Flag*. Leaves oblong-lanceolate, villose, plaited; tube longer than the spathes; root round, compressed, about the size of the small Spring Crocus; the skin red; from this arise five or six sword-shaped hairy leaves, from two to four inches long, and one-third of an inch broad, dark green, sitting close at the base, but spreading upwards like the sticks of a fan; between these rises the flower-stalk, six or eight inches in length, naked to the top, terminated by a spike of deep blue flowers; corolla divided to the base into six obtuse parts, equal in size and division. It flowers in May, and the seeds ripen in July; soon after which, the stalk and leaves decay to the root.—Native of the Cape. See the third species.

6. *Gladiolus Strictus*; *Upright Corn Flag*. Leaves linear-lanceolate, villose, plaited; tube equal to the spathe. This varies with a blue corolla; the tube and the base of the segments are very dark purple; and with a pale purple corolla, the tube blue. It flowers in June; and is a native of the Cape. See the third species.

7. *Gladiolus Tristis*; *Square-stalked Corn Flag*. Leaves linear-cross-shaped; corollas bell-shaped. From the root come out two or three narrow leaves, a foot and a half long, having a longitudinal furrow in the middle, and ending in acute points; they are of a deep green, and stand erect. Between these arises a slender taper stalk, about the same length as the leaves, having one or two short acute-pointed leaves on the lower part, embracing the stalk at their base; flowers alternate, distant; tube of the corolla curved downwards, not so long as in the other sorts. It flowers at the end of May, and the seeds ripen about six weeks after.

GLADIOLUS — Cape Corn Flag.

P. 650.

GUNDELIA TOURNEFORTII.

Linneus gave the name *tristis* to this species, from the gloomy colour of its flowers. They are very frequently of a pale yellow or sulphur colour, shaded in particular parts with very fine pencillings, especially on the under side; but they vary much with different shades of white and green, yellow, flesh-coloured, blue, purple, and violet. Thunberg has distinguished sixteen of these varieties. It is commonly said to produce only two flowers on a stem; but there are frequently more. They generally emit a most fragrant odour, when they expand.—Native of the Cape.

8. *Gladiolus Carinatus*; *Spotted-stalked Corn Flag*. Leaves linear, keeled on both sides, smooth; tube of the corolla shorter than the spathes and the borders; stigmas undivided, folded together; stalk a foot and a half high, and round; flowers sweet; tube subcylindric, little more than half an inch in length, whitish; border subcampanulate, subringent; the three upper divisions obovate, oblong, twice as long as the tube, pale violet; the three lower narrower, that in the middle the same length with the three upper ones, yellow below the middle; the side ones shorter, yellow in the middle. It flowers in April and May.—Native of the Cape of Good Hope.

9. *Gladiolus Blandus*; *Blush-coloured Corn Flag*. Leaves linear-lanceolate, nerved, smooth; flowers in spikes, the upper segment reflex; stigmas slightly two-lobed; tube of the corolla narrow, compressed, little bent, an inch and a half in length, pale red; filamenta white, half the length of the corolla; antheræ oblong, linear, erect, blue; style white, longer than the filamenta; stigmas three, patulous, dilated at the top into two lobed laminae, villose at the edge. The flowers vary in colour from white to pale pink, and are scentless. It flowers in June.—Native of the Cape.

10. *Gladiolus Undulatus*; *Waved Corn Flag*. Leaves sword-shaped; petals nearly equal, lanceolate, waved; stalk a foot and a half high; flowers alternate in a double row, yellowish-white, or pale blush-colour; proper spathes two-leaved, the inner leaf smallest; tube of the corolla long, filiform; the six parts of the border nearly equal, in form of a Lily, waved, especially the alternate ones.—Native of the Cape.

11. *Gladiolus Recurvus*; *Recurved Corn Flag*. Leaves sword-shaped; petals nearly equal, lanceolate, bowed back. The flowers are ranged on one side of the stalk near the top, and stand pretty far asunder; corolla curved; segments of the border almost equal, ending in blunt points; the lower segments turning downwards, the upper erect, and spreading open; the colour pale bluish, approaching to white; each segment marked with a broad, purple, divided line along the middle. The flowers have an agreeable violet odour; they appear at the end of May, and the seeds ripen in July.—Native of the Cape.

12. *Gladiolus Spicatus*; *Spiked Corn Flag*. Leaves linear; stem extremely simple; scape simple, round, sheathed, erect, a span high; flowers in spikes, distich, imbricate, blue, about twelve pairs in a spike of an inch long.—Native of the Cape.

13. *Gladiolus Alopecuroides*; *Fox-tail Corn Flag*. Leaves linear; spike distich, imbricate. The spike is covered, like that of the Plantain, with very numerous small flowers, but in a double row. It varies with the scape simple and branched, with corollas white and blue.—Native of the Cape.

14. *Gladiolus Angustus*; *Narrow-leaved Corn Flag*. Leaves linear, smooth; flowers in spikes, distant; the upper segments of the corolla straight; stigmas spatulate, undivided; scape simple, or but little branched, sheathed, round, striated, smooth, flexuose, erect, a foot high; flowers all on the same side, ascending, on one or two spikes a hand in length;

rachis angular, flexuose, twisted, smooth; spathes the length of the tube of the corolla, shorter than the branches, green.—Native of the Cape.

15. *Gladiolus Flavus*; *Yellow Corn Flag*. Leaves lanceolate-sword-shaped, flat; the throat of the upper lip of the corolla has three laminae, shaped like the nail, and placed perpendicularly; bractes acuminate. This differs from the sixteenth species, in having the bractes acuminate, the whole corolla intensely yellow, and the leaves a little broader. It flowers in February and March.—Native of the Cape.

16. *Gladiolus Securiger*; *Copper-coloured Corn Flag*. Leaves linear-sword-shaped, flat; the throat of the upper lip has three laminae, shaped like the nail, and placed perpendicularly; bractes shorter; stalk roundish, a little shorter than the leaves, sometimes branched; bractes short, ovate, obtuse, sometimes gashed at the tip, membranaceous; corollas pale tawny; tube funnel-shaped, less than an inch in length; segments of the border oblong-ovate, obtuse, sometimes obscurely emarginate, shorter than the tube, the three upper ones having in the chaps a yellow spot, with a border of red round it, and three flat obtuse yellow laminae, a line and half in diameter. It flowers in May.—Native of the Cape.

17. *Gladiolus Ramosus*; *Branched Corn Flag*. Stem branched; leaves linear.—Native of the Cape.

18. *Gladiolus Capitatus*; *Crowned Corn Flag*. Stem branched; heads peduncled; root tuberous. This is a very large plant, with blue flowers.—Native of the Cape.

19. *Gladiolus Crispus*; *Curled Corn Flag*. Leaves lanceolate, crenate, waved; flowers directed the same way; spikes two; tube filiform, long; stem round, with one or two crenate-waved leaves on it; glumes obtuse, with a scariose, toothletted, red margin; tube of the corolla twice as long as the border. This is two feet high.—Native of the Cape.

20. *Gladiolus Junceus*; *Slender Corn Flag*. Leaves broad-lanceolate; culm branched; flowers directed the same way; style six-parted; stem a hand only in height, filiform, smooth, with one or two patulous branchlets; flowers alternate, sessile; glumes ovate, entire; corolla violet-coloured, with a filiform tube, longer than the border.—Native of the Cape.

21. *Gladiolus Anceps*; *Double Corn Flag*. Leaves sword-shaped, waved; stem branched, acipital, divaricate; flowers alternate at the tips of the branches; spathes very obtuse, purple at the edge; tube of the corolla three or four times as long as the border.—Native of the Cape.

22. *Gladiolus Gramineus*. Petals lanceolate, bristle-shaped, acuminate; stem more than a foot high, round, smooth, and even, with few flowering branches; flowers few, at the end of the stem and branches; spathes ovate-acuminate; corolla whitish, with a violet-coloured base, small, without a tube, six-parted.—Native of the Cape.

23. *Gladiolus Marginatus*. Leaves cartilaginous, margined, smooth, many-nerved; spike lengthened; flower alternate, nodding; stems the thickness of a goose-quill; spike very long, slightly flexuose between the flowers; spathes distant, the length of the bractes, which are often jagged at the tip; tube of the corolla twice as long as the spathes; segments of the border nearly equal, oblong, elliptic, purple.—Native of the Cape.

24. *Gladiolus Montanus*; *Mountain Corn Flag*. Leaves sword-shaped, nerved, smooth; flowers in spikes; corolla ringent; stem round, leafless; spike oblong; with the flowers rather remote; root-leaves narrow, linear, not above a line in breadth, but nearly the length of the stem, smooth and even; upper lip or helmet of the corolla three-parted; the middle segment arched or bowed in, channelled, linear, ovate at the

tip; lateral segments spreading, divaricate.—Native of the Cape. See the third species.

25. *Gladiolus Falcatus*. Stem simple; leaves sickle-shaped; flowers alternate; style trifid; scape compressed, striated; flexuose, smooth, a hand in height; one or two leaves obversely stem-clasping, ovate-lanceolate, sickled, bluntish, entire, striated, smooth; spathes green, obtuse, much shorter than the tube; corolla blue, with a spreading border.—Native of the Cape.

26. *Gladiolus Flexuosus*. Leaves linear; stem simple, flexuose; flowers in spikes, ringent; tube long; scape round, flexuose, erect, smooth, a foot high; spathes oblong, lanceolate, acuminate, smooth, shorter than the tube of the corolla; spike ovate, four or five flowered; corolla whitish flesh-colour, with a tube double the length of the spathe, and a ringent border.—Native of the Cape.

27. *Gladiolus Longiflorus*; *Long-flowered Corn Flag*. Stem round; tube of the corolla very long; spathes and leaves linear, smooth; scape round, simple, and many-spiked, erect, smooth, a foot high and more; flowers alternate, pale flesh-colour, very many, close; bractes membranaceous, striated, very short.—Native of the Cape.

28. *Gladiolus Spathaceus*. Stem branched; flowers in imbricate spikes; spathes membranaceous, awned; leaves plaited; scape sheathed, a span high, terminated by several spikes; flowers whitish, with the tube of the corolla many times longer than the spathes.—Native of the Cape.

29. *Gladiolus Setifolius*. Stem branched; corolla ringent; the lowest leaf filiform, setaceous; scape many-spiked, very seldom simple, flexuose, erect, smooth, a hand high, with round erect branches; flowers alternate, white, ringent, with the tube scarcely longer than the spathes.—Native of the Cape.

30. *Gladiolus Cardinalis*; *Superb Corn Flag*. Leaves sword-shaped, many-nerved; flowers directed the same way; many on a stem; corolla upright, with a bell-shaped border; flowers fine scarlet, with large white, and somewhat rhomboidal spots on several of the lowermost divisions of the corolla. Strong plants will throw up a stem three or four feet high, dividing at top into several branches. It flowers with us in July and August.—Probably a native of the Cape. Introduced from Holland a few years ago; and first flowered with Messrs. Lewis and Mackie, at Kingsland; and in 1790, at Messrs. Greenwood's and Co. Kensington.

31. *Gladiolus Milleri*. Leaves with many prominent ribs; flowers bell-shaped, inclined one way; tube fleshy, slender. The root is bulbous, in shape and size like that of the Vernal Crocus: from this spring up five or six long narrow leaves, deeply furrowed; between these arises the flower-stem, about a foot and a half high, bending on one side, bearing towards the top five or six flowers, each having a two-leaved sheath; they are of a pure white when they first open, but afterwards change to a yellow colour.—Native of the Cape.

Glasswort. See *Salicornia*.

Glastonbury Thorn, so famous in legendary lore, buds and blossoms in the midst of winter. The story of its budding always upon Christmas-day, is false; though, if the winter be mild, it buds about the latter end of December, but later if it be severe.—See *Mesphilus*.

Glauca; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none, unless the corolla be so called. *Corolla*: petal one, five-parted, bell-shaped, upright, permanent; segments obtuse, rolled back. *Stamina*: filamenta five, subulate, upright, the length of the corolla; antheræ roundish. *Pistil*: germen ovate; style filiform, the length of the stamina; stigma capitata. *Peri-*

carp: capsule globular, acuminate, one-celled, five-valved. *Seeds*: five, roundish. *Receptacle*: very large, globular, hollowed for the reception of the seeds. *Observe*: The cover of the flower is perhaps a calix more properly than the corolla. ESSENTIAL CHARACTER. *Calix*: one-leaved, bell-shaped. *Capsule*: one-celled, five-valved, five-seeded.—The only known species is,

1. *Glauca Maritima*; *Sea Milkwort*, or *Black Saltwort*. Root perennial, creeping; stems about four inches high, erect, branched a little; leaves sessile, oval-oblong, or oval-lanceolate, succulent, opposite at bottom, but among the flowers alternate; flowers almost sessile, axillary, solitary, from about the middle of the stem purple, greenish-white, white, or striped.—It is found on the sea-coast, and on salt-marshes at a distance from the sea, and even about Upsal in Sweden, which is at a great distance from the ocean. It is a pretty little plant, enlivening large tracts of the dreary situations where it is found. The whole plant is succulent, and salt to the taste. Cows eat this herb, and it is used for a pickle. It flowers in June, and continues the rest of the summer; but is seldom cultivated in gardens.

Glechoma; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, cylindrical, streaked, very small, permanent; mouth five-cleft, acuminate, unequal. *Corolla*: one-petalled, ringent; tube slender, compressed; upper lip erect, obtuse, semibifid; lower spreading, larger, obtuse, trifid; middle segment larger, emarginate. *Stamina*: filamenta four, under the upper lip, of which two are shorter; each pair of antheræ converging in form of a cross. *Pistil*: germen four-cleft; style filiform, bending beneath the lip; stigma bifid, acute. *Pericarp*: none; calix cherishing the seeds in its bosom. *Seeds*: four, ovate. ESSENTIAL CHARACTER. *Calix*: five-cleft; each pair of antheræ converging in form of a cross.—The only species is,

1. *Glechoma Hederacea*; *Ground Ivy*, *Gill*, *Cal's-foot*, *Tun-hoof*, *Robin-run-in-the-hedge*, or *Ale-hoof*. Leaves kidney-shaped, crenate, or scalloped. Root perennial, sending out trailing four-cornered shoots, producing roots at the joints, and spreading wide; the flowering-stalks spring from the joints, which are woolly, these are upright, but weak, square, hirsute with hairs turning downward, from four to six inches high; the leaves are beset underneath with hollow dots, in which are glands secreting an essential oil, and above with little eminences, but which do not secrete any odoriferous oil, so that this surface being rubbed gives out no peculiar scent, whereas the under surface affords a pleasant reviving smell; peduncles axillary, opposite, short, branched, supporting from three to five flowers; corolla blue, sometimes varying to white; the larger middle segment of the lower lip marked with purple dots of a deeper colour, and hairy at the base; stamina sometimes in the spring imperfect, with filamenta only half the usual length, terminated by a reddish blunt point, or sometimes by effete antheræ; when perfect, the antheræ, after bursting, form a cross, or the shape of the letter X; the leaves are often deformed with red hairy tumors, which are the galls of the cynips *glechomæ*.—Ground Ivy expels the plants which grow near it, and thus impoverishes the pastures: the leaves were formerly thrown into the vat with ale, to clarify it, and to give it a flavour. This was called *Gill-ale*, Ground Ivy being named *Gill*, or *Gill-creep-by-ground*, in some places. From this use of the plant, and the form of its leaves, it has also the names of *Ale-hoof* and *Tun-hoof*, but has gradually fallen into

disuse since the introduction of hops. Cattle seem in general to avoid it, though Linneus says that sheep eat it; horses are not fond of it; and it is refused by cows, goats, and swine. It is said to be injurious to those horses that eat much of it; although the expressed juice, mixed with a little wine, and applied morning and evening, destroys the white specks which frequently infest their eyes. This plant has a peculiarly strong smell, with a bitterish and somewhat aromatic taste; it was formerly in a high repute for a pectoral, detergent, aperient, diuretic, and corroborant, and was particularly recommended in pulmonary and nephritic complaints. In obstinate coughs it is still a favourite remedy with the country people, though seldom prescribed by medical practitioners, and wholly discarded from the materia medica of the London college. Mr. Ray cites a remarkable instance of its efficacy in removing a violent and inveterate headache, by drawing the juice of the plant up the nostrils; but Dr. Cullen will not allow it to be of any utility, except as an errhine: he thinks the use of it in ale to be frivolous, and declares, that in many cases where he had seen it employed, there was no evidence either of its diuretic or pectoral effects. The usual manner of taking it is in an infusion, or tea; the expressed juice is also used with honey in coughs; a conserve or syrup is also made with it. The distilled water is wholly useless. The conserve made of the young tops in the spring, or the juice made into a syrup, is excellent for colds, coughs, and shortness of breath; and the infusion, made strong, and drank as tea, is serviceable in all complaints of the breast and lungs. The expressed juice snuffed up the nose, is an excellent, and often an instantaneous remedy for the headache, and may be advantageously used in inflammations of the eyes, arising from external violence. Notwithstanding what Dr. Cullen advances against the use of this plant in ale, Meyrick asserts, that the leaves, when bruised, and thrown into the vat with the liquor, not only effectually clarify and give it an agreeable flavour, but also communicate an antiscorbutic virtue.—It is so common under hedges, on banks, in woods, and sometimes in dry pastures, that it is never cultivated in gardens. It varies in size, as well as the degree of colour in the flower, according to its situation: the flowers appear in April, May, and June. A plant so universally esteemed by the multitude, was sure to acquire many names. To those already enumerated we have to add that of *Hay-maids*; the Germans call it, *gundelreben*, *gundermann*, *grundermann*, *gundelrüb*, *gundrebe*, *grundrebe*, *gunderlunze*, *donnerrebe*, *erdepheu*, *erdenkranzlein*, *meerwurzel*; the Dutch call it, *aardveil*, *hondsdrif*, *onderhave*; the Danes, *vedbende*; the Swedes, *jordrefrot*; the Italians, *ellera terrestre*; and the Spaniards, *hidra terrestre*.

Gleditsia; a genus of the class Polygamia, order Diœcia. —GENERIC CHARACTER. *Male*: a long, compact, cylindrical ament. *Calix*: perianth proper, three-leaved; leaflets patulous, small, acute. *Corolla*: petals three, roundish, sessile, patulous, like the calix; nectary turbinate, with the other parts of the fructification growing to the mouth. *Stamina*: filamenta six, filiform, longer than the corolla; antheræ incumbent, oblong, compressed, twin. *Hermaphrodite*: in the same ament with the males, usually terminating. *Calix*: perianth four-cleft, otherwise as in the male. *Corolla*: petals four, otherwise as in the male; nectary as in the male. *Stamina*: as in the male. *Pistil*, *Pericarp*, and *Seed*: as in the female. *Female*: a lax ament, on a distinct plant. *Calix*: perianth proper, as in the male, but five-leaved. *Corolla*: petals five, long, sharp, from upright spreading; nectaries two, short, like filamenta. *Pistil*: germen broad, flattened, longer than the corolla; style short, reflex; stigma

thick, the length of the style, along which it grows, pubescent at top. *Pericarp*: legume very large, broad, extremely flattened, divided by several transverse partitions, and filled with pulp. *Seeds*: solitary, roundish, hard, shining. ESSENTIAL CHARACTER. *Hermaphrodite*. *Calix*: four-cleft. *Corolla*: four-petalled. *Stamina*: six. *Pistil*: one. *Male*. *Calix*: three-leaved. *Corolla*: three-petalled. *Stamina*: six. *Female*. *Calix*: five-leaved. *Corolla*: five-petalled. *Pistil*: one. Legume.—The species are,

1. *Gléditsia Triacanthos*; *Three-horned Acacia*. Leaflets ovate-oblong; spines very frequent, in all the varieties axillary, and commonly triple. It rises with an erect trunk to the height of thirty or forty feet, and is armed with spines, three or four inches long, which have two or three smaller ones coming out from the side, and are frequently produced in clusters at the knots of the stem; leaves bipinnate, composed of ten pairs of leaflets, of a lucid green, and sessile; the flowers come out from the side of the young branches, and being of an herbaceous colour, make no figure: legume nearly a foot and a half long, and two inches broad; seeds smooth, surrounded by a sweet pulp. The leaves seldom come out till June in this country, and the flowers, not till the end of July; neither does the tree produce any flowers until it has grown to a large size. There are several varieties, with the spines stronger and weaker, and different in number.—These trees are propagated by seeds, which must be procured from America; those of the first are annually sent to England in plenty, by the title of *Locust*, or *Honey-locust*, to distinguish them from the False *Acacia*, which is frequently called *Locust-tree* in America. The seeds may be sown upon a bed of light earth in the spring, burying them half an inch deep; and, if the spring should prove dry, they must be frequently watered, otherwise the plants will not come up the first year, for sometimes the seeds remain two years in the earth before they appear; so that those who wish to save time, should sow the seeds as soon as they arrive, and plunge the pots into a moderate hot-bed, observing to water them frequently; by this method most of the plants will come up in the same season; but these should be gradually inured to bear the open air, for if they are continued in the hot-bed, they will draw up weak. The plants in pots will require frequent waterings during the summer season; but those in the full ground will require much less, except in very dry seasons. In autumn, those in the pots should be placed under a hot-bed frame, to protect them from frost, for these young plants generally keep growing late in the summer, and the upper part of their shoots being tender, the early frost of the autumn often kills the end of them, if they are not protected, and this frequently occasions great part of the shoots decaying in winter; for which reason, those plants in the full ground should be covered with mats in autumn, on the first appearance of frost, for a small frost in autumn will do more mischief to these young shoots which are full of sap, than severe frost when the shoots are hardened. In the following spring these plants may be transplanted into nursery beds, at a foot distance row from row, and six inches asunder in the rows; but this should not be performed till April, after the danger of harder frost is over, for as the plants do not put out their leaves till very late, there will be no hazard in removing them any time before May. If the season should prove dry, they must be watered; and if the surface of the beds be covered with moss or mulch, to prevent the earth from drying, it will be of great service to the plants; which may remain two years in these beds, during which time they must be constantly kept clean from weeds, and in the winter there should be some rotten tan or other mulch spread over the surface of the

ground to keep out the frost. If the plants thrive well, they will be fit to transplant to the places where they are to remain after two years' growth, for they do not bear removing when large; the best season for transplanting these trees is late in the spring; they thrive best in a deep light soil, for in strong shallow ground they become mossy, and never grow large; they should also have a sheltered situation, for when much exposed to winds, the branches are frequently broken, when fully clothed with the leaves, which do not appear till June. As this is an elegant tree, it should appear singly in the openings of plantations, wherever it can be well sheltered from cold winds.

2. *Gleditsia Monosperma*; *Swamp Locust Tree*. Branches somewhat thorny; little leaves ovate-oblong, sharp; pods containing only one seed. It flowers in July, and is a native of Carolina and Florida. This plant is only considered by Miller, a variety of the first species; but being fully satisfied, with Fred. Pursh, that it is entirely distinct from *Gleditsia Triacanthos*, we have copied his specific description.

Glinus; a genus of the class Dodecandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, concave, coloured within, permanent. *Corolla*: none; nectaries often five, flat, resembling petals, narrow, shorter than the calix, unequally bifid or trifid. *Stamina*: filamenta about fifteen, (Gærtner says, fifteen to twenty,) subulate, flat, the length of the calix; antheræ erect, upright, compressed, twin. *Pistil*: germen superior, five-cornered; styles five, short, (Gærtner says one, five-cleft;) stigmas simple. *Pericarp*: capsule ovate, five-celled, five-cornered, five-valved. *Seeds*: very many, roundish, in a single row under the valves, tubercled, affixed at the base to a small swelling membrane. *Observe*: The nectaries of Linneus are what Gærtner calls the petals. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: none; nectaries cloven bristles. *Capsule*: five-cornered, five-celled, five-valved, containing numerous seeds.—The species are,

1. *Glinus Lotoides*; *Hairy Glinus*. Stems procumbent, jointed, hairy; leaves obovate; root annual; flowers nearly sessile, crowded together; capsule ovate-pyramidal, thin, pusted by the protuberating seeds; partitions inserted in the middle of the valves.—Native of the south of Europe, and the Levant.

2. *Glinus Dictamnoides*. Stem frutescent, prostrate; leaves orbicular, tomentose, flat; calicine leaflets lanceolate; branches alternate; both they and the stems tomentose at top, but with hairs less distinct than in the first species; peduncles at the joints aggregate, short.—Native of the East Indies.

3. *Glinus Setiflorus*. Stem shrubby; leaves obovate, plaited; calicine leaflets ovate. The whole plant is hoary, with very close hairs, longer than in the first species; flowers axillary, several; peduncles very short; spinules rigid, minute, from the base of the peduncles, permanent.—Native of inundated woods, in Arabia Felix, during the rainy season.

Globba; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth superior, one-leaved, cylindrical, with a trifid mouth, permanent. *Corolla*: monopetalous, cylindrical, with a trifid equal mouth. *Stamina*: filamenta two, filiform, middling in length; antheræ fastened longitudinally to the filamenta. *Pistil*: germen inferior; style bristle-shaped, of a middling length; stigma sharp. *Pericarp*: capsule roundish, three-celled, three-valved. *Seeds*: very many. ESSENTIAL CHARACTER. *Calix*: superior, trifid. *Corolla*: equal, trifid. *Capsule*: three-celled. *Seeds*: very many.—The species are,

1. *Globba Marantina*. Spike terminating, erect; stem

simple, herbaceous, about two feet high; flowers remote, each involved in an ovate bracte, longer than the flower.—Native of the East Indies.

2. *Globba Nutans*. Spike terminating, pendulous. Rumphius makes two varieties of this, the great and the small: the first has a very straight firm stem, from fourteen to eighteen feet in height, two inches in diameter at bottom, naked for six feet from the root, and stout enough for walking-canes; the upper part is soft, and is eaten in some places; leaves three feet long, and more than two hands broad, thin, smooth, with many parallel transverse veins, bending upwards near the edge, forming slight ridges on the upper, and furrows on the lower surface; fruit the size of a pigeon's egg, red. The leaves of the smaller sort are more wandering, narrower, and draw more to a point at the base; the primary stem is two or three feet in length, and leafless, producing abundance of oblong flowers in bunches, like the Hyacinth.—Native of the East Indies.

3. *Globba Uviformis*. Spike lateral; stem from seven or eight to twelve or fourteen feet high, the thickness of a finger; leaves from fourteen to sixteen inches long, and from four to six fingers broad, smooth, and dark green above, pale green and lanuginose beneath: the fructification issues from the side of the stem, eighteen inches or two feet above the root, in a spathed bunch or spike a hand in length, containing many white flowers, which are succeeded by fruit resembling grapes, but larger, white, becoming black, or of the colour of smoke, and are sometimes eaten.—Native of the East Indies.

4. *Globba Japonica*. Raceme terminating, drooping; leaves sword-shaped, entire; the stem is sheathed with leaves, simple, round, streaked, smooth, upright, two feet high or more; flowers many; rachis flexuose, a hand in length; peduncle scarcely a line long, nodding a little, one-flowered; style filiform; seeds surrounded by a white connecting membrane, angular, smooth, brown; capsule ovate.—Native of Japan, where the fruit ripens in December and January.

Globe Amaranth. See *Gomphrena*.

Globe Flower. See *Trollius*.

Globe Thistle. See *Echinops*.

Globularia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: common perianth, imbricate with scales the length of the disk, and equal; proper one-leaved, tubular, five-cleft, sharp, permanent, (four or five toothed, the teeth bristle-shaped and acuminate, according to Gærtner.) *Corolla*: universal, nearly equal; proper monopetalous, tubular at the base; border five-parted; upper lip very narrow, two-parted, shorter, lower of three larger equal segments. *Stamina*: filamenta four, simple, the length of the corollule; antheræ distinct, incumbent. *Pistil*: germen ovate, superior; style simple, the length of the stamina; stigma obtuse. *Pericarp*: none; proper calix converging, inclosing the seed. *Seed*: solitary, ovate. *Receptacle*: common, oblong, separated by chaffs. ESSENTIAL CHARACTER. *Calix*: common imbricate; proper tubular, inferior; corollets the upper lip two-parted, lower three-parted. *Receptacle*: chaffy.—The species are,

1. *Globularia Longifolia*; *Long-leaved Globularia*. Stem shrubby; all the leaves linear-lanceolate, quite entire; heads axillary. This rises much higher than the next species, having a hard white wood, with a large pith, and a scabrous light brown or gray bark; the branches towards their ends very thick set with leaves, without any order, they are two inches long, and a third part of an inch broad in the middle; the nerves yellowish green; flowers small, blue, in round heads.—It flowers in July and August, and is a native of Madeira. This, and the eighth species, are somewhat

tender, and should be sheltered from the frost in winter under a frame, but in summer should be exposed with other hardy exotic plants, and will require to be frequently watered in dry weather. These may be propagated by seeds, or by parting their roots, as is directed for the fourth sort.

2. *Globularia Alypum*; *Three-tooth-leaved Globularia*. Stem shrubby; leaves lanceolate, three-toothed, and entire; heads terminating. This has a hard woody stem, about two feet high, with many woody branches, beset with leaves like those of the Myrtle; the flowers are produced on the tops of the branches in a ball, and are of a blue colour. It flowers from August to November.—Native of the south of Europe, and of Barbary. From the violent purging quality of this shrub, it acquired the name of *herba terribilis*, in English, *herb terrible*; but, in the abundance of purging medicines that we possess, this is seldom if ever used. This plant may be propagated by cuttings, which should be cut off in April, just before they begin to make new shoots: the cuttings should be planted into pots filled with light fresh earth, and then placed in a very moderate hot-bed, observing to water and shade them until they have taken root, when they may be taken out of the bed, and inured to bear the open air by degrees. In summer these plants may be exposed with other hardy exotic plants, and in winter they should be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but should be screened from hard frost, which will destroy them if they are exposed thereto, but in mild winters they will live in the open air. It never produces good seeds in this country.

3. *Globularia Bisnagarica*. Stem shrubby; root-leaves wedge-shaped, retuse; stem-leaves lanceolate, flowers in a blue terminal head.—Native of woods in India.

4. *Globularia Vulgaris*; *Common Globularia*, or *Blue Daisy*. Stem herbaceous, a span high; stem-leaves lanceolate; root-leaves three-toothed, numerous, like those of the Daisy, but thicker, petioled, placed in a ring, ovate-obtuse, quite entire, emarginate; the nerve produced into a small awn or point; corollets of a fine blue; germen villose. It varies with a white flower, and with a leafless stalk. It usually flowers in May and June.—Native of many parts of Europe, as Sweden, the south of France, Germany, Switzerland, Austria, Carniola, Hungary, Savoy, Italy, and Spain. This, together with the fifth, sixth, and seventh species, may be propagated by parting the roots, after the manner of Daisies. The best season for parting and transplanting of the plants is in September, that they may take new root before the severe weather comes on. They should be planted in a shady situation, and require a moist loamy soil, in which they will thrive much better than in a light ground and an open situation; but the plants should not be removed oftener than every other year, if required to flower strong.

5. *Globularia Spinosa*; *Prickly-leaved Globularia*. Root-leaves crenate, prickly; stem-leaves quite entire, mucronate; stem a hand in height, dark green, with oblong narrow leaves at the base, not notched, but ending in prickles; heads of flowers longer than in the preceding species.—It flowers in May, and is a native of Spain.

6. *Globularia Cordifolia*; *Wedge-leaved Globularia*. Stem almost naked; leaves wedge-shaped, three-cusped, the middle cusp least; root large, woody, producing many tufts of leaves.—It flowers in June and July, and is a native of Switzerland, Austria, Carniola, Hungary, Piedmont, and Arragon.

7. *Globularia Nudicaulis*; *Naked-stalked Globularia*. Stem naked; leaves quite entire, lanceolate; flowers usually trifid, but sometimes quadrifid.—It flowers in July, and is a native of Switzerland, Austria, Carniola, Savoy, and Piedmont.

8. *Globularia Orientalis*. Stem almost naked; heads of flowers alternate, sessile, from seven to ten, at the summit of the stem; leaves lanceolate-ovate, entire; root perennial.—Native of Natolia.

Gloriosa; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong-lanceolate, waved, very long, wholly reflex. *Stamina*: filamenta six, subulate, shorter than the corolla, from straight patulous; antheræ incumbent. *Pistil*: germen globular; style filiform, longer than the stamina, inclined; stigma triple, obtuse. *Pericarp*: capsule superior, oval, three-lobed, three-celled, three-valved. *Seeds*: several, globular, berried, in two rows. *Observe*: This beautiful genus is nearly allied to *Erythronium*. ESSENTIAL CHARACTER. *Corolla*: six-petalled, waved, reflex. *Style*: oblique.—The species are,

1. *Gloriosa Superba*; *Superb Lily*. Leaves alternate, smooth, each ending in a tendril. This has a long fleshy root, of a whitish colour, and a nauseous bitter taste, from the middle of which rises a round weak stem, requiring support, and with that growing to the height of eight or ten feet; flowers at the upper part of the stem, from the side, on slender peduncles, hanging down, at first of an herbaceous colour, but changing to a beautiful flame colour. It flowers in June and July, but seldom perfects seeds in this country. The stalks decay in autumn; the roots remain inactive all the winter, and new stalks appear in March. The roots and every part of the plant are poisonous.—Native of Malabar and Guinea. As neither this nor the second species are often known to produce seeds in this country, they are generally propagated by their roots; those of the first sort creep and multiply pretty fast. The roots may be taken out of the ground when their stalks are decayed, and preserved in sand during winter; but they must be kept in a stove or a warm room, where they can receive no injury from the cold; and in the spring, they must be planted in pots filled with light earth, and plunged into the tan-bed in the stove: but others choose to let the roots continue in the ground all the winter, keeping the pots in the tan-bed. Towards the latter end of March, or the beginning of April, their stalks will appear; and some tall sticks should be put down to support them, otherwise they will trail over the neighbouring plants, and the first species will fasten to the plants by the tendrils. The stalks of this species will rise ten or twelve feet high, if the roots be strong; and some of them will produce two or three flowers, which make a fine appearance during their continuance, but seldom last more than ten days or a fortnight. In summer, while growing, they will frequently require to be watered, but must only have small quantities, as they are always liable to rot. Those roots which are not taken out of the pots in winter, should be transplanted, and parted in the beginning of March, before they put out new fibres or stalks, for they must not be removed when they are in a growing state. The pots should not be over large, for unless the plants be rather confined, they will not put out strong stalks; the largest roots may be planted in two-penny pots, but the smaller will only require pots that are five or six inches wide at top. A great degree of heat is necessary to make the first species flower.

2. *Gloriosa Simplex*. Leaves acuminate, smooth, about three inches long and two broad, but having no tendrils; they have a strong disagreeable scent when handled, and the flower is said to be blue.—The seeds were sent to Mr. Miller by the gardener to the French king at Trianon, and were brought from Senegal. This plant has not yet appeared in any of the gardens either in France or England.

Glossoma; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, turbinate, four-toothed, superior, permanent. *Corolla*: petals four, lanceolate, acute, bowed back; nectary a rim round the base of the style. *Stamina*: filamenta four, very short; antheræ oblong, almost united into a cylinder, prolonged at the tip into a membranaceous strap or scale, gaping on the inside. *Pistil*: germen inferior; style filiform, the length of the stamina; stigmas four, acute. *Pericarp*: drupe spear-shaped, one-celled, crowned with the calix. *Seed*: single, ovate, streaked. ESSENTIAL CHARACTER. *Calix*: turbinate, four-toothed, superior. *Corolla*: four-petalled. *Antheræ*: almost united, with a membranaceous scale at the end. *Stigmas*: four.—The only known species is,

1. *Glossoma Guianensis*. This is a middling-sized shrub, five or six feet high; the bark brown; the wood yellow, hard, and compact; branches jointed, and four-cornered; leaves opposite, cruciate, six inches and a half long, and two and a half wide, entire, smooth, thick, elliptic, acuminate, on very short petioles; stipules short, acute, at the base of the petioles deciduous; peduncles axillary, bearing two, three, or four flowers, each on its proper pedicel, bracted at the base; corolla white.—It flowers in September, and is a native of Guiana, where *Vitomita* is the vernacular name.

Glossopetalum; a genus of the class Pentandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, very small, five-toothed, permanent. *Corolla*: petals five, lanceolate, spreading, acute; at the tip of each a linear-lanceolate truncate strap, nearly the length of the petal, and lying in it. *Stamina*: filamenta five, very short; antheræ roundish. *Pistil*: germen roundish, surrounded by a gland, bearing the petals and stamina; style none; stigmas five, acute. *Pericarp*: roundish, five-grooved, one-celled. *Seeds*: five, angular. ESSENTIAL CHARACTER. *Calix*: very small, five-toothed. *Petals*: five, with a strap at the tip of each.—The species are,

1. *Glossopetalum Glabrum*. Leaves smooth. This is a tree, the trunk of which rises to the height of sixty feet or more, and is from two to three feet in diameter. The bark is smooth and gray; the wood white, and of a loose texture. The petiole is short, and has two small, narrow, deciduous stipules at the base; peduncles solitary, axillary, two inches long, bearing many flowers in a spherical head; corolla yellow; berry black.—Native of Guiana, where it flowers in November. The natives make canoes of the trunk.

2. *Glossopetalum Hirsutum*. Leaves hairy. The trunk of this species is only from twenty to twenty-five feet in height. The bark is wrinkled, blackish, marked with white; the leaves are covered with short hairs on both sides: the juice is used against inflammations in the eyes; they are bitter, and so also is the bark.—Native of Guiana and Cayenne, where its vernacular name is *Goupi*.

Gloxinia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth superior, five-leaved; leaflets equal, lanceolate, serrulate at the tip; the three upper ones nerved, the two lower bent down with the nectary, permanent. *Corolla*: monopetalous, irregularly campanulate; tube scarcely any; border oblique, five-cleft; segments roundish, the four upper spreading and entire, the lowest straight, concave, toothed. *Stamina*: filamenta four, with the rudiment of a fifth, two scarcely shorter, inserted into the receptacle, fastened to the lower margin of the corolla, sickled, pubescent, converging laterally above; antheræ ovate, two-celled, peltate, united within the opening of the corolla. *Pistil*: germen inferior, turbinate, striated;

style filiform, the length of the stamina; stigma capitate, the length of the antheræ. *Pericarp*: capsule one-celled, or half-celled; receptacles two, opposite, two-parted, fastened to the sides of the capsule by the partition. *Seeds*: very numerous, inserted into the receptacles. *Observe*. L'Heritier remarks, that it is distinct from *Martynia*, by its inferior germen; from *Gesneria*, by its bell-shaped corolla, with the upper segment bent back; and from *Cyrilla*, by its bell-shaped corolla, without the tricallos mouth. ESSENTIAL CHARACTER. *Calix*: superior, five-leaved. *Corolla*: bell-shaped, with the border oblique; filamenta, with the rudimentum of a fifth, inserted into the receptacle.—The only known species is,

1. *Gloxinia Maculata*; *Spotted Gloxinia*. Root perennial, thick, fleshy, divided into knots, which are scaly, somewhat like those of toothwort; stems several, about a foot high, thick, succulent, purplish, terminated by a short spike of blue flowers, or rather an erect raceme, leafy or bracted, in which the flowers are axillary, solitary, peduncled, bright blue, and sweet-scented; corolla hirsute on the outside, inserted into the receptacle, larger than the calix; the base is gibbous in front, very large, melliferous within, and dark purple.—Native of South America. This plant must be constantly preserved in the stove, and plunged into the bark-bed. During the winter season, much water will rot the roots. In the middle of March, just before it begins to shoot, the roots may be parted, and transplanted into middling-sized pots, filled with light rich earth, and plunged into the bark-bed, which should then be renewed with fresh tan. When the plants come up, they must be frequently refreshed with water in small quantities; and as the season becomes warmer, a large share of fresh air should be admitted. They should not be placed where they are shaded or overhung by other plants; nor should they be shifted or transplanted when they are in leaf, for that will prevent their flowering. As this increases very fast by the roots, there is no necessity for using other methods to propagate it.

Gluta; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, very thinly membranaceous, bell-shaped, obtuse, shorter than the germen, deciduous. *Corolla*: petals five, lanceolate, longer than the calix, spreading at top, but below, as far the middle, glued to the column of the germen. *Stamina*: filamenta five, bristle-shaped, of a middling length, inserted into the tip of the column; antheræ versatile, roundish. *Pistil*: germen obovate, sitting on an oblong column; style filiform, of a middling length; stigma obtuse. ESSENTIAL CHARACTER. *Calix*: bell-shaped, deciduous; petals five, glued at bottom to the column of the germen; filamenta inserted into the tip of the column; germen sitting on an oblong column.—The only known species is,

1. *Gluta Benghas*. A tree, with branches leafy at the end; leaves alternate, sessile, broad-lanceolate, about a foot in length, veined, naked, on the flowering branches only a hand long, more obtuse, and crowded; panicle terminating, peduncled, with flowers the size of those of cabbage; fructification singular; and, if we were to suppose the petals to be separated from the column, the situation of the stamina would be as in *Passiflora*.—Native of Java.

Glycine; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, compressed; mouth two-lipped; upper lip emarginate, obtuse; lower longer, trifid, acute; the middle tooth more produced. *Corolla*: papilionaceous; banner obcordate, the sides bent down, the back gibbous, the tip emarginate, straight, repelled from the keel; wings oblong, towards the

tip ovate, small, bent downwards; keel linear, sickle-shaped, bent upwards; at the tip pressing the banner upwards, obtuse, towards the tip broader. *Stamina*: filamenta diadelphous, (simple, and nine-cleft,) only a little divided at the tip, rolled back; antheræ simple. *Pistil*: germen oblong; style cylindrical, rolled back in a spiral; stigma obtuse. *Pericarp*: legume oblong. *Seeds*: kidney-form. **ESSENTIAL CHARACTER.** *Calix*: two-lipped. *Corolla*: the keel turning back the banner at the tip.—The species are,

1. *Glycine Subterranea*; *Procumbent Glycine*. Leaves ternate, radical; stalks procumbent, flexuose; peduncles two-flowered; root annual; stalks several, a span in length, very rigid, close to the ground, or descending to it, round, hairy, unbranched; stipules two, lateral, permanent, very shortly peltate, ovate, quite entire, very small, hairy, flat; partial stipules to each lateral leaflet, solitary; to the middle one, two oblong, smooth, sessile, upright, concave; flowers upright; corolla pale yellow; banner obovate, streaked, upright; wings very blunt, as long as the banner, spread out; keel as long as the wings, blunt. As soon as this plant is out of flower, the peduncle perforates the earth, like the *Trifolium Subterraneum*, and *Arachis Hypogæa*, and the seeds ripen under ground.—It is a native of Brazil and Surinam, and is common on the coast of Africa. In Surinam, it is called *gobbe-gobbe*, and being planted in a sandy soil, with the addition of a little clay, bears abundance of fruit, which is a welcome repast to the inhabitants, who boil it before it becomes ripe, like green peas.

2. *Glycine Monoica*; *Pale-flowered Glycine*. Leaves ternate, almost naked; stalks hairy; racemes pendulous; fruit-bearing flowers apetalous; racemes many-flowered; flowers like those of *Vicia Cracca*, with the banner pale violet, the wings and keel white; they have the stamina and pistils, but the former being effete, they bear no fruit.—It flowers here in September, and is a native of North America.

3. *Glycine Debilis*; *Hairy Glycine*. Leaves ternate; leaflets oval, hairy underneath; legumes subsolitary, linear, many-seeded; style permanent, upright; root biennial.—It flowers in June and July, and is a native of the East Indies.

4. *Glycine Caribbæa*; *Trailing Glycine*. Leaves ternate, subvillose; leaflets rhomb-shaped; racemes patulous; stalk shrubby, twining; stems ash-coloured, the thickness of a quill, smooth; racemes axillary, lateral, slender, elongated, many-flowered; corolla yellow, the border variegated underneath with purple lines; legume hirsute, an inch long. It flowers in September and October.—Native of the West Indies.

5. *Glycine Triloba*; *Three-lobed Glycine*. Leaves ternate; leaflets lobed; stalk prostrate; peduncles two-flowered. The whole plant is prostrate, and does not climb. The root is annual. The flowers are yellow, smaller, and generally two together.—Native of the East Indies.

6. *Glycine Villosa*; *Villose Glycine*. Leaves ternate, three-lobed, villose; racemes axillary; stem filiform, angular, twining, flexuose, tomentose, as is also the whole plant; raceme peduncled, with two, four, or five flowers.—Native of Japan.

7. *Glycine Javanica*; *Java Glycine*. Leaves ternate; stalk villose; petioles rough-haired; bractes lanceolate, minute; stem twining, with yellow reflex hairs scattered over it; pedicels yellow, with close hairs; stipules to the petioles oval, long, to the peduncles lanceolate; peduncles the length of the leaves, terminated by an ovate-oblong close spike of nodding violet-coloured flowers, with very minute bractes between them.—Native of the East Indies, and near Nagasaki in Japan, where it is called *fajo mame*, and flowers in September and October.

8. *Glycine Comosa*; *Bearded Glycine*. Leaves ternate, hirsute; racemes lateral. This rises from two to three feet high, with slender herbaceous stalks; flowers axillary, lateral; the naked part of the peduncle is about two inches long; the spike is about the same length, and recurved; corolla small, of a fine blue colour.—Native of moist shady places in Virginia. This, and the tenth species, are hardy enough to endure the open air in England. They may be propagated by seeds, or by parting of the roots; the former is the best method, where good seeds can be obtained. They may be sown on a bed of light earth in the spring; and, if the season should prove dry, they must be frequently refreshed with water, otherwise they will remain long in the ground, without vegetating. When the plants come up, they must be kept clean from weeds in the summer; and in the autumn, when the stalks are decayed, if some rotten tanner's bark be spread over the surface of the ground, it will protect the roots from being injured by the frost. In the spring, the roots should be transplanted to the places where they are designed to remain, which must be in a warm sheltered situation, but not too much exposed to the sun, and in a light soil, where they will thrive, and produce flowers annually. If they be propagated by parting of the roots, it should be done in the spring, before the roots begin to shoot: but they should not be parted oftener than every third year; for when they are often removed, they will not flower so strong.

9. *Glycine Phaseoloides*; *Phaseolus Glycine*. Leaves ternate, villose underneath; racemes terminating; stem twining to a considerable height, and bearing many flowers towards the top. The legumes have two seeds, and are contracted in the middle.—Native of Jamaica and St. Domingo.

10. *Glycine Tomentosa*; *Downy Glycine*. Leaves ternate, tomentose; racemes very short, axillary; legumes two-seeded; root perennial; stalks twining, from a foot and a half to four feet in height, three-cornered, hairy. From the bosom of the leaves, three or four small flowers come out, on very short peduncles, of a pale yellow colour; the banner broadish, the wings narrow, and the keel compressed. The plant called *Dolichos Pubescens* by Linneus, is probably only a variety of this species.—Native of Virginia, where it is called *mountain pea*. It flowers from June to September, and ripens the early flowers in autumn. In addition to what is said under the eighth species, we have here to add, that as this is the tenderest of the two, the seeds may, for greater security, be sown in a hot-bed, and some of the plants kept in the green-house, or against a south wall, to be protected occasionally in severe weather, by putting dung to the roots.

11. *Glycine Reticulata*; *Netted-leaved Glycine*. Leaves ternate, oblong-lanceolate, pubescent, the veins like network underneath; racemes axillary, subsessile; legumes oblong, compressed; stem twining, angular, softly villose, subcanescent; pedicels solitary, distant; bractes ovate, attenuated, deciduous; seeds two.—Native of Jamaica.

12. *Glycine Bituminosa*; *Clammy Glycine*. Leaves ternate; flowers racemed; legumes tumid, villose; stem twining, obtuse, angled, pubescent; stipules ovate, acuminate, nerved; corollas yellow, streaked on the outside, and at the tip of the keel violet-coloured; seeds four, small, globular, a little flattened, black.—It flowers from April to September, and is a native of the Cape of Good Hope. This, together with the twenty-first, twenty-third, twenty-fourth, and twenty-fifth species, may all be raised from seed in the green-house or Cape stove.

13. *Glycine Nummularia*. Leaves ternate, very obtuse; racemes with flowers in pairs; legumes sessile, suborbiculate, compressed; stem herbaceous, twining, angular, pubescent;

petioles the length of the leaves; stipules ovate, deciduous; peduncles axillary, solitary, filiform, longer than the leaves, standing out undivided; flowers in three pairs, very remote, sessile, reflex, small.—Native of the East Indies.

14. *Glycine Labialis*; *Labiata Glycine*. Twining: leaves ternate, obovate, somewhat hoary; flowers axillary, heaped; corolla somewhat two-lipped; stalk twining, the thickness of a thread; stipules none; peduncles very short; calix tubular, five-toothed; the teeth nearly equal; style short; seed seven to nine, yellow.—Native of the East Indies.

15. *Glycine Striata*; *Striated Glycine*. Twining: leaves ternate, oblong, very softly hoary; racemes axillary, the length of the leaves; legumes extremely hirsute; stems woody, round, hirsute; petioles hirsute, round, not grooved or angular; all the stipules linear, and acuminate; calix hairy, one-third shorter than the petals; the tube bell-shaped and very short; the limb four-cleft; the clefts lanceolate and acuminate, the lowest a little longer, the uppermost broader, not emarginate; banner of the corolla striated, purple, green at the base, without any calluses; wings erect, narrower and shorter than the keel, purple; keel almost without colour, the length of the banner, cloven at the back almost to the top, emarginate in front at the tip; germen hairy, linear, compressed; style of the same length and in the same situation with the stamina, ending at top in a blunt dusky stigma, not bearded; seeds several, shining brown, variegated.—Native of South America.

16. *Glycine Rosea*; *Roscate Glycine*. Twining: leaves ternate; leaflets cordate-ovate, acute, quite entire; peduncles three-flowered; legumes compressed, keeled, one-seeded.—Native of the Society Islands in the South Seas.

17. *Glycine Lucida*; *Shining Glycine*. Twining: leaves ternate; leaflets ovate, acuminate, quite entire; racemes terminating, glandular; pedicels in threes; legumes inflated, containing two seeds.—Native also of the Society Islands.

18. *Glycine Suaveolens*; *Sweet-smelling Glycine*. Shrubby, upright, hoary; leaves ternate, ovate, acute; flowers axillary, solitary; legumes containing two seeds. The whole of this shrub is hoary, clammy, and sweet; peduncles upright, filiform, jointed, and bracted in the middle, one-flowered; bractes in pairs, subulate, caducous; seeds black, smooth, with a callous whitish heart.—Found by Kœaig, among rocks, near Madras, in the East Indies.

19. *Glycine Apios*; *Tuberous-rooted Glycine*. Leaves unequally pinnate, ovate-lanceolate, with seven leaflets. This has a tuberous root, from which, in the spring, come out slender twining stalks, which rise the height of eight or ten feet. The flowers come out in short spikes from the sides of the stalks; they have little scent, appear in August, but do not produce seeds in England. Parkinson calls this plant *Virginia Earth-nuts*.—It is propagated by parting the roots, and each of the tubers will grow: the best time for this, is at the end of March, or the beginning of April, before they put out shoots. The roots should be planted in a warm situation, and, in hard frost, covered with tan or mulch to protect them, otherwise they will not live abroad in this country; where they have been planted against a south wall, they have thriven and flowered extremely well, which they seldom do in any other situation; and those roots which are planted in pots rarely flower, nor do their stalks rise near so high as those which are planted in the full ground.

20. *Glycine Frutescens*; *Shrubby Glycine*, or *Carolina Kidney-bean Tree*. Leaves unequally pinnate; stalk perennial, woody, twisting themselves together, and twining round any trees that grow near, and will rise to the height of

fifteen feet or more. The flowers are produced in clusters from the axils, and are of a purple colour. They appear from June to September.—It is increased by laying down the young branches in October, which will be well rooted in twelve months from that time, especially if they are duly watered in dry weather, and may then be transplanted, either into a nursery for a year to acquire strength, or to the place where they are to remain for good, which should be in a warm light soil, and a sheltered situation, where they will endure the cold of our ordinary winters very well; and, if their roots be covered with straw, fern, pease-haulm, or any other light covering, there will be no danger of their being destroyed by the frost.—Native of the Cape.

21. *Glycine Monophylla*; *Simple-leaved Glycine*. Leaves simple, cordate; stalk pubescent, three-cornered, the thickness of a thread, prostrate; stipules in pairs; peduncles axillary, solitary, one-flowered, capillary, longer than the petioles; germen villose.—Native of the Cape of Good Hope. It flowers in August.

22. *Glycine Picta*; *Painted Glycine*. Leaves ternate, lanceolate, villose; racemes axillary, peduncled; stem erect, shrubby; branches angular, striated, subtomentose, with purplish hairs; petiole very short; stipule opposite to the leaf, subbid; the segments awl-shaped; pedicels short; flowers spreading, approximating; calix hoary, two-lipped.—Found in Guiana, and in the island of Trinidad. It requires the protection of the bark-stove.

23. *Glycine Bimaculata*; *Two-spotted Glycine*. Stem twining, smooth, and even; leaves simple, cordate-oblong; racemes many-flowered. This plant rises up with a twining shrubby stalk, to the height of six or eight feet or more; multiplying greatly by age, it becomes loaded with a profusion of purple flowers, growing in racemes; the richness of the corolla is enlivened by two green spots at the base of the banner. In England, the flowers generally fade, without producing any seed-vessels; though perfect seeds have been ripened, from which a plant was produced, that bore flowers in the garden of John Ord, Esq. at Walham Green. It begins to flower in February, and continues during the summer. This is one of the first Botany Bay plants that flowered in this country, and is one of the most ornamental. Mr. Curtis thinks, that both this and the next species may probably succeed in the open air, in warm sheltered situations, especially if a little protected in severe weather.

24. *Glycine Rubicunda*; *Red Glycine*. Stem perennial, twining; leaves ternate; leaflets suboval, quite entire; peduncles subtriflorous. Almost the whole plant is covered with hairs, pressed close; corolla scarlet, mixed with dull purple; banner bent back, so as to lie on the calix, and cover it, scarlet on the ends and on the sides, purple in the middle, except towards the base, where it is whitish; stamina very manifestly diadelphous.—It flowers from April to June, and is a native of New South Wales.

25. *Glycine Coccinea*; *Scarlet Glycine*. Leaves ternate; leaflets roundish, waved. Shrubby, climbing, growing many feet high when supported, and producing a great number of flowers on its pendent branches; flowers generally in pairs, of a glowing scarlet colour, rather inclined to purple at the base of the keel; the bottom of the banner is decorated with a large yellow spot, verging to green.—It flowers from April to June, and was introduced from New South Wales.

Glycyrrhiza; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved; tubular, two-lipped, permanent; upper lip three-parted; the lateral segment linear, the middle one broader,

bifid, the lower entirely simple, linear. *Corolla*: papilionaceous; banner ovate-lanceolate, straight, longer; wings oblong, very like the keel, but a little larger; keel two-petalled, acute, with a claw the length of the calix. *Stamina*: filamenta diadelphous, (simple and nine-cleft,) straight; antheræ simple, roundish. *Pistil*: germen shorter than the calix; style subulate, the length of the stamina; stigma obtuse, ascending. *Pericarp*: legume ovate or oblong, compressed, acute, one-celled. *Seeds*: very few, kidney-form. **ESSENTIAL CHARACTER.** *Calix*: two-lipped; upper lip three-parted, lower undivided. *Legume*: ovate, compressed.—The species are,

1. *Glycyrrhiza Echinata*; *Prickly-headed Liquorice*. Legumes prickly; leaves stipuled, with the terminating leaflets sessile. The stems are two or three feet high, nearly simple, leafy, round, and striated. The flowers appear in a roundish head: they are produced in shorter spikes than those of the second species, their colour a dull purple; the pods are very short, and broad at their base, ending in acute points, and armed with sharp prickles. The whole plant is somewhat clammy to the touch. It flowers from April to June, and in warm seasons will perfect seeds in England.—Native of Monte Gargano, in Apulia; the north of China; and of Tartary.

2. *Glycyrrhiza Glabra*; *Common Liquorice*. Legumes smooth; no stipules; the terminating leaflet petioled. The roots run very deeply into the ground, and also creep to a considerable distance, especially where they stand long unremoved. From these arise strong herbaceous stalks, four or five feet high; leaves composed of four or five pairs of ovate leaflets, terminated by an odd one; these and the stalks are clammy, and of a dark green; flowers in axillary spikes, standing erect, and of a pale blue colour; pods short, containing two or three seeds.—Native of the south of Europe, France, Spain, Italy, also of China, where it is cultivated, as well as in Germany and England; with us at Pontefract in Yorkshire, Worksop in Nottinghamshire, Godalmin in Surry, and, of late years, in the gardens near London. It appears from Turner's Herbal, that it was cultivated in England in 1562; and Stow expressly says, "the planting and growing of licorish begun about the first year of Queen Elisabeth," (1558.) Gerard, in 1597, says, that he has plenty in his garden; and the poor people of the north parts of England manured it with great diligence, whereby they obtained great plenty. Ray asserts the English liquorice to be superior to the foreign. The quantity now imported from Spain is said to be annually not less than 4000 quintals, or nearly 250 tons; a considerable part of which is supposed to be used by the porter-brewers of London. Liquorice-root contains a great quantity of saccharine matter, with some portion of mucilage. Lightly boiled in a little water, it gives out nearly all its sweetness: the decoction, pressed through a strainer, and inspissated with a gentle heat till it will no longer stick to the fingers, affords a better extract than that brought from abroad, under the name of *Spanish-juice*, and will often amount in quantity to nearly half the weight of the root. Large quantities of extract of liquorice have been annually imported from Spain, but the shops seldom afford any that is perfectly genuine; the makers, both foreign and domestic, being either very slovenly in the preparation, or else they designedly mix it with sand, and other impurities. When carefully extracted, it is exceedingly sweet, more agreeably tasted than the root itself, and of a pleasant smell. It dissolves in boiling water, without leaving any sediment. Rectified spirit takes up the sweet matter of the liquorice, equally with water; and as it dissolves much less of the insipid mucilage,

the spirituous tincture and extract are sweeter than the watery. Before the roots are boiled, it is best to cut them into small pieces, that they may more readily give out their virtues; for if the boiling be too long continued, the rich sweet taste, for which the extract is so justly esteemed, will be greatly injured. For the same reason, the quantity of water ought not to be more than is absolutely necessary to extract the virtues of the root. A quart, or at most three pints, will be found a sufficient quantity for a pound of liquorice. It would be of considerable advantage to the preparation, and probably less expensive to the preparers, to use the juice of the roots, which might be obtained by pressing them between iron rollers, in the manner practised in the West Indies, for obtaining the juice of the sugar-cane, instead of the above process of decoction. Both the extract and the fresh root, in substance, are excellent for coughs, hoarseness, shortness of breath, and other disorders occasioned by an acrimonious state of the humours. They promote expectoration, thicken the juices, increase the urinary discharge, and are serviceable in the gravel, and similar disorders. It was prescribed by the first practitioners in physic, in dropsies, to prevent thirst, for which it is indeed an excellent thing, though probably the only one of the sweet class that does so; sugar, and other substances of a like nature, generally increasing, rather than alleviating that sensation. The infusion is also a commodious vehicle for other medicines.—*Culture.* Most plants thrive best in a rich soil, but Liquorice will not grow in any other; and to have it in any degree of perfection, the soil must not only be rich, but deep, as the thriving of it depends entirely on those two circumstances. We expect to see the roots of this plant a yard or more in length; and it must have a free passage, otherwise they will not be straight, which regularity of form is not only more pleasing to the eye, but a real advantage, for the crooked ones are never so tender or full of juice as the other, nor do they attain their due degree of growth in so short a time. The proper ground then for producing Liquorice in perfection, should have a coat of mellow black mould, at least three feet deep, without any great mixture of other matter in the way. This is the best natural soil for this valuable plant, and where it can be procured should always be preferred. But there are other soils, which, though not quite so well adapted by nature for the culture of Liquorice, may be so prepared by art and industry, as very well to answer the purpose. The best of these are, first, a rich loam, without much clay in its composition; and, secondly, a deep, warm, sandy soil, that is not barren, but, together with its lightness and dryness, has some richness. In all these soils, the depth must be at least a yard, before there is any hard bottom; and that must be examined, for if it should turn out a clay, the Liquorice will never thrive, because of the coldness and moisture with which such an under stratum is always attended; the wet lodging upon it, and starving the whole soil. To ensure success in the planting of Liquorice, the soil should possess the four following properties: depth, that it may penetrate and attain its full growth; lightness, that it may make its way easily; warmth, to promote its growth; and richness, to afford it nourishment. Liquorice, though raised in the field, requires a kind of garden culture, and the spade is a much more proper instrument to prepare the land with for its reception than the plough, for it requires to be broke, and made fine to a depth which the latter can never reach. There is one comfort, however, arises to the husbandman, which is, that if the land requires an expensive tillage, only a small quantity is required, as a few acres will yield an amazing produce of this root; and the price it will bear is so

much greater than that of most other things he can raise on it, that there is no room left for him to repine at the charges. Having therefore made choice of a proper piece of land for the purpose, let it be thoroughly dunged with good rotten dung, and after being ploughed up in the latter end of the summer, and laying all the winter to mellow, in the spring let it be dug in the following manner. In the middle of February, let the labourers be sent in, and properly looked over, to see that they do not perform their work slightly. They must dig every part of the earth thoroughly to the depth of three feet, and take care to break every lump they meet with, though but small, in order that the ground may lie smooth, with a level surface, and be nearly as fine as sand all the depth. The expense of doing this is very considerable, but it is absolutely necessary; the profit will be answerable; and the husbandman may rest assured, that by every shilling he would save in not having this work well performed, he would lose ten at least in the crop. When the whole piece of ground intended for the plantation is thus prepared, the sets are to be put in, and the same care and attention are requisite here, as in the other parts of the business, for the least omission or neglect is sure to be attended with loss. The first thing to be regarded in this respect, is the choice of the plants or sets; and the second is, placing them properly in the ground. Choice should be made of such only as are in good condition, and have, as the planters call it, a good eye or bud. They are either raised from seeds, or procured from the heads of the old roots, most commonly the latter, and should be about a foot in length, sound, fresh, and clear on the surface. About the beginning of March, when the sets are chosen, and the ground is perfectly prepared, is the season for planting, which should be performed in the following manner. Let there be got in readiness a gardener's line, of such a length as to extend from one side of the ground to the other, if it be but small; but if larger, it may be removed from place to place occasionally. A couple of sticks sharpened at the end, and a ball of cord, is all that is necessary for this purpose. Besides the line, the planter must be furnished with a setting-stick, which may be of any convenient length; but the best way is to have it of a certain dimension, that it may serve for a measure; and for this purpose, it should be just a foot and a half long, with a handle or crutch at the top like a spade, and a point made of a square piece of iron in form of a very large spike, and hollowed at the upper end to receive the wood. All things being in readiness, let the line be drawn at about the distance of a foot from the outside of the prepared ground. The planter then taking his sets in his apron, or a basket, and the setting-stick in his hand, may begin to plant, placing the first set at about half the stick's length from the end of the line. When he has done this, let him measure from it along the line the length of his setting-stick, and at that distance plant another, and so on for the whole length. The manner of putting in the sets is this: let the end of the setting-stick, which is pointed with iron, be thrust into the ground till the handle almost touches the surface, and then being gently drawn out again, there will remain a hole about sixteen inches deep, into which is to be put a set of the Liquorice, carefully and evenly thrusting it down till the head of it, where the bud or eye is, be one inch or a little more below the surface; the other end will then about reach the bottom of the hole, and a little mould being drawn over the top, the set will be completely well planted. The remaining part of the row is to be planted exactly in the same manner; and when that is completed, a second is to be begun at the distance of two feet and a half from it. But in planting this, it will be best not to place the

plants exactly opposite to those in the last row, but in the middle between them. The second row being put in, the line is to be drawn for a third, and the plants in this should be set opposite to those in the first row, which being done, every fourth plant of the first and third row will have one plant of the second row in their centre. This method is to be followed throughout the whole field, and is called the quincunx manner of planting; the effect of which is, that look whichever way you will at the plantation, when the stems are risen, they will appear in regular rows the whole extent of the ground. The whole being planted, the earth is to be finely raked, and the surface made perfectly level. Thus it is to be left for the present; and the advantages of so regular a piece of husbandry will sufficiently recompense the planter's trouble. The heads of the young plants will quickly appear, and weeds of the annual kinds will spring up in abundance along with them; these may be easily and expeditiously destroyed by going over them with the hand-hoe. This hoeing must be occasionally repeated during the summer; the expense attending it will be but small, and all the care requisite in performing it is, to avoid cutting or wounding the young plantation. The ground being thus kept clear during the summer, it will be well worth while to turn the whole over, one spit deep between the rows, as soon as the leaves begin to decay: and a month or two after, let a small quantity of very rotten dung be scattered all over the surface; this will cover the crowns of the young plants, and defend them from the severity of the winter's frost, and when those are past, the rains will in a manner dissolve the very substance of the dung, and convey its richness into the heart of this fine loose earth, for the better nourishment of the plants. In the spring, what remains will be dug in by turning the spaces between the rows over again, where, by mixing and fermenting with the mould, it will break and divide the soil, as well as enrich it farther. All that remains to be done the second summer, is to keep the plants free from weeds; and at the end of the third, they will be ready to take up for use.

3. *Glycyrrhiza Hirsuta*; *Hairy Liquorice*. Legumes hirsute; the terminating leaflet petioled. This strongly resembles the two preceding species; but the pods are hairy and longer.—Native of the Levant.

4. *Glycyrrhiza Asperima*; *Rough Liquorice*. Legumes smooth; leaflets elliptic, cusped; stalk hispid, scabrous; roots slender and very long, extremely sweet, especially in the spring. The flower pale violet colour.—Found between the Wolga and the Jaick.

Gmelina; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, very small, subglobular, four-toothed, permanent. *Corolla*: one-petalled, bell-shaped, patulous; the border four-cleft; the upper segments wider and vaulted; the lower and lateral segments obtuse, smaller, spreading, rounded. *Stamina*: filamenta four, two of which are thicker, and two bowed in and ascending; antheræ, two thicker, parted, two smaller, simple. *Pistil*: germen roundish; style the length of the smaller stamina; stigma simple. *Pericarp*: drupe ovate, one-celled. *Seed*: nut ovate, smooth and even, two-celled; Gærtner says three-celled, with the lowest cell barren. ESSENTIAL CHARACTER. *Calix*: slightly four-toothed. *Corolla*: four-cleft, bell-shaped. *Antheræ*: two-parted, two simple. *Drupe*: with a two or three celled nut.—The species are,

1. *Gmelina Asiatica*. A tree, with round, stiff, upright branches; leaves opposite, petioled, ovate, tomentose underneath, having frequently a shorter sharp lobe on each side; spines axillary, opposite, horizontal, pubescent at the tip,

the length of the petioles; flowers from the end of the tender twigs, on peduncles; the fruit a berried drupe, the size of jujubes, black and smooth; the shell bony, thick at top, with two small lateral lobes, remarkably acuminate at bottom.

Gnaphalium; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common rounded, imbricate, with the marginal scales rounded, scariose, coloured. *Corolla*: compound; corollets hermaphrodite, tubular, with apetalous females sometimes intermixed; hermaphrodites funnel-form, with a five-cleft reflex border. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; anthera cylindrical, tubulous. *Pistil*: germen ovate; style filiform, the length of the stamina; stigma bifid; in the females reflex. *Pericarp*: none; the calix permanent, shining. *Seeds*: solitary, oblong, small, crowned with a capillary or feathered down. *Receptacle*: naked. ESSENTIAL CHARACTER. *Calix*: imbricate, with the marginal scales rounded, scariose, coloured. *Down*: feathered; or simple. *Receptacle*: naked.—The numerous species of this genus are either undershrubs or herbs; the leaves are placed alternately, and are for the most part hoary: the flowers usually terminate the stem and branches in globes or corymbs: the calix is permanent, with yellow or white scales. The first twelve species, and most of the others, may be increased by slipping off the heads, or by cuttings, during any of the summer months; they should be planted in a bed of light earth, or in pots in a gentle hot-bed, and covered with hand-glasses, or shaded with mats, observing to refresh them frequently with water in small quantities; these cuttings will put out roots in six or eight weeks, and must then be planted in pots filled with light earth, and placed in a shady situation till they have taken new root, when they may be removed to an open one, and placed among other hardy exotics, till the middle or end of October; at which time they should be placed under a common frame, where they may be protected from frost, but in mild weather they should be exposed to the open air.—The species are,

* *Shrubby, with white Flowers.*

1. *Gnaphalium Eximium*; *Choice Gnaphalium*. Leaves sessile, ovate, crowded, upright, tomentose; corymb sessile. Stem the thickness of a finger, and tomentose; flowers globular, with the calices as large as the outer joint of a finger, consisting of imbricate, roundish, scariose, concave, obtuse, smooth, purplish scales.—Native of the Cape.

2. *Gnaphalium Arboreum*; *Tree Everlasting*. Leaves sessile, linear, smooth on the upper surface, rolled back along the edge; flowers in a kind of head, on elongate peduncles. This is a shrub the height of a man, determinately branched; the leaves resemble those of Rosemary, crowded; corymb very much crowded. It flowers during most part of the year.—Native of the Cape.

3. *Gnaphalium Grandiflorum*; *Great-flowered Everlasting*. Leaves stem-clasping, ovate, three-nerved, lanuginous on both sides. Branches round, simple, tomentose; flowers large, roundish, snow-white, in roundish, heaped, solitary cymes, on long tomentose scaly peduncles.—Native of the Cape.

4. *Gnaphalium Fruticans*; *Fruiting Gnaphalium*. Leaves ovate, stem-clasping; stem rigid; cyme sessile. Stem the thickness of a finger, determinately branched, villose; flowers terminating, and heaped into a sessile head; calix yellow on the outside, but white within.—Native of the Cape.

5. *Gnaphalium Crispum*; *Crisped Gnaphalium*. Leaves tomentose underneath, scabrous above; root-leaves petioled, oblong; stem-leaves embracing, waved. Peduncle elongated,

tomentose, terminated by a compound many-flowered cyme; flowers small; outer calices red, inner yellow.—Native of the Cape.

6. *Gnaphalium Appendiculatum*; *Appendiculated Gnaphalium*. Leaves sessile, imbricate, lanceolate, woolly, appendicled at the tip with a scariose membrane. Stem clothed with leaves up to the cyme. It is remarkable for a little, lanceolate, scariose membrane, terminating the leaf.—Native of the Cape.

7. *Gnaphalium Coronatum*; *Crowned Gnaphalium*. Leaves sessile, lanceolate; corymbs compound, sessile; peduncles leafless; calices crowned. Stems woody, with villose branches.—Native of the Cape.

8. *Gnaphalium Discolorum*; *Coloured Gnaphalium*. Leaves sessile, lanceolate; calices white; lower scales flesh-coloured. Stems under-shrubby; common peduncles elongated.—Native of the Cape.

9. *Gnaphalium Muricatum*; *Prickly Gnaphalium*. Leaves subulate, mucronate; umbel compound; calices cylindrical, containing about three flowers. Stem erect, round, pubescent; branches patulous, simple, alternate, or somewhat heaped, lightly tomentose. This varies with leaves sharp or prickly, like those of juniper.—Native of the Cape.

10. *Gnaphalium Ericoides*; *Heath-leaved Everlasting*. Leaves sessile, linear; outer calices rude, inner flesh-coloured. The branches are wand-like, rigid, unequal.—Native of the Cape.

11. *Gnaphalium Teretifolium*; *Crowded Everlasting*. Leaves crowded, almost columnar; corymbs branched; calices ferruginous on the outside. Stem ash-coloured, round, sub-tomentose; branches leafy, white, tomentose; branchlets determinate, umbelled, erect, each loaded in the middle with other short aggregate branchlets.—Native of the Cape.

** *Shrubby, with yellow Flowers.*

12. *Gnaphalium Mucronatum*; *Pointed Everlasting*. Leaves subulate, mucronate; calicine scales roundish. Branches a span long, erect, simple, round, slightly tomentose, ash-coloured; flowers six, large, in panicles, terminating, contracted, on one-flowered tomentose peduncles.—Native of the Cape.

13. *Gnaphalium Stoechas*; *Common Shrubby Everlasting*. Leaves linear; corymb compound; branches wand-like. Stem about three feet high, with long slender irregular branches, the lower ones having blunt leaves two inches and a half long, and an eighth of an inch broad at the end; those on the flower-stalks are very narrow, and end in acute points. The whole plant is very woolly; flowers terminating in a compound corymb; calices at first silvery, but turning to a yellow sulphur. If gathered before the flowers are much opened, the heads will continue in beauty many years, if kept from air and dust. The flowers are androgynous; and have been formerly recommended as attenuants, discutients, and diaphoretics, but are not used in common practice.—Native of Germany, France, Spain, and Italy. This, together with the thirteenth, fourteenth, twenty-fifth, and thirty-sixth species, is so hardy, as, in very mild winters, to live abroad in warm borders near walls, with little shelter.

14. *Gnaphalium Ignescens*; *Red-flowered Everlasting*. Leaves sublancoate, tomentose, sessile; corymbs alternate, conglobate; flowers globular. Stem and leaves woolly; the former a foot high, sending out a few side-branches, terminated by a compound corymb, the heads of which are small, of a gold colour, changing to a red as they fade.—Native place unknown.

15. *Gnaphalium Dentatum*; *Toothed Everlasting*. Leaves wedge-shaped, toothed, sessile; corymb simple. The whole

plant is hoary; branches scarcely a span long, and round; flowers at the ends of the branchlets few, small, shining, in oblong heads.—Native of the Cape.

16. *Gnaphalium Serratum*; *Serrated Everlasting*. Leaves stem-clasping, lanceolate, serrate, naked on the upper surface. This is an elegant plant, suffruticose, soft and silky, yellow, much branched, with procumbent, simple, pubescent runners; flowers terminating, very many, in a close compact head, each on short pedicels.—Native of the Cape.

17. *Gnaphalium Patulum*; *Spreading Everlasting*. Leaves stem-clasping, spatulate; corymbs aggregate; branches spreading. Branches filiform, a foot or more in length, round, white, tomentose, patulous, somewhat branched; cymes terminating, loose, on long peduncles, tomentose, leafless; flowers large, peduncled. It flowers from August to January.—Native of the Cape.

18. *Gnaphalium Petiolatum*; *Petioled Everlasting*. Leaves ovate, quite entire, petioled; flowers crowded, terminating. Nearly related to the foregoing species.—Native of the Cape.

19. *Gnaphalium Crassifolium*; *Thick-leaved Everlasting*. Leaves broad-lanceolate, subpetioled, leathery, tomentose; corymb compound; stalk proliferous. Stem a foot high, proliferous, branched, perennial, except the proliferous branch; flowers numerous; calices pale yellow; corollas of a deep purple. The florets before they open appear white. It flowers from July to September.—Native of Majorca and Minorca.

20. *Gnaphalium Maritimum*; *Sea Everlasting*. Very much branched; leaves lanceolate, sessile, sharpish; inmost calicine scales gold-coloured. This shrub is four feet high, with pubescent branches; corymbs terminating, close, roundish, on very short peduncles; flowers gold-coloured.—Native of the Cape.

21. *Gnaphalium Repens*; *Creeping Everlasting*. Leaves linear; stem creeping, straight; branches upright, very simple. The stem is perennial, perfectly simple, filiform, angular, four feet high; branches alternate, two inches in length, bearing both leaves and flowers; flowers yellowish, the size of hemp seed.—Native of the Cape.

22. *Gnaphalium Umbellatum*; *Umbellated Everlasting*. Leaves in bunches, subulate, twisted; umbels simple, terminating, sessile. The herb of this plant bears a strong resemblance to the ninth species, but it differs in having a regular umbel, larger flowers, and the scales of the calix are of a beautiful red, in which last circumstance it resembles a *Xeranthemum*.—Native of the Cape.

23. *Gnaphalium Hispidum*; *Hispid Everlasting*. Leaves linear, semicylindric, grooved, hispid, patulous; heads terminating, simple. This species is easily known by the stiff bristles on its acerose leaves, and by its aggregate flowers.—Native of the Cape.

*** *Herbaceous, with yellow Flowers.*

24. *Gnaphalium Cylindricum*; *Cylindrical Everlasting*. Leaves sessile, oblong, tomentose; corymbs unequal; calices smooth, cylindric, sessile. Herb branched, diffuse, a span in length, tomentose all over; calices very long, imbricated with equal, ovate, bluntish scales.—Native of the Cape.

25. *Gnaphalium Orientale*; *Eastern Everlasting*. Leaves linear-lanceolate, sessile; corymb compound; peduncles elongated. Stem seldom rising more than three or four inches high, and putting out many heads; flower-stems eight or ten inches high, with narrow hoary leaves all the way, terminated by a compound corymb of bright yellow flowers in large heads, coming out in May, and continuing in succession most part of the summer. It has been long in Portugal, where, in the winter season, they ornament the churches with

the flowers. Of this species there are two kinds, the Broad-leaved, and the Narrow-leaved. The shrubby or narrow-leaved variety grows naturally at the Cape; it differs from the other in rising with stalks four or five feet high, dividing into many branches, having long narrow leaves placed alternately; the corymbs loose, and the flowers on long pedicels.

26. *Gnaphalium Arenarium*; *Sandy Everlasting*. Leaves lanceolate, the lower ones obtuse; corymb compound; stalks quite simple. This is an annual hoary plant, with an oblong root; stem upright, a foot or more in height, white with down. The shining yellow heads of flowers are two lines in length and breadth; the calicine scales are ovate, blunt, and lemon-coloured, as are also the corollas. It is supposed to preserve woollen clothes from the moth; and was formerly much recommended in dysenteries, but is now disused.—Native of Scania, Denmark, and Germany, where it is found in dry sandy pastures and hills, flowering from July to September; also of Japan, where it is used for moxa, and as tobacco, and is found by way-sides, and in ditches, flowering from December to April.—This, with the rest of the European sorts, if the seeds are permitted to scatter, will come up with greater certainty than if they were sown; but they are rather regarded as weeds, than as garden plants.

27. *Gnaphalium Rutilans*; *Shining-flowered Everlasting*. Leaves lanceolate; corymb decomposed; stalk branched at bottom. Stem slender, sending out many lateral branches below, with narrow leaves, hoary on their under side. The flowers are produced in a compound corymb at the ends of the branches; at their first appearance they are of a pale red, but afterwards change to a gold colour; the calices are small and dry, like the other species of *Everlasting*.—Native of the Cape; flowering from the end of June till August.

28. *Gnaphalium Milleflorum*; *Many-flowered Everlasting*. Flowers corymbed, fastigate, reddish-white; calices cubeylindric. Stalk a foot high, tomentose; corymb terminating, with above fifty flowers in it; corollas yellow.—Native of the Cape.

29. *Gnaphalium Imbricatum*; *Imbricated Everlasting*. Leaves lanceolate, tomentose; calicine scales reflex; stalk branched. Stem ash-coloured, tomentose, diffused, erect, scarcely a foot high; branches alternate, wand-like, simple, tomentose, erect.—Native of the Cape.

30. *Gnaphalium Cymosum*; *Branching Everlasting*. Leaves lanceolate, three-nerved, smooth on the upper surface; raceme terminating; stalk branched at bottom. Perennial; about eighteen inches high; stalks woody, cylindric. The flowers are entirely of a gold colour, and smooth, with blunt scales; they are very numerous, small, and oblong, and, like the leaves, emit, when rubbed, an odour like that of southernwood.—It flowers from April to August, and is a native of the Cape.

31. *Gnaphalium Nudifolium*; *Naked-leaved Everlasting*. Leaves lanceolate, three-nerved, naked, with netted veins; root-leaves lanceolate-ovate, by no means tomentose, scarious about the edges. Stalk simple, a foot high, having smaller leaves of a more lanceolate shape at bottom, and naked at top; flowers golden, in a compound corymb. Perennial.—Native of the Cape.

32. *Gnaphalium Luteo-album*; *Jersey Everlasting*, or *Cudweed*. Leaves half stem-clasping, sword-shaped, repand, obtuse, pubescent on both sides; flowers conglomerate. This is an annual plant, and very woolly; stalks many, upright, a foot or eighteen inches in height. It flowers from July till September. There is a variety with narrow leaves, higher, and more branched stalks; the flowers in close bunches on the tops of the stalks, of a pale yellow colour.—Native of the

south of France, Spain, Portugal, Switzerland, Germany, the island of Jersey, the sea-coast of Wales, the west of England, and near Bosnor rocks in Sussex; in sandy grounds, or on dry banks and walls; found also in New Caledonia. This will come up better from scattered seeds, than when they are sown by art; but if the seeds be sown, it must be soon after they are ripe. The plants require only to be kept clean from weeds, and to be thinned where they are too close.

33. *Gnaphalium Albescens*; *Whitish Everlasting*. Snowy tomentose; leaves linear-lanceolate; stalk upright, undivided at bottom; branches terminating, fastigiate; flowers crowded, conical. Shrubby.—Native of Jamaica.

34. *Gnaphalium Pedunculare*; *Peduncled Everlasting*. Leaves spatulate, somewhat stem-clasping, tomentose underneath; calicine scales sharpish. Stalk herbaceous, a foot and a half in height, branched, diffused, with elongated branches.—Native of the Cape.

35. *Gnaphalium Odoratissimum*; *Sweet-scented Everlasting*. Leaves decurrent, mucronate, tomentose on both sides, flat. Stems about three feet high, dividing into many irregular branches, terminated by a compound corymb of flowers, closely joined, of a bright gold colour, but small, and changing to a darker colour as they fade.—Native of the Cape.

**** *Herbaceous, with white Flowers.*

36. *Gnaphalium Sanguineum*; *Bloody Gnaphalium*. Leaves decurrent, lanceolate, tomentose, flat, with a little naked point at the end. Stems about six inches high, with lanceolate-acute leaves, woolly, terminated by a large corymb of flowers, sitting very close, and of a fine red colour.—Native of Egypt and Palestine.

37. *Gnaphalium Fœtidum*; *Strong-scented Everlasting*. Leaves stem-clasping, quite entire, acute, tomentose underneath; stalk branched. This is an annual plant, sending out many oblong blunt leaves near the root; stems a foot and half high, terminated by a corymb of flowers, which have large silvery calices, that will retain their beauty several years. It varies with golden calices.—Native of the Cape.

38. *Gnaphalium Undulatum*; *Waved Everlasting*. Leaves subdecurrent, lanceolate, waved, acute, tomentose underneath; stalk branched. Annual; stems about a foot high. The flowers are in a terminating corymb; they are white, and appear in July. The whole plant has a disagreeable odour.—Native of the Cape.

39. *Gnaphalium Americanum*; *West-Indian Everlasting*. Root-leaves lingulate-lanceolate, snow-white beneath; stalk simple, upright, tomentose; flowers spoked, and lateral, sessile, crowded. It is annual, and seldom rises above six or nine inches in height. Flowers yellowish, and dispersed pretty thick about the top of the stalk, which puts on the appearance of a shorter spike.—Native of Jamaica, in the coldest mountains of Liguanea.

40. *Gnaphalium Crispum*; *Curled Everlasting*. Leaves stem-clasping, spatulate, tomentose; calices very obtuse, plaited, and waved, tomentose at the base. Stalks simple, hardish, tomentose, throwing out small branches from the axils, which, as well as the whole plant, are very white. The corymbs are leafless.—Native of the Cape.

41. *Gnaphalium Helianthemifolium*; *Dwarf-Cistus-leaved Everlasting*. Leaves somewhat stem-clasping, lanceolate; corymbs compound; calicine scales somewhat plaited. Stalks wand-like, branched, tomentose.—Native of the Cape.

42. *Gnaphalium Squarrosum*; *Square Everlasting*. Leaves sessile, tongue-shaped, tomentose; the inner calicine scales subulate, and bowed back. Stalks ascending, simple, scarcely a foot high, very tomentose; flowers terminating, crowded.—Native of the Cape.

43. *Gnaphalium Stellatum*; *Starry Everlasting*. Leaves sessile, lanceolate, villose; calices acute, flesh-coloured on the outside. Stalks several, half a foot high; flowers glomerate.—Native of the Cape.

44. *Gnaphalium Obtusifolium*, or *Polycephalum*; *Blunt-leaved Everlasting*. Leaves lanceolate; stalk tomentose, panicled; flowers glomerate, conical, terminating. Stems single, about nine inches high; flowers in spikes from the side of the stalks, of a dirty white colour. Annual.—Native of Virginia, Pennsylvania, and New England.

45. *Gnaphalium Margaritaceum*; *American Everlasting*, or *Cudweed*. Leaves linear-lanceolate, acuminate, alternate; stalk branched at top; corymbs fastigiate. Root perennial, creeping, and spreading far, so as to become a troublesome weed; stalks extremely downy, white. The flowering branches form a broad flat bunch; each branch contains numerous crowded heads, on short, branched, downy peduncles, but the middle ones sessile; scales of the calix bluntly ovate, white, not downy. A decoction of the flowers and stalks is used in America, to foment the limbs for pains and bruises. It flowers from July to September.—Native of North America, where it grows in vast quantities in uncultivated fields, glades, and hills, and is called *life everlasting*, because the silvery heads, properly dried, will keep their beauty long without changing. It is found also in Kamtschatka; and has been long known in the English gardens, though none of our old herbalists mention its being found wild in this island. It has been observed near Bocking in Essex, and in various parts of Wales. Both it and the next species will thrive almost any where, and are easily propagated by their creeping roots.

46. *Gnaphalium Plantagineum*; *Plantain-leaved Everlasting*. Runners procumbent; stalk very simple; root-leaves ovate, very large. Perennial. From the main stalk come out runners, which take root in the ground; stem-leaves narrow, woolly, alternate; flowers in a terminating corymb, white, and small, appearing in June and July.—Native of North America. See the preceding species.

47. *Gnaphalium Dioicum*; *Mountain Everlasting*, *Cudweed*, or *Cat's-foot*. Runners procumbent; stalk quite simple; corymb simple; flowers divided. Root woody, brown, strikes deep, throwing out a few fibres; stems erect, simple, from two or three to six or seven inches high, white, downy. The root-leaves form a thick tuft, and are oval at the extremity, tapering into a long footstalk; they are green, and slightly hairy above, beneath white, with a thick down; flowering-heads three to eight crown the stem in a close bunch, on short peduncles. It rarely happens that any ripe seed is produced, indeed plants that creep by the root are often sterile. It flowers in May and June.—Native of open downs in most parts of Europe. In England it is found on Newmarket heath, and Gogmagog hills; on Canham heath, near Bury; Swaffham and Stratton heaths in Norfolk; in Cornwall, and Wales; on Bernack and Wittering heaths, in the northern counties; and in Scotland.

48. *Gnaphalium Alpinum*; *Alpine Everlasting*. Runners procumbent; stalk quite simple; heads leafless; flowers oblong. Root perennial; stalks simple, hardly a finger's length; root-leaves lanceolate, wedge-shaped, the upper surface green, smooth, and even, the under white, with a streaked nap, so that the edge, even of the upper surface, appears white.—Native of the Lapland Alps, and of Switzerland.

49. *Gnaphalium Indicum*; *Indian Everlasting*. Leaves lanceolate; stalk very much branched, diffused; corymbs unequal; calices coloured within. Perennial; flowers small; calicine scales ovate, brown, those surrounding the disk

dilated, round, and white, so that the heads are brown, with a white crown.—Native of the East Indies and Cochin-china.

50. *Gnaphalium Purpureum*; *Purple Everlasting*. Leaves lanceolate, naked; stalk erect, quite simple; flowers in lateral sessile spikes. They appear in summer and autumn.—It is an annual plant, and a native of Carolina and Virginia.

51. *Gnaphalium Denudatum*; *Bare Everlasting*. Leaves spatulate, underneath snowy-white tomentose, smooth and even above. Stalks prostrate, filiform, hardish, with alternate upright branches; corymb or umbel terminating, and very short; flowers peduncled; calix green, with a short white ray.—Native of the Cape.

**** *Resembling Filago, herbaceous.*

52. *Gnaphalium Sylvaticum*; *Wood Everlasting, English or Upright Cudweed*. Stalk quite simple, upright; flowers scattered. This is a biennial plant. In woods, one stem, from twelve to eighteen inches high, generally grows from the root. In open ground, the root-leaves form a thick tuft, and from among them arise several shorter stems, sometimes not more than three inches high, at first often declining, but very soon ascending. The leaves are green and hairy above, white and thickly downy beneath; flowers in a long spike, composed of very short branches, bearing from one to five or more flowers; scales of the calix bluntly oval, greenish at the base, yellowish-brown upwards, smooth, with shining margins.—It flowers in August, and is a native of most parts of Europe. In Great Britain, it has been remarked at Norwood in Surry; on Hampstead heath, and in the woods adjoining; near Charlton; about Harefield; in Gamburgay park, Cambridgeshire; in Armingdale wood near Norwich; on Naseby-field and Thorp Malsor in Northamptonshire; in rough pastures near Fladbury in Worcestershire; on a sandy heath, a mile from Shiffnal, on the road to Wolverhampton; on the banks of the canal, in the parish of Cosely in Warwickshire; on the great island in Winandermere, and on the Highlands of Scotland, and in some parts of South Wales.

53. *Gnaphalium Spicatum*; *Spiked Everlasting*. Stems herbaceous, quite simple; flowers in whorls; leaves in bundles, linear, revolute; calicine scales scariose, ferruginous, shining, ovate, lanceolate.—Native of Egypt.

54. *Gnaphalium Verticillatum*; *Whorled Everlasting*. Stalk quite simple; flowers in whorls; leaves linear. The whole plant, and even the flowers, are ash-coloured.—Native of the Cape.

55. *Gnaphalium Oculus Cati*; *Cat's-eye Everlasting*. Stalk prostrate; leaves ovate; flowers glomerate, terminating, extremely villose; calix concealed by a very thick white nap; corollas small, surrounded by nap.—Native of the Cape.

56. *Gnaphalium Pilosellum*; *Bald Everlasting*. Leaves lanceolate, five-nerved, tomentose underneath; stalk naked; flowers in heads. Scape twice as long as the leaves, hairy.—Native of the Cape.

57. *Gnaphalium Declinatum*; *Creeping Everlasting*. Leaves linear-lanceolate; the calices with a white lanceolate ray. Stalks prostrate, filiform; flowers in a terminating, fastigate, leafless corymb; florets many, in a small calix.—Native of the Cape.

58. *Gnaphalium Coronatum*; *Rayed Everlasting*. Leaves lanceolate; calices with a manifold roundish ray; flowers in corymbs, heaped; peduncles leafy.—Native of the Cape.

59. *Gnaphalium Supinum*; *Dwarf Everlasting, or Cudweed*. Stalk simple, procumbent; flowers scattered. Perennial. Root-leaves in tufts, half or three-quarters of an inch long, narrow, linear-lanceolate, slightly hairy above, downy beneath, but greenish; stem two or three inches high,

with two or three longer and sessile leaves. It flowers in July and August, and is a native of the Swiss and Italian Alps, and the tops of the Highland mountains in Scotland.

60. *Gnaphalium Uliginosum*; *Marsh Everlasting, or Cudweed*. Stalk branched, diffused; flowers crowded, terminating. Stem from three to seven inches or more high, upright, covered with thick down, and much branched; leaves elliptical, tapering into a long footstalk, slightly downy and greenish above, more so and whitish beneath. The ends of the branches are crowded with numerous heads of nearly sessile flowers, which appear in August.—Native of marshy places in most parts of Europe.

61. *Gnaphalium Glomeratum*; *Cluster-flowered Everlasting*. Stalk diffused; inner scales of the calices subulate and naked; leaves somewhat stem-clasping. Annual; heads leafy; branches higher than the stalks.—Native of the Cape.

* *New Species.*

62. *Gnaphalium Japonicum*. Herbaceous; upright leaves linear-sword-shaped, snowy-white underneath; heads terminating. Root fascicled, with small fibres, annual; stalks one or two, simple, naked at top, white with down, a span and a half in height; flowers on the stalk terminating, glomerate, sessile, purplish; the heads the size of a large pea.—It flowers in August, and is a native of Japan.

63. *Gnaphalium Trinerve*. Shrubby; leaves sessile, lanceolate, three-nerved, silvery-white underneath; heads terminating.—Native of New Zealand.

64. *Gnaphalium Lanatum*. Herbaceous, woolly; leaves linear-oblong, callous-mucronate at the tip; corymb contracted; stalk very simple.—Native of New Zealand.

65. *Gnaphalium Involutum*. Herbaceous; leaves linear, elongate, mucronate, tomentose underneath; head terminating, leafy.—Native of New Zealand.

66. *Gnaphalium Sigatum*. Herbaceous; branches assurgent; leaves ovate-lanceolate, sinuate, toothed, hairy on both sides. Stem four feet high, simple, erect; leaves large, alternate; flowers yellow, in terminating erect panicles; the marginal scales of the calix being red, and membranaceous.—Native of Cochin-china.

Gnetum; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Ament of whorls*, remote, callous, thickened, propped underneath with a partial calicle: this is peltate, orbicular, flat, quite entire, and contains sessile floscules; the males at bottom, the females above in the same whorl. *Males*. *Calix*: scale ovate, minute, coloured. *Corolla*: none. *Stamina*: filamentum single, filiform, longer than the scale; antheræ double, connected. *Female*. *Calix*: scale torn, rude. *Corolla*: none. *Pistil*: germen ovate, immersed in the receptacle of the whorl, the length of the stamina; style conic, short; stigma trifid, acute. *Pericarp*: drupe ovate, one-celled. *Seed*: nut oblong, streaked. ESSENTIAL CHARACTER. *Male*. An *ament* with scales. *Corolla*: none. *Filamenta*: one, with two antheræ. *Female*. An *ament* with scales. *Corolla*: none. *Style*: with a bifid stigma. *Drupe*: with one seed.—The only known species is,

1. *Gnetum Gnemon*. Branches stiff-jointed, broader below the joints; leaves opposite, petioled, lanceolate, ovate, quite entire, smooth, and even; aments axillary, peduncled, in pairs from each axil, in small whorls, from an orbicular, perfoliate, entire bracte, callous above, in which the floscules are immersed; the females above, or towards the rachis, usually six or seven in number; the males towards the edge, or below. *Gnemon* is the vernacular name in Ternate, &c.—It is a native of the East Indies, where the leaves, male catkins, and fruit, are eaten, though not in a raw state.

Gnidia; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, funnel-form, coloured; tube filiform, very long; border four-parted, flat. *Corolla*: petals four, sessile, flat, shorter than the calix, and inserted into it. *Stamina*: filamenta eight, bristle-shaped, erect, almost the length of the flower; antheræ simple. *Pistil*: germen ovate; style filiform, inserted into the side of the germen, the length of the stamina; stigma capitate, hispid. *Pericarp*: none; fruit in the bottom of the calix. *Seed*: single, ovate, obliquely acute. **ESSENTIAL CHARACTER.** *Calix*: funnel-form, four-cleft. *Petals*: four, inserted into the calix. *Seed*: one, somewhat berried.—These are shrubby plants, except the last; and are usually increased by cuttings, planted during the summer months in pots filled with light earth, plunged into a very moderate hot-bed, covering the pots closely with bell or hand glasses, to exclude the air, and shade them during the day: they will put out roots in six weeks, when they should be gradually inured to the open air. In winter, place them in a dry airy glass-case, where they may enjoy free air in mild weather, and be protected from frost and damp air.—The species are,

1. *Gnidia Pinifolia*; *Pine-leaved Gnidia*. Leaves scattered, linear; floral-leaves in whorls. Stem three or four feet high, with a few side-branches; the flowers come out almost in whorls from between the leaves, at the extremities of the branches, on short peduncles; calix and petals white. It varies with blue flowers.—Native of the Cape.

2. *Gnidia Radiata*; *Radiated Gnidia*. Leaves subulate, three-sided, erect; heads terminating, sessile, radiate; bractes lanceolate. This is a rough proliferous shrub; flowers somewhat villose on the outside.—Native of the Cape.

3. *Gnidia Simplex*; *Flax-leaved Gnidia*. All the leaves linear, acute; flowers terminating, sessile. Stems half a foot high, unequal, roughened with the tubercles from leaves that are fallen; the floral-leaves are not broader than the rest; are oblong, acuminate.—Native of the Cape.

4. *Gnidia Tomentosa*; *Rough Gnidia*. Leaves scattered, ovate-oblong, smooth, scabrous about the edge; petals small, emarginate.—Native of the Cape.

5. *Gnidia Sericea*; *Silky Gnidia*. Leaves ovate, tomentose; floral-leaves in fours. Throat of the corolla crowned with eight coloured threads, the same length with the corolla itself, on the outside of the petals.—Native of the Cape.

6. *Gnidia Oppositifolia*; *Opposite-leaved Gnidia*. Leaves opposite, lanceolate. The uppermost leaves are blood-red at the extremity.—Native of the Cape.

7. *Gnidia Capitata*. Leaves scattered, lanceolate, smooth; flowers in heads, fortified with bractes; peduncles naked. Stem shrubby, with upright round purplish branches; flowers aggregate, peduncled.—Native of the Cape.

8. *Gnidia Filamentosa*. Leaves elliptically ovate, very smooth, approximating; flowers in heads; filamenta capillary. This is a very smooth shrub, tubercled with the scars of fallen leaves.—Native of the Cape.

9. *Gnidia Imbricata*. Leaves oblong, imbricated in four rows, silky; flowers terminating in the axils of the leaves.—Native of the Cape.

10. *Gnidia Sparrmanni*. Leaves linear, subulate, flat above, sharp; flowers in pairs, axillary. Branches smooth and even, not tomentose.—Native of the Cape.

11. *Gnidia Daphnæfolia*. Decandrous: leaves oblong, flat, quite entire; head terminating, peduncled, involucred; flowers five-cleft. The leaves are alternate.—Native of the island of Madagascar.

Goat's Thorn. See *Astragalus*.

Golden Flower. See *Chrysanthemum*.

Golden Rod. See *Solidago*.

Golden Rod Tree. See *Bosea*.

Goldilocks, Goldyllocks. See *Chrysocoma*.

Gold of Pleasure. See *Myagrum*.

Gomphia; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets lanceolate, sharpish, nerved, coloured, deciduous; two with a membrane on both sides, one with a membrane on one side only, and two without any. *Corolla*: petals five, spreading longer than the calix, somewhat unequal; claws shorter than the calix, widening gradually into roundish, flat, entire laminas. *Stamina*: filamenta ten, thick, angular, very short; antheræ upright, paralleloiped, drawn to a point at top, gaping at the tip on the outside, with a double hole, shorter than the calix. *Pistil*: germen sitting on a short, fleshy, angular receptacle, five-cornered, and five-cleft; style longer than the stamina, five-furrowed; stigma sharp. *Pericarp*: berries from one to five, generally two, ovate, obliquely attenuated at the base, somewhat compressed, obtuse, upright, sitting on a very large globular receptacle, for receiving a single berry, or lobed for several berries, which are each fixed to a lobe. *Seed*: solitary, ovate. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled. *Berries*: one to five, on a large receptacle. *Seed*: solitary.—The species are,

1. *Gomphia Angustifolia*. Leaves lanceolate, serrate on the outside; panicle terminating; petals longer than the calix. This tree is only about twelve feet high, with a slender trunk; the bark is brownish red; the wood whitish, with a greenish heart; the flowers are yellow, and have no scent.—Native of the East Indies.

2. *Gomphia Nitida*. Leaves ovate-lanceolate, acuminate, serrate; panicles terminating; calices equal to the corolla. Branches alternate, flexuose at the top, covered with a brown bark, round, smooth, as is the whole plant; flowers before their evolution ovate, obtuse; petals yellow.—Native of the West Indies.

3. *Gomphia Lævigata*. Leaves lanceolate, very obtuse, quite entire, emarginate; panicle terminating. This is also a smooth plant; the branches are alternate, and covered with an ash-coloured bark; petiole very short, thickened at the insertion; calicine leaflets lanceolate.—Native of the East Indies.

Gomphrena (GLOBE AMARANTH); a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth coloured, outer three-leaved; leaflets two, converging, keeled. *Corolla*: five-petalled, upright; petals subulate, permanent, rude, villose; nectary a cylindrical tube, the length of the corolla, with a five-toothed patulous mouth. *Stamina*: filamenta five, scarcely observable, within the mouth of the nectary; antheræ upright, closing the mouth of the nectary. *Pistil*: germen ovate, with a point; style cloven half way, filiform; stigmas simple, the length of the stamina. *Pericarp*: capsule roundish, circumcised. *Seed*: single, large, roundish, with an oblique tip. *Observe*: What is here called the corolla, is rather the calix. **ESSENTIAL CHARACTER.** *Calix*: coloured, outer three-leaved; leaflets two, converging, keeled. *Petals*: rude, villose. *Nectary*: cylindrical, five-toothed. *Style*: cloven half way. *Capsule*: one-seeded.—The species are,

1. *Gomphrena Globosa*; *Annual Globe Amaranth*. Stem upright; leaves ovate-lanceolate; heads solitary; peduncles two-leaved. This is an annual plant, rising with an upright

branching stalk, about two feet high; leaves opposite, sessile, quite entire, hispid; branches and peduncles also opposite, the latter axillary, long, and naked, except that there are two short leaves close under each head of flowers; these heads, at their first appearance, are globular, but as they increase in size become oval.—Native of India. The flowering heads are beautiful, and if gathered before they be too far advanced, will retain their beauty for several years: the seeds ripen late in autumn, and the plant decays soon after. There are two varieties: one has fine bright purple, another white or silvery heads. They never alter from seeds, so that they are permanent varieties, although in other respects they do not differ; there is also one with mixed colours, but whether it was accidentally produced from the seeds of the former, it is difficult to determine. There are also two other varieties, which grow naturally in the West Indies, one with purple and the other with white heads, which are much smaller and rounder than those before mentioned. The plants grow much larger, and spread more into branches, and they are later before they flower, so that in cold seasons the seeds rarely ripen in England: these are called *bachelor's buttons* by the inhabitants of America. Loureiro also mentions a variety found in Cochin-china, with white ovate heads, in which all the florets are fertile, whereas in the purple variety most of them are barren.—*Propagation and Culture.* This species is a very ornamental plant in gardens, and is now very commonly cultivated in those of Great Britain. In Portugal, and other warm countries, it is cultivated to adorn their churches in the winter, for if the flowers be gathered when they are fully grown, and dried in the shade, they will retain their beauty a long time, especially if they are not exposed to the air. This plant is annual, and can only be propagated by seeds, which should be sown on a good hot-bed in the beginning of March; but unless the seeds be previously taken out of their chaff covering, it will be proper to soak them in water for twelve hours before they are sown, which will greatly facilitate their growing. When the plants are come up half an inch high, they should be transplanted on a fresh hot-bed, at about four inches' distance, observing to shade them until they have taken root; then they should have fresh air admitted to them every day, in proportion to the warmth of the season; they will also require to be frequently refreshed with water. In about a month's time, if the hot-bed be of a proper warmth, the plants will have grown so large as nearly to meet, and will require more room, to prevent them from being drawn up weak; a fresh hot-bed should then be prepared, into which a sufficient number of three-farthing pots should be plunged, filled with light rich earth, and when the bed is in a proper temperature of warmth, the plants should be carefully taken up with balls of earth to their roots, and each planted into a separate pot, observing to shade them until they have taken new root; and afterwards treat them in the same manner as other tender exotic plants. When the plants have filled these pots with their roots, they should be shaken out of the pots, and their roots on the outside of the ball of earth must be carefully pared off; then they should be put into pots a size larger, and, when there is a conveniency of a deep frame to plunge the pots into another gentle hot-bed, it will bring the plants early to flower, and cause them to grow much larger than those which are placed abroad. In July the plants should be gradually inured to bear the open air, into which they may be removed about the middle of that month, and intermixed with other annual plants to adorn the pleasure-garden; but it will be prudent to keep a plant or two of each sort in shelter for seeds, because when the

autumn proves cold or wet, those plants which are exposed abroad seldom produce good seeds.

2. *Gomphrena Perennis*; *Perennial Globe Amaranth.* Leaves lanceolate; heads two-leaved; florets separated by a proper perianth. Stems upright, hairy, slender; heads of flowers terminating, small, spreading, so that the calices appear distinct; they are of a pale straw colour, and appear in July.—Native of South America.

3. *Gomphrena Hispida*; *Hairy Globe Amaranth.* Stem upright; heads two-leaved; leaves crenate. It is a cubit and a half high; the heads of flowers rounded, oblong, at first white, but becoming blue.—Native of Malabar.

4. *Gomphrena Brasiliensis*; *Brazilian Globe Amaranth.* Leaves ovate-oblong; stem upright; heads peduncled, globular, leafless. This is rather taller than the first sort; the heads are white, smaller, and composed of smaller calices, without any leaves at the base.—Native of Brazil.

5. *Gomphrena Serrata*; *Serrated Globe Amaranth.* Stem upright, brachiate; heads solitary, terminating, sessile; calices serrate. Stems more slender and tall than those of the first species, and growing irregularly; leaves smaller, but of the same shape; flowers in spikes at the ends of the branches, broken or divided into three or four parts, small, and of a pale purple colour.—The seeds of this species were imported from Campeachy. Cultivated like the first species. The plants will live two or three years in a stove, and the seeds will sometimes ripen in England.

6. *Gomphrena Interrupta*; *Interrupted Globe Amaranth.* Stem almost upright; spike interrupted. Root annual; stem shrubby at the bottom, from one to two feet high; leaves at the root aggregate, sessile, above opposite, lanceolate, obtuse, tomentose, beneath white, lanuginous, soft; flowering-stems leafless, stiff, whitish, except that they are often purple towards the end; flowers in spikes, aggregate, sessile, interrupted, lanuginose.—Native of dry sandy fields in the southern parts of Jamaica.

7. *Gomphrena Flava*; *Yellow Globe Amaranth.* Peduncles opposite, bifid, three-headed, middle head sessile. At each joint of the stem two opposite peduncles are produced, longer than the leaves, trifid at top, with one globular head of flowers at each division, having no leaves immediately under them.—Native of La Vera Cruz.

8. *Gomphrena Arborescens.* Arborescent, hairy, somewhat twining. Stem round, simple, hairy; leaves opposite, in short petioles, oval, obtuse, leathery, quite entire, having hairs scattered over them. Several bracts under each flower, sharper than the leaves, and of the same length with the flower; flowers aggregate, terminating, the size of a walnut.—Found in New Granada, by Mutis.

9. *Gomphrena Angustifolia.* Leaves linear-lanceolate, smooth; heads terminating, oblong, subtriphylloous. Stem herbaceous, erect, four-cornered, with short hairs pressed close; branches opposite, quite simple, higher than the stem, subfiliform, two-leaved; peduncles terminating the branches, elongated. It has the habit of a *Gomphrena*, but differs in having a single style.—Native of the East Indies.

Gonatocarpus; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: four-cleft, permanent. *Stamina*: filamenta four, inserted into the corolla. *Pistil*: germen inferior; style single. *Pericarp*: drupe subglobular, eight-cornered, crowned with the permanent corolla, one-celled. *Seed*: single. **ESSENTIAL CHARACTER.** *Corolla*: four-cleft. *Drupc*: eight-cornered, one-seeded.—The only known species is, -

1. *Gonatocarpus Micranthus.* Root fibrous, annual; stem one or more, four-cornered, decumbent at the base, branched

at top, scarcely a span in height; leaves opposite, on very short petioles, ovate, acute, serrate, smooth, spreading a line in length; flowers on the branches in spikes, remote, mostly on one side, drooping, minute. It flowers in August.—Found in abundance about Nagasaki.

Goodenia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets equal, awl-shaped, erect, permanent. *Corolla*: one-petalled, superior; tube cloven on the upper side, from top to bottom; limb five-cleft; segments equal, obovate, directed forwards. *Stamina*: filamenta five, shorter than the tube, and projecting through its fissure; antheræ linear, vertical, two-celled. *Pistil*: germen inferior, five-angled; style simple, longer than the stamina, and standing out with them; stigma cup-shaped, ciliated. *Pericarp*: capsule two-celled, two-valved, bursting at top, and becoming revolute; the partition, which is parallel to them, remaining erect. *Seeds*: several in each cell, imbricated, lenticular. ESSENTIAL CHARACTER. *Corolla*: longitudinally cloven on the upper side, exposing the organs of fructification; border five-cleft, leaning one way; antheræ linear. *Stigma*: cup-shaped, ciliated. *Capsule*: two-celled, two-valved, with a parallel partition. *Seeds*: many, imbricated.—The plants belonging to this genus must be raised from seeds brought from their native country; when once obtained, they may be readily increased from cuttings. They are not very tender, but may be preserved in the dry-stove, or a good glass-case.—The species are,

1. *Goodenia Ovata*; *Ovate Yellow Goodenia*. Leaves ovate, toothletted-serrate, both they and the corollas smooth; fruit linear. Stem shrubby, erect, angular, branched, leafy; flowers yellow, from three to five in a dichotomous panicle, arising solitary from each axil of the uppermost leaves, and about half as long as the corresponding leaf; peduncles somewhat angular, smooth, with two awl-shaped bractes at each subdivision; calicine leaflets smooth; corolla tubular; tube smooth, greenish, and striated externally; border yellow, membranous, with a thick greenish plait running from the tube to the point of each segment behind.—Native of Port Jackson, New South Wales.

2. *Goodenia Albida*; *White-flowered Goodenia*. Leaves obovate, toothed, both they and the corollas smooth; style and stem hairy.—Native of New South Wales.

3. *Goodenia Paniculata*; *Panicled Yellow Goodenia*. Leaves obovate-lanceolate, toothed, both they and the corollas hairy; stem almost naked, panicled.—Native of Port Jackson, New South Wales.

4. *Goodenia Bellidifolia*; *Daisy-leaved Yellow Goodenia*. Leaves obovate, toothletted, fleshy; stem almost naked, spiked; corolla hirsute on the outside; fruit four-valved.—Native of Port Jackson, New South Wales.

5. *Goodenia Stricta*; *Rigid Blue Goodenia*. Leaves lanceolate, entire or toothed, fleshy, smooth; corolla hirsute on the outside; stigma contracted at the mouth. It flowers in October, and is a native of Port Jackson, New South Wales, in marshy ground.

6. *Goodenia Ramosissima*; *Branching Blue Goodenia*. Leaves linear-lanceolate, somewhat toothed, both they and the stem hispid; style very hirsute at top; corolla hairy on the outside. Stem herbaceous, two or three feet high, much branched and straggling, round, rough with short stiff hairs, as are also the leaves; flowers solitary, terminating the branches, and appearing in October; the plaits of the corolla are externally hairy; the antheræ are very minutely bearded.—Found at Port Jackson, in New South Wales.

7. *Goodenia Heterophylla*; *Various-leaved Goodenia*

Leaves entire, toothed or lobed, hairy; fruit roundish; corolla almost naked.—Native of New South Wales.

8. *Goodenia Hederacea*; *Trailing Goodenia*. Leaves roundish, entire, or five-lobed; corolla woolly on the outside; stem prostrate.—Native of New South Wales.

9. *Goodenia Lævigata*; *Smooth Goodenia*. Leaves ovate-lanceolate, toothed, smooth. Stems round, smooth, green below, purplish above; flowers axillary, forming a thin spike, sessile, pale violet, having a peculiar and rather unpleasant smell; at the side of each flower, are two long narrow bractes; calicine leaflets short, ovate, appearing edged with hairs when magnified; germen oblong, usually abortive with us. It flowers from July to October.—Native of Botany Bay.

Gooseberry. See *Ribes*.

Goose-foot. See *Chenopodium*.

Goose-grass. See *Galium Aparine*.

Goose-grass, Great. See *Asperugo*.

Goose-tongue. See *Achillea*.

Gordonia; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth outer four-leaved, deciduous; inner five-leaved; leaflets roundish, concave, permanent. *Corolla*: petals five, obovate, concave, large, united at the base. *Stamina*: filamenta numerous, filiform, coalescing at the base into an obtuse body; antheræ oval, upright. *Pistil*: germen ovate; style short, five-cornered; stigmas five, sharp, horizontal. *Pericarp*: capsule ovate, sharp, five-celled; cells bifid half way, five-valved. *Seeds*: two, with a leafy wing on one side. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five, united at the base by means of the nectary. *Filamenta*: inserted into the nectary. *Capsule*: superior, five-celled. *Seeds*: winged.—The species are,

1. *Gordonia Lasianthus*; *Smooth Loblolly Bay*. Leaves leathery, smooth on both sides; flowers peduncled. The stem is five or six feet high, and branched; the leaves four inches long, and one inch and a half broad in the middle, slightly indented on their edges, and of a thick consistence: the flowers axillary, on very long peduncles; the petals are yellow and thick; the stamina are joined at their base to the style, and form a short column, but spread open at the top, filling the mouth of the tube.—Native of North America. As this plant grows naturally in water, it is not kept alive in this country without difficulty. Mr. Miller raised several plants, which continued till winter, but not one of them survived, though he placed some of them in the stove, and supplied them with an abundance of water.

2. *Gordonia Pubescens*; *Pubescent Loblolly Bay*. Leaves pubescent beneath; flowers subsessile. Branches subpubescent; flowers axillary, sessile towards the tops of the branches; leaflets of the outer calix subovate, acuminate at the tip, tomentose, as are also those of the inner. It has been long in the open air in the garden at Trianon in France; but, like the rest of the trees and shrubs from South Carolina, is not very capable of enduring cold. The flowers are white; but they come out so late, that the frost destroys them before they expand.—Native of South Carolina.

3. *Gordonia Franklinia*; *Franklin's Gordonia*. Leaves smooth; flowers sessile; fruits globular. This beautiful tree-like shrub rises with an erect trunk, to the height of about twenty feet, with alternate branches; leaves oblong, narrowed towards the base, serrate, sessile or subsessile; flowers towards the extremity of the branches, solitary, sitting close in the bosom of the leaves, often five inches in diameter when fully expanded; petals snow-white, the lower one hollow, formed like a cap or helmet, entirely excluding the other four, until the moment of expansion; its exterior surface is

covered with a short silky hair; the borders of the petals are curled or plaited. Fruit a large round, dry, woody pericarp, opening at each end by five alternate fissures, containing ten cells, each filled with dry woody cuneiform seeds. The flowers have the fragrance of a China orange.—Discovered on the banks of the Altamaha river in Georgia.

Gorteria; a genus of the class Syngenesia, order Polygamia Frustranea.—GENERIC CHARACTER. *Calix*: common one-leaved, imbricate with spiny scales; the inner ones gradually longer, straight, bristle-shaped, rigid. *Corolla*: compound, radiate; corollets hermaphrodite, several in the disk; female fewer in the ray; proper of the hermaphrodite funnel-form, five-cleft; of the female ligulate, lanceolate. *Stamina*: in the hermaphrodites, filamenta five, short; antheræ cylindrical, tubular. *Pistil*: of the hermaphrodites, germen villose; style filiform, the length of the corollet; stigma bifid: of the females, germen obsolete; style none; stigma none. *Pericarp*: calix unchanged, deciduous. *Seeds*: in the hermaphrodites solitary, roundish; down simple, woolly; in the females none. *Receptacle*: naked, yet not so in every species. ESSENTIAL CHARACTER. *Calix*: imbricate with spiny scales. *Corolla*: of the ray ligulate. *Down*: woolly. *Receptacle*: naked.—Most of these plants may be increased by cuttings, planted in a shady border during any of the summer months; afterwards they may be treated like other plants from the Cape. See *Arctotis*.—The species are,

1. *Gorteria Personata*; *Annual Gorteria*. Leaves lanceolate, entire, and sinuate; stem upright; flowers peduncled. Stems a span high, little branched, roundish, hairy. The receptacle is bristly, rough in the middle, excavated in the circumference; florets in the centre male, in the disk androgynous, and of these not more than five fertile; in the ray, female or neuter, and barren; seeds woolly, but without down or feather. When the flower comes to maturity, the aperture of the calix being very narrow, the seeds do not fall out, but the whole drops together. Hence, when one of them germinates, the radical not only perforates the bottom of the calix, but is so firmly united to it, that the young plant bears the maternal calix, permanent above the root. There is no other instance of this economy, except in *Neurada*. It flowers in July and August, and being annual, can only be raised from seeds.—Native of the Cape.

2. *Gorteria Rigens*; *Great-flowered Gorteria*. Leaves lanceolate, pinnatifid; stem depressed; scapes one-flowered. This is a low spreading plant, with woody stalks, six or eight inches long, trailing on the ground, having two or three side-branches, each terminating in a close head of leaves, which are narrow, green on their upper, but silvery on their under surface, and cut into three or five segments at the end. The peduncles arise from these heads, are six inches long, naked, and support one large orange-coloured flower; each floret in the ray has a dark mark towards the base, with white intermixed. The green-house can scarcely boast a more showy plant: the flowers will only expand in the heat of the sun, but, when expanded, exhibit an unrivalled brilliancy of appearance.—It flowers in May and June, and was brought from Holland.

3. *Gorteria Echinata*; *Prickly Gorteria*. Leaves oblong, sinuate-gashed, with small thorns; stems ascending; receptacles chaffy. Stem a foot high, angular, red, commonly smooth, but sometimes lanuginous here and there. Flowers terminating, solitary; outer scales of the calix short, palmate, spinous; inner longer, lanceolate, ending in a thorn, and armed with spinules at the base on each side; corollets of the ray wholly barren; the petal four-cleft at the end, an inch long, spreading, yellow, but near the tip underneath of

a dirty purple colour. It flowers in July, is annual, and can only be propagated by seeds.—Native of the Cape.

4. *Gorteria Squarrosa*; *Cobweb Gorteria*. Leaves lanceolate, decurrent, adnate, ciliate-spinulous; flowers sessile. Stem proliferous, villose; branches from the base of the stalk; calix terminating, squarrose, with leaflets bowed back, like those on the stem; ray of the flowers yellow.—It flowers from June to August.

5. *Gorteria Setosa*; *Bristly Gorteria*. Leaves lanceolate, decurrent, adnate, ciliate-spinous; flowers terminating. Stem five feet high, upright, very much branched; branches alternate; colour of the flowers yellow, the ray violet-coloured underneath. It differs from the preceding species, in the stem being neither villose nor proliferous; the leaves not imbricate, downwards, but broader, shorter, with yellow bristles standing out on the edge; the flowers peduncled, not sessile; and finally, in the colour of the ray beneath.—Native of the Cape.

6. *Gorteria Ciliaris*; *Ciliate Gorteria*. Leaves imbricate, ciliate, in two rows; the outer cilia, and the terminating spine, reflex. The leaves are imbricated, and pressed to the stalks, so as to cover them in an extraordinary manner. It flowers in May and June.—Native of the Cape.

7. *Gorteria Fruticosa*; *Shrubby Gorteria*. Leaves lanceolate, entire, tooth-spinous, tomentose beneath; stem shrubby, slender, three feet high, sending out a few weak branches, which are tomentose and white; flowers terminating, subsolitary, peduncled, the peduncle longer than the flower; corolla yellow, radiate. The ray has many flowers, and is twice the length of the calix; the disk is convex; the segments of the florets linear; seeds villose; crown of the seeds star-form, with many leaflets. It flowers in August and September.—Native of the Cape. This species is increased by planting the small heads at the ends of the branches in June and July. They must be closely covered with either bell or hand glasses, and carefully screened from the sun. When they are well rooted, they should be put each into a small pot, and, in winter, placed in an airy glass-case, secure from damp. The same treatment will be proper for any other sorts, and indeed for most shrubby plants that will not take from cuttings in the ordinary way.

8. *Gorteria Herbacea*; *Herbaceous Gorteria*. Stem-leaves clasping, ciliate; root-leaves unarmed, villose underneath. Stem scarcely a foot high, herbaceous, smooth, very little branched; root-leaves broad-lanceolate, petiolate, quite entire, bluntish; stem-leaves alternate, cordate, acute, the upper ones gradually shorter; flowers terminating, sessile; calix like that of an artichoke, but scarcely bigger than a plum.—Found by Thunberg at the Cape.

9. *Gorteria Hispidia*; *Hairy Gorteria*. Leaves oblong, ciliate-spinous, upright, smooth; calices entire, ending in a thorn. It is a large shrubby plant.—Native of the Cape.

10. *Gorteria Spinosa*; *Thorny Gorteria*. Leaves oblong, sessile, tooth-spinous, spreading, smooth; calices ciliate-spinous; flowers upright.—Native of the Cape.

11. *Gorteria Cernua*; *Drooping Gorteria*. Leaves oblong, clasping, tooth-spinous, spreading, smooth; calices ciliate-serrate; flowers drooping. The base of the calix is singular, with ripe seeds, and resembles the fruit of *Medicago*. It flowers in May.—Native of the Cape.

12. *Gorteria Uniflora*; *One-flowered Gorteria*. Leaves lanceolate, undivided, tomentose underneath; stems one-flowered, depressed, a span high, simple, herbaceous, leafy on all sides; ray of the flower yellow. It has the appearance of the second species, and is suspected to be a variety of it.—Native of the Cape.

13. *Gorteria Barbata*; *Bearded Gorteria*. Leaves elliptical,

tic-lanceolate, tooth awned; calices peduncled, ciliate-setaeous. Stems diffused, simple, white, tomentose; peduncle terminating, very long, leafless, putting off a white nap, one-flowered. The outer order of leaflets in the calix is of the same form with the leaves; the inner is coloured, more copious, narrower, and ends in abundance of bristles, that are twice as long as the flower.—Native of the Cape.

Forz. See *Ulex*.

Gossypium; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth double; outer one-leaved, trifid, flat, larger; inner one-leaved, bluntly emarginate, in five rows, cup-form. *Corolla*: petals five, obcordate, flat, spreading, fastened by their base to the tube of the stamina. *Stamina*: filamenta numerous, uniting at bottom into a tube, separate at, and below the tip, lax, inserted into the corolla; antheræ kidney-form. *Pistil*: germen roundish; style columnar, the length of the stamina; stigmas three or four, thickish. *Pericarp*: capsule roundish, acuminate, three or four-celled; partitions contrary. *Seeds*: very many, oval, involved in cotton. ESSENTIAL CHARACTER. *Calix*: double; outer trifid. *Capsule*: four-celled. *Seeds*: wrapped in cotton.—All the species of cotton plants are very tender, and will not endure the open air in England.

—The species are,

1. *Gossypium Herbaceum*; *Common Cotton*. Leaves five-lobed, without glands underneath; stem herbaceous. Root tapering, woody, with numerous fibres, annual; seedlobes two, kidney-form, terminating gradually in a long petiole, with the figure of a halved funnel. Stem three feet high, upright, round, pubescent, as is the whole of the herb, at the bottom brown, with light chinks at the top spotted with black; branches axillary, scarcely longer than the leaf at their origin; leaves alternate, only half the length of the petiole, tomentose, odorous when young; calix outer, when closed three-cornered, when open, three-parted almost to the base; segments heart-shaped, gashed, shorter by half than the corolla, dotted with black; inner cylindrical, only one-third of the other's length, upright, five-parted, with short blunt segments, dotted like the inner; corolla monopetalous, with a very short tube, and a five-parted spreading border; the segments blunt, crenate at the side, pale yellow, with five red spots at bottom, and deciduous; filamenta coalescing into a pyramid; germen superior, ovate; style filiform; stigma four-fold; capsule bluntly three-cornered, three-valved, three-celled; seeds ovate, about three in each cell, convex on one side, more flat on the other, immersed in fine cotton.—This is the common Levant cotton, which is cultivated also in several islands of the Archipelago; and in Malta, Sicily, and the kingdom of Naples; as well as in most parts of Asia. Few plants are more useful, since it furnishes materials for clothing in the four quarters of the world, particularly to the Asiatics. The seeds also are an article of food, and esteemed wholesome.—*Propagation and Culture*. Both this and the third species will ripen their seeds in England, if they be sown upon a good hot-bed early in the spring. When the plants come up, they must be removed into separate pots, and plunged into the bark-bed to bring them forward: when they are too tall to remain under the frames, remove them into the tan-bed in the stove; and when the roots have filled the pots, remove them into larger. With this management, the flowers will appear in July, and the seeds ripen towards the end of September. Cotton is propagated in the West Indies by the seed, which is set in rows, about five feet asunder, at the end of September, or beginning of October; at first but slightly covered; but after it is grown up, the root is well moulded. The seed is subject to decay

VOL. I.—53.

when it is set too deep, especially in wet weather. The soil should not be stiff, nor shallow, because this plant has a tap-root. The ground is hoed frequently, and kept very clean about the young plants, until they rise to a moderate height, otherwise they are liable to be destroyed by caterpillars. It grows from four to six feet high, and produces two crops annually; the first in eight months from the time of sowing the seed; the second within four months after the first; and the produce of each plant is reckoned about one pound weight. The branches are pruned or trimmed after the first gathering; and if the growth be over luxuriant, this should be done sooner. When great part of the pods are expanded, the wool is picked, and afterwards cleared from the seeds by a machine, called a gin, composed of two or three smooth wooden rollers, of about one inch diameter, ranged horizontally, close, and parallel to each other, in a frame; at each extremity, they are toothed or channelled longitudinally, corresponding one with the other; and the central roller being moved with a treadle or foot-lath, resembling that of a knife-grinder, makes the other two revolve in contrary directions. The cotton is laid, in small quantities at a time, upon these rollers, whilst they are in motion; and readily passing between them, drops into a sack, placed underneath to receive it, leaving the seeds, which are too large to pass with it, behind. The cotton, thus discharged from the seeds, is afterwards hand-picked, and cleansed thoroughly from any little particles of the pods or other substances, which may be adhering to it. It is then stowed in large bags, where it is well trod down, that it may lie close and compact; and the better to answer this purpose, some water is every now and then sprinkled upon the outside of the bag; the marketable weight of which is usually three hundred pounds. An acre may be expected to produce from two hundred and forty pounds, to that quantity; or two hundred and seventy pounds on an average. The shrub cotton will rise from seeds very easily, if sown on a good hot-bed early in the spring; if they be brought forward in the same manner as directed for the others, the plants will be five or six feet high in the same summer; but it is difficult to preserve them through the winter, unless they are hardened gradually during the warm weather; for when they are forced on at that time, they will become so tender, as to be incapable of resisting the least injury. In autumn, they must be placed in the bark-stove, and kept in the first class of heat, otherwise they will not live through the winter in England.

2. *Gossypium Arboreum*; *Tree Cotton*. Leaves palmate, with lanceolate lobes; stem shrubby, eight feet high, the thickness of the human leg, with a rugged brown bark, and long, diffused, twisted branches; flowers entirely yellow, terminating, solitary; outer calix three-leaved, large, gashed, erect; the inner calix five-notched; capsule commonly three-cornered, three-valved, three-celled, subovate, acuminate, rugged.—Native of the East Indies, and the Eastern coast of Africa.

3. *Gossypium Hirsutum*; *Rough Cotton*. Leaves five-lobed with one gland underneath; the twigs and petioles pubescent. Stem shrubby, a fathom in height, erect, striated; branches hirsute; petioles round, striated, dotted with black, hirsute. There is a single glandular pore on the midrib underneath, and sometimes two or three on the next nerves; peduncles three times shorter than the petioles, stiff, thick, hirsute, dotted with black; outer calix three or five cleft; the segments ovate, acute, rough with hairs; the inner truncate, with three blunt teeth; petals rounded, retuse, entire, yellow at the base, purple at the tip, pubescent on the outside; germen ovate, acuminate, dotted with black; style longer

than the stamina, three or five-cleft at top, inclined. This species, says Browne, is in a few gardens in Jamaica, but is not much cultivated; for the cotton is not thought to be so good; and the seeds are so small, that it is a difficult matter to separate them from the cotton. It grows, however, more luxuriant than the common sort, and rises generally from seven to nine feet high, bearing a great number of seed-vesels on all the branches. Swartz mentions a variety of this species, which is called *cotonier de soie*, the cotton of which is better than any of the rest.

4. *Gossypium Religiosum*; *Spotted-bark Cotton Tree*. Leaves three-lobed, acute, with one gland underneath; twigs spotted with black. According to Swartz, the stem is a fathom in height, biennial, roundish, rugged; branches spreading very much, angular, striated; upper leaves three-lobed, lower five-lobed; lobes ovate, entire, nerved, pubescent, with three glandular pores underneath on the mid-ribs of the leaves; petioles long, round, patulous, hirsute, with black atoms scattered over them; flowers opposite to the petioles, large, fulvous, on dotted peduncles; outer calix subtrophylous, pubescent, dotted; the segments large, deeply and unequally toothed; the inner is very short, and five-lobed, in waves; capsule leathery, thickish, three-celled, three-valved; the partitions inserted in the middle of the valves, which are wrinkled within, and the edges turn back after they are open. There is no receptacle, but the seeds are fixed in a double row to the central angle of the cells; seeds about six in each cell, ovate, tapering towards the umbilicus, convex on one side, angular on the other, and white. It flowers in July.—Native of India, China, and the Society Isles. In China it is cultivated for the purpose of making the cloth usually called Nankeens in Europe, the down having a yellow tinge, which it preserves when spun and woven into cloth.

5. *Gossypium Latifolium*; *Broad-leaved Cotton*. Leaves acute, the lowest undivided, the rest three-lobed, with one gland underneath. Stem four or five feet high, perpendicular, straight at the base, the thickness of a swan's quill; above flexuose and thicker, somewhat angular, swelling at the origin of the branches, green, rugged, pubescent, branched; flowers solitary, commonly one only on each branch; peduncle short, three-sided, opposite to the leaf. The stem, branches, petioles, peduncles, young leaves, and smaller veins of those which are more advanced, are dotted with black. The calix also is dotted; the outer three-leaved, and also three-sided; the leaflets cordate, lacinated; the segments lanceolate, converging; the inner only one-third of the length, urceolate, striated, five-parted, with short acuminate segments; corolla as large as that of the Hollyhock, white, turning red as it withers, without any spots at the base, where it is hirsute; pistil longer than the stamina; seeds in each cell four to six or more, in a double row, involved in very white cotton.—Cultivated in the West Indies.

6. *Gossypium Barbadosense*; *Burbadoes Cotton Tree*. Leaves three-lobed, quite entire, with three glands underneath. Stem from six to fifteen feet in height, suffruticose, biennial, smooth; branches almost erect, round and smooth, or pubescent; petioles five or six inches long, roundish, patulous, smooth, or sometimes pubescent, one-flowered; flowers large, yellow, finally turning red; outer calix half five-cleft; segments acute, smooth, or pubescent, or having black atoms scattered over them; inner having three or five minute blunt teeth; petals having a purple spot at the base, and smooth on the outside; filamenta shorter than the petals; antheræ yellow or fulvous; germen roundish, acuminate; style three or five cleft at top; capsule ovate, roundish,

smooth, sometimes dotted with black, three-celled, three-valved; seeds oblong, eight to twelve, black, easily separated from the cotton. Swartz informs us, that this, and the third and fourth species, are not easily distinguished; for they vary in the size of the parts, the division and pubescence of the leaves, the colour, adherence, and tenacity of the cotton, and the number of glands at the back of the leaves; so that it is difficult to ascertain which are species, and which are varieties. This is the species which is so much cultivated in the West Indies, and forms a considerable branch of their exports. An emulsion of the seeds of this plant is recommended in the bloody flux; and an oil is obtained from them by expression, which supplies the boiling-house lamps in some plantations.—See the description of the method of cultivation under the first species.

Gouania; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodites*. *Calix*: perianth one-leaved, superior, funnel-form, five-cleft; tube permanent; segments ovate, acute, spreading, deciduous. *Corolla*: none. *Stamina*: filamenta five, subulate, length of the calix, and alternate with the segments; antheræ roundish, incumbent, veiled; veil like a cowl, elastic. *Pistil*: germen inferior; style subulate, half three-cleft; stigmas obtuse. *Pericarp*: fruit dry, three-sided, divisible into three seeds. *Seeds*: three parts of the fruit roundish, inclined to three-sided, two-winged. *Males*, on the same plant. *Calix*, *Corolla*, and *Stamina*: as in the hermaphrodites. *Pistil*: germen none; style as in the hermaphrodites; stigmas obscure, or none. ESSENTIAL CHARACTER. *Hermaphrodites*. *Calix*: five-cleft. *Corolla*: none. *Antheræ*: five, under a veil. *Style*: three-cleft; fruit inferior, tripartite. *Male*: similar, but without germen and stigma.—The only known species is,

1. *Gouania Domingensis*; *Chaw Stick*. Stem shrubby, and climbing like hops by axillary tendrils; leaves ovate or oblong-ovate, acuminate, or blunt with a point unequally serrate-toothed, or slightly crenate only, smooth, deep green, alternate, petioled, two inches long; racemes furnished with one or two leaflets. The male flowers have no pistil whatsoever; but there are three or four flowers in a hundred, that have a style without any germen.—Native of woods in St. Domingo. Sow the seeds on a hot-bed, early in the spring; and when the plants are strong enough, transplant each into a small pot filled with light rich earth, and plunge the pots into a moderate hot-bed of tanners' bark, watering and shading the plants until they have taken new root. In winter, plunge them into the bark-bed in the stove, and water them frequently. The stems must be supported, and they seldom produce flowers before the third summer.

Gourd, Bitter. See *Cucumis*.

Gourd, Sour. See *Adansonia*.

Grafting, is the taking a shoot from one tree and inserting it into another, in such a manner, as that both may unite closely, and become one tree; this is called, by the ancient writers in husbandry and gardening, *incision*, to distinguish it from inoculating or budding, which they call *inserere oculos*. The peculiar advantage of grafting is, that it enables us to propagate any curious sorts of fruit, so as to be certain of the kinds, which cannot be done by any other method; for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as are not worth cultivating; but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock or tree on which they are grafted, for

though the grafts receive their nourishment from the stocks, yet their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken; the only alteration is, that when the stocks on which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they will not make half so much progress as they otherwise would have done, nor will the fruit they produce be so fair, and sometimes not so well flavoured. The shoots are termed *cions* or *grafts*, and in the choice of them the following directions should be carefully observed: 1. That they are shoots of the preceding year, for when older they never succeed well. 2. Always take them from healthy and fruitful trees, for if the trees from whence they are taken be sickly, the grafts very often partake so much of the parent distemper, as rarely to get the better of it, at least for some years; and when they are taken from young luxuriant trees, whose vessels are generally large, they will continue to produce luxuriant shoots, but are seldom so productive as those taken from fruitful trees, whose shoots are more compact, and the joints closer together: it will always be some years before the luxuriant grafts begin to produce fruit, even when managed with the greatest skill. 3. Prefer those grafts which are taken from the lateral or horizontal branches, to those from the strong perpendicular shoots, for the reasons before given. These grafts or cions should be cut off from the trees before the buds begin to swell, which is generally three weeks or a month before the season for grafting; therefore when they are cut off, they should be laid in the ground with the cut downwards, burying them half their length, and covering their tops with litter, to prevent their drying; if a small joint of the former year's wood be cut off the cion, it will preserve it the better, and when they are grafted, this may be cut off; for at the same time, the cions must be cut to a proper length before they are inserted in the stocks; but, till then, the shoots should remain in their full length, as they were taken from the tree, which better preserves them from shrinking. If these cions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month or longer, but these should be cut off earlier from the trees, than those which are to be grafted near the place where the trees are growing.—Having given directions for the cions and grafts, we next come to that of the *stock*, which is a term applied to the trees intended for grafting; these are either such old ones as are already growing in the places where they are to remain, whose fruit is intended to be changed, or young trees, which have been raised in a nursery for a supply to the garden; in the former case, there is no other choice but that of the branches, which should be such as are young, healthy, well-situated, and have a smooth bark: if these trees are growing against walls, or espaliers, it will be proper to graft six, eight, or ten branches, according to the size of the tree, by which they will be much sooner furnished with branches again, than when a less number of cions are put in; but in standard trees, four, or at most six cions, will be sufficient. In the choice of young stocks for grafting, you should always prefer such as have been raised from the seed, and that have been once or twice transplanted: next to these, are those stocks which have been raised from cuttings or layers; but those which are suckers from the roots of other trees should always be rejected, for these are never so well rooted as the others, and constantly put out a great number of suckers from their roots, whereby the borders and walks of the garden will be always pestered with them during the summer season, which is not only unsightly, but they

also take off part of the nourishment from the trees. If these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened and more compact than those which have grown close, and have been thereby drawn up to a greater height; the wood of these will be soft, and their vessels large, so that the cions grafted into them will shoot very strong, but they will be less disposed to produce fruit than the others; and when trees acquire an ill habit at first, it will be very difficult to reclaim them afterwards.—Having directed the choice of cions and stocks, we have now to describe the *operation*; in order to which, the operator must be provided with the following tools: 1. a neat small hand-saw, to cut off the heads of large stocks; 2. a good strong knife with a thick back, to make clefts in the stocks; 3. a sharp penknife, to cut the grafts; 4. a grafting chisel, and a small mallet; 5. a wedge, to keep open the clefts in large stocks till the insertion of the graft; 6. bass strings, or woollen yarn, to tie the grafts with, and such other instruments and materials as will be necessary and suitable to the kind of grafting to be performed; 7. a quantity of clay, which should be prepared a month before it is used, and kept turned and mixed like mortar every other day; this is to be made after the following manner: Procure a quantity of strong fat loam; then take some new well-fed horse-dung, and break it in amongst the loam, and if you cut a little straw or hay very small, and mix amongst it, the loam will hold together the better; and if there be a quantity of salt added, it will prevent the clay from dividing in dry weather; these must be well stirred together, with the addition of water, as in making mortar. The whole mass should be hollowed like a dish, and filled with water, and kept every other day stirred; but it ought to be remembered, that it should not be exposed to the frost or drying winds, and the oftener it is stirred and wrought the better. Of late years, some persons have made use of another composition for grafting, which they have found more effectually to exclude the air than the clay just described: this is composed of turpentine, bees' wax, and resin, melted together, which, when of a proper consistence, may be put on the stock round the graft, in the same manner as the clay is usually applied, and though it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay; and as cold will harden this, there is no danger of its being hurt by frost, which is very apt to cause the clay to leave, and sometimes fall off; and when the heat of summer comes on, this mixture will melt, and fall off without any trouble. In order to use this, there should be a tin or copper pot, with a conveniency under it to keep a very gentle fire with small coal, otherwise the cold will soon condense the mixture; but you must be careful not to apply it too hot, lest the heat should injure the graft.—There are various ways of grafting; we shall enumerate five of the principal. 1. *Grafting in the rind*, called also shoulder-grafting, which is only proper for large trees; this is termed crown-grafting, because the grafts are set in the form of a circle or crown, and is generally performed about the latter end of March, or the beginning of April. 2. *Cleft Grafting*, which is also called stock or slit-grafting; this is proper for trees or stocks of a lesser size, from an inch to two inches or more in diameter; this grafting is to be performed in the months of February or March, and supplies the failure of the escutcheon-way, which is practised in June, July, and August. 3. *Whip Grafting*, which is also called tongue-grafting; this is proper for small stocks of an inch, half an inch, or less diameter; this is the most effectual way of any, and which is most in use. 4. *Grafting by approach*, or *ablactation*. This is to be performed when the stock you would

graft on, and the tree from which you take your grafts, stand so near together, that they may be joined; this is to be performed in the month of April, and is also called inarching, and is chiefly used for Jasmines, Oranges, and other tender exotic trees. 5. *Grafting in the root*; which is of later invention than any of the former ways, and in many circumstances may be an improvement of them all.—The season for grafting must be regulated by the weather: our climate is so uncertain in the spring, that it is better to defer it till the circulation of the sap is brisk, and the buds of the stocks are beginning to break into leaves, observing only, that the weak shoots of tender trees will not admit of being so long cut as the more hardy: it is indispensably necessary never to graft while it actually freezes or rains.—We come next to the manner of performing the several ways of grafting: The first method, which is termed rind or shoulder grafting, is seldom practised, except upon large trees, where either the heads or the large branches are cut off horizontally, and two or four cions put in, according to the size of the branch or stem; in doing this, the cions are cut flat on one side, with a shoulder to rest upon the crown of the stock, then the rind of the stock must be raised up, to admit the cion between the wood and the bark of the stock, which must be inserted about two inches, so as the shoulder of the cion may meet, and closely join the crown of the stock; and after the number of cions are inserted, the whole crown of the stock should be well clayed over, leaving two eyes of the cions uncovered therewith, which will be sufficient for shooting: this method of grafting was much more in practice formerly than at present; the discontinuance of it was occasioned by the ill success it was attended with, for as these cions were placed between the rind of the stock and the wood, they were frequently blown out by strong winds, after they had made large shoots, which has sometimes happened after five or six years' growth, so that whenever this method is practised, there should be some stakes fastened to support the cions, until they have almost covered the stock.—The next method is termed cleft or stock grafting; this is practised upon stocks, trees, or branches, of a smaller size, as from one to two inches in diameter, and may be used with success where the rind of the stock is not too thick, which would prevent the inner bark of the cion from joining that of the stock. The head of the stock or branch may be cut off with a slope, and a slit made the contrary way, in the top of the slope, deep enough to receive the cion, which should be cut sloping like a wedge, so as to fit the slit made in the stock, being careful to leave that side of the wedge which is to be placed outward much thicker than the other: in putting the cion into the slit of the stock, there must be great care to join the rind of the cion to that of the stock, for if these do not unite, the grafts will not succeed: when this method of grafting is used to stocks which are not strong, it will be proper to make a ligature of bass, to prevent the slit of the stock from opening; then the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the cions above the clay for shooting.—The third method is termed whip or tongue grafting; which is the most commonly practised by the nursery-men, especially for small stocks, or branches of an inch, half an inch, or less, because the cions much sooner cover the stocks in this method than in any other. This is performed by cutting off the head of the stocks sloping; then there must be a notch made in the slope towards the upper part downwards, a little more than half an inch deep, to receive the cion, which must be cut with a slope upward, and a slit made in this slope like a tongue, which

which tongue must be inserted into the slit made in the slope of the stock, and the cion must be placed on one side of the stock, so as that the two rinds of both cion and stock may be equal, and join together exactly; then there should be a ligature of bass to fasten the cion so as that it may not be easily displaced; it should lastly be clayed over, as in the former methods.—The fourth sort of grafting, termed inarching, grafting by approach, or ablation, is only to be performed when the stocks, which are designed to be grafted, and the tree from which the graft is to be taken, stand so near together, or may be brought so near together, as that their branches may be bent and united; this method of grafting is commonly practised on tender exotic plants, and some other sorts, which do not succeed by any of the former methods. In performing this operation, a part of the stock or branch must be slit off about two inches in length, observing always to choose a smooth part of the stock; then a small notch should be made down in this slit of the stock, in the same manner as has been directed for whip-grafting; then the branch of the tree designed to be inarched, should have a part slit off in like manner as the stock, and a slit made upward in this, so as to leave a tongue, which tongue should be inserted into the slit of the stock, observing to join their rinds equally, that they may unite well together; then make a ligature of bass, to keep them exactly in their situation, and afterward clay this part of the stock over well, to keep out the air. In this mode of grafting, the cion is not separated from the tree until it is firmly united to the stock, nor is the head of the stock or branch, which is grafted, cut off till this time, and only half the wood pared off with a slope, about three inches in length, and the same of the cion or graft. This method of grafting is performed later in the season than the others; it is generally undertaken in the month of April, when the sap is flowing, at which time the cion and stock will join together, and unite much sooner than at any other season. The Walnut, Fig, and Mulberry, will take by this method of grafting, and will not succeed by any other: there are also several sorts of Evergreens, which may be propagated by this method of grafting; but all the trees which are grafted in this way are weaker, and never grow to the size of those which are grafted in the other methods; therefore this is rarely practised, but on those trees which will not take by any other method.—The fifth mode, root-grafting, is performed by cutting the clean smooth roots of the stocks in pieces five or six inches long, and as large or a little larger than the graft; let them be whip-grafted, and tied together very close, so as to prevent the wet from affecting the wounded parts; and plant them so deep, that the graft, which should be four or five inches long, may be about half buried. By this method the grafts themselves will root, and preserve a nearer similitude of the tree from whence they were taken; and after two or three years the stock may be cut quite away, and the graft left to maintain itself. In practising this method, the grafts may be an inch or two longer than is directed for the others.—The next thing necessary to be known by those who would practise this art, is, what trees will take and thrive by being grafted upon each other. No correct directions have hitherto been given by any of the numerous writers upon this subject, whose works strangely abound with radical mistakes; but as it would swell this interesting article beyond all bounds, were all the sorts of trees which will take upon each other by grafting to be here enumerated; we shall only give such general rules as will be sufficient to ensure the success of those persons who observe them. All trees of the same genus, that is, which agree in their flower and fruit, will take

upon each other; for instance, all the Nut-bearing trees may be safely grafted on each other, as may all the Plum-trees, including also the Almond, Peach, Nectarine, Apricot, &c. which agree exactly in their general characters, by which they are distinguished from all other trees; but as many of these are very subject to emit large quantities of gum from those parts which are deeply cut or wounded, (for the tender trees of this kind, such as Peaches and Nectarines, are most subject to these gummy exudations,) it is found to be the safest way to have recourse to budding or inoculation: see *Inoculation*. All such trees as bear cones will do well upon each other, though they may differ as to one being evergreen, and the other shedding its leaves in winter, as is observable in the cedar of Libanus, and the Larch-tree, which are found to succeed very well upon each other; but these must be grafted by approach, for they abound with a great quantity of resin, which is apt to evaporate from the graft, if separated from the tree before it is joined with the stock, by which they are often destroyed. The Laurel likewise on the Cherry, and *vice versâ*. All the mast-bearing trees will also take upon each other, and those which have a tender soft wood will do well if grafted in the common way; but those that are of a firm contexture, and are slow growers, should always be grafted by approach. By strictly adhering to these rules, the operation will seldom miscarry when rightly performed at a proper season, unless the weather should prove very bad, as it sometimes happens, whereby whole quarters of fruit-trees miscarry. And it is by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; for, being grafted upon stocks of the same sort which are hardy, the grafts are rendered more capable to endure the cold, as has been experienced by most of our valuable fruits now in England, which were formerly transplanted here from more southerly climates, and were at first too impatient of our cold to succeed well abroad, but have been, by budding or grafting upon more hardy trees, rendered capable of resisting our severest cold.

Grass, is a general name applied to those herbaceous plants that are employed in the feeding and fattening of cows, sheep, &c. It has been long since observed, in an able treatise on the grasses of this country, that much of our meadow and pasture land may be rendered infinitely more valuable than it is at present, by the introduction of some of the best Grasses we possess. This opinion prevails among the more enlightened agriculturists of the present age, some of whom have endeavoured to excite the husbandman to collect and cultivate seeds of this sort, by writings fraught with the soundest reasonings; while others have endeavoured to attract him by the offers of well-directed premiums. Hitherto, however, neither the able arguments of the one, nor the liberal rewards of the other, have been found sufficient to induce the husbandman to deviate from the beaten track; and Mr. Stillingfleet, the author above alluded to, sensibly adds, "It is wonderful to see how long mankind has neglected to make a proper advantage of plants of such importance, and which, in almost every country, are the chief food of cattle. The farmer, neglecting to distinguish and select

grasses for feed, fills his pastures either with weeds, or bad and improper grasses; when, by making an easy experiment, he might, after some trials, ensure the introduction of the best and most productive grasses that his land would bear. At present, if a farmer wants to lay down his land to grass, what does he do? he either takes his seed indiscriminately from his own foul hay-rick, or sends to his next neighbour for a supply: by this means, besides a certain mixture of all sorts of rubbish, (which must necessarily happen,) if he chance to have a large proportion of good seeds, it is not unlikely but that what he intends for dry land may come from moist, where it grew naturally; and from the contrary. This is such a slovenly method of proceeding, that one can hardly believe it to be universal; yet it generally prevails with respect to all grasses, except the Darnel-grass, and what in some few counties is known by the name of Suffolk-grass; and this latter instance is owing, it is believed, more to the soil than any care of the husbandman. Now, (continues he,) would the farmer be at the pains of separating, *once in his life*, half a pint or a pint of the different kinds of grass seeds, and take care to sow them separately; in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds separately over the nation, by supplying the seed-shops." The number of grasses fit for the farmer, probably does not exceed half a score: and how small would be the trouble, and how great the reward, of such a task! Would not any one be looked upon as almost insane, who should sow wheat, oats, rye, peas, beans, vetches, buck-wheat, turnips, and seeds of all sorts, together? Yet this is perpetually done with respect to grasses, although it is both unprofitable and absurd.—It is also asserted by Mr. Kent, that meadow and pasture land is oftener neglected than ploughed land, notwithstanding it generally admits of a much greater proportion of improvement. The best grasses cannot be collected at too great an expense; for he has seen a small spot of land in the middle of a large piece, which was laid down twelve or fourteen years since, upon an estate in Hertfordshire, with some choice seeds, at the same time when the remainder of the field was laid down with common seeds; and this spot is considerably better than the rest. From these experiments, and his own observations, he is clearly of opinion, that any person who has land calculated for grass, may improve it by this method of laying it down, to a much greater degree than he can in the common way. Dr. Anderson has likewise observed, in the second volume of his *Essays*, that although it is probable that none of the grasses that have been hitherto cultivated by the farmer, are of the most proper kind for pasturage; yet there is little reason to doubt, but that many of the most valuable kinds for this purpose would admit of being cultivated with the same ease as some of those are with which we are well acquainted; if they were properly separated from others, and cultivated with equal care. But so long as we shall remain ignorant of the peculiar properties of each kind of grass, so as not to be able to distinguish the good from the bad, it is not surprising that we should remain firmly persuaded that nature alone can provide valuable pastures, and that age is so essentially necessary for bringing them to their ultimate perfection: for if we allow our fields to remain uncultivated, without having sowed them with any kinds of grass seeds, it must ever happen that the seeds of such grasses as are brought by the wind or otherwise from the neighbouring fields, will there take root, and in time establish themselves. And as it may sometimes happen, that some of the most valuable pasture grasses may there abound; the field, in these cases, will become filled

with their seeds; and in due time may afford the most valuable pasture. But if bad kinds of grasses should abound in the neighbourhood, more than the good, the field will naturally become filled with the seeds of these useless plants, many of which are hard and abiding; so that if the field be once filled with them, the pasture will of course be of little value, if it should be allowed to remain undisturbed for any length of time. Let the reader therefore consider, how numerous the circumstances are, that must accidentally concur together, before it is possible to receive a very fine field of pasture grass from the hands of nature alone; he will then perceive how improbable it is, that they should concur to produce their full effect in any one field whatever. There must be no roots of bad grasses, nor seeds of robust annuals, in the soil, when it is left out from tillage; and the seeds of the most valuable kinds of grasses must be in the neighbourhood, in such abundance as to fill the whole world sufficiently at once. Nor is this all, for as there is, no doubt, a considerable variety of valuable kinds of grass, some of which are naturally fitted to grow to perfection in one kind of soil, or upon that soil when in certain circumstances, while others would thrive best upon another soil, or upon that soil only in certain peculiar circumstances; it must so happen, that these very plants which are best adapted to the soil in the state it may be in at the time, should be found in abundance in the neighbourhood of the field. Neither must there be found near that any sort of robust quick-growing plant, the seeds of which, by being blown upon that field, might suddenly rush up and suffocate in their infancy these tender and valuable plants; nor must there be found any kinds of bad grass, that, by being established along with the good in any proportion, might tend to diminish the value of the pasture. Now let any one reflect on the infinite diversity these few particulars may admit of, and think how utterly impossible it is, that all the favourable circumstances, without any that are unfavourable, should concur in any one case; and he will acknowledge, that those who found their hope of obtaining the most valuable pastures only upon the fortuitous concurrence of all these circumstances, or who imagine that every pasture which is old must on that account of necessity be good, act in direct contradiction to the plainest dictates of reason and common sense. For although it should be allowed, that the grasses hitherto cultivated are not of the most proper sort for forming good pastures, and that therefore, on some occasions, much better natural pastures may be met with than could be formed by means of any of these; yet it by no means follows from thence, that if the farmer were perfectly acquainted with the value and distinguishing qualities of each kind of natural grass, and knew the soil and culture that best agreed with it, the most advantageous manner of rearing it, and every other particular relative to its respective economy, he might not perhaps have it in his power to form artificial pastures, as much excelling the natural, as these last at present usually exceed the former; for were he possessed of the knowledge above supposed, he could at once fill the soil with the seeds of those valuable grasses, which he knew were best adapted to it, and thus effectually exclude the admission of every useless plant, or pernicious kind of grass, that might be brought from the neighbouring fields by the wind, or by other accidental causes. Let us, therefore, instead of contenting ourselves on all occasions with such pastures or grass lands as nature may afford, rather study to improve those that are indifferent, by endeavouring to obtain a knowledge of such plants as might afford the most valuable pasture, and cultivating these with assiduity and care. The inattention of the improving far-

mers of Great Britain, to this subject, has been unaccountable. In order to prevent the public from being imposed upon by specious accounts of new grasses, it is necessary strenuously to endeavour to discover what are the particular purposes for which any one plant could be deemed valuable; and in what respects it ceases to be of any value at all: for as there is no plant that can be alike useful on all occasions; if we lose sight of this most necessary distinction; it may often lead us to rear a particular plant for purposes which it was never fitted to answer; and our failure may cause it to be rejected, where it might prove extremely proper and beneficial. It is stated, that Ray grass continues to be the only grass, the seeds of which can be purchased, for the purpose of laying down meadow and pasture lands; and every intelligent farmer knows how inadequate that grass is for such a purpose. Why, indeed, the *Lolium Perenne*; *Ray* or *Rye Grass*, should originally have been made use of in preference to all the other grasses, cannot perhaps be satisfactorily accounted for. It probably owes its introduction to accident, or to its being a common grass, the seeds of which were easily collected, rather than to its being preferred from any investigation of its merits, compared with the others. However this may be, there appears to be no reason for excluding the others; for it would appear exceedingly improbable, that of upwards of a hundred grasses, taking the word *grass* in its strict sense, that are growing wild in this country, the Author of nature should have created only one, as suitable to be cultivated for pasturage or fodder. Since this period, however, most of the natural grasses have been cultivated for the purpose of affording seed, which may be procured genuine from many seedsmen in most places. Taking it for granted then, that there are other grasses superior in many respects to the *Ray* grass, this question naturally arises: How comes it, that they have not found their way into general use? To this it may be replied, that improvements in any science, especially in agriculture, are slow in their advances; and perhaps no class of men adheres more pertinaciously to old prejudices, than that respectable class of invaluable men, the farmers. The difficulty of distinguishing the grasses from each other, has, no doubt, been one grand obstacle: many of these plants are so much alike, that the most discriminating botanist is often at a loss to know some of them apart: there is also another cause, which may have operated against their introduction: grasses, as well as other plants, have been frequently recommended from a partial and limited observation of them, by persons who neither knew them well, as botanists or agriculturists, or who have recommended them merely to gain by the credulity of the public. But perhaps the chief reason has been, that persons, who might be expected to make the improvements, have not enjoyed the means of making the experiment, owing to the difficulty of obtaining such sorts of grass seeds as may be most suitable for the purpose. It appears, however, that in the herbage of good meadows or grass lands, there should be a combination of produce, batableness or feeding, and early growth. The first is, in most cases, the grand object of the agriculturist; since it is the quantity chiefly which enables him to pay his rent, and support his cattle; to obtain this, the judicious husbandman spares no expense in labour or manure. But it does not follow, that produce is to be attended to solely, or that, for its sake, we are to cultivate rough Cock's-foot Grass, Meadow-sweet, and such coarse plants. Grasses which are recommended for being remarkably grateful to cattle, as the Sheep's Fescue-grass, or for the sweetness of their foliage merely, if found to be deficient in the grand article of produce, will never answer the farmer or grazier's purpose, since, to be a

good meadow, it must be productive. Cattle have undoubtedly their particular likings, with respect to food, in which, though we cannot properly judge of it, they should be sometimes indulged; but this practice must not be carried too far, for as the farmer cannot afford to feed his ploughmen on sucking pigs and poultry, neither can he generally indulge his cattle with the finer or more delicate hay or herbage. Besides, we do not know but that the most productive grasses may also be the most nutritious, or that cattle will not as eagerly eat the herbage or hay of the Meadow Fox-tail grass, as of the fine bent, *Agrostis Capillaris*, and Pro-cumbent Trefoil, or *Trifolium Procumbens*. Moreover, cattle are frequently known to thrive on food to which they are habituated by necessity, though, at first, they could scarcely be prevailed on to touch it. Persons, in making experiments, are very apt to conclude too hastily from the appearance which a plant assumes, on its being first planted or sown: the most insignificant vegetable will often make a great show, when its fibres have fresh earth to shoot into; but the trial comes, when the object of our experiment has been in a meadow or pasture several years, when its fibres, from long growth, are matted together, and it meets with powerful neighbours to dispute every inch of ground with it: if it then continue to be productive, it must have merit. We see that Lucern, when left to itself, is soon overpowered; if we sow Broad-leaved Clover, which is most undoubtedly a perennial, the first year we shall have a great crop of Clover; let this field be left to itself, and the Clover, like the Lucern, will yearly diminish, not because it is a biennial, as some have supposed, but because plants, hardier or more congenial to the soil, usurp its place: this shews then, that at the same time we introduce a good plant, that plant must also be a powerful one, able to keep possession, and continue to be productive. With regard to the second quality, or that of the cattle's thriving on the food they eat; this is undoubtedly of great consequence, and it is to be regretted, that our knowledge of the most nutritive herb is so limited; of those plants which have been cultivated, we are able to speak with some certainty; it is well known, that Clover, Lucern, Saint-foin, Tares, and several other plants, have a tendency to fatten cattle; but what grasses, or other plants, which have not been subjected to a separate cultivation, have this particular tendency, remains to be ascertained by experiment. But as leguminous plants, in general, are found to agree with cattle, we may reasonably conclude, that a certain quantity of them must be proper in pastures. Certain pastures are found to be more bateable or feeding than others; but whether this arises from their situation, or their particular produce, remains also to be discovered by further observation. Respecting the third quality, or the early growth of plants, as the farmers and graziers unitedly complain of the want of early herbage in the spring; those plants, therefore, which are found to put forth early foliage, and to be grateful to cattle, are deserving of great attention. As far as grasses are concerned, the Sweet-scented Vernal, the Meadow Fox-tail, the Smooth and Rough-stalked Meadow Grass, will effect all that can be expected from those of British growth; much, very much, however, will depend on seasons: if the winter be very severe, or north-easterly winds prevail in the spring, grassy herbage will be backward: to counteract the effects of such seasons, our pastures should be warmly situated, not drenched with moisture, sheltered by thick hedges, and divided into small enclosures; in short, a set of enclosures should be formed for this very purpose, where there is a prospect of its answering the designs of the cultivator. But where early pasturage is the desideratum, other plants, as

well as grasses, may deserve a place amongst them, as Ribwort or Rib-grass, *Plantago Lanceolata*, Dandelion, *Leontodon Taraxacum*, Broad-leaved Clover, *Trifolium Pratense*, with many others of the same kind. And as an early herbage, though it be valuable for pasturage, is no less so for hay; by the middle of May at furthest, a meadow of this sort would be fit for mowing, and the second hay-making might commence by the time that hay-making usually takes place in the country. We have sometimes thought, but perhaps the idea is too speculative, that we ought to have two sorts of meadow, one for hay, the other for pasture; that our hay meadow should consist entirely of grasses, and chiefly for this reason, that the hay would thereby be much sooner made, which is an object of consequence at all times, but particularly when the process commences in May. In June and July, the more powerful heat of the sun is able to extricate the thick leaves and stalks of the more succulent plants; but in the necessary prolongation of this business, the grasses must materially suffer. But for the purpose of pasturage, the farmer should be chiefly directed to such sorts of grasses as have the propensity of running to leaves, in preference to such as abound more in flower-stalks or stems. Experiment has proved, that extraordinary fertility arises from unusual circumstances concurring and favouring, in an uncommon degree, the growth of various grasses; consequently, in the forming and improving of grass lands, the most certain plan will be to cultivate the seeds of such grasses as may be most adapted to them, and afterwards sow them at proper seasons upon the lands, when they have been put into a condition suitable for their reception.—The directions given for cultivating, and collecting the seeds of various grasses that have been found to be very productive, are as follows. If a piece of ground, which is neither very moist nor very dry, can be procured, it will answer for all the seeds; they may then be sown on one spot; but if such a piece cannot be obtained, they must be sown on separate spots, according to their respective qualities; no matter whether in a garden, a nursery, or a field, provided it be well secured and clean. Dig up the ground, level and rake it, then sow each kind of seeds thinly in a separate row, each row nine or twelve inches apart, and cover them over lightly with the earth; the latter end of August, or the beginning of September, will be the most proper time for this business. If the weather be not unusually dry, the seeds will soon vegetate; and the only attention they will require, will be careful weeding: in about a fortnight after their coming up, such of the plants as grow thickly together may be thinned, and those which are taken up transplanted, so as to make more rows of the same grass. If the winter should be very severe, though natives, yet as seedlings they may receive injury; therefore it will not be amiss to protect them with mats, fern, or by some other contrivance. Advantage should also be taken of the first dry weather in the spring, to roll or tread them down, in order to fasten their roots in the earth, which the frost generally loosens: care must still be taken to keep them perfectly clear from weeds. As the spring advances, many of them will throw up their flowering-stems, and some of them will continue to do so all the summer. As the seed in each spike or panicle ripens, it must be carefully gathered, and sown in the autumn; at which time, the roots of the original plants, which will now bear separating, should be divided and transplanted, so as to form more rows; the roots of the Smooth-stalked Meadow Grass, in particular, creeping like couch-grass, may readily be increased in this way; and thus, by degrees, a large plantation of these grasses may be formed, and much seed collected for the farmer's use. But a more

ready way, according to a late writer, is for the farmer to notice that species of grass most affected by his soil, and carefully to gather the seed from a piece of old meadow, purposely left three or four weeks longer than common, or at least long enough to become sufficiently ripe. He should not scruple the trouble of selecting the heads as they lie in the swathe; but they who desire not to be so particular, will thresh out the seed together, either in the field, or before it shall have been heated in the mow. Good seeds of different sorts of grasses may now also be procured from different seedsmen in large towns, and other places; but the collection, sold under the title of hay-seeds, should never be trusted to in any respect. Mr. Curtis, from the numerous applications that were made to him by gentlemen for grass-seeds, was induced to select such as appeared to him the most useful, and thereby render the public an essential service. He wished, at least, to put in their power to decide on a matter which had been long agitated, and which he was far from being the only one that entertained the sanguine hopes of its proving a great national advantage. The grasses he has recommended, will, he is confident, do all that our natural grasses can do: they are six of those which constitute the bulk of our best pastures; most of them are early, all of them are productive, and they are adapted to such soils and situations as are proper for meadows and pastures. They are, however, in common with other plants, liable to produce small or great crops, according to particular seasons, or to the fertility or barrenness of the soil on which they are sown and cultivated. The names of these grasses, with the order of their flowering, is as follows. 1. Sweet-scented Vernal: 2. Meadow Fox-tail: 3. Smooth-stalked Meadow: 4. Rough-stalked Meadow: 5. Meadow Fescue: 6. Crested Dog's-tail. The Meadow Fox-tail, and Rough-stalked Meadow Grass, are fittest for moist land; the Meadow Fescue, or Sweet-scented Vernal, are the most proper for land, either moist or moderately dry; and the Smooth-stalked Meadow Grass, and Crested Dog's-tail, are those that are best suited for dry pastures, and other similar lands. Mr. Curtis observes, that many more grasses might be deservedly added to the above list, but expresses his doubts, whether by recommending more, he might not increase the difficulty of introducing grass-seeds, without any adequate advantage in return. We shall, however, subjoin a list of other grasses, which may be useful to those agriculturists who wish to obtain all possible information upon the subject. 1. *Avena elatior*, or Tall Oat Grass. It is early, very productive, affording a plentiful aftermath; and, for its excellence, approaches to the *Alopecurus Pratensis*, for which it may prove a good substitute: 2. *Avena flavescens*, or Yellow Oat Grass; affecting dry soils; it is rather early, and tolerably productive: 3. *Bromus mollis*, or South Brome Grass; this, as an early grass, might probably be cultivated to advantage, but, like other grasses, it sheds the seeds, and withers before the whole is ready for mowing: 4. *Cynosurus cœruleus*, or Blue Dog's-tail Grass; this is the earliest of all our grasses, but is neither productive nor of a good quality: 5. *Dactylis glomeratus*, or Rough Cock's-foot Grass; a rough, coarse, but extremely hardy and productive grass, common in orchards and meadows, and appearing rather early: 6. *Festuca ovina*, Sheep's Fescue Grass; native of dry elevated heaths and commons, unproductive, with a hard and wiry foliage; it grows to be only a small plant, even in a rich moist soil: 7. *Hordeum murinum*, Wall Barley Grass, or Squirrel-tail Grass; common by walls, and the sides of paths. It is very injurious to horses, when mixed among their hay, by the awns or beards of the ears sticking in their mouths: 8. *Hordeum pratense*, or Meadow Barley Grass; taller and more delicate,

sometimes forming great part of the crop in good meadows. It is neither very early, nor remarkably productive, and would probably be as injurious to horses as the preceding sort: 9. *Holcus lanatus*, or Meadow Soft Grass; hardy and productive, flowering a month later than the *Anthoxanthum*; foliage soft and woolly: 10. *Holcus mollis*, or Creeping Soft Grass; it grows well in sandy soils, and bears drought: 11. *Lolium perenne*, or Ray Grass; wiry, with little foliage in upland pastures, but in rich meadows its foliage is abundant, and of rapid growth: 12. *Poa annua*, or Dwarf Meadow Grass; perpetually flowering, and seeding most rapidly, unless prevented by cold, growing in almost any soil or situation, but never acquiring any great height; its foliage is tender, and grateful to cattle, but liable to be killed by winter's frost, and summer's drought: 13. *Phleum pratense*, or Meadow Cat's-tail Grass; imported from America, under the name of Timothy Grass. It is very productive in wet situations, but coarse in quality, and late in appearance, beside having no one excellence which *Alopecurus pratensis* does not possess in an equal or superior degree: 14. *Triticum repens*, Creeping Wheat Grass, Quick, or Couch Grass. Too well known to farmers and gardeners, as an early, but most troublesome weed.—*Grass for meadows and pastures.* The land on which grass-seed is intended to be sown, should be well ploughed, and cleared from the roots of noxious weeds, such as Couch Grass, Fern, Rushes, Heath, Gorse, Broom, Restharrow, &c. which, if left in the ground, will soon get the better of the grass, and overrun the land. Therefore, in such places where any of these weeds abound, it will be a good method to plough up the surface in April, and let it lie some time to dry; then harrow the roots into small heaps, and burn them. The ashes so produced, when spread on the land, will be a good manure for it; but where Couch Grass, Fern, or Restharrow, is in plenty, the land must be twice or thrice deeply ploughed in dry weather, and the roots carefully harrowed off after each ploughing, which is the surest means of destroying them: where the land is low, and of a stiff clayey nature, which holds water in winter, it will be of singular service to make some underground drains, to carry off the wet, which, if detained too long on the ground, will turn the grass sour. The method of making these drains is described under the article *Meadow*; which see. Before the seed is sown, the surface of the ground should be made level and fine, otherwise the seed will be buried unequally. When the seed is sown, it must be gently harrowed in, and the ground rolled with a wooden roller, which will smooth the surface, and prevent the seeds from being blown into patches. When the grass comes up, if there should be any bare spots where the seed has not grown, they may be sown again, and the ground rolled, which will fix the seeds, and the first kindly showers will bring up the grass, and make it very thick. Where the land is designed to continue in pasture, it should be sown with the best sorts of grass seeds, and white Dutch Clover, or what is commonly called Honey-suckle Grass in many parts of England; but there is a great difficulty of procuring good seeds, which can only be removed by selecting the best sorts in the manner already described; for in the all good pastures near London, which abound with the best sorts of grass, the hay is commonly cut before the seeds of the grass are ripe; so that those seeds which are procured from the stables where the horses are fed with the best sort of hay, are little more than chaff, or at best are only such as are of the early kinds of grass, with a great quantity of Plantain, and other weeds, which has discouraged many gentlemen from sowing them: and as it requires more time and attention to collect a sufficient quantity

of the purer sorts of grass-seeds, we would recommend those who will not, or cannot, make that profitable experiment, which we have endeavoured to describe in the former part of this article, to set some of those upland pastures, which are least infested with weeds, and afford the sweetest herbage, aside to stand for seeds; and although, by so doing, the hay will be less valuable, yet from the sale of the seeds, it may answer better to the possessor, than to mow it merely for the hay; for any gentleman, who has regard to the beauty of his land, had better pay six times the price for even such seeds as these, rather than purchase the ordinary sort; for the first cost of seeds is not to be put in competition with the beauty and advantage of having such as are good; which, when the land is brought to a good sward, which may be done in one year, where it is properly prepared and sown, may be easily kept in good order, and annually improved by good management, so as to last as long as that good management continues. Forty years ago, some land was sown in the following manner, and affords to this day the most excellent pasture. It abounded with many bad weeds, so that it became necessary to give a summer and winter's fallow; during which, it was five times ploughed, and ten times harrowed, to destroy the weeds, and make the surface of the ground fine. In August, it was sown with the best grass-seeds that could be procured, three bushels of which, with nine pounds of the white Dutch Clover-seeds, were allowed to each acre: as there happened rains soon after the seed was sown, the grass came up well, but mixed with a great number of weeds: it was afterwards rolled; and that summer, there was more than two tons of hay per acre mowed off the land; and by constant weeding twice a year, sweeping it with a bush harrow, rolling and dressing of the land, the grass has been since greatly improved, and is now as good a pasture as any in England. Large tracts of land laid down in the same manner have succeeded equally well; so that many years' experience, upon an extended scale, confirms this to be the surest means hitherto adopted, for obtaining good pastures. The generality of farmers, to whom this plan is proposed, will object to the first loss of their crop, and also to the after expense of weeding, rolling, &c. as too great for common practice. Long experience, however, on the contrary, testifies, that whoever will be at the expense, will find their account in it; for the crops of hay will be so much better, and the after-pasture also, that it will more than pay the expense; and the verdure of these pastures is delightful to all those who have any taste for natural beauties.—*Grass for gardens.* The English grass is of so good a quality for walks or grass-plats, that if they be kept in good order, they have that exquisite beauty, which exceeds those of France, or any other country. But green walks and green plats are not generally made by sowing the grass-seed, but by laying turfs; and indeed, the turfs from a fine common or down, are, for that purpose, much preferable to sown grass. In sowing a fine green plat, there is a difficulty in getting good seed; it ought not to be such as is taken out of the hay-loft without distinction; for that seed shooting too high, and making large stalks, the lower part will be naked and bare; and however frequently mowed, will come to nothing but tufts of weeds and quick-grass, very little better than that of the common fields. If walks or plats be made by sowing, the best way is to procure the seed from those pastures where the grass is naturally fine and clear, or else the trouble of keeping it from spiry and bent grass will be great, and it will hardly ever look handsome. In order to sow grass-seed, the ground must be first dug or broken up with a spade; and when it has been dressed and laid even, it must be very finely

raked over, and all the clods and stones taken off, and covered over an inch thick with good mould, to facilitate the growth of the seed; this being done, the seed is to be thrown pretty thick, that it may come up close and short; and it must be raked over again, to bury and cover the seed, that if the weather should happen to be windy, it may not be blown away. As to the season of sowing grass, the middle or latter end of August is a good time, because the seed naturally requires nothing but moisture to make it grow; if it be not sown till the latter end of February, or the beginning of March, if the weather prove dry, it will not so soon make the walks or quarters green. It is also best to sow it in a mild day, and inclining to rain; for that, by sinking down the seed in the earth, will cause it to shoot the sooner. But where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the White Trefoil, or Dutch Clover, sown with it; for this will make a fine turf, mitch sooner than any other sown grass, and will retain a better verdure than any of the grass tribe. After the seed is well come up, and the grass is very thick, and of a beautiful green, it will require a constant care to keep in order: this consists in mowing the grass often; for the oftener it is mowed, the thicker and handsomer it grows; it must also be rolled with a cylinder, or roller of wood, to level it as much as possible. If grass be neglected, it will run into quick-grass and weeds, and then the only way to recover it, is either by sowing it, or laying it over again, and that once in every two years; but if the ground be well cleared from the roots of strong weeds, and the turf taken from a fine level common, it will continue handsome for several years, provided it be well kept. In order to keep grass-plats or walks handsome, and in good order in autumn, you may sow some fresh seeds over any places that are not well filled, or where the grass is dead, to renew and furnish them again; but there is nothing which so much improves grass, as the constantly rolling and polling it, to destroy worm-casts, and refine the turf. It is a general practice, when turf is laid in gardens, to cover the surface of the ground under the turf, either with sand or very poor earth; the design of which is, to keep the grass fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not so for such ground as is middling or poor; for the grass will soon wear out, and decay in patches. When turf is taken from a common or down, there should be regard had to the cleanliness of it; such as is full of weeds should be rejected, for it will be a very tedious task to weed them out after the turf is laid; and unless this be done, the grass will never appear handsome. Where turf is designed to remain for years, without renewing, there should be a dressing laid upon it every other year, either of very rotten dung, ashes, or, where it can be easily procured, very rotten tan. These dressings should be laid on early in winter, that the rain may wash them into the ground before the drought of the spring comes on; otherwise they will occasion the grass to turn when the warmth of summer begins. Where grass is well dressed, and kept well rolled and mowed, it may be kept very beautiful for many years; but where it is neither dressed nor fed with sheep, it will rarely continue handsome more than eight or ten years.—The grasses so extensively useful in rural economy, are chiefly to be found in the second order of the third class, *Triandria Digynia*, in the Linnean system. However numerous and distinct from each other they may be, they generally agree in the following particulars, which form, when taken together, the natural character of this tribe or family. The *calix* is a glume or chaff, in most species, composed of two valves, one larger and gibbous, the other

smaller and flat. The *corolla* is also a bivalve glume, and is accompanied by a very small, superior, two-leaved nectarium, of an oblong form. The *stomina* are three in number; the filamenta capillary; the antheræ oblong and bicapsular. There are two pistils, which are pubescent, reflex, or bent back from each other, and terminated by pubescent stigmas. One seed only, or grain, succeeds to each flower; it has no pericarp, but is covered by the calix, corolla, or both; it is of an oblong form, drawn to a point at both ends, and monocotyledonous, or composed of one lobe only. Besides this agreement in the fructification, although grasses are exceedingly difficult to distinguish from each other, they are known at first sight from all other plants, owing to their peculiar appearance or *habit*, as botanists have agreed to term it. Their stalk is simple or unbranched, straight, hollow, and jointed; their leaves are quite entire, of a long linear shape, acuminate, or drawing gradually to a point at the end, marked with lines parallel to the midrib or middle nerve; upon the culm or stalk there is only one of these leaves to each joint, arising from a sheath which invests the stalk, usually to a considerable distance. The seed, it is well known, is farinaceous, or abounding in meal, and is the principal food of many tribes of birds, as the seeds of the larger sorts, which we call corn, are of mankind. One genus of grass, the *Anthoxanthum*, differs from the rest, in having two stamina only; and there are several genera, which, having male flowers mixed with the hermaphrodites, are placed by Linneus in his class *Polygamia*.

Grass, Arrow-headed. See *Triglochin*.

Grass, Artificial. The grasses vulgarly called artificial, are mostly leguminous plants, totally different in every respect from grasses, except in being used as food for cattle; they belong to the class *Diadelphia*. See *Hedysurum*, for *Saintfoin*; *Medicago*, for *Lucern*; and *Trifolium*, for *Clover* and *Trefoil*.

Gratiola; a genus of the class *Diandria*, order *Monogynia*.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, upright; segments awl-shaped, permanent. *Corolla*: monopetalous, unequal; tube longer than the calix; border four-parted, small; the upper segment broader, emarginate, reflex, the rest straight, equal. *Stamina*: filamenta four, awl-shaped, shorter than the corolla, the two lower shorter than the others, and barren, the two upper fastened to the tube of the petal; antheræ roundish. *Pistil*: germen conic; style straight, awl-shaped; stigma two-lipped, after fecundation converging. *Pericarp*: capsule ovate-acuminate, two-celled, two-valved. *Seeds*: very many, small. *Observe*: The essence of the character consists in the two barren antheræ. **ESSENTIAL CHARACTER.** *Calix*: seven-leaved, the two outer patulous. *Corolla*: irregular, reversed. *Stamina*: two, barren. *Capsule*: two-celled.—The species are,

1. *Gratiola Officialis*; *Official Gratiola*, *Hedge-hyssop*, or *Water-hyssop*. Leaves lanceolate-serrate; flowers peduncled. Root perennial, creeping, thick, fleshy, with many slender fibres; stalks several, upright, a foot or more in height, smooth, jointed; leaves opposite, sessile, pointed, bright green, smooth, two inches long, and about two lines broad; flowers solitary, axillary, upright, on peduncles half an inch long, appearing in June and July, and continuing to August; calix usually seven-cleft; corolla shaped like that of the Foxglove, but small, and of a pale yellowish colour, or pale purple, with red streaks, sometimes white; the throat is hairy. The whole plant is very bitter, and nearly resembles the Foxglove, both in external appearance and virtues. Taken in moderate doses it purges briskly, and in larger quantities also vomits, and by thus operating carries off watery humours, and removes obstructing matter in a very powerful degree. The juice is a rough but excellent medicine in dropsies, and a strong decoction or infusion soon cures the jaundice: the root dried and powdered is frequently given successfully in the sciatica and rheumatic complaints, and in small doses will effectually destroy worms in the stomach and intestines, and by its purging qualities carries off that mucous and slimy matter in which they are there bred and harboured. The root of this plant very much resembles *Ipecacuanha* in its nature and effects, and is equally to be depended on in purgings, the bloody flux, and agues. Cattle will not touch this plant on account of its extreme bitterness; so that Haller assures us, there are meadows about Yverdun, in France, entirely useless through the abundance of this plant.—Native of the South of Europe, generally found in moist pastures; common in many parts of Switzerland, Carniola, Austria, in the Palatinate, Silesia, France; about Turin, Padua, and other parts of Italy. This, together with the fifth species, are easily propagated by parting the roots in autumn, when the stalks decay: the plants should have a moist soil and a shady situation, for in dry ground they often decay in summer, unless plentifully watered.

2. *Gratiola Monnieria*; *Thyme-leaved Gratiola*. Leaves oval-oblong; peduncles one-flowered; stalks creeping. Root jointed, creeping, with small fibres; stalk herbaceous, inclined to be simple, round, leafy, smooth, somewhat erect,

declining at bottom; peduncles longer than the leaves, filiform, solitary, axillary, one-flowered; corolla blue, inclined to bell-shape, a little flattened, five-cleft; the divisions nearly equal, the three upper ovate, spreading, the two lower converging, somewhat bent down. This small creeping plant sticks very close to the ground, and casts a few slender fibres from every joint as it creeps; the whole plant seldom exceeds seven or eight inches in length, but it generally grows in beds, and spreads thick upon the ground, throwing out a few simple side-branches, which make it very remarkable, and give it a pretty appearance when it flowers, which is from July to September.—Native of low moist soils in the East and West Indies, and South Sea Islands.

3. *Gratiola Repens*; *Creeping Gratiola*. Leaves ovate; stem creeping; calix five-leaved; style bifid.—Native of Jamaica.

4. *Gratiola Rotundifolia*; *Round-leaved Gratiola*. Leaves ovate, three-nerved. Stems a finger high, quadrangular, smooth, creeping at the base; peduncles axillary, solitary, naked, alternate, one-flowered, longer than the leaves; stamina two, capsules compressed, roundish.—Native of sandy grounds in Malabar.

5. *Gratiola Hyssopoides*; *Hyssop-leaved Gratiola*. Leaves ovate-lanceolate, subserrate, much shorter than the internodes. Stem filiform, upright, smooth, a foot high; peduncles axillary, alternate, solitary, one-flowered, several times longer than the leaves; calix very small; corolla much larger than the leaves, ringent.—Native of the rice-grounds of Tranquebar, in the East Indies. See the first species.

6. *Gratiola Virginica*. Leaves lanceolate, obtuse, somewhat toothed. Stem procumbent, varying much in size; peduncles axillary, one-flowered. The corolla is white, and the flowers are not followed by seeds in England.—It grows naturally in moist places in North America, where it rises more than a foot high, but with us does not exceed eight inches: it is also a native of Malabar.

7. *Gratiola Peruviana*. Flowers subsessile. This plant has grown nine inches high, with a weak stalk, in our climate; leaves opposite, serrate, three-quarters of an inch long, and half an inch broad; the flowers come out single on each side of the stalk, they are white, and much smaller than the common sort.—Mr. Miller received the seeds from Carthage, in New Spain, where it was found in places where there had been standing waters, which were then dried up.

8. *Gratiola Lobelioides*. Stem almost naked, stipuled; leaves oblong, quite entire; panicle dichotomous; capsules subglobular. Root numerous, in bundles, short, simple; stalk simple, upright, round, having an obscure broad furrow on each side, slightly streaked, smooth, with five stipuled joints, a foot high; panicle terminating, lax, thin, with peduncles mostly simple, alternate, remote, round, smooth, or sometimes with a few scattered hairs, slender, nearly equal, with bractes at the base, reddish green; flowers inferior; corolla tube streaked with a darker colour; border bell-shaped, the upper segment scarcely ascending, obcordate, flattish, shorter than the others, blue, the side ones straight, obliquely retuse at the ends, a little longer than the upper one, and of the same colour, the lower one spreading, obcordate, flattish, adorned with a white heart-shaped spot, and a few blue dots, and twice as large as the others; throat naked, a little flattened; germen superior, ovate, smooth, with a small furrow on each side.—Native of rice-fields in Tranquebar.

9. *Gratiola Grandiflora*; *Great-flowered Gratiola*. Stems decumbent; leaves ovate, serrate; peduncles opposite; capsules subulate. Stems angular, bifid, smooth; flowers large in proportion to the other parts; capsules long.—Native of

Tranquebar, Madras, Siam, and Malacca, where it is found in moist fat soils.

10. *Gratiola Veronicifolia*; *Veronica-leaved Gratiola*. Stem creeping; leaves ovate-lanceolate, sharply serrate; flowers terminating, opposite. Stems angular, diffused, procumbent; flowers small, deep blue, bracted and peduncled; capsule five-cleft, linear.—Native of Tranquebar, Madras, &c.

11. *Gratiola Oppositifolia*. Stem ascending; leaves lanceolate-serrate; peduncles opposite to the leaves. Stems seldom upright, quadrangular, streaked.—Native of moist places and rice-grounds in Tranquebar.

12. *Gratiola Stricta*. Leaves ovate; spike long, terminating. Stem suffruticose; flowers white, dotted with red, sessile, in a simple erect spike; calix none, except a triple bracte under the flower.—Native of Cochin-china.

13. *Gratiola Linifolia*. Leaves linear, entire; flower-stalks axillary, the length of the leaves.—Native of Portugal.

14. *Gratiola Latifolia*. Smooth: leaves ovate, obtuse, obscurely crenate, or entire; flowers sessile.—Found near Port Jackson and Van Diemen's Land.

15. *Gratiola Pubescens*. Clothed with glandular hairs: leaves lanceolate, toothed; flowers nearly sessile.—Found in New Holland.

16. *Gratiola Pedunculata*. Clothed with powdery down: leaves lanceolate, toothed in their fore part, scarcely longer than the flower-stalk.—Native of Port Jackson, New South Wales.

Gravel.—There are different sorts of gravel: that upon Blackheath is said to be the best in England; it consists of smooth even pebbles, which, when mixed with a due quantity of loam, will bind very close, and preserve a beautiful appearance longer than any other sort. Some recommend a soil of iron-mould gravel, or gravel with a little binding loam amongst it, than which nothing they say binds better, when it is dry, but in wet weather it is very liable to stick to the shoes, and will never appear handsome. Sometimes loam is mixed with gravel that is over sandy or sharp, which should be well blended together, and suffered to lie in heaps, after which it will bind like a rock. There are many kinds of gravel which do not bind, and thereby cause a continual trouble of rolling, to little or no purpose; as for such, if the gravel be loose or sandy, you should take one load of strong loam to two or three of gravel, and so cast them well together, and turn this mixture over three or four times, that they may be properly blended together: when this is properly done, it will bind well, and not stick to the feet in wet weather. There are many different opinions about the choice of gravel; some are for having it as white as possible, and in order to make the walks more so, they roll them well with stone rollers, which are often hewn by the masons, that they may add a whiteness to the walks; but this renders it very troublesome to the eyes, by reflecting the rays of light so strongly, and on that account should be avoided. Such gravel as will lie smooth, and reflect the least, should be preferred. Some fall into the error of screening the gravel too fine; it should first be cast into a round heap, and will afterwards be the better for only having the great stones raked off. Others are apt to lay gravel-walks too round, but this is also an error, which makes the walks appear narrow; one inch rise is enough in the crown for a walk of five feet wide, and the same proportion will be sufficient for every other width. For the depth of gravel-walks a foot thickness will be quite sufficient, but then there should always be a depth of rubbish laid under the gravel, especially if the ground be wet, for then too much care cannot be taken to fill the bottom of the walks with large stones, flints, brick, rubbish,

chalk, or any other materials which can be best procured, which will drain off the moisture from the gravel, and prevent it from becoming poachy in wet weather; but as it may be difficult in some places to procure a sufficient quantity of these materials to lay in the bottom of the walks, there may be a bed of heath or furze, whichever can be procured at the least expense, laid under the gravel to keep it dry; and if either of these be used green, they will lie a long time, as they will be covered from the air, and these will prevent the gravel from getting down into the clay, and will always keep the gravel dry. In making of gravel-walks, there must be great regard had to the level of the ground, so as to lay the walks with easy descents towards the low parts of the ground, that the wet may be drained off easily; for if this be omitted, the water will remain upon the walks a considerable time after long rains, which will render them unfit for use, especially where the ground is naturally wet or strong; but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have sink-stones laid by the sides of the walks, at convenient distances, to let off the wet, and where the ground is naturally dry, the water will soon soak away: the drains of the sink-stones may be contrived so as to convey the water into sess-pools, from which the accumulated water will gradually disappear in a short time; but in wet land there should be under-ground drains to convey the wet off, either into ponds, ditches, or the nearest place to receive it; for where this is not provided for, the walks will never be so handsome or useful. The month of March is the properest time for laying gravel; it is not prudent to perform it sooner, or to lay walks in any of the winter months: some persons indeed turn up gravel-walks in ridges in December, in order to kill the weeds; but this is very wrong, for besides that it deprives them of the benefit of them all the winter, it does not answer the end for which it is done, but rather the contrary; for though it does kill the weeds for the present, yet it adds a fertility to them, and ensures their future increase. If constantly rolling the ground after the rains and frost will not effectually kill the weeds and moss, turn the walks in March, and lay them down at the same time. In order to destroy worms, which spoil the beauty of both gravel and grass walks, some have recommended the watering them well with water in which walnut-tree leaves have been steeped, and made very bitter, especially those places most annoyed with them; but if in the first laying of the walks there is a good bed of lime-rubbish laid in the bottom, it is the most effectual method to keep out the worms, for they will never come near lime.—See vol. II. p. 786.

Greek Valerian. See *Polemonium*.

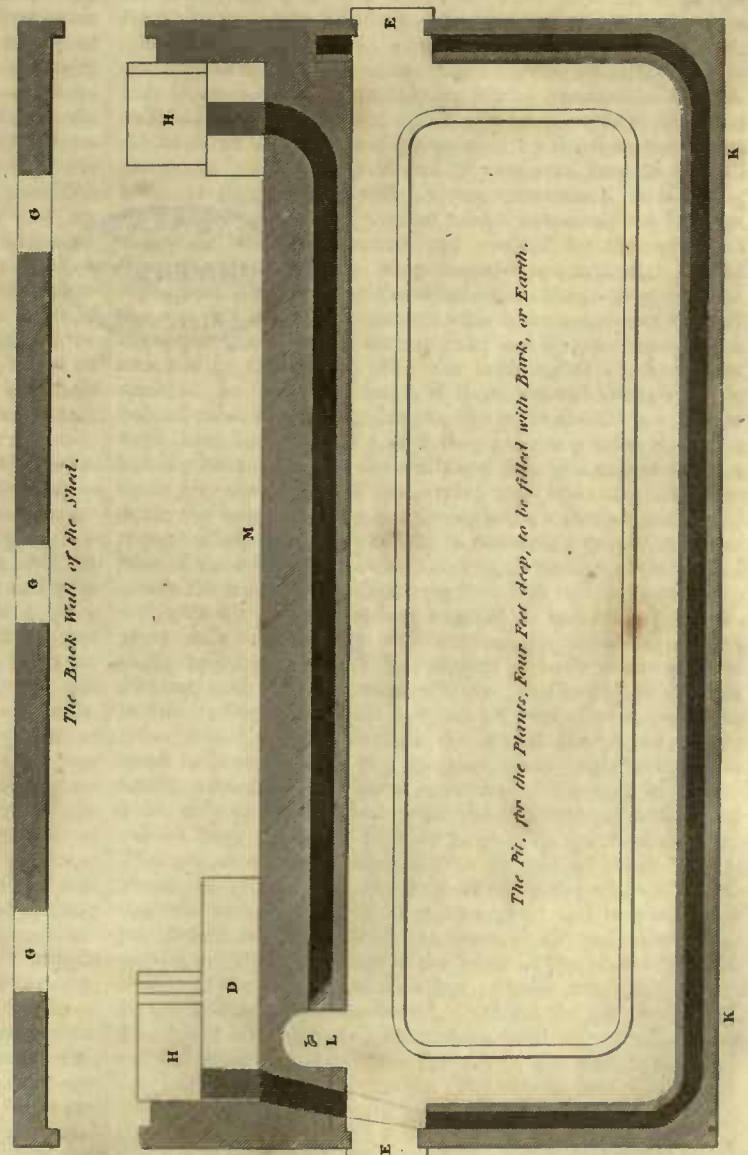

Greenhouse and Conservatory.—These are buildings erected on the best principles for protecting and preserving such sorts of plants as are too tender to live in the open air. The greenhouse was originally a room in a garden, not far from the house, facing the south, and having large windows from top to bottom, built for the reception of Oranges, Myrtles, and a few other plants which were brought from temperate climates. This building had no flues, or contrivances of any sort for increasing the natural heat, but the air of the room was warmed merely by the sun. A great variety of curious exotic plants having been introduced into the English gardens, soon after the middle, and towards the end, of the last century, flues were added to the greenhouse, and many other improvements and contrivances adopted into its structure. As to the length of the Greenhouse, says Mr. Miller, it must be proportioned to the number of plants it is to contain, or the fancy of the owner; but the depth should never be

greater than the height in the clear, which in small or middling houses may be sixteen or eighteen feet, but in large ones from twenty to twenty-four feet is a good proportion; for if the greenhouse be long and too narrow, it will have a bad appearance from both within and without, nor will it contain so many plants, if proper room be allowed for passing in front and at the back of the stands on which the plants are placed; and, on the other hand, if the depth of the greenhouse be more than twenty-four feet, there must be more rows of plants placed to fill the house, than can with convenience be reached in watering and cleaning; nor are houses of too great depth so proper for keeping of plants as those of moderate size. The windows in front should extend from about one foot and a half above the pavement, to within the same distance of the ceiling, which will admit of a cornice round the building over the heads of the windows. As it is necessary to have these windows so long, it will be impossible to make them in proportion as to their breadth, for if the sashes be more than seven or seven feet and a half broad, they will be troublesome to move up and down, and their weight will cause them to decay very quickly. The piers between the windows should be as narrow as is consistent with their necessary strength to support the building, for which reason stone is preferable, or hard well-burnt bricks. If these piers be made of stone, they should be two feet and a half in diameter, worked as columns, cylindrical, whereby the rays of the sun will not be obstructed so much as if they were square; but if they be built of bricks, it will be proper to make them three feet in front, and they may be sloped off towards the inside to admit the sun. If a house four tools, &c. be erected at the back of the greenhouse; the back wall need not be more than two bricks and a half in thickness; but if not, it must be three bricks or three bricks and a half thick to keep out the frost. The floors of the greenhouse may be laid with Bremen squares, Purbeck stone, or broad tiles, and must be raised two feet above the ground, where the soil is dry; but if the situation be moist and springy, the floor should be raised at least three feet above the surface, and if the whole be arched with low brick arches under the floor, it will tend to prevent the damps from rising in winter. These damps are often very hurtful to the plants, especially in great thaws, when the air is often too cold to be admitted into the house to remove the damps. Under the floor, about one foot from the front, a flue one foot in width, and two feet in depth, may be carried the whole length of the house, which may be returned against the back wall, and carried up in proper funnels adjoining to the hot-house, three times over each other, by which the smoke may pass off. The fire-place may be at one end of the house, and the door at which the fuel is put in, as well as the ashes-grate, may be contrived to open into the tool-house, so that it may be quite hid from sight, and kept dry. The fuel also may be laid in the same shed, and thus will always be ready for use. The wall on the back part of the house should be either laid over with stucco, or plastered with mortar, and white-washed, to keep out the frost, which will penetrate through the walls, especially when it is attended with a strong wind. To prevent frost from penetrating through the roof, reeds, heath, or furze, should be laid between the ceiling and the tiles; and care taken in framing the joints, that the weight may not lie upon the ceiling; for they should be laid a foot thick at least, as smooth as possible, and fastened down well with laths, and then covered over with a coat of lime and hair; which will keep out the air, and also prevent mice and other vermin from entering, which, if left uncovered, they would certainly do. In the Greenhouse

West End of the Building.

UNIVERSITY
OF
CALIFORNIA

there should be tressels, which may be moved in and out, upon which rows of planks should be fixed, so as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants may be so situated as not to interfere with each other. The lowest row of plants, or forwardest towards the windows, should be placed about four feet from them, that there may be a convenient breadth left next the glasses to walk in front; and the rows of plants should rise gradually from the first, in such a manner that the heads of the second row should be entirely advanced above the first, the stems only being hid; and at the back of the house there should be allowed a space of at least five feet, for the conveniency of watering the plants, and to admit a current of air round them, that the damps arising from their perspiration may be the more readily dissipated; which, by being pent in too closely, often occasions a mouldiness upon the tender shoots and leaves, and when the house is closely shut up, this rancid and stagnating vapour is often very destructive, and on this account the plants should never be crowded together, nor should succulent plants be placed among them. The plants are put into the Greenhouse in October, or as soon as the morning and evening frosts come on: in this situation they remain till the end of May or the middle of June, according to the season; when they are removed to the place where they are to stand through the summer. When first brought out, they should be placed in some sheltered sunny place, for a fortnight, till they are inured to the open air; then set them in any open exposure, where they are to remain for the summer; supplying them plentifully with water in hot dry weather, all the woody or shrubby kinds in particular. Before the plants are removed out of the Greenhouse, it is necessary to shift at least all the small plants; that is, to take them out of their pots, to cut off part of their roots round the ball of earth, and to put them again into the same pot, if the plant be in an unhealthy state; or, if healthy, into one a size larger, shortening the irregular side-branches as they may require, and tying them up neatly. The mould into which the plants are to be shifted, is of considerable importance; the best is to be obtained from commons where sheep and cattle pasture, particularly in low places, where the finest grass grows in the deepest soil. A foot of the top soil with the turf may be taken off; and if it be a sandy or hazel loam, it will do alone; but if it be a strong loam, some sand and black peaty or moorish soil should be added. Such soils, laid in a heap for at least six of the winter months, and frequently turned over, will suit most greenhouse plants. Aloes, Mesembryanthemums, Ixias, and such liliaceous plants in general as are inhabitants of exotic houses and glass-cases, require a soil which is a degree lighter, and which will not retain the water, but let it pass readily; and a little coal-ashes at the bottom of each pot may be very useful for this purpose. The great number of Ericas or Heaths, and other beautiful plants from the Cape of Good Hope, from America, and Botany Bay, delight and flourish in that sort of earth which comes nearest to their native soil. Thus the heaths like a black peat or moorish soil, and the others that which is made a degree stronger with loam.—*Conservatory.* Greenhouse and Conservatory have been generally considered as synonymous terms for a house of a certain construction, destined to the preservation of exotic plants throughout the winter. Their essential difference is this: In the Greenhouse, the trees and plants are either in tubs or pots, and are placed on stands or stages through the winter, till they are removed into some sheltered situation abroad for the summer. In the Conservatory, the ground plan is laid out in beds and borders, made up of the

best compositions of soils that can be procured, three or four feet in depth. In these the trees and plants, taken out of their tubs or pots, are regularly planted in the same manner as hardy plants in the open air. Instead of taking out the plants in summer, as in the Greenhouse, the whole of the glass roof is taken off, and the plants are thus exposed to the open air; and at the approach of autumn frosts the lights are again put on, and remain so till the May or June following. It is evident that the building here called a Conservatory may also be used as a Greenhouse, at the discretion of the owner, by introducing stages instead of beds, and in that case the glass roof may be fixed. In Mr. Miller's plan, the Greenhouse or Conservatory is placed exactly fronting the south, one of the wings or stoves facing the south-east, and the other the south-west; so that from the time of the sun's first appearance upon any part of the building, until it goes off at night, it is constantly reflected from one part to the other, and the cold winds are also kept off from the front of the centre building. In the area many of the more tender exotic plants may be placed in the summer season; and in the spring, before the plants can be set out, the beds and borders of this area may be full of Anemonies, Ranunculuses, early Tulips, &c. which will be past flowering, and the roots fit to take out of the ground, by the time the plants are taken out. In the centre of this area, may be a small basin of water, which will be very convenient for watering the plants, not only on account of its nearness, but because the water will be softened and warmed by the reflection from the glasses. The wing facing the south-east should always be preferred for the warmest, or bark-stove, because the sun, at its first appearance in the morning, shines directly upon the glasses, and, warming the air of the house, gives new life to the plants, after the long nights of the winter season. In these buildings, if there are not sheds running behind them their whole length, the walls should not be less than three bricks thick, and if they are even more it will be better; because where the walls are thin and exposed to the open air, the cold will penetrate, and when the fires are made the heat will come out through the walls, so that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the house, and in general the closer and better these houses are built, the less fuel will be required to warm them; so that the first expense in building them properly and substantially will be the cheapest.—Besides these buildings, it will be proper to have deep *Hot-bed Frames*, such as are commonly used to raise large annuals in the spring, into which may be set pots of such plants as come from Carolina, Virginia, &c. whilst the plants are too small to bear the open air; as also many other sorts from Spain, and other southern countries of Europe, which require only to be screened from the violence of frosts, and should have as much free air as possible in mild weather. This cannot be better effected than by one of these frames, where the glasses may be taken off every day when the weather will permit, and put on every night; and in hard frosts the glasses may be covered with mats, straw, pease-haulm, or similar materials, to preserve the roots of the plants from the frost. If these pits be sunk a foot or more below the surface of the ground, it will be better, provided the ground be dry. The sides of the frame should be built with brick, and a curb of wood laid round on the top of the wall, into which the gutters whereon the glasses slide may be laid. The back wall may be four feet high, and two bricks and a half thick; the front one a foot and a half; the width of the inside of the frame, about six feet; and the length in proportion to the number of plants to be contained in it.

Grewia; a genus (according to Linneus) of the class Gynandria, order Polyandria; removed by Schreber into the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets lanceolate, upright, leathery, coloured within, spreading, deciduous. *Corolla*: petals five, the same form with the calix, often smaller, emarginate at the base; nectary, a scale inserted into each petal at the base, thickish, bent in, inclined to the rim, surrounding the style. *Stamina*: filamenta very numerous, the length of the petals, bristle-shaped, inserted into the base of the germen; antheræ roundish. *Pistil*: germen pedicelled, roundish, sitting on a columnar upright receptacle, surrounded by a five-cornered rim; style filiform, the length of the stamina; stigma obtuse, four-cleft. *Pericarp*: berry four-lobed, four-celled. *Seeds*: solitary, globular, usually two-celled. **ESSENTIAL CHARACTER.** *Calix*: five-leaved, coloured within. *Petals*: five, with a nectareous scale at the base of each. *Berry*: four-celled.—The species are,

1. *Grewia Occidentalis*; *Elm-leaved Grewia*. Leaves obovate, bluntly serrated, smooth; flower-stalks solitary, club-shaped, single-flowered. This plant will grow to the height of ten or twelve feet, and has a stem and branches very like those of the small-leaved Elm, the bark being smooth, and of the same colour as that of Elm when young; the leaves are also very like those of the Elm, and fall off in winter; the flowers are produced singly along the young branches from the axils, and are of a bright purple colour; they appear towards the end of July, and continue through August to the beginning of September, but are never succeeded by fruit in this country.—Native of the Cape; and long cultivated in our greenhouses, flowering most part of the summer.—*Propagation and Culture.* The common *Grewia* may be propagated by cuttings or layers: the cuttings should be taken off and planted in April, before the buds swell, for they do not succeed well after; these cuttings should be planted in small pots filled with loamy earth, and the pots should be plunged into a moderate hot-bed of tanners' bark, where, if they are duly watered, and in the heat of the day sheltered from the sun, they will take good root in about two months, and may then be gradually inured to bear the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn, when they must be removed into the greenhouse. The best time to lay down the layers of this plant, is in the spring, before the buds come out, and these will be rooted by the same time the following year, when they may be cut off from the old plants, and planted each into a separate pot filled with a soft loamy soil. The best time to remove or transplant this plant is, either in the spring just before the buds begin to swell, or in autumn when the leaves begin to drop; for in summer, when the plants are in full leaf, it will be very improper to disturb them. In winter they should be placed in the greenhouse, for they are too tender to live abroad in England; but they should have as much free air as possible in mild weather, for they only require to be protected from frost, and after their leaves are fallen they will require very moderate watering; but in summer they should be watered three or four times a week in dry weather, and placed in a sheltered situation, with other hardy greenhouse plants, where they will add to the variety.—The other species of this genus will not live through an English winter, unless they are placed in a warm stove; nor do those plants thrive well which are placed on shelves in the dry-stove; therefore the only method to ensure their succeeding is, to place them in the bark-bed in the tan-stove. In summer these plants require a good share of free air to be admitted to them, and

should have water three or four times a week in warm weather; but they must be kept warm in winter, and sparingly watered.

2. *Grewia Populifolia*; *Poplar-leaved Grewia*. Leaves orbiculate; peduncles solitary, one-flowered. This is a branching shrub; the branches are slender, smooth, and ash-coloured; leaves shorter and rounder than the first species, on longer and more slender stalks; bractes in pairs, on the middle of the peduncle, deciduous; calicine leaflets linear, obtuse, villose, smooth within, coloured; petals linear, shorter than the calix. It is allied to the first species, but of a looser habit.—Native of Arabia, where it is called *Chaddr*, or *Nabba*; also of the East Indies.

3. *Grewia Orientalis*; *Oriental Grewia*. Leaves sublan- ceolate; flowers solitary. This is a middling sized tree. Peduncles from the axils tomentose, trifid, three-flowered. Berry subglobular, depressed, becoming obtusely four-cornered, and drying, succulent; the skin when fresh saffron coloured, villose, flesh pulpy, fungacious; stones hard like grape-stones, having a deep furrow on the back, two-celled. It flowers in July and August.—Native of the East Indies.

4. *Grewia Lævigata*. Leaves elliptic, acuminate, smooth on both sides, quite entire at the base; peduncles three-flowered. Branches with a purple bark dotted with white; pedicels almost the length of the petioles.—Native of the East Indies.

5. *Grewia Glandulosa*. Leaves ovate, lanceolate, acuminate, smooth on both sides, glandular at the base; flowers solitary, subsessile. Branches somewhat rugged; petiole short; flowers axillary, on very short peduncles.—Native of the Isle of France.

6. *Grewia Hirsuta*. Leaves lanceolate-ovate, soft; calices very hairy; peduncles many-flowered. Branches soft with hairs, especially at top; flowers subsessile, with a three-leaved lanceolate involucre; petals very short, oblong, ciliate.—Found by Koenig on the tops of mountains in the East Indies.

7. *Grewia Excelsa*. Leaves oblong, beneath tomentose, hoary; peduncles axillary, often solitary, three-flowered; pedicels angular.—Found in Arabia.

8. *Grewia Asiatica*; *Asiatic Grewia*. Leaves cordate, serrated at the base, white and downy beneath, flower-stalks aggregate, much longer than the footstalks; column naked, as long as the germen. A tree with the branches scarcely tomentose; stipules lanceolate; petioles round, tomentose, one-fifth the length of the leaves; peduncles axillary, usually in fours, trifid, three-flowered, half the length of its leaves; petals not bigger than the calix; berries small, red, acid.—Native of Surat, in the East Indies.

9. *Grewia Tiliæfolia*. Leaves cordate, roundish, smooth on both sides; peduncles shorter than the petiole. Branches smooth, with brown bark, very minutely dotted with ash-colour, the younger ones subvillose; petioles powdered at the tip, scarcely thickened; stipules half-cordate, acuminate, shorter than the petiole; peduncles axillary, two or three together, three-flowered; involucre three-leaved; leaflets lanceolate, obtuse, concave, the length of the pedicels; fruit two-grained.—Native of the East Indies.

10. *Grewia Mallocoeca*; *South Sea Grewia*. Leaves cordate, ovate-oblong, crenate, scabrous; pedicels axillary, three-flowered; fruit tetracoccus. The difference by which it is distinguished from other species is difficult to make out. It is distinct by having no scales to the petals, the germen sessile, and the stones or nuts not two-celled. The berry is obtusely four-cornered, depressed, scabrous on all sides, with minute bristles. Seeds solitary, and four in the whole berry, obovate,

remarkably tapering downwards, somewhat livid.—Native of the island of Tongatabu and Huabeine in the South Seas.

11. *Grewia Velutina*. Leaves oval, serrated, very soft on both sides, hoary underneath; peduncles axillary, about three together, three-flowered; stem shrubby. All parts of the plant very soft with nap. Petioles very short; stipules bristle-shaped, deciduous; peduncles the length of the petioles. Flowers smaller than those of the eighth species.—Native of Arabia and the East Indies.

12. *Grewia Salvifolia*; *Sage-leaved Grewia*. Leaves oblong, quite entire; flowers axillary, several pedicelled; petals bowed back, linear. This is a shrub. Peduncles three or more, tomentose, short; flowers upright; calix five-toothed, tomentose; petals tomentose, upright, yellow, bifid at the tip.—Native of the East Indies.

13. *Grewia Microcos*. Leaves ovate, oblong; flowers paniced. This is a tree. The flowers are terminating, and the calices tomentose.—Native of the East Indies.

Grias; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, cup-shaped; mouth four-cleft, finally lacerated. *Corolla*: petals four, roundish, concave, coriaceous. *Stamina*: Filamenta numerous, setaceous, longer than the corolla, inserted into the receptacle; antheræ roundish. *Pistil*: germen somewhat depressed, immersed in the calix; style none; stigma thickish, four-cornered, hollowed out crosswise. *Pericarp*: drupe large, one-celled, acuminate at the base and tip. *Seeds*: nucleus scored with eight furrows. ESSENTIAL CHARACTER. *Corolla*: four-petalled. *Calix*: four-cleft. *Stigma*: sessile, cross-shaped. *Drupe*: with an eight-furrowed nucleus.—The only known species is,

1. *Grias Cauliflora*; *Anchovy Pear*. Branches at the top simple, short, or none; leaves on short petioles, pendulous, two or three feet long, wedge-shaped at the base, oblong, attenuated, entire, marked with nerves and veins, wrinkled, smooth; flowers from the stem, yellowish-white, fragrant, on very short, scaly, many-flowered peduncles; pedicels short, crowded, one-flowered; corollas about the size of a half-crown. This tree frequently grows to the height of fifty feet, and the uprightness of the growth, and the largeness of the leaves, give it a very elegant appearance. The fruit is pickled in the West Indies, and eaten in the same manner with the East Indian Mango, which it exactly resembles in taste; it is about the size of an alligator's egg, and much like it in shape, only a little more acute at one end, and of a brown russet colour.—Native of all the hottest parts of the West Indies, and common in many parts of Jamaica, growing generally in low moist bottoms, or shallow waters. To propagate it, put the stones into the ground soon after the fruit is gathered, and keep the plants constantly in the bark-bed in the stove. In the West Indies the seeds grow very readily, wherever they meet with a sufficient quantity of moisture, and propagate so thick, that the trees are always found formed into thickets, or large clusters.

Grielium; a genus of the class Decandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, spreading, deeply five-cleft, flat at the base, sharp, equal, permanent. *Corolla*: petals five, spreading, large, obovate, sessile, tapering at the base; nectaries oblong; glands placed round the germen, and united so as to form a crown. *Stamina*: filamenta ten, filiform, somewhat rigid, equal, permanent, the length of the calix; antheræ ovate-oblong, upright. *Pistil*: germina five, distinct, awl-shaped, upright, shorter than the stamina; styles none; stigmas capitate, warty. *Pericarp*: capsules five, oblong, acuminate, hard, formed from the calix, five or ten celled. *Seed*: solitary,

oblong. *Observe*. It is not certain whether there be a difference of sex, or a withering of the pistil in some individuals. ESSENTIAL CHARACTER. *Calix*: deeply five-cleft. *Petals*: five. *Filamenta*: permanent. *Capsules*: five, with one seed in each.—The only known species is,

1. *Grielium Tenuifolium*. Stem shrubby, diffuse and very much branched, clothed, like the leaves, with a white cottony down. The petals are blue, with livid yellow claws. Capsule inferior, with the calix closely adhering, and serving as a bark to it at bottom, flattish at top, and surrounded with a ring of hard bony tubercles, within which it is crowned with the permanent filamenta and styles; it has ten cells, but no valves: to each style there are two cells, but all of them are placed in a ring, regularly round the axis of the fruit, and deeply immersed in the substance of the calix. There is no receptacle, but the seeds are fixed to the tip of the cells, only one in each; the form is elliptic, beaked at top, plano-convex, or flatted lens-shaped, of a reddish chestnut colour.—Native of the Cape.

Grimmia; a genus of the class Cryptogamia, order Musci. ESSENTIAL CHARACTER. *Capsule*: ovate. *Fringe*: simple, of sixteen teeth, broadest at their base. *Flowers*: terminal. *Veil*: cylindrical.—Twenty-nine species have been described; some of them belonging to the Linnean species of Bryum.

Grislea; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth, one-leaved, awl-shaped, inclined to bell-shape, upright, four-toothed, coloured, permanent. *Corolla*: petals four, ovate, from the incisures of the calix extremely minute. *Stamina*: filamenta eight, awl-shaped, upright, long, ascending; antheræ simple, upright, roundish. *Pistil*: germen superior, globular, pedicelled; style filiform, the length of the stamina; stigma simple. *Pericarp*: capsule globular, shorter than the calix, one-celled. *Seeds*: very many, roundish, very small; receptacle large. *Observe*: Sometimes one third part is added to the parts of the flower. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Petals*: four, from the incisures of the calix. *Filamenta*: very long, ascending. *Capsule*: globular, superior, one-celled, containing many seeds.—The species are,

1. *Grislea Secunda*. Leaves ovate, lanceolate, smooth, on petioles; raceme terminating; flowers all facing one way. This is a tree, with round scattered branches. Calices of a dark brownish crimson, bell-shaped, slightly angular; petals, stamina, and style, of an elegant scarlet.—Native of South America.

2. *Grislea Tomentosa*. Leaves half-lanceolate, with a cordate base, whitish beneath, sessile; racemes axillary, short. Stem, and principal branches, erect, smaller, ascending; bark rust-coloured; calix red, six-toothed, equal, permanent; petals six, small, lanceolate.—This is a beautiful flowering shrub, a native of the hills and valleys through the northern provinces of the Carnatic in the East Indies. The bright red calix, retaining its colour till the seeds be ripe, gives this plant a very showy appearance. Linneus says it is also a native of the West Indies.

Gronwell. See *Lithospermum*.

Gronovia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft beyond the middle, bell-shaped, coloured, permanent; divisions semi-lanceolate, upright. *Corolla*: petals five, extremely minute, roundish, from the clefts of the calix. *Stamina*: filamenta five, capillary, length of the corolla, inserted into the calix, alternate with the petals; antheræ erect, heart-shaped, twin. *Pistil*: germen inferior; style filiform, longer than the stamina; stigma capitate, undivided. *Pericarp*: berry dry, roundish, coloured, one-celled. *Seed*:

single, roundish, large. **ESSENTIAL CHARACTER.** *Petals*, five, together with the *Stamina*, inserted into the bell-shaped corolla. *Berry*: dry, five-cornered, inferior, containing one seed.—The only known species is,

1. *Gronovia Scandens*; *Climbing Gronovia*. This is an annual plant, which sends forth many trailing branches like those of the *Cucumber*, closely set with broad leaves, in shape like *Vine-leaves*; those on the stalk are covered with small spines, or rather hooked hairs, which sting like the *nettle*: the branches have many tendrils, by which they fasten themselves to other plants, and thus will rise to the height of six or eight feet. The flowers are small, axillary, and in bunches, of a greenish yellow colour, and make no great appearance. It has a strong smell.—Native of *Vera Cruz*. This being a very tender plant, must be raised on a hot-bed early in the spring, and afterwards placed in the bark-stove.

Ground Ivy. See *Glechoma*.

Groundsel. See *Senecio*.

Groundsel-tree. See *Baccharis*.

Guaiacum; a genus of the class *Decandria*, order *Monogynia*.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate-oblong, concave, obtuse, spreading, deciduous; the two outer ones a little smaller. *Corolla*: petals five, roundish-obovate, obtuse, concave, spreading, longer than the calix, ending in short claws, inserted into the receptacle. *Stamina*: filamenta subulate, broader at the base, upright, shorter than the corolla, inserted into the receptacle; antheræ oblong, finally recurved. *Pistil*: germen broader above, angular, pedicelled; style short, subulate; stigma simple, acute. *Pericarp*: capsules two to five, on very short pedicels, compressed, membranaceous, covered with a pulpy rind, gibbous on the outside, united on the inside, separating when ripe, gaping. *Seeds*: solitary, bony, oblong. **ESSENTIAL CHARACTER.** *Calix*: five-cleft, unequal. *Petals*: five, inserted into the receptacle. *Capsule*: angular, five-celled.—The species are,

1. *Guaiacum Officinale*; *Official Guaiacum*, or *Lignum Vita*. Leaflets in two pairs, obtuse. This grows to be a very large tree, covered with a hard, brittle, brownish bark, not very thick. The wood is firm, solid, and ponderous, appearing very resinous, of a blackish yellow within, and of a hot aromatic taste. The smaller branches have an ash-coloured bark. *Petals* ovate, entire; leaflets two pairs, elliptic, sessile, entire, veined, shining. *Browne* describes this tree as an evergreen of a dark gloomy cast, continuing its verdure in the driest seasons, and at times throwing out a great number of blue flowers, which are succeeded by compressed berries of a roundish form. The tree takes many years to arrive at its full growth. The roots run far into the ground perpendicularly, contrary to the usual growth of timber-trees in the *West Indies*, which generally shoot the largest prongs of their roots in an horizontal direction, and are commonly observed to run very near the surface. The bark is thick and smooth; the wood of a dark olive colour, and cross-grained, the strata running obliquely into one another in the form of an X. As timber, it answers where strength and duration are required, and its weight no impediment. It takes a fine polish, and answers well in the *turner's lathe*; but is now chiefly used for the sheaves of ships' blocks. The tree rises to the height of forty feet, and measures from fifteen to eighteen inches in diameter. It is certainly one of the most valuable in the *West Indies*; since the body, the bark, gum, fruit, leaves, and blossom, are all applicable to some useful purpose. The gum is obtained by jagging the body of the tree in *May*. It exudes copiously from the wounds, though gradually; and when a quantity is found accumulated, hardened by exposure

to the air and sun, it is gathered and packed in small kegs. This gum is sometimes suspected to have been sophisticated by the negroes, with the gum of the *Manchineal-tree*, to which it bears some similitude at the first appearance; but it is easily distinguished by dissolving a little in spirits: the true gum imparts a whitish tinge; but the *Manchineal* gives a greenish cast: and this is still further distinguishable by pouring a little of the same tincture into water, which takes from the *Guaiacum* almost immediately the complexion of milk. The fruit is purgative; and for medicinal use, far excels the bark. From the flowers is prepared also a laxative syrup, resembling syrup of *Violets*. The fresh bark opens the body, and is deemed a sweetener of the blood; but the pulp of the berries purges and vomits very violently. The resinous parts of the tree are of a warm, active nature, and found by long experience to attenuate and dissolve the blood: they are esteemed specifics in old venereal taints, chronic rheumatisms, and other disorders arising from the sizyness of the juices, and generally administered in decoctions, (the resin sometimes in boluses,) ordered for a continuance: but great care must be taken to moderate or temper the native acrimony of these medicines in the beginning of a course, and to prepare the body for the use of them; the neglect of which has been frequently the cause of very dismal consequences in hot climates, and may probably have the like effects sometimes in colder regions. There is a tincture made with the gum of this tree, that has been sometimes administered with success, as well as the powder itself, in obstinate intermittent and remittent fevers; in which cases they commonly procure a few stools, as well as promote a general discharge by the skin. The foliage of this tree is of a very detersive nature, and frequently used to scour and whiten the floors in most houses about *Kingston*: the infusion of them is also used to wash painted linens, and other stained garments; which it is said to do very effectually, without changing the lustre of their dyes. The wood and resin only are now used in *Europe*. Since the introduction of mercury, it is seldom prescribed in the *lues venerea*; if, when occasionally employed in syphilis, it is rather with a view to correct other vitia in the habit. *Dr. Cullen* looks upon it as analogous to the balsams and turpentine, and as having a considerable power in stimulating the extreme vessels; and thus accounts for its efficacy in chronic rheumatism; and from its passing off by the pores of the skin, he considers it as a probable remedy in some cutaneous disorders. In the *London Dispensatory* there is a tincture of Gum *Guaiacum* (*Pulvis Aloeticus cum Guaiaco*), and the wood is an ingredient in *Decoctum sarsaparilla compos*. The *Edinburgh college* have directed an elixir to be prepared with rectified spirit, or with the vinous spirit of sal ammoniac: some object to the spirituous tincture, and *Dr. Cullen* prefers the diffusion of the gum in water.—It is a native of the *West Indies*. In *Jamaica* it is abundant on the south side, but is seldom found in any other part of the island.—This, and the second species, can only be propagated by seeds procured fresh from the countries where they naturally grow. As soon as they arrive they should be sown in pots, filled with light earth, and plunged into a good hot-bed, and, if the seeds be good, they will appear in six weeks or two months; in six weeks more they will be strong enough for transplanting; then they should be carefully taken out of the seed pots, so as to preserve their roots as entire as possible, and each planted in separate small pots filled with light earth, and plunged into a new hot-bed of tanners' bark, where they must be shaded from the sun till they have taken fresh root; then they must be treated in the same manner as other tender exotic plants

from warm countries, admitting a large share of free air to them when the weather is warm; at which time it must be given with great caution, for too much wet will infallibly destroy them; while the plants are young, they may be kept during the summer season in a hot-bed of tanners' bark under a frame; but in the autumn they must be removed into the bark-stove and plunged into the hot-bed of tan, where they should constantly remain, and must be treated in the same manner as other tender plants, being careful not to give them too much water in the winter, when it is very prejudicial to them; and in summer they should have a large share of free air admitted to them every day. With this treatment the plants will thrive very well; but being plants of slow growth in their own country, cannot be expected to make great progress in Europe. In their native country, they grow very readily from seed, and seem fond of a dry soil with a hot exposure.

2. *Guaiacum Sanctum*; *Holy Guaiacum*. Leaflets many pairs, obtuse. It has many leaflets placed along the midrib by pairs; they are rounded and obtuse at their ends, but narrow at their base, of the same consistence with those of the first sort, but of a darker green colour. The flowers are produced in loose bunches towards the ends of the branches, are of a fine blue colour, and the petals are fringed on their edges. This is called *Bastard Lignum Vitæ*, in some of the West India Islands. See the first species.

3. *Guaiacum Afrum*. Leaflets many pairs, acute; branches rigid; leaves alternate, with eight pairs of leaflets; stipules pressed close to the branches, subulate, very small.—Native of Mossel-bay, near the Cape of Good Hope. This will live in a good green-house all the winter, but in summer it must be placed abroad with other green-house plants. It is of a slow growth, and is with difficulty propagated by layers.

4. *Guaiacum Dubium*. Leaves conjugate, oblong, lanceolate, obtuse.—Native of Tongatabu in the South Seas.

Guarea; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, four-parted, flattish, short. *Corolla*: petals four, spreading, lanceolate, obtuse; nectary tubular, cylindrical, quite entire, length of the corolla, contracted at the throat. *Stamina*: filamenta none; antheræ eight, growing to the inner edge of the nectary, ovate. *Pistil*: germen roundish, on a very short pedicel; style subulate, thick, length of the nectary; stigma four-cornered, depressed. *Pericarp*: capsule roundish, large, subsessile, four-grooved, four-celled, four-valved. *Seeds*: solitary, oblong, with a scarlet aril. *Observe.* It should be distinguished from *Trichilia*, to which it is nearly allied. **ESSENTIAL CHARACTER.** *Calix*: four-cleft. *Petals*: four. *Nectary*: cylindrical, bearing the antheræ at its mouth. *Capsule*: four-celled, four-valved. *Seeds*: solitary.—The only known species is,

1. *Guarea Trichilioides*; *Ash-leaved Guarea*. This is a middling-sized tree, with a smooth trunk; racemes a foot long, axillary, subdivided, loose; the branches many-flowered; the peduncles very short; calix four-cornered, minute; segments blunt, spreading; leaves pinnate, without an odd leaflet. All parts of this plant, especially the bark, smell strong of musk, and may be used instead of that perfume, for many purposes. The wood is full of a bitter resinous substance, which renders it unfit for rum hogsheads; being observed to communicate both its smell and taste to all spirituous liquors: but it is often cut for staves and heading, when there is a scarcity of other timber. The powder of the bark is said to be a good emetic; and is sometimes used among the negroes for that purpose.—Native of South America and the West India islands, in woods, and by river-sides, where it flowers

in January and February. The English call it *musk-wood* and *alligator-wood*; the French *bois rouge*.

Guettarda; a genus of the class Monœcia, order Heptandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, cylindrical, very short, quite entire, the outer edge more prominent, deciduous. *Corolla*: one-petalled, funnel-shaped; tube cylindrical, long; border six to nine cleft, with rounded lobes shorter than the tube. *Male Flowers.* *Stamina*: filamenta four to six or seven in the throat of the corolla; antheræ linear. *Pistil*: style filiform. *Female Flowers*, in the same plant. *Pistil*: germen roundish, inferior; style filiform, longer than the stamina; stigma subovate. *Pericarp*: drupe dry, roundish, depressed, torose, (according to Jussieu with a sinous nut, six-celled, and containing six seeds.) *Seed*: nut lobed, celled, perforated in the periphery for cells; kernels solitary, four to six, roundish, bent at right angles. **ESSENTIAL CHARACTER.** *Calix*: cylindrical. *Corolla*: six or seven cleft, funnel-shaped. *Pistil*: one. *Drupe*: dry.—The species are,

1. *Guettarda Speciosa*. Leaves roundish, acute, heart-shaped at the base, naked on both sides; flowers seven or nine cleft. A tall tree, with numerous, purplish, slightly downy branches: the fruit is globose, depressed, its nut containing six seeds.—Native of Java, and cultivated in various parts of the East Indies for the fragrance of its flowers.

2. *Guettarda Argentea*. Leaves roundish, acute, heart-shaped at the base, downy beneath; flowers five-cleft. A small tree, eight or ten feet high; the stem three or four inches in diameter.—Native of Jamaica.

3. *Guettarda Rugosa*. Leaves subcordate, ovate, acute, tomentose beneath, scabrous above; flowers white, with six stamina; branches round, opposite, scarred, smooth below, villose above; tube of the corolla an inch and a half long, soft, and somewhat silky; fruit the size of a pea, ash-coloured, with villose hairs.—Native of the East and West Indies.

4. *Guettarda Elliptica*. Leaves elliptic, pubescent; flowers with four stamina.—Native of Jamaica.

5. *Guettarda Membranacea*. Leaves ovate, acuminate, membranaceous, subhispidly scabrous; flowers whitish, with four stamina.—Native of St. Domingo.

Guilandina; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed; tube short, turbinate, permanent, with an oblique mouth; border five-parted, nearly equal, spreading, deciduous; divisions oblong, broader on the outside, and rounded; the two upper ones a little shorter, the lowest a little longer. *Corolla*: petals five, inserted into the neck of the calix; the uppermost roundish, concave, ascending, a little shorter, the rest oblong, broader in front, rounded at the tip, reflex-spreading, longer than the calix, and the two lowest a little longer than the middle ones. *Stamina*: filamenta subulate, thicker at the base, and villose, decumbent, inserted into the neck of the calix, shorter than the corolla, unequal; the lower ones gradually longer; antheræ oblong, affixed to the back. *Pistil*: germen oblong; style filiform, length of the stamina; stigma simple. *Pericarp*: legume rhomboidal, the upper suture convex, from swelling compressed, one-celled, with transverse partitions. *Seeds*: bony, globular-compressed, solitary between the partitions. **ESSENTIAL CHARACTER.** *Calix*: one-leafed, salver-shaped. *Petals*: inserted into the neck of the calix, nearly equal. *Seed-vessel*: a legume.—The species are,

1. *Guilandina Bonduc*; *Yellow Bonduc*, or *Nicker Tree*. Prickly: pinnas ovate, with solitary prickles on the leaflets; leaves nearly a foot and a half long, composed of six or seven pairs of pinnæ, each of which has as many pairs of leaflets,

which are ovate and entire; the principal midrib of the leaf is armed with short crooked single thorns, placed irregularly; the stalks are also armed with thorns, which are larger. The stalks at first grow erect, but afterwards twine about the neighbouring trees and shrubs; the flowers are in long axillary spikes; legume broad, thick, three inches long, and two broad, closely armed with slender spines, opening with two valves, each enclosing two hard seeds, about the size of children's marbles, of a yellowish colour.—Native of the East and West Indies. This, together with the second, third, and fourth species, will not live through the winter in England, unless placed in a warm stove, and the pots plunged into the tan-bed. They are propagated by seeds; but those of the two first sorts are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they will remain years in the ground without vegetating: when the plants come up, they will be fit to transplant in a short time; then they should be each transplanted into a small pot, filled with light fresh earth, and plunged into a moderate hot-bed of tanners' bark, shading them till they have taken fresh root. They must afterwards be treated as other tender exotic plants, giving them a large share of air in warm weather, and but little water; and when the plants have advanced to be too tall to remain in the frames, they must be removed into the bark-stove, and plunged into the hot-bed, where they will make great progress, provided they have not too much water, especially during the winter season.

2. *Guilandina Bonducella*; *Gray Bonduc*. Prickly: pinnas oblong-ovate; with double prickles on the leaflets. This differs from the first species in having much smaller leaves, set closer together; and below each pair of leaflets are two short, stiff, crooked spines, which are opposite; the flowers are of a deeper yellow, and the seeds are ash-coloured. The seeds are said to be useful in intermittents when powdered; and both these, and those of the preceding species, are taken by the negroes in venereal cases. The whole plant is weakly, and spreads a great way about the roots, or rises among the neighbouring bushes wherever it finds a due support. The stalk and branches are very full of thorns that arch backwards. The seeds are gray, and commonly used instead of marbles by boys in the sugar colonies. In Egypt, the nuts of both these sorts are used by the women, strung in necklaces, and hung about their children by way of amulets, to guard them from sorcery. They are often cast ashore on the north-west coasts of Ireland and Scotland, and are called by the inhabitants of the latter Moleuca Beans. This tree makes a good fence.—It is a native of both Indies, China, and New Zealand.

3. *Guilandina Nuga*. Stem unarmed; the primary petiole of the leaves with double prickles underneath; branches thorny; leaves thick, solid, smooth, opposite; flowers yellow; legumes smooth. A weak trailing shrub, with a hard wood, which distils gum when wounded.—Native of Amboyna and Malabar, in swamps by the sides of rivers.

4. *Guilandina Moringa*; *Smooth Bonduc*. Unarmed: leaves subbipinnate; lower leaflets ternate. This tree has a thick root, of a softer substance than usual: the trunk is of a middling size, from twelve to twenty feet in height, smooth, with an ash-coloured bark; branches rather erect. The root, when young, is scraped, and used by the inhabitants of Egypt as horse-radish is in Europe, having much the same sharp taste; as have also the seeds.—Native of the East Indies; cultivated in Jamaica and Egypt. This species requires the same treatment as those before mentioned, but the seeds will grow without being steeped in water, and the

plants are with difficulty shifted from one pot to another, for their roots are large, fleshy, and have but few fibres; so that unless great care be taken, all the earth will fall away from them, which often causes their stalks to decay almost to the root, and sometimes occasions the loss of the plants.

5. *Guilandina Dioica*; *Hardy Bonduc*. Unarmed: leaves bipinnate at the base and tip, simply pinnate; stem erect, thirty feet high or more, dividing into many branches, covered with a very smooth bluish ash-coloured bark.—Native of Canada. This sort will live abroad, and is never hurt by frost. It is propagated by cutting off some of the horizontal roots, or by suckers. It requires a light, but not a very moist soil.

6. *Guilandina Gemina*. Prickly: leaves pinnate; calix five-leaved; fruit in pairs; stem shrubby, large, suberect, with many climbing branches, on which are many recurved, scattered prickles; flowers yellow, in compound, loose, terminating racemes; seeds two or three, roundish, shining, ash-coloured, very hard, containing a roundish oily kernel like an almond.—Native of Cochinchina.

Gum Succory. See *Chondrilla*.

Gundelia; a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: common scarcely any, except the leaves surrounding the compound receptacle. *Corolla*: compound tubular, uniform; corollules hermaphrodite, five, equal; proper one-petalled, club-shaped; border bellying, five-cleft, upright. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular, long. *Pistil*: germen ovate, immersed in the receptacle, crowned with very small scales, inferior; style filiform, longer than the corolla; stigmas two, revolute. *Pericarp*: none; but the seeds are totally immersed and hid in the receptacle. *Seeds*: solitary, roundish, acuminate, crowned with an obscure rim; the side-ones are abortive. *Receptacle*: common conic, covered on every side with partial receptacles, divided by three cusped chaffs; partial obtusely conic, quadrangular, truncate, with five little pits, one of which is in the centre, the others in the circumference, for the insertion of the five floscules. *Observe*. One central flower hermaphrodite; four marginal male. ESSENTIAL CHARACTER. *Calix*: scarcely any, five-flowered. *Corolla*: tubular, male and hermaphrodite. *Receptacle*: chaffy. *Down*: none.—The only known species is,

1. *Gundelia Tournefortii*. Root perennial, running deep into the ground; stalks seldom more than a foot and a half high; the under leaves are long, narrow, and serrate, the teeth ending in a spine; the other leaves are broader, irregularly flashed to the midrib, and armed at the points with sharp prickles. It is a milky plant, and has the habit of a thistle. The flowers appear in June, and the seeds ripen in August.—It is propagated by seed, which should be sown in the beginning of March, in a warm dry border of fresh but lean earth, in the place where the plants are designed to remain. When the plants come up, they must be carefully cleaned from weeds; as they grow large they should be thinned, leaving the plants which are designed to remain about two feet asunder, that they may have room to spread. After this there is no other culture required, but to keep them clear from weeds. In two years they will produce their

flowers, and will make a fine appearance among other hardy plants in the pleasure garden. The plants lose their stalks and leaves in autumn, but their roots will abide many years.

Gunnera; a genus of the class Gynandria, order Diandria.—**GENERIC CHARACTER.** *Calix*: ament verticilled; scales one-leaved, one-flowered, setaceous, the length of the flower, permanent; perianth none, except the crust of the seed, which has two seeds. *Corolla*: none. *Stamina*: filamenta two, very short, opposite, sitting on the sides of the germen on the outside of the teeth; antheræ oblong. *Pistil*: germen ovate, with two teeth at the tip; styles, two short, subulate, between the teeth of the germen; stigmas simple. *Pericarp*: none. *Seed*: single, ovate, the bark formed from the crust of the perianth. **ESSENTIAL CHARACTER.** *Ament*: with one-flowered scales. *Calix* and *Corolla*: none. *Germen*: two-toothed. *Styles*: two. *Seed*: one.—The only species yet discovered is,

1. *Gunnera Perpensa*; *Marsh Marigold-leaved Gunnera*. Leaves radical, cordate, obtuse, smooth, veined, repand, tooth-crenate, with the petioles scarcely pubescent; scapes two feet high; ament terminating, long, compound; the subdivisions scattered, simple, distinct; bractes lanceolate, short; floscules naked.—Native of the Capé.

Gustavia; a genus of the class Monadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: none, but the receptacle above surrounded with a rim, flat, broad, bald. *Corolla*: petals six or eight, slightly connected at the base, ovate, sessile, large. *Stamina*: filamenta very numerous, shorter than the petals, uniting at the base into an upright bell, distant from the style; antheræ small, oblong, shorter by half than the petals. *Pistil*: germen turbinate, inferior, flat, bald between the petals and the style; style conical, very short, permanent; stigma blunt. *Pericarp*: berry subglobular, subconical, truncate, six-celled, crowned with the rim of the receptacle. *Seeds*: beans several, oval, smooth, mutilated on one side at the base, with a cartilaginous twisted appendix. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: several. *Berry*: many-celled. *Seeds*: appendicled.—The only known species is,

1. *Gustavia Augusta*. This tree has thickish branches, and is from twenty to thirty feet high; leaves alternate, subsessile, somewhat crowded, in the upper part broad-lanceolate, narrower at the base, from a span to a foot in length, ribbed, subserrate, smooth on both sides; peduncles from one to three, terminating, bearing one flower, and having one joint; flower very specious, larger than the White Water-lily, with a large, naked, bald disk or receptacle between the corolla and the style; petals white, with red tips, the consistence of the White Lily, which it resembles in smell; but the wood is extremely fetid, even after it is dry; the inhabitants use it for hoops.—Native of Surinam and the island of Cayenne.

Gymnanthes; a genus of the class Monœcia, order Monadelphia.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: ament compound, with pedicels tripartite, or trichotomous, anther-bearing. *Corolla*: none. *Stamina*: filamenta naked, on pedicels tripartite or trichotomous, scattered, placed on every side of the ament, very short, deciduous; antheræ oblong, minute, three-celled. *Female Flowers.* on the same, or a different shrub, solitary or amentaceous. *Calix*: perianth none, but one or two scales at the base of the germen. *Corolla*: none. *Pistil*: germen roundish, superior; styles scarcely any, or very short, three-corned; stigmas three, linear, acute, channelled, reflex. *Pericarp*: capsule trilocular, three-celled, three-valved. *Seeds*: solitary, roundish. **ESSENTIAL CHARACTER.** *Male*: ament

naked; perianth and corolla none; stamina, pedicels three-parted, or three-forked, anther-bearing. *Female*: ament or germen, pedicelled; corolla none; style trifid. Capsule, trilocular, three-celled.—The species are,

1. *Gymnanthes Elliptica*. Dioicous: stamina three-parted; females amentaceous.—Native of Jamaica.

2. *Gymnanthes Lucida*. Monoicous; stamina trichotomous; females solitary, pedicelled.—Native of Hispaniola.

Gynopogon; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, very small, half five-cleft, permanent; segments linear, acute, erect. *Corolla*: monopetalous, contorted; tube cylindrical, ventricose below the tip, contracted at the throat; border flat, five-parted; segments ovate. *Stamina*: filamenta five, very short, inserted into the tube above the middle; antheræ erect, linear, within the tube. *Pistil*: germen ovate; style filiform, shorter by half than the tube; stigma globular, two-lobed, villose at the tip. *Pericarp*: berry pedicelled, subglobular, coriaceous, filled with the seed. *Seeds*: single, cartilaginous, subbilocular; with one or two kernels. *Observe.* The fruit is generally abortive, the seed not having kernels; the germina when cut through have two cells, and two seeds in each cell. **ESSENTIAL CHARACTER.** *Calix*: half five-cleft, inferior, permanent. *Corolla*: five-parted; tube ventricose below the tip; throat contracted; stigma globular, two-lobed. *Berry*: pedicelled, subglobular. *Seed*: cartilaginous, subbilocular.—The species are,

1. *Gynopogon Stellatum*. Leaves in whorls, three together, lanceolate.—Native of the Society and Friendly Islands, in the South Seas.

2. *Gynopogon Alyxia*. Leaves in whorls, five together, obovate.—Native of Norfolk Island.

3. *Gynopogon Scandens*. Leaves opposite, ovate, ribbed.—Native of Otaheite.

Gypsophila; a genus of the class Decandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth bell-shaped, angular, five-parted; leaflets ovate, permanent. *Corolla*: petals five, ovate, obtuse, spreading, subsessile. *Stamina*: filamenta subulate, spreading; antheræ roundish. *Pistil*: germen almost globular; styles filiform, gaping; stigmas simple. *Pericarp*: capsule globular, one-celled, five-valved. *Seeds*: very many, roundish. **ESSENTIAL CHARACTER.** *Calix*: one-leaved, bell-shaped, angular. *Petals*: five, ovate, sessile. *Capsule*: globular, one-celled.—The plants of this genus, possessing no great beauty, are rarely cultivated, except in botanic gardens. They are propagated by seeds, sown in a bed of light earth, and when the plants are fit to remove, they may be transplanted into the places where they are designed to remain, and will require no other culture but to keep them clean from weeds; for the roots of most sorts will continue several years, and annually produce flowers and seeds. The species are,

1. *Gypsophila Repens*; *Creeping Gypsophila*. Leaves lanceolate; stamina shorter than the emarginate corolla. The whole plant is smooth; root perennial, woody, very long, as thick as the little finger; stems many, in a close tuft, spread every way, half a foot in length, perennial; flowers remote, few, on bifid or trifid peduncles; corolla white or red, spreading very much; petals flat, a little attenuated towards the base, more or less emarginate, twice as long as the calix; capsules blunt.—It flowers in September, and is a native of Siberia, Austria, Switzerland, and Provence.

2. *Gypsophila Prostrata*; *Trailing Gypsophila*. Leaves lanceolate, smooth and even; stalks diffused; pistils longer than the bell-shaped corolla; root perennial; stems several, smooth, round, about a foot in length, reddish at the joints;

corolla white.—It flowers from June to September, and is supposed to inhabit the mountainous parts of Europe.

3. *Gypsophila Paniculata*; *Panicled Gypsophila*. Dioicous: leaves linear, lanceolate, the lower ones scabrous; stamina minute; styles longer than the corolla; root perennial, thick, fleshy; stems several, round, jointed, prostrate, a foot and a half long, the thickness of a quill, below villose and rugged, four-cornered, and simple, above smooth; flowers numerous, and without scent; petals white, oblong, blunt, quite entire, twice as long as the calix. It flowers in July and August.—Native of Hungary, Siberia, and Tartary.

4. *Gypsophila Viscosa*; *Clammy Gypsophila*. Leaves ovate-lanceolate, smooth, and even, at the base cordate and clasping; the internodes of the branches clammy in the middle; petals retuse; root annual, slender; stem erect, slender, branched almost from the bottom, from a span to a foot high; the whole plant very smooth and glaucous; flowers the size of those in the first and second species; corolla scarcely red, scentless; petals oblong, emarginate.—Native of the Levant.

5. *Gypsophila Ascendens*. Leaves lanceolate-linear; stalks prostrate; corolla, stamina, and pistils, all of the same length; root perennial, whitish, branched; and woody; stems very many, round, smooth, much jointed, leafy, herbaceous, purple at the base, and procumbent, then ascending; flowers white.—Native country unknown.

6. *Gypsophila Altissima*; *Upright Gypsophila*. Leaves lanceolate, three-nerved; stalks straight.—It is perennial, flowers in July, and is a native of Siberia.

7. *Gypsophila Struthium*; *Shrubby Gypsophila*. Leaves linear, fleshy, axillary, crowded, columnar; stem shrubby at the bottom, with leafy rudiments from the axils of the leaves, which are longer than the internodes, and acute at the end; flowers in corymbs, white, with ovate petals.—The ancients used this plant instead of soap, and it still answers this purpose in some parts of Spain, where it naturally grows.

8. *Gypsophila Fastigiata*; *Triangular-leaved Gypsophila*. Leaves lanceolate-linear, obscurely three-cornered, smooth and even, obtuse, directed one way; root perennial, very long, the thickness of a finger, white, woody; stalks several, stiff, jointed, smooth, more than a foot long, branched, ending in a dense fastigiata cyme of flowers; petals pale rose-colour. Linneus observes, that in Sweden the flowers are always white, and fastigiata in its wild state. The root, like that of the foregoing species, has a saponaceous quality, and, boiled, with linen or woollen, may be used instead of soap; it is bitter, and has a solvent aperient quality.—Native of Germany, Sweden, Switzerland, Siberia, &c. It flowers from June to August.

9. *Gypsophila Perfoliata*; *Perfoliate Gypsophila*. Leaves ovate-lanceolate, half stem-clasping; root perennial, strong, fleshy, striking deep into the ground, sending up stalks two and three feet in height, as thick as the little finger at bottom, swelling at the joints, branching at short intervals from top to bottom; flowers numerous, before they expand purple, but becoming paler, and at length white; capsule obtusely four-cornered, four-valved. It flowers in July and August.—Native of Spain and the Levant.

10. *Gypsophila Muralis*; *Wall Gypsophila*. Leaves linear, flat; calices leafless; stalk dichotomous; petals crenate; root annual, slender, small; stalk diffused, a span in length, weak, and therefore seldom upright. The flowers come out at the divisions of the stalk singly, on setaceous peduncles, one at the end. In England it flowers from June to October.—Native of Lapland, Sweden, Germany, Switzerland, France, and Siberia.

11. *Gypsophila Rigida*. Leaves linear, flat; stalks dichotomous; peduncles two-flowered; petals emarginate. From a very fibrous root spring numerous little stems, not more than a span high, jointed, branched; flowers pale red.—Native of the south of France, and Siberia.

12. *Gypsophila Saxifraga*; *Small Gypsophila*. Leaves linear; calices angular, with four scales; corollas emarginate; root perennial, woody, branched; stalks in tufts, procumbent, a span long, or about nine inches in length, very much branched, bent, and changing their direction at every joint; flowers on long peduncles, on the extreme subdivisions, which are almost naked; petals emarginate, white, with rose-coloured lines. It flowers in July and August.—Native of France, Switzerland, Austria, and Carniola.

Gyrocarpus; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite*: calix four-leaved, unequal. *Corolla*: none. *Nectary*: four clubbed glands. *Stamina*: four. *Pistil*: one. *Style*: none. *Capsule*: one-celled, one-seeded, ending in two long membranaceous wings. *Male*. *Calix*: five-leaved, equal. *Nectary* and *Stamina*: as in the hermaphrodite, without pistil.—The only species is,

1. *Gyrocarpus Asiaticus*. Leaves deeply heart-shaped, undivided, or slightly lobed, downy beneath; panicles clustered, many-flowered, small, and yellowish; fruit the size of a filbert. A large tree, flowering just before the foliage appears.—Grows in the mountainous parts of Coromandel: called by the natives *Tanucoo*; and by the English Cattamaran-wood tree; the light white wood being excellent for cattamarans, or rafts.

H Æ M

HÆMANTHUS; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre six-leaved, very large, bearing an umbellule; leaflets erect, oblong, permanent. *Corolla*: monopetalous, erect, six-parted; parts erect, linear; tube very short, angular. *Stamina*: filamenta six, subulate, inserted into the tube, and longer than the corolla; antheræ incumbent, oblong. *Pistil*: germen inferior; style simple, length of the stamina; stigma simple. *Pericarp*: berry roundish, three-celled. *Seeds*: solitary, three-cornered. ESSENTIAL CHARACTER. Involucre six-leaved, many-flowered. *Corolla*: six-parted, superior. *Berry*: three-celled.—The species are,

1. *Hæmanthus Coccineus*; *Scarlet Hæmanthus*, or *Blood-flower*. Leaves tongue-shaped, flat, smooth and even, pressed close to the ground, in two rows; umbel contracted, fastigiata,

H Æ M

shorter than the involucre; border patulous; root large and bulbous, from which the leaves issue. The flowers are produced in autumn, just before the new leaves come out; they are of a bright red, in a large cluster, two or three inches from the bulb.—Native of the Cape of Good Hope. This, and the seventh species, are not easily propagated in Europe, because their roots do not produce a sufficient quantity of offsets; hence the Dutch gardeners obtain their supplies from the Cape of Good Hope. They will not bear the open air of England during winter; the roots must therefore be planted in a pot filled with light loamy earth, and in the winter should be placed in a dry glass-case, where, during that season, the leaves will be in full vigour, and make a pretty appearance, when intermixed with other plants in the stove. Although they seldom flower here, they deserve a place in every garden

where there is a convenience for keeping them: the roots may be taken up when the leaves are decayed, and kept out of the ground till August, when they should be new-potted, and may remain abroad till the end of September, at which time they may be removed into the glass-case; they will require frequent waterings while growing, but not in large quantities. If a border be made against the front of the green-house or stoves, which may be contrived so as to be covered with glasses in winter, in which these roots, with those of the African Gladiolus, *Ixia*, Persian Cyclamen, &c. are planted in the full ground, they will flower more constantly, and the footstalks will rise much higher than those kept in pots.

2. *Hæmanthus Punicus*; *Waved-leaved Hæmanthus*, or *Blood-flower*. Leaves oblong, elliptic, acute, retuse, waved, six to eight inches long, and two broad in the middle; umbel contracted, fastigiate; border and stamina erect; roots composed of many thick fleshy tubers, forming a head, out of which arises a fleshy spotted stalk, spreading at the top into several spear-shaped leaves, which are waved on their edges; stalks a foot high. From the side of the stalk, near the ground, breaks out a strong fleshy scape, six or eight inches long, with a large cluster of yellowish red flowers at the top.—Native of Africa. This plant was first brought to Holland, from whence it has been dispersed all over Europe. It may be propagated by parting the roots; the best time for this is in the spring, before the plants put out new stalks, which is also the proper season for shifting and new potting them; but as the roots do not multiply very fast in offsets, the best way is to propagate them from seeds, which they ripen plentifully in England: these should be sown soon after they become ripe, in pots filled with light earth, and kept in the stove all the winter: if these pots be plunged into the tan-bed in the bark-stove, in the vacancies between the plants, the earth will be kept warm, and will not dry so fast, as when they are placed in a dry-stove, while the seeds will be the sooner prepared to vegetate. In the spring the pots may be taken out of the stove, and plunged into a hot-bed, which will bring up the plants: they must have air admitted to them every day in mild weather, to prevent their drawing up weak; and when they are fit to remove, they may be each planted in a separate small pot filled with light earth, and plunged into the hot-bed again, to promote their taking new root; then they must be gradually hardened, and afterwards may be removed into the dry-stove, where they should constantly remain, otherwise the plants will not thrive and flower in this country. They must be sparingly watered in winter, for their roots, being fleshy and succulent, are apt to rot with moisture. In summer, during warm weather, they require a large share of air, and frequent waterings, especially when in flower.

3. *Hæmanthus Pubescens*; *Downy-leaved Hæmanthus*. Leaves oblong-lanceolate, hirsute on every side; umbel fastigiate, rounded; border and stamina erect.—It flowers in August, and is a native of the Cape of Good Hope.

4. *Hæmanthus Ciliaris*; *Fringed Hæmanthus*. Leaves lanceolate, smooth, ciliate; involucre broad, shorter than the rounded umbel; border reflex.—Native of the Cape.

5. *Hæmanthus Toxicarius*; *Fan-leaved Hæmanthus*. Leaves in two rows, oblong, flattish, smooth; peduncles longer than the spathe and flower; flowers flesh-coloured.—Native of the Cape.

6. *Hæmanthus Spiralis*; *Spiral-stalked Hæmanthus*. Leaves bristle-shaped; scape filiform, at the base spiral and flexuose; involucre subulate, shorter than the umbel, which bears from one to four flowers. It flowers here in September.—Native of the Cape of Good Hope.

7. *Hæmanthus Carinatus*; *Keel'd Hæmanthus*. Leaves linear, keeled. This species has a large bulbous root, sending out three or four leaves, a foot long or more, not flat, but hollowed like the keel of a boat, and more erect than those of the first sort, but not quite so broad; the flowers are of a paler red.—Native of the Cape of Good Hope. For its propagation, see the first species.

8. *Hæmanthus Multiflorus*; *Many-flowered Hæmanthus*, or *Blood-flower*. Leaves three together, ovate-lanceolate, acuminate, keeled, waved, upright; umbel close, globular; petals spreading; bulb from one to three inches in diameter, the upper parts tinged of a red colour, and speckled like the stalk; scape from eight to eighteen inches in height, speckled with dark red almost to the top, round or flattened, sometimes fluted on one side; corolla of a clear shining blood-red colour, divided to the bottom into six narrow parts, which are pointed, and spread out wide; the leaves stand in some plants nearly as high as the bottom of the flowers, in others as high as the top, or even higher, and do not display themselves entirely till after the flowers are passed.—Native of Sierra Leone. To bloom successively, it must be kept in the stove.

Hæmatoxyllum; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, coloured; tube very short, pitcher-shaped, fleshy, permanent; border five-parted, spreading, deciduous; parts oblong, blunt, the four upper ones equal, the lowest a little longer than the rest. *Corolla*: petals five, lanceolate, broadest at top, blunt, veined, spreading, nearly equal, inserted into the calix, and larger than its divisions. *Stamina*: filamenta ten, subulate, hairy at bottom on the inside, upright, unequal, scarcely longer than the corolla, inserted into the calix; antheræ oval, small. *Pistil*: germen oblong-sabre-shaped, compressed; style capillary, bent at the tip, longer than the stamina; stigma funnel-shaped. *Stamina*: legume lanceolate, flat, blunt, one-celled, edged on each side with a thickish suture that does not open, opening by the bursting of the valves in the middle longitudinally, and dividing into two unequal boat-shaped parts. *Seeds*: few, oblong, compressed, furrowed, fixed to one of the sutures. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Legume*: lanceolate; valves boat-shaped.—The only species is,

1. *Hæmatoxyllum Campechianum*; *Logwood*, *Bloodwood*, *Campeache-Wood*. The stem rises from sixteen to twenty-four feet high, is generally crooked, and seldom thicker than a man's thigh; branches subdivided, flexuose, prickly, round, ash-coloured; leaves pinnate; petioles alternate, patulous, round, smooth; leaflets four pairs, on very short petiolules, generally obcordate, entire, small, veined, very smooth and shining, spreading in the day-time, but at night upright, converging; flowers in racemes, peduncled, numerous, small, reddish-yellow, on short, scattered, simple, coloured peduncles. The flowers appear in March and April, and the seeds ripen in July.—This tree grows naturally in the Bay of Campeache, at Honduras, and in other parts of the Spanish West Indies. It was first propagated in Jamaica, in the year 1715, from seeds brought from the Bay of Campeache, and it now grows wild in the neighbourhood of Savannah la Mar, in such quantities as to be extremely inconvenient to the land-holders, occupying that district, in the same manner as the Opopanax and Cashew have the southern parts of Middlesex county. It was first introduced to prevent the necessity of forming settlements upon the Spanish Main; but the result did not fully answer the benevolent intentions of those who first cultivated it. It makes an impenetrable and beautiful fence. The smaller stems are made into hoops. Both the bark and gum are gentle subastringents, but the last excels, and adds a sweetness

to its virtue, which makes it more agreeable to the palate. The inner bark is red, and the wood hard. The wood, says Hill, is a very powerful medicine, to stop fluxes of the belly, and overflowings of the menses: the best way of giving it is in form of an extract, which is to be made by boiling down a strong decoction of it to the consistence of honey; in this form it will keep a long time, and is always ready for use. A strong decoction of this wood, says Meyrick, is found very efficacious for stopping obstinate purges, without contracting the fibres, as the common astringents do: it sheathes and blunts acrimonious humours, and has more of a balsamic than an astringent taste: it strengthens the stomach and bowels, and indeed the general habit, and is an agreeable medicine to take, being free from any thing disgusting to the taste, and almost void of smell: the decoction is made by boiling three ounces of powdered logwood in four pints of water, till it comes to a quart, and then adding about two drachms of cinnamon, which must be allowed to boil together with the logwood a few minutes longer; then, after letting it cool, the liquor must be strained off for use, and may be taken to the amount of three or four ounces, three or four times a day. This decoction is equally agreeable, mild, and safe, and has this advantage attending it, that it may be administered with equal safety, whether the disorder be attended with a fever or not: it commonly tinges the stools, and sometimes the urine, of a deep reddish purple colour; of which circumstance the patient ought to be apprised, that he may not alarm himself, by supposing the colour of the discharge owing to blood. Logwood is a well-known ingredient in dyeing: stuffs, however, would take only a slight and fading colour from logwood, if they were not previously prepared with alum and tartar; a little of the former is also added to the bath, and by these means a tolerably good violet colour is produced. A blue colour may be obtained from this wood, by mixing verdigris with the bath, and dipping the cloth till it has acquired the shade which is desired: the grand use of logwood, however, is for blacks, to which it gives a lustre and velvet cast, and for grays of certain shades: it is also of very extensive use for different compound colours, which it would be difficult to obtain of equal beauty and variety by means of drugs affording a dye of greater permanency. It is used for dyeing silk, violet; for this the silk must be scoured, alumed, and washed, because without the alum it would only take a reddish tinge that would not stand wetting. To dye silk thus, it must be turned in a cold decoction of logwood, till it has acquired the proper colour: if the decoction were used while hot, the colour would be in stripes very uneven. Bergman has observed, that a fine violet might be produced from logwood, by impregnating the silk with solution of tin; in fact we may thus obtain, particularly by mixing logwood and Brazil-wood in various proportions, a great number of fine shades, more or less inclined to red, from the lilac to the violet hue.—The seeds of this tree are frequently brought from America, and, when fresh, will grow readily, if sown upon a good hot-bed; if the bed be kept in a moderate temperature they will grow to be upwards of a foot high in the first year: while the plants are young they are generally well furnished with leaves, in which they are often afterwards very deficient, making but little progress. They are very tender, and should be constantly kept in the bark-stove, where, if duly watered, and the stove be kept in a due degree of heat, they may be easily preserved. In the West Indies, it thrives best in low swampy lands, or shallow waters, on a rich and tolerably firm soil.

Hair-bell. See *Hyacinthus*.

Hair Grass. See *Aira*.

Halbert Weed. See *Calea Lobata*.

Halesia; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, very small, superior, four-toothed, permanent. *Corolla*: monopetalous, bell-shaped, ventricose; mouth four-lobed, blunt, patulous. *Stamina*: filamenta twelve, (seldom sixteen,) subulate, upright, a little shorter than the corolla; antheræ oblong, blunt, upright. *Pistil*: germen oblong, inferior; style filiform, longer than the corolla; stigma simple. *Pericarp*: nut corticate, oblong, narrowing to both ends, four-cornered, the corners membranaceous, two-celled. *Seeds*: solitary. ESSENTIAL CHARACTER. *Calix*: four-toothed, superior. *Corolla*: four-cleft. *Nut*: quadrangular, with two seeds.—The plants of this genus are propagated by seeds, when they can be procured fresh from the places of their natural growth; they should be sown in pots as soon as they arrive, placing the pots in the ground where they may only have the morning sun: the seeds often remain a year in the ground; therefore the earth in the pots should not be disturbed, until there be no probability that the seeds will grow. When the plants come up, screen them from the sun, and water them frequently, but sparingly. In the following autumn, the pots should be placed in a common frame, where the plants may enjoy the free air in mild weather, and be screened from frost: in the succeeding spring, and before they begin to shoot, they should each be put into a small pot, plunging the pots in a frame shaded from the sun. In the third spring they may be turned out of the pots, and planted where they are to remain.—The species are,

1. *Halesia Tetraptera*; *Four-winged Halesia*, or *Snowdrop Tree*. Leaves lanceolate-ovate, serrate, sharp-pointed, alternate, on short glandular footstalks. This tree frequently comes up with two or three stems, from fifteen to twenty feet high, sending out branches towards their tops; the flower hanging in small bunches, all along the branches, each gem producing from four to eight or nine; they are of a pure snowy whiteness; and as they blow early in the spring, before the leaves appear, and continue for two or three weeks, they make a most elegant appearance; the flowers are succeeded by a tolerably large four-winged fruit, hanging also in bunches, and very agreeable to the taste. The wood is hard and veined; and the bark of a darkish colour, with many irregular shallow fissures. It flowers in April and May.—Native of South Carolina, on the banks of the Santee river.

2. *Halesia Diptera*; *Two-winged Halesia*. Leaves ovate; petioles smooth and even; fruit mucronate, with two large wings opposite to each other, and two minute.—Native of Georgia, on the banks of the Savannah river.

3. *Halesia Parviflora*. Flowers small. This much resembles the first species.—Found in Florida, near Matanza.

Halleria; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, trifid, flat, spreading, very obtuse, permanent; the upper cleft, twice as broad as the rest. *Corolla*: monopetalous, ringent; tube roundish at the base, bent in with a swelling throat; border upright, oblique, four-cleft; the upper cleft a little longer than the others, blunt, emarginate; the side ones shorter, broader, sharper; the lowest very short, very slender, and very sharp. *Stamina*: filamenta four, bristle-shaped, straight, inserted into the tube, longer than the corolla; antheræ roundish, twin. *Pistil*: germen superior, ovate, ending in a style longer than the stamina; stigma simple. *Pericarp*: berry roundish, two-celled. *Seeds*: small, flat, roundish, winged. ESSENTIAL CHARACTER. *Calix*: trifid. *Corolla*: quadrifid. *Filamenta*: longer than the corolla. *Berry*: superior, two-celled.—The species are,

1. *Halleria Lucida*; *African Fly-Honeysuckle*. This plant grows to the height of six or eight feet, with a woody stem, well furnished with branches; leaves ovate, serrate, opposite, and continuing green through the year; the flowers come out singly, and are of a red colour, but being intermixed with the leaves, and growing scatteringly on the branches, are not easily discerned; they come out in June, and the seeds ripen in September. Native of the Cape of Good Hope.—These may be propagated by cuttings; which, if planted in June, in pots of light earth, will soon take root: the plants may be exposed in summer, and will require plenty of water at that season; in the winter they must be housed with the Myrtles, and other hardy exotics, which require much air in mild weather.

2. *Halleria Elliptica*. Leaves elliptical, acute, strongly serrated; calix four-cleft. The leaves of this are thicker than those of the former, tapering at each end, and more coarsely serrated; and the corolla less curved.—Common in woods at the Cape.

Halm, or *Helme*. See *Arundo Arenaria*.

Haloragis; a genus of the class Octandria, order Tetragynia.—**GENERIC CHARACTER.** *Calix*: perianth quadrifid, superior, fastened about the germen, permanent. *Corolla*: petals four, oblong, blunt, concave, spreading, with narrow claws, inserted into the calix. *Stamina*: filamenta eight, filiform, upright, shorter than the corolla, inserted into the calix; antheræ oblong, four-furrowed, upright. *Pistil*: germen inferior; styles four, upright; stigmas simple, blunt. *Pericarp*: drupe dry, roundish, crowned with the permanent calix. *Seed*: nut bony, four-celled, with one kernel in each cell. **ESSENTIAL CHARACTER.** *Calix*: four-cleft, superior. *Petals*: four. *Drupe*: dry, enclosing a four-celled nut.—

The species are,

1. *Haloragis Prostrata*. Leaves oblong, quite entire, mucronate; branches four-cornered, smooth; flowers axillary, solitary, pedicelled; fruits globular. When the fruit is in a state of maturity, the plant greatly resembles the *Ammannia Latifolia*.—Native of Botany island, near New Caledonia; and found in the Isle of Proes, in the South Seas.

2. *Haloragis Cercodia*. Leaves serrate; flowers about six in a whorl. The plant is about two feet high, branched, panicked, and upright; stalk quadrangular, and red, small, green, with a red tinge, pendulous.—Native of New Zealand.

3. *Haloragis Racemosa*. Leaves lanceolate, serrated; flowers in terminal and axillary clusters; stem shrubby, branched, near two feet high.—Native of the south coast of New Holland.

4. *Haloragis Digynia*. Leaves scattered, linear, entire; clusters leafy, terminal.—Native of the same part as the preceding.

Hamamelis; a genus of the class Tetrandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: involucre three-leaved, three-flowered; the two inner leaflets roundish, smaller, blunt; the outmost larger, lanceolate; perianth double; the outer two-leaved, smaller, roundish; the inner four-leaved, upright; the leaflets oblong, blunt, equal. *Corolla*: petals four, linear, equal, very long, blunt, reflex; nectary of four truncate leaflets, growing to the corolla. *Stamina*: filamenta four, linear, shorter than the calix; antheræ two-horned, bent in. *Pistil*: germen ovate, villose, ending in two styles, which are of the same length with the stamina; stigmas capitate. *Pericarp*: nut ovate, half covered with the calix, blunt, furrowed on both sides at the tip, having two little horns spreading horizontally, two-celled, two-valved. *Seeds*: one in each cell, oblong, narrow at the base. **ESSENTIAL CHARACTER.** *Involucre*: three-leaved. *Peri-*

anth: four-leaved. *Petals*: four. *Nut*: two-horned, two-celled.—The species are,

1. *Hamamelis Virginica*; *Witch Hazel*. This tree has a woody stem, from two to three feet high, sending out many slender branches; leaves oval, indented on their edges, having great resemblance to those of the Hazel, and placed alternately on the branches: these leaves fall away in autumn, and then the flowers come out in clusters from the joints, but are not followed by seeds in England. The Indians consider this tree as a valuable article in their materia medica; they apply the bark, which is sedative and discutient, to painful tumors and external inflammations. A cataplasm of the inner rind is said to be very efficacious in removing painful inflammations of the eyes.—Native of America, from Canada to Carolina. This plant is propagated by laying down the young branches in autumn; they will take root in a year, if sufficiently watered in dry weather. Many of the plants in our gardens have been produced from seeds imported from America: these always remain a year in the ground, so that they should be sown in pots for the convenience of plunging them into the earth in a shady part of the garden, where they may remain all the summer, and will only require to be kept free from weeds, and to be watered in very dry weather.

2. *Hamamelis Macrophylla*. Leaves large, punctated on their lower side with rough tubercles.—Found in Georgia, and North Carolina.

3. *Hamamelis Parvifolia*. Leaves smaller, oblong-ovate, upper part undulated and grossly crenate, under side pubescent, somewhat hirsute; segments of the calix oblong; stamens and perigynous filaments often nearly equal. A shrub every way smaller than the first species; the calix somewhat coloured and diaphanous, and petals bright yellow.—Found on the mountains of Pennsylvania.

Hamellia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-parted, acute, very small, superior, upright, permanent. *Corolla*: monopetalous; tube five-cornered, very long; border five-parted, equal, small, acute. *Stamina*: filamenta subulate, inserted at the middle of the corolla; antheræ oblong, linear, the same length with the corolla. *Pistil*: germen ovate, with a conical tip, inferior; style filiform, the same length with the corolla; stigma linear, blunt. *Pericarp*: berry oval, furrowed, five-celled, crowned. *Seeds*: very many, roundish, compressed, very small. **ESSENTIAL CHARACTER.** *Corolla*: five-cleft. *Berry*: five-celled, inferior, many-seeded.—The species are,

1. *Hamellia Patens*. Racemes terminating, coloured; leaves ternate, villose, pubescent. This is a shrub, or small tree, growing five or six feet high; branches diverging, spreading, round, smooth; petioles coloured; the midrib red; flowers directed one way, subsessile, distant, bright red or scarlet.—Native of the hedges and mountains of Hispaniola. This plant is propagated by seeds when they can be procured fresh from the country where it naturally grows. They should be sown in small pots, and plunged into a moderate hot-bed. The plants generally appear in five or six weeks, and should then be treated in the same way as other plants from the same countries; admitting air in warm weather, and gently refreshing them with water. As the seeds are seldom brought to England, the plant may be propagated by cuttings, which, if planted in small pots, plunged into a moderate hot-bed, and closely covered with either bell or hand glasses, will put out roots in about six weeks. They flower in July, and make a pretty appearance.

2. *Hamellia Grandiflora*. Clusters terminal or axillary;

flowers few, on longish stalks; tube inflated; leaves three together, lanceolate-acute, nearly smooth; corolla of a fine golden yellow, with a spreading border.—Native of the West Indies.

3. *Hamellia Axillaris*. Clusters from the forks of the stem; flowers turned to one side, numerous, small, pale yellow; leaves opposite, smooth, dark green.—Native of Jamaica and Hispaniola.

4. *Hamellia Chrysantha*. Clusters terminal; partial flower-stalks long and slender; corolla shining, yellowish-orange; leaves opposite, obovato-lanceolate, pointed, very smooth.—Found on the West side of Jamaica.

Hardbeam Tree. See *Caspinus*.

Hard-grass. See *Dactylis Glomerata*.

Hare's-Ear. See *Bupleurum*.

Hare's-Foot Fern. See *Trichomanes*.

Hare's-Tail Rush. See *Eriophorum Vaginatium*.

Hartogia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-cleft, smooth, permanent; clefts acute, very short. *Corolla*: petals four, ovate, obtuse, spreading. *Stamina*: filamenta four, very short, inserted into the base of the germen; antheræ ovate, furrowed. *Pistil*: germen superior, ovate, smooth; style simple, subulate; stigma acute. *Pericarp*: drupe juiceless, ovate, smooth, or a little roughish, scarcely as big as a hazel nut. *Seed*: nut with two seeds, somewhat fleshy. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: four, spreading. *Drupe*: ovate, enclosing two seeds.—The only species is,

1. *Hartogia Capensis*. A shrub six feet high, with oblong, serrate, blunt, smooth leaves; flowers small, in short, axillary, drooping clusters.—Found in the woods near the Cape.

Hart-Root. See *Athamanta Cervaria*.

Hart's-Tongue. See *Asplenium Scolopendrium*.

Hasselquistia; a genus of the class Pentandria, order Digenia.—GENERIC CHARACTER. *Calix*: umbel spreading; umbellules ten, five of which are in the circumference; the rudiment of the central umbellule is a mortified vitiated body, pedicelled, somewhat three-sided, fleshy, depressed, dark-coloured, hoary above, with white hair: involucre very small, five-leaved, subulate, reflex; involuclers halved; those of the outer ones three-leaved, subulate, nodding, shorter than the umbellule: umbel, when fruit-bearing, converging. *Corolla*: flowers radiate, even of the inner umbellules: floscules of the ray hermaphrodite; petals unequal, bowed in and bifid; the outermost petal two clefts, and the next single one large, so that in each corollule there are four clefts large, and six small: floscules of the inner disk male; petals nearly equal, bowed in and bifid, all the clefts small. *Stamina*: filamenta five to all the floscules, longer than the smaller petals; antheræ roundish. *Pistil*: germen inferior; styles filiform, permanent; stigmas obtuse. *Pericarp*: none. *Seeds*: outermost double, oval, smooth, the edge thicker, crenulate; inner solitary, hemispherical, drooping, pitcher-shaped, with the side hollow; these are also furnished with two styles; in the inner disk none. ESSENTIAL CHARACTER. *Corolla*: radiated in the disk, male. *Seeds*: in the circumference double, with a notched edge; in the disk solitary, pitcher-shaped, hemispherical.—The species are,

1. *Hasselquistia Egyptiaca*; *Egyptian Hasselquistia*. Leaves pinnate; leaflets pinnatifid; root fusiform, smaller than the finger, white, annual; stem a foot and half high, upright, round, white, with rough hairs, finally muricate, scabrous; umbels of flowers at the top of the stem, and at the ends of all the branches; peduncle five-cornered, muricate; corolla white; antheræ greenish; stamina and styles white. Biennial.—Native of Egypt, where it flowers in July. This and the

next being natives of warm countries, are with difficulty preserved in England. Sow the seeds in pots about the middle of August, placing them where they may have only the morning sun; in October remove them into a common frame; and in the spring following place them in the full ground. They will flower in June.

2. *Hasselquistia Cordata*; *Heart-leaved Hasselquistia*. Leaves heart-shaped; stem upright, flexuose, a little streaked, hairy at bottom; umbel copious, flat, white, without the central body; marginal petals of the umbellules two, larger, flat, obovate; the rest nearly equal, small, ovate, entire; flowers white. Annual.—Native place unknown. For its propagation, see the preceding species.

Hebenstreitia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, membranaceous, emarginate, gaping longitudinally underneath. *Corolla*: monopetalous, one-lipped; tube cylindrical, longer than the calix, gaping on the lower side half way; border ascending, flattish, quadrifid, the clefts nearly equal. *Stamina*: filamenta four, of which the upper pair is inserted into the edge of the corolla under the throat, and stands out, the lower anterior pair is bent back to the sides; antheræ crescent-shaped, compressed, truncate outwards. *Pistil*: germen very small; style filiform, flexuose, bent back through the fissure of the corolla; stigma simple. *Pericarp*: capsule oblong, one-celled, two-valved. *Seeds*: two, oblong, convex on one side, three-furrowed, flat on the other. ESSENTIAL CHARACTER. *Calix*: emarginate; cleft underneath. *Corolla*: one-lipped; lip ascending, four-cleft. *Stamina*: inserted into the edge of the border of the corolla. *Capsule*: containing two seeds.—The species are,

1. *Hebenstreitia Dentata*; *Tooth-leaved Hebenstreitia*. Leaves linear, toothed; spikes smooth; stalks upright, a foot high, with simple ascending branches next the root, and under the spike; corolla white, with a red throat, singular in having the stamina placed on the very edge of the fissure; seeds subelliptic, acuminate at the tip, slightly emarginate at the base, pale straw-colour, fixed to the bottom of the capsule, without any receptacle. The flowers are destitute of scent in the morning; at noon they are stinking and nauseous; in the evening ambrosial, like the Oriental Hyacinth. Biennial, flowering from February to November.—Native of the Cape of Good Hope.

2. *Hebenstreitia Ciliata*. Leaves linear, toothed; calices three-valved, ciliate. This plant bears a strong resemblance to the preceding species.—Native of the Cape.

3. *Hebenstreitia Integrifolia*. Leaves linear, quite entire. This appears to be a mere variety of the foregoing species.—Native of the Cape.

4. *Hebenstreitia Cordata*; *Heart-leaved Hebenstreitia*. Leaves somewhat fleshy, cordate, sessile. This is an undershrub. Stem upright, whitish, smooth and even, sparingly branched only at top; spike terminating, sessile; corolla white, with a flesh-coloured throat; antheræ compressed, yellow.—Native of the Cape of Good Hope.

5. *Hebenstreitia Erinoides*. Leaves oblong, serrate, hairy; bractes entire, hispid.—Native of the Cape.

6. *Hebenstreitia Fruticosa*; *Shrubby Hebenstreitia*. Leaves lanceolate, toothed, smooth; bractes entire; stem shrubby.—Native of the Cape.

7. *Hebenstreitia Aurea*; *Golden-flowered Hebenstreitia*. Leaves somewhat cylindrical, obtuse, entire; spikes smooth, formed of beautiful golden-coloured flowers, variegated with deep orange, very fragrant in an evening.—Native of the Cape. It may be increased by cuttings, which, if taken off in May, will become flowering plants in September.

Hedera; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: involucre of a simple umbel, very small, many-toothed; perianth very small, five-toothed, surrounding the germen. *Corolla*: petals five, oblong, spreading, with the tips hewed inwards. *Stamina*: filamenta five, subulate, upright, of the same length with the corolla; antheræ trifid at the base, incumbent. *Pistil*: germen turbinate, surrounded by the receptacle; style simple, very short; stigma simple. *Pericarp*: berry globular, one-celled. *Seeds*: five, large, gibbous on one side, angular on the other. **ESSENTIAL CHARACTER.** *Petals*: five, oblong. *Berry*: five-seeded, surrounded by the calix.—The different species of *Hedera* are easily propagated by the trailing branches, which send forth roots their whole length; or by cuttings planted on a shady border in autumn, which by the following autumn will be fit to plant where they are designed to remain; or by seeds sown after they are ripe, which is in the beginning of April: if these be kept moist and shaded, they will grow the same spring, otherwise they will remain a year in the ground.—The species are,

1. *Hedera Helix*; *Common Ivy*. Leves ovate and lobed, alternate, evergreen, glossy, smooth. The trunk in old trees is covered with an ash-coloured chopped bark; in the young branches it is of a green or purple colour. The petioles are long, and dilated at the base. The flowers are yellowish, or greenish-white, in a very close thick umbel, at the extremities of the twigs. The berry is placed below the receptacle of the flower, and is crowned with the five-cornered streaked rudiment of it; at first it is succulent, with a purple juice, afterwards it becomes coriaceous, dry, and very obscurely quinquangular. The seeds are wrinkled and yellowish. The wood is soft and porous, so as to transmit liquids if turned to a sufficient degree of thinness. In its variegated state it sometimes appears almost white.—The roots are used by leather-cutters to whet their knives upon. The branches, being very full of leaves, are as effectual as any thing to protect the tender blossoms of Apricots, Peaches, and Nectarines, against the cold winds and frosts of February and March. As a medicine it is scarcely admitted into modern practice. The leaves have a nauseous taste. Haller says, they are given in Germany as a specific in the atrophy of children. Common people apply them to issues and corns. The berries have a little acidity; and, when taken inwardly, purge and vomit. In Galicia they give the seeds bruised in pleurisies, to the quantity of two tea-spoonsful every eight hours. In warm climates a resinous juice exudes from the stalks, or may be procured by wounding them: it is insipid and inodorous, but inflames in burning, with a pleasant aromatic smell, and then has a slight astringency. It tinges spirit of wine of a reddish brown colour, and is said to be aperient, resolutive, and balsamic: but it is not in use. Country people apply the berries to issues, to increase the discharge. Meyrick informs us, that a decoction of the leaves destroys vermin in the heads of children, and heals the soreness which they occasion. An infusion of the berries is frequently found serviceable in rheumatic complaints, and is reported to have cured the dropsy. The juice snuffed up the nose occasions

a pretty considerable discharge of mucus and watery humours from the head.—In the latter part of the 17th century, when it was the fashion to fill gardens with all sorts of sheared evergreens, many of these plants were trained into round heads, clipped into globes, cones, &c. and, being so hardy as not to be injured by weather, and growing in any soil, were then much esteemed: since this taste has been exploded, the Ivy is seldom admitted into gardens, unless to cover walls, or to run over ruins, for which purpose no other plant is so well adapted. Mr. Curtis, however, observes, that few people are acquainted with the beauty of Ivy when suffered to run up a stake, and at length to form itself into a standard; the singular complication of its branches, and the vivid hue of its leaves, give it one of the first places amongst evergreens in a shrubbery. In woods, when suffered to grow large and rampant, this plant, by twining round the bodies of timber-trees, does them great damage, and therefore should be carefully destroyed, as it easily may be by cutting any where through its trunk. But in ornamental outlets, where evergreens do not abound, a few trees covered with Ivy have a very pleasing effect, and induce birds of song to haunt those thickets for the sake of the berries and shelter. It produces very picturesque effects in large masses of ruined buildings: but that it is injurious to them, cannot be denied, when we consider that it must harbour wet and filth, and that the branches will make their way into any fissure or defect in the wall, and enlarge it. It is a parasitical shrub; and while fixed to any support, or left to trail upon the ground, the stalks are slender and flexible; but when it has reached to the top of its support, they shorten and become woody, forming themselves into large bushy heads. As long as the stalks are suffered to trail, Ivy does not produce any flowers; and in this state it is called *Barren* or *Creeping Ivy*; but when the branches get above their support, they produce flowers at the end of every shoot; these are succeeded by berries, formed into round bunches, called by the ancients *Corymbi*, and turning black before they are ripe. In this state it is called *Climbing* or *Berried Ivy*.—It is found wild all over Europe; but Linnæus informs us it is by no means common in Sweden. Kalm remarks, that he never saw the Common Ivy in North America, except once against a stone building, and that it was apparently brought from Europe, and planted there. Thunberg observed it in Japan, and says that the leaves are commonly undivided there, and not lobed. It begins to flower with us in September, and is much resorted to by bees and flies, when little other food is to be had. The berries increase during the winter, are full formed in February, and ripen in April; furnishing food for wild pigeons, blackbirds, thrushes, and other birds in the spring. Sheep are fond of Ivy, which is a warm and wholesome food for them in hard weather; and therefore in snowy seasons the shepherds cut down the boughs for their flocks to browse on, which is a very ancient practice.

2. *Hedera Capitata*; *Cluster-flowered Ivy*. Leaves elliptical, entire; racemes compound, terminating; flowers sessile, in little heads; stem arborescent, eight feet high in the stove, erect, cylindrical, abruptly branched; bark brown, a little cracked; branches curved upwards, leafy, terminated by flowers, which are numerous, white, and so small that the structure is not readily to be understood; each stands on its proper involucre, resembling a calix of one leaf, in five divisions; externally powdery; permanent.—This fine plant was discovered by Jacquin in the woods of Martinico.

3. *Hedera Quinquifolia*; *Five-leaved Ivy*. Leaves quinate, ovate, serrate; racemes trifid, twice dichotomous, fine, umbelled; calix very short, bluntly toothed, red at tip; petals

blunt, arched at the tip, green.—It grows naturally in all the northern parts of America, was first brought to Europe from Canada, and has been chiefly employed to cover walls or high buildings; which this plant will do in a short time, for it will shoot almost twenty feet in one year; but as the leaves fall off in autumn, and are late before they come out in the spring, it is not much esteemed, unless where better things will not thrive. As it receives no injury from smoke, or the closeness of the air, it is proper to cover buildings in great towns. The stalks put out fibres, like the Common Ivy, which insinuate themselves into the joints of a wall. It was cultivated here in 1629.

4. *Hedera Pendula*. Leaves ovate-lanceolate, entire; peduncles very long, pendulous.—Native of Jamaica.

5. *Hedera Nutans*. Leaves elliptic, coriaceous; umbels nodding, hemispherical.—Native of Jamaica.

6. *Hedera Terebinthinacea*. Leaves in sevens, elliptic, quite entire. The whole plant is smooth; clusters compound; partial flower-stalks umbellate.—Native of Ceylon.

Hedge Hyssop. See *Gratiola*.

Hedge Mustard. See *Sisymbrium* and *Erysimum*.

Hedge Nettle. See *Galeopsis*.

Hedges.—Hedges are either planted to make fences round enclosures, or to part off and divide the several portions of a garden: when they are designed as outward fences, they are planted with Hawthorn, Crabs, or Black-thorn, which is the Sloe; but those hedges which are planted in gardens, either to surround wilderness quarters, or to screen the other parts of a garden from sight, are planted with various sorts of plants, according to the fancy of the owner; some preferring evergreen hedges, in which case the Holly is best, next the Yew, then Laurel, Laurustinus, Phillyrea, &c.; others, who make choice of the deciduous plants, prefer the Beach and Hornbeam, English Elm, or the Alder, to any other. Those hedges which are intended for outside fences are generally made of White or Haw Thorn. It will be proper, before planting, to consider the nature of the land, and what sorts of plants will thrive best in that soil; and also what the soil is from whence the plants are to be taken: for if the land they are taken from be much better than that in which they are to be planted, it will be more difficult to get them to grow. As for the size, the sets ought to be about as large as a goose-quill, and cut within about four or five inches of the ground; they should be fresh taken up, straight, smooth, and well rooted. Those plants which are raised in the nursery are to be preferred to all others. The time for planting is February, March, and April. Secondly, if the hedge have a ditch, it should be made six feet wide at top, and one foot and a half at bottom, and three feet deep, that each side may have a proper slope; for when the banks are made too upright, they are very subject to fall down after every frost or hard rain; besides, if the ditches are made narrower, they are soon choked up in autumn by the falling leaves, and the growth of weeds, nor are they a sufficient fence to the hedge against cattle where they are narrower. Thirdly, if the bank be without a ditch, the sets should be placed in two rows almost perpendicular, at the distance of a foot from each other, in the quincunx order, so that in effect they will be but six inches asunder. Fourthly, the turf should be laid with the grass-side downwards, on that side of the ditch the bank is designed to be made, and some of the best mould should be laid upon it, to bed the sets; they are then to be planted upon it about a foot asunder, so that the ends may stand upright. Fifthly, when the first row is planted, it must be covered with mould, and the turf laid upon it as before; so that when the bank is a foot high you may plant another row of sets against the spaces of the lower ones, covering them as before. The

bank is to be topped with the bottom of the ditch, and a dry or dead hedge laid on the other side, to defend the plantation from cattle. In the making of these dead hedges there should be stakes driven into the loose earth, at about two feet and a half distance, so low as to reach the firm ground: for this purpose oaken stakes are most esteemed, and next to them the Black-thorn and Sallow. The small bushes must be laid at the bottom, but not too thickly, which would cause the bushes to rot; but the upper part of the hedges should be laid with long bushes, to bind the stakes in with, by interweaving them. In order to render the hedge yet stronger, you may edder it, as it is called, that is, bind the top of the stakes in with long small poles, or sticks, on each side; and when the eddering is finished, drive the stakes anew, because the waving of the hedge and eddering is liable to loosen the stakes. The plants must be constantly kept weeded, and secured from being cropped by the cattle, and in February it will be proper to cut it within an inch of the ground, if it was not done before; which will cause it to shoot strong, and greatly adjust its growth. When a hedge is of about eight or nine years' growth, it will be proper to plash it; the best time for this work is either in October or February. When a hedge is grown old, say about twenty or thirty years' growth, and there are in it old stubs as well as new shoots, the old stubs should be cut sloping off within two or three inches of the ground, and the best and longest of the middle size should be left to lay down; and some of the strongest, at the height of five or six feet, in proportion to the intended height of the hedge, may be left to serve instead of stakes, and fresh stakes should be put into those places where they are wanting. The hedge should then be thinned, so as to leave on their stubs only such shoots as are designed to be of use, that there may be room left to put a spade in between them; the ditch also should be cleansed, and each side of the slopes kept as in a new ditch, and where the earth is washed from the roots, or is hollow, face it anew with so much of the first spit of earth that is dug out of the ditch, as there is occasion for, and lay what is dug out at the second spit, on the top of the bank; for if it be laid on the side or face of the bank, it will slip into the ditch again when wet comes, and also take a great deal of the bank along with it. In plashing, there are two extremes to be avoided; the first is, laying it too low and too thick, because it makes the sap run all into the shoots, and leaves the plashes without nourishment, which, with the thickness of the hedge, kills them; secondly, it must not be laid too high, because this draws all the sap into the plashes, and so causes but small shoots at the bottom, and makes the hedge so thin, that it will neither hinder the cattle from going through, nor from cropping of it. When the shoot that is designed to be plashed is bent, give it a small cut with a bill, half through, sloping a little downwards, and then weave it about the stakes; and when the whole is finished, train off the small superfluous branches that straggle too far out on both sides of the ledge. If the shrubs be very old, cut them quite down, and secure them with good dead hedges on both sides, till the young shoots are got up tall enough to plash, and plant new sets in the void spaces. In making a hedge, if it be set with Crab-stock, it will be proper to leave one standing uncut up at every thirty or forty feet, if the ground on both sides of the hedge be your own; which being done, they may be so ordered, by pruning or staking, that one may lean into one ground and the other into another. These stocks should be pruned up every year, till they are brought out of the reach of the cattle, and then they may be grafted with a red-streak, gennet-moil, or whatever kind of cider

Apple the planter may prefer. If the stocks be of Apple kernels, they may stand ungrafted, for many of them will yield very good cider fruit; but then such stocks as are not grafted will be longer before they bear, and also when you do graft, you may be certain of your kind; but if you find a very natural stock, which by leaf, shoot, and bud, appears likely, you may try it, and so you may procure a fine new fruit; and if you do not like it, you may graft it when you please. With respect to the rest of the hedge, when it has shot four or five years, you may lay it to make a fence: for the doing of which, take the following directions; first, at every laying to lay down some old plashes, or, if the hedge be thin, young ones; but they may be so laid, as to point with their ends to the ditch-side of the bank, the ends being kept low on the bank; by being so ordered, they will the better thicken the bottom of the hedge, and keep up the earth of the bank. Secondly, to heighten the bank every time you lay earth on it, so as to cover the layers, all but the ends; this earth will very much help the sets, and by heightening the banks, and deepening the ditch, you will render the fence the better. Thirdly, not to cut the plashes too much, but just so as they may bend down well; not to lay them too upright, as some do, but to lay them near to a level; for by so doing, the sap will the better break out at several places, and not run so much to the ends, as it will when they lie too much upon the slope. If you have much wood to spare, you may cut up great part of those that grow near the ditch, but then the banks should be hung with bushes, to prevent cattle from cropping them during the first year: these will shoot strong, secure the hedge, keep up the bank, and thicken the bottom of the hedge. Fourthly, take care to lay the hedge pretty thick, and turn the beard on the ditch-side; but you must not let the beard hang uncut, though it makes a good show at the first making, but you must cut off all the straggling boughs within half a foot of the hedge on both sides, which will cause it to shoot strong at these places, and make the hedge much thicker. Fifthly, if the bank be high, the hedge should be made so low that it may just serve for a fence the first year, for it will soon grow higher; and the lower the hedge is made, the faster the sets will grow, and also will be thicker at the bottom; but care must be taken to preserve it from cattle, on the field-side, for the first two years that it is made. Sixthly, if you would have a good hedge, or fence, you should new-lay it once in fourteen or fifteen years, and constantly root out Elder, Traveller's Joy, which some call Bull-bine, Briony, &c. and do not leave too many high standards or pollards in it, though the Elin is one of the best; also no dead wood is to be left in the bottom of the hedges, for that will choke the quick; but if there be a gap, the dead hedge should be made at a distance.—The Crab is also frequently planted for hedges, and if the plants are raised from the kernels of the small wild Crab, they are much to be preferred to those which are raised from kernels of all sorts of apples without distinction; because the plants of the true small Crab never shoot so strong as those of Apples, and may therefore be better kept within the proper compass of a hedge; and as they generally have more thorns upon them, they are better guarded against cattle; besides, the plants of the Crab will grow more equal than those which are raised from the kernels of various kinds of apples, for these always produce a variety of plants which differ from each other in their manner of growth, as much as in the size and flavour of their fruits, so that hedges formed of them will neither appear so well, nor can be so well managed, as the other. Some persons intermix Crab with the White-thorn in their hedges; but this is not a good method,

for the plants of the Crab will grow much stronger than those of the White-thorn, so that the hedges will not be of equal growth; which is not near so beautiful or useful, as when the plants of a hedge keep pace in their growth. The Black-thorn or Sloe is also frequently planted for hedges, and is a strong durable plant for that purpose, especially as it is so strongly armed with thorns, that cattle seldom care to browse upon it: but where this is planted, the best way is, to raise the plant from the stones of the fruit; for all those which are taken from the roots of old trees, spawn and put out suckers in such plenty from their roots, as to spread over, and fill the neighbouring ground to a considerable distance on each side of the hedges; and this plenty of suckers drawing away the nourishment from the old plants of the hedge, they never grow so well as where there are few or no suckers produced; which the plants propagated from stones seldom send forth, or at least but sparingly, and therefore they are easily removed. The best method of raising these hedges is, to sow the stones in the place where the hedge is intended, when it can be conveniently done, for then the plants will make much greater progress than those which are transplanted: but the objection to this method will arise from the difficulty of securing the young plants from the cattle; yet this can have little force, when it must be considered, that if the hedge be planted it must be fenced for some years, to prevent the cattle from destroying the sets; therefore the same fence will do for it when sown, nor will it require a fence much longer than the other, for the plants which stand unremoved, will make a better fence in seven years, than that which is transplanted when the plants be of three or four years' growth. The stones of this fruit should be sown early in January, if the weather will permit; but when they are kept out of the ground longer, it will be proper to mix them with sand, and keep them in a cool place. The bushes of the Black-thorn are by much the best of any for making of dead hedges, being more lasting, and having so many thorns, that neither the cattle nor the hedge-breakers will care to meddle with it. They are also the best to be used for underground drains, for the draining of land; for they will remain sound a long time, after the air is excluded from them.—The Holly is sometimes planted for hedges, and is a very strong and durable fence; but where it is exposed there will be great care necessary to prevent it from being destroyed. It is by far the most beautiful plant that is used for hedges, and being an evergreen, will afford much better shelter in winter than any other kind of hedge, especially as the leaves are armed with thorns, which prevent the cattle from browsing on it. This plant however is of slow growth, so that hedges planted with it require to be fenced a much longer time than most others. This defect will exclude it from general use: yet in such grounds as lie contiguous to or in sight of gentlemen's houses, hedges of Holly will have a very pleasing effect, especially where they are well kept, as they will preserve their beauty at all seasons; and in the spring of the year, when the sharp winds render it unpleasant to walk abroad, these hedges will afford a good shelter for keeping off the cold winds. The surest method of raising a Holly hedge is, by sowing the berries in the place where they are to stand; but these berries should be buried in the ground a whole year before they are sown; by which method they will be prepared to grow in the following spring. The way of doing this is, to gather the berries about Christmas, which is the time they are usually ripe, and put them into large flower-pots, mixing some sand with them; then dig holes in the ground, into which the pots must be sunk, covering them over with

earth about ten inches thick: in this place they remain till the following October, and should then be taken up, to be sown wherever the hedge is to be raised. The ground for this hedge ought to be well trenched, and cleared from the roots of all bad weeds, bushes, and trees. Two drills should then be made about a foot distance from each other, and about two inches deep, into which the seeds should be scattered pretty close, lest some should fail; for it is better to have too many plants come up than to feel a deficiency. When the plants come up they must be carefully weeded, for if the weeds be permitted to grow among them, they will soon destroy or weaken them so much, that they will not recover their strength in a long time. This should be constantly observed by every person who is desirous to have good hedges of either sort; for when the weeds are suffered to grow near the plants, they will not only rob them of a great part of their nourishment, but also prevent them from putting out shoots near the ground, which will cause the bottom of the hedge to be thin and naked. When Holly hedges are intended to be kept very near, they should be sheared twice a year, in May and August; but if they are merely employed as fences, they will not require shearing more than once a year, which should be about the latter end of June, or the beginning of July; and if this be well performed, the hedges may be kept in a very orderly state. The fences which are made to secure these hedges from cattle while they are young, should be contrived to admit as much free air as possible, for that is absolutely necessary for the growth of the plants, which seldom thrive well when crowded on each side with dead hedges. The best sort of fences for this purpose, are those which are made with posts and rails; or, instead of rails, three ropes drawn from post to post, through holes in each post. This is the cheapest fence of this kind, and will appear very handsome; but where the sheep are not admitted into the fields, only two ropes will be required to keep off larger cattle. If the ropes be well besmeared with a composition of melted pitch, brown Spanish colour, and oil, mixed well together, they will last sound several years; and these sorts of fences never obstruct the air, while the place being at the same time open to view, the weeds will be more easily discovered than where the fences are close. In the latter case, the hedges are sometimes suffered to be overrun with weeds, by their being excluded from sight, and are frequently forgotten, especially in moist weather, when the weeds grow most luxuriantly. There are some persons who intermix Holly with the White-thorn in making their hedges, which will have a good effect when rightly managed, especially when young; but when this is practised, the Holly should be planted so near, as that the hedge may be entirely formed of it as it grows up, when the White-thorn should be quite rooted out; for as they will not keep pace in their growth, they cannot appear to advantage where they remain intermixed. When a hedge of Holly is intended to be made by plants, the ground should be well branched, as has been already advised for the seeds; and unless the soil be very wet, the plants should be set in October, but in wet grounds March is preferable. These plants should by no means be taken from a better soil than that in which they are to be replanted, for then they are often longer before they recover from the change than those which are taken from a leaner soil. If the plants have been removed two or three times before, they will have better roots, and will be in less danger of miscarrying; besides, they may be removed with balls of earth to their roots. When the frost comes on, if mulch be laid upon the ground near the roots of the plants, it will prevent the tender fibres, which may then have been put out, from being destroyed by the

cold. We would never advise the planting of hedges with Holly plants of above five or six years' growth, from the berries; for when the plants are older, if they take to grow, they are longer before they form a good hedge, than plants which are much younger; and if the plants have been twice before transplanted, they will more certainly grow.—Ornamental hedges, such as are used in gardens, are sometimes planted with evergreens, especially if they are not intended to grow very high, for then they are planted with deciduous trees. Evergreen hedges are formed from Holly, Yew, Laurel, Laurustinus, Phillyrea, Alaternus, Evergreen Oak, and some others of less note. The Holly is preferable to any other, for the reasons above advanced. Next to this, most persons prefer Yew, on account of its growing very close; for when these hedges are well kept, they will be so thick as that a bird cannot get through them; but the dead colour of the Yew renders these hedges less agreeable to the eye.—The Laurel is one of the most beautiful greens of any of the evergreen trees: but then it shoots so luxuriantly as to make it difficult to keep the hedges planted with it in any tolerable shape; besides, the leaves being very large, will be often clipped with the shears when the hedge is dressed, which gives them a bad appearance: therefore where there are hedges of this kind, it will be the best way to prune them with a knife, cutting the shoots just down to a leaf; and although by this method the hedge cannot be rendered so even as when cut with shears, yet it will preserve a much better appearance than when most of the leaves are cut through and stubbed by the shears.—The Laurustinus is also a very fine plant for this purpose; but the same objection is to be made to this as has been advanced against the Laurel; and as one of the greatest beauties of this plant is in its flowers, which are produced in the winter and spring, so when these are sheared, the flowers are generally cut off, by which their beauty is lost. Nor can this be avoided where the hedge is to be kept in close order, and hence this plant is not so proper for that purpose; but in places where walls and other fences are designed to be hid, there is not any plant better adapted than this, provided it be rightly managed; for the branches of this plant are slender and pliable, so that they may be trained up close to the fence, so as to cover it entirely; and if, instead of clipping it with shears, a pruning knife be employed, they may be so managed as to have them full of flowers from the ground upward. This may be effected by pruning them in April, when the flowers are going off, cutting out those shoots that have flowered, or project too far from the fence, always cutting close to the leaf, that no stubs may be left; but those new shoots of the same spring must by no means be shortened, because the flowers are always produced at the extremity of the shoots of the same year; therefore when these are topped, as they must be by shearing, there can be few or no flowers upon these plants, except towards the top, where the shears have not passed. By this method of knife-pruning, the leaves will also be preserved entire, and the hedge may always be kept enough within compass, and so thick as fully to answer the purpose of covering the fence; and if the shoots be suffered to grow rather irregularly, it will make a better appearance than any thorn-hedge whatever. The small-leaved and the rough-leaved Laurustinus, are the best sorts for this purpose, because their branches grow closer together than those of the shining-leaved; they are also hardier, and flower much better in the open air.—The true Phillyrea is the next best plant for hedges. It is called the true Phillyrea, to distinguish it from the Alaternus, which is simply called the Phillyrea. The branches are strong, the leaves large, and of a deep green colour. It is of middling growth: hedges planted with this

may be laid up to the height of ten or twelve feet; and if these hedges are kept narrow at the top, that there may not be too much width for the snow to lodge upon them, they may be rendered very close and thick, and being of a very good green colour, will make a fine appearance. The *Alaternus* was formerly much more cultivated in the English gardens than at present. It was often planted to form hedges; but the branches are too pliable, being frequently displaced by strong winds, which render these hedges unsightly; they also shoot very irregularly and thin, so that the middle of the hedge is frequently open and wide, and only the sides of them can be kept tolerably close, and that must be by often clipping them. If we add to this, their being frequently laid or broken down by snow in the winter, it must be deemed an improper plant for this purpose.—The *Ilex*, or Evergreen Oak, is also planted for hedges, and where these are designed to grow pretty tall, it is a fit plant for the purpose, because it is a plant of large growth, especially the sort which is most common in England; for there are two sorts of them, which grow in the south of France and Italy, that are of much humbler growth, and better adapted to this purpose, especially when a high hedge is not wanted; but they are not common in Great Britain. When these hedges are planted very young, and kept close-trained from the beginning, they may be very close from the ground to the height of twenty feet or more, but must always be kept narrower at the top than below, that too much snow may not lodge upon and break them down in the winter.—There are also some persons who have planted the *Pyracantha*, or Evergreen Thorn, Juniper, Box, Cedar of Virginia, Bay, &c. as also the *Atriplex*, or Sea Purslane, the *Furze*, the *Rosemary*, and several other plants, for hedges; but the five sorts first mentioned having very pliant branches, which will require to be supported, and the last being often destroyed by severe frost, are unfit for this purpose; nor are there any other sorts of evergreen plants in the English gardens, which are so well adapted for hedges as those we have already pointed out.—The deciduous trees which are usually planted to form hedges in gardens, are the following sorts: The *Hornbeam*, which is most esteemed, especially in places where they are not required to be very high, or not wanted to grow very fast; for this plant while young does not make so great progress as many others: as it is of slower growth, the hedges formed of it may be kept neat with less trouble than most other plants will require, and the branches naturally growing very close, they will make one of the closest hedges of all the deciduous trees; but as the leaves of this tree continue upon the branches all the winter, and until the buds in the spring force them off, they have a bad appearance during the winter season. In Westphalia, and other parts of Germany, the *Hornbeam* is in great repute for hedges. The German husbandman throws up a parapet of earth, with a ditch on each side, and plants his sets, raised from layers, in such a manner as that every two plants intersect each other; there he scrapes off the bark, and binds them close together with straw. The plants consolidate, and form a living palisado, which being pruned annually with discretion, will in a few years make an impenetrable fence. It is not uncommon in Germany to see the sides of high-roads thus guarded for many miles together. The *Hornbeam* is not delicate in point of soil; will put out strong lateral shoots within three inches of the ground; and is of quick growth. The *Beech* is also a very proper tree for this purpose, having the same good qualities as the *Hornbeam*; but the leaves of this continue late in winter upon the branches, when they will have a bad appearance; besides, the litter which is occasioned by their leaves gradually falling most part of the

winter, prevents the garden from being made clean a great while longer than if there were none of these planted. The *Small-leaved English Elm*, is also a proper tree for tall hedges: if these be planted young, and kept closely clipped from their first setting out, the hedges may be trained up to the height of thirty or forty feet, and be very close and thick the whole height. But when these trees are planted for this purpose, they should not be crowded so close together as they generally are: by which method, when the trees have stood some years, if they have thriven well, their stems will approach so near each other as that few branches can be maintained below, whereby the bottom of the hedge will be naked; therefore they should not be planted closer together than seven or eight feet, or if they be ten feet it will be still better, from the ground upward. The *Dutch Elm* was formerly in great esteem for hedges, being quick of growth, and thriving in such soils as the *English Elm* would not grow in; but the wretched appearance which these hedges made, after they had been growing a few years, caused them to be very generally discontinued, for a more unsuitable plant was never introduced into gardens. The *Lime-tree* has also been recommended for hedges, and in some of the old gardens there were many planted with this tree, which, for a few years after planting, made a tolerable appearance, especially when they grew upon a moist soil; but after they had stood some years, they grew very thin at bottom, and by being sheared at the top, they were rendered very stubby and unsightly: their leaves growing very thinly upon the branches, and these frequently turning of a black disagreeable colour, and falling off very soon in the autumn, and sometimes in the summer in dry seasons, has brought these trees into so much disrepute, that few persons at present will make use of them for this purpose: nor should any of the very strong shooting trees be applied to this use; for the more they are cut the stronger they will shoot, and of course will appear very unsightly; besides, the often cutting of the hedges occasions great trouble and expense, and frequent litters in gardens. The *Alder* is frequently planted for hedges, and where the soil is moist, there is not any of the deciduous trees equal to it for this purpose; for the leaves are of a lively green, continuing fresh till late in the autumn; and when they decay their litter is soon over, for they all drop in a short time.—There are, besides the trees above mentioned, many of the flowering shrubs which have been planted to form hedges; such as *Roses*, *Honeysuckles*, *Sweetbriar*, &c. but these make a bad appearance, being more difficult to train; and if they are cut to keep within compass, their flowers, which are their greatest beauty, will be entirely destroyed. But as these are but of low growth, they are not proper to plant where the hedges are to be of any height. The taste in gardening has been greatly improved of late years; clipped hedges have been almost excluded, and it is to be hoped that they will soon be wholly banished, as both troublesome and unnatural.

Hedwigia; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, cup-shaped, four-toothed: teeth minute, ovate, sharp, upright. *Corolla*: monopetalous, tubulous; tube the length of the calix, narrower at top; border quadrifid; the clefts ovate, sharp, upright, converging. *Stamina*: filamenta eight, broad, inserted into the base of the corolla, incumbent on the germen; antheræ minute, oblong, sharp, converging above the stigma. *Pistil*: germen conical, eight-streaked, superior; style none; stigma blunt. *Pericarp*: tricoccos, (composed as it were of three ovate-acuminate capsules,) large, three-celled. *Seeds*: nuts solitary, ovate, acuminate, one side

convex and very smooth, the other wrinkled and unequal; kernels the shape of the nuts. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Corolla*: four-cleft. *Style*: none. *Capsule*: tricocous. *Seed*: a nut.—The only species is,

1. *Hedwigia Balsamifera*. Leaves oval, ending in a lengthened point at top, without any indentations, thin, shining, waved, yellowish-green, five or six inches long, and three inches wide, ranged in pairs along a midrib, terminated by an odd one. The flowers grow in a raceme at the extremities of the branchlets, and are white. The fruit is the size of a small nut, divided in two or three parts, covered with a green coriaceous rind, and containing a white fleshy sweet pulp, having an aromatic smell: each division has in it a flattened woody shell, enclosing a bitter oily kernel. This is a lofty tree, growing to the height of more than sixty feet, with a trunk four or five feet in circumference; outer bark gray and even; inner red, thick, and gummy; wood solid, and reddish, and is used as timber for various purposes. An aromatic oil is drawn from the kernels, which is much esteemed in disorders of the breast. The red gum that issues from the bark has a strong aromatic smell, and is much used in the cure of wounds. It is supposed that the wild swine first discovered this use of it; and hence it has acquired the name of *Bois Cochon*, or *Hog's-wood*.—Native of St. Domingo.

Hedycarya; a genus of the class Diœcia, order Icosandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, flat-wheel-shaped, eight or ten cleft; clefts lanceolate, nearly equal; in the female permanent. *Corolla*: none. *Male*. *Stamina*: filamenta none; antheræ very many, (fifty,) oblong, four-furrowed, bearded at the tip, distributed along the whole bottom of the calix. *Female*. *Pistil*: germina numerous, flattened-globular, placed each on a cylindrical pedicel in the middle of the calix; styles none; stigmas little protuberances scattered over the germina. *Pericarp*: none. *Seeds*: nuts six or ten, pedicelled, globular, somewhat bony; kernels solitary, globular. *Receptacle*: in the middle of the calix, woody. **ESSENTIAL CHARACTER.** *Calix*: eight or ten cleft. *Corolla*: none. *Male*. Filamenta none; antheræ in the bottom of the calix, four-furrowed, bearded at the tip. *Female*. Germina pedicelled; nuts pedicelled, one-seeded.—The only known species is,

1. *Hedycarya Dentata*. A smooth shrub. Leaves alternate, oblong, serrate, on short petioles, very smooth, veined; the veins almost transverse; racemes axillary; calices hirsute; nuts very sweet.—Native of New Zealand.

Hedychium; a genus of the class Monandria, order Monogynia. **ESSENTIAL CHARACTER.** *Anther*: two-lobed, recurved, terminal, embracing the style, without any appendage. *Outer limb* of the *Corolla*: in three equal linear lobes; *inner*, in three parts, two-lipped. *Flower*: reversed. *Tube*: longer than the limb.—The species are,

1. *Hedychium Coronarium*; *Sweet-scented Garland Flower*. Leaves lanceolate; bractes imbricated, elliptical; lip cloven.—Native of the East Indies, where it is very generally cultivated for ornament.

2. *Hedychium Ellipticum*. Leaves elliptical, smooth; bractes imbricated, elliptical; lip entire.—Native of the East Indies.

3. *Hedychium Spicatum*. Leaves lanceolate; spike elongated; bractes convoluted, single-flowered; stamen much shorter than the lip.—Native of the East Indies.

Hedycreea; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, hemispherical, five-toothed; teeth sharp, patulous. *Corolla*: none. *Stamina*: filamenta five, inserted into a ring, surrounding the calix within, below the teeth, opposite to and

shorter than they; antheræ roundish. *Pistil*: germen roundish, villose, superior; style longer than the calix, bristle-shaped, villose; stigma blunt. *Pericarp*: drupe oval, soft, fibrous within, one-celled. *Seed*: nut ovate, covered with fibres, one-celled; the shell hard. **ESSENTIAL CHARACTER.** *Calix*: one-leafed, hemispherical, five-toothed. *Corolla*: none. *Drupe*: oval, one-celled. *Nut*: ovate, covered with fibres, one-celled; the shell hard.—The only species known is,

1. *Hedycreea Incana*. The extremities of the branches and twigs have oval leaves, ending in a point, smooth and green on the upper surface, covered with a very white down underneath, and placed alternately; their petiole is short, accompanied at the base by two opposite stipules. The flowers grow in a spike at the ends of the branches and twigs; they are white, close, and sessile. The fruit is of the size of a large olive, white, dotted on the outside with red; the pulp is white, melting, and of a sweetish taste; the shell or nut is bony, and separates with difficulty from the fibres in the pulp; the kernel is two-lobed. This tree grows only to the height of three or four feet, with a trunk five or six inches in diameter. The bark is ash-coloured, very thin, falling in large pieces, and renewing itself every year. The wood is hard, whitish, and when sawed has the smell of rancid oil.—Native of Guiana, where it is called *caligni* by the natives, who are very fond of the fruit, which is ripe in November and December.

Hedysosmum; a genus of the class Monœcia, order Polyandria.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: ament without scales, covered on every side with staminas; perianth none. *Corolla*: none. *Stamina*: filamenta none; antheræ very many, imbricately heaped together, upright, oblong, acuminate at the tip, converging at the base into an oblong ament, and placed on a linear receptacle. *Females, solitary on the same tree.* *Calix*: perianth one-leafed, covering the germen, three-toothed at the tip; teeth minute, upright. *Corolla*: none. *Pistil*: germen oblong, three-cornered; style very short, three-cornered; stigma simple, obtuse. *Pericarp*: berry roundish, three-cornered, small, superior. *Seed*: single, hard, three-sided, shining. **ESSENTIAL CHARACTER.** *Male. Ament*: covered with antheræ. No perianth, corolla, or filamenta. *Female. Calix*: three-toothed. *Corolla*: none. *Style*: one, three-cornered. *Berry*: three-cornered, one-seeded.—The species are,

1. *Hedysosmum Nutans*. Stem shrubby; branches loose; leaves lanceolate, acuminate.—Native of Jamaica.

2. *Hedysosmum Arborescens*. Stem arborescent; branches stiff, upright; leaves ovate-lanceolate.—Native of Jamaica.

Hedyotis; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, four-parted, superior, permanent; parts linear, sharp. *Corolla*: monopetalous, funnel-shaped, a little longer than the calix, half four-cleft; clefts patulous, nearly equal. *Stamina*: filamenta four, subulate, inserted at the sinuses of the corolla; antheræ roundish. *Pistil*: germen roundish, inferior; style filiform, the length of the stamina; stigmas two, thickish. *Pericarp*: capsule twin-globular, two-celled, gaping next the coronal; calix with a transverse cleft. *Seeds*: few, angular. **ESSENTIAL CHARACTER.** *Corolla*: monopetalous, funnel-shaped. *Capsules*: two-celled, many-seeded, inferior.—The species are,

1. *Hedyotis Maritima*. Leaves oval, blunt, on short petioles, fleshy; flowers opposite, sessile; stems herbaceous, prostrate, a hand in length, smooth and even; fruit the size of coriander.—Native of the East Indies.

2. *Hedyotis Pumila*. Leaves ovate, sharp; flowers alternate, peduncled; root annual; stems little, branched, a hand in

length, smooth and even; capsule roundish, crowned with the four teeth of the calix.—Native of Tranquebar.

3. *Hedyotis Fruticosa*. Leaves lanceolate, petioled; corymbs terminating, involucre. Stem four-cornered; stipules ovate, rhomboid, broad, short; corymbs brachiate, or trifid; calix four-cleft; style bifid, blunt.—Native of Ceylon.

4. *Hedyotis Auricularia*; *Earwort*. Leaves lanceolate-ovate; flowers in whorls. Stems smooth, long; branches long, jointed, alternate. It is accounted a specific in deafness.—Native of Ceylon.

5. *Hedyotis Herbacea*. Leaves linear-lanceolate, opposite, smooth, quite entire; stem herbaceous, dichotomous; peduncles in pairs. Stem eight inches high, slender, procumbent; flowers axillary, in pairs, but often solitary; corolla white, subcampanulate.—Native of Ceylon and Cochin-china.

6. *Hedyotis Graminifolia*. Leaves linear; stem decumbent; panicle racemed, with the flowers directed one way; peduncles following the sun. Perennial; stems filiform, a foot long; corolla blue; the segments before noon expanding very wide, in the evening two upright, and two bent back.—Native of the East Indies.

7. *Hedyotis Hispida*. Leaves linear-lanceolate; flowers in whorls. Stems half a foot in length, decumbent, quadrangular, hispid, with a branch or two; petioles extremely hispid, united with the filiform torn stipules so as to form a short sheath; calix hispid; stamina the length of the corolla; style longer, club-shaped; capsule half-two-celled, the partition disappearing in the middle, and not reaching to the tip; seeds many.—Brought from Canton in China.

8. *Hedyotis Rupestris*. Leaves four-faced, awl-shaped, channelled; flowers sessile, axillary; corollas villose, with a crooked tube. This is a shrub, seldom exceeding three feet in height; branches diffused, often procumbent at the base, otherwise erect. The flowers are yellow, without scent, sessile, axillary, solitary.—Native of Havannah, on rocks near the sea-coast, and of Jamaica.

9. *Hedyotis Diffusa*. Leaves lanceolate, acute, rough-edged; flower-stalks simple, axillary, alternate; fruit nearly globose; stem procumbent.—Native of the East Indies.

10. *Hedyotis Serpylloides*. Leaves ovate; stipulas fringed; flowers in dense, sessile, terminal clusters.—Found in Guadaloupe.

Hedypnois; a genus of the class Syngenesia, order Polygamia Equalis.—GENERIC CHARACTER. *Calix*: common calicled, cylindrical, ten-leaved or thereabouts, permanent; scales linear, erect, acute, equal; calicled at the base, with fewer, narrower scales, which are short and close. *Corolla*: compound, subimbricate, uniform; corollules hermaphrodite, many. Proper monopetalous, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubulous. *Pistil*: germen oblong; style filiform, length of the stamina; stigmas two, reflex. *Pericarp*: none; common calix hardened, converging, almost globular, covering the marginal seeds with its scales. *Seeds*: solitary, somewhat oblong, bowed in a little, streaked, roughish, the length of the calix. The outer crowned, with the calicle membranaceous, erectish, obscurely five-cornered, toothletted; pappus none. The inner crowned, with the calicle obscure, many-bristled, very short, within which is a pappus of five erectish awned chaffs. *Receptacle*: naked. ESSENTIAL CHARACTER. *Calix*: calicled, with short scales. *Seeds*: crowned with the calicle; outer without down, covered up in the scales of the calix; inner having a down of five erectish awned chaffs. *Receptacle*: naked, hollow, and dotted.—This genus embraces some species of *Hyoseris* and of *Crepis*; and, according to Jussieu, *Lapsana Zacintha*. For Hudson's

species of *Hedypnois*, see *Apargia*. See also *Leontodon* and *Tragopogon*, to which this genus is nearly allied.

Hedysarum; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, half five-cleft; clefts subulate, upright, permanent. *Corolla*: papilionaceous, streaked; banner reflex-compressed, ovate-oblong, emarginate, long; wings oblong, narrower than the other petals, straight; keel straight, compressed, broader outwardly, transversely blunt, from the base to the swelling part bifid. *Stamina*: filamenta diadelphous, simple, and nine-cleft, bent in at a right angle; antheræ roundish, compressed. *Pistil*: germen slender, compressed, linear; style subulate, bent in with the stamina; stigma very simple. *Pericarp*: legume with roundish compressed joints; two-valved, and containing one seed. *Seed*: kidney-shaped, solitary. *Observe*. The pericarp differing in this genus has occasioned its being unnaturally separated into several genera. ESSENTIAL CHARACTER. *Corolla*: keel transversely obtuse. *Legume*: jointed, with one seed in each joint.—The species are,

* *With simple Leaves.*

1. *Hedysarum Alhagi*; *Prickly Hedysarum*. Leaves lanceolate, obtuse, very smooth, pale green, on short footstalks; stem shrubby, thorny, about three feet high, branching out on every side. From under the leaves come out thorns nearly an inch long, of a reddish-brown colour. The flowers come out from the side of the branches in small clusters; they are purple in the middle, and reddish about the rims; legumes sickle-shaped.—Native of the Levant. This plant produces the manna used in Persia, very different from that of the flowering Ash, which is the common kind. The drug is principally collected about Tauris; and is known by the name of *trungibin*, or *terenjabin*. It is a natural exudation from the leaves and branches, which takes place only in very hot weather: at first it resembles drops of honey, but soon thickens into little solid grains.—It is propagated by seeds, which will frequently lie a year in the ground before they vegetate: sow them therefore in pots filled with light earth, and plunge them into a moderate hot-bed: if the plants do not appear by the beginning of June, take the pots out of the bed, and place them where they may have only the morning sun, and in the autumn plunge them into an old bed of tanners' bark under a frame; in spring plunge them in a fresh hot-bed, which will bring up the plants; when they are fit to remove, put them separately into small pots filled with light earth, and plunge them into a very moderate hot-bed, shading them from the sun till they have taken new root; then gradually inure them to the open air, into which remove them in June, placing them in a sheltered situation, where they will remain till the autumn; when they ought to be plunged into an old tan-bed under a frame, where they may be protected from frost, and in mild weather enjoy the free air. In a warm border, by covering it in frosty weather, this plant will endure our winters when they are not severe.

2. *Hedysarum Bupleurifolium*; *Hare's-ear-leaved Hedysarum*. Leaves lanceolate, acute; stem unarmed; stipules scarious, the length of the petioles; legumes even-jointed, upright, equal. It varies with lanceolate and cordate-oblong leaves.—Native of India. This, and the seventeen following species, are all too tender to endure the open air of our climate. They are propagated by seeds, which must be sown upon a hot-bed early in the spring. When the plants are fit to remove, they must be each planted in a separate small pot, filled with light earth, plunging them into a fresh hot-bed, where they should be screened from the sun till they have taken new root; after which they may be treated in the same manner as other tender plants; always keeping them in the

bark-stove or glass-case, otherwise they will not produce seeds, nor even always flower, in England. They require as much air as possible in warm weather. Many of the sorts seldom flower till the second year.

3. *Hedysarum Linifolium*; *Flax-leaved Hedysarum*. Leaves linear; hoary; stem prostrate; racemes very short, axillary; legumes globular, small, snow-white, with a permanent style, one-jointed.—Native of the East Indies.

4. *Hedysarum Nummularifolium*; *Moneywort-leaved Hedysarum*. Leaves wedge-shaped; stems long, angular, diffused; stipules awl-shaped, longer than the petiole, patulous, very small, clothing the stem; spikes solitary from the axils, on a long peduncle; flowers very small; the legumes declined, crescent-shaped, hispid on the back, containing one seed.—Native of the East Indies.

5. *Hedysarum Moniliferum*; *Necklace Hedysarum*. Leaves orbiculate; legumes necklace-shaped, globular, jointed; stems a span long, prostrate; stipules two-parted, streaked, sharp, scarioso; heads of flowers axillary; perennial.—Native of the East Indies.

6. *Hedysarum Styrcifolium*; *Storax-leaved Hedysarum*. Leaves cordate, orbiculate, retuse, smooth on the upper surface, tomentose underneath; stem shrubby, and, like the whole plant, villose; stipules lanceolate.—Native of China.

7. *Hedysarum Reniforme*; *Kidney-leaved Hedysarum*. Leaves kidney-shaped; stem columnar, annual, a foot and a half high, branched, slender, smooth, procumbent; flowers violet-coloured, in terminating spikes or racemes, consisting of few flowers.—Native of India, and the suburbs of Canton in China.

8. *Hedysarum Sororium*. Leaves kidney-shaped, emarginate; stem three-sided, herbaceous, sarmentose, smooth, a foot high; petiole almost the length of the leaf; stipules two, oval, small, petioled at the base of the petioles, so that the leaves might in strictness be looked upon as ternate.—Native of the East Indies.

9. *Hedysarum Vespertilionis*; *Bat-winged Hedysarum*. Leaves simple and ternate, somewhat crescent-shaped, variegated, yellow, red, and green; middle leaflets two-lobed; lobes lanceolate, divaricate; legumes plaited; stem four feet high, upright, very straight, almost simple, round, but four-cornered at the top, furrowed, hispid with very fine hairs, frequently having one or two short upright branchlets; flowers in a simple, long, upright, terminating spike or raceme; corolla white; banner broad, cordate, converging, a little longer than the calix; wings bent in, shorter than the banner, keel of an intermediate length.—It is a native of Siam, from whence it has been carried into Cochin-china, where it is cultivated for its beauty, for in a gentle breeze the leaves as they move resemble as many variegated butterflies.

10. *Hedysarum Gangeticum*; *Oval-leaved Hedysarum*. Leaves ovate, acute, stipuled. This is an annual plant, about three feet high, having a slender stalk, inclining to be shrubby; flowers minute, in long terminating spikes; banner and keel of the corolla yellow; wings violet-coloured.—Native of India and the suburbs of Canton.

11. *Hedysarum Maculatum*; *Spotted Hedysarum*. Leaves ovate, obtuse; stems several, from a band to a long span and a foot in height, either upright or declining, round, slender, roughish with slender hairs, pressed close; flowers on the upper part of the stalk, in pairs one above another, or sometimes three together, on very slender peduncles, forming a long thin spike, in which each pair of flowers is placed in a contrary situation to the next.—Native of the East Indies.

12. *Hedysarum Latebrosum*. Leaves ovate, serrulate; legumes hid by a vaulted, supine, scarioso bracte; stem some-

what shrubby, naked, with a few wand-like divaricate round branches; flowers axillary, peduncle very short, two-flowered, with a leafy bracte, resembling a dry wrinkled leaf, and defending the legume from birds.—Native of India.

13. *Hedysarum Vaginale*; *Sheathed Hedysarum*. Leaves cordate-lanceolate; petioles simple; stipules sheathing. This plant is annual, herbaceous, and procumbent; stipules acuminate; spikes towards the ends of the stems long and narrow; branches few; legumes cylindric, smooth-jointed, straight, dividing by joints, though they are scarcely apparent on the outside, and there are no divisions within.—Native of India.

14. *Hedysarum Glumaceum*. Leaves simple, lanceolate; stipules and calices scarioso; legumes wrinkled, perennial; stems woody, procumbent, wand-like, round, smooth, a foot high; raceme terminating, when in flower two inches long, when in fruit elongated; flowers usually in pairs, seldom solitary.—Native of the Cape of Good Hope.

15. *Hedysarum Imbricatum*; *Imbricate-leaved Hedysarum*. Leaves cordate, sessile, stipuled, the upper ones imbricate, flower-bearing; stems herbaceous, filiform, diffused, branched; flowers among the upper leaves, solitary, sessile, shorter, hid by the leaves.—Native of the Cape of Good Hope.

16. *Hedysarum Triquetrum*; *Triangular-branched Hedysarum*. Leaves oblong; petioles winged; branches three-sided; stems many, perennial, shrubby, procumbent, three feet long, with three side-branches; flowers purple, in spikes or racemes, mostly terminating; banner roundish. In the Cochin-chinese plant, the leaves have not rounded margins, nor refracted petioles, as the plant of Ceylon has; they have both lanceolate stipules, and the stem inclining to red at the end. The Chinese call it *Kasongso*.—Native of India, China, and Cochin-china.

17. *Hedysarum Strobiliferum*; *Strobile-bearing Hedysarum*. Bractes of the strobiles inflated, cordate, obtuse. This is a tree, with oblong-ovate alternate leaves, quite entire, and petioled; stipules subulate; branches round. There are strobiles from the axils of the leaves, as in the Hornbeam, on a simple flexuose peduncle.—Native of India.

18. *Hedysarum Gramineum*; *Grass-leaved Hedysarum*. Leaves linear, lanceolate; stipules scarioso; racemes naked; pedicels two-flowered; teeth of the calix bearded. This shrub is determinately branched; stems round, stiff, jointed; racemes stiff, elongated, leafless; peduncles in pairs, one-flowered, distant; corolla small, purple.—Native of India.

** *With conjugate Leaves.*

19. *Hedysarum Diphyllum*; *Two-leaved Hedysarum*. Leaves binate, petioled; bractes in pairs, ovate, acute, sessile; annual; stem herbaceous, procumbent, filiform, round, smooth; peduncles axillary, terminating, longer than the leaves, upright, stiff, many-flowered; flowers alternate, on very short pedicels, between two opposite bractes, acuminate at both ends; corolla yellow or purple.—Native of Jamaica, South America, and the East Indies.

*** *With ternate Leaves.*

20. *Hedysarum Adscendens*. Leaves roundish, pubescent underneath; stem columnar; branches declined, ascending, hairy; racemes simple, erect, axillary.—Native of Jamaica.

21. *Hedysarum Pulebellum*. Bractes in pairs, conjugate, orbiculate, marked with lines; stem shrubby, upright, three feet high, round, smooth; branches many, oblique, obtusely angular; spikes of flowers long, straight, terminating; corolla yellow; legume flat, straight, acuminate, composed of two joints defended by the bractes.—Native of India and China.

22. *Hedysarum Elegans*. Leaves obtuse, tomentose on both sides; bractes conjugate, ovate; legumes bowed; stem

somewhat shrubby, upright, three feet high, branched; spikes upright, mostly terminating; flowers heaped, yellow, each with two hairy bractes, marked with lines.—Native of China, near Canton.

23. *Hedysarum Spartium*. Leaves ternate and simple, somewhat tomentose; stem dichotomous; flowers in pairs; legumes jointed, hispid. This is a whitish plant, with shrubby variegated stems, very short blunt stipules, and oblong leaves; flowers scattered, subpedicelled, in pairs or solitary; corolla yellow, with the claw the length of the calix, and the border flat.—Native of India.

24. *Hedysarum Lineatum*. Leaves oblong, marked with lines; racemes axillary, pendulous; stem straight; legumes rhomb-shaped, of one joint only, with one seed.—Native of Ceylon.

25. *Hedysarum Supinum*. Leaves ovate, bluntish, hoary-villose underneath; stem branched, procumbent; racemes simple, erect, terminating; root long, small, woody. Stems a foot long, reddish, rough, round, woody; corolla purple; legumes crooked, forming a semicircle, brown; the joints united by so small an isthmus, that when they adhere by their roughness to the clothes, they separate; whence the Portuguese name of *Erva de Amor*, or Love-Herb.—It grows almost every where in the woods of Jamaica.

26. *Hedysarum Canum*. Leaves ovate, acuminate, hoary underneath; stem columnar, branched, erect; racemes terminating, erect; legumes declined, rough with hairs. The stalks are terminated by long spikes of small purple flowers, which are succeeded by narrow pods, straight on one side, but jointed on the other.—Native of Jamaica and Hispaniola.

27. *Hedysarum Retroflexum*. Racemes erect; legumes pendulous, many-jointed, compressed, with one edge repand, and from four to seven joints; leaflets ovate, tomentose, underneath silky.—Native of India.

28. *Hedysarum Trigonum*. Leaves ovate, acute, rough with hairs; stem climbing, three-sided; racemes very long, axillary; legumes writhed, bent in. It is a climber, and raises itself generally to the top of the tallest trees in the wood. The stem is every where beset with small hooked bristles or rough hairs. The leaves are much like those of the Kidney-bean; and all the branches terminate in a large and beautiful flower-spike.—Native of Jamaica.

29. *Hedysarum Umbellatum*. Peduncles umbelliferous; stem shrubby. This shrub has woody branches, the lower ones round and brown, the upper ones angular and villose; peduncles axillary, solitary, shorter than the petioles; flowers white.—Native of India, Tanna, and New Caledonia.

30. *Hedysarum Biarticulatum*. Stem undershrubby; legumes two-jointed; leaves like those of Trefoil, with ovate-oblong smooth leaflets, almost equal; flowers in spikes.—Native of India and China.

31. *Hedysarum Lappaceum*. Leaves ternate, obcordate; flowers axillary, subsolitary; legumes two-jointed, with hooked bristles; stems suffruticose, prostrate, pubescent, round, the thickness of a pigeon's quill, very much branched; stipules minute, awl-shaped; flowers on short peduncles, solitary, seldom two together; germen villose.—Native of the East Indies.

32. *Hedysarum Heterocarpon*. Flowers panicle-spiked; legumes jointed, the lowest one-seeded; stipules bristle-shaped; stems round, herbaceous; spike of flowers narrow. There is a variety which is more procumbent, with blunter leaflets: the lowest legumes of this are not always one-jointed.—Native of Ceylon, China, Japan, and the Society Isles.

33. *Hedysarum Viscidum*. Legumes membranaceous, even, entire; stem and branches hispid. The upper branches are

hispid, with spreading viscid hairs; leaves on longish petioles; leaflets broad, from round inclined to rhomb-shape.—Native of India.

34. *Hedysarum Scorpiurus*. Leaves oblong, hirsute underneath; stems procumbent, three-cornered; racemes axillary; legumes roundish, upright. This plant grows in tufts, and seldom rises above sixteen or seventeen inches from the root.—Native of Jamaica and Hispaniola.

35. *Hedysarum Canadense*; *Canadian Hedysarum*. Leaves simple and ternate; stem even; flowers racemed. This is an upright plant, and mostly smooth; stem streaked, and angular; leaflets lanceolate; stipules awl-shaped. It is perennial. A native of Virginia and Canada, where it is found flowering in July and August.—The seeds of this plant may be sown in the beginning of April, in a light fresh earth. When the plants are come two inches high, they should be transplanted where they are to remain for good; but if they are not too thick in the seed-bed, they may be suffered to remain there until the following autumn, at which time they should be carefully taken up, and transplanted into the borders where they are designed to stand; for their roots generally run down very deep, so that it is unsafe to remove them often. This plant produces its flowers about the same time of the year as the former, and, if the season proves favourable, perfects its seeds in autumn; and the roots will abide in the open air very well, resisting the severest cold, provided they be planted in a dry soil.

36. *Hedysarum Gyran*; *Sensitive Hedysarum*. Leaves oval-lanceolate, obtuse, the lateral ones minute; racemes terminating and axillary, rather simple, many-flowered, long; leaflets pubescent; flowers nodding; bractes solitary, membranaceous, cordate, under the flowers deciduous; calix erect, two-lipped; upper lip trifid, lower with two smaller contiguous teeth; banner of the corolla largish, roundish, entire, brown with dusky streaks; wings connected with the keel by their upper edge, brown; keel longer than the wings, bifid at the base and tip, compressed, ferruginous; legume on a short pedicel, compressed, channelled on the back, crenate in front, gaping, containing five or six kidney-form oblong seeds. The leaves are of a bright green, with the middle part of a more glaucous appearance than the rest. This is a wonderful plant, on account of its voluntary motion, which is not occasioned by any touch, irritation, or movement in the air, as in *Mimosa*, *Oxalis*, and *Dionæa*, nor is it so transitory as in *Amorpha*. No sooner, says Linneus, had the plants raised from seed acquired their ternate leaves, than they began to be in motion this way and that; this movement did not cease during the whole course of their vegetation, nor were they observant of any time, order, or direction; one leaflet frequently revolved, whilst the other on the same petiole was quiescent; sometimes a few leaflets only were in motion, then almost all of them would be in movement at once: the whole plant was very seldom agitated, and that only during the first year. It continued to move in the stove during the second year of its growth, and was not at rest even in winter. Swartz observes, that the motion is irregular, and that it sometimes ceases entirely; that it is immovable in a very hot day, being only slowly agitated in the evening. In our climate, the leaves in general only make a feeble attempt at exerting this extraordinary faculty towards the middle of the day. We are at a loss to account for this motion, which does not depend upon any external cause that we can trace, and which we are not able to excite by any art that we possess. It is not the action of the sun's rays, for the plant is fond of shade, and the leaves revolve well on rainy days, and during the night: exposed to too much wind

or sun, it is quiet. Perhaps, says Linneus, there may be some part in vegetables, as in animals, where the cause of motion resides.—It is a native of Bengal, near the Ganges; and is there called *Buram chadali*, or *Burram chadali*. It grows luxuriantly in the gardens of Jamaica.

37. *Hedysarum Canescens*; *Rough-leaved Hedysarum*. Leaves scabrous underneath; stem hispid; flowers racemed, conjugate. This is an upright hairy plant; the leaflets are ovate; stipules awl-shaped, subcordate; flowers white.—Native of Virginia.

38. *Hedysarum Repandum*. Leaves ternate, repand-crenate; racemes terminating, elongated. The stem is woody, round, purplish, pubescent at top; leaflets on a short petiole, ovate, unequal; petioles two inches long, pubescent, jointed, and thicker at the base, with two bristle-shaped scales between the leaflets; stipules lanceolate, ciliate; peduncle terminating, erect, half a foot long; flowers very remote, purple, before they open drooping; legume linear.—Native of Arabia.

39. *Hedysarum Adhærens*. Leaves ternate, oblong; racemes axillary; legumes cylindric, jointed, villose; stems weak, simple, three-sided, somewhat hairy; leaflets petioled, an inch long, the side ones smaller, having long hairs thinly scattered over both surfaces, and pressed close to them; petioles an inch and a half long, hairy.—Native of the West Indies.

40. *Hedysarum Marilandicum*; *Maryland Hedysarum*. Leaves roundish; stem frutescent, branched very much; legumes jointed, even; root perennial; flower-stems squarish and roughish, with small flowers, distant from each other, in two long rows, on short slender peduncles; corolla purple fading to blue; banner broadish, first concave, then spreading, having greenish spots at the base; wings applied to the keel, of a purple colour; keel compressed, whitish towards the base.—Native of Virginia, Carolina, and Maryland.

41. *Hedysarum Tortuosum*; *Twisted-podded Hedysarum*. Leaves oval-oblong, obtuse, smoothish; racemes erect, axillary; legumes twisted, compressed, pubescent. It grows erect, and rises generally to the height of two feet and a half or more; flowers in spikes thinly placed, on pedicels half an inch long; corolla of a pale purple colour.—It is common in the remote hills and inland parts of Jamaica, Santa Cruz, and Vera Cruz.

42. *Hedysarum Spirale*; *Spiral-podded Hedysarum*. Leaves ovate, obtuse, smooth; stem very much branched, with diffused branches; racemes loose, divaricate; legumes spirally twisted; flowers small, of a pale purplish colour. Annual.—Native of Jamaica.

43. *Hedysarum Frutescens*. Leaves subovate, villose underneath; stem frutescent; root perennial; flowers at the ends of the branches in short spikes, purplish-yellow and small.—Sent by Dr. Dale from South Carolina. This may be raised in the same manner as directed for the second species. In summer the plants may be exposed to the open air, but in the autumn they must be placed under a frame to screen them from frost; the following spring some of these plants may be shaken out of the pots, and planted in a warm border, where, if the summer prove warm, they will flower, but these seldom perfect their seeds; therefore two or three plants should be put into larger pots, and plunged into a moderate hot-bed, which will bring them early to flower, and if the glasses be kept over them in bad weather, these will ripen their seeds in autumn; and the roots will continue some years, if screened from frost in winter.

44. *Hedysarum Axillare*. Leaves rhomboid-rounndish; stem creeping, rooting; petioles upright; scapes axillary,

longer than the leaves. This runs many feet from the main roots, commonly casting a few fibres from all the joints that touch the ground, which greatly forwards its luxuriant growth. The leaves are marked with some prominent veins on the under side, and are seldom less than an inch and a half in length.—Common in the shady hills of Jamaica and St. Domingo.

45. *Hedysarum Viridiflorum*; *Green-flowered Hedysarum*. Leaves sharpish; stem upright; racemes very long, upright; perennial.—Native of North America.

46. *Hedysarum Hirtum*. Leaves oval; stem shrubby; spikes oblong; calices and fruits hirsute, one-seeded; legumes of one joint, ovate-acute. In gardens, the first year it bears mutilated flowers, and yet is fruitful. The second year the corollas are white.—Native of Virginia.

47. *Hedysarum Junceum*; *Slender-branched Hedysarum*. Leaves lanceolate; legumes one-jointed, rhomb-shaped; peduncles subumbelled, lateral; root perennial; stem herbaceous, two feet high, rushy, wand-like, round, somewhat furrowed, smooth, somewhat pubescent towards the end; branches of the same length and structure with the stem, alternate, few; flowers in pairs, erect, pedicelled; corolla white; banner broad, roundish, scarcely emarginate, with blood-red streaks at the base; wings ovate, rounded at the tip; keel bifid from the tip to the middle; the lobes rounded. It flowers in July and August.—Native of India.

48. *Hedysarum Violaceum*; *Violet-flowered Hedysarum*. Leaves ovate; flowers in pairs; legumes naked, veined, jointed, rhomb-shaped; flowers violet-coloured, in pairs, usually connected by their proper pedicels, in some glomerate from the axils of the leaves, in others fixed here and there on filiform peduncles.—Native of North America.

49. *Hedysarum Paniculatum*; *Panicled Hedysarum*. Leaves linear-lanceolate; flowers panicled; legume rhomb-shaped; flowers purple.—Native of Virginia.

50. *Hedysarum Nudiflorum*; *Naked-flowered Hedysarum*. Flowering-stem naked; leafy stem angular; flowers purple.—Native of Virginia.

51. *Hedysarum Repens*; *Creeping Hedysarum*. Leaves obcordate; stems procumbent; racemes lateral; flowers variegated red and white, or sometimes white only, on long axillary upright peduncles, disposed in a small spike; legumes short, acuminate, smooth, compressed, containing one very small ovate seed.—Native of both Indies.

52. *Hedysarum Hamatum*; *Hook-podded Hedysarum*. Leaves nerved, naked; spikes sessile; legumes two-seeded, covered, having a hooked point; root long, deep; stems many, round, hairy, from seven or eight inches to a foot in length, creeping, branched; leaflets small, smooth, shining, ciliate, having many beautiful white nerves on the under surface. The flowers come out towards the top; they are of an orange colour, with a little purple in the middle.—Native of Jamaica, Hispaniola, and Ceylon. There is a variety, the stems of which are from one to two feet in length, shrubby, gray, branched into many twigs, which are green and hoary; leaflets purple on the edge, having purple spots on their backs, and a down of the same colour; petioles half an inch long; flowers on the tops of the twigs, yellow, several opening successively. Swartz makes it a distinct species under the name of *Stylosanthes Viscosa*.—Native of Jamaica and Ceylon.

53. *Hedysarum Triflorum*. Leaves obcordate; stems procumbent; peduncles one-flowered, seldom three together; roots simple, long; flowers minute, scarlet; legume small, peduncled, crenate in front, containing three or four seeds, which are roundish and minute. It wakes at ten o'clock in

the morning, and sleeps at four in the afternoon.—Native of both Indies and China. There is a variety of this species found in Ceylon and China.

54. *Hedysarum Barbatum*; *Bearded Hedysarum*. Racemes oblong, somewhat branched; legumes bent in; calices hairy; stem procumbent, from three to five inches in length, branched, round, somewhat shrubby at the base, even; branches procumbent, almost simple, short, round, pubescent; flowers terminating in a sort of spike, comose; peduncles long, two, approximating, filiform; the flowers nodding, pale blue.—Native of Jamaica, in the dry sandy parts.

55. *Hedysarum Lagopodioides*. Racemes oblong; legumes bent in; calices hirsute; stem undershrubby, upright, two feet high, round, hispid, with diffused branches; flowers dark purple, in oblong, dense, very hirsute, terminating spikes; seeds flattish, brown, even, small.—Native of China and New Caledonia.

56. *Hedysarum Microphyllum*. Leaves ovate, villose; stem frutescent, upright, smooth; flowers terminating, panicled; petioles capillary, purple, smooth; flowers on capillary pedicels, alternate or subdichotomous, flexuose, purple, hispid; corolla purple.—It flowers in August and September, and is a native of Japan.

57. *Hedysarum Racemosum*. Leaves oblong, stipuled, smooth; stem frutescent, upright; racemes axillary, upright, very long; legumes smooth. Racemes a hand or more in length, from upright spreading, capillary, smooth, often several; pedicels solitary or in pairs, one-flowered, very short, capillary.—Native of Japan.

58. *Hedysarum Caudatum*. Leaves oblong, smooth; stem herbaceous; panicle terminating; calix hirsute; corolla purple; legume almost linear, with ferruginous down on it.—Native of Japan.

59. *Hedysarum Tomentosum*. Leaves tomentose underneath; stem angular, tomentose; racemes axillary. The whole plant, except the surface of the leaves, is tomentose; stipules two, at the base of the petiole, broad at the base, bristle-shaped.—Native of Japan.

60. *Hedysarum Sericeum*. Leaves emarginate, villose; stem frutescent, upright; flowers axillary, solitary, on very short peduncles; stipules bristle-shaped; calices silky, tomentose. It flowers in September and October.—Native of Japan.

61. *Hedysarum Virgatum*. Leaves obtuse, with a point; stem angular, hairy; peduncles capillary, three-flowered: it is herbaceous, with hairy angles, upright, purplish; branches alternate, filiform, angular, hairy, from erect spreading, wand-like; flowers axillary; peduncles hairy, three-flowered at the tip, from spreading reflex, an inch long.—Native of Japan.

62. *Hedysarum Pilosum*. Leaves ovate, acuminate; stem decumbent, rough with hairs; racemes axillary; each raceme has about four flowers; peduncle capillary, scarcely the length of the petiole; corolla purple. It flowers in September.—Native of Japan.

63. *Hedysarum Striatum*. Leaves oblong, stipuled; stem herbaceous; flowers axillary, solitary; stipules at the base of the petiole, ovate, membranaceous, ferruginous, pressed close; flowers single, on very short peduncles from the axils of the leaves; calix hairy; corolla purplish.—Native of Japan.

64. *Hedysarum Volubile*; *Twining Hedysarum*. Leaves ovate-oblong; stem twining; root perennial; spikes of flowers axillary, on very long, slender, smooth, peduncles; flowers distant, two or three together, generally opposite; banner broadish, first concave, then flat, and bent back, with a green-

ish spot at the base; wings of a middling length, applied to the keel, which is compressed and cuspidate; the whole of a very lively purple, except in the hidden parts of the banner, which changes to an obscure dun colour.—Native of North America.

65. *Hedysarum Triangulare*. Leaves ovate, acute, marked with lines; all the nerves underneath, with the midrib above, are very tomentose; umbels axillary; branches three-sided, flexuose; flowers small, sessile, in a peduncled axillary umbel; angles of the branches tomentose.—Thunberg gathered it in Java.

**** *With pinnate Leaves.*

66. *Hedysarum Argentatum*; *Silvery Hedysarum*. Leaflets silky underneath, and shining; legumes jointed; stem leafless; scapes the length of the leaves, or higher, somewhat tomentose, white; spike terminating; calicine leaves near the length of the corolla, which is violet-coloured or white, with the wings shorter than the banner; the legume consists of two or three lanuginous joints, enveloped in the dry flower.—Perennial, and a native of Siberia.

67. *Hedysarum Alpinum*; *Alpine Hedysarum*. Legumes jointed, smooth, pendulous; stem upright, somewhat shrubby, round, simple, branched; flowers yellow, in small upright racemes.—Native of Siberia and Cochinchina.

68. *Hedysarum Obscurum*; *Creeping-rooted Hedysarum*. Stipules sheathing; stem upright, flexuose; flowers pendulous; root perennial, creeping; root-leaves on the flowering plant none; stem-leaves few, alternate; leaflets three to eight on each side, with an odd one, ovate, oblong; flowers eight lines in length, imbricate, pendulous, on short peduncles, varying in number, having no scent; corolla violet-purple or red, seldom white; banner spotted with white above the claw; that and the wings nearly of the same length; the keel shorter; germen commonly red.—It flowers on the higher Alps, of which it is a native, in July.

69. *Hedysarum Coronarium*; *Common Hedysarum*, or *French Honeysuckle*. Legumes jointed; prickly, naked, straight; stem diffused; root biennial. From the angles which the leaves form with the stem and branches, peduncles come out five or six inches in length, sustaining spikes of beautiful red flowers, which open in June and July, and perfect seeds in September, after which the roots commonly decay; but if the plants be cut down before they seed, they will last longer.—It is a native of Spain and Italy. Ray observed it in Sicily. In Calabria it grows wild in great luxuriance, near four feet high, affording excellent nourishment to horses and mules, both green and made into hay; but it does not endure the spring well in the north of Italy; and on that account we may reasonably infer that it could not be profitably cultivated in England. Osbeck mentions, that he saw it brought into Cadiz in great bundles, as food for the cattle. In German, French, Italian, and Spanish, it has the name of *Sulla*; the Germans also call it *Kronenkleee*, *Schildkleee*, and *Spanische Klee*: The French also use the names of *Sainfoin d'Espagne*, and *Sainfoin à bouquets*; and the Dutch call it *Sierlyk haanekop*. In England it was formerly called *Red Satin-Flower*, or *Red-flowered Fitchling*, as well as *Red* or *French Honeysuckle*, the name it still retains.—It may be propagated by sowing the seeds in April, in a bed of light fresh earth; and when the plants come up, they should be transplanted into other beds of the like earth, and in an open situation, at about six or eight inches' distance from each other, leaving a path between every four rows, to go between them to hoe and clear them from weeds. In these beds they may remain till Michaelmas, and may be then transplanted into the large borders of a parterre or pleasure-garden, allowing

them at least three feet distance from other plants, amongst which they should be interspersed, to continue the succession of flowers; where they will make a fine appearance when blown, especially the red sort, which produces very beautiful flowers. As these plants decay after they have perfected their seeds, there should annually be a fresh supply of plants raised, where they are desired, for the old roots seldom continue longer. They are very proper ornaments for large borders, or to fill up vacancies among shrubs; but they grow too large for small borders, unless their stalks are pruned off, leaving only two or three on each plant, which, if kept upright with sticks, will prevent their hanging over other flowers.

70. *Hedysarum Flexuosum*; *Waved-podded Hedysarum*. Legumes jointed, prickly, flexuose; stem diffused. The stalks rise nearly a foot high, and the leaves are composed of two or three pairs of ovate leaflets, terminated by an odd one. The flowers come out in spikes at the tops of the stalks, and are of a pale red, intermixed with a little blue. They appear in July, and are succeeded by jointed pods, which are waved on both sides, forming an obtuse angle at each joint; the seeds ripen in autumn.—Native of the Levant. This and the two following species should be sown in April where they are to remain, and require only to be thinned where they are too near, and kept free from weeds.

71. *Hedysarum Humile*; *Dwarf Hedysarum*. Legumes jointed, rough; wings of the corolla obsolete; spikes hirsute; stems depressed, half a foot in length, usually with one branch and leaf only; root perennial; leaflets obovate, oblong, villose underneath. It is an annual plant, and flowers in July and August.—Native of the south of France and Spain. See the preceding species.

72. *Hedysarum Spinosissimum*; *Prickly Hedysarum*. Legumes jointed, prickly, tomentose; stem diffused; annual. The legume has generally two orbicular joints equally prickly; the stem is terminated by small spikes of purple flowers, which are succeeded by small rough legumes.—Native of Spain and Portugal. See the 70th species.

73. *Hedysarum Virginicum*. Stem shrubby; legumes jointed, smooth, peduncled, upright; leaflets oblong, blunt, small, many; flowers violet-coloured, in terminating spikes. The legumes are slender, with roundish, flattened seeds.—Native of Virginia and Cochinchina.

74. *Hedysarum Fruticosum*. Leaflets alternate, oblong, soft; stipules subulate; racemes axillary; joints of the legumes netted; corollas purple; legumes flattened, with the joints wrinkled and netted. It is a very handsome plant, grateful to horses, and extremely useful in fixing driving sand.—Native of Siberia.

75. *Hedysarum Pumilum*. Stem undershrubby; wings shorter than the banner, and banner shorter than the keel; legumes one-seeded. This is a small shrub, only a hand in height; spike smooth; banner half the length of the keel, which is very large, broad, and blunt; calix even, with very short awl-shaped teeth.—Native of Spain.

76. *Hedysarum Argenteum*. Leaves pinnate; legumes one-seeded, wrinkled; spikes ovate, very hairy; stems erect, hairy; root-leaves simple; petiole elliptic, the next ternate; flowers crowded; cauline peduncles axillary, elongated, higher than the stem, tomentose, hoary at top; corolla purple, half the length of the calix; banner orbiculate; wings minute.—Native of the Levant and Barbary.

77. *Hedysarum Onobrychis*; *Cultivated Hedysarum*, *Saintfoin*, or *Cock's Head*. Legumes one-seeded, prickly; wings of the corolla equal in length to the calix; stem elongated; root perennial; peduncles long, slightly hairy, bear-

ing numerous flowers in a long spike, thickly imbricate upwards, each with an awl-shaped bracte, longer than the pedicle; corolla standard oval, slightly emarginate, partly bent back, shorter than the keel, flesh-coloured, striated with red veins; wings not longer than the teeth of the calix, hooked near the base, pale flesh-colour; keel broad, bent with an obtuse angle at the top, flesh-coloured, with a deeper red beneath. It is much cultivated in several parts of Europe, in dry soils, for feeding cattle; and is found in England on Gogmagog hills, Newmarket heath, about Royston in Norfolk, on Salisbury plain, in Cambridgeshire, Hertfordshire, on Epsom downs, Cotswold hills, about Malton in Yorkshire, and generally in all other hilly situations and calcareous soils. It yields great abundance of excellent fodder, but is supposed to be much sooner damaged by rain, when cut, than any other sort of plant usually mown for hay. The old English names were *Medick Vetchling*, and *Cock's Head*. The modern name of *Saintfoin* came from France, whence we originally had the seed. The Germans have many names for it: they call it *Espazette*, *Esper*, *Sparsette*, *der Gemeine Sussklee*, *Hahnenkopf*, *Hahnenkamm*, *Hahnen Kammklee*, *Grosser Turkischer Klee*, *Turkischer Kleberklee*, *Schweizerklee*, *Wickenklee*, *Eselswicken*, *Heilighen*, *Stachelheu*; *Stachelahre*, *Weidhopsfenkraut*, *Gurtriemen*, *Frauenspiegel*, *rothe Ransen*, *Sainfoin*. The Dutch call it *Haanckammeetje*: the Swedes and Danes, *Esparsset*, and *Sainfoin*: the French *Sainfoin*, (*Saintfoin*), *Esparcette*, *Foin de Bourgogne*: the Italians, *Cedrangola*: the Spanish and Portuguese, *Pipirigallo*.—Native of England, France, Flanders; many parts of Germany, as the Palatinate, Bohemia, Silesia; in Austria, Carniola, Switzerland, Savoy, Italy, Spain, Siberia; on hilly pastures, and open downs, particularly in a calcareous soil. If sown upon a dry, gravelly, or chalky soil, it will continue eighteen or twenty years; but on a deep moist soil the roots will run down into the ground, and in the winter season the moisture will rot them; so that it seldom lasts two years in such places. It is esteemed one of the best sorts of fodder for most cattle, and is a great improvement to chalky hills, upon which it succeeds better than in any other soil, and will continue many years, provided there be a surface of six or eight inches upon the chalk. The best time for sowing the seed is the beginning or middle of April, according to the season, observing always to do it in dry weather, otherwise the seeds will be apt to burst, and never come up. The seed being large, the common allowance is four bushels to an acre, but three bushels are amply sufficient. If it were sown in rows, as directed for Lucerne, it would be a great improvement to the plants; for, when these have room enough, they branch out on every side, and become very strong; and by hoeing between them the natural grass may be kept down, which, if permitted to grow, will rob the Saintfoin of its nourishment, and in time destroy it. Saintfoin is frequently sown with Oats or Barley, but this is a very bad method, for what is gained from the crop of corn, will be doubly lost in the Saintfoin; and this generally holds true in most sorts of grass-seeds, for the corn growing over it, so weakens the crop beneath, that it scarcely recovers its strength in a year after. The ground in which the seed is sown should be well ploughed, and made very fine. If it be sown in drills, the drills should be eighteen inches asunder, and about an inch deep; if the plants come up too thick, they should be hoed out to the distance of six or eight inches, when the ground is hoed to destroy the weeds. The first year, by no means feed the crop down; for, the crown of the roots being young and tender, cattle would eat it so low as entirely to destroy the

roots; and, if large cattle were let in upon it, they would trample it down so much as to prevent its shooting again; the first year therefore it should be mowed, and this should be done when it is in flower. The sooner it is carried off the ground when cut, the better it will be for the plants. It does not require to be so often turned as other hay, for the stalks being large they will not lie so close in the cocks as to ferment; in catching-weather, therefore, the cocks may be made large, and, if they be turned and spread every other day, or once in three days, there will be little danger of its heating so as to receive damage; but if it be spread, and much exposed to rain and dew, the goodness of the hay will be exhausted. The crop will be fit to cut the first year towards the end of July, or at the beginning of August. After this is cleared off, the roots will soon shoot again, and by the end of September, provided the season be favourable, there will be a fine crop fit for feeding. Sheep will enrich the ground with their dung, and greatly strengthen the roots; but they should not be suffered to remain upon it longer than the middle of November the first year; and the succeeding years, when the crop is cut early, it should not be fed upon longer than the middle of September. The most common time of sowing Saintfoin is in the spring; and it is even commonly reputed bad husbandry to sow it in the autumn, because the frost is apt to draw it out of the ground. It has, however, been sown with success in October along with Wheat or Rye, after Winter Tares. The crop was good, even the first season, though it happened to be a very dry one; whereas it is well known that Saintfoin sown in the spring yields a very scanty crop the first year, even when assisted with manure. At either season it is commonly sown with corn; but it is still doubtful whether the crop of artificial grass may not be diminished in proportion as the crop of corn flourishes. Other seeds are sometimes sown with it, to give a crop the first year, as White Clover, common Red Clover, and Trefoil: of these the first is much the best. The quantity of seed usually sown is at least four bushels, and some sow five; though Mr. Miller is for sowing a less quantity. In drilling, two bushels are sufficient; but this is not a common practice with Saintfoin. One of the best preparations for Saintfoin is, to take two crops of Turnips in succession, and then in the spring to sow four bushels of this seed with two bushels of Barley. Coal-ashes are a good dress for Saintfoin; and sown a still better, in the quantity of from ten to twenty bushels on an acre, laid on early in the spring. It is much infested with a kind of grass which botanists call *Bromus Sterilis*, and farmers know by the name of Black-grass. The scythe slips over it; the seed ripens very early, and is difficult to separate from the Saintfoin seed. It may easily be pulled up by hand. When the crop begins to fail, or the land is wanted for something else, a Saintfoin lay may be broken up successfully for Potatoes; for the red worm, which makes such ravages if corn be sowed without paring and burning, will not touch the Potatoes. The hay made from plants saved for seed is no better fodder than chopped straw or chaff; and to have the hay in perfection, it should be cut before it begins to flower, when the juice abounds, and it will nourish cattle much more than when it stands to be in full flower. This plant is exceedingly wholesome for horses, and is esteemed one of the best sorts of food for cattle, especially in the spring, nor is there any danger attending the use of it, as there is in Clover. It produces abundance of milk; and butter made of that milk is very good. Since it has been introduced into England, many dairy farms have been set up, where it was formerly impracticable: and if this plant and Lucerne was properly cultivated to such an extent as they might be,

not only a much greater quantity of milch cows could be maintained, but a greater number of black cattle might be fattened, and more sheep and hogs, which would be a great improvement to many estates in hilly countries: for, by increasing the live-stock, there will be an addition of manure for dressing the land in proportion. Saintfoin is allowed on all hands to be an admirable improvement on lime-stone rocks and chalk downs; which, in order to be cultivated to the greatest advantage, should be in this course, with no more arable than is necessary for the change. Thus, if Saintfoin last sixteen years, as it certainly will, if properly managed, then sixteen parts of the down should be Saintfoin, and as many more parts as there are years necessary for tillage before the ground should be sown with it again: suppose this period to be five years, the portions would then be,

Suppose each part to contain twenty-seven acres, then there would be two hundred and seventy acres of Saintfoin; and so on. Saintfoin is also a vast improvement in thin, loose, dry, sandy loams, upon marl or chalk bottoms. Thin soils that wear out or tire of clover, are laid down to great advantage with it, will last twenty years, and pay the farmer as well as his best corn crops. If a flock of sheep be an object of primary importance, this plant will afford them plenty of dry food for winter in hard weather. An acre of indifferent land will yield two tons of Saintfoin dry, and therefore twenty acres will serve a thousand sheep for a month, supposing a sheep eats three pounds of hay in a day, which is a large allowance. Now, the expense of an acre of Saintfoin, including fourteen shillings for rent, tithe, and poor, is about one pound; whereas that of an acre of Turnips will be two pounds seven shillings. Eight acres and a half of Turnips then balance twenty acres of Saintfoin. Now, a thousand sheep will eat two acres and a half of Turnips in a day; and therefore seventy-five acres will be required for a month, or, at the lowest calculation, twenty-four acres; the expense of which is fifty-six pounds eight shillings, to be set against twenty pounds, the expense of Saintfoin. Some green food, however, should be joined with the hay, for milch ewes or cattle. Green Borecole, the Turnip-rooted Cabbage, or the Swedish Turnip, would answer this purpose; being hardy, and standing above the snow. One great advantage of this, in common with other artificial grasses, is, that even in a dry season from a ton to a ton and a half of hay may be obtained from an acre, when natural meadows unwatered will produce only half a ton. Modern authors affect to write *Sainfoin*, as if the term meant *wholesome hay*; whereas it is called *Sainfoin*, or holy hay, from a presumption of its superior excellence. Ignorant persons confound it with Cinquefoil, from the sound merely; for no two vegetables can be more different.

78. *Hedysarum Saxatile*; *Rocky Hedysarum*. Legumes one-seeded, furrowed, without prickles; wings of the corolla very short; scapes subradicate; stems under ground woody, above ground scarcely any: the spike resembles that of the foregoing species, but is whitish.—Native of Provence, the county of Nice, and Siberia. Perennial.

79. *Hedysarum Caput Galli*; *Cock's-Head Hedysarum*. Legumes one-seeded; teeth of the crest subulate; wings very

short; stem diffused; root white, annual; flower twice as long as the calix; banner ovate, retuse; keel shorter than the banner; wings very small, one-fourth the length of the calix.—Native of France and Sicily, flowering in July and August.

80. *Hedysarum Crista Galli*; *Cock's-Comb Hedysarum*. Legumes one-seeded, prickly; divisions of the crest lanceolate, toothletted; root annual.—Native of the Levant.

81. *Hedysarum Crinitum*; *Hooked-podded Hedysarum*. Racemes long; legumes bent in; stem shrubby, five feet high, round, tomentose, with diffused branches; flower violet-coloured, in a close, round, straight, terminating spike, a foot long; bractes lanceolate, acuminate, ciliate, two-flowered.—Native of India, Cochin-china, and China.

82. *Hedysarum Conosum*. Leaves pinnate, lanceolate; racemes elongated, cylindric; stem shrubby; branches angular, villose; flowers crowded on very short pedicels. Jacquin describes it as a very handsome plant, with a perennial root; an upright round stem, a foot and half high, leafy all over, closely hispid, with very minute white hairs; flowers at first red, but changing to blue, and soon falling.—Found by Kœnig in the East Indies, and by Insert on the coast of Guinea.

83. *Hedysarum Cornutum*; *Horned Hedysarum*. Leaflets linear; legumes one-seeded, even; stems shrubby; peduncles permanent, thorny; flowers three or four, alternate, pedicelled, placed before the tip of the peduncle.—Native of the Levant.

84. *Hedysarum Incanum*; *Hoary-leaved Hedysarum*. Leaves without stipules, hoary underneath; stem erect; flowers in racemes, drooping, flesh-coloured. It has no stipules.—Native of Japan.

85. *Hedysarum Lineare*; *Linear-leaved Hedysarum*. Leaflets lanceolate-linear; spikes terminating; legumes straight, smooth, and even; stem diffused, suffruticose, two feet high. The root is thought to be deobstruent, an emmenagogue, and to create an appetite.—Native of Cochin-china.

86. *Hedysarum Sericeum*. Leaves ternate; leaflets ovate, silky underneath; flowers in spikes, axillary and terminating; stem shrubby, six or seven feet high, dividing into several branches; flowers small, and of a bright purple colour; legumes flat, smooth, jointed, about an inch long.—Native of La Vera Cruz.

87. *Hedysarum Villosum*. Leaves ternate; stem diffused, villose; flowers in terminating spikes; calices very villose. This is an annual plant, seldom rising more than eight or nine inches high, sending out several branches from the root, which are diffused and hairy; spikes close and short; corolla purple.—Native of La Vera Cruz.

88. *Hedysarum Glabrum*. Leaves ternate; leaflets obovate; stem panicled; legumes smooth, lunulate, compressed, oblique to the stem, one-seeded.—Native of Campeachy.

89. *Hedysarum Scandens*. Leaves ternate; leaflets obovate; stem twining; spike very long, bent back. It climbs to the height of ten or twelve feet. Flowers dark purple, sitting close to the stalk.—Native of La Vera Cruz.

90. *Hedysarum Pedunculatum*. Leaves ternate; the middle leaflet on a longer petiole; racemes axillary, upright, very long; root perennial; stem annual, erect, about two feet high. The flowers are produced in long axillary spikes, growing erect; they are small, and of a bright yellow colour, sessile, and succeeded by jointed pods, straight on one side.—Native of South Carolina.

Heisteria; a genus of the class Decandria, order Monogymia.—GENERIC CHARACTER. *Calx*: perianth one-leaved, bell-shaped, five-cleft, acute, small, permanent. *Corolla*: petals five, ovate, acute, concave, spreading. *Stamina*:

filamenta ten, ovate, acute, flat, upright, alternately shorter; antheræ roundish. *Pistil*: germen roundish, flattened; style upright, short; stigma four-cleft, obtuse. *Pericarp*: drupe oblong, flattened at the tip, placed on a very large coloured calix. *Seed*: nut oval, obtuse. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: five. *Drupe*: with a very large coloured calix.—The species are,

1. *Heisteria Coccinea*. This is an inelegant branching tree, twenty feet in height. Leaves oblong, quite entire, drawing to a sickle-shaped point, shining, on short petioles, alternate, half a foot in length; flowers small, peduncled, axillary, with white corollas; calix in the flower small and green, in the fruit scarlet, with a very large spreading limb, and short, very blunt, roundish segments.—Native of Martinico, in close woods near torrents, flowering in February and March, and fruiting in June. The French inhabitants call it *Bois Perdrix*, birds being very fond of the fruit.

2. *Heisteria Cauliflora*. Leaves oblong, somewhat obovate, tapering at the base; flowers from the stem and naked branches; calix of the fruit closed, deeply lobed.—This lofty tree is found in Guiana.

3. *Heisteria Parvifolia*. Leaves ovate, pointed, shining; flowers axillary; calix of the fruit widely spreading, with deep ovate lobes.—Found in Sierra Leone.

Helenium; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common simple, one-leaved, many-parted, spreading; leaflets about twenty, gradually drawing to a point. *Corolla*: compound, radiate; corollets hermaphrodite, numerous in the disk; females as many as there are parts of the calix, in the ray. Proper of the hermaphrodites tubular, shorter than the calix, five-toothed; of the females ligulate, broader outwards, trifid at the tip, longer than the calix. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: in the hermaphrodites; germen oblong; style filiform, length of the stamina; stigma bifid: in the females, germen oblong; style very short; stigma bifid. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites, solitary, obovate, angular, crowned with a small five-toothed calicle: in the females, very like the others. *Receptacle*: naked, convex; the calicine chaffs only of the ray separating the florets. ESSENTIAL CHARACTER. *Calix*: simple, many-parted. *Corollets*: of the ray, semitrifid. *Down*: five-awned. *Receptacle*: naked, excepting the calicine chaffs in the ray.—The species are,

1. *Helenium Autumnale*; *Smooth Helenium*. Leaves very smooth. It rises to the height of six or seven feet in good ground; the roots when large send up a great number of stalks, which branch towards the top. The leaves sit close to the stalks, and from their base is extended a leafy border along the stalk, so as to form what was generally termed a winged stalk, but Linneus calls it a decurrent leaf; the upper part of the stalk divides, and from each division arises a naked peduncle about three inches long, sustaining one large bright yellow flower, shaped like a Sun-flower, but much smaller, having long rays, which are jagged pretty deep into four or five segments; these appear in August, and there is a succession of flowers on the plants till the frost puts a stop to them. The whole plant is intensely bitter, with something of the aroma of *Anthemis Nobilis*, and would probably answer all its medicinal properties.—Native of America, where it grows in great plenty in the woods, and other shady places and moist grounds of Virginia and New England. This, as well as the next species, may be propagated by seeds, or by parting their roots; but the latter is generally practised in this country, because they seldom perfect seeds here, but if the

seeds are procured from abroad, they should be sown in the beginning of March on a border of light earth: and if the seeds should not come up the first year, the ground should not be disturbed, because they often remain a whole year in the ground before the plants come up; in which case there is nothing more to be done, but to keep the ground clear from weeds, and wait until the plants rise. When they appear, if the season proves dry, they must be often watered, which will greatly forward their growth; and where the plants come up too close to each other, they should be thinned, and transplanted out into beds a foot asunder every way, being careful to shade them until they have taken root, as also to water them in dry weather. In autumn they may be transplanted where they are to remain, and the following summer they will produce their flowers, which will continue till the frost prevents them; and their roots will abide many years, and afford many offsets, by which they may be increased. The best season to transplant the old roots, and to part them for increase, is in the end of October, when their flowers are past, or the beginning of March, just before they begin to shoot; but if the spring should prove dry, they must be duly watered, otherwise they will not produce so many flowers the same year: these plants should not be removed oftener than every other year, if they be expected to flower strong.

2. *Helenium Pubescens*; *Downy Helenium*. Leaves pubescent. This has the appearance of the preceding species, but the leaves are not three inches long, and are more than an inch broad in the middle, ending in acute points, and are sharply serrate on their edges. The flowers stand upon shorter peduncles, growing closer together. They both flower at the same season.—Native of North America.

3. *Helenium Longifolium*. Leaves linear-lanceolate, entire, very smooth; flower-stalks greatly elongated, naked. A more slender plant than the first species, with leaves twice or thrice as long, and much narrower.—Native of North America.

4. *Helenium Quadridentatum*. Upper leaves entire, smooth, broad at the base; florets of the disk four-cleft; root annual; stem two feet high, much branched; flowers much smaller than the other species, orange-coloured; flower-stalks long, slender, simple, naked, terminal, and solitary.—Native of Carolina and Louisiana.

Helianthus; a genus of the class Syngenesia, order Polygamia Frustranea.—GENERIC CHARACTER. *Calix*: common imbricate, somewhat squarrose, expanded; scales oblong, broadish at the base, gaping every where at the tips. *Corolla*: compound radiate; corollets hermaphrodite, very numerous, in the disk; females fewer, much longer in the ray. Proper of the hermaphrodites, cylindric, shorter than the common calix, bellied at the base, orbiculate, depressed; border five-toothed, sharp, spreading: of the females, ligular, lanceolate, quite entire, very long. *Stamina*: in the hermaphrodites, filamenta five, curved, inserted below the belly of the corollet, the length of the tube; antheræ cylindric, tubular. *Pistil*: in the hermaphrodites, germen oblong; style filiform, length of the corollet; stigma two-parted, reflex: in the females, germen very small; style and stigma none. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites, solitary, oblong, blunt, four-cornered, compressed at the opposite angles; the inner ones narrower, crowned with two lanceolate, acute, deciduous chaffs: in the females none. *Receptacle*: chaffy, large, flat; chaffs lanceolate, acute, two separating each seed, deciduous. ESSENTIAL CHARACTER. *Calix*: imbricate, somewhat squarrose. *Down*: two-leaved. *Receptacle*: chaffy, flat.—The species are,

1. *Helianthus Annuus*; *Annual Sun-flower*. All the leaves cordate, three-nerved; peduncles thickening; flowers drooping; root annual. Stem single or branched, from five or six, to ten or fourteen feet in height, and in hot climates twenty or more; when vigorous, the size of a man's arm; leaves alternate, a span or a span and a half in length, and almost as much in breadth, rough, serrate, acuminate, hanging down at the end, on oblong petioles; flower single, nodding, a foot or more in diameter. The semiflorets, or ligulate floscules in the ray, are usually of a fine golden colour, and nearly an inch in breadth, ending in a point which is commonly bent back. The seeds are numerous, black, variegated, or white; and when these have quitted their cells, the receptacle looks like a honeycomb. The great size of the whole compound flower recommends it to the student for the examination of the floscules, which, in the class Syngenesia, are usually very small. The whole plant, and particularly the flower, exudes a thin, pellucid, odorous resin, resembling Venice turpentine. The seeds are excellent food for domestic poultry. The varieties are those with double flowers, and deep yellow, and sulphur-coloured. This flower becomes double by the change of tubular into ligular florets, like those in the ray, only smaller. Gerarde observes, that it was called Indian Sun-flower, or flower of the Sun, *Corona Solis*, and *Sol Indianus*, because it resembles the radiant beams of the sun. The report of its turning with the sun is a vulgar error. Gerarde says he could never observe it; and we have seen four flowers on the same stem pointing to the four cardinal points. It flowers from June to October. Native of Mexico and Peru.—This and the second species are easily propagated by seeds sown in March upon a bed of common earth; and when the plants come up, thin them where they are too close, and keep them clean from weeds: when the plants are grown six inches high, they may be taken up with balls of earth to their roots, and planted into the large borders of the pleasure-garden, observing to water them till they have taken new root; after which they will require no other care but to keep them clear from weeds. In July the great flowers upon the tops of the stems will appear, amongst which the best and most double flowers of each kind should be preserved for seeds; for those which flower later upon the side-branches are neither so fair, nor do they perfect their seeds so well, as those which are first in flower: when the flowers are quite faded, and the seeds are formed, the heads should be carefully guarded from the sparrows, which will otherwise devour most of the good seeds; and about the beginning of October, when the seeds are ripe, the heads, with a small part of the stem, should be cut off, and hung up for a month in a dry airy place until the seeds are perfectly dry and hard, when they may be easily rubbed out, and put into bags or papers, preserving them from vermin until the season for sowing them.—The perennial sorts rarely produce seeds in England, but most of them increase very fast at their roots, especially the creeping-rooted kinds, which spread too far for small gardens. They are all very hardy, and will grow in almost any soil or situation; they are propagated by parting their roots into small heads, which in one year's time will increase greatly. The best season for this work is in the middle of October, soon after the flowers are past, or very early in the spring, that they may be well rooted before the droughts come on; otherwise their flowers will be few in number, and not near so fair, and by this means their roots will be weak; but if they be planted in October, it will supersede the trouble of watering them, as they will be securely rooted before the dry weather arrives, and will then only require to be carefully weeded.

2. *Helianthus Indicus*; *Dwarf Annual Sun-flower*. All the leaves cordate, three-nerved; peduncles equal; calices leafy. This is suspected to be a variety of the foregoing; though it constantly preserves its distinction. It grows only from eighteen inches to three feet in height. It is probably a native of Mexico or Peru.

3. *Helianthus Multiflorus*; *Perennial Sun-flower*. Lower leaves cordate, three-nerved; upper ones ovate. The stems are many, upright, from five to nine feet high, branching; the stem, and each branch, terminated by a flower, the principal one eight to ten inches in diameter, the lateral ones gradually smaller. There is a constant succession of flowers from July to November. Native of Virginia.—This, which is the most common in our English gardens, is the largest and most valuable, and is very proper furniture for large borders in great gardens, as also for bosquets of large growing plants, or to intermix in small quarters with shrubs, or in walks under trees, where few other trees will thrive; it is also a great ornament to gardens within the city, where it grows in defiance of the smoke better than most other plants; and, for its long continuance in flower, deserves a place in most gardens, for the sake of its flowers, to adorn halls, chimneys, &c. in a season when we are at a loss for other flowers. It begins flowering in July, and continues till October.—There is a variety of this species with very double flowers, which is now become so common in the English gardens, as to have almost banished the single sort from hence.

4. *Helianthus Tuberosus*; *Tuberous-rooted Sun-flower*, or *Jerusalem Artichoke*. Leaves ovate-cordate, triple-nerved; stems several, rough, hairy, streaked, from ten or twelve to sixteen feet in height, the size of a child's arm; branches many, long from bottom to top; flowers terminating, small; florets in the ray twelve or thirteen. These seldom blow before October, and in some seasons they do not expand at all. The seeds never ripen here: roots creeping, with many tubers clustered together, thirty, forty, or fifty, from one plant, measuring a peck, or in good soils half a bushel; they are like the common potatoe, red on the outside, and very irregular in their shape, the size of a man's fist at biggest. "Mr. John Goodyer received in 1617, two small roots no bigger than hen's eggs, from Mr. Franquevill of London; the one he planted, and the other he gave to a friend. The root he planted produced a sufficient number to supply all Hampshire." This note is dated the 17th of October, 1621; and Johnson observes, that his friend took it presently upon the first arrival into England. If this were the era of the first introduction of Jerusalem Artichoke, it seems surprising, even allowing for the facility with which it is increased, that so soon as the year 1629, or even earlier, it should have become so common in London, that even the most vulgar began to despise it; whereas, when first received among us, it was, as Parkinson says, a "dainty for a queen." Our ancestors boiled them tender, and, after peeling, ate them sliced and stewed with butter, wine, and spices. Thus, says Parkinson, they were a dish for a queen, being as pleasant as the bottom of an artichoke: but their too frequent use, owing to their being so plentiful and cheap, hath rather bred a loathing than a liking of them. They also baked them in pies, with marrow, dates, ginger, raisins, sack, &c. Notwithstanding what our old authors have above advanced, it is probable that this root was discontinued from a notion of its flatulent quality. The potatoe seems to be more nutritious and wholesome. It is not necessary therefore now to enforce the cultivation of Jerusalem Artichoke as the general article of food, but it certainly makes an agreeable variety at good tables. There is no better reason for the common English name, than that the root, when

boiled, has the taste of an artichoke bottom: Parkinson therefore would have it called Potatoes of Canada, because the French brought them first from Canada into these parts; not that Canada is their original country, for they are unquestionably the produce of a hot climate, being natives of Brazil.—These plants are propagated by planting the smaller roots, or the larger ones cut in pieces, observing to preserve a bud to each separate piece, either in the spring or autumn, allowing them a good distance, for their roots will greatly multiply; in the following autumn, when their stems decay, the roots may be taken up for use. They should be planted in some remote corner of the garden, for they are very unsightly while growing, their roots overrun every thing, and they cannot easily be destroyed. When desired for a crop, the sets should be planted in an open part of the kitchen-garden, in rows three feet or more asunder, at least eighteen inches distant from each other, and four or five inches deep. The best time for this is the latter end of March. A light soil suits them best. Some persons cut the stalks half way down, at the end of July or the beginning of August; because they shade the ground too much, and from their great height are apt to be blown down. They may be taken up for present use in September, and the whole crop may be housed in October. If kept in sand, and in a dry place, they will continue the whole winter.

5. *Helianthus Decapetalus*; *Ten-petalled Sun-flower*. Stem smooth at bottom; leaves lanceolate-cordate, triple-nerved; ray of the flower ten-petalled; peduncles scabrous. This resembles the third species very much, but it differs in having the stem, which scarcely attains the height of a man, scabrous, but smooth at bottom.—Native of Canada.

6. *Helianthus Frondosus*. Calix squarrose, waved, leafy; rays eight-petalled; leaves ovate; stem scabrous at bottom. This is allied to the foregoing species.—Native of Canada.

7. *Helianthus Strumosus*; *Carrot-rooted Sun-flower*. Root fusiform, white and fleshy; stems several, nine or ten feet high, round, rough, somewhat hirsute, streaked, subdivided into numerous branches; leaves alternate, a hand long, an inch or more broad, acuminate, rough, dark green, slightly notched about the edge; flowers terminating in corymbs; petals pale yellow, ending in a bifid point; leaflets of the calix produced into long leaves. The roots are bitterish, aromatic, and not disagreeable: they are eaten by the Canadians, among whom this plant grows wild. It flowers from July to September.

8. *Helianthus Giganteus*; *Gigantic Sun-flower*. Leaves alternate, lanceolate, scabrous, ciliate at the base; stem stiff, smooth. This strongly resembles the preceding species, but the leaflets of the calix are shorter, and not so copious. There are usually sixteen florets in the ray. It flowers in August and September.—Native of Pennsylvania.

9. *Helianthus Altissimus*; *Tall Sun-flower*. Leaves alternate, broadish, lanceolate, scabrous; petioles ciliate; stem stiff, smooth. This strongly resembles the preceding species, but the leaflets of the calix are shorter, and not so copious. There are usually sixteen florets in the ray. It flowers in August and September.—Native of Pennsylvania.

10. *Helianthus Angustifolius*. Leaves alternate, linear; stem purplish, a foot and half in height; disk of the corolla brown; ray deep yellow, emarginate.—Native of Virginia.

11. *Helianthus Divaricatus*; *Rough-leaved Sun-flower*. Leaves opposite, sessile, ovate-oblong, three-nerved; panicle dichotomous; stem scarcely the height of a man, extremely even at top, but with scattered rough hairs, purple, with a glaucous bloom; flowers in a panicle, with trichotomous

branches, yellow, small, peduncled, with the middle peduncle simple; peduncles somewhat scabrous. It flowers from August to October.—Native of North America.

12. *Helianthus Atro-rubens*; *Dark-red Sun-flower*. Leaves opposite, spatulate, crenate, triple-nerved, scabrous; calicine scales erect, the length of the disk; stem commonly single, about the size of a swan's quill at bottom, from eighteen inches to three feet and more in height, round, dusky purple, rough, with abundant whitish hairs; root-leaves flat, hairy, smaller than those of the stem, which are twisted and waved, especially towards the lower end, rough with frequent hairs, and on the lower ones particularly with small tubercles; flowering-branches divaricate; the disk of the flower dark red; floscules in the ray yellow, marked with a few lines, pointed and entire, sometimes in very old flowers divided into segments. It flowers in September and October, and continues two or three years.—Native of Carolina and Virginia.

13. *Helianthus Mollis*. Leaves ovate, acuminate, very rough on the upper surface, and soft underneath.—It flowers from July to October, and is found in the exsiccated swamps of Pennsylvania and Virginia.

Heliconia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: spathes common and partial alternate, distinct, with hermaphrodite flowers; perianth none. *Corolla*: petals three, oblong, channelled, erect, acute, equal. Nectary two-leaved; one leaflet nearly equal to the petals; the other very channelled, hooked, opposite. *Stamina*: filamenta five, (according to Adanson, six,) filiform; antheræ long, erect. *Pistil*: germen inferior, oblong; style shorter than the stamina; stigma long, slender, curved, with a terminating head. *Pericarp*: capsule oblong, truncate, three-sided, three-celled. *Seeds*: solitary, oblong. *Observe*. This genus is distinguished from *Musa* by a tricoccus capsule, and there is some doubt whether it ought not to be transferred to the class Hexandria. ESSENTIAL CHARACTER. *Spathes*: both general and partial. *Perianth*: none. *Corolla*: three-petalled. *Nectary*: two-leaved. *Pericarp*: tricoccus. *Seeds*: solitary. *Capsules*: fleshy, three-celled, according to Swartz.—The species are,

1. *Heliconia Bihai*; *Bastard or Wild Plantain*. Leaves and spadix radical; spathes distich, cordate; nectary ventricose, bifid at the tip. This is a very large herbaceous plant, from ten to twelve feet in height. The leaves have long sheathing footstalks, their bases enfolding one another so as to resemble a stem about five feet high, and as thick as a man's thigh, after which the stalks spread into two rows; the leaf itself is six or eight feet long, and eighteen inches wide, linear, entire, rounded at each end, flat, smooth, pliable, with one rib, and numerous parallel veins. The flowers have five perfect filamenta shooting from the bottom of the real flower-leaf, and one imperfect filamentum from the nectarium. The berries are small and succulent, and contain each three hard rugged seeds.—This beautiful plant is a native of bogs in Guiana and the Caribbee islands; it also grows wild in most of the cooler mountains of Jamaica, and thrives very luxuriantly in every rich well-shaded gully among the woods.

2. *Heliconia Psittacorum*. Leaves on the stem rounded at the base; spadix terminating, flexuose; spathes lanceolate; nectary lanceolate, concave, entire. This plant bears a great resemblance to *Canna*, and grows to the height of eight feet, with a simple smooth stem; flowers pedicelled, crowded, upright, an inch long, fulvous, on round peduncles, half an inch long; corolla three-sided, the two upper petals erect, linear, acute, keeled, converging, glued to the nectary, the uppermost only trifid, the lower petal embracing the upper

petals and nectary at the base, a little wider, keeled, ventricose, brownish-green at top.—Native of Jamaica in wet parts of mountain-woods; also of South America.

3. *Heliconia Hirsuta*. Leaves rounded at the base, simply nerved, very smooth; inflorescence hirsute; spadix flexuose; nectary lanceolate, adnate; stem very smooth; spathes alternate in two rows, lanceolate, awl-shaped, channelled, ascending, the lower ones larger, with a hispid keel, peduncles from nine to twelve in the axils of the spathes, upright, round, very hirsute, short, leafless, one-flowered; corolla curved, two-petalled; upper petal complicated, hispid, bifid at the tip; lower broader, complicated, hispid, oblong, with a brown mark on the inside at the top.—Found in South America by Mutis.

Helicteres; a genus classed by Linneus in Gynandria, order Decandria; by Schreber, in Decandria Monogynia; and by Swartz, in Monadelphia Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubulous, half-ovate, obliquely spreading, unequally five-cleft, coriaceous. *Corolla*: petals five, oblong, equal in breadth, fixed to the receptacle, longer than the calix; claws long, with a tooth on each side at the base; nectary of five petal-shaped, lanceolate, very small leaflets, covering the germen. *Stamina*: filamenta five, ten, or more, very short; antheræ oblong, lateral. *Pistil*: receptacle filiform, very long, bowed back, bearing an ovate germen at the tip; style subulate, longer than the germen; stigma subquincifid. *Pericarp*: capsules five, often twisted spirally, one-celled. *Seeds*: very many, angular. *Observe*. In some species Jacquin and others have observed dodecandrous and polyandrous flowers, and straight capsules. One species has no corolla. ESSENTIAL CHARACTER. *Pentagynous*. *Calix*: one-leaved, oblique. *Petals*: five. *Nectary*: of five leaflets. *Capsules*: five, twisted.—The plants of this genus are propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are come up strong enough to remove, they should be each planted in a separate small pot, filled with light earth, and plunged into a moderate hot-bed of tan, observing to shade them from the sun until they have taken new root; then they should be treated in the same way as other tender plants from hot countries, raising the glasses every day in fine weather, that the plants may enjoy fresh air, without which they would be drawn up weak. In the summer the plants may remain under the frames, if there be sufficient height for them to grow; but in autumn they must be plunged into the tan-bed in the stove, where they should always remain, being careful to shift them into larger pots when they require it, and not to give them too much wet in the winter, but in summer they should have a large share of air in warm weather, and require to be often refreshed with water. These plants have often flowered in the Chelsea garden during the second year of their production from seeds, and have sometimes ripened seeds. They will live several years with proper management.—The species are,

1. *Helicteres Baruensis*; *Small-fruited Screw Tree*. Decandrous; leaves cordate, serrate; fruit twisted, with straight tips. This is an upright tree, about twelve feet in height, branching but a little; the younger branches, peduncles, and petioles, are tomentose; peduncles many-flowered, terminating, thick; the flowers have no scent; petals whitish; seeds about fifty in each capsule, obovate, angular, smooth, of a brown chestnut-colour. The bark of the trunk and principal branches, being easily peeled off, and very tough, is used instead of ropes.—Native of the island of Baru, in woods near the coast; and of the West Indies.

2. *Helicteres Isora*; *Great-fruited Screw Tree*. Decan-

drous: leaves cordate, serrate; the whole fruit twisted. Swartz describes it, "Leaves elliptic, subcordate; fruit subulate at the tip." A small upright tree, about twelve feet high, branching but little; peduncles many-flowered, terminating, glandular; petals white, obtuse, reflex.—This curious shrub, as Browne calls it, is very frequent in the lower gravelly hills of Jamaica.

3. *Helicteres Hirsuta*. Decandrous: leaves cordate, serrate; fruit oblong, five-celled, straight, very hirsute; stem shrubby, six feet high, upright, round, hairy, with diffused branches; peduncles many-flowered, axillary; corolla dusky purple. In this and the fifth species, the stamina are not gynandrous, but rather monadelphous; nor ought the pedicel supporting the germen to be looked upon as a receptacle, for it is entirely detached from the stamina.—Native of the woods of Cochin-china.

4. *Helicteres Undulata*. Decandrous: leaves lanceolate, waved; flowers in heaps; siliques five, stellate. This is a middle-sized tree, with spreading branches; flowers small, mostly terminating; calix none; corolla greenish-red; siliques oblong, thick, scarlet, straight above, convex underneath; seeds few, ovate, smooth, brown, fleshy, adhering to each valve by their proper pedicels.—Native of Cochin-china, in woods.

5. *Helicteres Angustifolia*. Decandrous: leaves lanceolate, quite entire; fruit ovate, straight; stem shrubby, five feet high, upright, branched; flowers pale purple, on two-flowered axillary peduncles.—Native of China, in the neighbourhood of Canton.

6. *Helicteres Pentandra*. Pentandrous: leaves ovate, floral leaves coloured, dusky purple; calices hispid with branching bristles.—Native of Surinam.

7. *Helicteres Carthaginensis*. Polyandrous: leaves cordate, serrate, tomentose on both sides; fruit oblong, straight. This is an upright tree, about twelve feet high; flowers extremely fetid, generally coming out with the leaves, but sometimes before them; calix brownish-yellow; petals purple. It has so much the habit of the first sort, that it can hardly be distinguished from it, except in the flower and fruit.—Native of the woods of Carthagena in New Spain, where it is found flowering in June and July.

8. *Helicteres Paniculata*. Polyandrous: leaves ovate, acute, smooth, petioled; flowers panicled; siliques five, stellate, oblong, two-valved, red. This is a large tree, with spreading branches; flowers in loose panicles, mostly terminating; calix none; corolla of a reddish colour, and spreading very much.—Native of the woods of Cochin-china.

9. *Helicteres Apetala*. Dodecandrous, apetalous: leaves five-lobed; siliques divaricate. This is an elegant tree, forty feet in height, with a large handsome head; the leaves are plaited, smooth above, subvillose beneath, upwards of a foot in diameter, and numerous; flowers also numerous, very fetid, dirty yellow with purple spots, without either petals or nectary, in large loose panicles at the ends of the twigs. It is apparent that the filamenta are the continuation of the bark, or outer part of the receptacle, but that the germen springs from the pith of it.—Native of Carthagena, in woods, flowering from May and June to September.

Heliocarpus; a genus of the class Dodecandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth four-leaved, coloured; leaflets linear, long, broadish, spreading, deciduous. *Corolla*: petals four, linear, much shorter than the calix, narrower. *Stamina*: filamenta sixteen, awl-shaped, almost the length of the calix; antheræ twin, linear, incumbent. *Pistil*: germen roundish; styles two, simple, upright, length of the stamina; stigmas acute, distant. *Pericarp*:

capsule turbinate-ovate, peduncled, compressed, surrounded perpendicularly on both sides with rays pinnately branched, two-celled, two-valved, with the partition contrary. *Seeds*, solitary, subovate. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Corolla*: four-petalled. *Styles*: simple. *Capsule*: two-celled, compressed, longitudinally radiated on both sides (according to Gærtner, superior, club-shaped, surrounded with filiform feathered rays.)—The only species known is,

1. *Heliocarpus Americana*; *American Heliocarpus*. It rises with a thick, soft, woody stalk, from fifteen to eighteen feet high, sending out several lateral branches towards the top; leaves heart-shaped, full of veins, serrate, ending in acute points, alternate, on oblique petioles three inches long. The flowers are produced at the ends of the shoots, in branching clusters, and are of a yellowish-green colour.—Found at La Vera Cruz. This plant is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a small pot, filled with light kitchen-garden earth, and plunged into a hot-bed, treating them in the same way as other tender plants which will not bear the open air in this country at any season of the year: while young, the plants require to be plunged into the tan-bed, but after they have acquired strength, they will thrive in the dry-stove. In winter they should have but little water, and must be kept warm; but in summer they should have plenty of fresh air in mild weather, and must be frequently refreshed with water. With this management the plants will flower the third year, and produce good seeds, and may be preserved by care for several years.

Heliophila; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets spreading, oblong, concave, membranaceous at the edge, deciduous; the two outer ones bladderly at the base. *Corolla*: four-petalled, cruciform; petals roundish, flat, sessile; nectaries two from the receptacle, bowed back towards the bladder of the calix. *Stamina*: filamenta six, awl-shaped, erect, the length of the calix, two opposite a little shorter; antheræ oblong, erect. *Pistil*: germen cylindrical; style shorter than the germen; stigma blunt. *Pericarp*: silique columnar, somewhat torulose, mucronate, two-celled, two-valved. *Seeds*: several. ESSENTIAL CHARACTER. *Nectaries*: two, bowed back towards the bladder of the calix.—The seeds of plants belonging to this genus may be sown in the spring on a south border; and when the plants come up, if they are thinned, and kept clean from weeds, it is all the culture they require.—The species are,

1. *Heliophila Integrifolia*; *Whole-leaved Heliophila*. Leaves lanceolate, undivided, rough with hairs above, smooth below; stalk erect, four or five inches high, sending out two or three side-branches; the flowers grow in a loose terminating bunch, and have no scent; the corolla resembles that of Flax or *Anagallis Monelli*; it is blue, and closes at night; the pods are nearly three inches long, taper, and contain a double row of three flat seeds.—Native of the Cape of Good Hope.

2. *Heliophila Coronopifolia*; *Buck's-horn-leaved Heliophila*. Leaves linear, pinnatifid. This is a smooth shrubby plant.—Native of the Cape of Good Hope.

3. *Heliophila Amplexicaulis*. Leaves stem-clasping, entire, smooth; siliques necklace-shaped.—Found by Thunberg at the Cape of Good Hope.

4. *Heliophila Incana*; *Hoary Heliophila*. Leaves spatulate, quite entire, pubescent; siliques villose, shrubby.—Found at the Cape, flowering in May and August.

5. *Heliophila Filiformis*; *Divaricated Heliophila*. Leaves subulate, filiform, smooth; siliques pendulous; branches divaricate; stem half a foot high, herbaceous, rushy; racemes

horizontal, on horizontal pedicels; petals spreading as the calix does, but nearly three times as large, pale, streaked; siliques awl-shaped, stiff, very smooth and even. It is annual, and flowers in July and August.—Native of the Cape.

6. *Heliophila Pusilla*; *Dwarf Heliophila*. Leaves linear; siliques necklace-shaped, upright. Annual. A span high, upright, branched.—Native of the Cape of Good Hope.

7. *Heliophila Flava*. Leaves linear; stems shrubby, rushy. It has the appearance of Broom, upright, sparingly branched, stiff; racemes terminating, long, simple; the flowers distant; petals obovate, the same size as the cabbage, yellow, veiny; the claws longer than the calix; germen ovate; it varies with red corollas. It is doubtful whether this be a natural species of this genus.—Native of the Cape of Good Hope.

8. *Heliophila Circæoides*. Leaves cordate; stem brittle, branched, herbaceous: the whole plant is succulent, weak, smooth; root fibrous, annual; petioles semicolumnar, channelled above, shorter than the leaf, spreading; flowers alternate, very remote, but towards the end nearer, peduncled; the flowering peduncles erect, a line in length, bearing one flower; fruit peduncles reflected; seeds three or four, roundish.—Native of the Cape of Good Hope.

9. *Heliophila Digitata*. Leaves palmate-pinnatifid, villose; pinnae linear. The stem thickens very much upwards, which gives this plant a very singular appearance.—Native of the Cape of Good Hope.

10. *Heliophila Pinnata*. Leaves trifid and pinnate; leaflets linear; siliques necklace-shaped, upright. This resembles the sixth species very much, but it has branched or pinnate leaves.—Native of the Cape of Good Hope.

Heliotrope. See *Heliotropium*.

Heliotropium; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, five-toothed, permanent. *Corolla*: monopetalous, salver-shaped; tube the length of the calix; border flat, half five-cleft, obtuse; clefts smaller, alternate, more acute, between the larger ones; throat naked. *Stamina*: filamenta five, very short, in the throat; antheræ small, covered. *Pistil*: germen four; style filiform, length of the stamina; stigma emarginate. *Pericarp*: none; calix erect, unchanged, cherishing the seeds in its bosom. *Seeds*: four, ovate, acuminate: according to Gærtner, nuts four, naked or corticate, not perforate. ESSENTIAL CHARACTER. *Corolla*: salver-shaped, five-cleft, with teeth interposed; the throat closed with arches.—The species are,

1. *Heliotropium Peruvianum*; *Peruvian Turnsole* or *Heliotrope*. Leaves lanceolate-ovate; stem shrubby; spikes numerous, aggregate-corymbed. This rises with a shrubby stalk from two to three feet high, dividing into many small branches; leaves three inches long, and an inch and a half broad in the middle, hairy, greatly veined, and ash-coloured on their under side, on short footstalks; the flowers are produced at the ends of the branches in short reflex spikes, growing in clusters; the peduncles divide into two or three, and these again into smaller ones, each sustaining a spikelet of pale blue flowers, which have a strong sweet odour, of a very particular nature, somewhat resembling that of bitter almonds.—It is a native of Peru. This is well known, and generally cultivated for the delightful scent of its flowers, which are of a blueish white, and produced in a stove, or warm green-house, at almost all seasons. It may be propagated either by seeds or cuttings. The seeds may be sown upon a moderate hot-bed in the spring; when the plants are fit to remove, transplant them into small pots filled with light earth, plunge them into a hot-bed, and shade them till they have taken new root; then inure them by degrees to the air, into

which remove them in summer, placing them in a sheltered situation: in autumn, house them in a good green-house, where they will flower during great part of the winter. If the cuttings be put into pots filled with light earth, during any of the summer months, and plunged into a moderate hot-bed, they will take root freely; but these do not make so good plants as those taken from seed. Mr. Curtis remarks, that a stove is most congenial to this plant in winter, when it must be carefully defended from the frost, so fatal to most of the natives of Peru. In hot weather it must be well watered.

2. *Heliotropium Indicum*; *Indian Turnsole* or *Heliotrope*. Leaves cordate-ovate, acute, somewhat scabrous; spikes solitary; fruits bifid; stem herbaceous, a foot and half or two feet high, round, scabrous, hirsute, subdivided; flowers sessile, pointing one way, approximating in a double row, small, blue; tube very long, cylindrical, not globular, as in the others; border scarcely half five-cleft; segments equal, blunt; throat five-rayed, orange-coloured, closed; germen in connate pairs. It is annual or biennial, flowers in July and August, and ripens seeds in September and October.—Native of the West Indies and Cochin-china. The variety, which Mr. Miller makes a distinct species, is a smaller plant, seldom above two feet high; the leaves are an inch and half long, and about half an inch broad; the spikes of flowers are very slender, and not more than two inches long; the flowers are small, and of a light blue colour.—This, together with the third and ninth species, require their seed to be sown on a hot-bed in the spring, and when the plants are fit to remove, transplant them on another hot-bed, to bring them forward, treating them in the same way as the Balsamine, and other tender annual plants. They should be taken up in June with balls of earth, and replanted in the borders of the flower-garden, where they will flower, and in warm seasons produce ripe seeds.

3. *Heliotropium Parviflorum*; *Small-flowered Turnsole* or *Heliotrope*. Leaves ovate, wrinkled, scabrous, opposite and alternate. This is nearly allied to the foregoing. Stem erect, pubescent, a foot high; most of the leaves opposite, except those in the middle of the stem, which are alternate, petioled, lucid, acute; peduncles opposite to the leaves, or from the divisions of the stem, longer than the leaves, erect, each having two recurved imbricate spikes; corolla minute, pervious, white with a yellow base. It is an annual plant, flowering in July and August.—Native of the West Indies. For its propagation and culture, see the preceding species.

4. *Heliotropium Inundatum*. Leaves oblong, obtuse, hirsute; spikes in fours, erect; stem shrubby.—Native of the Caribbee Islands.

5. *Heliotropium Europæum*; *European Turnsole* or *Heliotrope*. Leaves ovate, quite entire, tomentose, wrinkled; spikes conjugate. This rises about seven or eight inches high, dividing into two or three branches, at the ends of which the flowers are produced in double spikes, joined at the bottom, about an inch long, turning backward; flowers white, appearing in June and July. There is a variety with large sweet flowers.—This, and the seventh species, are annuals, which succeed better from the seeds scattered in autumn, or are sown at that season, than in the spring, when they seldom appear in the same season; but if the seeds be suffered to shed, these plants will maintain themselves without any other culture, but keeping them clean from weeds, and thinning them where too close.

6. *Heliotropium Malabaricum*. Leaves ovate, plaited, strigose, quite entire; spikes almost solitary.—Native of Malabar.

7. *Heliotropium Supinum*; *Trailing Turnsole* or *Heliotrope*. Leaves ovate, quite entire, tomentose, plaited; spikes

solitary. This is smaller than the fifth species, with more slender branches, somewhat lanuginous, and prostrate; the root small and annual; flowers white.—Native of the Cape of Good Hope; flowering in June and July. For its propagation and culture, see the fifth species.

8. *Heliotropium Fruticosum*. Leaves linear-lanceolate, hairy; spikes solitary, sessile; stem shrubby, two feet high, very much branched; branches stiff, scabrous, and ash-coloured; spikes always single, and not much bent, small and slender; flowers terminating, on short pedicels, pointing one way, on short, axillary, hispid peduncles; corolla white; border five-cornered; throat closed, pale, having five rays from the centre to the angles of the border.—Native of the West Indies, near the sea-shore. This, and the seventeenth and eighteenth species, are propagated by seeds, but the difficulty of getting them fresh from America, and the uncertainty of their growing unless they are sown abroad, and brought over in earth, has made them scarce in Europe.

9. *Heliotropium Curassavicum*; *Glaucous Turnsole* or *Heliotrope*. Leaves lanceolate-linear, smooth, without veins; root annual; stem round, very smooth, with a glaucous bloom on it; branches trailing, a foot or more long; spikes in pairs, on a common peduncle, and recurved; corolla white, with a yellow base and an open throat; the fruit is an ovate globular berry, containing four nuts, drying up as it grows ripe, and divisible into four parts: it flowers in June and July.—Native of the West Indies. See the second species.

10. *Heliotropium Orientale*. Leaves linear, smooth, without veins; spikes conjugate; flowers scattered. It is a small procumbent creeping plant: annual.—Native of Asia.

11. *Heliotropium Gnaphaloides*. Leaves linear, obtuse, tomentose; peduncles dichotomous; flowers of the spikes in fours; stem frutescent. It is an upright shrubby plant, commonly about two feet high, and sometimes, but rarely, rising to the height of six feet; branches round, little divided, the older ones blackish, the younger scarred at bottom where leaves have grown, all together forming a convex, white, handsome head, visible far off at sea; flowers small, with the calices of all so connected, that no one can be taken out without tearing the next. This species is distinguished by its copious, narrow, thick, and silvery leaves.—Native of Cuba, Jamaica, Barbadoes, and St. Eustatia, in all of which it is found upon the coast. It is propagated by seeds, which must be procured from the places where it naturally grows, for it never produces any in Europe; these seeds should be sown in a tub of earth in the country, for when the dried seeds come over, they seldom grow; and if they do, it is not before the second year: so that if the seeds be sown as soon as ripe in a tub of earth, when they arrive in England, the tub should be plunged into a hot-bed of tanners' bark, which will bring up the plants; and when they are fit to remove, they should be each planted in a separate small pot filled with soil composed of sand and light undunged earth, with a little lime-rubbish well mixed together, then plunged into a hot-bed of tanners' bark, and shaded until they have taken new root; after which they must be treated in the same manner as other tender exotic plants, always keeping them in the tan-bed in the stove, giving them but little water during the summer.

12. *Heliotropium Scabrum*. Leaves lanceolate, strigose; stem branched, diffused; root simple, fusiform; flowers terminating, heaped, small, white, fenced with leaves.—Sent by Kœnig from the East Indies.

13. *Heliotropium Marifolium*. Leaves lanceolate, hispid; stems procumbent, somewhat shrubby; spikes simple, alternate, copious without order, not compact, with bractes of the same shape with the leaves; flowers white, hirsute on the

outside, as also are the calices; root woody.—Native of the East Indies.

14. *Heliotropium Coromandelianum*. Leaves obovate, villose, entire; spikes simple and conjugate; seeds dotted; root simple, fusiform; stems erect and prostrate, hispid.—Native of the East Indies, and also of Arabia.

15. *Heliotropium Capitatum*. Leaves oblong-ovate, quite entire, smooth, hoary underneath; flowers in axillary heads; stem arborescent. It rises with a shrubby stalk six or seven feet high: the young branches are closely covered with a white down, and the leaves on them are very hoary and entire, but those of the older branches are greener, and some of them are notched on their edges. At each joint of the stalks appear two short branches opposite, with small hoary leaves placed opposite: these when bruised emit a strong odour very disagreeable to some persons, and by others reckoned very pleasant. They rarely flower in England. Mr. Miller cultivated them for forty years, and only saw them once in flower. The flowers are white, collected in roundish heads, which turn backward and sit close to the branches; the leaves continue all the year.—Both this and the next species are too tender to endure the winter of this country in the open air. They must be protected from the frost in a green-house, and may be ranged with Myrtles and other hardy green-house plants, where they may have a large share of air in mild weather, and be treated in the same way: they are easily propagated by cuttings during any of the summer months. If the cuttings be planted in a shady border, and duly supplied with water, they will take root in five or six weeks, and may then be potted, and placed in a shady situation till they have taken new root, after which they may be treated as the old plants.

16. *Heliotropium Canariense*. Leaves ovate, crenate, opposite; flowers in dichotomous axillary heads; stem arborescent, three or four feet high. The leaves, when bruised, emit an agreeable odour, for which it is by some persons much esteemed. The gardeners have given this plant the title of *Madame de Maintenon*, but on what account we do not know.—Native of Canada. For its propagation and culture, see the preceding species.

17. *Heliotropium Procumbens*. Stem procumbent; leaves ovate, tomentose, quite entire; spikes solitary, terminating. It is an annual plant, with trailing stalks six or seven inches long, with small leaves. The flowers are produced at the ends of the branches, in single short spikes, which are reflexed; they are small and white, making little appearance.—Native of Carthage in New Spain. For its propagation and culture, see the eighth species.

18. *Heliotropium Americanum*. Leaves oblong-ovate, tomentose; spikes conjugate, terminating; stem shrubby. This rises with a shrubby stalk, three feet high, dividing into slender branches, which are closely garnished with leaves, placed without order. The flowers are produced at the ends of the branches in double spikes, which are slender, short, and straight, not recurved as the other species; flowers small and white; plant perennial.—Native of La Vera Cruz, where it was found growing in great plenty. For its propagation &c. see the eighth species.

19. *Heliotropium Tetrandrum*. Leaves ovate-lanceolate, smooth, opposite; spikes heaped, terminating; stem herbaceous, annual, one foot high, somewhat erect, diffused, whitish, obtusely four-cornered, with purple joints; flowers red, in long close spikes.—Found in the gardens of Cochin-china.

20. *Heliotropium Undulatum*. Leaves lanceolate, hispid, rolled back at the edge, waved; spikes conjugate; corollas villose; stem procumbent; branches a span long and more; calix hairy, five-cleft, with linear blunt segments; corolla

hairy on the outside, longer than the calix.—Native of Arabia.

21. *Heliotropium Lineatum*. Leaves elliptic, petioled, rolled back at the edge, flat; spikes conjugate; stem procumbent; branches slender, a span long, villose, tomentose above; corolla smooth, longer than the calix; tube widening at the top. Distinguished from the preceding, by the form and hairiness of the leaves, with the edge not at all waved; by the presence of bractes; by the smoothness of the corolla, and by the stigma being quite entire.—Native of Arabia.

22. *Heliotropium Ternatum*. Leaves in threes, and alternate, lanceolate, hoary underneath; spikes terminating, conjugate; branches round, hoary, with small hairs pressed close; corolla white.—Native of the West Indies.

23. *Heliotropium Pinnatum*. Leaves pinnate; stem erect, herbaceous, simple, only branching a little at the base, a foot high, the size of a goose-quill, villose; peduncles axillary and terminating; flowers crowded.—Found in the Straits of Magellan.

24. *Heliotropium Amplexicaule*. Leaves lanceolate, obtuse, half stem-clasping; spikes branching; stem shrubby; branches hairy; from the axils there are rudiments of branchlets; peduncle terminating, hairy, twice or thrice dichotomous at top; tube of the corolla twice as long as the calix, with fewer villose hairs scattered over it.—Found in Brazil.

Hellebore. See *Helleborus*.

Hellebore, White. See *Veratrum*.

Helleborine. See *Arethusa Divaricata*.

Helleborus; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: none, unless the corolla, which in some species is permanent, be so called. *Corolla*: petals five, roundish, blunt, large; nectaries several, very short, placed in a ring, one-leaved, tubular, narrower at bottom; mouth two-lipped, upright, emarginate, the inner lip shorter. *Stamina*: filamenta numerous, subulate; anthers compressed, narrower at bottom, upright. *Pistil*: germina about six, compressed; styles subulate; stigmas thickish; (Gærtner says, pistilla five or more, permanent.)

Pericarp: capsules (leguminous, beaked, according to Gærtner) compressed, two-keeled, the lower keel shorter, the upper convex, gaping. *Seeds*: several, round, fixed to the suture.

Observe. The first species drops its petals, the other sorts retain them, and they become green: the number of pistils varies much. ESSENTIAL CHARACTER. *Calix*: none. *Petals*: five, or more (or *Calix*: five-leaved, *Corolla*: none.) *Nectary*: two-lipped, tubular. *Capsule*: many-seeded.—The species are,

1. *Helleborus Hyemalis*; *Winter Hellebore* or *Aconite*. Flowers solitary, sitting in the upper leaf; root tuberous, transverse, with many dependent fibres, putting up several naked stems or scapes, simple, smooth, round, from an inch or two to four inches in height, terminated by a single leaf, spreading out horizontally in a circle, divided into five parts almost to the base, and the parts simple or divided into two, three, or four lobes. In the bosom of this sits one large, upright, yellow flower; the petals ovate, marked with lines, converging a little, deciduous, usually six in number, or from six to eight; pistils six, or from four to six; and stamina about thirty. This, like all the other Hellebores, is a powerful medicine, and requires great caution in the application: see the third and fifth species. Gerarde calls it *Winter's Wolf's-bane*, and *Small Yellow Wolf's-bane*; and is now generally known by the name of *Winter Aconite*.—Native of mountainous situations in Austria, Silesia, Switzerland; also of Lombardy and other parts of Italy. This flowers very early in the spring, which renders it worthy of a place in all curious gardens, especially as it requires

but little room: it is propagated by offsets, which the roots send out in plenty; these roots may be taken up and transplanted any time after their leaves decay, which is generally from the beginning of June till October, when they will begin to put out new fibres; but as the roots are small, and nearly of the colour of the ground, so, if care is not taken to search them, many of the roots will be left in the ground: they should be planted in small clusters, otherwise they will not make a good appearance; for single flowers of this small kind, when scattered about the borders, can scarcely be seen at a distance; but when planted in bunches alternately with Snowdrops, will have a good effect, as they flower at the same time, and are much of a size. This plant flowers so early, that it is liable to be cut off by severe frosts.

2. *Helleborus Ranunculinus*; *Ranunculus-leaved Hellebore*. Flowers solitary, peduncled; leaves digitate, multifid, gashed; stem a hand in height, upright, round, smooth, leafy at the top, sustaining one or two flowers, which are axillary, solitary, peduncled, upright, and yellow. It is very nearly related to the preceding species, but handsomer.—Tournefort imported it from Cappadocia.

3. *Helleborus Niger*; *Black Hellebore*, or *Christmas Rose*. Stem almost naked, with one or two flowers; leaves pedate; roots perennial, creeping, entangled, very black on the outside, externally rough and knotted; with many long, simple, perpendicular fibres; corolla very large, generally white at first, but frequently with a tint of red, growing deeper with age, and finally becoming green. It derives the name of *Black Hellebore* from the colour of the root; and of *Christmas Rose*, from the time of flowering and the colour of the corolla.—Native of Italy, Austria, Idria, and Silesia, in mountainous situations, flowering from December to March. This species has usually been taken for the true *Black Hellebore* of the ancients, till Tournefort discovered the mistake. See the fifth species. Culpeper confounds this plant with the sixth species; but his account will apply equally well to both. He says it is not safe to give it raw, and that if any harm arise from taking it in that state, the common cure is to take goat's milk; and where that cannot be obtained, such milk as can be gotten. The roots, adds he, are very effectual against all melancholy diseases, especially such as are of long standing, as quartan agues and madness; it helps the falling sickness, the leprosy, both the yellow and black jaundice, the gout, scurvy, and convulsions: but, unfortunately, this renowned barberist has forgotten to inform us, what quantity is to be taken for the dose, and also the manner of application; so that we cannot avail ourselves of his experience and skill. Although many writers consider the root a perfectly innocent and safe medicine, yet as we find several examples of its poisonous effects, it should always be employed with great caution: It seems to have been principally owing to its purgative quality, that the ancients esteemed this root such a powerful remedy in maniacal disorders; because they suppose it evacuated the black bile, from which those diseases were then thought to proceed: but, though evacuations are often found necessary in various cases of alienation of mind, yet as they can be produced with more certainty and safety by other medicines, this catholicon of antiquity seems now almost entirely abandoned. It is however still used in small doses of six or eight grains, for attenuating viscid humours, promoting the uterine and urinary discharges, and opening inveterate obstructions of the remoter glands; it often proves a powerful emmenagogue in plethoric habits, where steel is considered as improper: it is also used in dropsies, and in some cutaneous diseases. The roots of the plant, says Dr. Hill, are the only parts to be used in medicine. These are of a bitter pungent taste, and,

if chewed for a few minutes, leaves a sensation of numbness on the tongue, which continues for a considerable time: given in substance, in doses of ten or fifteen grains, it purges roughly, and, to such as are of robust habits, may prove serviceable in dropsical complaints; but cloves, cardamoms, or some other warm spice, should always be joined with it, to correct its ill qualities, and render the use of it more safe: taken in smaller doses, it promotes urine and perspiration, and is very much extolled for its singular efficacy in obstructions and suppressions of the menses: it is likewise useful in all hysteric, nervous, and hypochondriacal complaints; and was at one time esteemed almost a specific for madness. There is a tincture of it kept in the shops, which is by far the best preparation for internal use: thirty or forty drops of this is a dose; but in order to be productive of any remarkable effects, the use of it must be persevered in for a considerable length of time.—Like most alpine plants, it loves a pure air, a moderately moist situation, and an unmanured soil. It will not thrive in the neighbourhood of London. The flowers being liable to be injured by frost, must be covered during the winter with hand-glasses, or preserved in pots in a common hot-bed frame, without which they cannot retain their beauty long. It is propagated by parting the roots in autumn.

4. *Helleborus Viridis*; *Green Hellebore*. Stem bifid; branches leafy, two-flowered; leaves digitate; peduncles axillary, an inch long, round, supporting two (sometimes only one) nodding green flowers; stem round, a little branched at top, leafy, reddish at the base, upright, smooth, a foot or eighteen inches high.—Native of France, Italy, Austria, Carniola, Silesia, and Switzerland. Ray, in his History, gives no hint of this or the next species being natives of England; and seems, in his Synopsis, to think that they are not aboriginals here. Bobart, however, speaks of this species as growing wild abundantly in Stokenchurch woods, and many other rocky and hilly situations: it is found near Cambridge; near Leeds in Yorkshire; near Arundel Castle, in Sussex; in various parts of Kent, Oxfordshire, and Northamptonshire. Parkinson mentions his having seen it in the woods in Worcestershire and Hampshire; it is found also among bushes in the woods and pastures of Dunglass Glen, Scotland: it flowers in March and April. If the seeds of this, and of the sixth species, be permitted to scatter, or are sown soon after they become ripe, the plants will come up early in the following spring, and when they have obtained sufficient strength, may be transplanted into woods or wilderness quarters, where they will thrive and flower very well in the shade, and make a good appearance when few other plants are in flower.

5. *Helleborus Officinalis*; *Black Hellebore*. Leaves pedate; flower-stalks radical, many-flowered; flowers white, turning purplish as they fade; bractees deeply lobed, serrated; roots black, fibrous, rather tuberous than creeping. This is the true Black Hellebore of the ancients, which ought to be used in medicine. The medicinal qualities of the root are acrid and violently purgative, and were supposed useful in maniacal cases.—Found on Mount Athos, on hills near Thessalonica, and near Constantinople.

6. *Helleborus Fœtidus*; *Stinking Hellebore*, or *Bear's-foot*. Stem many-flowered, leafy; leaves pedate; root small, but bent with a prodigious number of slender dark-coloured fibres: at the divisions of the branches are oval lanceolate stem-clasping stipules deeply bifid at the extremity; at the base of each peduncle, an oval lanceolate entire bracte; both these are frequently tinged with purple; flowers almost globular, pendent on peduncles, forming a sort of umbel.—Native of Germany, Switzerland, France, and England, preferring a

chalky soil, among bushes, flowering early in the spring. This species is always green, whereas the fourth species dies down to the root every year. It is often called Black Hellebore, and is frequently used as an anthelmintic; the powder of the dried leaves being the preparation principally made use of, and this in doses of about fifteen grains for children, the decoction of about a drachm of the green leaves being considered as equal to fifteen grains of the dry ones: it is usually repeated on two, and sometimes three, successive mornings; and seldom fails to bring away worms, if there be any in the intestinal tube. A decoction of the roots is a violent purge, and should be very sparingly used. Country people cut them into pieces; they insert these pieces into holes made in the ears and dewlaps of cattle, which produces a suppuration and discharge that proves serviceable in many disorders. The powder of the roots or leaves strewed on issues, greatly promotes the discharge, and consequently renders them more efficacious.

7. *Helleborus Lividus*; *Livid, Purple, or Great Three-flowered Black Hellebore*. Stem many-flowered, leafy; leaves ternate; flowering from January to May. This resembles the fourth species, but differs from it in having trifoliate leaves, which are broader, entire, with a smoother surface; and the stalks rise higher than any of our common sorts.—Native place unknown. It is propagated by parting its roots in autumn, and by seeds: but few of the latter ripen in general, nor do the roots make much increase: this is the real cause of its present scarcity. As it flowers in February, and is a singular plant, it well deserves to be admitted into every collection.

8. *Helleborus Trifolius*; *Small Three-leaved Hellebore*. Scape one-flowered; leaves ternate; stem leafless; flower minute, resembling that of the Parnassia, white, and sometimes yellow.—It is a native of Denmark, Siberia, Hudson's Bay, and of Canada; where it is so abundant in the woods as to cover the ground in many parts: it commonly chooses mossy places that are not very wet; Woodsorrel and Alpine Circæa are its companions. It is universally called *Tissavoyanne jaune*, by the Canadian French. The leaves and stalks are used by the Indians, for giving a fine yellow colour to several kinds of work, which they make of skins; and the French use it to dye wool yellow. It flowers in June and July.

Helmet Flower. See *Aconitum*.

Helonias: a genus of the class Hexandria, order Trigynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong, equal, deciduous. *Stamina*: filamenta six, subulate, a little longer than the corolla; anthers incumbent. *Pistil*: germen roundish, three-cornered; styles three, short, reflex; stigmas blunt. *Pericarp*: capsule roundish, three-celled. *Seeds*: roundish. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: six-petalled. *Capsule*: three-celled.—The plants of this genus may be increased by offsets, taken from the roots in autumn; or by seeds, which should be sown soon as ripe: they prefer a light fresh soil, and are hardy enough to thrive in the open air. They must not be removed oftener than once in three or four years; and they are as long in coming to flower from the seed.—The species are,

1. *Helonias Bullata*; *Spear-leaved Helonias*. Leaves elliptic-lanceolate, somewhat spatulate, ribbed; root perennial, composed of many thick fleshy fibres; the stalk is terminated by a close obtuse spike of dark red flowers, some of which are barren.—Native of moist shady places near Philadelphia, where it is called *Stargrass* by the natives; and is of an acrid aromatic flavour. It flowers in April and May.

2. *Helonias Asphodeloides*; *Grass-leaved Helonias*. Stem-leaves setaceous; stem extremely simple, two feet high; flowers white, in a simple terminating raceme, on peduncles

longer than the flowers. It very much resembles an Asphodel, but has three recurved styles.—Native of Pennsylvania and Virginia. It flowers in May and June.

3. *Helonias Pumila*. Radical leaves obovate, those on the stem lanceolate; cluster cylindrical; flowers with narrow white petals and yellow antheræ.—Native of Virginia, Canada, &c.

Helvella; a genus of the class Cryptogamia, order Fungi.—GENERIC CHARACTER. Pileus on the stem smooth on both sides; seeds thrown out from under the surface.—Persoon enumerates nine species; one without a stalk; three with a furrowed stalk; and five with a smooth or even one. The following are of each section.

1. *Helvella Acaulis*. Sessile, waved, expanded, reddish-brown, paler and fibrous underneath.—Found in the ground in Fir forests.

2. *Helvella Mitra*. Pileus tumid, many-lobed, of a blackish livid hue; stalk furrowed and cellular, whitish.—Common, growing on the ground, and is, like the Morel, eatable.

3. *Helvella Esculenta*. Stalk smooth; pileus reddish-brown, roundish, its surface crumpled and cellular. This is often confounded with the true Morel.

Hemerocallis; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: six-parted, bell-funnel-form; tube short; border equal, spreading, more reflex at top. *Stamina*: filamenta six, subulate, the length of the corolla, declining, upper ones shorter; antheræ oblong, incumbent, rising. *Pistil*: germen roundish, furrowed, superior; style filiform, the length and situation of the stamina; stigma obtusely three-cornered, rising. *Pericarp*: capsule ovate, three-lobed, three-cornered, three-celled, three-valved. *Seeds*: very many, roundish. ESSENTIAL CHARACTER. *Corolla*: bell-shaped, the tube cylindrical. *Stamina*: declining.—The species are,

1. *Hemerocallis Flava*; *Yellow Day Lily*. Leaves linear-subulate, keeled; corollas yellow. It has strong fibrous roots, to which hang knobs or tubers, like those of the Asphodel, from which come out leaves two feet long, with a rigid midrib, the two sides drawing inward, so as to form a sort of gutter on the upper side: the flower-stalks rise two feet and a half high, having two or three longitudinal furrows; these are naked, and at the top divide into three or four short peduncles, each sustaining one pretty large yellow flower, shaped like a Lily, having but one petal, with a short tube, spreading open at the brim, where it is divided into six parts: they have an agreeable scent, from which some have given this plant the title of Yellow Tuberosé. It flowers in June, and the seeds ripen in August.—There is a variety with smaller roots and leaves: both are natives of Siberia, Hungary, Dalmatia, Istria, and has found its way into Switzerland and Silesia. This, and the other species, are easily propagated by offsets, which the roots send out in plenty; they may be taken off in autumn, (that being the best season for transplanting the roots,) and planted in any situation, for they are extremely hardy, and will require no culture but weeding, and room sufficient to spread their roots. The first species may also be propagated by seeds, which, if sown in autumn, the plants will come up in the following spring, and these will flower in two years; but if the seeds are not sown till spring, the plants will not come up till the year after. In a moist soil and shady situation they thrive better than in dry ground.

2. *Hemerocallis Fulva*; *Copper-coloured Day Lily*. Leaves linear-subulate, keeled; corollas tawny or copper-coloured. This is a much larger plant than the first, and the roots spread and increase much more; the flower-stalks are as thick as a man's finger, and rise nearly four feet high; they are naked, without joints, and branching at the top, where

there are several copper-coloured flowers, shaped like those of the Red Lily, and as large. The stamina are longer than those of the preceding species, and their summits are charged with a copper-coloured farina, which sheds on being touched. The flowers appear in July and August, and only last each one day, though there is a succession on the same plant for a fortnight or three weeks.—Native place of growth uncertain. In Japan it varies with a double flower; and in China and Cochinchina the inhabitants boil the flowers, both fresh and dry, commonly with their meat. It is a very unsuitable plant for small gardens, and best adapted for plantations.

3. *Hemerocallis Lancifolia*. Leaves lanceolate, seven-nerved; scape round, jointed, upright, smooth, longer than the leaves; flowers at the top of the scape in racemes, drooping; corolla white.—Native of Japan, where it is frequently kept in gardens and houses for its elegance; flowering in August and September.

4. *Hemerocallis Japonica*. Leaves ovate, wavy, many-nerved; petioles winged, membranaceous, a hand in length or rather more.—Native of Japan.

5. *Hemerocallis Cordata*. Leaves heart-shaped, veined; stem round, upright, smooth, a foot high or more; flowers terminating, alternate, upright. Gærtner doubts whether this be a genuine species of *Hemerocallis*, since it differs so much in the fruit.—Native of Japan, where it is frequently cultivated.

6. *Hemerocallis Graminea*; *Narrow-leaved Day Lily*. Leaves channelled, nearly triangular; bractæ short and membranous; corolla swelling at the base, its inner segments crisped at the base; stigma three-lobed.—Native of Siberia.

Hemimeris; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted almost to the base, much shorter than the corolla; parts ovate, unequal, permanent. *Corolla*: monopetalous, wheel-shaped, ringent; tube very short, (scarcely any,) intruded, white; upper lip cloven, with a kind of bag at the base, composed of little nectareous pits; lower concave, blunt. *Stamina*: filamenta two or four, filiform, inserted into the base of the lower lip, bent round; antheræ very small, heart-form, cohering, yellow. *Pistil*: germen superior, sharp, smooth; style thread-form, of the same length and in the same situation with the stamina; stigma simple, sharpish. *Pericarp*: capsule ovate, sharp, twin, gibbous at the base on one side, two-celled, two-valved. *Seeds*: very many, smooth. *Observe*. Allied to *Antirrhinum*, but differing in the form of the corolla. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: wheel-form; upper lip cloven, with a nectareous bag at the base.—The species are,

1. *Hemimeris Sabulosa*. Diandrous: leaves opposite, pinnatifid; stem prostrate.—Native of the Cape.

2. *Hemimeris Montana*. Diandrous: leaves opposite, ovate, serrate; stem upright.—Native of the Cape.

3. *Hemimeris Diffusa*. Didynamous: leaves alternate and opposite, pinnatifid; stem patulous.—Native of the Cape.

Hemionitis, or *Mule Fern*; a genus of the class Cryptogamia, order Filices or Ferns.—GENERIC CHARACTER. Capsules digested into lines, meeting together, either intersecting each other or branched.—The species are,

1. *Hemionitis Lanceolata*. Fronds lanceolate, quite entire; leaves plane and simple, seldom exceeding sixteen or eighteen inches in length, when most luxuriant; they grow in tufts from a strong fibrous root. This plant is commonly found on the trunks of trees, in the cooler and more shady inland woods of Jamaica.—Neither this nor any of its genus is often propagated in gardens. They must be all procured from the country where they naturally grow; planted in pots filled with loamy undug earth; and placed in the stove: in

summer they must be frequently watered, but they require little in winter. They require abundance of free air in summer.

2. *Hemionitis Lineata*. Frond lanceolate-linear; lines of fructifications nearly parallel, longitudinal.—Native of Jamaica.

3. *Hemionitis Parasitica*. Fronds ovate, acuminate; shoots chaffy, creeping; leaves about two inches long, and one and a half over where broadest.—Creeping on trees in the cooler inland woods of Jamaica.

4. *Hemionitis Palmata*. Fronds palmate, hirsute; roots many, fibrous, black; stalks black, cornered, about six inches high, covered with ferruginous hair: the whole frond is like the leaf of a creeping *Ranunculus*.—Found between Savannah and Two-mile Wood in Jamaica, and also in Martinico.

5. *Hemionitis Japonica*. Fronds bipinnate; pinnae lanceolate, entire. The fructifications are in trichotomous lines, over the whole lower surface.—Native of Japan.

6. *Hemionitis Reticulata*. Fronds lanceolate-sickled, quite entire; veins netted.—Native of the Society Islands.

7. *Hemionitis Esculenta*. Frond pinnate; pinnae alternate, lanceolate, crenate, slightly eared at the base. This species is a foot and half high or more; stipe smooth, grooved; roots, esculent.—Native of the East Indies.

8. *Hemionitis Triloba*. Frond pinnate; leaflets three-lobed, sinuated, taper-pointed, downy, stalked, the terminal one large, very deeply three-lobed; lines of capsules numerous.—A very elegant Fern: native of the Brazils.

9. *Hemionitis Acrostichoides*. Fronds pinnate, distinct; leaflets broad-lanceolate, taper-pointed, waved or crenate; fructifications confluent.—Gathered at Sierra Leone.

Hemlock, Common. See *Conium*.

Hemlock, Water. See *Cicuta*.

Hemp, Bastard. See *Datisca*.

Hemp, Virginia. See *Acrida*.

Henbane. See *Hyoscyamus*.

Heracleum; a genus of the class Pentandria, order Digenia.—GENERIC CHARACTER. *Calix*: umbel universal, manifold, very large, partial flat; involucre universal, many-leaved, caducous, partial halved on the outside; leaflets three to seven, linear-lanceolate, the exterior ones longer; perianth obscure. *Corolla*: universal not uniform, radiate; floscules all generally fertile; proper of the disk equal, five-petalled; petals bent in and hooked, emarginate; of the ray unequal, five-petalled; the outer ones larger and more bifid, oblong, hooked. *Stamina*: filamenta five, longer than the corollets; antheræ small. *Pistil*: germen subovate, inferior; styles two, approximating, short; stigmas simple. *Pericarp*: none; fruit elliptic, compressed, emarginate, striated in the middle on both sides, margined. *Seeds*: two, ovate, leafy, and compressed. *Observe*. In some species the radiate female flowers are fertile; the male ones of the disk are abortive, being destitute of stigmas. The first and second species are hermaphrodite throughout, and sometimes the involucre is entirely wanting. The second species has uniform flowers. ESSENTIAL CHARACTER. *Involucre*: caducous. *Corolla*: difform, inflex-emarginate. *Fruit*: elliptic, emarginate, compressed, striated, margined.—To propagate the plants of this genus, sow their seeds in autumn; in the spring, when the plants are up, hoe the ground, cutting up the weeds, and thinning the plants as directed for Parsneps.—The species are,

1. *Heracleum Sphondylium*; *Common Cow-Parsnep*. Leaflets pinnatifid, even; flowers radiate; root biennial, thick, yellowish without, white within, running deep into the ground,

sweet to the taste, with some acrimony; stem two, three, and four feet high, round, furrowed, rough with white hairs, hollow within, branched from the bottom; leaves hairy and scabrous, frequently a foot in length, and more than half that in breadth, pinnate and waved. The universal umbel is flat, and has ten, twelve, or more rays; the partial umbel has upwards of thirty; florets white, greenish-white, or purplish; they have a horned appearance before they expand, particularly the outer ones, which are four times the size of the inner petals; the central flowers are frequently abortive. The seeds have a strong smell, somewhat like that of a bug; but are accounted diuretic and stomachic. Linneus says that the plant is used in Scania for the dysentery; and Gmelin informs us that the inhabitants of Kamtschatka, about the beginning of July, collect the footstalks of the radical leaves, and after peeling off the rind, which is very acrid, dry them separately in the sun, and then, tying them in bundles, lay them up carefully in bags placed in the shade, where they become covered with a yellow saccharine efflorescence, tasting like liquorice, which being shaken off, is eaten as a great delicacy. The Russians distil an ardent spirit from the stalks thus prepared, by first fermenting them in water with the greater bilberries; and the spirit thus produced is said to be more agreeable to the taste than spirits made from corn. The leaves are a favourite food with rabbits and swine: horses are said not to like them, but cows, sheep, and goats, are partial to them. The Germans call this plant *Heilkrout*, *Barenklaw*; the Dutch, *Heilruid*, *Beerrenklaaw*; the Danes, *Bjorneklov*; the Swedes, *Biornsløka*; the French, *la Berce*; the Italians, *Sfondilio*; the Spaniards, *Essondilio*; the Portuguese, *Canabraz*; and the Russians, *Putschki*, *Slatkaja trawa*. The old English writers call it *Cow Parsnep*, *Meadow Parsnep*, and *Madnep*. It is called *Hogweed* in Norfolk; and in various parts of England the dry stalks are named *Kexes* or *Kocksies*, in common with those of some other plants.—Native of most parts of Europe, in moist and fertile soils, flowering from May to July.

2. *Heracleum Angustifolium*; *Narrow-leaved Cow-Parsnep*. Leaves crosswise pinnate; leaflets linear; corollas flosculose. It is probably a mere variety of the foregoing. Hudson remarks, that the distinction of the flosculose and radiate corolla is very uncertain.—It grows plentifully near Berkhamstead in Hertfordshire, near the place where Ray found it; and where both sorts may be seen growing from the same root. There are other varieties also not worth enumerating.

3. *Heracleum Sibericum*; *Siberian Cow-Parsnep*. Leaves pinnate; leaflets in fives, the middle ones sessile; corollets uniform; root biennial; stem deeply furrowed, hispid; flowers flosculose, by no means radiate; petals green, bent in, not at all emarginate; universal involucre none. The Kamtschadales extract a kind of spirit from this species, which is called *Raka*.—Native of Siberia.

4. *Heracleum Panaces*; *Palmated Cow-Parsnep*. Leaves pinnate; leaflets in fives, the middle ones sessile; flowers radiate; root biennial; stem much taller than the common sort, attaining the height of six feet, hirsute, round, slightly angular, branched; flowers large, radiate, greenish or yellowish white. Gerarde calls it *Hercules All-Heal*.—Native of Italy, Silesia, and Siberia.

5. *Heracleum Austriacum*; *Austrian Cow-Parsnep*. Leaves pinnate, wrinkled and scabrous on both sides; flowers subradiate; root knotty, with circles round it, and a few fibres; stem from a foot to two feet in height, slightly angular, striated, solitary, smooth, soft, with a white pile only towards the top, scarcely branched. It flowers in July and August.—Native of Austria, Carniola, and Silesia.

6. *Heracleum Alpinum*; *Alpine Cow-Parsnep*: Leaves

simple; flowers radiate; stem from eighteen inches to three feet high, round, smooth, jointed; corollas white, radiate, smaller than in the rest.—Native of the Swiss Alps, Provence, and Silesia.

7. *Heracleum Lanatum*. Petiole of the leaves woolly and very villose; seeds orbiculate; flowers white.—Found in shady woods on rich moist soil, in Canada and Pennsylvania, flowering in June and July.

Herb Bennet. See *Geum*.

Herb Christopher. See *Actæa*.

Herb Paris. See *Paris*.

Herb Robert. See *Geranium*.

Heritiera; a genus of the class Monœcia, order Monadelphia, or, according to Schreber, order Syngenesia.—**GENERIC CHARACTER.** *Male Flowers*, smaller than the females. *Calix*: perianth one-leaved, bell-shaped, five-toothed. *Corolla*: none. *Stamina*: filamentum in the centre of the calix, columnar, conic-subulate, below the tip surrounded by antheræ, from five to ten in number, minute, united into a cylinder. *Female Flowers*, in the same plant with the males, larger. *Calix*: as in the males. *Corolla*: none. *Stamina*: filamenta none; antheræ ten, inserted into the receptacle at the base of the germina, two between each, twin, minute, perhaps barren. *Pistil*: germina five, semi-ovate, compressed, smooth; styles conical, short, in flowering-time cohering at the tip; stigmas club-shaped. *Pericarp*: five drupes, juiceless, spreading very much, oval, flattish above, convex underneath, keeled and winged, one-celled. *Seeds*: solitary, subglobular, large. **ESSENTIAL CHARACTER.** *Male*. *Calix*: five-toothed. *Corolla*: none. *Filamenta*: columnar. *Antheræ*: from five to ten, below the top. *Female*. *Calix*: five-toothed. *Corolla*: none. *Germina*: five, sessile. *Drupes*: five, dry, with one subglobular seed.—The only species yet discovered is,

1. *Heritiera Littoralis*; *Looking-glass Plant*. A tree with alternate, oval-oblong, obtuse, perennial, thick, veined, smooth, quite entire, petioled leaves.—Found in Ceylon and Pulo Condore, and generally a native of the East India islands, in a wet sandy soil, flowering from August to November.

Hermannia; a genus of the class Monadelphia, order Pentandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-cleft, roundish, inflated; the little clefts bent in, permanent. *Corolla*: pentapetalous, spiral against the sun; claws the length of the calix, with a little membrane on each side converging into a cowed nectareous tube; border spreading, broadish, blunt. *Stamina*: filamenta five, broadish, very slightly coalescing at bottom into one body; antheræ upright, acuminate, converging. *Pistil*: germen roundish, five-sided, five-cornered; styles five, filiform, approximating, subulate, longer than the stamina; stigma simple. *Pericarp*: capsule roundish, five-sided, five-celled, gaping at the top. *Seeds*: very many, small; according to Gærtner, kidney-form. **ESSENTIAL CHARACTER.** *Styles*: five. *Capsule*: five-celled. *Petals*: semitubular at the base, oblique.—The plants of this genus are all propagated by planting cuttings of them during any of the summer months, in a bed of fresh earth, observing to water and shade them until they are well rooted, which will be in about six weeks after planting: then take them up with a ball of earth to their roots, and plant them into pots filled with light fresh earth, placing them in a shady situation until they have taken fresh root; after which they may be exposed to the open air with Myrtles and Geraniums, until the middle or end of October; when they must be removed into the green-house, observing to place them in the coolest part of the house, where they may have as much free air as possible; for if they are too much drawn in the house, they will appear

VOL. I.—57.

faint and sickly, and seldom produce many flowers; whereas when they are only preserved from the frost, and have a great share of free air, they will appear strong and healthy, and produce large quantities of flowers in April and May, during which season they make a very handsome appearance in the green-house: they must also be frequently watered, and will require to be new-potted at least twice every year, in May and September, without which their roots would be so matted as to retard their growth. These plants, except the ninth and twenty-first species, seldom produce good seeds in England, which is probably owing to their having been long propagated from cuttings only, for they are generally fruitful when raised from seeds.—The species are,

1. *Hermannia Althæifolia*; *Marshmallow-leaved Hermannia*. Leaves ovate, crenate, plaited, tomentose; flowering calices bell-shaped, angular; stipules oblong, leafy. This seldom rises more than two feet and a half high; the stem is not very woody, and the branches are soft and tender.—Native of the Cape of Good Hope.

2. *Hermannia Plicata*; *Plaited-leaved Hermannia*. Leaves cordate-ovate, toothletted, plaited, tomentose; flowering calices oblong-ovate, subcylindrical. It flowers in November and December.—Native of the Cape of Good Hope.

3. *Hermannia Candicans*; *White Hermannia*. Leaves ovate, serrated, subcordate, blunt, tomentose; flowering calices patulous, somewhat angular; stipules subulate. The whole plant is covered with a very white down.—Native of the Cape of Good Hope.

4. *Hermannia Salvifolia*. Leaves ovate, entire, wrinkled, tomentose, hispid; flowers drooping.—Native of the Cape of Good Hope; found there by Thunberg.

5. *Hermannia Biserrata*. Leaves ovate, lanceolate, unequal, serrate, smooth; flowers drooping.—Found by Thunberg at the Cape of Good Hope.

6. *Hermannia Trifurca*. Leaves lanceolate, entire, three-toothed; flowers in racemes, pointing one way; petals blue.—Native of the Cape of Good Hope.

7. *Hermannia Alnifolia*; *Alder-leaved Hermannia*. Leaves wedge-shaped, marked with lines, plaited, crenate-emarginate. It rises with a shrubby stalk six or eight feet high, dividing into many erect irregular branches, covered with a brown bark. The flowers are produced in short spikes on the upper part of the branches; they are small, and of a pale yellow colour, appearing in April and May, and ripening into seed in August.—Native of the Cape of Good Hope.

8. *Hermannia Odorata*; *Sweet-scented Hermannia*. Leaves oblong-lanceolate, tomentose, wrinkled underneath, the lower one truncate and toothletted; calices pitcher-shaped and angular. It flowers most part of the year.—Native of the Cape of Good Hope.

9. *Hermannia Hyssopifolia*; *Hyssop-leaved Hermannia*. Leaves lanceolate, blunt, serrate. It rises with a shrubby stalk to the height of seven or eight feet, sending out many woody lateral branches, growing very erect. The flowers come out in small bunches from the side of the stalk: they are of a pale straw colour, appear in May and June, and are frequently followed by seeds, which ripen in the latter part of August.—Native of the Cape of Good Hope.

10. *Hermannia Lavendulifolia*; *Lavender-leaved Hermannia*. Leaves lanceolate, blunt, quite entire. This has shrubby branching stalks, which are very bushy, but seldom rise more than a foot and a half high, and are very slender. The flowers come out singly from the side of the stalk, are small and yellow, and continue most part of the summer.—Native of the Cape of Good Hope.

11. *Hermannia Denudata*; *Smooth Hermannia*. Leaves

lanceolate, sharp, even, serrate at top; stems upright, round, smoothish, stiff; corolla yellow. It flowers from May to July.

—Native of the Cape of Good Hope.

12. *Hermannia Glabrata*. Leaves lanceolate, sharp, gash-serrate, smooth; flowers drooping.—Native of the Cape.

13. *Hermannia Ciliaris*. Leaves lanceolate, sharp, entire, and serrate, ciliate.—Native of the Cape of Good Hope.

14. *Hermannia Linifolia*. Leaves linear; peduncles one-flowered.—Native of the Cape of Good Hope.

15. *Hermannia Filifolia*. Leaves linear, three-sided, quite entire.—Native of the Cape of Good Hope.

16. *Hermannia Trifoliata*. Leaves ternate, sessile, plaited, retuse, tomentose; stem creeping; branches narrow; flowers pendulous.—Native of the Cape of Good Hope.

17. *Hermannia Triphylla*. Leaves ternate, petioled, flat, obovate; stems herbaceous; stipules small; petals the length of the leaves: the whole plant has hairs thinly scattered over it.—Native of the Cape of Good Hope.

18. *Hermannia Grossularifolia*; *Gooseberry-leaved Hermannia*. Leaves lanceolate, pinnatifid, rough. This is of lower stature than the seventh species, but sends out a greater number of branches, which spread wide on every side. The flowers are produced in short close spikes at the end of every shoot, so that the whole shrub seems covered with them; they are of a bright yellow, and appear towards the end of April, but are not succeeded by seeds in England.—Native of the Cape of Good Hope.

19. *Hermannia Pulchella*. Leaves lanceolate, pinnatifid; pinnae entire and gashed; stem upright, even.—Found by Thunberg, at the Cape of Good Hope.

20. *Hermannia Diffusa*. Leaves lanceolate, pinnatifid; pinnae entire and toothed; peduncles capillary, two-flowered; stem procumbent.—Native of the Cape of Good Hope.

21. *Hermannia Hirsuta*. Leaves simple and ternate, hirsute, sessile. It rises with a shrubby hairy stalk about two feet high, sending out many side-branches, which grow very erect; the flowers are produced towards the end of the branches; they are large, and of a deep yellow colour, with large, swollen, hairy calices. It continues flowering most part of the summer.—Native of the Cape of Good Hope.

Hermas; a genus of the class Polygamia, order Monœcia. —GENERIC CHARACTER. *Hermaphrodite*, umbel terminating. *Calix*: umbel universal, many-rayed, hemispheric; partial many-rayed; central ray flower-bearing, the rest without any floret; involucre universal, many-leaved, lanceolate, short, permanent; partial, of one or two leaves, lanceolate, the length of the partial umbel: proper perianth obscure, five-toothed. *Corolla*: universal flosculous; of the proper, petals five, oblong-ovate, upright, flat, entire, equal. *Stamina*: filamenta five, filiform, shorter than the petals; antheræ barren, oblong. *Pistil*: germen inferior, compressed, larger than the corolla; styles two, filiform, upright, longer than the corolla; stigmas obtuse. *Pericarp*: none; fruit orbicular, emarginate at the base, gaping at the angles. *Seeds*: two, cordate-orbicular, compressed, flat, margined, marked with a single longitudinal elevated streak. *Male*, umbels lateral, later, of the same plant. *Calix*: umbel universal, as in the hermaphrodite; partial, many-rayed, the rays all flower-bearing; involucre as in the hermaphrodites; perianth scarcely any. *Corolla*: as in the hermaphrodites. *Stamina*: filamenta five, filiform, length of the corolla; antheræ pollen-bearing, oval, nearly twin. ESSENTIAL CHARACTER. *Hermaphrodite*. *Umbel*: terminating. *Involucre*: universal and partial; umbellets with truncate rays, the central one floriferous. *Petals*: five. *Stamina*: five, barren. *Seeds*: in pairs, sub-orbiculate. *Male*. *Umbels*: lateral, with universal and par-

tial involucre; umbellets many-flowered. *Petals*: five. *Stamina*: five, fertile.—For the mode of propagating and cultivating the plants of this genus, see *Bupleurum*.—The species are,

1. *Hermas Depauperata*. Stem shrubby: leaves oblong, embracing, toothed, villose underneath. This is an umbelless plant, with the leaves radical, subpetioled, cordate, coriaceous, white-tomentose underneath; umbels at the ends of the stem and branches, peduncled, compound.—Native of the Cape.

2. *Hermas Gigantea*. Leaves lanceolate-ovate, lanuginose above, underneath tomentose, entire, a foot in length, and a span in breadth; stem four feet high, with a small leaf or two towards the lower part; the axils villose. The wool scraped from the leaves is used at the Cape of Good Hope (where it is a native) for tinder, like that obtained from the *Artemisia* in China and Japan.

3. *Hermas Capitata*. Stem tomentose; leaves subcordate, serrate; umbels capitate; heads three, alternate, peduncled, composed of florets, scarce visibly pedicelled, as in the flowers of the class Syngenesia.—Native of the Cape.

4. *Hermas Quinquedentata*. Stem smooth; leaves ovate, five-toothed, tomentose underneath; umbel solitary. This is very distinguishable from the rest, by its small leaves with five fine deep serratures.—Native of the Cape.

5. *Hermas Ciliata*. Stem smooth; leaves ovate, ciliate, tomentose underneath; umbels several.—Discovered by Thunberg at the Cape of Good Hope.

Hernandia; a genus of the class Monœcia, order Triandria.—GENERIC CHARACTER. *Male Flowers*, by pairs, lateral in each umbel. *Calix*: involucre partial, four-leaved, three-flowered; leaflets ovate, obtuse, spreading very much; perianth none. *Corolla*: petals six, subovate, spreading, the three inner ones narrower; nectary six glands, round-headed, placed round the filamenta. *Stamina*: filamenta three, shorter than the petals, inserted into the receptacle; antheræ upright, oblong, large. *Female Flower*, intermediate. *Calix*: involucre common with the males; perianth inferior, one-leaved, bell-shaped, entire, permanent, (according to Gærtner, inflated.) *Corolla*: petals six or eight, of which four are interior and narrower, all sitting on the germen; nectary glands four, obovate, alternate with the interior petals. *Pistil*: germen roundish; style filiform; stigma oblique, somewhat funnel-shaped, large. *Pericarp*: drupe dry, ovate, eight-furrowed, one-celled, enclosed in a very large, inflated, roundish, fleshy, coloured perianth, with the mouth entire. *Seeds*: nut globular, slightly depressed. ESSENTIAL CHARACTER. *Male*. *Calix*: three-parted. *Corolla*: three-petalled. *Female*. *Calix*: truncate, quite entire. *Corolla*: six-petalled. *Drupe*: hollow, with an open mouth, and a moveable nucleus. (*Nut*: superior, clothed with the calix, inflated. *Seeds*: globular, and bony, according to Gærtner.) —The species are,

1. *Hernandia Sonora*; *Whistling Hernandia*. Leaves pel-tate. This is an upright lofty tree, with an elegant head; the flowers are of a pale yellow colour, in panicled racemes; the calices of the fruit are yellow. It is very common in the West Indies, in gullies, near rills of water; the English there call it *Jack-in-a-box*, and the French *Myrobolan*. Dr. Patrick Browne says it is common in Barbadoes and Montserrat, where it grows to a considerable size; but that he had not seen it in Jamaica, though he had been credibly informed that it is frequent in the parish of Portland. He attributes the whistling noise which the motion of these plants produces to the cups that sustain and partly envelop the nuts, which, he adds, are very large, and, as they move in the wind, produce sound enough to alarm unwary travellers. The seeds are very oily.—Sow the well-ripened seeds of these plants in a hot-bed

in the spring; when the plants are two inches high, transplant each into a separate pot, filled with fresh rich earth, and plunged into the hot-bed again, observing to water and shade them until they have taken root; after which admit air to them in proportion to the warmth of the air, or the heat of the bed, and water them frequently. As the plants advance, remove them into larger pots, being careful not to break the roots, and to preserve a good ball of earth to them: if their leaves hang, screen them from the sun until they have taken new root. Shift them in July, that they may be well rooted before the cold approaches. Keep them constantly in the bark-stove; in winter give them a moderate share of heat, and in summer plenty of air when the weather is hot. With this management, the plants will grow to the height of sixteen feet or more, and the leaves being very large, will make a beautiful appearance in the stove.

2. *Hernandia Ovigera*; *Egg-fruited Hernandia*. Leaves ovate, petioled at the base. A tree, with leaves six inches long; fruit the size of an egg, and similar in structure to that of the first species.—Native of the East Indies.

3. *Hernandia Guianensis*. Leaves heart-shaped, oblong, pointed, folded; bracts whorled. This tree is sixty feet in height, and has a light aromatic wood, and leaves longer in proportion than the last species: it is rendered very conspicuous by its very numerous grayish flowers.—Native of Guiana. The inhabitants use the kernels as a purgative.

Herniaria; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, sharp, spreading, coloured within, permanent. *Corolla*: none. *Stamina*: filamenta five, subulate, minute, within the parts of the calix; antheræ simple; there are also five barren filamenta, alternating with the segments of the calix. *Pistil*: germen ovate; style scarcely any; stigmas two, acuminate, the length of the style. *Pericarp*: capsule small, in the bottom of the calix, covered, scarcely gaping. *Seed*: solitary, ovate-acuminate, shining. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: none. *Stamina*: five, barren, besides the fertile ones. *Capsule*: one-seeded.—The species are,

1. *Herniaria Glabra*; *Smooth Rupturewort*. Herbaceous and smooth. It is chiefly distinguished from the next species by the smoothness of its habit: the stalks are trailing and many, forming a little tuft, the length of the finger, or at most six inches, round, with many alternate branches; leaves ovate or ovate-lanceolate, something like those of Wild Thyme, opposite, sessile or subsessile, smooth, bright green; flowers axillary, glomerate, sessile, six or eight together, at the joints of the stem and branches. This plant was formerly in some reputation, not only for curing ruptures, but the stone, gravel, and dropsy; it was also given in disorders of the eyes, but has now fallen into utter disuse. Withering and Pollich, however, still aver that it increases the secretions by the kidneys, and that the juice will remove specks from the eyes. It is salish and astringent, and, according to Krockner, is agreeable to sheep. Mr. Miller remarks, that the herb-women used commonly to bring the Parsley-Breakstone, or *Aphanes Arvensis*, to market instead of this plant.—It is common in the sandy soils of Switzerland, Sweden, Denmark, Germany, France, Italy, Carniola; with us in England, at the Lizard Point, Cornwall, flowering in July.

2. *Herniaria Hirsuta*; *Hairy Rupturewort*. Herbaceous and hairy. The general opinion concerning this plant is, that it is a mere variety of the former; but whether specifically distinct or not, it is easily distinguished by the whole plant being hairy.—It flowers in July and August, and is a native of Germany, Switzerland, Italy, Carniola, and has been found with us close to Colney Hatch, near Barnet.

3. *Herniaria Froticosa*; *Shrubby Rupturewort*. Stems shrubby; flowers four-cleft. This has stalks trailing on the ground, with small hairy leaves like the second sort; the flowers also bear a great resemblance to that. It is perennial, and may be propagated by cuttings.—Native of Spain.

4. *Herniaria Alpina*. Leaves obovate, acute, fringed at the margin; flowers densely clustered, five-cleft, hairy; root extremely long, and simple.—Native of the hills of Dauphiny.

Hesperis; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets lanceolate-linear, from parallel converging, at top incumbent, at bottom gaping, deciduous: of these, two opposite ones are gibbous at the base. *Corolla*: four-petalled, cruciform; petals oblong, the length of the calix, a little bent back obliquely, contrary to the sun's apparent motion, ending in attenuated claws, the length of the calix. *Stamina*: filamenta six, subulate, the length of the tube, two of them shorter by half than the others; antheræ linear, upright, reflex at the tip; an acuminate honied gland between each shorter stamen and the germen, and surrounding the stamen. *Pistil*: germen the length of the calix, prismatic, four-cornered; style none; stigma two-parted, placed on the inside, oblong, upright, forked at the base, converging at the tip, withering. *Pericarp*: silique long, pressed flat, stiff, and straight, two-celled, two-valved; the valves of the same length with the partitions. *Seeds*: very many, ovate, compressed. ESSENTIAL CHARACTER. *Petals*: bent obliquely; a gland within the shorter stamina. *Siliqua*: stiff. *Stigma*: with a forked base and converging tip. *Calix*: closed.—The species are,

1. *Hesperis Tristis*; *Night-smelling Rocket*. Stem hispid, branched, spreading. The leaves of this sort are much larger than those of the Garden Rocket, and of a paler green, the stalks are closely set with bristly hairs; the flowers grow in loose panicles at the top of the stalk, and appear about the same time as the Garden Rocket. It is much cultivated on the Continent, for the great fragrantcy of its flowers in the evening. The German ladies place pots of it in their apartments; whence it has obtained the name of Dame's Violet.—Native of the outskirts of woods and shrubby ditches, in Germany, flowering in May. It is propagated by seeds in the same way as the Garden Rocket; which see. It is not quite so hardy, being very subject to rot in winter, especially in a moist soil or in rich land; it should be planted therefore in a dry poor soil and a warm situation. If some plants be set in pots, and placed under a common frame in winter, it will be sure to preserve them.

2. *Hesperis Matronalis*; *Garden Rocket*. Stem simple, upright; leaves ovate-lanceolate, toothletted; petals emarginate, with a point. It rises with an upright stalk a foot and half high, with spear-shaped leaves, which sit close to the stalk, and are slightly indented on their edges, ending in acute points; the flowers are produced in a loose thyrse on the top of the stalks; the petals are roundish, and indented at the points, of a deep purple colour, and smell very sweet, especially in the evening, or in cloudy weather. The Garden Rocket with purple flowers was formerly more plentiful in England, and has been neglected merely because the flowers are single and make but little show, although their scent is so grateful that they deserve a place in every good garden.—This grows naturally in Italy. There are several varieties of this plant; one with white flowers, but having less scent; another with double white flowers, mentioned by Johnson in 1633; and a third called the Siberian Rocket, which is nearly the same in all its parts with the common Garden Rocket. Mr. Ray

observed the wild single sort between Salerno and Naples. The Siberian Rocket is very fragrant.—This being biennial, young plants should be raised every year, to supply the place of those which decay: if the seeds are permitted to scatter, the plants will come up without trouble in the spring; but if they are sown, the best season for it is in the autumn; because those sown in the spring often fail when the season proves dry, or will remain long in the ground before they vegetate. It will thrive better in a loamy undunged soil than in rich land.

3. *Hesperis Inodora*; *Scentless Rocket*. Stem simple, upright; leaves subhastate, toothed, blunt. It rises with an upright stalk nearly two feet high; the flowers grow in loose spikes on the top of the stalks; in some they are white, in others purple, and sometimes both colours striped in the same flower; but having no odour, they are not so deserving of being introduced into gardens. From this species the double white and purple Rockets have been accidentally obtained: they are much esteemed for the beauty of their flowers; and if they also possessed the agreeable odour of the Garden Rocket, they would be some of the best furniture for the borders of the flower-garden, for, though scentless, many highly esteem them for the beauty of their flowers. This sort being naturally biennial, the plants with single flowers rarely survive the second year; nor will those with double flowers continue much longer; so that unless young plants are annually raised to supply the place of the old ones, there will soon be a scarcity of them. There should be some strong roots of each sort kept apart for this purpose, which are not intended to flower: when these have shot up their flower-stalks about six inches high, they should be cut close to the bottom; each of these may be divided in the middle to make two cuttings, which should be planted in a soft, gentle, loamy soil, to an east exposure, where they may have only the morning sun. They may be planted near together, so as to be covered with hand or bell glasses, which should be put over them after the cuttings have been well watered, and closely shut down, drawing the earth round the rim of the glasses to exclude the air; then the glasses should be shaded with mats every day when the sun is hot; and if the cuttings be gently refreshed with water once in seven or eight days, it will be sufficient, for too much moisture would rot them. After they are watered, the glasses should be shut down closely as before. In five or six weeks the cuttings will begin to put out roots, and will shoot up; then the glasses should be gradually raised on one side to admit the air to them, that they may be hardened, and prevented from drawing up weak. When they have made good roots, they should be carefully removed, and planted in an east border about eight or nine inches asunder, observing to shade and water them till they have again taken root; after which they will only require to be kept clean till autumn, when they may be transplanted into the borders of the pleasure-garden where they are designed to flower. The roots which are thus cut down, will send up more stalks than before; and when these are of a proper height, they may be cut off, and treated in the same way: so that when the roots are sound, two or three crops of these cuttings may be taken from them, and thus the old roots may be continued much longer than if they were permitted to flower, which will always secure a supply of good plants for the flower-garden.

4. *Hesperis Africana*; *African Rocket*. Stem very much branched and diffused; leaves lanceolate, petioled, sharply toothed, scabrous; siliques sessile; the stem, leaves, and pods of this plant, are rough with three-barbed hairs; the flowers are flesh-coloured, with narrow, sublanceolate, bluntish petals.—It is annual, and a native of Africa. If the seeds be permitted to scatter, the plants will come up without care,

and only require to be kept clean from weeds; or they may be sown in the spring or autumn where they are to stand, for they do not bear transplanting well.

5. *Hesperis Verna*; *Early-flowering Rocket*. Stem upright branched; leaves cordate, stem-clasping, serrate, villose; the stalk rises nine inches high, branching towards the top; the flowers are produced in loose panicles at the ends of the branches, they are of a lively purple colour; and those plants which rise in the autumn, flower in the spring.—Native of the south of France. The seeds sown in the autumn succeed much better than those sown in the spring.

6. *Hesperis Lacera*. Leaves runcinate; siliques tricuspidate, knotted. It is a low annual plant, with pointed leaves, having the borders indented as if torn; the corolla is purple, and the flower has an unpleasant smell.—Native of Portugal and the south of France. If the seeds be sown in the spring upon sheltered borders where the plants are to remain, and they are thinned and kept clean from weeds, the plants will flower in July, and produce ripe seeds in autumn.

7. *Hesperis Laciniata*. Stem branched; leaves unequally jagged; corolla sulphur-coloured; root biennial; the whole plant villose with short hairs; stalks round.—Native of Piedmont, about La Briga and Sospello, on rocks exposed to the sun.

8. *Hesperis Pinnatifida*. Leaves serrate, superior, lanceolate, inferior, winged on the under side. It flowers in June.—Native of the shady woods of Kentucky and Tennessee.

Heuchera; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calx*: perianth one-leaved, five-cleft, rounded, narrow; clefts obtuse. *Corolla*: petals five, inserted into the edge of the calix, oval-linear, the length of the calix. *Stamina*: filamenta five, subulate, upright; antheræ roundish. *Pistil*: germen roundish, half five-cleft, ending in straight styles, the length of the stamina: (according to Gærtner, permanent, subulate-setaceous, long, diverging;) stigmas blunt. *Pericarp*: capsule ovate, acuminate, half five-cleft, two-beaked, two-celled, the beaks bent back; (according to Gærtner, inferior, closely barked by the calix, opening by a hole within the styles.) *Seeds*: many, small. **ESSENTIAL CHARACTER.** *Petals*: five. *Capsule*: two-beaked, two-celled.—These plants are propagated by parting the roots in autumn, and should be planted in a shady situation: they will bear the open air in England.—The species are,

1. *Heuchera Americana*; *American Heuchera*, or *Sanicle*. Scapes almost naked; thyrses elongated; root-leaves seven-lobed, on long petioles, doubly and sharply crenate; root perennial; scapes a foot high, dividing at top into a loose panicle, sustaining many small hairy flowers of an obsolete purple colour. Perennial.—It flowers in May; ripens seed in August; and is a native of Virginia.

2. *Heuchera Dichotoma*. Stem branched; peduncles two-flowered, axillary; leaves linear-lanceolate, opposite, entire on the stem. This species, in the appearance of the flower, recedes a little from the characters of the genus, but not so much as to justify the institution of a new genus for it. The whole plant is hairy; peduncle emerging laterally from the bosom of the divarications of the branches, erect, long, dilated at the base, two-flowered, with two small pedicels, of which one is longer than the other; seeds many, minute.—Native place uncertain.

Hibiscus; a genus of the class Monadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth double; outer many-leaved, permanent; leaflets linear, more rarely one-leaved, many-cleft; inner one-leaved, cup-shaped, half-five-cleft, permanent, or five-toothed, deciduous. *Corolla*:

petals five, roundish-oblong, narrower at the base, spreading, fastened at the bottom to the tube of the stamina. *Stamina*: filamenta very many, united at bottom into a tube, at top (in the apex and surface of this) divided and loose; antheræ kidney-form. *Pistil*: germen roundish; style filiform, longer than the stamina, five-cleft at top; stigmas headed. *Pericarp*: capsule five-celled, five-valved; partitions contrary, doubled. *Seeds*: solitary or several, ovate-kidney-form. **ESSENTIAL CHARACTER.** *Calix*: double, the outer of many leaves or segments. *Stigmas*: five. *Capsule*: of five cells, with several seeds.—The species are,

1. *Hibiscus Moscheutos*; *Musk Hibiscus*. Leaves ovate, acuminate, serrate; stem very simple; petioles floriferous; root perennial; stalk single, two feet high, or more; flowers large, purple. It is remarkable in this species, that the flower springs from the petiole of the leaf, as in *Turnera Ulmifolia*.—Native of Virginia and Canada; though Cornutus informs us, that it originally came from the woods of Africa. This, the second, twenty-second, thirty-fifth, and fortieth species, are hardy enough to bear the open air in England; but the two first, and thirty-fifth, seldom flower in the open air of our climate, unless in very warm summers, though the roots will live when planted in a sheltered situation. The only way to have these plants flower here, is to keep the roots in pots, and to shelter them under a frame in winter, and in the spring plunge them into a gentle hot-bed, which will cause them to put out their stalks early, and when the stalks are so high as to reach the glasses, the pots may be removed into a glass-case; where, if they are duly supplied with water, and have plenty of air in hot weather, they will flower very well in July, and in warm seasons will ripen their seeds.

2. *Hibiscus Palustris*; *Marsh Hibiscus*. Stem herbaceous, very simple; leaves ovate, slightly three-lobed, tomentose underneath; flowers axillary; root perennial; the peduncles come out singly from the axils of the upper leaves; they are longer than the petiole, but do not spring from it, are jointed, and support one very large bright purple-coloured flower.—Native of moist ground in Virginia and Canada: flowers here in July and August. For its propagation, see the first species.

3. *Hibiscus Micranthus*; *Minute-flowered Hibiscus*. Leaves roundish, entire, serrate; corollas reflex, oblique; root annual; stem round, upright, simple, a foot high; flowers minute, on the summit of the stem; seeds lanuginous.—Found by Kœnig in the East Indies. This plant, like the majority of those belonging to this genus from warm countries, must be kept in the bark-stove, where some of them will make a most splendid appearance. The principal mode of propagating them is by seeds, sown on a good hot-bed in the spring. The plants should be afterwards removed into pots filled with light earth, and plunged into a fresh hot-bed, treating them afterwards in the same way as the Amaranths. The more tender sorts must be plunged in autumn in the tan-bed, there to remain, and to be treated like other tender plants from the West Indies, and allowed but little water in winter. The perennials may be propagated by cuttings.

4. *Hibiscus Microphyllus*; *Minute-leaved Hibiscus*. Leaves oval, rough-haired, serrate in front; stem shrubby; peduncles axillary, solitary, the length of the leaves, jointed towards the top, thicker.—Native of the Cape.

5. *Hibiscus Urens*. Tomentose; leaves kidney-shaped, crenate; calices woolly. This herb is slightly stinging; peduncles usually longer than the leaf; flowers axillary, two or three together, sessile, glomerate; corolla small in proportion to the calix, purple.—Native of the Cape of Good Hope. This, together with the sixth, the twenty-fourth,

twenty-eight, and thirty-ninth species, require the protection of the green-house, Cape-stove, or glass-case.

6. *Hibiscus Præmorsus*; *Round-leaved Shrubby Hibiscus*. Leaves roundish, tooth-serrate, retuse, pubescent: the leaves are as it were truncate in the middle, crenulate, five-nerved, and soft; the flowers are small and yellow; the capsules small, five together, tubercled, with a point.—This beautiful shrub flowers from June to August, and is a native of the Cape of Good Hope. For its propagation and culture, see the third and preceding species.

7. *Hibiscus Cordifolius*; *Heart-leaved Hibiscus*. Arborescent, tomentose; leaves cordate, ovate, serrate; flowers peduncled, terminating; calix many-leaved, linear, long: the flower is middle-sized.—Native of South America. For its propagation and culture, see the third species.

8. *Hibiscus Rigidus*. Suffruticose, hirsute; branches simple; leaves oblong, serrate; limb of the corolla reflex; seeds woolly; the twigs are long, filiform, quite simple, stiff, the stipules erect, bristle-shaped, stiff; and the peduncles axillary, one-flowered.—Native of Ceylon. For its propagation and culture, see the third species.

9. *Hibiscus Sororius*. Leaves cordate, crenate, scabrous; outer calices round, dilated at the end; stem herbaceous or suffruticose, columnar, hairy all over, supported by trees; peduncles axillary, the length of the leaves, solitary, pubescent, one-flowered.—Native of Surinam. For its propagation and culture, see the third species.

10. *Hibiscus Cancellatus*. Stem weak, rough with hairs; leaves cordate, serrate; calices globular, having twenty subulate rays, rough with hairs; peduncles axillary, one-flowered, longer than the petioles.—Native of Surinam. For its propagation and culture, see the third species.

11. *Hibiscus Populneus*; *Poplar-leaved Hibiscus*. Leaves cordate, quite entire; stem arborescent. It is a tree fifteen feet or more high, with a trunk larger than a man can compass; capsule globular, berrid, and closed; outer calix three-leaved, caducous; inner obscurely five-toothed, permanent. The wood is white and soft, and the bark like that of the Lime-tree; the branches long and spreading; corolla large, yellowish-white, inclining to green, becoming red as it decays, without scent.—Native of sandy soils in the East Indies, where it produces flowers plentifully during the greatest part of the year. For its culture and propagation, see the third species.

12. *Hibiscus Tiliaceus*; *Lime-tree-leaved Hibiscus*. Leaves cordate, roundish, undivided, acuminate, crenate; stem arborescent; outer calix one-leaved, ten-toothed. This rises with a woody, twisted, pithy stem, from eight to ten, twelve, and fifteen feet high, but has rather a smaller trunk than the preceding species, dividing into several spreading branches towards the top, which are covered with a brown bark and a woolly down: the flowers are produced towards the upper part of the twigs, from the axils, on peduncles an inch long, branched, and supporting several flowers, forming all together loose spikes; in figure and colour they resemble the foregoing, but they are smaller, and roughish on the outside, nor are they so curled and wrinkled; on the lower part of the neck, instead of the five-leaved rose which there is in that, we have a large round spot of a dusky red purple colour.—Native of the East Indies, and of almost every country within the tropics. This plant flowers in the second year, if brought forward; otherwise not before the third or fourth. It will bear the open air in summer in a warm situation, but will not make any great progress. In the island of Otaheite they make matting of the bark; also ropes and lines, from the size of an inch to that of a small packthread; and fishing-nets. They also suck the bark

for food when the bread-fruit fails; and in New Caledonia the inhabitants frequently subsist on it, though it is insipid food, affording very little nourishment. These accounts are attested by Hawkworth and Forster.

13. *Hibiscus Simplex*. Leaves cordate, three-lobed, repand, quite entire; stem arboreous, entirely simple.—Native of Asia. Propagated in the same way as the third species.

14. *Hibiscus Ovalifolius*. Leaves oval, and subangular; outer calices five-leaved. The flowers have the size and appearance of those of the thirty-third species; seeds villose. For its propagation and culture, see the third species.

15. *Hibiscus Rosa Sinensis*; *Chinese-Rose Hibiscus*. Leaves ovate-acuminate, serrate; stem arboreous. In India it attains to the size of an ordinary tree; with us it is a round-stemmed, erect shrub with alternate spreading branches, that are wand-like, leafy, brownish green, and nearly smooth; flowers axillary, solitary, peduncled, large, of a deep scarlet colour; peduncles twice as long as the petioles, round, straight, thicker towards the top, with a joint beyond the middle.—It is extremely common in the gardens of China and the East Indies, but its native country is unknown. Loureiro however affirms that it is spontaneous, as well as cultivated, both in China and Cochin-china; and that it is so common in the latter, that they have entire hedges of it to their gardens. It has been long known from its appearance on Chinese screens and paper-hangings. The variety with double flowers is most frequently cultivated both in the East and in European hot-houses; it is indeed rarely seen with single ones. Loureiro remarks also, that the double-flowered white variety is more difficult to cultivate, and differs a little from the others in having gash-serrate leaves. He likewise mentions another variety with large, double, brick-coloured flowers. But in so favourite a plant, we should not be surprised if there were many more varieties. Rumphius says, that the white-flowered variety is not esteemed in the East, for the inhabitants of India are extremely partial to whatever is red, which they consider as a colour tending to exhilarate. They form these handsome flowers into garlands and festoons on all occasions of festivity, and even in their sepulchral rites. They are put also to a use which seems very inconsistent with their elegance and beauty, that of blacking shoes, from which they derived the name of *Rosæ Calceolariæ*, and *Shoe-flower*. The women employ them to colour their hair and eye-brows black. Mr. Miller, who cultivated this flower as far back as the year 1731, informs us that he had never seen it with single flowers, which even now are rarely met with in our stoves. With double flowers it is common, thrives well, and is in blow during the greatest part of the summer. The single flowers are certainly of short duration, but that defect is compensated by their curious and beautiful structure.—This most splendid and beautiful plant is perennial, and may be propagated by cuttings, but requires the protection of a hot-house or of the bark-stove.

16. *Hibiscus Brasiliensis*; *Brasilian Hibiscus*. Leaves cordate, toothletted; outer calix double the length of the other; stem shrubby; branches rough with hairs; stipules awl-shaped; peduncles one-flowered, longer than the leaves.—Native of Brazil. For its propagation and culture, see the third species.

17. *Hibiscus Hirtus*; *Hairy Hibiscus*. Leaves lanceolate-ovate, acuminate, serrate; branches scabrous; stem herbaceous. This is a small plant, with a purple corolla and woolly seeds.—Native of the East Indies. For its propagation and culture, see the third species.

18. *Hibiscus Phœniceus*; *Purple Hibiscus*. Leaves ovate, acuminate, serrate; peduncles jointed, thickened above the

joints; lobes longer; calices naked; seed woolly.—Linneus has called this a variety of the preceding, but it appears to be a distinct species. It is a very beautiful shrub, blows in our stoves the whole summer, and is highly ornamental with its deep red flowers. For its propagation, see the third species.

19. *Hibiscus Mutabilis*; *Changeable Rose-Hibiscus*. Leaves cordate, five-angled, obscurely serrate; stem arboreous, pale, single, smooth, spreading out wide into leafy branches at top, the wood resembling that of the Fig; petioles rough, thick, three or four inches in length; peduncles thicker towards the top, sometimes tinged with red, sustaining large handsome flowers, which alter their colour; for at their first opening they are white, then they change to a blush rose colour, and as they decay turn to a purple. In the West Indies all these changes take place in one day; but in England, where they last nearly a week, the changes are not so sudden.—It is a native of the East Indies and Japan. The French first carried the seeds to their settlements in the West Indies; and the inhabitants of the British colonies there, being supplied with the seeds from them, have given it the name of Martinico Rose. It varies with double flowers, from which the single is frequently produced; but the seeds of the single seldom vary to the double. It blows in our stoves in November and December, and is much cultivated in the gardens of China and Cochin-china.—The plants of this sort should not be quite exposed to the open air the first season; and the first winter will require the warmth of a moderate stove; but as they acquire more strength, they will need less care, for they will bear the open air in summer in a warm sheltered situation, and will survive the winter in a good green-house, provided they have not too much moisture; but the plants thus hardily treated will not make so great progress nor flower so well, as with a little additional warmth; and if too tenderly managed, will draw up weak, and be less likely to flower.

20. *Hibiscus Spinifex*; *Prickly-fruted Hibiscus*. Leaves cordate, crenate, undivided; capsules set with spines standing out. It flowers here in July.—Native of the West Indies. For its propagation and culture, see the third species.

21. *Hibiscus Solandra*; *Maple-leaved Hibiscus*. Leaves subcordate, three-cusped, serrate; calices uncalicled; root annual; stalk upright, branched on every side, round, hollow, a foot and a half high; racemes terminating, upright, villose, two inches long; flowers alternate, stiff, four or five lines wide; peduncles upright, round, villose, jointed at the tip, becoming twice or thrice longer when in fruit; filaments shorter than the corolla. It flowers in July and August.—Native of the Isle of Bourbon. For its propagation and culture, see the third species.

22. *Hibiscus Syriacus*; *Syrian Shrubby Hibiscus*, or *Althæa Frutex*. Leaves wedge-form, ovate, gash-serrate towards the end; stem arboreous. It rises to the height of six or seven feet, sending out many woody branches covered with a smooth gray bark; the flowers come out from the wings of the stalk at every joint of the same year's shoot; they are large, and shaped like those of the Mallow, having five large roundish petals, which join at their base, spreading open at the top in the shape of an open bell: they appear in August, and if the season be not over warm, there will be a succession of flowers during a part of September. It is commonly called *Althæa Frutex* by the nursery gardeners, who propagate the shrubs for sale: there are four or five varieties, which differ in the colour of their flowers; the most common has pale purple flowers, with dark bottoms; another has bright purple flowers with black bottoms; a third, white flowers with purple bottoms; a fourth, variegated flowers with dark bottoms; a

fifth, pale yellow flowers with dark bottoms; but the last is very rare at present in English gardens; and a sixth with double flowers. There are also two sorts with variegated leaves, which by some are much esteemed.—It is a native of Syria, and very much cultivated for hedges in Japan and Cochin-china. It is propagated by seeds, which should be sown in pots filled with light earth at the latter end of March, and plunged into a gentle heat to forward the growth of the seeds. When the plants appear, they must be inured to the open air, and in May the pots may be plunged into the ground in a border exposed to the east, where they may have the morning sun. They will require nothing but weeding and watering during the first summer, but in autumn it will be proper to remove the pots under a common frame, to screen them from the frost; or, where there is not such conveniency, they may be plunged close to a hedge, pale, or wall, or to a good aspect; and in severe frosts they should be covered with mats, straw, or other light covering; for although these plants, when they have obtained strength, will resist the cold of our winters, yet the young plants, the shoots of which are tender, frequently receive injury from the first frost in autumn; so that if they are not screened the first year, they are often killed to the ground. Towards the latter end of March will be a good time to transplant them. The spot of ground prepared to receive them should then be divided into beds four feet broad, with paths of two feet broad between them. The plants must then be shaken out of the pots with the earth adhering to them, and carefully separated, for their roots are very tender and apt to break with little force, and replanted about nine inches asunder in the beds; so that if four rows be planted in each bed, there will be six inches allowed between the outside rows and the paths. The ground should be gently closed about the roots, to prevent the air penetrating to them; and if a little old tanners' bark or mulch is laid over the surface of the beds, it will prevent the earth from drying, and be of great use to the plants. During the succeeding summer they must be kept free from weeds; and should the next winter prove severe, it will be prudent to cover the plants again in autumn, especially if they shoot late in the season, or the autumn prove cold and moist, for then the plants will be in great danger of having their tops killed. In these beds they may remain two years, by which time they will be fit to transplant to where they are intended to remain; for if kept longer in the nursery, they will not remove so well. The best time for transplanting these plants is the end of March, or the beginning of April, for they seldom begin to shoot till the end of April, or the beginning of May; they should have a light soil, not too wet, for in strong land their stems grow mossy, and they never thrive after. They may also be propagated by layers; and by cuttings, which, if planted the latter end of March, in pots filled with light earth, and plunged into a gentle heat, will take root; but the plants thus raised are not so good as the seedlings. The several varieties may be increased by grafting upon each other, which is the common method of propagating those with striped leaves.

23. *Hibiscus Ficulneus*; *Fig-leaved Hibiscus*. Leaves palmate, five-cleft; stem prickly; flowers peduncled. The flowers come out singly from the axils; they hang down, are small, and white with purple bottoms, and are succeeded by short obtuse capsules; they open only when the sun shines, and that but for a few hours in the morning; for about noon they nod or hang down, and the petals spread irregularly. It flowers from June to August.—Native of Ceylon. For its propagation and culture, see the third species.

24. *Hibiscus Speciosus*; *Smooth Hibiscus*. Leaves palmate, smooth; segments lanceolate, serrate; stem, peduncles,

and calices, even.—It is a native of South Carolina, and flowers in September. Perennial. See the third and fifth species.

25. *Hibiscus Sabdariffa*; *Various-leaved Hibiscus*. Leaves serrate, the lower ovate, undivided, the upper seven-parted; stem unarmed, one to three feet high, of a blood-red colour; root annual, single, descending; flowers sessile, axillary, solitary, largish; petals veined, of a very pale sulphur colour, with a dark blood-red bottom.—It is a native of India, and has been long known in England. Gerarde and Parkinson call it *Thorny Mallow*. It flowers from June to September. In the West Indies it is known by the name of *Red Sorrel*. The calices and capsules, freed from the seeds, make very agreeable tarts; and a decoction of them sweetened and fermented is commonly called there *Sorrel cool drink*, which is a small diluting liquor, much used in our colonies, and reckoned very refreshing in those sultry climates. For its propagation and culture, see the third species.

26. *Hibiscus Cannabinus*; *Hemp-leaved Hibiscus*. Leaves serrate, the upper palmate, five-parted, having one gland underneath; stem prickly, five feet high or more; root annual; flowers sessile, axillary; the corolla large, of a pale sulphur colour, with a dark purple bottom. The bark of this and of the foregoing species is full of strong fibres, which the inhabitants of the Malabar coast prepare and make into cordage, and it seems as if it might be wrought into fine strong thread of any size.—Native of the East Indies. For its propagation and culture, see the third species.

27. *Hibiscus Surattensis*; *Prickly-stalked Hibiscus*. Prickly, with prickles curved back; leaves five-lobed; outer calices appendicled; stipules half-cordate; flowers peduncled; stem round, upright, stiff, two feet high, spotted with purple towards the top; corolla yellow, with a dark purple base.—The leaves are gratefully acid, and are eaten in the East Indies and Cochin-china, where it is a native: they also assist in dissolving hard tumours, &c. but for that purpose the roots are thought to be most efficacious. Annual: flowers with us in July. See the third species.

28. *Hibiscus Pedunculatus*. Hirsute: leaves five-lobed, toothed; peduncles axillary, one-flowered, elongated.—Native of the Cape of Good Hope. For its propagation and culture, see the third and fifth species.

29. *Hibiscus Manihot*; *Palmated-leaved Hibiscus*. Leaves palmate-digitate, seven-parted; stem and petioles unarmed. It rises with an herbaceous smooth stalk, three or four feet high. The flowers are produced from the wings of the stalks towards the top, standing on short peduncles; they are composed of five large sulphur-coloured petals, which, when open, spread five inches wide; they have a dark purple bottom; and are succeeded by large, pyramidal five-cornered, erect seed-vessels, which are filled with pretty large seeds, having little smell or taste. In Japan the mucilage of the root of this plant is employed to give consistence to paper. It flowers in July and August.—Native of China and Japan. This species will produce flowers and perfect seeds in the first season. The plants may be preserved by a moderate warmth through the winter, though few persons will take that trouble after they have ripened their seeds, as the young plants make a better appearance.

30. *Hibiscus Abelmoschus*; *Target-leaved Hibiscus*. Leaves subpeltate, cordate, seven-angled, serrate; stem hispid, herbaceous, three or four feet high, sending out two or three side-branches, all of which, as well as the stem, are hairy. The flowers come out from the wings of the stalk upon pretty long peduncles, which stand erect; they are large, of a sulphur-colour, with dark purple bottoms, and are succeeded by pyramidal five-cornered capsules, filled with large seeds,

of a very musky odour, so that a few of them are sufficient to perfume a whole room. They may undoubtedly be used in scenting powders and pomatums, instead of the animal musk, which is a scarce and dear commodity; and are accordingly put to that use in Paris. In Arabia and Egypt, they grind these seeds, and mix the powder with their coffee, to render it more agreeable to the head and stomach. The official names are, *Abelmoschus*, from the Arabic *Ab-el-mosch*, grain or seed of musk; and *Bammia Moschata*. These seeds seem to have a claim, as a medicine, to the cordial and nervine virtues, experienced from most other substances of that class. In its native country it is biennial, but seldom survives a year here.—Native of the East and West Indies.

31. *Hibiscus Esculentus*; *Eatable Hibiscus*. Leaves five-parted, pedate; inner calices bursting at the side. This rises with a soft herbaceous stalk, from three to five feet high, dividing at top into many branches. The flowers are axillary, of a pale sulphur colour, with dark purple bottoms; small, and of a very short duration, opening with the rising sun, but fading long before noon in warm weather. The capsules are of different forms, in some not thicker than a man's finger, and five or six inches long; in some very thick, but not so long; in some erect, and in others inclined.—It is common in the West Indies, where the inhabitants cultivate it for the capsules, which they gather green, to put into their soups and pepper-pots. They are generally boiled separately, and added just before the messes are taken off the fire: but the seeds may be boiled in broth, like barley, or any other ingredient, for they are not so mucilaginous. The pods, boiled and buttered, make a rich dish; but they are used only in private families in this form. They are full of a nutritive mucilage. It is known in Jamaica by the name of the *Okro* plant; in China and Cochinchina, it is cultivated in gardens, for the beauty and colour of the flower, which is nevertheless void of scent: with us it is annual, and flowers in June and July. It will live in a warm border, and thrive for a time in a good season; but with the first cold or bad weather, the leaves drop off: it seldom flowers, and never perfects seeds; so that it requires shelter, especially in cold wet weather.

32. *Hibiscus Clypeatus*; *Shielded Hibiscus*. Leaves cordate, angular; capsules turbinate, truncate, hispid. This shrub is the height of a man; stem upright, branched, round, pubescent; peduncles one-flowered; corollas pale, sometimes dusky yellow. It is found, but not in abundance, in coppices near the coast of the island of Jamaica, where it is commonly called *Congo Mahoe*; the negroes affirming, that it came originally from Africa. See the third species.

33. *Hibiscus Vitifolius*; *Vine-leaved Hibiscus*. Leaves five-angled, sharp, serrate; stem unarmed, a foot and half high, somewhat tomentose; flowers drooping; peduncles axillary, solitary, one-flowered, leafless, the length of the leaves; corolla large, yellow, with a dark purple base: annual.—Native of the East Indies. See the third species.

34. *Hibiscus Zélanicus*. Leaves cordate-hastate; peduncles alternate, one-flowered, jointed; corolla flesh-coloured.—Native of the island of Ceylon. For its propagation and culture, see the third species.

35. *Hibiscus Virginicus*. Lower leaves cordate, acuminate, serrate, upper hastate; stem green, upright; peduncles one-flowered, solitary, axillary, forming something of a naked raceme at top.—Native of salt marshes in Virginia. See the first species.

36. *Hibiscus Pentacarpus*; *Five-seeded Hibiscus*. Lower leaves cordate, angular; upper subhastate; flowers nodding a little; pistil drooping; root perennial; stem three feet high,

narrow; peduncles axillary, on the top of the plant, solitary, naked, longer than the petiole, one-flowered; corolla spreading, pale red, nodding a little; capsule globular.—It grows near Venice, in marshy places, and was also found near Astracan. Though the roots will live in the open ground, yet our summers are not warm enough to bring it to flower: the seeds therefore should be sown in a hot-bed, and when the plants are fit to remove, they should each be planted in a separate small pot, and plunged into a moderate hot-bed, allowing them sufficient air in warm weather. It may stand in the open air in summer, but will seldom flower, unless kept in a deep frame, where it will continue, and flower for several years.

37. *Hibiscus Hastatus*. Hoary: leaves oblong, simple, three-lobed at the base, quite entire; raceme terminating.—Native of the Society Isles. See the third species.

38. *Hibiscus Fraternalis*. Leaves three-lobed; outer calices with round rays, mucronate and concave at the tip; stem herbaceous, smooth and even, as is the whole plant; corolla yellow.—Native of Surinam. See the third species.

39. *Hibiscus Æthiopicus*; *Dwarf Wedge-leaved Hibiscus*. Leaves subcuneate, slightly three-toothed, the upper ones opposite. This is a small shrub: flowers terminating, peduncled, solitary, the peduncles shorter than the leaf.—Native of the Cape of Good Hope. For its culture and propagation, see the third and fifth species.

40. *Hibiscus Trionum*; *Bladder Hibiscus*. Leaves three-parted, gashed; capsule ovate; inner calix inflated; seeds several. It rises with a branching stalk, a foot and a half high, having many short spines, which are soft. The flowers come out at the joints of the stalks, upon pretty long peduncles; each flower is composed of five petals, which spread open at the top, and form an open bell-shaped flower: these have dark purple bottoms, but are of a pale sulphur colour above, tinged sometimes partially with pale purple on the outside, where they are also ribbed; the corolla becomes wholly purple after it has folded up again. This is an annual plant, growing naturally in some parts of Italy and Austria.—It has been long known in the English gardens by the title of *Venice Mallow*; Gerarde and Parkinson call it *Mallow*, or *Flower of an Hour*, and *Good Night at Noon*, or *Good Night at Nine*, for they say it opens about eight o'clock, and shuts up again at nine. The flowers are certainly of short duration, and in hot weather continue but a few hours open: however, there is a succession of them daily for a considerable time, in June, July, and August. There are several varieties: two are natives of the Cape of Good Hope. This plant is propagated by seeds, which should be sown where the plants are designed to remain; for they do not bear transplanting well. If the seeds are sown in autumn, the plants, coming up early in the spring, will flower in the summer, and those which are sown early in the spring, will succeed them; so that by sowing them at three different seasons, they may be continued in succession till the frost stops them. They only require clearing from weeds, and thinning them where they are too close; and if the seeds are permitted to scatter, the plants will come up full as well as when sown, so that it will maintain its situation, unless it be weeded out.

41. *Hibiscus Elatus*. Leaves cordate, roundish, entire; peduncles very short, one-flowered; calix ten-toothed. This is a tree, growing to a considerable size; the wood is of a dark olivaceous colour; the bark pretty smooth, and the trunk tall and straight: the flowers are large and open, not unlike those of the yellow Lily either in size or appearance. It is reckoned excellent timber. All the tender parts of the tree abound with a delicate mucilage, which may be used instead of the more common medicines of this tribe. The bark

is made into ropes of all sorts.—Native of Jamaica, where it is called *Mahot* or *Mahoe-tree*. See the third species.

42. *Hibiscus Clandestinus*. Stem virgate, rough with hairs, shrubby, three feet high; leaves ovate, sharp, somewhat three-lobed; flowers minute, closed, axillary, solitary: peduncles longer than the leaf, upright, jointed, and thicker towards the tip; corolla whitish, villose, scarcely larger than the calix, becoming violet-coloured as it withers; petals ovate, never expanding; seeds blackish, with a very white wool drawn over them.—Native of Senegal.

43. *Hibiscus Tomentosus*. Leaves heart-shaped, angular, serrate, tomentose; stem arboreous, seven or eight feet high, covered with a whitish bark.—Native of the West Indies.

44. *Hibiscus Cordifolius*. Leaves heart-shaped, hirsute, crenate; flowers lateral, of a bright yellow colour; stem arboreous, branched.—Native of the West Indies.

45. *Hibiscus Bahamensis*. Leaves oblong-cordate, smooth, toothletted, hoary underneath, with very large flowers. It has a perennial root, but annual stalks, four feet high, at the tops of which the flowers are produced: they are very large, and of a light purple colour, with dark bottoms, and are succeeded by short capsules.—Native of the West Indies.

Hickery. See *Juglans*.

Hieracium; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common imbricate, ovate; scales several, linear, very unequal, longitudinal, and incumbent. *Corolla*: compound, imbricate, uniform; corollules hermaphrodite, numerous, equal; proper monopetalous, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubulous. *Pistil*: germen subovate; style filiform, the length of the stamina; stigmas two, bowed back. *Pericarp*: none; calix converging, ovate. *Seeds*: solitary, obtusely four-cornered, short; down capillary, sessile. *Receptacle*: naked. ESSENTIAL CHARACTER. *Calix*: imbricate, or caliculate, ovate. *Down*: simple, sessile. *Receptacle*: naked.—Most of the plants of this genus are reputed to be weeds, and very few of them are cultivated, except in botanic gardens. If their seeds be permitted to scatter, they will in general propagate themselves; and, being mostly perennial, they may all be increased by parting the roots. The seeds should be sown on a border with an eastern aspect, in March; and when the plants come up they must be kept clean from weeds, till they are strong enough to remove, which will be by the beginning of June; then they should be transplanted to a shady border of undug ground, at six inches' distance; observing to water them if the weather should prove dry, till they have taken new root; after which, if they are kept clean from weeds, they will require no other culture; in the autumn they should be transplanted where they are designed to remain; in the following summer they will flower and produce ripe seeds, and the roots will continue some years, if not planted in a rich moist soil, which frequently occasions their rotting in winter. They may also be propagated by parting the roots in autumn.—The species are,

* *With a one-flowered Scape.*

1. *Hieracium Incanum*; *Hoary Hawkweed*. Leaves quite entire, somewhat toothletted, lanceolate, scabrous; root thick, perennial, blackish on the outside, white within; stems round, upright, twice or thrice the length of the leaves; corolla yellow.—Native of the mountains of Austria, Carniola, and the Palatinate; flowering in May.

2. *Hieracium Pumilum*; *Dwarf Hawkweed*. Leaves ovate; petioles dilated; scapes with one or two flowers; roots perennial, creeping, branched; stems half a foot in height,

generally procumbent and reddish; corolla pale yellow, broadish, with five teeth at the end.—Found upon the Alps, and Glaciers, in Switzerland, Savoy, and Dauphiny, among the pebbles and fragments of rocks.

3. *Hieracium Alpinum*; *Alpine Hawkweed*. Leaves oblong, entire, toothed; scape almost naked; calix hairy. This species is chiefly distinguished by the whole of the plant, but especially the calix, being covered with long white hairs; and the scales of the calix being remarkably loose: root perennial and fibrous; stalk about five inches high, generally terminated by one large flower, but seldom more than two; corolla pale yellow. It flowers in July and August.—Native of Lapland, Switzerland, Dauphiny, Savoy, Carniola, Silesia, and the mountains both of Wales and Scotland.

4. *Hieracium Taraxaci*. Leaves lanceolate, toothed, smooth; scape almost naked; calix hirsute; stalk six inches high, smooth towards the base, but hairy near the top, bearing a single yellow flower; perennial: flowering in July.—Native of the mountains of Switzerland, Scotland, and Wales.

5. *Hieracium Alpestre*. Leaves lanceolate, toothed, smooth; scape with a leaf and a flower or two; calix hirsute, cylindrical; root-leaves on short petioles, having large teeth about the edge, almost linear, broader at the end; corolla short, not large, yellow; perennial.—Native of Austria and Silesia.

6. *Hieracium Venosum*; *Vein-leaved Hawkweed*. Leaves wedge-shaped, rough with hairs; scape very thick, upright; stem branched, leafless; flowers small, yellow.—Native of Virginia and Maryland.

7. *Hieracium Pilosella*; *Mouse-ear Hawkweed*. Leaves quite entire, ovate, tomentose underneath; stem throwing out runners; root perennial, creeping; flowers early, an inch in diameter; corolla pale yellow, or sulphur colour, composed of about fifty florets, the outer having a broad purple stripe on the under side; each floret has five teeth at the end. According to Linneus, the flowers of this plant commonly open at eight in the morning, and close about two in the afternoon. An insect of the coccus or cochineal kind is found at its roots; but it has not been observed in England. It differs from other milky plants of this class, in being less bitter, and more astringent. On account of this astringency it was admitted into the shops as a medicine, under the name of *Auricula Muris*, or *Mouse-ear*; but it is now little regarded. Culpeper says, that the green leaves bruised, and applied to any cut or wound, will soon heal it; and Meyrick and Hill both recommend it as an excellent astringent, and say that the powder may be given in immoderate menstrual discharges, and other bleedings, whether internal or external. A strong decoction of it is good in purges attended with bloody stools, also for the bleeding of the piles; and the leaves boiled in milk are a good external application for the same purpose. It flowers from May to September, and is very common on dry pastures, sunny banks, and walls.

** *With a many-flowered Scape.*

8. *Hieracium Dubium*; *Creeping Hawkweed*. Leaves entire, ovate-oblong; runners creeping. There is a diversity of opinion among botanists concerning this plant. It appears considerably to resemble the foregoing species, but is larger, and has the leaves hairy, not tomentose underneath; corollas pale yellow on both sides. Kroker distinguished it from the *Mouse-ear*, by its having fewer (only two or three) flowers; by its lesser stature; entire leaves, on very short petioles; having very few long hairs; and being in other respects smooth. It flowers in July and August. Sheep are reported to eat this plant, although the *Mouse-ear* is reputed to be

injurious to them.—Native of Sweden, Switzerland, Germany, Dauphiny, and in moist places upon the mountains of England, as near Rydall in Westmoreland.

9. *Hieracium Auricula*; *Narrow-leaved Hawkweed*. Leaves quite entire, lanceolate; runners creeping; root præmorse, with numerous simple fibres; scape upright, naked, scarcely half a foot high, having a few scattered hairs on it; flowers in a panicle, from three to six. It may be distinguished from the preceding species, by its having a higher stalk, and more flowers; longer, narrower leaves, more hirsute, with shorter hairs; the flowers sulphur-coloured; the calix, like the stalk, having black bristles scattered over it: it flowers in July, and is perennial.—Native of Lapland, Sweden, Switzerland, Germany, Dauphiny, and England, upon mountains: it is found on Dalehead, not far from Grass-mere, Westmoreland.

10. *Hieracium Cymosum*; *Small-flowered Hawkweed*. Leaves lanceolate, entire, hairy; scape almost naked, hairy at the base; flowers in a kind of umbel; root præmorse. According to Villars, this species is easily distinguishable. The stem is straight, about a foot high, terminated by a cyme of flowers so close that the peduncles are seen with difficulty, though they are branched. He mentions two varieties; one with red flowers, and another with from three or four to six scattered flowers, as large again as the common sort. Perennial. Flowering in June.—Native of Russia, Deamark, Germany, Switzerland, and Dauphiny.

11. *Hieracium Præmorsum*; *Truncate-root Hawkweed*. Leaves ovate, somewhat toothed; scape branched, upper flowers coming out first; root perennial, fibrous; flowers in a panicle containing frequently from sixteen to twenty; they are small, each supported on a simple pedicel, which has a lanceolate stipule at the base, forming altogether a sort of spike. This herb watches from seven o'clock in the morning to six in the evening, when the panicle of flowers also nods. It flowers in May and June.—Native of Sweden, Germany, Switzerland, and Siberia.

12. *Hieracium Aurantiacum*; *Orange-flowered Hawkweed*. Leaves entire; stem almost naked, quite simple, hairy, corymbiferous; root perennial, creeping; stipules very small, lanceolate; flowers eight or ten, on short pedicels, forming a short panicle; corolla dark red. It flowers from June to autumn, and forms large tufts if planted in shady places, and varies much in the colour of the flower, from red to orange, and several shades of yellow. It is called by our old writers *Golden Mouse-ear*; and, when of a dark colour, *Grim the Collier*.—Native of Austria, Switzerland, Silesia, Dauphiny, and Piedmont.

13. *Hieracium Gronovii*; *Gronovius's Hawkweed*. Stem panicled, almost naked; root-leaves obovate, quite entire, hairy.—Native of Virginia.

14. *Hieracium Gmelini*; *Gmelin's Hawkweed*. Stem panicled; root-leaves ovate, serrate, smooth; calix simple; scales eight or ten.—Native of Siberia.

15. *Hieracium Sanctum*; *Palestine Hawkweed*. Leaves lyrate, blunt, toothed; root thick, long, like *Naveros*, with one or two branches; corollas yellow.—Native of Palestine, the south of France, and the county of Nice.

16. *Hieracium Capense*; *Cape Hawkweed*. Lower peduncles higher; leaves oblong, toothed, scabrous; scape a foot high, even, with a few very small awl-shaped leaves alternately scattered over it; flower terminating, from the axil of the leaves.—Native of the Cape of Good Hope.

*** *With a leafy Stem.*

17. *Hieracium Montanum*; *Mountain Hawkweed*. Stem with one or two flowers; leaves lanceolate, toothed; root per-

ennial, single, deep, blackish; flower large; corolla yellow.—Native of the mountains of Savoy and Dauphiny, in pastures.

18. *Hieracium Paniculatum*; *Panicled Hawkweed*. Stem upright; leaves alternate, lanceolate, naked, toothed; panicle capillary, terminating, variously branched, with very slender divaricating peduncles; bractea at the ramifications, very short, bristle-shaped; flowers small.—Native of Canada.

19. *Hieracium Porrifolium*; *Leek-leaved Hawkweed*. Stem branched; leaves lanceolate-linear, almost entire; root-leaves lanceolate, upright, with one or two sharp teeth, even, having a few villose hairs along the keel; stem-leaves minute, very few; corolla yellow. The whole plant, says Villars, has the smell of the Wild Lettuce in a greater degree than any of the Hawkweeds. Perennial.—Native of the south of France, the Valais, Austria, Silesia, and Italy.

20. *Hieracium Chondrilloides*; *Gum-succory Hawkweed*. Stem branched; stem-leaves elongate-toothed, smooth; root-leaves lanceolate, entire; peduncles from the upper axils of the leaves, the same height with the stem, solitary, almost naked, one-flowered; corolla yellow.—It flowers in June and July, and is a native of the south of France, Austria, and Silesia.

21. *Hieracium Murorum*; *Wall Hawkweed*. Stem branched; root-leaves ovate, toothed; stem-leaf smaller. This plant varies exceedingly, as appears from the different figures which are given of it. The general appearance is as follows: Root simple, producing one slender stem, a foot or fifteen inches high, cylindrical, having soft hairs scattered over it, slightly striated, reddish towards the base; sometimes naked or nearly so, sometimes clothed with leaves nearly similar to the others, only more acute; flowers in a branched panicle, on separate peduncles, with each an awl-shaped bractea; calix of numerous, unequal, linear, lanceolate leaves, the lower one spreading; corolla yellow; seeds nearly cylindrical, furrowed, smooth, dark purple, crowned with a sessile down, as long as the seed: ray simple, the length of the calix. Linneus observes, that the flowers open about six in the morning, and close about two in the afternoon. Lightfoot says, that about eighteen days elapse between the first expansion of the flower and the ripening of the seed. Our old authors call it *French* or *Golden Lungwort*. There are many varieties.—Comino in various parts of England.

22. *Hieracium Humile*. Stem few-flowered, scarcely higher than the lower leaves, which are hirsute and gashed.—Native place unknown.

23. *Hieracium Paludosum*; *Marsh Hawkweed*. Stem panicled; leaves clasping, toothed, smooth; calices hispid; root perennial; flowers single; peduncles smooth. The flowers open at six in the morning, and close again at five in the afternoon. Possibly it may be only a variety of the twenty-first species, though it has acquired from its place of growth so very different an appearance.—Native of many parts of Europe, in moist meadows and woods, and by the sides of mountains, rivers, and rivulets. It is found in several parts of the northern counties of England, and also in Scotland.

24. *Hieracium Lyratum*; *Siberian Hawkweed*. Stem many-flowered; leaves lyrate, smooth; calix and peduncles hispid. Nearly allied to the foregoing.—Native of Siberia.

25. *Hieracium Cerinthoides*; *Honeywort Hawkweed*. Root-leaves obovate, toothletted; stem-leaves oblong, half-clasping; root perennial, black, branched, frequently ending abruptly; plant evergreen; peduncles one-flowered, ash-coloured, and hispid, with long hairs, single from the axils. Gouan remarks, that it varies in its native place, with a stem scarcely a hand in height, with two flowers, and a single leaf, if any.—Native of the Pyrenees.

26. *Hieracium Amplexicaule*; *Heart-leaved Hawkweed*. Leaves stem-clasping, heart-shaped, somewhat toothed; peduncles one-flowered, hirsute; stem branched, a foot high. The panicle has a pile between the hairs, by which it is almost tomentose. The constant characters of the species, in all its varieties, are,—the great quantity of glandular hairs, which give it the smell of Baum, or new honey; the openness of the lower scales of the calix; the russet colour of the whole plant; and the hairs of the egret brittle, and elbowed at the base.—Native of the Pyrenean mountains.

27. *Hieracium Pyrenaicum*; *Pyrenean Hawkweed*. Leaves stem-clasping, obovate-lanceolate, toothed backwards; stem simple; calices loose. This species varies so much as not to be easily determined. One variety has a root perennial, fibrous, forming a tuft, whence spring several stems a foot and half high; peduncles several, solitary, from the upper axils, each terminated by one large yellow flower, in which the florets are separated and dispersed. Native of Dauphiny.—Another has the stem two feet high, upright, slightly striated, hairy, branched only at top; peduncles or branches three inches long, axillary, alternate, clothed at top only with very small, loose, wandering scales; corolla yellow. Native of the Pyrenean mountains.—In a third variety, from a woody, perennial, brown, divided root, arise a few simple, round, upright stalks, striated, and more or less hispid at top, annual, from a foot to a foot and a half in height; peduncles three or four, (sometimes only a single terminating one,) axillary, solitary, almost of the same height, upright, hispid, striated, leafless, or having only one or two ciliate bractes; flower large and elegant, yellow. It flowers in August, and is a native of Austria.—A fourth variety, has the stem-leaves much sagittate, with very acute earlets; peduncles long, one-flowered, swelling below the flower, black with hairs; down simple, sessile.—Native of Switzerland.

28. *Hieracium Molle*; *Soft-leaved Hawkweed*. Leaves lanceolate, almost entire, soft, the lower ones petioled; flowers on peduncles, forming a kind of corymb; root perennial, blackish, bitten, and furnished with long, white, round fibres: it produces annually a simple, upright, striated, purplish, somewhat bairy, leafy stem, of about a foot or two in height; the top of which is divided into a few single-flowered footstalks of about an inch and half long, and a little bairy; corolla deep yellow, with antheræ and stigma of the same colour. It grows about the borders of the subalpine woods, flowering in July, and producing seeds in August: but when cultivated in a garden, it flowers about the end of May or beginning of June, and grows more branchy from the bosoms of the leaves; but in other respects does not change its habit.—Native of Austria: found also in Scotland in the year 1780.

29. *Hieracium Stipitatum*. Stem branched, with only a leaf or two; leaves toothed; down stiped. This plant grows a foot high or higher. From a perennial, bitten, oblique round root, of about an inch and half long, and the thickness of a quill, of a palish brown colour, and increased by small fibres, it produces annually a solitary, round, somewhat striated, fistulous stem, smooth below, and above rather hispid, with scattered dark hairs; the corollules are yellow, and five-toothed; antheræ brown. It is found on hilly meadows, flowering in June, and seeding in July.—Native of Austria.

30. *Hieracium Villosum*; *Villose Hawkweed*. Stem branched; leaves hirsute; root-leaves lanceolate-ovate, toothed; stem-leaves clasping, heart-shaped; root-leaves lanceolate, broadish. It varies, says Jacquin, so much in different soils, that it is difficult to give such a description as will agree with every individual. Root knobbed, unequal, blackish, perennial, with round whitish fibres; flowers large, handsome, yellow;

calix loose, with black dots, and much white wool; seeds short, with a sessile simple egret, appearing toothed with a magnifier. The hairs on this plant are almost all very white, long, and feathery; there are some, however, shorter, and terminated by a gland.—Both it and its varieties are natives of Dauphiny, Switzerland, Austria, Bohemia, and Silesia, in mountain pastures. It has also been found on the moist rocks of Ben Nevis, a high mountain in Scotland.

31. *Hieracium Glutinatum*; *Clammy Hawkweed*. Leaves lanceolate, runcinate, somewhat scabrous; flowers in umbels; stem striated; root annual.—Native of the south of France.

32. *Hieracium Kalmii*; *Kalm's Hawkweed*. Stem upright, many-flowered; leaves lanceolate, toothed; peduncles tomentose at the top of the stalk, alternate, commonly simple and one-flowered; with fewer linear bractes; flowers small, terminating, upright.—Found by Kalm in Pennsylvania.

33. *Hieracium Undulatum*; *Wave-leaved Hawkweed*. Stem branched; leaves elliptic, toothed, waved, hairy; hairs plumose.—Native of Spain.

34. *Hieracium Sprengerianum*; *Branched Hawkweed*. Stem branched; leaves half stem-clasping, oblong, repand, hispid; calices terminating, several, peduncled, scatteringly haired.—Native of Portugal.

35. *Hieracium Spicatum*; *Hairy Hawkweed*. Stem many-flowered; leaves stem-clasping, hairy, thinly toothed. The smallness and great number of flowers in this plant, joined to their conical form, and the disposition of the branches, which subdivide and divaricate at right angles, distinguish it from all the known *Hieraciums*.—Native of Switzerland, Dauphiny, and Piedmont. Found also in woods in the south part of Scotland.

36. *Hieracium Sabaudum*; *Shrubby Hawkweed*. Stem upright, many-flowered; leaves ovate-lanceolate, toothed, half stem-clasping; root fibrous, perennial, yellowish ash-colour on the outside, white within; branches subdivided, and the last subdivisions one-flowered; peduncles erect, whitish, with pubescence, a little thicker at top, having scales scattered over them forming a thin corymb; flowers yellow, an inch and half in diameter. They open at seven in the morning, and close between one and two in the afternoon, in July, August, and September. It varies with leaves covered with a short and just perceptible down, so as to have the appearance of being smooth; with one flower only on a stem; and with broad lanceolate leaves on short footstalks.—Native of most parts of Europe; not common in Great Britain.

37. *Hieracium Umbellatum*; *Umbelled or Bushy Hieracium*. Leaves linear, somewhat toothed, scattered; flowers in a kind of umbel; root perennial, præmorse or truncate, yellow on the outside, white within, having many fibres in bundles; stem from two to four feet high, upright, simple, round, striated, hollow, nearly smooth, green, frequently dotted with red alternately, especially towards the top, dividing into branches; flower large, yellow, containing as far as ninety-seven florets. This species is often confounded with the preceding, by intermediate individuals partaking of the characters of both, and perhaps they are more distinguishable by the eye than by the specific differences. Mr. Curtis thinks, that the most obvious character of this species consists in the shortness of its leaves. It is a strong-smelling plant; and in Scania is used as a dye, communicating to wool an elegant and beautiful colour. It flowers in July, August, and September.—Native of dry pastures in most parts of Europe. It is not common in England, but is found on the sandy or gravelly heaths about Hampstead, Barnet, and Charlton; in the neighbourhood of London; and near Hildersham and Gamlingay, in Cambridgeshire.

**** *Other species from Villars and Allioni.*

38. *Hieracium Halleri*. Leaves lanceolate, toothed, obscurely villose; stem somewhat branched, stiff, six or eight inches high, straight, stout, terminated by one, two, or three flowers, hirsute, with long lanuginose hairs, and others that are smaller, placed on a black base, which gives a roughness to the stem; calix oval; scales lanuginose, separate, dirty gray, a little viscid.—Native of Switzerland, Savoy, &c.

39. *Hieracium Valde Pilosum*. Stem straight, almost simple; leaves stem-clasping, woolly; calices imbricate. This is thought to be a variety of the thirtieth species.

40. *Hieracium Cydoniæfolium*. Stem straight, branching from the axils; leaves oblong-elliptic, half stem-clasping, toothed; calices hispid, blackish; flowers middle-sized, in a gray and blackish calix; perennial.—Native of Dauphiny.

41. *Hieracium Scorzonæfolium*. Leaves linear-lanceolate, glaucous, and hairy; stem oblique, hairy and hoary, few-flowered; root oblique, truncated, and perennial.—Native of the beds of torrents in the Alps, and in Dauphiny.

42. *Hieracium Glaucum*. Leaves lanceolate, glaucous; stem branched, stiff, a foot or eighteen inches high, having little, oval, acuminate, sessile leaves at the division of the branches; flowers middle-sized.—Native of Dauphiny.

43. *Hieracium Staticifolium*. Stem almost naked; leaves ligulate, obtuse; flower sulphur-coloured; root very thick and deep, frequently forked at the upper part, perennial; flowers large, pale-yellow or sulphur-coloured, turning green in dying.—Native of Dauphiny, Piedmont, and Switzerland.

44. *Hieracium Saxatile*. Leaves roundish, quite entire; stem almost naked, a few inches high, terminated by a few flowers; seeds blackish, their receptacle manifestly villose.—Native of Dauphiny and Italy.

45. *Hieracium Lawsonii*. Leaves oblong, villose, quite entire; stem straight, many-flowered; root thick, truncate, perennial, covered with russet membranes: the peduncles have two scales near the calix, and one leaf at their base: the hairs of the calix are in part glandular.—Native of Dauphiny; found also in the north of England.

46. *Hieracium Andryaloides*. Leaves densely tomentose, curled or sinuate at the base; stem spreading; root oblique, thick, perennial.—Native of Dauphiny.

47. *Hieracium Liottardi*. Leaves lanceolate, toothed; stem upright, two-flowered. This plant, which is cottony, like the last, and small, is distinguished by its lanceolate toothed leaves.—Native of Dauphiny.

48. *Hieracium Jacquini*. Leaves pinnatifid at the base, hirsute, green; calicine hairs glandular; stem with about two flowers; root thick, oblique, fibrous, truncated, perennial; calix villose, blackish, with a few glandular hairs; egret sessile, with simple hairs, slightly toothed.—Native of Dauphiny.

49. *Hieracium Lanceolatum*. Stem straight, stiff; leaves lanceolate, toothed; flowers in a kind of corymb, in a blackish calix; root perennial.—Native of Dauphiny.

50. *Hieracium Pulmonaroides*. Leaves lanceolate, tooth-sinuate, those on the stem sessile; peduncles proliferous; root perennial, oblique, thick, covered with scales; stem about a foot high, terminated by several middle-sized flowers in a calix.—Native of Dauphiny, on walls.

51. *Hieracium Albidum*. Leaves gaawn, ligulate, hispid; stem subdichotomous, few-flowered; root perennial, long, oblique, simple, woody; flowers large, reddish on the outside, pale yellow within; seeds short, brown, crowned by a sessile egret of simple hairs, but toothed and russet: the whole plant is rough, of a yellowish green, and covered with glandular hairs, that give it a disagreeable smell.—Native of sunny pastures, on the high mountains of Dauphiny and Savoy.

52. *Hieracium Pappuleum*. Leaves lyrate-spatulate, toothed; stem-leaves with two ears, embracing the stem on both sides; stem striated, viscid, two-flowered, a foot long, firm, thick; root perennial, simple, thick, dividing at top into two parts, one of which produces a stem without leaves at the base, and the other a bundle of root-leaves without stem for the most part. The stem is terminated by one, two, three, and even as far as fourteen pretty large flowers, which are all on separate peduncles.—Native of Dauphiny, where it is found in alpine meadows.

53. *Hieracium Florentinum*. Stem brachiate, few-flowered; leaves lanceolate, long-haired; calices smooth. This plant is about a foot high, with an upright stem, not putting out runners; calix very smooth; flowers small, heaped on the top of the stem: perennial.—Native of Switzerland, the Valais, and Piedmont.

54. *Hieracium Capillaceum*. Stem almost naked, one-flowered; leaves nerved, grassy, quite entire; root thick, black, perennial; scape a hand in height, almost naked, simple, one-flowered.—Native of the county of Nice, about Sospello.

55. *Hieracium Succisæfolium*. Leaves smooth, quite entire; root-leaves elliptic, on long petioles; stem-leaves clasping, with blunt hooks; root perennial; calix black and hairy.—Native of Switzerland and Piedmont.

High-Taper. See *Verbascum*.

Hillia; (so named in honour of Sir John Hill, M.D.) a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth double; lower six-leaved; leaflets opposite, unequal, oblong, entire; the two inner smaller, embracing the germen, deciduous, coloured: upper two to four leaved; leaflets lanceolate, acute, erect, permanent. *Corolla*: monopetalous; tube cylindric, very long, striated, towards the border ventricose; border six-cleft; clefts long, reflex, contorted, revolute. *Stamina*: filamenta six, very short, inserted below the border into the belly of the tube; antheræ oblong, two-celled within the throat of the corolla. *Pistil*: germen inferior, oblong, obscurely six-cornered; style filiform, thick, the length of the tube; stigma thickened, compressed, bifid. *Pericarp*: capsula elongated, angular, two-celled, opening longitudinally into two valves, crowned with the leaflets of the upper calix. *Seeds*: numerous, pappose, round a linear receptacle; down capillary. **ESSENTIAL CHARACTER.** *Calix*: double; lower six-leaved. *Corolla*: very long, contorted. *Capsule*: two-celled, two-valved, crowned. *Seeds*: downy.—The species are,

1. *Hillia Longiflora*. Corollas six-cleft, clefts lanceolate, revolute; leaves ovate, acute. This is a shrub with an ascending stem, a fathom in height, branched, loose, smooth, brittle, covered with an ash-coloured shining bark; branches simple, leafy, round, smooth, brittle; flowers terminating, sessile, solitary, very long, white, and very sweet.—Native of Jamaica and Martinico, in wet coppices upon the mountains. It is not parasitical, but creeps among old mossy wood; flowering in summer.

2. *Hillia Triandra*. Corollas four-cleft, four-stamined; clefts ovate; leaves obovate, wedge-shaped at the base. This shrub is three or four feet high; with creeping roots, throwing out long fibres. The flowers are terminal and axillary, sessile, solitary, yellowish-white.—It is a native of Jamaica.

Hippia; a genus of the class Syngenesia, order Polygamia Necessaria. *Calix*: common, hemispherical, somewhat imbricate, with ovate scales. *Corolla*: compound, discoid; floscules male, several in the disk; females ten in the circumference: proper of the males funnel-form, five-cleft, upright; of the females obsolete, tubulous, slightly three-cleft.

Stamina: in the males, filaments five, very short; antheræ cylindric, shorter. *Pistil*: in the females, germen margined, large; style bifid; stigmas upright. *Pericarp*: none; calix unchanged. *Seeds*: in the females oval, with a very wide rim all round, naked. *Receptacle*: naked. **ESSENTIAL CHARACTER.** *Calix*: hemispherical, subimbricate. *Corollas* of the ray ten, obsolete, subtrifid. *Seeds*: with a broad margin, naked. *Down*: none. *Receptacle*: naked.—The species are,

1. *Hippia Integrifolia*; *Annual Hippia*. Hispid, erect: leaves ovate, serrate, five-nerved; racemes terminating.—Native of the East Indies.

2. *Hippia Minuta*; *Minute Hippia*. Herbaceous, procumbent, creeping, smooth: leaves pinnate; peduncles axillary, one-flowered; stems procumbent, jointed, putting out rooting fibres at every joint; flowers small.—Native of South America.

3. *Hippia Frutescens*; *Shrubby Hippia*. Shrubby, villose: leaves pinnatifid; flowers corymbed; stem shrubby, five or six feet high, sending out branches on every side the whole length. The flowers are produced in small roundish bunches at the ends of the branches: they are of a sulphur colour, and appear in May: but there is a succession of flowers on the same plant during great part of the summer.—Native of the Cape. The seeds of this plant rarely ripen in England; but it is easily propagated by cuttings planted in a bed of loamy earth, during any of the summer months. Shade them from the sun until they have taken root, and refresh them frequently with water; take them up with balls of earth about their roots, plant them in pots, and place them in a shady situation until they have taken new root; then remove them to a sheltered place among other hardy exotics, and in October put them into shelter. This plant requiring only protection from frost, must not be too tenderly treated.

Hippocratea; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, five-parted, very small; leaflets roundish, spreading, incumbent, smaller than the corolla. *Corolla*: petals five, ovate, spreading, permanent, excavated at the tip, villose. *Stamina*: filaments three, contiguous to the germen and style, awl-shaped, reflex at the tip; antheræ roundish, with a transverse groove. *Pistil*: germen roundish; style three-sided, awl-shaped, longer than the stamina; stigma blunt. *Pericarp*: capsules three, obcordate or elliptic, compressed, large, with two-valved cells; valves keeled and compressed. *Seeds*: in fives or sixes, oblong, with a membranaceous wing, at first soft, but afterwards hardening like nuts, with oblong kernels. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Petals*: five. *Capsule*: three, obcordate, or elliptic.—The species are,

1. *Hippocratea Volubilis*. Racemed, corymbed: leaves ovate-lanceolate, serrate. This is a scandent plant, and not twining, growing to the height of eight or ten feet, with very slender stalks; flowers terminating, subsessile, crowded, greenish white, minute.—Native of Carthage in New Spain, and several of the West India islands. Swartz says it flowers in the spring; Jacquin saw it flowering both in April and December, and gathered the fruit in July. He informs us, that in the dry season, when all the trees lose their leaves, this plant, with the Capers and a few others, continue flourishing.

2. *Hippocratea Comosa*. Panicles comose; peduncles multifid, capillary; leaves ovate, acuminate, entire.—Native of Hispaniola, flowering in February.

3. *Hippocratea Indica*. Panicles axillary, opposite, peduncled; leaves opposite, short-petioled, oval, sawed, smooth,

shining, about two inches long.—A large twining shrub, native of forests, hills, and uncultivated places on the coast of Coromandel.

Hippocrepis; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: umbel simple; perianth one-leafed, five-toothed, (the upper toothlets joined, and less divided,) permanent. *Corolla*: papilionaceous; banner heart-shaped, with a claw the length of the calix; wings ovate-oblong, blunt; keel lunulate, compressed. *Stamina*: filaments diadelphous, simple and nine-cleft, ascending; antheræ simple. *Pistil*: germen slender, oblong, ending in a subulate ascending style; stigma very simple. *Pericarp*: legume compressed and membranaceous, very long, curved inwards, one of the sutures many times cut almost to the top into roundish sinuses, and hence consisting of several joints obtusely triangular, connected by the upper suture. *Seeds*: solitary in each joint, oblong, incurved. *Observe.* The **ESSENTIAL CHARACTER** consists in the horse-shoe form of the *Legume*. These plants are propagated by seed, which should be sown in the autumn wherever the plants are intended to remain; when they are come up, weed them, and thin them where too close, which is all the culture they require.—The species are,

1. *Hippocrepis Unisiliquosa*; *Single-podded Horse-shoe Vetch*. Legumes sessile, solitary, straight. This is an annual plant, which sends from the root several trailing stalks a foot long, that divide upwards into smaller branches. Leaves pinnate, composed of four or five pairs of narrow small leaflets terminated by an odd one. From the wings of the stalk come out single flowers, which are yellow, and are succeeded by single pods sitting close to the stalks, which are about two inches long, and a third of an inch broad, bending inwards like a sickle, and divided into many joints, shaped like a horse-shoe. This flowers in June and July, and ripens seed in autumn, soon after which it decays.—Native of Italy, and the south of Europe. Observed by Ray near Leghorn and Naples.

2. *Hippocrepis Multisiliquosa*; *Many-podded Horse-shoe Vetch*. Legumes peduncled, crowded, circular, smooth, lobed on the outer margin; leaves and calices smooth: the trailing stalks of this plant bear a great resemblance to those of the preceding, but its flowers are produced on long axillary peduncles; they are small, yellow, and many clustered together.—Native of the south of Europe. Like the preceding it is annual, and decays in autumn after the seeds are perfected.

3. *Hippocrepis Balearica*; *Shrubby Horse-shoe Vetch*. Legumes peduncled, crowded, smooth, lobed on the outer margin; leaves and calices somewhat hairy; stems ancipital; root short, woody, the thickness of a finger: the flowers have a small degree of sweetness; corolla yellow. It flowers in May and June.—Native of Minorca. The roots will last two or three years in good ground in a green-house.

4. *Hippocrepis Comosa*; *Tufted Horse-shoe Vetch*. Legumes peduncled, crowded, arched, rugged, sinuated on both margins; root perennial, thick, woody, fibrous, yellow on the outside, white within. The whole plant is smooth; stems trailing, ascending, grooved, from two to nine inches long, much branched; leaves pinnate, of numerous obovate emarginate leaflets, with an odd one; peduncles axillary, from two to five inches long; flowers six to eight or ten, disposed in a circle round the top of the peduncle, after flowering bent down; corolla yellow.—It flowers from April to July, and is found in the calcareous soils of Germany, Italy, France, Austria, and England.

5. *Hippocrepis Barbata*; *Bearded Horse-shoe Vetch*. Le-

gumes pedunculated, straight; spike oblong, terminating; stem suffruticose, four feet high, upright, round; leaves ovate, entire, smooth, ternate, the middle leaflet larger; flowers purple.—Native of Cochin-china. It has not yet been introduced into the gardens of Europe.

Hippomane; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Male Flowers*, in a terminating ament. *Calix*: perianth one-leaved, roundish, belying, with the mouth converging, emarginate. *Corolla*: none. *Stamina*: filamenta single, filiform, twice as long as the calix; antheræ four, roundish, fixed crosswise to the sides of the filamentum towards the tip. *Female Flower*, terminating, solitary, in the same plant. *Calix*: perianth three-leaved, withering; leaflets roundish, concave, blunt, converging. *Corolla*: none. *Pistil*: germen ovate, large; style very short; stigma slightly seven-cleft, sharp, reflex. *Pericarp*: drupe globular, very large, one-celled, crowned with the permanent stigmas; or a tricocous capsule. *Seed*: nut woody, irregular, acuminate, excavated with little pits and apophyses, seven-celled, seven-valved; kernels solitary, roundish. ESSENTIAL CHARACTER. *Male Ament*. *Perianth*: bifid. *Corolla*: none. *Female*. *Perianth*: trifid. *Corolla*: none. *Stigma*: three-parted. *Drupe*, or *Capsule*: three-grained.—These plants can never be expected to rise to any great height in Europe, though in the stoves they may be easily raised from good seeds. They must be sown upon a hot-bed, and when the plants come up, they should be each planted in a small separate pot filled with light sandy earth, and plunged into a good bed of tanners' bark. They require the same treatment as other tender plants; but must not have much wet, for they abound with an acrid milky juice, and it is certain that most plants which do, are soon killed by much moisture. These plants must be removed into the stove and plunged into the tan-bed, in autumn, where they may be suffered to remain in winter, giving them very little water; but plenty of air in summer, when they may be watered once or twice a week: this management may raise them to the height of five or six feet, and their green shining leaves form a pleasing variety during winter in the stove.—The species are,

1. *Hippomane Mancinella*; *Manchineel Tree*. Leaves ovate, serrate, biglandular at the base; stalks half as long as the leaves. The trunk is of a middling size, with a gray, even, thick, milky bark, and a hard wood, which is yellowish, with gray or blackish veins; flowers in aments or spikes; fruit a drupe, the colour, size, and form of an apple, smooth, with a soft spongy flesh, a sweet smell, and an insipid caustic taste. Within is a nut with from three to five cells, with a single seed in each, which is three-cornered, covered with a shining silvery skin, and having the taste of a hazel-nut. Mr. Miller describes the fruit as about the size and shape of a Golden Pippin, turning yellow when ripe. The European nations have, with little variation, given it the Spanish name of *Mancanilla*, or little apple. It drops from the tree in great quantities, not rotting, but drying up, and does not seem to be eaten by any animal, except perhaps by a species of crab, which resorts to these trees in incredible quantities, but probably rather for shelter than for food. Dr. Patrick Browne informs us, that he has known many people who have ignorantly eat of this fruit, which they had mistaken for crab-apples: they generally vomited in a short time, and continued to complain of a burning heat in the mouth, throat, and stomach, for many hours after. The juice of the buds of the White Cedar is esteemed an antidote to this poison, and is generally used with some success; but oily mixtures and emulsions are the most effectual assistants, and seldom fail to afford relief. He

adds, that he has never known any to die by this poison, though he has seen some who have eaten nine or ten of the apples at a time. Long says, that though the green fruit may be destructive in considerable quantities, yet small quantities may be taken without danger, and it is too disagreeable from its acrimony to excite any desire of eating it, and even when ripe is too insipid to raise any pleasure; though goats, sheep, and macaws, feed greedily upon it in that state. The first accounts of this tree were very much exaggerated. It was said to be dangerous to sit or lie under it, and that the rain which falls from the leaves will raise blisters in the skin. Professor Jacquin informs us, that he and his companions reposed upwards of three hours under a Manchineel-tree, without receiving any injury, and that he experienced rain dropping from the leaves to be perfectly innocent. Long also says, that the negroes do not suffer any inconvenience from drops of the juice accidentally falling on their skin when felling this tree, or hacking off the limbs; but if it chance to fly into their eyes, it will give them a severe pain for several hours: and Jacquin likewise acknowledges, that a drop of that milky juice with which the whole tree abounds, falling on any part of the hand, except the palm, will immediately raise a blister. The wood of this tree is frequently of a fine grain, and very beautifully clouded. It will take a fine polish, and being very durable, and not subject to be eaten by the worm, it is much esteemed in the West Indies for making cabinets, bookcases, &c. The wood-cutters are said to make a fire round the body of the tree before they venture to fell it, to avoid the danger of losing their sight by the caustic juice flying into their eyes. If the juice fall upon linen, it will turn it black; and when the linen is washed, it falls into holes. The carpenters generally cover their faces while working at this wood, for if any of the saw-dust get into their eyes, it will produce an inflammation. The Indians are said to poison their arrows with the juice of this tree; and it exudes a gum which has been given medicinally instead of gum guaiacum.—The Manchineel-tree is common on the sandy coasts of America and the West Indies, generally growing at some small distance from the surf. It flowers in May, and the fruit ripens in July. Jacquin says it is a lofty handsome tree, with a very branching spreading head, having something of the air of a Pear-tree.

2. *Hippomane Biglandulosa*; *Gum Tree*. Leaves ovate, oblong, biglandular at the base. This tree is from twenty to fifty feet high, with an even, brownish, ash-coloured bark; spikes terminating and lateral, clustered, rather to be called aments. A single ament of male flowers, at the beginning of the flowering time, springs among other small ones, flowers, and falls: thick scales like glands cover the ament, commonly a pair opposite to another pair, ovate, thick, pressed close, adnate; perianth from the sinus of two scales, tubular, irregularly four-cleft, blood-red. The whole tree contains a great quantity of milky juice, which becomes a resin or gum of a thick sticky consistence, dirty colour, opaque, and of little or no smell: this generally serves for the boiling-house lamps, in every part of the country where the tree is frequent, and is much used for birdlime. The wood is soft and coarse, and not much esteemed; it is used however for making hoghead staves. The flowers appear in March and September.—Native of mountains on the continent of America, and in the West India Islands: found also in New Spain.

3. *Hippomane Spinosa*. Leaves subovate, tooth-spiny. This is seldom more than twenty feet high. The leaves greatly resemble those of the Holly; they are set with sharp prickles at the end of each indenture, and are of a lucid green, continuing all the year.—Native of South America.

Hibb. sculp.

HIPPOMANE MANCINELLA — *Manchineel Tree.*

Hippophæ; a genus of the class Diœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male.* *Calix*: perianth of one leaf, two-parted, two-valved, with the bottom entire; the parts roundish, blunt, concave, upright, converging at the tips, and gaping on the sides. *Corolla*: none. *Stamina*: filamenta four, very short; antheræ oblong, angular, almost the length of the calix. *Female.* *Calix*: perianth one-leaved, ovate-oblong, tubular, club-shaped, with the mouth cloven, deciduous. *Corolla*: none. *Pistil*: germen roundish, small; style simple, very short; stigma thickish, oblong, upright, twice as long as the calix. *Pericarp*: berry superior, subglobular. *Seeds*: single, oblong, hard, shining. *Observe.* Hermaphrodite flowers have sometimes been observed among the males. **ESSENTIAL CHARACTER.** *Male.* *Calix*: two-parted. *Corolla*: none. *Female.* *Calix*: tubular, cloven. *Corolla*: none. *Style*: one. *Berry*: one-seeded.—These shrubs may be easily propagated by suckers from the root, taken off in autumn, and transplanted into a nursery. After one year's growth they will be fit to transplant where they are to remain. They may also be increased by layers, but the roots spread, and put out such abundance of suckers, that there is no necessity to be at this trouble. There being little beauty in these shrubs, it will be sufficient to have one or two of them in plantations.—The species are,

1. *Hippophæ Rhamnoides*; *Common Sea-Buckthorn*, or *Sallow Thorn*. Leaves lanceolate, scattered, about two inches long, of a silvery white beneath. It rises with shrubby stalks eight or ten feet high, sending out many irregular branches, which have a brown bark silvered over. The branches spread wide, are straight, stiff, and thorny at the ends, the lesser ones numerous, scattered, short, and spreading. Flowers solitary, appearing before the leaves, generally abortive, unless the shrub grows in its natural situation. The female flowers are sessile in the axils of the lower leaves: the male flowers are subsessile, somewhat spiked, disposed in four rows along the lesser branches. The flowers come out from the branchlets of the former year. The berries are very abundant, gratefully acid, and much eaten by the Tartars. They are the principal food of the peasants upon Mount Caucasus. The fishermen of the Gulf of Bothnia prepare a rob from them, which imparts a grateful flavour to fresh fish. In sunny situations this shrub is planted for hedges; and is used for dyeing yellow. Cows refuse it; goats, sheep, and horses, eat it. It varies with red berries. Miller says, that he has observed it only with yellow berries in England, but that he had seen it on the sand-banks in Holland with red berries. The Germans call it *Haftdorn*; the Dutch, *Duinbessen*; the Swedes and Danes, *Haftorn*; the French, *Argoussier*; the Spaniards, *Espino Amarillo*; the Russians, *Rakitnik*. It flowers in April and May; Ray says in June, and Miller in July.—Native of many parts of Europe, on sandy sea-coasts. In England it is found near Sandwich, Deal, Folkstone, and the Isle of Shepey in Kent; upon Cley and Sheringham cliffs, and between Yarmouth and Winterton, in Norfolk; in Lincolnshire; and at Whitby and Lyth, in Yorkshire.

2. *Hippophæ Canadensis*; *Canadian Sea Buckthorn*. Leaves ovate. This has the appearance of the preceding species, but the leaves are broader, and only half the length; the branches are opposite; and the racemes simple among the first leaves, upright, and shorter by half than the leaves.—Native of Canada.

3. *Hippophæ Argentea*. Leaves ovate, obtuse, glabrous on both sides. This shrub resembles *Eleagrus Orientalis* so much, that they might easily be mistaken for each other when without fruit; but this species bears really a berry different from the drupe of the other genus.—Found by Mr. Lewis on

the banks of the Missouri. Mr. T. Nuttall, who has recently travelled through various parts of North America, and is as skilful as he is indefatigable in botanical researches, has added to the specific description of this plant given by Lewis, the important particular, that the perianth is four-cleft.

Hippuris; a genus of the class Monandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: a two-lobed rim, crowning the germen. *Corolla*: none. *Stamina*: filamentum one, upright, placed within the anterior lobe of the calix; antheræ roundish, compressed. *Pistil*: germen oblong, inferior; style one, awl-shaped, upright, from the hinder lobe of the calix, longer than the stamen; stigma sharp. *Pericarp*: none. *Seed*: one, roundish, naked. **ESSENTIAL CHARACTER.** *Calix*: a two-lobed rim to the germen. *Corolla*: none. *Stigma*: simple. *Seed*: one, inferior.—The species are,

1. *Hippuris Vulgaris*; *Common Mare's Tail*. Leaves eight at a joint, awl-shaped; root perennial, creeping, white, jointed; the joints furnished with numerous capillary fibres: stems numerous, a foot and half or more in height, upright, quite simple, smooth, striated, round, jointed, spongy; the pith like a thread in the centre, compact, and in the roots tough; flowers axillary, sessile, one to each leaf, in the whorls that are above water. Linneus remarks, that the flower of this plant is as simple as can be conceived, having neither calix nor corolla, only a single stamen and pistil, and one seed. The situation also of the leaves, in whorls, is not usual in European plants, except in the natural order of stellatæ. At the beginning of the summer, the flowers are mostly hermaphrodite, but at the close of it many of them are female. Gerarde calls this plant, *Female Horse-tail*, and Parkinson *Marsh Barren Horse-tail*: Mr. Hudson first named it *Mare's-tail*. The French call it *Pesse d'Eau*, a translation of one of its old names *Linnopeuce* or *Water Pine*. The Germans call it, *Schafthalm*, *Tannenwedel*; the Dutch, *Kattestaart*, *Paardestaart*; the Danes, *Hesterumpe*, *Van-Studeknæ*; the Swedes, *Hastvans*; and the Italians, *Hippuride*.—Native of many parts of Europe, in ponds, ditches, marshes, and rivers, especially where there is a depth of mud, and the frost cannot reach the roots. In quiet waters it grows upright, in running waters it bends with the stream, but in large lakes rises to the height of several feet. In some countries it is a troublesome weed in rivers, and chokes up the ditches; but by absorbing a great quantity of inflammable air, it is reputed to assist in purifying the putrid air of marshes. Gmelin says, that the wild ducks in the north feed upon it. Goats are also said to eat it. We do not know that it is of any other use. It flowers from May to August, and is not very common in England, though found in several parts of Cambridgeshire, Oxfordshire, Westmoreland, Staffordshire, Leicestershire. Near London it is more rare: Blackstone found it in Harefield river, and upon Uxbridge moor; Hudson, in the New River near Hornsey; and Dr. Milne, near Stoke Newington and Highgate.

2. *Hippuris Tetraphylla*; *Four-leaved Mare's Tail*. Leaves four at a joint, oblong, blunt. This is always very distinct from the preceding, by its only having four leaves to a whorl, and their being spatulate-ovate and blunt. It has the appearance of *Elatine Alsinanstrum*, and is clearly a gynandrous plant.—Native of Sweden; first discovered by Schulsen near Abo in Finland.

3. *Hippuris Indica*; *Indian Mare's Tail*. Scape naked, four feet high, very straight and simple, round, striated; root tuberosous. This is a stemless plant, with a fibrous creeping root, having many roundish, scattered, small, black, hairy tubers, which are eatable.—Native of the marshes of Cochinchina.

Hip (or *Hep*) *Tree*. See *Rosa Canina*.

Hiræa; a genus of the class Decandria, order Trigynia.

—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, upright, very small, permanent. *Corolla*: petals five, roundish, concave, with long claws. *Stamina*: filamenta ten, capillary, united at the base, the outer ones shorter; anthers roundish, upright. *Pistil*: germen roundish; styles three, simple, upright; stigmas bifid, blunt, spreading. *Pericarp*: capsules three, upright, keeled on the back; each having a single spreading wing on the outside at the base, and a double one at the tip, not gaping. *Seeds*: solitary, roundish. *Observe*. Swartz says, that this genus is too nearly allied to *Triopteris*: differing in having three two-winged capsules, instead of a three-celled capsule with three wings. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: roundish, with claws. *Capsules*: three, closed, single-seeded, with two or three unequal wings. *Seeds*: two; (Jacquin says, solitary.)—The known species are,

1. *Hiræa Reclinata*. This is a small tree, seldom exceeding fifteen feet in height, and dividing into round, long, smooth, bending and reclining branches, by which it supports itself on neighbouring shrubs; bark ash-coloured; leaves oblong, a little broader at top, blunt at both ends, quite entire, smooth underneath, having soft, decumbent, scarcely conspicuous hairs on the upper surface, and being from three to six inches long; the petiole has two upright bristly stipules at the base; common peduncles thick, very short, and numerous, beautifully surrounding entire and very long branches, and, by means of twelve semioval short bractes, finish in a quadrilocular top; the partial peduncles being one-flowered, an inch long, solitary, and therefore four to each common peduncle; flowers beautiful, but without scent, yellow, an inch in diameter.—Native of woods in Carthage, New Spain: flowering in June, and ripening seeds in September.

2. *Hiræa Odorata*. A shrub: leaves ovate, acute, opposite, entire, veiny; smooth above, downy beneath; clusters copious at the ends of the branches, axillary, forming a terminal leafy panicle, with downy stalks; flowers fragrant.—Found in Guinea.

Hirtella; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted; parts subovate, reflex, unequal, permanent. *Corolla*: petals five, roundish, concave. *Stamina*: filamenta three or five, bristle-shaped, flattish, very long, permanent, at length rolled in spirally; anthers orbiculate. *Pistil*: germen roundish, compressed, and declining, villose; style filiform, almost the length of the stamina, arising from the depressed side of the germen; stigma simple. *Pericarp*: berry oval, broader at top, a little compressed, obscurely three-cornered, at whose base, in front, lie a villose germen and style. *Seed*: one, large, of the same form with the pericarp. ESSENTIAL CHARACTER. *Petals*: five. *Filamenta*: very long, permanent, spiral. *Style*: lateral. *Berry*: one-seeded.—The species are,

1. *Hirtella Americana*. Leaves ovate-lanceolate; branchlets hirsute; racemes upright, simple; flowers five-stamined. This is a tree, with a trunk from twenty-five to thirty feet in height, and a ferruginous bark; petals rounded, with claws, emarginate, bluish; germen rounded, villose; berry obovate, compressed, hairy, rough, dry.—Native of Cayenne.

2. *Hirtella Triandra*. Leaves oblong, acuminate; racemes compound, loose; flowers three-stamined. This is a branching tree, which sometimes rises twenty feet high, but is generally less. The flowers have no scent; the stamina and style are placed cross-wise. The calicine segments are ovate, roundish, concave, equal, reflex; petals spreading, equal,

deciduous, white; stigma simple.—It flowers in April and May, and is found in Jamaica, Martinico, and St. Domingo.

3. *Hirtella Pendula*. Clusters compound, terminal, long, pendulous, hairy; leaves oblong, pointed, heart-shaped at the base, downy beneath; stamina three.—Grows in the W. Indies.

4. *Hirtella Paniculata*. Leaves elliptic, shining, with hairy subcoriaceous racemes, upright; flowers five-stamined; branches round, with a purplish bark, rough-haired at top; stipules awl-shaped, very rough-haired; pedicels copious, alternate, solitary, or sometimes, but seldom, two together; bractes ovate, frequently two on the pedicel, hirsute on the outside, and others lanceolate at the base of the pedicel; filamenta five, long; style hirsute at the base.—Native of Cayenne.

Hoeing,—is beneficial to plants: first, for destroying weeds; secondly, because it disposes the ground better to imbibe the night dews, keeps it in a constant freshness, and adds a vigour to the plants and trees, by which their fruit becomes more abundant, as well as more nutritious. This operation is performed by the hand. Of the instrument called a Hoe, (and well known to every gardener,) there are several sizes. The smallest, called an Onion Hoe, is used not only to cut up young weeds, but to thin the Onions, by removing all such as are too close. The next size is nearly four inches and a half broad, and is called a Carrot Hoe, from being used for Carrots, or any other crops where the same distance is required to be left between the plants. The largest size is about seven inches broad, and is frequently called a Turnip Hoe, from its being used in hoeing Turnips, but which is generally employed by the Kitchen-gardeners for hoeing between all their crops which are planted out, or stand so far asunder as to admit an instrument of this breadth to pass between the plants. Besides these sorts of hoes, which are contrived to draw towards the person who uses them, there is another of a different form, which is called a Dutch Hoe, designed to be pushed from the person using it, so that he does not tread over the ground which is hoed. This is a very proper instrument for scuffling over the ground to destroy weeds, whenever the plants will admit of its being used; and a person will go over a much greater space of ground with one of these instruments, than with the common hoe; but they are not so proper for hoeing our crops so as to leave the plants at a proper distance, nor will it penetrate the ground so far; therefore the other sort of hoe is to be preferred to this, because it stirs the ground and loosens the surface, thereby promoting the growth of the plants. There has been of late years another instrument introduced into the field culture, called the Horse Hoe, which is a sort of plough with the share set more horizontally than that of the common plough. The utility of Horse-hoeing is, first, in proportioning the number of plants which the ground is supposed to be capable of nourishing; the second is, that by frequently stirring the surface of the land, all weeds which rob the crop of its nourishment are destroyed, and the clods of earth divided and pulverized, so that the roots of the plants can more easily penetrate them, and search their proper food; besides, the dew and moisture are easily imbibed in the loose ground, whereby the plants receive a greater share of nourishment. There are few persons who properly consider of what consequence the stirring and breaking of the ground is to all crops growing therein. It has frequently been tried, when the crop has been so bad as to be thought not worth standing, which has been occasioned by the great quantity of rain binding the surface of the ground so closely that the plants could find no nourishment, but have changed from their usual verdure to a purple colour, and made no progress: yet when the clods have been broken, and the ground hoed, they have put forth new roots,

and flourished exceedingly. From many repeated trials of this kind, it is evident that if the Wheat in general were sown in rows, so that the plough might be brought between the rows in the spring, to loosen the ground, which by the winter's rains may have been too closely bound, the crop would more than double what is the common produce. And by this method of husbandry we can affirm, that all crops will be so much improved, as doubly to repay the difference of expense, while less than a sixth part of the seed will be enough for the same ground. The common swing plough answers all the ends of Horse-hoeing.

Hoffmannia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, four-toothed, superior; teeth upright, sharp. *Corolla*: monopetalous, salver-shaped; tube so short as to be next to none; border four-parted; parts lanceolate, spreading. *Stamina*: filamenta none; antheræ four, fixed to the base of the tube, linear-subulate, upright, pressed close to the style. *Pistil*: germen inferior, oblong-four-cornered; style subulate, the length of the stamina; stigma blunt, scarcely emarginate. *Pericarp*: berry oblong, slightly four-cornered, crowned, two-celled, two-valved. *Seeds*: numerous, roundish, fixed to receptacles in each cell. ESSENTIAL CHARACTER. *Calix*: four-toothed. *Corolla*: salver-shaped, four-parted. *Filamenta*: none. *Berry*: two-celled, many-seeded.—The only known species is,

1. *Hoffmannia Pedunculata*. Stem herbaceous, two or three feet long, branched, smooth; branches round and hairy; leaves stalked, opposite, ovate, pointed, entire; calix coloured; corolla yellowish at the points, striated with red at the bottom of the segments.—Native of Jamaica.

Hog Plum. See *Spondias*.

Hog's-Fennel. See *Peucedanum*.

Hog-weed. See *Boerhavia Heracleum*, and *Polygonum*.

Holcus; a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite Flowers*, sessile. *Calix*: glume one-flowered, two-valved, subovate, obtuse, coriaceous, awnless; outer valve large, concave, slightly three-toothed at the tip, embracing the inner valve, which is oblong, rolled up on the sides. *Corolla*: glume two-valved, tender, villose, less than the calix; outer valve smallest, placed within the inner calicine valve, in most of the species bifid at the tip, and awned; awn from the cleft of the glume, long or short, jointed, twisted, sometimes none; nectary three-leaved, two of the leaflets cartilaginous, truncate, the third opposite, ovate, or lanceolate, villose. *Stamina*: filamenta three, capillary, very tender; antheræ oblong, bifid. *Pistil*: germen ovate; styles two, capillary, diverging; stigmas oblong, feathered. *Pericarp*: none, but the glumes of the corolla and calix are rolled about the seed, and enclose it. *Seed*: solitary, ovate, covered, armed with the awn of the corolla, which however easily falls off. *Male Flowers*, peduncled, solitary, or in pairs, accompanying the hermaphrodite, smaller. *Calix*: glume two-valved; valves ovate-lanceolate, sharpish, chaffy, awnless; the outer valve concave, embracing the inner, which is narrower. *Corolla*: glume two-valved, smaller, more tender; outer valve within the inner valve of the calix, shorter, two-toothed, awnless; the inner valve doubled up on the edges; nectary as in the hermaphrodites. *Stamina*: filamenta three, as in the hermaphrodites. *Pistil*: germen small, angular, abortive; styles two, bristle-shaped; stigmas none. ESSENTIAL CHARACTER. *Hermaphrodite*. *Calix*: glume one or two flowered. *Corolla*: glume awned. *Stamina*: three. *Styles*: two. *Seed*: one. *Male*. *Calix*: glume two-valved. *Corolla*: none. *Stamina*: three.—The species are,

1. *Holcus Spicata*; *Spiked Holcus*. Glumes two-flowered, awnless; flowers in pairs, involucre with a pencil; spike ovate-oblong; culm two feet high, and about the thickness of a swan's quill.—An annual grass; and a native of the East Indies.

2. *Holcus Bicolor*; *Two-coloured Holcus*. Glumes smooth, black; seeds globular, white-awned. This is an annual grass, greatly resembling the next species, but still very distinct from it, by its black calices, and seeds of a snowy whiteness.—Native of Persia.

3. *Holcus Sorghum*; *Indian Holcus*, or *Millet*. Glumes villose; seed compressed, awned; panicle contracted, ovate, upright, but drooping as it ripens. There are several varieties of this species; the most remarkable is the red-seeded one cultivated among the Caffres. Of this, the calix when ripe is cartilaginous, pale chestnut-coloured, very smooth, shining, only half the length of the seed, which is naked, obovate, globular, much acuminate towards the base, red, not shining. Miller describes this and the sixth species together, and indeed they differ so little as scarcely to merit being considered as a distinct species. According to him, the stalks of these plants rise five or six feet high, are strong, reedy, and like those of the Maize or Turkey Wheat, but smaller. The leaves are long and broad, having a deep furrow through the centre, where the midrib is depressed on the upper surface, and is very prominent below. The leaves are two feet and a half long, and two inches broad in the middle, embracing the stalks with their base. The flowers come out in large panicles at the top of the stalks, resembling at first appearance the male spikes of the Turkey Wheat: these are succeeded by large roundish seeds, which are wrapped round with the chaff.—They are both natives of India, where the grain is much used to feed poultry, and is frequently sent to Europe for the same purpose. This is much cultivated in Arabia, and most parts of Asia Minor. It has been introduced into Italy, Spain, Switzerland, and some parts of Germany. In China, Cochinchina, and the West Indies, where it grows to the height of five or six feet or more, and is esteemed a hearty food for labourers, it is called Negro Guinea Corn. Its long awns or bristles defend it from the birds. In Arabia it is called *Dora* or *Durra*; the flour is very white, and they make good bread of it. The bread made from it in some parts of Italy and Portugal is however dark and coarse. In Tuscany it is chiefly used for feeding poultry and pigeons; and even swine, cattle, and horses. Cæsalpinus says, however, that cattle when fed upon the green herb are liable to swell and die, although they thrive on it when dried; in which state brushes are made of it in Italy, some of which Mr. Ray observed in the Venetian shops. The Germans call this plant *Mohrhirse*, *Sorgsamen*, *Sorgsaat*, *Welsche Hirse*, and *Indische Hirse*; the Dutch, *Gewoon Zorghzaad*, *Negerkoorn*; the French, *Houque Sorgo*, *Grand Millet*; the Italians, *Saggina Sagginella*, *Sorgo*, *Melica*; the Spaniards, *Alcandia*, *Melca*; the Portuguese, *Millo Largo*; the Tartars, *Myssur*, *Suburge*; the Japanese, *Sioku*, *Kibi*; and the inhabitants of Guinea, *Guiarnatt*.—The autumns of England are seldom dry and warm enough to ripen the seeds well in the field. Those who propagate them should sow the seeds on a warm border, or upon a gentle hot-bed, in March; and when the plants come up, they should be thinned, and planted at the distance of a foot asunder in the rows, which should be at three feet distance. The culture after this is to keep the ground clear from weeds, and draw the earth up with a hoe to the stems of the plants; if the season prove warm, their panicles will appear in July, and the grain will ripen in September, except in bad seasons, when it is liable to fail. It is

thought that if the seeds were procured from Germany and Switzerland, (climates not very different from our own,) that Sorghum might be advantageously cultivated upon some of the warmer soils of our island.

4. *Holcus Halepensis*; *Panicled Holcus*. Glumes smooth; hermaphrodite flowers awnless, female awned; culm smooth and even; panicle spreading, purple; awns white at the tip. To each female or hermaphrodite flower, there are two male flowers, which are pedicelled. The root is perennial, and increased by lateral runners, like the reed. Allioni says it grows wild near Turin, and other parts of Montserrat.—Native of Syria.

5. *Holcus Nitidus*. Glumes one-flowered, villose, all the flowers awnless; culm round, upright, with bearded joints; panicle upright; peduncles in a sort of whorl. It is smaller than the preceding in all its parts, but has the same habit.—Native of the East Indies.

6. *Holcus Saccharatus*; *Yellow-seeded Holcus*. Glumes villose, all the seeds awned; root biennial; panicle large, diffused. The male flowers scarcely open. The villosity of the calix is as inconstant as the colour, and is almost always lost in maturity; the colour generally changes to dark or black; these circumstances therefore are unfit to use for specific distinctions. This and the third species differ little in habit or any thing else, except the one having a naked, and the other an incrustated seed. Browne calls it Guinea Wheat, and says it had been lately introduced into Jamaica.—Native of the East Indies, and cultivated in China and Cochin-china. See the third species.

7. *Holcus Mollis*; *Soft Holcus*, or *Creeping Soft-grass*. Glumes two-flowered, almost naked; hermaphrodite, floret awnless; male with a knee-jointed awn. It resembles the next species. Mr. Curtis says it is usually a smaller plant, or, if it be as tall, that it has a much more scanty panicle. The spikelets have not that brilliant colour which marks those of the next species at their first appearance. This grass also rarely occurs, except in and about woods and in hedges; whereas the Lanatus is a very general grass in meadows. It flowers in July, and is a very troublesome weed with its creeping roots, especially in arable lands.

8. *Holcus Lanatus*; *Woolly Holcus*, or *Meadow Soft-grass*. Glumes two-flowered, villose; hermaphrodite, floret awnless; male with a recurved awn; root perennial, but not creeping; stems from two to three feet high, upright, round, pubescent, with three or four joints. The velvet-like softness of the whole plant, and the redness of the opening panicle, render this grass very conspicuous. It abounds in meadows, is frequent by road-sides, and sometimes grows on walls. It flowers in June and July. Haller speaks highly of this grass as food for cattle, but it is not at all esteemed among us. The seed however being easily collected, is sometimes sent to London in great quantities as pure grass-seed. Lightfoot says that the stalks are used for making ropes for fishing boats in the isle of Skye; but there are better grasses for this purpose. Young, in his *Annals*, says, that a gentleman's horses having been much disordered with a malady which caused an extraordinary discharge of urine; the hay on which they fed, being examined, was found to contain scarcely any other grass but this; and that on changing the hay, the distemper ceased. This fact should be well ascertained, before the *Holcus Lanatus* is recommended as one of the most valuable kinds of meadow-grasses, as it is by Dr. Anderson; though since he calls it *Creeping Soft-grass*, and talks of its running roots, he may mean the preceding species, which certainly is one of the vilest weeds in arable lands. On the other hand, Mr. Marshall, in his *Rural Economy of Yorkshire*, says,

that it is far from an eligible grass for cultivation, is now entirely exploded by judicious husbandmen, and has been supplanted by Ray-grass; the growers of the seed being the only persons who have profited by its cultivation, eighty bushels having been produced from an acre. It is known in Yorkshire by the name of *White Hay Seeds*. In his *Minutes of the Midland Counties*, he says it ranks high as a pasture plant, at least for cattle; that a piece which abounds in it to one half, is esteemed excellent for cheese, favourable to the rearing of young heifers, and the fattening of Scottish bullocks; and that cattle of all kinds fare well upon it, except horses. For the propagation of this and the preceding species, see *Grass*.

9. *Holcus Laxus*. Glumes two-flowered, smooth, awnless, acuminate; panicle crowded, oblong; culms two feet high, narrow, somewhat nodding; peduncles usually two-flowered. This has the habit of *Aira Cœrulea*.—Native of Virginia and Canada. See *Grass*.

10. *Holcus Striatus*. Glumes two-flowered, striated, awnless, acuminate; panicle crowded, oblong.—Native of the marshes of Virginia. See *Grass*.

11. *Holcus Serratus*. Glumes two-flowered, pubescent, awnless; leaves serrate; root perennial, creeping, covered at top with sheaths of leaves in clusters; culms decumbent at bottom, branched, covered with the sheaths of leaves below, naked above, a foot high, even, quite simple, almost leafless.—Found at the Cape of Good Hope.

12. *Holcus Odoratus*; *Sweet-scented Holcus*. Glumes three-flowered, awnless, acuminate; hermaphrodite, flower two-stamined; root perennial, jointed, creeping; culm three feet high, with few joints. This grass has a sweet smell, and is collected into bundles, to lay among clothes and linen; and is hung over beds in some countries, with a view to procure sleep.—Native of wet pastures in the colder parts of Europe, and also of Canada, and Siberia. See *Grass*.

13. *Holcus Redolens*. Glumes three-flowered; side florets, male awned, hairy at the edge; the middle one subhermaphrodite, awnless; culm upright, a foot high, smooth, sheathed; panicle patulous, with filiform pedicels; stamina three, fertile in the males, barren in the middle flower.—Native of Terra del Fuego.

14. *Holcus Latifolius*. Glumes three-flowered, the first floret unarmed, two prickly at the edge; leaves subovate; culm even, scarcely a foot high.—Found in China.

15. *Holcus Pertusus*; *Perforated Holcus*. Spikes digitate; glumes with the outer valve punched with a hole in the middle; culm jointed, even, ascending, branched, about a foot high.—Native of the East Indies.

16. *Guinea Grass*, (so called from its having been originally introduced into the West Indies from the coast of Africa,) according to Browne, is a species of *Holcus*. The characters of it, he says, agree pretty well with those of *Panicum* in general, but the flowers commonly grow very luxuriant, and though often hermaphrodite, are generally observed to be male and female distinct, surrounded by separate involucre, and standing on distinct pedicels within the same calix. The blades of this grass, when flourishing, appear not unlike those of Wheat, only rather longer and broader; and the stalks, during the first growth, are also much like those of Wheat, but they get weaker and less the oftener the grass is fed upon or cut, till at last it becomes a fine, rich, and entire swath. It appears capable of thriving in any situation, climate, or soil, and can bear the effects of dry or wet weather in a most remarkable manner. In wet weather it may be cut once in a fortnight, and sometimes oftener, when the land is new or fertile. In dry weather it is long before it withers; and, when reduced to such a state as to seem totally destroyed, will revive in a

few hours after a slight shower; so that when so little rain falls as to be of no service to common pastures, this will be fit for use in a few weeks; and in some situations, not exposed to the sun, it will flourish from occasional dews only. When ready to feed, it is from six to eight feet high, but it is generally fed on or cut when only three or four. It seems to have reached all parts of the world, and to be every where esteemed for its great usefulness.—In the West Indies it is cultivated by making the land perfectly bare by hoeing, and then digging holes from three to five feet distance, according to the quality of the soil. The holes should be large, and deep enough to bury a few roots of the grass at a good depth. These roots are procured from a neighbouring nursery or field, and the grass being topped within three or four inches, they are put into the holes, well covered with earth, and pressed down with the foot: care is taken to keep the plants free from weeds by repeated hoeings. The best months for planting are April and May, for the grass will then seed in September and October, at which time it produces in abundance. The ground must be quite clean when the seed is ready to drop; and if the spaces between the roots are then stirred by the hoe, it will be found very beneficial. When the seed is all fallen, stock are turned in, to tread it into the ground, and feed upon the grass. In very rich and new land, the grass at first will grow so rank as to produce very thick stalks, which, by running up the noses of the stock, will prevent them from eating it so close as they otherwise would. When, however, it is eaten as near the ground as possible, the remaining grass, with the roots which were planted, are dug out with the hoe, and burnt off. After this, the grass, if favourable rains come, will grow from the seed, and, by covering the ground, in May following will be perfectly established for several years; according to the quality of the land, to be cut for hay, or to stand for pasture. Whenever the grass grows thin, holes may be opened in such places, and roots again planted to supply it; and, by this attention, a field will scarcely ever be so totally worn out, as to require the labour of entirely replanting it at any one time. If a little care only be taken of this grass in its infancy, it will soon overcome all other grasses and weeds; and in ground full of stones and rocks, though planted at random, and at great distances, as the soil admits, it will spread itself about them in a few months, and at last entirely cover them. If the stalks of this grass be buried a few inches deep, each joint of it will take root, and grow luxuriantly; or it may be propagated directly from sowing the seed, the ground being previously prepared for that purpose; but the seed will lie many months in the ground before it makes its appearance. Some planters do not stock up the roots which are planted, when the grass has seeded; and others depend upon what they afford, by continually feeding or cutting the grass when at a certain height, without ever suffering it to seed.

Holosteum; a genus of the class Triandria, order Trigonium.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, permanent. *Corolla*: petals five, two-parted, blunt, equal. *Stamina*: filamenta three, filiform, shorter than the corolla; antheræ roundish. *Pistil*: germen roundish; styles three, filiform; stigmas bluntish. *Pericarp*: capsule one-celled, subcylindric, gaping at the tip. *Seeds*:

very many, roundish. *Observe.* In the third species, the petals are subtrifid, less than the calix. In the fifth species the petals are three or two-toothed; stamina three or five; styles three or four; capsule six-valved at the tip. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five. *Capsule*: one-celled, subcylindrical, opening at top.—The species are,

1. *Holosteum Cordatum*; *Heart-leaved Holosteum*. Leaves subcordate; stems decumbent, creeping, somewhat rigid at bottom; peduncles lateral, elongated, ascending, seven-flowered, one in the middle, and three on each side, from a peduncle farther branched.—Native of Jamaica and Surinam. In the former it is common, and thrives very luxuriantly. Browne calls it the Larger American Chickweed, and says that it grows in tufts, and seldom rises above ten or twelve inches from the ground; that the smaller birds feed much upon the seeds, which are seldom put to any other use, except that large wads of the fresh plant, heated over a gentle fire, are sometimes applied to hard and painful swellings, in order to relax the parts, and dispose the obstructions to a resolution.

2. *Holosteum Diandrum*; *Two-stamined Holosteum*. Stems procumbent, very rigid; leaves roundish; flowers two-stamined; capsule roundish. This plant is very small, seldom rising above six or seven inches from the ground.—Annual, and a native of Jamaica.

3. *Holosteum Succulentum*; *Succulent Holosteum*. Leaves elliptic, fleshy; petals white, subtrifid, smaller than the calix.—Native of New York.

4. *Holosteum Hirsutum*; *Hairy Holosteum*. Leaves orbiculate, hirsute.—Native of Malabar.

5. *Holosteum Umbellatum*; *Umbelled Holosteum*. Flowers umbelled; root annual, slender, a little branched, fibrous, running perpendicularly down; stems numerous, filiform, jointed, round, perfoliate, upright, from two or three, to six inches high, having mostly three joints; the space between the two lowest is smooth, the others for the most part viscid and hairy; calix never opening, marked at the base with black dots; petals white, or bluish-coloured tinged on the outside, converging, concealed within the calix, so that the tips only peep out. Villars makes two species of this: 1. smooth, with triandrous flowers; 2. hairy, with decandrous flowers. The first smooth, smaller, and greener; the second very villose, larger, ash-coloured, green all over; the peduncles and calices not clammy as in the other, which is more common. Hudson and Withering place it among the *Cerastia*; whilst Swartz would remove the *Aksine Media*, or Common Chickweed, into this genus. It is an annual plant, flowering in April and May.—Native of Spain, Italy, France, Germany, Switzerland, and England; where it was first noticed on the walls of Norwich, and also upon walls and banks in the neighbourhood: it has also been found near Bury in Suffolk.

Homalium; a genus of the class Polyandria, order Trigynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, six or seven cleft; clefts ovate-lanceolate, sharp, spreading very much. *Corolla*: petals six or seven, ovate, flat, a little longer than the calix, spreading very much; nectary-glands six or seven, flat, alternate with the petals. *Stamina*: filamenta eighteen or twenty-eight, subulate, upright, the length of the corolla, of which three or four are inserted into the receptacle among the glands before the base of the petals; antheræ roundish, small. *Pistil*: germen roundish, villose, immersed in the base of the calix; styles three, upright; stigmas simple. *Pericarp*: capsule woody, ovate, one-celled. *Seeds*: very many, and very small. ESSENTIAL CHARACTER. *Calix*: six or seven parted. *Corolla*:

six or seven petalled. *Stamina*: twenty-one, in three bodies. *Pericarp*: one-celled, many-seeded.—The species are,

1. *Homalium Racemosum*. Leaves serrate; racemes axillary, and terminating; flowers peduncled. This is a lofty branching tree, with the habit and leaves of the Elm.—Native of Martinico and Jamaica.

2. *Homalium Racoubea*. Leaves toothed, coriaceous; racemes terminating; flowers subsessile. This is a shrub, with a trunk of about three or four feet high, and four or five inches in diameter; the bark is whitish; the branches tortuous and spreading, and seven or eight feet long. The flowers are borne on spikes springing from the bosoms of the upper leaves; they are sessile, and of a yellow colour.—Native of Guiana, flowering in May.

3. *Homalium Angustifolium*. Leaves elliptic-lanceolate, slightly waved, entire; partial flower-stalks very short; petals obovate; clusters axillary, simple, scarcely the length of the leaves; flowers nearly sessile, and essentially distinguished by the obovate petals.—Native of Sierra Leone.

Hopea; a genus of the class Polyadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bell-shaped, five-cleft; clefts ovate, blunt, permanent. *Corolla*: petals five, oblong, concave, connected at the base by the intervention of the bunches of stamina. *Stamina*: filamenta very many, bristle-shaped, longer than the corolla, connected at the base in five bodies; antheræ quadrangular. *Pistil*: germen inferior, roundish; style gradually thickening, the length of the corolla, permanent; stigma thickish, obliquely depressed. *Pericarp*: drupe dry, oval-cylindric, gibbous, crowned with the calix. *Seed*: nut smooth, three-celled, protracted by a blunt tip. **ESSENTIAL CHARACTER.** *Calix*: five-cleft, superior. *Corolla*: five-petalled. *Stamina*: many, connected in five bodies. *Style*: one. *Drupe*: with a three-celled nut.—The only known species is,

1. *Hopea Tinctoria*. This is a tree, with alternate, petioled, simple, oblong, lanceolate-ovate, subserrate, shining, nerveless, sweet leaves. The peduncles burst forth from buds upon the topmost branchlets, eight or ten together, before the leaves, and are disposed in a very short spike, on very short one-flowered pedicels, clothed with small, concave, villose leaflets. The flowers are succeeded by subsessile fruits, below the leaves, in a very short spike. It flowers early in the spring, and is then extremely sweet. The juice or decoction of the leaves will dye linen and silk of a bright yellow colour.—Native of Carolina.

Hordeum; a genus of the class Triandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: common receptacle lengthened into a spike; glume six-leaved, three-flowered; flowers sessile; leaflets distant, in pairs, linear, acuminate. *Corolla*: two-valved; lower valve bellying, angular, ovate-acuminate, longer than the calix, ending in a long awn; inner valve lanceolate, flat, smaller; nectary two-leaved; leaflets ovate, sharp, ciliate. *Stamina*: filamenta three, capillary, shorter than the corolla; antheræ oblong. *Pistil*: germen ovate-turbinate; styles two, villose, reflex; stigmas similar. *Pericarp*: none: the corolla grows round the seed, without opening. *Seed*: oblong, bellying, angular, acuminate on both

ends, marked with a groove on one side. *Observe*. In some of the species all the three flowers contained in an involucre are hermaphrodite, and fertile; in others the side flowers are males, and the middle one only is hermaphrodite and fertile. **ESSENTIAL CHARACTER.** *Calix*: lateral, two-valved, (valves narrow, acuminate, distant, all together forming a six-leaved involucre,) one-flowered, by threes, at each toothlet of the rachis.—The species are,

1. *Hordeum Vulgare*; *Spring Barley*. All the florets hermaphrodite, and awned in two very upright rows. Of the Spring Barley, which is principally cultivated in England, the farmers make two sorts, viz. the Common, and the Rath-ripe Barley, which are in fact the same: for the Rath-ripe is only that which has been long cultivated upon warm gravelly lands. The seed of this, when sown in a cold or strong land, will the first year ripen near a fortnight earlier than the seeds taken from strong land; therefore the farmers in the vales generally purchase their seed-barley from the warm land; for, if saved in the vales two or three years, it will become full as late in ripening as the common Barley of their own product; and the farmers on the warm lands are also obliged to procure their seed-barley from the strong land, to prevent their grain from losing its bulk and fulness. This sort of Barley is easily distinguished by the two orders of beards, or awns, which stand erect; the chaff being also thinner than that of the second and fourth sorts, it is esteemed better for malting.—The second description, Winter or Square Barley, Bear, or Big, is rarely cultivated in the southern parts of England; but in the northern counties and in Scotland is generally sown, being much hardier than the other species, and will bear the cold. It has its grains disposed in six rows: the grain is large and plump, but it is not so good for malting, which is the reason for its not being cultivated in the southern parts of the island, where the other sorts thrive well, and are better adapted to that purpose. The third sort, is the Common, or Long-eared Barley, which is cultivated in many parts of England, and is an exceedingly good sort, though some farmers object to it, because the long and heavy ears, they say, are more apt to lodge. This has the grains regularly ranged in a double row, lying over each other like tiles on a house, or the scales of fishes. The husk or chaff of this Barley is also very thin, and is much esteemed for malting.—The fourth kind is generally called Sprat or Battledore Barley: it has shorter and broader ears than any of the other sorts; the awns or beards are longer, and the grains are placed close together, and the awns being long, the birds cannot so easily get out the grain. This seldom grows so tall as the other species; and the straw being shorter and coarser, does not make very good fodder for cattle. In Spring Barley, the lower flowers are frequently imperfect; the spike is as it were distinct, though there are several rows; in all the flowers the two glumes or chaffs of the calix are shorter than the flower, awl-shaped, and end in a short awn or beard; the outer corolline chaff is much hollowed, with the sides folded in, the back ciliated, and the tip continued into an awn three inches in length; the inner chaff is awnless. It is not known where this, or any other sort of grain, grows wild. Cardan pretended that Barley was a native of Athol in Scotland. Reidesel says the same of Sicily: and it has lately been affirmed to be found on the banks of Samara, a river of Tartary. Diodorus Siculus ascribes the first culture of Barley to Osiris, who discovered it in a wild state. The ancients fed their horses with Barley as we do with Oats. It was eaten also in bread by the lower sort of people; and the gladiators were called *Hordearii*, or *Barley-men*, from their feeding on this grain. Some of the southern parts of Europe annually produce two crops of Barley: one sown in autumn,

and cut in May; and another sown in spring, and cut in autumn. In some of the northern parts of Europe it is called *Korn*, or Corn, exclusively, and is more cultivated because it ripens in less time than any other kind of grain. In Lapland, fifty-eight days only, or about two months, elapse between the sowing and cutting of it. But it is the Rath-ripe, or Patney Barley, which is annually sown in northern climates. *Hordeum Celeste*, or Siberian Barley, (called *Himmelgerste*, or *Himmelskorn*, by the Germans; *Himmelsbygg* or *Thorebygg*, by the Danes; *Himmelskiorn*, by the Swedes; and *Orge Celeste*, by the French,) was only introduced into England in May 1767. It has a broader blade, of a much deeper green, than common Barley at first coming up. The ears are shorter, having only from five to nine grains in length, whereas those of the common sort have from nine to thirteen; and in all stages it is a fortnight forwarder than common Barley. The two sorts being sown in the same field on the 28th of April 1774, to the quantity of three bushels of each, the common Barley produced thirty-six bushels and a half, weighing fifty-two pounds each, and the Siberian produced thirty-two bushels weighing fifty-eight pounds each. But the soil was very dry, and much inclined to a gravel, greatly to the disadvantage of the Siberian Barley, which requires a richer land.—*Propagation*. We shall now direct our attention to the propagation and culture of this most important article. The directions given apply generally to the four first species of this genus; all the sorts of which are sown in the spring of the year, in a dry time, in some very dry light land: the usual time is early in March, but in strong clayey soils, it is not sown till April, and sometimes not until the beginning of May; but when it is sown late, if the season does not prove very favourable, it will be late in autumn before the Barley become fit to mow, unless it be the Rath-ripe sort, which is often matured in nine weeks after the seed has been sown. Some sow Barley upon land where Wheat grew in the former year; but when this is practised, the ground should be ploughed in the beginning of October during dry weather, and laid in small ridges, that the frost may have more power over it; which will render it mellow, and greatly improve it. This should be ploughed again in January, or at the beginning of February: it will break and prepare the ground better; which should be ploughed a third time in March, and laid even where it is not very wet; but in strong wet lands, the ground should be laid round, and the furrows made deep to receive the wet. When this is finished, the common method is to sow the Barley-seed with a broad-cast at two sowings; the first being harrowed in once, the second is harrowed until the seed is buried: the common allowance of seed is four bushels to an acre. This is the quantity of grain usually sown by the farmers; but if they could be prevailed on to alter this practice, they would soon find their account in it; for if less than half that quantity be sown, there will be a much greater produce, and the corn will be less liable to lodge; for when corn or any other vegetable stands very close, the stalks are drawn weak, and incapable of resisting the force of winds, or bear up under heavy rains; but when they are at a proper distance, their stalks will be more than twice the size of the other, and are seldom laid. In fields where there has been a foot-path through the middle, the corn which came up thin on each side the path has been observed to stand upright, when all the rest on either side has been laid flat upon the ground: and whoever will observe these roots of corn near the paths, will find them tiller out, that is, have a greater number of stalks by four times than any other parts of the field. Experiments have been made by sowing Barley in rows, in divers parts of the same field, and the grains sowed thin in the rows, so that the roots were

three or four inches asunder in the rows, and the rows a foot distance; the intermediate spaces of the same field were at the same time sown broadcast in the usual way; and the consequence was this, the roots which stood thin in the rows tillered out from ten or twelve to upwards of thirty stalks on each root; the stalks were stronger, the ears longer, and the grains larger, than any of those sown in the common way; and when those parts of the field where the corn was sown in the usual way have been lodged, the parts thinly sown have maintained their upright position against wind and rain, though the rows have been made not only lengthways but across the lands in several positions, so that there could be no alteration in regard to the goodness of the land, or the situation of the corn. Therefore where these experiments have been frequently made, and always attended with equal success, there can be no room to doubt which of the two methods is more eligible, since, if the crops were only supposed to be equal in both, the saving more than half the corn sown is a very great advantage, and deserves national consideration, for in scarce times such a saving might be of great importance to the public. It is true, farmers in general are very apt to complain if their corn does not come up so thick as to cover the ground green in a short time, like grass-fields: but it is often observed, that when, from the unfavourableness of the season, it has come up thin, or when part has been accidentally killed, the corn has been much stronger, the ears longer, and the grain plumper, so that the produce of those years has exceeded that of other years when it had come up thick; for the natural growth of corn is to send out many stalks from a root, and not to rise so much in height; therefore it is entirely owing to the roots standing too near each other, that the stalks are generally drawn up tall and weak. I have had (says Mr. Miller) eighty-six stalks upon one root of Barley, all of which were strong, producing longer ears and better-filled grain than any which I ever saw in the common method of husbandry, although the land upon which it grew was not remarkably rich: but I have frequently observed on the side of hot-beds in kitchen-gardens, where Barley-straw has been used for covering the beds, that some of the grains left in the ears having dropped out and grown, the roots have produced from thirty to sixty stalks each, every one three or four times larger than they ever grow in the common way: but to this, (continues Mr. Miller,) I know it will be objected, that although upon rich land in a garden these roots may probably have so many stalks, yet in poor land they will not produce so much, and therefore a greater quantity of seed must be sown to make the crop worth standing. Now this is one of the greatest fallacies that can be imagined, to suppose that poor land can nourish more than twice the number of roots in the same space as rich land; yet it is the general practice to act upon this absurd supposition, as if it were really true. A greater quantity of seed is allowed for poor land than for richer ground, the sower not considering that where the roots stand so close they will deprive each other of their nourishment, and starve themselves; which is always the case where the roots stand close. The truth of this will be evident to any person who will observe that part of a field where the corn happens to be scattered in sowing it, and those places where, by harrowing, the seed is drawn up into heaps; the latter will starve, and never grow to a third part of the size to which they attain wherever the seed happens to have been loosely sown: yet common as this is, our farmers surely cannot be aware of it, otherwise they would not continue their old mode of sowing: if they know it, their prejudice must be strong in the extreme.—When the Barley is sown, the ground should be rolled after the first shower of rain, to break the

clods and lay the earth smooth, which will render it better to mow, and also cause the earth to lie closer to the roots of the corn; which will be of great service to it in dry weather. Where Barley is sown upon newly-broken-up land, the usual method is to plough up the land in March, and let it lie fallow until June, at which time it is ploughed again, and sown with Turnips, which are eaten by sheep in winter. The dung of the sheep greatly improves the land; and in March following the land is ploughed up again, and sown with Barley as before. Many persons sow Clover with their Barley; some have sown Lucerne with it; but this is not judicious, for where there is a good crop of Barley, the Clover or Lucerne must be so weak as not to pay for standing; so that the better way is to sow the Barley alone without any crop among it, and then the land will be at liberty for any other crop when the Barley is taken off the ground: yet this custom of sowing Clover, Rye-grass, and other grasses, with corn, has been so long and universally established among farmers, that we have little hope of prevailing upon them to relinquish this absurd practice, which can only be defended upon the ground of its having been handed down to them by their predecessors. When the Barley has been up three weeks or a month, it will be a very good method to roll it over with a weighty roller, which will press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground, which will be of singular service in dry seasons. This rolling of it before it stalks, will cause it to tiller out and produce a greater number of stalks; so that if the plants should be thin, it will cause them to spread so as to fill the ground, and likewise strengthen the stalks. The time for cutting Barley is when the red colour of the ears is off, the straw turns yellow, and the ear begins to hang down. In the north of England the Barley is always reaped and made up into sheaves like Wheat, by which method less corn is lost, and the whole may be more conveniently stacked. But this cannot be so well practised in rich lands like those in the neighbourhood of London, where there are weeds among the corn; and especially in moist seasons: in these cases the Barley must lie on the swathe till all the weeds are dead; and as it is apt to sprout in wet weather, it must be shaken up and turned every fair day after rain, to prevent it. When carried in, it ought to be thoroughly dry; for if stacked wet it turns musty, and if too green will burn in the mow. The common produce of Barley is two and a half or three quarters on an acre.—*Soil proper for Barley.* The best soil for Barley is the dry and heathy, rather light than stiff, yet of sufficient tenacity and strength to retain the moisture. If the land be poor, it ought also to be dry and warm; and if so, will often produce better corn than richer land in a cold and wet situation. Much Barley, however, is grown on heavy land, both after Wheat and on a fallow; but this is no proof of its being a good rule, for we have already shewn the unreasonable nature of several of the customary modes of cultivating this grain. Barley usually succeeds Wheat or Turnips, sometimes Vetches and other crops, or is put in on a fallow or on turf. After Wheat, the soil is winter-fallowed by three ploughings: first lengthways in November; the second across in March; and the last or seed-ploughing lengthways. The soil is harrowed between the two last ploughings, and the quick, if any, destroyed. In Norfolk, when Wheat-sowing is finished, the farmer begins to *scale* in his Wheat-stubbles for a winter fallow. If the land lies in narrow work, the ridgelets are split; if in warps, the ground is likewise ploughed clean, but very fleet. At the beginning of March the land is harrowed, and presently after the Wheat-stubbles are taken up by a full-pitch cross-ploughing; or if the season be wet, and the soil heavy, he reverses the ridges.

In April he harrows, and begins stirring for Barley, with another full-pitch ploughing, lengthways; generally gathering the soil either into five-pace or ten-pace warps, in which it lies until seed-time; when it is harrowed, rolled, sown, ploughed fleet, reversing the warps, and *slading* down the furrows; so as to render the entire surface as even and level as may be. After Turnips the soil is generally broken up as fast as the Turnips are got off; if early in winter, by rice-balking; if late, by a plain ploughing. The general practice, if time will permit, is to plough three times; the first fleet or shallow, the second full-pitch, and the last a mean depth, with which the seed is ploughed in. But when it is late before the Turnips are got off, sometimes the ground is only ploughed once, and the seed sown above; but more frequently it is broken by three ploughings, as above, even when there is not more than a week to perform them in. Such is the practice in Norfolk, where the farmers are generally very skilful in the art of cultivating Barley. They seem fully aware of the tenderness of this plant in its infant state, and of its rootlings being unable to make the necessary progress in a compact or cold soil, and therefore exert every means in their power to make their soil friable and pulverous. To this intent it is sometimes two-furrowed, and even a fourth earth is given, especially in a cold wet season. Nor is this caution confined to Turnip-barley, but should be extended more or less to Stubble-barley, which certainly requires less care. As the soil is kept open by the indigested stubble, and the roots of grasses and other weeds, from which Turnip-fallows at least ought to be free, that will perhaps account for the superiority of Stubble-barley, over that produced by a Turnip-fallow, however well-timed and manured. In Essex they plough five times; four in the fallow-year, throwing the land on to the ridge for winter by the fourth; then they take the first opportunity of hard frosts to carry on their composts, at the rate of twenty or thirty loads to the acre. The compost consists of farm-yard dung mixed up with turf. They then take care, as soon as the land is dry enough, to plough and sow the Barley from the last week of February to the middle of April; but if the seed is not in the ground in March, they despair of a great crop. This Barley culture is very good. It is an excellent practice to plough and sow in the spring, instead of giving preparatory ploughings when the seed should be in the earth. When Barley is put on turf, or after hay or Clover, &c. the turf is generally broken by a winter fallow, and the soil treated in other respects as after Wheat. In very light dry soils it may be right to break the flag as little as possible, provided the grass be killed: in this case they do not break up the turf till after Christmas. With this process the Norfolk farmers sow the Barley above furrow. Barley is seldom manured for, except when sown after ley: after Wheat and Turnips no manure can be requisite, if the ground had been manured for the former; but on a fallow it is manured as for Wheat.—*Quantity of seed, preparation for, and method of sowing.* In addition to what has been already advanced on this head in the former part of the present article, we have to observe, that many farmers sow four bushels of seed on an acre, while some few sow no more than two bushels. Four bushels is very general, but in some places three bushels and a half, and in others three bushels, is the average or medium quantity of Barley sown. The following experiments confirm Mr. Miller's theory of sowing thinner on poorer soils. On an acre of poor land, worth three-and-sixpence per acre, two bushels of Barley were sown; on the next adjoining acre, three bushels; and on the next, four bushels. The result was, that the crop was best from two bushels, next best from three, and the worst from four; which is the greatest quantity of seed that ought ever to be sown,

Bringing and liming seed-barley previously to sowing it, is a common practice, which is reprobated by some, who think even liming prejudicial. Such as are of the latter opinion, recommend the sprinkling a little soot in the water, to secure the seed from insects. It is certain that Barley which has been wetted for malting, and begins to sprout, will come up sooner in a dry seed-time; and in such a season this grain will not only lie long in the ground, but come up and ripen very unequally. To avoid these evils, and give the infant Barley an advantage over seed-weeds, and a chance of coming to market sooner, it seems a good method to steep the seed intended for sowing. This may be either done in clean water, or the drainings of the dung-heap, in which it may lie covered for twenty-four hours, or even longer, if the land be dry, and there be no likelihood of rain for ten days. Sow the grain wet from steeping, without any thing, or with sifted wood-ashes. The sower must put in a fourth or a third more seed in bulk than he would of dry grain, the seed being swelled in that proportion; and he may expect it up in a fortnight at farthest. The common method of sowing Barley is broadcast at two sowings; the first harrowed in once, the second twice. In Norfolk, almost all the Barley is sown under-furrow; that is, the surface having been smoothed by the harrow and roller, the seed is sown and ploughed under with a shallow furrow: a method admirably adapted to a light dry soil; and indeed to any soil which is light enough to produce good Barley, provided it be rendered sufficiently fine, and the seed be not buried too deep. However, if the season be wet, and the soil cold and heavy, good farmers not unfrequently sow Barley above, as is the general custom in other countries. And this seems to be a reasonable practice; for in a dry spring and light land, sowing under seems most eligible; and in a cold spring, or when the soil is rough with clods, sowing above appears to be equally good management.

—*Drill-sowing.* Grain sown by hand broadcast must fall at unequal depths; the seeds constantly sprout at different times: that which is buried where the earth is moist soon appears, whilst such as is near the surface lies baking in the heat of the sun, and does not vegetate till plentiful rains have moistened the soil: hence that inequality of crop to which Barley is particularly liable. Of the two common methods of sowing Barley, ploughing-in buries too deep, and that sown under the harrow is too much exposed to birds; whereas by the *drill* the seeds are all regularly deposited at their proper depth. To this advantage peculiar to drilling, we may add the saving which is made in the seed, and the opportunity this plan affords of keeping the crop perfectly clean by hoeing. The quantity of seed used in drilling by different persons is from six pecks to three bushels; but it is bad economy in general to be too niggardly of seed, and therefore it is not advisable to sow less than two bushels on an acre. If, however, it should be thought proper to use even three bushels, that will secure a considerable saving. Drilling indeed cannot be so well practised on heavy soils; but it may have place on those which are light and friable, which are peculiarly adapted to Barley. Such soils as are not injured by horses going repeatedly on them, and being almost always under command, the horse-hoe may go over them whenever the farmer is most at leisure. Dr. Hunter, in his *Georgical Essays*, gives the following account of an experiment upon this subject. "In the spring of the year 1769, I sowed an acre of Barley in equidistant rows, with the drill-plough, in a field which was sown with the same grain, and upon the same day, broadcast. The broadcast took three bushels per acre; the drill required only six pecks. The drills were eight inches asunder, and the seed was lodged about two inches within

the soil. The acre was drilled within the hour. In the course of growing, the drilled Barley seemed greener, and bore a broader leaf, than the broadcast. When the ears were formed throughout the field, the ear of the drilled Barley was plainly distinguished to be nearly half an inch longer than the broadcast, and the grains seemed fuller and better fed. Being at a loss to account for this, (continues Dr. Hunter,) I dug up some roots of both, and found that the pipe of communication between the seminal and coronal roots of the drilled Barley was considerably longer than in the broadcast. The produce of two hundred square yards of the broadcast and drilled Barley was carefully housed, and afterward threshed out. The drilled exceeded the other nearly one-fifth in measure, and was two pounds heavier per bushel."—*Time of sowing Barley.* The farmer is governed by seasons, and by other necessary work which he may have to perform; but to sow early when he can, is one of the most important precepts in the culture of Barley. If three ploughings can be given in time, it is best to get in the seed sometime in March at farthest; and some farmers, rather than defer the sowing, will throw in the crop on one earth. In Norfolk, they commonly sow on their light lands in April, and on the moist lands in May; and they think that, where they are much subject to weeds, they have the best crops when they sow late. Early sowing, however, has been gaining ground for some years past. And it appears from an experiment accurately made by a very intelligent cultivator, that more grain was produced from sowing in January, than at any other time. The land was a deep sand, valued at six or seven shillings the acre; it had been under Clover, and was ploughed as for Wheat in November, in the middle of which month two bushels of Barley were sown and harrowed in upon one earth only. The same quantity was sown in the middle of every month till the following May inclusive. The first sown came up a week sooner than the Wheats sown on the same day by the side of it, and was very flourishing till the first sharp frost set in, which damaged the blade, but did not seem to affect the root. The other sowings had two earths; one cast, or half the seed, was ploughed in, and the other half harrowed in; the second sharp frost killed some of the second sowing, and a good deal of the first; but both together, with the third sown in January, seemed to suffer still more by the sharp cutting winds in the month of March, when there was no snow to cover the blade. These three sowings, particularly the first, had their plants very much thinned by the frosts and winds; although the roots that were left stubbed very much in the spring, and had very long ears, with from thirty to thirty-six grains in each. The sowings in February and March lost few if any of their plants, and were both forward enough to be harvested on the same day with the preceding sowings. That sown in April was a full fortnight later, and the last, sown in May, was entirely destroyed by rooks, there being no other sown so late in the neighbourhood. It would have been the same with the early sowings, had not the evil been guarded against. However advantageous therefore early sowing may be, yet neither this nor any other laudable practice will be of any avail in open fields where lands are intermixed, unless where there is a general consent; and if one farmer only were to sow early, he must have as many keepers as he has pieces of land, and thus obtain better crops than his neighbours at a ruinous expense. The whole land sown in the above experiment was seventy-two square yards, or little more than two-thirds of an acre; and all the sowings were by the side of each other on the same piece of land. Three swaths of each sowing, twelve yards in length, where the soil was most equal, were threshed out, and each parcel was dressed and measured into

a sack separately as soon as threshed. All the Barley sown was of the Zealand stock, and the produce was as follows:

		Coomb. Bush. Peck. Qt.			
1 November,	3 Pecks of seed per Acre produced	12	2	1	0
2 December,	3 Pecks 1 Pint.....	12	3	1	1 1/2
3 January,	3 Pecks 4 Pints.....	13	0	0	6
4 February,	2 Pecks 14 Pints.....	11	2	2	2
5 March,	2 Pecks 10 Pints.....	10	3	3	7
6 April,	2 Pecks 2 Pints.....	8	3	2	3

Cultivation after seeding. Whether grass-seeds be sown over the Barley or not, the surface is harrowed presently after the last ploughing; and when the Barley is up, it is run over with a light roller, to break the clods, and close the earth about the roots. Of this, however, we have treated before, and have only to add, that in heavy lands, if the harrow leaves any clods, they are broken with the clodding-beetle, and if any quick is pulled up, it is destroyed. When the Barley has been up three weeks or a month, it is a good way to roll it again with a heavy roller, which will prevent the sun and air from penetrating the ground so as to injure the roots. It will also cause the Barley to tiller out, so that if the plants be thin, the ground will be filled, and the stalks strengthened. If the blade should grow too rank, mowing is a much better method than feeding it down with sheep; because the scythe takes off only the rank tops, but the sheep, being fond of the sweet end of the stalk next the root, will often bite so close as to injure its future growth.—There are two preparations of Barley to be met with in the shops; the one called French or Scotch, the other Pearl Barley. Two ounces of either of these, after being washed from the mealy matter which adheres to them, in cold water; then boiled a few minutes in about half a pint of water, which is to be thrown away; and, lastly, put into two quarts of boiling water, and the coction continued till one half is wasted; makes a most elegant and grateful beverage, which is extremely useful in the gravel, stone, strangury, and heat of urine; likewise in fevers of the ardent kind, and other acute disorders, where cooling and diluting fluids are necessary. A strong infusion of malt in boiling water is a pleasant, and frequently efficacious, remedy for worms in children.—For further particulars, see *Triticum*.

2. *Hordeum Hexastichon*; *Winter or Square Barley*, or *Bear*, or *Big*. All the florets hermaphrodite, and awned, the grains placed regularly in six rows. This has a much thicker spike than the common Spring Barley, and is also much shorter, but the number of grains in each ear or spike is greater in the proportion of at least three to two; forty-two grains being commonly counted, when common Barley had only twenty-two. The ear is seldom more than two inches in length; it is square, with two rows of grains on two of the sides; on the other two, a single row of grains runs up the middle, so that the former rows are awned only laterally, and the latter on the sides and along the middle also. The lower flowers are imperfect in both; the outer valve of the corollas has a rough awn or beard, from four to six inches in length.—This species is rarely cultivated in the southern parts of England, the grain, though large and plump, not being esteemed so good for malting as common Barley; but in the northern counties, and in Scotland, it is generally sown, because it will bear the cold much better. In some of the more southern parts of Europe it is sown in autumn.—For the best methods of cultivating it, see the preceding species.

3. *Hordeum Distichon*; *Common Barley*. Lateral florets male, and awnless; grains angular, imbricated. This essentially differs from the two preceding species; the spike or ear is very long, flattened, or transversely greater in breadth than

thickness, with a double row of defective, or male, and consequently barren florets, on each flat side, and a single row of fertile florets at each edge. The valves of the calix, outer glume, husk, or chaff, are linear, and shorter by half than the corolla or inner chaff, which ends in an awn or beard that is straight, and sixteen times its own length: when ripe it is coriaceous, angular, and continues close about the grain; when this is taken off, the grain appears of an ovate form, grooved, and angular.—There is a variety which, according to Mortimer, was cultivated in Staffordshire; a sort of naked Barley, or Wheat-Barley, the ear shaped like Barley, but the grain like Wheat; it was much sown at Rowley, Hamstal, and Redmore, where they call it Brench Barley: he adds, that it yields well, and makes good bread and malt. As this grain is not noticed in Mr. Pitt's View of the Agriculture of this county, drawn up for the consideration of the Board of Agriculture, and printed in 1796, we may conclude that it is no longer cultivated in Staffordshire. Villars describes it as having a larger finer grain, of the size and weight of Wheat, and separating from the husk; from which it derives its name, (*Nudum*.) It is more difficult to cultivate, but yields a larger produce, and is of a better quality, than the common Barley. See the first species.

4. *Hordeum Zeocriton*; *Sprat or Battledore Barley*. Lateral florets male, awnless; grains angular, spreading, corticated. This differs from the common sort, in being of a lower stature, and in having a shorter and broader ear, with closer grains, standing out more from the rachis, and having shorter awns. Between the two rows of fertile flowers, are two other rows of male or barren flowers, as in the preceding species, but more conspicuous. For the cultivation of this, see the first species.—Under this last of the edible species of this genus, we shall subjoin the various names of the grain, which these first four sorts alike produce, and which the press of more important matter excluded from the particulars detailed in the first. It may be useful to know what names different nations call this important article of sustenance. The German name is *Gerste*; the Dutch, *Gerst*; the Danish, *Byg*; the Swedish, *Bugg*, *Kiorn*, or *Korn*; the French, *Orge*; the Italian, *Orzo*; the Spanish, *Cebada*; the Portuguese, *Cevada*, or *Sevada*; and the Russian, *Jetchschmen*, or *Jesmin*.

** *Grasses*.

5. *Hordeum Bulbosum*; *Bulbous Barley-grass*. Florets in threes, fertile, awned; involucre bristle-shaped, ciliate. This has obtained its name from its bulbous roots, wrapped up in whitish or brownish broad membranaceous fibrous coats, and having strong fibres hanging from them; culms two or three, from a foot or eighteen inches to three and even four feet high, in different situations, with four or five joints; leaves a span or a foot, sometimes only a hand long, a line and half or two lines wide; spike narrow, three or four, sometimes nearly six inches long, and three or four lines broad.—Native of Italy, and the Levant.

6. *Hordeum Murinum*; *Wall Barley-grass*. Lateral florets male, awned; middle involucre ciliate. Common Wall Barley-grass, Way-barley, Way-bennet, or rather Way-bent; called also Wild Rye, or Rye-grass; has an annual root; numerous stems a foot or eighteen inches in height, round, smooth, frequently branching at bottom, where they are procumbent, and bend at the joints; leaves from three or four to six inches in length, and a quarter of an inch in breadth, covered with a soft down on both sides; spikes from two to three inches long, pale green.—This is a very common grass by the side of paths and under walls, whence its trivial names both in Latin and English. It flowers during the

greater part of the summer; and is said to be well known to the innkeepers of the isle of Thanet, under the name of Squirrel-tail Grass. They find that, if horses feed on it some time, the beards stick into their gums, and make them so sore that they are in danger of being starved. This fact seems corroborated by the circulation of handbills, informing travellers that at such inns they might depend on having hay without any mixture of Squirrel-tail Grass: but as Wall Barley-grass is never found in the body of a meadow, it may be doubted whether it is not the next species which produced this bad effect; and if so, that cannot be recommended as fit for culture. It is an old notion, that this grass is Barley degenerated, though it bears most resemblance to Rye: the error is too vulgar and obvious to require refutation.

7. *Hordeum Pratense*; *Meadow Barley-grass*. All the florets awned, the lateral ones male; all the involuclers rugged. Linneus supposed this to be a mere variety of the preceding: Ray however observes, that it differs in being much taller, and having shorter spikes and awns. Its height is almost double that of the other; the spike is greener, only half as long, and square, with the awns of the calix as long as those of the corolla. The middle floret is smooth; the two laterals, though they have a pistil as well as stamina, yet being minute, never come to maturity. Mr. Miller pronounces this to be a very good grass for pastures, and says it has perennial roots, with leafy stalks which do not become stiff and harsh; and that, if duly rolled, the roots will mat, and form a very close sward. It is, however, a late grass, and thought to be less productive than some others.—For *Ray-grass*, which is sometimes, but erroneously, called *Rye-grass*, and is very different from this, see *Lolium Perenne*.

8. *Hordeum Maritimum*; *Marsh Barley-grass*. Flowers awned, the lateral ones male; involuclers rugged, the interior ones of the males semi-lanceolate. This grass at first sight resembles the common Wall Barley-grass, insomuch that it might be doubted, until experiments are made by culture, whether it be a distinct species; because salt water and sea air will alter the appearance of grasses. It differs, however, in having shorter pyramidal spikes, made up of a greater number of florets more crowded together, with the awns more standing out, those at bottom longest, and becoming gradually shorter towards the top of the spike.—This is marked as annual both by English and foreign botanists. Allioni says it evidently differs from the next species, and that in cultivation it acquires a loftier culm, with a spike twice or thrice as long as in the wild plant, but that the character of the incurved culm continues. It flowers in June and July.—Native of Barbary, and the southern parts of Europe, and of England, in salt marshes near the sea.

9. *Hordeum Jubatum*; *Long-bearded Barley-grass*. Awns and involuclers bristle-shaped, and very long: the stem-leaves are four or five inches long, and a line or a line and a half wide, villose, with short hairs above; below, especially towards the top, rough if drawn downwards through the fingers. This has the habit of the sixth species, but the involuclers and bristle-shaped awns are four times the length of the whole spike, which gives this grass a singular appearance. Linneus calls it a native of Canada, but subsequently a native of Smyrna; in which Scheuchzer coincides. The *Kew Catalogue* assigns it to Canada and Hudson's Bay, and calls it a biennial plant. There is much uncertainty concerning it.—For the three last species, see *Grass*.

Hot-beds, are beds used in gardening, made with fresh horse-dung or tanners' bark, and covered with glasses, to defend them from cold winds. They appear to have been long known and used in our gardens. By the skilful management of them, we may imitate the temperature of warmer climates; by which means the seeds of plants brought from any of the countries within the torrid zone, may be made to flourish under the intense cold of the most inhospitable regions. Hot-beds should be formed in a dry piece of ground, under a sunny exposure, well fenced in either by walls or good ship planks, ten feet high to the north, and six feet high to the south, apart from the rest of the kitchen-garden, and as near to the stable dung-heap as possible, to avoid labour and dirt in barrowing. Sixty feet in breadth, and an hundred feet in length, will contain a sufficient extent of ground for winter framing for Mushroom-beds; forced Asparagus, Peas, Kidney-beans, Strawberries, Radishes, Salad-herbs, early Cucumbers and Melons; annuals for the flower-garden; to bring forward perennials and shrubs, as Pinks, Carnations, bulbous plants, Lily of the Valley, Roses, Honeysuckles, and innumerable others. Under the south fence there may be frames for forcing fruit, the management of which is directed under the respective articles. If the dung employed in making hot-beds be new and strong, there will be no necessity for mixing sea-coal ashes, leaves of trees, or tan, as Mr. Miller directs; these are of use only for strengthening the heat, and rendering it more durable, when the dung is in some measure exhausted by having been too long in the dung-heap. In fresh dung, these additions frequently render it too fierce and burning. The hot-beds commonly used in kitchen-gardens are made with new horse-dung mixed with the litter of a stable, and a few sea-coal ashes, when the dung is not fresh. This should remain six or seven days in a heap, and being then turned over, and the parts mixed well together, it should be again cast into a heap; where it may continue five or six days longer, by which time it will have acquired a due heat. The hot-beds are then made in the following manner. Dig out a trench of a length and width proportionable to the frames you intend it for; and if the ground be dry, let it be about a foot or a foot and a half deep; but if wet, not more than six inches; then wheel the dung into the opening, observing to stir every part of it with a fork, and lay it even and smooth all over the bed, placing the bottom part of the heap, which is commonly free from litter, upon the surface of the bed: and if it be intended for a bed to plant out Cucumbers for good, you must make a hole in the middle of the place designed for each light, about ten inches over and six deep; which should be filled with good fresh earth, thrusting in a stick to shew the places where the holes are; and then cover the bed all over with the earth that was taken out of the trench, to the depth of four inches; and put on the frame, letting it remain till the earth be warm, which commonly happens in three or four days after the bed is made, and

then the plants may be placed in it. But if the hot-bed be designed for other plants, there need be no holes made in the dung; but after having smoothed the surface with a spade, you should cover the dung about three or four inches thick with good earth, putting on the frames and glasses as before. In making these beds, care must be taken to settle the dung close with a fork; and if it be pretty full of long litter, it should be trod down equally on every part. During the first week or ten days after the bed is made, you should cover the glasses but slightly in the night, and carefully raise them to let out the steam; but as the heat abates, the covering should be increased; and as the bed grows cold, fresh dung should be added round the sides of it. The hot-bed made with tanners' bark, is however much preferable to that described above, especially for all tender exotic plants and fruits, that require an even degree of warmth to be continued for several months; which cannot be produced by horse-dung. The manner of making them is, first dig a trench about three feet deep in dry ground, and not above a foot in wet soils. This trench must be raised two feet above the ground. The length must be proportioned to the frames intended to cover it, but it should never be less than ten or twelve feet long, and six wide. The trench should be bricked or planked up round the sides, to the above-mentioned height of three feet, and filled in the spring with fresh bark, recently drawn out of the tanners' vats, and from which also all the moisture has been previously drained, by laying it in a heap for three or four days. As the bark is put in, beat it down gently, and equally, with a dung fork; but it must not be trodden, for that would prevent its heating, by settling it too close. When this is done, put on the frame, covering it with glasses; and in about ten days or a fortnight it will begin to heat; at which time plunge your pots of plants or seeds into it, observing not to tread down the bark in doing it. These beds will continue three or four months in a good temper of heat; and if you stir up the bark pretty deep, and mix a load or two of fresh bark with the old when you find the warmth decline, you will preserve its heat two or three months longer. Many persons lay hot horse-dung in the bottom of the trench, under the bark; but this ought never to be practised, unless the bed be wanted sooner than the bark would heat of itself, and even then there ought only to be a small quantity of dung at the bottom. The frames which cover these beds, should be proportioned to the different plants they are designed to contain. If they are to cover the Ananas or Pine-apple, the back part of the frame should be three feet and a half high, and the lower part fifteen inches, which will be a sufficient declivity to carry off the wet; and the back part will be high enough to contain the large fruiting plants, and the lower side will be sufficient for the shortest plants; so that by regularly placing them according to their height, they will not only have an equal distance from the glasses, but also appear much handsomer to the sight. And although many people make their frames deeper, that is certainly high enough to contain the plants without bruising their leaves, and is much better than allowing them a larger space; for the deeper the frame is made, the less will be the heat of the air enclosed therein, there being no artificial warmth but what the bark affords, which will not heat a large space of air: therefore as the pine-apple requires to be constantly kept very warm, in order to ripen the fruit well, it must follow, a greater depth will not be so favourable. But if the bed be intended for taller plants, then the frame must be made in depth proportionable thereto; but if it be for sowing seeds, the frame need only be about fourteen or sixteen

inches high at the back, and seven inches deep in the front, by which means the heat will be much greater, and it is commonly the proportion of the frames usually employed in kitchen-gardens. Their length is generally according to the fancy of the owner; but they commonly contain three lights in each, and are generally about eleven feet long. They sometimes contain four lights; but this is too great a length for the boxes, for the frames thus made are not so handy to remove as when they are shorter, and are more subject to decay at the corners. Some indeed have them to contain but two lights, which is very handy for raising Cucumbers and Melon plants while young; but is too short for a bark-bed, as it will not admit a sufficient quantity of bark to continue the warmth for any considerable time. Whenever frames are made very deep, it is much the better way to have them made to take asunder at the four corners, so that they may be removed with ease, and that the frame may not be spoiled by the difficulty in pulling it off, to put in new bark, or remove the old. Farther directions respecting hot-beds and their management may be found in the culture prescribed for Cucumbers and Melons under the article *Cucumis*.

Hot-House. See *Stove*, and vol. ii. p. 778.

Hottentot Cherry. See *Cassine Maurocenia*.

Hottonia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted; parts linear, from erect spreading. *Corolla*: one-petalled, salver-shaped; tube the length of the calix; border five-cleft, flat; clefts ovate-oblong, emarginate. *Stamina*: filamenta five, awl-shaped, short, upright, opposite to the clefts of the corolla, and placed on the tube; antheræ oblong. *Pistil*: germen globular-acuminate; style filiform, short; stigma globular. *Pericarp*: capsule globular, acuminate, one-celled; placed on the calix. *Seeds*: very many, globular; receptacle globular, large. ESSENTIAL CHARACTER. *Corolla*: salver-shaped. *Stamina*: placed on the tube of the corolla. *Capsule*: one-celled.—The species are,

1. *Hottonia Palustris*; *Common Water Violet*. Peduncles in naked whorls of several flowers; leaves in whorls, pinnate. The root consists of numerous white capillary fibres, which strike deep into the mud. The stem is a scape a foot high, simple, upright; flowers pale purple or white, with a yellow eye, in several whorls one above another, forming altogether a handsome spike. This singular plant has the leaves under water, and the upper part of the flowering stem only above. The flowers are beautiful, and the leaves afford a refuge, perhaps even nourishment, to the fresh-water periwinkle and other small shell-fish.—A native of this country: it abounds in ditches and marshes, stagnant waters, and slow-running streams, flowering in May and June, and continuing a long time in flower. There is a variety with flowers of a deep rose-colour, and smaller leaves. The old writers call this plant *Millefolium*, from the abundance of its leaves; and *Viola*, which was a favourite name for the Stock-Gilliflower, and many other handsome-flowered plants besides the Violet. The English, besides Water Violet, call it Water-Milfoil or Yarrow, and Water-Gilliflower; the Germans name it, *Wasserviole*; the Dutch, *Waterviolier*; the Danes, *Vandrolleike*; the Swedes, *Vattenrolleka*; the French, *Plumeau*, *Plume d'Eau*, *Plumette*, *Violette Aquatique*, *Giroflée d'Eau*, *Millefeuille d'Eau*, *Hottone*; and the Italians, *Miriofillo Aquatico*.—This elegant species may be propagated in deep standing waters by dropping the seeds as soon as they are ripe into the water, where they are designed to grow; and if not disturbed they will appear and increase abundantly in the following spring.

2. *Hottonia Indica*; *Indian Water Violet*. Peduncles axil-

lary, one-flowered; leaves in whorls, trifid or thrice trifid; stem a finger's length, quite simple. Linneus says the genus of this plant is doubtful. It has been made into a new genus by Mr. Browne, under the name of *Linnophila*.—Native of Ceylon.

3. *Hottonia Sessiliflora*; *Sessile-flowered Water Violet*. Flowers in leafy whorls, sessile; leaves in whorls, bipinnate and trifid; stem simple, sometimes with a branchlet at top.—Found by Burmann in the East Indies.

4. *Hottonia Littoralis*; *Sea Water Violet*. Leaves ovate-oblong, opposite, quite entire; flowers solitary; stem commonly quite simple, about eight inches high, upright. The flowers are purple, axillary, and peduncled, resembling those of the second species, but the leaves are very different.—Native of Cochin-china.

Hovenia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, hairy at the base within, permanent, five-parted; parts ovate, reflex, deciduous. *Corolla*: petals five, obovate, very obtuse, patulous, rolled up, involving the stamina, inserted into the calix between the segments, and of the same length with them. *Stamina*: filamenta five, inserted into the base of the calix, and a little shorter; antheræ roundish, hid within the petals. *Pistil*: germen superior; style upright, much shorter than the calix; stigmas three, from patulous reflex, blunt. *Pericarp*: capsule ovate-globular, three-furrowed, three-celled, three-valved. *Seeds*: solitary, lens-shaped, very smooth. *Observe*. Sometimes, but seldom, the calix is four-parted, and there are only four stamina. ESSENTIAL CHARACTER. *Petals*: five, convoluted. *Stigma*: trifid. *Capsule*: three-celled, three-valved.—The only known species is,

1. *Hovenia Dulcis*. Root perennial; stem arboreous, thick, nine feet high; branches round, smooth; leaves alternate, petioled, subcordate, ovate, acuminate, serrate, hanging down, nerved, smooth, a hand in length; flowers small, white, axillary, and terminating; panicle dichotomous, compressed; peduncles subcylindric, dichotomous, thickening after flowering-time, with a sweet red pulp, which is eaten by the Japanese, and tastes somewhat like a pear. The flowers, which readily fall off, appear from June to August, and ripen into fruit in November.—Native of Japan, near Nagasaki.

Hound's Tongue. See *Cynoglossum*.

Houseleek. See *Sempervivum*.

Houstonia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, four-toothed, upright, permanent. *Corolla*: one-petalled, funnel-shaped; tube cylindric, long; border four-parted, spreading; parts roundish. *Stamina*: filamenta four, in the neck of the corolla, very small; antheræ simple. *Pistil*: germen superior, roundish, compressed; style simple, shorter than the stamina; stigma bifid, acute. *Pericarp*: capsule roundish, twin, gaping transversely at top, two-celled, two-valved; valves opposite to the partition. *Seeds*: few, (three or four), small, ovate, adhering to the partition. (Jussieu observes, that the germen of the second species is certainly inferior.) ESSENTIAL CHARACTER. *Corolla*: one-petalled, funnel-form. *Capsule*: superior, two-celled, two-seeded; (according to Gærtner, three or four seeds in each cell.—The species are,

1. *Houstonia Cœrulea*; *Blue-flowered Houstonia*. Root-leaves ovate; stem compound; first peduncles two-flowered. This is a vernal plant, with terminating flowers. From a slender root it produces small, oblong, pointed leaves, spreading on the ground in a ring; among these, slender smooth stalks arise, at the height of two inches, forming a joint, and furnished with two or three small leaves; here they divide into two and

sometimes three slender branches or peduncles, an inch or two in length, having at the end of each a single flower; flower of a fine pale blue, or almost white, with a yellow eye, jasmine-like, pretty, but scentless.—Native of Virginia, and other parts of North America. This species, says Mr. Curtis, is quite hardy in England, best cultivated in a pot, with plenty of moisture, and easily propagated by parting its roots. With a little attention, it flowers perpetually in spring, summer, and autumn.

2. *Houstonia Purpurea*; *Purple-flowered Houstonia*. Leaves ovate-lanceolate; corymbs terminating; flowers superior. This has leaves in pairs, resembling those of Chickweed or large Alsine. The flower is of a reddish purple.—Native of Maryland; where it is also found with a narrower leaf.

3. *Houstonia Serpyllifolia*. Stalk procumbent; leaves spatulate, obtuse; peduncles terminating, long, bearing each a single blue flower.—Found upon high mountains near rivulets and springs from Virginia to Carolina.

4. *Houstonia Tenella*. Stalk creeping, filiform; leaves orbiculate, acute, nervose; peduncles terminal, very long, bearing each a single purple flower. It much resembles the preceding species, though something smaller.—Found on high mountains in North Carolina.

5. *Houstonia Angustifolia*. Stalk erect, very branchy, glabrous; leaves linear; flowers terminal, fasciculated, sessile, purple-coloured.—Found in sandy fields along the sea-coast from Carolina to Florida.

Houttuynia; a genus of the class Monœcia, order Monandria; according to Thunberg, class Polyandria, order Polygynia.—GENERIC CHARACTER. *Male Flowers*. *Calix*: spathe, four-leaved; leaflets ovate, concave, obtuse, coloured; spadix oblong, the length of the spathe, covered with fructifications. *Corolla*: none. *Stamina*: filamenta very many, intermixed with the germina, about seven round each germen, very short; antheræ twin, ovate. *Females*. *Calix*: spathe and spadix common with the males. *Corolla*: none. *Pistil*: germina very many, intermixed with the stamina; (according to Loureiro, germina three-cornered; style none; stigmas three, oblong, reflex.) *Pericarp*: capsule three-cornered, three-celled, three-valved, opening at the top. *Seeds*: many, ovate, small. ESSENTIAL CHARACTER. *Calix*: four-leaved. *Corolla*: none. *Stamina*: mixed with the pistils, seven about each germen.—The only known species is,

1. *Houttuynia Cordata*. This plant has the habit of Polygonum, with stipules like that; root annual, fibrous; stems simple, herbaceous, grooved, flexuose, upright, a hand, a span, or a foot in height, smooth in all its parts; leaves alternate, petioled, cordate, cuspidate, entire, paler underneath; petioles striated, stipuled at the base, shorter than the leaf; flowers from the sheath of the petiole, solitary, peduncled; peduncle the length of the petiole. It is difficult to determine the number of stamina in this genus, because there is no calix, corolla, or scales, to separate the germina. It ought however to be referred to the class Polyandria, the stamina being scattered over an elongated receptacle, among several germina.—Discovered by Thunberg in Japan, where it is very common in the ditches between Miaco and Jedo, flowering in May and June. Loureiro also found it in the gardens of Cochin-china, where it is eaten in salads, and is esteemed attenuant, resolvent, and emmenagogue.

Hudsonia; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved, tubular, cylindric, with a patulous mouth; leaflets lanceolate-linear, blunt. *Corolla*: none. *Stamina*: filamenta fifteen, capillary, shorter than the calix; antheræ roundish. *Pistil*: germen superior, ovate; style filiform,

the length of the calix; stigma blunt. *Pericarp*: capsule cylindrical, shorter by half than the calix, one-celled, three-valved. *Seeds*: three, rounded on one side, angular on the other. **ESSENTIAL CHARACTER.** *Calix*: five-leaved, tubular; (according to Jussieu, three-leaved above, three-parted.) *Corolla*: none; (petals five, and very small, according to Bergius.) *Stamina*: fifteen. *Capsule*: one-celled, three-valved, three-seeded.—The only species known is,

1. *Hudsonia Ericoides*. This is a shrub, with the appearance and habit of Heath. Branchlets filiform, scattered, imbricate; leaves subulate-acerose, hirsute; when tender still more hirsute and hoary, so that those on the extreme branchlets seem as if they had leafy gems scattered over them; peduncles from the leafy gems solitary, filiform, longer than the leaves; calix erect, pubescent.—Native of New Jersey and Virginia.

Hugonia; a genus of the class Monadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved; segments ovate, acute, concave, coriaceous, permanent, the two outer ones larger; (Gærtner says, five-leaved.) *Corolla*: petals five, roundish, large, emarginate, spreading, narrowed at the base, fixed at the base by slender claws to the little pitcher or stamina. *Stamina*: filamenta ten, awl-shaped, equal, shorter than the corolla, connected at bottom into a little pitcher; antheræ roundish, furrowed, incumbent. *Pistil*: germen roundish; styles five, filiform, longer than the stamina; stigmas capitate, orbicular, flat. *Pericarp*: drupe globular, one-celled; (according to Gærtner, a berried drupe.) *Seed*: nut globular, deeply striated, ten-celled; kernels oblong, compressed, bowed at the back. *Observe.* The two outer segments of the perianth are wholly tomentose on the outside; the middle one is also tomentose, except that part where it is covered by one of the former, and there it is smooth and shining, as are the two inner ones, which are tomentose at the tip only. Five of the filamenta are a little shorter than the rest. The alternate kernels seem frequently to be abortive; which is perhaps the cause why Cavanilles makes the fruit to be five-celled. In the drupe which Schreber opened, there were more than five kernels. **ESSENTIAL CHARACTER.** Five-styled. *Corolla*: five-petalled. *Drupe*: with a striated nut.—One species only is known,

1. *Hugonia Mystax*. Spines opposite, revolute. This is a tree, with an irregular bark. Branchlets short, alternate, spreading, leafy at the end; leaves oval, quite entire, smooth, petioled, clustered; flowers several, in clusters from the ends of the branches, white; the fruit is a berried, spherical, succulent drupe; the skin is very thin, papery, tough, white, with a very polished shining surface. The root is esteemed useful as a topical application to inflamed or swelled parts, and even the bite of the hooded serpent. It is also given internally for febrile disorders in children, for the colic, worms, &c.—Native of the East Indies.

Humble Plant. See *Mimosa*.

Humulus; a genus of the class Diœcia, order Pentandria.—**GENERIC CHARACTER.** *Male.* *Calix*: perianth five-leaved; leaflets oblong, concave, blunt. *Corolla*: none. *Stamina*: filamenta five, capillary, very short; antheræ oblong. *Female.* *Calix*: involucre universal, four-parted, sharp; partial, four-leaved, ovate, eight-flowered; to each flower a perianth, one-leaved, ovate, very large, outwardly flat on one side, converging at the side. *Corolla*: none. *Pistil*: germen very small; styles two, subulate, patulous; stigmas sharp. *Pericarp*: none. *Calix*: enclosing the seed at the base. *Seed*: roundish, covered with a coat. **ESSENTIAL CHARACTER.** *Male.* *Calix*: five-leaved. *Corolla*: none. *Female.* *Calix*: one-leaved, spreading obliquely, entire. *Corolla*: none. *Styles*: two. *Seed*: one, within a leafed calix.—The only species is,

1. *Humulus Lupulus*; *Hops*. Root perennial; stems weak and twining, not climbing by tendrils, but ascending a prop, trees, or shrubs, in a spiral, always with the sun, that is from right to left, or from east to west by the south; this direction it has in common with Tamus or Black Briony, Lonicera or Honeysuckle, and several others; but more turn the contrary way, or from left to right, as Phaseolus or Kidney Beans, and several other leguminous plants, Convolvulus, &c. The Hop stems are angular, striated, and rugged, with very minute prickles; leaves opposite, stalked, heart-shaped, undivided or three-lobed, often five-lobed, serrated, veiny and harsh; stipules two or four, cordate, bifid, at each joint; flowers greenish yellow; the males on branched peduncles; the females on a distinct plant, in axillary, stalked, ovate, drooping catkins.—Native of hedges and bushy places in a moist deep soil, in various parts of Europe, as well as in North America, blossoming in July.—*Propagation and Culture.* As we feel it our duty to afford every information which our limits will admit, concerning this invaluable plant, we shall first treat—*Of the choice of soil.* The Hop-planters esteem the richest and strongest grounds the most proper; and if it be rocky within two or three feet of the surface, the Hops will prosper well; though they will not thrive on a stiff clay, or spongy wet land. The Kentish planters account new land best for Hops: they plant their Hop-gardens with Apple-trees at a large distance, and with Cherry-trees between; so that when the land has done its best for Hops, which they calculate will be at the end of ten years, the trees may begin to bear. The Cherry-trees last about thirty years; and by the time the Apple-trees become large, they cut down the Cherry-trees.—As to the *situation* of a Hop-ground, one that inclines to the south or west is the most eligible; but if it be exposed to the south-east or north-west winds, there should be a shelter of some trees at a distance, because the north-east winds are apt to nip the tender shoots in the spring; and the south-west winds frequently break and blow down the poles at the latter end of the summer, and very much endanger the Hops. In the winter time provide your soil and manure for the Hop-ground against the following spring. If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your Hop-hills; but if it be new dung, then let it be mixed as before till the spring in the next year; for new dung is very injurious to Hops. Dung of all sorts was formerly more commonly made use of than at present, especially when rotted and turned to mould, and they who have no other manure must use it; which if they do, cows' or hogs' dung, or human ordure, mixed with mud, may be a proper compost, because Hops delight most in a manure that is cool and moist.—*Planting.* Hops require to be planted in a situation so open as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middle of large plantations, while the outsides remain unburnt. As for the preparation of the ground for planting, it should in the preceding winter be ploughed and harrowed even: then lay upon it in heaps a good quantity of fresh rich earth, or well-rotted dung and earth mixed together, sufficient to put half a bushel in every hole, to plant the Hops in, unless the natural ground be very fresh and good. The hills where the Hops are to be planted should be eight or nine feet asunder, that the air may freely pass between them, for in close plantations they are very subject to what the Hop-planters call the fire-blast. If the ground be intended to be ploughed with horses between the hills, it will be best to chequer them in squares; but if the ground be so small

that it may be done with the breast-plough or spade, the holes should be ranged in squares. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made. Persons ought to be very curious in the choice of plants, as to the *kind* of Hops; for if the garden be planted with a mixture of several sorts of Hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner. The two best sorts are the White and the Gray Bind; the latter is a large square lop, more hardy, and is a more plentiful bearer, besides ripening later than the former. There is another sort of the White Bind, which ripens a week or ten days before the common; but this is tender, and a less plentiful bearer, although it has the advantage of coming first to market. But if three grounds, or three distant parts of one ground, be planted with these three sorts, there will be this convenience, that they may be picked successively as they become ripe. The sets should be five or six inches long, with three or more joints or buds on them. If there be a sort of Hop you value, and would increase the plants and sets from, the superfluous binds may be laid down when the Hops are tied, cutting off the tops, and burying them in the hill; or, when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set next spring. As to the seasons for planting Hops, the Kentish planters most approve the months of October and March, both which sometimes succeed very well; but the sets are not to be had in October, unless it be from some ground that is to be destroyed; and there is some danger also that the sets may be rotted, if the winter prove very wet; hence March is the most usual time of procuring them, when the Hops are cut and dressed. As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about, sloping, the tops meeting at the centre; they must stand even with the surface of the ground; let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it. The ground being thus planted, all that remains to be done that summer, is to keep the hills clear from weeds, and to dig up the ground about the month of May, raising a small hill round about the plants. In June you must twist the young branches or binds together into a knot; for if they are tied up to small poles the first year, in order to have a few Hops from them, it will not countervail the weakening of the plants. A mixture of dung or compost being prepared for your Hop-ground, the best time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung-cart may not injure the hops, nor furrow the ground: if this be not done, then you will be obliged to wait till the frost has hardened the ground, so as to bear the dung-cart; and this is also the time to carry on your new poles to recruit those that are decayed, and to be cast out every year. If you have good store of dung, the best way will be to spread it in the alleys all over the ground, and to dig it in the winter following. The quantity they will require will be forty loads to an acre, reckoning about thirty bushels to the load. If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the rest in another, or even a third year: for there is no occasion to dung the ground in this manner oftener than every three years. Those who have but a small quantity of dung, usually content themselves with laying on about twenty loads upon an acre every year: this they lay on the hills either about November or in the spring; which last some account the best time, when the Hops are dressed, to cover them after they are cut; but if it be done at this time, the compost or dung ought to

be well rotted and fine.—*Dressing.* As to the dressing of Hops, when the Hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it. About the end of February, if the Hops were planted the spring before, or if the ground be weak, they ought to be dressed in dry weather; but if the ground be strong and in perfection, the middle of March will be a good time; and the latter end of March or the beginning of April, if it be apt to produce over-rank binds, may be soon enough. Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds during the year preceding, and also all the young suckers, that none be left to run in the alley and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low which was left highest the preceding year. By pursuing this method, you may expect to have stronger buds, and also keep the hill in good order. In dressing those Hops, which have been planted the year before, you ought to cut off both the young tops and the dead suckers which have sprung up from the sets, and also to cover the stocks with a fine earth a finger's length in thickness.—*Poling.* About the middle of April the Hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill, to prevent the binds from entangling; and a space between two poles ought to be left open to the south, to admit the sun-beams. The poles ought to be in length sixteen or twenty feet, more or less, according as the ground is in strength; and great care must be taken not to over-pole a young or weak ground, for that will draw the stock too much, and weaken it. If a ground be over-poled, you are not to expect a good crop from it; for the branches which bear the Hops will grow very little till the binds have overreached the poles, which they cannot do when the poles are too long. Two small poles are sufficient for a ground that is young. If you wait till the sprouts or young binds are grown to the length of a foot, you will be able to make a better judgment where to place the largest poles; but if you stay till they are so long as to fall into the alleys, it will be injurious to them, because they will entangle one with another, and will not clasp about the pole readily. Maple or Aspen poles are accounted the best for Hops, on which they are thought to prosper, because of their warmth, or else because the climbing of the Hop is assisted by the roughness of the bark. But for durability, ash or willow poles are preferable; but chestnut poles are the most durable of all. If, after the Hops are grown up, you find any of them have been under-poled, taller poles may be placed near those which are too short, to receive the binds from them.—*Tying.* As to the tying of Hops, the buds that do not clasp of themselves to the nearest poles when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so closely as to hinder them from climbing up the pole. This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for are to be plucked up: but if the ground be young, then none of these useless binds should be plucked up, but should be wrapped up together in the middle of the hill. When the binds are grown

beyond the reach of your hands, if they still forsake the poles, you must employ a stand-ladder in tying them up. Towards the latter end of May, when you have made an end of tying them, the ground must have the summer dressing, which consists in casting up some fine earth with the spade into every hill; and a month after this is done, you must hoe the alleys with a Dutch hoe, and make the hills up to a convenient size.—*Gathering.* About the middle of July, Hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be formed of their ripeness, by their strong scent, their hardness, and the brownish colour of their seeds. When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage, by breaking the branches and bruising and discolouring the Hops; and it is very well known, that Hops picked green and bright, will sell for a third more than those which are discoloured and brown. The most convenient way of picking them is into a long square frame of wood, called a *bin*, with a cloth hanging on tenter-hooks within it, to receive the Hops as they are picked. The frame is composed of four pieces of wood joined together, supported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this serves to lay the poles upon which are to be picked. This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and six or eight persons may work at it, three or four on each side. It will be best to begin to pick the Hops on the east or north side of your ground, if you can do it conveniently, which will prevent the south-west wind from breaking into your garden. Having made choice of a plot of ground containing eleven hills square, place the bin upon the hill which is in the centre, having five hills on each side; and when these hills are picked, remove the bin into another piece of ground of the same extent, and so proceed till the whole Hop-ground is finished. When the poles are drawn up to be picked, you must take care not to cut the binds too near the hills, especially when the Hops are green, because that will make the sap flow excessively. The Hops must be picked very clean, that is, free from leaves and stalks; and, as there shall be occasion, two or three times in the day the bin must be emptied into a Hop-bag made of coarse linen cloth, and carried immediately to the kiln, or oast, in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured. In hot weather no more poles should be drawn than can be picked in an hour; and they should, if possible, be gathered in fair weather, when the Hops are dry, which will save some expense in firing, and preserve their colour better when they are dried. The crop of Hops being thus bestowed, you are to reserve the poles against another year. They should be laid up in a shed, with the haulm first stripped off from them; but if you have no shed, set up three poles in the form of a triangle, or six poles, if you please, wide at bottom: and having fixed them in the ground, and bound them together at the top, set the rest of your poles about them; and being thus disposed, those on the outside only will be exposed to the injuries of the weather, for all the inner poles will be kept dry except at the top, whereas if they were on the ground, they would receive more damage in a fortnight than by their standing all the rest of the year.—*Drying.* The best method of drying Hops is with charcoal on an oast, or kiln, covered with haircloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or bricklayer, in those countries where Hops grow

or malt is made, knows how to build them. The kiln ought to be square, and may be of ten, twelve, fourteen, or sixteen feet over at the top, where the Hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the beguels of the steddle where the fire is kept; thus, if the kiln be twelve feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionably in other dimensions. The Hops must be spread even upon the oast, a foot thick or more, if the depth of the curb will allow it: but care should be taken not to overload the oast, if the Hops be green or wet. The oast ought to be first warmed with a fire before the Hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the Hops, nor must it be suffered to sink or slacken, but rather be increased till the Hops be nearly dried, lest the moisture or sweat which the fire has raised fall back or discolour them. When they have lain about nine hours, they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried, by the brittleness of the stalks and the easy falling of the Hop-leaves. It is found by experience, that the turning of Hops, though it be after the most easy and best manner, is not only an injury and waste to the Hops, but also an expense of fuel and time, because they require as much fuel and as long a time to dry a small quantity by turning them, as a large one. Now this may be prevented by having a cover, to be lowered down or raised at pleasure, to the upper bed whereon the Hops lie. This cover may also be tinned, by nailing single tin plates over the face of it; so that when the Hops begin to dry, and are ready to turn, that is, when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the Hops, like a reverberatory, which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every Hop be equally dried.—*Bagging.* As soon as the Hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately they will powder, but if they lie awhile, (and the longer they lie the better, provided they be covered close with blankets to secure them from the air,) they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep. The common method of bagging is as follows: they have a hole made in an upper floor, either round or square, large enough to receive a Hop-bag, which consists of four ells and a half of ell-wide cloth, and also contains ordinarily two hundred and a half of Hops; they tie a handful of Hops in each low corner of the bag, to serve as handles to it; and they fasten the mouth of the bag so placed that the hoop may rest upon the edges of the hole. Then he that is to tread the Hops down into the bag, treads the Hops on every side, another person continually putting them in as he treads them, till the bag is full; which being well filled and trodden, they unrip the fastening of the bag to the hoops, and let it down, and close up the mouth of the bag, tying up a handful of Hops in each corner of the mouth, as was done in the lower part. When Hops are thus packed, after being well dried, and laid up in a dry place, they will keep good several years; but care must be taken that they be neither destroyed nor spoiled by the mice making their nests in them.—In order to have Hops of a good quality, 1st, They ought to be ripe before they are gathered, and in becoming so they pass from a green to a rich yellow colour. 2dly, They ought to grow on

a soil that, instead of enlarging the size of the Hop, grows them full of farina, or, as the country people call it, condition. 3dly, They ought to be very much, but slowly dried, and then packed for market in the thickest covering that can be found, to preserve their strength. The colour of Hops which hang till they are ripe, can never be so beautiful as if they were gathered green, for they are generally bruised by the equinoctial winds; but the quality of their bitter is of a superior flavour, goes further, and will never deceive in brewing; they will also keep good, when full dried, many years.— Having detailed the practice of the Kentish Hop-planter, we proceed generally to notice those which are of any importance in other countries. Though Mr. Miller mentions only three varieties of the Hop, yet in Surry they have what they call the Orchard Hop, which bears a long square strobile, and is perhaps the same with Mr. Miller's first sort; the Streaked Bind; two or three varieties of White Bind; Smooth and Rough Red Bind. The most esteemed are the Streaked and the White Bind. The Smooth Red is of little value; and, as to the last, it is generally eradicated whenever it appears. The White Canterbury Bind is mostly in use. The Golden Hop, with a white bind, which is probably the same with Mr. Miller's Oval Hop, ripens later than the other, and therefore on that account may be useful to the planter. There is also the Cluster Hop, produced from a White Bind, but having the Hops growing more in clusters than the others. The Streaked Bind is a desirable Hop, for a part at least of a plantation, being early, of a pleasant flavour, and generally of a good size. As to the term *garlick*, it is not appropriate to any one variety; for they will all acquire that sort of smell from distemper. In Surry they have not the practice of planting Cherry or Apple-trees, as in Kent. About Atton they generally plant their Hops six feet square; but about Farnham they plant much nearer: the superiority of their soil enables them to do this with success; but in blighted years they suffer more than the Atton planters, the circulation of air being much obstructed by the closeness of the hills. In Worcestershire, the Red, Green, and White Hop, are cultivated. A difference in the method of cultivation, is probably the real source of these distinctions. Two sorts, however, are in particular esteem both with the planter and merchant; the Golden Vine, brought from the neighbourhood of Canterbury; and the Mathan White, the name of which denotes it to be a native of this plantation, and of the parish of that name. The most hardy, and that which will flourish with the least attention, and is least liable to suffer from the seasons, is the Red; which is perhaps the original stock. The next is the Green, which is also the most productive. The tenderest, though at the same time the most valuable, is the White. The plantations of Worcestershire, are principally to the west of the Severn, increasing as they approach the banks of the Teame, and the confines of Herefordshire. The situations preferred are, a gentle descent, with a south, south-west, or western exposure, screened at a distance, to the north and east, by high ground, or plantations of timber, but not so as to prevent a free ventilation: the soil, a deep loamy land, or strong clay, after it has been thoroughly limed and manured; but, above all, a boggy soil, when completely drained, and duly meliorated, is said to produce the best Hops. When meadow or pasture land is broke up for this purpose, it is either dug, or the sward being first pared thinly off by the paring plough, it is buried by the furrow plough working full ten inches deep. Old tillage, when converted into Hop-grounds, requires to be very completely cleared of weeds; to be thoroughly manured: and to have the ridges or lands entirely levelled.

The different manners in which they are worked, are the tump, and the ploughed grounds; the former by hand, and the latter by plough: the first are laid out in the quincunx form, each tump or hill being at the distance of from five to seven feet from the centre of the other. On these, the distance between the rows is from three to four feet; that between the rows, from seven to nine; the greater or lesser space always being ploughed, as the land is either richer or poorer. In the ploughed, if the circumstances of the ground will admit of it, the rows run mostly north and south, with a view to admit the sun more generally when it has most force; but it should be long and narrow, its greatest length extending east and west, which direction is to be preferred, for receiving the morning sun, by which means the chills of the night are soonest dissipated. The sets are procured from the sets or roots of the stocks, at the annual time of dressing, in the latter end of March or beginning of April. They must have two joints each, the roots striking from that in the ground, and the vine shooting from that above: four are planted to a stock, at the distance of about four or six inches from each other, all inclining or pointing, so as to meet together in the centre. Two methods are here observed in planting young Hop-grounds: The first and most general is, to plant the sets on the situation in which they are to remain, immediately after they are parted from the old stocks. In the second, the sets are planted in nurseries, in rows about three inches asunder, with about five or six inches between the rows; here they grow till the month of October, when they are transplanted into the Hop ground. Under this latter management, if the roots be good, one will be sufficient for a stock. In removing them, great care is taken to make the opening to receive them so large as not to confine the roots. When planted from the stocks, a hole made with a peg to place them in, is all that is required. The nursery has certainly great advantage; besides the saving of a considerable expense, where the sets are to be purchased, the land may be worked through the summer, to prepare it for the plantation. During the first year, the grounds are ploughed, hoed, or kerfed, three times: they produce no Hops; but a good crop of peas, beans, cabbage, or turnips, is obtained between the rows. The second year they are poled, and yield half a crop; and the third year produce in perfection. When they have reached this state, the management is uniformly as follows: They are gone over mostly four times with the plough or kerf at the beginning of March. The first business is to throw down the tumps and rows of the former year, and to work in the manure, previously brought on in the winter. This manure consists of fresh earth, rotten dung, or a compost of dung, earth, and lime, judiciously proportioned, according to the nature of the soil; each acre receiving no less than sixty cart-loads, for a good dressing: this is repeated as the nature of the land renders it necessary. The stocks are now pruned, and the remains of the old vines and superfluous shoots are removed with the Hop-knife. The second moulds up the tumps and rows; the succeeding ones complete moulding up the plants, and destroy the weeds. The tumps are formed round, flat at top, and about twenty inches in diameter, and somewhat broader at the bottom. The ploughed lands are thrown up much in the same manner as for Potatoes or Beans, only higher, and with more soil. The shoots begin to appear in April, and the poles are pitched at the latter end of the same month, or beginning of May. These are set two or three to a stock, at a foot distance from each other, with great regularity and exactness, and inclining a little outwards over the alleys. Some attention is necessary, in this part of the business, not to overpole

the plants, either in number or length of the poles, as it weakens them; and by drawing the vine out to too great a length, renders them less productive. About the close of this month, and at the beginning of June, women are employed to direct the vines to the poles, and tie them with dried rushes: this is continued till they are out of reach. The only care then remaining, is to keep under weeds, and to govern the plantations occasionally, to replace any vines that may stray, and repair any damage arising from the weather. When they have reached their full growth, which is in some measure regulated by the number and length of the poles, the side-shoots put out. The method of topping the vines, to promote lateral shoots, said to be practised in other plantations, is never used in this. About the second week of September they ripen, when the Hop-pulling begins. In a plentiful year it continues six weeks, more or less, according to the crop. The cribs are now placed, beginning on that part which lies most exposed to the sun, as being soonest ripe; one, two, or more, as the proprietor's plantation is large or small, and he has the convenience of kilns to dry them in. Each crib has eight or ten pickers, women and children, who, where they are industrious, and employed upon a tolerable crop, will gather from six to eight bushels a day, which about fills the sack in which they are carried green to the kiln; eight of these sacks, when dried, make about one hundred weight: but in some seasons, there is not half this quantity produced. The pickers come from the neighbouring counties, but most of them from Wales. From the cribs, the Hops are conveyed to the kilns, four or five of the sacks before alluded to at a time, on a horse, and are dried as soon as possible; as they damage considerably if suffered to lie long together before they are put in the kilns. They will heat in six or eight hours, and lose colour; to avoid which the kilns are kept constantly employed day and night. The time the Hops take in drying, is from eight to twelve hours, according as they are ripe and dry. Great attention and considerable judgment are necessary in this part of the business; the whole of the year's expenses and labour, and, at times, property to some amount being at stake on a single kiln, it is usually entrusted to those who have been long used to the practice. The general principle on which they proceed, is to begin with a very gentle fire, till warmed through; the heat is then gradually increased, and continued till the cove or fruit-stalk is quite sunk and dry. They are then removed, and thrown together in a heap, in a corner of a large room appropriated to this purpose, and frequently turned from one side to the other, in order to cool them completely before they are bagged.—Their method of bagging them is as follows: a strong hoop is fastened round the mouth of the sack, which is then let down through a circular opening in the floor, made for this purpose; a few are first put in, when the man who is principal in this part of the business gets in, and by constant treading presses them down as closely as he can. A second person is employed in breaking them, that is, tearing the flowers, &c. from the fruitstalk, and throwing them into the bag as they are wanted: thus they proceed till it is full, when the mouth is loosened from the hoop, and closed, leaving at each corner of the sack a space for the hand, for the better convenience of those who are employed in carrying them. After the seasons are over, the poles are set up, as before described in the Kent management.—Different opinions are entertained respecting the superiority of the tump and plough management; the former certainly has the advantage in many particulars, and is said to be cheaper, and more productive; but as it is impossible, from the present extent of the plantation, that any considerable proportion

can be worked in this manner, from want of hands, the inquiry is not of much consequence. The expenses of these plantations may be calculated from the following statements. As they always occupy the most valuable part of the farm, the rent cannot be set down lower than thirty-one shillings per acre, and in some instances is much higher. The acre is not to be estimated as statute measure, but after the rate of one thousand stocks to an acre, which is in general one-fifth less. The expense of manure is very heavy, as they produce none, except the ashes from the burning of the vines and leaves; so that, were justice done to the rest of the land, the greater part ought to be procured from home. The price of muck or dung is about six shillings per waggon-load, or three shillings per ton, (when purchased from stables where the horses are plentifully fed with corn, it is higher in proportion,) and is frequently to be fetched eight or ten miles. The Hop-grounds are sometimes worked through the several seasons, as they are termed, at a fixed price, which is from fifteen to twenty shillings per acre, according to the differing qualities of soil. The seasons are four, and thus divided:—throwing down and cutting; spreading and pitching poles; kerfing and tumping; and stripping and piling poles. Sometimes the workmen agree for a shilling a day, with drink; or some parts are taken by the acre, as pitching poles, three shillings; stripping and piling, two shillings and sixpence, to three shillings and sixpence. The women employed to tie the vines, receive sixpence per day, with two quarts of drink; or they take them by the year, at three shillings or three shillings and sixpence per acre. The Hop-pullers receive from sixpence to eightpence per day; with a pint of thickened milk, or something similar, every morning for breakfast; two quarts of drink per day, and two dinners every week. The coal, which is pit-coal charred, employed to dry them, is also an expensive article, and is principally brought from Pinsax in Worcestershire, at a distance of several miles from some of the plantations, where it costs twopence halfpenny or threepence per bushel, twenty-eight of which make a ton; two of which tons will be consumed in drying a ton of Hops. The dryer is paid from twelve shillings to twenty-one shillings per week, varying according to the number of kilns he has to attend; his meat and drink is also provided for him. The person who has the management of the bagging is paid fourpence per hundred-weight, exclusive of his assistant. There are different articles used for bagging; the Lubecks, and a sort of cloth manufactured at Dudley in this county, are most in use, particularly the latter. The price varies according to the demand. The Lubecks are dearest; they cost in general from twenty-eight to thirty-four shillings per piece, and are thirty-six yards long, and about thirty-one inches wide. The Dudleys cost from twenty-two to thirty-two shillings, and are of the same dimensions, each piece making eight sacks, four yards and three quarters long.—The culture of Hops at Hedingham castle in Essex, is perhaps as good as in any part of England; though the quality of those produced at Farnham in Surry is thought by some to be superior. At the former place there are fifty-five or fifty-six contiguous acres, remarkable for yielding an almost certain crop. The soil is a moore marsh, improved into a rich loam on the surface. They are persuaded here that Hops succeed better in very large plantations than in small ones; and observe, that the outside parts of their contiguous acres do not answer equally well with the more central divisions. If, therefore, a man increase his Hop-ground, it should not be in distinct plantations, but united to what he had before. In Essex they are too apt to use long poles, even such as are two rods in

length, and thirteen inches round at bottom, costing three pounds per hundred. To form a plantation, they fallow the land a year, ploughing it three or four times. In November they plant three sets to a hill, and a thousand hills to an acre. They put on no manure, if the ground be good; and dig it over as soon as planted, on account of its being trodden. In the second year nothing is done but keeping the ground clean, by skimming and harrowing; after Michaelmas they put on sixty loads of compost to an acre: gloves' and tailors' shreds are accounted a good dressing. In the third year, in February they cut down to the crown of the plant, or the black rind. At the end of March they pole the ground, three poles to a hill: after poling, they dig round the plant. As to the Hop-grounds in Suffolk, the soil they plant upon about Stowmarket, is a black loose moor, on a gravelly bottom, very wet and boggy, lying on a dead level with the river that runs by the town; the more boggy and loose it is, the better the Hops thrive, especially if the gravel be within three feet, and the neighbouring grounds rise so as to shelter them very well. In preparing for Hops, they form beds sixteen feet wide, around which they dig trenches about three feet wide, and two feet, or two feet and a half deep; the earth that comes out being spread upon the beds, and the whole dug and levelled. Upon this, in March they form holes six feet asunder every way, twelve inches in diameter, and a spit deep, consequently there are three rows on each bed. Into each hole they put half a peck of very rotten dung or rich compost, scatter earth upon it, and plant seven sets in each, drawing earth enough to them afterwards to form something of a hillock. Some in the first years sow Kidney-beans or common Beans, or plant Cabbages; but others do not reckon this a good way. In two or three weeks, according to the season, they will be fit to pole with old short poles, to which they tie all the shoots or vines, and then keep the land clean by hoeing and raking; and at Midsummer they hill them. The produce the first year is from three to one hundred-weight of Hops on an acre. Manure is not always given, but amounts on an average to ten loads a year. They keep it till it will run through a sieve, which they prefer to a more putrid state. Three poles are put to each hill: they are generally of ash, and the length preferred is twenty-four feet; when a Hop rises much above a pole, they set another to take the shoot, to prevent its falling, impeding the circulation of air, and entangling with the poles of other hills.—*Produce.* The charge of an acre of Hop-ground, in most parts of England where Hops are cultivated, is thus computed: three pounds per acre for the husbandry; four pounds for the wear of the poles; five pounds for picking and drying; one pound ten shillings for dung; one pound for rent, (though in some places they pay four or five pounds per acre yearly for the rent of the land,) and ten shillings for tithe: in all, about fifteen pounds a year. The English Hop-planters, therefore, think they have but a moderate return, when the produce of an acre of Hops does not sell for more than thirty pounds. They frequently have fifty, sixty, eighty, or a hundred pounds; and in a time of general scarcity, considerably more: so that, upon the whole, if the total charge of an acre of Hops be computed at fifteen pounds a year, and its average produce at thirty pounds, the clear profit from an acre will be fifteen pounds a year. The quantity of Hops produced on different soils in different years, varies from almost nothing, or perhaps two hundred-weight, to twenty and even twenty-four hundred-weight on an acre: but the average produce on middling soils, may be estimated at six, and on such as are better, at seven or eight hundred-weight. Some mention nine hundred-weight, which may be occasionally produced, but ought not to be looked

upon as general. In some places the expenses on an acre of Hops may be estimated at thirty pounds, including rent, taxes, &c. so that taking seven hundred-weight as the average produce, the planters must greatly lose when they sell at four guineas per hundred: but we have already seen that this article is liable to such fluctuations that the average price obtained must be much more; and indeed if it were not, the planters could not continue to cultivate it. Hops are occasionally very profitable, although extremely uncertain in their produce, which always must be very expensive. To lessen the expense of poling and the trouble of picking, it has been suggested, that planting Hops in the form of an espalier might probably answer; for it is observed, when a pole falls, and another is obliged to be fixed in a lateral position, the hop always bears more by being thus trained horizontally, and Hops in an espalier might be picked as forward as the planter chose, without cutting the vines. If Hops also were only planted in such soils and situations as are well adapted to them, there would be a much greater probability of an efficient crop; and by this means, though the expense would not be diminished, the average profit would be increased. Savings might certainly be made in cultivating only on proper soils, where a less quantity of manure is wanted, than upon such as are congenial to this crop; or in the vicinity of great towns, where abundance of manure can be easily procured; by attention to the quality, operation, and effect of different manures, with the best time of laying them on; by uniting the business of maltster to that of hop-grower, by which the malt-office may save the expense of building an oast, or kiln, for drying them; and by other attentions, of which the Hop-planter ought to be the best judge. The tithe of Hops ought surely to be regulated, where the expense to the cultivator is so very considerable.—*General Observations.* It is a general opinion among the Hop-planters, that the plants which bear the male flowers, or the Wild Hops, as they call them, are of no service in securing or increasing a crop; they are therefore in general cast out. It would be well, however, if some accurate experiments were made on this subject. As to the soil, there will be no doubt of Hops thriving when there is good marl or chalk, or even a moist rock at bottom, with a surface of tolerably deep mould frequently manured. The best soil certainly is a strong loam; clay, and a light black loam, are both bad. In general, however, every other year is often enough to manure the Hop-ground; and twenty cart-loads to each acre, a sufficient quantity. It is the common practice to lay the dung on the crown of the hill, that the winter rains may carry it down to the roots; but some spread the dung over the ground in autumn, and seldom dig it in before February. Part of it is brought to hills in the course of hilling the Hops in summer, and part remains in the intervals for the nourishment of the fibres. Though, in very favourable soils, Hops may be continued on the same spot at pleasure, yet it is generally advisable to break up the Hop-yard entirely in twenty or thirty years, when the soil will be found in high order for almost any crops for some years after, particularly for potatoes, of which an immense burden may be produced from such ground. In the preparation for planting, and the manner of it, the practice is very various. The ground is generally ploughed and harrowed well the winter before it is intended to be planted: but that does not seem necessary; for by the time the workmen have gone over it, first to set out the hills, and tisen to dig the holes and plant the Hops, the ground becomes so trodden as to be little the better for ploughing. A better method seems to be, to prepare the ground well the summer before, and sow it with Turnips, by which means it is

thoroughly cleaned; and early in winter, or if in autumn the better, either to pull up the Turnips, or feed them off with sheep, as occasion may require, and so let it remain till the spring; and then plant the Hops, and dig the ground. Sow Turnips again in the ensuing summer, and as these must be hoed twice, the young Hops are cleared at the same time. When they are spent, care must be taken, if they are fed off on the ground, to do it in dry weather. Thus the land being dressed by the sheep, will not at first require so much manure. Beans also, or Potatoes, may be planted the first year between the hills; and either mode will bring some profit during the very time in which the Hops afford none. October is the most proper season for planting with cuttings of the last year, or nursery plants, as they are usually called. In Worcestershire, when the Hop-grounds are come to perfection, it is the general practice to exclude every other growth, and trust to them alone for a return of the great expense at which they are cultivated. Under this management, those which have been uniformly attended to in their prime, and not weakened by over-poling, will continue to produce plentifully from twenty to thirty years, and in some instances much longer; care being taken to replace the stocks that accidentally decay. On the other hand, fresh grounds are generally allowed to produce the finest Hops, and in the greatest abundance. The circumstance of those Hops which are most in request ripening nearly all at one time, is a considerable inconvenience both to the owner and holder of the estate; as they damage so soon, whether left on the wires when ripe, or gathered, if not dried immediately. Hence it is necessary to have buildings and a number of kilns in proportion to the size of the plantations, and more hands during the season than would be otherwise wanted. Could those sorts which ripen earlier be improved, or any others introduced that do so, it would be an important acquisition. The parts necessary to perfect the seeds, are found on different plants; and as the greatest stress is laid on these, it may be proper to notice, that the practice of removing the barren stocks may be carried too far: it is an inquiry worth attending to, whether this be not the cause, in some instances, of the early decay on many grounds. In cutting Hops, a necessary caution should be observed respecting such as are young, not to use the knife too freely the first year. At this age, a sufficient number of joints should be left below the knife; and if the plants are weak, it may be as well only to trim off the dead bind of the last year. Experience will best teach the planter when his Hops are fit for picking. It is nevertheless better to begin too soon than too late, as the high winds which prevail towards the equinox many times produce more injury to the planter, than he would sustain by beginning a day or two before his Hops were thoroughly ripe. It is the prevailing opinion, that the last-picked Hops will weigh heavier when dried than the first; but the experiments of Mr. Prowting, of Chewton, have demonstrated this to be a vulgar error. He calculates that a bushel of green Hops, in a favourable year, will yield about a pound and a half in weight when dried. In Worcestershire, most of the estates which grow many Hops, have plantations for raising the poles. Ash and barked oak are preferred; but willow, poplar, and alder, are also used. Where the estate does not produce a sufficiency, they are bought at the woods and coppices in the neighbourhood, at from five to fifteen shillings per hundred. Their length is from eight to eighteen and twenty feet, according to the goodness of the lands, and they last seven or eight years with care. The sets cost from two shillings to two-and-sixpence per hundred: their length is from eight to eighteen. In this county, the average of general expenses is thus calculated:

workmanship twenty-five to thirty shillings per acre; picking, drying, charcoal, sacks, and duty, thirty shillings per hundred-weight. The implements used throughout this plantation are, the plough, the kerf, the spade, iron crow, and Hop-knife. The plough is the common one of the district; the kerf is a large hoe, with a plate about nine inches broad and thirteen deep; the spade needs no particular description; the crow is an iron bar, about four feet and a half long, generally square at top, with a large point, in the octagon form, used to make the hole in the ground for pitching the poles; the Hop-knife resembles the sickle in make, an old one being often converted to this purpose, by grinding off its saw-edge, and giving it a sharp one in its stead; when made for the purpose, it is something smaller. The crib and bags have been already described; the sacks, in which they are carried from the Hop-ground to the kiln, are made of the same materials as the bags. In Essex the poles most esteemed are the chestnut, ash, oak, willow, and maple; all fourteen years growth from a wood, or eleven from a plantation. Mr. Boys, in his *Agricultural Survey of Kent*, enumerates the following things as necessary to a Hop-ground of four or five acres. 1st, An oast or kiln about sixteen feet square, costing, when substantially built and allowing stowage-room, from £150 to £200. 2nd, A set of picking baskets, about twelve in number, and a good scale-beam and weights. 3rd, A skim made with a frame like a wheelbarrow, which is also very useful for tearing up weeds on summer fallows. 4th, A harrow drawn by one horse, with a small wheel in front, to go round at the ends of the plantation; and a pair of handles to be holden by the man who follows it, in order to keep it from bruising the binds. 5th, An iron peeler, to make holes for the poles to be fixed in; and a Hop-dog to wrench them up. — *Diseases.* The Hop-grower has many enemies to dread. A fly, similar to that which proves so fatal to Turnips, attacks them on their first appearance in the spring, and sometimes entirely destroys the first shoots. It is a very small animal, which, on your approaching to touch it, retreats into the ground with the nimbleness of a flea. Chalky land is much subject to them, and they seem to be produced by warm dry weather. In Surrey, a handful of dry ashes scattered over every hill is thought very serviceable in driving them away: but the Essex planters esteem it better to dung highly, that the plants may grow out of danger, for they are considered safe when they reach two feet high; they do not therefore apply any thing to stop it, thinking that a shower of rain will complete the cure. The next enemy is the fly mentioned by Mr. Miller, by which he means the long-winged fly, as the Surrey planters call it. The appearance of these vermin is dreaded as a pestilence; they are the forerunners of lice, and at last generally ruin the crop. The lice do not appear to eat, but to poison, the leaf; they are worst in thick, cloudy, hot, and moist weather. Many suppose that the rain will wash them off, but this seems to have no foundation, for they generally shelter themselves on the under side of the leaf, where no rain can touch them. Lightning seems to be their greatest enemy. These flies and lice are all aphides, some of which are winged, and others not: and the honeydew, so destructive to the Hop, is their excrement; it causes their leaves to turn black, shrink, and at length fall off. Sometimes they are so infested with this distemper, and the lice united, as to perish entirely, and require to be planted anew for many hills together. Another calamity to which Hops are liable is, the red blight. This seldom attacks them till they come to maturity, causing the Hops to assume a reddish or rather deep yellow colour, and the leaves frequently to grow pale and sickly. When this happens, they

acquire a garlic-like smell, and ought to be picked with the greatest expedition. This disorder appears to be incident to particular lands, especially those of a light poor quality, and therefore is in all probability a natural decay, and not a blight. Dr. Withering's observations on the honey-dew deserve to be introduced to the notice of planters. He says, if the Hop-yards were covered with stones, the plants would be less liable to suffer from the honey-dew and otter-moth, for the honey-dew is the excrement of a species of louse; but these insects seldom increase so as to endanger the plant, unless it is in a weak condition; and the larvæ of the otter-moth at the roots, first occasion the plant to be sickly. Now when the Hops grow wild in stony places, and fissures of rocks, where the moth cannot penetrate to deposit its eggs, the Hop is never known to suffer from the honey-dew. Admitting this view of the disease, might not the practice of smoking the fruit plantations on the first alarm of a blight, as practised in some fruit countries, be applied here to those of Hops? The other injuries to which they are liable still remain without a remedy. A free circulation of air through them, and complete draining of the land, are the only alleviations. The use of the kerf is certainly attended with one disadvantage: the person using it, in some measure defeats the intention of his own labour, as he must, in some degree at least, tread down again the soil he had just loosened; and often reset a weed which he had just before turned up; but the greater dispatch made with this implement will always secure it a preference before the spade.—*Uses of Humulus Lupulus.* The Society for the Encouragement of Arts, Manufactures, and Commerce, at London, offered premiums in the year 1760 for cloths made from Hop-stalks or binds. The year following, Mr. Cooksey produced some specimens of cloth, and was of opinion that it would answer very well the purpose of fine sacking and coarse bagging for Hops. He had kept the material too long under water; and found that at the end of six weeks or two months the binds afforded filaments sufficiently strong and fine for any purpose. In 1791, Mr. John Locket, of Donnington, near Newbury, in Berkshire, had the premium adjudged to him for cloth made from these stalks, or Hop-vines, as they are here called. They were cut in lengths of about two or three feet; put into a boiler in which was some lye that linen had been boiled in for bleaching; and then boiled till the rind easily separated from the stalk. When cool, they were stripped so freely that children might do it; and the yield was great in proportion to the quantity of stalks. The same method was then followed as in working hemp or flax; but it is much more stubborn than either, and therefore not so well adapted for making fine cloth: the fibres are also so united with a very adhesive matter, that they do not easily separate; but for sacks and cordage, it may certainly be very serviceable. Some of it was hackled, while it was wet soon after it was taken off, yet it did not separate the fibres. Carding seems to work it best, and to make it like cotton. Of the piece of cloth exhibited, the warp was hackled and the woof carded. The Swedes make a strong cloth from the stalks, which must be gathered for this purpose in autumn. The use of Hops for preserving beer, and the cultivation of the plant, were introduced into England from Flanders, in the middle of the sixteenth century. Ground Ivy (see *Glechoma Hedracea*) was generally used for preserving beer, before the introduction of Hops. Since their introduction, many wholesome plants have undoubtedly been used as succedaneums when Hops were scarce, and of course exorbitantly dear; as, the roots of Ginger and Gentian; the seeds of Coloquintida; and the herbs of Horehound, Wormwood, Broom; *Carduus Benedictus*, *Centauria Calatrava* or *Star Thistle*,

Marsh Trefoil, or *Buck Bean*; the last of which is much recommended as a more wholesome bitter than even that extracted from Hops, in the proportion of only two ounces where a pound of Hops was employed. All brewers, however, are enjoined, under a severe penalty, to use no other bitters than Hops in their malt liquors; but there is evident reason to conclude that this law is of no avail; so much so, indeed, that we fear our readers will ask for what intent we have gone into so long a detail upon an article which bids fair to be wholly excluded from modern breweries. Those who have invested large capitals in the immense breweries of London, Dublin, and other cities, take care to cry out when the Barley and Hop-harvests fall short or fail; but we wish to know what concern they really have in these articles. The amazing difference between the beverage brewed in families from the materials which the law enjoins the brewers to employ, when used in the same proportions, and with all the advantages of preparing larger quantities, and of better apparatus, on the brewers' side, is universally known to be in favour of brewing at home. What then is the cause of an effect so opposite to what the public have a right to expect? The cause has been traced to the employment of foreign, and, we fear, even of noxious drugs. They explore, as Mr. Gifford observes, the East Indies for the *Menispermum Coculus*, or *Coculus Indicus*; this is their substitute for malt. The West Indies furnish them with *Quassia*, &c. and Spain with *Liquorice*. These two last might be tolerated, but they are not the proper materials for producing the wholesome beverage which used to regale our forefathers. The former ingredient is used in the East Indies, by pounding the berries into a kind of paste, which, cast into water, intoxicates the fish so that they are caught by the hand. From this circumstance some conclusion may be formed as to its properties and effects when introduced into the human frame. Not content with these, that most abominable of all abominations, Tobacco, is notoriously used as a substitute for the Hop; and green vitriol, with other poisons too numerous to name, are added, to mature the deleterious mixture. Hence it is that the poor mechanic is drawn into habitual inebriation: he cannot slake his thirst, without causing it to return with greater force at very short intervals; unconscious of the cause, he repeats the draught, and the consequences are disease, and premature, and even sudden, death. Half the apoplexies, says an eminent physician in the British metropolis, arise not so much from drinking spirits, as from the noxious ingredients, particularly green vitriol, administered in the malt liquors there consumed. When will the strong arm of power put a stop to these iniquities? when will our rulers extend it, to protect the health, morals, and happiness of the community, and arrest the deadly ravages of those unprincipled men, who wallow in ill-gotten wealth for a few years, and then bequeath immense revenues for their profuse descendants to scatter to the winds?—*Medical Properties.* A decoction of the roots of Hops, from one to two ounces, or an extract from them, to the quantity of twenty or thirty grains, is said to be sudorific, answering the purpose of *Sarsaparilla*. Both these and the strobiles have a balsamic principle, and are thought to be serviceable in removing obstructions, correcting the viscosity of the lymph, opening the pores of the skin, and cleansing the kidneys. The young shoots are eaten early in the spring as *Asparagus*, and are sold under the name of Hop-tops, which are said to be diuretic, and good for the scurvy, taken by infusion. Hill says, that a decoction of fresh-gathered Hops is good against the jaundice; and adds, that the powder of Hops dried in an oven has been often known to cure agues, but admits that upon this last there is no absolute dependence.

The heads and tendrils are used to purify the blood in the scurvy, and most cutaneous diseases; decoctions of the flowers, and syrups thereof, are efficacious in pestilential fevers; juleps and apozems were formerly made with Hops for hypochondriacal and hysterical affections, and to promote the menses. A pillow stuffed with Hops, and laid under the head, is said to promote sleep in fevers attended with a delirium. Culpeper concurs in all that has been above advanced, concerning the virtues of this plant; and adds, that they help to cure the French disease, and that the decoction of the flowers and tops do help to expel poison that any one hath drank. Gerarde says, the juice of Hops openeth the belly, and driveth forth yellow and coleric humours, and purgeth the blood from all filthiness: the decoction openeth the stoppings of the liver, the spleen, and kidneys, and purgeth the blood, by the urine.

Hura; a genus of the class Monœcia, order Monadelphia. —GENERIC CHARACTER. *Male flowers.* *Calix*: ament from the divarication of the branches, oblong, drooping, covered with sessile spreading florets; scales oblong; perianth within each scale of the ament, cylindrical, two-leaved, truncate, very short. *Corolla*: none. *Stamina*: filamenta cylindrical, a little longer than the calix, peltate at the tip, rigid, below the tip twice or thrice verticelled with tubercles; antheræ two, immersed in each tubercle, oval, bifid. *Female flowers*, in the same plant. *Calix*: perianth one-leaved, cylindrical, furrowed, truncate, quite entire, closely surrounding the germen. *Corolla*: none. *Pistil*: germen roundish, within the calix; style cylindrical, long; stigma large, funnel-shaped, plano-convex, coloured, twelve-cleft, blunt, equal. *Pericarp*: woody, orbiculate, or globular-flattened, torose, with twelve furrows, twelve-celled; cells dissilient, crescent-shaped, with an elastic dagger-point at the end. *Seeds*: solitary, compressed, suborbiculate, large. ESSENTIAL CHARACTER. *Male*. Ament imbricated; perianth truncated. *Corolla*: none. *Filament*: cylindrical, peltate at the tip, surrounded by very many antheræ in pairs. *Female.* *Calix* and *Corolla*: none. *Style*: funnel-form. *Stigma*: twelve-cleft. *Capsule*: twelve-celled. *Seed*: one.—The only known species is,

1. *Hura Crepitans*; *Sand Box-tree*. It rises with a soft woody stem to the height of twenty-four feet, dividing into many branches, which abound with a milky juice, and have scars on their bark, where the leaves have fallen off. The branches are garnished with heart-shaped leaves; the biggest eleven inches long, and nine broad in the middle; indented on their edges, having a prominent midrib with several transverse veins from that to the sides, which are alternate: they stand upon long slender footstalks. The male flowers come out from between the leaves, upon peduncles which are three inches long; they are formed into a close spike or catkin, forming a column, lying over each other like the scales of a fish. The fruit is very curious in its structure; and the tree, when it grows well, is very spreading and shady. It sometimes attains the height of thirty-five or forty feet, and casts a shade of sixty feet diameter. But owing to the rapidity of its vegetation, its parts are of so loose a texture, that a loud clap of thunder, or a sudden gust of wind, frequently causes the largest boughs to snap asunder. Linneus says, the wood is fit for joists and spars; which Long denies, declaring it fit only for fuel. Linneus also remarks, that if the juice get into the eyes it will bring on blindness after the eighth day; but we do not know whether this be accurate or not. The roasted seeds, according to Hernandez, will purge and vomit. Browne tasted one of them, which at first appeared to be both mild and pleasant; but it soon began to warm and scald both his palate and throat, on which account he judged it to be an

improper purgative. The fruit is large, often brought to Europe, and used as a sand-box; but if suffered to hang too long before gathering, in a dry warm room, it will explode with great violence.—Native of South America. Browne makes this tree of the same genus with the Hippomane, or Manchineel. This tree is propagated by seeds, which should be sown early in the spring, in pots filled with light rich earth, and plunged into a hot-bed of tanners' bark. If the seeds be fresh, the plants will appear in about five or six weeks after they are sown. As the plants will advance very fast where due care is taken of them, they should have a large share of fresh air in warm weather, to prevent their drawing up weak. When about two inches high, they should be transplanted each into a separate small pot, filled with light rich earth, and again plunged into the hot-bed of tanners' bark, being careful to shade them from the heat of the sun, until they have taken new root; after which they must have free air admitted to them by raising the glasses in proportion to the warmth of the season, and gently watering them. When the plants have filled these small pots with their roots, they must be shaken out of them, and their roots trimmed, and then placed in larger pots, filled with the same kind of rich earth, and plunged again in the hot-bed, where they may remain till Michaelmas, provided the plants have room without touching the glasses. At Michaelmas, they require to be removed into the bark-stove, and plunged into the warmest part thereof: during the winter season they must be sparingly watered, for as the plants have succulent stalks, much water will rot them: and if not kept very warm, they will not live in this country, the open air of which they cannot endure even in the warmest part of the year. The ample leaves of this plant, which are of a beautiful green colour, afford an agreeable variety among other tender exotics in the stove. It grows naturally in the Spanish West Indies, from whence it has been introduced into the British colonies; and is much cultivated in Jamaica for its beauty, and the fine shade it yields. In those climates it prefers a deep rich soil, and thrives best near water. It is become pretty common in the English gardens, where it has grown twelve or fourteen feet high, producing flowers, but no fruit that we have ever yet heard of.

Hyacinthus; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: monopetalous, campanulate; border six-cleft, reflex; nectary, three honied pores at the tip of the germen. *Stamina*: filamenta six, awl-shaped, shorter; antheræ converging. *Pistil*: germen superior, round, three-cornered, three-furrowed; style simple, shorter than the corolla; stigma obtuse. *Pericarp*: capsule roundish, three-sided, three-celled, three-valved. *Seeds*: in pairs, (generally,) roundish. ESSENTIAL CHARACTER. *Corolla*: bell-shaped, with three honied pores by the germen.—The species are,

1. *Hyacinthus non scriptus*; *Common Hyacinth* or *Harebells*. Corollas tubular, bell-shaped, six-parted; segments rolled back; bractes in pairs; root a roundish bulb, the size of a nutmeg; scape from six inches to a foot in height, upright, round, smooth, and solid, bowed down when it begins to flower; leaves four, six, or sometimes more, only half the length of the scape, and about half an inch broad, keeled, hollow, smooth, shining, grass-green, flaccid, bending downwards, ending in an acute point; flowers in a long raceme or spike, from eight to twelve, often more, all pointing one way, pedicelled, pendulous, sweet-smelling, of a blue or violet colour, varying to white and flesh-colour, six-parted to the very base; bractes two to each flower, lanceolate, and nearly upright. The honied pores which Linneus gives as

the essential character of the genus, are not discoverable in this species: this has led Dr. Withering to wish the plant had been arranged under the genus *Scilla*; in which Dr. Stokes concurs, thinking it has more of the habit and even structure of *Scilla* than of *Hyacinthus*. The drooping of the flowers distinguishes it from *Scilla Campanulata*, a plant often found in our gardens, flowering at the same time. The fresh root is poisonous, but may be converted into starch. Gerarde says, that they are full of a slimy glueish juice, which serves to set feathers upon arrows instead of glue, and to paste books with, and that they make the best starch next to Wake-robin roots. Hill informs us also, that the root is full of a slimy juice, and that a decoction of it operates by urine. Dried and reduced to powder, it is of a balsamic and somewhat styptic nature. The virtues of it are little known, but there are few of the remedies employed for the cure of that weakening complaint, the Whites, equal to this; the dose, however, ought not to exceed three grains. Our old botanists name this plant *Anglicus*, and English *Hyacinth*, from its extreme commonness in many parts of our island. Gerarde calls it Blue Harebells, or English *Jacinth*; and it is the "azur'd Harebell" mentioned in Shakspeare's *Cymbeline*. The French call it, *Jacinte des Bois*; and the Germans, *Niederlandische*, or *Englische Hyacinthe*. It adorns our woods, coppices, and hedge-rows, with its flowers in the spring-months, and is very common with the blue flowers: carnation and white flowers are not so common. Gerarde found them near Colchester in Essex; at Southfleet, near Gravesend; and in the neighbourhood of Canterbury, in Kent; at Bath, in Somersetshire; and Warrington, in Lancashire. Ray observed the white flowers at Scadbury park in Kent, and Dr. Stokes near Worcester. It is also found in the enclosures about Streatham and other places in Surrey: it is seldom admitted into gardens. Mr. Curtis remarks, that the seeds are not ripened till the end of the year; and that on being sown, they did not rise till the second year.—Native of France, Flanders, Switzerland, Italy, Spain, and Persia. See the thro species.

2. *Hyacinthus Cernuus*; *Bending Hyacinth*. Corollas bell-shaped, swelling at the base, six-parted; raceme drooping. This resembles the preceding, but is smaller; the raceme is more nodding; the corollas flesh-coloured, not blue. The corolla swells out at the base, which is by no means the case in the first species. Miller, Ray, and Caspar Bauhin, however, thought it a variety, differing principally in having the flowers of a blush peach-colour. That which Mr. Miller absurdly calls *Hyacinthus Utrinque Floribus*, does indeed seem to be a variety of this species. It has blue flowers disposed on every side of the stalk, which rises about nine inches high; the thyrse of flowers is large when the roots are strong. He adds, that it is a native of Spain and Italy, and was formerly preserved in gardens, but having been neglected for the fine varieties of the Eastern *Hyacinths*, is now become scarce. This is the case with many of our old favourites, which are cast out, to make room for new comers. It is seldom cultivated in gardens.—Native of Spain. See the next species.

3. *Hyacinthus Serotinus*; *Late-flowering Hyacinth*. Outer petals almost distinct, inner co-adunate; bulb ovate-conical, solid, covered with brown skins; scape single, a foot high, smooth; leaves channelled, sheathing the scape at the base; flowers in a raceme all pointing the same way, drooping a little, each on a short peduncle, with an awl-shaped bracte at the base; corolla of a dull greenish red colour. When the flowers first appear, of a light, but, according to Miller, fading to a worn-out purple colour. Gerarde describes them as of a very dusky colour, as it were mixed with purple, yellow, and

green; without any smell. Parkinson, who calls it Spanish Dun-coloured *Jacinth*, says it is of a purplish colour, with some white and green as it were mixed among it. Ray observes, that the plants which he raised from seed of the same root, varied in the colour of their flowers, some being dusky, and others almost green. It flowers in June, later than the other *Hyacinths*, and hence Clusius called it *Serotinus*.—Native of Spain, near Aranjuez; and of Barbary, in the neighbourhood of Fez and Morocco. This, as well as the first, second, and fifth species, are seldom admitted into gardens, having been almost totally neglected since the introduction of the Eastern *Hyacinths*. Those, however, who wish to preserve them, may effect it without much trouble, for their roots propagate plentifully in any soil or situation, and only require to be taken up every second or third year soon after the leaves decay, and to replant them in the following autumn; for if permitted to remain longer in the ground, their roots will multiply to such a degree as to render their flowers very small and weak. They may all be increased, either by seeds or offsets, from the old bulbs, but it is only practised in these four species.

4. *Hyacinthus Viridis*. The outermost segments of the corollas awl-shaped and very long. This is of the same stature with the next species, but the corolla is green.—Native of the Cape of Good Hope.

5. *Hyacinthus Amethystinus*; *Amethyst-coloured Hyacinth*. Corollas bell-shaped, half six-cleft, cylindrical at the base. This has a smaller flower; the petals are cut half their length, and are reflex at the brim; the lower part is cylindrical, a little swelling at the base, and of a deeper blue. The root, according to Clusius, is the size of a small olive, covered with a brown skin; leaves five or six, longer and narrower than in the first sort, striated and keeled, lying mostly on the ground; scape slender, a long span in height, round, smooth, glaucous, having six or seven flowers at top, (according to Ray, sometimes twelve or more,) nodding, on pedicels half an inch in length; they are of a bright blue, without any scent. Most of them, says Parkinson, have white stripes and edges, and they vary to pure white, and a fine decayed pale red colour, with deeper-coloured veins running along the three outer segments. Mr. Miller says, it was formerly called Coventry Blue *Hyacinth* by the gardeners.—Native of Spain, Italy, and Russia, flowering in May.

6. *Hyacinthus Revolutus*; *Wave-leaved Hyacinth*. Corollas bell-shaped, six-parted, revolute; leaves oblong, waved.—Native of the Cape of Good Hope.

7. *Hyacinthus Orientalis*; *Garden Hyacinth*. Corollas funnel-form, half six-cleft, swelling at the base, with two small bractes under each pedicel. It has a large coated bulb, viscid, and of a sweetish taste, from the bottom of which spring the roots, which are long round fibres, of a middling thickness; from the middle of it rises a single naked stem or scape, and from the top six, seven, or more leaves, which are broadish, keeled, pale green at bottom, but of a darker green towards the end. From the middle of the scape, to the top, come out the flowers, one above another, not pointing the same way, as in the Harebell, but standing on different sides of the stalk, three, four, five, and up to twelve in number, each nodding on pedicels half an inch in length, usually of a very dark green colour, and having a pair of small bractes at the base; the corolla is near an inch in length, almost cylindrical, except at the base, where it swells or bellies out, and at the top the segments are turned back a little. These flowers have a very sweet smell, and are much valued for the variety of their colours; pure white, white tinged with blue, all shades of blue even to the dark violet, and all

shades of red purple, from the faint blush to the deep red; they are also sometimes yellow. Culture and great attention have also brought these plants to be very strong, and their flowers to be very large and double. It seems to have been brought into England some time in the sixteenth century, yet the double flowers were not much esteemed, long after the Hyacinth had attracted the attention of the florists. The beauty of this celebrated flower was then supposed to consist in the regularity and equality of the petals, and the uniformity of the colours. The first double flower, cultivated by Peter Voorhelm, was named Mary, which variety is lost, as well as the two next that were produced: the *King of Great Britain*, which is now looked upon as the oldest double Hyacinth, appeared about the beginning of the last century; it was greatly preferred to all the flowers then known, and the price rose to about a thousand florins. From that time the greatest attention has been paid at Haarlem to the raising and cultivation of this elegant flower; and such has been the rage for it, that nearly two hundred pounds sterling has been given for a single root. The gardeners there distinguish nearly two thousand Hyacinths by name, and generally publish catalogues of them from year to year. New varieties are annually produced, and whole acres together are covered with this flower, in the circuit of that town alone. The Hyacinths are distributed into classes, from their colours; the principal of which are, blue, red, purple, and white, with some yellow; and they are subdivided from the shades of each colour: as, of the blues; deep blue, violet blue, blue purple, porcelain blue, agate blue, sky blue, French gray, &c.: of the reds; deep or full red, rose-coloured, carnation, &c.: also from the mixtures of different colours or shades; as light blue with a deep blue or purple eye; light red, with a deep red eye; white, with a rose-coloured, blue, purple, or yellow eye; white and red of different shades; and blue, violet, and purple, of different shades mixed; also, yellow with a purple eye, &c. Some have their petals striped with a paler or deeper colour; and all these varieties are found both in single and double flowers; but the latter only are now much regarded among florists, unless it be for producing seeds, by which alone they can procure new varieties. The principal properties of a fine double Hyacinth are the following. 1. The stalk should be tall, strong, and upright; the flowers (or bells, as the florists term them) sufficiently numerous, each suspended by a short strong peduncle, in an horizontal position; the whole having a compact pyramidal form, with the crown, or uppermost flower, perfectly erect. 2. The flowers large, well filled with broad bold petals, appearing rather convex than flat or hollow, extending to the middle of the stalk. 3. The plain colours, clear and bright, strong, not pale; and mixed colours elegantly blended.—It is a native of the Levant, very abundant about Aleppo and Bagdat, where it flowers in February: in our climate, it flowers in March and April.—*Propagation and Culture.* The method of raising these flowers from seed, is, first, in the middle or latter end of August to provide good seed, saved from good semi-double, or such single flowers as are large, and have good properties; then procure some square shallow boxes or pots, with holes to let off the moisture; fill them with fresh, light, sandy soil; lay the surface level, and sow the seeds on it as equally as possible; cover them half an inch thick with the same light earth; place them so as to enjoy the morning sun, until the latter part of September, then remove them into a warmer situation, and towards the end of October place them under a common hot-bed frame, to protect them from hard frosts during the winter and spring months, but admitting the air in mild weather. The young

plants will appear at the end of February, or beginning of March, and must be carefully protected from frost, but never covered except at night, or in very rough weather, for covering causes them to grow up tall and slender, and prevents the growth of the roots. In the middle of April, during fine weather, the boxes may be removed out of the frame, and placed in a warm situation, observing to water them in dry weather, and to keep them very clean from weeds. At the beginning of May, the boxes should be removed into a cooler situation, to avoid the heat of the summer, which they cannot sustain. They must not be placed under the dripping of trees, nor yet be watered after the blades have decayed, for that would rot their roots: weeding them should be diligently performed. At the end of August, sift a little light rich earth over the boxes, and again remove them into a warmer situation, and treat them, during the winter, spring, and summer months, as before directed; about the middle of the next August, prepare a bed of light, rich, sandy soil, in proportion to the quantity of seedling plants. Having levelled the surface very even, take the earth from the boxes in which your plants were raised, into a sieve, in order to obtain all the roots, which, if they have grown well, will be about the thickness of a small quill; these roots should be placed upon the bed, about two or three inches asunder, observing to set the bottom part of their roots downwards, and cover them over, two inches thick, with the same light earth: but as it may be impossible to get all the small roots out of the earth in the boxes, let it be spread out evenly upon another bed, and covered with light earth, by which method all the roots, however small, will be saved. These beds must be arched over with hoops, and in very hard frosty weather be covered with mats, to protect them from frost; and in the spring, when the green leaves are above ground, if the weather should be very dry, you must refresh them sparingly with water, for nothing is more injurious to these bulbs than too much moisture. During summer, the beds must be constantly kept clear from weeds, but the plants must have no water after the blades are decayed. In autumn, stir the surface of the bed with a very short hand-fork, taking great care not to thrust it so deep as the roots, which, if injured, generally perish soon after. Then sift a little fresh, light, rich earth over the bed, about an inch thick, or somewhat more, and again cover them in winter, as before directed. In this bed, the roots may continue two years, observing to treat them both in summer and winter as before; then the third year the roots should be carefully taken up, a little before the leaves decay, re-laying them horizontally three weeks in the ground to ripen, after which they may be kept out of the ground till the end of August, when they should be planted into new beds prepared as before, placing them at the distance of six inches asunder. Here the roots may remain till they flower, during which time they should be treated as before, with this difference only, that instead of covering them with mats in the winter, the surface of the ground should be covered with tanners' bark. When their flowers begin to shew themselves, mark all such as appear to have good properties, by thrusting down a small stick near each root, which roots, at the time of taking up, should be selected, and replanted by themselves. When the green leaves begin to decay, take up the roots, raise a bed of light earth into a ridge, the better to shoot off the moisture; laying the roots into the earth again in an horizontal position, leaving the green leaves hanging out of the ground from the roots, whereby the great moisture contained in their very succulent leaves and flower-stalks, may be exhaled, and prevented from returning to the

roots, which is often the cause of their rotting after they are out of the ground. In this ridge the roots should remain until the leaves are quite dried off, when they must be taken up, and after being cleared of all manner of filth, which would be hurtful to them, they must be laid up in boxes, where they may be preserved dry until September, which is the proper season for planting them again.—*Of the Dutch Hyacinths.* Want of skill alone, in Mr. Miller's opinion, is the cause of the frequent failure which English florists meet with in the culture of these noble flowers; for he thinks they may thrive at least nearly as well in England as in Holland. The soil in which they succeed best is a light, sandy, fresh rich earth, composed half of fresh earth, taken to the depth only of eight or nine inches, with the sward, off the surface of a common pasture-land, which is usually a sandy loam: to this a fourth part of sea-sand, and another of rotten cow-dung, which should be mixed well together, cast into a heap that the turf may rot, and turned over once every three weeks or a month. If this compost be made two years before it is used, it will be much better: but if you must use it sooner, it should be the oftener turned, that the parts may the better unite. This soil should be laid to the depth of two feet on the beds designed for the Hyacinths; and if you lay a little rotten cow-dung or tanners' bark at the bottom, which may be within the reach of the fibres, but should on no account touch the bulb, it will be better. If the soil be very wet where these beds are made, raise them ten or twelve inches above the surface of the ground; if dry, not above three or four inches. Prepare the beds as follows: take all the former old earth out of the bed to the depth you intend, which should be nearly three feet: spread some rotten cow-dung or tan in the bottom, six inches thick, and level. Upon this lay the above compost two feet deep, levelling very even. Then score out the distances for the roots, which should be eight inches square, in straight rows each way: place your roots exactly in the squares, observing to set the bottom part downwards; then cover the roots six inches deep with the same prepared earth, taking care not to displace any of the roots; and if the tops of the beds be made a little rounding, to shoot off the wet, it will be of service in moist ground, provided the middle of the beds be not made too high, which is a fault the other way. The best season for planting these roots is the middle or latter end of September, according to the earliness or lateness of the season; but it is not advisable to plant them when the ground is very dry, unless there be a prospect of rain, for if the dry weather continue long after they are planted, the roots will acquire a mouldiness which will certainly destroy them. The beds will require no further care till the severe frost sets in; then let rotten tan be spread over them to the depth of four inches: and if the alleys on each side of the bed be filled up either with rotten tan, dung, or sand, it will keep the frost from penetrating through the sides to the roots of the plants. In very hard winters it will be proper to lay peas-haulm or straw over them, which will keep out the frost better than mats, and, lying hollow, will admit the air to the surface of the ground, and also permit the exhalations to pass off, whereby the earth will be kept dry, and the roots be prevented from rotting, which is often the consequence of covering the beds too closely. This light covering must be removed in mild weather, and used only in very hard frosts, for where the beds are covered with tan or sea-coal ashes, no common frost can penetrate through: and if these coverings be suffered to remain in mild weather, the flower-stems will be drawn up to a great height, and become very weak: and the footstalks of the flowers will be long and slender, and therefore incapable of supporting the

bells, which is a great disadvantage to the flowers, one of the greatest beauties of which consists in the regular disposition of their bells. When the hoops are fixed over the beds, the rotten tan should be nearly all removed as carefully as possible, that the leaves may not be bruised or injured. It had better be done by hand, as the flower-stem of the Hyacinth will be then breaking out of the ground. When the flower-stems have reached their height, before the flowers expand, place a short stick down by each root, to which, with a wire formed into a hoop, the stem of the flower should be fastened, to support them from falling; otherwise, when the bells are fully expanded, their weight will incline them to the ground, especially if they are not screened from the wind and rain. During their season of flowering they should be covered in the heat of the day from the sun and heavy rains, and frosty nights; but the morning and evening sun, with gentle showers, they ought to enjoy. With this management you may continue your Hyacinths in beauty at least one whole month, and sometimes more, according to their strength, or the favourableness of the season. When their flowers are quite decayed, and the tops of the leaves begin to change colour, you must carefully raise the roots out of the ground with a narrow spade, or some other handy instrument, which is what Dutch gardeners call *lifting* them. In doing this the instrument must be carefully thrust down by the side of the root, being cautious not to bruise it, as well as to put the implement below the bottom of the root; then, by the forcing of the spade on one side, the fibres of the root are raised, and separated from the ground. This is intended to prevent their receiving any more nourishment from the ground; for by imbibing too much moisture at this season, the roots frequently rot after they are taken up. About a fortnight after this operation, the roots should be entirely taken out of the ground, and carried to beds upon which the morning sun only shines, and laid upon a ridge with their leaves out, to drain off the moisture, as before directed. Here they should remain until the green leaves are entirely decayed, which perhaps may be in three weeks' time. The Dutch gardeners term this the ripening of the roots, because it causes them to become firm, smooth in the outer cover, and of a bright purple colour: whereas the roots which are permitted to remain undisturbed till the leaves and stalks are quite decayed, will be large and spongy, with their outer coats of a pale yellow colour; for the stems of many of these flowers are very large, and contain a great quantity of moisture, which, if suffered to return into the roots, would infallibly destroy many of them. After they are ripened, take them out of the ground, and wipe them clean with a soft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie singly, and be exposed to the air, but carefully preserved from moisture. They should not be suffered to remain where the sun may shine upon them; and may be thus preserved until September, which is the season for replanting them. You must then separate all the strong-flowering roots, planting them in beds by themselves, that they may make an equal appearance in their flowers. The offsets and smaller roots may be planted in a separate bed for one year, to acquire strength, and at the end of a second year will probably be as vigorous as the older roots. The single and semi-double flowers should be planted also in a bed by themselves, where they must be carefully sheltered, as before directed, especially from frost, until the flowers are blown; at which time their covering should be entirely removed, the open air admitted, and the flower-stalk supported with sticks, which, though the weather may soon deface the beauty of their flowers, is yet absolutely

necessary to promote their seeding. When the seeds are quite ripe, cut off the vessels, and preserve them with the seeds therein until the season for sowing. Observe, however, that after these flowers have produced seeds, they seldom flower so well again, at least not in two years after; so that the best method to obtain good seeds is to plant new roots every year for that purpose. Although these roots are by most persons taken up every year, yet, where the ground has been well prepared, they may remain two years, and will increase more in the second year than the first: but the flowers are certainly more liable to degenerate; therefore those who cultivate them for sale take up their roots annually, when they are large and saleable, but leave the offsets and small roots two years in the ground. There are some persons who suffer their Hyacinth roots to remain three or four years unremoved, which causes a much greater increase of roots than when they are annually taken up; but the roots by this great increase are frequently degenerated, so as to produce single flowers. Single Hyacinths may be planted a week or two sooner than the double ones, and will bloom two or three weeks earlier; upon these the cultivator must depend for seed, for the double ones rarely produce any. Save your seed from those plants which have strong straight stems, and a regular well-formed pyramid of flowers which are semi-double: do not gather it till it is perfectly black, when the pericarp will appear yellow on the outside, and begin to open; then cut off the stem, and place it in a dry airy cool place, till the time of sowing, which may be either the end of October, the beginning of March, or in August; which last Mr. Miller recommends. Some say, that if the bulbs of double Hyacinths be planted sooner than the middle of October, they will be apt to come up during the winter, and thus be injured by severe frosts; and if it be deferred later than the middle of November, the bulbs will begin to put out fibres, which will weaken them. Such bulbs as are four or five years old flower strongest in England, and after this gradually decline: but in Holland, the same bulb will produce bloom twelve or thirteen years together, nor is it ever known to die through mere age. Persons who are nice about their flowers, erect a covering over them during the flowering time, to keep off the rain without excluding the light, and to keep off cold winds, which are frequently very injurious at the early season in which these delicate flowers are in bloom. This awning should be of coarse linen, on a frame of wood, made to roll up easily, that in mild cloudy weather the flowers may have the full benefit of the sun and air: and it should not continue on more than a fortnight or three weeks, for it weakens the bulbs. Florists differ as to the proportion of the materials of the compost in which the bulbs are to be planted. Some, instead of half fresh earth, recommend only one-third, with the same quantity of rough sea or river sand, and the remaining part to be one-fourth old rotten cow-dung and the rest the earth of decayed leaves. Some put in tanners' bark, rotten wood, or old saw-dust: others reprobate tan, as retaining an astringency which is pernicious to delicate bulbous flowers. In using fresh earth from a pasture, it is necessary to guard against the wire-worm, by minutely inspecting the heap as it is turned over, and picking out that destructive reptile, which is of a yellow colour and about an inch long. The beds should be in a dry airy part of the garden, with a southern exposure, sheltered from the north and east, six feet distant at least from the fence, and made sloping a little towards the sun. The Hyacinth succeeds best in situations near the sea. In more inland parts, the florist must annually introduce fresh bulbs to supply deficiencies, by keeping a reserve in deep narrow pots, to fill up the vacancies in his beds.

8. *Hyacinthus Corymbosus*. Corollas funnel-form; raceme erect; leaves linear, very narrow, commonly three, shorter than a finger's length; scape shorter than the leaves, terminated by a corymb of purple flowers, cloven half way down; style the length of the corolla.—Observed in pastures near the Cape.

9. *Hyacinthus Romanus*; *Roman Grape Hyacinth*. Corollas bell-shaped, half six-cleft, in racemes; stamina membranaceous; leaves very long, the width of the finger; raceme long, round, with very numerous flowers, which are white, and cut beyond the middle; antheræ blue.—Found in the fields near Rome.

10. *Hyacinthus Muscari*; *Musk Hyacinth*. Corollas ovate, all unequal, with one braete under the pedicel, and another above it; roots large, oval, bulbous; from them arise several leaves eight or nine inches long, and half an inch broad; out of the middle of these springs the stalk, six inches high, which sustains the flowers; it is naked below, but the upper parts are garnished with small flowers growing in a spike having ovate pitcher-shaped petals, which are reflexed at their brim, and are of an ash-coloured purple, or obsolete faded colour, but have an agreeable musky scent, and, when in some quantity, will perfume the air to a considerable distance. It flowers in April, and ripens seed in July. Of this there are two varieties; one with the same coloured, but larger flowers, on the lower part of the spike, while the flowers on the upper part are yellow, and emit a very grateful odour. Another, with very large yellow flowers, sells for a guinea a root among the Dutch florists. Native of the Levant.—This, with the 9th, and 13th species, will thrive in the open air, and require no other culture but to take up the roots every second or third year, to separate the bulbs; for some of them multiply fast, and when the bunches of bulbs become large, they do not flower so strong. They ought to be taken up soon after their stalks and leaves decay, and spread on a mat in a dry shady room for a fortnight, to dry; after which they may be kept in boxes till Michaelmas, when they may be planted in the border of the flower-garden, and treated in the same way as the common Hyacinths. They are easily increased by offsets, which they send out in plenty; so that there is no occasion to sow the seeds, unless it be to gain new varieties.

11. *Hyacinthus Convallarioides*; *Lily Hyacinth*. Corollas bell-shaped, ovate, pendulous; scape filiform; flowers without leaves, yellow.—Found by Thunberg at the Cape.

12. *Hyacinthus Monstrosus*; *Feathered Hyacinth*. Corollas subovate; root large, bulbous, producing several plain leaves, a foot long, and half an inch broad; flower-stalk a foot and half high, naked at the bottom for about seven or eight inches, above which the panicles of flowers begin and terminate the stalks. The flowers stand upon peduncles, which are more than an inch long, each sustaining three, four, or five flowers, the petals of which are cut into slender filamenta like hairs: they are of a purplish blue colour, and having neither stamina nor germen, never produce seeds. It flowers in May; and after the flowers are past, the stalks and leaves decay to the root, and new ones arise in the following spring.—Native of the south of Europe.

13. *Hyacinthus Comosus*; *Purple Grape Hyacinth*. Corollas angular-cylindrical, the upper ones barren, on longer pedicels; bractes small, acuminate; bulb as large as a middling-sized onion; leaves five or six, a foot or eighteen inches long; flower-stalks above a foot high, lower half naked, upper half sustaining a loose raceme of flowers; the lower flowers are farther asunder, and upright before they expand, but whilst they continue, and afterwards, stand out horizontally on pedicels half an inch long; their colour is a yellowish green, with blue or purple at the end; these are fertile.

The upper ones are smaller, barren, stand upright, form a corymb, and are blue or violet, as are also their long pedicels. Parkinson remarks, that "the whole stalk with the flowers upon it doth somewhat resemble a long purse-tassel, and thereupon divers gentlewomen have so named it." This species is more distinguished by its singularity than its beauty, and by the difference between the lower and the upper barren flowers. It varies with white and blue flowers, but the purple is most common. They appear with us at the end of April and beginning of May. Mr. Miller received both roots and seeds from Spain and Portugal.—Native of the corn-fields in the south of Europe. Mr. Curtis calls it *Tassel Hyacinth*: this is the name Parkinson alluded to; see above.

14. *Hyacinthus Botryoides*; *Blue Grape Hyacinth*. Corollas globular, uniform. Leaves channelled, cylindrical, strict, three lines wide, straight on account of their short petioles; spike with from twenty to thirty flowers; the teeth of the corolla are white, and the uppermost are small. It differs from the next species, in having the leaves upright, the bunch of flowers smaller, the flowers themselves larger, rounder, of a paler and brighter blue. It is now seldom met with but in long-established gardens; whenever once admitted, it is not easily rooted out; and if permitted to scatter its seed, will fill the ground with its roots.—Native of the vineyards and arable fields of France, Italy, and Germany. This and the next species are alike troublesome by their great increase; and this will not flower readily in an open border. It is a good method to plant the bulbs in moderately sized pots, filled with light earth, and to plunge them in the borders to flower: in the autumn they should be taken out, and the offsets thrown away.

15. *Hyacinthus Racemosus*; *Clustered Grape Hyacinth*. Corollas ovate, the upper ones sessile; bractes solitary, very short; leaves loose. Bulb small; scape a span high, blue under the flowers, compressed at top, terminated by a close globular spike or raceme, of from forty to fifty dark blue flowers, with a three-cornered mouth: they are imbricated downwards, have very short peduncles, a sweetish smell, somewhat like new starch or plums: hence Mr. Curtis calls it the *Starch Hyacinth*. This is more common in our gardens than the preceding, for which it is often mistaken: it flowers in April and May.—Native of corn-fields in the south of Europe.—For its propagation and culture, see the preceding species.

16. *Hyacinthus Brevifolius*; *Short-leaved Hyacinth*. Corollas six-parted; raceme drooping; leaves shorter than the scape.—Native of the Cape.

17. *Hyacinthus Flexuosus*; *Bending Hyacinth*. Corollas bell-shaped; raceme upright; leaves linear, longer than the scape.—Native of the Cape.

Hydnum; a genus of the class Cryptogamia, order Fungi.—GENERIC CHARACTER. A horizontal fungus, echinated beneath with awl-shaped fibres. These awl-shaped bodies, which Linneus compares to the prickles of a hedge-hog, are soft, solid, conical, or cylindrical substances, emitting seeds from every part of their substance. Linneus has six species of this fungus, five with stems, and one stemless. Of these Hudson has three, all having a stem. Dr. Withering enumerates five with a stem, and six without. Swartz has added three from Jamaica; and Albertini has added two more very minute species.—They chiefly grow upon decaying wood.

Hydrangea; a genus of the class Decandria, order Digenia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-toothed, permanent, small. *Corolla*: petals five, equal, roundish, larger than the calix. *Stamina*: filamenta ten, longer than the corolla, alternately longer and shorter; an-

theræ roundish, twin. *Pistil*: germen roundish, inferior; styles two, short, distant; stigmas blunt, permanent. *Pericarp*: capsule roundish, twin, two-beaked with the double style, angular with several nerves, crowned with the calix, two-celled, with a transverse partition, opening by a hole between the horns. *Seeds*: numerous, angular, acuminate, very small. ESSENTIAL CHARACTER. *Capsule*: two-celled, two-beaked, containing many seeds. *Corolla*. five-petalled. *Calix*: five-cleft, superior.—The species are,

1. *Hydrangea Arborescens*; *Shrubby Hydrangea*. Leaves ovate, smooth, alternate; stamina longer. This has a spreading woody root, which produces several soft, pithy, woody stems, from three to four feet high; they are four-cornered when young, and have a green bark, but as they grow older they become taper, and have a light brown bark; leaves at each joint opposite, three inches long, and two broad near the base, pointed, serrate, deep green above, pale underneath, with many transverse veins; flowers terminating in a cyme; corolla small, white, having an agreeable odour. They appear towards the end of July, and in August, but seldom perfect their seeds in England.—Native of Virginia and Canada. It is easily increased, by parting the roots at the end of October, which is also the best time to transplant them. It should have a moist soil, for it grows naturally in marshy places, and requires no other culture but to be kept free from weeds, and to have the ground between them dug every winter. If the stalks should be killed by severe frosts, the root will send out new ones in the spring.

2. *Hydrangea Radiata*; *Downy Hydrangea*. Leaves lobed, tomentose underneath. The stem is rather shrubby, branched, and growing to the height of about five feet. The leaves are broad, heart-shaped, and serrated: they are foot-stalked, and stand opposite; the lower surface is downy, of a silvery appearance.—Found in Carolina and Florida.

3. *Hydrangea Hortensis*; *Garden Hydrangea*, or *Chinese Guilder Rose*. Leaves elliptical, serrate, very smooth; stamina all of an equal length. Root fibrous, much branched, whitish; stems several growing together, erect, shrubby, branched, round, with a smooth brown bark; branches opposite, each pair crossing the others, round, smooth, leafy, green, with dark purple spots, flowering at the top; cymes terminating, the size and figure of the Common Guilder Rose, and, like that, almost entirely composed of radiated abortive flowers, of a beautiful rose colour, inodorous, green when young, as well as in decay.—Native of China and Japan. Loureiro informs us, that on dissecting the germen, and viewing it with a microscope, it appeared to be many-seeded, which confirms the idea of its being an *Hydrangea*. It is much valued on account of the profusion of its elegant flowers, which are botanically termed *monstrous*, in the same manner as the *Viburnum Opulus*, or European Guilder Rose.—This beautiful plant being very easily increased by cuttings, has been pretty generally diffused within these few years. It thrives best in a good rich loam. Some trials have been made with it abroad, and it is hardy enough, in a sheltered situation and warm soil, to endure most of our winters; but it does not flower so well in the open air as in a green-house: superfluous plants only should, therefore, be ventured in the open borders of the flower-garden.

Hydrastis; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals three, ovate, regular. *Stamina*: filamenta numerous, linear, compressed, a little shorter than the corolla; antheræ compressed, blunt. *Pistil*: germen numerous, ovate, collected into an ovate head; styles very short; stigmas broadish, compressed. *Pericarp*: berry compounded of oblong

granulations. *Seeds*: solitary; oblong. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: three. *Nectary*: none. *Berry*: composed of one-seeded acini, or granulations.—The only known species is,

11. *Hydrastis Canadensis*; *Canadian Yellow Root*. The root is composed of thick fleshy tubers, of a deep yellow colour within, but covered by a brown skin, sending out fibres from every part in the spring. It sends up one or two stalks, about nine inches high, at their first appearance of a light green, but afterwards changing to a purplish colour, and hairy towards the top. Each stalk has one or two leaves, the lower petioled, but the upper embracing; and is terminated by one flower, which is white, and of very short duration, seldom continuing above three or four hours after its expansion. The fruit is red and succulent, a compound berry, like the Raspberry and Mulberry, but not the least resembling the Strawberry in structure.—It flowers in May and June; and is a native of Canada. This plant not increasing much, is rather uncommon in the English gardens: it delights in great shade and moisture; and when planted in dry ground, or much exposed to the sun, it rarely lives through one summer. In a moist loamy soil and shady situation, it will flourish, if left undisturbed three or four years.

Hydrocharis: a genus of the class Dicoecia, order Enneandria.—**GENERIC CHARACTER.** *Male*. *Calix*: spathe three-flowered, two-leaved, oblong; perianth proper three-leaved; leaflets ovate-oblong, concave, membranaceous at the edge. *Corolla*: petals three, roundish, flat, large. *Stamina*: filaments nine, awl-shaped, upright, in three rows, the middle one puts forth an awl-shaped stipe from the inner base, like a style, which is placed in the centre; the two others are connected at the base, so that each inner filament coheres with each outer; antheræ simple. *Pistil*: the rudiment of a germen in the centre. *Female*. *Calix*: spathe none; flowers solitary. *Perianth*: as in the male, superior. *Corolla*: as in the male. *Pistil*: germen roundish, inferior; styles six, the length of the calix, compressed, bifid, channelled; stigmas bifid, acuminate. *Pericarp*: capsule coriaceous, roundish, six-celled. **SEEDS**: numerous, very small, roundish. **ESSENTIAL CHARACTER.** *Male*: spathe two-leaved. *Calix*: trifid. *Corolla*: three-petalled. *Filamenta*: the three inner style-bearing. *Female*. *Calix*: trifid. *Corolla*: three-petalled. *Styles*: six. *Capsule*: six-celled, many-seeded, inferior.—The only known species is,

1. *Hydrocharis Morsus Ranæ*; *Frog-bit*. Root of many long, thick, white fibres; leaves at each joint of the stalk six or eight together, floating, roundish, kidney-shaped, fleshy, smooth, thick, perfectly entire, almost transparent, reddish underneath, marked with a few circular and many transverse veins: they are about an inch and half in diameter, and when dry, on removing the outer skin, a most beautiful close net-work of veins is seen. Leaf-stalks and flower-stalk each from six to seven inches long; the latter upright, in the male producing three or four flowers, in the female only one; corolla white, with a yellow bottom, a little wrinkled and tender; calix yellow. There is a variety with a double, very sweet-smelling flower, found by Mr. Ray in a ditch by the side of Audrey Causeway, close to the great wooden bridge in the Isle of Ely. Hill and Meyrick inform us, that the leaves of these plants are of a very cooling nature, and are often externally applied by the country people for swellings and inflammations. It flowers from June through the autumn.—Native of most parts of Europe, in deep ditches, and slow streams with a muddy bottom; multiplying itself greatly by runners, which shoot out to a great length, and at the joints drop down long roots which penetrate deep into the mud.

Hydrocotyle; a genus of the class Pentandria, order Digenia.—**GENERIC CHARACTER.** *Calix*: umbel simple; involucre commonly four-leaved, small; perianth scarcely any. *Corolla*: universal uniform in figure, not in situation; florets all fertile; proper five-petalled; petals ovate, acute, spreading, entire. *Stamina*: filaments five, awl-shaped, shorter than the corolla; antheræ very small. *Pistil*: germen upright, compressed, orbiculate, inferior, peltate; styles two, awl-shaped, very short; stigmas simple. *Pericarp*: none; fruit orbiculate, compressed, transversely bipartite. *Seeds*: two, semi-orbiculate, compressed. **ESSENTIAL CHARACTER.** *Umbel*: simple, with a four-leaved involucre. *Petals*: entire. *Seeds*: semi-orbiculate, compressed.—The species are,

1. *Hydrocotyle Vulgaris*; *Common Marsh Pennywort*. Leaves peltate, crenate; umbels five-flowered. Roots perennial, capillary, whitish; stems creeping, round, smooth, striking root at the joints; leaves smooth, glossy, bright green, about an inch in diameter; leaf-stalks about two inches long; common peduncles single, axillary from the base of the leaf-stalks, which are terminated by two umbels or glomerules, one springing out of the other, each containing from four or five to six and nine florets, which are very small, reddish white, or rose-colour, on very short pedicels; seeds of a pale brown colour. The rot in sheep has been vulgarly attributed to this plant, whereas it is pretty certain that neither sheep nor any other quadruped ever eat it. It flowers with us from May or June through July or August; and is a native of the marshes all over Europe, and also of Jamaica and Japan.—There is a variety of this species, called the Italian Floating Hydrocotyle, which has very slender simple fibres, collected into a head, issuing from the joints of the stems, and fastening themselves into the mud. It is a native of Italy. The flowers of these plants being small and hidden by the leaves, are not much remarked, though they are abundant in their season; but the plant is easily known by the petiole of the leaf being inserted into the middle of it, a circumstance uncommon in European plants. Gerarde calls it Water Pennywort, Sheep-killing Penny-grass, and Penny-rot; the Germans call it, *Wassernabel*, *Sumps-nabel*; the Dutch, *Water-navel*; the French, *Hydrocotille Commune*, *le Goblet*, *l'Eenelle d'Eaux*, *l'Herbe des Patagons*; and the Spaniards, *Sombrera d'Agua*.

2. *Hydrocotyle Umbellata*; *Navelwort*. Leaves peltate, crenate-gashed; umbels many-flowered. Linnæus describes it as so like the common sort that it has been confounded with it; but it differs in having the scape twice as long as the leaves, and more than twenty florets in a simple umbel.—Native of the marshes of Jamaica.

3. *Hydrocotyle Americana*; *American Navelwort*. Leaves kidney-form, sublobate, crenate. It has the appearance and size of the first species.—Native of North and South America, and the East Indies.

4. *Hydrocotyle Hirsuta*; *Hairy Navelwort*. Hirsute; leaves kidney-form, lobate, crenate; whorls four-flowered.—Native of Hispaniola.

5. *Hydrocotyle Asiatica*. Leaves kidney-form, toothletted.—Native of the East Indies, Japan, and the Cape.

6. *Hydrocotyle Chinensis*. Leaves linear; umbels many-flowered.—Native of China.

7. *Hydrocotyle Villosa*. Leaves cordate, entire, villose. Root fibrous; peduncles several, filiform, shorter than the leaves, one-flowered.—Native of the Cape.

8. *Hydrocotyle Glabra*. Leaves obovate, smooth; stems creeping; flowers axillary, peduncled.—Native of the Cape.

9. *Hydrocotyle Virgata*. Leaves linear, smooth.—Native of the Cape.

10. *Hydrocotyle Linifolia*. Leaves linear-lanceolate, hirsute, entire. It resembles the preceding, but has longer leaves and peduncles.—Native of the Cape.

11. *Hydrocotyle Tomentosa*. Leaves obovate, toothed, tomentose; root caulescent, branched on the surface of the earth. The whole plant hoary, tomentose; peduncles lateral next the lower leaves, and of the same length with them; receptacle of the flowers very dark purple; petals white.—Native of the Cape.

12. *Hydrocotyle Tridentata*. Leaves wedge-shaped, trifid, villose.—Native of the Cape.

13. *Hydrocotyle Ranunculoides*. Leaves five-parted, gashed; stem creeping, jointed; umbels simple; petals white.—Native of Mexico, discovered by Mutis.

14. *Hydrocotyle Erecta*. Leaves cordate, crenate; scapes the length of the petioles, having a few flowers at the top.—Native of Jamaica.

15. *Hydrocotyle Moschiata*. Leaves kidney-form, seven-lobed, serrate, villose; umbels many-flowered.—Native of New Zealand.

Hydrolea; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth five-parted; parts oblong, acute, unequal, permanent. *Corolla*: one-petalled, wheel-bell-shaped; tube shorter than the calix; limb five-parted, spreading; segments ovate, incumbent. *Stamina*: filamenta five, awl-shaped, cordate at the base; antheræ oblong, curved, incumbent. *Pistil*: germen ovate; styles two, filiform, spreading; stigmas truncate. *Pericarp*: capsule ovate, two-celled, two-valved; partition contrary. *Seeds*: very many, minute, imbricated, with an ovate large receptacle. *Observe*. In some flowers the calix and corolla are six-cleft, with six stamina. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: wheel-shaped. *Filamentu*: cordate at the base. *Capsule*: two-celled, two-valved.—The species are,

1. *Hydrolea Spinosa*; *Prickly Hydrolea*. Stem with axillary spines; flowers clustered, terminating; spines axillary, spreading.—Native of South America.

2. *Hydrolea Inermis*; *Unarmed Hydrolea*. Stem unarmed; flowers solitary, lateral, blue; corolla wheel-bell-shaped. Annual.—Native of moist places near Canton in China.

3. *Hydrolea Zeylanica*. Stem unarmed; flowers subracemed; leaves lanceolate, alternate, petioled, oval-oblong, quite entire, sharpish, even; peduncles opposite to the leaves, axillary, or terminating; one-flowered; corolla blue.—Native of the East Indies.

4. *Hydrolea Trigynia*. Stem spiny; leaves oblong, hirsute; flowers three-styled, axillary.—Native of the West Indies.

Hydrophylax; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, upright, four-parted, superior, permanent; segments ovate, acute, margined, somewhat fleshy. *Corolla*: one-petalled, funnel-form; tube longer than the calix; limb angular, four-cleft; segments ovate, revolute; throat bearded. *Stamina*: filamenta four, placed on the tube, decurrent, upright, longer than the corolla; antheræ subhastate. *Pistil*: germen oblong, inferior; style filiform, curved; stigma bifid. *Pericarp*: berry juiceless, ovate, compressed, with three ribs on each side, the middle one higher, with an attenuated margin, a little bowed in, fungous, two-celled, with a transverse partition. *Seeds*: solitary, oblong, bowed in a little, three-sided; two-grooved on the inner side, somewhat rugged. ESSENTIAL CHARACTER. *Calix*: four-parted. *Corolla*: funnel-form. *Fruit*: ancipital, one-seeded.—The only known species of this genus is,

1. *Hydrophylax Maritima*. Root simple, filiform, blood-

red, long, fleshy, sweet; stem creeping, filiform, smooth, coloured, jointed, sheathed with blunt, membranaceous, permanent sheaths, very long; leaves opposite, spreading, ovate-acute, quite entire, approximating, fleshy, shining; flowers axillary, subsessile, usually two together, but not opposite, erect; corolla pale blue; antheræ blue. It has the appearance of *Arenaria Rubra Maritima*, but is larger.—Found in the driving sand upon the sea-shore near Guduluhr in the East Indies.

Hydrophyllum; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, scarcely shorter than the corolla, spreading, permanent, with awl-shaped segments. *Corolla*: one-petalled, bell-shaped, five-cleft; segments upright, obtuse, emarginate. Nectary a cleft closed by two longitudinal converging plates, fastened to the petal within the middle of each segment. *Stamina*: filamenta five, awl-shaped, longer than the corolla; antheræ incumbent, oblong. *Pistil*: germen superior, ovate, acuminate; style awl-shaped, the length of the stamina; stigma bifid, acute, spreading. *Pericarp*: capsule globular, one-celled, two-valved. *Seed*: single, round, large; (according to Gærtner, four, resting within a berried receptacle.) ESSENTIAL CHARACTER. *Corolla*: bell-shaped, having five longitudinal melliferous streaks on the inside. *Stigma*: bifid. *Capsule*: globular, two-valved.—The plants of this genus endure cold well, but require to be planted in a moist rich soil, and shady situation, and will not thrive in a warm dry soil unless constantly watered in dry weather. They may be increased by parting the roots in autumn, and will require abundant watering, if not well rooted before the spring.—The species are,

1. *Hydrophyllum Virginicum*; *Virginian Water-leaf*. Leaves pinnatifid. The root is composed of many strong fleshy fibres, which spread wide on every side; from this arise many leaves on footstalks five or six inches long, of a lucid green. The flowers rise with footstalks from the root, having one or two small leaves of the same shape with the lower; they are in loose clusters hanging down, and of a dirty white colour, making no great show; seeds regularly four, but often fewer, nestling in the receptacle, irregularly ovate and angular, elegantly netted, with very minute excavations. It flowers here in May and June, sometimes ripening seed in August.—Native of moist spongy ground in Virginia and Carolina.

2. *Hydrophyllum Canadense*; *Canadian Water-leaf*. Leaves lobate, angular. It has the same structure as the preceding, differing only in the leaves, which have the same shape as those of the Maple. It flowers in May; and is a native of Canada.

3. *Hydrophyllum Appendiculatum*. Plant very rough; radical leaves somewhat winged; bunches of flowers subpinnulate; flowers pale blue, the calix extremely hispid, and almost the length of the corolla.—Found on shady rocks near springs in Virginia; also near Harper's Ferry, Tennessee, North America.

4. *Hydrophyllum Lineare*. Leaves linear; branches elongated.—Found by Mr. Lewis on the banks of the Missouri.

Hymenæa; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, coriaceous; tube short, turbinate, compressed, permanent, with an oblique mouth; limb five-parted, almost regular, upright, deciduous; segments ovate, blunt; two opposite, flatish, a little broader; two others concave, with one side narrower. *Corolla*: five-petalled, inserted into the neck of the calix, somewhat subpapilionaceous; petals almost equal; banner, the two uppermost petals obliquely ovate, obtuse,

sessile, at the upper concave segment of the calix; wings, two petals similar, lateral, a little narrower; keel, the lowest petal, channelled and excavated, approximating to the wings, within the hollow segment of the calix. *Stamina*: filamenta ten, distinct, awl-shaped, erect, bent down above the middle, very long, between the keel and the wings, inserted into the neck of the calix; antheræ linear, fixed by the back. *Pistil*: germen sabre-shaped, compressed, pedicelled; style very long, bristle-shaped, bent down; stigma thickened, obliquely truncate. *Pericarp*: legume woody, very large, ovate-oblong, obtuse, one-celled, filled with farinaceous pulp. *Seeds*: several, four to eight, large, ovate, wrapped up in pollen and fibres. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Petals*: five, almost equal. *Style*: twisted inwards. *Legume*: filled with a farinaceous pulp.—The only known species is,

1. *Hymenæa Courbaril*; *Loeust Tree*. Stem large, covered with a russet bark, dividing into many spreading branches, garnished with smooth stiff leaves which stand by pairs, their base joining at the footstalk. The flowers are produced in loose spikes at the end of the branches, some of the short ligneous footstalks supporting two, and others three flowers, which are composed of five yellow petals striped with purple; and are succeeded by thick fleshy brown pods, shaped like those of the garden bean, six inches long, and two and a half broad, of a purplish brown colour, and ligneous consistence, containing three or four seeds, enclosed in a whitish substance of fine filamenta as sweet as honey. This substance, which purges when fresh gathered, but loses that property as it grows old, is eaten by the Indians with great avidity. The wild bees are fond of building their nests in this tree, which grows to a considerable size, and is looked upon as excellent timber; but it must be very old before it is cut, otherwise the heart will be but small. It is in great request for wheel-work in the sugar-mills, particularly for cogs to the wheels, being extremely hard and tough, capable of receiving a fine polish, and so heavy that a cubic foot weighs a hundred pounds. From between the principal roots of the tree a fine yellowish or red transparent resin, called gum-anime, exudes. It is collected in large lumps, and makes a varnish superior to Chinese lacca, when dissolved in the highest rectified spirits of wine. It burns readily, and with a clear flame, emitting a grateful fragrant smell, on which account it is sometimes ordered by way of fumigation, in the chambers of persons labouring with asthmas or suffocating catarrhs. Its vapours not only strengthen the head, but all parts of the body affected with cold. Some apply it outwardly, dissolved in oil or spirits of wine, to strengthen the nerves. An oil may be distilled from it, efficacious in palsies, cramps, and contractions of the sinews. A decoction of the leaves expels flatulencies; and gives ease in colic pains, by gently opening the bowels; and the inward bark is an excellent vermifuge, in substance or decoction.—Native of the West Indian Islands, where it grows in great plenty. It is easily raised from fresh seeds, which must be sown in pots, and plunged into a hot-bed of tanners' bark. There should be but one seed put into each pot, or, if there be more, when the plants appear they should be all drawn out to one, soon after they come up, before their roots entangle, when it will be hazardous doing it; and if great care be not taken, the plant intended to be left, may be drawn out with the other. As the roots are but slender, this plant is very difficult to remove, for unless a ball of earth be preserved to their roots, they seldom survive their removal, and on that account they must be seldom transplanted from one pot to another. The plants must constantly remain in the tan-bed in the stove, and should be treated in the same way as other tender plants of the same country, giving them but

little water, especially in the winter. They make considerable progress for two or three months after they first appear; after which they will perhaps stand a whole year without shooting, growing very like the Cashew-nut, or Anacardium, and being very difficult to preserve long in this country.

Hyobanche; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth seven-leaved; leaflets linear, acuminate, erect, the length of the corolla. *Corolla*: one-petalled, ringent; upper lip vaulted, emarginate; lower none. *Stamina*: filamenta four, twin, inserted into the base of the corolla, of a middling length; antheræ ovate, nodding, opening on the upper side. *Pistil*: germen ovate; style filiform, curved at the top; stigma thickened, blunt, emarginate. *Pericarp*: capsule roundish, two-celled. *Seeds*: numerous, small. *Observe*. The calix and corolla prevent it from being associated with *Orobanche*. **ESSENTIAL CHARACTER.** *Calix*: seven-leaved. *Corolla*: ringent, without any lower lip. *Capsule*: two-celled, many-seeded.—The only known species is,

1. *Hyobanche Sanguinea*. Stem half a foot high, quite simple, woody, thick, closely imbricated with leaves, or rather ovate scales, convex on the outside, smooth, blunt; spike terminating, dense, fleshy, villose, the length of the stem, and three times as broad, imbricated with bractes and flowers. The whole plant resembles the *Orobanche* in structure, but is blood-red.—Parasitical at the roots of shrubs, at the Cape of Good Hope.

Hyoseyamus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, ventricose at bottom, with a five-cleft sharp mouth, permanent. *Corolla*: one-petalled, funnel-form; tube cylindrical, short; limb from erect spreading, half five-cleft; segments obtuse, one broader than the others. *Stamina*: filamenta five, awl-shaped, inclining; antheræ roundish. *Pistil*: germen roundish; style filiform, the length of the stamina; stigma headed. *Pericarp*: capsule ovate, obtuse, marked with a line on each side, two-celled, two capsules closely approximating, with a lid opening horizontally; receptacles half ovate, fixed to the partition. *Seeds*: numerous, unequal, irregular. *Observe*. The seventh and eighth species differ in having the fruit seldom opening, and a more regular corolla. **ESSENTIAL CHARACTER.** *Corolla*: funnel-form, obtuse. *Stamina*: inclined. *Capsule*: two-celled, covered with a lid.—This genus consists of biennial plants, which perish soon after they have perfected their seeds. They flower in June and July, and their seeds ripen in the autumn, which, if permitted to scatter, will produce plenty of the plants in the following spring; or if the seeds be sown at that season, they will succeed much better than plants sown in the spring, which seldom come up in the same year. They are all hardy except the second species, and require no other culture than weeding and thinning where they grow too close.—The species are,

1. *Hyoseyamus Niger*; *Black or Common Henbane*. Leaves stem-clasping, sinuate; flowers sessile. It has long fleshy roots, which strike deep into the ground, and are branched; bottom leaves soft, deeply gashed on their edges, and spreading on the ground. The stalks, which do not rise till the second spring, have leaves of the same shape, but smaller and clasping, and about two feet high: on the upper part are flowers standing on one side in a double row, sitting close to the stalk alternately. The corolla is yellow, or rather pale yellowish-brown, beautifully netted with purple veins, and a dark purple eye or base; seeds very abundant, gray, excavated and angular. The whole plant is covered with unctuous fetid hairs, producing a strong and peculiar odour, greatly

HYPERICUM MONOGYNUM — *Chinese St. John's Wort*

H. Frederick, sc.

affecting the head of some persons as soon as they come within its atmosphere. Linneus says, that it is not touched by any animal except the goat, who is not partial to it. He informs us that the roots of it scattered about a house will drive away mice; but who would endanger the lives of children and ignorant persons by strewing their apartments with so dangerous a root, which the illustrious Swede himself acknowledges to have been frequently eaten for parsnips, producing delirium, madness, convulsions, and death. The root, herb, and seeds, taken internally, are deservedly reputed poisonous, for well-attested instances of their bad effects are recorded. Notwithstanding this, however, Henbane has been used as a medicine from time immemorial, and there is no doubt of its being a useful medicine under proper management. The Edinburgh college orders the expressed juice of the plant to be evaporated to an extract, in which state it may perhaps be advantageously joined with opium, where the purgative effects of that medicine are desirable, and costiveness is to be avoided: the dose is from half a scruple to half a drachm. Villars says, the extract may be safely given in a dose of two or three grains, gradually increasing the quantity; but that it ought to be prepared from the plant just going into flower, and in balneo mariæ, for it has neither odour nor activity, if the plant be young, or if the extract be made with an open strong fire. He administered it internally in epilepsy and convulsions, and found that it put off the fits, and diminished their violence, though it did not effect a cure. Baron Stoerck, and others, have not only recommended it in the above disorders, but in mania, hæmoptoe or spitting of blood, the dry cough, and universally wherever an anodyne is wanting to quiet the nervous irritation; beginning with a single grain of the extract, and gradually increasing the dose to five grains. Some more daring practitioners proceed as far as fifteen grains; but in general it is more advisable to continue the use of the medicine longer, than to give it in very large doses. It has been administered, even in a cataract, to the quantity of two grains, mixed with Mercurius Dulcis. The leaves, bruised and fried, have been successfully applied to the piles, and in muscular spasms. Like other narcotics, they assist in softening indurations of the glands. An oil expressed from the seeds is used outwardly as an anodyne; and the common people sometimes smoke them for the toothache, or put a piece of the root boiled in milk at the root of the tooth. The roots also cut in pieces, and strung like beads, are used for anodyne laces to hang about children's necks, for preventing fits, and causing the teeth to breed easily. A decoction of the Henbane has been given in clysters, to assuage pangs of the intestines; but this is dangerous; and, indeed, taken altogether, Henbane is a medicine not to be trifled with, nor to be at all taken without good advice. Mr. Miller warns us, that a mixture of these roots having been imported with Gentian, were productive of very bad effects.—A variety of this species, has the corolla and antheræ of a pure brimstone colour, without the least tinge of purple. The seeds being sown in the botanic gardens at Chelsea, produced the very same variety. Henbane is a biennial plant, flowering in June, and native of waste places, particularly near towns and villages in most parts of Europe. It probably obtained its English name from a notion that it is injurious to poultry, which, whether true or not, we have had no opportunity of ascertaining. The Germans call it, *Bilsenkraut*; the Dutch, *Bilsenkruid*; the Danes *Bulme*, *Honsebane*, &c.; the Swedes, *Bolmort*, *Honsabale*; the French, *La Jusquame*; the Italians, *Giusquiamo*, *Fava-porcina*; the Spaniards, *Beleno*, *Veleno*; the Portuguese, *Mienendro*, *Velenho*, *Yoscramo*; and the Russians, *Belena*.

2. *Hyoscyamus Reticulatus*; *Egyptian Henbane*. Stem-leaves petioled, cordate, sinuate, acute; floral-leaves quite entire; corollas ventricose. It rises with a branching stalk two feet high; the whole plant is smooth; flowers on a very short peduncle; corolla bell-shaped, red, beautifully netted with dark veins. Annual, flowering in July.—Native of Egypt, Syria near Aleppo, and of the island of Candia. This plant requires a warm situation and a dry soil, in which it will endure the winter better than in rich ground.

3. *Hyoscyamus Albus*; *White Henbane*. Leaves petioled, sinuate, obtuse; flowers sessile. This resembles the Black in most circumstances, but the leaves are more rounded or obtuse, petioled, sinuate, very soft, bearded with white hairs, as is also the stem; flowers fewer, the lower on longer peduncles, the upper on very short ones. The corolla varies with the base dark purple or green.—Annual, flowering in August, and a native of the south of Europe. The seeds, which are very numerous, small, compressed a little, incurved or kidney-form, closely scrobiculate and whitish ash-coloured, are recommended as cooling, emollient, and excellent to ease pain. They procure sleep like opium, but without affecting the head. Taken in doses of half a scruple, they assuage the pain arising from colic, and are excellent in coughs and other disorders of the breast, spitting of blood, immoderate menstrual discharges, and all other hæmorrhages.

4. *Hyoscyamus Auræus*; *Golden-flowered or Shrubby Henbane*. Leaves petioled, toothed, acute; flowers peduncled; fruits pendulous. This is a perennial plant, with weak stalks requiring support. The flowers come out at each joint of the stalk; they are large, and of a bright yellow, with a dark purple bottom. The style is much longer than the corolla. Prosper Alpinus, and others, make two varieties of this, differing only in size, and the shade of colour in the corolla. It flowers most part of the summer, and sometimes ripens seed in autumn.—Native of Candia, and other parts of the Levant. The seeds sown in pots as soon as they are ripe, and placed under a hot-bed frame in winter, will produce plants in the spring, but rarely succeed if put in the ground at that season. This species will last several years in pots, if screened from the frosts in winter, when it must be placed under a common hot-bed, where it may enjoy as much free air as possible, and will thrive better there than if more tenderly treated. It may be easily propagated by cuttings, which, if planted in a shady border during any of the summer months, will take root in five or six weeks, and may be removed into pots, and treated like the old plants.

5. *Hyoscyamus Muticus*; *Awnless Henbane*. Leaves petioled, ovate, acute-angular; calices awnless; bractes undivided. Stem a foot high, a finger thick, erect, roundish; corolla on the outside at first green, then whitish, on the inside very dark purple, with the two lowest segments whitish, but finally the whole corolla becomes white and unspotted. Biennial.—Native of Egypt and Arabia.

6. *Hyoscyamus Pusillus*; *Dwarf Henbane*. Leaves lanceolate, toothed; lower floral leaves in pairs; calices spiny. Stem a hand high, brittle, oblique, undivided, having long hairs; corolla yellow, with a dark throat. Annual; flowering in July.—Native of Persia.

7. *Hyoscyamus Physaloides*; *Purple-flowered Henbane*. Leaves ovate, quite entire; calices inflated, subglobular. Root perennial; stems a foot high, simple, erect, round, rough-haired; corollas purplish, funnel-form, upright.—Native of Siberia.

8. *Hyoscyamus Scopolia*; *Nightshade-leaved Henbane*. Leaves ovate, entire; calices inflated, bell-shaped, even. Root perennial, transverse, knobbed, thick, irregular, branched,

flexuose, the thickness of the human thumb; stem herbaceous, upright, round, smooth; peduncles one-flowered, pendulous from the axils, weak, two inches long; corolla of the same shape and colour as in *Atropa Belladonna*; seeds kidney-form, rather large, elegantly dotted very closely in rows, with little holes, and of a very pale yellow colour. It flowers with us in May; and in April in the woods of Idria in Friuli, of which it is a native.

Hyoseris; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common cylindrical, angular, consisting of about eight leaves, permanent; scales lanceolate, erect, acute, slightly keeled, equal; calicled at the base, with fewer, very short, close scales. *Corolla*: compound subimbricate, uniform, composed of many hermaphrodite corollets; proper one-petalled, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: germen oblong; style filiform, the length of the stamina; stigmas two, reflex. *Pericarp*: none; the common calix close or spreading. *Seeds*: solitary, oblong, membranaceous, streaked on one side along the middle, almost the length of the calix. ESSENTIAL CHARACTER. *Calix*: almost equal; down hairy and calicled; receptacle naked.—All the plants belonging to this genus, except the sixth, are hardy, and may easily be propagated from seeds either sown in the spring, or left to scatter of themselves. They require in general a dry soil.—The species are,

* *Stem naked.*

1. *Hyoseris Fœtida*; *Stinking Hyoseris*. Scapes one-flowered; leaves pinnatifid; seeds naked. Root perennial, single, cylindrical, thick, woody, fetid; flower middle-sized, yellow above, and red beneath. The whole plant has a disagreeable smell, and much resembles *Dandelion*, but the flower is smaller, and of a deeper yellow colour. They appear in July.—Native of the mountains of Italy, Dauphiny, Carniola, and Switzerland, and found in various parts of Germany and France.

2. *Hyoseris Radiata*; *Starry Hyoseris*. Scapes one-flowered; leaves smooth, runcinated, with toothed angles, lacinated at top. The peduncles and rachis of the leaves farinaceous.—Native of the south of France; the county of Nice, on hills near the coast; and of Spain.

3. *Hyoseris Lucida*; *Shining Hyoseris*. Scapes one-flowered; leaves somewhat fleshy, runcinate, angular, toothed. This very much resembles the preceding, but the leaves are thicker, lucid, and more shortly toothed. It flowers from June to August.—Native of the Levant.

4. *Hyoseris Scabra*; *Rugged Hyoseris*. Scapes one-flowered; leaves rugged; seeds downy. Annual.—Native of Sicily, Nice, and neighbourhood of Villa Franca.

5. *Hyoseris Virginica*; *Virginian Hyoseris*. Scapes one-flowered; leaves lanceolate, lyrate, smooth; corolla deep yellow; seeds four-cornered.—Native of Virginia.

6. *Hyoseris Pygmæa*; *Dwarf Hyoseris*. Scapes one-flowered; leaves spatulate, toothed, ciliate; calices hairy; hairs and cilia forked; down stiped, feathered. This is an annual plant, flowering in June and July; and a native of Madeira. It can only be raised in a green-house.

7. *Hyoseris Minima*; *Least Hyoseris*. Stem divided, naked; peduncles thickened. Root annual, small but woody, with a few rigid fibres; stems several, six to nine inches high, naked, round, smooth; leaves spreading in a circle, bluntly oval, tapering into the footstalks, toothed on the sides; corolla yellow; seeds oval, striated. Dr. Withering calls this plant Small Swine's-eye.—It flowers in May and June, and is a native of most parts of Europe, in pastures and corn-fields of

a sandy soil. Though not very common in England, it is found about Hampton Court, and in Teddington field; near Walthamstow, in Essex; Pershore, in Worcestershire; in the neighbourhood of Norwich; near Gamlingay, in Cambridgeshire; Spratton, in Northamptonshire; and about Forfar, and between Dundee and St. Andrews, in Scotland.

** *Stem leafy.*

8. *Hyoseris Hedypponis*; *Branching Hyoseris*. Fruits ovate, smooth; stem branched, weak, and bending at each joint; flower yellow, small, nodding. It flowers in June.—Native of the south of Europe.

9. *Hyoseris Rhagadioloides*; *Nipplewort Hyoseris*. Fruits ovate, hairy; stem branched.—It is an annual plant, flowering in July and August, and native of the south of Europe.

10. *Hyoseris Cretica*; *Cretan Hyoseris*. Fruits ovate, rugged; stem branched. Root annual, round, fibrous, white within, brown without; flowers solitary, erect, terminating, and axillary; corollets short, pale yellow. It flowers in May and June; with us in June and July.—Native of Candia, of the county of Nice, and common about Madrid.

11. *Hyoseris Montana*. Plant very glabrous, proeumbent; leaves lanceolate, very entire; scape one-flowered.—Found by Michaux on the mountains of Carolina.

12. *Hyoseris Angustifolia*. Leaves linear-lanceolate; scape one-flowered; flowers large, bright yellow.—Found in pastures and fields in Virginia and Carolina.

13. *Hyoseris Caroliniana*. Leaves lyrate at the base; scape one-flowered.—Native of Carolina.

Hypecoum; a genus of the class Tetrandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved, small; leaflets ovate, acute, erect, opposite, deciduous. *Corolla*: four-petalled, the two outer petals opposite, broader, trifid, obtuse, the two inner alternate with the others, semitrid; the middle segment concave, compressed, erect. *Stamina*: filamenta four, awl-shaped, erect, covered by the middle segment of the inner petals; antheræ erect, oblong. *Pistil*: germen oblong, cylindrical; styles two, very short; stigmas acute. *Pericarp*: siliques long, curved inwards, jointed. *Seed*: solitary in each joint of the pericarp, globular, compressed. ESSENTIAL CHARACTER. *Calix*: two-leaved. *Petals*: four, the two outer broader and trifid. *Fruit*: a siliques.—The plants of this genus being all annual, are propagated by seeds, which should be sown soon after they are ripe, on a bed of light fresh earth, where they are to remain, for they seldom succeed if transplanted. When the plants come up, clear them from weeds, and thin them to the distance of six or eight inches. When the seeds are sown in the spring, and the season proves dry, they will not grow the first year, but if the ground be kept clean from weeds, and not otherwise disturbed, the plants will come up in the following spring. The seeds will sometimes lie even till the third spring. Hence it is best to sow them in a warm border in autumn, which will produce stronger plants, and be more likely to perfect seeds than those sown in spring. The seeds should be divested of their fungous covering before they are sown, for that adheres so close that it prevents their growing until it be decayed. If the seeds are allowed to scatter, they will frequently come up of themselves without any care. In large gardens, these plants, which require little room, when intermixed with other small annuals, will make a pretty appearance in the borders.—The species are,

1. *Hypecoum Procumbens*; *Procumbent Hypecoum*. Siliques bowed, compressed, jointed. Root simple, sometimes bifid, long, but annual, having only a few fibres; leaves divided by many incisures resembling those of *Fumitory*, pale green with a tinge of grayish or glaucous colour, spread on

the ground; stems several, slender, somewhat compressed, naked at bottom, but having two or three small leaves at top; peduncles each sustaining one small yellow flower, appearing in June and July, producing seed in August.—Native of the south of Europe.

2. *Hypericum Pendulum*; *Pendulous Hypericum*. Siliques pendent, not jointed, bivalved, incurvated. Stalks slender. This flowers and seeds at the same time as the first species.—Native of the south of France.

3. *Hypericum Erectum*; *Upright Hypericum*. Siliques erect, round, torulose.—The juice of this and of the other species is of a yellow colour, resembling that of Celandine, and is said to operate like opium.—Native of Dauria and Istria.

Hypelate; a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** *Hermaphrodite Flowers.* *Calix*: perianth five-leaved, seldom four-leaved; leaflets ovate, concave, spreading, deciduous, two less than the others. *Corolla*: petals five, ovate, a little less than the calix, deciduous, with a nectariferous umbilicus about the germen. *Stamina*: filamenta eight, spreading round the base of the germen, the length of the corolla; antheræ ovate, cordate. *Pistil*: germen globular, superior; style short, upright; stigma bent down, three-sided, three-grooved, acute. *Pericarp*: drupe pulpy, roundish. *Seed*: nut oval, very smooth, with a single kernel. *Male Flowers* on the same tree, but upon a distinct panicle; calix and corolla as in the hermaphrodite: nectary also as in that; from the middle of this, the *Stamina*: filamenta eight, converging at the base, from erect reflex, and ascending, broader at the base; antheræ ovate, cordate. *Pistil*: three-cornered rudiment of a germen; style awl-shaped, very small. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled. *Stigma*: bent down, three-cornered. *Drupe*: one-seeded.—The only known species is,

1. *Hypelate Trifoliata*. This shrubby tree has several trunks, each as big as a man's leg, straight, eight or nine feet high, covered with a smooth cinnamon-coloured bark. Browne observes, that it is full of slender branches, and furnished with many leaves, of the same texture and grain as those of *Lignum Vitæ*, yet remarkably different in form and disposition.—Native of the low lands of Jamaica.

Hypericum; a genus of the class Polydelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth five-parted; segments subovate, concave, permanent. *Corolla*: petals five, oblong-ovate, obtuse, spreading, wheel-shaped, according to the sun's apparent motion. *Stamina*: filamenta numerous, capillary, united at the base in five or three bodies; antheræ small. *Pistils*: germen roundish; styles three, sometimes one, two, or five, simple, distant, the length of the stamina; stigmas simple. *Pericarp*: capsule roundish, with the same number of cells as there are styles. *Seeds*: very many, oblong. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Petals*: five. *Filamenta*: many, connected at the base in five bundles.—This extensive genus consists of herbs, shrubs, or under-shrubs, with cylindrical, ancipital, or quadrangular stems; roots perennial; leaves simple, opposite, sessile, entire, frequently with pellucid dots; flowers sometimes in cymes, but more frequently in corymbs, with the peduncles often trichotomous and three-flowered, terminating or axillary also; corolla yellow and brilliant. The whole herbage generally smooth, with glandular pellucid dots, and an aromatic scent; rarely downy. *Linneus* divides this genus into four subordinate parts from the number of styles. The predominating number however is three. *Jussieu* remarks, that it admits of being split into six genera: 1. With five styles, No. 1 to 12; and a capsule with five cells.—2. With three styles, and a three-celled capsule, with the

pencils of filamenta scarcely united at the base, as No. 14, &c.—3. With a soft pericarp resembling a berry, almost one-celled, turgid, with a blood-red juice, No. 13, &c. This division has three styles, and in other respects resembles that immediately preceding.—4. With three styles, and a pericarp of three cells, No. 48, &c. the filamenta united up to the middle, the disk of the germen glandular, as are also the claws of the petals.—5. With two styles and a two-celled pericarp, No. 54, 55, &c.—and, 6. With one style, No. 56, 57, &c. or five styles so closely joined as to seem one.—The species are,

* *With five Styles.*

1. *Hypericum Balearicum*; *Warted St. John's Wort*. Stem shrubby; leaves and branches warted. It rises with a slender, quadrangular, shrubby stalk about two feet high, but in its native soil attains the height of seven or eight feet, sending out several weak branches of a reddish colour, and marked with scars where the leaves have fallen off. Flowers terminating, large, bright yellow; capsules pyramidal, having a strong smell of turpentine, and filled with small brown seeds. It has a succession of flowers during great part of the year, and is therefore valuable.—Native of Majorca. This plant requires no artificial heat. If placed in a dry airy glass-case in winter, where protected from frost, it will thrive better than in a warmer situation. Damp air, however, must be avoided. They should be sparingly watered in winter, but three times a week in summer, when they may also be exposed to the open air. They are propagated by cuttings planted in June, in pots filled with light earth, and plunged into a very moderate hot-bed, shading them from the sun, and refreshing them with water. They will put out roots in six or seven weeks, when they should be carefully taken up, and each planted in a separate small pot, placing them in the shade till they have taken new root; then they should be removed to a sheltered situation, where they may remain till frost comes, when they must be put into a green-house or glass-case. It may also be increased by seeds in autumn.

2. *Hypericum Kalmianum*; *Virginian St. John's Wort*. Stem shrubby; leaves linear-lanceolate. Shrubby with quadrangular branches: at the end of each branch is produced one pretty large flower, with a blunt calix; stamina as long as the petals.—Native of North America. This, with the other North American sorts, seldom producing any seeds here, may be increased by parting the roots in autumn. It should have a light soil, and an open situation.

3. *Hypericum Cayanense*; *Cayenne St. John's Wort*. Corollas bearded; calices striated; leaves ovate; stem shrubby. This is an upright branching tree, eighteen feet high; racemes compound, terminating; petals white, hirsute within; fruit a berry, with a fulvous staining juice; seeds numerous.—Native of Cayenne.

4. *Hypericum Bacciferum*; *Berry-bearing St. John's Wort*. Corollas bearded; calices even; leaves ovate; stem shrubby, three fathoms high; flowers terminating, panicled, on short peduncles.—Native of Mexico and Brazil. It is a hardy plant.

5. *Hypericum Calicinum*; *Great-flowered St. John's Wort*, or *Tutsan*. Flowers solitary; stem suffruticose, branched; calices obovate, very blunt; leaves distich, oblong. The stalks of the large-flowering *Tutsan* are slender, and incline downwards; flowers terminating, peduncled, solitary, bright yellow. The stems are only tinged with red in some places; the leaves on the young shoots are of a beautiful light green, of regular ovate form, and half embrace the stem. It is very hardy, and increases much by the creeping roots. Like the *Periwinkle*, it is a plant well adapted to cover a bank, or bare spots under trees, where few other plants will thrive.—Native

of the country near Constantinople. To propagate it, part the roots in October.

6. *Hypericum Pyramidatum*; *Pyramidal St. John's Wort*. Flowers subpanicled; stem slightly four-cornered, herbaceous, branched; calices ovate, acute. It flowers in July and August.—Native country unknown.

7. *Hypericum Alterniflorum*; *Alternate-leaved St. John's Wort*. Flowers axillary, solitary; leaves lanceolate, alternate; stem shrubby.—Native of the East Indies.

8. *Hypericum Syriacum*; *Syrian St. John's Wort*. Calices leafy; stem herbaceous; leaves alternate, ovate, acute. Stem about a foot high; flowers panicled on the branches, terminating; petals ovate, concave, coriaceous.—Native of dry places in the Syrian desert.

9. *Hypericum Guineense*; *Guinea St. John's Wort*. Flowers subumbelled; stem shrubby; branches round; leaves ovate, acute; bark ash-coloured.—Native of Guinea.

10. *Hypericum Petiolatum*. Stem arboreous; leaves ovate. Panicle terminating, brachiata, the length of the leaf; petals obovate, straighter on one side, the length of the calix. It has the appearance of Bay, and abounds with a saffron-coloured juice.—Native of New Granada.

11. *Hypericum Patulum*. Flowers solitary, terminating; stem frutescent, lax; leaves ovate, rolled back at the edge. Corolla yellow, reddish underneath.—Native of Japan.

12. *Hypericum Ascyron*. Stem four-cornered, herbaceous, erect, simple; leaves even, quite entire. Flowers terminating; calix green; corolla pale yellow; petals an inch long.—Found upon the Pyrenees; also in Siberia and Canada. Linneus says the leaves are acute.

** *With three Styles.*

13. *Hypericum Androsæmum*; *Common Tutsan*. Fruits berried; stem shrubby, ancipital. Stem suffruticose or under-shrubby, two feet high, of a reddish colour, and smooth; branches spreading; leaves opposite, sessile, ovate, entire, smooth, dark green, glaucous on the under side, netted with numerous projecting veins and nerves, which become ferruginous through age; flowers small for the size of the plant, disposed in a cyme; peduncles round, smooth, usually two or three flowered, but sometimes one-flowered. The leaves, says Hill, are an excellent cure for fresh wounds: scarcely any thing is equal to them. Those that are young and tender at the tops of the branches, should be chosen. They are to be bound upon the wound, and will soon stop the bleeding. Many other plants are celebrated for this virtue, but the effects of this are so very singular and efficacious, that no other can be compared with it for healing fresh wounds. From this the French call it *La Toute Saine*; and the English, *Tutsan*: it is also called *Park-leaves*, from being frequently found in parks. It flowers from July to September.—Native of woods and moist hedges in the southern parts of Europe and Britain: it is sometimes found about Hampstead and Highgate; on Bacher-heath and Harefield, Middlesex; in the Oak-of-Honour-wood, near Peckham Rye, and in several parts of Norwood. In many parts of England it is more common; as, in the Duke of Bridgewater's woods at Askeridge, and near Berkhamstead, Hertfordshire; in lanes at the foot of Malvern Hill, Worcestershire; and between Worcester and Tewkesbury; in Shot-over plantations; Stokechurch and Nettlebed woods, Oxfordshire; near Pengwarry in Cornwall; in rocky woods in Westmoreland; at King's Cliff in Northamptonshire; and in Scotland in the woods at Inverary; and at Loch Ransa in the isle of Arran. It is not frequent in gardens, but in plantations it is as ornamental as many others. It may be increased by parting the roots, and loves shade, with a strong soil.

14. *Hypericum Olympticum*; *Olympian St. John's Wort*. Calices acute; stamina shorter than the corolla; stem shrubby. It rises with many upright woody stalks about a foot high: leaves small, lanceolate, sessile, opposite; flowers terminating, three or four together; petals oblong, bright yellow.—Native of the Levant. It is propagated by parting the roots in September, because the seeds seldom ripen in this country. It will live in the open air, in a warm situation and dry soil: but it will be proper to keep a plant or two in pots, to be sheltered under a frame in winter, to protect them from severe frost. If this be increased by seeds, they should be sown soon after they are ripe, in pots filled with light earth, and placed under a frame in winter; in spring the plants will appear, and when they are fit to remove, may be planted in a warm border, or in pots, and treated as the old plants.

15. *Hypericum Foliosum*; *Shining St. John's Wort*. Stamina the length of the petals; calices lanceolate, acute; leaves oval-oblong, sessile, smooth: it flowers in August.—Native of the Azores.

16. *Hypericum Floribundum*; *Many-flowered St. John's Wort*. Calices ovate, acute, subeiliate; stamina shorter than the corolla; leaves lanceolate-elliptic, stem shrubby.—It flowers in August, and is a native of Madeira.

17. *Hypericum Arborescens*; *Tree St. John's Wort*. Corollas and calices even, smooth; leaves elliptic; racemes brachiata; stem arborescent. Branches quadrangular at the top, smooth, with a purplish bark; peduncles compressed.—Native of the East Indies.

18. *Hypericum Gramineum*; *Grass-leaved St. John's Wort*. Stem herbaceous, four-cornered, dichotomous; leaves oblong-parabolic, or ovate-lanceolate. Peduncles terminating, and at the divisions filiform, solitary, one-flowered, an inch long.—Native of New Caledonia, in the South Seas.

19. *Hypericum Chinense*; *Chinese St. John's Wort*. Peduncles axillary, two-flowered; leaves ovate-lanceolate, quite entire. This is a small tree or shrub, with alternate branches; styles broadish; germen three-cornered.—Imported from China.

20. *Hypericum Cochin-chinense*; *Cochin-chinese St. John's Wort*. Peduncles axillary, five-flowered or thereabouts; leaves subpetioled, very close together; stem arboreous. This is a middle-sized tree, about sixteen feet high, with ascending branches, divided into many dusky-red branchlets; petals scarlet, ovate, oblong, entire, spreading. The wood of this tree is red, heavy, hard, and tough, and is used for making oars and yards of vessels. The juice of the flowers dyes of a golden colour.—Native of the woods of Cochin-china.

21. *Hypericum Petiolatum*. Leaves ovate, petioled, quite entire, tomentose underneath; stem shrubby, four-cornered, compressed; stipules none; corymb brachiata; sets of stamina oblong, very handsome. This and the tenth species are inadvertently named alike.—Native of Brazil.

22. *Hypericum Canariense*; *Canary St. John's Wort*. Calices blunt; stamina shorter than the corolla; stem shrubby. It rises six or seven feet high, dividing into branches at top; leaves oblong, set by pairs close to the branches, with a strong odour, but less powerful than that of the twenty-fourth species, the flowers of which, those of this plant very much resemble. It flowers from July to September. Native of the Canary Islands. This, with the two following species, are propagated by suckers taken off in March, just before they begin to shoot, and planted in a light dry soil; or by cuttings, planted at the same season; or by seeds sown in autumn as soon as they are ripe: but as they multiply fast by suckers, the other methods are seldom used.

23. *Hypericum Elatum*; *Tall St. John's Wort*. Calices lanceolate-ovate, acute; stamina longer than the corolla; leaves ovate-oblong; stem shrubby; it flowers in July and August.—Native of North America. See the preceding species.

24. *Hypericum Hircinum*; *Stinking Shrubby St. John's Wort*. Stamina longer than the corolla; stem shrubby, ancipital. It rises with shrubby stalks about three feet high; flowers in terminating bunches; petals oval. It flowers from July to September.—Native of the south of Europe. See the twenty-second species.

25. *Hypericum Ægyptiacum*; *Egyptian St. John's Wort*. Nectaries of the petals lanceolate; stems suffruticose, compressed. A low branched shrub, with leaves like those of Knot-grass, ovate, very small, acuminate, veinless, sessile, longer than the joints of the branches; flowers commonly in pairs, on the branchlets.—Native of Egypt.

26. *Hypericum Orientale*; *Oriental St. John's Wort*. Stipules reflex; leaves oblong, toothleted, crenate. Roots in old plants hard, woody, and more than half a foot in length; in young plants a tuft of yellowish fibres three or four inches long; stems from six inches to a foot in height, some upright, others ascending, pale green, a line in thickness, with a small wing descending from one leaf to another. The whole plant has a resinous smell. It varies much in size, as does also the flower, the petals being sometimes ten lines in length. The leaves are bitter, and a little viscid.—Native of the Levant.

27. *Hypericum Scabrum*; *Rugged St. John's Wort*. Stem round, suffruticose, muricated; leaves oblong. Flowers small, in terminating corymbs.—Native of Arabia, &c.

28. *Hypericum Repens*; *Creeping St. John's Wort*. Stem round, creeping; leaves lanceolate-linear, obtuse. Root perennial; flowers terminating, three, the middle one sessile.—Native of the Levant and of Palestine.

29. *Hypericum Prolificum*; *Proliferous St. John's Wort*. Primordial flowers sessile; stem ancipital, shrubby; leaves lanceolate-linear; stamina not longer than the petals. It flowers from June to August.—Native of North America.

30. *Hypericum Ericoides*; *Heath-leaved St. John's Wort*. Leaves linear, imbricated.—Native of Spain and Portugal.

31. *Hypericum Canadense*; *Canadian St. John's Wort*. Leaves linear-lanceolate; stem herbaceous, quadrangular; pericarpia coloured, twice as long as the calix. This has the appearance of Lesser Centaury. Panicle dichotomous, with pedicelled flowers, which are very small, the size of those of Spurge. It flowers from July to September.—Native of North America, and of Canada.

32. *Hypericum Virginicum*; *Virginian St. John's Wort*. Flowers nine-stamined; stem round; leaves ovate, embracing.—Native of North America.

33. *Hypericum Mexicanum*; *Mexican St. John's Wort*. Branches simple; leaves imbricate, ovate. Stems a foot high; petals linear.—Native of New Granada.

34. *Hypericum Lævigatum*; *Smooth St. John's Wort*. Leaves ovate, somewhat stem-clasping; calicine leaflets ovate, acute; panicle trichotomous; middle-flower sessile. It flowers in July.—Native of North America.

35. *Hypericum Reflexum*; *Reflex-leaved St. John's Wort*. Leaves sessile, lanceolate, approximating, reflex; branches tomentose, panicle terminating. This is a large shrub, with divaricating branches.—Native of the island of Teneriffe.

36. *Hypericum Quadrangulum*; *Square-stalked St. John's Wort*, or *St Peter's Wort*. Leaves ovate, with pellucid dots; stem quadrangular, herbaceous. It is distinguished from all the other species by its square stalk. Root peren-

nial, somewhat creeping and fibrous; stems a foot to eighteen inches high; branches decussately opposite; leaves blunt, smooth, strongly marked with seven or nine ribs; flowers small, terminating in close panicles; branchlets deep red, or blood-colour; peduncles very short; bractes subulate, in pairs; petals finely grooved, concave, marked with lines and dots, filled with a purple liquor, which stains paper with a muddy purple permanent stain. It flowers in July.—Native of most parts of Europe, in moist hedges, shady places, wet meadows, by rivulets, and in bogs. This, with the thirty-seventh, eighth, and ninth; the forty-second, fifth, and ninth; being wild plants, are seldom cultivated in gardens: they are not, however, without their beauty, and may be increased by parting their roots, and permitting their seeds to scatter.

37. *Hypericum Perforatum*; *Common or Perforated St. John's Wort*. Stem ancipital; leaves blunt, with pellucid dots. Root perennial, woody, brown. The whole plant is sprinkled over with small black glands, and is quite free from hairs; peduncles from the axils of the upper leaves, two-edged, supporting many flowers in a bushy panicle.—The common people of France, Germany, and Portugal, gather it with great ceremony on *St. John's Day*, and hang it in their windows, as a charm against storms, thunder, and evil spirits, mistaking the meaning of some medical writers, who have fancifully given this plant the name of *Fuga Daemonum*, from a supposition of its efficacy in maniacal and hypochondriacal disorders. In Scotland also it is carried about as a charm against witchcraft and enchantment; and they fancy it cures rosy milk, which they suppose to be under some malignant influence, by milking afresh upon the herb. Although *St. John's Wort* is not much regarded in the present practice, yet its sensible qualities, and the repeated testimonies of its virtues, entitle it, as Dr. Cullen observes, to farther trials. To the taste it is astringent and bitter, and its effects seem chiefly to be diuretic. From possessing properties which have been generally called balsamic, it has been used as a vulnerary in external wounds and internal hæmorrhages; for the former purpose the tops and flowers of the plant are infused in oil, and for the latter, an infusion of the plant is made in the manner of tea. It has likewise been given in ulcerations of the kidneys, and has been supposed to possess virtues as a febrifuge. The leaves given in substance are said to destroy worms. The semitransparent dots on the leaves are the receptacles of an essential oil. The flowers tinge spirits and oils of a fine purple colour, which is probably derived from the little glands upon the antheræ and edges of the petals. The dried plant boiled with alum dyes wool of a yellow colour. Hill observes, that the virtues attributed to this plant are at once numerous and very wonderful. He says, an infusion of the young tops is good in the jaundice; its operation is by urine, the quantity of which it considerably increases if the use of it be continued for some time. The expressed juice is a remedy for spitting of blood; and the powdered leaves are frequently given by country people for the worms, as also in gouty and rheumatic complaints, and in agues.—It is common in woody thickets, hedges and dry banks, flowering from July to September.

38. *Hypericum Dubium*; *Imperforate St. John's Wort*. Stem imperfectly four-edged; leaves blunt, without pellucid dots; calicine leaflets elliptical. In habit, size, and colour, it nearly agrees with the preceding, but differs essentially in having no pellucid dots apparent on the leaves, and in the calicine leaves being elliptical and obtuse. It flowers in July and August.—Native of Germany, Dauphny, and England; growing plentifully about Sapen in Worcestershire, at Hafod in Cardiganshire, and at Downton Castle near Ludlow.

39. *Hypericum Humifusum*; *Trailing St. John's Wort*. Flowers axillary, solitary; stems aneipital, prostrate, filiform; leaves smooth. Root perennial, yellow, fibrous; stems numerous, about eighteen inches in length, reddish, branched at top; peduncles axillary and terminating, solitary, or sometimes in pairs. It is the least of our wild *Hyperica*, scarcely inferior to any in beauty and delicacy, and is not unfrequent in gravelly pastures, in fields that have long lain untilled, on heaths, especially where the soil is moist and clayey, and sometimes in woods; flowering from June to August.

40. *Hypericum Crispum*; *Curled-leaved St. John's Wort*. Stem round; leaves sessile, lanceolate, waved and toothed at the base.—Native of Calabria, Sicily, and Greece.

41. *Hypericum Linarifolium*; *Toadflax-leaved St. John's Wort*. Calices serrate-glandular; stem round, upright; leaves linear, blunt, smooth. Branches nearly as high as the stem; corollas small, a little longer than the calix.—Found on the heaths near Bayonne and in Navarre.

42. *Hypericum Montanum*; *Mountain St. John's Wort*. Calices acute, serrate-glandular; stem round, upright; leaves oblong, smooth, embracing, sharpish; petals sometimes dotted towards the top.—Native of many parts of Europe, in woods and thickets, in high situations. Found in Britain, near Croydon in Surry; in Charlton-wood, Kent; on the Bath-hills near Bungay, in Suffolk; near Stokenchurch, Henley, and Maple-Durham, in Oxfordshire; near Pershore and Bredon-hill in Worcestershire; in many parts of the west of England; in the isle of Anglesea, North Wales; near Ingleton, and Furness Fells, in the north; and in some parts of Scotland.

43. *Hypericum Barbatum*; *Bearded-flowered St. John's Wort*. Calices and petals ciliate and dotted; leaves dotted. Root perennial; stem upright, simple, smooth, round, about a foot high, tinged with purple; flowers terminating, few, without smell.—Native of Austria, where it was found in pastures by wood-sides, flowering in June, and perfecting seeds in July and August.

44. *Hypericum Glandulosum*; *Glandulous St. John's Wort*. Calices serrulate-glandular; leaves lanceolate, glandular at the edge; stem shrubby. Branches obscurely four-cornered, smooth, dichotomous; corolla pale yellow with brown dots. It flowers from May to August.—Native of Madeira.

45. *Hypericum Hirsutum*; *Hairy St. John's Wort*. Calices serrate-glandular; stem round, upright; leaves ovate, subpubescent. Root perennial, fibrous; flowers terminating in an oblong panicle forming a kind of spike. It differs from the common *St. John's Wort* in being taller, having the stem perfectly round and hoary, and the edge of the calix beset with black glands. Linneus says, that the flowers close in the night.—It flowers from June to August; and is oftenest found in woods and coppices, though frequently found in hedges.

46. *Hypericum Tomentosum*; *Woolly St. John's Wort*. Calices serrate-glandular; leaves half stem-clasping, flexuose, tomentose; stems prostrate. It flowers from July to September.—Native of the south of Europe.

47. *Hypericum Perfoliatum*; *Perfoliate St. John's Wort*. Stem subaneipital; leaves stem-clasping, ovate; cyme with sessile flowers. It flowers in May and June.—Native of Italy.

48. *Hypericum Elodes*; *Marsh St. John's Wort*, or *St. Peter's Wort*. Stem round, creeping, villose; leaves villose, roundish. Flowering branches ascending, five or six inches high; the panicle terminating, at first becomes lateral by the protrusion of the stem beyond it, and is dichotomous, rarely producing more than from five to ten flowers, which appear in July and August, and seldom expand except in bright sunshine; petals yellow or reddish yellow, twisted spirally,

or sometimes merely folded up.—It has been observed in the northern parts of France, but is most common in England, where it is found in bogs; as on Hayes common in Kent, Dersingham Moor near Lynn, and other Norfolk bogs, the Gamlingay bogs in Cambridgeshire, on Birmingham heath, and in some parts of Cornwall.

49. *Hypericum Pulehrum*; *Elegant St. John's Wort*. Calices serrate-glandular; stem round; leaves stem-clasping, cordate, smooth. The whole plant is smooth; flowering branches or peduncles round, slender, axillary, with from one to three flowers at top; petals oblong-ovate, slightly striated, on the under side tinged with bright orange, slightly serrated, and edged with the same dark-coloured glands.—Native of most parts of Europe, in woods, on heath-banks, and in hedges, especially in a clayey soil; flowering in June and July. It is a hardy plant.

50. *Hypericum Nummularium*; *Moneywort-leaved St. John's Wort*. Calices serrate-glandular; leaves cordate-orbicular, smooth. Stems two or three, round, simple, five or six inches long, prostrate; flowers three or five, terminating, large. It is a very small plant; the leaves differ from those of all the other species, in being thick and fleshy, though very hard, and uniform throughout.—Native of Dauphiny, near the Grand Chartreuse.

51. *Hypericum Japonicum*; *Japanese St. John's Wort*. Leaves sessile, ovate, entire; stem herbaceous, four-cornered, decumbent at the base. Root with capillary fibres; flowers small, peduncled, solitary, and terminating in the axils of the panicle; peduncles capillary, one-flowered, upright.—Native of Japan, where it is found flowering in June.

52. *Hypericum Erectum*; *Upright St. John's Wort*. Leaves stem-clasping, lanceolate, acute; stem round, herbaceous. Flowers terminating, about three together; peduncles and pedicels filiform, like the stem, leafy, fastigate; corolla scarcely longer than the stamina.—Native of the mountains of Japan, flowering in August.

53. *Hypericum Coris*; *Heath-leaved St. John's Wort*. Calices serrate-glandular; leaves subverticillate. Stem round, a long span in height; flowers terminating in a loose spike, on one-flowered peduncles, which, as well as the bractes, are full of large black glands; petals large in proportion to the plant, marked with lines. This is an elegant little evergreen, forming a pretty bush, and flowering during most of the summer.—Native of the south of Europe, and of many parts of the Levant and Crimea. It is propagated by cuttings, and may stand in the open air, with a reserve of plants in very severe weather: but it is commonly considered a green-house plant.

*** With two Styles.

54. *Hypericum Mutilus*. Leaves ovate, sessile; they are glaucous, pressed close to the stem, and scarcely conspicuous.—Native of watery places in Virginia.

55. *Hypericum Setosum*. Leaves linear. Stem shrubby, four-cornered, hairy, branching like Horse-tail; leaves very small, hairy, pressed so close to the stem as scarcely to be visible. Flowers golden-coloured.—Native of Virginia and Carolina.

**** With one Style.

56. *Hypericum Revolutum*. Leaves linear-lanceolate, rolled back at the base; stamina shorter than the corolla. Stem shrubby, smooth with a brown wrinkled bark; flowers terminating, solitary; germen ovate.—Native of Arabia.

57. *Hypericum Monogynum*; *Chinese St. John's Wort*. Stamina longer than the corolla; calices coloured; stem shrubby. Root composed of many woody fibres striking deep into the ground; stems several, shrubby, nearly two feet high, covered with a purplish bark; leaves stiff, smooth,

about two inches long, of a lucid green on the upper surface, and gray underneath, with many transverse veins. Flowers terminating in small clusters, each on a short peduncle; calicene segments divided almost to the bottom, obtuse, deep purple; petals large, obtuse, bright yellow, concave; germen ovate. It continues in flower from March to September.—Native of China. It may be propagated by slips from the root, or by laying down the branches. If by slips, they should be planted in the same spring on a moderate hot-bed; the layers should be made at the same time to take root by autumn, when they may be transplanted into pots, and sheltered under a frame in winter. In spring, part of these may be set in a warm border, and the others continued in pots to be screened in winter.

**** *Styles united.*

58. *Hypericum Amœnum.* Terminal flowers subsolitary, sessile; leaflets of the calix ovate, acuminate; petals deflex, longer than the stamina; styles united together, of the length of the stamina. This elegant species grows to the height of about two feet or more. Every branchlet has from one to three large flowers, of a bright golden yellow; the petals turn downwards, and leave the large crown of the stamina in an upright situation, which, with the beautiful red ovate germen in the centre, gives the flower a particularly pleasing appearance.—Native of South Carolina and Georgia.

59. *Hypericum Glaucum.* Branches cylindrical; leaves oblong, cordate; leaves of the calix ovate, acute, longer than the petals; stamina equal to the petals; styles united together; flowers large.—Native of Florida.

60. *Hypericum Densiflorum.* Plant very branched; little branches somewhat cylindrical; leaves linear-lanceolate; stamina and styles united together, and shorter than the petals; flowers in very abundant and close panicles.—Found on the ridges and in the savannas of the Virginian mountains.

61. *Hypericum Galioides.* Branchlets tetragonal; leaves linear, sessile, revolute on the margin. About two feet high when in flower.—Found from New Jersey to Carolina, in moist sandy places near rivulets.

62. *Hypericum Triplinerve.* Plant erect, somewhat branched; leaves linear; flowers racemose-paniculated; corolla unequal; calices acute. It has pale yellow flowers.—Found upon the banks of the Ohio.

63. *Hypericum Sphærocarpum.* Plant erect, very glabrous; leaves oblong; panicles naked, dichotomous; styles three, united or distinct; capsules globose.—Native of Kentucky, New Jersey, &c.

64. *Hypericum Procumbens.* Leaves linear; leaflets of the calix oblong, lanceolate, acute; stamina shorter than the corolla; styles united; calix as large as the corolla.—Native of the dry sunny hills of Kentucky.

Hyphydra; a genus of the class Monœcia, order Gynandria.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: perianth one-leafed, three-parted; lobes obovate, concave, curved in at top, smooth. *Corolla*: none. *Stamina*: filamenta six, capillary, long, inserted above the germen at the corners; antheræ roundish. *Pistil*: germen empty, inflated, membranaceous, hexagonal, truncate at top; style capillary, the length of the stamina; stigma none. *Female Flowers.* *Calix*: none. *Corolla*: none. *Stamina*: none. *Pistil*: germen roundish, with three streaks; style triangular; stigmas three, acute. *Pericarp*: capsule membranaceous, one-celled, three-valved. *Seed*: single, ovate, striated. **ESSENTIAL CHARACTER.** *Male.* *Calix*: one-leafed, three-parted. *Corolla*: none. *Stamina*: six, inserted above the germen. *Female.* *Calix* and *Corolla*: none. *Style*: triangular, with three stigmas. *Capsule*: one-celled, three-valved. *Seed*: single.—The only known species is,

1. *Hyphydra Fluvialilis.* Stems and branches slender; leaves alternate, long, narrow, lanceolate, smooth, acuminate, marked with lines, ciliate, embracing. Some of the stems are erect, others decumbent, the last of which throw out roots; flowers in capitate bundles, each composed of a male flower, involved in a long sharp bracte, ciliate at the edge, and a female flower included with three bractes of the same form: they are axillary, and on a slender peduncle.—This little plant is a native of Guiana, and grows three or four feet under water, flowering in February.

Hyppium; a genus of the class Cryptogamia, order Musci.—**GENERIC CHARACTER.** *Capsule*: oblong; peristomium double; outer with sixteen broadish teeth; inner membranaceous, equal, lacinated; segments broadish, with capillary ones interposed. *Males*: gemmaceous on different plants. *Or thus.* *Peduncle*: from a lateral tubercle, fenced with scales; capsule outer fringed with sixteen teeth. *Male*: a bud, generally on a different plant, withering. This is a very numerous genus of *Mosses*, which has been thrown into seven divisions by Dr. Withering, in order to facilitate the investigation of the species. His arrangement contains seventy species. Hudson's *Flora Anglica*, forty; and there are also fifty species in the fourteenth edition of the *Systema Vegetabilium*, besides the new species discovered by Dickson, &c.

Hypochæris; a genus of the class Syngenesia, order Polygamia Æqualis.—**GENERIC CHARACTER.** *Calix*: common roundish, imbricated, ventricose at the base; scales lanceolate, acute. *Corolla*: compound imbricated, uniform; corollets hermaphrodite, equal, numerous; proper one-petalled, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: germen ovate; style filiform, the length of the stamina; stigmas two, reflex. *Pericarp*: none; the calix converging, globular, acuminate. *Seeds*: solitary, oblong; down feathered, stipitate. *Receptacle*: chaffy; chaffs lanceolate-linear, the length of the seeds. *Observe.* In the third and fifth species the seeds of the disk have a stipitate down, but in those of the ray it is sessile. **ESSENTIAL CHARACTER.** *Calix*: subimbricate. *Down*: feathered. *Receptacle*: chaffy.—The species are,

1. *Hypochæris Helvetica*; *One-flowered Hypochæris.* Stem simple, leafy, one-flowered; leaves lanceolate, toothed. Root perennial, almost fusiform, thickish, somewhat woody, sometimes divided, dark brown on the outside, white within, milky, putting up one, sometimes two or three stems, among abundance of radical leaves; flowers very large, from erect spreading; corollets numerous, long, deep yellow, five-toothed, with yellowish-white villose hairs at the base.—Native of the mountains of Carinthia, Dauphny, &c.

2. *Hypochæris Maculata*; *Spotted Hypochæris.* Stem almost naked; branch solitary; leaves ovate-oblong, entire, toothed. Root thick and long, abounding with milky juice, as does the rest of the plant. The flower opens at six in the morning, and closes at four in the afternoon; seeds wrinkled. The leaves are boiled in Smoland, and eaten like cabbage. The country people believe the plant to be a cure for tetters, and other cutaneous eruptions, possibly on account of its spotted leaves; which, though bitter, are eaten greedily by ruminating animals.—It flowers in July, is perennial, and a native of many parts of Europe. Though not common in England, it is found on the Gogmagog hills and Newmarket heath, in Cambridgeshire; on Bernack-heath in Northamptonshire; and about Malham Cove, Cartmell Wells, and near Settle, in Yorkshire.

3. *Hypochæris Glabra*; *Smooth Hypochæris.* Leaves shining; flowers small. Root annual, the thickness of a crow-

quill, tapering, furnished with few fibres, pale brown; peduncles scaly, a little thickened under the flower. It may be distinguished by the smallness of the flowers, not exceeding the size of a silver threepence, while the heads containing the seeds are altogether as large in proportion to the size of the plant. The flowers are open from about nine in the morning till about one or two in the afternoon. It delights in a sandy soil and exposed situation, and flowers in June.

4. *Hypochaeris Radicata*; *Long-rooted Hypochaeris*. Leaves runcinate, obtuse, rugged; stem branched, naked, even; peduncles scaly. Root perennial, the thickness of the little finger, running deeply into the earth, generally simple, of a whitish colour, and milky within; flowers large, closing at three in the afternoon. It is distinguished from *Leontodon Autumnale*, by the length of the root, from whence it derives its trivial name. In barren soils it occurs of a much smaller size, five or six inches high, with an unbranched stem, or with one flower, almost sessile on the side.—It is common on dry banks, heaths, and pastures, flowering from May to September; and in the early part of summer is a conspicuous plant, and is called *Hawkweed*, in common with many others. Dr. Withering has named it *Cat's Ears*.

5. *Hypochaeris Minima*; *Least Hypochaeris*. Leaves sinuate-lyrate; stem with scaly appendices at top. Root downright, two or three inches long, annual, fibrous; stem naked, simple, one-flowered, a palm in height, smooth; flower small, equal.—Native of Italy and Naples, on volcanic ground, particularly the Solfaterra, flowering from May to June.

Hypoxis; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: glume two-valved. *Corolla*: one-petalled, superior; limb six-parted; segments ovate-oblong, spreading, permanent. *Stamina*: filamenta six, very short, capillary; antheræ oblong, shorter than the petals. *Pistil*: germen inferior, turbinate; style filiform, the length of the stamina; stigma bluntish. *Pericarp*: capsule somewhat oblong, narrower at the base, crowned with the permanent corollas, three-celled, three-valved; (according to Gærtner, valveless.) *Seeds*: very many, roundish. ESSENTIAL CHARACTER. *Calix*: a two-valved glume. *Corolla*: six-parted, permanent, superior. *Capsule*: narrower at the base.—The species are,

1. *Hypoxis Erecta*; *Upright Hypoxis*. Hairy, with ovate capsules. Root tufted, with fleshy branched fibres; stems two or three, shorter than the leaves, upright, round, hairy, reddish above, each bearing one upright flower; corolla externally green and hairy, with a red rib, internally concave, yellow, smooth, without veins or nerves.—It flowers in June; and is a native of North America.

2. *Hypoxis Decumbens*; *Trailing Hypoxis*. Hairy, with club-shaped capsules: bulb roundish, fleshy, brown, putting out fibres from the side; peduncles radical from the sheaths among the leaves; seeds wrinkled, black. The roots came accidentally into Mr. Miller's hands among some Allspice plants, and he cultivated them in 1755. It flowers most part of the year.—Native of Jamaica, in sandy fields, among the mountains. It will not thrive well in England, unless the pots be plunged into a hot-bed of tanners' bark, and the air kept up to the heat assigned for Ananas. In this situation the plants will succeed, produce plenty of flowers, and perfect the seeds, which, if suffered to scatter, will produce plenty of young plants; or, if they be sown in pots soon after they are ripe, and planted into the tan-bed, will come up in about six weeks, and, when they are fit to transplant, may be treated in the same manner as the old plants.

3. *Hypoxis Spicata*; *Spiked Hypoxis*. Upright: leaves ensiform, falcate, smooth; flowers in spikes. Root composed

of capillary fibres in bundles; flowers from the middle to the top of the spikes, alternate, remote, very many; capsule and rachis very rough with hairs.—It flowers in May and June, and is a native of Japan.

4. *Hypoxis Plicata*; *Plaited-leaved Hypoxis*. Scape one-flowered, three-sided; leaves lanceolate, plaited, villose; bulb globular; corolla yellow.—Native of the Cape. For the treatment of this, and the other Cape sorts, see *Albuca*.

5. *Hypoxis Stellata*; *Spotted-flowered Hypoxis*. Scape one-flowered; leaves linear, striated; petals spotted. This is a beautiful little bulbous plant, with a dark spot at the claws of the petals; leaves like those of *Narcissus*, the length of the scape, which is sheathed below the middle; the spathe permanent, acuminate, flat; filamenta, very short; style three-cornered.—Native of the Cape.

6. *Hypoxis Aquatica*; *Aquatic Hypoxis*. Leaves linear; scapes umbelled, or one-flowered. Leaves radical, loose, bending at the end; scapes filiform, the height of the water; flowers in some solitary, hermaphrodite, in others umbelled, male.—Found in watery ditches at the Cape.

7. *Hypoxis Serrata*; *Channel-leaved Hypoxis*. Leaves channelled, smooth, ciliate-serrate; scapes one-flowered. It flowers in July.—Native of the Cape.

8. *Hypoxis Villosa*; *Hairy Hypoxis*. Leaves linear, ensiform, villose; stigma simple, three-cornered, acute. It varies in size. Capsule small, narrower at the base, so as to be almost club-shaped.—Native of the Cape.

9. *Hypoxis Fascicularis*. Tube of the flowers very long.—Native of Syria, near Aleppo.

10. *Hypoxis Sessilis*. Hairy, stemless: fructifications subradical; leaves linear, straight. The leaves are a span in length, keeled, like those of *Juncus Pilosus*, hairy all over, pale green; petals pointed, plaited, three outer broader, green, hairy. Seeds round, black, and shining. It flowers at the latter end of June.—Native of Carolina.

11. *Hypoxis Minuta*. Leaves three-sided, fleshy, smooth; scapes bifid. Bulb conical, large in proportion to the plant; corolla spreading, snow-white; filamenta shorter than the corolla.—Native of the Cape.

12. *Hypoxis Ovata*. Leaves ovate-lanceolate, entire, smooth; scapes one-flowered; flower white, and pretty.—Found at the Cape.

13. *Hypoxis Alba*. Leaves cylindric, smooth; scapes subbid; petals unspotted. A small plant.—Found by Thunberg at the Cape.

14. *Hypoxis Aurea*. Stemless, hairy; scape one-flowered; capsules oblong. An annual plant: leaves awl-shaped, channelled, reflexed, half a foot long, clustered; corolla bell-shaped, equal, golden coloured within, greenish on the outside, hairy.—Native of Cochinchina, where it was found on a sandy hill called *Sou Koung*.

15. *Hypoxis Graminea*. Scape four-flowered; leaves very long, shorter than those of grass, very narrow, and double the length of the scape.—Found from New Jersey to Carolina, in dry sandy fields and woods.

Hyptis; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth turbinate, half five-cleft, permanent; segments lanceolate, acute, almost equal, upright. *Corolla*: one-petalled, ringent; tube funnel-form; throat widened; limb spreading very much, resupinate; upper lip, (which is the lower in situation,) trifid; lateral segments ovate, acute, the middle one roundish, concave, obtuse; lower lip (in situation the upper) semibifid; segments semiovate, flat, acute. *Stamina*: filamenta four, awl-shaped, erect, of which two are shorter; antheræ twin, hanging down. *Pistil*: germen four-cleft; style filiform;

stigma bifid or simple. *Pericarp*: none; the calix fostering the seeds. *Seeds*: four. **ESSENTIAL CHARACTER.** *Calix*: turbinate. *Corolla*: with a very spreading border; lower lip semibifid. *Anthers*: hanging down.—The species are,

1. *Hyptis Verticillata*. Leaves lanceolate; flowers in whorls. This shrub is ten feet high, with one or two upright woody stems; corolla white.—Native of St. Domingo.

2. *Hyptis Capitata*. Leaves ovate; flowers in heads. Stems suffruticose, two or three feet high or more, becoming woody, commonly four-cornered, brown; branches annual, herbaceous, subdivided; peduncles axillary, solitary, four-cornered, slender, from two to three inches long, beaving at the end numerous flowers collected closely into a semi-globular head; the petals are white, with sometimes a tinge of flesh-colour; antheræ yellow. The whole plant is inodorous.—Native of St. Domingo, where it flowers in December and January.

Hyssop. See *Hyssopus*.

Hyssop, Hedge. See *Gratiola*.

Hyssopus; (*Hyssop*) a genus of the class Didynamia, order Gymnospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, cylindrical, oblong, striated, acutely five-toothed, permanent. *Corolla*: one-petalled, ringent; tube cylindrical, slender, the length of the calix; throat inclined; upper lip straight, flat, short, roundish, emarginate; lower lip trifid; lateral segments shorter, blunt, the middle one crenate, obcordate, acute, with distant lobes. *Stamina*: filamenta four, upright, longer than the corolla, distant; the two upper ones shorter, but the two longer nearer to the lower lip; antheræ simple. *Pistil*: germen four-parted; style filiform, under the upper lip, and of the same length; stigma bifid. *Pericarp*: none; the calix fostering the seeds. *Seeds*: four, subovate. **ESSENTIAL CHARACTER.** *Corolla*: lower lip with a small middle crenate segment. *Stamina*: straight, distant.—The species are,

1. *Hyssopus Officinalis*; *Common Hyssop*. Spikes directed one way; leaves lanceolate. Height a foot and half; stems first square, afterwards round, with small sessile leaves in pairs on their lower part, and seven or eight very narrow erect leaves or bractes, springing from the same joint; on the upper part, flowers in whorls, the lower ones half an inch apart, the upper almost joined; antheræ twin; seeds black. There are many varieties of this plant. The leaves vary in colour as well as the flowers, some being white striped with green, or half green and half white; others with the leaves wholly yellow, or but a little green in them: others yellow, as the Gold Hyssop; which, Parkinson says, was "of so pleasant a colour in his time, that it provoked many gentlewomen to wear them in their heads and on their arms, with as much delight as many fine flowers can give." The leaves are also sometimes curled or cramped at the edges, so that each leaf seems to be composed of many. It also varies in the stem, and in the scent, which is sometimes stronger than common, approaching to that of musk. Ray enumerates nine varieties. The roots will abide many years. The whole plant has a strong aromatic smell. It flowers in July and August, and ripens seed in

September. Meyrick remarks, that it is a plant of very considerable virtues, particularly in disorders of the breast and lungs. A strong infusion, or tea, made with the young tops, is not particularly unpleasant, and is the best mode of using it. There are few better medicines for coughs, hoarsenesses, and obstructions of the breast. The infusion, made into a syrup with honey, is excellent for the same purposes. The tea, when plentifully taken, removes obstructions of the viscera, and operates powerfully by urine. It should be gathered when just beginning to flower. The green herb bruised, with the addition of a little sugar, is said to heal cuts and green wounds with great expedition.—Native of the south of Europe. This plant, with all its varieties, may be propagated by seeds or cuttings: if by seeds, they must be sown in March, upon a bed of light sandy soil, and when the plants come up, they should be transplanted out to the places where they are to remain, placing them at least a foot asunder each way; but if they are designed to abide in those places for a long time, two feet distance will be small enough, for they grow pretty large, especially if they are not frequently cut to keep them within compass. If you would propagate them by cuttings, they should be planted in April or May, on a border where they may be defended from the violent heat of the sun; and being frequently watered, they will take root in about two months; after which they may be transplanted where they are to continue, managing them as was before directed for the seedling plants. They are very hardy, and will endure the cold of our winters in the open air, provided they are planted in a dry undunged soil; for a rich soil causes them to grow so luxuriantly in summer that they are the less able to resist the cold of the winter, while those plants which we frequently find growing out of the joints of old walls, will better resist the severest frost, and be much more aromatic.

2. *Hyssopus Lophanthus*; *Mint-leaved Hyssop*. Corollas resupinate; lower stamen shorter than the corolla; leaves obovate. Root strong, fibrous, perennial, sending out many square stalks, which divide into smaller branches; flowers produced at each joint in small clusters; corollas blue. The flowers appear in June and July, and the seeds ripen in September.—Native of Siberia. Both this and the following species are very hardy, and may be easily propagated by sowing seeds in autumn, for those sown in the spring often lie a year in the ground before they vegetate. When the plants come up, keep them clean from weeds, and thin them where they are too close. The following autumn transplant them where they are to remain, and the roots will last several years.

3. *Hyssopus Nepetoides*; *Square-stalked Hyssop*. Stem sharp, quadrangular. Root perennial; leaves oblique, heart-shaped, serrate, acute, on short footstalks; flowers yellow, in close thick spikes, four or five inches long; upper lip of the corolla divided into two roundish segments. There is a variety with purple stalks and flowers, the leaves on longer footstalks, and the spikes of flowers thicker. Gouan remarks, that this plant has the appearance of *Galeopsis*.—Native of Virginia and Canada.

J A C

JACA Tree. See *Artocarpus*.

Jacquinia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets roundish, concave, permanent. *Corolla*: one-petalled; tube bell-shaped, ventricose, longer than the calix; border ten-cleft; divisions roundish, of which the five interior ones are shorter. *Stamina*: filamenta five, awl-

J A C

shaped, arising from the receptacle; antheræ spear-shaped. *Pistil*: germen ovate; style the length of the stamina; stigma headed. *Pericarp*: berry roundish, acnminate, one-celled. *Seed*: single, roundish, cartilaginous. **ESSENTIAL CHARACTER.** *Corolla*: ten-cleft. *Stamina*: inserted into the receptacle. *Berry*: one seeded.—These plants must be kept in the bark-stove, giving them little water in winter, and in

warm weather plenty of fresh air. They are raised from seeds procured from the countries where they grow naturally, and afterwards from cuttings, but it is with difficulty that these take root.—The species are,

1. *Jacquinia Armillaris*; *Obtuse-leaved Jacquinia*. Leaves obtuse, coriaceous; flowers in racemes; berries four-seeded or thereabouts. This a very elegant upright shrub, seldom more than four or five feet high; peduncles scattered, spreading, one-flowered; flowers small, stiffish, white, smelling like Jasmine, and retaining their sweet scent several days; berry roundish, smooth, the size of a large pea, of a reddish orange colour, and containing an orange-coloured pulp; seeds four, sometimes (but seldom) three or five, ovate, smooth, shining, cartilaginous, brownish yellow. The berries are eaten by small birds; and the seeds are strung for bracelets by the Caribbees, whence the French in the islands call this shrub *Bois Bracelets*; and Linneus gives it the trivial name of *Armillaris*. The Spaniards call it *Barbasco*, or *Verbascum*.—It flowers in February and March; and is a native of South America and the West India islands, where it is found on the calcareous rocks of Jamaica, Curaçoa, Martinico, Carthage, &c.

2. *Jacquinia Venosa*; *Vein-leaved Jacquinia*. Leaves ovate, lanceolate, veined, submembranaceous.—Native of the West Indies.

3. *Jacquinia Ruscifolia*; *Prickly Jacquinia*. Leaves lanceolate, acuminate. This is a shrub three feet in height, with all the habit of the preceding: it differs in having the leaves lanceolate, acuminate, pungent, extremely stiff, and shorter; the peduncles are as pendulous as in that, and one-flowered.—Native of South America.

4. *Jacquinia Linearis*; *Linear-leaved Jacquinia*. Leaves linear, acuminate. This is a shrub two feet in height, very much branched, of the same habit with the two preceding, but not so neat; leaves extremely rigid, pungent, like thorns, generally four together in whorls at each joint; peduncles one-flowered, solitary, terminating, pendulous, shorter than the leaves; flowers stiffish, and without any smell; petals white, with all the segments convex, the outer ones spreading, the inner almost erect; berries yellow.—Native of the island of St. Domingo, about Port-au-Prince, on the coast, flowering and fruiting in January.

Jasione; a genus of the class Syngenesia, order Monogamia.—**GENERIC CHARACTER.** *Calix*: perianth common ten-leaved; alternate leaflets inferior, narrower, including very many flowers on very short peduncles, permanent; perianth proper five-cleft, superior, permanent. *Corolla*: proper one-petalled, regular, deeply five-cleft; divisions lanceolate, upright. *Stamina*: filamenta five, awl-shaped, short; antheræ five, oblong, connected at the base. *Pistil*: germen roundish, inferior; style filiform, length of the corolla; stigma bifid. *Pericarp*: capsule roundish, five-cornered, crowned with the proper calix, subbilocular, gaping at the tip, with a round hole; partition divided at the axis. *Seeds*: many, subovate; receptacle subglobose, pedicelled, free, in the base of the capsule. *Observe.* The central floscules are often abortive, with an undivided club-shaped stigma. **ESSENTIAL CHARACTER.** *Calix*: common ten-leaved. *Corolla*: five-petalled, regular. *Capsule*: inferior, two-celled.—The only known species is,

1. *Jasione Montana*; *Mountain Jasione*, or *Hairy Sheep's Scabious*. Root annual, rigid, whitish, and fibrous; stems many, erect, or procumbent, from a span to a foot in height or more, somewhat rigid, beset with rough short hairs, angular, striated, green, often tinged with purple; for something more than one-third of their height, they are clothed

with numerous leaves, which are linear or linear-lanceolate, waved at the margin, bluish at the end, hairy on both surfaces, sessile, and pointing upwards: the remainder of the stem is naked, and terminated by one flowering head; corolla blue, sometimes varying to white; stigma club-shaped, purple. Linneus remarks, that the leaves are obscurely serrated. Leers asserts that the calix has constantly twenty leaflets, in four rows, subserrated, the outer ones gradually larger. The antheræ are at first almost wholly united, but when the pollen is evacuated, they spread, and are joined only at the base; the central florets are barren, with the stigma club-shaped, quite entire, having pollen scattered over it, and not villose; the capsules are on very short pedicels, and never ripen. The lateral florets in great numbers are fertile; they have also a club-shaped stigma, which afterwards becomes bifid; because the antheræ of these have evacuated their pollen before the stigma bursts, it seems probable that the fecundation is made by the antheræ of the barren florets. The styles of the barren florets are all upright, but those of the fertile florets are bent down, for the easier reception of the pollen. In the above curious account of the process of fecundation, the botanist cannot but remark the affinity it bears to the genuine plants of the class Syngenesia, where Linneus placed it, and from whence modern reformers have removed it. In its general appearance it so resembles a Scabious, as to be taken for one by unskillful botanists. It varies much in size, and on the sea-coast of Cornwall is only about an inch high when full grown, and the whole plant is very hairy. Linneus informs us that bees are particularly fond of the flowers of this plant, the whole of which is milky, and sometimes eaten by sheep. Ray calls it *Rampions* with scabious-like heads; and *Withering*, *Scabious Sheep's-bit*.—It flowers from June to August; and is common on dry sandy grounds, heaths, and hilly pastures. The younger Linneus, in his *Supplement*, mentions a variety with perennial roots, the stem higher than in the common sort, and the heads of the flowers larger.

Jasminum; a genus of the class Diandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubulated, oblong; mouth five-toothed, upright, permanent. *Corolla*: one-petalled, salver-shaped; tube cylindrical, long; border five-parted, flat. *Stamina*: filamenta two, short; antheræ small, within the tube of the corolla. *Pistil*: germen roundish; style filiform, length of the stamina; stigma bifid. *Pericarp*: berry oval, smooth, two-celled or two-capsuled. *Seeds*: two, large, ovate-oblong, arillated, convex on one side, flat on the other. *Observe.* The shape of the flower varies as to acuteness or obtuseness; the berry is in some simple, in others dicoccus. **ESSENTIAL CHARACTER.** *Corolla*: salver-shaped. *Berry*: dicoccus. *Seeds*: solitary, arillated.—The species are,

1. *Jasminum Sambac*; *Arabian Jasmine*. Leaves opposite, simple, elliptic, ovate and subcordate, membranaceous, opaque; branchlets and petioles pubescent; calcine segments awl-shaped. It rises with a winding stalk to the height of fifteen or twenty feet, sending out small branches; leaves smooth, nearly three inches long, and two broad, on short footstalks. The flowers are produced on the ends of the branches, and also upon the side-shoots, on short peduncles, each generally sustaining three flowers; the tube of the corolla narrow, about half an inch long, cut at the top into eight obtuse segments, which spread out quite flat. The flowers are of a pure white, and have a most agreeable odour, somewhat like orange flowers, but sweeter; when fully blown, they drop out of their cups on being shaken, and frequently fall out in the night, changing soon to a purplish colour. The

plants continue flowering great part of the year, when they are kept in a proper temperature of warmth.—This beautiful plant, so much esteemed for its highly odoriferous flowers, is a native of the East Indies, where it is much cultivated, as well as in China and in the West Indies. There are several varieties of it in those countries: we have it both with single and double flowers, and also with double large flowers; which last grows naturally at Malabar, and, being very fragrant, the women there string its flowers round their necks by way of ornament.—These plants are frequently imported from Italy by the Italian gardeners, who bring orange-trees for sale; but as they are always grafted upon stocks of the Common Jasmine, and do not keep pace with the growth of the stock, they become very unsightly; besides, the stocks are very apt to shoot from the bottom, and if these shoots be not constantly rubbed off, they will starve the graft. The best method therefore to obtain plants is by layers or cuttings: the former is the surest method, for unless the cuttings be very carefully managed, they will not take root; and the stems being pliable, may easily be brought down, and laid in pots filled with a soft loamy soil, plunged into a hot-bed of tan. If the branches be laid down in the spring and carefully watered, they will put out roots by autumn, when they should be cut from the old plants, and each transplanted into a separate small pot, and then plunged into the tan-bed, where they should be shaded from the sun till they have taken new root. Cuttings may be planted from May to August, in pots filled with the same earth, and plunged into a moderate hot-bed of tanners' bark. The pots should be large enough to contain ten or twelve cuttings, and should be closely covered with bell or hand glasses to exclude the air, shaded from the sun in the heat of the day, and gently refreshed with water when the earth is dry; they will have taken root by August, when they may be transplanted into separate pots, and treated in the same way as the layers. This plant may be preserved in a moderate degree of warmth, but will thrive much better in the bark-stove, and produce a greater quantity of flowers; as the leaves continue all the year, it will make a fine appearance at all seasons in the stove, and it will produce flowers great part of the year.

2. *Jasminum Glaucum*; *Glaucous-leaved Jasmine*. Leaves opposite, simple, lanceolate, shining; calicine segments awl-shaped. This is a shrub with round, even, opposite branches; peduncles terminating, three-cleft or three-flowered; flowers larger than those of Common Jasmine. It flowers in August.—Native of the Cape.

3. *Jasminum Capense*; *Cape Jasmine*. Leaves opposite, ternate, ovate, acuminate; stem erect; leaves angular.—Found by Thunberg at the Cape.

4. *Jasminum Azoricum*; *Azorian Jasmine*. Leaves opposite, ternate; leaflets ovate and subcordate, waved; branchlets smooth, round; segments of the corolla equal to the tube. It has long slender branches, which require support, and may be trained twenty feet high; flowers terminating in loose bunches; the corolla is of a clear white, and has a very agreeable scent. It flowers from May to November.—Native of the Azores. This species is pretty hardy, and only requires to be sheltered from severe frost. It is a green-house plant, but will live against a warm wall if dung be laid to the roots, and a mat laid over it in frosty weather. It deserves a place in every green-house, for the leaves being of a shining green, make a good appearance all the year, and the flowers affording a fine scent, and continuing long in succession, render it very valuable. It is propagated in the same manner as the twelfth species; which see.

5. *Jasminum Angulare*; *Angular Jasmine*. Leaves opposite, ternate; leaflets ovate, obtuse; branchlets angular, both

they and the petioles villose; peduncles axillary, three-flowered.—Native of the Cape.

6. *Jasminum Auriculatum*; *Malabar Jasmine*. Leaves opposite, ternate, on the flowering branchlets simple; calices angular; branches round and pubescent. Corolla an inch long, smooth.—Native of Malabar.

7. *Jasminum Flexile*; *Flexuose Jasmine*. Smooth: leaves opposite, ternate; racemes axillary, brachiate; stem climbing; branches round.—Native of the East Indies.

8. *Jasminum Didymum*. Smooth: leaves opposite, ternate; leaflets ovate-lanceolate; racemes axillary. This seems to be a climbing shrub.—Native of the Society Isles.

9. *Jasminum Simplicifolium*. Leaves opposite, ovate, lanceolate, simple.—Native of the Friendly Islands.

10. *Jasminum Fruticans*; *Common Yellow Jasmine*. Leaves alternate, ternate; leaflets obovate and wedge-shaped, obtuse; branches angular; calicine segments awl-shaped. It has weak angular branches which require support, and will rise to the height of eight or ten feet, if planted against a wall or pale. The calix is deeply five-cleft.—Native of the south of Europe, and the Levant. Besides the common name of Yellow Jasmine, Parkinson has those of Shrubby Trefoil and Make-bate, which are now obsolete. This plant was formerly more cultivated than at present, for as the flowers are destitute of scent, few persons regard them; besides, it often produces so many suckers as to become troublesome; and as it cannot be kept in order for standards, it is seldom introduced into gardens at present. It is easily propagated by suckers or layers.

11. *Jasminum Humile*; *Italian Yellow Jasmine*. Leaves alternate, acute, ternate and pinnate; branches angular; calicine segments very short. This species also was annually brought from Italy by those who imported Orange-trees; the flowers are generally larger than those of the preceding, but have very little scent, and are seldom produced so early in the season: it flowers from July to September.—Native country unknown. This is less hardy than the preceding species, but will endure the cold of our ordinary winters in a warm situation: it may be propagated by laying down the tender branches, or by budding or inarching it upon the common yellow sort; the latter mode is preferable for obtaining hardier plants: it should be planted against a warm wall, and in severe winters will require to be sheltered with mats; it must be dressed and pruned in the same way as the White Jasmine.

12. *Jasminum Odoratissimum*; *Yellow Indian Jasmine*. Leaves alternate, bluntish, ternate and pinnate; branches round; calicine segments very short. This rises with an upright woody stalk eight or ten feet high, covered with a brown bark, sending out several branches, which want no support; leaflets of a lucid green, ovate and entire, continuing green all the year. The flowers are produced in bunches at the ends of the shoots; the corolla has a long slender tube, and the segments are blunt and spreading; the whole is of a bright yellow colour, and has a most grateful odour. The flowers come out from July to October and November, and are frequently succeeded by oblong oval berries, which turn black when ripe, and have each two seeds.—Native of Madeira. It is propagated either by the seeds, or by laying down the tender branches; if by seeds, which it sometimes produces in England, make a moderate hot-bed in the spring, into which plunge some small pots, filled with fresh light earth, and in a day or two after, when you find the earth in the pots warm, put in the seeds, four in each pot, covering them about an inch thick with the same light earth, which, when dry, must be frequently refreshed with water in small quantities; about

six or eight weeks after sowing, the plants will appear above ground, at which time it will be necessary to remove the pots into another fresh hot-bed, of a moderate temperature, in order to bring the plants forward; water them as often as is necessary, and in the great heat of the day the glasses should be tilted pretty high, and shaded with mats, to prevent the plants from being scorched with heat. About the middle of May begin to harden them to the open air, by taking off the glasses when the weather is warm: but this must be cautiously done, for exposing them at first to a very hot sun would greatly injure them. The glasses should be taken off first in warm cloudy weather, or during gentle showers, and so gradually inure them to bear the sun. In June take the pots out of the hot-bed, and remove them to some well sheltered situation; where they may remain until the beginning of October; at which time they must be carried into the green-house, observing to place them where they may enjoy as much free air as possible when the windows are opened, as well as stand clear from the branches of other plants. During winter they will often require watering sparingly; and in March should be each removed into a separate pot, observing not to take the earth from their roots. If they be then plunged into a fresh moderate hot-bed, it will greatly facilitate their rooting again: when rooted they must have plenty of air; for if too much drawn, they will become weak in their stems, and incapable of supporting their heads, which is a great defect in these trees. In the middle of May remove them into the open air, to harden; observing, as before directed, to place them in a situation that is defended from strong winds. In winter, house them as before, and continue the same care, with which they will thrive very fast, and annually produce great quantities of flowers. They are pretty hardy, and only require to be protected from hard frosts in winter: and as they are much hardier than the Spanish, would probably live in the open air if planted against a warm wall; but there is this difference between the two plants, that these have large, thick, evergreen leaves, so that if they were covered with mats, as is directed for the Spanish Jasmine, the leaves would rot and decay the shoots, but as these will only require to be covered in extreme frost, if their roots are well mulched, and a mat or two hung over them in ordinary frosts, it will be sufficient; and these mats being either rolled up or taken quite off in the day, there will be no great danger of their being hurt. In the spring they should be pruned, and have all their decayed branches removed; but none of the other branches must be shortened, as is directed for the Spanish sort, for the flowers of this kind are produced only at the extremity of the branches; hence if the branches be shortened, the flowers will be cut off, and as the branches are of a more ligneous substance than the other, they will not produce shoots strong enough to flower the same year. To propagate this plant from layers, lay down the shoots in March, and if you give them a little cut at the joint, as is practised in laying Carnations, it will promote their rooting, observing to refresh often with water when the weather is dry; and the plants will be rooted by the succeeding spring, fit to be transplanted; when they must be placed in pots filled with light earth, and managed as was before directed for the seedlings. This sort is frequently propagated by inarching the young shoots into stocks of the Common Yellow Jasmine, but the plants so raised do not grow so strong as those which are upon their own stock; besides, the Common Yellow Jasmine is very apt to send out a great number of suckers from the root, which renders the plants unsightly, and, if not taken off as fast as they are produced, will rob them of their nourishment.

13. *Jasminum Officinale*; *Common White Jasmine*. Leaves opposite, pinnate; leaflets acuminate; buds almost upright. Stem shrubby, weak, climbing, round, smooth, branching; leaflets usually seven, broad-lanceolate, quite entire, smooth, dark green, the end one larger and more pointed than the rest; peduncles few-flowered; corolla white, odorous: they are the only part of the plant used in medicine. An infusion of five or six ounces of them picked clean from the leaves, in a quart of boiling water, being strained off and boiled into a syrup, with the addition of a sufficient quantity of honey, is an excellent medicine in coughs, hoarsenesses, and other disorders of the breast. There is also an oil, or, as it is commonly called, an essence, prepared from these flowers, which is used in perfumes, but seldom applied to any medical purposes. We are not certain as to the native country of our Common White Jasmine: though it has been long inured to our clime, so as to thrive and flower extremely well, yet it never produces any fruit in England: it is probably a native of the East Indies. The name Jasmine, has been corrupted into Jessamine, Gelsemine, Jessmia, Jessamy, and Gesse. The Germans call it *Jasmin*, *Jesmin*, *Schasmin*, *Schelsemine*, *Vioreben*; the Dutch, *Jasmin*; the Swedish, Danish, and French, *Jasmin*; the Italians, *Gelsomino*; the Spaniards, *Jazmin*; the Portuguese, *Jasmin*, *Jesmin*, *Jasmino*; and the Arabians, *Jasmin*, *Kajan*.—This is easily propagated by laying down the branches, which will take root in one year, and may then be cut from the old plant, and set where they are intended to remain. It may also be propagated by cuttings, which should be planted early in autumn, and in severe winters the surface of the ground between them should be covered with tan, sea-coal ashes, or sawdust, which will prevent the frost from penetrating deep into the ground, and preserve the cuttings: or pease-haulm, or other light covering, should be laid over them, where the former cannot be procured; but these coverings must be removed when the weather is mild, as they will keep off the air, and occasion damps, which often destroy them. When these plants are removed, they should be planted where they are designed to be continued, which should be either against some wall, pale, or other fence, where the flexible branches may be supported; for although it is sometimes planted as a standard, and formed into a head, yet it will be very difficult to keep it in any handsome order; or if you do, you must cut off all the flowering branches, for the flowers are always produced at the extremity of the same year's shoots, which, if shortened before the flowers are blown, will entirely deprive the trees of flowers. They should be permitted to grow rude in the summer, for the reason before given: nor should you prune or nail them until the latter end of March, when the frosty weather is past, for if the frost should set in after their rude branches are pruned off, and the stronger ones be exposed to it, they will hardly escape being killed: but on the other hand, as this plant is very backward in shooting, there will be no danger of injuring it by late pruning. There are two varieties with variegated leaves, one with white, and the other with yellow stripes, but the latter is the most common: these are propagated by budding them on the plain Jasmine; and it often happens that the buds do not take, but yet communicate their gilded miasma to the plants, so that in a short time after, many of the branches, both above and below the places where the buds have been inserted, have been thoroughly tinged; and in the following year, very distant branches, which had no other communication with those which were budded than by the root, have been as completely tinged as any of the nearer branches, so that the juices must have descended

into the root. These two striped sorts should be planted in a warm situation, especially the white-striped; for they are much more tender than the plain, and are very subject to be destroyed by great frosts when exposed. They should have a south or south-west aspect, and in very severe winters must have their branches covered with mats or straw, to prevent their being killed. The yellow-striped is not so tender, and may be planted against walls to east or west aspects; but neither of these are so much esteemed as formerly.

14. *Jasminum Grandiflorum*; *Spanish or Catalonian Jasmin*. Leaves opposite, pinnate; leaflets bluntish; buds horizontal. It has much stronger branches than the preceding sort, of which it was once supposed to be a mere variety. The leaflets are placed closer, and are of a lighter green; the side ones are obtuse, but the odd one ends in an acute point. The flowers are axillary, on peduncles two inches long, each sustaining three or four flowers, of a blush red on their outside, but white within.—Native of the East Indies, and of the island of Tobago, where the woods are full of it. It came to us from Spain, and thus it acquired its name of Spanish *Jasmin*. It is propagated by budding or inarching it upon the common White *Jasmin*, on which it takes very well, and becomes hardier than those which are upon their own stocks. But the plants are seldom raised in England, being brought annually from Italy in great numbers. We shall therefore proceed to detail the management of such plants as are usually brought into England. They are generally tied up in small bunches containing four plants, with their roots wrapped in moss to prevent them from drying, which, when the ship has a long passage, will often occasion them to put out long shoots from their roots, and which shoots must always be taken off before they are planted, otherwise they will exhaust the whole nourishment of the plant, and destroy the graft. In choosing these plants, observe carefully if their grafts be alive and in good health; for if they are brown and shrunk, they will not push out, so that there will be only the stock left, which is of the common sort. When you receive them, clear the roots of the moss, and take off all the decayed branches: place the roots in a pot or tub of water, which should be set in the green-house, or some other room, where it may be screened from the cold; in this situation they may continue two days, after which prune off all the dry roots, and cut down the branches within four inches of the place where they were grafted, planting them in pots filled with fresh light earth; then plunge the pots into a moderate hot-bed of tanners' bark, observing to water and shade them as the heat of the season may require. In about a month or six weeks after, they will begin to shoot, when you must carefully rub off all such as are produced from the stock below the graft; and admit a great share of air, by rising the glasses in the heat of the day. As the shoots extend, they should be topped, to strengthen them, and by degrees should be hardened to endure the open air, into which they should be removed in the beginning of June, but must have a warm situation the first summer, for they will not make much progress if greatly exposed to the wind, being rendered somewhat tender by the hot-bed. If the summer prove warm, and the trees have succeeded well, they will produce some flowers in the autumn following, though they will be few in number, and not near so strong as they will be in the succeeding year, when the trees have acquired better roots. These plants are commonly preserved in green-houses with Oranges, Myrtles, &c. and during the winter season will require to be frequently watered, which should be sparingly performed each time, especially in cold weather. In April their shoots should be shortened down to four eyes, and all the weak branches cut off; and if you have the con-

venience of a glass stove or a deep frame to place the pots in at that season, it will be of great service in forwarding the flowering of the plants. They ought not, however, to be too much forced; and as soon as they have made shoots three or four inches long, the glasses should be opened in the day-time, that the plants may by degrees be inured to the open air, into which they may be removed by the latter end of May, or the beginning of June, otherwise their flowers will not be so fair, nor continue so long. If the autumn prove favourable, they will sometimes continue to produce fresh flowers until November, and will sometimes continue flowering much later when they are strong; but in mild weather they must have a great share of air, otherwise the flower-buds will grow mouldy, and decay. Although most people preserve these plants in green-houses, yet they will endure the cold of our ordinary winters in the open air, when planted against a warm wall, and covered with mats in frosty weather; they will also produce ten times as many flowers in one season as those kept in pots, and the flowers will also be much larger. They ought not, however, to be planted abroad till they have acquired strength; so that it will be necessary to keep them in pots three or four years, to shelter them from the severities of winter; and when they are planted against a wall, which should be in May, that they may take good root in the ground before the succeeding winter, you must turn them out of the pots, preserving the earth to their roots, and having made holes in the border where they are to be planted, place them therein with their stems close to the wall; then fill up the holes round their roots with good fresh rich earth, and give them some water, to settle the ground about them, nailing up their shoots to the wall, and shortening such of them as are very long, that they may push out new shoots below to furnish the wall, continuing to nail up all the shoots as they are produced. In the middle, or towards the latter end of July, they will begin to flower, and continue to produce new flowers until the frost prevents them; which, when you observe, carefully cut off all the tops of such shoots as have buds formed upon them, as also those which have the remains of faded flowers left: for if these are suffered to remain on, they will soon grow mouldy, especially when the trees are covered, and thereby infect many of the tender branches, and greatly injure the trees. Towards the middle of November, if the weather prove cool and the nights frosty, begin to cover the trees with mats, which should be nailed pretty closely over them, and done when the trees are perfectly dry, otherwise the wet being lodged upon the branches will cause a mouldiness, which the exclusion of the air will convert into a rot: hence it will be very necessary to take off the mats as soon as the weather will permit, to prevent this, and keep them closely covered at night and in frosty weather; at which time some mulch should be laid upon the surface of the ground about their roots, and some hay-bands fastened about their stems; to which, in very severe weather, a double or treble covering of mats over the trees should be added, by which precautions they may be preserved through the hardest winters. In the spring, take off these coverings by degrees; but take care not to expose them too soon to the open air, as also to guard them against the morning frosts and dry easterly winds, which are so destructive to tender plants in the month of March. The covering should not be wholly removed until the middle of April, when the season is settled; at which time you should prune the trees, cutting out all decayed and weak branches, shortening the strong ones to about two feet long, which will cause them to shoot strong and produce many flowers.—There is a variety of this with semi-double flowers, which is only to be found in some curious gardens

though it is common in Italy, from whence it is sometimes brought over amongst the single; the flowers of which have only two rows of leaves, and is rather cultivated for curiosity than for any extraordinary beauty. It may be propagated by budding upon the Common White, as has been directed for the single, and must be treated in the same manner.

15. *Jasminum Nervosum*; *Nerve-leaved Jasmine*. Leaves ovate, three-nerved. Stem shrubby, long, climbing, round, even; flowers pure white, scentless.—Native of the hedges of Cochin-china.

16. *Jasminum Trinerve*; *Three-nerved Jasmine*. Leaves opposite, simple, ovate, attenuated, three-nerved; peduncles axillary, one-flowered. Corolla an inch long, smooth, with lanceolate segments.—Native of Java.

17. *Jasminum Scandens*; *Climbing Jasmine*. Leaves opposite, simple, ovate-oblong, attenuated; panicles brachiate; calicine segments bristle-shaped, reflex. Peduncles short; pedicels very short.—Native of Bengal, climbing to the tops of trees.

Jatropha; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth scarcely manifest. *Corolla*: one-petalled, funnel-form; tube very short; border five-parted; divisions roundish, spreading, convex, concave beneath. *Stamina*: filamenta ten, awl-shaped, approximated in the middle, the five alternate ones shorter, upright, shorter than the corolla; antheræ roundish, versatile. *Pistil*: a weak rudiment, latent in the bottom of the flower. *Female Flowers* in the same umbel with the males. *Calix*: none. *Corolla*: five-petalled, rosaceous. *Pistil*: germen roundish, three-furrowed; styles three, bifid; stigmas simple. *Pericarp*: capsule roundish, trilocous, three-celled; cells bivalved. *Seeds*: solitary, roundish.—ESSENTIAL CHARACTER. *Male*. *Calix*: none. *Corolla*: one-petalled, funnel-form. *Stamina*: ten, alternately longer and shorter. *Female*. *Calix*: none. *Corolla*: five-petalled, spreading. *Styles*: three, bifid. *Capsule*: three-celled. *Seed*: one.—The species are,

1. *Jatropha Gossypifolia*; *Cotton-leaved Physic Nut*, or *Wild Cassava*. Leaves five-parted; lobes ovate, entire, ciliate; bristles glandular, branched on the petioles. Stem from two to three feet high, herbaceous, branched, smooth; common peduncle terminating; partial cymed, bifid; male flowers very copious, females solitary, in the forks of the peduncles; corolla deeply five-parted, dark purple.—Native of the West India Islands, and very common all over Jamaica, where the soil is dry and gravelly, and the situation warm. It grows most luxuriantly about houses where the ground is warmed with dung, and rises in such places to the height of three feet and a half, or more. It is very beneficial in every plantation where they keep much poultry, which are very fond of the seeds. A decoction of the leaves is sometimes used as a purgative in the dry belly-ache; and hence the plant has been called *Belly-ache Weed*. Browne names it *Wild Cassava*, or *Casadar*. It is cultivated for food; and propagated by cutting the stalks into lengths of seven or eight inches, which when planted put out roots.

2. *Jatropha Glauca*; *Glaucous-leaved Physic Nut*. Calicled: leaves five-cleft and three-cleft, serrate-toothed; petioles naked; stipules palmate. Stem herbaceous, erect, a foot high, pubescent; peduncles towards the top, opposite to the leaves, three inches long, the height of the stem. It is distinguished from the preceding at first sight by its glaucous hue.—Native of Arabia and the East Indies. This, and most of the other sorts, are easily propagated by seeds, which should be sown on a good hot-bed in the spring; and when the plants are fit to remove, they should be each transplanted

into a small pot filled with light earth, and then plunged into a fresh-hot bed of tanners' bark, carefully shading them till they have taken fresh root; afterwards they must be treated in the same manner as other tender plants from hot countries, admitting fresh air to them daily, in proportion to the warmth of the season; but as many of the sorts have succulent stalks, some of which have a milky juice, they must have but little water, being soon destroyed by wet.

3. *Jatropha Spinosa*; *Prickly-stalked Physic Nut*. Calicled: leaves three-parted; lobes angular upwards, and quite entire; stem shrubby, prickly. Corolla five-petalled.—For its propagation and culture, see the preceding species.

4. *Jatropha Variegata*; *Variegated Physic Nut*. Calicled: leaves lanceolate, quite entire. Corymbs axillary, shorter than the leaf; corolla five-petalled; petals oblong; antheræ eight.—For its propagation and culture, see the second species.

5. *Jatropha Glandulosa*; *Glandular Physic Nut*. Calicled: leaves five-lobed, villose; lobes toothletted, glandular; stem shrubby, without stipules. This and the preceding species, though they are furnished with a calix, are distinct from the genus *Croton*, the flowers in that being in spikes.—For its propagation, &c. see the second species.

6. *Jatropha Moluccana*; *Molucca Physic Nut*. Leaves ovate, quite entire, somewhat toothed. This is a tree, with alternate, ovate, or ovate-cordate leaves, with some scarcely-conspicuous angles, or one or two teeth. Corymb terminating, variously dichotomous. Swartz says, that it ought to constitute a distinct genus.—Native of the Molucca Islands, and of Ceylon.

7. *Jatropha Divaricata*; *Divaricated Physic Nut*. Leaves ovate, acuminate, entire, very smooth; racemes divaricating.—Native of Jamaica. For its propagation, &c. see the second species.

8. *Jatropha Curcus*; *Angular-leaved Physic Nut*. Leaves cordate, angular. Stem a fathom in height, sometimes seven or eight feet, but rarely more, round, smooth, and branched; flowers in terminating cymes, males pale yellow, females green.—Native of South America, and the islands in the West Indies. Brown says it is very common in all the sugar colonies, and is frequently cultivated in inclosures, but dies after a few years. The leaves are much used in resolute baths and fomentations, and the seeds sometimes as a purgative, but they operate violently, and are on that account now but little used. Gærtner suggests, that it was first observed by Boyle, and that the fruit might be eaten with safety if the embryo were taken out. For the propagation and culture, see the second species.

9. *Jatropha Multifida*; *French Physic Nut*. Leaves many-parted, even; stipules bristle-shaped, multifid. It grows to the height of five, six, or seven feet, with a very smooth suffrutescent stem, and spreading branches: peduncles terminating, very long, round, thick, very smooth, subdivided; flowers small, red.—It is now very common in most of the islands in the West Indies, but was first introduced from the continent into the French Islands, and is therefore called *French Physic Nut* in the British Islands. It is much cultivated in Jamaica, and forms no small ornament in their flower gardens with its large bunches of beautiful red flowers. The whole plant distils a tenacious watery liquor. The seeds are purgative, but so violent in their operation, that they are now rarely administered, although it was formerly almost the only purgative medicine used among the Spaniards. It flowers from June till August. For its propagation and culture, see the second species.

10. *Jatropha Manihot*; *Eatable-rooted Physic Nut*, or *Cassava*. Leaves palmate; lobes lanceolate, quite entire,

even. This plant shoots from a tough, branched, woody root, the slender collateral fibres of which swell into those fleshy conic masses, for which the plant is cultivated; and rises by a slender woody knotted stalk, to the height of four, five, or six feet, and sometimes more. The flowers are produced in umbels at the top of the stalks, some male and others female; petals five, spreading. This plant, which formerly supplied the greatest part of the sustenance of the native Indians, is now raised in most parts of America, and generally considered as a very beneficial vegetable, yielding an agreeable wholesome food, which, with its easy growth, and hardy nature, afford it an universal recommendation. It grows to perfection in about eight months, but the roots will remain a considerable time in the ground uninjured. They are generally dug up as occasion requires, and prepared for use in the following manner: first well washed and scraped, then rubbed to a pulpy farina on iron graters, put into linen or palm-leaf bags, and placed in a convenient press until the juice is entirely extracted. The farina is then taken out, and spread in the sun for some time, pounded in large wooden mortars, run through coarse sieves, and afterwards baked on convenient iron plates. These are placed over proper fires, and when hot bestrewed with the sifted meal to whatever size or thickness people please to have the cakes made: this agglutinates as it heats, grows gradually harder, and when thoroughly baked is a wholesome well-tasted bread. *Tapioca* is also prepared from this root. What is expressed from the farina is frequently preserved and employed in many economical uses: in boiling it throws up a thick viscid scum, which is always thrown away, and the remaining fluid is sometimes diluted and kept for common drink, and is thought very much to resemble whey in that state. Some use it in sauce, for fish and many other sorts of food, as it was used by the native Indians long before Europeans had landed in those parts of the world. The juice of the root is sweetish, but more or less of a deleterious nature, both in a fresh and a putrid state, though it hardly retains any thing of this quality while in a state of fermentation. The milky juice swallowed, or the root eaten without preparation, brings on convulsions, and occasions violent retching and purging: it acts only on the nervous system, and produces no inflammation in the stomach; but the stomach of one poisoned by it, appears both in man and other animals to be contracted one half. However violent the rough juice may be found immediately after it is expressed, it is certain that swine eat the roots daily without any detriment; and a little mint-water and salt of wormwood will calm the most violent symptoms that arise on taking it, and prevent all bad consequences, even in the human species, if but speedily administered. The farina, while yet impregnated with the juice, makes an excellent salve, which seldom fails to cleanse and heal the most desperate sores: where these are very foul, or the parts too much relaxed, it is sometimes mixed with a few pounded tobacco leaves; and has been often found effectual where common ointments have not had the least force; it is also used by way of poultice, and is an excellent resolutive. In Madagascar, Cassava is the ordinary food of the Blacks; and the French call it, *Madagascar Bread*. In the West Indies it is called *Cassava*, *Cassada*, or *Cassadar*; in Brazil, *Mandihoca*, *Manuba*; whence we have the name *Manihot*; and in French, *Manihot*. The Caribes call it *Juka*, or *Yuka*; which name is adopted by the Germans and the Spaniards, who call it *Yucca de Cassabe*. At Rio Janeiro they call it the Flour or Meal of the Cassava root, or *Farinha de Pao*, Wood Flour, and not Powder of Post, as it has been absurdly translated.—It flowers here in July and August. The Cassava root thrives best in the West Indies, in a free mixed soil, is pro-

pagated by the bud or gem, and is generally cultivated in the following manner: The ground is first cleared, and hoed up into shallow holes of about ten or twelve inches square, and seldom above three or four inches in depth. When they intend to plant, they provide a sufficient number of full-grown stems, and cut them into junks of about six or seven inches long, as far as they find them tough and woody, and well furnished with prominent well-grown hardy buds: of these they lay one or two in every hole, and cover them over with mould from the adjoining bank; but care must be taken to keep the ground clean till the plants rise to a sufficient height to cover the mould, and to prevent the growth of all the weaker weeds.

11. *Jatropha Janipha*; *Carthaginian Physic Nut*. Leaves palmate; lobes quite entire, the middle ones on both sides lobed with a sinus. This is an upright shrub, smooth all over, abounding in an aqueous juice, that is somewhat clammy, and has the smell of Walnut leaves. Roots very tuberous, like those of *Asphodel*, in bundles; racemes loose, bearing a few female flowers below many males; corolla yellowish and brownish green. In close woods it frequently rises with a weak, unbranched, rod-like stem, to the height of twenty feet, and it retains this habit in the European stoves.—Native of South America, common about Carthage, flowering almost the whole year; also of China, where, Loureiro says, it is used not raw but boiled, as a resolutive, like the preceding.

12. *Jatropha Urens*; *Stinging Physic Nut*. Leaves palmate, toothed, prickly. Root thick, swelling, fleshy, from which arises an herbaceous stalk as thick as a man's thumb, four or five feet high, dividing into several branches, closely armed with long brown spines. The flowers are produced in umbels at the top of the branches, standing upon long naked peduncles; they are of a pure white colour. The nerves of the leaves are armed with stinging spines.—It flowers from May to July; and is a native of Brazil. There is a variety with leaves divided like the common Wolf's-bane.

13. *Jatropha Herbacea*; *Herbaceous Physic Nut*. Prickly: leaves three-lobed; stem herbaceous. The whole plant is closely armed with long stinging bristly spines. The flowers grow in an umbel at the ends of the branches; they are small, of a dirty white colour.—Native of La Vera Cruz. It is an annual plant: if the seeds be sown early in the spring, and the plants are brought forward, they will perfect their seeds the same year; but the other sorts are perennial, and do not flower till the second or third year.

14. *Jatropha Elastica*; *Caoutchouc*, or *Elastic Gum Tree*. Leaves ternate, elliptic, quite entire, hoary underneath, on long petioles. This tree is described as very lofty and straight, and quite naked up to the head, which is very small; the trunk of the largest is only about two feet in diameter: the fruit is triangular, enclosing three seeds: these seeds or kernels, peeled and boiled in water, yield a thick oil, which the Indians use as butter with their food; the wood of the tree is light, and fit for masts.—It is a native of Guiana, of Quito, and Brazil, particularly in Para, where it is called *Massaradub*. The Indians, by an incision in the bark, extract a viscid white substance, like that which issues from the Fig-tree; they receive it into earthen moulds, to make rings, bracelets, girdles, syringes, hats, boots, flambeaux, figures of animals, &c. The Abbé Rochon says, that the inhabitants of Madagascar also make flambeaux of it, which burn without wicks, and afford them a very good light when they go out to fish in the night-time. *Caoutchouc* has the extensibility of leather, with very considerable elasticity; spirit of wine makes no impression on it, but it dissolves in ether and linseed oil, or in nut oil digested gently in a sand bath;

there are also other fat and oily substances which affect it very sensibly. The Chinese have been long acquainted with the art of dissolving it, and of giving it various colours; but perhaps the purpose to which it has been most universally applied, is that of obliterating pencil lines, for the reader will by this time suspect it to be nothing less than our famous India Rubber, to which artists and accountants are under such great obligations. It was first found by Mons. Condamine, in 1745, upon the banks of the river of Amazons, and is very common in Quito, where it is called *Hheve*. There are several trees which yield the resin called elastic gum, or a juice very similar; as, *Ficus Indica*, *Cecropia Peltata*, *Siphonia Caoutchouc*, *Artocarpus Integrifolia*, and *Urceola Elastica*.

Iberis; a genus of the class Tetradynamia, order Siliculosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets obovate, concave, spreading, small, equal, deciduous. *Corolla*: four-petalled, unequal; petals obovate, obtuse, spreading; claws oblong, upright: of these the two exterior petals are far larger, and equal to each other; the two interior very small, reflex. *Stamina*: filamenta six, awl-shaped, upright, of which the two lateral ones are shorter; antheræ roundish. *Pistil*: germen roundish, compressed; style simple, short; stigma obtuse. *Pericarp*: silicle upright, suborbiculate, compressed, emarginate, surrounded by a sharp edge, two-celled; partition lanceolate; valves navicular, compressed, carinated. *Seeds*: a few, subovate. *Observe*. The sixth species has nearly equal flowers, and a subquadrangular silicle: the silicle is not emarginate in the seventh species. *Is the partition bipartite in all the species?* ESSENTIAL CHARACTER. *Corolla*: irregular, with the outer petals larger. *Silicle*: emarginate, many-seeded: (in some of the species one seed only in each cell.)—The species are,

1. *Iberis Semperflorens*; *Broad-leaved Evergreen Candy-tuft*. Frutescent: leaves wedge-shaped, quite entire, blunt. A shrubby plant, seldom rising above a foot high, having many slender branches, which spread on every side, and fall towards the ground if they are not supported; they are well furnished towards their extremities with leaves, which continue green all the year; in summer the flowers are produced at the end of the shoots; they are white, and grow in an umbel, continue long in beauty, and being succeeded by others, the plants are rarely destitute of them, from the end of August till the beginning of June, which circumstance makes this a very valuable plant.—Native of Persia and Sicily. It is somewhat tender, and generally sheltered during winter in a green-house, where, being placed among other diminutive plants to the front of the house, it makes a pleasing variety, flowering throughout the winter; but though usually thus treated, in moderate winters it will live in the open air, if it be planted in a warm situation and on a dry soil; and if in very hard frost it be covered either with mats, reeds, straw, or pease-haulm, it may be preserved very well, and these plants which grow in the full ground will thrive better, and produce a greater number of flowers, than those which are kept in pots: but the soil in which these are planted, should not be over-rich nor too wet, for in either of these they will grow too vigorously in summer, which will place them in greater danger of suffering by the frost in winter; but when they grow on a gravelly soil, or among lime rubbish, their shoots being short, strong, and not so replete with moisture, will better resist the cold. The plant rarely produces seeds in England, and is therefore only propagated by cuttings, which, if planted during the summer months, and shaded from the sun, and duly watered, will be rooted in two months,

and may afterwards be either planted in pots, or into the borders where they are designed to stand.—There is a variety with striped leaves; but not being so hardy as this, must be more tenderly treated in winter, and may also be increased by cuttings.

2. *Iberis Sempervirens*; *Narrow-leaved Evergreen Candy-tuft*. Frutescent: leaves linear, quite entire, acute. This is of humbler growth than the first species, seldom rising more than six or eight inches high, nor are the branches woody, but herbaceous. The leaves continue green throughout the year.—It flowers from April to June, and is a native of the island of Candia, on rocky ground. As this species rarely produces seeds in England, it is increased by slips, which easily take root in summer: the plant may be treated in the same manner as the first sort, and will thrive in the open air.

3. *Iberis Garexiana*. Leaves oblong-lanceolate, acute; stems fruticulose, diffused, flexile, warted; branchlets leafy, upright. Root horizontal, with many fibres; stems many, depressed, brown, round, naked, commonly simple; corolla white, the two outer petals double the size of the others. It has no smell. The seed-vessel differs no otherwise from a capsule, than in having deciduous valves, and it has only a single seed in each of the two cells.—Native of Piedmont, about Strop, above Tende, in the high mountains between Briga and Carlin, and above Frabrosa.

4. *Iberis Gibraltaria*; *Gibraltar Candy-tuft*. Frutescent: leaves toothed at the tip. Stems many, thick, green, striated, ascending, from a foot to eighteen inches in length, divided into several branches; flowers terminating in corymbs, first white, afterwards pale purple, without scent, the two outer petals broader and longer: the flowers bear some resemblance to those of the eighth species, but when they blow in perfection; they are usually twice as large; hence they are highly ornamental in the green-house early in the spring, at which time they appear. It is nearly allied to the first species, but is less shrubby and woody; the leaves are toothed towards the end, and the flowers are in larger corymbs.—Native of Spain. It is easily raised from cuttings, and may be kept through the winter in a common hot-bed frame; in mild winters it will stand abroad, especially if sheltered among rock-work: moisture often destroys it in the winter season; the moisture ought therefore to be dissipated by gentle heat.

5. *Iberis Saxatilis*; *Rock Candy-tuft*. Suffrutescent: leaves lanceolate-linear, fleshy, acute, quite entire, ciliate. Root woody, hard, twisted, and large; stems diffused, numerous, branched at the base, scarred with fallen branches and leaves, three or four inches high; the stems and branches are almost naked at top, and terminate in a corymb of white or purple flowers: in the progress of the inflorescence the corymb becomes a raceme. It varies with leaves almost flat, and little, if at all, ciliated.—Native of the South of France and Italy. This, and the two following species, are propagated by seeds sown on a shady border in autumn: when the plants are strong enough to remove, transplant them into a shady border, where they are to remain, and they will require no other care but to keep them clean from weeds. The flowers of this plant have a pleasant smell.

6. *Iberis Rotundifolia*; *Round-leaved Candy-tuft*. Herbaceous: leaves ovate; stem-leaves embracing, even, juicy. Stems naked, slender, creeping, branched; flowers in racemes on spreading peduncles; calix reddish; petals purple, with the border entire, blunt, oval; seed smooth. It flowers from May to July. This, and all the preceding sorts, are perennial: the following are annual, except the next, which seems to be perennial.—Native of Switzerland,

Carniola, the south of France, Italy, and Silesia. See the fifth species.

7. *Iberis Cepeæfolia*; *Onion-leaved Candy-tuft*. Herbaceous: leaves ovate; stem-leaves sessile, even, juicy. Root long, round, slender, fungous, branched, creeping obliquely, reddish violet-coloured on the outside; stems several, scarcely half a span in height, prostrate, with the flowering tops curved upwards; petals obovate, oblong, entire, equal, lilac-coloured; flowers sweet-smelling like the preceding: they appear in May.—Native of Carinthia. See the fifth species.

8. *Iberis Umbellata*; *Purple Candy-tuft*. Herbaceous: leaves lanceolate, acuminate, the lower serrate, the upper quite entire. Root annual, white, oblong, fusiform; stem upright, leafy, half a foot, or a span to a foot in height; flowers in a hemispherical corymb, on peduncles half an inch in length; the usual colour is a pale purple, but there is one variety with bright purple, and another with white flowers. The flowers appear in June and July, and may be continued in succession till autumn.—Native of the south of Europe. This, with the ninth and eleventh species, are sown in small patches upon the borders of the flower-garden: and, by sowing them at three or four different times, there may be a succession of them in flower till autumn; when they are grown up, they should be thinned, that they may put out side-branches, flower stronger, and continue longer in beauty. This plant was formerly sown for edgings; for which it is, like all other annuals, extremely unfit.

9. *Iberis Amara*; *White Candy-tuft*. Herbaceous: leaves lanceolate, acute, somewhat toothed; flowers in racemes. Linæus observes, that this resembles the preceding very much, being only smaller; it differs however in many other respects: stem seven or eight inches high, pubescent, somewhat rugged, branched; branches diffused, alternate; leaves bright green, thickish, smooth; flowers white, in a terminating spike-like raceme, or rather in a corymb lengthened into a raceme as the inflorescence advances.—Native of Switzerland, Germany, Austria, south of France, and England, where it is found about Henley, Nettlebed, and Mungewell, in Oxfordshire, and on Wallingford common, in Berkshire.

10. *Iberis Linifolia*; *Flax-leaved Candy-tuft*. Herbaceous: leaves linear, quite entire; stem-leaves serrate; stem panicled; corymbs hemispherical. Root simple, white, twisted, having few fibres; stem herbaceous, straight, slender, branched at top; branches mostly bifid; flowers in corymbs, the outer ones peduncled, with the two outer petals larger; the colour is purple, and they appear in July. It is an annual plant.—Native of Spain, Portugal, and Provence.

11. *Iberis Odorata*; *Sweet-scented Candy-tuft*. Herbaceous: leaves linear, widening at top, and serrate. This seldom grows so large as the Purple Candy-tuft, and the flowers are much smaller, but have an agreeable odour: they are in close corymbs, and of a snowy whiteness.—Native of the mountains near Geneva.

12. *Iberis Arabica*. Herbaceous: leaves ovate, smooth, veinless, quite entire; silicles two-lobed at the base and tip.—Native of Arabia and Cappadocia.

13. *Iberis Nudicaulis*; *Naked-stalked Candy-tuft*, or *Rock-cress*. Herbaceous: leaves sinuate; stem naked, simple. The stems are from two to four inches in height, numerous, decumbent when young, but finally upright, simple, round, and smooth; root-leaves spread on the ground in a circle, petioled; flowers in a terminating spike-like raceme, small, white, and scentless, on peduncles half an inch long, and spreading wide.—Native of most parts of Europe, in dry and barren soils. It is found on Hounslow-heath, Putney and Barnes commons, and near Hampton-court and Richmond;

at Blackheath by the road from Greenwich to Lewisham; at Ilford, in Essex; near Gamlingay, in Cambridgeshire; Bungay, in Suffolk, and near Norwich; near Pensham, in Worcestershire; at Harmer-hill, near Salop; at Nottingham-park; at Little Creaton, in Northamptonshire; between Corby Castle and Carlisle; and in some parts of Scotland. This diminutive plant is rarely admitted into gardens; the seeds may be sown in autumn where the plants are designed to remain, and require no other care but to keep them clean from weeds.

14. *Iberis Pinnata*; *Winged Candy-tuft*. Herbaceous: leaves pinnatifid. Stem about a foot and a half in height, commonly simple, but sometimes with a branch or two; flowers in a corymb, clear white, seldom purple.—It flowers from July to August, and is a native of the south of Europe.

Ice-House; a building sunk in the ground, to preserve ice in the summer season. In the choice of a situation for an ice-house, the principal regard should be that of a dry spot of ground, for wherever there is moisture the ice will melt; therefore in all strong lands, which retain the wet, there cannot be too much care taken to make drains all round the building to carry off all moisture; which, when lodged near the building, will produce a damp that will always be prejudicial to the preservation of the ice. The next consideration must be, to have the place so elevated that there be descent enough to carry off whatever wet may fall near the building, or from such portions of the ice as may occasionally melt; also, that the place be as much exposed to the sun and air as possible, and not placed under the drip or in the shade of trees, as has been so often practised, under a false notion, that, if it should be exposed to the sun, the ice will melt away in summer; which never can be the case where there is sufficient care taken to exclude the outward air, (which must always be attended to in the building of these houses,) for the heat of the sun can never penetrate through the double arches of the building, so as to add any warmth to the air: but when it is entirely open to the sun and wind, all damps and vapours will be thereby removed from about the building, which cannot be kept too free from moist vapours. The form of the house may be adapted to the fancy of the owner, but the well into which the ice is to be put, should be circular, and the diameter and depth proportioned to the quantity of ice it is proposed to contain. It is best to take care that it be amply capacious, so as to hold an abundance; for, when the house is well built, it will keep the ice for two or three years, which will secure this advantage, that the stock will hold out during a mild winter whenever it may occur. If the quantity required is not great, a well of six feet diameter and eight feet depth will be large enough; but for a large consumption it should not be less than nine or ten feet in diameter, and as many deep. Where the situation is either dry chalk, gravel, or sand, the pit may be entirely below the surface of the ground; but in strong loam, clay, or moist ground, it will be better to raise it so high above the surface as to obviate the approach of wet. At the bottom of the well, there should be a space left two feet deep, to receive any moisture which may drain from the ice, from which a small underground drain should be laid to carry off the water. Over this should be placed a strong grate of wood, to let the moisture descend. The sides of the well must be walled up with brick or stone, at least two feet thick; but the thicker the better, for the less danger there will be of the ice being affected by any external cause. When the well is brought within three feet of the surface, there must be another outer wall or arch begun, and carried up to the height of the top of the intended

arch of the well; and if there be a second arch turned over from this well, it will add to the goodness of the house; but if not, then the plate into which the roof is to be framed must be laid on this outer wall, which should be carried high enough above the inner arch to admit of a door-way in, to get out the ice. If the building is to be covered with slates or tiles, there should be a thickness of reeds laid under, to keep out the sun and external air: if these reeds be laid two feet thick, and plastered over with lime and hair, there will be no danger of the heat getting through it. The external wall need not be circular; it may be either square, hexangular, or octangular, and, where it stands much in sight, may be contrived so as to form a good object. The aperture at the mouth of the well need not be above two feet and a half in diameter, and there should be a stone fitted to stop it, and the aperture must be closed up as secure as possible after the ice is put in, and all the vacant space above and between this and the outer door must be filled close with barley straw, to exclude the air. The building being finished, should have time to dry before the ice is put into it, for the damp of green walls frequently melts the ice. Upon the wooden grate, at the bottom of the well, some small faggots should be laid, and if a layer of reeds be smoothly placed upon these, it will be better for the ice to lie upon than the straw, which is commonly used. In choosing ice, observe, the thinner it is, the better it may be broken to powder, and the more easily it will unite when put into the well. Care must be taken to ram it close, and, by laying straw all round the wall, to allow a vacancy of about two inches to drain off the moisture that may be occasioned by the melting of the ice on the top, which, if not drawn off, will melt the ice downwards. A little saltpetre mixed with the ice, at every ten inches or a foot thickness, when it is put into the well, will cause it to unite more closely into a solid mass: and there must be a crow, or other iron instrument, always in readiness to break it up, taking out no more at each time than is immediately wanted.

Jesuit's Bark. See *Cinchona*.

Jew's Mallow. See *Corchorus*.

Ignatia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, short, bell-shaped, five-toothed; teeth upright, ovate, obtuse. *Corolla*: one-petalled, funnel-form; tube filiform, of a span length, smooth, upright; border flat, five-parted; divisions oblong, obtuse, perfectly entire. *Stamina*: filamenta five, inserted into the receptacle, length of the tube, thread-shaped, very smooth; antheræ five, converging into an oblong column, which is five-cornered, sharp, and rough. *Pistil*: germen very small, ovate, very smooth; style filiform, length of the stamina; stigma slender, two-parted; divisions awl-shaped. *Pericarp*: berry pear-shaped, large, one-celled, with a thick woody bark. *Seeds*: several, covered with a thin cuticle, solid, horny, very hard; the lateral ones irregularly tetragonal, with the inner sides flat, the outward gibbose, the interior oblique; the central one hexagonal, with flat sides. **ESSENTIAL CHARACTER.** *Calix*: five-toothed. *Corolla*: funnel-form, very long. *Fruit*: one-celled, many-seeded.—The species are,

1. *Ignatia Amara*; *Bitter Beans*. Leaves ovate, acute; stem scandent; peduncles axillary, four-flowered or thereabouts. This is a branching tree; the branches long, round, very smooth, climbing; flowers very long, nodding, white, in small panicles; fruit ovate, with a very smooth dry rind.

—Native of the East Indies and Philippine Islands, whence it has been transported to Cochinchina, and other countries, for cultivation. The seeds, known by the name of *St. Ignatius's Beans*, are much used in the East Indies, and are reputed to be tonic, diaphoretic, emmenagogue, and anthelmintic. They are used in the pituitary apoplexy, colic, cardialgia, intermittent fevers, suppression of the menses, and bites of venomous animals. The dose is from six to twelve grains, reduced to powder, either in wine or water. They never produce any bad effect, although they do not always operate, but are often productive of great relief; too large a dose will bring on vertigo and convulsions, which may be easily removed by drinking freely of lemonade. The younger Linneus erroneously asserts, that the seeds are as poisonous to animals as those of the *Nux Vomica*; for a whole nut, weighing a diachm, has been given to oxen, buffaloes, horses, and swine, without any ill effect.

2. *Ignatia Longiflora*. Leaves oblong, waving, acuminate; peduncles terminating, six-flowered, or thereabouts. This is a branching shrub, five or six feet high, with a smooth green bark, and a white hard wood; corolla white, with a tube a foot in length. It flowers in November, and fruits in January.

—Native of Guiana on the banks of large rivers. The Caribbee name is *Aymara-Posoqueri*.

Ilex; according to Linneus, a genus of the class Tetrandria, order Tetragynia; according to Hudson, class Polygynia, order Diœcia.—**GENERIC CHARACTER.** *Calix*: perianth four-toothed, very small, permanent. *Corolla*: one-petalled, four-parted, wheel-shaped; divisions roundish, spreading, rather large, with cohering claws. *Stamina*: filamenta four, awl-shaped, shorter than the corolla; antheræ small. *Pistil*: germen roundish; style none; stigmas four, obtuse. *Pericarp*: berry roundish, four-celled. *Seed*: solitary, bony, oblong, obtuse, gibbose on one side, cornered on the other. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Corolla*: wheel-shaped. *Style*: none. *Berry*: four-seeded.—The species are,

1. *Ilex Aquifolium*; *Common Holly*. Leaves ovate, acute, spiny, shining, waved; flowers axillary, subumbelled. It rises from twenty to thirty feet high, and sometimes more, for Bradley mentions a tree sixty feet high; but its ordinary height is not above twenty-five feet. The trunk is covered with a grayish smooth bark; and those trees which are not lopped or browsed by cattle, are commonly furnished with branches for the greatest part of their length, and form a sort of cone. Flowers in clusters from the base of the petioles, on very short peduncles, each sustaining five, six, or more flowers, which appear in May; the corolla of a dirty white. They are succeeded by roundish scarlet berries about Michaelmas, continuing most part of the winter. Mr. Miller says, "In some plants I have observed the flowers were wholly male, and produced no berries; in others female and hermaphrodite; but I found all three upon some old trees growing in Windsor Forest." The late Sir William Watson also made an observation of the same sort. Gerarde remarked hermaphrodite flowers with five petals on one tree, and male flowers with a four-parted petal and an abortive germen on another tree. Professor Martin also says, that in the trees which he observed, the petals were four-parted; and Dr. Withering remarks, that he found the Holly in flower so late as the second week in June, and then all the flowers had four stamens and four pistils; which Haller confirms. Mr. Hudson, however, describes a five-toothed calix and five-parted corolla in the hermaphrodite, with five stamens, five stigmas, and a four-seeded berry; in the male, a four-toothed calix, a four-parted corolla, and four stamens: but whether this be

from his own observation, or only founded on Gerarde's, we are at a loss to know. He has removed the Holly from the class where Linneus and others have placed it, into the class Polygamia, order Diœcia, where it certainly ought to be found, according to the above observations. But it is judiciously remarked by Dr. Stokes, that "before it is removed to another class, it is proper to shew that the majority of the other species are liable to similar sexual variations."—This beautiful tree deserves a place in all plantations of evergreens and shrubs, where its shining leaves and scarlet berries make a fine appearance; and, if a few of the best variegated sorts be properly intermixed, they will enliven the scene. The Holly makes an impenetrable fence, and bears cropping well; nor is its verdure, or the beauty of its scarlet berries, ever observed to suffer from the severest of our winters; it would therefore form a better fence than the Hawthorn, were it not for the slowness of its growth whilst young, and the difficulty of transplanting it when grown to a moderate size; but if it once take well, the hedge may be rendered so close and thick, as to exclude all sorts of animals. Evelyn's impregnable Holly hedge, four hundred feet in length, nine feet high, and five thick, has been much celebrated by himself, Mr. Ray, and others. Mr. Miller says, that a Holly hedge should never be clipped with shears, because, when the leaves are cut through the middle, they are rendered unsightly; and should therefore be cut with a knife, close to a leaf; and although by this method it is not shorn so even, it will have a much better appearance. This may be done to ornament a garden hedge, but it is obviously impracticable upon a large scale. The clipping a Holly hedge should not be done later than July. The Holly does best in cold stony lands; prospers on gravel, over chalk; and refuses not, says Mr. Butcher, the poorest, hot, sandy, gravelly, and rocky ground, nor the coldest clay; on which last, however, it has been observed to advance with a most discouraging slowness. Mr. Marshall relates, "that in the Wolds of Yorkshire, he has seen the Holly raised, by the practice of a man who paid great attention to the business of hedge-planting, with an unusual rapidity and certainty;" this man's secret would be of inestimable value to the public, and perhaps our intelligent readers in that part of the kingdom, may think it worth their while to endeavour to discover and make it known. Forty or fifty varieties, depending on the variegations of the leaves or thorns, and the colour of the berries, all derived from this one species, are raised by the nursery gardeners for sale, and were formerly in very great esteem, but are now less regarded, since the old taste of filling gardens with shorn evergreens has been laid aside; a few, however, of the most lively varieties, would have a good effect in plantations during the winter season, if properly disposed.—The following are the most beautiful varieties: Painted Lady; British; Bradley's-best; Phyllis, or Cream; Milkmaid; Prichet's-best; Cheyne's; Glory of the West; Broderick's; Partridge's; Herefordshire white; Blind's Cream; Longstaff's; Eales's; Gold-edged, and Silver-edged Hedge-hog Holly; Chohole; Box-leaved Green; Chimney-sweeper; Glory of the East; Wife's; Gray's; Common-blotched; Yellow-blotched Hedge-hog; Blotched Yellow-berried; Mason's; Copper-coloured; Sir Thomas Frankland's Britain; Whitmill's; Bradley's Long-leaved; Bradley's Yellow; Bridgman's; Well's; Glass's; Bagshot; Brownrig's; Lanton; Aslet's; The Union; Fuller's Cream; Capel's Mottled; and the White-berried. Of all the varieties above enumerated, the Hedge-hog Holly is the most remarkable. The leaves are not so long as those of the common Holly, and have the edges armed with stronger

thorns, standing close together, the upper surface set very close with short prickles: as it retains its difference when raised from berries, Mr. Miller insists that it is a distinct species: he informs us that there are two varieties of it with variegated leaves, one green and yellow, and the other green and white. It grows naturally in Canada.—The wood of the Holly-tree, says Evelyn, is the whitest of all hard woods, and is used by the inlayers, especially under thin plates of ivory. The mill-wrights, turners, and engravers, prefer it to any other; it makes the best handles and stocks for tools, flails, riding-rods, and carters' whips, bowls, clivers, and pins for blocks, and is also excellent for door bars and bolts; it is made even into hones for setting razors: and takes so fine a polish, that it is very suitable for several kinds of furniture. Mr. Miller mentions the floor of a room laid in compartments of this wood, with mahogany, which had a very pretty effect. It is much used with box, yew, and white-thorn, in the Tunbridge ware, and in veneering, and is sometimes stained black to imitate ebony. Sheep are fed during winter with the croppings; birds eat the berries: and the bark fermented, and afterwards washed from the woody fibres, makes the common *birdlime*.—The berries are of a warm carminative nature, and good for relieving the colic; they may be taken to the number of twelve or fourteen at a time; and as they purge, often occasion a considerable evacuation of wind and slime by stool. A decoction of the leaves in milk or ale, produces the same effects, and is serviceable in pains and weakness of the back. A person who was noted for his success in the cure of rheumatic complaints, used no other medicine than a decoction of the young buds or leaves of this tree in water, which, after being strained, was sweetened with coarse sugar, and given to the patient to drink, while warm in bed, to the amount of half a pound weight of the liquid, three or four times a day, till the pain was removed, or at least alleviated; it operated in all cases as a very powerful sudorific; and plenty of small diluting liquors were ordered to be drank during the operation. Culpeper says, "that the dry berries, pounded into powder, will stop fluxes, bloody fluxes, and immoderate menstrual evacuations; and that the bark and leaves are excellent to foment broken bones, or dislocated joints." This tree grows wild in many parts of Europe, North America, Japan, and Cochin-china; and is found in woods and forests in many parts of England, where it is called Hulver and Hulme, as well as Holly: the Germans give it many names, such as *Stechpalme*, *Christdorn*, *Walddistel*, &c.; the Danes call it *Stikpalme*, *Christtorn*, &c.; the Swedes *Jernek*, and *Christtorn*; the French, *Le Houx*, *Le Grand Housson*, *L'Agron*, *Grand Pardon*, *Bois Franc*; the Italians, *Agrifoglio*, *Alloro Spinoso*; the Spaniards, *Acebo*, *Agrifolio*; the Portuguese, *Azevinho*, *Agrifolio*, *Aquifolio*; and the Russians, *Wassoscheld*, *Ostrokrof*, and *Padub*.—The Holly is propagated by seeds, which never come up the first year, but lie in the ground like the Haws; the berries therefore should be buried in the ground, in a large pot or tub, one year, and then taken up in the autumn, and sown upon a bed exposed only to the morning sun; the following spring the plants will appear, and must be kept clean from weeds; and if the spring should prove dry, it will be of great service to the plants if they are watered once a week, but in small quantities, for much moisture is very injurious to them when young: in this seed-bed the plants may remain two years, and then should be transplanted in the autumn, into beds at about six inches' distance each way, where they may stand two years longer, during which time they must be kept constantly clean from weeds; and, if the plants have thriven well, they will be strong enough to transplant where they are intended

to remain; for when they are transplanted at that age, there will be less danger of their failing, and they will grow larger than those removed at a later period: if the ground, however, be not ready to receive them at that time, they ought to be transplanted into a nursery, in rows at two feet distance, and one foot asunder in the rows, where they may remain two years longer; and if they are designed for grafting or budding with any of the variegated kinds, that should be performed after the plants have grown one year in this nursery; but the plants so budded or grafted, should remain two years after that in the nursery, that they may make good shoots before they are removed. The best time for removing Hollies, is in the autumn, especially in dry land; but where the soil is cold or moist, they may be transplanted with great safety in the spring. Evelyn declares, that he has raised hedges four feet high in four years from seedlings taken out of the woods; and that the varieties with white berries, and gold and silver leaves, may be raised from seeds sown and planted in a gravelly soil, mixed with store of chalk, and pressed hard down. The stocks will be fit to be grafted or budded at four or five years' growth; the grafting must be done in March, and the budding in July. For sowing, Boucher directs that the berries should hang on the trees till December, or, if they could be defended from birds, till February or March; as soon as they are gathered, throw them into a tub with water, and rub them between your hands till the seeds are divested of their thick glutinous covering; pour off the water, with the light seeds and mucilage, and spread the seeds on a cloth, in a dry airy place, rubbing them frequently, and giving them a fresh cloth daily, till the seeds are quite dry: if this be done in autumn or winter, mix them with sand, and keep them dry till spring; but if they have been gathered in spring, let them be immediately sown; this may be done any time, during seasonable weather, in March or April, in beds of loose light mould.

2. *Ilex Opaca*; *Carolina Holly*. Leaves ovate, acute, spiny, smooth, flat; flowers scattered at the base of the last year's shoots. It flowers in May and June.—Native of Carolina.

3. *Ilex Perado*; *Thick-leaved Smooth Holly*. Leaves ovate, with a point, unarmed, almost entire. It flowers in April and May.—Native of Madeira.

4. *Ilex Prinoides*; *Deciduous Holly*. Leaves elliptic-lanceolate, acute, deciduous, serrate; serratures without prickles. It flowers in July.—Native of Carolina and Virginia.

5. *Ilex Cassine*; *Dahoon Holly*. Leaves alternate, distant, evergreen, lanceolate, serrate; serratures acuminate. It rises with an upright branching stem to the height of eighteen or twenty feet; leaves four inches long, of a thick consistence, light green: the flowers come out in thick clusters from the sides of the stalks, they are white, shaped like those of the common Holly, but smaller; both the female and hermaphrodite flowers are succeeded by small roundish berries, making a fine appearance in winter; but they have not as yet produced any fruit in England. There are two varieties; one with broader leaves, the other with narrower leaves, with scarcely any serratures.—Native of Florida and Carolina. It is tender while young, and requires protection in the winter till the plants are grown strong and woody, when they may be set in the full ground, in a warm situation, where they will endure the cold of our ordinary winters very well, but must be protected from severe frost, which would destroy them. It is propagated from seeds in the same manner as the common sorts, and the seeds will lie as

long in the ground; they should therefore be buried a year in sand; when taken up, they should be sown in pots filled with light earth, and placed under a frame in winter, and in the spring the pots should be plunged into a hot-bed, which will bring up the plants; they must be preserved in the pots while young, and sheltered in winter under a common frame till they have obtained strength, when in the spring they may be turned out of the pots, and planted in the full ground in a warm situation.

6. *Ilex Vomitoria*; *South Sea Tea*, or *Evergreen Cassine*. Leaves alternate, distant, oblong, blunty, crenate-serrate; serratures without prickles. It rises to the height of ten or twelve feet, sending out branches from the ground upwards, which form themselves into a sort of pyramid; leaves about the size, shape, texture, and colour, of the Small-leaved *Alaternus*, but somewhat shorter, and a little broader at the base; the flowers are produced in close whorls at the joints of the branches, near the footstalks of the leaves, they are white, and are succeeded by red berries, which continue upon the plants most part of the winter, and, being of a bright red colour, make a fine appearance, intermixed with the green leaves; from the berries continuing so long untouched by the numerous birds of their native climate, they are fairly suspected of having a poisonous quality. The leaves of this tree are not so bitter as those of the *Cassine*, or *Cassioberry* bush, especially when green, and are therefore preferred for making an infusion in the manner of tea; which the Indians reckon very wholesome, and is the only physic they use in some parts. At a certain time in the year they come down by droves, from a distance of some hundred miles, to the coast, for the leaves of this tree, which is not known to grow at any considerable distance from the sea; they make a fire on the ground, and putting a great kettle of water on it, throw in large quantities of these leaves, and seating themselves round the fire, from a bowl that holds about a *pint*, begin drinking large draughts, which in a short time occasions them to vomit easily and freely: thus they continue drinking and vomiting for two or three days, until they have sufficiently evacuated and cleansed their stomachs, and then, every one taking a bundle of the tree to carry with him, they all return to their respective habitations. This plant is generally supposed to be the same as that which grows in Paraguay, where the Jesuits raise a great revenue from the leaves.—Native of West Florida, Carolina, and some parts of Virginia. It is propagated by seeds, sown in pots filled with light sandy earth, and plunged into a gentle hot-bed, observing to water them frequently until the plants appear, which is sometimes in five or six weeks' time, but at other times they will remain in the ground until the second year; therefore, if they should not come up in two months, remove the pots into a shady situation, where they may remain till October, being careful to keep them clean from weeds, and now and then, in dry weather, give them a little water; then remove the pots into shelter during the winter, and in March put them upon a fresh hot-bed, to forward the seeds for vegetation: when the plants come up, gradually expose them to the open air, to inure them to the climate, yet they should not be exposed to the open sun at first, but have the morning sun only, placing them for some time where they may be sheltered from cold winds: as they grow slowly, they should be kept in pots four or five years.

7. *Ilex Asiatica*. Leaves broad, lanceolate, blunt, quite entire.—Native of the East Indies.

8. *Ilex Cuneifolia*. Leaves wedge-form, three-cusped.—Native of South America.

9. *Ilex Integra*. Leaves oblong, obtuse, entire; peduncles one-flowered. Stem shrubby, upright.—Native of the Cape.

10. *Ilex Rotunda*. Leaves rounded, acute, entire; peduncles umbelliferous. Stem shrubby; branches subumbelled, somewhat knobbed.—Native country unknown.

11. *Ilex Crenata*. Leaves ovate, crenate; peduncles on the branches scattered, bearing two or three flowers. Stem shrubby, upright; peduncles simple.—Native country unknown.

12. *Ilex Emarginata*. Leaves obovate, emarginate; flowers axillary, usually in pairs. Stem shrubby; flowers peduncled.

13. *Ilex Serrata*. Leaves ovate, acute, ciliate, serrate; flowers axillary, solitary. Stem shrubby, upright, branching very much; flowers on filiform drooping peduncles, half a line long; corolla four-petalled. It flowers in June.

14. *Ilex Japonica*. Leaves opposite, sessile; flowers in terminating racemes. Stem shrubby, smooth, low; peduncles from the axils of the bractes, solitary, one-flowered, capillary; corolla subrotate; petals obovate, entire, white. It flowers in April.—Native place unknown.

15. *Ilex Latifolia*. Leaves ovate, serrate; flowers axillary, aggregate. Stem arborescent; branches rigid, angular, brown; flowers superaxillary, many together from the gems, on short peduncles.—Native place uncertain.

16. *Ilex Crocea*. Leaves oblong, serrate; serratures ciliate-spiny.—Native of the Cape.

17. *Ilex Myrsinites*. Leaves small, opposite, oblong, or subovate, obtuse; margin bent back, partially serrate; branches cylindrical, dark brown, and thickly set with leaves; peduncles axillary, very short, one-flowered; flowers minute, white; calix four-cleft; corolla rotated, four-cleft; filamenta four, of the length of the calix; germen superior, oval; style very short, clavated; stigma four-lobed, thick; seed one, elliptical.—This very curious plant is a native of North America.

Illecebrum; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, cartilaginous, five-cornered, with coloured leaflets, which are sharp with distant points, permanent. *Corolla*: none. *Stamina*: filamenta five, capillary, within the calix; antheræ simple. *Pistil*: germen ovate, sharp, ending in a short bifid style; stigma simple, obtuse. *Pericarp*: capsule roundish, acuminate, both ways five-valved, one-celled, covered by the calix. *Seed*: single, roundish, sharp on both sides, very large. *Observe*. The fruit in several species is different. ESSENTIAL CHARACTER. *Calix*: five-leaved, cartilaginous. *Corolla*: none. *Stigma*: simple. *Capsule*: five-valved, one-seeded.—The species are,

1. *Illecebrum Brachiatum*. Stem upright, herbaceous, brachiate; leaves opposite, even. Spikes several, small, villose, white: annual.—Native of the East Indies.

2. *Illecebrum Sanguinolentum*. Frutescent: leaves opposite; spikes compound, heaped. Stem usually prostrate, and very much branched; antheræ yellow; pistil purple.—It is a perennial plant; and a native of the East Indies.

3. *Illecebrum Canariense*; *Canary Illecebrum*. Shrubby: leaves elliptic, acute; stipules and bractes ovate, shorter; panicles terminating, dichotomous. This is distinguished from the rest by its woody stem, and terminating dichotomous panicles.—Found on the island of Teneriffe.

4. *Illecebrum Lanatum*; *Woolly Illecebrum*. Leaves ovate, somewhat hairy; spikes lateral; calices woolly. Stem rigid, somewhat hairy, branched only at the base. It is biennial, and flowers most part of the year; it varies in size. The great Woolly *Illecebrum* has solitary, not aggregate spikes. Retzius mentions a remarkable variety with round leaves,

found in Malabar.—This, with all the natives of the East and West Indies, or other hot climates, are tender, and will not thrive in the open air in England; their seeds therefore must be sown on a hot-bed, in the spring, with *Amaranthus*, *Gomphrena*, and other tender plants; afterwards, if plunged into the tan-bed in the stove, they will put out roots, whereby they may be propagated in plenty: where seeds cannot be obtained, they may be increased this way, and the perennial sorts by cuttings.

5. *Illecebrum Javanicum*; *Spear-leaved Illecebrum*. Leaves lanceolate, tomentose; spikes cylindrical, numerous, terminating.—Native of the East Indies.

6. *Illecebrum Verticillatum*; *Whorled Knot Grass*. Flowers in whorls, naked; stems procumbent. Leaves opposite, oval, keeled, fleshy, smooth; flowers small, sitting in the axils of the leaves, white, shining, cartilaginous.—Native of many parts of Europe, in wet pastures. It is sometimes found in Devonshire, and the western parts of Cornwall, flowering in July and August.

7. *Illecebrum Suffruticosum*; *Shrubby Knot Grass*. Flowers lateral, solitary; stems suffruticose. It has woody stems about a foot high, with small leaves like those of *Polygonum*. It flowers from May to August; and is a native of the south of Europe. This species, as well as the eighth, tenth, and twelfth, which are natives of the south of Europe, may be propagated by seeds sown on a bed of light earth, in the beginning of April; the plants will come up in May, and should be kept clean from weeds till they are fit to remove, when they should be carefully taken up, planting some of each sort in small pots, and the other in a dry warm border, observing to water and shade them until they have taken new root, after which, those that are planted in the full ground will require no other culture but to keep them clean from weeds; for in the ordinary winters of England, they will survive in the open air; but as they are sometimes killed in severe winters, some should be set in pots to be placed in a common frame, where they may enjoy the open air in mild weather, but be screened from frost. But as their seeds do not constantly ripen, they may also be increased by cuttings, which, if carefully taken off in May and June, and planted in a shady border, will put out roots in two months. In moist weather they may be transplanted, and afterwards treated as the old plants.

8. *Illecebrum Cymosum*; *Flat Knot Grass*. Spikes cymed, directed one way; stem diffused. Root annual; stems two to four inches long; leaves obovate, in fours or thereabouts, linear, thickish; flowers in spikes composed of cymes, both lateral and terminating; calices coloured, vaulted at the tip, awned; germen roundish.—Native of the isle of Elba, the south of France, and of Portugal.

9. *Illecebrum Aristatum*; *Bearded Illecebrum*. Flowers subs fascicled; leaves lanceolate, silky, awned. It flowers in June and July.—Native of the Canaries.

10. *Illecebrum Paronychia*; *Mountain Knot Grass*. Flowers fenced, with shining bractes; stems procumbent; leaves even. The flowers appear in June, and there is generally a succession of them for at least two months; and when the autumn proves warm, the seeds will ripen at the beginning of October. The heads of flowers come out from the joints of the stalk, having neat silvery bractes surrounding them, which make a pretty appearance.—It is perennial, and a native of the south of Europe.

11. *Illecebrum Divaricatum*; *Forked Illecebrum*. Flowers bracted, subs fascicled; peduncles dichotomous, panicled; leaves ovate-oblong, petioled.—It flowers in July and August; and is a native of the Canary Islands.

12. *Illecebrum Capitatum*; *Hooded Knot Grass*. Flowers with shining bractes, hiding terminating heads; stems somewhat erect; leaves ciliate, villose underneath. This is an annual plant, which distinguishes it from the tenth species. Villars contradicts this, and says it is perennial.—Native of Provence, Spain, and the Levant.

13. *Illecebrum Benghalense*. Stem upright, herbaceous; leaves alternate and opposite, lanceolate, pubescent. Root annual; spikes small, hirsute, white, not only from the axils of the leaves, but also at the top, where they glomerate without the leaves.—Native of Bengal, Java, &c.

14. *Illecebrum Arabicum*. Flowers scattered, heaped; bractes shining, equalling them; stems procumbent.—Found in Arabia.

15. *Illecebrum Acayraatha*; *Creeping Illecebrum*. Stems creeping, hairy; leaves ovate, mucronate, one opposite, smaller; heads subglobular, somewhat spiny. Root annual. From the axils of the leaves proceed heads of flowers, the whole length of the stem, but especially on the extreme branchlets; they are chaffy, prickly, and composed of many pale juiceless scales, in which very minute and scarcely conspicuous flowers lie concealed.—Native of Buenos Ayres.

16. *Illecebrum Polygonoides*. Stems creeping, rough-haired; leaves broad-lanceolate, petioled; heads orbiculate, naked. Flowers axillary, white, and under them a three-leaved bracte shorter than the flower. Browne says that this little plant is found creeping in all the low lands and dry savannas about Kingston in Jamaica; that it generally grows in tufts, and spreads about six or eight inches from the root. He calls it Hairy Rupturewort, supposing it to be a *Herniaria*.—Native of the sea-shores of America.

17. *Illecebrum Ficoideum*. Stems creeping, smooth; leaves broad-lanceolate, petioled; heads orbiculate, pubescent. It puts out roots at every joint. Heads of flowers roundish, sessile, numerous. Jacquin says, it abounds so in the meadows of Martinico as to be a noxious weed. It grows wild in Spain.—Native of the coast of America.

18. *Illecebrum Sessile*; *Sessile-flowered Illecebrum*. Stems creeping, bifariously tomentose; leaves lanceolate, subsessile; heads oblong, smooth. Flowers white, in round, axillary heads, often two together. Annual, flowering from July to October.—Native of the East Indies, and of wet places about Canton in China.

19. *Illecebrum Vermiculatum*. Stems creeping, smooth; leaves subcylindric, fleshy; heads oblong, smooth, terminating. This plant spreads a great way among the grass, and throws out a few fibrous roots at every joint. The whole plant has a reddish-brown cast, and something the appearance of *Portulacca*, or Purslain.—Native of Brazil and Curaçao. Very common about Rock-river in Jamaica, and on the sandy shores of South America.

20. *Illecebrum Alsinifolium*. Stems diffused; leaves ovate; flowers heaped; bractes shining.—Native of Spain.

21. *Illecebrum Frutescens*. Stems shrubby, diffused, dichotomous; leaves opposite, mealy. Root woody, branched, gray; spikes solitary, axillary, sessile whilst flowering, but peduncled whilst fruiting, ovate, imbricate, three lines long; flowers crowded very close, imbricate, sessile, of an herbaceous colour, two lines long. The flowers appear and ripen into seed in summer.

Illicium; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: perianth six-leaved, deciduous; the three inferior leaflets oval; the three superior alternate ones narrower, and resembling petals. *Corolla*: petals many, (twenty-seven,) disposed in a triple series; the nine inferior obtuse, concave; the nine middle shorter and

narrower; the interior nine shorter and narrower still. *Stamina*: filamenta very many, (thirty,) short, depressed; antheræ upright, oblong, obtuse, emarginate. *Pistil*: germina very many, (twenty,) disposed in a circle, ending in very short spreading styles; stigmas at the upper side of the style, oblong. *Pericarp*: capsules several, (Loureiro says eight,) ovate, compressed, hard, spreading into a circle, bivalve, (but according to Loureiro, one-valved; and to Gærtner, opening at the upper edge.) *Seed*: solitary, ovate, rather compressed, glossy. ESSENTIAL CHARACTER. *Calix*: six-leaved. *Petals*: twenty-seven. *Capsule*: several, disposed in a circle, bivalve, one-seeded.—The species are,

1. *Illicium Anisatum*; *Yellow-flowered Starry Aniseed Tree*. Flowers yellow. Stem arboreous, a fathom or more in height, smooth all over; leaves aggregate, in threes or fours, elliptic, broader near the tip, evergreen, two inches long; flowers axillary, peduncled, solitary; capsules six or eight, ovate-lanceolate, compressed a little, horizontal, of a substance like cork, rugged without, smooth and even within, having a strong smell of Anise when rubbed. The whole plant, but especially the fruit, has a pleasant aromatic smell, and a sweetish subacid taste. It is stomachic and carminative, and is used in eastern countries in the colic, rheumatism, &c. In China it is also in frequent use for seasoning dishes, especially such as are sweet. The Japanese plant bundles and garlands of this tree in their temples before their idols, and on the tombs of their friends. They also use the pounded bark as incense to their idols; and when finely powdered, this bark is used by the public watchmen to make a chronometer, for measuring the hours, by slowly sparkling at certain spaces as it burns in a box, in order to direct when the public bells are to sound.—Native of China and Japan. It may be propagated by seeds, if they can be procured; or by laying down the young branches; or by cuttings, which strike freely. It requires the same management as *Gardenia*; which see.

2. *Illicium Floridanum*; *Red-flowered Aniseed Tree*. Flowers red. Stem arboreous; general appearance like that of the preceding species; petals from twenty to twenty-seven; leaves extremely fragrant.—Native of Florida.

Immortal Flower, or *Life Everlasting*. See *Gnaphalium*. *Impatiens*; (Balsam) a genus of the class Syngenesia, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved, very small; leaflets roundish, acuminate, equal, placed towards the sides of the flower, coloured, deciduous. *Corolla*: five-petalled, ringent; petals unequal, of which the superior is roundish, flat, upright, slightly trifid, constituting the upper lip; lower pair reflex, very large, outwardly larger, obtuse, irregular, constituting the lower lip; intermediate pair opposite, rising from the base of the upper petal; nectary one-leaved, receiving in the manner of a hood the base of the flower, oblique at the mouth, rising outwardly, ending in a horn at the base. *Stamina*: filamenta five, very short, narrower towards the base, incurved; antheræ as many, connate, divided at the base. *Pistil*: germen superior, ovate, acuminate; style none; stigma simple, shorter than the antheræ. *Pericarp*: capsule one-celled, five-valved, springing open elastically, the valves rolling up spirally. *Seeds*: several, roundish, fixed to a columnar receptacle. *Observe*. In some species the middle petals are wanting, and in some the horn of the nectary; the capsule also differs in figure. ESSENTIAL CHARACTER. *Calix*: two-leaved. *Corolla*: five-petalled, irregular, with a cowed nectary. *Capsule*: superior, five-valved. The seed of all the plants of this genus, except the eighth and twelfth, should be sown on a moderate hot-bed in the spring, and when they are come up about an inch high, they should be transplanted on another hot-bed

at about four inches' distance each way: observing to shade them from the sun till they have taken new root; after which they should have a large share of free air admitted in favourable weather, to prevent them from drawing up tall and weak. They will require to be often refreshed with water, but it should be sparingly given, as their stems are succulent and apt to rot. When the plants are grown so large as to touch each other, they should be carefully taken up with balls of earth to their roots, and each planted in a separate pot filled with light fresh earth, and plunged into a very moderate hot-bed under a deep frame, to admit the plants to grow, shading them from the sun until they have taken fresh root. They should then have a large share of air admitted to them daily, to harden them by degrees so as to bear the open air, into which some of them may be removed in July. They must be placed in a warm situation, where, if the season proves favourable, they will flower, and make a fine appearance. It will be proper, however, to reserve a part under a glass-case or deep frame, in order to obtain good seeds; for those abroad will not ripen their seed unless the summer turn out very warm. The plants thus sheltered will daily require a large portion of free air, to prevent them from becoming sickly: and they must not be too much exposed to the mid-day sun in very hot weather, for that makes their leaves flag, and makes the plants themselves require more water than is wholesome for them; therefore shade them three or four hours in the middle of the day, and they will retain their beauty longer. Those who are curious to preserve these plants in perfection, pull off all the single and plain-coloured flowers from those which they preserve for seeding, leaving those only which are double and have good colours; and they may thus be continued without degenerating in the least.—The species are,

* *With one-flowered Peduncles.*

1. *Impatiens Chinensis*; *Chinese Balsam*. Peduncles one-flowered, solitary; leaves opposite, ovate; nectaries bowed. Flowers red purple. This is an annual plant, a foot high, upright, round, alternately branched, red.—Native of China.

2. *Impatiens Latifolia*; *Broad-leaved Balsam*. Peduncles one-flowered, solitary; leaves ovate; serratures lanceolate; nectaries longer than the flower. The spur is awl-shaped, almost the length of the peduncle. Annual.—Native of the East Indies.

3. *Impatiens Rosmarinifolia*; *Rosemary-leaved Balsam*. Peduncles one-flowered, solitary; leaves opposite, linear. Nectary larger than the petals.—Native of Ceylon.

4. *Impatiens Capensis*. Peduncles one-flowered, solitary; leaves ovate; notches piliferous.—Native of the Cape.

5. *Impatiens Bifida*. Peduncles one-flowered, solitary; leaves oblong, serrate; nectaries very long, bifid.—Native of the Cape.

6. *Impatiens Oppositifolia*; *Opposite-leaved Balsam*. Peduncles one-flowered, aggregate; leaves opposite, linear. This is an upright plant, with a succulent jointed stem; flowers small, with a nectary much shorter than the petals.—Native of Ceylon. Annual.

7. *Impatiens Cornuta*; *Horned Balsam*. Peduncles one-flowered, aggregate; leaves lanceolate; nectaries longer than the flower, which are purple or white; spur three times as long as the petals, somewhat bowed. The Ceylonese call it *kudaetu-kola*, or Swallow-leaf.—It is not only a native of Ceylon, but of Cochin-china; where the inhabitants use a decoction of the leaves to wash their head and hair, to which this plant, which is a common weed in their gardens, gives a very sweet odour.

8. *Impatiens Balsamina*; *Garden Balsam*. Peduncles

one-flowered, aggregate; leaves lanceolate, the upper ones alternate; nectaries shorter than the flower, which comes out from the joints of the stem. This plant in its wild state is about two feet high, with an upright, round, hispid, juicy, white stem, and ascending branches. Flowers red or white, coloured. This plant enlarges very much by culture, and becomes very branching. "I have seen," says Professor Martyn, "the stenis seven inches in circuit, and all the parts large in proportion, branched from top to bottom, loaded with its party-coloured flowers, and thus forming a most beautiful bush." The varieties which cultivation has produced in this elegant flower are numerous; such as white, purple, red, striped, and variegated of these different colours, single and double of each. Mr. Miller particularly mentions two varieties, which may perhaps belong to some of the other species. First, the Immortal Eagle, a most beautiful plant, from the East Indies; the flowers double, much larger than those of the common sort, scarlet and white, or purple and white; and as the flowers are abundant, the plant is very valuable. Secondly, the Cockspur, from the West Indies; which has single flowers as large as the other, but never more than half double, and only with red and white stripes. This is apt to grow to a very large size before it flowers, which is very late in autumn, so that in bad seasons there will be scarcely any flowers, and the seeds seldom ripen.—Native of the East Indies, China, Cochin-china, and Japan, where the natives use the prepared juice for dyeing their nails red. The common single sort will spring in the open ground; and where the seeds scatter they will come up in the spring. But such self-sown plants do not come to flower so early as those which are raised upon a hot-bed, although they will continue later in the autumn; but to have good flowers, the plant must be raised upon a hot-bed. Gerard directs the seeds to be sown at the beginning of April in a bed of horse-dung, and replanted abroad from the said bed into the hottest and most fertile place of the garden, when they have got three leaves apiece.

9. *Impatiens Mutila*; *Mutilated Balsam*. Peduncles one-flowered; leaves lanceolate, serrate, opposite; nectaries mutilated. Stem annual, a foot and a half high, upright, round, with ascending branches; flowers scarlet, on one-flowered subsolitary peduncles.—Cultivated in Cochin-china, probably from China.

10. *Impatiens Cochleata*; *Spiral Balsam*. Peduncles one-flowered; leaves oblong, subserrate, opposite; nectaries spiral; root creeping. Stem annual, a foot high, upright, jointed, red, almost without branches; flowers scarlet, very handsome, but not sweet; capsule fleshy.—Cultivated in China.

** *With many-flowered Peduncles.*

11. *Impatiens Triflora*; *Three-flowered Balsam*. Peduncles three-flowered, solitary; leaves narrow, lanceolate. Stem upright, jointed; flowers large, with the horn of the nectary blunt, curved inwards, thick, scarcely the length of the flower.—Native of Ceylon, and according to Mr. Miller, of many parts of India. He says, the flowers being smaller than the common sort, are not worth cultivating for their beauty; but Burman asserts, that they are large and very elegant.

12. *Impatiens Noli Tangere*; *Common Yellow Balsam*. Peduncles many-flowered, solitary; leaves ovate; joints of the stem swelling. Root annual; stem a foot high, upright, and, like the branches, of a pale yellowish green, smooth and shining, somewhat transparent, thickest at the joints, succulent and brittle; flowers yellow, the lateral petals spotted with red, by cultivation changing to pale yellow or purplish; seeds large, angular, striated. The elasticity of the seed, which when ripe are thrown out with considerable force upon

any thing touching the capsule, has furnished this plant with names in most of the European languages. Hence we call it, *Quick-in-hand*, (alive as it were in the hand,) and *Touch-me-not*. The Germans call it, *springsame*, *springraut*; the Swedes, *springhorn*; the Danes, *springhorn* or *springurt*; the French, *impatiente*, *ne me touchez pas*, from the Latin *impatiens* and *non tangere*, and also *balsamic jaune*; the Italians, *erba impaziente*, *balsamina gialla*; the Spaniards, *noquierus tocarme*, *balsamina amarilla*; and the Portuguese, *melindre nao me toques*. In the day-time the leaves are expanded, but they hang pendent at night, contrary to what is observed in most plants, which, from a deficiency of moisture, or too great perspiration from heat, commonly droop their leaves during the day. The whole plant is rather acrid, so that no animal but the goat is said to eat it. Notwithstanding this, it was formerly considered as diuretic and vulnerary, and was given to relieve the hæmorrhoids and the strangury. Boerhaave considered it as poisonous.—This is the only species of *Impatiens* found wild in Europe. It is also found in Canada. With us it occurs in Wales, and the northern counties of England, in moist shady places, and by the banks of rivulets: as, on the banks of Winandermere, near Amble-side, near Rydall Hall, and between both those places in Westmoreland; in the parish of Satterthwaite, and on the banks of Coniston Lake, in Lancashire; and about Bingley in Yorkshire; flowering in July and August.—If the seeds of this plant be permitted to scatter, they generally succeed better than when they are sown: for unless they are sown in the autumn soon after they are ripe, they seldom grow. They only require weeding and thinning, and delight in a moist soil and shady situation.

Imperatoria; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal, flat-spreading; partial unequal: involucre universal none; partial very slender, with one or two leaflets, almost the length of the umbel; perianth proper, obscure. *Corolla*: universal uniform; floscules all fertile; proper of five petals, inflex-emarginate, nearly equal. *Stamina*: filamenta five, capillary; antheræ roundish. *Pistil*: germen inferior; styles two, reflex; stigmas obtuse. *Pericarp*: none; fruit roundish, compressed, gibbose in the middle, margined, bipartite. *Seeds*: two, ovate, marked on one side with two furrows, surrounded by a broad margin. ESSENTIAL CHARACTER. *Fruit*: roundish, compressed, gibbose in the middle, surrounded by a margin. *Petals*: inflex-emarginate.—The only known species is,

1. *Imperatoria Ostruthium*; *Masterwort*. Root running obliquely in the ground, the thickness of a man's thumb, fleshy, aromatic, with a strong acrid taste, biting the tongue and mouth like Pellitory of Spain. Leaves rising immediately from the root, on footstalks seven or eight inches long, dividing into three very short ones at the top, each sustaining a trilobate leaf, indented on the border. The footstalks are deeply channelled, and when broken emit a rank odour. The flower-stalks rise about two feet high, and divide into two or three branches, each being terminated by a pretty large umbel of white flowers, whose petals are split; succeeded by oval compressed seeds, like those of Dill, but larger. The flowers appear in June, and ripen seeds in August. The root of this plant is warm and aromatic; a sudorific, diuretic, and sialagogue: it is recommended in dropsies, and debilities of the stomach and bowels. An infusion of it in wine is said to have cured quartans that resisted the bark. When chewed, it excites a copious flow of saliva, with a warm and not disagreeable sensation in the gums, and frequently cures the rheumatic toothache. It is most efficacious when newly taken out of

the ground; and the best manner of giving it is in a light infusion. Gerarde says, "it greatly helpeth such as have taken great squats, bruises, or falls from some high place, dissolving and scattering abroad congealed and clotted blood within the body: the root with his leaves stamped and laid vpon the members infected, cureth the biting of mad dogs, and of all other venomous beasts."—Native of many parts of the Alps, Austria, Silesia, &c. and found on the banks of the Clyde in Scotland, and in the isle of Bute, near Mount-Stewart. This plant is cultivated in gardens to supply the markets. It may be propagated either by seeds or by parting the roots: the former should be sown in autumn, soon after they are ripe, on a bed or border in a shady situation; observing not to sow the seeds too thick, nor to cover them too deep. The plants will appear in the spring, and should be carefully weeded, and refreshed with water in dry seasons, which will greatly encourage their growth. Towards the beginning of May, if you find the plants come up too close together, prepare a moist shady border, and thin the plants carefully, leaving them about six inches asunder; and plant those which you draw up into the border about the same distance apart every way, taking care to water them in dry seasons until they have taken root; after which these plants, as well as those remaining in the seed-beds, will require no other culture but to keep them clear from weeds; which may be easily effected by hoeing the ground between the plants now and then in dry weather; and stirring the ground also will be very serviceable to them. The following autumn they should be transplanted where they are designed to remain, which should be in a rich moist soil, and a shady situation, where they will thrive much better than if exposed to the sun in a dry soil, where they will require a continual supply of water in dry weather. They must not stand less than two feet distant every way. When rooted, they require only to be kept clear from weeds; and in the spring, before they shoot, to have the ground gently dug between them, being careful not to injure the roots. With this management they will continue several years, and produce abundance of seeds. To propagate them by offsets, part the roots at Michaelmas, and plant them in a shady situation, at the same distance as directed for the seedling plants, observing to water them until they have taken root, after which they may be managed exactly in the same way as the seedlings.

Inarching; a method of grafting, commonly called *grafting by approach*. This is used when the stock intended to be grafted upon, and the tree from which the graft is to be taken, stand so near, or can be brought so near, that they may be joined together. The manner of performing it is this: take the branch you would inarch, and having fitted it to that part of the stock where you intend to join it, pare away the rind and wood on one side about three inches in length: after the same manner cut the stock or branch in the place where the graft is to be united, so that the rind of both may equally join together, at least on one side, that the sap may meet; then cut a little tongue upwards in the graft, and make a notch or slit in the stock downwards to admit it, so that when they are joined, the tongues will prevent their slipping, and the graft will more closely unite with the stock. Having thus placed them exactly together, tie them with bass, or other soft bandage; then cover the place with grafting clay, to prevent the air from drying the wound, or the wet from rotting the stock. Fix a stake in the ground, to which the stock, or branch and graft, should be fastened, to prevent the wind from separating them. In this manner they are to remain about four months, by which time they will be sufficiently united, and the graft may then be cut

from the parent tree, observing to slope it close off from the stock; and if at any time the joined parts be covered with fresh grafting-clay, it will be of great service to the graft. This operation is always performed in April or May, that the graft may unite with the stock before the succeeding winter. It is commonly practised upon Oranges, Myrtles, Jasmines, Walnuts, Firs, Pines, and several other trees, which will not succeed so well by common grafting or budding. On Oranges it is chiefly practised as a curiosity, to have a young plant with fruit upon it, in a year or two from seed, by inarching a bearing branch into a young stock; but these plants are seldom long-lived, and, as they rarely grow large, we would by no means advise it.

Indian Arrow Root. See *Maranta*.

Indicum, Indigo. See *Indigofera*.

Indigo, Bastard. See *Amorpha*.

Indigofera; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, spreading, nearly flat, five-toothed. *Corolla*: papilionaceous; standard rounded, reflex, emarginate, spreading; wings oblong, obtuse, spreading at the inferior margin, of the shape of the standard; keel obtuse, spreading, deflex, marked on each side by an awl-shaped hollow dagger or point. *Stamina*: filamenta diadelphous, disposed in a cylinder, ascending at their tips; anthers roundish. *Pistil*: germen cylindrical; style short, ascending; stigma obtuse. *Pericarp*: legume roundish, long, (Gærtner says linear-oblong, commonly four-cornered.) *Seeds*: numerous, kidney-shaped; (according to Gærtner, kidney-retuse, or cuboid.) **ESSENTIAL CHARACTER.** *Calix*: spreading. *Keel* of the corolla with an awl-shaped spreading spur on each side. *Legume*: linear.—The species are,

1. *Indigofera Sericea*; *Silky-leaved Indigo*. Leaves simple, lanceolate, silky; spikes sessile; stem shrubby. Spike terminating, ovate, villose, with bractes the length of the calices between the flowers; keel of the corolla shorter than the other petals, dark purple, with a long claw, and on each side a spur.—It is a native of the Cape of Good Hope. Like all the other species from that country, it only requires the protection of a dry-stove or glass-case; and may be propagated by cuttings, though some of them do not strike readily. Those that ripen their seeds here, may be propagated from them.

2. *Indigofera Oblongifolia*; *Oblong-leaved Indigo*. Leaves simple, oblong, silky; racemes axillary. This is a shrub, with tomentose silky branches; flowers numerous; standard of the corolla very finely villose; calix silky-tomentose.—Native of Egypt and Arabia.

3. *Indigofera Linifolia*; *Flax-leaved Indigo*. Leaves simple, linear, hoary; legumes globular. Stem short, upright; flowers three or four, on short pedicels in the axils of the leaves, red; fruit globular, crowned with the style, snow-white, one-seeded.—Native of the East Indies, and, like the other species imported from thence, propagated by seeds, which should be sown in a hot-bed early in the spring; and when the plants come up two inches high, they should be transplanted into small pots filled with good fresh earth, and the pots must be plunged into a hot-bed of tanners' bark. When the plants have acquired some strength, the glasses

must be raised in the day-time. The perennials may also be increased by cuttings.

4. *Indigofera Ovata*; *Ovate-leaved Indigo*. Leaves simple, ovate; stem herbaceous.—Native of the Cape.

5. *Indigofera Spinosa*; *Thorny Indigo*. Leaves ternate, obovate; peduncles spinescent; stem shrubby. A shrub, with an ash-coloured bark, and very much branched: calix villose, five-cleft.—Native of the East Indies.

6. *Indigofera Trifoliata*; *Trifoliate Indigo*. Leaves ternate; flowers sessile, natural.—Native of the East Indies.

7. *Indigofera Psoraloides*; *Long-spiked Indigo*. Leaves ternate, lanceolate; racemes very long; legumes drooping. Peduncle angular, longer than the leaves, in a many-flowered raceme; pedicels very short; corollas red; germen channelled.—It flowers from July to September; and is a native of the Cape of Good Hope.

8. *Indigofera Candicans*; *White Indigo*. Leaves ternate, lanceolate-linear, silky underneath: spikes peduncled, few-flowered; legumes cylindrical, straight. The flowers are red, not many, five to eight or nine in a spike; they appear from July to September. This species is distinguished by the whiteness of the stem and under side of the leaves.—Native of the Cape.

9. *Indigofera Amœna*; *Scarlet-flowered Indigo*. Leaves ternate, oval, somewhat hairy; branches round; spikes peduncled; stipules bristle-shaped; calices loose; stem frutescent. It flowers in March and April.—Native of the Cape.

10. *Indigofera Procumbens*; *Prostrate Indigo*. Leaves ternate, obovate; stem herbaceous, prostrate; spikes peduncled; peduncles many times longer than the leaves; flowers dark purple.—Native of the Cape.

11. *Indigofera Sarmentosa*; *Dwarf Indigo*. Leaves ternate, ovate, subsessile; peduncles axillary, two-flowered or thereabouts; stem prostrate, filiform. It flowers in June.—Native of the Cape.

12. *Indigofera Denudata*. Leaves ternate, ovate, smooth; racemes peduncled, longer than the leaf; stem shrubby, upright.—Native of the Cape.

13. *Indigofera Mexicana*. Leaves ternate; panicle branched into spikes; stem shrubby.—Found by Mutis in New Granada.

14. *Indigofera Trita*. Leaves ternate, ovate, acute; racemes short; stem upright.—Native of the East Indies.

15. *Indigofera Coccinea*. Leaves ternate, ovate-oblong; peduncles many-flowered, axillary; legumes round, bowed. Corolla scarlet, with two long reflex spurs to the seed.—Native of China about Canton.

16. *Indigofera Rotundifolia*. Leaves ternate, roundish, tomentose on both sides; racemes short, axillary; stem twining; corollas yellow, with two long, awl-shaped, curved spurs to the heel.—Native of China, about Canton.

17. *Indigofera Bufalina*. Leaves ternate, ovate, smooth; racemes axillary; legumes thick, villose; stem climbing.—Native of Cochinchina.

18. *Indigofera Fliformis*. Leaves quinate, oblong, villose; flowers in spikes, peduncled; peduncles and branches filiform; stem upright.—Native of the Cape.

19. *Indigofera Coriacea*; *Leathery-leaved Indigo*. Leaves quinate, obovate, mucronate, hairy; stipules awl-shaped; legumes straight, smooth.—It flowers in July and August, and is a native of the Cape.

20. *Indigofera Digitata*. Leaves digitate; racemes peduncled; stem shrubby.—Native of the Cape.

21. *Indigofera Stricta*. Leaves pinnate, smooth, oblong; racemes axillary, scarcely peduncled; stem shrubby, upright.—Native of the Cape.

22. *Indigofera Frutescens*. Leaves pinnate, ovate, smooth; racemes axillary, peduncled; stem shrubby, upright.—Native of the Cape.

23. *Indigofera Cytisoides*; *Angular-stalked Indigo*. Leaves quinate, pinnate, and ternate; racemes axillary; stem shrubby. Standard of the corolla upright. It flowers in July.—Native of the Cape.

24. *Indigofera Fragrans*. Leaves quinate, pinnate; leaflets ovate, hairy, the outmost larger; legumes four-cornered. Stems round, somewhat hairy; leaflets hairy on both sides, the end one obovate and larger than the others; peduncles longer than the leaf, axillary, bearing from three to five flowers; corollas red.—Native of the East Indies.

25. *Indigofera Enneaphylla*; *Trailing Indigo*. Leaves pinnate, wedge-shaped, in sevens; stem prostrate; spikes lateral. Plant depressed to the ground; corolla dark purple, with the bark of the standards paler, and recurved a little to the horns of the keel; seeds two.—Native of the East Indies.

26. *Indigofera Semitrijugata*. Leaves pinnate, obcordate, in fives; legumes subsipated, pendulous, torulose; stem prostrate, suffruticose. A small shrub, with round simple branches, villose, hoary, as is the whole plant; flowers somewhat remote, commonly from eleven to thirteen; spikes axillary, longer than the leaves.—Native of the East Indies and Arabia.

27. *Indigofera Pentaphylla*; *Five-leaved Indigo*. Leaves pinnate, oval, in fives; stems prostrate; peduncles two-flowered; flowers red.—Native place unknown.

28. *Indigofera Glabra*; *Smooth Indigo*. Leaves pinnate and ternate, obovate; racemes very short; legumes horizontal, columnar. Peduncles axillary, having frequently three alternate flowers. It is an annual plant, with a smooth stem and leaflets.—Native of the East Indies.

29. *Indigofera Hirsuta*; *Hairy-leaved Indigo*. Leaves pinnate, hirsute; stem upright; flowers in spikes; legumes pendulous, woolly. Stem lofty, hairy; spikes upright, longer than the leaves, axillary, very hirsute.—Native of the East Indies.

30. *Indigofera Spicata*; *Spiked Indigo*. Leaves pinnate, obovate; flowers in spikes; legumes columnar, torulose, pendulous; stem decumbent. Stem herbaceous and villose; spikes longer than the leaves, thrice the size when in fruit.—Native of Arabia.

31. *Indigofera Angustifolia*; *Narrow-leaved Indigo*. Leaves pinnate, linear; racemes elongated; stem shrubby. Stipules acrose, minute; corolla ash-coloured, purple on the outside; keel with spurs. It flowers from June to October.—Native of the Cape of Good Hope.

31. *Indigofera Anil*; *Wild Indigo*. Leaves pinnate, lanceolate; racemes short; stem suffruticose. This plant has the habit and appearance of the next species. Mr. Miller says it grows to the height of five or six feet, and that, being a much larger plant, it will afford a greater quantity of Indigo from the same compass of ground than any of the other species, especially if cut before the stalks grow woody; and that it will also grow on poorer land.—Browne says it is a native of the East Indies, and also very common in Jamaica, growing wild in all the savannas, where it has undoubtedly been cultivated in former times; for there we often meet with some of those Indigo works which were then used, remaining very perfect to this day. This is the hardiest plant belonging to the genus; and grows very luxuriantly, even in the driest savanna lands; but it does not yield the greatest quantity of pulp: the dye, however, extracted from it, is generally the best, of a fine copperish cast, and a close grain.

33. *Indigofera Tinctoria*; *Dyer's Indigo*. Leaves pinnate,

obovate; racemes short; stems suffruticose. Branches like the stem, alternate, upright; leaflets in four pairs or more, very blunt with a point, smooth, very finely villose underneath, almost equal; racemes from the axils of the leaves; legumes drooping, subcolumnar, sharp, straight, very finely villose.—Linneus says that it is almost an exotic in Ceylon, but common in Paliacotta and Coromandel. According to Loureiro, it is spontaneous in China and Cochin-china. Dr. Patrick Browne, besides the Wild Indigo, mentions two other sorts, which he calls the *Indigo*, and the *Guatemala Indigo*: the first seldom above two feet and a half high, and seeming to divide rather than to branch in its growth, yielding more of the dye than any of the others, and generally preferred, though subject to many more mischances: the second, commonly three or four feet high, throwing out many suberect branches as it rises; this is harder than the former, and affords a finer pulp, but yields a less quantity, and is only cultivated where the seasons are certain, or in mixt fields. The ancients were acquainted with the dye which we call Indigo, under the name of *Indicum*. Pliny knew that it was a preparation of a vegetable substance, though he was ill informed both concerning the plant itself, and the process by which it was prepared for use. From its colour, and the country from which it was imported, some authors call it *Atrimentum Indicum*, and *Indicum Nigrum*. The American name is *Nil*, or *Anil*, from which the Portuguese have adopted their *Anil*, or *Anileira*; the other European nations generally call it Indigo. The Arabian name is *Nile*; and the Chinese, *Tien Laam*, or *Sky Blue*.—The works for steeping and fermenting the Indigo in the West Indies, consist of three or five square cisterns or vats, well cemented, terraced, and seasoned. They are made gradually smaller, and so situated as to have the top of the second and third on a line with the bottom of the first, or a little lower; and the top of the fourth and fifth on a line with, or lower than, the bottom of the second and third. The first is called the *steeper*, and is generally made about eight or ten feet square, by four deep, and opens into the second and third by round holes, made close to the bottom, so as to discharge all the tincture readily. The second, or second and third vats, are called the *beaters*. If there be only one, and the liquor is to be worked up with hand-buckets, it should be eight or ten feet square, and six deep; but if there be two, and the tincture is to be beaten with an engine, they should be so deep as to hold all the liquor a good way below the main or horizontal axis into which the buckets are fixed; and the walls should be nearly as high over the rollers as the cistern is deep below them, to prevent the wasting of the tincture. After the liquor is well beaten, it is left to settle; and when the pulp is deposited, the clear fluid is drawn off by a vent placed some inches above the bottom of each cistern: and the remainder is discharged into the fourth and fifth cisterns, by convenient outlets placed close to the bottom. These last cisterns are small, and are generally made square, and proportioned to the quantity of pulp such works commonly produce at a time. When the works are in good order, and the plants cut and carried to them, they are laid in the steeper; and when that is pretty full, boards are laid over them supported by props, from the beams that overlay the cistern: when these are well settled, they pour in as much water as will cover the weed, and leave it to digest and ferment until the greatest part of the pulp is extracted, without letting the tender tops run to putrefaction: and in the management of this point, the judgment of the planter chiefly consists; for, if he draws off the water but two hours too soon, he loses the greatest part of the pulp; and if the fermentation runs but two hours too long, the

whole is spoiled: they frequently, therefore, draw out a handful of the weed, and when they find the tops grow very tender and pale, and observe the stronger leaves change their colour to a less lively pale, then draw the liquor off without delay. They soon learn to know this critical point, by the height of the fermentation, and grain of the tincture; of which they frequently beat a little in a silver cup kept for that purpose; the pulp being thus extracted, the tincture is discharged into the beaters, and there worked up by two or three negroes, each with a bucket, or by an engine; they agitate it until the dye begins to granulate, or float in little foscule in the water, which separation is greatly forwarded by a gradual addition of clear lime-water: the different stages of this operation are distinguished by examining a small quantity of the liquor in the silver cup from time to time; and a little experience soon teaches them when to stop, by a single drop upon the nail, at any degree of height, as they would have their Indigo of a deep copperish blue, or of a paler colour: the liquor is now left undisturbed, until the foscule settle, then the water is discharged, and the magma, or mud, let out by a lower vent into its proper receptacles; this is again, by some, put into a caldron, and heated over a gentle fire, but not so as to boil, and then emptied into little bags to drain; by others, it is not heated, but immediately put into the bags; it is afterwards put into square boxes, with the sides not above four inches deep, that it may dry the sooner, without crumbling.—*Propagation and Culture.* In the West Indies, Indigo seems to thrive best in a free rich soil, and a warm situation; but, to answer the planter's ends, it should be cultivated where it may be frequently refreshed with moisture: having chosen a proper piece of ground, and cleared it, hoe it into little trenches, not above two inches or two inches and a half in depth, nor more than fourteen or fifteen inches asunder; in the bottom of these, at any season of the year, strew the seeds pretty thickly, and immediately cover them: as the plants shoot, they should be frequently weeded, and kept constantly clean, until they spread sufficiently to cover the ground. Those who cultivate great quantities, only strew the seeds pretty thickly, in little shallow pits, hoed up irregularly, but generally within four, five, or six inches of one another, and covered as before: plants raised in this manner are observed to answer as well, or rather better, than the others, but require more care in the weeding. They grow to perfection in two or three months, and are observed to answer best when cut in full blossom; this is done with rape hooks, a few inches above the roots: they are then tied in loads, carried to the works, and laid by strata in the steeper. Seventeen negroes are sufficient to manage twenty acres of Indigo; and one acre of rich land will, with good seasons and proper management, yield five hundred pounds of Indigo in twelve months; for the plant ratoon, and gives four or five crops a year, but must be afterwards replanted. Mr. Miller is of opinion that the planters of Indigo sow their seeds too thick, which draws up the plants with slender stems, not sufficiently furnished with leaves, and those leaves not so large and succulent as if the plants were allowed a greater share of room. It is a common observation among the cultivators of Woad, that when the plants spire, and have narrow thin leaves, they produce little dye; they not only therefore make choice of rich strong land, but carefully thin the plants, to allow them room to spread, and produce large succulent leaves. If the planters of Indigo in America would imitate the cultivators of Woad in this practice, they would certainly find it highly advantageous. Another error is, suffering the plants

to stand too long before they cut it; for the older it is, the drier and firmer are the stalks, and the less will be dissolved by fermentation; nor will the faces of old plants be half so beautiful: it is therefore highly desirable, that the planters should try the effects of sowing thin, keeping the plants perfectly clean, and cutting them while young and full of juice. The dearth of labour in the West Indies may be the principal objection to this method of cultivation. To avoid this, the seeds might be sown with a drill plough; and, by the use of the hoe-plough, ten acres may be kept free from weeds, at as little expense as one with the hand-hoe; and, by stirring the ground often, and earthing up the plants, they would grow much stronger, be less liable to be destroyed by insects, and produce larger and more succulent stalks and leaves. Though all seasons will admit of sowing Indigo, care must be taken to avoid a drought, because the seeds may be eaten by vermin, carried away by the wind, or choked by the weeds; the planters usually choose a season that promises rain, and then they are sure of seeing the plant spring up in three or four days, and in about two or three months after, it is fit for cutting: in rainy seasons the cutting may be repeated every six weeks; cutting in dry weather kills the plant, which, if that is avoided, continues to afford fresh crops for two years.

34. *Indigofera Disperma*: *Two-leaved Indigo*. Leaves pinnate, oval; racemes elongated; legumes two-seeded.—Native of the East Indies.

35. *Indigofera Argentea*; *Silvery-leaved Indigo*. Leaves ternate and pinnate, obovate, silky; legumes torulose, pendulous. The whole plant silky and glaucous.—Found in Egypt and the East Indies.

Inocarpus; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, bifid; divisions roundish, nearly equal. *Corolla*: one-petaled, tubular; tube cylindrical, the length of the calix, (Thunberg says, shorter;) border five or six parted, longer than the tube; divisions linear, acute, undulated, often reflex. *Stamina*: filamenta ten or twelve, very short, inserted into the tube, the alternate ones inferior; antheræ ovate, twin, upright. *Pistil*: germen oblong, villose, superior; style none; stigma an excavated point. *Pericarp*: drupe ovate, incurved, compressed, large, one-seeded. *Seed*: a nut, interwoven with woody fibres; kernel compressed, oval. **ESSENTIAL CHARACTER.** *Calix*: bifid. *Corolla*: funnel-form. *Stamina*: in a double row. *Drupe*: one-seeded.—The only known species is,

1. *Inocarpus Edulis*. Forster describes it as a lofty tree the thickness of a man's body, with a brown chinky bark; the branches woody, round, spreading, variously divided; leaves subdistich, ovate-oblong, scarcely cordate, blunt and retuse, seldom acute, spreading, netted with abundance of veins, a span long, and on young trees a foot; racemes filiform, quite simple; pedicels very short, scattered, clustered; flowers dusky white, scarcely half an inch in length. The kernel, which is kidney-shaped, and about an inch in diameter, is sweetish, but not so pleasant as the Chestnut, harder, and less farinaceous. The bark is astringent, and is used to cure the dysentery. The natives of New Guinea smear the heads of their arrows with the expressed resinous juice; and the kernel of the nut is roasted and eaten by the inhabitants of the Society and Friendly Islands, in the New Hebrides, New Guinea, in the Moluca Isles, and at Amboyna, where it is indigenous.

Inoculating; or *Budding*: this is commonly practised on all sorts of stone fruit, particularly Peaches, Nectarines, Cherries, and Plums, also Oranges and Jasmynes, and is preferable

to any sort of grafting for most sorts of fruit. The method of performing it is as follows: you must be provided with a sharp penknife, having a flat haft, the use of which is to raise the bark of the stock, and admit the bud; procure also some sound bass-mat, which should be soaked in water to increase its strength, and make it more pliable: then having taken off the cuttings from the trees you would propagate, choose a smooth part of the stock, about five or six inches above the surface of the ground, if designed for dwarfs; three feet, for half standards; but six feet for standards: then with your knife make an horizontal cut across the rind of the stock, and from the middle of that cut make a slit downwards, about two inches in length, so that it may be in the form of a T; care must be taken not to cut deeper than the bark, lest you wound the stock; then having cut off the leaf from the bud, and left the footstalk remaining, you should make a cross cut, about half an inch below the eye, and with your knife slit off the bud, with part of the wood to it, in form of an escutcheon; then with your knife pull off that part of the wood which was taken with the bud, observing whether the eye of the bud be left to it or not, for all those buds which lose their eyes in stripping should be thrown away, being good for nothing: after this, having gently raised the bark of the stock, where the cross incision was made, with the flat haft of your penknife clear to the wood, you should thrust the bud therein, observing to place it smooth between the rind and the wood of the stock, cutting off any part of the rind belonging to the bud which may be too long for the slit made in the stock; and so having exactly fitted the bud to the stock, tie them closely round with bass-mat, beginning at the under part of the slit, and proceeding to the top, taking care not to bind round the eye of the bud, which should be left open. When the buds have been inoculated three weeks or a month, you will see which of them have taken; those of them which appear shrivelled and black, being dead, but those which remain fresh and plump, you may depend are joined; you should therefore loosen the bandage, which, if not done in time, will greatly injure, if not destroy, the bud. In March following cut off the stock, about three inches above the place of inoculation, sloping it, that the wet may pass off, and not enter the stock; to this part of the stock left above the bud, it is very proper to fasten the shoot that proceeds from the bud, which would be in danger of being blown out by strong winds: but this must continue no longer than one year, after which it should be cut off close above the bud, that the wounded part may be the more readily barked over. The time for inoculating is from the middle of June until the middle of August, according to the forwardness of the season, and the particular sorts of trees to be propagated; but the time may be easily known by trying the buds whether they will come off well from the wood; however, the most general rule is, when you observe the buds formed at the extremity of the same year's shoots, which is a sign of their having finished their spring growth. The first tree commonly inoculated is the Apricot, and the last the Orange tree, which should never be attempted till the middle of August, and in cloudy weather; for if done in the middle of the day, during very hot weather, the shoots will perspire so fast, as to leave the buds destitute of moisture; nor should you take off the cuttings of the trees long before they are used, for if you are obliged to fetch your cuttings from some distance, which often happens, it will be judicious to provide a tin box or case, having a socket about ten inches long, and a cover to the top, which must have five or six holes: in this socket, put as much water as will

fill it about two or three inches high, and place the cuttings therein, in an upright position, so that that part which was cut from the tree, may be set in the water; and fasten down the cover, to keep out the air: the minute holes in the cover will suffice to let the perspiration of the branches pass off, which, if pent in, would be very injurious to them: be careful also to carry it upright, that the water may not reach to the buds, for it is very imprudent to water them all over, and so saturate the buds with moisture, that they have no attractive force left to imbibe the sap of the stock, whereby they very often miscarry. Although it is the ordinary practice to divest the bud of that part of the wood which was taken from the shoot with it, yet in many sorts of tender trees it is best to preserve a little wood to the bud, without which they often miscarry; the want of attention to this circumstance has caused some people to imagine, that certain trees are not to be propagated by inoculation; whereas, they would have succeeded, had they performed it by this method.

Inula; a genus of the class Syngenesia, order Polygamia Superflua.—GENERIC CHARACTER. *Calix*: common imbricated; leaflets lax, spreading, the exterior ones larger, of equal length. *Corolla*: compound radiated, broad; corollules hermaphrodite, equal, very numerous in the disk; females strap-shaped, numerous, crowded in the ray: proper of the hermaphrodite, funnel-form; border five-cleft, rather upright; females strap-shaped, linear, perfectly entire. *Stamina*: in the hermaphrodite, filamenta five filiform, short; antheræ cylindric, composed of five smaller linear conjoined ones, each ending below in two straight bristles of the length of the filamenta. *Pistil*: in the hermaphrodites, germen oblong; style filiform, length of the stamina; stigma bifid, rather upright; in the females, germen long; style filiform, half bifid; stigmas erect. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites, solitary, linear, four-cornered, pappus capillary, length of the seeds: in the females, like the hermaphrodites. *Receptacle*: naked, flat. *Observe*. This genus differs not only from *Aster*, but from most others, in having the antheræ terminated below by ten bristles; but this is not apparent in all the species. ESSENTIAL CHARACTER. *Receptacle*: naked. *Down*: simple. *Antheræ*: ending in two bristles at the base.—The species are,

1. *Inula Helenium*; *Elecampane*. Leaves stem-clasping, ovate, wrinkled, tomentose underneath; scales of the calices ovate. Root perennial, thick, fusiform, brown, branching, and aromatic. It is one of the largest of our herbaceous plants, being from three to five or six feet high, with the stem striated and downy, branched towards the top; lower leaves on footstalks a foot long, and four inches broad in the middle, downy beneath; flowering heads very large, single, terminating the stem and branches; florets all yellow; seeds columnar, four-cornered; pappus, egret, or down, white.—The root is esteemed a good pectoral, and a conserve of it is recommended in disorders of the breast and lungs, to promote expectoration: an infusion of it fresh, sweetened with honey, is said to be an excellent medicine in the whooping cough; and a decoction, outwardly applied, to cure the itch. Bruised and macerated in urine, with balls of ashes and whortle berries, it dyes a blue colour. The decoction of it cures sheep that have the scab; hence in some countries it is called *Seabwort*; and in others *Horse-heal*, from its reputed virtues in curing the cutaneous diseases of horses. The officinal name is *Enula Campana*, whence our English *Elecampane* is derived; the Germans call it *alant*, *aland*, *alantwurz*, *olant*, *oltwurz*, *helenenkraut*, *glockenwurz*; the Dutch, *gewoon* and *alant*, *alantwortel*; the Danes, *aland*, *alandsroed*; the

Swedes, *alandsrot*; the French, *l'inule aunée, l'aunée, l'enule-campagne, l'herbe contre lagale*; the Italians, *enula, enula-campagna, ella, elenio*; the Spaniards and Portuguese, *enula-campagna, ala*; and the Russians, *dewjatschid, dew-esil, oman, krun*. It flowers in June and July, and the seeds ripen at the end of August.—Native of Japan, Denmark, Germany, Flanders, Switzerland, Austria, France, Piedmont, Spain, and Britain. In Essex it is frequent, and not uncommon in Norfolk; it is found at Mettingham, in Suffolk; near Madingley, in Cambridgeshire; Ripton, and Warboys, in Huntingdonshire; Dunstable, and Pertenhall, in Bedfordshire; on the side of Bredon-hill, in Worcestershire; and about St. Ives, in Cornwall, &c. In Scotland, it is doubtful whether it be a native.—It may be propagated by seeds, which should be sown in autumn, soon after they are ripe, for if kept to the spring, they seldom grow; but where permitted to scatter, the plants will come up in the following spring, without any care, and may either be transplanted in the succeeding autumn, or, if they are designed to remain, they should be hoed out to the distance of ten inches or a foot each way, and constantly kept clean from weeds: the roots will be fit for use in the second year. But most people propagate the plant by offsets, which, if carefully taken from the old roots, with a bud or eye to each, will take root very easily: the best time for this, is in autumn, as soon as the leaves begin to decay: they should be planted in rows, about a foot asunder, and nine or ten inches' distance in the rows; in the following spring, the ground must be kept clean from weeds, and, if slightly dug in autumn, it will greatly promote the growth of the roots, which will be fit for use after two years' growth, but will abide many years, if permitted to remain; however, the young roots are certainly preferable to those that are old and stringy. It loves a loamy soil.

2. *Inula Odora*; *Sweet-rooted Inula*. Leaves stem-clasping, toothed, extremely hirsute; root-leaves ovate; stem-leaves lanceolate; stem few-flowered. Flowers one or two, peduncled, yellow; root perennial, with an aromatic smell and taste.—Native of Provence, Narbonne, Sicily, and Italy. This, with the 3d, 4th, 5th, 16th, 17th, 18th, 19th, 22nd, 24th, and 25th species, which are abiding plants, will thrive and flower in the open air in England: they may all be propagated by parting their roots; the best time for doing this is in autumn, at which time the plants may be removed, and intermixed with other flowering plants, in the borders of large gardens, where they will make an agreeable variety during their continuance in flower. As their roots multiply pretty fast, they should be allowed room to spread, and not be planted nearer than two feet from other plants. If they are removed every third year, it will be often enough, provided the ground between them be dug every winter; and if kept clean from weeds in summer, they will require no other care. As some of them produce good seed in England, they may be propagated by sowing their seeds in autumn, on a border of light earth, exposed to the east, where the morning sun only is admitted; in the spring, when the plants appear, they should be kept clean from weeds till fit to remove, when they may be transplanted on a shady border, six inches asunder, observing to shade and water them till they have taken root. Clean them from weeds during the summer, and in autumn transplant them into borders where they are to remain.

3. *Inula Suaveolens*; *Woolly-leaved Inula*. Leaves elliptic, attenuated at the base, subpetioled, hairy, lower toothed; stem many-flowered. Root scentless, acrid, consisting of a bundle of round dirty white fibres, issuing from a thicker

head; stem usually single, upright, round, purplish, villose, leafy, a foot and half high, branching only at top into few-flowered peduncles; flowers sweet-smelling; radial corollets shorter than the calix, and three-toothed. It flowers from June to August.—Native of the south of Europe.

4. *Inula Oculi Christi*; *Hoary Inula*. Leaves stem-clasping, oblong, entire, hirsute; stem hairy, corymbed. Root perennial; flowers in a corymb, of a fine yellow or golden colour, large, but smaller than the first sort, appearing in July.—Native of Austria, the south of France, and Silesia.

5. *Inula Britanica*; *Creeping-rooted Inula*. Leaves stem-clasping, lanceolate, serrate, distinct, villose underneath; stem branched, upright, villose. Root perennial; stem dividing into two or three upright branches or peduncles, each sustaining one pretty large flower, of a deep yellow colour. They are in beauty in July, but seldom ripen seeds here. There is a variety with the stems and under surface of the leaves more villose, and the petals of the ray very narrow.—Native of Germany, Scania, Siberia, and Piedmont.

6. *Inula Dysenterica*; *Common or Middle Fleabane*. Leaves stem-clasping, cordate-oblong; stem villose, panicled; calicine scales bristle-shaped. Root perennial, creeping, whitish, the thickness of a goose-quill, with largish fibres; branches like the stem, upright, the latest growing to the greatest height; flowers an inch or more in diameter, terminating, single, or two together, forming a sort of corymb; florets all yellow, exceedingly numerous in the disk. Ray-observes, that the leaves when bruised smell like soap. Ruty informs us, that the juice is saltish, and warms the mouth a little; that the decoction is somewhat acrid in the throat, and at the same time astringent, and turning green with vitriol of iron; that the infusion is also somewhat astringent, very bitter in the throat, and turning black with vitriol of iron. Linneus mentions his having been informed by General Keit, that the Russian soldiers, in their expedition against Persia, were cured of the bloody flux by this plant; this induced Linneus to name it *Dysenterica*. Our old authors call it *Middle Fleabane*, it being supposed, when burning, to drive away fleas and other insects by the smoke. Forskal says, the Arabians call it, *rarajeub*, or *Job's tears*, from a notion that Job used a decoction of this herb to cure his ulcers. It was formerly recommended in the itch, and other cutaneous disorders.—Native of most parts of Europe, in moist meadows, watery places, by the sides of ditches, brooks, and rivers; flowering from July to October, and frequently overrunning large tracts of land. Few cattle will touch it.

7. *Inula Viscosa*; *Clanmy Inula*. Leaves lanceolate, toothletted, sessile, reflex at the base; peduncles lateral, one-flowered, leafy.—Native of the south of Europe. See *Erigeron Viscosus*, which is the same plant.

8. *Inula Undulata*; *Wave-leaved Inula*. Leaves stem-clasping, cordate-lanceolate, waved. Stem a foot high, round, upright, submentose; peduncles terminating, one-flowered. Flowers in July.—Native of Egypt. This, with the ninth and twelfth species, being annual plants, and natives of hot countries, must be propagated by seeds raised in a hot-bed, and kept in the bark-stove.

9. *Inula Indica*; *Indian Inula*. Leaves stem-clasping, cordate-lanceolate, serrate; peduncles one-flowered, filiform; flowers globular.—Native of the East Indies.

10. *Inula Pulicaria*; *Trailing Inula*, or *Small Fleabane*. Leaves stem-clasping, waved; stem prostrate; flowers sub-globular, with a very short ray. Annual; with a very trailing stem not at all hairy, and a globular calix. The flowers are solitary, of a pale dull yellow. There is a variety of this with scarcely any flowers of the ray.—Native of Scania,

where water stagnates in the winter, and even in the streets of Lund.

11. *Inula Uliginosa*; *Small Dwarf* or *Marsh Inula*, or *Fleabane*. Upper leaves stem-clasping, lanceolate, wavy, blunt; stem upright, woolly towards the top; calices cylindrical. Root annual, fibrous, whitish, jointed, generally crooked; flowers terminating, numerous, broad, short, cylindrical, on single or branched leafy peduncles, the last-blown standing considerably above the others. This plant is also said to drive away fleas and gnats, and is given by some to horses for the botts.—Native of many parts of Europe, where water has stagnated during the winter, by road-sides, on the borders of ponds, &c. particularly in a stiffish soil. It flowers from August to October. It is seldom admitted into gardens.

12. *Inula Arabica*; *Arabian Inula*. Leaves oblong, sessile; peduncles filiform; calices cylindrical. This resembles the preceding species so much, that it should be distinguished from it with caution: the peduncles are longer, often in pairs; ray of the corolla longer; disk narrow.—Native of Arabia and the East Indies.

13. *Inula Spiræifolia*; *Spiræa-leaved Inula*. Leaves subsessile, ovate-oblong, naked, netted, clustered, serrulate; flowers terminating, subsessile. The flowers are scarcely peduncled.—Native of Italy. This, with the two next, and the twenty-seventh species, are propagated by seeds, which should be sown on a bed of light earth early in the spring. In May the plants will appear, and should be kept clean from weeds till they are fit to transplant; when they should be planted in an east border, at about twelve inches' distance each way, watering and shading them till they have taken new root; after which they will only require to be kept clean from weeds till the autumn, when they should be planted where they are designed to remain.

14. *Inula Squarrosa*; *Net-leaved Inula*. Leaves sessile, oval, even, netted-veined, subrenate; calix squarrose. Stem pubescent, striated, often one-flowered; root perennial. The flowers are pretty large, of a pale yellow colour; they appear in July, but are not followed by seeds in this country. In the autumn this plant puts on a different appearance: the stalk dies, and several young ones spring from the root, like those of the seventh species, weak, red, clammy-haired; leaves soft, ovate-lanceolate, clammy-pubescent, sessile, with a smell like Elder. It was long mistaken for the sixteenth species, through the above variety in its habit.—Native of Italy and the south of France. This seldom continues above two or three years, and therefore young plants should be constantly raised from seeds to succeed the old ones.

15. *Inula Bubonium*. Leaves lanceolate, somewhat rigid, toothletted, subvillose, sessile; stem and branches subfloriferous; calix squarrose. Root perennial, consisting of numerous long and thick fibres. The whole plant has some smell, and a bitter unpleasant taste.—It flowers in August and September, and is a native of Austria.

16. *Inula Salicina*; *Willow-leaved Inula*. Leaves lanceolate, recurved, serrate, scabrous; branches angular; lower flowers highest. Root perennial, aromatic, subastringent, smelling like cinnamon; flowers terminating on alternate, one-flowered, grooved, reddish peduncles, forming all together a corymb. It differs from the next species in having the stem smooth, grooved or angular at top, and the leaves smooth, except that the edge is rugged.—Native of Germany, Switzerland, Austria, and the south of France.

17. *Inula Hirta*; *Hairy Inula*. Leaves sessile, lanceolate, recurved, subserrate-scabrous; stem roundish, somewhat hairy; lower flowers highest. Flowers handsome, an inch

and a half in diameter. It flowers, with us, from June to September.—Native of France, Germany, Switzerland, Austria, and Siberia.

18. *Inula Mariana*; *American Inula*. Leaves sessile, lanceolate, subserrate, hairy; peduncles subuniflorous, somewhat clammy, leaflets linear. The whole plant has soft white hairs thinly scattered over it, especially the lower surface of the leaves. The flowers terminate the stem in a sort of corymb, but the peduncles or branches are commonly one-flowered, with pedicelled glands scattered over them.—Native of Maryland and South Carolina.

19. *Inula Germanica*; *German Inula*. Leaves sessile, lanceolate, recurved, scabrous; flowers somewhat sickle-shaped. Stem upright, a foot or eighteen inches high, round, pubescent, somewhat rugged, a little branched at top, and curved towards the bottom; flowers small, terminating in a sort of close umbel.—Native of the south of France, Germany, Austria, and Siberia.

20. *Inula Japonica*; *Japanese Inula*. Leaves sessile, lanceolate, toothletted; peduncles rod-like, one-flowered. Stem herbaceous, round, striated, villose, upright, a foot high and more.—Native of Japan.

21. *Inula Dubia*; *Doubtful Inula*. Leaves sessile, oblong, ciliate; stem one-flowered. Stem herbaceous, simple, striated, villose, as is the whole plant; flexuose-erect, a foot high, leafless at top; flower terminating, solitary; calix very hirsute, equal. This plant is doubtful as to what genus it belongs.—Native of Japan.

22. *Inula Ensifolia*; *Sword-leaved Inula*. Leaves sessile, linear, acuminate, nerved, smooth, scattered; stem one or two-flowered, annual. Root perennial. The flowers have a little smell.—Native of Austria, on rocks and among bushes: flowering in August.

23. *Inula Crithmoides*; *Trifid Inula*, or *Golden Sampire*. Leaves linear, fleshy, three-cusped. Root perennial, fibrous; stems firm, smooth, striated, much branched; flowers solitary, on thick peduncles, at the summit of the upper branches, very handsome, having yellow rays, and an orange disk. According to Miller, it rises with an upright stalk, a foot and half high; leaves succulent, fleshy, an inch and quarter long, and one-eighth broad, ending in three points, and coming out in clusters. It flowers in July, and ripens seeds in autumn. The younger branches are frequently sold in the London markets for Sampire; but it is a villanous imposition, because this plant has none of the warm aromatic taste of the true Sampire. See *Crithnum Maritimum*.—Native of the coasts of the Mediterranean Sea, Arabia, Barbary, Spain, Portugal, France, and England, in salt-marshes and a muddy soil. It is plentiful near Sheerness, and in the Isle of Shepey; and has been observed in a marsh near Hurst Castle, opposite to the Isle of Wight; on the rocks at Llandwyo, in Anglesea; and on the banks of the river just above Fulbridge, at Maldon in Essex.

24. *Inula Provincialis*; *Oval-leaved Inula*. Leaves subserrate, tomentose underneath; root-leaves petioled, ovate; stem upright, one-flowered. Flowers rather large; peduncle swelling below the flower. Haller says this is a handsome plant, with a woody root having abundance of fine fibres. It flowers in July and August.—Native of the south of France, where it was found about Narbonne; on the Corbieres, a part of the Pyrenees; also in the upper Valais, and on the mountains of Piedmont.

25. *Inula Montana*; *Mountain Inula*. Leaves lanceolate, hirsute, quite entire; stem one-flowered; calix short, imbricate. Root hard, fibrous; flowers large; florets of the disk very numerous, of the ray as far as thirty, broad, three-

IPOMEA QUAMOCLIT — Wing-leaved Ipomea.

Fig. 6.

INULA MARIANA — American Inula.

toothed. It varies with subserrate leaves and small flowers. Linneus observes, that the calix and structure of this plant makes it very nearly allied to the Aster; and that it is covered with a snowy-white pubescence.—Native of Spain, and of the country about Montpellier and Vienna; and in the southern part of Dauphiny; near Turin, and in other parts of Sardinia; in the vineyards of the Palatinate; and in Switzerland, and the Valais. It flowers in July and August, but will rarely ripen seed here.

26. *Inula Æstuans*. Leaves spatulate, tomentose underneath.—Native of South America.

27. *Inula Bifrons*. Leaves decurrent, oblong, toothletted; flowers heaped, terminating, subsessile. Stem a foot high, somewhat rigid, corymbed, with a strong smell like Tansy; flowers yellow, with a short ray. Biennial. It flowers in July and August, but never perfects seeds in this country.—Native of Italy, Provence, and the Pyrenees. See the 13th species.

28. *Inula Cœrulea*; *Blue-flowered Inula*. Leaves decurrent, obovate, subserrate; stem suffruticose; flowers sessile, terminating. Though this has a blue ray to the flower, in which it differs from all the *Inulas*, yet its appearance or habit is quite foreign to that of the genus *Aster*. The branches are one-flowered.—Native of the Cape of Good Hope: annual. This, and the two following, may be increased by cuttings, and must be kept in the dry stove.

29. *Inula Aromatica*; *Aromatic Inula*. Leaves linear, quite entire, tomentose, scattered; stem shrubby. Flowers solitary, terminating, sessile; ray of the flower pale whitish flesh-colour.—Native of the Cape.

30. *Inula Pinifolia*; *Pine-leaved Inula*. Leaves subulate, linear, three-sided, clustered very much; stem shrubby, half a foot high, very rugged with the fallen leaves.—Native of the Cape.

31. *Inula Fœtida*; *Stinking Inula*. Leaves lanceolate-linear, quite entire; corymbis branched; rays of the flower very short. Stems several, a foot high, straight, branched, rough with harsh hairs; leaves hirsute, not unlike those of *Hysop*; flowers golden-coloured.—Native of Malta.

32. *Inula Canariensis*; *Canary Inula*. Leaves linear, fleshy, three-cusped; stem shrubby. This rises with several shrubby stalks, near four feet high; which divide into smaller branches; leaves in clusters, narrow, fleshy, divided into three segments at their points. The flowers come out on the side of the branches at the top of the stalks, and are small, and of a pale yellow, appearing in August.—Native of the Canary Islands. It will not bear the open air in our winters, and must be removed into shelter in autumn, but still have as much free air as possible in mild weather, that it may not be drawn up weak. They must have very little water in cold weather; as their stalks and leaves are succulent, they are very apt to rot. In summer they should be placed abroad, with other hardy exotic plants, in a shaded situation, where they will add to the variety, though they seldom flower except in very warm summers. They are easily propagated by cuttings planted during summer in a shady border, where they will take root in a short time.

33. *Inula Satureioides*; *Savory-leaved Inula*. Leaves linear, hirsute, opposite; peduncles naked, one-flowered. It rises with a shrubby stalk nearly two feet high; at the ends of the branches arise naked peduncles, four or five inches long, sustaining one small yellow radiated flower.—Found at La Vera Cruz. It is propagated by cuttings during the summer season, which must be planted on a bed of light earth, and shaded till they have taken root; after which, the plants must be treated in the same manner as other hardy exotics.

34. *Inula Fruticosa*; *Shrubby Inula*. Leaves lanceolate, acute, three-nerved underneath; calicic scales acute; stem shrubby. Stem ten or twelve feet high, divided into several woody branches; at the ends of which the flowers are produced; they have very large scaly calices, are as large as a small sun-flower, and of a pale yellow colour.—Native of Carthage in New Spain. This is too tender to bear the open air of England, and must be constantly kept in the bark-stove. It is propagated by seeds, which must be procured from the country where it naturally grows, for it does not produce any here. The seeds must be sown upon a hot-bed, and when the plants are fit to remove, they should be each put into a small pot filled with light earth, and plunged into a fresh hot-bed; treating them in the same manner as other tender plants from the same country.

35. *Inula Graminifolia*. Stalk very simple; leaves lanceolate, linear, very entire, erect, nervose; corymb compound, lax; calices turbinate. It rises a foot high, with small flowers.—Found in the sandy woods from Pennsylvania to Florida.

Job's Tears. See *Coix*, and *Inula Dysenterica*.

Jonequetia; a genus of the class Decandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets roundish, deciduous. *Corolla*: petals five, roundish, concave, spreading, longer than the calix. *Stamina*: filamenta ten, shorter than the corolla, growing to a glandule; antheræ roundish. *Pistil*: germen pentagonal, surrounded by a glandule; styles none; stigmas five. *Pericarp*: capsule nearly globose, roundish-pentacoccell, one-celled, five-valved. *Seeds*: five, ovate, arillated, each affixed to the valves. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five, spreading. *Filamenta*: growing to a glandule. *Styles*: none. *Capsule*: subglobular, one-celled, five-valved, five-seeded.—The only known species is,

1. *Jonequetia Guianensis*. This is a very large tree, with a trunk forty or fifty feet high, and two or three feet in diameter, with a smooth russet bark, and a white uncompact wood. It has a great number of branching boughs at top, those in the middle erect, the rest horizontal and spreading in all directions. Leaves alternate, unequally pinnate; leaflets in three, four, or five pairs; petiole almost cylindric, eight or nine inches long, fleshy at the base; flowers small, white, axillary, and terminating in large wide scattered panicles.—Native of Guiana, where it is called *Tapiriri*; flowers in November, and bears fruit in April.

Jonquil, Jonquilla. See *Narcissus*.

Ipecacuanha Plant. See *Psychotria Emetica*.

Ipecacuanha, Bastard. See *Asclepias Curassavica*.

Ipecacuanha, False. See *Triosteum Angustifolium*.

Ipomœa; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-toothed, oblong, very small, permanent. *Corolla*: one-petalled, funnel-form; tube subcylindric, very long; border five-cleft, spreading; divisions oblong, flat. *Stamina*: filamenta five, awl-shaped, almost the length of the corolla; antheræ roundish. *Pistil*: germen roundish; style filiform, length of the corolla; stigma headed, globose. *Pericarp*: capsule roundish, three-celled. *Seeds*: some subovate. *Observe*. This genus is rather too nearly allied to *Convolvulus*, but differs in the lengthened tube of the corolla, and the headed stigma. ESSENTIAL CHARACTER. *Corolla*: funnel-form. *Stigma*: headed, globose. *Capsule*: three-celled.—The species are,

* *Flowers distinct*.

1. *Ipomœa Quamoclit*; *Wing-leaved Ipomœa*. Leaves pinnatifid, linear; flowers subsolitary, pendulous. Stems slen-

der, twining, and rising by support to the height of seven or eight feet, sending out several side-branches, which twine about each other and the principal stem, and about any neighbouring plants. The leaves are composed of several pairs of very fine narrow lobes, not thicker than sewing-thread, an inch long, of a deep green. The flowers come out singly from the side of the stalks, on slender peduncles about an inch long: the tube of the corolla is about the same length, narrow at bottom, but gradually widening to the top, where it spreads open, flat, with five angles; it is of a most beautiful scarlet-colour, making a fine appearance. Browne says, it is cultivated in many of the gardens of Jamaica, on account of its elegant flowers, and minutely dissected thick foliage. He calls it *American Jessamine*, and says it seldom rises above four feet from the ground. It is called *Sweet William* and *Indian Pink* in the West Indies. The flowers appear in July and August, and continue in succession great part of September. Annual.—Native of the East Indies. It is propagated by seeds sown on a hot-bed (for it will not endure the open air of England) in the spring; and as the plants will soon appear, they should be each transplanted into a small pot filled with light earth, before they twine about each other, for then it will be difficult to disengage them without breaking their tops. When they are potted, they should be plunged into a new hot-bed, and sticks placed down by each plant for their stalks to twine about; after they have taken new root, they should have a good share of air in warm weather, to prevent their drawing up weak; and when they are advanced too high to remain under the frame, they should be removed into the tan-bed in the stove, where they should have support, for their branches will extend to a considerable height. They begin to flower in June, and the seed will ripen very well in autumn.

2. *Ipomœa Rubra*; *Upright Ipomœa*. Leaves pinnatifid, linear; flowers in racemes, pendulous. The young plants in the first year produce numerous leaves, spreading in a circle, elegantly jagged; from the centre of these, the second year, arises a straight stem, the thickness of a straw, about three-quarters of a yard in height, clothed from top to bottom with leaves; flowers from the top of the stem and the ends of the side-branchlets, peduncled, pendulous, usually solitary, but forming all together a thyrse; corolla of a bright red colour, darker on the outside, within paler, and variegated with white spots and purple streaks.—Native of Carolina, in low sandy places, flowering in June.

3. *Ipomœa Umbellata*; *Umbelled Ipomœa*. Leaves digitate, in sevens; peduncles umbelled, very short. Flowers abundant.—Native of South America.

4. *Ipomœa Carolina*; *Carolina Ipomœa*. Leaves digitate; leaflets petioled; peduncles one-flowered. Stem slender, trailing; outside of the corolla light green, inside purple.—Found upon rocks in many of the Bahama Islands.

5. *Ipomœa Coccinea*; *Scarlet-flowered Ipomœa*. Leaves cordate, acuminate, angular at the base; peduncles many-flowered. Stem herbaceous, twining, quadrangular, smooth, flexuose; flowers long, scarlet, longer than those of the first sort. Browne observes, that it is remarkable for the curved or arched figure of the tube in the corollas. It is an annual plant, six or eight feet high: the corolla is not so deeply coloured as that of the first sort; and there is a variety with orange-coloured flowers. This, as well as the seventh species, is propagated by seeds sown on a hot-bed in the spring, and when the plants come up, if they are gradually hardened, and afterwards transplanted into a warm border, in favourable seasons they will flower, and produce good seeds.

6. *Ipomœa Lacunosa*; *Starry Ipomœa*. Leaves cordate,

acuminate, scrobiculate, angular at the base; peduncles one or two flowered, shorter than the flower. Stem from a foot to two feet in height, slightly angular, procumbent unless supported, and then climbing; flowers usually solitary, but sometimes two on a peduncle, small, white, the edges slightly tinged with purple: it flowers here in July. Annual.—Native of Virginia and Carolina.

7. *Ipomœa Solanifolia*; *Nightshade-leaved Ipomœa*. Leaves cordate, acute, quite entire; flowers solitary, of a rose colour.—Native of America.

8. *Ipomœa Tuberosa*; *Tuberous-rooted Ipomœa*. Leaves palmate; lobes in sevens, lanceolate, acute, quite entire; peduncles three-flowered. Root tuberous; stems several, shrubby, twining, woody at bottom, and the thickness of the human thumb; flowers yellow: Miller says, bright yellow, Linneus, sulphur-coloured, and Loureiro, purple. It is handsome, two inches in diameter, smelling sweet; capsule membranaceous, shining, subpellucid, square with blunted angles, large, two-celled; in each cell two black villose seeds, among the largest of the genus. This plant is wonderfully beautiful when in flower, and the very fragrant odour of the flowers gives it an additional value. It is much used in the West Indies for arbores, for which it is very fit, on account of the multitude of its branches and evergreen leaves, which the sun cannot penetrate; it spreads to such an extent, that it may be carried over an arbour of three hundred feet in length, from one root. Every part of the plant is purgative, and abounds with milk. Scammony might probably be made from the milky juice of the root. Loureiro asserts, that the tubes are eatable, like *Convolvulus Batatas*, which they very much resemble in taste, size, and shape.—Native of the West Indies. The natives call it *Seven-year Vine*, or *Spanish Arbour-Vine*. It is a perennial plant, but too tender to thrive in the open air of our climate. The seeds must be sown upon a hot-bed in the spring; and when the plants come up, be transplanted into separate pots, and plunged into a fresh hot-bed; but as they will soon grow too tall to stand under a frame, they should be removed into the bark-stove, where they must be supported, to prevent them from twining about the surrounding plants. As they extend their shoots to a very great length, they require a tall stove, without which they will never produce flowers.

9. *Ipomœa Digitata*; *Hand-leaved Ipomœa*. Leaves palmate; lobes in sevens, blunt; peduncles three-flowered; flowers purple; seeds brown.—Native of the West Indies. This, with the twentieth and twenty-third species, must also be raised on a hot-bed, in the spring, and afterwards planted in separate pots, plunging them into another hot-bed, where they may remain till they reach the glasses, when they should be removed into a glass-case, where they may have room, and be screened from the cold, but should have a large share of free air admitted to them in warm weather: thus treated, the plants will flower, and produce ripe seeds.

10. *Ipomœa Bona Nox*; *Prickly Ipomœa*. Leaves cordate, acute, quite entire; stem prickly; flowers in threes; corollas undivided. This is an annual plant, growing to a very great length, covering sometimes many trees, or the banks of rivers for many paces, having a round and reddish stalk, armed with blunt, herbaceous, short, variously-shaped prickles, and winding itself about anything that comes within its reach, or creeping along the surface of the ground. The flowers are axillary, many, on peduncles an inch long; tube of the corolla seldom less than from three to four inches in length; border white, five inches in diameter, a little sinuated, and has five green streaks on the outside. It flowers here in July and August.—Native of the West Indies.

11. *Ipomœa Campanulata*; *Bell-flowered Ipomœa*. Leaves cordate; peduncles many-flowered; outer perianth orbicular; corollas bell-shaped, lobed, and thicker than in any of the other species.—Native of the East Indies.

12. *Ipomœa Violacea*; *Purple-flowered Ipomœa*. Leaves cordate, quite entire; flowers crowded; corollas undivided. The round green sarments or stalks of this plant mount about any tree, shrub, or hedges, to a great height, clothing them green, with their many branches and leaves; flowers pale purple, (Miller says blue, with their brims not angular, but entire,) very large, bell-shaped; capsule brown, having about five valves.—Native of the West Indies.

13. *Ipomœa Verticillata*; *Whorl-flowered Ipomœa*. Leaves cordate; peduncles axillary, in threes, reflex; calices hispid. Stem seeming to be decumbent, flexuose, half a foot high, branched at the base.—Native country unknown.

14. *Ipomœa Carneæ*; *Flesh-colour-flowered Ipomœa*. Leaves cordate, smooth; peduncles many-flowered; corollas margined. Stem shrubby, in open places almost upright, and supporting itself to the height of a man, but in woods climbing twenty feet high; flowers elegant, but void of smell, three inches in diameter, flesh-coloured, opening in succession; they appear in February and March. Capsules brown and shining, containing blackish seeds wrapped up in abundance of brown ash-coloured wool.—Native of sandy coppices near Carthage, on the coast of South America.

15. *Ipomœa Repanda*; *Repand-leaved Ipomœa*. Leaves cordate, oblong, repand; peduncles branched, in cymes; stems round, twining. The plant is very smooth all over, and probably annual; the flowers are elegant, very shining scarlet, inodorous, numerous, two inches in diameter, but the segments being plaited on the sides, appear at first sight much narrower and lanceolate. They appear in December and January.—Native of Martinico, in coppices on the hills near the town of François.

16. *Ipomœa Filiformis*; *Filiform Ipomœa*. Leaves cordate, blunt, with a point, quite entire; peduncles in racemes, filiform. The whole plant is very smooth, and climbs up shrubs to the height of ten feet; racemes axillary, very loose, slender, and longer than the leaves, spreading out stiffly; flowers purple, inodorous, very numerous; capsules brown, enclosing smooth black seeds.—It flowers from November to January, and is a native of woods, especially on the borders of salt marshes in Martinico.

17. *Ipomœa Hastata*; *Halbert-leaved Ipomœa*. Leaves sagittate, hastate; peduncles two-flowered; flowers yellow.—Native of Java.

18. *Ipomœa Sanguinea*; *Bloody-flowered Ipomœa*. Leaves cordate, three-lobed; side-lobes angular and sublobed behind; peduncles three-flowered; calices smooth. Stem twining, angular, with decurrent lines.—Native of Santa Cruz.

19. *Ipomœa Glaucifolia*; *Glaucous Ipomœa*. Leaves sagittate, truncated behind; peduncles two-flowered. Root perennial; stem half a yard or more high, slender, twining; flowers small, flesh-coloured, or very pale purple.—Native of Mexico.

20. *Ipomœa Triloba*; *Three-lobed Ipomœa*. Leaves three-lobed, cordate; peduncles three-flowered. Root annual; stem twining, angular, ten or twelve feet high; corollas cylindrical, violet-coloured; stigmas two, globular; capsules hairy.—Native of the West Indies and Japan, where it flowers from August to October.

21. *Ipomœa Parviflora*; *Small-flowered Ipomœa*. Leaves cordate, five-lobed, palmate; umbels axillary, peduncled; calices and capsules hairy. Stem twining, smooth, triangular; flowers purple.—Native of Jamaica.

22. *Ipomœa Hederifolia*; *Ivy-leaved Ipomœa*. Leaves three-lobed, cordate; peduncles many-flowered, in racemes. It is an annual.—Native of South America.

** Flowers aggregate.

23. *Ipomœa Hepaticifolia*; *Hepatica-leaved Ipomœa*. Leaves three-lobed; flowers aggregate; colour blue or purple.—Native of Ceylon and Cochinchina.

24. *Ipomœa Tamnifolia*; *Black Briony-leaved Ipomœa*. Leaves cordate, acuminate, hairy; flowers aggregate, closely heaped together in heads, and surrounded with many hairy leaves; they are of a blue colour, soon withering, and becoming brown or black, are very small, short, divided into five roundish segments, commonly plaited and converging, and seldom expanding till about noon, when the sun shines hot.—Native of South Carolina.

25. *Ipomœa Pes Tigridis*; *Palmated Ipomœa*. Leaves palmate; flowers aggregate. The flowers are white, small, five or seven alternately in each head.—Native of the East Indies.

26. *Ipomœa Simplex*; *Entire-leaved Ipomœa*. Leaves lanceolate, entire; flowers solitary.—Native of the Cape.

27. *Ipomœa Zeylanica*; *Ceylonese Ipomœa*. Floral leaflet under each calix one, lanceolate, sessile, permanent, three times as long as the calix. The fruit of this species is properly a berry, fleshy, globular, mucronate at top.—Native of Ceylon, where it is named *kiritella*.

Iresine; a genus of the class *Diœcia*, order *Pentandria*.

—GENERIC CHARACTER. *Male*. *Calix*: perianth two-leaved, very small, acute, glossy. *Corolla*: petals five, sessile, lanceolate, erect; nectary of five scales, the stamina being interposed. *Stamina*: filamenta five, upright; antheræ roundish. *Female*. *Calix* and *Corolla*: as in the male. *Pistil*: germen ovate; style none; stigmas two, roundish. *Pericarp*: capsule oblong-ovate. *Seeds*: few, downy. ESSENTIAL CHARACTER. *Calix*: two-leaved. *Corolla*: five petalled. *Male*. *Nectaries*: seven. *Female*. *Stigmas*: two, sessile. *Capsule*: with tomentose seeds.—The only known species is,

1. *Iresine Celosia*. Stems weak, requiring support, rising ten or twelve feet high, having large knots at each joint, with oval-lanceolate, or oval-entire smooth leaves; flowers terminating in slender loose panicles, covered with a silky down, and of a pale yellow colour; they appear in July and August, and in warm seasons ripen seeds in autumn. A white wool bursts out from among the scales, after the flowering time is past.—It is found upon a cretaceous soil in Jamaica, and most of the other West India islands.

Iris; a genus of the class *Triandria*, order *Monogynia*.

—GENERIC CHARACTER. *Calix*: spathe bivalve, separating the flowers, permanent. *Corolla*: six-parted; petals oblong-obtuse, the three exterior ones reflex, the interior upright and sharper: all connected at the claws into a tube of different lengths in the different species. *Stamina*: filamenta three, awl-shaped, incumbent on the reflex petals; antheræ oblong, straight, depressed. *Pistil*: germen inferior, oblong; style simple, very short; stigmas three, petaliform, oblong, carinated within, furrowed without, incumbent on the stamina, two-lipped; outer-lip smaller, emarginate, inner larger, bifid, subinflected. *Pericarp*: capsule oblong, cornered, three-celled, three-valved; seeds several, large. *Observe*. The nectary in the first nine species is a longitudinal villose line, engraven on the base of the reflex petals; but in others it consists of three melliferous pores at the base of the flower; the capsule in some is trigonal, in others hexagonal. ESSENTIAL CHARACTER. *Corolla*: six-petalled, unequal petals alternate, jointed and spreading.

Stigmas: petal-form, cowl'd, two-lipp'd.—Most of the plants of this genus are cultivated in flower-gardens for their beauty; and would doubtless be more valued, if they were not easily procured and propagated. All the hardy sorts are generally propagated by parting their roots, which most of them multiply fast enough. The best time for removing and parting the roots is in autumn. All those which spread much at their roots, should be transplanted every other year, to keep them within bounds: indeed, the large-growing kinds are most of them too spreading for the flower-garden, so are only fit to fill up spaces between trees and shrubs in large plantations, where they will have a good effect when flowering.—The species are,

* *Bearded*; having the spreading Petals furnished with hairs. Leaves ensiform.

1. *Iris Ciliata*; *Ciliate-leaved Iris*. Bearded: leaves ensiform, ciliate. Bulb ovate, fibrous, netted, the size of a hazelnut; scapes several, most of them concealed by the sheaths of the leaves, and a single one only flowering; corolla yellow, the smaller petals obovate; capsule three-cornered, three-grooved.—Native of the Cape of Good Hope, on the hills near Cape Town. This, like all the rest from the Cape, must be kept in the dry-stove, and increased and managed in the same way as the Cape bulbs.

2. *Iris Minuta*; *Minute Iris*. Bearded: leaves ensiform, smooth; scape one-flowered; petals oblong, acute. Bulb ovate, netted, the size of a large pea; corolla yellow; the smaller petals lanceolate.—Found on Leuwestart mountain, near Cape Town.

3. *Iris Pumila*; *Dwarf Iris*. Bearded: leaves ensiform, smooth; scape one-flowered; petals oblong, blunt. Root brownish on the outside, white within, knobbed with pale fibrils. All the petals are almost entire, blue or purple, varying much in colour, insomuch that the same flower changes, and from blue becomes more and more red. It flowers in April.—Native of Austria and Hungary, on open hills. There are many varieties of this sort, with white, straw-coloured, pale blue, blush-coloured, yellow-variable, blue-variable, and other colours in the flower, which are now greatly neglected. This, and the 3d, 4th, 6th, 23d, 24th, 34th, 36th, and some others, may be propagated by seeds sown soon after they are ripe, when the plants will come up in the following spring; but if the seeds be sown in the spring, they will lie a year in the ground before they vegetate; when the plants appear they must be kept clean from weeds, and in the following autumn should be transplanted into beds at ten inches or a foot distance, where they may remain till they flower, which will be in the second summer after transplanting. They will grow in almost any soil or situation; and as they grow in small compass, may be admitted into large borders, or clumps of flowers in the pleasure-garden, where they will add to the variety.

4. *Iris Susiana*; *Chalcedonian Iris*. Bearded: leaves ensiform, smooth; scape one-flowered; petals rounded. Corolla the largest of all the species, very thin; the claws of the larger petals purple on the outside, dotted and streaked with purple within. Mr. Miller observes, that the three upright petals of the flower are almost as broad as a hand, but very thin, striped with black and white; the three bending petals, or falls, of a darker colour: hence some gardeners call it the "*Mourning Iris*." It flowers at the end of May or beginning of June, but never bears seeds in England. Clusius informs us, "that this magnificent Iris, which takes its name from Susa in Persia, was brought from Constantinople to Vienna and Holland, in 1573." It flowers well in favourable situ-

ations, but succeeds best in a pure air, loamy soil, and sunny exposure; moisture, which favours the growth of most of the genus, is injurious, and sometimes even fatal, to this species. As it rarely ripens seed in England, it is generally increased by roots; and being unable to bear severe seasons, it will be prudent to keep a few roots of it in pots, either in a green-house or hot-bed frame, during the winter, or it may be purchased of the importers of bulbs from Holland, at a reasonable rate. It bears forcing well.

5. *Iris Florentina*; *Florentine Iris*. Bearded: leaves ensiform, smooth, shorter than the subtriflorous scape, which bears two or three flowers. Lower petals connate at the base, the claws of the larger ones thickish, with a thin winged edge an inch long, green on the outside, bearded within, with white cilia, yellow at the tip; smaller petals oblong, blunt, emarginate, white; stigma snowy white. Our old writers called this White Flower-de-luce, or Flower-de-luce of Florence. The root of this plant is extremely acrid, and when chewed excites a pungent taste in the mouth, which continues some hours: this acrimony is almost wholly dissipated when the plant is dried, the taste then being slightly bitter, and the smell agreeable, approaching to that of violets. No essential oil has been hitherto obtained from this root, but spirituous tinctures of it contain more of its virtues than watery infusions. The fresh root is a powerful cathartic, and for this purpose its juice has been employed, in the dose of a drachm and upwards, in dropsies. It is now chiefly used in a dry state, and is said to be good for complaints of the lungs, coughs, and hoarseness; but, we believe, it is more valuable for the pleasantness of its perfume, and the flavour which it communicates, than for any other use. For medicinal uses the roots are generally imported from Leghorn.—Native of the south of Europe.

6. *Iris Biflora*; *Twice-flowering Iris*. Bearded: leaves ensiform, smooth, shorter than the subtriflorous scape; petals violet-coloured, entire.—Native of Portugal and Spain.

7. *Iris Aphylla*; *Leafless Iris*. Bearded: leaves ensiform, smooth, equalling the many-flowered almost naked scape. This has four large bright purple flowers, which stand above each other, and have purplish sheaths; the three bending petals, or falls, are striped with white from the base to the end of the beard; the capsules are large, blunt, and triangular. It flowers at the end of May, and the seeds ripen at the beginning of August.—Native place unknown.

8. *Iris Variegata*; *Variiegated Iris*. Bearded: leaves ensiform, smooth, equalling the many-flowered scape. Flowers at the top of the scape divided, alternate, coming out successively, handsome yellow, netted with black.—It flowers in June, rarely seeds in England; and is a native of Hungary. Gerarde calls it Variable Flower-de-luce.

9. *Iris Germanica*; *German Iris*, or *Garden*, or *Blue Flower-de-luce*. Bearded: leaves ensiform, smooth, sickle-shaped, shorter than the many-flowered scape. This has the largest leaves of all the species; they are of a grayish colour, and spread wide, embracing each other at their base, where they are purplish. The stalks rise nearly four feet high, and divide into several branches, each supporting three or four flowers, which are covered with a thin sheath; the three bending petals or falls are of a faint purple inclining to blue, with purple veins running lengthwise; the beard is yellow, and the three erect petals or standards are of a bright blue, with some faint purple stripes: the flowers have an agreeable scent. It flowers in May and June.—Native of Germany, Switzerland, and Dauphiny. The fresh roots of this plant, which are a strong irritating cathartic, may be given in hydropic cases, in doses of one or two drachms,

to three or four ounces, but must be largely diluted with watery or vinous liquors, to prevent its inflaming the throat. The remarkable differences in the dose, as directed by different practitioners, appear to arise from this circumstance, that some have employed the juice in the recent turbid state, loaded with the acrimonious cathartic matter of the root, while others used such as had been depurated by settling, and which had deposited its more active and acrimonious particles. Hill says, two ounces of it bruised, and infused four or five hours in a quarter of a pint of strong beer, is a strong purge, of great efficacy in dropsical complaints. The root, suspended in wine and beer, prevents those liquors from becoming stale, and communicates a very pleasant taste and smell to the wine. The juice is also sometimes used as a cosmetic, and for the removal of freckles from the skin. A most beautiful paint or colour is prepared from the flowers, in the following manner; they are gathered before quite open, and bruised in a stone mortar with a wooden pestle, then put into a glass, and placed for some days in a cellar, or other moist place; in about a fortnight, the mass, which will have become liquid, is to be set over the fire in a glass pot, till about a third part is evaporated; then more or less roche-alum is to be added, till it becomes clear, and acquires a fine blue colour; it may then be put into shells, and used as a water-colour.

10. *Iris Lurida*; *Dingy Iris*. Bearded: stem higher than the leaves, and many-flowered; outer petals revolute, inner from erect bent in, somewhat waved, and slightly emarginate; stigmas dirty yellow, pale purplish above. This plant may be a variety of the next species, but is scentless. It flowers in April.—Native of the south of Europe.

11. *Iris Sambucina*; *Elder-scented Iris*. Bearded: leaves ensiform, smooth, erect, shorter than the many-flowered scape; petals bent down flat. It differs from the ninth species, in having the larger petals of a deep violet colour, and subemarginate; the smaller petals emarginate, and of a deeper blue colour. It derives its trivial name from the smell of the flowers, which is very like that of Elder in bloom. They appear at the end of May.—Native of the south of Europe.

12. *Iris Squalens*; *Brown-flowered Iris*. Bearded: leaves ensiform, smooth, erect, shorter than the many-flowered scape; petals bent down and folded back. The roots of this species are very thick and fleshy, divided into joints, spreading just under the surface of the ground; they are of a brownish colour on their outside, but white within; the stalks divide into three branches, each of which produces two or three flowers, one above another, at distances, each enclosed in a sheath; they have three large violet-coloured petals, which turn backwards, and are called *falls*; these have beards near an inch long on their midrib towards their base, and have a short arched petal which covers the beard, with three broad erect petals of the same colour, called *standards*. Capsule three-cornered, filled with large compressed seeds. It flowers in June, and ripens seed in August. There is a variety with blue standards, and purple falls; and one with pale purple standards, another with white, and a third with a smaller flower; but these are accidental varieties, which have come from seeds.—Native of the south of Europe.

13. *Iris Compressa*; *Flat-stalked Iris*. Bearded: leaves ensiform, smooth; scape panicled, compressed. Stem frutescent, compressed, smooth, branching dichotomously, jointed, decumbent; branches alternate, elongated, like the scape, one-flowered; corolla white; claws of the larger petals a little widened, bearded within, clotted with yellow; a yellow spot in the flexure; border blunt.—Native of South Africa.

14. *Iris Cristata*; *Crested Iris*. Bearded: beard crested; stem mostly one-flowered, the length of the leaves; germina three-cornered; petals almost equal. Root tuberous, creeping; stems several, short, inclining upwards, compressed, leafy; flower generally solitary, a little shorter than the leaves, erect, of a pale purplish blue; outer petals drooping, obtuse, blue, with deeper blue spots, crested in the place of the beard with three longitudinal, elevated, waved ribs, variegated with orange and yellow. It flowers in May.—Native of North America.

15. *Iris Dichotoma*; *Forked Iris*. Bearded: leaves ensiform, smooth; stem panicled, round. Branches simple, elongated, naked; flowers on long peduncles, pale purple, the smallest of the genus.—It flowers in August, and is a native of Siberia.

** *Leaves linear.*

16. *Iris Tripetala*; *Three-petalled Iris*. Bearded: leaf linear, longer than the one-flowered scape; petals alternate, awl-shaped. Bulb striated, globular, fibrilled; flower terminating, solitary; corolla blue, with a yellow joint; claws of the larger petals broader, linear, dotted on the inside with blue, having a nectareous hollow at the base.—Native of the Cape of Good Hope, near Cape Town, and Picketberg, &c.

17. *Iris Tricuspis*; *Trifid-petalled Iris*. Bearded: leaf linear, longer than the subbiflorous scape, alternate; petals trifid. Bulb the size of a hazel nut; border of the larger petals white, suborbiculate, with a point: it varies much in the shape and colour of the larger petals, and very much in the colours, blue, purple, yellow, white, and spotted.—Native of the Cape, on the hills below Duyvelsberg, in Swartland, and near Berg-riviere. Mr. Curtis describes it as a small delicate Iris, about a foot and a half high, with very narrow leaves, bearing on the top of the stalk one, or at most two flowers; three of the petals are large and white, with a brilliant blue spot at the base of each, edged on the outer side with deep purple: the delicacy of the flower, and the eye-like spot at the base of the three petals, render it, he says, one of the most striking plants of the genus. The root of the plant which he describes came from Holland.

18. *Iris Plumaria*; *Feathered Iris*. Bearded: leaves linear; scapes many-flowered; stigmas setaceous, multifid. Petals connate at the base; claws of the larger ones obovate, greenish on the outside, with a thinner blue edge, pale blue within.—Native of the Cape, below Duyvelsberg.

*** *Beardless.—Leaves ensiform.*

19. *Iris Xiphium*; *Bulbose-rooted Iris*. Beardless: leaves ensiform, channelled, awl-shaped, shorter than the two-flowered scape. The flowers are blue, with emarginate petals. Miller makes two distinct species; which Martyn gives as varieties: there are many varieties of these; the most common colour is blue, deeper or lighter; but it is also yellow, white, blue with white or yellow falls, violet-coloured with blue falls, and variegated.—Native of the south of Europe. It was discovered by the duchess dowager of Portland, on the river side, near Fladbury, in Worcestershire. This, and the thirtieth species, are propagated by offsets from the roots. The bulbs of this species need not be taken up oftener than every other year; and of the latter every third year; this should be done soon after their leaves decay, to prevent them from sending out fresh fibres; nor should they be kept above a month out of the ground, which would cause them to shrink, and flower weakly in the ensuing year. They may be propagated from seeds in the same way as the *Hyacinth*: indeed, the varieties of this species can only be obtained that way; the thirtieth does not vary even from seeds,

These flowers thrive best in a light sandy loam, which will be the better when taken from a pasture ground with the sward, and laid in a heap to rot; for these bulbs do not flourish in a dunged soil, nor should they be too much exposed to the sun; but in an east border they will thrive, and flower extremely well.

20. *Iris Pseudacorus*; *Common Yellow* or *Water Iris*, *Flower-de-luce* or *Water Flag*. Beardless: leaves ensiform, alternate; petals smaller than the stigma. Root fleshy, the thickness of the thumb, spreading horizontally near the surface, blackish on the outside, reddish and spongy within; leaves from the root, two or three feet long, upright, an inch or more in breadth; stem-leaves shorter, forming a sheath at the bottom; scapes from one to three feet in height, upright, alternately inclined from joint to joint, round or flatted a little, smooth and spongy; peduncles axillary, flat on one side, and smooth, each sustaining two or three flowers; corolla yellow, the three outer petals large.—It is common in most parts of Europe, in marshy meadows and fens, by the sides of rivers, brooks, lakes, pools, and ditches, flowering at the end of June or beginning of July. It is sometimes called *Skeggs* or *Lugs*. The root has an acrid burning taste, and the juice, when snuffed up the nostrils, produces a great heat in the mouth and nose, occasioning a copious discharge, and hence it is recommended as a sialagogue and errhine. This root is such a powerful astrigent, that it has been used instead of galls in making ink, and also for the purpose of dyeing black; and owing to that quality it has been successfully given in diarrhœas, for which purpose it should be well dried, for the fresh root and its juice is so strong a cathartic, that eighty drops of the latter produced repeated evacuations, after jalap, gamboge, &c. had failed: this dose was given every hour or two in a little syrup of Buckthorn, and had very speedy effects, causing the patient to discharge by stool several Scots pints of water in the course of the night; and by continuing to use it in increased doses, it cured an inveterate dropsy. Hence Withering says, that, in dropsical cases, attended with obstinate obstructions of the viscera, eighty or a hundred drops of the juice of this root may be given every two hours. Gordon, one of the old writers on medicine, declares, that if man can administer any thing to cure the dropsy, this root will; and Hill says his practice confirms the remark. The expressed juice is also said to be an useful application to serpiginous eruptions, and scrofulous tumors. The root of this plant is recommended by Brookes as a remedy for the toothache. M. Lovrat, a French chemist, has discovered, that the seed, when dried by heat, and freed from the friable shell which envelopes it, produces a beverage similar to coffee, but much superior in taste and flavour.

21. *Iris Foetidissima*; *Stinking Iris*, or *Stinking Gladwyn* or *Gladdon*. Beardless: leaves ensiform; scape one-angled. Root thick, tufted, fibrous. The broken leaves emit a strong odour, not much unlike that of hot roast beef at the first scent, but, if smelt too close, becoming disagreeable. Dr. Withering compares the smell of them to rancid bacon. Corolla of a lurid purplish ash-colour, not smelling in the night-time. It runs much at the root, and flowers sparingly.—It is a native of France and Italy; in England also, it is found near Hornsey; about Charlton-wood, and between Eltham and Chislehurst, in Kent; near Braintree and Woodford in Essex; Bath-hills, Ditchingham, Norfolk; near Cherry-hinton, Feversham, Fulborn, and Triploew in Cambridgeshire; between Dunstable and St. Albans; near Pershore in Worcestershire; and very commonly in all the south-west counties. It is found on hedge banks and sloping grounds, flowering from the end of June till August. The country

people in some parts of England purge themselves with the decoction of this plant. Those who would not have it work too strongly, make an infusion of the sliced roots in ale; and some take the leaves, which are more convenient for tender stomachs. The juice of the root has also been used as an emmenagogue, as well as for cleansing eruptions of various kinds. Hill says the juice of the root promotes urine and the menses; that the dried root, in powder or infusion, is good in all hysteric disorders, fainting, and nervous complaints. Needham says, that, taken inwardly, and applied outwardly to the affected part, in the form of a poultice, it is an excellent remedy for the scrofula or king's-evil. Gerarde says, "the root of Gladdon is of great force against wounds and fractures of the head: for it draweth out all thorns, stubs, prickles, &c. without griefe.—The root given in wine, profiteth much against convulsions, ruptures, the paine of the huckle bones, the strangury, and the flux of the belly, and take away the cause of the laske, otherwise no doubt it moueth vnto the stoole.—The seed therefore mightly purgeth by vrine, as Galen saith; and the country people have found it true."

22. *Iris Virginica*; *Virginian Iris*. Beardless: leaves ensiform; scape ancipital. Root white within, black without, the thickness of the thumb, having white fibres, and bristly at top with the remains of the leaves; flowers elegant, but without scent; claws of the outer petals channelled, green on the outside, yellow on the inside, streaked with dark purple. It flowers in June and July.—Native of Virginia.

23. *Iris Versicolor*; *Various-coloured Iris*. Beardless: leaves ensiform; scape round, flexuose; germina subtrigonal. Flowers blue, large. Mr. Curtis remarks, "that this species has, for the most part, a stalk unusually crooked or elbowed." It flowers in May and June.—Native of North America.

24. *Iris Ochroleuca*; *Pale Yellow Iris*. Beardless: leaves ensiform; scape subcylindric; germina hexagonal. Larger petals dilated at the base, with dusky veins; lesser snowy white, with yellowish veins at the base; stigma snowy white; capsule hexagonal, with blunt angles. This being the highest species of *Iris* cultivated in our gardens, Mr. Curtis calls it *Tall Iris*. It flowers in July.—Native of the Levant.

25. *Iris Halophila*; *Long-leaved Iris*. Beardless: leaves ensiform, those next the root very long; stem round; germina hexagonal.—Native of Siberia.

26. *Iris Spathacea*; *Long-spathed Iris*. Beardless: leaves ensiform, rigid; scape round, two-flowered; spathes very long.—Native of the Capé, near Wolfveckraal, and Langekloof, near Keurbooms riviere.

27. *Iris Ramosa*; *Branching Iris*. Beardless: leaves ensiform; stem panicled, many-flowered; flowers yellow.—Native of the Cape.

**** *With linear Leaves.*

28. *Iris Sisyrinchium*; *Crocus-rooted Iris*. Beardless: leaves linear, waved, reflex; scape one-flowered. Petals purple, with a yellow spot in place of the beard. It flowers in May. Gerarde and Parkinson name it *Spanish-nut*.—Native of Spain and Portugal; and found also in Sicily.

29. *Iris Verna*; *Spring Iris*. Beardless: leaves linear, flat; scape one-flowered, shorter than the leaves; root fibrose, (alternate petals equalling the others;) the flower is purple, with blue standards. It appears in May.—Native of North America.

30. *Iris Persica*; *Persian Iris*. Beardless: leaves linear, flat; scape one-flowered, alternate; petals shorter, (inner petals very short and spreading.) Root oval, bulbous; flower-stalks seldom above three inches high, supporting one or two flowers, enclosed in spathes; these have three erect petals or standards, of a pale sky-blue colour, and three

reflexed petals or falls, which on their outside are of the same colour, but the lip has a yellow streak running through the middle, and on each side are many dark spots, with one large deep purple spot at the bottom. It is greatly esteemed for the beauty and extreme sweetness of its flowers, as well as for its early appearance in the spring; for it is generally in perfection in February, or at the beginning of March, according to the forwardness of the season. Like the Hyacinth and Narcissus, it will blow within doors in a water-glass, but stronger in a small pot of sand or sandy loam, and a few of its flowers will scent the whole apartment.—See the nineteenth species. In propagating it from seed, the boxes in which the seeds are sown, should be put under a garden frame in winter, to shelter them from hard frost.

31. *Iris Angusta*; *Narrow-leaved Iris*. Beardless: leaf filiform, linear, upright, smooth; scape smooth, one or two-flowered; spathes blunt. Bulb ovate, tunicated, smooth, fibrose, the size of a hazel-nut; flowers terminating; claws of the larger petals yellow with the edge white, dotted with purple on both sides; smaller petals lanceolate, blunt, yellow, streaked with dusky purple on the outside.—Native of the Cape, on the hills below Duyvelsberg, and Lewekopp.

32. *Iris Setacea*; *Bristle-leaved Iris*. Beardless: leaf filiform, linear, upright, smooth; scape smooth, one-flowered; spathes acute, membranaceous. Flowers small and blue.—Native of the Cape.

33. *Iris Tenuifolia*; *Slender-leaved Iris*. Beardless: leaves filiform, linear; scape two-flowered. Flower terminating, pale blue; outer lip of the stigma very short and blunt.—Native of Siberia, in the sands of Dauria, and near the Wolga.

34. *Iris Graminea*; *Grass-leaved Iris*. Beardless: leaves linear; scape subdiflorous, ancipital; germina hexagonal. Flowers two or three, small; the petals have a broad yellow line with purple stripes; the three falls are of a light purple colour striped with blue, and have a convex ridge running along them; the others are of a reddish purple, variegated with violet, and smell like fresh plums.—Native of Austria.

35. *Iris Spuria*; *Spurious Iris*. Beardless: leaves linear; scape round, subtriflorous; germina three-cornered. Stem two or three feet high; flowers commonly two, with light blue standards, and purple variegated falls, having a broad white line in the middle instead of the beard. It flowers in July.—Native of wet meadows in Germany and Austria.

36. *Iris Sibirica*; *Siberian Iris*. Beardless: leaves linear; scape round, subtriflorous; germina three-cornered; flowers blue, in brown scarioso spathes. It flowers in May and June.—Native of Siberia, Austria, and Switzerland.

37. *Iris Flexuosa*; *Wave-leaved Iris*. Beardless: leaves linear, flexuose; stem three-flowered, round, thick; germina three-cornered. Flowers terminating, three, the middle one peduncled, the others, as also the lower solitary one, subsessile; corolla white; the reflex petals have the border tooth-letted, the claw linear, yellow, with violet-coloured veins; the upright petals shorter by half, wholly white, waved, with very narrow claws. It is very like the preceding species.—Native of the same places.

38. *Iris Martinicensis*; *Martinico Iris*. Beardless: leaves linear; petals with little glandular pits at the base; germina three-cornered. Stem upright, roundish, two feet high, simple; flowers few, coming out successively from the same spathe, yellow, without scent, peduncled. It flowers here in June; but in Nov. and Dec. in Martinico and St. Lucia, where it is found in moist and mountainous woody pastures.

39. *Iris Pavonia*; *Peacock Iris*. Beardless: leaf linear, smooth; scape one or two flowered. Scape round, jointed, villose, simple, a foot high, sustaining one or two flowers,

which are orange-coloured, with black spots and dots at the base, and a heart-shaped blue spot above the base, which at bottom is tomentose and black.—Native of the Cape, in Swartland, &c. among bushes.

40. *Iris Crispa*; *Curl-leaved Iris*. Beardless: leaves linear, curled. Scape grooved, flexuose, divided at top, a hand or more in height; flowers terminating, alternate, the lower peduncled, three or four in number; corolla six-petalled; alternate petals larger; border ovate, obtuse, veined, yellow, and very finely dotted at the flexure. This varies in the colour of the corolla, yellow, with blood-red veins, blue, and flesh-colour.—Native of the Cape of Good Hope, on the hills near Cape Town.

41. *Iris Papilionacea*. Beardless: leaves linear, reflex, rough-haired. Bulb ovate, coated, the size of a pea; scape upright, hairy, divided, many-flowered, a hand in height; flowers expanding successively. There are also several varieties of this species, with the petals and pistils red within, a yellow spot at the knee, and a dusky circle; and the larger petals yellow, with a green circle at the knee; the borders of the lesser petals and inner lips of the stigmas blood-red.—Common on the hills about Cape Town.

42. *Iris Edulis*; *Edible Iris*. Beardless: leaf linear, pendulous, smooth; scape smooth, many-flowered. Flowers solitary, or several alternate, chiefly directed one way; petals connate at the base. It varies with blue, white, and yellow flowers, the first having dusky streaks, and the last spotted. This, as also several of the African sorts, furnish nutriment both to men and monkeys. The bulbs with the scapes collected in bundles, and gently boiled, are esteemed pleasant and nourishing.—Common at the Cape, in the sands of Greonekloof, Swartland, on Duyvelsberg, and the low plains near Cape Town.

43. *Iris Tristis*; *Drooping Iris*. Beardless: leaves linear, smooth; scape rough-haired, branched; smaller petals narrower by half than the others, ovate, lanceolate; tube greenish, connate at the base; all the borders dull-coloured or rufescent, with a red keel, bright yellow at the bending.—Native of the Cape, below Duyvelsberg, near Cape Town.

44. *Iris Polystachya*; *Branching Iris*. Beardless: leaves linear, flat; scape smooth, branched. Flowers large, handsome, blue with yellow at the flexures.—Native of the Cape, between Sondag-riviere and Visch-riviere.

45. *Iris Viscaria*. Beardless: leaves linear, flat; scape viscid. Border of the larger petals ovate, bluntish, whitish at the flexure.—Native of the Cape, in Saldanha-bay.

46. *Iris Bituminosa*. Beardless: leaves linear, spiral; scape viscid. Flowers solitary, on peduncles; corolla reflex, yellow all over.—Native of the Cape, near Berg-riviere, &c.

47. *Iris Tuberosa*; *Snake's-head Iris*. Beardless: leaves quadrangular. This has a tuberous root: from this arise five or six narrow, long, four-cornered leaves; and from between these the stalk supporting one small flower of a dark purple colour.—Native of the Levant. It is propagated by the roots, which send out offsets, and may be taken up and transplanted when their leaves decay, but should not be kept long out of the ground. If planted in a deep loose soil, the roots will run down, and be lost in a few years where they are not disturbed; so they should be annually transplanted, and have a shallow soil. They are hardy, and only require weeding. If they are to be increased, they should not be removed oftener than once in three years. They flower best when planted to an east aspect. The distance which should be allowed is six inches square, and they should be planted three inches deep in the ground. As they multiply pretty fast by the roots, few persons raise them from

seeds, which, nevertheless, may be done in the way directed for the Bulbous Iris and Hyacinth. In light land it will be proper to lay rubbish in the bottom of the border where the Iris is planted, to prevent the roots from running deep into the ground, or they will seldom produce flowers.

***** *New Species.*

48. *Iris Japonica*. Bearded; leaves ensiform, falcated, shorter, smooth; scape compressed, many-flowered; corollas one-petalled, white.—Native of Japan.

49. *Iris Orientalis*. Beardless: leaves linear; scapes sub-biflorous, round, jointed; germina three-cornered; corollas netted.—Native of Japan.

50. *Iris Ensata*. Beardless: leaves linear; scape sub-biflorous, round; germina hexagonal.—Native of Japan.

51. *Iris Cuprea*. Beardless: stalk cylindrical, flexuose: leaves broad-sword-shaped; stigmata linear, short; petals reflected, emarginated, obovate; capsules large, hexagonal; flowers of a fine copper-colour, veined with purple.—Found by Mr. Euslen, collector to Prince Lichtenstein of Austria, on the eastern banks of the Mississippi, near New Orleans.

52. *Iris Prismatica*. Leaves long and very narrow; capsules elongate, prismatical, and acute on both sides; flowers pale purple.—Found in the deep swamps of New Jersey.

Iron-wood. See *Fagara* and *Sideroxylon*.

Iron-wort. See *Galeopsis* and *Sideritis*.

Isatis; a genus of the class Tetradynamia, order Siliculosa.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved; leaflets ovate, rather spreading, coloured, deciduous. *Corolla*: four-petalled, cross-shaped; petals oblong, obtuse, spreading, gradually attenuated into the claws. *Stamina*: filamenta six, upright, spreading, length of the corolla: of these two are shorter; antheræ oblong, lateral. *Pistil*: germen oblong, ancipital, compressed, -length of the shorter stamina; style none; stigma obtuse, headed. *Pericarp*: silicle oblong, lanceolate, obtuse, compressed, ancipital, one-celled, not gaping, bivalve; valves navicular, compressed, keeled, deciduous. *Seed*: single, ovate, within the centre of the pericarp. **ESSENTIAL CHARACTER.** *Silicle*: lanceolate, one-celled, one-seeded, deciduous, bivalve; valves navicular.—The species are,

1. *Isatis Tinctoria*; *Dyer's Woad*. Root-leaves crenate; stem-leaves sagittate; silicles obcordate. This is a biennial plant, with a fusiform fibrose root; stem upright, round, smooth, woody at bottom, branched at top; flowers small, terminating the stem and branches in a close raceme; both corolla and calix yellow; petals notched at the end. The stalks of the cultivated plant rise nearly four feet high, dividing into several branches, with arrow-shaped leaves sitting close; the ends of the branches terminated by small yellow flowers, in very close clusters; the pods are shaped like a bird's tongue, half an inch long, and one eighth of an inch broad, turning black when ripe. It flowers in July, and the seeds ripen in the beginning of September. Mr. Miller mentions another species, which he calls the Dalmatian Woad, with flowers of a brighter yellow colour, and larger than the above; but it is probably only a variety.—*Dyer's Woad* is a native of several parts of Europe, as on the coast of the Baltic and German Ocean, by way-sides in Switzerland; and in England, in and on the borders of corn-fields, as at New Barns, near Ely, and by the river Wear near Durham, &c. Linneus says, it is a maritime plant; but as it seems probable that it is the plant with which Pliny informs us, the ancient Britons painted their bodies, it must in that case be a native of our islands. Stow and Hume record, that "Good Queen Bess" took such a dislike to the smell of this herb, that she prohibited its cultivation. We were formerly dependent upon France for supplies of Woad, which is much employed by dyers for pro-

ducing blue, and forming the basis of black and many other colours.—*Propagation and Culture.* It is sown upon fresh land in good heart, for which the cultivators of Woad pay a large rent: they generally choose to have their lands situated near great towns, where there is plenty of dressing; but they never stay long on the same spot, for the best ground will not admit of being sown with Woad more than twice, for if it be oftener repeated, the crop will seldom defray the expense of its culture. After having selected a good spot of land, which should not be too light and sandy, nor over stiff and moist, but rather a gentle hazel loam, whose parts will easily separate; the next is, to plough this up just before winter, laying it in narrow high ridges, that the frost may penetrate through them to mellow and soften the clods; then in the spring plough it again cross-ways, laying it again in narrow ridges: after it has lain some time in this manner, and the weeds begin to grow, it should be well harrowed, and the large perennial weeds must be rooted out, and carried off the ground; which should be ploughed a third time in June, with narrow furrows, and as deep as the plough will go, that the parts may be as well separated as possible; and when the weeds again appear, repeat the harrowing, which will destroy them. At the end of July, or in the beginning of August, the land should be ploughed for the last time, and laid smooth. When there is a prospect of showers, it should be harrowed, to receive the seeds, which should be sown either in rows with the drill-plough, or in broad-cast, after the common method. It will be proper to steep the seeds one night in water, which will prepare them for vegetation, and if they be sown in drills with the plough, they must be covered by an instrument fixed to the plough for that purpose; but those which are sown broad-cast in the common way, must be well harrowed in. If the seeds be good, and the season favourable, the plant will appear in a fortnight, and in a month or five weeks after will be fit to hoe: the sooner the hoeing is performed after the plants are distinguishable, the better they will thrive, and the weeds, being then young, will be destroyed. The method of hoeing these plants is the same as for Turnips, with this difference only, that these require less thinning; for, at the first hoeing, if they be separated at the distance of three or four inches, and at the last to six inches, it will be space enough for the growth of the plants. If the thinning be carefully done in dry weather, most of the weeds will be destroyed; but as some of them may escape in this operation, and young weeds will arise, the ground should be a second time hoed in October, in dry weather, when the plants must be singled out to the distance at which they are to remain. The ground will then remain free from weeds till the spring, when young weeds will come up; therefore about a fortnight in April will be a good time to hoe the ground again, as the weeds will then be young, and it may be performed in less than half the time it would require if they were permitted to grow large; besides, the sun and wind will much sooner kill them. This hoeing will also stir the surface of the ground, and greatly promote the growing of the plants: if it be performed in dry weather, the ground will remain free till the first crop of Woad is gathered, after which it should be again well cleared; and if this be carefully repeated after the gathering of each crop, the land will always lie clean, and the plants will thrive better. The expense of the first hoeing will be about six shillings per acre, and for the after-hoeings half that price will be sufficient, provided they are performed when the weeds are young. If the land in which the seed is sown should have been in culture before for other crops, so not in good heart, it will require dressing before it is sown, in which rotten stable-dung is preferable to any other; but

this should not be laid on till the last ploughing before the seeds are sown, and not spread but as the land is ploughed, that the sun may not exhale the goodness of it, which is soon evaporated if it be spread on the ground in summer. The quantity should not be less than twenty loads to each acre, which will keep the ground in heart till the crop of Woad be spent. The time for gathering the crop is according to the season, but it should be performed as soon as the leaves are fully grown, while perfectly green; for, when they begin to change pale, great part of their goodness is gone, and the quantity also will be much diminished. If the land be good, and the crop well husbanded, it will produce three or four gatherings, but the two first are the best, and are commonly mixed together when used. The after crops are always kept separate, for if mixed they would be of little value. The two first crops will sell at from twenty-five to thirty pounds and upwards per ton, but the latter will not bring more than seven or eight, and sometimes not so much. An acre of land will produce a ton of Woad, and in good seasons nearly a ton and half. When the planters intend to save the seeds, they cut three crops of the leaves, and then let the plants stand till the next year for seed; but if only one crop is cut, and that only of the outer leaves, letting all the middle leaves stand to nourish the stalks, the plants will grow stronger, and produce a much greater quantity of seeds. These seeds are often kept two years, but it is always best to sow new seeds when they can be obtained. The seeds ripen in August, and should be gathered when the pods turn to a dark colour; which is best done by reaping in the same way as for Wheat, spreading the stalks in rows upon the ground. In four or five days' dry weather the seeds will be fit to thresh out; but if they lie long, the pods will open and let them fall out. Some Woad-planters feed down the leaves in winter with sheep, which is a very bad method; for all plants which are to remain for a future crop, should never be eaten by cattle, for that greatly weakens them. Those who cultivate this commodity, have gangs of people who have been bred to the employment, so that whole families travel about from place to place, wherever their principal fixes on land for the purpose. These persons, however, always go on in one track, just as their predecessors taught them, nor have their principals deviated much from the practice of their ancestors; so that there is a large field for improvement, if any of the cultivators of Woad should happily prove men of genius, who could be prevailed upon to adopt the garden culture of this plant. The method practised by some of the most skilful gardeners in the culture of Spinach, would be a great improvement to this plant; for some of them have improved the Round-leaved Spinach so much by culture, as to have the leaves more than six times the size they formerly were, and their fatness has increased in the same proportion upon the same land; which has been affected by thinning the plants while young, and keeping them free from weeds.—Woad, besides the use of it among dyers, is possessed of several medicinal virtues. A strong infusion of the tops of the plant operates by urine; and, when continued to be used for a considerable time, is excellent for curing obstructions of the liver and spleen.

2. *Isatis Lusitanica*; *Portugal Woad*. Root-leaves crenate; stem-leaves sagittate; silicles subtomentose; flowers white.—Native of Portugal and the Levant.

3. *Isatis Armena*; *Armenian Woad*. Leaves quite entire, cordate, blunt behind; silicles cordate. Stem a foot high, loaded with yellow flowers.—Native of dry pastures, by the side of brooks, in Armenia.

4. *Isatis Ægyptiaca*; *Egyptian Woad*. All the leaves toothed. Annual, and a native of Egypt.

5. *Isatis Alpina*; *Alpine Woad*. Leaves lanceolate, half embracing, cordate; silicles ovate. Stem half a yard high; flowers in a sort of umbel, in short racemes, yellow, on yellow filiform peduncles.—Native of the mountains of Piedmont. This, and the three preceding sorts, are not cultivated for use, but are preserved only in botanic gardens. The second and fifth may be propagated by seeds sown in autumn; the third and fourth are too tender to live in the open air, and must be raised by seeds on a hot-bed in the spring.

Ischæmum; a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** *Calix*: glume two-flowered, bivalve, cartilaginous, placed transversely; valves nearly equal, the exterior subovate, gibbose, with a bifid tip, sharp; the upper part of the back flat in the middle, striated, emarginated; the interior oblong, acuminate or awned at the tip, the back beneath the tip increased by a longitudinal membrane. *Floscule*: exterior male, interior hermaphrodite, each less than the calix. *Corolla*: in the hermaphrodite, a bivalve glume: valves membranaceous, thin, colourless; the exterior bellied, either mutic or awned, bifid to the very awn, acute; awn long; slender, jointed, tortile beneath; the interior lanceolate, acute, conduplicate at the edges. In the male, a bivalve glume rather firmer, diaphanous, rather coloured; the exterior oblong, bellied, contracted above, sharp, mutic; the interior oblong, obtuse, with concave back, acutely margined; margin thinner. *Nectary*: in each two-leaved; leaflets small, spatulate, truncate-emarginate. *Stamina*: filamenta three, capillary, short; antheræ oblong, bifid on both sides. *Pistil*: in the hermaphrodites, germen oblong; styles two, capillary, erect, shorter than the corolla; stigmas oblong, plumose, spreading, exserted. *Pericarp*: none; calix and corolla unchanged. *Seed*: (in the hermaphrodite) single, oblong, linear, convex on one side. *Observe*. The flowers are spiculated, and grow double; the one sessile, the other seated on a broad glumaceous footstalk; each hermaphrodite. **ESSENTIAL CHARACTER.** *Hermaphrodite. Calix*: glume two-flowered. *Corolla*: two-valved. *Stamina*: three. *Styles*: three. *Seed*: one. *Male. Calix and Corolla*: as in the other. *Stamina*: three.—The species are,

1. *Ischæmum Muticum*. Leaves lanceolate; flowers awnless. Culms a foot or eighteen inches high; spike two-parted, terminating, joined so as to appear one, or one divided to the base.—Native of the East Indies, and of the Isle of Tanna.

2. *Ischæmum Aristatum*. Leaves lanceolate; calices two-flowered; pedicels ciliate; each female flower with a twisted knee-jointed awn. Culm a foot and half high, branched, decumbent, and rooting with hairy joints.—Native of China.

3. *Ischæmum Imberbe*. Leaves lanceolate; florets naked; outer valve of the sessile calix having two knobs on each side, and the corolla elongated by a twisted awn. Culms two feet high, leafy, somewhat branched.—Native of the East Indies.

4. *Ischæmum Barbatum*. Leaves lanceolate; calices two-flowered, bearded at the base, and ciliate at the edge, the edge of the sessile one with two knobs on each side; awn twisted, knee-jointed. Culm like the preceding; spike longer, two-parted, awned, with the teeth of the rachis ciliate-bearded.—Native of Java.

5. *Ischæmum Muricum*. Spike two-parted; calix and seed awned. Culms filiform, slender, simple, a long span in height; spikes closely converging, cylindrical, two inches long.—Native of the Isle of Tanna, on dry sand, near the coast.

6. *Ischæmum Involutum*. Spike directed one way, awnless, four-flowered, involved in a leafy cone or receptacle.—Native of the Society Isles, Otaheite, &c.

7. *Ischæmum Importunum*. Panicle contracted; corollas

one-valved. Root-perennial, simple, long, jointed, white, very tough; flowers ovate, smooth, awnless, small.—Native of Cochin-china, where it is a troublesome weed.

8. *Ischæmum Rugosum*. Outer barren glumes transversely wrinkled; male and female florets fertile, one only awned. Root annual. Plant from seven inches to a foot in height.—Native of the East Indies.

Isertia; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, superior, coloured, four or six toothed, permanent. *Corolla*: one-petalled, funnel-form; tube long, cylindrical, slightly curved; border six-cleft; divisions subovate, rather upright, villose. *Stamina*: filamenta six, very short, within the mouth of the corolla; antheræ linear, fastened by the back, upright. *Pistil*: germen inferior, roundish; style filiform, surrounded at the base by a glandule; stigma six-cleft. *Pericarp*: pome subglobose, crowned with the calix, succulent, six-celled; the shell of the cells fragile. *Seeds*: several, small, angular, rough. **ESSENTIAL CHARACTER.** *Calix*: coloured, four or six toothed. *Corolla*: six-cleft, funnel-form. *Pome*: subglobular, six-celled, many-seeded.—The species are,

1. *Isertia Coccinea*. Leaves opposite, disposed cross-wise, smooth, entire, oval, ending in a long point; flowers terminating in a large straight panicle, the branches of which are opposite and subdivided, and come out from between two little scales; tube of the corolla two inches long, bright red. It is a tree, with a trunk ten or twelve feet in height, and about eight inches in diameter; the bark wrinkled, and of a russet colour; the wood light, and of a loose texture; it is bitter. The Creoles use a decoction of the leaves in fomentations.—Common in the island of Cayenne, and on the continent of Guiana, flowering and bearing fruit great part of the year.

2. *Isertia Parviflora*. Leaves oblong, the lower ones somewhat heart-shaped at the base; bunch of flowers ovate.—Found in Trinidad.

Isnardia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth bell-shaped, half four-cleft; divisions ovate, spreading. *Corolla*: none, unless the calix be so termed. *Stamina*: filamenta four, growing from the middle of the calix; antheræ simple. *Pistil*: germen inferior; style simple, longer than the stamina; stigma thickish. *Pericarp*: capsule four-cornered, obtuse, covered by the calix, and crowned, four-celled, four-valved; valves obscurely keeled, thick, fungous, attenuated on the margin; partitions opposite to the valves. *Seeds*: very many, oblong, sharp, affixed to the pillar. **ESSENTIAL CHARACTER.** *Calix*: four-cleft. *Corolla*: none. *Capsule*: four-celled, covered by the calix.—The only known species is,

1. *Isnardia Palustris*. Flowers axillary, opposite, sessile, and green. It is creeping and floating; and has been determined by Swartz to be a species of *Ludwigia*, frequent in the rivers of Jamaica, with petals to the flower, though fugacious. Annual.—Found in the rivers of Italy, France, Alsace, Russia, Jamaica, and Virginia.

Isoetes; a genus of the class Cryptogamia, order Filices.—**GENERIC CHARACTER.** *Male Flowers*, solitary, within the base of the inner leaves. *Calix*: scale cordate, acute, sessile. *Corolla*: none. *Stamina*: filamenta none; antheræ roundish, one-celled. *Female Flowers*, solitary, within the base of the outer leaves of the same plant. *Calix*: as in the males. *Corolla*: none. *Pistil*: germen ovate, within the leaf. *Pericarp*: capsule subovate, two-celled, concealed within the base of the leaf. *Seeds*: numerous, globular. **ESSENTIAL CHARACTER.** *Male. Antheræ*:

within the base of the frond. *Female. Capsule*: two-celled within the base of the frond.—The species are,

1. *Isoetes Lacustris*; *Common Quillwort*. Leaves awl-shaped, semicylindrical, curved back. Root fibrous; fibres numerous, simple, slender, striking deep into the mud; leaves in thick tufts, extremely like young Rushes, at the base swelling into a kind of bulb, covered by a thin skin, filled with numerous whitish minute seeds. The edges of the inflated base of the outer leaves, where the female flowers reside, form a thin fine membrane, which so closely embraces the gibbous part of the inner leaf, where the male flower is found, as to exclude the water; and by this admirable contrivance, the flowers of each sex are not only near each other, but, though at the bottom of a lake, are kept perfectly dry. Flowering from May to September.—Native of the mountain lakes in the north of Europe; and, with us, of those in Westmoreland, Cumberland, Wales, and Scotland.

2. *Isoetes Coronandeliana*; *Coromandel Quillwort*. Leaves filiform, erect, smooth. This is larger than the preceding, which it very much resembles.—Native of Coromandel, in wet places that are inundated in the rainy season.

Isopyrum; a genus of the class Polyandria, order Polygynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals five, ovate, equal, spreading, deciduous; nectaries five, equal, tubular, very short, with a three-lobed mouth, the outer lobe larger, the receptacle inserted within the petals. *Stamina*: filamenta numerous, capillary, shorter than the corolla; antheræ simple. *Pistil*: germen very many, ovate; styles simple, the length of the germen; stigmas blunt, the length of the stamina. *Pericarp*: capsules several, lunulate, recurved, one-celled. *Seeds*: very many. *Observe.* This genus is very nearly allied to that of *Helleborus*, but extremely different in habit. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: five. *Nectary*: trifid, tubular. *Capsule*: recurved, many-seeded.—To propagate these plants, sow the seeds in a shady border soon after they are ripe, or permit them to scatter; and when they come up, keep them clean from weeds.—The species are,

1. *Isopyrum Fumaroides*. Stipules awl-shaped; petals acute. Leaves shaped like those of *Fumitory*, small, and of a gray colour; the stalk is naked to the top, where there is a circle of leaves just under the flowers, which are small, of an herbaceous colour on the outside, and yellow within; they appear in the beginning of April, and ripen seeds in May. Annual: three or four inches high.—Native of Siberia.

2. *Isopyrum Thalictroides*. Stipules ovate; petals obtuse. Stem commonly single, near a foot high, terminating in a few spreading slender peduncles, each bearing one small flower; the petals of which, from five to six in number, are first white, but turn to red or purple. All the leaves have a pale roundish stipule on each side; stamina from thirty to thirty-six. It flowers at the end of March, and ripens seed in May. Perennial.—Native of the south of Europe, and found also in Austria, flowering in April or May.

3. *Isopyrum Aquilegioides*. Stipules obsolete. Stem a long span in height, slender, having two or three short, entire, stipular leaves on it, and a single blue flower five times less than that of the preceding. It is the *Aquilegia Viscosa* of Linneus.—Native of the mountains of Switzerland, Moravia, Trent, and the Apennines, in meadows, flowering in the spring.

Itea; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-cleft, upright; segments lanceolate, acute, permanent, coloured. *Corolla*: petals five, sessile, lanceolate, acuminate, spreading, deciduous. *Stamina*: filamenta five, awl-shaped, upright, the length of the corolla, inserted into the base of the

calix; antheræ roundish, incumbent. *Pistil*: germen ovate, superior; style permanent, cylindrical, the length of the stamina; stignas two, blunt. *Pericarp*: capsule ovate, longer than the calix, mucronated by the style, two-celled, two-valved, many-seeded. *Seeds*: very small, oblong, shining. *Observe*. The second species has the petals inserted, not into the calix, but the receptacle; the style bifid, and the capsule not opening. **ESSENTIAL CHARACTER**. Capsule two-celled, two-valved, many-seeded; stigma emarginate.

—The species are,

1. *Itea Virginica*; *Virginian Itea*. Leaves ovate, acute, serrate. This shrub is six or seven feet high, sending out many branches from bottom to top; at the extremity of the same year's shoots, in the month of July, are produced fine spikes of white flowers, three or four inches long, and erect. When this shrub is in vigour, it is entirely covered with these flowers, and makes an elegant appearance.—Native of North America. It will live in the open air in England, but will not thrive upon dry gravelly ground. It is propagated by layers; these, if put down in the autumn, will put out roots, so as to be fit to remove in the following autumn, when they may be transplanted to a nursery, or to the place where they are to remain.

2. *Itea Cyrilla*; *Entire-leaved Itea*. Leaves lanceolate, entire, membranaceous. A shrub, three feet high; stem upright, somewhat branched, round, ash-coloured; flowers scattered, pedicelled, spreading, white, two or three lines in diameter; petals longer than the calix; racemes very many, lateral, at the base of the new shoots, one from each bud, on short peduncles, spreading, four to six inches long.—Native of Carolina and Jamaica. It requires the protection of a green-house; and may be increased by layers and cuttings.

Iva; a genus of the class Monœcia, order Pentandria.—**GENERIC CHARACTER**. *Calix*: common roundish; leaflets about five, subovate, blunt, almost equal, permanent, containing very many florets. *Corolla*: compound, convex; corollets, male very many in the disk; female five in the ray; proper, males one-petalled, funnel-form, five-toothed, the length of the calix; females none. *Stamina*: males, filamenta five, bristle-shaped, the length of the corollet; antheræ erect, approximating. *Pistil*: females, germen oblong, the length of the calix; styles two, capillary, long; stigmas acute. *Pericarp*: none; calix unchanged. *Seeds*: solitary, naked, the length of the calix, at top thicker, blunt. *Receptacle*: chaffy; chaffs linear, interior. **ESSENTIAL CHARACTER**. *Male Calix*: common, three or five leaved. *Corolla*: of the disk one-petalled, five-cleft. *Receptacle*: with hairs or linear chaffs. *Female*: in the ray, five, or fewer. *Corolla*: none. *Styles*: two, long. *Seeds*: naked, blunt.—The species are,

1. *Iva Annuæ*; *Annual Iva*. Leaves lanceolate-ovate; stem herbaceous. Branches from the sides of the stalk; both branches and stalks are terminated by small clusters of pale blue flowers, which appear in July, and the seeds ripen in autumn.—Native of South America and the West Indies. Sow the seeds on a moderate hot-bed, and, when the plants are fit to remove, transplant them to another hot-bed, and treat them as is directed for *Impatiens*.

2. *Iva Frutescens*; *Shrubby Iva*, or *Bastard Jesuit's Bark Tree*. Leaves lanceolate; stem shrubby. Branches terminated by small clusters of pale purple flowers, which appear in August.—Native of Virginia and Peru. This shrub has been preserved in the green-house, though it seldom suffers from the cold of our ordinary winters, if planted in a dry soil and a sheltered situation. If the branches be laid in the spring, they will put out roots in six months;

or if the cuttings be planted in a border in May, they will take root.

Judas Tree. See *Cercis*.

Juglans; a genus of the class Monœcia, order Polyandria.—**GENERIC CHARACTER**. *Male Flowers*: *Calix*: ament cylindrical, imbricate, scattered all round, with one-flowered scales, turned outwards; perianth elliptic, flat, six-parted; segments upright, concave, blunt. *Corolla*: none. *Stamina*: filamenta many, eighteen to twenty-four, (or, according to Gærtner, twelve to twenty-four,) very short; antheræ oval. *Female Flowers*: heaped. *Calix*: perianth one-leaved, bell-shaped, four-cleft, upright, very short, one-flowered. *Corolla*: one-petalled, four-cleft, upright, acute, a little larger than the calix. *Pistil*: germen oval, large, inferior; style very short; stigmas two, large, reflex, jagged at top. *Pericarp*: drupe dry, oval, large, one-celled. *Seed*: nut very large, roundish, netted, grooved, half four-celled; (according to Gærtner, corticated, two-valved;) nucleus four-lobed, variously grooved. **ESSENTIAL CHARACTER**. *Male*. *Calix*: one-leaved, scale-form. *Corolla*: six-parted. *Filamenta*: eighteen. *Female*. *Calix*: four-cleft, superior. *Corolla*: four-parted. *Styles*: two. *Drupe*: with a grooved nucleus.—The species are,

1. *Juglans Regia*; *Common Walnut-tree*. Leaflets about nine, oval or oblong, smooth, subserrate, almost equal, the odd one petioled. A large and handsome tree, with strong spreading boughs. Leaves pinnate, with a very strong but not unpleasant smell; leaflets three pairs (sometimes two or four) nearly equal, entire, smooth, and shining; male flowers in close pendulous subterminating aments; females scattered, frequently two or three together; fruit an ovate, coriaceous, smooth drupe, enclosing an irregularly-grooved nut, which contains a four-lobed oily eatable kernel, with an irregular knobbed surface, and covered with a yellow skin.—The varieties of the common Walnut are, the large Walnut, the thin-shelled Walnut, the double-bearing Walnut, and the late-ripe Walnut. They all vary again when raised from the seed, and nuts from the same tree will produce different fruit: persons therefore who plant the Walnut for its fruit, should choose their trees in the nurseries, while they have their fruit upon them. The flowers begin to open about the middle of April, and are in full blow by the middle of May, before which time the leaves are fully displayed. Even in the south of France, this tree is frequently injured by spring frosts; and to avoid this, the Swiss engraft the common stocks with the late-ripe variety, which does not produce its fruit before the month of May or June. This might probably be too late for us; but in those climates, where, though they are warmer than ours, the olive will not succeed, and where the fruit of the Walnut is therefore of much consequence for the oil which it yields, it may be worth attending to. In France and Switzerland the wood is still in as great request for furniture, as it formerly was in England, until superseded by Mahogany. It is of singular use with the joiner for the best-grained and coloured wainscot; with the gunsmith, for stocks; with the coach-maker, for wheels and the bodies of coaches. The cabinet-maker uses it for inlaying, especially the firm and close timber about the root, which is admirable for flecked and cambleted works. To render this wood the better coloured, joiners put the boards into an oven after the batch is drawn, or lay them in a warm stable; and, when they work it, polish it over with its own oil very hot, which makes it look black and sleek, and the older it is, the more estimable: but then it should not be put in work till thoroughly seasoned, because it is very liable to shrink. It is most unfit for beams or joints, because of its brittleness. The enormous size to which this tree will grow,

and the prodigious quantity of timber it will produce, may be judged from what Evelyn reports, that Scamozzi, the Italian architect, saw a table of Walnut tree in Lorrain, twenty-five feet in breadth, all of one piece, and of competent length and thickness! The younger timber is held to make the better coloured work; but the older, being more firm and close, is finer cabled for ornament. Those trees which are raised from the thick-shelled fruit become the best timber; but the thin-shelled yield better fruit. Besides the uses of the wood, the fruit, when tender and very young, is used for preserves. The oil is of extraordinary use with the painter, in whites and other delicate colours, also for gold-size and varnish, and for polishing walking-sticks and other works which are wrought in with burning. They fry with this oil in some places, in others they eat it instead of butter; and at Berry in France, where they have little or none good; they plant these trees all over the country for that very purpose, as well as to supply their lamps with oil. The unripe fruit has been long eaten pickled: and is directed for medicinal use by the London College as an anthelmintic; and many authors recommend it for destroying worms. An extract is the most convenient preparation, as it may be kept for a sufficient length of time, and made agreeable to the stomach by mixing it with cinnamon-water. In this state the Walnut is also said to be laxative, and of use in apthous affections and sore throats. The vinegar in which they have been pickled is a very useful gargle. The kernel is similar in qualities to the almond; the oil also does not congeal by cold, and answers the medicinal purposes of the oil of almonds. The bark, says Hill, taken either in substance, when dried and powdered, or made into a strong infusion and drank, vomits easily and plentifully; and the bitter skin with which the kernels are covered may be given in doses of three drachms, for allaying fluxes. The husks and leaves being macerated in warm water, and that liquor poured on grass-walks and bowling-greens, infallibly kills the worms, without endangering the grass. This, says Dr. Hunter, arises not from any thing peculiarly noxious in the decoction, but worms cannot bear the application of any thing bitter to their bodies; which is the reason that bitters, such as gentian, are the best destroyers of worms lodged in the bowels of animals. Worms are seldom observed in the intestines of the human body, excepting in cases where the bile is either weak or deficient. The dye made of this lixive will colour woods, hair, and wool; and the green husks boiled, make a good colour to dye a deep yellow without any mixture. Those nuts which come easily out of their husks, should be laid to mellow in heaps, and the rest exposed in the sun till the shells dry, else the kernels will be apt to perish; some again preserve them in their own leaves, or in a chest made of Walnut-wood; others in sand, especially for a seminary. Old nuts are not wholesome till macerated in warm water; but, if you bury them in the earth in pots, out of the reach of the air, and so as no vermin can attack them, they will remain remarkably plump the whole year round, and may be easily blanched. In Spain they strew the gratings of old and hard nuts, first peeled, into their tarts and other meats. For the oil, one bushel of nuts will yield fifteen pounds of peeled and clear kernels, and these half as much oil, which, the sooner it is drawn, will produce more plentifully, but not of so good a quality as when the nut is drier. The lees or marc of the pressing is excellent to fatten hogs with. After the nuts are beaten down, the leaves should be swept into heaps, and carried away, because their extreme bitterness impairs the ground.— Little use having been made of the wood during late years, the old trees that have been cut down have not been always

replaced by young ones, and thus the plantations of this tree have gradually diminished. The wood is now principally used for making gun-stocks; and the fruit being eaten only ripe in desserts, or green in pickles, there is not so much call for it as there was formerly. The English name Wall-nut, is a corruption of *Gaul-nut*; which leads us to conclude that it was imported from France into Great Britain. The French call the tree *noyer*, and the fruit *noix*; as the Romans called it exclusively *nux*, or *The Nut*; the Germans name it *walnuss*, or *welsche nuss*. Its native place of growth is uncertain, but Persia seems the most probable. It is much cultivated in some parts of Italy, France, Germany, and Switzerland. In several places between Hanau and Frankfort, in Germany, no young farmer is permitted to marry a wife, till he bring proof that he has planted a stated number of Walnut-trees. It was formerly much cultivated in England, particularly on the chalk-hills of Surry.—*Propagation and Culture.* These trees are propagated by planting their nuts, which seldom produce the same sort of fruit as is sown; so that the only way to secure the desired sort, is to sow the nuts of the best kinds; and if this be done in a nursery, the trees should be transplanted out when they have had three or four years' growth, to the place where they are designed to remain; for these trees do not bear transplanting when they are of a large size; therefore there may be a good number of the trees planted, which need not be put at more than six feet apart, as that will be far enough asunder for them to grow until they produce fruit; when those, the fruit of which is of the desired kind, may remain, and the others cut up to allow them room to grow: by this method a sufficient number of the trees may be generally found amongst them to remain, which will thrive and flourish greatly when they have room. But as many people do not care to wait so long for the fruit, the next best method is to make choice of some young trees in the nurseries, when they have their fruit upon them; but though these trees will grow and bear fruit, yet they will never be so large, or so long-lived, as those which are planted young. All the sorts of Walnuts which are propagated for timber, should be sown in the places where they are to remain; for the roots of these trees always incline downward. If the roots be stopped or broken, it will prevent their aspiring upward, so that they afterwards divaricate into branches, and become low spreading trees; but such as are propagated for fruit, are greatly improved by transplanting, which causes them to produce larger fruit, and in greater abundance; and it is a common observation, that downright shoots greatly encourage the luxuriant growth of timber in all sorts of trees; but such trees as have their roots spreading near the surface of the ground, are always the most fruitful and best flavoured. The nuts should be preserved in their outer covers in dry sand till February; when they should be planted in lines, at the distance you intend them to remain; but in the rows they may be placed pretty close, for fear the nuts should miscarry; and the young trees, where they are too thick, may be removed, after they have grown two or three years, leaving the remainder at the distance they are to stand. In transplanting these trees, observe never to prune either their roots or large branches, both which are very injurious to them; nor should you be too busy in lopping or pruning the branches, when grown to a large size, for that often causes them to decay; but when it is necessary to cut off any of the branches, it should be done early in September, (for at that time the trees are not so subject to bleed,) that the wound may heal over before the cold increases: the branches should always be cut off quite close to the trunk, otherwise the stump which

is left, will decay, and rot the body of the tree. The best season for transplanting these trees, is as soon as the leaves begin to decay, when, if they be carefully taken up, and their branches preserved entire, there will be little danger of their succeeding, although they be eight or ten years old; but it must be remarked, that trees removed at that age, will neither grow so large, nor continue so long, as those that are removed when younger. This tree delights in a firm, rich, loamy soil, or such as is inclinable to chalk or marl; and will thrive very well in stony ground, and on chalky hills, as in the large plantations near Leatherhead, Godstone, and Carshalton, in Surry, where great numbers of those trees are planted upon the downs, and annually produce large quantities of fruit. The distance between these trees ought not to be less than forty feet, especially if regard be had to their fruit; though when they are only designed for timber, if they stand much nearer it promotes their upright growth. The Black Virginian Walnut is much more inclined to grow upright than the common sort, and the wood being generally of a more beautiful grain, renders it preferable to that, and better worth cultivating. Some of the wood is so beautifully veined with black and white, that, when polished, it appears at a distance like polished marble. The cabinet-makers esteem it highly for inlaying, as well as for bedsteads, stools, chairs, tables, and cabinets, for all which purposes it is one of the most durable woods of English growth, and less liable to be infested with insects than most other kinds, which is probably owing to its extraordinary bitterness: but it is not proper for buildings of strength, being liable to break off very short. The general opinion is, that the beating off the fruit improves the trees; which is improbable, because in doing it the younger branches are generally broken and destroyed; but as it would be exceedingly troublesome to gather it by hand, so in beating it off great care should be taken that it be not done with violence, for the reason before assigned. In order to preserve the fruit, it should remain upon the trees till it is thoroughly ripe, when it should be beaten down, and laid in heaps for two or three days; after which it should be spread abroad, and in a little time the husks will easily part from the shells: they should then be well dried in the sun, and laid up in a dry place, secured from mice and other vermin; in this place they will remain good for four or five months. If put into an oven gently heated, and, after remaining four or five hours to dry, be packed up in oil-jars or any other close vessel, mixing them with dry sand, they will keep good six months. The oven dries the germen, and prevents their sprouting, but when too hot will cause them to shrink. In setting the nuts, Dr. Hunter recommends drills to be made at one foot asunder, and two inches and a half deep, into which put the nuts four inches apart. Evelyn advises some chopped furze to be mixed with them, to preserve them from vermin. The spring following, the plants will come up; and in two years they will be of a proper size to plant out in the nursery. There, having shortened their tap-roots, plant them in rows two feet and a half asunder, and at the distance of a foot and a half in the rows. Here they may remain till they are of a proper size for their final planting. If they are to be planted in fields, they should be risen out of the reach of cattle before they are removed from the nursery, which should be done with great caution; the knife should be very sparingly applied to the roots, and they should be planted as soon as possible after taking up, soon after the fall of the leaf. In raising the Walnut for fruit, Mr. Boucher recommends flat stones, tile-sherds, or slates, to be buried eight inches

deep under the nuts when they are set, the distance to be six inches, and the depth two inches. After two seasons, remove them early in autumn, and plant them fourteen or sixteen inches asunder, on the same kind of bottom, or any hard rubbish, to prevent them from striking downwards, and cause them to spread their roots on the surface. At the end of two or three years repeat this again, making the bedding at the depth of fifteen or sixteen inches, and planting them two feet asunder: here let them remain for three or four years, when they will be fit to remove for the last time. The soil for fruit should be dry and sound, with a sandy, gravelly, and chalky bottom. The trees managed in this way will have higher-flavoured fruit, that ripens earlier, and they will bear a plentiful crop, twenty years sooner than in the usual method. The best manure for them is ashes, spread at the beginning of the winter after the lands have been first ploughed or dug. As the plants raised from nuts of the same tree will bear fruit of very different qualities, Mr. Boucher advises the inarching of one of the best sorts on the Common Walnut-tree; by which method the planter is both sure of his sort, and will have fruit in one third of the time in which he could obtain it from the nut. This however is only practicable in a few situations; and a Walnut-tree is generally about twenty years in bearing fruit from the nut. If these trees be intended to form a wood, for which purpose they answer extremely well, Dr. Hunter advises to take them out of the nursery when they are three or four feet high, to replant them three yards asunder, and thin them when their heads begin to interfere; this method will draw up these large and branching trees with beautiful stems to a great height. For raising timber, Mr. Boucher's plan is, to set the nuts in February, in drills five feet asunder, eighteen inches distant in the rows, and two or three inches deep, taking up every other plant after two years. They may then stand thus four or five years longer, the ground between being cropped with turnips, cabbages, or other kitchen-garden plants. From time to time, the least promising may be cut off below ground, when they are near touching each other, till they are left at the distance of thirty feet.—All the other sorts of Walnuts are propagated in the same way, but as few of them produce fruit in England, their nuts must be procured from North America. They should be gathered when fully ripe, and put up in dry sand, to preserve them in their passage to England. The sooner they are planted after their arrival, the greater chance there will be of their succeeding: when the plants come up, keep them clean from weeds. If they shoot late in the autumn, and their tops are full of sap, cover them with mats or other light covering, to prevent the early frosts from pinching their tender shoots, which often causes them to die down a considerable length before spring; but if they are screened from these early frosts, the shoots will become firmer, and better able to resist the cold. Some of the sorts being tender while young, require a little care for the two first winters, but afterwards will be hardy enough to resist the greatest cold of this country. The black Virginia Walnut, which is the most valuable, is as hardy as the common sort. They all require the same culture as the Common Walnut; but grow best in a soft loamy soil, not too dry, and where there is a depth of soil for their roots to run down. The Hickory when young is very tough and pliable, sticks of it are therefore much esteemed; but the wood, when large, being very brittle is not of any great use.

2. *Juglans Alba*; *White Walnut-tree*, or *Hickory*. Leaflets seven, lanceolate, serrate, the odd one sessile. The leaves differ from the common sort, in being serrated, narrower,

and sharper-pointed. The fruit is shaped like the Common Walnut, but the shell is not furrowed, and is of a light colour. It is a tall tree, and often grows to a large bulk, the body being from two to three feet in diameter. The kernel is sweet and well-tasted: the Indians draw a wholesome and pleasant oil from it, and store up the nuts for winter provision. Hogs, squirrels, and other animals, feed upon them. The wood, though coarse-grained, is much used for many agricultural implements. Of the saplings or young trees are made the best hoops. There is a variety, the branches of which are smaller and more spreading, but the leaves narrower, and the bark less wrinkled.—Native of North America.

3. *Juglans Nigra*; *Black Walnut Tree*. Leaflets many, (about fifteen,) oblong-lanceolate, serrate; fruits globular, valveless; nuts wrinkled; male ament sessile, simple; females peduncled. This tree grows to a large size. The leaves, when bruised, emit a strong aromatic flavour, as does also the outer cover of the nuts, which is rough, and rounder than that of the Common Walnut; the shell is very hard and thick, and the kernel small, but very sweet. Catesby remarks, that it seems to have taken its name from the colour of the wood, which approaches nearer to black than that of any other tree that affords so large timber, and is esteemed for making cabinets, tables, &c. Mr. Miller declares it to be the most valuable wood of all the sorts of Walnut, and that some of the trees are beautifully veined, and will take a good polish, while others have very little beauty. Its growth is remarkably quick; and the roots spread out horizontally to a considerable distance. Nothing will grow under its shade, and, when planted in an orchard, it destroys all the apple-trees that are planted near it. It appears to be much hardier than our Common Walnut-tree, for in Pennsylvania and New Jersey, when the Peach-trees, Hickories, and Mulberry-trees, have been much injured by frost, the Black Walnut has sustained no damage. At eight or ten years old it begins to bear plenty of fruit, and with age increases in fertility. Jacquin observed trees in New Jersey that were forty-four years old, nine fathoms high, and three ells and a half in diameter at the distance of an ell from the ground.—It is found in many parts of the American continent, particularly in North America, where it is much planted near houses for the shade.

4. *Juglans Oblonga*; *Oblong-fruited Walnut-tree*. Leaflets many, (six or eight pairs,) ovate-lanceolate, serrate, pubescent with the petioles; nuts deeply sinuate-grooved; leaves scentless.—Native of North America.

5. *Juglans Cinerea*; *Ash-coloured Walnut-tree*. Leaflets eleven, lanceolate, shorter on one side of the base. The leaves are rougher, and of a deeper green than those of the Black Walnut, and having nothing of the aromatic scent which they have. The fruit is very long, the shell deeply furrowed and very hard, and the kernels small, but well-flavoured. Jacquin says, that in habit, trunk, and bark, it is the same with the third species.—Native of North America.

6. *Juglans Compressa*; *Flat-fruited Walnut-tree*. Leaflets three pairs, lanceolate, serrate, smooth, nearly equal; fruit flattened. A tree, of a middle size. The young shoots are covered with a very smooth brownish bark, but the stems and older branches have so rough and scaly a bark, that it is called *Shagbark* in North America, where it is a native.

7. *Juglans Angustifolia*; *Narrow-leaved Walnut-tree*. Leaflets thirteen, linear-lanceolate, serrate, sessile, equal at the base; nuts elliptic. This is thought to be the same as, or a mere variety of, the preceding.—Native of North America.

8. *Juglans Baccata*. Leaflets in threes. This tree is in height about twenty feet, as thick as the human thigh; leaves terminating, always three together. The fruit hangs from

the branches on peduncles an inch in length; it is yellowish, oval, as big as a nutmeg, having, under a very thin mucilaginous pulp, a large hard and woody shell.—Native of Jamaica.

9. *Juglans Olivæformis*. Leaflets numerous, lanceolate, subfalcated, serrated; fruit oblong, tetragonal; nut small, olive-shaped, smooth, with a very thin shell, and a delicious kernel. It blossoms in April and May.—Found on the banks of the Ohio, Mississippi, and other rivers in Upper Louisiana.

10. *Juglans Sulcata*. Leaflets obovate, lanceolated, acuminate, serrated; fruit subrotund, four-keeled; nut subglobular, large, slightly compressed; kernel finely tasted.—Found in the fertile valleys of the Alleghany mountains, where the Americans call it, *Thick-shell-bark Hickory*, *Springfield* or *Gloucester Nut*.

11. *Juglans Amara*. Leaflets ovate, oblong, acuminate, slightly serrated, smooth on both sides; fruit subglobose; nuts small; kernel bitter.—It grows in dry fertile woods, and on the mountains from New England to Maryland.

12. *Juglans Porcina*. Leaflets lanceolate, acuminate, serrated, glabrous; fruit pear-shaped or globose; nut smooth, and very hard. There are two varieties, one with the fruit globose, and the nut obovate; and the other with the fruit turbinate, and the nut oblong.—Native of North America.

13. *Juglans Aquatica*. Leaflets narrow, lanceolate, acuminate, subserrate, sessile; fruit pedunculate, ovate; kernel extremely bitter.—Found in the swamps and rice-fields of America. Michaux calls it, *Water Bitter-nut Hickory*.

14. *Juglans Myristicæformis*. Leaflets ovate-lanceolate, acuminate, serrate, smooth; fruit oval, rugose-scabrous; nut brown, with white lines, oval, slightly acuminate, very hard. It is called the *Nutmeg Hickory*, and is but little known.—Native of South Carolina.

Juncus; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: glume two-valved; perianth six-leaved; leaflets oblong, acuminate, permanent. *Corolla*: none, unless the coloured perianth be regarded as a corolla. *Stamina*: filamenta six, capillary, very short; antheræ oblong, erect, the length of the perianth. *Pistil*: germen three-cornered, acuminate; style short, filiform; stigmas three, long, filiform, villose, bent in. *Pericarp*: capsule covered, three-sided, three or one-celled, three-valved. *Seeds*: some, roundish. ESSENTIAL CHARACTER. *Calix*: six-leaved. *Corolla*: none; capsule one-celled. These plants agree with the Grasses in the glumes of their flowers, and the sheaths of their leaves: they differ in having the stems filled with pith, whereas the stems of Grasses are always hollow. The Rushes naturally form two divisions, one without leaves, and the other with leafy stems; which has induced some authors to divide them into two genera; but all classical botanical writers, says Dr. Smith, have judiciously preserved this very natural genus entire, notwithstanding the capsule is in some species one-celled, in others three-celled.—The species are,

* *With naked Culms.*

1. *Juncus Acutus*; *Prickly Large Sea Rush*. Culm round, almost naked; panicle conglomerate, with almost equal branches; involucre two-leaved, spinose; seeds ovate. Root perennial.—Native of France, Italy, Carniola, and of Wales, on the coast of Merionethshire.

2. *Juncus Maritimus*; *Hard Sea Rush*. Culm round, almost naked; panicle with unequal branches, one twice as long as the rest; involucre spinose; seeds lanceolate. The leaves are extremely rigid and sharp. It is found on the west coast of Wales; in the salt marshes about Maldon in Essex; on the coast of Norfolk and Lancashire; and is planted on the sea-banks in Holland. The roots run deep into the sand,

and mat so much, that they hold it together. On the Maese, &c. they grow upwards of four feet high; and in the summer, when they are fully grown, the Dutch cut them, tie them up in bundles, dry them, and work them into baskets, &c.

3. *Juncus Conglomeratus*; *Round-headed Rush*. Culm naked, stiff; head lateral. Root perennial, horizontal, close, covered with ovate scales; fibres filiform, very long; head of flowers roundish.—Native of Europe, on moist meadows and heaths.

4. *Juncus Effucus*; *Common Soft Rush*. Culm naked, stiff, smooth; panicle lateral, scattered, close; root-scales opaque. Culm three feet high, easily broken, filled with a soft pith. Flowers brownish; seeds fulvous. They are sometimes used for making little baskets; and the pith of both makes wicks for watch-lights, and toys.—This, and the next species, both grow on moist, strong, uncultivated lands, in most parts of England, and consume the herbage where they are suffered to remain. The best method of destroying them is, to fork them up clean by the roots in July, and, after having let them lie a fortnight or three weeks, to put them in heaps, and burn them gently: the ashes will be good manure for the land. But to prevent their growing again, and to make the pasture good, the land should be drained; and then, if the roots be annually drawn up, and the ground kept duly rolled, the Rushes may be subdued. They flower in July and August.—Native of Europe, in wet meadows, marshes, &c.

5. *Juncus Tenax*; *Common Hard Rush*. Culm naked, stiff, striated; panicle lateral, thin; root-scales shining. Root perennial.—It is common in pastures and by road-sides, in a moist soil, in England, Madeira, and New Zealand.

6. *Juncus Inflexus*; *Bending Soft Rush*. Culm naked, membranaceous, and curved in at top; panicle lateral. Roots tufted; flowers abundant, on many peduncles, issuing from a cleft in the culm. This has often been mistaken for the preceding.—Native of the south of Europe, in clear water, upon a strong soil.

7. *Juncus Filiformis*; *Least Soft Rush*. Culm naked, filiform, nodding; panicle lateral. Roots perennial, horizontal, creeping; peduncles mostly simple, bearing one flower, rarely more, triangular, furnished with a few sheath-like scales at their base; seeds small, numerous.—Native of Lapland, Switzerland, Germany, Italy, and Britain, where it has been observed on turf-bogs near Ambleside in Westmoreland; at Windermere in Cartmel; near Derwentwater in Cumberland; and on Ben Lawers in Scotland.

8. *Juncus Trifidus*; *Three-flowered Rush*. Culm naked; leaves and three flowers terminating. Root perennial, woody, striking deep, creeping with blackish fibres, putting forth close tufts of stems and leaves.—Native of Lapland, Denmark, Switzerland, France, Silesia, and of Scotland on the summits of the Highland mountains.

9. *Juncus Squarrosus*; *Moss Rush*, or *Goose Corn*. Culm naked; leaves bristle-shaped; heads glomerate, leafless. Root perennial. Horses are said to eat it. It indicates a barren soil; and the leaves, lying close to the ground, elude the stroke of the scythe.—It flowers in June and July; and is found on moist heathy ground, and turf-bogs, all over Europe.

10. *Juncus Punctorius*; *Prickly Rush*. Culm naked, round; leaf round, jointed, mucronate; panicle glomerate. Root-leaves none.—Native of the Cape.

11. *Juncus Bicornis*. Culm erect, naked; leaves subcæteous, cæniculate, plain; involucre cæteous, diphyllous, erect; flowers distinct; calix linear, lanceolate, very sharp.—Found in Carolina and Georgia, in sandy wet fields near ponds.

12. *Juncus Setaceus*. Culm naked, filiform, waving;

umbels lateral, compound, with but few flowers; peduncles with many flowers; calix subnlate.—Found in low grounds from Virginia to Canada.

13. *Juncus Marginatus*. Leaves plain, glabrous; corymb terminal, simple, proliferous.—Found on dry shady hills in Pennsylvania.

** *With leafy Culms.*

14. *Juncus Nodosus*; *Knotty Rush*. Leaves knotted, jointed, petals mucronate.—Native of North America.

15. *Juncus Compressus*; *Lesser Jointed Rush*. Culm leafy, decumbent; leaves compressed, knotted-jointed; panicle compound. Root perennial, horizontal, woody, round, fibrose.—Native of meadows and marshes.

16. *Juncus Nemorosus*; *Greater Jointed Rush*. Culm leafy, erect; leaves roundish, knotted-jointed; panicle superdecompound.—Native of moist woods.

17. *Juncus Uliginosus*; *Least Jointed Rush*. Culm leafy; flowers in bundles; bundles proliferous; leaves bristle-shaped, jointed-knotted. This differs from the two preceding species in having either all the flowers, or a few of them, growing out into green and purple bundles of leaves. It also frequently produces bunches of reddish leaves, instead of umbels of flowers, in bogs and ditches in the autumn. These leaves seem to put on this appearance from some obstruction in the growth of the plant, occasioned by an insect of the Coccus tribe.—Native of wet heaths and bogs; as of Gamlingay heath, Bullington green, and Eynsham heath, &c.

18. *Juncus Alpinus*; *Alpine Jointed Rush*. Culm leafy; leaves sessile, jointed-knotted; panicle simple; glumes awned.—Native of the Alps, and mountains of Dauphiny.

19. *Juncus Bulbosus*; *Bulbous Rush*. Leaves linear, channelled; capsules blunt. Root perennial, horizontal, extremely fibrose; flowers solitary, small, coloured, terminating, most usually in threes, the middle one axillary, sessile. With us, this Rush varies in height from two inches to two feet, and is sometimes viviparous. It flowers in August.—Native of wet meadows, heaths, and of the sea-coast.

20. *Juncus Bufonius*; *Toad Rush*. Culm dichotomous; leaves angular; flowers solitary, sessile. Root annual, fibrose. It flowers from May to August.—Native of wet gravelly or sandy pastures, especially where water stagnates in winter.

21. *Juncus Stygius*. Leaves bristle-shaped, somewhat depressed; peduncles in pairs, terminating; glumes solitary, subbiflorous. Root perennial, simple, jointed, with solitary radicles, covered with the remains of the leaves of the preceding year. Linneus obtained it from Lapland.—Native of the woody bogs of Sweden.

22. *Juncus Jacquini*. Leaf awl-shaped; head terminating; four-flowered, or thereabouts. Root perennial, brown, horizontal, knobbed, sending forth very long fibres perpendicularly.—Native of the Alps; flowering in June.

23. *Juncus Biglumis*. Leaf awl-shaped; glume two-flowered, terminating. Root perennial, fibrose, simple, perpendicular. Culm an inch high.—Native of the Lapland Alps.

24. *Juncus Triglumis*. Leaves flat; glume three-flowered, terminating. Culms in tufts, three inches high or more, soft, covered at the base with brown sheaths.—Native of the Lapland Alps, Denmark, Switzerland, Austria, Italy, and Siberia.

25. *Juncus Pilosus*; *Small Hairy Wood-Rush*. Leaves flat, hairy; corymb somewhat branched; flowers solitary. Root perennial, with numerous brown fibres, and short pointed shoots, so that it is somewhat creeping; culms many, about a span or more in length, nearly upright; root-leaves numerous, three or four inches long; flowers forming a spreading panicle. This is found only in woods and shady situations, which perhaps accounts for its flowering earlier than any of

the others; for unless the season be very unfavourable, it will begin to flower in February, and is not usually out of bloom till the beginning of May.

26. *Juncus Spadicicus*. Leaves flat, hairy from the sheath; flowers very small, corymbed, solitary, shortly awned. Culm not more than a foot high; root-leaves scarcely two lines in breadth, subhirsute.—Native of the Alps.

27. *Juncus Sylvaticus*; *Great Hairy Wood-Rush*. Leaves flat, hairy; corymb decomposed; flowers in bundles, sessile. In some situations this species is very large and tall; but it more usually occurs with a stalk little more than a foot high.—It is not uncommon in woods, and flowers in May.

28. *Juncus Niveus*; *White-flowered Rush*. Leaves flat, somewhat hairy; corymbs shorter than the leaf; flowers in bundles. This is the handsomest belonging to the genus; culm three feet high.—Native of the Alps, of Switzerland, &c.

29. *Juncus Campestris*; *Hairy Field Rush*. Leaves flat, somewhat hairy; spikes sessile and peduncled. Root perennial, somewhat woody, with numerous blackish fibres, creeping; culm simple, from three to nine inches high; flowers ten or twelve in each spikelet, sessile: they appear in April and May, and ripen seeds in June. It indicates a dry and not luxuriant pasture. The hairs proceed from the edges of the leaves, and appear as if left by some animal in rubbing against them.—Most frequently found in dry pastures.

30. *Juncus Spicatus*; *Spiked Rush*. Leaves flat; spike racemed, nodding, composed of many flowers.—Native of Lapland, Denmark, and Scotland.

31. *Juncus Serratus*. Leaves ensiform, flat, serrate, hoary underneath; sheaths of the panicle awl-shaped, perfoliate. Culms leafy, round, as thick as the little finger, from four to six feet high.—Native of the Cape.

32. *Juncus Grandiflorus*. Leaf round; culm one-flowered; flower upright, single, naked. Scarcely a foot high, very smooth.—Native place unknown.

33. *Juncus Polycephalus*. Stalk erect, with but few leaves; leaves nodose, articulate; calices linear, triandrous. There are two varieties; one with thicker leaves, compressed, and the other with subfiliform leaves.—Found in inundated places from Pennsylvania to Carolina.

34. *Juncus Aristatus*. Root bulbous; stalk foliose, erect, compressed; leaves narrow, subcanaliculated; panicles compound.—Found in the low grounds of Georgia and Carolina.

35. *Juncus Tenuis*. Stalk foliose, simple; leaves canaliculate; corymb terminal, dichotomous, shorter than the bractes; capsules oblong, obtuse, shorter than the calix.—Found in abundance in Georgia and Carolina.

36. *Juncus Campestris*. Leaves plain, pilose; spikes pedunculate, ovate, somewhat stooping.—Found on dry sunny hills from Pennsylvania to Carolina.

Jungermannia; a genus of the class Cryptogamia, order Algæ.—GENERIC CHARACTER. *Male Flowers*: sessile, clustered, on the leaves, stem, and frond. *Calix*: scarcely any. *Corolla*: none. *Stamina*: filamenta hardly any; antheræ ovate, one-celled, gaping at the tip. *Female Flowers*, on the same or on a separate individual. *Calix*: perianth upright, tubular, truncated, crenated or lacinated. *Corolla*: calyptra sessile, smaller than the perianth, subglobose, closed on every side, membranaceous, tender, crowned by the style, at length bursting at the tip. *Pistil*: germen oblong, involved by the calyptra, sessile; style straight, short, passing through the top of the calyptra; stigma simple. *Pericarp*: capsule seated on a long and very tender bristle, globose, one-celled, at length gaping longitudinally into four valves, which are equal, spreading, permanent. *Seeds*: many, globose, adhering by twisted elastic threads, fixed to the bottom, tip, disk,

or margin of the valves. *Observe*. Several germina are often found in one perianth, of which, however, only one grows to maturity.—Thirty species of these Mosses are arranged in five subdivisions, in the fourteenth edition of the *Systema Vegetabilium*. Hudson enumerates thirty species, in the second edition of his *Flora Anglica*; and Dr. Withering, in his *Arrangement of British Plants*, describes 48 species, which he distributes into four divisions; many of which are beautiful objects of microscopic observation. It is thought that our native species amount to above sixty, and that in all 150 *Jungermannia* might easily be reckoned up.

Jungia; a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: common many-leaved; leaflets somewhat spreading, linear, obtuse, channelled, shorter than the partial perianth, involving three or four flowers; perianth partial, many-leaved, almost equal, many-flowered; leaflets oblong, channelled, obtuse, upright. *Corolla*: compound uniform; corollets hermaphrodite, equal; proper one-petalled, funnel-shaped; tube gradually widened; border two-lipped; the exterior division rolled back, longer, linear, toothed at the tip; the interior two-parted; the segments two, upright, sharp. *Stamina*: filamenta five, very short, inserted into the tube; antheræ connate. *Pistil*: germen inferior, linear, cornered; style filiform; stigmas two, revolute, obtuse. *Pericarp*: none. *Calix*: unchanged. *Seed*: solitary, cornered; down long, sessile, feathered. *Receptacle*: chaffy; chaffs resembling the calicine leaflets. ESSENTIAL CHARACTER. *Calix*: common three-flowered. *Receptacles*: chaffy; florets tubular, two-lipped; outer-lip ligulate, inner two-parted.—The only known species is,

1. *Jungia Ferruginea*. Stems woody, covered with a ferruginous down; leaves alternate, petioled, remote, flat, rounded, five-lobed, cordate at the base; lobes rounded, blunt, hirsute, and underneath hairy; panicle terminating, large, decomposed; heads of flowers small, heaped.—Native of South America.

Juniperus; a genus of the class Diœcia, order Monadelphia.—GENERIC CHARACTER. *Male*. *Calix*: ament conical, consisting of a common shaft, on which are disposed three opposite flowers in triple opposition, a tenth terminating the ament; each flower has for its base a broad, short, incumbent scale, affixed to the column of the receptacle. *Corolla*: none. *Stamina*: filamenta (in the terminal floscule) three, awl-shaped, united below into one body; in the lateral flowers scarce manifest; antheræ three, distinct in the terminal flower, but fastened to the calicine scale in the lateral ones. *Female*. *Calix*: perianth three-parted, very small, growing to the germen, permanent. *Corolla*: petals three, permanent, rigid, acute. *Pistil*: germen inferior; styles three, simple; stigmas simple. *Pericarp*: berry fleshy, roundish, marked on the lower part with three opposite obscure tubercles, (from the calix having grown there,) and at the tip by three teeth, (which before were the petals,) umbilicated. *Seed*: three ossicles, convex on one side, cornered on the other, oblong. ESSENTIAL CHARACTER. *Male*. *Calix*: of the ament a scale. *Corolla*: none. *Stamina*: three. *Female*. *Calix*: three-parted. *Petals*: three. *Styles*: three. *Berry*: three-seeded, irregular with the three tubercles of the calix.—These plants are all propagated by sowing their seeds as soon as they are ripe, if they can be procured; for if kept until the spring before they are sown, they will not come up till the second year. The ground in which the seeds of the hardy sorts are sown, should be fresh and light, but it should not be dunged; when it is well dug and levelled, sow the seeds pretty thick, and sift some earth over them to the depth of half an inch; this bed will only require weeding,

and, towards the middle or latter end of April, some of the plants will appear above ground, though probably the greatest part of them may lie till the following spring before they come up: therefore the beds should be carefully weeded, and watered in very dry weather, which will greatly promote the growth of those plants that are up, and also cause the other seeds to vegetate; but if the bed in which these are sown, is much exposed to the sun, it should be shaded with mats in the day, for, when the plants first come up, they will not bear much heat. In this bed they should remain till the next spring, or second autumn, when you must prepare beds, into which they are to be transplanted, they should be also of light, fresh, undunged soil, well dug, cleansed from all noxious weeds, and levelled. In the beginning of October, which is the proper season for removing these plants, raise them up with a trowel, preserving as much earth as possible to their roots, and plant them into beds about five or six inches asunder each way, or eighteen inches by nine or ten, giving them some water, to settle the earth to their roots: if it should prove very dry weather, you must lay a little mulch upon the surface of the ground, round their roots, which will be very serviceable to the plants; but, as many of the seeds will be yet left in the ground where they are sown, the beds should not be disturbed too much, in taking up the plants: they may remain two years in these beds, observing to keep them clear from weeds: in the spring, stir the ground between them gently, that their roots may the more easily strike into it; after that, they should be transplanted, either into a nursery, at the distance of three feet row from row, and eighteen inches asunder in the rows, or into the places where they are to remain; the best season for transplanting them, we have already observed, is in the beginning of October: they should then be carefully taken up, preserving a ball of earth to their roots, and, when replanted, the roots should be mulched, which, if carefully attended to, and watering them in dry weather till they have taken root, will ensure their growth. They are extremely hardy in bearing cold, and will survive our severest winters, provided they are not planted in a moist or rich soil. Most of them may also be propagated by cuttings, which, if planted in autumn, or at the end of August, in a shady border, will take root: but those plants which are raised from cuttings will never grow so upright, nor to so large a size, as the plants that are raised from seeds; so that raising them by cuttings is practised on those only which do not perfect seeds in England. As several species grow to the height of eighteen or twenty feet, the procuring as many of the sorts as can be gotten from the countries of their growth, will be adding to the variety of our evergreen plantations, which cannot be too much propagated in England, where the winters are in general so temperate, that they may thrive to advantage; almost all of them are hardy enough to live in the open air, and are well worth propagating, as they add to the beauty and variety of a plantation, and especially as some of them rise to such a height that they may produce much useful timber, and may be adapted to such soils as will not suit any other trees. The tender sorts may also acquire strength to resist the frost, for we find many plants that will not live in the open air when first imported, become naturalized, and defy the severest cold of our variable climate. In order to increase the height of these trees, their under branches should be taken off, especially where they are inclined to grow strong; but they must not be kept very closely pruned, for that would retard their growth; for all these evergreen trees do more or less abound with a resinous juice, which, in hot weather, is very apt to flow out from such places as are wounded; so that it

will not be advisable to take off many branches at once, especially in hot weather, when their sap would flow so plentifully as to render the trees weak and unhealthy.—The species are,

1. *Juniperus Thurifera*; *Spanish Juniper*. Leaves imbricate in four rows, acute. It grows to the height of twenty or thirty feet. Berries very large, black when ripe.—Native of Spain and Portugal.

2. *Juniperus Barbadosensis*; *Barbadoes Juniper*. All the leaves imbricate in four rows, the younger ovate, the older acute. This has been confounded with the next species; but the berries are smaller, and of a light brown colour when ripe.—It is a native of the West Indies, where it rises to be one of the largest timber-trees; the wood is frequently fetched from thence by the inhabitants of North America, for building ships. It also grows in China and Japan.

3. *Juniperus Bermudiana*; *Bermudas Juniper*. Lower leaves in threes, upper in pairs, decurrent, awl-shaped, spreading, acute. The berries are produced towards the end of the branches, and are of a dark red colour, inclining to purple. The wood has a very strong odour, and was formerly in great esteem for wainscoting rooms and also for furniture.—Native of America. Dr. Patrick Browne says that it grows very plentifully in most of the blue mountains of Jamaica, where it is frequently cut down for planks, &c. He says, it is a good timber-wood, admired for its smell, lightness, and close even grain; very fit for wainscoting, and all the inward parts of cabinet-work. It is of a reddish colour, very sweet, and commonly known in England by the name of Cedar-wood. There are several sorts of wood called by that name; but this is the wood used for pencils, wainscoting rooms, and building staircases, because it continues sound longer than most other sorts of timber, which is perhaps owing to some extreme bitter in the resin with which the tree abounds; for it is very remarkable, that worms do not eat the bottoms of the vessels built with this wood, as they do those that are built with Oak, so that vessels built with it are the best for the West Indian seas; but unfortunately the wood is so brittle, and splits so much when struck with a cannon-ball, that it would not at all answer for ships of war. This tree is not only a native of Bermuda, but of the Bahamas.—They are propagated by seeds, in the same way as the first species, except that they should be sown in pots or tubs of earth, that they may be removed into shelter in the winter time, otherwise the young plants will be injured by hard frosts; but they will only require to be placed under a common hot-bed frame, where the glasses may be kept off, and the free air constantly admitted in fine weather: these seeds always remain in the ground till the second year before they come up, therefore the earth in the pots should not be disturbed; and in the summer time they should be placed in the shade, to prevent the earth from drying too fast; they should be often watered in very dry weather, but in small quantities at each time: the next spring, when the plants come up, they must be carefully cleared from weeds, and in dry weather refreshed with water; but should stand during the summer in a place defended from strong winds; and in winter, must be placed under frames, where they may be covered in hard frosty weather, but must have free air when the weather is mild: in the following April, transplant them each into a single halfpenny pot filled with fresh light earth, being careful to raise them up with a ball of earth to their roots; and when they are planted, water them, to settle the earth to the roots, and place the pots in a warm situation, defended from sun and wind; but if you can conveniently plunge the pots into a

moderate hot-bed, it will greatly promote their taking new root: they must be screened from the powerful heat of the sun till they have taken root, and may then be gradually exposed to the open air: if you suffer the pots to remain plunged all the summer, it will preserve the earth in them from drying so fast as it would, if they were set upon the ground. In October, you should again remove these plants into shelter, or else plunge their pots into the ground, under a warm hedge, where they may be protected from the cold north and east winds; and in the spring following, you must shift the plants into pots of a larger size, taking away some of the earth from the outside of the ball, and adding some fresh: after this, continue to manage them as was before directed, until you plant them out in the places where they are designed to remain, which should not be done till they are four or five years old, by which time they will be strong enough to bear the cold of our common winters. The reason for directing these plants to be preserved in pots, until they are planted out for good, is, because they are difficult to transplant, and, being tender, will require some shelter while young: and whoever observes the method here laid down, will find the plants so managed to gain two years' growth in six, from those raised in the open air, besides being less liable to be destroyed; and as the trouble and expense of raising them this way is not great, it is worth practising, since in a few years the trees will recompense the trouble.

4. *Juniperus Chinensis*; *Chinese Juniper*. Leaves decurrent, imbricate, spreading, clustered; stem-leaves in threes; branch-leaves in fours. A shrub three feet high, with twisted and very spreading branches.—Native of China.

5. *Juniperus Sabina*; *Savin*. Leaves opposite, erect, decurrent; the oppositions boxed. Mr. Miller makes two species of the Common or Cypress-leaved and Tamarick-leaved or Berry-bearing Savin, as he calls it: the former, he says, has been erroneously supposed to be a mere variety: it rises to the height of seven feet, and produces great quantities of berries, whereas the latter very rarely produces either flowers or seeds in our gardens. The latter seldom rises more than three or four feet high, sending out its branches horizontally to a considerable distance every way. The berries are smaller than those of the Common Juniper, and the whole plant has a very rank odour when handled.—Native of the south of Europe, and the Levant. It is more powerful in its operations, as a medicine, than the Common Juniper, and has been much famed as an emmenagogue; it heats and stimulates the whole system very considerably, and is said to promote the fluid secretions. The leaves and tops have a very strong disagreeable smell, and a hot bitterish taste; they give out their active matter to watery liquors, and still more completely to rectified spirit. When distilled with water, they yield a large quantity of essential oil. Decoctions of the leaves inspissated to the form of an extract, retain a considerable share of their pungency and warmth, together with their bitterness, and have some degree of smell, but not resembling that of the plant itself. On inspissating the spirituous tincture, there remains an extract consisting of two distinct substances; of which one is yellow, oily, bitterish, and very pungent; the other black, resinous, tenacious, less pungent, and very astringent. Though Savin has sometimes failed when used as an emmenagogue, it has also been sometimes found too powerful, so as to produce dangerous consequences. Dr. Home used it with great success in cases of amenorrhœa, given in powder, from a scruple to a drachm thrice a day. Upon the whole, therefore, Savin may be considered as a warm stimulant and aperient, particularly serviceable in uterine obstructions, proceeding from a laxity

of the vessels, or a cold sluggish disposition of the juices. The distilled oil, in addition to the powers just mentioned, in doses of two or three drops, is a strong diuretic, and impregnates the urine with its smell. Country people give the juice, mixed with milk, to their children, in order to destroy the worms, which it generally carries off by stool. The leaves cut small, and given to horses mingled with their corn, destroys those troublesome vermin called the bots.—It may be propagated by slips, which will grow at any time. The upright Savin also may be increased by slips planted in moist weather in August, and kept shaded, and watered in dry weather afterwards. The striped Savin must be increased in the same way, from the branches which are the most variegated. They may also be raised by berries, when the plants produce any, and from these the most upright and best plants are raised. The Common Savin should not be neglected, because it is so very hardy as never to be injured by the severest frosts; and, as it spreads its branches near the ground, if the plants be placed on the borders of woods, they will have a good effect in winter, by screening the nakedness of the ground from sight.

6. *Juniperus Virginiana*; *Virginian Juniper*, or *Red Cedar*. Leaves in threes, fastened at the base, the younger ones imbricate, the older spreading. Berry dark blue, covered with a whitish resinous meal. Mr. Miller has two species. The first, he says, grows naturally in most parts of North America, where it is called Red Cedar, to distinguish it from a sort of Cypress, which is there called White Cedar; of this there are two varieties, one of which has leaves in every part like those of the Savin, and, upon being rubbed, emit a very strong ungrateful odour; this the Americans call Savin Tree. The second of Miller's species has leaves like the Swedish Juniper, but the upper leaves are like those of the Cypress; which difference it constantly retains. Sloane says, it grows to be one of the largest and highest timber-trees in Jamaica, affording very large boards of a reddish-brown colour, close and firm texture, shining, very odorous, extremely like Bermudas Cedar, but being towards its outsides of a paler colour, and looser texture: it is much used for wainscoting rooms, making escritaires, cabinets, &c.; cockroaches and other insects disliking the smell of it. In its native country it grows to a great height; but with us there are very few trees that exceed thirty feet high, though there is no doubt of their growing larger, for they thrive very fast after the first three years. They are propagated by seeds, which must be procured from Virginia or Carolina, (for they seldom produce seeds in England,) and sown as was directed for the other Junipers: but as this seed cannot be procured in England till spring, so, when sown at that season, it remains in the ground until the succeeding spring before the plants appear; the beds therefore must remain undisturbed, and be kept clear from weeds, for it is sometimes two years after sowing before they come up. When the plants appear, they must be carefully weeded, and refreshed with water in dry weather, to forward their growth: in the following autumn, they should have a little rotten tan laid between them, to keep out the frost; in this bed the plants may remain till they have had two years' growth; they should then be transplanted into other beds, as directed for the other species, observing to preserve a ball of earth to their roots, and, after they are planted, to water them carefully in dry weather, and cover the surface of the ground with mulch, to prevent the sun and wind from drying the earth so as to affect their roots; they may remain two years in these beds, keeping them clear from weeds, and in winter laying fresh mulch upon the

surface of the ground round their roots, to preserve them from frost; by which, while the plants are so young, they are liable to be injured, if much exposed, but when they have acquired strength, they will resist the severest of our cold. After two years, they should be either removed into the nursery, (as was directed for the first species,) or transplanted where they are intended to remain, observing always to take them up carefully, otherwise they are subject to fail upon transplanting; as also to mulch and water the ground as before, until they have taken root; after which, they will require no further care, than only to keep the ground clear about their roots, and to prune up their side branches to make them aspire in height. The soil in which these trees are finally planted, should be fresh and light, but must not be dunged, especially at the time when they are planted, for dung is very injurious to them, unless it be quite rotted to mould: hence the mulch laid upon the surface of the ground should not be dung, but rather some old tanner's bark, or sea-coal ashes, which will prevent the frost from penetrating deep into the ground. These trees being thus managed, will, in a very few years, rise to a considerable stature, and will resist the sharpest frost of our climate exceedingly well; and, by the variety of their evergreen leaves, and manner of growth, will greatly add to the beauty of all plantations where they are rightly disposed: unfortunately, however, there are few persons who consider the different growth of the several trees with which they compose such plantations, so as to place the tallest-growing trees the backwardest from sight, and the next tallest next to them, gradually diminishing, till we come to the Common Juniper, and others of the same growth; whereby all the trees will be seen, and the gradual declivity of their tops will exhibit a verdant slope, and be much more agreeable to the sight, as well as more advantageous to the growth of the trees, than to place shrubs of humble growth near such plants as will grow to the first magnitude, and not only hide the shrub from sight, but overshadow and destroy it: nor can the distance which each requires be so justly proportioned any other way; for in this distribution, the larger trees being separated by themselves, may be placed at a due distance; and then those of a middling growth succeeding, may be accordingly allowed sufficient room; and the smaller, which are next the sight, being placed much closer, will hide the naked stems of the larger trees, and produce an agreeable effect to the eye.

7. *Juniperus Communis*; *Common Juniper*. Leaves in threes, spreading, mucronate, longer than the berry. It is a low shrub, seldom rising above three feet high; much branched, rigid, smooth, evergreen. The juice of the whole plant is a kind of turpentine. The male flowers are sometimes on the same flowers with the female, but at a distance from them: but they are commonly on distinct plants: the female flowers are succeeded by roundish berries, which are first green, but when ripe, of a dark purple colour. There are two varieties; the Swedish, or *Tree-Juniper*, and the *Alpine*, or *Mountain Juniper*, which are scarcely to be distinguished from the common sort; the first varies with narrower leaves and longer berries, the second with broader and thicker leaves and oval berries. When planted in a good soil, the Juniper will rise fifteen or sixteen feet high, and form a well-looking bushy shrub, which is easily transplanted, and bears cropping. Grass will not grow beneath it, but the *Avena Pratensis* destroys it. The wood is hard and durable, and the bark may be made into ropes. Spirit, impregnated with the essential oil of these berries, is every where known by the name of *gin*. Gum Sandarach, known

under the name of *Pounce*, in its powdered form, is the produce of this shrub. Horses, sheep, and goats, feed upon this plant; several insects, as the *Cimex Juniperus*, *Thrips Juniperina*, and *Coccinella Novempunctata*, live upon it; indeed, sometimes the leaves of the calix grow double the usual size, approaching, but not closing, and the three petals fit exactly close, so as to keep the air from the *Tipulæ Juniperi*, or *Juniper Spiders*, which inhabit them. This plant is celebrated for its diuretic properties; the berries are principally used; and a spirit prepared from them is kept in the shops, and used plentifully in hydropic cases, and in diuretic draughts; these berries, boiled in water, yield a sweet decoction tasting very strongly of the Juniper; from this decoction, a quantity of sugar may be obtained: the berries are also considered as stomachic, carminative, and diaphoretic; of their efficacy in many hydropical affections, we have various relations from physicians of high authority, such as Du Verney, Boerhaave, Hoffman, and Van Swieten. Authors, however, do not seem agreed which preparation of the Juniper is most efficacious; some preferring the rob or inspissated decoction; of which the celebrated Cullen disapproved, alleging, that in boiling it loses great part of its essential oil, in which he thought the virtue of Juniper principally consisted. Hoffman, on the other hand, strongly recommends the rob, which he declares to be of great utility in weakness of the stomach and intestines, especially for elderly persons; but, as the modern practice generally depends on more powerful medicines, the Juniper being considered in a secondary view, it may perhaps be allowed that as good a form as any for its use, is that of a simple decoction, which either by itself, or with the addition of a small quantity of gin, may be a useful drink for hydropic patients. Medical writers have also recommended it in scorbutic cases, and in some cutaneous diseases; but in these cases, a decoction, prepared from the wood and the tops of the plant, is thought preferable to that from the berries. Linneus informs us, that his countrymen, the Swedes, prepared a beer from the berries, which they consider as very efficacious in scorbutic cases, and that the Laplanders drink infusions of Juniper berries, as we do tea and coffee, for the same purpose. Hill says, the berries are excellent in colicky complaints, and for the stone and gravel. He agrees with Hoffman in observing that the rob or jelly made from the berries is excellent in catarrhs, defluxions or humours on the lungs and breast, weakness and debility of the stomach and intestines, difficulty of making water in people of an advanced age, and other similar disorders. Juniper wine is sometimes made, and is said to be very wholesome.

8. *Juniperus Oxycedrus*; *Brown-berried Juniper*. Leaves in threes, spreading, mucronate, shorter than the berry. Height ten or twelve feet, branched the whole length. This shrub will be feathered from top to bottom, if left untouched from the first planting, or if not crowded with other trees. The leaves are awl-shaped, and finely spread open; they are also very short, sharp-pointed, and give the shrub a fine look; and the large brownish-red berries make a handsome appearance when they are ripe, being as large as a hazel-nut.—Native of Spain, Portugal, and the south of France.

9. *Juniperus Phœnicea*; *Phœnician Juniper*, or *Cedar*. Leaves in threes, obliterated, imbricated, obtuse. It grows with the branches in a pyramid. Ray thinks it scarcely distinct from the following species.—Native of the south of Europe and the Levant.

10. *Juniperus Lycia*; *Lycian Juniper*, or *Cedar*. Leaves in threes, imbricate on all sides, ovate, obtuse. The branches are erect, and covered with a reddish-brown bark; leaves

small, obtuse; male flowers at the ends of the branches, in a conical ament; and the fruit single from the axils below them, on the same branch; berries large, oval, brown. Pallas says it is difficult to distinguish it from the Savin; that the bruised leaves have the same smell; and that the principal difference consists in the greater thickness of the shoots, and in the leaflets being acute and less clustered. He says the leaves are never in threes with them.—Native of the south of France, the Levant, and Siberia. This is the species from which the gum resin, called *Olibanum*, is obtained; it has a strong smell, and a somewhat bitterish and pungent taste. Though not the same substance as is sold by the above name in the shops, it is supposed to have been the incense used by the ancients in their religious ceremonies, and has been adopted by the Roman Catholics in their churches, for similar uses. As a medicine, it has chiefly been used in disorders of the head and breast, and in hæmoptoes, and alvine and uterine fluxes, from a scruple to the amount of a drachm or more each dose. It has also been employed in plasters, and as an ingredient in various pills.

11. *Juniperus Drupacea*. Leaves in threes, spreading, acute, three times shorter than the drupe; nut three-celled. Stem frutescent, erect, branched; branches spreading; branchlets three-sided.—Native of Mount Cassius.

12. *Juniperus Daurica*; *Siberian Juniper*. Leaves opposite, acute, imbricate, decurrent, spreading, awl-shaped. This is usually shrubby, with the stems lying prostrate on the rocks, the principal ones often the thickness of the human arm; branches thickish, testaceous; shoots green, dichotomous.—Native of Siberia.

Jupiter's Beard. See *Anthyllis*.

Jussieua; (Tree Primrose) a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-cleft, superior, small; leaflets ovate, acute, permanent. *Corolla*: petals five, roundish, spreading, sessile. *Stamina*: filamenta ten, filiform, very short; antheræ roundish. *Pistil*: germen oblong, inferior; style filiform; stigma headed, flat, marked with five streaks. *Pericarp*: capsule oblong, crowned, five-celled, gaping at the corners. *Seeds*: very many, disposed in rows. ESSENTIAL CHARACTER. *Calix*: four or five parted, superior. *Petals*: four or five. *Capsule*: four or five celled, oblong, gaping at the corners. *Seeds*: numerous, minute.—The species are,

1. *Jussieua Repens*; *Creeping Jussieua*. Creeping: flowers five-petalled, ten-stamined; leaves ovate-oblong. Roots simple, filiform, short; stem branching, creeping; branches somewhat succulent, round, smooth; leaves scattered, small, entire, very smooth. The flowers are small and yellow. There is a variety with herbaceous, ascending, simple, even stems. They flower in spring.—Native of moist watery places in Jamaica; where, Brown says, it is frequent in our low lands about Plantain-garden river. This, with all the plants of the genus, should be sown early in the spring, in pots filled with a soft loamy soil, and plunged into a moderate hot-bed; but as the seeds often lie a whole year in the ground before they vegetate, the earth must be kept moist, and the glasses of the hot-bed shaded in the heat of the day, by which means their vegetation will be hastened. When the plants come up, and are fit to remove, they should be each planted into a small separate pot filled with light loamy earth, and plunged into a hot-bed of tanner's bark, where they should be shaded from the sun till they have taken new root, then have free air admitted to them every day, in proportion to the warmth of the season: water should be frequently given, but in small quantities. When the roots have filled these small pots, the plants should be removed into others a size

larger, and if too tall to stand under the frames of the hot-bed, must be placed in the bark-stove, where they may remain to flower and perfect their seeds: for when the plants rise early in the spring, and are brought forward in hot-beds, all the sorts will flower, and perfect their seeds in the same year; which is better than to have them to keep through the winter.

2. *Jussieua Tenella*. Smooth: flowers five-petalled, subsessile; leaves opposite, linear-lanceolate, quite entire.—Native of Java.

3. *Jussieua Peruviana*. Upright: flowers five-petalled; peduncles leafy.—Native of Lima.

4. *Jussieua Pubescens*; *Hairy Jussieua*. Upright, villose: flowers five-petalled, ten-stamined, sessile. Stem usually brown, strong, four or five feet high, having several hairy, red, angular branches; this is set on every side with long, narrow, hairy-nerved leaves; flowers large, yellow.—Native of Jamaica.

5. *Jussieua Suffruticosa*; *Shrubby Jussieua*. Upright, villose: flowers four-petalled, eight-stamined, peduncled. It rises with a shrubby stalk three feet high, and sends out several side-branches; petals yellow.—Native of India.

6. *Jussieua Erecta*; *Upright or Red-stalked Jussieua*. Upright, smooth: flowers four-petalled, eight-stamined, sessile. Root annual; stem from two to four feet high, herbaceous, very much branched, four-cornered, smooth, reddish. Flowers abundant, yellow, small.—It is a vernal marsh-plant, native of Jamaica, and of the other West India Islands; also of the American continent; and of Ceylon, Java, and Japan.

7. *Jussieua Inclinata*. Upright, smooth: flowers four-petalled, eight-stamined, peduncled. Stem simple, round, thick, porous, watery, rooting at the lower joints; peduncles one-flowered. Annual.—Native of the marshes of Surinam.

8. *Jussieua Octovalvis*. Upright: flowers four-petalled, eight-stamined, peduncled; capsules many-valved; leaves lanceolate, acuminate. Flowers on short peduncles, large, yellow; seeds very many, roundish.—Native of South America and the West Indies, in marshy watery places.

9. *Jussieua Hirta*. Upright, hirsute; flowers four-petalled, eight-stamined; leaves ovate, acuminate, rough-haired underneath. A shrubby plant, with a hispid stem; branches hispid, alternate.—Native of South America and Jamaica.

10. *Jussieua Onagra*. Upright, smooth, branching: flowers four-petalled, eight-stamined, sessile; leaves lanceolate. Flowers small, yellow.—Native of South America.

11. *Jussieua Hirsuta*. Upright, hirsute, simple: flowers five-petalled, ten-stamined, sessile; leaves lanceolate. Stalks red, three feet high, hairy, and channelled; petals yellow.—Native of La Vera Cruz.

12. *Jussieua Grandiflora*. Leaves very entire; lower leaves spatulate; upper leaves lanceolate; flowers decandrous, large, and yellow; peduncles and calices villose. Roots creeping.—Found in the swamps of Virginia and Carolina, about the Dismal Swamp.

13. *Jussieua Subacaulis*. Leaves linear-lanceolate; flowers solitary, octandrous, pedunculated, small, and yellow; filamenta alternate, very short; petals obovate.—Found by Lewis on the banks of the Missouri.

Justicia; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, very small, five-parted, acute, upright, narrow. *Corolla*: one-petalled, ringent; tube gibbose; border two-lipped; lip superior, oblong, emarginate; lip inferior, of the same length, reflex, trifid. *Stamina*: filamenta two, awl-shaped, hid under the upper lip; antheræ upright, bifid at the base. *Pistil*: germen top-shaped; style filiform, length and situation of the stamina; stigma simple. *Pericarp*: capsule oblong,

obtuse, narrowed at the base, two-celled, two-valved; the partition opposite to the valves, gaping with an elastic claw. *Seeds*: roundish. *Observe*. Some species recede so much from this character as to seem a distinct genus. **ESSENTIAL CHARACTER.** *Corolla*: ringent. *Capsule*: two-celled, opening with an elastic claw. *Stamina*: with a single anther. —It appears from the recent observations of Jacquin, Jus-sieu, Vahl, and others, that the two antheræ on each filamentum are not a sufficient generic distinction; for in some species of *Dianthera* the filamenta are divided into two segments, each of which has an anther; but in others the filamenta are undivided, and have two antheræ indeed, but so approximated as almost to coalesce into one. But not only *Diantheræ*, properly so called, have two antheræ, but most of the *Justiciæ*, if not all, are really *Diantheræ*; for not only several of Linneus's *Justiciæ* have two antheræ quite distinct, (as *Hyssofolia*, *Orchioides*, &c.) but the rest have generally twin or double antheræ, with this difference, that, being parallel to each other, they seem to be but one, although they are really two. If this natural genus, consisting of *Justicia* and *Dianthera*, is to be separated, Vahl recommends it to be grounded on the capsule rather than the antheræ.—These plants are all the produce of warm climates; not one a native of Europe. They may be increased, some by seeds, others by layers and cuttings, but the latter modes are mostly practised, as the seeds are obtained with difficulty.—The species are,

* *With a double Calix.*

1. *Justicia Fastuosa*; *Superb Justicia*. Shrubby: leaves lanceolate-elliptic; flowers in terminating thyrses; calices two-flowered. Stem smooth, round, and even; leaves opposite, petioled, quite entire, hairy underneath, and round the edges; flowers very abundant, clustered in axillary racemules.—Native of Arabia Felix, and the island of St. Johanna.

2. *Justicia Forskahlei*. Shrubby: leaves ovate, acuminate; flowers in axillary and terminating thyrses; calices one-flowered.—Native of Arabia Felix.

3. *Justicia Purpurea*. Herbaceous: branches pubescent; flowers in axillary and terminating spikes; bractes lanceolate, smooth. Stem rooting, brachiate; corollas purple.—Found near Canton in China.

4. *Justicia Verticillaris*. Villose: leaves ovate; flowers axillary, in whorls; outer calices awnless.—Native of the Cape.

5. *Justicia Aristata*. Villose: leaves ovate; flowers axillary, in whorls, subsessile; outer calices awned.—Native of the Cape.

6. *Justicia Chinensis*. Herbaceous: leaves ovate; peduncles axillary, in whorls, trifid; bractes ovate, mucronate, coloured at the base. Stems procumbent, a foot long, branched at bottom; corolla pale violet colour.—Native of China.

7. *Justicia Triflora*. Herbaceous: leaves ovate; peduncles axillary, elongated, subtriflorous; bractes linear-lanceolate, —Native of Arabia Felix.

8. *Justicia Serpens*. Herbaceous, creeping: leaves oblong, smooth; flowers axillary, solitary. Stem filiform.—Native of the Isle of France.

9. *Justicia Sulcata*. Herbaceous: leaves ovate-cordate; spikes terminating; flowers in whorls. See *Dianthera Sulcata*.

10. *Justicia Bicaliculata*. Leaves ovate-acuminate; flowers in axillary dichotomous panicles; outer bracte linear, double the length of the other; antheræ binate. Flowers purple.—Native of the East Indies.

11. *Justicia Bivalvis*. Shrubby: leaves ovate-lanceolate; peduncles axillary, trifid, lateral; pedicels two-flowered; bractes ovate, awned, nerved; capsule villose.—Native of the East Indies and Arabia Felix.

** *With a single Calix.*—*Corollas two-lipped; lips undivided.*

12. *Justicia Sexangularis*; *Chickweed-leaved Justicia*. Herbaceous: leaves ovate; peduncles three-flowered; bractes wedge-shaped; antheræ parallel. The flowers appear in small spikes at the sides of the branches, and are of a beautiful carmine colour; stalk upright. It is annual, and a native of La Vera Cruz and Jamaica.—This, as also the 13th, 16th, 72d, 79th, and 80th species, may be propagated by seeds sown early in the spring, in small pots filled with light fresh earth, and plunged into a moderate hot-bed of tanner's bark, observing to water the earth gently when it appears dry. As the seed frequently lies a year in the ground, the pots must not be disturbed in case they should not immediately appear. In the winter, they should be kept in the stove, and the spring following plunged into a fresh-hot-bed. When the plants begin to appear, the glasses of the hot-bed should be raised every day in warm weather, to admit fresh air; they ought also to be frequently watered at the same time, but in small quantities while they are young, as they are subject to rot at bottom with much moisture. When the plants are about two inches high, take them up carefully, and transplant each into a small pot filled with fresh light earth, plunging them into the hot-bed again, and watering and shading them till they have taken new root: then they should have air admitted every day in proportion to the warmth of the season, and should be duly watered every two or three days in hot weather. As the plants advance in their growth, they should be shifted into larger pots; for when their roots are too much confined, they will not make any considerable progress. To over-pot them, however, would be of still worse consequence than the other, because, when they are planted in very large pots, they will starve, and decay, without producing any flowers. They are too tender to endure the open air in this country; therefore should always remain in the hot-bed, giving them air in hot weather, and the 12th sort should be brought forward as far as possible in the spring, that it may flower early, otherwise it will not produce good seeds in England.

13. *Justicia Scorpioides*. Shrubby: branches round; leaves lanceolate-ovate, hirsute, sessile; spikes axillary, recurved; bractes minute; antheræ parallel. Flowers large, of a carmine colour, and ranged on one side at the spike; stem brittle, five or six feet high, sending out many branches.—Discovered at Vera Cruz. See the preceding species. This and the seventy-ninth species should remain in the hot-bed during the summer season, provided there be room for them under the glasses without being scorched; but at Michaelmas they should be removed into the stove, and plunged into the bark-bed, where they must remain during the winter season, observing to keep them warm, as also to water them gently once or twice a week, according as they shall require. The following summer these plants will flower, and abide several years; but they rarely produce good seeds in Europe.

14. *Justicia Assurgens*. Herbaceous: branches angular; leaves ovate-elliptic; spikes axillary and terminating, branched; flowers alternate; bractes linear; antheræ parallel.—Native of Jamaica.

*** *Corollas two-lipped; lower lip divided.*

15. *Justicia Acaulis*. Stemless: leaves crenate; veins villose underneath. Root pubescent, woolly at top.—Native of the East Indies.

16. *Justicia Ecbolium*; *Long-spiked Justicia*. Shrubby: spikes terminating, four-cornered; bractes ovate, imbricate, ciliate, mucronate; upper lip linear, reflex; antheræ paral-

lel. Stem roundish, compressed, jointed. Mr. Miller says that it rises ten or twelve feet high in its native soil; and that the flowers grow from the ends of the branches in very long spikes, and are of a greenish colour with a shade of blue.—Native of the East Indies, and Cochin-china. This is propagated in the same way as the twelfth species; but may be more hardily treated when the plants have obtained strength. It may also be increased by cuttings, as is directed for the sixty-fourth species, and when the plants are two or three years old, they will thrive with a moderate degree of warmth in winter. In summer they may be placed abroad two months during the warmest season, but always in a sheltered situation; and when the nights begin to grow cold, they must be removed into the stove, but still have free air admitted to them in warm weather.

17. *Justicia Pulcherrima*. Shrubby: spikes axillary, and terminating; bractes ovate-imbriate, ciliate, awnless; upper lip lanceolate, straight. Stem upright, five or six feet high; flowers without smell, in four rows, of a fine bright red.—Native of South America, near Carthagen.

18. *Justicia Carthaginensis*. Herbaceous: leaves elliptical; spikes axillary and terminating; bractes imbricate, all wedge-shaped, ciliate; upper lip emarginate; antheræ binate. This appears to be an annual plant. It is upright, growing six feet high among bushes and in hedges, but only three feet in other situations; flowers void of scent, purple.—Native of Carthagen in Spanish America.

19. *Justicia Tetragona*. Shrubby: leaves crenate, smooth; spikes terminating, four-cornered; bractes ovate, imbricate in four rows, keeled, ciliate. Branches round, smooth, opposite.—Sent from Cayenne.

20. *Justicia Coccinea*; *Scarlet-flowered Justicia*. Shrubby: leaves and bractes elliptical, acuminate; upper lip undivided; antheræ parallel. Stem six feet high, nearly erect, round, covered by a smooth brown bark, cracking longitudinally; spikes terminating, mostly solitary, erect, simple, dense, many-flowered; flowers sessile, one between each pair of the smaller bractes, erect, large, handsome, scarlet, becoming tawny in decay: they are only to be found on old plants, and have no smell. The leaves when bruised have an herbaceous scent. This is the largest species known in England, and, when cultivated, grows in the hot-house almost to the size of a tree.—Native of South America.

21. *Justicia Hirsuta*. Herbaceous: leaves toothed; spikes axillary and terminating, four-cornered; bractes ovate, imbricate, hirsute. Flowers opposite, with two bristle-shaped bractes at the base.—Native of Java.

22. *Justicia Sphærosperma*. Herbaceous: spikes axillary, opposite, in pairs on each side; bractes linear, elongated; seeds globular, shining. Branches round.—Native of the Caribbee islands.

23. *Justicia Gandarussa*. Shrubby: leaves lanceolate, elongated; spikes terminating, leafy; flowers in whorls; bractes minute; upper lip undivided; antheræ binate; stem smooth, round.—Native of the East Indies.

24. *Justicia Procumbens*. Herbaceous: stem procumbent; leaves lanceolate, quite entire; spikes axillary and terminating; calices four-cleft.—Native of Ceylon and Java.

25. *Justicia Echioides*. Herbaceous: leaves lanceolate-linear, rough-haired; spikes axillary, opposite, pointing one way, ascending; antheræ parallel, bearded at the base.—Native of the East Indies.

26. *Justicia Longifolia*. Herbaceous: leaves lanceolate, elongated; spikes axillary, in pairs, opposite, pointing one way. Stem smooth; flowers alternate; corolla small.—Native of the island of Mahe.

27. *Justicia Latifolia*. Shrubby: leaves ovate, acuminate; spikes terminating, somewhat branched; lower flowers in whorls; branches round, smooth.—Native of the East Indies.

28. *Justicia Picta*. Shrubby: leaves ovate, painted; spikes axillary, and terminating; flowers in whorls; upper lip bifid; antheræ parallel. Stem striated, eight feet high, corolla red.—Native of the East Indies.

29. *Justicia Nitida*. Shrubby: leaves elliptic, acuminate; racemes spike-form, whorled; bractes minute; pedicels and calices smooth; antheræ parallel.—Native of the West Indies, as Martinico, Guadeloupe, and Santa Cruz.

30. *Justicia Stricta*. Herbaceous: leaves lanceolate-elliptic; racemes axillary, two-parted, pointing one way; filaments smooth. Stem smooth, quadrangular; flowers small.—Native of Malabar.

31. *Justicia Paniculata*. Herbaceous: leaves lanceolate; panicles axillary and terminating, dichotomous; flowers pointing one way; filaments hirsute; capsules compressed.—Native of the East Indies.

32. *Justicia Nutans*. Herbaceous: leaves toothed; racemes terminating, nodding at top; flowers inverted. Stem very finely striated.—Native of Java.

33. *Justicia Nasuta*. Suffruticose: leaves elliptic, quite entire; peduncles axillary, dichotomous, upper lip upright, bifid; antheræ divaricating.—The bruised leaves are used in the East Indies, where it is a native, for the cure of cutaneous eruptions.

34. *Justicia Scandens*. Shrubby: leaves ovate, acuminate, subrepand; branches villose; peduncles axillary, trichotomous, divaricating. It varies with the branches and veins of the leaves less villose.—Native of Malabar.

35. *Justicia Ciliaris*. Herbaceous: leaves lanceolate, bluntish; flowers axillary, opposite; antheræ parallel, appended. The whole plant is rugged. It flowers throughout the summer; scentless.—Native place unknown.

36. *Justicia Secunda*. Herbaceous: leaves ovate-lanceolate, acuminate; racemes terminating, compound; racemelets pointing one way; antheræ binate; flowers on the racemelets alternate, four or five, on short pedicels; corolla purple.—Native of the island of Trinidad.

37. *Justicia Debilis*. Shrubby: spikes axillary and terminating; bractes ovate, imbricate, ciliate; antheræ binate. See *Dianthera Debilis*.

38. *Justicia Violacea*. Shrubby: leaves lanceolate; spikes terminating; bractes lanceolate, imbricate, ciliate; antheræ binate. See *Dianthera Violacea*.

39. *Justicia Rohrii*. Herbaceous: leaves elliptic, quite entire; spikes terminating, compound, imbricate, pubescent; bractes ovate; antheræ binate. Stem upright, somewhat hoary. Flowers opposite.—Native of Cayenne.

40. *Justicia Polystachya*. Herbaceous: leaves lanceolate-ovate; spikes axillary, opposite, pointing one way; bractes ovate, hirsute; antheræ binate. Flower solitary, sessile, in the axils of the bractes.—Native of Cayenne.

41. *Justicia Retusa*. Herbaceous: leaves ovate, acuminate; spikes terminating; bractes obovate, subretuse, imbricate; antheræ binate. The whole plant smooth: corolla large, purple, cloven beyond the middle; stamina the length of the upper lip.—Native of the island of Santa Cruz.

42. *Justicia Flava*. Shrubby: leaves lanceolate-oblong; spikes terminating; flowers in pairs; bractes lanceolate, blunt. See *Dianthera Flava*.

43. *Justicia Americana*. Herbaceous: leaves linear-lanceolate; spikes axillary, solitary, like corymbs; peduncles filiform, alternate, the length of the leaves; antheræ binate. See *Dianthera Americana*.

44. *Justicia Punctata*. Herbaceous: leaves lanceolate-ovate; spikes terminating; flowers remote, in a sort of whorl; bractes lanceolate, acuminate. See *Dianthera Punctata*.

45. *Justicia Eustachiana*. Shrubby: leaves oblong, acuminate; spikes axillary and terminating; flowers in remote whorls, two or three together, solitary at top; bractes wedge-shaped. Flowers purple, inodorous.—Native of the West Indies, common on the open arid hills of St. Eustatia.

46. *Justicia Pectoralis*. Herbaceous: leaves lanceolate, petioled; spikes panicled; bractes minute; upper lip undivided; antheræ binate. An upright plant, two or three feet high; flowers numerous, red, sessile. The whole plant has the smell of new hay, mixed with a refreshing aromatic scent.—Native of St. Domingo and Martinico. The inhabitants make a syrup of it, which they use in disorders of the breast. The bruised leaves are also good in wounds and cuts; and hence the French call this plant *herbe à charpentiere*.

47. *Justicia Comata*. Herbaceous: leaves linear-lanceolate, subsessile; spikes subumbelled, whorled; bractes minute; antheræ binate. See *Dianthera Comata*.

48. *Justicia Undulata*. Herbaceous: leaves lanceolate, waved; peduncles terminating, umbelled, simple, and trifid; antheræ binate. Capsules villose.—Observed by Kœnig in Malabar.

49. *Justicia Frondosa*. Herbaceous: umbels axillary, peduncled, compound; peduncles elongated; bractes ovate, rhombed, smooth, blunt; antheræ binate. Stem round, smooth.—Native of Otaheite.

50. *Justicia Pubescens*. Shrubby: peduncles axillary, opposite, four-flowered, pedicelled; bractes ovate-roundish, mucronate, pubescent; antheræ binate. Stem branched, pubescent, round.—Native of Botany Island.

51. *Justicia Lævigata*. Shrubby: peduncles axillary, opposite, three-flowered, pedicelled; bractes oblong, mucronate, pubescent; antheræ binate. Stem covered with an ash-coloured bark, except at top, where it is green.—Native of Java.

52. *Justicia Cuspidata*. Peduncles axillary, in whorls, subtriflorous, pedicelled; bractes wedge-form, awned; antheræ binate.

53. *Justicia Biflora*. Suffruticose: peduncles axillary, two-flowered, pedicelled, equalling the leaves; bractes awl-shaped; antheræ binate. Branches obscurely quadrangular, smooth; pedicels unequal.—Native of the East Indies.

54. *Justicia Sessilis*. Shrubby: leaves ovate-acute, subserrate; flowers solitary, sessile; upper lip quite entire. Flowers inodorous, purple.—Native of the West Indies, in the coppices and hedges of the island of St. Eustatia, where it is found flowering in August.

55. *Justicia Nigricans*. Shrubby: leaves lanceolate-linear, blunt, blackish; spikes distich, terminating. Stem upright, six feet high; corolla white, variegated with red.—Native of Cochin-china.

56. *Justicia Tinctoria*. Herbaceous: leaves lanceolate, subrenate, pubescent; flowers axillary, heaped. Corolla rose-coloured. The leaves dye cloth of a fine green colour.—Native of Cochin-china.

*** *Corollas ringent.*

57. *Justicia Adhatoda*; *Malabar Nut*. Arboreous: leaves ovate-lanceolate, acuminate; spikes axillary, opposite; bractes ovate-elliptic, leafy; antheræ parallel. It rises with a strong woody stem to the height of twelve or fourteen feet, sending out many spreading branches; flowers on short spikes at the end of the branches; corolla white, with some dark spots. It flowers in July, but does not bear seeds in England.—Native of Ceylon. It may be propagated by

cuttings, which, if planted in pots during June or July, and plunged into a very moderate hot-bed, will take root. They must be screened from the sun, and will succeed the better for the exclusion of the external air. It may also be propagated by laying down the young branches, which will take root in the tubs or pots in one year; then the young plants should be put each into a separate pot, filled with soft loamy earth, and placed in the shade till they have taken new root, when they may be placed in a sheltered situation during the summer; but in winter they must be housed, and treated in the same way as Orange-trees, with only this difference, that they require more water.

58. *Justicia Betonica*. Shrubby: leaves elliptic; spikes terminating, elongated; bractes ovate-acuminate, membranaceous, netted, coloured; antheræ binate, appendicled.—Native of the East Indies.

59. *Justicia Repens*. Herbaceous: leaves elliptic, subsessile; spikes axillary and terminating, pointing one way, smooth; bractes ovate, membranaceous at the edge; antheræ binate, appendicled.—Native of Ceylon.

60. *Justicia Pectinata*. Herbaceous: leaves oblong; spikes axillary, pointing one way, tomentose; bractes half lanceolate, distich. Corolla minute, white, with a green upper lip.—Native of the East Indies.

61. *Justicia Sanguinolenta*. Herbaceous: stem creeping; leaves oblong; peduncles axillary, solitary, one-flowered. The whole plant is of a blood-red colour, whence it derives its trivial name.—Native of Ceylon.

62. *Justicia Japonica*, *Herbaceous*: leaves ovate-oblong, acuminate; peduncles axillary, alternate, four or five flowered; pedicelled; bractes lanceolate-ciliate. See *Dianthera Japonica*.

63. *Justicia Trisulca*. Shrubby: leaves oblong, blunt; peduncles axillary, subtriflorous, opposite; flowers sessile; antheræ binate. This is a stiff shrub, with opposite, distorted, warted, round branches; corolla an inch and a half in diameter.—Native of Arabia Felix.

64. *Justicia Hyssopifolia*; *Snap Tree*. Shrubby: leaves lanceolate, blunt; peduncles axillary, one or two flowered; bractes shorter than the calix; calicine segments oblong; antheræ binate, appendicled. Stem from three to four feet high, sending out branches on every side from the bottom, so as to form a pyramid; flowers white, with long calices; capsules oblong, when ripe throwing out their seeds, whence its name of Snap-trec.—Native of the Canary islands. It is propagated by cuttings during any of the summer months; they should be planted in pots filled with light loamy earth, plunged into a moderate hot-bed shaded from the sun, and now and then gently refreshed with water; they must not have much air admitted to them. In about two months the cuttings will have taken root, then they must be gradually inured to the open air, by placing them in a sheltered situation, where they may remain till autumn. If they take root early in the summer, separate them each into a small pot, placed in the shade; but if it be late in the season before they have taken root, let them remain in the same pots till the following spring. In winter these plants must be placed in a warm green-house, or moderately warm stove, for they are impatient of cold and damp, nor will they thrive in too much warmth; they often require watering in winter, but it must be sparingly given. In summer they must be removed into the open air in a warm sheltered situation, and in warm weather have plenty of water.

65. *Justicia Orchioides*. Shrubby: leaves lanceolate, sessile; peduncles axillary, solitary, one-flowered; bractes shorter than the calix; antheræ binate, appendicled. This

is a very stiff smooth shrub, with small crowded harsh leaves: the flowers are white, with a reddish tinge about the palate, and grow solitary or in pairs, on axillary stalks, longer than the leaves. It flowers in August and September.—Native of the Cape.

66. *Justicia Madurensis*. Shrubby: leaves oblong, toothed; peduncles axillary, one-flowered. Stem solid, round, smooth, whitish; bractes in pairs, deciduous; flowers few.—Native of Madura.

67. *Justicia Cuneata*. Shrubby: leaves obovate, emarginate; flowers axillary, solitary, sessile; antheræ binate. Corolla like that of the Snap-tree.—Native of the Cape.

68. *Justicia Tranquebarensis*. Suffruticose: leaves obovate, on hoary branches; flowers axillary, solitary, sessile; bractes remote, obovate; antheræ binate, appendicled. Stem round, red, covered with slender white soft hairs.—Found by Kœnig in Tranquebar.

69. *Justicia Odora*. Shrubby: branches smooth; leaves roundish; flowers axillary, solitary, sessile, opposite. Stem ash-coloured.—Native of Arabia Felix, where they make wreaths of it to wear about their heads on festivals. It has little scent while green, but, when dried, smells like Anthoxanthum, or Vernal Grass.

******Corollas almost equal.*

70. *Justicia Infundibuliformis*. Shrubby: leaves lanceolate-ovate, in fours; spikes terminating. Branches round; corolla handsome, white, with a filiform tube.—Native of the East Indies.

71. *Justicia Sinuata*. Shrubby; leaves linear, oblong, sinuate-pinnatifid; peduncles axillary, trifid; corolla salver-shaped; antheræ parallel.—Native of the Isle of Tanna in the South Seas.

72. *Justicia Spinosa*. Shrubby: leaves ovate or obovate; spines axillary; lateral peduncles simple; corollas salver-shaped; antheræ parallel. Stem five feet high, dividing into few, round, weak, pliant, leafy, very long branches; flowers inodorous, less than an inch long, purple. It is armed with strong, opposite, very spreading, awl-shaped, acuminate spines, half the length of the leaves; between the leaves and spines come out the peduncles, three or four together.—Native of St. Domingo and Jamaica. See the twelfth species. It, as well as the 80th, must constantly remain in the bark-stove.

73. *Justicia Repanda*. Shrubby: leaves elliptic, repand; peduncles axillary, trifid; corollas salver-shaped; antheræ parallel.—Native of the isle of Tanna.

74. *Justicia Armata*. Shrubby, prickly; leaves oblong, emarginate, coriaceous, shining.—Native of Jamaica.

75. *Justicia Acicularis*. Shrubby, diffused, spiny: spines bristle-shaped; flowers peduncled, axillary, solitary.—Native of Jamaica.

******New Species.*

76. *Justicia Reptans*. Stem herbaceous, creeping; leaves blunt; spikes terminating, undivided. Annual.—Native of St. Domingo.

77. *Justicia Humifusa*. Stem herbaceous, decumbent; leaves ovate and cordate; spikes umbelled. Annual.—Native of Jamaica.

78. *Justicia Nemorosa*. Stem herbaceous, four-cornered, somewhat upright; leaves ovate-lanceolate; spikes ovate. Perennial.—Native of St. Domingo and Jamaica.

79. *Justicia Fruticosa*. Shrubby: leaves ovate or ovate-lanceolate, hirsute, petioled; bractes cordate acuminate. It rises with a hairy stem four or five feet high; flowers in loose clusters, from the axils towards the end of the branches, of a pale red colour.—Discovered by Dr. Houstoun, at Campeachy. See the twelfth species.

80. *Justicia Arborea*. Arboreous: leaves lanceolate-ovate, sessile, tomentose underneath; flowers in clustered terminating spikes. It rises with a strong woody stem twenty feet high, dividing into many crooked irregular branches: the flowers are small and white.—Sent from Campeachy. See the twelfth species.

Ivy. See *Hedera*.

Ivy, Ground. See *Glechoma*.

Ixia; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: spathe bivalve, inferior, shorter than the corolla; valves oblong, permanent, the exterior wider, sheathing the interior. *Corolla*: one-petalled, regular, superior; tube filiform, gradually enlarged, straight; border regular, bell-shaped, six-parted; divisions oblong, obtuse, equal, spreading. *Stamina*: filamenta three; thread-subulate, inserted into the tube near the orifice, shorter than the corolla; antheræ oblong, furrowed. *Pistil*: germen inferior, triangular; style simple, filiform, upright; stigmas three, filiform. *Pericarp*: capsule ovate, three-sided, obtuse, three celled, three valved. *Seeds*: several, roundish, smooth. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled, tubular; tube straight, filiform; border six-parted, bell-shaped, regular, or nearly so; stigmas three or six, simple.—Several of the plants of this genus will ripen their seeds in our climate, and may be propagated by sowing the seeds in pots, and plunging them into a moderate hot-bed, which will bring up the plants much sooner than when they are sown in the full ground. When fit to remove, they should each be set in a small pot filled with light earth, and, if they are placed under a frame till they have taken good root, it will greatly forward their growth; afterwards they may be placed in the open air, in a sheltered situation, and may remain there till autumn, when they must be placed under a frame to screen them from the frost. In the spring the plants may be turned out of the pots and planted in a warm border, where they will endure the cold of common winters very well; but in severe frosts they are often killed, unless protected by tan, or some other covering. They multiply very fast by offsets, so that when they are once obtained, there will be no occasion to raise them from seeds: most of them will flower in the ensuing season; whereas those from seeds are three or four years before they flower. The stalks and leaves of these plants decaying to the root in autumn, the roots in borders should then be covered two or three inches thick with tan, to keep them from frost, and also from mice, which are very fond of them. The spring before the roots shoot, is the best time to remove and part them; but this should not be done oftener than every third year, for if oftener parted, they will not flower well.—The species are,

1. *Ixia Fruticosa*; *Shrubby Ixia*. Stem branched, covered with imbricate leaves. Flowers terminating, blue; tube of the corolla yellow, half an inch long.—Native of the Cape of Good Hope, and of Terra del Fuego.

2. *Ixia Minuta*; *Minute Ixia*. Scapes one-flowered, shorter; leaves even. Bulb globular, covered with a net, the size of a pea: tube of the corolla white, with purple streaks; antheræ upright, yellow.—Native of the Cape.

3. *Ixia Bulbocodium*; *Crocus-leaved Ixia*. Stem one-flowered; leaves linear, closely complicated; stigmas six. Flower lateral, inodorous; corolla pale violet, yellow on both sides at the base. It flowers about the middle of April; but the blossoms do not fully expand unless exposed to the sun, nor are they of long duration. It affects dry hilly situations.—Native of Italy. This is not the *Bulbocodium* of Miller.

4. *Ixia Rosea*; *Rose-coloured Ixia*. Scapes one-flowered; leaves linear, nerved, incrassated at the edge; stigmas six.

IXIA — Deep Yellow Cups Ixia.

Flowers at the ends of the branches, rather large, coming one after the other; tube of the corolla very short; segments of the border yellow within. It varies with the three inner segments of the corolla yellow, and the three outer green; the three inner white-yellow, and the three outer greenish; the three inner blue-white, the three outer greenish; the three inner white, the three outer green; with corollas wholly yellow, or wholly blue, or rose-coloured with a yellow base. It varies also in the size of the flowers.—Native of the Cape.

5. *Ixia Parviflora*; *Small-flowered Ixia*. Leaves linear, compressed; segments of the corolla lanceolate, retuse, the inner scarcely wider; stigmas bifid, spreading, revolute.—Gathered wild in Jersey by Mr. R. Finlay.

6. *Ixia Fugax*; *Fugacious Ixia*. Leaves linear, compressed; segments of the corolla linear-lanceolate, blunt, the inner wider and more erect; stigmas bifid, horizontal, recurved.—Native of the Cape.

7. *Ixia Humilis*; *Humble Ixia*. Scape branched; flowers pointing one way; leaves grooved, erect, longer. It varies with the corolla yellow, whitish, rufescent, or flesh-coloured; with an undivided few-flowered scape, and a branched many-flowered scape.—Native of the Cape.

8. *Ixia Pilosa*; *Hairy Ixia*. Leaves linear, hairy, shorter; flowers alternate, sessile, somewhat nodding; corolla rufescent without, white within. The flowers open from four in the afternoon.—Native of the Cape.

9. *Ixia Hirta*; *Rough-haired Ixia*. Leaves ensiform, rough-haired, shorter; flowers pointing one way, dark blue.—Native of the Cape.

10. *Ixia Secunda*; *One-ranked Ixia*. Leaves elliptic, ensiform, shorter; scape villose, rugged; flowers generally from five to six, upright, blue. It varies with the scape simple and branched.—Native of the Cape.

11. *Ixia Crispa*; *Wave-leaved Ixia*. Leaves linear, waved, shorter; flowers alternate. Tube of the corolla greenish; segments of the border blue. It varies with the scape simple and branched, and with the corollas blue and white.—Native of the Cape.

12. *Ixia Cinnamomea*; *Cinnamon-coloured Ixia*. Leaves lanceolate, waved, shorter; flowers alternate; bulb conical; tube of the corolla a little enlarged, and somewhat reddish, purplish.—Native of the Cape.

13. *Ixia Corymbosa*; *Corymbed Ixia*. Leaves lanceolate, waved, shorter; scape ancipital. It varies with white and blue flowers.—Native of the Cape.

14. *Ixia Linearis*; *Linear-leaved Ixia*. Leaves linear, shorter; scape simple upright. Bulb ovate, fibrous, even, the size of a hazel nut; flowers terminating the branches, at the end of the scape.—Native of the Cape.

15. *Ixia Capillaris*; *Slender-scaped Ixia*. Leaves linear, shorter; scape branched; spathe scariosa. Bulb netted, fibrous, the size of a hazel nut.—Native of the Cape.

16. *Ixia Setacea*; *Bristle-leaved Ixia*. Leaves linear, shorter; scape flexuose, smooth. The three outer segments of the border of the corolla are white within, red-streaked without; the three inner entirely white. It varies with a greenish corolla, white at the tips, and with a yellow corolla, with the base of the border dusky; with the scape one-flowered, many-flowered and simple, many-flowered and branched.—Native of the Cape.

17. *Ixia Scillaris*; *Squill-flowered Ixia*. Leaves linear, shorter; flowers pointing one way; raelis flexuose. Scape round, upright, smooth.—Native of the Cape.

18. *Ixia Aulica*; *Cluster-flowered Ixia*. Flowers in racemes; bractes entire; leaves ensiform, flat, nerved, even. It flowers in April.—Native of the Cape.

19. *Ixia Bulbifera*; *Bulb-bearing Ixia*. Leaves ensiform, shorter; spathes membranaceous, bristle-shaped, jagged. Flowers three or more, large, with the rachis between the flowers flexuose. It varies with the corolla purple, red, white, and yellow; with the scape very short and simple, higher and branched, and bulbiferous.—Native of the Cape.

20. *Ixia Aristata*; *Bearded Ixia*. Leaves ensiform, smooth; flowers alternate, sessile; spathes the length of the tube, and jagged. Bulb netted, the size of a hazel-nut; scape simple, round, upright, smooth, from a hand to a foot in height, or more; corollas white, flesh-coloured. It varies with whitish corollas having a purple star, and violet-coloured and yellow.—Native of the Cape.

21. *Ixia Reticularis*; *Netted Ixia*. Border of the corolla four times as long as the tube, recurved, funnel-form at the base; segments spatulate, somewhat acuminate, the inner narrower; filamenta erect; stigmas at the base of the antheræ.—Native of the Cape.

22. *Ixia Villosa*; *Dark-red Ixia*. Leaves oblong, lanceolate-acute, villose, somewhat plaited, distich; tube equal to the spathe. Flowers alternate, sessile, upright, often three.—Native of the Cape.

23. *Ixia Pendula*; *Pendulous-flowered Ixia*. Leaves linear-ensiform, shorter; scape branched; spikes pendulous. Root jointed like a necklace; corollas on the branches alternate, large, flesh-coloured, with a short tube. This is the loftiest of the genus, and the large pendulous corollas are very handsome.—Native of the Cape. It is well worth the trouble of cultivating.

24. *Ixia Flexuosa*; *Bending-stalked Ixia*. Leaves linear; raceme flexuose, many-flowered. Bulb very small, round; stem very slender, round, a foot and half high. The corolla is pure white, and small.—Native of the Cape.

25. *Ixia Polystachia*; *Many-spiked Ixia*. Leaves ensiform, shorter; scape branched; flowers alternate, unspotted; border of the corolla incurved, and spreading very much; segments lanceolate, blunt, equal in breadth; filamenta spreading and recurved; stigmas at the base of the filamenta. Stalk slender, ten inches high; flowers from the side in one or two clusters, and at the top of the stalk in a loose spike: they are of a pure white, and appear in May.—Native of the Cape.

26. *Ixia Longiflora*; *Long-flowered Ixia*. Leaves ensiform, linear, stiff; tube filiform, very long. Scape four or five spans high, the thickness of a rye-straw, upright, round, even, yellowish, naked at top, and branched; flowers in spikes, yellow. This is easily distinguished by the extraordinary length of the tube of the corolla. The flowers appear from April to June.—Native of the Cape.

27. *Ixia Plantaginea*; *Fox-tail Ixia*. Leaves linear, stiff; spike distich, imbricated. Root consisting of several little bulbs; flowers very small. It varies with the corollas white and blue.—Native of the Cape.

28. *Ixia Marginata*; *Broad-leaved Ixia*. Many-spiked: leaves ensiform, nerved, thicker at the edge; spikes pressed close; tube curved inwards; stigmas six. Flowers large, pendulous.—Native of the Cape.

29. *Ixia Patens*; *Spreading-flowered Ixia*. Leaves ensiform, smooth; raceme terminating; corolla bell-shaped, patulous; alternate segments narrower; filamenta upright; stigmas above the base of the antheræ. Flowers in a sort of spike containing from ten to twenty. It flowers in April.—Native of the Cape.

30. *Ixia Maculata*; *Spotted Ixia*. Leaves ensiform, shorter; scape branched; flowers alternate; corollas spotted at the base. Bulb double the size of a hazel-nut, oval and

compressed; stalk slender, stiff, a foot and a half long, naked to the top, where it is terminated by a round bunch of flowers, on short peduncles, of a deep yellow colour, with a dark purple bottom.—Native of the Cape.

31. *Ixia Deusta*; *Copper-coloured Ixia*. Leaves lanceolate, nerved; flowers alternate, sessile; tube shorter than the bractes; borders blunt, the outer spotted at the base, and keeled; stigmas under the middle of the antheræ. It flowers in May.—Native of the Cape.

32. *Ixia Crocata*; *Crocus-leaved Ixia*. Leaves ensiform; flowers alternate; tube the length of the bractes; borders of the corolla ovate, quite entire, hyaline at the base; stigmas at the tip of the antheræ. The flowers appear in May and June, they point one way, are bell-shaped, with a short orange-coloured tube, with a paler hyaline or transparent mark above the mouth of the tube. This is one of the handsomest of the genus, and, like all the rest, becomes handsomer and more branched by cultivation.—Native of the Cape.

33. *Ixia Squalida*; *Squalid Ixia*. Leaves linear-lanceolate; flowers alternate, sessile; tube longer than the bractes; borders ovate-oblong; stigmas below the tip of the antheræ. It strongly resembles the preceding, and flowers in May.—Native of the Cape.

34. *Ixia Lancea*. Leaves ensiform, shorter; flowers pointing one way; scape simple, flexuose. Flowers about six, purplish-white.—Native of the Cape.

35. *Ixia Pentandria*. Leaves ensiform, shorter; flowers five-stamined. Scape branched or simple, round, flexuose, smooth, a foot high; spike of flowers long, interrupted, flexuose; tube of the corolla greenish, short; segments of the border purple.—Native of the Cape.

36. *Ixia Falcata*. Leaves ensiform, reflex-sickle-shaped, shorter. Bulb conical, imbricate downwards, truncated, with a sharp fibrose margin, the size of a pea; flowers alternate, one or more; tube of the corolla red. It varies with the scape simple or branched, a hand or a span in height; with flowers alternate, or pointing one way.—Native of the Cape.

37. *Ixia Excisa*. Leaves ovate, shorter; flowers pointing one way; scape flexuose. Bulb globular, smooth, less than a pea; scape round, upright, smooth, one-flowered or many-flowered, a finger or a hand in length; tube of the corolla red.—Native of the Cape.

38. *Ixia Chinesis*; *Chinese Ixia*. Leaves ensiform; panicle dichotomous; flowers peduncled. Scape round, fistulous, jointed, upright, simple at bottom: the flowers are of a yellow colour within, and variegated with dark-red spots, the outside orange-colour. The Indians consider this plant as an antidote to poisons in general, and regard the bruised root as peculiarly efficacious in curing the bite of the serpent called Cobra de Capello.—Native of the East Indies, China, Cochinchina, and Japan.

39. *Ixia Fallax*. Border of the corolla incurved, and spreading very much; segments oval, slightly emarginate, equal in breadth; filamenta spreading, and recurved; stigmas as at the base of the filamenta; corolla violet-coloured.—This, and the remaining species, are taken from Mr. Salisbury's Catalogue of Plants in the Botanic garden at Chapel Allerton.—They are all natives of the Cape.

40. *Ixia Mutabilis*. Border of the corolla reflex, salver-shaped at the base; segments broadly obovate, retuse, the inner narrower; filamenta from upright spreading; stigmas below the apex of the tube. Border of the corolla one, and one-third longer than the tube.

41. *Ixia Socialis*. Border of the corolla horizontal; segments elliptical, the outer emarginate, the inner narrower, blunt; filamenta from upright spreading; stigmas at the

middle of the filamenta. Border of the corolla four-sevenths longer than the tube; corolla white, with a green base.

42. *Ixia Lineata*. Border of the corolla incurved, and spreading very much; segments oval, blunt, inner narrower; filamenta recurved at the tip; stigmas below the tip of the filamenta. Border of the corolla one and a half longer than the tube.

43. *Ixia Amœna*. Border of the corolla incurved and horizontal; segments oval-lanceolate, somewhat retuse, inner narrower; filamenta from upright spreading; stigmas at the base of the filamenta. Corolla rose-purple-coloured, with a deep purple base; limb longer by half than the tube.

44. *Ixia Retusa*. Border of the corolla incurved, and spreading very much; segments oval, retuse, inner narrower; filamenta upright; stigmas at the middle of the filamenta. Limb of the corolla as long again as the tube.

45. *Ixia Spectabilis*. Border of the corolla incurved and horizontal; segments lanceolate, outer emarginate, inner narrower, blunt; filamenta from upright spreading; stigmas at the base of the filamenta. Flowers peduncled, and forming a dense pyramidal spike; border of the corolla three times longer than the tube, deeply six-parted, green or blue-green, with a dark purple base. It flowers from May to August.

46. *Ixia Concolor*. Border of the corolla incurved, and horizontal; segments elliptical, blunt, inner narrower; filamenta from upright spreading; stigmas above the middle of the antheræ. Limb of the corolla five times longer than the tube; corolla deep red.

47. *Ixia Conica*. Border of the corolla reflex, shaped like a dish at the base; segments elliptical, blunt, inner broader; filamenta upright; stigmas above the base of the antheræ. Corolla vermilion-coloured, with a variegated star at the base; limb twice as long as the tube.

48. *Ixia Conspicua*. Border of the corolla incurved and horizontal; segments elliptical, blunt, inner narrower; filamenta from upright recurved; stigmas at the base of the filamenta. Corolla orange-coloured, with a dark base; limb one-third longer than the tube.

49. *Ixia Concinna*. Border of the corolla reclining, funnel-form at the base; segments elliptical, blunt, inner narrower; filamenta from upright recurved; stigmas below the middle of the filamenta. Corolla pale yellow; limb longer by half than the tube.

50. *Ixia Columnaris*. Border of the corolla the length of the tube, reflex, salver-shaped at the base; segments elliptical, the inner a little wider; filamenta monadelphous; stigmas above the base of the antheræ. Limb of the corolla the same length as the tube.

51. *Ixia Erosa*. Margins of the nerves duplicate-ciliate; base of the corolla funnel-form; segments elliptical, gnawn at the tip. This sort is singular in its almost total want of a tube, but in other respects has the characters of this genus.

52. *Ixia Tardiflora*. Border of the corolla recurved at top; segments broadly spatulate, emarginate, the three lower at the disk of the base within, putting out a little keel; stigmas at the base of the antheræ. The limb of the corolla is six times longer than the tube.

53. *Ixia Propinqua*. Border of the corolla recurved and spreading at top; segments spatulate, slightly emarginate, the three lower approximating a little, at the disk of the base within, putting out a little keel; stigmas at the middle of the antheræ.

54. *Ixia Ambigua*. Border of the corolla recurved a little at top; segments rhomb-spatulate, equal in breadth, the outer somewhat gibbous at bottom, emarginate, inner blunt; stigmas above the middle of the antheræ. Limb of the corolla

three and a half longer than the tube.—The roots of this (and indeed of almost all the plants of this genus) are frequently eaten by the inhabitants of the Cape of Good Hope, where it is a native.

Ixora; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-parted, very small, upright, permanent. *Corolla*: one-petalled, funnel-form; tube cylindrical, very long, slender; border four-parted, flat; divisions ovate. *Stamina*: filamenta four, above the mouth of the corolla, very short; antheræ oblong. *Pistil*: germen roundish, inferior; style filiform, length of the tube; stigma two-cleft. *Pericarp*: berry roundish, two-celled. *Seeds*: by fours, convex on one side, cornered on the other. *Observe.* Gærtner says the seeds are solitary; partition perforated through the middle. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled, funnel-form, long, superior. *Stamina*: above the mouth. *Berry*: four-seeded.—The plants of this genus are propagated from seeds, when the seed can be procured from their native countries; for they do not perfect seeds in England. They should be sown as soon as they arrive, in small pots, and plunged into a hot bed: if they arrive in autumn or winter, the pots may be plunged into the tan-bed in the stove, between the pots of other plants, where they will take up little room; but when they arrive in the spring, it will be best to plunge them into a tan-bed under frames. The seeds when fresh will sometimes come up in about six weeks; when not fresh, they often lie four or five months, and sometimes even a whole year, in the ground. On this account the earth should not be thrown out of the pots till there is no hope of their growing. When they come up, and are fit to remove, they should be each placed in a separate small pot, filled with light earth; and afterwards treated in the manner directed for the Coffee-tree. They may also be increased by cuttings during the summer months. The cuttings should be planted in small pots, plunged into a moderate hot-bed, covering them close with bell or hand glasses, to exclude the external air, and shading them carefully from the sun in the heat of the day, until they have put out good roots; when they should be parted, and each put into a separate pot, treating them as the seeding plants. Mr. Curtis remarks, that though we have been accustomed to treat the *Ixoræ* as stove-plants, they may perhaps be more hardy than we suspect.—The species are,

1. *Ixora Coccinea*; *Scarlet Ixora*. Leaves oval, half stem-clasping; flowers in bundles. Stem woody, five or six feet high, sending out many slender branches, covered with a

brown oark; flowers with very long tubes, cut into four ovate segments, and of a deep red colour.—Native of the East Indies, China, and Cochin-china.

2. *Ixora Alba*; *White Ixora*. Leaves lanceolate-ovate: flowers in bundles. The flowers terminate in small clusters, have long slender tubes, divided into four segments at top, and are white and scentless; stem woody, six or seven feet high, sending out weak branches.—Native of the East Indies and Cochin-china.

3. *Ixora Americana*; *American Ixora* or *Jasmin*. Leaves in threes; lanceolate-ovate; flowers thyrsoïd. The flowers appear at the ends of the branches in a loose spike, are white, and have a scent like *Jasmin*; whence, in Jamaica, and other islands of the West Indies, where it is a native, it is called Wild *Jasmin*. It rises with a shrubby stalk four or five feet high, sending out slender branches, opposite.

4. *Ixora Fasciculata*. Leaves ovate, elliptic, those of the branchlets subfasciated; peduncles subtriflorous.—Native of Jamaica.

5. *Ixora Multiflora*. Leaves lanceolate-ovate, bundled; peduncles aggregate, one-flowered, very short; berries one-seeded.—Native of Jamaica.

6. *Ixora Montana*. Leaves turbinate-oblong, cordate at the base; flowers fastigiate. Stem shrubby, upright, branched, four feet high; flowers terminating, scarlet. Perhaps a variety of the first species.—Native of Cochin-china.

7. *Ixora Novemnervia*. Stem scandent; leaves nerved, rough; cymes terminating. This is a large, climbing, branched, unarmed shrub; flowers white; stamina above the throat; stigma ovate, bifid.—Native of Cochin-china.

8. *Ixora Violacea*. Leaves nerved, hairy; flowers axillary; they are violet-coloured. This also is a large, climbing, branching, unarmed shrub.—Native of Cochin-china.

9. *Ixora Parviflora*. Leaves subsessile, lanceolate-oblong; panicle terminating. Branches smooth, jointed, round at bottom, but compressed at top; flowers scarlet, some say white.—Native of the East Indies.

10. *Ixora Flammea*. Leaves elliptic-lanceolate, bluntish, stalked, narrow at the base; segments of the corolla orbicular, obtuse, rather convex; style extended to half the length of the limb. Flowers flame-coloured, splendid.—Native of Java and China.

11. *Ixora Longifolia*. Leaves ovato-lanceolate, taper-pointed; segments of the corolla elliptical, sharpish, reflexed. Corymbs of innumerable flowers, of a vermilion hue inside, become darker by age.—Native of most of the islands in the East Indies.

K Æ M

KÆMPFERIA; a genus of the class Monandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth superior, obscure. *Corolla*: one-petalled; tube long, slender; border flat, six-parted; the three alternate divisions lanceolate, equal; the other two divisions ovate; the upper one two-parted, the divisions obcordate; all equal in length. *Stamina*: filamentum one, membranaceous, subovate, emarginate; antheræ linear, doubled, entirely adnate, scarce emerging from the tube of the corolla. *Pistil*: germen roundish; style the length of the tube; stigma two-plated, roundish. *Pericarp*: capsule roundish, three-sided, three-celled, three-valved. *Seeds*: several. *Observe.* It rarely bears fruit: the germen is seated near the root. **ESSENTIAL CHARACTER.** *Corolla*: six-parted, three of the parts larger, spreading, one or two parted. *Stigma*: two-plated.—The species are,

K Æ M

1. *Kæmpferia Galanga*; *Galangale*. Leaves ovate, sessile; segments of the corolla lanceolate-linear. It is an annual, stemless, juicy plant; root bulbous, palmate, creeping; flowers radical, solitary, juicy, very white, with a large violet spot in the middle. The smell of the whole plant is aromatic, pleasant, and permanent; the taste is sharpish; the colour of the root white within, purple on the outside. An infusion of the roots (which are kept by the druggists) in boiling water, or a tincture made with brandy, is a good medicine in windy complaints, and other disorders of the stomach, as well as for head-aches, which arise in general more from debility than any other cause.—Native of the East Indies. This and the next species, being natives of hot countries, will not bear the open air in England, and require a warm stove to preserve them through the winter: but as

their leaves decay in the autumn, the plants should not have too much wet while they remain in an inactive state. If they are placed in the bark-stove, and treated in the same manner as is directed for Ginger, they will thrive and produce plenty of flowers every summer. They are both propagated by parting their roots, the best time for which is in the spring, before they put out their leaves.

2. *Kæmpferia Rotunda*. Leaves lanceolate, petioled; segments of the corolla linear. The roots are shorter than the above, growing in large clusters, covered with an ash-coloured skin, white within. The flowers appear in the spring, before the leaves; they are sweet-scented, white, except the lower lip, which is of a light purple, prettily variegated.—Native of the East Indies.

3. *Kæmpferia Angustifolia*. Upper segments of the inner limb of the corolla linear, obtuse; lower one emarginate; leaves lanceolate, pale beneath. It flowers in the stove about March or April.—Native of the East Indies.

4. *Kæmpferia Ovata*. Lower segments of the inner limb of the corolla lanceolate, undivided; leaves ovate. Root a globose tuber, an inch in diameter, yellow internally, with concentric red and orange lines; flowers six or seven from the centre among the leaves, short-lived, white, with a tinge of red; tube much longer than the limb.—Native of the East Indies.

Kale. See *Brassica Oleracea*.

Kalmia; (Dwarf American Laurel,) a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, small, permanent; segments imbricate, acute, rather columnar. *Corolla*: one-petalled, salver-funnel-form; tube cylindrical, longer than the calix; border with a flat disk, the margin upright, half five-cleft; ten nectariferous hornlets projecting outwardly from the corolla, and surrounding it where the border of it is upright. *Stamina*: filamenta ten, awl-shaped, upright, spreading, rather shorter than the corolla, inserted into the base of the corolla; antheræ simple. *Pistil*: germen roundish; style thread-form, longer than the corolla, bent down; stigma obtuse. *Pericarp*: capsule subglobose, depressed, five-celled, five-valved, five-partite. *Seeds*: numerous. *Observe*. The horned nectaries projecting outwardly from the corolla, and surrounding it, sufficiently distinguish this genus from the *Bicornes*. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: salver-form, with the border five-horned beneath. *Capsule*: five-celled.—The species are,

1. *Kalmia Latifolia*; *Broad-leaved Kalmia*. Leaves ovate-elliptic, by threes, and scattered; corymbs terminating. This shrub in its native soil continues flowering great part of the summer, and is one of the greatest ornaments of the country. Deer feed on its green leaves with impunity, yet in severe winters, when cattle and sheep are obliged to feed on it alone, great numbers of them die. The stem rises to the height of ten or twelve feet, and is sometimes as large as the small of a man's leg. The flowers burst out from their empalements in June, forming a round bunch or corymbus, sitting very close to the branch: they are of a pale blush colour, the inside of the petal of a peach colour. The wood is like that of Box, very close-grained, heavy, and hard. The Indians are said to make small dishes, spoons, and other domestic utensils, out of the roots, which are large, of a soft texture, and easily wrought while green, but when dry becoming hard and smooth.—Native of Carolina, Virginia, and other parts of North America, where it is generally found upon rocks, hanging over rivulets, and on the sides of barren hills, in most sterile soils. The *Kalmias* multiply in America by their creeping roots, and here by throwing up suckers, if

not removed. The seeds seldom ripen in England, and those sent from America lie in the ground a whole year before the plants appear, and afterwards make very little progress. The plants that come up from suckers are most likely to produce others, and flower much sooner. They succeed best in a northern aspect, well sheltered, in a moderately moist situation, upon loam and bog-earth, and in a pure air. The first sort being difficult to propagate by suckers or layers, is generally raised from American seeds.

2. *Kalmia Angustifolia*; *Narrow-leaved Kalmia*. Leaves lanceolate; corymbs lateral. Stem from three to six feet high, dividing into small woody branches; flowers in loose bunches, on the side of the branches, upon slender peduncles: they are bright red when they first open, but afterwards fade to a blush or peach-bloom colour. The varieties with pale and deep red flowers, differ in their habit: the latter, the most humble of the two, not only produces the most brilliant flowers, but in greater abundance.—It is a native of North America, and is reputed poisonous to sheep and cattle. It is extremely hardy, thrives best in bog-earth, and is generally propagated by layers. See the first species.

3. *Kalmia Glauca*; *Glaucous Kalmia*. Leaves opposite, oblong, levigated, glaucous underneath, revolute; corymbs terminating; branchlets ancipital. It flowers in April and May; rarely exceeding two feet high.—Native of Newfoundland.

4. *Kalmia Hirsuta*. Leaves ovate, attenuated to both ends; peduncles axillary, one-flowered; flowers purple-coloured, in racemes. It can hardly be kept alive in this country by the most careful management.—Native of Carolina, North America.

5. *Kalmia Cuneata*. Leaves scattered, sessile, cuneate-oblong, pubescent underneath, slightly aristated at the extremity; corymbs lateral, with few flowers, which are white, with red at the bottom.—Native of the mountains of Carolina.

Kidney-Bean. See *Phaseolus*.

Kidney-Bean Tree. See *Glycine*.

Kidney-Vetch. See *Anthyllis*.

Kidneywort. See *Saxifraga*.

Kiggelaria; a genus of the class Diœcia, order Decandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, five-parted, concave; divisions lanceolate, concave. *Corolla*: petals five, lanceolate, concave, rather longer than the calix, and forming with it a pitcher-shaped figure. *Nectary*: glandules obtusely three-lobed, middle lobe largest, depressed, coloured, each growing to the claw of each petal. *Stamina*: filamenta ten, very small; antheræ oblong, shorter than the calix, gaping at the tips with two holes. *Female*. *Calix* and *Corolla*: as in the male. *Pistil*: germen roundish; styles five, simple; stigmas obtuse. *Pericarp*: capsule leathery, globose, rough, one-celled, five-valved. *Seeds*: about eight, roundish, cornered on one side, covered by a proper coat. ESSENTIAL CHARACTER. *Male*. *Calix*: five-parted. *Corolla*: five-petalled. *Glands*: five, three-lobed. *Antheræ*: perforated at the tip. *Female*. *Calix* and *Corolla*: as in the male. *Styles*: five. *Capsule*: one-celled, five-valved, many-seeded.—The only known species is,

1. *Kiggelaria Africana*. This is a tree, exceeding the height of a man, with the trunk and branches gray; leaves alternate, lanceolate, petioled, smooth, stiff, and straight, sharply serrate, acute, spreading. On the male plant, one or two branched peduncles bear several flowers, nodding, in a panicle; the petals are white, and the nectaries yellow. The female produces a single flower on a simple peduncle.—Native of the Cape of Good Hope. It will not live in the open air of our climate, and therefore cannot grow very large. They are very difficult to propagate except by seeds,

which are seldom ripened in England. The best time to plant the cuttings is in the spring, just before the plants begin to shoot: they should be placed in pots of soft loamy earth, and plunged into a very moderate hot-bed, covering them close with a glass to exclude the air. They must be shaded from the sun; and have very little water after their first planting. If any of them grow, remove them into separate small pots filled with loamy earth, and expose them to the air in a sheltered situation till autumn, when they must be removed into the green-house, and treated in the same manner as Orange-trees.

King's-Spear. See *Asphodelus*.

Kleinhofia; a genus of the class Gynandria, order Decandria, according to Linneus: but Schreber classes it under Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets oblong, nearly equal; the lower one rather shorter, deciduous. *Corolla*: petals five, lanceolate, sessile, rather longer than the calix; the upper one shorter, wider, and arch-truncated; nectary central, seated on a column of the length of the calix, surrounded at the base by glandules, ascending at the tip, bell-shaped, very small, half five-cleft; divisions recurved. *Stamina*: filamenta fifteen, very small, three of them sitting on each division of the nectary, two of them being terminal, the third rather lower; antheræ twin. *Pistil*: germen in the hollow of the nectary, ovate, five-cornered; style simple; stigma somewhat crenated. *Pericarp*: capsula five-lobed, five-cornered, ten-valved, inflated. *Seeds*: solitary, roundish, sub-echinated. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled. *Nectary*: bell-shaped, peduncled, staminiferous. *Capsule*: inflated, five-lobed.—The only known species is,

1. *Kleinhofia Hospita*. Leaves alternately scattered, longer than the petioles; flowers in racemes, small, numerous, bright purple; trunk the height of a common apple-tree, thick, incurved, and knobbed. The whole plant is smooth; its leaves, when bruised, especially the young ones, smell like violets.—Native of Java, Amboyna, and the Philippine Islands, where it flowers frequently in the year, and has commonly fruit on it, but most abundantly in October.

Knapweed. See *Centaurea*.

Knautia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth common, containing the floscules disposed in a simple orb, simple, cylindric, oblong, upright; divisions awl-shaped, approximated, of the number of the floscules; perianth proper, very small, crowning the germen, quite entire, coriaceous, pervious at top. *Corolla*: universal equal; proper one-petalled, unequal; tube the length of the calix; border unequal, four-cleft, the exterior segment larger, ovate. *Stamina*: filamenta four, longer than the tube of the corolla, inserted into the receptacle; antheræ oblong, incumbent. *Pistil*: germen inferior; style filiform, length of the stamina; stigma thickish, two-cleft. *Pericarp*: none. *Seeds*: solitary, four-sided, crowned with the down, and covered with the proper involucre of the flower; receptacle common, scarcely remarkable, flat, naked. *Observe.* This genus is distinguished from *Scabiosa* by the tubulated calix, and the simple orbit of flowers. **ESSENTIAL CHARACTER.** *Calix*: common, oblong, simple, five to ten flowered; proper simple, superior. *Corollets*: irregular. *Receptacle*: naked.—The species are,

1. *Knautia Orientalis*. Leaves gashed; corollets in fives, longer than the calix. It rises with an upright, branching stalk, four feet high; the branches terminated by single peduncles, each supporting one flower, with the florets of a

bright red colour. It is annual, and a native of the Levant.—This, and the other species also, are easily propagated. If the seeds be permitted to scatter in the autumn, the plants will come up soon after; and if some of them be planted in the borders of the pleasure-garden, or among low shrubs near the walks in October, the plants will survive the winter, and flower in June.

2. *Knautia Proponica*. Upper leaves lanceolate, quite entire; corollets in tens, equal to the calix. Stem biennial, the thickness of a finger, two feet high, villose.—Observed by Forskal in the Levant.

3. *Knautia Palæstina*. Leaves entire, six-leaved; seeds pappose. Stem upright, straight, round, brachiate, somewhat hairy, scarcely a foot high; leave opposite, hairy. It is an annual plant.—Native of Palestine.

4. *Knautia Plumosa*. Upper leaves pinnate; calices ten-leaved; seeds pappose. Stem upright, straight, round, brachiate, pubescent, a foot and a half high; corolla pale blue.—Native of the Levant.

Knee Holly, Knee Holm, Knee Hulm. See *Ruscus*.

Knot Grass. See *Illecebrum Verticillatum*, and *Polygonum Maritimum*.

Knoxia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, superior, small, deciduous; leaflets sharp-pointed, one lanceolate, thrice the size of the rest. *Corolla*: one-petalled, funnel-form; tube filiform, long; border four-parted; divisions equal, somewhat oblong, rounded. *Stamina*: filamenta four, capillary, within the mouth of the corolla; antheræ oblong, equal. *Pistil*: germen roundish, inferior; style filiform, length of the stamina; stigmas two-headed. *Pericarp*: fruit naked, subglobose, sharp-pointed, furrowed. *Seeds*: two, roundish, sharp-pointed, outwardly convex, marked with three streaks; inwardly flat, connected at the upper part to a thread-form receptacle. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled, funnel-form. *Seeds*: two, grooved. *Calix*: one leaflet larger.—The only known species is,

1. *Knoxia Zeylanica*. This plant has the appearance of a Plumbago, or a Lychnis. Stem upright, a foot high, smooth, jointed; leaves opposite, lanceolate, subsessile, veinless, smooth; spikes long, narrow, with scattered sessile flowers.—Native of Ceylon, and other parts of the East Indies.

Koelreuteria; a genus of the class Polygamia, order Monœcia. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: four. *Nectary*: double, four scalelets and three glands. *Stamina*: eight, fixed to a column. *Germen*: three-sided, fixed to the same column. *Capsule*: three-celled, with two seeds in each.—The only known species is,

1. *Koelreuteria Paulinioides*. Leaves equally pinnate, with six pairs of leaflets, which are ovate, lacinate, serrate, acute, smooth, flat.—It is a polygamous tree; and a native of China.

Kobresia; a genus of the class Monœcia, order Triandria.—**GENERIC CHARACTER.** *Male.* *Calix*: the inner scales of a catkin, each oblong, slightly concave, single-flowered, permanent, sometimes wanting. *Corolla*: none. *Stamina*: filamenta three, capillary, erect, longer than the calix; antheræ vertical, linear, erect. *Female.* *Calix*: the outer scales of the same catkin, rather larger, sheathing, elliptic-oblong, single flowered, permanent. *Corolla*: none. *Pistil*: germen superior, triangular; style cylindric, short; stigmas three, bristle-shaped, downy. *Pericarp*: none, except the permanent scales. *Seed*: one, triangular pointed, hard, naked. **ESSENTIAL CHARACTER.** *Male.* *Calix*: the inner scales of an imbricated catkin, solitary. *Corolla*: none. *Female.*

Calix: the outer scales of the same catkin, sheathing, permanent. *Corolla*: none. *Stigmas*: three. *Seed*: triangular, naked.—The species are,

1. *Kobresia Scirpina*. Spike solitary, simple, cylindrical. Root perennial, tufted, consisting of numerous blackish fibres running deep into the crevices of rocks; stems numerous, about a span high, composing dense tufts; spike terminal, solitary, erect, of from ten to twenty pair of flowers; glumes brown, shining. Native of dry elevated spots in the mountains of Savoy, Italy, the Tyrol, &c.

2. *Kobresia Caricina*. Spike compound, dense, somewhat ovate; spikelets alternate, imbricated.—Native of Mount Cenis, in moist muddy spots.

3. *Kobresia Cyperina*. Umbel twice compound, leafy; spikes cylindrical; spikelets spreading; male flowers without their proper calix.—Grows in the Caraccas, in wet situations.

Königia; a genus of the class Triandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: perianth three-leaved; leaflets ovate, concave, permanent. *Corolla*: none. *Stamina*: filamenta three, capillary, shorter than the calix; antheræ roundish. *Pistil*: germen ovate; styles none; stigmas three, (often only two,) approximated, villose, coloured. *Pericarp*: none; but the calix protects the seeds, without entirely covering it. *Seeds*: single, ovate, naked, length of the calix, terminated by the permanent stigmas. **ESSENTIAL CHARACTER.** *Calix*: three-leaved. *Corolla*: none. *Seed*: one, ovate, naked.—The only known species is,

1. *Königia Islandica*. Stem a finger's length, somewhat succulent, with very few branches opposite to the leaves, and spreading very much.—Native of Iceland, where it was found by Kœnig, (after whom it has been named,) in overflowed clayey soils, both on the mountains and the coast.

Krameria; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none, except the corolla be so termed. *Corolla*: petals four, equal, spreading, oblong, acute, the uppermost wider, the lateral ones ovate; nectaries two, the upper superior, erect, linear, three-parted; divisions linear, thickish, ovate at the tips, membranaceous, the lower inferior, two-leaved; leaflets linear, convex, clavated, wrinkled. *Stamina*: filamenta four, within the nectary, ascending; antheræ small, with two foramina at the tip. *Pistil*: germen ovate; style awl-shaped, ascending, length of the stamina; stigma acute. *Pericarp*: berry dry, globose, unilocular, echinated on all sides with stiff hairs directed backwards. *Seed*: single, ovate, smooth, hard. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: four-petalled. *Nectary*: upper three-parted, lower two-leaved. *Berry*: dry, echinated, one-seeded.—The only species yet discovered is,

1. *Krameria Ixina*. A shrub with alternate lanceolate leaves; flowers alternate, in terminating racemes.—Found in South America.

—*Kuhnia*; a genus of the class Syngenesia, order Polygamia *Æqualis*.—**GENERIC CHARACTER.** *Calix*: perianth common oblong, imbricated; scales very many, unequal, lanceolate, gibbose, permanent. *Corolla*: common equal; floscules from ten to fifteen; corollets one-petalled, funnel-form, twice the length of the calix; border five-cleft, upright. *Stamina*: filamenta five, capillary, very short; antheræ sub-cylindric, shorter than the tube of the corollet, gaping with a lip at the top. *Pistil*: germen inferior; style the length of the stamina; stigmas two, clubbed. *Pericarp*: calix unchanged. *Seeds*: solitary, oblong, columnar, striated, smooth, crowned with a feathery down, longer than the calix or seed. *Receptacle*: naked, scrobicular, somewhat rugged.

ESSENTIAL CHARACTER. *Flowers*: floscular. *Calix*: imbricate, oblong, cylindrical. *Down*: plumose. *Receptacle*: naked. *Style*: deeply bifid. *Stigmas*: club-shaped. *Antheræ*: distinct.—The species are.

1. *Kuhnia Eupatorioides*. Leaves alternate, petioled, broad-lanceolate, naked, somewhat wrinkled, veined underneath, somewhat toothed, with the middle serratures larger; branches alternate from the middle of the stem; stem a foot and half high, upright, even, and stiffish; corollas white; stamina yellowish white.—Native of Pennsylvania.

2. *Kuhnia Criteonia*. Leaves narrow-lanceolate; upper leaves linear, very entire, sessile. The flowers are of a pale yellow. The whole plant is pubescent. It flowers in August and September.—Found on the mountains of Pennsylvania and Virginia.

Kyllingia; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: ament ovate or oblong, imbricated; scales oblong, distinguishing the flowers. *Glume*: unequal, compressed, bivalve; valves lanceolate, channelled, acute, much shorter than the corolla, the one shorter than the other. *Corolla*: glume longer than the calix, compressed, bivalve; valves keeled, unequal, divaricated at the tips, of which one is larger, lanceolate, very sharp, complicated, embracing the margin of the other; the other shorter, narrower. *Stamina*: filamenta three, awl-shaped, flat; antheræ linear, erect. *Pistil*: germen obovate, flattened, gibbose on one edge; style filiform; stigmas two or three, capillary. *Pericarp*: none; the glumes of the corolla preserving the seed till ripe. *Seed*: oblong, three-sided, destitute of hair. **ESSENTIAL CHARACTER.** *Ament*: ovate or oblong, imbricate. *Flowers*: with a bivalve calix and corolla.—The species are,

1. *Kyllingia Monocephala*. Culm filiform, three-sided; head globular, sessile; involucre three-leaved, very long. Culm a foot high. Native of the West Indies, where it is very common; also of Japan, and of the Society Isles.

2. *Kyllingia Triceps*. Heads terminating in threes, or thereabouts, glomerate, sessile. Culm half a foot high, commonly decumbent at the base, naked, three-cornered.—Native of both Indies, Japan, and the Society Isles.

3. *Kyllingia Panicea*. Umbel terminating with spikes, sessile and peduncled, cylindrical, imbricated; universal involucre four-leaved, or thereabouts; partial none. Culm setaceous, three-sided, a span high, without knots, leafy at bottom, naked above.—Native of the East Indies.

4. *Killingia Filiformis*. Umbel terminating, simple: spikes sessile and peduncled, ovate; spikelets ovate, acute: involucre three-leaved; partial none.—Native of Jamaica and Hispaniola.

5. *Kyllingia Umbellata*. Umbel terminating; spikes sessile and peduncled, cylindrical, squarrose; universal involucre many-leaved; partial three-leaved. Culm three-sided, striated, slender, a foot at the base, naked above.—Found by Kœnig in the East Indies.

6. *Kyllingia Sumatrensis*. Umbel terminating; spikes sessile and peduncled, cylindrical, squarrose; universal involucre many-leaved; partial none.—Found by Wennerberg in Sumatra.

7. *Kyllingia Cyperina*. Culm three-sided, striated, leafy at the base; umbel simple; spikes strict, sessile; universal involucre many-leaved, very long; partial none.—Native of the East Indies.

8. *Kyllingia Pumila*. Culm setaceous; floscules diandrous; capitulum globose, sessile, solitary; involucre short.—It flowers and grows in the western parts of South Carolina and Georgia.

INDEX OF DISEASES,

REFERRING TO MEDICINAL PLANTS IN VOL. I.

- ABDOMEN**, Swelling of, see *Curcuma Longa*, 411.
- Abscess**, see *Asclepias Vincetoxicum*, 131.
- Acrid Juices**, see *Amygdalus Communis*, 91.
- Acrimonious Humours**, see *Amygdalus Communis*, 91; *Hæmatoxyllum Campeachianum*, 653.
- Ague**, see *Acorus Calamus*, 57; *Aloe Socotorina*, 79; *Angelica Archangelica*, 102; *Anthemis Nobilis*, 103; *Anthemis Pyrethrum*, 104; *Artemisia Vulgaris*, 125; *Asarum Europæum*, 130; *Betula Alnus*, 170; *Carduus Marianus*, 250; *Cinchona Officinalis*, 301; *Citrus Aurantium*, 316; *Fraxinus Excelsior*, 578; *Gentiana Centaurium*, 603; *Geum Urbanum*, 611; *Gratiola Officinalis*, 642; *Humulus Lupulus*, 715; *Hypericum Perforatum*, 729; *Imperatoria Ostruthium*, 748.
- Ague Kernels**, see *Artemisia Vulgaris*, 125.

- Eyes, Inflammations of the*, see *Antirrhinum Elatine*, 108;

Antirrhinum Linaria, 109; Apium Petroselinum, 111; Borago Officinalis, 179; Calendula Officinalis, 224; Centaurea Cyanus, 276; Chelidonium Majus, 288; Conium Maculatum, 347; Erica Vulgaris, 506; Glechoma Hederacea, 617.

Eyes, Spots on the, see Chelidonium Majus, 288; Glechoma Hederacea, 617; Heruaria Glabra, 683.

F.

Face, Affections of the, see Anthemis Pyrethrum, 104.

Falling Sickness, see Anagallis Arvensis, 93; Betonica Officinalis, 166; Cardamine Pratensis, 247; Conium Maculatum, 347; Digitalis Purpurea, 454. See *Epilepsy*.

Fevers, see Anagallis Arvensis, 93; Andropogon Nardus, 97; Anthemis Nobilis, 103; Arctium Lappa, 116; Aristolochia Serpentaria, 122; Arnica Montana, 123; Artemisia Spicata, 125; Artemisia Anna, 125; Asclepias Vencetoxicum, 131; Berberis Vulgaris, 166; Borago Officinalis, 179; Calendula Officinalis, 224; Cinchona Officinalis, 301; Citrus Aurantium, 316; Cornus Mascula, 367; Cucumis Melo, 401; Daphne Laureola, 434; Dictamnus Albus, 453; Digitalis Purpurea, 454; Dorstenia Contrayerva, 469; Echium Vulgare, 483; Galega Officinalis, 588; Garcinia Mangostan, 595; Gentiana Lutea, 600; Guaiacum Officinale, 648; Hordeum Vulgare, 704; Humulus Lupulus, 716.

Fistula, see Corium Maculatum, 347.

Fits, see Ferula Assafetida, 557.

Flatulence, see Anomum Galangale, 89; Angelica Archangelica, 102; Carum Carui, 261; Coriandrum Sativum, 365; Cuminum Cyminum, 406; Dorstenia Contrayerva, 469; Hymenæa Courbaril, 724; Kæmpferia Galanga, 781.

Flatulent Colics, see Anomum Zinziber, 89; Anethum Graveolens, 100.

Fluor Albus, see Cinchona Officinalis, 301. See *Whites*.

Flux, see Ajuga Reptans, 70; Cluytia Eluteria, 330; Equisetum Sylvaticum, 503; Fragaria Vesca, 574; Hæmatoxyllum Campechianum, 653; Ilex Aquifolium, 743; Juglans Regia, 765; Juniperus Lycia, 774.

Fomentation, see Ægopodium Podagraria, 63; Anthemis Nobilis, 103; Artemisia Abrotanum, 124; Artemisia Maritima, 124; Artemisia Absinthium, 125; Gnaphalium Margaritaceum, 627; Jatropha Curcus, 738; Ilex Aquifolium, 743.

Freckles, see Fumaria Officinalis, 585.

G.

Gangrene, see Chærophyllum Sylvestre, 283; Conium Maculatum, 347. See *Mortification*.

Gargle, see Juglans Regia, 765.

Gleets, see Conium Maculatum, 347.

Gout, see Aristolochia Longa, 122; Athamanta Cervaria, 145; Betonica Officinalis, 168; Fragaria Vesca, 574; Galium Verum, 591; Gentiana Centaurium, 603; Hypericum Perforatum, 729.

Gravel, see Alcæa Rosea, 72; Althæa Officinalis, 82; Amygdalus Communis, 91; Anagallis Arvensis, 93; Anthemis Nobilis, 103; Aphanes Arvensis, 110; Apium Petroselinum, 111; Apium Graveolens, 111; Arbutus Uva Ursi, 116; Arctium Lappa, 116; Arum Maculatum, 128; Arundo Phragmites, 129; Asplenium Ceterach, 137; Betula Alba, 167; Bidens Tripartita, 171; Bryonia Alba, 201; Cotyledon Umbilicus, 374; Crithmum Maritimum, 386; Daucus Carota, 438; Dictamnus Albus, 453; Fraxinus Excelsior, 579; Fraxinus Rotundifolia, 580; Galium Aparine, 593; Glycyrrhiza Glabra, 623. See *Diuretics and Stone*.

Gums, see Aquilegia Vulgaris, 114.

H.

Hæmorrhage, Internal, see Achillea Ptarmica, 54; Agrimonia Eupatoria, 67; Alchemilla Vulgaris, 72; Antirrhinum Elatine, 108; Artemisia Chinensis, 126; Chelidonium Majus, 288; Cinchona Officinalis, 301; Cluytia Eluteria, 330; Delphinium Consolida, 441; Fungi, 586; Galium Verum, 591; Geum Rivale, 612; Hyoscyamus Albus, 725; Hypericum Perforatum, 729. See *Bleeding and Styptic*.

Headache, see Achillea Ptarmica, and Achillea Moschata, 54; Amomum Galangale, 89; Anthemis Pyrethrum, 104; Betonica Officinalis, 168; Cardamine Pratensis, 247; Cheiranthus Cheiri, 285; Clematis Recta, 322; Coriandrum Sativum, 365; Echium Vulgare, 483; Glechoma Hederacea, 617; Kæmpferia Galanga, 781. See *Nervous Complaints*.

Head, Disorders of the, see Amomum Cardamomum, 89; Anemone Nemorosa, 100; Asarum Europæum, 130; Delphinium Staphisagria, 443; Fumaria Officinalis, 585; Heder Helix, 657; Hymenæa Courbaril, 724; Juniperus Lycia, 774.

Heartburn, see Amygdalus Communis, 91. See *Stomachics*.

Heat of the Stomach, see Anethum Feniculum Azoricum, 101. See *Stomachics*.

Hectics, see Copaifera Officinalis, 361.

Hoarseness, see Adiantum Capillus Veneris, 60; Allium Sativum, 75; Althæa Officinalis, 82; Amygdalus Communis, 91; Erysimum Officinale, 521; Erysimum Alliaria, 522; Glycyrrhiza Glabra, 623; Hyssopus Officinalis, 733.

Hooping Cough, see Fraxinus Rotundifolia, 580; Inula Helenium, 752.

Humours, see Artemisia Abrotanum, 124; Carlina Acaulis, 257; Glycyrrhiza Glabra, 623.

Hypochondria, see Anthemis Nobilis, 103; Ballota Nigra, 158; Borago Officinalis, 179; Fumaria Officinalis, 585.

Hysterics, see Anthemis Nobilis, 103; Anthemis Cotula, 104; Artemisia Abrotanum, 124; Artemisia Vulgaris, 125; Ballota Nigra, 158; Bryonia Dioica, 201; Bubon Galbanum, 203; Cardamine Pratensis, 247; Carlina Acaulis, 257; Carum Carui, 261; Chenopodium Ambrosioides, 290; Cheoopedium Vulvaria, 290; Crocus Officinalis, 386; Dictamnus Albus, 453; Eryngium Fœtidum, 520; Ferula Assafetida, 557; Galium Verum, 591; Helleborus Niger, 677; Humulus Lupulus, 716; Iris Fœtidissima, 760.

I.

Imposthumes, see Anethum Graveolens, 100.

Inflammations, see Betula Alnus, 170; Citrus Aurantium, 317; Cotyledon Umbilicus, 374; Datura Stramonium, 487; Hydrocharis Morsus Ranæ, 722.

Intermittents, see Arnica Montana, 123; Artemisia Spicata, 124; Athamanta Cervaria, 145; Cinchona Officinalis, 301; Citrus Medica, 315; Citrus Aurantium, 317; Cluytia Eluteria, 330; Gentiana Lutea, 600; Geum Urbanum, 611; Guaiacum Officinale, 648. See *Ague and Tertians*.

Issues, see Heder Helix, 657.

Itch, see Berberis Vulgaris, 166; Conium Maculatum, 347; Conyza Squarrosa, 358; Gentiana Centaurium, 603; Inula Helenium, 752; Inula Dysenterica, 753. See *Cutaneous Eruptions and Scabs*.

J.

Jaundice, see Agrimonia Eupatoria, 67; Agrostemma Githago, 68; Aloe Socotorina, 79; Anthemis Nobilis, 103; Antirrhinum Linaria, 109; Aphanes Arvensis, 110; Apium Petroselinum, 111; Aquilegia Vulgaris, 114; Arctium Lappa, 116; Artemisia Absinthium, 125; Asarum Euro-

pæum, 130; *Asclepias Vincetoxicum*, 131; *Asperula Odorata*, 135; *Betonica Officinalis*, 168; *Borago Officinalis*, 179; *Bryonia Dioica*, 201; *Calendula Officinalis*, 224; *Cardamine Pratensis*, 247; *Chelidonium Majus*, 288; *Convolvulus Arvensis*, 351; *Crithmum Maritimum*, 386; *Curcuma Longa*, 411; *Cuscuta Europæa*, 412; *Cynara Scolymus*, 417; *Daucus Carota*, 438; *Dipsacus Fullonum*, 462; *Eryngium Maritimum*, 521; *Erysimum Cheiranthoides*, 522; *Eupatorium Cannabinum*, 533; *Fragaria Vesca*, 574; *Fraxinus Excelsior*, 579; *Gentiana Centaurium*, 603; *Gratiola Officinalis*, 642; *Humulus Lupulus*, 715; *Hypericum Perforatum*, 729.

Jaundice, Black, see *Fumaria Officinalis*, 585.

Juices, see *Glycyrrhiza Glabra*, 623.

K.

Kidneys, Disorders of, see *Bixa Orellana*, 174; *Curcuma Longa*, 411; *Dolichos Pruriens*, 466; *Humulus Lupulus*, 716; *Hypericum Perforatum*, 729.

L.

Lethargy, see *Anthemis Pyrethrum*, 104.

Lice, see *Delphinium Staphisagria*, 443; *Euonymus Europæus*, 520; *Gentiana Centaurium*, 603.

Limbs. See *Pains of the Limbs*.

Liver Complaint, see *Achillea Ageratum*, 53; *Anagallis Arvensis*, 93; *Aphanes Arvensis*, 110; *Asperula Odorata*, 135; *Asplenium Ceterach*, 137; *Dipsacus Fullonum*, 461; *Eryngium Maritimum*, 521; *Fraxinus Excelsior*, 578; *Isatis Tinctoria*, 762.

Loathing, see *Anthemum Fœniculum Azoricum*, 101. See *Loss of Appetite*.

Loss of Appetite, see *Centaurea Benedicta*, 277.

Lumbago. See *Pains of the Back*.

Lunacy. See *Madness*.

Lungs, Obstructions of, &c. see *Adiantum Capillus Veneris*, 60; *Betonica Officinalis*, 168; *Borago Officinalis*, 179; *Carlina Acaulis*, 257; *Glechoma Hederacea*, 617; *Hyssopus Officinalis*, 733.

Lungs, Ulcerated, see *Anagallis Arvensis*, 93; *Glechoma Hederacea*, 617.

M.

Madness, see *Datura Stram.* 437; *Hyoscyamus Niger*, 724. *Measles*, see *Aquilegia Vulgaris*, 114; *Asclepias Vincetoxicum*, 131; *Calendula Officinalis*, 224.

Menses, see *Agrostemma Githago*, 68; *Anagallis Tenella*, 93; *Anethum Graveolens*, 100; *Anthemis Cotula*, 104; *Aristolochia Clematitis*, 122; *Artemisia Vulgaris*, 125; *Arundo Phragmites*, 129; *Asarum Europæum*, 130; *Asclepias Vincetoxicum*, 131; *Asphodelus Ramosus*, 136; *Ballota Nigra*, 158; *Bryonia Dioica*, 201; *Bubon Galbanum*, 202; *Calendula Officinalis*, 224; *Carlina Acaulis*, 257; *Chelidonium Majus*, 288; *Conium Maculatum*, 347; *Crithmum Maritimum*, 386; *Crocus Officinalis*, 387; *Cupressus Sempervirens*, 409; *Curcuma Longa*, 411; *Cynoglossum Officinale*, 419; *Equisetum Sylvaticum*, 503; *Galium Verum*, 591; *Hæmatoxylum Campechianum*, 653; *Helleborus Niger*, 677; *Humulus Lupulus*, 716; *Hyoscyamus Albus*, 725; *Iris Fœtidissima*, 760; *Juniperus Sabina*, 772.

Menses, Overflowing of the, see *Achillea Millefolium*, 54; *Alchemilla Vulgaris*, 72; *Citrus Aurantium*, 316; *Curcuma Longa*, 411; *Cynoglossum Officinale*, 419; *Daucus Carota*, 438; *Equisetum Sylvaticum*, 503; *Geranium Robertianum*, 609; *Hieracium Pilosella*, 689; *Ilex Aquifolium*, 743.

Milk, Curdling of Women's, see *Apium Petroselinum*, 111.

Milk, Nurses', see *Anethum Fœniculum Azoricum*, 101.

Mortification, see *Cinchona Officinalis*, 301.

Mushrooms, Poisonous, see *Anethum Fœnic. Azoricum*, 101.

N.

Nervous Complaints, see *Actæa Spicata*, 59; *Amomum Zerbumbet*, 89; *Amyris Balsamifera*, 92; *Artemisia Abrotanum*, 124; *Ballota Nigra*, 158; *Bystropogon Suaveolens*, 214; *Cardamine Pratensis*, 247; *Carlina Acaulis*, 257; *Cheiranthus Cheiri*, 285; *Citrus Aurantium*, 316; *Dorstenia Contrayerva*, 469; *Echium Vulgare*, 483; *Ferula Assafœtida*, 558; *Geum Urbanum*, 611; *Helleborus Niger*, 677; *Hymenæa Conrbaril*, 724; *Iris Fœtidissima*, 760.

Nephritic Pains, see *Amygdalus Communis*, 91; *Glechoma Hederacea*, 617. See *Gravel, Stone*, and *Strangury*.

O.

Obstructions of the Viscera, see *Adiantum Capillus Veneris*, 60; *Æthusa Meum*, 65; *Antirrhinum Linaria*, 109; *Artemisia Absinthium*, 125; *Asclepias Vincetoxicum*, 131; *Asperula Odorata*, 135; *Asplenium Scolopendrium*, 137; *Asplenium Ceterach*, 137; *Asplenium Ruta Muraria*, 138; *Borago Officinalis*, 179; *Bryonia Alba*, 201; *Cardamine Pratensis*, 247; *Chærophyllum Sylvestre*, 283; *Chelidonium Majus*, 288; *Cochlearia Officinalis*, 333; *Convolvulus Arvensis*, 351; *Crithmum Maritimum*, 386; *Crocus Officinalis*, 387; *Curcuma Longa*, 411; *Daucus Carota*, 438; *Eryngium Maritimum*, 521; *Erysimum Cheiranthoides*, 522; *Fraxinus Excelsior*, 578; *Fumaria Officinalis*, 585; *Galium Aparine*, 593; *Genista Tinctoria*, 599; *Gentiana Centaurium*, 603; *Gratiola Officinalis*, 642; *Helleborus Niger*, 677; *Humulus Lupulus*, 715; *Hyssopus Officinalis*, 733.

Obstructions of the Liver, see *Cuscuta Europæa*, 412; *Fraxinus Excelsior*, 578. See *Liver Complaint*.

P.

Pains in the Side, see *Artemisia Spicata*, 125.

Pains in the Limbs, see *Ægopodium Podagraria*, 63; *Cheiranthus Cheiri*, 285.

Palpitation of the Heart, see *Citrus Medica*, 315.

Palsy, see *Arnica Montana*, 123; *Asarum Europæum*, 130; *Betonica Officinalis*, 168; *Cardamine Pratensis*, 247; *Cochlearia Officinalis*, 333.

Paralytics, see *Anthemis Pyrethrum*, 104; *Arum Maculatum*, 128; *Carophyllum Aromaticum*, 262; *Cochlearia Armoracia*, 334; *Daphne Mezereum*, 433.

Perspiration, see *Anagallis Arvensis*, 93; *Anthemis Nobilis*, 103; *Artemisia Abrotanum*, 124; *Artemisia Spicata*, 125; *Calendula Officinalis*, 224; *Carlina Acaulis*, 257; *Chelidonium Majus*, 288; *Conium Maculatum*, 347; *Crocus Officinalis*, 387; *Dorstenia Contrayerva*, 469; *Echium Vulgare*, 483; *Fragaria Vesca*, 574; *Helleborus Niger*, 677.
